Abstract

Chronic constipation is a relatively frequent symptom; among its subtypes, the so called-colonic inertia represents a disease condition that is often considered for surgery. However, to date, there has been no agreement on definition of colonic inertia, and a literature review showed that this definition was given to numerous entities that differ from each other. In this paper these concepts are reviewed and a more stringent definition of colonic inertia is proposed.

INTRODUCTION

Starting from the (interrupted) building of the Babylon Tower, human beings have been plagued by a difficulty in understanding each other, even for that concerns trivial concepts. This is especially true in the medical field, and the concept of functional gastrointestinal disorders appears to be a particularly fertile one. In fact, apparently simple complaints such as dyspepsia, diarrhea and constipation bear no single label and are still variously defined. A few years ago, a process was started that aimed at having at least a common discussion ground in defining functional gastrointestinal disorders. This process, through the work of several working teams, produced a series of documents to define the various functional gastrointestinal entities by means of the so-called Rome Criteria, now in their second version (Rome II Criteria)^[1].

Defining and diagnosing constipation

Chronic constipation is one of the most common gastrointestinal complaints^[2], and is usually defined by symptoms such as infrequent bowel movements, the presence of hard stools, an excessive time necessary to evacuate, straining, and the sense of incomplete evacuation of the bowel^[3].

The Rome II Criteria for constipation^[4] are shown in Table 1. Although these criteria represent a common ground to define constipation for research purposes, they do not take into consideration the various types of constipation, which may further be classified in to three main subgroups: normal transit constipation, disorders of defecatory or rectal evacuation (outlet obstruction), and slow transit constipation (STC)^[5].

Recent guidelines on constipation^[6] thoroughly summarize the current diagnostic approach to this symptom, obviously taking into account the fact that the suggested diagnostic tests still do not have their sensitivities established and the details

of their performances have not been well specified^[7]. Colonic transit studies with radiopaque markers are simple and reproducible tests^[8] that can be recommended for any patient undergoing evaluation for constipation. Other tests mainly focus on the anorectal and pelvic function: the balloon expulsion test (simple, inexpensive)^[9] is a useful screening one for major evacuatory dysfunctions; defecography (simple, minimal radiation exposure) can quantify defecatory function^[10]; anorectal manometry (variable methodologies, data from different centers not standardized) is useful to exclude Hirschsprung's disease and provide supportive data for a diagnosis of pelvic floor dysfunction^[11]. These tests are commonly employed in the diagnostic work-up of constipated patients, with further specific tests (rectal perception or distention or electrical stimuli, electromyography of the external sphincter or puborectalis, pudendal nerve terminal motor latency, pancolonic electromyography or manometry) usually being carried out only in clinical research or not generally applicable in common daily practice^[12].

Colonic inertia: a "smoky" entity

Among the above reported subtypes of constipation, the STC one (characterized by an abnormally delayed colonic transit time) represents approximately 15-30% of constipated patients^[13] and usually includes those with intractable constipation^[14]. The latter are usually those "refractory" to medical management, often labeled as "colonic inertia" patients, and frequently referred to the surgeon for a more drastic approach^[15]. However, it appears to be some semantic confusion concerning the term colonic inertia, which is often inappropriately used to define various types of constipation (see below).

How is colonic inertia perceived?

An internet-based search strategy of the Medline and Science Citation Index was performed using the keywords colon, colonic, inertia in various combinations with the Boolean operators AND, OR and NOT. Only articles related to human studies were used, and manual cross-referencing was also performed. Articles published in English between January 1965 and October 2003 were selected; however, a search in non-English languages and in older than 1965 journals was also performed in our library. Letters and case reports were excluded, and abstracts quoted only when the full papers were unavailable.

Table 2 summarizes the various definitions of colonic inertia found in literature, according to the method employed for diagnosis; however, although grouped together for practical purposes, it must be noted that even these subgroups have some internal differences which increase the simple definition of this entity to a number of twelve, and make difficult the interpretation of results.

According to the most frequently performed diagnostic study, radiopaque markers transit, colonic inertia patients have been classified as: (1) having a delayed transit with markers scattered throughout the viscus^[16-20], with exclusion of obstructed defecation on manometry or defecography^[21,22]; (2) synonymous of STC (without specification of markers' distribution)^[23-34]; (3) presenting markers' delay in the ascending^[35] or the right colon^[36]; (4) showing a delayed transit only in the left colon, or in both the left and right colon^[37]; or (5) displaying a delayed right and left colonic transit, but with normal transit in the sigmoid colon and rectum^[38].

Table 1 Rome II Criteria for constipation^[4]

Two or more of the following for at least 12 wk (not necessarily consecutive) in the preceding 12 mo:
- Straining during >25% of bowel movements;
- Lumpy or hard stools for >25% of bowel movements;
- Sensation of incomplete evacuation for >25% of bowel movements;
- Sensation of anorectal blockage for >25% of bowel movements;
- Manual maneuvers (digital evacuation, support of the pelvic floor) to facilitate >25% of bowel movements;
- Less than 3 bowel movements per week;
Loose stools are not present, and there are insufficient criteria for irritable bowel syndrome

Table 2 The various definitions of colonic inertia in literature*According to radiopaque transit studies:*

- Delayed colonic transit with markers distributed throughout the colon;
- Colonic inertia equates to slow transit constipation;
- Delayed transit in the right colon;
- Delayed transit in the left colon, or both in the left and right colon;
- Delayed transit in the right and left colon, with normal transit in the sigmoid and rectum

According to scintigraphic transit studies:

- Scintigraphic delay in the transverse and splenic flexure;
- Scintigraphic delay in the cecum, ascending colon, hepatic flexure, and transverse colon;
- Scintigraphic delay in the whole colon

According to manometric and/or electromyographic findings:

- Almost complete or complete absence of colonic motility

Miscellaneous:

- Decreased colonic motility;
 - Severe constipation and abdominal pain, abnormal transit study, normal anorectal manometry;
 - Refractory constipation and motility abnormalities only of the lower gastrointestinal tract
-

Analysis of these reports shows that, whereas patients in group 1 could indeed somewhat represent a homogeneous group, those in groups 2-5 are highly heterogeneous, and probably include subjects with specific abnormalities (particularly outlet obstruction).

As regards colonic inertia patients defined by scintigraphic transit, they have been classified as: (1) with delay limited to the transverse colon and the splenic flexure^[39]; (2) with delay limited to the cecum, ascending colon, hepatic flexure, and transverse colon^[40]; and (3) with delay in the whole colon^[41]. Once again, it may be noted that colonic inertia is differently defined by different authors, and the patients under investigation do not represent a homogeneous entity.

Things are not better when colonic inertia patients are classified on the basis of instrumental evaluations, which include: (1) a generic "decrease" of colonic motility^[42]; (2) disturbance of colonic motility, defined by severe constipation and abdominal pain, abnormal transit study, and normal anorectal manometry^[43]; (3) refractory constipation and motility abnormalities only of the lower gastrointestinal tract^[44]; and (4) complete or almost complete absence of colonic motility, documented by manometry or electromyography^[45-48]. Again, the great variability of definitions makes likely confusion between entities, as some of the patients in groups 1-3 could easily fit criteria for the irritable bowel syndrome.

The above considerations, far from the simple semantic misunderstanding, are important in that many of the reports described in these series came from surgical groups, and were pertinent to patients in whom a surgical operation was performed, or to patients evaluated for surgery. It is therefore intuitive that such a confusion in defining an entity with potential surgical implications also generates confusion on which patients should be referred for surgery, objective evidence indicates that severely constipated patients judged to be "intractable" might actually respond to colonic pharmacologic stimulation^[49,50], suggesting that they might be responsive to more aggressive forms of medical treatment.

Toward a definition of colonic inertia

On the above grounds, colonic inertia should be better defined, and it should not be synonymous of STC or other well-categorized subtypes of constipation. The Rome Criteria have already given us a common definition of functional constipation and pelvic floor dyssynergia^[51], and STC is well recognized by the delayed colonic transit with radiopaque markers scattered within the colon, there might be the possibility of an intermediate form combining the two entities.

Colonic inertia could be characterized as a distinct form: in fact, the term *inert* literally means "(1) *inactivity* or (2) *activity or motion modest or absent*"^[52]. Under these terms, this (actually rare) form might be defined by: (1) severe functional constipation (according to Rome Criteria); (2) absence of outlet obstruction; (3) delayed transit with markers distributed throughout the colon; (4) manometric and/or electromyographic documentation of absent or almost absent colonic motor activity (including responses to meals); and (5) no response to pharmacologic stimulation (bisacodyl, others) during colonic motility recording.

It remains to be shown, however, whether this definition could predict the success of surgery more accurately, help select more accurately those patients actually needing surgery, as their colon is beyond each possible therapeutic rescue, and better understand the basic mechanisms of constipation through selection of more homogeneous cohorts of patients.

Abstract

AIM: To evaluate the diagnostic value of assaying telomerase activity in ascites cells for the differential diagnosis of malignant and non-malignant ascites.

METHODS: Ascites from 40 patients with hepatocellular carcinoma (HCC), 31 with non-HCC gastrointestinal carcinoma (CA), and 24 with liver cirrhosis (LC) were analyzed for telomerase activity. The telomerase activities in cell pellets from ascites were measured according to the Telomeric Repeat Amplification Protocol (TRAP) and quantified with a densitometer.

RESULTS: Positive telomerase activity was detected in 16 of 31 (52%) CA patients, 10 of 40 (25%) HCC patients, and 1 of 24 (4%) LC patients ($P < 0.001$). The telomerase activity was higher in the ascites of CA patients than in the ascites of HCC or LC patients (CA: 22.9 ± 5.8 , HCC: 6.7 ± 2.5 , LC: 1.3 ± 1.3 , $P = 0.001$). Cytology was positive in 18 CA patients (58%) and 1 HCC patient (2.5%), respectively. The positive telomerase activity was not related to patients' age, gender, and ascitic protein concentration, but to white blood count ($r = 0.31$, $P = 0.002$), neutrophil count ($r = 0.29$, $P = 0.005$), and the C-reactive protein level ($r = 0.29$, $P = 0.018$). When the results of both cytological examination and telomerase assay were considered together, the sensitivity increased to 77% for CA patients, 25% for HCC patients, and 48% for all 71 gastrointestinal cancer patients.

CONCLUSION: Combining cytological examination of ascites with telomerase activity assay significantly improves the differential diagnosis between malignant and non-malignant ascites.

INTRODUCTION

Ascites is a common complication of malignancy. Carcinoma of any organ can metastasize to the peritoneum. Gastric, colon, pancreatic, ovarian, breast, and lung carcinomas, as well as lymphoma, are the most common tumors associated with malignant ascites^[1]. Hepatocellular carcinoma (HCC) is the leading cause of cancer mortality in Asia^[2]. Ascites is also commonly seen in HCC patients, especially in terminal stage or when complicated with liver cirrhosis (LC). The pathophysiological mechanisms for the ascites production in LC are quite distinct from those for malignancy-related ascites^[3]. The conventional diagnostic methods are sometimes inefficient and unsatisfactory to diagnose ascites as malignancy-related. For example, malignant ascites could be diagnosed by cytological examination of the ascitic fluids in only 50-70% of patients with ascites^[1].

Telomeres (special DNA structures that contain TTAGGG repeats at the ends of all eukaryotic chromosomes) have important functions in protecting genomic DNA from degradation and deleterious recombination events^[4]. Telomerase, an RNA-dependent DNA polymerase, can maintain the telomeric length by acting as a reverse transcriptase^[4]. In humans, tumor cells escape programmed cell senescence through reactivation of telomerase^[5]. These immortalized cells can compensate for telomeric shortening at each cell division, leading to progressive neoplastic evolution^[5,6]. Telomerase re-expression was found in 85% of human malignant tumors^[7-10]. The use of telomerase assay for cancer diagnosis might be possible because telomerase is thought to be re-expressed in malignant lesions but rarely in normal somatic cells^[7-10]. Some studies also suggested that the telomerase activity of ascites could be a sensitive marker for differentiating malignancy-related ascites from nonmalignant ascites^[11-13]. However, these studies included only small numbers of gastrointestinal tract cancer and HCC patients.

This study was to assess the diagnostic value of using telomerase activity assay to distinguish digestive tract cancer-derived ascites from benign ascites.

MATERIALS AND METHODS

Patients

Ninety-five patients with ascites undergoing a therapeutic or diagnostic paracentesis in Taipei Veterans General Hospital were enrolled prospectively into this study. These patients were divided into three groups on the basis of the cause of the ascites.

HCC Group consisted of 40 patients with HCC. The diagnoses were made by imaging studies (abdominal sonography and/or computed tomography and/or magnetic resonance imaging) and serum α -fetoprotein levels above 400 IU/mL in 34 patients, and were confirmed by liver biopsy in the remaining 6 patients.

CA Group consisted of 31 patients with non-HCC gastrointestinal carcinoma, including 10 gastric, 8 colon, 10 pancreatic cancers, and 3 cholangiocarcinomas (19 with liver metastasis and 12 without). All diagnoses were histologically confirmed.

LC Group comprised 24 patients with sterile uncomplicated cirrhotic ascites. Liver cirrhosis was diagnosed by typical clinical findings (splenomegaly, ascites and/or esophageal

varices), imaging studies (abdominal sonography and/or computed tomography and/or magnetic resonance imaging) and laboratory findings in 20 patients, and was confirmed by a liver biopsy in the remaining 4 patients. The serum α -fetoprotein level was <20 IU/mL, and an ultrasound showed no evidence of malignancy in each patient.

Ascitic fluids were subjected to routine assays, such as cell count and categorization, Gram's stain and culture, total proteins, albumin, and cytological examination. Blood samples for serum albumin determination were also taken at the same time as the above measurements to calculate the serum-ascites albumin gradient (SAAG). The ascites was also centrifuged and the sediment was detected with the Telomeric Repeat Amplification Protocol (TRAP). The samples were collected in heparinized containers and centrifuged at 2 000 r/min for 10 min at 4 °C. The supernatant was decanted. Cells were washed twice with ice-cold phosphate-buffered saline (PBS) and were stored in a 1.5-mL tube at -80 °C until assay. For bloody specimens, excessive RBCs were removed by Ficoll-Hypaque density-gradient centrifugation^[14]. All samples were coded so that technicians running the assays were blinded as to the source of the samples.

Telomeric repeat amplification protocol (TRAP)

The telomerase activity was assayed according to the protocol described previously^[15]. Cell lysates were prepared in 200 μ L of lysis buffer consisting of 10 mmol/L Tris-HCl (pH 7.5), 5 g/L CHAPS, 1 mmol/L MgCl₂, 1 mmol/L EGTA, 100 mL/L glycerol, 0.1 mmol/L benzamidine, and 5 mmol/L β -mercaptoethanol. Aliquots of extracts were treated with or without RNase A (Sigma, St. Louis, MO) in a final concentration of 0.05 mg/mL for 30 min at 37 °C. Then, each TRAP reaction was performed at 30 °C for 30 min in 50 μ L of reaction mixture containing 200 ng of cell lysates, 20 mmol/L Tris-HCl (pH 8.3), 0.5 g/L Tween-20, 1.5 mmol/L MgCl₂, 63 mmol/L KCl, 1 mmol/L EGTA, 250 μ mol/L dNTPs, Primer Mix (Intergen Co., Purchase, NY), and 2 units of Taq polymerase (Roche Molecular Biochemicals, Indianapolis, IN), and followed by 33 cycles of PCR: at 94 °C for 0.5 min and 59 °C for 0.5 min. One half of each reaction mixture was resolved in a 125 g/L polyacrylamide gel, and after staining with SYBR® Green (Molecular Probes, Eugene, OR), the image of the telomeric repeat pattern was printed and quantified within a range from 50 to 100 base pairs by Alpha-InnoTech IS500 Digital Imaging System (Avery Dennison, CA). All samples were run in duplicate and the reproducibility was confirmed. All extracts that produced 6-base-pair ladders were tested for sensitivity to RNase A pretreatment, which is indicative of real telomerase activity.

The positive telomerase activity in the ascites cell pellet was calculated according to TPG (Total Product Generated) = $(X - X_0) C_R / C (R - R_0) \times 100$, X: density of sample, X₀: density of heat- or

RNase-treated sample, C: density of internal standard of the sample, C_R: density of internal standard of the control template, R: density of control template, and R₀: density of lysis buffer.

Statistical analysis

Results were expressed as mean \pm SE. Unpaired Student's *t*-test or one-way analysis of variance (ANOVA) was used to analyze continuous variables between groups. Chi-square test or Fisher's exact test was used for comparison of categorical variables. Pearson's correlation was performed to determine whether a relationship between two parameters was significant. Sensitivities and specificities were calculated in accordance with standard methods. Statistical analyses were performed using the SPSS software (SPSS 10.0, SPSS Inc., Chicago, IL). Results were considered statistically significant at $P < 0.05$.

RESULTS

Patient characteristics

The composition of the patients' ascites is shown in Table 1. The ascites protein level was significantly higher in CA than in HCC and LC patients ($P < 0.001$). In addition, the SAAG of HCC and LC relative to CA patients was significantly elevated ($P < 0.01$). The white blood cells in the ascites consisted mainly of lymphocytes in all groups of patients (CA: 74 \pm 5%, HCC: 72 \pm 5%, LC: 86 \pm 4%). The high mean PMN count in HCC patients resulted from blood leakage due to tumor rupture in some HCC patients.

Cytological examination of ascites

Positive cytological examination of ascites was recorded in 18 of 31 (58%) CA patients and 1 of 40 (2.5%) HCC patients. As a control group, none of LC samples showed a positive cytological outcome (Table 2). For the totally 71 gastrointestinal cancer patients, the diagnostic specificity of our cytological examination reached 100%. Because a positive cytological result could make a diagnosis of malignancy, our data suggested that the conventional cytological examination had a sensitivity of 58% for diagnosing the ascites of CA patients, while the sensitivity was only 2.5% for the HCC ascites.

Telomerase activity in ascites

Ascitic telomerase activity was detected by TRAP assay. Representative examples of the results are shown in Figure 1. Positive telomerase activity was detected in 16 of 31 (52%) CA patients and 10 of 40 (25%) HCC patients (Table 2). Only one LC patient (4%) showed positive ascitic telomerase activity ($P < 0.001$). Among CA patients, 5 of 10 gastric cancers (50%), 3 of 8 colon cancers (38%), 7 of 10 pancreatic cancers (70%), and 1 of 3 cholangiocarcinomas (33%) were positive for ascitic telomerase activity (Table 2).

Table 1 Clinical characteristics and ascitic fluid analyses

	CA	HCC	LC
Number of patients	31	40	24
Age (yr)	65 \pm 2	65 \pm 2	67 \pm 2
Sex: Male/Female	21/10	35/5	18/6
Protein (g/dL)	2.9 \pm 0.2	1.5 \pm 0.1 ^d	1.5 \pm 0.2 ^d
SAAG (g/dL)	1.1 \pm 0.1	2.0 \pm 0.2 ^b	2.0 \pm 0.2 ^b
WBC (cells/mm ³)	481 \pm 107	847 \pm 590	149 \pm 27
RBC (cells/mm ³)	13 093 \pm 7 975	192 633 \pm 104 982	3 730 \pm 1 515
PMN (cells/mm ³)	177 \pm 78	698 \pm 550	20 \pm 8
Lymphocytes (cells/mm ³)	305 \pm 77	149 \pm 46 ^a	128 \pm 26 ^a

Data are expressed as mean \pm SE. CA: non-HCC gastrointestinal cancer, HCC: hepatocellular carcinoma, LC: liver cirrhosis, SAAG: serum-ascites albumin gradient, WBC: white blood count, PMN: polymorphonuclear cells. ^a $P < 0.05$, ^b $P < 0.01$, ^d $P < 0.001$ if compared with CA patients.

Table 2 Comparison of telomerase activity assay and cytological examination (n, %)

Group (n)	Underlying diseases (n)	Positive telomerase	Positive cytology
CA (31)		16 (52)	18 (58)
	Gastric cancer (10)	5 (50)	6 (60)
	Colon cancer (8)	3 (38)	4 (50)
	Pancreatic cancer (10)	7 (70)	8 (80)
	Cholangiocarcinoma (3)	1 (33)	0 (0)
HCC (40)		10 (25)	1 (2.5)
LC (24)		1 (4)	0 (0)

CA: non-HCC gastrointestinal carcinoma, HCC: hepatocellular carcinoma, LC: liver cirrhosis.

P N CA1 CA2 CA3 CA4 CA5 LC HCC TSR8

Figure 1 Representative results of ascitic telomerase activity assay. Lane P: positive control, Lane N: heat-inactivated sample, TSR8, quantitation control, CA: non-HCC gastrointestinal carcinoma, HCC: hepatocellular carcinoma, LC: liver cirrhosis.

It was noted that telomerase activity was higher in the ascites of CA patients than in the ascites of HCC and LC patients (CA: 22.9 ± 5.8 , HCC: 6.7 ± 2.5 , LC: 1.3 ± 1.3 , $P = 0.001$, Figure 2). In addition, as shown in Table 3, the telomerase activity was not related to patients' age, gender, serum albumin and ascitic protein amount, but to patients' white blood count ($r = 0.31$, $P = 0.002$), blood neutrophil count ($r = 0.29$, $P = 0.005$), and C-reactive protein level ($r = 0.29$, $P = 0.018$).

**Figure 2** Individual and mean values of telomerase activities in CA, HCC and LC ascites.

When the results of both cytological examination and telomerase assay were combined together, the sensitivity increased to 77% (24/31) for CA patients, 25% (10/40) for HCC patients, and 48% (34/71) for the 71 gastrointestinal cancer patients. While cytological examination alone had a sensitivity of 27% (19/71) and telomerase assay alone had a sensitivity of 37% (26/71).

Table 3 Correlation between ascitic telomerase activity and clinical parameters

	<i>r</i>	<i>P</i>
Age (yr)	-0.05	0.65
Sex: Male/Female	-0.18	0.09
Serum albumin	-0.03	0.81
Ascites protein	0.08	0.44
Blood WBC	0.31	0.002
Blood neutrophil	0.29	0.005
Serum C-reactive protein	0.29	0.018

WBC: white blood count.

DISCUSSION

Diagnosis of cancer primarily depends on pathological examination. Ascites is a common complication of malignant neoplasms. The conventional cytological assessment of ascitic fluid can provide highly specific and accurate diagnoses of malignancies, but its unsatisfactory low sensitivity does not allow pathologists to early differentiate malignant ascites from non-malignant ascites^[16]. Some studies have suggested that assay of telomerase activity in ascites might be an alternative method to improve the diagnosis^[11,12]. However, only small numbers of patients with gastrointestinal tract cancers and HCC were included in those studies. The present study is the first one evaluating the value of telomerase activity assay in differential diagnosis of malignant and nonmalignant ascites of gastrointestinal cancers.

In our study, the sensitivity of telomerase activity assay of ascites from CA patients was 52%, comparable to that (58%) by cytological examination. This result is consistent with a previous report^[11]. However, our TRAP sensitivity seemed to be less than that reported in another paper about ovarian cancers^[17]. Although the average incidence of abnormal telomerase activity occurred in as high as 85% of human cancer patients, the incidence varied with different cancer types^[8,18]. Among these, kidney, ovarian, and breast cancers showed the highest mean values of quantitatively assessed telomerase activities^[19].

Ascites is commonly seen in HCC patients, especially in decompensated stages. Concomitant cirrhosis was present in more than 97% of HCC patients^[20]. Not only the tumor growth, but also the underlying liver cirrhosis, led to ascites^[20,21]. In analysis of our 24 LC and 40 HCC patients, only one HCC patient had a positive cytological diagnosis. This agrees with previously published data showing that malignant cells detected in ascites occurred in only 0-12% of the HCC patients^[20-24], suggesting cytological examination is not an efficient tool for distinguishing HCC ascites from non-HCC LC ascites. Assay of telomerase activity (which was positive in 25% of HCC ascites samples were positive) is obviously better than the conventional cytological assessment.

Moreover, we speculated combining the results of both cytological examination and telomerase activity assay might improve diagnosis. We were able to identify malignancy in 77% of CA patients and 25% of HCC patients. For all 71 gastrointestinal cancer patients, the sensitivity of diagnosis increased to 48% (by the combination of both techniques) from 27% (by the cytological examination alone). Our study results thus indicate that TRAP assay is a useful tool for detecting cancer cells in ascites from gastrointestinal cancer patients.

Noteworthy, ascitic telomerase activity of gastrointestinal cancers is correlated with the increase in blood leukocytes and C-reactive protein. Leukocytosis and C-reactive protein are major markers of inflammation and cancer^[25,26]. The source of

telomerase activity in ascitic cells could be cancer cells shed into the ascitic fluid or ascitic fluid leukocytes that were up-regulated by cancer-related cytokines^[27-35]. Whatever the mechanism(s), assay of telomerase activity in ascitic cells may provide an adjunct to cytological examination in the diagnosis of digestive tract cancers.

Abstract

AIM: Hepatocellular carcinoma (HCC) patients manifest a variety of paraneoplastic syndromes. Thrombocytosis was reported in children with hepatoblastoma. The aims of this study were to evaluate the prevalence and clinical significance of thrombocytosis in HCC patients and its relationships with serum thrombopoietin (TPO).

METHODS: We retrospectively reviewed clinical, biochemical and image data of 1 154 HCC patients. In addition, we measured platelet count and serum TPO in HCC patients with and without thrombocytosis, in patients with cirrhosis, chronic hepatitis and healthy subjects in a cross-sectional study.

RESULTS: Thirty-one (2.7%) of 1 154 HCC patients had thrombocytosis (platelet count $\geq 400 \text{ K/mm}^3$). HCC patients with thrombocytosis were significantly younger, had a higher serum α -fetoprotein, higher rate of main portal vein thrombosis, larger tumor volume, shorter survival, and were less likely to receive therapy than HCC patients without thrombocytosis. Multivariate logistic regression analyses showed that tumor volumes $\geq 30\%$ and serum α -fetoprotein $\geq 140 000 \text{ ng/mL}$ could significantly predict thrombocytosis. HCC patients with thrombocytosis had a significantly higher mean serum TPO than those without, as well as patients with cirrhosis, chronic hepatitis and healthy subjects. Platelet count and serum TPO dropped significantly after tumor resection in HCC patients with thrombocytosis and re-elevated after tumor recurred.

Furthermore, the expression of TPO mRNA was found to be more in tumor tissues than in non-tumor tissues of liver in an HCC patient with thrombocytosis.

CONCLUSION: Thrombocytosis is a paraneoplastic syndrome of HCC patients due to the overproduction of TPO by HCC. It is frequently associated with a large tumor volume and high serum α -fetoprotein.

INTRODUCTION

Hepatocellular carcinoma (HCC) is the most common malignancy in Taiwan. During its clinical course, patients may manifest a variety of paraneoplastic syndromes, including hypercholesterolemia, hypoglycemia, hypercalcemia, and erythrocytosis^[1]. According to our previous reports, the prevalence of paraneoplastic syndromes was 11.4-12.1% for hypercholesterolemia, 2.8-5.3% for hypoglycemia, 1.8-4.1% for hypercalcemia, and 2.5-3.1% for erythrocytosis^[2-6]. Thrombocytosis has been found in children with hepatoblastoma and other malignancies^[7-9]. The prevalence and clinical significance of thrombocytosis in adult patients with HCC have not been previously reported.

Human thrombopoietin (TPO), also known as megakaryocyte growth factor, is known to play a key role in the development of megakaryocytes^[10,11]. TPO is secreted principally by hepatocytes and bone marrow stromal cells^[10-14]. In addition, the expression of TPO gene has been found in both rat and human hepatoma cell lines^[15,16]. The relationships between serum TPO levels and platelet counts in HCC patients, especially those associated with thrombocytosis, are of clinical interest. Our aim was to evaluate the prevalence of thrombocytosis in Chinese patients with HCC in a retrospective study. The clinical, biochemical and image characteristics of HCC patients with thrombocytosis were evaluated. Moreover, in order to evaluate the role of serum TPO in the manifestations of thrombocytosis in HCC patients, serum TPO levels were measured in HCC patients (with and without thrombocytosis), cirrhotic patients, chronic hepatitis patients, and normal subjects in a cross-sectional study.

MATERIALS AND METHODS

The clinical, laboratory and image data were retrospectively reviewed in 1 269 consecutive patients diagnosed with HCC at the Division of Gastroenterology, Taipei Veterans General Hospital, from January 1991 to December 1994^[6]. Of these patients, 1 253 were enrolled in this study who met the following criteria: (1) histological proof of HCC; or (2) at least two typical HCC image findings (ultrasonography, computerized tomography, celiac angiography or magnetic resonance imaging) along with a serum AFP of more than 20 ng/mL. Among

the 1 253 patients, data of 1 197 cases were analyzed after excluding the patients with incomplete examination and data for analysis. Finally, data of 1 154 patients were selected for analyses in this study after excluding 43 patients with an evidence of acute infections or gastrointestinal bleeding. Patients with polycythemia vera were also excluded.

We defined hypercholesterolemia in HCC patients as a serum cholesterol level greater than 250 mg/dL (two standard deviations above the mean value of age-and-sex-matched healthy controls); hypoglycemia as plasma glucose less than 60 mg/dL; hypercalcemia as corrected serum calcium level more than 11.0 mg/dL; and erythrocytosis as a hemoglobin level greater than 16.7 gm/dL or hematocrit greater than 50% as in our previous reports^[2-6]. Thrombocytosis was defined as having a platelet count greater than 400 K/mm³.

To compare the serum TPO level, 18 consecutive HCC patients with thrombocytosis and 72 age-sex-tumor volume matched HCC patients without thrombocytosis were consecutively collected in a cross-sectional study from January 1999 to December 2000. In addition, 42 age-sex-matched cirrhotic patients and 66 chronic hepatitis patients were randomly selected for comparison. The etiologies of chronic hepatitis and cirrhosis were either viral hepatitis B or hepatitis C, which were all confirmed by liver biopsies. None of the patients with chronic hepatitis or cirrhosis received interferon or other antiviral treatments before blood sampling. Alcoholic patients were not enrolled. Patients were also excluded if an acute infection or gastrointestinal bleeding was noted during enrollment. In addition, 62 healthy subjects who received their annual physical examinations at Taipei Veterans General Hospital, and whose age and sex were matched with the aforementioned 90 HCC patients, were randomly selected as healthy controls. Sera of the aforementioned subjects or patients were stored in aliquots at -70 °C until analyzed.

The underlying liver cirrhosis in HCC patients was diagnosed histologically or by characteristic image findings with the presence of ascites or esophageal varices. Patients with cirrhosis were given a score from 5-15 according to Child-Pugh's classification^[17]. Tumor volume was calculated from computerized tomographic films and was expressed as percentages of tumor volume in total liver volume. The grade of differentiation and arrangement of tumor cells were assessed by a liver pathologist according to the classification of Edmondson and Steiner^[18]. The pathologist was not given any clinical information pertaining to the biopsy specimens.

All clinical data of HCC patients including age, sex, Child-Pugh's scores, liver biochemistries (measured by a Hitachi Model 736 automatic analyzer, Tokyo, Japan), prothrombin time, and complete blood counts were recorded when an HCC was first diagnosed or at the time the thrombocytosis developed. Serum α -fetoprotein (AFP) was measured by a commercial kit (ELSA2-AFP, CIS bio-international, Cedex, France). Anti-HCV was measured by a second-generation enzyme immunoassay kit (Abbott Laboratories, Chicago, IL, USA). The serum markers of hepatitis B surface antigen (HBsAg) and antibody to hepatitis D virus (Abbott Laboratories) were recorded. Distant metastases to extrahepatic regional lymph nodes or other organs were evaluated by image studies. Methods of therapy for HCC, including surgical resection of tumors, transcatheter arterial chemoembolization (TACE), sono-guided percutaneous ethanol injection, or systemic chemotherapy and survival times were recorded in each patient. This study was approved by Taipei Veterans General Hospital, Taiwan.

Serum TPO levels were quantitatively measured by a solid phase enzyme immunoassay (Quantikine, R&D systems, Abingdon, UK). For the expression of TPO mRNA, an equal amount of fresh frozen tumors and non-tumor parts of the liver samples from a patient with thrombocytosis who received lobectomy

for HCC were homogenized with a pestle. Total RNA was purified by TRIZOL reagent (Invitrogen and Life Technologies, Rockville, MD, USA). Reverse transcription-polymerase chain reaction (RT-PCR) was carried out to amplify 1 μ g RNA using the First-strain cDNA Synthesis Kit (Amersham Pharmacia Biotech, Buckinghamshire, UK) according to the instruction manual. PCRs were carried out with 35 cycles at 94 °C for 1 min, at 60 °C for 1 min and at 72 °C for 1 min. Primer sequences were sense: 5'-TGCGTTTCCTGATGCTTGAG-3' and anti-sense: 5'-AACCTTACCCTTCCTGAGACA-3'^[12]. β -actin was used as an internal standard and diethyl pyrocarbonate-treated water was used as a negative control. The analysis of PCR products was performed by 20 g/L agarose gel electrophoresis. For quantitation of TPO mRNA, the PCR product was purified by the QIAquick Gel Extraction Kit (QIAGEN GmbH, Hilden, Germany) and $A_{260\text{ nm}}$ was measured to estimate the DNA contents. Serial dilutions of this standard were then included in the following real-time PCR along with samples to produce a standard curve. Quantitative PCR was performed in 20 μ L reaction capillaries using 1 \times DNA master SYBR Green I mix (Roche Diagnostics, Indianapolis, IN, USA), bovine serum albumin, 4 mmol/L MgCl₂, 200 μ mol/L dNTPs, 0.4 U InViTaq-polymerase (InViTec; Berlin, Germany), 1 μ L cDNA and 0.5 μ mol/L of the TPO-specific sense and antisense primers. DNA amplification, data collection and analyses were performed with LightCycler (Roche Diagnostics)^[19]. The program was optimized and performed finally as denaturation at 94 °C for 30 s followed by 40 cycles of amplification (at 94 °C for 0.1 s, 60 °C for 0.1 s, 72 °C for 20 s). The temperature ramp rate was 20 °C/s. At the end of each extension step, the fluorescence of each sample was measured to allow the quantification of the PCR product. After the PCR was completed, the melting curve of the product was measured by a temperature gradient from 60 °C to 96 °C at 0.2 °C/s with continuous fluorescence monitoring to produce a melting profile of the primers. For normalization, the amount of TPO amplicon was divided by the amount of β -actin amplicon of the respective sample.

All data are expressed as mean \pm SD. Results were compared between groups using the Chi-square test, Fisher's exact test, Student's *t*-test, Mann-Whitney test or cross tabulation depending on the type of data analyzed. Survival adjusted for therapy was analyzed using the Kaplan-Meier method and was compared using the log rank method. Univariate and multivariate logistic regression using SPSS software (SPSS Inc., Chicago, IL, USA) were performed to evaluate the predictive values of the patients' clinical, laboratory, and tumor features associated with thrombocytosis. For all tests, only the results with *P* values less than 0.05 (two-tail test) were considered to be statistically significant.

RESULTS

Among the 1 154 HCC patients (1 005 males, 149 females, mean age 62.0 \pm 12.0 years, with a range of 13 to 84 years), 735 (63.7%) patients were HBsAg positive, 180 (15.6%) were anti-HCV positive, 49 (4.3%) were positive for both HBsAg and anti-HCV and 19 (1.6%) were positive for HBsAg and antibody to hepatitis D virus. The mean serum AFP level was 43 983 \pm 163 097 ng/mL (median 268 ng/mL, range 3-1 892 500 ng/mL).

Totally, 243 (21.1%) of 1 154 patients had paraneoplastic syndromes during the clinical course of HCC, in which 175 had a single paraneoplastic manifestation and 68 had multiple paraneoplastic manifestations. Thirty-one (2.7%) of 1 154 HCC patients had thrombocytosis (mean platelet count 484 \pm 87 K/mm³, range 403-688 K/mm³). The prevalence of hypercholesterolemia was 12.6%, hypoglycemia was 5.4%, hypercalcemia was 4.4%, and erythrocytosis was 3.2%. Eighteen of 31 HCC patients with thrombocytosis had other paraneoplastic manifestations

(11 with hypercholesterolemia, 1 with hypoglycemia, 4 with hypercholesterolemia and hypoglycemia, 1 with hypercholesterolemia and hypercalcemia, and 1 with hypercholesterolemia, hypoglycemia and hypercalcemia). Nine hundred and eleven HCC patients were free of paraneoplastic manifestations.

In comparison of the clinical, laboratory data and tumor features between HCC patients with thrombocytosis and those without, HCC patients with thrombocytosis were significantly younger in age, had a higher mean serum AFP level, higher rate of main portal vein (MPV) thrombosis, bilobar tumor involvement, larger tumor volume, were less likely to receive or be suitable for HCC therapy, and had a shorter survival time than those without thrombocytosis (Table 1). HCC patients with thrombocytosis tended to have more extra-hepatic metastases than those without thrombocytosis (32% vs 19%, $P = 0.059$). There were no significant differences in sex distribution, viral etiologies, mean Child-Pugh's scores, and rates of cirrhosis between the two groups. Two hundred and fifty-eight (22%) of 1154 HCC patients and 10 (32%) of 31 patients with thrombocytosis had their HCC tissues for histological analyses. Among the 10 HCC patients with thrombocytosis, tumor cell arrangement showed a trabecular pattern in 7 patients, and a mixed trabecular and acinar pattern in 3. Tumor cell differentiation revealed grade I in 3 patients, grade II in 4 patients, and grade III in 3 patients. The tumor cell arrangement and differentiation showed no significant differences between patients with and without thrombocytosis.

Age, sex, viral hepatitis markers, serum AFP, MPV thrombosis, metastases, bilobar tumor involvement, and tumor volumes were

all selected as independent variables in logistic regression analyses, with the presence of thrombocytosis as the dependent variable. The continuous variables were transformed to categorical variables with the cut-off points determined by the Receiver Operating Characteristic Curve. In an univariate analysis, an age <60 years, serum AFP >140 000 ng/mL, tumor volume >30% of the total liver volume, bilobar tumor involvement, and MPV tumor thrombosis were significantly correlated with the presence of thrombocytosis (Table 2). In a stepwise multivariate analysis, a tumor volume >30% (odds ratio: 9.901, 95% confidence interval: 2.187-44.402, $P = 0.003$) and serum AFP >140 000 ng/mL (odds ratio: 2.660, 95% confidence interval: 1.090-6.487, $P = 0.031$) were significant predictive variables associated with the presence of thrombocytosis in HCC patients.

In the cross-sectional study, the mean platelet count was 440 ± 43 K/mm³ (range 401 to 540 K/mm³) in 18 HCC patients with thrombocytosis, 174 ± 100 K/mm³ (range 102 to 396 K/mm³) in 72 HCC patients without thrombocytosis, 72 ± 29 K/mm³ (range 18 to 154 K/mm³) in 41 patients with cirrhosis, 178 ± 48 K/mm³ (range 105 to 300 K/mm³) in 66 patients with chronic hepatitis, and 212 ± 35 K/mm³ (range 125 to 347 K/mm³) in 62 healthy controls. The mean serum TPO level was significantly higher in HCC patients with thrombocytosis (404 ± 196 pg/mL), when compared with HCC patients without thrombocytosis (181 ± 85 pg/mL), cirrhotic patients (103 ± 34 pg/mL), chronic hepatitis patients (113 ± 46 pg/mL), and healthy subjects (123 ± 53 pg/mL) (Figure 1). Serum TPO levels were positively correlated with platelet counts among 90 HCC patients ($r = 0.474$, $P < 0.001$). Among the 10 HCC patients with thrombocytosis, the

Main portal vein tumor thrombosis	3.408	1.435-6.467	0.004

¹Significantly predictive variables in multivariate analyses.

mean platelet count dropped significantly from 420 ± 48 K/mm³ to 278 ± 38 K/mm³ ($P < 0.001$) after a surgical tumor resection or TACE, while the mean platelet count for HCC patients with thrombocytosis, who did not receive any therapy, showed a progressive increase during follow up.

Figure 2 illustrates the relationship of platelet counts with the serum levels of cholesterol, AFP and TPO in a 36-year-old HCC male patient. The serum AFP level was 164 000 ng/mL and serum HBsAg was positive. Image studies revealed a large tumor mass over the right lobe of liver with an invasion to the left medial segment. Hypercholesterolemia (serum cholesterol level 602 mg/dL) and thrombocytosis (platelet count 403 K/mm³) were noted at the diagnosis of HCC. He received a surgical removal of tumors followed by chemotherapy with 5-fluorouracil for 12 wk. Platelet counts, serum levels of cholesterol and AFP dropped significantly after a surgical removal of the tumors. However, all re-elevated when the tumor recurred 18 wk after surgical treatment. Serum TPO level was 360 pg/mL before surgery (platelet count 403 K/mm³), and fell to 130 pg/mL one week after operation (platelet count 120 K/mm³). Figure 3 shows the qualitative expression of TPO mRNAs using RT-PCR in tumor and matched non-tumor tissues of the resected liver samples. The expression of TPO mRNAs was more intensive in tumor than in the non-tumor liver tissues. The results from the quantitative real-time PCR also revealed that the concentration of TPO mRNAs in tumors was 1.92 times greater than in matched non-tumor liver tissues.

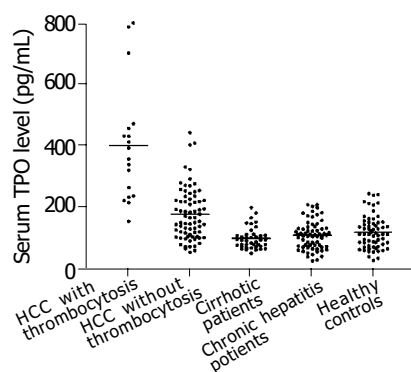

Figure 1 Distribution of serum thrombopoietin levels in hepatocellular carcinoma (HCC) patients with and without thrombocytosis, patients with cirrhosis, chronic hepatitis and healthy subjects. The mean serum thrombopoietin level in HCC patients with thrombocytosis was significantly higher than in HCC patients without thrombocytosis, patients with cirrhosis, chronic hepatitis and healthy subjects.

Figure 2 Clinical course of a hepatocellular carcinoma patient with thrombocytosis. The serum alpha-fetoprotein (AFP) level was 164 000 ng/mL before tumor resection. Hypercholesterolemia (serum cholesterol level: 602 mg/dL) and thrombocytosis (platelet count: 403 K/mm³) were noted before operations. The platelet counts, serum levels of cholesterol

and AFP fell significantly after a surgical removal of the tumors. However, all re-elevated when the tumor recurred 18 wk after surgical treatments.

Figure 3 Analyses of thrombopoietin from tumor tissues (T) and non-tumor liver tissues (L) in a hepatocellular carcinoma patient with thrombocytosis using reverse-transcription polymerase chain reaction. β -actin was used as an internal standard (B). N: negative control. Results from an agarose gel electrophoresis showed a more intense density of thrombopoietin band from tumor tissues when compared with non-tumor liver tissues.

DISCUSSION

Common paraneoplastic syndromes seen in HCC patients include hypercholesterolemia, hypoglycemia, hypercalcemia, and erythrocytosis^[1]. Thrombocytosis has been reported in children with hepatoblastoma^[7-9]. The prevalence of thrombocytosis in HCC patients has not been previously reported. Our results showed that 2.7% of HCC patients had thrombocytosis which was defined as a platelet count >400 K/mm³. The prevalence of thrombocytosis might be underestimated because most HCC patients were associated with liver cirrhosis, and thrombocytopenia was frequently seen in these patients.

The clinical significance of thrombocytosis in HCC patients were similar to HCC patients with other paraneoplastic syndromes, including hypercholesterolemia, hypoglycemia, hypercalcemia, and erythrocytosis^[2-6]. Large tumor volumes, high serum AFP, high rates of MPV tumor thrombosis, low rates of receiving therapy and poor prognosis have been identified in HCC patients with thrombocytosis. According to the multivariate logistic regression analyses, HCC patients with thrombocytosis were characterized by a large tumor volume and high serum AFP. HCC patients with thrombocytosis seemed to have a similar life expectancy as HCC patients with erythrocytosis or hypercholesterolemia, and had a better prognosis than patients with hypoglycemia and hypercalcemia which were usually pre-terminal events^[6].

Before the cloning of TPO, the cause of thrombocytosis in children with hepatoblastoma and in other malignancies remains unclear. TPO, a glycoprotein hormone, is a potent stimulator of the growth and maturation of megakaryocytes and platelet production^[10,11]. The main sites of TPO production are the liver and, to a lesser degree, the kidneys, bone marrow and spleen. Messenger RNA transcripts of TPO have been found mainly in the liver and released into circulation^[14-16]. Most TPO is bound with and degraded by circulating platelets and megakaryocytes in the bone marrow, and the serum level is low. Circulating TPO levels are inversely correlated with the number of TPO receptors (c-Mpl-molecules) in regulating megakaryocytopoiesis and platelet production. When thrombocytopenia develops, binding receptors decrease and serum TPO levels increase. Elevated TPO levels stimulate megakaryocytopoiesis and result in increased platelet production^[20-25]. This reverse relationship of platelet counts and serum TPO levels has been found in patients

with hematological diseases^[26,27]. Patients with cirrhosis were frequently associated with low platelet counts. However, serum TPO levels in cirrhotic patients were found to be lower than chronic hepatitis patients or normal subjects due to inadequate TPO production by the diseased livers^[28-32]. Serum TPO of cirrhotic patients increased after orthotopic liver transplantation, which was followed by an increase in platelet counts^[14,33-35]. Our results revealed serum TPO levels were significantly lower in cirrhotic patients than in patients with chronic hepatitis or normal controls, and were consistent with previous reports.

Despite the fact that hepatoma cells have been found to express TPO *in vitro* and in animal models, the mechanisms by which thrombocytosis develops in HCC patients have not been studied. According to our results, HCC patients with thrombocytosis had a significantly higher mean serum TPO level than HCC patients without thrombocytosis. In addition, the platelet counts and serum TPO levels in HCC patients with thrombocytosis dropped after a surgical removal of the tumor or TACE, and re-elevated when a tumor recurred. Changes of platelet counts and serum TPO levels were parallel to the changes of serum AFP. Furthermore, by using the reverse transcription and real-time PCR methods, we demonstrated that the expression of TPO mRNA was more in tumor tissues than in matched non-tumor tissues in an HCC patient with thrombocytosis. Our results were consistent with the report that thrombocytosis in patients with hepatoblastoma was related to increased TPO production in tumors^[9]. Thus, we speculate that thrombocytosis in HCC patients is due to the overproduction of TPO by tumors, and mostly in patients with a large tumor burden. The mechanisms of thrombocytosis in HCC patients are similar to those for other paraneoplastic manifestations. Hypoglycemia has been related to the overproduction of insulin-growth-factor II with insulin-like activities^[2]. The cause of hypercalcemia has been related to overproduction of a parathyroid-related protein which interacts with parathyroid hormone receptors^[4,36]. Elevation of serum erythropoietin has been seen in HCC patients with erythrocytosis^[5,37].

In conclusion, thrombocytosis is one of the paraneoplastic syndromes in patients with HCC, due to the overproduction of TPO by HCC. HCC patients with thrombocytosis are associated with a large tumor volume and high serum AFP level.

Abstract

AIM: To investigate the potential involvement of leptin in carcinogenesis of hepatocellular carcinoma (HCC) and to elucidate the etiology, carcinogenesis and progress of HCC.

METHODS: Expressions of Ob gene product, leptin and its receptor, Ob-R were investigated in 36 cases of HCC specimens and corresponding adjacent non-tumorous liver tissues with immunohistochemical staining. The effect of leptin on proliferation of Chang liver cell line and liver cancer cell line SMMC-7721 was studied with cell proliferation assay (MTT).

RESULTS: Leptin expression was detected in 36 cases of adjacent non-tumorous liver tissues (36/36, 100%) with moderate (++) to strong (+++) intensity; and in 72.22% (26/36) of HCC with weaker (+) intensity ($P < 0.05$). Thirty of 36 (83.33%) cases of adjacent non-tumorous liver tissues were positive for Ob-R, with moderate (++) to strong (+++) intensity. In HCC, 11/36 (30.56%) cases were positive, with weak (+) intensity ($P < 0.05$). In cell proliferation assay, leptin inhibited the proliferation of Chang liver cells. The cell survival rate was 10-13% lower than that of the untreated cells ($P > 0.05$). Leptin had little effect on the proliferation of liver cancer cells ($P > 0.05$).

CONCLUSION: High level expression and decreased or absent expression of leptin and its receptor in adjacent non-tumorous liver cells and HCC cells, inhibitory effect of leptin on the proliferation of normal Chang liver cells and no effect of leptin on proliferation of liver cancer cells, may provide new insights into the carcinogenesis and progression of human HCC. It could be assumed that leptin acting as an inhibitor and/or promoter, is involved in the process of carcinogenesis and progress of human HCC.

INTRODUCTION

Leptin, a circulating hormone secreted by adipocytes, is one of the major adipose cytokines acting as an important signaling molecule in energy regulation and food intake, and controls body weight homeostasis^[1-3]. It modulates various physiological and pathophysiological states, including lipid metabolism, hematopoiesis, thermogenesis, obesity, and polycystic ovary syndrome^[1,4]. Besides, leptin is also involved in obesity and carcinogenesis of some human cancers.

Recent studies suggested that leptin might play an important role in the process of initiation and progression of human cancers^[2,3,5-12], but there were a difference and discordance among the results. Circulating levels of leptin were higher in cases of breast cancer^[5], colorectal cancer^[8], prostate cancer^[6], eudiometrical cancer^[13], and lower in cases of uterine leiomyomas than the controls^[10], or had no difference in breast cancer^[14]. One study showed that leptin might play a role in the development of prostate cancer^[11]. Another study suggested plasma leptin was not associated with prostate cancer risk^[10]. On the other hand, studies suggested that leptin expression was associated with invasive potential of functioning pituitary adenomas^[15], and influenced cellular differentiation and the progression of prostate cancer^[11]. *In vitro* experimental studies, leptin not only stimulate proliferation of some human cancer cell lines, including breast cancer cell lines (ZR75-1, MCF-7, T-47D)^[2,7,9,16-18], esophageal cancer cell lines (KYSE410, 150), prostate cancer cell lines (DU145 and PC-3)^[2,3], acute myelogenous leukemia (AML)^[19] cell lines, but also inhibited the growth of some human cancer cell lines, such as pancreas cancer cell lines (PANC-1, Mia-PaCa)^[2]. The study results indicated that leptin had divergent effects on human cancer cell proliferation.

Hepatocellular carcinoma (HCC) is one of the most common malignancies in the world, and causes an estimated one million deaths annually. It has a poor prognosis due to its rapid infiltrating growth and complicating liver cirrhosis^[20,21]. Epidemiological studies suggested that obesity was a risk factor of HCC complicated with alcoholic liver disease and cryptogenic cirrhosis^[22,23]. Clinical investigations showed that serum leptin levels in alcoholic and post-hepatitis liver cirrhosis patients with or without HCC increased significantly compared with those in control subjects^[24-30], suggesting that leptin is involved in the etiology of hepatocellular carcinoma (HCC) in cirrhotic patients. Therefore, we hypothesized that leptin might be associated with the growth of liver cells and HCC cells, and played a role in carcinogenesis of hepatocellular carcinoma, but such a study has been reported. In order to confirm this hypothesis, the expression of leptin in human HCC and adjacent non-tumorous liver tissues was analyzed by immunohistochemical staining, and the effect of leptin on proliferation of normal liver cells and HCC cells *in vitro* was studied in this study.

MATERIALS AND METHODS

Immunohistochemical analysis of leptin and Ob-R expressions in human HCC and adjacent non-tumorous liver tissues

Patients and samples HCC specimens and corresponding adjacent non-tumorous liver tissues were collected from 36

patients surgically treated in West China Hospital of Sichuan University in China in 2000, all the patients were informed and consented to use their samples for this study. Of the 36 patients, 29 (80.56%) were males, 7 (19.44%) were females, their age ranged from 27 to 68 years (mean, 49.4 years), Twenty patients (20/36, 55.56%) were infected with HBV, 32 (32/36, 88.89%) were complicated with liver dysfunction, and 10 (10/36, 27.78%) with liver cirrhosis. None had any treatment before the surgical operation. All patients were diagnosed as HCC. The tissue specimens were routinely processed, formalin-fixed, and paraffin- embedded. Paraffinized sections were made for hematoxylin and eosin (HE) and immunohistochemical staining.

Reagents Ob (A-20) and Ob-R (H-300) rabbit anti-human polyclonal antibodies were purchased from Santa Cruz Biotechnology, USA. S-P immunohistochemical staining kit (SP9001) was purchased from Beijing Zhongshan Biological Technology Ltd.

Method Leptin protein and Ob-R were detected immunohistochemically with S-P method. Briefly, tissue sections were deparaffinized and rehydrated through graded alcohols. Antigen retrieval was performed by heating in microwave oven in 0.1 mol/L citrate buffer (pH 6). Then, endogenous peroxidase activity was blocked with 30 mL/L H_2O_2 , and after treatment with normal goat serum, the sections were incubated with Ob (A-20) or Ob-R (H-300) rabbit anti-human polyclonal antibodies at a dilution of 1:100, overnight at 4°C, with biotinylated second antibody for 20 min, and with streptavidin/peroxidase for 30 min at room temperature. Subsequently, the sections were subjected to color reaction with 0.2 g/L 3,3 diaminobenzidine tetrahydrochloride containing 0.05 mL/L H_2O_2 in PBS (pH 7.4), and counterstained with hematoxylin lightly. In each staining run, a known leptin positive sample of fat tissue was added as a positive control, and a section of the same fat tissue incubated in PBS instead of Ob or Ob-R was included as a negative control.

Semi-quantitative evaluation was used to determine positively expressed cells by viewing 10 vision fields at $\times 400$. Negative (-) indicated cells were stained less than 10%, mildly positive (+) showed 11-25% cells were stained, moderately positive (++) demonstrated 26-50% cells were stained, strongly positive (+++) revealed over 50% cells were stained. The intensity of staining in positive cells was compared with the negative control and scored as follows: negative (-), weak (+), moderate (++) , strong (+++), the last three grades were all regarded as positive.

Proliferation assay in vitro

Reagents Chang liver cell line (ATCC CCL13) and liver cancer cell line SMMC-7721 were obtained from Shanghai Cell Biology Institute of Chinese Academy of Sciences. Human recombinant leptin was a product from Signa-Aldrich, Inc. USA. RPMI-1640 was the product of Gibco/BRL (Invitrogen Corporation, USA). Fetal bovine serum (FBS) was purchased from Huaxi Biology Institute (Chengdu, China). Trypsin, 3-(4, 5-dimethylthiazol-2-yl)-2, 5-diphenyltetrazolium bromide (MTT), and DMSO were purchased from the Sino-American Biotechnology Company of Beijing.

Cell culture Both Chang liver cell line and SMMC-7721 cell line were cultured in RPMI-1640 medium supplemented with 100 mL/L FBS, 100 U/mL penicillin, and 100 μ g/mL streptomycin, at 37°C in a humidified atmosphere containing 50 mL/L CO_2 .

Proliferation assay (MTT) Chang liver cells and SMMC-7721 cells were suspended at a concentration of 5×10^4 /mL Then 200 μ L of the cell suspension was placed in each well of a replicate 96-well microtiter plate. The cells were allowed to adhere overnight. Then different concentrations (10, 20, 40, 80, 160, 320 ng/mL) of leptin were added to each kind of cells. MTT assay was performed after 1-, 3-, 5-d growth. A 20 μ L of 5 mg/mL of MTT was added to each well followed by incubation for 4 h at 37°C. Formazan products were solubilized with DMSO; A values were

read with an enzyme-linked immunosorbent assay reader (Bio-Tek, Houston, USA) at wavelength of 570 nm. All experiments were performed in triplicate. The effect of leptin on proliferation of Chang liver cells and SMMC-7721 cells were expressed as cell survival rates: A value of the treated group \div A value of control group $\times 100\%$.

Statistics analysis

The data of immunohistochemical staining were analyzed with chi-square test. The data of cell proliferation assay were analyzed with variance analysis. $P < 0.05$ was considered statistically significant.

RESULTS

Leptin expression in human HCC and adjacent non-tumorous liver tissues

The expressed Ob gene product, leptin was detected in all 36 specimen from adjacent non-tumorous liver tissues (36/36, 100%), with moderate (++) to strong (+++) intensity. The expression rate in HCC was 72.22% (26/36), but the intensity was weaker (+) than that in adjacent non-tumorous liver tissues (Figure 1), a significant difference in leptin expression was found between adjacent non-tumorous liver tissues and HCC ($P < 0.05$). Ten of 36 specimens from HCC (10/36, 27.78%) even lost the expression of leptin, but Kupffer cells and vascular endothelial cells expressed high levels of leptin (Figure 2).

Figure 1 Expression of leptin in adjacent non-tumorous liver live cells (left) and absent expression in HCC cells (right). S-P immunohistochemical staining $\times 200$.

Figure 2 Absent expression of leptin in HCC cells, Kupffer cells and vascular endothelial cells expressed high levels of leptin. S-P immunohistochemical staining $\times 400$.

Ob-R expression in human HCC and adjacent non-tumorous liver tissues

Thirty out of 36 specimens from adjacent non-tumorous liver tissues (30/36, 83.33%) were positive for Ob gene receptor product, with a moderate (++) to strong (+++) intensity. Only

11 of 36 specimens from HCC (11/36, 30.56%) were positive, with a weak (+) intensity. The expression of Ob-R was significantly lower than that of adjacent non-tumorous liver tissues ($P < 0.05$).

Effect of leptin on the proliferation of Chang liver cells *in vitro*

Leptin inhibited the proliferation of Chang liver cells on the 5th d after leptin treatment at various concentrations. The cell survival rate was 10-13% lower than that of the untreated cells (Figure 3A), although without statistical significance ($P > 0.05$).

Effect of leptin on proliferation of SMMC-7721 cells *in vitro*

Leptin had little effect on the proliferation of liver cancer cells (Figure 3B), the cell survival rate on each day after leptin treatment was lightly lower than that of the controls, but no statistical significance was found ($P > 0.05$).

Figure 3 Effect of leptin at different concentrations (ng/mL) on proliferation of Chang liver cells and liver cancer cells on d 5 (MTT assay). A: Effect of leptin at different concentrations (ng/mL) on proliferation of Chang liver cells on d 5 (MTT assay), B: Effect of leptin at different concentrations (ng/mL) on proliferation of liver cancer cells on d 5 (MTT assay).

DISCUSSION

It has found that certain cancers are associated with obesity, including breast, prostate, colon, uterus, renal cell, pancreas carcinoma and esophagus adenocarcinoma^[2,22,31]. Leptin, an Ob gene product, could control body weight homeostasis through food intake and energy expenditure, and was closely associated with obesity^[1-3]. Although epidemiological observation showed that obesity was a risk factor of HCC complicated with alcoholic liver disease and cryptogenic cirrhosis^[22,23,32], clinical investigations have identified that serum leptin levels in alcoholic and post-hepatitis liver cirrhosis patients with or without HCC are increased significantly in comparison with those in control subjects^[22,24-30]. There was no study on the role of leptin in carcinogenesis of human hepatic cellular carcinoma^[2,22-30].

The present study investigated the expression of leptin and its receptor Ob-R in both adjacent non-tumorous liver tissues and HCC tissues with immunohistochemical staining, and found that adjacent non-tumorous liver cells expressed higher levels of leptin and its receptor than corresponding HCC cells, about one fourth of HCC tissues lost the expression of leptin, and

two thirds had no Ob-R expression (Figures 1, 2). These findings suggest that leptin could act *in vivo* as a paracrine/endocrine growth factor towards hepatocytes, and played a possible role in the process of initiation and progression of HCC, which could thus contribute to the explanation of the reasons why alcoholic and post-hepatitis liver cirrhosis patients with or without HCC had high levels of serum leptin^[24-30] and the reasons why obesity was a risk factor of developing HCC^[22,31].

In proliferation assay *in vitro*, leptin had differential effects on the proliferation of human cancer cells. It caused growth potentiation in breast, esophagus, and prostate cancer cells, but inhibited the proliferation of pancreatic cancer cells^[2,19,32]. In MCF-7 cells, leptin and high glucose stimulated cell proliferation as demonstrated by the increases in DNA synthesis and expression of cdk2 and cyclin D1. However, they had no significant effect on the proliferation of multidrug-resistant human breast cancer NCI/ADR-RES cells^[16]. In this study, leptin alone showed some inhibitory effect on the proliferation of normal Chang liver cells, and no effect on liver cancer SMMC-7721 cells. However, Chang liver cell line was originally thought to be derived from normal liver tissue, but was subsequently found on the basis of isoenzyme analysis, HeLa marker chromosomes, and DNA fingerprinting, to have HeLa cell contamination when it was established (www.atcc.org). Therefore, these findings *in vitro* might be associated with different biological characteristics of cancer cells to react to leptin treatment, and/or the organ derivation of cancer cell lines^[2]. In addition, Chang liver cell line was not a good control of normal liver cells.

In vivo animal experiments findings showed that Leptin was a growth factor that could stimulate proliferation of colonic epithelial cells in mice^[33]. It is also a profibrogenic cytokine and could play a key role in liver fibrosis^[34]. *ob/ob* mice having a naturally occurring mutation in the *ob* gene that prevents the synthesis of leptin had an increased incidence of HCC^[31]. This study showed that leptin had some inhibitory effect on the proliferation of normal Chang liver cells and no effect on the proliferation of on liver cancer SMMC-7721 cells (Figures 3A,3B), and adjacent non-tumorous liver tissues could express higher levels of leptin and its receptor than the corresponding HCC cells (Figure 1). It could be assumed that leptin acting as an inhibitor and/or promoter, was involved in the process of carcinogenesis and progression of human HCC. In addition, the high levels of leptin expression in Kupffer cells and vascular endothelial cells might be associated with liver cirrhosis^[24,27,35,36], and angiogenesis of cancer tissues^[1,14,37], because these lesions might deteriorate HCC.

In summary, a preliminary investigation of the possible involvement of leptin in carcinogenesis of human hepatocellular carcinoma was performed in this study to elucidate the etiology and carcinogenesis of HCC. To the best of our knowledge^[2,20-30], this is the first report on involvement of leptin in HCC. The presence of leptin and its receptor in adjacent non-tumorous liver and HCC cells, and the effects of leptin on proliferation of normal Chang liver cells and liver cancer cells may provide new insights into the carcinogenesis and progression of human HCC.

Abstract

AIM: To study oval cells' pathological characteristics and relationship with the occurrence of hepatocellular carcinoma (HCC); to observe the form and structural characteristics of oval cells; to explore the expression characteristics of C-kit, PCNA mRNA and *c-myc* gene during the occurrence and development of HCC and the effect of ulinastatin (UTI) on C-kit and PCNA expression.

METHODS: One hundred and twenty-five SD rats fed on 3,3'-diaminobenzidine (DAB) to construct HCC models were divided into control group, cancer-inducing group and UTI intervention group. In each group, rat liver samples were collected at weeks 2, 4, 6, 8, 10, 12, 14, 16, 18, 20, 22 and 24 respectively to study pathological distribution characteristics of oval cells in the process of carcinogenesis under optical microscope. Oval cells were separated by the methods of improved density gradient centrifugation and their structural characteristics were observed under optical microscope and electronic microscope respectively; the oval cells expressing C-kit and PCNA in the collected samples were observed by the methods of immunohistochemistry and image analysis and the expression of *c-myc* mRNA was also detected by reverse transcription polymerase chain reaction (RT-PCR).

RESULTS: Oval cells proliferated firstly in the portal area then gradually migrated into hepatic parenchyma in the inducing group and intervention group. The oval cells distributed inside and outside the carcinoma nodes. The oval cells presented the characteristics of undifferentiated cells: a high ratio of nucleolus and cellular plasm and obvious nucleoli, rare organelle in plasm. Only a few mitochondria and endoplasmic reticulum and some villus-like apophysis on surface of cells could be seen. Cells stained with C-kit and PCNA antibody were mainly oval cells distributed in the portal area. The expression of *c-myc* mRNA increased with the progression of HCC. However, in the intervention group, UTI could retard its increase.

CONCLUSION: Oval cells work throughout the development of HCC, and might play important roles in this process. *c-myc* gene may be a kind of promoter gene of HCC, and play a key role in hepatic injury and development of HCC. UTI could retard the occurrence of HCC.

INTRODUCTION

HCC is one of the most common malignant carcinomas in China. Because of its high rate of metastasis and recurrence and lack of typical symptoms in early stage, HCC has the second mortality rate among all the malignant carcinomas^[1,2]. Up to now, obvious progress has been made in the study of cell origin of HCC. One is that HCC is originated from abnormally differentiated oval cells, the other is that it results from dedifferentiation of mature liver cells. In order to probe the relationship between oval cells and HCC, we explored the pathologic distribution characteristics, structural features of oval cells in the pathogenesis of HCC in experimental SD rats and the expression characteristics of C-kit, PCNA and *c-myc* genes in oval cells.

MATERIALS AND METHODS

Materials

One hundred and twenty-five clearing SD rats (100±20 g) (Experimental Center of Zhongshan University) were fed in the environment of 18-28 °C and 40-70% humidity in Animal Feeding Unit, Zhujiang Hospital, First Military Medical University. DAB (Dako, Japan) was used as inducing drug for HCC in rat; proline, asparagic acid, serine phenylalanine, tyrosine pyruvate sodium, transferring, epidermal growth factor (EGF) (Sigma, USA) and F12, F12/DMEM (1:1) (Gibco, USA), and fetal bovine serum (Sijiqing Co, Hangzhou, China) were used for culture medium for oval cells. Collagenase VI and density gradient centrifugation (percoll) (Sigma) were used for separating oval cells. C-kit polyclonal antibody (Sigma), immunohistochemical kits (SABC methods) and poly-lysine for adhibiting section, neutral resin for envelop section (Boshide Co, Wuhan); PCNA immunohistochemical kits (SP methods), DAB dyeing reagent (Zhongshan Co, Beijing); *c-myc* mRNA kit, total RNA extraction kits, DNA marker (100 bp), primers for polymerase chain reaction (PCR) and RNasin (Huamei Bioengineering Co), M-MLV reverse transcriptase (Promega USA), *Taq* DNA polymerase (Gibco), 4×dNTP (Sigma), amplification primer for reverse transcription polymerase chain reaction (RT-PCR) were synthesized by Shanghai Biotech Co. according to the GenBank database.

Methods

HCC model The method of constructing HCC model in the cancer-inducing group and inter group was according to the references^[3,4]. After fed on DAB for 14 wk, rats were given normal drinking water, but in control group, the rats were fed on standard food. In the interference group, as soon as the DAB was administrated, UTI (2-10⁴ U/kg) was injected into abdominal cavity, twice a week until wk14^[5,6]. One hundred and twenty-five clearing SD rats were divided into control group (24 rats), cancer-inducing group (48 rats) and UTI interference group (48 rats), the other 5 rats were used to construct the

model of oval cells proliferation. Each group was divided into 12 sub-groups, and there were 2 rats in sub-group of the control group and the cancer-inducing group, 4 rats in sub-group of interference group. Two pieces of 1 cm×1 cm×1 cm tissue taken from the right liver lobe of each rat in sub-group were fixed in 40 g/L formaldehyde and 2-4 pieces of soybean-sized tissue taken from the left liver lobe of each rat in sub-group were placed respectively in the 0.5 mL centrifuge tube and preserved in a refrigerator at -80 °C at wk 2, 4, 6, 8, 10, 12, 14, 16, 18, 20, 22 and 24 respectively during construction of HCC model. The samples of right liver lobes were sliced serially to count cancerous nodes under low power microscope. Nodes more than 0.05 mm² were measured by the gridding ocular micrometer.

Separation of oval cells When the rats have been fed DAB for 4 wk, a large number of oval cells proliferated from the hepatic portal area, which could be identified by HE dyeing section analysis. Firstly, D-Hanks' solution was perfused through portal vein until the liver color turned yellow, then 1 g/L collagenase IV was affused to digest liver. The digested liver was put in a beaker, washed 3 times with Hank's solution, and minced thoroughly at the same time, then 0.6 g/L collagenase IV was added to further digest liver for 30 min at 37 °C. The cell suspension was filtrated through 100 holes/cm² sieve, then centrifuged at 300 r/min at 4 °C for 5 min, the cell suspension was extracted and centrifuged again at 2 000 r/min at 4 °C for 10 min. The upper layer solution abandoned, then cells were suspended again with 10 mL F12 solution. The density gradient centrifugation solution (percoll) was blended with 100 g/L NaCl at a ratio of 9:1 and diluted with F12 into the solution of 90%, 70% and 50%, respectively. Ten mL of each solution was put in a high-speed centrifugation tube of 50 mL, according to the concentration gradient of 90%, 70% and 50%. A 10 mL cell suspension was placed on the top of each tube, then centrifuged for 30 min at 4 °C, 12 000 g so that the oval cells were located between the centrifugation solution of 70% and 50%, then the oval cell suspension was extracted carefully to another tube. Hanks' solution was added with 5 kU/L benzylpenicillin and streptomycin A, then centrifuged at 1 000 r/min for 5 min, the precipitate was retained. Culture medium F12/DMEM (1:1) solution was added to suspend cells. Then the suspension was inoculated into 25 cm³ plastic culture bottles, according to the density of 2×10⁸/L, placed into incubating cabin with 5 mL/L CO₂ at 37 °C. After 24 h the culture solution was replaced and oval cells could be seen adhering to the bottle wall.

Culture of oval cells The culture medium consisted of 200 mL/L fetal bovine serum which was diluted with the solution of DMEM/F12(1:1) containing epidermal growth factor (20 µg/L), transferring (20 µg/L) and some kinds of amino acid. The culture medium was replaced every 2 or 3 d. When cells overgrew in the bottles, some parts of cells were transferred into another culture bottle. The culture medium in the bottles was extracted; F12 solution was added to clean the cells three times, then mixed with 2.5 g/L pancreatin to digest. The cells were observed under the microscope for about 1 min, then oval cells could be seen floating and then the culture medium was added to terminate digestion. After the cells were separated completely, they were inoculated into another bottle.

C-kit immunohistochemistry Carry sheet glasses were treated by polylysine. Paraffin sections (5 µm thick) were dewaxed by dimethylbenzene and alcohol respectively. After washed by 0.01 mol/L PBS for 2 min 3 times, the sections were incubated in 3 mL/L H₂O₂ solution for 10 min to inactivate endogenous peroxides, heated in citric acid sodium solution in microwave oven at 100 °C to retrieve antigen for 10 min and then cooled for 25 min. After washed with 0.1 mol/L PBS for 2 min 3 times, they were incubated with normal goat serum to block nonspecific binding of antibodies for 10 min at room temperature. The sections were then incubated with IgG of rabbit antiserum

against mouse at 37 °C for 24 h or at 4 °C overnight, washed with 0.01 mol/L PBS for 3 times for 2 min each, then incubated with goat IgG anti-rabbit at 37 °C for 20 min, washed with 0.01 mol/L PBS for 2 min 3 times, Reagent SABC was added and incubated at 37 °C for 20 min, section were washed again with 0.01 mol/L PBS for 3 times. The immunoreacted cells were then visualized by using DAB kits as follows: a drop of reagent A, B and C was added into 1 mL distilled water, then they were blended completely and dripped on the sections. The sections were counterstained with hematoxylin for 50 s, then dehydrated and observed with light microscope.

PCNA immunohistochemistry (SP methods) The SABC reagent was replaced by the solution of streptavidin marked with horse-radish peroxidase in the first steps and the other steps were the same as C-kit immunohistochemistry. C-kit protein was stained brown yellow. The localization of C-kit protein and its change in quantity were observed when the rats' livers were injured. PCNA protein was stained as brown yellow. The localization of PCNA positive cells in the hepatic lobule was observed and PCNA labeling index (proliferating index) was calculated by randomly observing 5 fields under high microscope in each section. The positive cells among 100 cells were counted in each field and mean values were taken.

RNA extraction and assessment The preserved 50-100 mg liver tissues were mixed and grinded evenly with 1 mL cold denaturant. A 1 mL lysis liquid was added into a 2.0 mL centrifuge tube and then mixed with 0.1 mL sodium acetate (pH4.0). A 100 mL phenol/chloroform mixture was mixed with the above mentioned liquid and intensely vibrated for 10 s, then placed on ice for 10 min. The liquid was centrifuged at 4 °C. The top layer liquid was transferred into a 1.5-mL centrifuge tube and kept at -20 °C for 15 min after mixed with isopropanol of identical volume. White jelly-like precipitate after centrifugation at 10 000 g for 15 min at 4 °C was the total RNA. RNA was resolved completely by 1 mL lysis and RNA precipitate and wall of the tube liquid were washed with 250 mol/L alcohol. Resolved RNA in RNase-free water and preserved it at -20 °C. The absorbance (A) of total RNA was measured by ultraviolet spectrophotometer and the RNA concentration(g/L) was $A_{260} \times \text{nucleic acid dilution times} \times 40/1\,000$ (A_{260}/A_{280}) (if A of RNA >1.8, the RNA is pure enough to be used in the following experiment).

Agarose electrophoresis RNA solution 1 µL mixed with 2 µL bromphenol blue buffer was electrophored in the level electrophoresis chamber treated by RNase-free water at 100 V for 20 min then the gelatum was taken to be observed. Three RNA straps of 28 s, 18 s, and 5 s could be seen through gel electrophoresis.

cDNA synthesis and PCR reaction A 2 µL (1 µg) total RNA, 4 µL (20 pmol) of c-myc downstream primer and 8 µL of RNA-free water were mixed well at the room temperature, put in water bath at 70 °C to degenerate for 5 min. Then they were put on ice for 1 min, centrifuged at 200 g for 30 s. A 5 µL M-MLV reverse transcriptase 5×Buffer, 5 µL dNTP (2.5 mmol/L), 5 µL rRNasin (20 U) and 5 µL M-MLV RT were added and the total reaction volume was 34 µL. The mixture was treated at 42 °C for 60 min and at 95 °C for 5 min to inactivate reverse transcriptase, then maintained at -30 °C. Sixteen µL of cDNA, 5 µL 10×Buffer (no MgCl₂), 3 µL solutions MgCl₂ (25 mmol/L), 4 µL (2.5 mmol/L) dNTP, 3 µL (15 pmol) of sense including target gene and mark gene respectively, 3 µL (15 pmol) antisense including target gene and mark gene respectively, 1 µL (3U) *Taq* DNA enzyme and 9 µL RNA-free water were mixed totally at the room temperature, and the above total reactive volume was 50 µL. Then a drop of paraffin oil treated at high temperature was added onto the surface of mixture, and degenerated at 94 °C for 5 min. PCR cycle was at 94 °C, 50 °C and 72 °C respectively, for 1 min each. After 35 cycles, an extension at 72 °C was performed

for 5 min.

Agarose electrophoresis A 8 μ L product of c-myc DNA was taken for caraphoresis in 20 g/L sepharose (containing small quantity EB), and two straps of 228-bp and 120-bp (the product of mark gene) were found under light. The caraphoresis strap of PCR was scanned and quantitatively analyzed with gel image analysis system.

Statistical analysis

Experiment results were analyzed with SPSS10.0 software. Data were analyzed with single-side analysis of variance and with LSD methods for inter-group analysis. Chi-squared test was used to compare rates between two groups. $P < 0.05$ indicates significant difference.

RESULTS

Pathological characteristics

The rats' liver cells in the early period of cancer-inducing group showed balloon-like degeneration under light microscope (1-8 wk). Since the 2nd wk in the cancer-inducing group, the oval cells started to proliferate in portal area and gradually migrated into liver parenchyma (Figure 1). The pseudo-lobules formed in the liver and oval cells migrated into lobules in the middle period from the 15th to 24th wk. The cancer cell nucleus presented in different sizes and karyokinesis often occurred. Cancer cells infiltrated toward the periphery of liver tissue, and at the same time, focal bleeding and necrosis obviously occurred. Huge amounts of leucocytes infiltration could be seen in the peripheral area of nodes and portal area, and lots of oval cell proliferations were shown in portal area and in cancer nodes (Figure 2). Beginning from the 2nd wk of cancer induction, the proliferation of oval cells could be seen in portal area. Firstly oval cells appeared in the epithelial lining of bile duct of portal area and then gradually proliferated and migrated into liver parenchyma. In the fibrosis formation period, the proliferation of oval cells could be seen in portal area and in its peripheral area. The volume of oval cells was about as big as one third of normal liver cells, round or oval-shaped and its margin was unclear with scant cytoplasm and basophils. The cell nucleus was round or oval shaped, with slight stain, vague membrane and obvious nucleolus. Oval cells proliferated first in portal area and then in liver limiting plate, migrated along liver sinusoids and to the middle part of lobules. These cells often presented as two lines or branches, destroying the neighboring liver cord. The left lobe liver cells were scattered among the proliferated oval cells that distributed inside and mainly outside of the cancer nodes. Oval cells showed the characteristics of undifferentiated cells: a big ratio of nucleus and plasm and obvious nucleoi, rare organele in plasm, only a few mitochondria, endoplasmic reticulum and some villus-like apophysis on surface of cells could be seen under the electronic microscope (Figure 3).

Figure 1 Early inflammatory liver tissues in cancer inducing group at the 2nd wk and the differentiation of oval cells in the portal area (HE staining, original magnification: $\times 200$).

Figure 2 A large quantity of oval cells gathered around the cancer nodes in cancer inducing group at 20th wk (HE staining, original magnification: $\times 200$).

Figure 3 Electron microscopic observation showed: the volume of oval cell was about as big as one third of normal liver cell, round or oval shaped, scant cytoplasm with unclear cell margin.

The effect of UTI on cancer induction: in the early period, the balloon-like degeneration of liver cells was much milder than that of the liver cells in cancer-inducing group. The balloon-like degeneration of liver cells was obvious in the middle period and local liver cells became necrosis, liver lobes were destroyed and the liver fiber proliferated and the pseudo-lobules formed in the local area with a large amount of oval cell aggregating in the portal area and liver parenchyma could be seen. In the period of carcinoma formation, pseudo-lobules were seen apparently in large parts of liver parenchyma and a large number of oval cells aggregated to an extreme extent. Some liver cancer cells with column-like or glandular-like structure appeared in part of liver parenchyma and oval cells scattered among the cancer cells. The neoplasia nodes were counted as in Table 1.

Table 1 Number of cancerous nodes and cancer nodes' area in rat liver (mean \pm SD, $n=8$)

t/wk	Cases of hepatic cancer		Number of cancerous		Area of cancer nodes (mm ²)

Characteristics of c-kit positive stain cells

C-kit positive stain localized in cell plasm in normal liver showed brown-yellow and was mainly in the mitotic and proliferating

liver cells. At the 2nd wk in the cancer-inducing group, some c-kit positive stain cells, mainly oval cells, appeared in the portal area and punctated positive pigmentations could be seen in liver lobules as well. At the 8th wk, oval cells in the portal area in the cancer-inducing group were obviously positively stained, with some positive pigmentation forming patches and some punctating in the rim of portal area (Figure 4). At the 14th wk, the normal liver structure was replaced by a lot of pseudo-lobule and still a large number of c-kit positive stain cells could be seen which mainly gathered in portal area. In the 22nd wk in the cancer-inducing group, a large number of cancerous nodes formed and some positive cells scattered among them (Figure 5). The characteristics of c-kit positive staining cells in the samples of intervention group was almost identical with that in cancer-inducing group.

Figure 4 Expression of c-kit in liver tissue in cancer inducing group at the 8th wk. The oval cells were mainly stained in portal areas (Immunohistochemistry, $\times 200$).

Figure 5 Expression of c-kit in the HCC tissue in cancer inducing group in the 24th wk (Immunohistochemistry, $\times 200$).

Characteristics of PCNA positive cells

PCNA positive staining located in the nucleus, as granules or diffusively. Occasionally positive stains were seen in normal liver tissue. At the 2nd wk of the cancer-induction, the PCNA positive cells firstly appeared among the oval cells in the portal area. At the 4th wk, a lot of hepatic cells were positively stained, especially in central vein area. At the 6th wk, also the middle stage of inflammatory process, PCNA positive cells were seen all over the lobules of liver. At the 8th wk, the number of PCNA cells was comparatively decreased and nuclei of positive cells around the portal area tended to become larger gradually. From the 10th to 14th wk, some of the proliferating hepatic fibers were lightly stained and the oval cells in portal area still over expressed PCNA. From the 16th to 24th wk, a large number of cancerous nodes formed and PCNA over expressed in some cancerous nodes (Figure 6), while the number of positive cells was relatively fewer in necrotic cancerous nodes than in other areas and the number of dotted positive stain cells adjacent to the carcinoma tissue was apparently fewer than inside the

carcinoma tissue. In the intervention group, PCNA positive stain cells firstly appeared among the oval cells in portal area, and then their number increased with the aggravation of hepatic intoxication by DAB. The PCNA positive stain rate and expression level reached the peak at the 10th wk in rat liver. The distribution characteristics of PCNA positive cells were similar to those in the cancer inducing group when HCC formed. The labeling index of PCNA positive stain cells is shown in Table 2.

Figure 6 PCNA expression in HCC tissue in the cancer inducing group at the 24th wk (Immunohistochemistry, $\times 200$).

c-myc gene expression

Expression of *c-myc* gene existed in normal rat liver tissue, but the expression quantity is relatively small. The expression of *c-myc* mRNA increased as soon as liver was intoxicated with DAB and its expression quantity tended to gradually increase with the aggravation of liver injury. In the period of carcinoma formation, *c-myc* mRNA expression level also gradually rose with the development of HCC (Table 2, Figures 7, 8). The intervention of UTI could not stop but could retard the increase of expression level of *c-myc* mRNA.

DISCUSSION

Oval cells are round or oval shaped with scant and basophilic cytoplasm, and round or oval shaped nucleus, small and clear light stained nucleolus and clear nuclear membrane. Because they can differentiate towards hepatic cells or bile duct epithelial cells when hepatic cells are severely injured or the proliferation is inhibited, oval cells are considered as a kind of progenitor cells with potential bilateral differentiation^[7]. It is reported that the activation of Ito cells was probably a precondition for the activation of oval cells and stimulates oval cells in the portal areas to migrate towards the hepatic fibrosis area. Consequently, oval cells may participate in the formation of HCC^[8-11].

There is no doubt that there are hepatic stem cells in hepatic tissues, but where do the hepatic stem cells come from? Some researchers thought that they were originated from the terminal biliary duct of portal area^[12,13], but some insisted that they were from the canal of Hering^[14-16], and some even found authentic evidence that the oval cells came from bone marrow stem cells^[17-20]. In order to identify the origin of hepatic stem cells and the relationship between hepatic stem cells and the development of HCC, we carried out the study on the surface marker antigen c-kit with immunohistochemical methods, and found that: (1) In the early stage of hepatic injury, the c-kit positive stain cells firstly appeared among the oval cells in the portal area. (2) In the late stage of inflammatory lesion, c-kit was over expressed in the oval cells in the portal area and positive pigmentation presented as patches. (3) During the period of hepatic proliferation and fibrosis, positive expression of c-kit in portal area decreased compared with that in the late stage of inflammatory lesion. (4) In period of the formation of HCC, heteromorphisms of cancer cells were obvious and c-kit was still expressed in portal area. (5) At the beginning of inflammatory lesion, there were small quantities of c-kit positive cells in hepatic lobules with smaller nuclei and more were found near portal area. During the period of hepatic fibrosis, c-kit positive cells were rarely seen in hepatic lobules, but during the formation of HCC, c-kit positive cells appeared both inside and around the cancerous nodes. (6) In the normal hepatic tissues, c-kit-positive stain cells could be occasionally observed in the mitotic and proliferating hepatic cells. From these results, we can conclude that: (1) Oval cells had the highest expression level of c-kit in the portal area from hepatic injury to the occurrence and development of HCC. As it has been proved that the oval cells originate from bile duct epithelial cells in the portal area, we suggest that the terminal bile ducts are an important source of hepatic stem cells. (2) In the course of hepatic injury, c-kit positive cells could be found in hepatic lobules as well, especially near the portal area, which may be related to migration of oval cells along hepatic fibrosis into hepatic lobules. (3) C-kit was not only expressed in hepatic stem cells, but in the mitotic and proliferating hepatic cells, which indicated that c-kit might be a specific mark antigen for a type of juvenile cells, express only in a certain stage of mitotic and proliferation of hepatic cells. (4) C-kit positive stain cells played a role in the whole process of occurrence and development

of HCC and appeared in cancerous nodes, so we thought that hepatic stem cells, just as was reported in literature, were involved in the occurrence and development of HCC.

PCNA is a type of M_r 36 000 nuclear protein which is only synthesized and expressed in proliferating cells. Cyto-dynamics shows that PCNA begins to increase in the late G₁ phase in the cell cycle, reaches the peak in the S phase and begins to decrease in the G₂-M phase, in this way it regulates the replication of DNA^[21-23]. Therefore, PCNA can effectively reflect the proliferation ability of cells. In this experiment we found that the high level expression of PCNA appeared firstly in the oval cells in portal area at the early stage of inflammation, significantly higher than adjacent tissue. When the mitosis and proliferation of hepatic cells were inhibited, oval cells presented firstly with active proliferation and DNA was synthesized in a large amount in nucleus. The farther they were away from the portal area, the more mature the oval cells differentiated and the larger the size of nucleus tended to be. Thus the expression of PCNA distributed radiatively and regionally around the portal area and the regional predominance was kept for a long time in the process of carcinoma induction. Oval cells took part in the whole process of development of HCC, we could speculate that there might be close relationship between the development of HCC and the PCNA overexpressing oval cells.

c-myc gene is a maintaining gene for malignant tissue, coding for a protein located in nucleolus, a type of DNA conjugated protein with the function of transcription regulation^[24-27]. This experiment suggested that the expression of *c-myc* gene increased slightly at the beginning of hepatic injury and the expression of *c-myc* mRNA increased progressively with the aggravation of hepatic injury. The expression of *c-myc* mRNA also tended to increase with the development of HCC. The above results indicated that: (1) As an oncogene, *c-myc* might be a promoter gene for HCC and played an important role in maintaining hepatic injury and hepatocyte carcinomatous change. (2) During the development of HCC, the expression level of *c-myc* continued to increase, indicating that *c-myc* was not only a maintaining gene for malignant carcinoma, but the quantity of its expression was a symbol for the degree of malignancy and progression of HCC.

UTI is a kind of broad-spectrum trypsin inhibitor extracted from human beings' urine. It has been found that UTI plays a prominent role in preventing cancer cells from spread. Some researchers pointed out that there were combination spots with UTI on the surface of nearly all kinds of cancer cells membrane and UTI could inhibit cancer cells to secrete granulocyte protein lyase, fibrinoclastase, matrix metalloproteinase and collagenase^[28,29], which can degrade peripheral matrix and lead tumor cells to spread, by combining with their receptors on the surface of cancer cell membrane. Some clinical reports showed that UTI could inhibit the cancer cells to combine with other anti-cancer drugs^[30]. In this experiment, the interference of UTI throughout development of HCC and its effect on HCC were observed. It was found that from the 14th to 16th wk, the occurrence rate of HCC in the interference group was 25% (2/8), which was significantly different ($P < 0.05$) from that of cancer induction group at the same time. During the 18th to 20th wk and the 22nd to 24th wk, the occurrence rate of HCC was both 50% (4/8), which was lower than that in the cancer inducing group at the same time. UTI's effect on inhibiting the occurrence of cancer was related to the following factors: (1) The occurrence of HCC needed certain micro-environment and UTI could inhibit some local cells from releasing inflammatory mediators by stabilizing lysosome membrane, then the inflammatory cells' chemotaxis was inhibited and local inflammation was relieved, thus it could inhibit the occurrence of tumor by stabilizing micro-environment. (2) Researches proved that UTI had fairly strong function to inhibit and clear away oxygen-derived free

radicals, while a lot of oxygen-derived free radical receptors existed on the surfaces of liver cells and oval cells, so possibly UTI could protect liver tissue from being damaged by oxygen-derived free radicals. Furthermore, during the whole process of cancer induction, the average cancer node area of liver rats in interference group was smaller than that of cancer inducing group at the same time points ($P < 0.05$), especially at the early stage of carcinogenesis, which indicated that UTI could partly inhibit the growth and local spreading of tumor cells.

The results that interference of UTI could not stop but could retard the increase of the expression of c-myc mRNA indicate two points: (1) UTI can prevent the occurrence of hepatic injury and HCC to some extent, but can not inhibit the expression of c-myc gene, which might be related with inhibitory effect on hepatic tissue inflammation and protective effect on hepatocytes of UTI. (2) The expression of c-myc gene closely relates to the severity of hepatic injury.

Abstract

AIM: To investigate the immunogenicity of candidate DNA vaccine against hepatitis C virus (HCV) delivered by two plasmids expressing HCV envelope protein 1 (E1) and envelope protein 2 (E2) antigens respectively and to study the effect of CpG adjuvant on this candidate vaccine.

METHODS: Recombinant plasmids expressing HCV E1 and E2 antigens respectively were used to simultaneously inoculate mice with or without CpG adjuvant. Antisera were then collected and titers of anti-HCV antibodies were analyzed by ELISA. One month after the last injection, animals were sacrificed to prepare single-cell suspension of splenocytes. These cells were subjected to HCV antigen specific proliferation assays and cytokine secretion assays to evaluate the cellular immune responses of the vaccinated animals.

RESULTS: Antibody responses to HCV E1 and E2 antigens were detected in vaccinated animals. Animals receiving CpG adjuvant had slightly lower titers of anti-HCV antibodies in the sera, while the splenocytes from these animals showed higher HCV-antigen specific proliferation. Analysis of cytokine secretion from the splenocytes was consistent with the above results. While no antigen-specific IL-4 secretion was detected for all vaccinated animals, HCV antigen-specific INF- γ secretion was detected for the splenocytes of vaccinated animals. CpG adjuvant enhanced the secretion of INF- γ but did not change the profile of IL-4 secretion.

CONCLUSION: Vaccination of mice with plasmids encoding HCV E1 and E2 antigens induces humoral and cellular immune responses. CpG adjuvant significantly enhances the cellular immune response.

INTRODUCTION

Hepatitis C virus (HCV) infection is a worldwide health problem^[1]. Up to now, no effective medical treatment is available for the majority

of HCV infected patients^[2,3], while new infections are continuously emerging from blood transfusion, needle sharing, unprotected sex, close contact of HCV infected patient and other unidentified sources^[4]. Thus to control the spread of HCV by vaccination becomes an urgent task, especially in developing countries including China, where there is a large infected population.

Various routes were taken to develop a vaccine against HCV infection. Recombinant HCV antigens purified from *E.coli*, yeast or insect cells could not protect the vaccinee from virus challenge^[5], possibly due to the fact that post-translational modification of the virus antigens in mammalian cells is greatly different from that in the bacterial or yeast cells. So the study on vaccine development has been focused on mammalian systems. Although many efforts have been made in vaccine development and some encouraging results have been obtained^[5-8], no effective vaccine is available.

The RNA genome of HCV has a high mutation rate, which explains the existence of many genotypes, subtypes and quasispecies^[9-10]. Although there is still a possibility to develop a universal vaccine against HCV of all genotypes, the use of local HCV strain in vaccine study is preferred. Our laboratory has been focusing on DNA vaccine development^[11] using an HCV strain isolated from a patient in northern China^[12], since DNA vaccine is effective in eliciting cellular immune responses^[13] which play key roles in viral clearance.

Envelope proteins were the first choice in the development of vaccines against virus infection. HCV envelope protein 2 has become the major target in HCV vaccine development not only because it is the putative major envelope protein^[14], but also because E2 could mediate the binding of HCV particle to host cells^[15] and is the ligand of the possible HCV receptor CD81 on the host cell surface^[16]. It makes E2 an attractive choice for vaccine development as it has been shown to be a major target of immune response in HCV infected patients^[17,18]. Previous studies also revealed multiple neutralizing epitopes in E2 proteins^[19-22]. Another envelope protein of HCV, E1, is also desirable for vaccine development, since its possible role in maintaining the natural conformation of E2 protein (through E1-E2 complex)^[23] and the possibility of its cooperation with E2 in mediating host cell binding and entry^[24]. However, low expression levels of both E1 and E2 proteins were observed when they were expressed in a single open reading frame (data not shown). In this study, we expressed HCV E1 and E2 proteins separately and analyzed the immune responses of DNA vaccination delivered by two plasmids encoding HCV E1 and E2 proteins respectively.

Recent studies showed that the immune system responded to CpG motifs by activating potent Th1-like immune responses^[25]. There have also been several reports demonstrating that CpG could enhance humoral immune responses elicited by DNA vaccination^[24,25], possibly due to indirect effect of enhanced cellular immune responses. The effect of CpG adjuvant on the immune response elicited by the candidate DNA vaccine was also investigated in this study.

MATERIALS AND METHODS

Plasmids, CpG oligodeoxynucleotide (ODN) and cells

For the construction of pSecTagB/sE2, the fragment of HCV

E2 (aa. 384–661) was amplified using plasmid pUC18/E^[12] as template with following primers: sense, 5'GGCGTTAAGCTTAA CACCTACGTG3' (HindIII site underlined); antisense, 5'CAG GAATTCTCACTCTGATCTATC3' (EcoRI site underlined). Insertion of the PCR product into pSecTagB (Invitrogen, California) resulted in pSecTagB/sE2, in which a secretion signal was provided at the N-terminal of E2 sequence. The recombinant plasmid was sequenced before further experiments.

HCV E1 encoding plasmid pSec-preS1-E1t340 (pSecTagB/sE1) was constructed as previously described^[26]. CpG ODN1826 with phosphorothioate backbone was synthesized in Promega (Shanghai) according to the published sequence 5'TCCATGACGTTCCTGACGTT3'^[27]. The cell line used for transient expression of the recombinant plasmids, BHK-21, was maintained in DMEM supplemented with 50 mL/L FCS and antibiotics under 50 mL/L CO₂ in a humidified 37 °C incubator.

Transient expression

Transfection of BHK-21 cells with HCV-encoding plasmid or empty vector using lipofectAMINE (Invitrogen) was done according to the manuals of the manufacturer. Cells were harvested 48 h after transfection, lysed in SDS-PAGE loading buffer, and subjected to SDS-PAGE (10%). The resolved samples were then transferred onto nitrocellulose membrane and probed with polyclonal anti-E1 (Liu *et al.*, unpublished data) or polyclonal anti-E2 antisera^[28]. The signals were visualized with SuperSignal West Pico stable peroxide solution (Pierce, USA).

DNA immunization and sera preparation

Four groups of 5 female BALB/c mice (6–8 weeks old) purchased from the Shanghai Laboratory Animal Center were injected 3 times in quadriceps muscles: group 1, with 100 µg pSecTagB in 100 µL PBS; group 2, with 50 µg pSecTagB/sS1E1 and 50 µg pSecTagB/sE2 in a total volume of 100 µL PBS; group 3, with 100 µg pSecTagB together with 10 µg CpG in a total volume of 100 µL PBS; group 4, with 50 µg pSecTagB/sS1E1, 50 µg pSecTagB/sE2 and 10 µg CpG in a total volume of 100 µL PBS. Injections were performed at 0, 4 and 8 wk and blood samples were taken at -2, 2, 6 and 10 wk. Mice were bled under anesthesia through the retro-orbital plexus. Blood was incubated at room temperature for 4 h and centrifuged at 2 700 r/min at 4 °C for 10 min. Obtained sera were stored at -20 °C.

Anti-HCV antibody analysis

Enzyme-linked immunosorbent assay (ELISA) was used to determine the presence of antibodies against HCV E1 and E2 antigens in serum samples. *E. coli*-expressed HCV E1 (aa 192 to 315) or HCV E2 (aa 450 to 565^[31]) was used to coat 96-well plates (MaxiSorp Surface, Nunc) at the concentration of 1 µg/mL. The antigens were suspended in PBS with 0.2 g/L sodium azide and incubated overnight at 4 °C. After the plates were washed with PBS plus 0.5 g/L Tween 20 (PBS-T) and blocked in blocking buffer (50 g/L fat-free milk powder in PBS-T), twofold serial dilutions of serum samples in blocking buffer were added and incubated for 2 h at 37 °C. After three wash steps with PBS-T, horseradish peroxidase (HRP) conjugated goat-anti-mouse IgG (Dako, Denmark; 1 000-fold diluted in blocking buffer) was added and incubated for 1 h at 37 °C. The plate was then developed with substrate buffer (50 mmol/L Na₂HPO₄, 25 mmol/L citric acid, 75 µg/mL 3,3',5,5'-tetramethylbenzidine, 0.15 mL/L H₂O₂). After 30 min of incubation at room temperature, the reaction was stopped by adding 0.5 mol/L H₂SO₄, and absorbance was measured at 450 nm on a microplate reader (Model 450, Bio-Rad Laboratories). Antibody titers were calculated as the highest dilution which gave a positive reading. The cutoff value was set as mean absorbency (A) of sera from the control mice vaccinated with non-recombinant plasmid multiplied by 2.

Preparation of splenocytes

Mice were sacrificed by cervical dislocation. Spleens from these mice were ground on metal mesh to prepare single-cell suspension in grinding media (RPMI1640 supplemented with 100 mL/L FCS, 1 mmol/L Sodium pyruvate and 50 µmol/L β-ME). Red blood cells were lysed by incubating the splenocyte preparations with lysis buffer (0.15 mol/L NH₄Cl, 10 mmol/L KHCO₂, 0.1 mmol/L EDTA, pH7.2–7.4) briefly and then washed with grinding media. The cells were resuspended in a small volume of grinding media and counted in the presence of Trypan blue. Splenocytes were immediately used for further experiments.

Assay for HCV antigen specific splenocyte proliferation

Splenocytes from vaccinated mice or naïve mice were diluted to 4×10⁶/mL with grinding media and plated onto 24-well-plates at 2 mL/well. The cells were *in vitro* stimulated with 500 ng E2 (aa 450 to 565^[31]) or mock stimulated for 3 d. The media were collected for cytokine assay. Fresh grinding medium with 0.5 µCi/mL [³H] thymidine (Amersham Pharmacia Biotech) was added for another 24 h. Cells were then washed with PBS and 100 g/L trichloroacetic acid (TCA), incubated with 100 g/L TCA for 10 min at 37 °C. Afterwards, TCA was removed and cells were lysed with lysis buffer containing 0.33 mol/L NaOH and 10 g/L sodium dodecyl sulfate (SDS). [³H] thymidine incorporation in the cell lysates was measured by liquid scintillation counting. Antigen specific proliferation was presented by stimulation index (SI): SI = cpm of the cells stimulated by antigen/cpm of mock stimulated cells. Splenocytes from naïve mice were used to monitor the specificity of this assay.

Analysis of HCV antigen specific cytokine secretion

Media from the *in vitro* stimulated splenocytes were collected and precleared by centrifugation at 10 000 g and 4 °C for 10 min. Concentration of INF-γ and IL-4 in the media was determined by ELISA using the mouse cytokine assay kits (Jingmei Biotech, Shenzhen) according to the protocols provided by the manufacturer. HCV E2 specific cytokine secretion was represented by stimulation index (SI): SI = cytokine secreted upon E2 stimulation/cytokine secreted upon mock stimulation. Splenocytes from naïve mice were used to monitor the specificity of this assay.

Statistical analysis

Statistical analysis was performed with unpaired 2-sided Student *t* test. Differences with *P* values <0.05 were considered significant.

RESULTS

Transient expression of HCV antigens in mammalian cells

Because the expression level was low when E1 and E2 were expressed in one open reading frame (data not shown), we expressed HCV E1 and E2 genes in separate plasmids in this study. To achieve high-level expression and proper post-translational modification of HCV envelope proteins, the pSecTagB vector with an efficient secretion signal of IgG molecules was chosen. Plasmid expressing HCV E2 was constructed as described in Materials and Methods. C-terminal hydrophobic sequence of E2 was truncated to facilitate the secretion of E2 and to obtain complex-type glycosylation modification, which was presented on the surface of HCV particles^[29]. Secreted E2 protein was shown to have better antigenicity, possibly due to its proper modification by Golgi enzymes^[30]. Plasmid pSecTagB/sE1 was taken as another component of the candidate DNA vaccine since high-level expression of E1 with this plasmid was observed previously in transiently and stably transfected NIH3T3 cells^[26]. Before vaccination experiment, BHK-21 cells were transfected with pSecTagB/sE1 and pSecTagB/sE2, respectively, to check if they

would properly express the target HCV proteins in this cell line. By Western blot, both E1 and E2 were detected as glycosylated proteins with MW higher than those of polypeptide backbones, respectively (Figure 1). Secreted products were also detected for E1^[26] and E2 (data not shown).

Figure 1 Transient expression with plasmids used in vaccination. Plasmids used for transfection are indicated at the top of each lanes. E1 and E2 products are indicated by arrowheads.

Humoral immune responses after DNA vaccination

DNA vaccination using the above characterized plasmids was carried out as described in Materials and Methods. After two injections, HCV E1 and E2 specific antibodies were detected in the sera of several mice. Without CpG adjuvant, the seroconversion rate was 2/5 for anti-E1 antibody, and 1/5 for anti-E2 antibody. When CpG was included as an adjuvant, the seroconversion rate was 3/4 for anti-E1 antibody and 2/4 for anti-E2 antibody. After the third injection, all animals became seroconverted to both anti-E1 and anti-E2 antibodies. The highest anti-E1 titer was 1:320 after the third injection for mice receiving plasmids only, while the highest titer for mice receiving plasmids with CpG was 80. The highest anti-E2 titers for both groups reached 1 280, but the average anti-E2 titer for mice receiving CpG was slightly lower than that for those receiving no CpG (Table 1).

E2 specific splenocyte proliferation

All the animals were sacrificed 30 d after the last injection to analyze cellular immune responses of the memory phase. Single-cell suspension of splenocytes was prepared for each individual animal. Splenocytes were immediately cultured in the presence of HCV E1 peptide or E2 protein. [³H] thymidine was then added to the cells to measure HCV antigen specific proliferation. In our experiments, HCV E1 specific proliferation was not observed, neither was E1 specific cytokine secretion (data not shown), possibly due to insufficient stimulation. For E2 specific splenocyte proliferation, as shown in Figure 2, animals vaccinated with pSecTagB only or pSecTagB plus CpG had stimulation indexes similar to that of naïve mice. Some of the animals vaccinated with

plasmids pSecTagB/sE1+pSecTagB/sE2 showed E2 specific splenocyte proliferation while the others did not. This gave an average SI slightly higher than that of pSecTagB vaccinated mice. Animals vaccinated with HCV gene encoding plasmids together with CpG all showed E2 specific splenocyte proliferation, which resulted in a significant difference ($P = 0.005$) of SI between animals injected with pSecTagB/sE1+pSecTagB/sE2+CpG and animals injected with pSecTagB+CpG.

Figure 2 E2-specific splenocyte proliferation. Error bars represent the standard errors. Asterisk indicates the significant difference of the average SI between animals injected with (pSecTagB/sE1+pSecTagB/sE2+CpG) and animals injected with (pSecTagB+CpG) ($P = 0.005$).

E2 specific cytokine secretion

Cellular immune responses were also evaluated by cytokine secretion assay of the *in vitro* stimulated splenocytes from all vaccinated animals. INF- γ secretion is a marker of Th1 type antigen-specific cellular immune responses and plays key roles in fighting virus infection. Mice injected with pSecTagB/sE1+pSecTagB/sE2 showed heterogeneous cellular immune responses, some had E2 stimulated INF- γ secretion, while the rest did not. This resulted in a slightly higher average of SI compared to the control group injected with pSecTagB (Figure 3A). Mice injected with pSecTagB/sE1+pSecTagB/sE2+CpG all showed highly E2-specific INF- γ secretion, showing a SI higher than 3, while the control group injected with pSecTagB+CpG had an average SI similar to those of naïve mice and mice injected with pSecTagB alone. The difference of SI between the experiment group and its control group was very significant ($P = 0.0003$).

IL-4 secretion is a marker of Th2-like cellular immune responses. No significant difference in IL-4 secretion was detected between all groups receiving different inoculums (Figure 3B). IL-4 secretion of the vaccinated animals was similar to that of naïve mice, indicating that Th2-like cellular immune response was decreased to basal level, if there was ever a Th2-like response. In terms of IL-4 secretion, no effect of CpG was detected.

Table 1 Anti-HCV titers¹ after the third injection

Vaccine	Anti-E1 titers				
	1	2	3	4	5
pSecTagB/sE1+pSecTagB/sE2 ²	320	40	Dead animal	320	320
pSecTagB/sE1+pSecTagB/sE2+CpG ³	80	80	Dead animal	80	80
	Anti-E2 titers				
	1	2	3	4	5
pSecTagB/sE1+pSecTagB/sE2 ²	160	160	Dead animal	1 280	1 280
pSecTagB/sE1+pSecTagB/sE2+CpG ³	160	160	Dead animal	160	1 280

¹Titers were determined as described in Materials and Methods. Serial dilution of anti-sera started from 1:40, thus titers lower than 40 were not determined and considered 0. ²The cutoff value was established as mean A of sera from the control mice vaccinated with pSecTagB. ³The cutoff value was established as mean A of sera from the control mice vaccinated with pSecTagB+CpG.

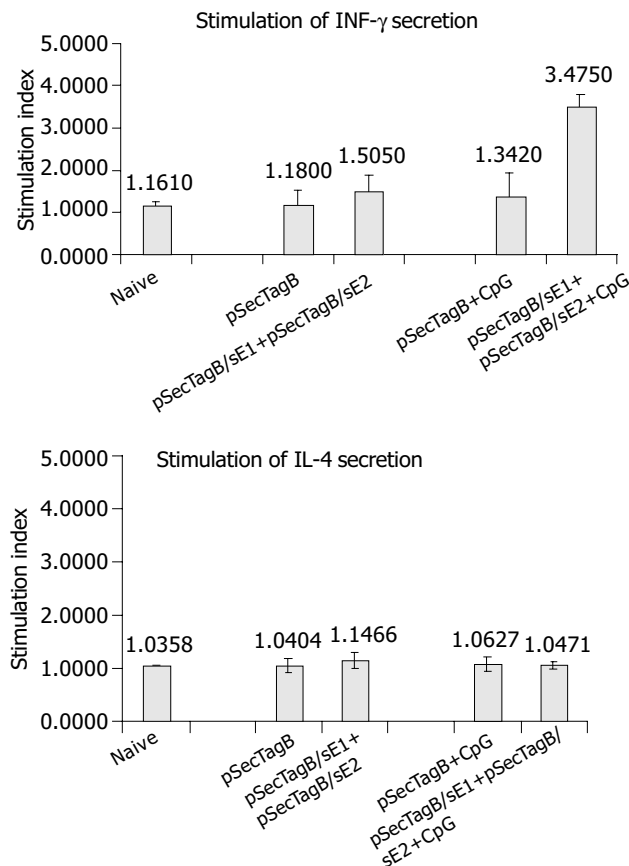

Figure 3 E2-specific cytokine secretion. Error bars represent the standard errors. Asterisk indicates the very significant difference of the average SI between animals injected with (pSecTagB/sE1+pSecTagB/sE2+CpG) and animals injected with (pSecTagB+CpG) in terms of INF- γ secretion ($P = 0.0003$).

DISCUSSION

In this study, target HCV antigens encoded by the DNA vaccine candidate, E1 and E2, were delivered by two separate plasmids that achieved higher-level expression and appropriate glycosylation of both antigens. DNA immunization results demonstrated that this DNA vaccine candidate could induce HCV specific humoral and cellular immune responses in mice. Anti-E2 titer obtained in this study was similar to our previous study^[11], which was also comparable to the results from other laboratories^[31-35]. We also detected comparable levels of anti-E1 antibodies in the sera of vaccinated mice, which together with anti-E2 antibodies, might be important in neutralizing the circulating HCV virus and preventing its spread in patients. HCV antigen specific splenocyte proliferation indicated that our candidate DNA vaccine was able to induce cellular immune response, which was critical in viral clearance. Cytokine secretion analysis revealed that the cellular immune response is Th1 type, which could activate CTL to remove cells with HCV antigen expression. Studies of HCV patients showed that protection against HCV infection was positively correlated with cellular immune responses^[36,37], indicating that cellular immune responses might be more important in evaluating a candidate vaccine. The ability of our candidate vaccine to induce HCV specific cellular immune responses makes it a favorable choice in the development of prophylactic and therapeutic vaccine against HCV.

CpG motif, that is, CpG dinucleotide in particular base context (XCGY, where X is any base but C, and Y is any base but G), was first found to be immunoinactive in activating B cells^[38]. These CpG motifs are prevalent in bacterial and many viral DNAs but are heavily methylated and suppressed in vertebrate genomes^[38,39]. Recent studies have shown that the immune

system could respond to CpG motifs by activating potent Th1-like immune responses^[23]. Several reports demonstrated that CpG could enhance humoral immune responses elicited by DNA vaccination^[24,25], possibly due to indirect effect of enhanced cellular immune responses. In our vaccination experiment, we observed that after the second injection, the seroconversion rate for mice receiving CpG adjuvant was higher than that for those not receiving CpG. This enhanced humoral immune response at the early stage was likely due to the indirect positive effect of CpG on antigen presentation (via activation of antigen presenting cells by Th1). However, after the third injection, when all animals became seroconverted, those who received CpG as an adjuvant showed lower titers of both anti-E1 and anti-E2. This was consistent with the notion that when Th1-like response is the major immune response, Th2-like response is usually inhibited, followed by decreased antibody production. Further analysis of antigen specific cytokine secretion was consistent with this explanation. E2 specific INF- γ secretion was enhanced in splenocytes from those animals receiving CpG in vaccination, while this adjuvant did not change the E2 specific IL-4 secretion profile. These results indicated that CpG enhanced the Th1-like cellular immune response.

Apart from DNA vaccine, live virus vaccine and peptide vaccine are also efficient in inducing cellular immune response. Live virus vaccine using several different viral vectors has been under investigation^[8,28,40], with continuous promising progresses. However, the interest in peptide vaccine is diminishing. The problem lies in the polymorphism of MHC molecules in the population. Certain individuals may have the MHC molecules necessary to bind a specific antigenic peptide, while others may not. Thus, the universality of a vaccine based on a specific peptide becomes a concern. Recently, combinational vaccination strategy with different species of vaccine components has been successful in laboratory in protecting against some elusive infectious reagents^[41,42]. Combinational vaccination could reduce host immune responses against the viral vector itself, thus enhancing the efficiency of delivery. More importantly, combinational vaccination with different components could activate different components of the host immune surveillance system and result in enhanced immune responses. Our next effort will be focused on combinational vaccination with DNA vaccine described above as one component.

ACKNOWLEDGEMENT

We thank Professor Yu Wang (Peking University) for providing HCV cDNA for this study.

Abstract

AIM: *Helicobacter pylori* (*H pylori*) has been linked to chronic gastritis, peptic ulcer, gastric cancer and MALT-lymphoma. The link of genotypes of *H pylori* to gastric cancer remains controversial. The aim of this study was to investigate the *H pylori* *vacA* alleles, *cagA* and *iceA* in patients with gastric cancer in Taiwan.

METHODS: Patients with gastric cancer, peptic ulcer and chronic gastritis were enrolled in this study. We obtained biopsy specimens from the stomach at least 2 cm away from the tumor margin in patients with gastric cancer, and from the antrum of stomach in patients with peptic ulcer or chronic gastritis. DNA extraction and polymerase chain reaction were used to detect the presence or absence of *cagA* and to assess the polymorphism of *vacA* and *iceA*.

RESULTS: A total of 168 patients (gastric ulcer: 77, duodenal ulcer: 66, and chronic gastritis: 25) were found to have positive PCR results of the biopsy specimens from patients with peptic ulcer and chronic gastritis. We found positive *cagA* (139/168, 83%), *m2* (84/168, 50%) and *iceA1* (125/168, 74%) strains in the majority of patients. In patients with gastric cancer, the *vacA* s1a and s1c subtypes were less commonly found than those in non-cancer patients (35/66 vs 127/168, $P = 0.0001$ for s1a and 13/66 vs 93/168, $P < 0.0001$ for s1c). In the middle region, the m1T strain in patients with gastric cancer was more than that of non-cancer patients (23/66 vs 33/168, $P = 0.02$).

CONCLUSION: In Taiwan, *H pylori* with positive *vacA* s1a, *cagA* and *iceA1* strains are found in the majority of patients with gastric cancer or non-cancer patients. In patients with gastric cancer, the *vacA* s1a and s1c subtypes are less and m1T is more than in patients with peptic ulcer and chronic gastritis.

INTRODUCTION

Helicobacter pylori (*H pylori*) is one of the most common bacterial infections of humans^[1]. It has been closely linked to chronic gastritis, peptic ulcer, gastric cancer and MALT-lymphoma^[2,3]. It has heterogeneous genotypes and phenotypes^[4,5].

The International Agency for Research on Cancer of the World Health Organization recommends that *H pylori* be classified as a group I carcinogen^[6]. In a long-term follow-up study, gastric cancers developed in 36 (2.9%) of the 1 246 infected and none of the 280 uninfected patients ($P < 0.001$)^[7]. Enomoto *et al.* and Uemura *et al.* also confirmed that very few patients who had gastric cancer were not infected with *H pylori*^[7,8].

The clinical outcome of *H pylori* infection was supposed to be linked to certain strains, *e.g.* vacuolating cytotoxin (*vacA*) and the cytotoxin-associated gene (*cagA*)^[9,10]. However, controversy exists concerning the relationship between *H pylori* and gastric cancer. It is now evident that approximately 25-50% of the world's population is infected by *H pylori*. Why, then, did only a minority of them develop gastric cancer? A report of an epidemiological study in Africa suggested that *H pylori* infection did not always directly correlate with the risk for gastric cancer^[11]. The same phenomenon occurred in southern Asia^[12]. The prevalence of *H pylori* is high in India and Bangladesh, but low gastric cancer rates have been reported. In addition, Louw *et al.* did not find difference in the prevalence of *H pylori* infection when comparing gastric cancer cases with matched controls^[13].

How could the above phenomenon be explained? Although *H pylori* infection is very common, there is geographic distribution of different subtypes^[14]. Is it possible that different subtypes of *H pylori* cause different outcomes? In Taiwan, specific genotypes of *H pylori* have been found in patients with peptic ulcer or non-ulcer dyspepsia^[15,16]. There is no report concerning the genotype of gastric cancer in Taiwan so far. The aim of this study was to determine the *vacA*, *cagA*, and *iceA* genotypes of *H pylori* in patients with gastric cancer as compared with those in patients with peptic ulcer or chronic gastritis in Taiwan.

MATERIALS AND METHODS

Patients with gastric cancer, peptic ulcers (gastric ulcer or duodenal ulcer, at least 5 mm in diameter) or chronic gastritis were invited to enter the study. Patients with pregnancy, bleeding tendency (platelet count less than 50 000/mm³, prothrombin time less than 30%, or taking anti-coagulants), age under 10, or over 90 years, and inability to cooperate were excluded from the study. The study was approved by the Clinical Research Committee of the Veterans General Hospital, Taipei.

Endoscopic examination and biopsy were performed after informed consent was obtained. In patients with peptic ulcer or chronic gastritis, we took one specimen from the antrum of

each patient for rapid urease test, one specimen from the gastric antrum for DNA extraction and PCR assay. In patients with gastric cancer, we took two specimens from the stomach at least 2 cm from the cancer part for rapid urease test and DNA extraction and PCR assay. Lysates of gastric mucosa biopsy specimens were used for PCR. DNA of gastric biopsy specimens was extracted according to the method described by Boom^[17]. Briefly, biopsy specimens were homogenized in guanidinium isothiocyanate, using a sterile micropestle. DNA was extracted, washed and eluted in 100 µL of 10 mmol/L Tris-HCL (pH 8.3). Two microliters of the eluted DNA were used for each PCR reaction.

All pathological samples from patients with gastric cancer were evaluated by a single experienced pathologist, and classified in accordance with the Lauren classification as diffuse, intestinal or mixed types^[18]. The description of advanced gastric cancer was based on Borrmann's classification^[19]. The morphological subtypes of early gastric cancer were classified according to the guidelines of Japanese Endoscopy Society^[20].

Oligonucleotide primers for PCR amplification of specific segments are shown in Table 1^[15,21,22]. For *vacA* evaluation, the PCR program comprised 35 cycles of denaturation (at 94 °C for 1 min), annealing (at 56 °C for 2 min, extension at 72 °C for 1 min), and one final extension (at 72 °C for 10 min). For *cagA*, amplification was performed with 35 cycles of denaturation (at 94 °C for 1 min, annealing at 56 °C for 2 min, extension at 72 °C for 1 min), and one final extension (at 72 °C for 5 min). For *iceA* amplification, amplifications were performed with 40 cycles of denaturation (at 95 °C for 30 s), annealing (at 50 °C for 45 s), extension (at 72 °C for 45 s) and one final extension (at 72 °C for 10 min).

The association between *H pylori* genotypes and clinical diseases was determined using the chi-square test with Yates' correction or Fisher's exact test when appropriate. A *P* value less than 0.05 was considered statistically significant.

RESULTS

Patients with peptic ulcer and chronic gastritis

Between January 2002 and February 2003, a total of 278 patients with peptic ulcer or chronic gastritis were included in this study. There were 200 males and 78 females with a mean age of 62.1 years, 95% C.I.: 61.1-64.3 years. One hundred and forty patients had gastric ulcers, 101 patients had duodenal ulcers, 37 patients

had chronic gastritis. Among these patients, 168 patients (65.9%) (comprising 25 patients with chronic gastritis, 77 patients with gastric ulcer, and 66 patients with duodenal ulcer) were found to have positive PCR (Table 2). Of them, the urease test was found to be positive in 152 patients (90.5%). There was no significant difference in age of the patients with chronic gastritis (mean: 51 years, 95% CI: 42.8-59.2 years), gastric ulcer (65.3 years, 62.3-68.9), duodenal ulcer (58.9 years, 54.7-63.1) and gastric cancer (69 years, 67-91).

In the s-region, *vacA* s1a was most frequently found (76%, 127/168, *P*<0.001 vs s1b, s1c and s2) followed by s1c (93/168, 55%), s1b (9/168, 5%), and s2 (2/168, 1%) (Table 3). In the m-region, m2 was most frequently found (84/168, 50%) (*P*<0.0001 vs m1T and m1), followed by m1T (33/168, 20%) and m1 (2/168, 2%). *CagA* was found in 139 patients (83%). *IceA1* was found most commonly in comparison with *iceA2* (125 vs 29, *P*<0.0001).

Patients with gastric cancer

A total of 167 patients with gastric cancers were enrolled in this study (mean age: 69 y/o, 95% CI: 67.0-91.0, sex M/F: 130/37). We obtained specimens through endoscopic biopsy from 66 patients and surgery from 101 patients. After PCR assessment of gastric specimens, a total of 66 patients (39.5%) were found to be positive (24 patients from endoscopic biopsy and 42 patients from surgical specimens) (Table 3). We found early gastric cancer in seven patients (type IIc: 2, IIc+III: 5) and advanced gastric cancer in 59 patients (Borrmann type I: 7, II: 28, III: 14, IV: 10) (Table 4).

Among these patients, 35 (53%) were found to have *vacA* s1a (*P*<0.001 vs s1c, s1b, and s2), followed by s1c (13 patients, 20%) (*P*<0.001 vs s1b and s2) and s1b (1 patient, 2%), s2 (1 patient, 2%) (Table 3). In the m-region, m2 was most commonly found (32 patients, 48%) (*P*<0.0001 vs m1) followed by m1T (23 patients, 35%) and m1 (1 patient, 2%). In the *iceA* subtypes, *iceA1* was most commonly found (39 patients, 59%) followed by *iceA2* (15 patients, 23%) (*P*<0.0001). *CagA* was found in 76% (50/66) of the patients.

The genotypes between early gastric cancer and advanced gastric cancer were similar (Table 4). There was no difference of genotypes according to Borrmann's classification (Table 5). Regarding the histological classification, there was no difference of genotypes among the diffuse type, intestinal type and mixed types (Table 6).

Comparison of gastric cancer patient with non-cancer (peptic ulcer and chronic gastritis) patients

In patients with gastric cancer, the *vacA* s1a and s1c subtypes were less commonly found than those in non-cancer patients (35/66 vs 127/168, $P < 0.001$ for s1a and 13/66 vs 93/168, $P < 0.0001$ for s1c) (Table 3). In the middle region, the m1T in patients with gastric cancer was more than that in non-cancer patients (23/66 vs 33/168, $P = 0.02$). There was no difference in *iceA* and *cagA* between patients with gastric cancer and non-cancer status.

DISCUSSION

This is the first study to investigate the allelic variations of *H. pylori vacA*, *cagA* and *iceA1* in gastric cancer patients in Taiwan. The results showed *vacA* s1a, m2, and *iceA1* predominated in patients with gastric cancer and those without.

H. pylori has become a world-wide infective agent ranging from 25% in developed countries to more than 80% in the developing world^[23]. Not all individuals infected with *H. pylori* developed gastric illness and this might be related to various factors such as environmental factors, host genetic factors, and bacterial virulent ability^[24]. Certain genotypes (*e.g.* *cagA*,

vacA s1a) have been closely related to severe clinical outcome and response to anti-*H. pylori* therapy^[25,26]. However, these findings were not supported by other studies^[27].

Different genotypes of *H. pylori* have been confirmed in patients with peptic ulcer or non-ulcer dyspepsia from diverse geographic areas^[14,23]. For example, in Northern and Eastern Europe, 89% strains were *vacA* s1a. *VacA* s1a and s1b were equally present in France and Italy. In Spain and Portugal, 89% of the strains were *vacA* s1b. While in north America, s1a and s1b were equally prevalent. *VacA* s1c was only found in East Asia. In Taiwan, *H. pylori* with *vacA* s1a was the major strain^[15,16]. Because of this diversity, it is interesting to analyze the genotypes in different areas.

In this study, predominance of *vacA* s1a was found in patients with gastric cancer (53%) and non-cancer status (76%). Our findings were similar to those reported by other authors in patients with peptic ulcer or non-ulcer dyspepsia^[15,16]. In Hong Kong and Korea, a low incidence of *vacA* s1a subtype was found^[28,29]. The previous Taiwan reports gave no data concerning *vacA* s1c^[6,15]. *VacA* s1c was frequently found (20% in gastric cancer and 55% in non-cancer) in this study. In contrast, *vacA* s1b and s2 were rare. Our findings were compatible with those

in mainland China^[30]. A high incidence of *vacA* s1c in this study was similar to the reports of Hong Kong^[28], Korea^[29], and Japan^[31], but different from those of the Western world^[14].

Concerning the m-region of *vacA*, m1 strains predominated in most Western reports^[14,23]. However, there were few m1 subtypes (2% in cancer and 2% in non-cancer) in this study. We used a modified primer (m1T)^[15] and found that some patients (35% in gastric cancer, 20% in non-cancer) with *H pylori* infection contained this genotype. M2 strains predominated (48% in gastric cancer and 50% in non-cancer) in this study. Our findings were consistent with reports from our previous experience^[32], other studies in Taiwan^[15,16], Hong Kong^[28], and mainland China^[30]. In contrast, Japan and Korea had a much lower incidence of m2 strain^[27,29]. We could not detect the m-region in some patients (15% in gastric cancer and 28% in non-cancer). This indicates a great variation in the *vacA* region in Taiwan, particularly in the mid-region locus. *H pylori* may have a different geographic evolution in Taiwan even compared with other East Asian countries.

IceA1 has been suggested to be related to peptic ulcer disease^[22,33]. But, like other authors, we doubted this finding^[27-29,32]. It has been found that *IceA1* is the predominant subtype of *ice* in the East Asia, while *iceA2* is the predominant subtype in the USA and Columbia^[27]. In this study, we found *iceA1* was the predominant subtype and showed no difference in patients with gastric cancer and non-cancer status.

The clinical relevance of putative virulence-associated genes of *H pylori* in patients with gastric cancer is a matter of controversy. Enomoto *et al.* found that 98% of patients with gastric cancer were *H pylori*-positive^[12]. Many studies suggested the strong association of certain genotypes of *H pylori* with gastric cancer^[34-38]. A significant association (o.r. 2.94) between *cagA* and gastric cancer was found in young Italian patients^[34]. Miehlke *et al.* suggested a significant association between the *H pylori vacA* s1, m1, *cagA* and gastric cancer^[35]. Kidd *et al.* confirmed that the *vacA* s1b, m1 and *iceA1* were closely linked to gastric cancer in South Africa^[36]. van Doorn *et al.* found a significant association between the presence of ulcers or gastric cancer and the presence of *vacA* s1 and *cagA*^[37]. Basso *et al.* and Qiao *et al.* also concluded that *H pylori* infection caused by *cagA* positive/*vacA* s1 was a frequent finding in patients with gastric cancer^[38,39].

However, some authors have presented different observations. Mitchell *et al.* compared serum antibody to *cagA* antigen in patients with gastric cancer and normal subjects^[40]. They found no association between *cagA* and gastric cancer in Chinese subjects. Other authors also confirmed no relationship between *cagA* status and the risk of gastric cancer^[41]. Some Japanese studies did not support the link of *vacA* and *cagA* with gastric cancer^[42,43]. In these Japanese studies, the majority of the controls had positive *vacA* and *cagA*. Therefore, they obtained a different result as compared with those of the Western studies. In addition, the case number was small in their series. Increased number is needed to avoid bias. In this study, we found no difference in *cagA* between gastric cancer and non-cancer status. But, we found less *vacA* s1a, s1c and more m1T in patients with gastric cancer.

There is a paucity of *iceA* allele data in isolates from patients with gastric cancer. Gastric cancer isolates from Japan and Korea were distinguished by the prevalence of *iceA1* (67%) while 75% of isolates from the USA were *iceA2*^[27]. In this study, we found that *iceA1* predominated (59%) in patients with gastric cancer.

Patients with histologic findings of severe gastric atrophy, corpus-predominant gastritis or intestinal metaplasia are at an increased risk for gastric cancer. *H pylori* carrying the *cagA* gene might have promoted the atrophic metaplastic mucosal lesions that represent the pathway in multistep intestinal type gastric oncogenesis^[25,44]. Correa *et al.* and Uemura *et al.* found

that severe atrophic gastritis accompanying intestinal metaplasia caused by persistent *H pylori* infection was closely related to the development of intestinal type gastric cancer^[9,45]. But, some authors present different results. No significant relationship was found between *H pylori* and diffuse type gastric cancer because atrophic change was not evident in these patients^[46,47]. In addition, other authors did not support this finding due to epidemiological and pathological evidence^[48,49]. In this study, we found no difference in genotypes among diffuse, intestinal and mixed types of gastric cancer. In addition, there was no difference of genotypes in patients with early and advanced gastric cancer. However, the case number should be increased to avoid type II error.

In conclusion, *vacA* s1a, m2, and *iceA1* predominate in patients with gastric cancer. As compared with those of non-cancer patients, patients with gastric cancer have less *vacA* s1a, s1c and more m1T subtypes. Genotypes are similar according to morphological and pathological classification.

Abstract

AIM: To construct a non-resistant and attenuated *Salmonella typhimurium* (*S. typhimurium*) strain which expresses conservative region of adhesin AB of *Helicobacter pylori* (*H pylori*) and evaluate its immunogenicity.

METHODS: The AB gene amplified by PCR was inserted into the expression vector pYA248 containing *asd* gene and through two transformations introduced into the delta *Cya*, delta *Crp*, delta *Asd* attenuated *Salmonella typhimurium* strain, constructing balanced lethal attenuated *Salmonella typhimurium* strains X4072 (pYA248-AB). Bridged ELISA method was used to measure the expression of AB antigen in sonicate and culture supernatant. According to the method described by Meacock, stability of the recombinant was evaluated. Semi-lethal capacity test was used to evaluate the safety of recombinant. The immunogenicity of recombinant was evaluated with animal experiments.

RESULTS: The attenuated *S. typhimurium* X4072 (pYA248-AB) which expresses AB was successfully constructed. Furthermore, bridged ELISA assay showed that the content of AB in recombinant X4072 (pYA248-AB) culture supernatant was higher than that was in thallus lytic liquor. And after recombinant X4072 (pYA248-AB) was cultured for 100 generations without selection pressure, the entire recombinant bacteria selected randomly could grow, and the AB antigen was detected positive by ELISA. The growth curve of the recombinant bacteria showed that the growth states of X4072 (pYA248) and X4072 (pYA248-AB) were basically consistent. The survival rate of C57BL/6 was still 100%, at 30 d after mice taking X4072 (pYA248-AB) 1.0×10^{10} cfu orally. Oral immunization of mice with X4072 (pYA248-AB) induced a specific immune response.

CONCLUSION: *In vitro* recombinant plasmid appears to be stable and experiments on animals showed that the recombinant strains were safe and immunogenic *in vitro*, which providing a new live oral vaccine candidate for protection and care of *H pylori* infection.

INTRODUCTION

The discovery of *Helicobacter pylori* (*H pylori*) has brought about a revolution in the research of etiological factor and prevention and cure of chronic gastritis, peptic ulcer and the associated diseases^[1,2]. It has been confirmed that *H pylori* is the main cause of chronic gastritis and peptic ulcer, and an important factor for the infection of gastric cancer and mucosa-associated lymphoid tissue (MALT) lymphoma and primary gastric non-Hodgkin's lymphoma^[3-7]. In 1994, the World Health Organization has defined it as a class I carcinogen, and direct evidence of its carcinogenesis has recently been demonstrated in an animal model and a retrospective cohort study and nested case-control study in China^[8,9]. Data of epidemiology showed that 50 percent of the population all over the world is infected with *H pylori*, and China has a high infection rate^[10]. Based on it, eradication of *H pylori* is one of the main methods for preventing and treating the above-mentioned diseases. At present, the widely used method for eradication of *H pylori* in clinical practice is the antibiotic treatment, though high the eradication rate is, such problems as high expenses, yearly reduced eradication rate resulting from gradually increasing drug-resistant strains, side effects of drugs and low patient compliance have still not been solved^[11-13]. Immunization against *H pylori* infection has been one of the most prospective treatments. In view of the fact that the conservative region of four confirmed adhesins is outer membrane protein and porin type component, outer membrane protein and porin are the excellent candidate components vaccination^[14-16]. In addition, the attenuated *Salmonella typhimurium* strain expressing foreign antigen is a very hopeful new-generation of vaccine. Experiments on human body indicated that the attenuated *Salmonella typhimurium* strain has very good endurance and immunogenicity, which can be used to transmit foreign antigen, therefore, the problem of adjuvant as well as the problem of high cost for taking subunit protein vaccine orally are solved. At present, the research of attenuated *Salmonella typhimurium* strain in application to *H pylori* vaccine has been done, but non-resistant and attenuated *Salmonella typhimurium* strain containing the balanced lethal system has not yet been applied to the research and production of *H pylori* vaccine. We attempted to construct the non-resistance and attenuated *Salmonella typhimurium* strain expressing AB, and to study its biological properties to pave the way for further research of biological treatment.

MATERIALS AND METHODS

Materials

The strains and plasmids used in the experimental processes are showed in Table 1.

Thirty specific-pathogen free male C57BL/6 mice, aged 4 wk, were purchased from Animal Center of our institute. Restriction enzymes, such as *EcoR* I, *Sal* I *etc.* and T4 DNA ligase, Vent DNA polymerase *etc.* were purchased from New England Biolabs corporation, Promega corporation and Sino-American Hua Mei Biotechnology Company, respectively. The goat anti-rabbit IgG-HRP and IgA-HRP were purchased from Sino-American Hua Mei Biotechnology Company. Our institute provided anti-AB antibody and AB antigen. DAP (50 mg/L) was purchased from Sigma corporation. Other reagents were analytically pure reagents produced in China.

Recombinant DNA techniques

The alkaline lysis method was chosen for rapid and large-scale preparations of plasmid DNA as described previously^[21]. In accordance with the the gene sequence in conservative region, we designed specific primers and added appropriate restriction enzyme sites on its 5' termini, which was synthesized by Shanghai Boya Co. The sequences of primers were as follows: conservative region 1: 5'-CCG GAA TTC AAC GCG CTC AAC AAT CAG-3'; conservative region 2, 5'-CAC GTC GAC CTA GAA TGA ATA CCC ATA AG-3'. Conservative region 1 and conservative region 2 contained *EcoR* I and *Sal* I sites, respectively. The template was pET-22b (+) -AB. PCR was performed by the hot start method. The PCR condition was that after initial denaturing at 95 °C for 30 s, each cycle of amplification consisted of denaturation at 95 °C for 30 s, annealing at 55 °C for 30 s and polymerization at 72 °C for 30 s, and a further polymerization for 10 min after 35 amplification cycles. PCR products were separated by electrophoresis analysis on a 8 g/L agarose gel. The PCR product was harvested from agarose gel, digested with *EcoR* I and *Sal* I, and inserted into the *EcoR* I and *Sal* I restriction fragments of the expression vector pYA248 using T4 DNA ligase. The resulting plasmids pYA248-AB were transformed into *E. coli* X6097, Salmonella typhimurium X3730 and X4072 one by one and positive clone was screened through assay of double restriction enzyme digestion. DNA sequence was performed with the DNA automatic sequencer.

Assay of AB protein expressed by recombiant strain

Recombinant strain *S. typhimurium* X4072 (pYA248-AB) cells, after being inoculated in the culture medium of LB liquids, were cultured with shaking at 37 °C for 15-16 h, and then centrifuged, to collect thallus and supernatant. Thallus, after being washed with saline once and centrifuged, suspended with deionized water. The suspension was sonicated on ice for three min, and centrifuged, to obtain the supernatant. Bridged ELISA was used to measure the expression of AB antigen in sonicate and culture supernatant.

Assay of stability of recombinant strain

The experiment testing stability of recombinant strain was performed according to the method described by Meacock^[37,38]. Ten percent of thallus, incubated with shaking at 37 °C overnight, was inoculated in LB culture medium containing DAP and was

further cultured for 12 h, from which the another 10 percent was inoculated in LB culture medium containing DAP and cultured for another 12 h, which was continued in the same way for up to 50 h. By this time, recombinant X4072 (pYA248-AB) cells had been cultured for 100 generations, and then it was diluted to 10⁶-fold. A total volume of 100 µL of the diluted solution was taken and paved on LB agar plate containing DAP. After being cultured overnight, 100 single thalluses were randomly selected and transferred on LB agar plate without containing DAP. Bacteria could not grow on agar plate without containing DAP liquids, means plasmid loss; through this method stability of recombinant plasmid was verified. Meanwhile, ELISA was used to measure the expression of AB antigen in the culture supernatant of these 100 thalluses.

Assay of growth curve of recombinant strain

Single clone *S. typhimurium* X4072 (pYA248) and *S. typhimurium* X4072 (pYA248-AB) were selected and inoculated in culture medium of LB liquid, respectively. After being cultured with shaking at 37 °C for 10 h, 50 µL of it was inoculated in 5 mL culture medium of LB liquid, followed by culture with shaking at 37 °C. The value of *A*₆₀ was measured once every other hour, from which growth curve was drawn.

Assay of immunology of recombinant strain

Three groups of 5 mice including controls were used as follows: (1) PBS control group was non-immunized mice that received PBS; (2) Salmonella control group was immunized with attenuated *S. typhimurium* X4072 (pYA248) strain; (3) The vaccine group was immunized with *S. typhimurium* X4072 (pYA248-AB) strain expressing AB. Prior to immunizations, the mice were left overnight without solid food and 4 h without water. A total volume of 100 µL of 30 g/L sodium bicarbonate were given orally using a stainless steel catheter tube to neutralize the stomach pH. Immediately after stomach neutralization, mice from PBS control group received 100 µL PBS, and mice from the Salmonella control group and Salmonella vaccine group, received 1.0×10⁹ colony forming units (c.f.u) of *S. typhimurium* strain X4072 (pYA248) and *S. typhimurium* strain X4072 (pYA248-AB), respectively, in a total volume of 100 µL. Water and food were returned to the mice after immunization. At 4 wk after immunization, mice were sacrificed by terminal cardiac puncture under metoxyfluorance anesthesia and the small intestines were taken from mice to prepare intestine fluid. Indirect ELISA was used to evaluate serum samples and intestine fluid from mice for AB-specific IgG or IgA. Purified *H. pylori* AB was used as the coating antigen in ELISA immunoassays.

RESULTS

Construction of recombinant plasmid containing *asd* gene and encoding AB gene

The size of plasmid pYA248 was 3.0 kb. Promotor was *P*_{trc} and multiclonal points included *EcoR* I *Hin* d III and *Sal* I *etc.* and pYA248 was digested with *EcoR* I and *Sal* I, and large E-S

sequences were recovered as vector. The same enzymes were used to completely digest AB PCR product and mixed with vector for connection after being recovered, and then transformed into *E. coli* X6097 by the means of CaCl_2 . Transformer could grow on LB agar plate without containing DAP and further extracted plasmid for verification. The results of double restriction enzyme digestion of recombinant plasmid pYA248-AB are showed in Figure 1.

Figure 1 Double restriction enzyme digestion map of recombinant plasmid PYA248-AB. Lane1: DNA marker; Lane2: PCR product; lane3: pYA248/*EcoRI*; lane4: pYA248-AB/*EcoRI*; lane5: pYA248-AB/*EcoRI*+*Sall*.

Construction of recombinant strain

Recombinant plasmid extracted from *E. coli* X6097 (pYA248-AB) was transformed into *S. typhimurium* X3730 and X4072 by the transformation of electricity one by one. Owing to the difference between two kinds of *S. typhimurium*, the best transformational conditions were worked out. By adopting the first condition: cuvette gap 0.2 cm, voltage 2.5 kV, field strength 12.5 E, capacitor 25 μF , resistor 200 Ω , time constant 4.5-5.0 ms, recombinant plasmid was transformed into *S. typhimurium* X3730 and then separated from it. By adopting the second condition: cuvette gap 0.2 cm, voltage 2.4 kV, field strength 12.0 E, capacitor 25 μF , resistor 400 Ω , time constant 9-13 ms, recombinant plasmid was transformed into *S. typhimurium* X4072, from which recombinant strain *S. typhimurium* X4072 (pYA248-AB) was obtained.

Assay of AB protein expressed in recombinant strain

The results of AB expressed in X4072 (pYA248-AB) culture and sonicate supernatant assayed by bridged ELISA are shown in Table 2. The fact that the content of AB in recombinant germ X4072 (pYA248-AB) culture supernatant was higher than that in sonicate supernatant indicated that AB existed mainly in culture supernatant was expressed in the form of secretion.

Table 2 Expression of AB in X4072 (PYA248-AB) assayed by bridged ELISA

Sample	$A_{492\text{nm}}$	P/N
Negative control of X4072 (pYA248) culture supernatant	0.04	
Negative control of X4072 (pYA248) sonicate supernatant	0.04	
Positive control of BL21 (pET-AB) periplasm	1.08	27.0
X4072 (pYA248-AB) culture supernatant	0.96	24.0
X4072 (pYA248-AB) sonicate supernatant	0.78	19.5

Assay of stability of AB antigen expressed in recombinant strain

After recombinant germ pYA248-AB was cultured 100 generations, 100 bacteria were randomly selected and then transferred onto LB agar plate containing DAP. All of them could grow and the AB antigen was detected positive by ELISA. For the recombinant the mean of the value of $A_{492\text{nm}}$ plus or minus standard deviation

was 0.979 ± 0.052 , and the value of $A_{492\text{nm}}$ of negative control X4072 (pYA248) was 0.040, which indicated that recombinant germ, after seeing cultured for 100 generations, could stably exist in attenuated *S. typhimurium* strain.

Growth curve of recombinant strain

Single clone X4072 (pYA248) and X4072 (pYA248-AB) were selected and then inoculated in the culture medium of LB liquid. After being cultured at 37 °C overnight, 50 μL of it was inoculated in 5 mL culture medium of LB liquid and then cultured with shaking at 37 °C. The value of A_{600} was measured and recorded once every other hour, from which growth curve (Figure 2) was drawn. It can be discovered from Figure 2 that the growth states of all bacteria were basically consistent, that is, metabolism of the bacteria were basically unaffected by transforming recombinant plasmid into attenuated *S. typhimurium* strain.

Figure 2 A growing curve of X4072 (PYA248) and X4072 (PYA248-AB).

Safety of recombinant strain

The results of experiments testing safety of C57BL/6 mice taking recombinant strain orally are shown in Table 3. After taking virulent strain $X3181 \times 10^7$ c.f.u, all the mice died within 5 d, but after taking recombinant strain X4072 (pYA248-AB) 1.0×10^{10} c.f.u, the survival rate was still 100 percent. It can be noticed from the table that the number of live bacteria of C57BL/6 mice taking recombinant strain orally was 10^3 fold more than that of the lethal dose of virulent strain X3181.

Table 3 Survival of mice after oral inoculation with virulent and recombinant *S. typhimurium* strains

Strain	Relevant phenotype	Inoculating dose (c.f.u)	Observation intervals (d)	Survival (live/total)
X3181	wild type	1.0×10^7	5	0/5
		2.6×10^5	30	2/5
X4072 (PYA248-AB)	Cya Crp-AB ⁺	1.0×10^{10}	30	5/5

Immunology of recombinant strain

The positive results detected by ELISA had colors, but the negative results had no colors, or weak colors. The five mice (group 3) serums and intestinal fluid immunized with vaccine *S. typhimurium* X4072 (pYA248-AB) showed positive results. In contrast, the mice serums and intestinal fluid of PBS control group and Salmonella control group showed negative results. It indicated *S. typhimurium* X4072 (pYA248-AB) could enable the organism to generate specific mucous membrane and humoral immunity.

DISCUSSION

S. typhimurium strain, through adhesion, invasion and inhabitation in intestine-associated lymph tissue, can be phagocytosed by macrophage and M cells in Peyer node and through mesentery

lymph node reaches liver and spleen, which further stimulate other organs and tissue to develop mucous membrane, cell and body fluid immunization responses effectively. In recent few years, the research and production of gastrointestinal tract vaccine with attenuated *S. typhimurium* strain as the release system have become a new trend in the research of a new-type recombinant live vaccine taken orally. In it, attenuated *S. typhimurium* strain as a kind of vaccine carrier carrying foreign antigen is, up to now, the most widely used strain. This is mainly due to the fact that the model of mice infected by *S. typhimurium* strain is basically consistent with the organism of man infected by typhoid, and the virulence factor of *S. typhimurium* strain has been deeply researched^[25,26]. The genes of virulence which have already been used in attenuated mutation of *S. typhimurium* strain include: *aro* gene controlling synthesis of aromatic compound^[22]; *gal E* gene affecting synthesis of lipopolysaccharide^[23]; *cya*, *crp* gene adjusting metabolic level of cyclic adenosine monophosphate(cAMP)^[24], *pur* gene controlling synthesis of purine organism^[25]; non-specific acid phosphoric acid enzyme *phoP* gene manipulating transcription of gene and *omp* gene adjusting porin expression *etc*^[26,27]. Many laboratories have successfully constructed attenuated and immunity *S. typhimurium* strain by mutating relative genes, which have been proved to be safe through experiments on animals, such as mice, cattle, and pig and even on human volunteers^[28-33]. But when these attenuated *S. typhimurium* strains are used to express foreign protective antigen, genes encoding protective antigen are usually cloned on a vector containing drug resistance gene. In order to make sure of the stability of plasmid, antibiotic must be used as selection pressure. According to the rules stipulated in American Food and Drug Administration, drug resistance plasmid can not exist in live vaccine and the stability of recombinant plasmid can not be maintained in human beings and animals by antibiotic^[28].

In order that foreign protective antigen can be stably expressed in attenuated *S. typhimurium* strain without antibiotic, a new type of plasmid vector system has been now developed, that is, the vector-host balanced lethal system. Host strain in the vector-host balanced lethal system is a type of chromosome mutant, and the mutated gene is housing keeping gene. Because the product of its encoding catalysed the genetic metabolic reaction of bacteria, the defects of the gene will certainly result in nutritious deficiency of bacteria, therefore, it can not grow in normal culture medium. Under this condition, plasmid must be necessary for the existence of bacteria. Once the transformed plasmid is lost, bacteria will not synthesize the essential substance so as not to grow in normal culture medium. Therefore, all bacteria that can grow in normal culture medium certainly contain recombinant plasmid, so as to construct the balanced lethal system. In this system, foreign protective antigen can be stably expressed without antibiotic in host stain. And the balanced lethal system constructed by *asd* gene has been widely used, for example, Redman *et al.*^[34] cloned the surface protein antigen gene of *streptococcus* to plasmid with *asd*, and then transformed it to $\Delta cya\Delta crp\Delta asd$ defective *S. typhimurium* strains which were taken by mice orally. The results showed that recombinant strain could induce mice to produce continuous reaction of antibody response^[34]. Scholars experimented $\Delta cya\Delta(crp cdt)\Delta asd$ expressing hepatitis B virus core pre S protein on adult women volunteers, showing that the strain could stimulate organism to develop system and mucous immunity response, and produce a unique secreted antibody (sIgA) in urinary and reproductive tract and intestinal tract^[35].

By adopting the system as described above, we successfully carried out the construction of attenuated *S. typhimurium* strain expressing AB. Because the cell wall of *S. typhimurium* strain is thick and so hard to be transformed, *E. coli* X6097 with

knocked out *asd* gene was used as host strain for screening recombinant clone. The screened recombinant plasmid was transformed electrically to host *S. typhimurium* X3730. X3730 with knocked out gene *asd* is the gene *galE* mutated strain of *S. typhimurium* strain LT-2 and loses the effect of restriction but possess the effect of modification, because of which plasmid transformed into *S. typhimurium* strain can obtain the methylated model of *S. typhimurium* strain and thus stably exists in *S. typhimurium* strain. Recombinant plasmid with methylated model extracted from X3730 was transformed into final *S. typhimurium* strain X4072 without restriction and so the construction work was finished.

Experiment on animals has proved that recombinant strain is safe. It was found by ELISA that AB protein was expressed mainly in the form of secretion, but the expression level was comparatively low. For recombinant strain with vaccine construction as the aim, however, a more important issue than high level expression is the stability of expressing foreign gene, because only when engineering bacteria can exist in body for a relatively long period and stably release antigen, it can effectively stimulate the immune system response of organism and expression with too high level may destroy the biological and chemical balance of strain as a complete organism which makes it hard for *S. typhimurium* strain to maintain the stable expression of foreign gene. The recombinant strain we constructed possessed a good stability, and under the condition without selection pressure, we recombinant plasmid could exist stably, and the foreign gene could also be expressed stably whose growth curve showed no obvious changes for expression of foreign gene. The main reason for it is probably that the expression level of foreign gene is suitable to *S. typhimurium* strain. In addition, according to Sutton *et al.*'s^[36] principle of immunization protection and cure of *H. pylori* "less is best", that is, low dose of antigen has better immunization effect, and maybe this *S. typhimurium* strain live vaccine expressing *H. pylori* antigen with a low but stable level can create better immunization effect. In this study, the serums and intestine fluid from the mice immunized with *S. typhimurium* X4072 (pYA248-AB) expressed specific antibody aimed to AB, but the serums and intestine fluid from the mice in the control group failed to express. These results suggest that *S. typhimurium* X4072 (pYA248-AB) might be a good candidate as a vaccine. However, whether it can be used as a vaccine or not need be researched further. To achieve his goal we are carrying out the associated experiments on animals now.

Abstract

AIM: To assess the mechanisms of protective action by different mild irritants through maintenance of gastric mucosal integrity and modulation of mucosal nitric oxide (NO) in experimental gastritis rats.

METHODS: Either 200 mL/L ethanol, 50 g/L NaCl or 0.3 mol/L HCl was pretreated to normal or 800 mL/L ethanol-induced acute gastritis Sprague-Dawley rats before a subsequent challenge with 500 mL/L ethanol. Both macroscopic lesion areas and histological damage scores were determined in the gastric mucosa of each group of animals. Besides, gastric mucosal activities of NO synthase isoforms and of superoxide dismutase, along with mucosal level of leukotriene (LT)₄ were measured.

RESULTS: Macroscopic mucosal damages were protected by 200 mL/L ethanol and 50 g/L NaCl in gastritis rats. However, although 200 mL/L ethanol could protect the surface layers of mucosal cells in normal animals (protection attenuated by N^G-nitro-L-arginine methyl ester), no cytoprotection against deeper histological damages was found in gastritis rats. Besides, inducible NO synthase activity was increased in the mucosa of gastritis animals and unaltered by mild irritants. Nevertheless, the elevation in mucosal LTC₄ level following 500 mL/L ethanol administration and under gastritis condition was significantly reduced by pretreatment of all three mild irritants in both normal and gastritis animals.

CONCLUSION: These findings suggest that the aggravated 500 mL/L ethanol-evoked mucosal damages under gastritis condition could be due to increased inducible NO and LTC₄ production in the gastric mucosa. Only 200 mL/L ethanol is truly "cytoprotective" at the surface glandular level of non-gastritis mucosa. Furthermore, the macroscopic protection of the three mild irritants involves reduction of LTC₄ level in both normal and gastritis mucosa, implicating preservation of the vasculature.

INTRODUCTION

Excessive ethanol ingestion can result in gastritis characterized by mucosal edema, subepithelial hemorrhages, cellular exfoliation and inflammatory cell infiltration^[1]. Alcohol has been shown to affect the mucosal barrier and histology^[2]. Morphologically, alcohol-induced gastric superficial injury involves mostly the inter-foveolar epithelium and gastric pits, and heals rapidly by restitution^[3]. On the other hand, the deeper lesions involve intramucosal hemorrhage and vascular engorgement^[4]. As a consequence of damage to microvessels, leakage of inflammatory mediators occurs, and vasoconstriction of submucosal arteries would result in ischemia. Eventually, these events would enhance the formation of more severe necrotic mucosal injury. Several products of arachidonate metabolism have been implicated to participate in the pathogenesis of ethanol-induced gastric mucosal damage^[5].

It is known that neuronal modulating processes such as the release of vasoactive mediators are crucial for the gastric mucosa to resist the continual onslaught of aggressive agents^[6]. Previous findings have suggested that there are interactions between the endothelium-derived vasodilator mediators, including that prostaglandins (PG), can regulate gastric mucosal microcirculation and integrity^[7]. Endothelial cells also release a highly labile humoral vasodilator substance, now known to be nitric oxide (NO), that mediates the vascular relaxation induced by vagal stimulation^[8]. Nonetheless, it should be noted that the production of NO from a calcium-independent (inducible) form of the enzyme could lead to cell injury in the endothelium^[9]. Thus, the induction of NO synthesis may not always be beneficial. For instance, formation and interaction between superoxide and NO radicals are the key elements of oxidative challenges in the gastric mucosa.

There are some endogenous proinflammatory mediators that could be activated during the aggressive attack of noxious agents or severe tissue trauma. Leukotriene (LT)₄ is one of these substances which would lead to microcirculatory disturbances and severe mucosal tissue injury^[10]. Such a detrimental action may somehow involve the generation of reactive oxygen free radicals. In other words, these effects could be modulated by enzyme systems of the oxygen-handling cells, such as superoxide dismutase (SOD), which are able to protect cells against the toxic effects caused by oxygen species^[11].

Acute hemorrhagic gastritis patients have underlying predisposing conditions such as alcohol abuse or use of NSAID. Besides endoscopic and surgical therapy, the focus on pharmacotherapy would be the enhancement of mucosal defense mechanisms so as to accelerate healing and prevent relapses^[12]. The present study attempted to illustrate that different mild irritants had differential modes of action in the adaptive cytoprotection against ethanol-induced gastric mucosal damage in animals under gastritis condition, whereas some of these involved modulation of eicosanoids and NO biosynthesis in the gastric mucosa. These data may also provide the explanation why gastritis can predispose the stomach to ulceration.

MATERIALS AND METHODS

Animals

Male Sprague-Dawley rats (240-260 g) were used after

acclimatization for at least three days in a controlled room with constant temperature (22 ± 1 °C) and humidity (65-70%). They were fed a standard diet of laboratory chow (Ralston Purina, USA) and had free access to tap water *ad libitum*. All experimental animals were deprived of food in individual wired cages 24 h beforehand.

Treatments and induction of gastritis

Animals in the "normal" (non-gastritis) groups received oral administration (10 mL/kg) of either distilled water or one of the three mild irritants, 200 mL/L ethanol, 50 g/L NaCl and 0.3 mol/L HCl via a stainless steel orogastric tube, 15 min before the administration of 500 mL/L ethanol (10 mL/kg). For animals that were used to demonstrate the action of mild irritants alone (basal), distilled water was given instead of 500 mL/L ethanol. All animals were sacrificed 30 min later.

To induce gastritis, 800 mL/L ethanol was given to the rats orally (10 mL/kg). The treated animals were returned to their home cages with provision of food and tap water. After 24 h, all the 800 mL/L ethanol-treated animals were deprived of food again, with tap water supply only. Similar experiments as those of the "normal" animals were performed using these gastritis rats 24 h following starvation (i.e. the experiments were carried out 48 h after the induction of gastritis). Our preliminary study showed that at this time point the gastritis animals were free from any gross macroscopic lesion or erosion, but the deeper mucosal cells comprising more than 800 mL/L of the total mucosal thickness were damaged or morphologically changed when observed microscopically.

In order to investigate the participation of the endogenous vasoactive mediator during the processes, N^G -nitro-L-arginine methyl ester (L-NAME, 12.5 mg/kg, i.v.) was pretreated 15 min before the administration of mild irritants to inhibit endogenous NO production^[13].

Macroscopic evaluation of gastric mucosal damage

The animals were sacrificed by a sharp blow behind the head and followed by cervical dislocation. Their stomachs were removed and opened along the greater curvature. After thoroughly rinsed in ice-cold saline solution and blotted dry, the area of macroscopic lesions on the mucosa was traced onto a glass slide, and measured by transparent 1-mm² grids^[14]. A section of each stomach tissue was removed and preserved for subsequent microscopic studies. Finally, the glandular mucosa of the rest of stomach tissue was scrapped by using a glass slide, weighed and immediately frozen in liquid nitrogen. The mucosal samples were stored at -70 °C until assayed for various endogenous mediators.

Histological evaluation of gastric mucosal damage

Within a week of formalin fixation, the gastric tissues were processed for paraffin embedding. A (1.0×0.5×0.3) cm³ block of gastric tissue was dehydrated by immersion in progressively increasing concentrations of ethanol. Slices of 6-μm thick sections were stained by the periodic acid-Schiff technique, and counterstained by Harris' hematoxylin solution. The stained sections were then left in the fume-cupboard overnight.

An Olympus microscope (200×) with a scaled eyepiece was used for the morphometric study. Any histological damage in a section was quantified according to the method from O'Brien and coworkers^[15]. The criteria for damage were the absence of gastric mucosal cells or the presence of grossly disrupted cells. The standards for evaluation of the severity of microscopic mucosal damage were as follows: type I damage-length of luminal surface mucous cells damaged or vacuolated, type II damage-extensive luminal surface cell damage with disrupted and exfoliated cells lining the gastric pits, type III damage-disrupted cells of the gastric glands beneath the damaged surface and gastric pit cells. For each tissue sample, four

measurements of the total mucosal length as well as the length with damaged or disrupted mucosal cells were examined (in mm) and averaged. The final index for the degree of histological damage was represented by the percentage of the damaged mucosal length in terms of the total length of the gastric mucosa.

Determination of NO synthase activity in gastric mucosa

A mucosal sample was placed in a buffer solution (pH 7.2) containing 10 mmol/L HEPES, 0.32 mol/L sucrose, 0.1 mmol/L EDTA, 1 mmol/L DL-dithiothreitol, 10 μg/mL of soybean trypsin inhibitor, 10 μg/mL of leupeptin, 2 μg/mL of aprotinin, and 1 mg/mL of phenyl-methanesulfonyl fluoride. The sample was homogenized for 20 s under ice-cold condition, and then centrifuged at 22 000 g for 30 min at 4 °C. An aliquot of 100 μL from the supernatant was withdrawn for protein assay^[16].

The NO synthase activity was determined from the conversion of [³H] L-arginine to the NO co-product citrulline^[17]. The supernatant was passed over a 0.75-mL column containing Dowex AG50WX-8 resins to remove any endogenous arginine^[18]. The reaction mixture comprised 100 μL of the supernatant and 150 μL of buffered solution (pH 7.2) containing 10 mmol/L HEPES, 0.7 mmol/L NADPH, 150 μmol/L CaCl₂, 7 mmol/L L-valine to inhibit any arginase^[19], and 1 μCi of [³H] L-arginine. The amount of [³H] L-citrulline formed in this reaction mixture represented the total NO synthase activity. A similar reaction mixture was also prepared, with the addition of 1 mmol/L EGTA, which removed Ca²⁺ ions from the system^[13]. Product formation that remained persistent in this system determined the inducible NO synthase activity. Incubation of the mixtures with or without EGTA was continued for 30 min at 37 °C. The reaction was terminated by adding 50 μL of 200 mL/L perchloric acid, and the solution mixture was neutralized by 160 μL of 1 mol/L NaOH^[20]. This was followed by the dilution with 540 μL of deionized water containing 1 mmol/L L-arginine and 1 mmol/L citrulline. Subsequently, the resulting 1 mL mixture in each reaction tube was applied onto a chromatographic column containing 0.5 g of Dowex AG50WX-8 resins^[21]. Following the separation from unreacted [³H] L-arginine by cation-exchange chromatography, the product [³H] L-citrulline was eluted through the column by 1 mL of deionized water and collected into a scintillation vial. The samples were counted for the amount of radioactivity using a liquid scintillation counter (2 000 CA, Packard, USA). The data obtained were corrected for background counts obtained by a similar procedure but with heat-inactivated mucosal tissue. The final results were represented as cpm/min/mg protein. Constitutive NO synthase activity was obtained by subtracting the inducible NO synthase activity by the total NO synthase activity.

Determination of LTC₄ level in gastric mucosa

The pre-weighed mucosal samples were homogenized for 15 s under ice-cold condition in phosphate buffer (50 mmol/L, pH 7.4) with indomethacin (28 μmol/L), to prevent any neoformation of cyclooxygenase products during the extraction process. The homogenized samples were then centrifuged at 1 400 r/min for 15 min at 4 °C. An aliquot of 100 μL from the supernatant was withdrawn for protein assay^[16]. The assay was carried out by using a LTC₄ [³H] RIA kit (NEN Dupont, USA.). A standard curve was constructed with a range of 0.025-1.6 ng/100 μL. The final values of the samples obtained were represented as pg/mg protein.

Determination of SOD activity in gastric mucosa

The pre-weighed mucosal samples were homogenized for 20 s under ice-cold condition in phosphate buffer (50 mmol/L, pH 7.4). The homogenized samples were then centrifuged at 20 000 g for 15 min at 4 °C. An aliquot of 100 μL from the supernatant was withdrawn for protein assay^[16].

The SOD activity in tissue homogenates was determined by the NBT reaction^[22]. A 10 μ L of the homogenates was added to a solution mixture containing 150 μ L each of 2 mmol/L xanthine, 2 mmol/L EDTA and 0.5 mmol/L NBT, 500 μ L of Na_2CO_3 and 75 μ g/mL of BSA. After being made up to a 2.85 mL solution with phosphate buffer, the mixture was incubated for 3 min in a 25 °C bath. Following that, 150 μ L of 0.12 μ mol/L xanthine oxidase was added to the mixture and 3 mL solution was incubated further at 25 °C for 20 min. The reaction was terminated by adding 1 mL of 0.8 mmol/L CuCl_2 solution to each tube. The inhibition of NBT reduction in each sample was determined spectrophotometrically at 560 nm and the final value of SOD activity was represented as units/mg protein.

Drugs

[^3H] L-arginine (specific activity = 36.1 Ci/mmol) and the [^3H] LTC₄ RIA kit were purchased from NEN DuPont (Boston, MA, USA.). L-NAME, DL-dithiothreitol, soybean trypsin inhibitor, leupeptin, aprotinin, phenylmethanesulfonyl fluoride, L-valine, L-arginine and DL-citrulline were all products of Sigma Chemicals (St. Louis, MO, USA.).

Statistical analysis

All the results were expressed as mean \pm SE of 6 animals per group. The means were compared by the analysis of variance followed by unpaired Student's *t* test. Differences were considered statistically significant if the *P* value was less than 0.05.

RESULTS

Adaptive cytoprotection of mild irritants against 50% ethanol-induced macroscopic lesion formation in gastritis rats (Table 1)

Under gastritis condition, there was a general aggravating effect on the macroscopic ethanol-evoked gastric mucosal damage in all experimental groups, when compared with the damaging effects of 500 mL/L ethanol in normal animals. The degree of

protection by 200 mL/L ethanol and 50 g/L NaCl in gastritis rats was lessened when compared to that in normal animals, while the gastroprotection of 0.3 mol/L HCl was completely relieved in gastritis animals. As in normal animals, L-NAME pretreatment alleviated the protective action of 200 mL/L ethanol in gastritis animals. Nonetheless, the protective action of 50 g/L NaCl was preserved under gastritis condition.

Table 1 Effect of mild irritants on 500 mL/L ethanol-induced macroscopic lesion formation in gastric mucosa of normal and gastritis rats, and modulation by pretreatment with L-NAME

Pretreatment	Macroscopic lesion areas (mm ²)

relieved. Five percent NaCl and 0.3 mol/L HCl did not exert any cytoprotective action in the histological level whatsoever.

Effects of mild irritants on NO synthase activity in gastric mucosa of gastritis rats, during basal condition or followed by 500 mL/L ethanol challenge (Table 3)

The condition of gastritis caused a profound elevation of inducible NO synthase activity as well as a reduction of constitutive NO synthase activity in all experimental groups. The elevation of constitutive NO synthase activity induced by 200 mL/L ethanol or 50 g/L NaCl was also alleviated in gastritis rats, with the inducible NO synthase activity remained unaltered by mild irritants. On the other hand, the overall inhibitory effect of 500 mL/L ethanol on mucosal constitutive NO synthase activity was relieved in gastritis animals, of which the activation of the constitutive isozyme by 200 mL/L ethanol and 50 g/L NaCl was also completely prevented.

Effects of mild irritants on SOD activity in gastric mucosa of gastritis rats, during basal condition or followed by 500 mL/L ethanol challenge (Table 4)

SOD activity was significantly increased in all gastritis animals, when compared to normal rats. On the other hand, neither the mild irritants nor 500 mL/L ethanol significantly altered SOD activity in the gastric mucosa.

Effects of mild irritants on LTC₄ level in gastric mucosa of gastritis rats, at basal condition or followed by 500 mL/L ethanol challenge (Table 5)

In general, there was a higher LTC₄ level in the gastric mucosa of all gastritis animals. Nevertheless, all three mild irritants significantly reduced the level of LTC₄ in the gastric mucosa of both normal and gastritis rats. Fifty percent ethanol significantly increased the amount of mucosal LTC₄ in normal animals, but not in gastritis animals. The ability of mild irritants to reduce mucosal LTC₄ level remained persistent in all 500 mL/L-ethanol-treated groups.

DISCUSSION

Previous studies investigating on the phenomenon of gastric

adaptive cytoprotection were conducted in normal animals. The present investigation demonstrated the adaptive cytoprotection of mild irritants in gastritis rats. It is known that after deep mucosal injury involving extensive hemorrhage and tissue destruction, as in the case of gastritis induced by 80% ethanol, epithelial restitution still occurred^[23]. The term “hemorrhagic gastritis” is a term used to describe the appearance of subepithelial hemorrhage in the stomach. Some patients with gastric subepithelial hemorrhage could be expected to have associated histologic gastritis. Hence, histological protection and the preservation of vascular integrity were the two main criteria of gastroprotection^[24]. Our findings indicated that the gross macroscopic protective actions of 200 mL/L ethanol and 50 g/L NaCl remained persistent in the gastritis stomach. The loss of protective effect of 0.3 mol/L HCl under gastritis condition implied that a normal functional mucosa could be essential for the protective mechanism of the mild acid. We previously reported that adaptive cytoprotection by 0.3 mol/L HCl was completely blocked by vagotomy, implicating that innervation of an intact vagus nerve was one of the prerequisites of this mild irritant to induce physiological responses in the mucosal oxyntic cells^[25]. Similarly, normal integrity of the mucosa that was interfered under gastritis condition may also be important for the protective action of HCl. Apart from that, 50 g/L NaCl and 0.3 mol/L HCl failed to preserve the mucosal cells histologically, even in non-gastritis normal animals, leaving 200 mL/L ethanol to be the only agent that could exert “true cytoprotection” at the surface glandular level. Nevertheless, the loss of histological protective ability of 200 mL/L ethanol during gastritis condition also suggests that the initiation of its histologic adaptive cytoprotection may also require an intact glandular mucosa to operate. Clinically, the histologic gastritis that attributed to ethanol was somehow related to the underlying presence of *H pylori*, although ethanol did not seem to initiate *H pylori*-associated histologic gastritis directly^[26]. Treatment of *H pylori* was associated with almost complete normalization of histologic findings^[27]. In other words, 200 mL/L ethanol may only be responsible for the improvement of macroscopic gastric mucosal lesion formation by surface epithelial restitution, while *H pylori* eradication is capable of restoring the deep subepithelial mucosa in histologic gastritis.

In general, inflammatory reactions were initiated and amplified by proinflammatory mediators from injured tissues as well as those being synthesized during the process^[28]. These substances could result in further local tissue injury by release and activation of destructive enzymes as well as production of oxygen-derived free radicals. Thus, removal of oxygen-derived free radicals could stimulate the healing of ethanol-induced acute gastric mucosal injury in rats^[29]. Increased superoxide generation was resulted from activation of polymorphonuclear leukocytes and macrophages, which were the stimuli that induced the production of NO by inducible NO synthase^[30]. NO produced in a relatively high concentration by this inducible enzyme might react with oxygen or superoxide to yield more reactive oxidants, such as the peroxynitrite^[31]. These secondary oxidants are believed to be responsible for most biological oxidative damages, and are often the targets of antioxidant defense. In the present study, inducible NO synthase activity was significantly increased for many folds in gastritis animals, which could be correlated with the aggravation in 500 mL/L ethanol-induced mucosal damage and the alleviation of the histological cytoprotection induced by 200 mL/L ethanol. Although the administration of 500 mL/L ethanol to normal rats did not cause any significant activation of inducible NO synthase activity, the activity of constitutive NO isozyme was inhibited. Production of NO from the calcium-dependent constitutive enzyme has been known to play a role in the modulation of gastric mucosal integrity^[32]. The general suppression of this constitutive isozyme in gastritis mucosa could be due to the loss of endothelial integrity. Alternatively, the gastroprotection caused by 200 mL/L ethanol and 50 g/L NaCl, which concurrently maintained the constitutive NO synthase activity following 500 mL/L ethanol challenge in normal animals, must be due to the preservation of endothelium and hence to maintain vascular integrity. However, L-NAME pretreatment only reversed the protective action of 200 mL/L ethanol but not that of 50 g/L NaCl, suggesting that the involvement of NO from the constitutive form in the anti-lesion action of NaCl is still uncertain. Nevertheless, the suppression of constitutive NO synthase activity and the loss of its activation by 200 mL/L ethanol in the gastritis mucosa may explain why gastritis provoked ethanol ulceration and attenuated the protective action of 200 mL/L ethanol, respectively^[33]. In addition, the damaged mucosa could activate the inducible NO isozyme and trigger the release of more free radicals, thus producing extensive tissue necrosis under gastritis condition.

Local SOD has been shown to abolish the gastric mucosal injury induced by the cytotoxic level of NO, possibly due to the prevention of peroxynitrite formation from interaction between superoxide and cytotoxic NO^[34]. Our results demonstrated that under gastritis condition, SOD activity was significantly elevated. This could be a defensive mechanism of the gastric mucosa that would be activated when a tremendous amount of superoxide and other free radicals was produced following severe tissue injury. Indeed, acute administration of either mild irritants or 500 mL/L ethanol did not induce a similar increase in SOD activity in the gastric mucosa. Hence, the acute protective action of mild irritants in both normal and gastritis rats did not seem to involve the modulation of mucosal SOD activity.

It was reported in a human study that the basal release of PGE₂ and LTC₄ in alcoholics was higher than that in healthy volunteers, and that alcohol administration could cause an increase in PGE₂ and LTC₄ in healthy volunteers^[35]. In addition, by using a rat model, the same group of investigators further proposed that the anti-lesion effect of some gastroprotective agents was related to the inhibition of LTC₄ formation and an increase in PGE₂ biosynthesis in the gastric mucosa^[36]. Our findings in fact indicated that LTC₄ level in the mucosa was significantly increased in gastritis rats, which was similar to the

state in alcoholics. Moreover, the challenge with 500 mL/L ethanol also stimulated an increase in LTC₄ level, as in the case of healthy volunteers. In fact, increased synthesis of mucosal PGE₂ in alcoholics could also indicate a defensive mechanism of the mucosa, mainly to counteract with the proinflammatory action of LTC₄ generated from the tissue. In the present study, mild irritants were able to induce a significant inhibition on the release of LTC₄ in both normal and gastritis mucosa. Reduction of this autacoid would attenuate vascular disturbances and decrease hemorrhagic lesions in the gastric mucosa^[37].

In summary, aggravation in 500 mL/L ethanol-induced gastric mucosal damages under gastritis condition can be due to increased mucosal biosynthesis of inducible NO and LTC₄. The protective action of 200 mL/L ethanol could be restricted to the surface mucosal cells, thus having no effect on deeper histologic lesions. In general, deep histologic protection by mild irritants could not be found in gastritis animals. On the other hand, mild irritants could also act by reducing gastric mucosal LTC₄ level, which can lessen gross vascular injury and subsequently reduce hemorrhagic lesion even in gastritis mucosa.

Abstract

AIM: To investigate gastrointestinal migrating myoelectric complex (MMC) and the effects of porcine motilin and ursodeoxycholic acid (UDCA) on MMC of gastrointestinal tract of different origins in fasted rats.

METHODS: Three bipolar silver electrodes were chronically implanted on the antrum, duodenum and jejunum. Seven days later 24 experimental rats were divided into 2 groups. One group was injected with porcine motilin *via* sublingual vein at a dose of 20 µg/kg, the other group was perfused into stomach with UDCA. The gastrointestinal myoelectric activity was recorded 1 h before and 2 h after the test substance infusions into the rats.

RESULTS: In all fasted rats a typical pattern of MMC was observed. Among the totally 68 activity fronts recorded in fasted rats under control, 67% started in duodenum, and 33% in antrum. MMC cycle duration and duration of phase III of antral origin were longer than those of duodenal origin. Administration of 20 µg/kg porcine motilin induced a premature antral phase III of antral origin. But perfusion into stomach with UDCA resulted in shorter MMC cycle duration, longer duration of phase III of duodenal origin, which were followed with shorter cycle duration and duration of antral phase III.

CONCLUSION: In fasted rats, MMC could originate from antrum and duodenum respectively. The characteristics of MMC of different origins may contribute to the large variations within subjects. The mechanisms of different origins of phase III may be different. Porcine motilin and UDCA could affect MMC of different origins of the gastrointestinal tract in fasted state, respectively.

INTRODUCTION

The migrating myoelectric complex (MMC) is a distinct pattern

of electromechanical activity observed in gastrointestinal tract during fasting. It is thought to serve a housekeeping role and sweep undigested residual through the digestive tract. Phase III of MMC originates at variable sites in the gut from the esophagus (especially from antrum and duodenum) to proximal ileum. Large variations in MMC characteristics were described both within subjects and between subjects. The reason for the large variation in MMC characteristics is unknown. However, regarding the supposed differences in mechanisms that regulate the phase III of MMC of antral or duodenal origins, different origin of phase III within subject could be a basis for the differences in MMC characteristics^[1,2].

Motilin, a 22 amino acid peptide secreted by endocrinocytes in the mucosa of the proximal small intestine, participates in controlling the pattern of smooth muscle contractions in the upper gastrointestinal tract. These bursts of motilin secretion are temporarily related to the onset of housekeeping contractions, which sweep the undigested material of stomach and small intestine^[3]. Previous studies showed that the enterohepatic circulation of bile acids and interdigestive motility must somehow be associated with each other. Phase III of MMC played an important role in the transport of bile acids from the proximal duodenum to the distal small intestine, where bile acids were absorbed for transport back to the liver.

The purpose of the present study was to investigate the gastrointestinal MMC characteristics with respect to the different origin of phase III in fasted rats. Furthermore, the effects of exogenous porcine motilin and UDCA on the interdigestive myoelectric activity were investigated and the relationship between the above two drugs and the MMCs of different origin in conscious rats were studied.

MATERIALS AND METHODS

Animal preparation

Twenty-four healthy Sprague-Dawley rats (15 male and 9 female) weighing 200-250 g were fed with a dry rat food, and tap water for drinking *ad libitum*. After fasted for one night, the rats were intraperitoneally anesthetized with sodium pentobarbital 30 mg/kg. The hair on the skull and abdomen was shaved. The surgery was done with sterile instruments, and under strict aseptic conditions. The abdominal musculature and peritoneum were opened through the linea alba. Three bipolar insulated silver electrodes made by Teflon-coated wire (0.5 mm in outer diameter, 20 cm in length) were implanted into the muscular layer of the bowel with a needle as a trocar. One millimeter of the wire was exposed near the implanted end, and the interval between pairs of electrodes should be 2.0-3.0 mm. The electrodes were placed on the gastric antrum at 5 mm proximal to the pylorus, on the duodenum and jejunum respectively at 1 cm and 15 cm distal to the pylorus. The bundled electrode wires were grasped by the clamp through a silastic tube (2.4 mm in diameter), which then passed through the subcutaneous tunnel from the abdominal incision to the back of the shoulder exit. During operation the intestine was kept moist with sterile 9 g/L NaCl solution, and 4 mL of this solution was applied intraperitoneally before closure of the abdomen to compensate for intraoperative fluid loss. The abdominal wall was closed in three layers with

running Vicryl 4-0 sutures. The rats were kept in a humidified incubator at 37 °C for 2 to 4 h after operation. Following this, they were individually housed with free access to water and food. Housing conditions were kept constant with temperature at 22 °C, humidity of 60% and a 12-h light/dark cycle. The rats were allowed to adjust to these conditions for 1 wk before experiment.

Motility recordings

Rats were fasted for 16 h with free access to water. The experiments were performed in conscious rats. The gastrointestinal myoelectric activity recordings were monitored by using an electrical swivel mechanism to a computerized, multichannel recorder (RM-6280C, Chengdu, China). Myoelectric activity was sampled at a rate of 1 kHz. The signals were amplified and bandpass filtered (frequencies above 0.3 Hz and below 100 Hz were cut off). The amplitudes of contractions were recorded in μV .

Experimental procedures

A randomized, placebo-controlled experiment was performed. The rats were coded and divided into 2 groups, 12 in each group. On each experimental day, at the beginning of the experiments, the gastrointestinal myoelectric activity was recorded for 1 h for each rat, and during this period at least 2 or 3 MMCs appeared. The substances were dissolved immediately before use in normal saline. In each group, 4 rats were placed as control that received placebo (vehicle), 0.2 mL saline containing 250 μg bovine serum albumin (BSA, Sigma). One group was injected with porcine motilin (Sigma) *via* sublingual vein at a dose of 20 $\mu\text{g}/\text{kg}$, and the other group was perfused into stomach with UDCA (Pharmaceutical Factory of Changzhou City) respectively. After the substances were used, the gastrointestinal myoelectric activity of the rats was continuously recorded at least for 2 h. After the conversion from analog to digital, the signals were stored on optical disk for later analysis.

Statistical analysis

All variables followed a normal distribution and are expressed as mean \pm SD unless otherwise stated. The presented means are unweighted means, *i.e.*, means of all subjects after first calculating the mean within each subject separately. The MMC characteristics such as MMC cycle duration, duration of phase III, mean amplitude and frequency of phase III were examined by using the ANOVA model, both before and after discrimination for antral or duodenal phase III origin effects. The homogeneity of variance for each variable, after being divided into antral and duodenal phase III origin effects, was tested and appeared equal. Within-subject and between-subject effects were analyzed by the ANOVA model. For the MMC cycle duration, the corresponding variance components between and within individuals were used to calculate the variance between individuals as a percentage of the total variance. To explain the importance of the factor preceding phase III origin in the total variance, the sum of squares of the factor preceding phase III origin was calculated as a percentage of the total sum of squares in the ANOVA model. The effects of unfamiliarity with gastrointestinal catheter studies on MMC cycle duration was examined using the ANOVA model. Student's *t* test was used to compare the different paired values before and after the test substances administration in the above 2 groups. Statistical significance was defined as two-tailed $P<0.05$.

RESULTS

MMC characteristics of different origin

In all fasted rats typical pattern of MMCs were observed. The total number of MMC cycles recorded was 68. The mean MMC cycle duration was 746 ± 140 s. In total, phase III cycles were

observed with 23 (33%) of antral origin and 45 (67%) of duodenal origin. Fifty-nine percent of the total variance in MMC cycle duration was explained by the within-subject variance. The duration and the amplitude of phase III were significantly different between subjects ($P<0.05$; Table 1). The large variation in MMC cycle duration is visible in Figure 1. The MMC cycle duration following a phase III of antral origin was significantly longer than those of duodenal origin ($P<0.05$; Table 2). When the factor preceding phase III origin was included in our model, this factor contributed significantly to the total variation in MMC cycle duration; 31% of the total sum of squares was explained by the factor preceding phase III in comparison to 36% explained by the between-subject variance. The duration of phase III for duodenum was significantly longer when it started in the antrum than in the duodenum ($P<0.05$). The other characteristics of MMC for duodenum were not significantly different between the phase III of the above two origins.

Table 1 MMC characteristics in 24 normal rats

MMC characteristics	mean \pm SD
MMC cycle duration/s	746 ± 140^a
Duration of phase III/s	214 ± 53^a
Amplitude of phase III/ μV	287 ± 23^a
Frequency of phase III/(bursts/min)	11.4 ± 0.3

Values are shown for duodenum. ^a $P<0.05$ vs between subjects.

Table 2 MMC characteristics of different origin of ongoing phase III ($n = 24$, mean \pm SD)

MMC characteristics	After phase III of antral origin	After phase III of duodenal origin
MMC cycle duration/s	901 ± 74	667 ± 91^a
Duration of phase III/s	271 ± 30	186 ± 35^a
Amplitude of phase III/ μV	292 ± 17	284 ± 25
Frequency of phase III/(bursts/min)	11.2 ± 0.5	11.6 ± 0.2

Values are shown for duodenum. ^a $P<0.05$ vs antral.

Figure 1 MMC cycle duration of all subjects following phase III. \circ , antral origin; \blacktriangle , duodenal origin; Solid line: antral mean MMC cycle duration (746.3); Dotted line: duodenal mean MMC cycle duration (667.0).

Effects of porcine motilin and UDCA

The effects of porcine motilin on the interdigestive gastrointestinal myoelectric activity were established within 1 to 2 min after the injection *via* sublingual vein at a dose of 20 $\mu\text{g}/\text{kg}$. A premature antral phase III which did not migrate caudad to the duodenum and jejunum was observed. And one injection only induced

one premature antral phase III. The characteristics of premature antral phase III were different significantly from those of normal antral phase III. The shorter duration and higher amplitude of premature antral phase III appeared (Figure 2). The effects of UDCA on the interdigestive gastrointestinal myoelectric activity were established within 3 to 4 min after the stomach was perfused of UDCA. The shorter MMC cycle duration, and the longer duration of phase III of duodenal origin, followed by the shorter cycle duration and duration of antral phase III were observed. There was no significant difference in the other parameters of MMC of antrum and duodenum before and after the treatment (Figure 3, Table 3). Furthermore, there was no significant difference in the MMC characteristics before and after placebo treatment in the above 2 experiments.

Table 3 Effects of UDCA on the interdigestive gastrointestinal myoelectric activity ($n = 8$, mean \pm SD)

MMC characteristics	Antrum		Duodenum	
	Before	After	Before	After
The number of MMC	7	11	11	21
MMC cycle duration/s	885 \pm 106	800 \pm 48 ^a	780 \pm 45	602 \pm 78 ^a
Duration of phase III/s	161 \pm 13	113 \pm 19 ^a	156 \pm 9	241 \pm 20 ^a
Amplitude of phase III/ μ V	297 \pm 11	284 \pm 20	288 \pm 22	285 \pm 19
Frequency of phase III/(bursts/min)	3.1 \pm 0.5	3.2 \pm 0.6	11.2 \pm 1.6	11.5 \pm 1.8

^a $P < 0.05$ vs before treatment.

Figure 3 Effects of UDCA on the interdigestive gastrointestinal myoelectrical activity in one case.

DISCUSSION

Gastrointestinal motility pattern could mainly be divided into the interdigestive and digestive states. The interdigestive state

is characterized by the cyclical occurrence of activity front, phase III contractions, which could occur in the antrum, duodenum and migrate to the small intestine. The digestive state is characterized by sustained contractions with different amplitude in the gastric antrum and small intestine. In our experiments, a typical pattern of MMC in interdigestive state was observed in all rats. The phases of the MMC can be distinguished: phase III, motor quiescence, phase III, a period of irregular contractile activity and phase III, a period of rhythmic contractions. The MMC pattern was disrupted by feeding, and irregular contractions with different amplitude were sustained in the antrum, duodenum and jejunum for at least 30 min after feeding. MMC was firstly described in the small intestine of fasting dogs and observed in the overall gastrointestinal tract of several species, including rats^[4-6]. In our study they have also been found in gastric antrum and small intestine. A method that could record the gastrointestinal myoelectrical activities in physiological conditions was established in our experiment. The model we have developed seemed to be suitable for studying the gastrointestinal myoelectric activities. The effects we obtained could be attributed to neither sedatives nor operative stress because of the method unable to record the gastrointestinal motility without the use of anesthesia. Furthermore, the surgical operations were well tolerated by the animals, especially by small animals. At present the method of stationary manometry was used in most of the experiments of this field^[7,8]. But it is not suitable for small animal experiments. Our method was simple, easy and successful. Few tissue was injured. Several pairs of electrodes could be implanted and work stably and repeatedly. The experimental techniques would be helpful for further studying the mechanisms of gastrointestinal motility.

A typical pattern of MMC was observed in all fasted rats. Among the totally 68 activity fronts recorded in them under control, 67% started in the duodenum, and 33% in the antrum. The MMC cycle duration and duration of phase III of antral origin were longer than those of duodenal origin. The MMCs were subject to large variations in its characteristics, both between subjects and within subjects. The reason for this wide variation is unknown. Our results contributed to a better understanding of this variation. Our study showed that MMC characteristics had close relationship with the origin of phase III. But Gregersen *et al.* described a positive correlation between the duration of phase III in the duodenum and the duration of the next MMC cycle^[9]. They could not attribute this to a difference in origin of phase III, most likely due to the limited number of observations within each subject. The percentages of antral and duodenal originated phase III observed within a subject would strongly affect the mean MMC cycle duration of this subject as well as the overall mean of a group of subjects^[10,11]. An explanation for the differences in MMC cycle duration and duration of phase III was that it might imply differences in the mechanism controlling interdigestive motility in antrum and small intestine. This may reflect functional differences existing in the hormonal mechanisms involved in the regulation of antral and duodenal phase III. It was thought that a difference might exist in the refractory period between the gastric antrum and small intestine, with a shorter refractory period in the duodenum compared with the antrum. Another possible reason may be the anatomic structure of rats. Because there is no gallbladder in rats, bile acids secreted to duodenum directly. In addition, our study could not explain why the density and the sensitivity of receptor in gastrointestinal tract changed^[12,13].

The mechanisms regulating MMC is not understood completely. Previous study showed that the area postrema of medulla oblongata, vagal innervation, enteric nervous system and gastrointestinal hormone could regulate the MMC. Among them motilin in plasma plays a very critical role in the initiation of MMC. Motilin is one of the gastrointestinal hormones. It

belongs to gut-brain peptide and distributes in the brain and gastrointestinal tract^[14-22]. Plasma levels of the motilin fluctuate in synchrony with the different phase of MMC. Motilin could stimulate the gastrointestinal motility of many animals, and there were species differences in its effects^[23]. After duodenectomy, no obvious phase III contractions were seen in the gastric antrum, but the contractile response of the stomach to exogenous motilin was similar to that of intact dogs^[24]. This experiment showed that endogenous motilin was released from duodenum. One research showed that the motilin could activate calcium current in human and canine jejunal circular smooth muscle. Furthermore, the density and sensitivity of motilin receptor of different parts of gastrointestinal tract were different. But recently the close relationship between motilin and MMC of antral but not duodenal origin was found^[25]. Porcine motilin could influence the MMC of antral origin in our experiment. Administration of 20 µg/kg porcine motilin could induce a premature antral phase III in rats. The characteristics of it were different significantly from those of normal antral phase III. But the results of our experiments were coincident with previous studies. Maybe the density and sensitivity of motilin receptor of antrum were higher than those of other parts of gastrointestinal tract^[12,13]. Some studies showed that duodenal pH governed interdigestive motility in humans. But neither duodenal acidification nor increases in motilin concentration were necessary to initiate MMC in man^[26]. Administration of a low dose of erythromycin induced an MMC that started from the gastric antrum, unaccompanied by a motilin peak. These findings showed that the activation of motilin receptor triggered the MMC.

Another important factor influencing MMC is enterohepatic cycle of bile acids. The enterohepatic cycle of bile acids had close relationship with MMC. The possible explanation was that the development of MMC of duodenal origin was not autonomous but dependent on the stimulation of bile acids to the local mucous of duodenum. Furthermore, duodenum, possibly by releasing endogenous motilin, might recruit and further augment the gastric response to initiation of the MMC of antral origin^[27-29]. So there are maybe two mechanisms for initiation of MMC in the stomach and duodenum. In our experiment perfusion into stomach of rats with UDCA could shorten the MMC cycle duration and elongate the duration of phase III of duodenal origin, which was followed by the contractions of antrum within a short time. We suggest that UDCA may drain into the duodenum influencing the MMC of duodenal origin and stimulate the release of endogenous motilin from the mucous of duodenum, because crushing the gallbladder of patient during operation could eject the bile acids and induce a higher level of plasma motilin. On the contrary, some researchers thought that bile acids in duodenum could not induce the release of motilin and affect the MMC^[30]. In the study of patients with gallstone, the motilin in plasma did not decrease obviously vs control group. But according to the above supposition, we could infer that the motilin in plasma should decrease obviously compared with control group because the motility of gallbladder decreased in most of the patients. The results obtained from this experiment did not coincident with those of previous experiments. Another research showed that the kinetics of duodenum did not change significantly after cholecystectomy. So these studies did not support the local stimulatory theory^[31,32]. But one study showed that the occurrence of MMC had close relationship with the increase of the plasma concentration of motilin and bile acids. Maybe it could explain the contradiction in this respect to some extent^[33]. But our study could not draw this conclusion.

Gastrointestinal motility disorder is common in clinical practice, and studying the mechanisms of it is very important to its diagnosis and therapy. Our study showed that the

mechanisms of different origin of phase III may be different and porcine motilin and UDCA could affect the MMC of different origin of the gastrointestinal tract in fasting state respectively. This may provide novel treatments for patients with disturbed gut motility.

Abstract

AIM: *Menoease Pills* (MP), a Chinese medicine-based new formula for postmenopausal women, has been shown to modulate the endocrine and immune systems^[1]. The present study investigated the effects of MP and one of its active ingredients, *ligustrazine*, on epithelial barrier and ion transport function in a human colonic cell line, T₈₄.

METHODS: Colonic transepithelial electrophysiological characteristics and colonic anion secretion were studied using the short circuit current (I_{sc}) technique. RT-PCR was used to examine the expression of cytoplasmic proteins associated with the tight junctions, *ZO-1* (zonula occludens-1) and *ZO-2* (zonula occludens-2).

RESULTS: Pretreatment of T₈₄ cells with MP (15 μ g/mL) for 72 h significantly increased basal potential difference, transepithelial resistance and basal I_{sc} . RT-PCR results showed that the expressions of *ZO-1* and *ZO-2* were significantly increased after MP treatment, consistent with improved epithelial barrier function. Results of acute stimulation showed that apical addition of MP produced a concentration-dependent (10-5 000 μ g/mL, EC_{50} = 293.9 μ g/mL) increase in I_{sc} . MP-induced I_{sc} was inhibited by basolateral treatment with bumetanide (100 μ mol/L), an inhibitor of the Na⁺-K⁺-2Cl⁻ cotransporter, apical addition of Cl⁻ channel blockers, diphenylamine-2, 2'-dicarboxylic acid (1 mmol/L) or glibenclamide (1 mmol/L), but not 4, 4'-diisothiocyanostilbene-2, 2'-disulfonic acid or epithelial Na⁺ channel blocker, amiloride. The effect of MP on *ZO-1* and *ZO-2* was mimicked by *Ligustrazine* and the *ligustrazine*-induced I_{sc} was also blocked by basolateral application of bumetanide and apical addition of diphenylamine-2, 2'-dicarboxylic acid or glibenclamide, and reduced by a removal of extracellular Cl⁻.

CONCLUSION: The results of the present study suggest that MP and *ligustrazine* may improve epithelial barrier function and exert a stimulatory effect on colonic anion secretion, indicating the potential use of MP and its active ingredients for improvement of GI tract host defense and alleviation of constipation often seen in the elderly.

INTRODUCTION

It is well known that the gastrointestinal (GI) epithelium of the host, as the first defense line, plays an important role in protecting enteric epithelia from invasion of most pathogens. Intestinal epithelial barrier function regulates epithelial ions and nutrient transport as well as host defense mechanisms. Epithelial membrane pumps, ion channels and tight junctions tightly control epithelial transcellular and paracellular fluxes^[2,3]. Cl⁻ secretion also provides an essential driving force for lubrication of intestinal contents during regular bowel movements or flushing of microbial organisms or artificial irritants in host defense responses^[4,5]. Epithelial Cl⁻ channels play an important role in regulation and maintenance of normal GI physiological functions. Abnormal regulation of Cl⁻ channels may result in diarrhea^[6-8] or constipation^[9,10]. While the latter represents one of the frequently encountered conditions in aged people, few remedies are available for alleviation of the condition in the elderly.

Menoease Pills (Modified *Bak Foong Pills*, MP), a newly developed formula based on traditional Chinese medicine *Bak Foong Pills* (BFP, also known as Baifeng Wan)^[11-17], has been designed for the use of postmenopausal women. It has been demonstrated that MP can regulate hormonal profiles (Gou *et al*, unpublished data) and immune system in the elderly^[11], indicating its beneficial effects for postmenopausal or elderly women. Since our previous studies have demonstrated that BFP could increase colonic epithelial Cl⁻ and pancreatic duct epithelial HCO₃⁻ secretion^[11,15,16] and both BFP and MP have a common active ingredient, *ligustrazine*, we undertook the present study to examine whether MP and *ligustrazine* exerted any effect on Cl⁻ secretion and epithelial electrophysiological characteristics using human colonic T₈₄ cells in conjunction with the short-circuit current technique and RT-PCR.

MATERIALS AND METHODS

Chemicals and solutions

Dulbecco's Modified Eagle's medium (DMEM)/F12, Hank's balanced salt solution (HBSS), and fetal bovine serum were from Gibco Laboratories (New York, NY). 4, 4'-diisothiocyanostilbene-2, 2'-disulfonic acid (DIDS) and glibenclamide were from Sigma (St. Louis, MO). MP was obtained from Eu Yan Sang Ltd (Hong Kong). Diphenylamine-2, 2'-dicarboxylic acid (DPC) was purchased from Riedel-de Haen Chemicals (Hannover, Germany). Calbiochem (San Diego, CA) was the source for amiloride hydrochloride and bumetanide. Krebs-Henseit (K-H) solution had the following composition (mmol/L): NaCl, 117; KCl, 4.5; CaCl₂, 2.5; MgCl₂, 1.2; NaHCO₃, 24.8; KH₂PO₄, 1.2; glucose, 11.1. The solution was gassed with 950 mL/L O₂ and 50 mL/L CO₂, at pH 7.4.

MP extraction

Five hundred gram of MP powder in 700 mL/L ethanol at a ratio of 1 to 10 (g/mL) was put in round-bottomed flask and boiled under reflux for 2 h. The mixture was filtered and the residues of MP were subject to the same treatment for a second time. The filtrates from the two treatment procedures were collected and put in the vacuum rotary evaporator for concentration. The extracts were collected and lyophilized by a freeze dryer.

Cell culture

Human colonic T₈₄ cells were purchased from American Type Culture Collection (Rockville, MD). The cells were grown in DMEM/F12 with 100 mL/L fetal bovine serum. For I_{SC} recording the cells (2–3×10⁵/mL) were plated onto each floating permeable support, which was made of a Millipore filter with a silicone rubber ring attached on top of it for confining the cells (culture area 0.45 cm²). For the RT-PCR analysis, cells were seeded on the Millipore filter with a confined culture area of 4.5 cm². Cultures were incubated at 37 °C in 950 mL/L O₂ and 50 mL/L CO₂ for 6 d before experiments. For the experiments of MP and *ligustrazine* pretreatments, MP (15 µg/mL) or *ligustrazine* (100 µmol/L) was added into the culture medium at 72 h before experiments, when the cells became semi-confluent.

Short-circuit current measurement

The measurement of I_{SC} has been described previously^[18]. Monolayers grown on permeable supports were clamped vertically between two halves of the Ussing chamber. The monolayers were bathed in both sides with Krebs-Henseit solution, which was maintained at 37°C by a water jacket enclosing the reservoir. The Krebs-Henseit solution was bubbled with 950 mL/L O₂ and 50 mL/L CO₂ to maintain the pH of the solution at 7.4. Drugs could be added directly to apical or basal side of the epithelium. Usually, the epithelia exhibited a basal transepithelial potential difference for every monolayer examined, which was measured by the Ag/AgCl reference electrodes (World Precision Instruction) connected to a preamplifier which was in turn connected to a voltage-clamp amplifier (World Precision Instruction, DVC-1000). In most of the experiments, the change in I_{SC} was defined as the maximal rise in I_{SC} following agonist stimulation and it was normalized to current change per unit area of the epithelial monolayer (µA/cm²). The total charges transported for 15 min (the area under the curve of the agonist-induced I_{SC} responses) were also used to describe the agonist-induced responses (µC/cm²). In each experiment, a transepithelial potential difference was 0.1 mV. The change in current in response to the applied potential was used to calculate the transepithelial resistance (TER) of the monolayer using Ohm's Law. Experiments were normally repeated in different batches of culture to ensure that the data were reproducible.

Reverse transcription PCR (RT-PCR) analysis

Total RNA (15 µg) was extracted from the T₈₄ (control, MP and *ligustrazine* pretreated). Expressions of *ZO-1* and *ZO-2* were analyzed by competitive RT-PCR. The specific oligo nucleotide primers for *ZO-1* was CCGTCCTCTGAGCCTGTAAG for sense and GGA TCTACATGCGACGACAA for antisense corresponding to nucleotides 3 100-3 470 with an expected cDNA of 371 bp^[19], and for *ZO-2* was GCCAAAACCCAGAACAAAGA for sense and ACTGCTCTCTCCACCTCCT for antisense corresponding to nucleotides 3 018-3 283 with an expected cDNA of 212 bp^[19]. GAPDH was used as an internal marker for semi-quantitative analysis of expressions of *ZO-1* and *ZO-2* of T₈₄ cells. The specific oligonucleotide primers for GAPDH were TCC CAT CAC CAT CTT CCA G for sense and TCC ACC ACT GAC ACG TTG for antisense corresponding to nucleotides 249-764 bp with an expected cDNA of 515 bp^[20].

Data analysis

Results were expressed as mean±SD. The number of experiments represents independent measurements on separate monolayers. Comparisons between groups of data were made by Student's *t*-test. A *P* value less than 0.05 was considered statistically significant. EC₅₀ values were determined by nonlinear regression using GraphPad Prism software.

RESULTS

Effect of pretreatment with MP on electrophysiological characteristics

Pretreatment of T₈₄ cells with MP 15 µg/mL (*n* = 15) for 72 h significantly increased the basal transepithelial potential difference from 0.39±0.07 to 2.27±0.59 mV (Figure 1A, *P*<0.01), basal I_{SC} from 3.05±0.44 to 7.14±1.80 µA/cm² (Figure 1B, *P*<0.05) and transepithelial resistance (TER) from 0.14±0.01 to 0.37±0.04 µC/cm² (Figure 1C, *P*<0.001).

Effect of pretreatment with MP on expressions of *ZO-1* and *ZO-2*

In order to see whether MP-induced TER increase was related to the cytoplasmic proteins associated with tight junctions, *ZO-1* (zonula occludens-1) and *ZO-2* (zonula occludens-2), we used RT-PCR analysis to examine the expression levels of *ZO-1* and *ZO-2* in T₈₄ cells (Figure 2A). Semi-quantitative analyses showed that the expression levels of both *ZO-1* and *ZO-2* after MP pretreatment were significantly elevated, the ratio of *ZO-1* to GAPDH was from 0.46±0.08 to 0.81±0.10 (*n*=6, *P*<0.05, Figure 2B), and the ratio of *ZO-2* to GAPDH was from 0.76±0.12 to 1.27±0.12 (*n* = 4, *P*<0.001, Figure 2C), indicating the enhancement of epithelial barrier function.

MP-induced I_{SC} response

As shown in Figure 3, apical addition of MP (10–5000 µg/mL) produced an I_{SC} increase which was concentration-dependent (Figure 3A) with an apparent EC₅₀ of about 293.9 µg/mL (Figure 3B). MP-induced changes in I_{SC} were calculated as total charges transported for 15 min (µC/cm², the area under the curve of the MP-induced I_{SC} responses for the given time period) since the current kinetics did not sustain. MP at 10, 50, 100, 500, 1 000 and 5 000 µg/mL produced I_{SC} increases of 306.7±25.5 (*n* = 4), 673.3±91.3 (*n* = 4), 1380.0±119.4 (*n* = 4), 7624.0±309.7 (*n* = 5), 9580.0±734.9 (*n* = 6) and 10053.3±979.1 µC/cm² (*n* = 4), respectively.

Anion dependence of MP-induced I_{SC}

In order to study the ion species involved in mediating MP-induced I_{SC}, a Na⁺ channel blocker, amiloride and a couple of Cl[−] channel blockers, DPC, glibenclamide and DIDS were examined (Figure 4). The change in I_{SC} was defined as the maximal rise in I_{SC} following MP stimulation and it was normalized to current change per unit area of the epithelial monolayer (µA/cm²). DPC (1 mmol/L, *n* = 4, Figure 4A) or glibenclamide (1 mmol/L, *n* = 5) added to the apical side reduced MP (500 µg/mL)-induced responses from 10.0±0.97 µA/cm² to 1.78±0.18 µA/cm² (*P*<0.01) or from 9.44±0.49 µA/cm² to 1.39±0.5 µA/cm² (*P*<0.001) respectively, but apical addition of amiloride (10 µmol/L, *n* = 4) or DIDS (100 µmol/L, *n* = 4) had no significant effects (Figure 4B). Basolateral addition of bumetanide (100 µmol/L, *n* = 6), a strong inhibitor of the Na⁺-K⁺-2Cl[−] cotransporter reduced the MP-induced I_{SC} from 9.33±0.64 to 2.31±0.74 µA/cm² (Figure 4B, *P*<0.01).

Mimicking effects of MP by *ligustrazine*

Similar to the effects of pretreatment with MP, treating T₈₄ cells with *ligustrazine*, one of the active ingredients of MP, for 72 h also increased the levels of *ZO-1* and *ZO-2*, the ratio of *ZO-1* to GAPDH was raised from 0.46±0.08 to 0.65±0.11 (*n* = 6, Figure 2B)

Figure 1 Effects of MP pretreatment on transepithelial electrophysiological characteristics. Comparison of potential difference (A) transepithelial I_{sc} (B) and transepithelial resistance (C) in T₈₄ cells with and without MP (15 μg/mL, 72 h) pretreatment. Values are mean±SE; ^{a(b)}P<0.01; ^{b(a)}P<0.05; ^{c(d)}P<0.001.

Figure 2 RT-PCR analyses of mRNA expressions of ZO-1 and ZO-2 in T₈₄ cells. (A) RT-PCR results with products as expected of ZO-1 and ZO-2 found in control, MP pretreatment and ligustrazine pretreatment. Semi-quantitative analyses of ZO-1 (B) and ZO-2 (C) expressions in T₈₄ cells without and with MP or ligustrazine pretreatment, which were shown in ratio of ZO-1 or ZO-2 to GAPDH (internal marker). Values are mean±SE; ^aP and ^{b(c)}P<0.05; ^{c(d)}P<0.001.

Figure 3 MP-induced I_{sc} in T₈₄ cell lines. A: Representative I_{sc} recordings in response to MP (10, 50, 100, 500, 1 000 and 5 000 μg/mL) added to the apical side. Arrowheads indicate the time of MP addition. B: The concentration-response curve for MP-induced responses. Different concentrations of MP were added to the apical side and each data was obtained from at least 3 individual experiments. Values are mean±SE of maximal I_{sc} increase.

Figure 4 Anion dependence of MP-induced I_{sc}. A: Representative I_{sc} recording with arrows indicating the time for apical addition of MP (500 μg/mL) and DPC (1 mmol/L). B: Summary of the effects of DPC (1 mmol/L, apical), glibenclamide (1 mmol/L, apical), bumetanide (100 μmol/L, basolateral), amiloride (10 μmol/L, apical) and DIDS (100 μmol/L, apical) on MP-induced I_{sc}. Values are mean±SE; ^bP<0.01.

Figure 5 Anion dependence of *ligustrazine*-induced I_{sc} . A: Representative I_{sc} recording with arrows indicating the time for apical addition of *ligustrazine* (1 mmol/L) and glibenclamide (1 mmol/L). B: Summary of the effects of removal of extracellular Cl^- , basolateral addition of bumetanide (100 μmol/L) and apical addition of DPC (1 mmol/L) on *ligustrazine*-induced I_{sc} . Values are mean±SE; ^d P , ^b P and ^f P <0.001.

and the ratio of ZO-2 to GAPDH was from 0.76 ± 0.12 to 1.33 ± 0.07 ($n = 4$, $P < 0.001$) (Figure 2C).

Acute stimulation with *ligustrazine* (1 mmol/L, apical side) produced a current increase which was similar to that induced by acute addition of MP (0.5 mg/mL, apical) ($n = 6$, Figure 5A). Removal of Cl^- from KHS ($n = 4$), apical addition of DPC or glibenclamide (1 mmol/L) ($n = 3$) and basolateral administration of bumetanide (100 mmol/L) ($n = 3$) reduced *ligustrazine*-induced current increases by 79.9% ($P < 0.001$), 82.4% ($P < 0.001$) and 96.2% ($P < 0.001$), respectively (Figure 5B).

DISCUSSION

The present study has provided scientific evidence for the pharmacological action of MP, a Chinese medicine-based formula for postmenopausal women, on the GI tract. The results demonstrated that MP could stimulate Cl^- secretion in human colonic epithelial cell line T₈₄. The supporting evidence includes: MP-induced responses were insensitive to Na^+ channel blockers; the response was inhibited by Cl^- channel blockers; and substantially inhibited by the $Na^+-K^+-2Cl^-$ cotransporter inhibitors. The stimulatory effects of MP on colonic anion secretion were mimicked by its active ingredient, *ligustrazine*. Since *ligustrazine* is an active ingredient common in both MP and BFP, a traditional formula previously shown to stimulate anion secretion by GI tract epithelia^[11,15,16], the present results suggest that *Ligustrazine* may be one of the responsible ingredients involved in mediating the secretory effects of both MP and BFP.

Apart from its acute stimulatory effects on colonic anion secretion, MP, by treating T₈₄ cells for 72 h, was also demonstrated to significantly alter the electrophysiological characteristics of the colonic epithelia. Increases in transepithelial potential and basal I_{sc} may represent an increased driving force for anion secretion and basal secretion, respectively. These results indicate long-term treatment of MP can promote colonic anion secretion, consistent with its acute effects. On the other hand, pretreatment of T₈₄ cells with MP also increased the transepithelial resistance, indicating its effect on improving epithelial barrier function. This was confirmed by RT-PCR results, which showed that pretreatment with MP significantly up-regulated gene expressions of tight junction related proteins, ZO-1 and ZO-2. Similar results were obtained using *Ligustrazine*, suggesting that *ligustrazine* was able to improve barrier function in addition to colonic secretion. It has been reported that an elevation of intracellular calcium could decrease the tight junction resistance in T₈₄ monolayers^[21]. Since *Ligustrazine* has been shown to decrease intracellular Ca^{2+} by inhibiting Ca^{2+} entry and/or Ca^{2+} release^[22,23], *ligustrazine* as well as *ligustrazine*-containing MP may strengthen tight junctions, thereby enhancing transepithelial resistance. In fact, we have found that intracellular calcium

could also be reduced by an apical addition of MP (data not shown), indicating a possible mechanism for improving barrier function. Further studies may be required to understand the detailed mechanisms.

Taken together, the present results have demonstrated that MP and *Ligustrazine* exert a stimulatory effect on gastrointestinal Cl^- secretion and improvement of epithelial barrier function. Since MP is designed for postmenopausal or elderly women, its demonstrated effects on the colonic epithelia, in addition to its beneficial effect on endocrine (Gou *et al.*, unpublished data) and immune systems previously shown^[1], suggest that MP and its active ingredient, *ligustrazine*, may be used to alleviate some of the GI tract disorders, such as infection and constipation, often seen in the elderly.

Abstract

AIM: To study morphologic and biomechanical changes of oesophagus in diabetes rats.

METHODS: Diabetes was induced by a single injection of streptozotocin (STZ). The type of diabetes mellitus induced by parenteral STZ administration in rats was insulin-dependent (type I). The samples were excised and studied *in vitro* using a self-developed biomaterial test machine.

RESULTS: The body mass was decreased after 4 d with STZ treatment. The length of esophagus shortened after 4, 7, 14 d. The opening angle increased after 14 d. The shear, longitudinal and circumferential stiffness were obviously raised after 28 d of STZ treatment.

CONCLUSION: The changes of passive biomechanical properties reflect intra-structural alteration of tissue to a certain extent. This alteration will lead to some dysfunction of movement. For example, tension of esophageal wall will change due to some obstructive disease.

INTRODUCTION

Esophagus is a distensible muscular tube that connects pharynx and stomach. The function of the esophagus is to transport food by peristaltic movement, which is the result of the interaction of the tissue forces in the esophageal wall and the hydrodynamic forces in the food bolus. Esophagus has been studied by radiography^[1], concurrent videofluoroscopy and manometry^[2,3], high-frequency ultrasonography^[4-6], and endoscopic sclerotherapy^[7,8]. Motility disorders^[9], bolus transport^[10,11], systemic sclerosis^[12], pain^[13], wall distensibility^[8], impedance planimetric characterization^[14] and the effects of epidermal growth factor^[15] on esophagus have been reported

in many papers. Since the function of esophagus is mainly mechanical, our work was focused on providing quantitative measurement of passive biomechanical properties of esophagus. Many investigations on biomechanics of esophagus are available in the literature^[16,17]. Gregersen *et al.* studied strain distribution in the layered wall^[18,19], relation between pressure and cross-sectional area^[20] and other biomechanical properties^[21-23] of esophagus. A more recent work used a novel ultrasound technique to study the biomechanics of the human esophagus *in vivo*^[24]. Patel represented biomechanical and sensory parameters of the human esophagus at four levels^[25]. Researchers have done a lot biomechanical studies on gastrointestinal tract such as intestine^[26,27], small intestine^[28-32], ileum^[33], duodenum^[34] and large intestine^[35,36].

Most previous studies have explained the relationship between the diabetes and gastrointestinal tract function^[37,38]. Some researches studied relationship between esophageal dysfunction and neuropathy^[39], oesophagus scintigraphy^[40] and the relationship between esophageal motility and transit^[41] in diabetic patients. More recently, Jorgensen reported tension-strain relations and morphometry of rat small intestine in experimental diabetes^[42]. Zhao introduced the remodeling of zero-stress state of small intestine in streptozotocin-induced diabetic rats^[43].

This paper presents the effect of experimental diabetes on the morphologic and biomechanical properties of the esophagus. The result of this study indicated that experimental type I diabetes caused significant changes in the passive biomechanical properties in the rat esophagus.

MATERIALS AND METHODS

Materials

Diabetes was induced by a single injection of streptozotocin (STZ). The form of diabetes mellitus induced by parenteral STZ administration in rats is insulin-dependent (type I). Twenty-seven rats were divided into 4 groups according to the survival time after STZ treatment: 4 d ($n = 7$), 7 d ($n = 7$), 14 d ($n = 7$), 28 d ($n = 6$). Another 8 rats were used as normal controls. The samples were taken from the middle part of esophagus. Two rings were cut from each end of the sample to measure the geometric parameters of the no-load state and the opening angle at zero-stress state. The remaining part was excised and studied *in vitro* using a self-developed biomaterial test machine.

Methods

Using this machine, the esophagus was stepwise elongated and inflated and continuously twisted in circumferential-longitudinal direction. In the normal controls and 28 d of diabetes group, after the intact esophagus was tested, the mucosa and muscle layers were separated using microsurgery and tested in the same loading procedure as mentioned above. The esophagus was treated as a membrane when the stress and strain were calculated, the longitudinal and circumferential stresses were considered to be evenly distributed along the wall thickness while the radial stress and other transverse shear stresses were

ignored. The torque vs twist-angle relation was approximately linear at a specified pressure and longitudinal stretch ratio. Thus, the shear modulus can be computed by the torque, twist angle and polar moment of inertial at this state. However, the shear modulus varied greatly with the changing inflation pressure and longitudinal stretch ratio.

Figure 1 Simplified diagram of biomaterial test machine. 1: Linear stage, 2: Torque transducer, 3: Organ bath, 4: Specimen, 5: Force transducer, 6: Motor for axial rotation, 7: Pressure transducer, 8: Infusion channel, 9: Motor for linear stage, 10: Rails for linear stage, 11: CCD camera, 12: Plastic rod.

RESULTS

Type I diabetes could induce the following effect on the biomechanical and morphologic properties of esophagus: body weight and morphology, shear modulus, circumferential and longitudinal stress-strain relationship, stress-strain relationship of muscle layer and mucosa layer.

Body weight and morphology

The body mass kept a steady increase in the control rats. But it went down after 4 d in the diabetes rat (Figure 2A). The length of esophagus *in vivo* obviously declined after 4, 7, 14 d, but it would return to normal level after 28 d (Figure 2B). The mass per unit length *in vitro* changed little (Figure 2C). In the intact esophagus, the opening angle increased after 14 d of STZ treatment (Figure 2D).

Shear modulus

Changes of elastic shear moduli in the course of diabetes development at longitudinal stretch ratio $\lambda_{zz} = 1.5$ and various

transmural pressure are shown in Figure 3A. Elastic shear modulus would rise with increased transmural pressure. Especially when transmural pressure was more than 0.25 kPa, the shear moduli for various transmural pressure were remarkably different. And diabetes has notably affected the shear modulus. This effect showed that shear moduli are obviously increased after 28 d.

Changes of elastic shear modulus in the course of diabetes development at transmural pressure $P = 1$ kPa and various longitudinal stretch ratio are pictured in Figure 3B. Elastic shear modulus would rise with increased longitudinal stretch ratio. Shear moduli were remarkably different at various longitudinal stretch ratios. And diabetes has notably affected the shear modulus. This effect demonstrated that shear moduli were obviously increased after 28 d of STZ treatment.

Circumferential and longitudinal stress-strain relationship

Figure 4A shows the changes of circumferential stress-strain relationship in the course of diabetes development at longitudinal stretch ratio $\lambda_{zz} = 1.5$ and various transmural pressure. All curves of experimental group inclined to left side except that after 4 d. The curve after 28 d was on the most left side. The circumferential stiffness increased after 7, 14, 28 d of diabetes.

The changes of longitudinal stress-strain relationship in the course of diabetes development at transmural pressure $P = 0.25$ kPa and various longitudinal stretch ratio are pictured in Figure 4B. The stress-strain curve after 28 d was obviously inclined to left side. So the longitudinal stiffness notably increased after 28 d.

Stress-strain relationship of muscle layer and mucosa layer

The circumferential stress-strain relationship of muscle layer and mucosa layer in the process of inflation at a longitudinal stretch ratio of 1.5 is pictured in Figure 5A. And the experimental diabetes was after 28 d. For muscle layer, there was no obvious difference between the control and diabetes groups. For mucosa layer, the stress-strain curve moved to left side in parallel. So circumferential stiffness of mucosa layer with diabetes was larger than that of control.

Figure 5B shows longitudinal stress-strain relationship of muscle layer and mucosa layer in the process of elongation at a transmural pressure of 0.25 kPa. For muscle layer, there was no obvious difference between control and diabetes groups. There was no notable difference for mucosa layer either.

Figure 2 Changes of body mass and esophagus morphology and opening angle at zero-stress state in the process of diabetes development. Dunnett's test result: significant difference vs normal control ($*P < 0.05$). A: Change of body mass, B: Change of *in vivo* length, C: Change of mass per unit length, D: Change of opening angle.

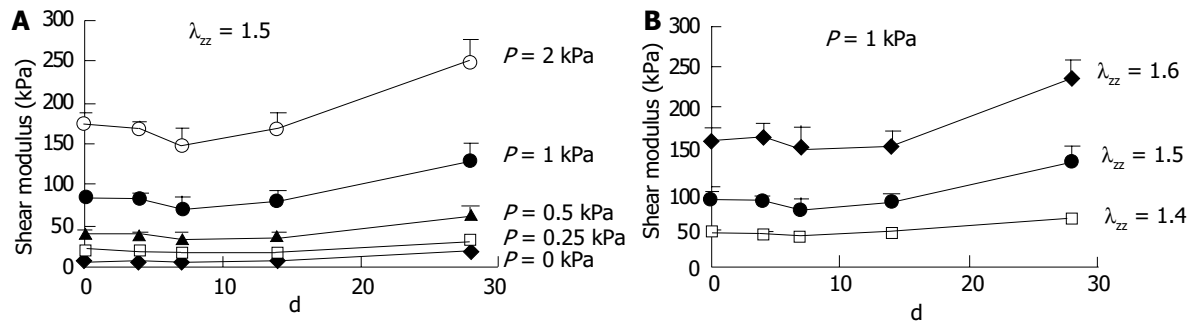

Figure 3 Change of elastic shear modulus in the process of diabetes development. A: Change at $\lambda_{zz} = 1.5$ and various transmural pressure, B: Change at $P = 1$ kPa and various longitudinal stretch ratio.

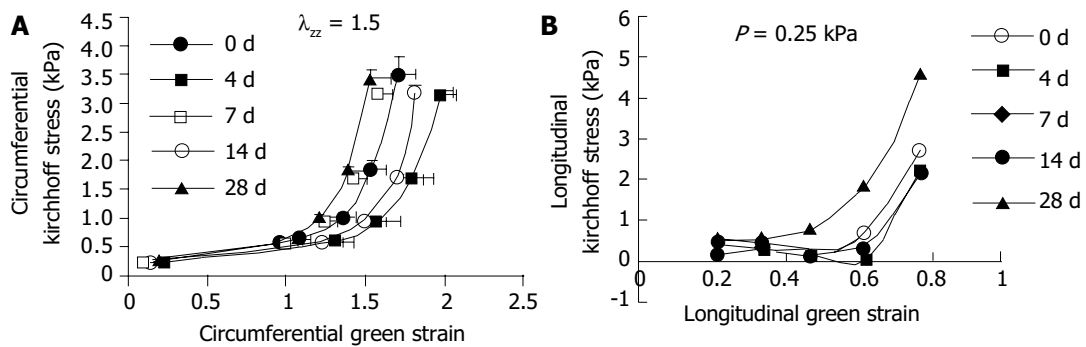

Figure 4 A: Change of circumferential stress-strain relation in the course of diabetes development at $\lambda_{zz} = 1.5$ and various transmural pressure. B: Change of longitudinal stress-strain relation in the course of diabetes development at $P = 0.25$ kPa and various longitudinal stretch ratio.

Figure 5 A: Circumferential stress-strain relation between muscle layer and mucosa layer in the process of inflation at a longitudinal stretch ratio of 1.5. N: Normal control, D: 28 d of diabetes. B: Longitudinal stress-strain relation between muscle layer and mucosa layer in the process of elongation at a transmural pressure of 0.25 kPa. N: Normal control, D: 28 d of diabetes.

DISCUSSION

A large number of studies have discovered that diabetes can affect the movement of oesophagus. Transportation of oesophagus may delay or slow down, and movement of esophagus can not coordinate.

This dysfunction of movement can be a result of muscle and nerve cooperative failure^[39-41,44-47]. Histologic research has proved that diabetes can destroy vagus nerve^[48]. Though there are many papers on movement and function of oesophagus in diabetes, few data on morphologic and passive biomechanical properties are seen. The change of passive biomechanical properties reflects intra-structural alteration of tissue to a certain extent. This alteration will result in some dysfunction of movement, for example, tension of esophageal wall will change due to some obstructive disease^[49,50], and therefore, it is necessary to study biomechanics and morphology together.

The body mass is decreased in rat with diabetes. This is

consistent with other studies^[43,51]. Diabetes will lead to hyperplasia of some organs. Hyperplasia of esophagus is less frequent than that of small intestine^[52,53]. Diabetes has caused rise of the opening angle of small intestine^[44], also it is seen for esophagus.

In this paper, the shear, longitudinal and circumferential stiffnesses were obviously elevated after 28 d with STZ treatment. Jorrensen^[42], Liu^[54] and Zhao^[51] have discovered that stiffness is raised in diabetes in small intestine, blood vessel and arterial wall.

We can draw a conclusion that the changes of passive biomechanical properties reflect intra-structural alteration of tissue to a certain extent. This alteration will lead to some dysfunction of movement.

Abstract

AIM: To develop an *in vitro* three-dimensional (3-D) angiogenesis system to analyse the capillary sprouts induced in response to the concentration ranges of basic fibroblast growth factor (bFGF) and vascular endothelial growth factor (VEGF) and to quantify their synergistic activity.

METHODS: Microcarriers (MCs) coated with human microvascular endothelial cells (HMVECs) were embedded in fibrin gel and cultured in 24-well plates with assay media. The growth factors bFGF, or VEGF, or both were added to the system. The wells ($n = 8/\text{group}$) were digitally photographed and the average length of capillary-like sprouts (ALS) from each microcarrier was quantitated.

RESULTS: In aprotinin-stabilized fibrin matrix, human microvascular endothelial cells on the MCs invaded fibrin, forming sprouts and capillary networks with lumina. The angiogenic effects of bFGF or VEGF were dose-dependent in the range from 10 to 40 ng/mL. At d 1, 10 ng/mL of bFGF and VEGF induced angiogenesis with an ALS of $32.13 \pm 16.6 \mu\text{m}$ and $43.75 \pm 27.92 \mu\text{m}$, respectively, which were significantly higher than that of the control ($5.88 \pm 4.45 \mu\text{m}$, $P < 0.01$), and the differences became more significant as the time increased. In addition, the combination of 10 ng/mL of bFGF and VEGF each induced a more significant effect than the summed effects of bFGF (10 ng/mL) alone and VEGF (10 ng/mL) alone when analyzed using SPSS system for general linear model (GLM) ($P = 0.011$), and that also exceeded the effects by 20 ng/mL of either bFGF or VEGF.

CONCLUSION: A microcarrier-based *in vitro* three-dimensional angiogenesis model can be developed in fibrin. It offers a unique system for quantitative analysis of angiogenesis. Both bFGF and VEGF exert their angiogenic effects on HMVECs synergistically and in a dose-dependent manner.

INTRODUCTION

Angiogenesis is a process by which new capillaries develop from an existing microvascular network. It is associated with a number of physiologic and pathologic conditions including malignancies, diabetic retinopathy, and rheumatoid arthritis. Angiogenesis in fibrin-based matrix is especially interesting because it is essential in tumor angiogenesis and wound healing.

Angiogenesis was first observed *in vitro* by Folkman and Haudenschild 20 years ago^[1]. After culture of endothelial cells, these cells organize spontaneously into capillary-like structures (CLS) with the presence of lumina. From a physiological point of view, an ideal *in vitro* system would take into account all the representative steps of *in vivo* angiogenesis, from detachment of endothelial cells from the vascular wall to final tubular morphogenesis and vascular network formation. It should be also rapid, easy to use, reproducible, and easily quantifiable. Depending on the way the cells reorganize, the *in vitro* models of angiogenesis described to date can be roughly classified into two categories: two-dimensional (2-D) and three-dimensional (3-D). While 2-D angiogenesis models lack the third dimension and obviously do not reflect all physiological steps, the 3-D models are closer to the *in vivo* environment, because they consider more steps of angiogenesis^[2].

A variety of 3-D *in vitro* models of angiogenesis have been developed in the past few years^[3-7] and have thus significantly increased our understanding of the roles of endothelial cells, extracellular matrix (ECM), growth factors and other bioactive molecules in angiogenesis.

In this study, we described an *in vitro* system of angiogenesis, which was based on microcarriers (MCs), human microvascular endothelial cells (HMVECs) and fibrin extracellular matrix. With this system, the angiogenic effect of basic fibroblast growth factor (bFGF) and vascular endothelial growth factor (VEGF) and their synergism were tested.

MATERIALS AND METHODS

Cell isolation and culture

HMVECs were isolated from juvenile foreskin as described previously^[8,9]. Briefly, the foreskin was cut into small pieces, washed with PBS and incubated with 15-20 mL of 2 g/L dispase in DMEM (Gibco BRL Cat# 11885-084) overnight (18-24 h) at 4 °C. The tissue pieces were transferred into DMEM and scratched with a scalpel. The remnants were discarded and the resulting cell suspension (containing HMVEC and other contaminating cell types) was centrifuged at 1 000 r/min for 5 min. The pellet was re-suspended in 10-15 mL of endothelial growth medium

(EGM) consisting of endothelial basal medium (EBM) (Clonetics, San Diego, CA), supplemented with 10 ng/mL epidermal growth factor (EGF) (Clonetics), 12 µg/mL bovine brain extract (BBE) (Clonetics), 1.0 µg/mL hydrocortisone (Clonetics), 100 U/mL penicillin (Clonetics), and 100 mg/mL streptomycin (Clonetics) in the presence of 150 mL/L normal human serum and seeded into a gelatin-coated 75-cm² tissue culture flask. Culture medium was changed every 2-3 d. Before the cultures were confluent (normally 5-7 d after seeding), the HMVECs were separated from the other cells in culture by immuno-magnetic isolation with CD31-Dynabeads following the manufacturer's instructions (DynaL A.S, Oslo, Norway). Endothelial cell cultures were characterized and determined to be >99% pure on the basis of the formation of typical cobblestone monolayer in culture and positive immuno-staining for factor VIII-related antigen (Beijing Zhongshan Biotechnology Co., Ltd). The purified HMVECs were cultured in EGM at 37 °C (50 mL/L CO₂) on gelatin-coated cell culture surfaces. All assays were conducted with cells in passages 6 to 8.

Microcarrier cell culture

Gelatin-coated cytodex-3 microcarriers (MCs) (Amersham Pharmacia Biotech, Piscataway, NJ) were prepared according to the recommendations of the supplier. Freshly autoclaved MCs were suspended in EGM and endothelial cells were added to a final density of 50-80 cells/MC. The cells were allowed to attach to the MCs in a 1.5 mL Eppendorf tube for 4 h at 37 °C. The MCs were then re-suspended in a larger volume of medium and cultivated for another 24-48 h at 37 °C (50 mL/L CO₂). MCs were gently agitated to prevent aggregation of individual MCs. MCs were used for angiogenesis assay when the endothelial cells on the MCs reached confluence^[10, 11].

Microcarrier-based fibrin gel angiogenesis assay

The microcarrier-based fibrin gel angiogenesis assay was performed as described^[10] with some modifications. Working solution of fibrinogen (Shanghai Raas Blood Product Co., Ltd) was prepared by dissolving the stock solution of fibrinogen (20 mg/mL in PBS) in EBM to a concentration of 1.0 mg/mL, supplemented with EGF and hydrocortisone at 10 ng/mL and 1.0 µg/mL, respectively. The 24-well plates were used for the assay. The bottom of each well was first covered with 250 µL fibrinogen solution, and the clotting was induced by addition of thrombin (0.5 U/mL). After 30 min of polymerization, another 250 µL of fibrinogen solution containing about 250 EC-coated MCs was added. The MCs were evenly distributed in the fibrinogen by gently shaking the culture plates, and polymerization was induced as described above. After complete polymerization, 1.0 mL of EBM supplemented with 10 ng/mL of EGF, 1.0 µg/mL of hydrocortisone and 50 mL/L adult human serum was added on the gel. To prevent excess fibrinolysis by fibrin-embedded cells, aprotinin was added to the growth media at 200 KIU/mL. For the experiments, which required bFGF (PeproTech EC Ltd) and/or VEGF (PeproTech EC Ltd), the components were added to both of the fibrinogen solution and the supernatant medium at the desired concentrations.

Quantification and statistics

At the time point of interest, six random fields of vision for every well were digitally photographed under inverted microscope, and the pictures were transferred to a computer. The quantification of capillary-like structure formation was performed as described by Xue and Greisler with some modifications^[12]. Briefly, a special grid was made by dividing a circle with radially oriented lines around 360 degrees with 10-degree intervals using Photoshop (version 6.0; Adobe Systems Inc). The digital photographs were transparently layered with

the grid. For each photographed microcarrier, the lengths of sprouts were measured on each of the grid lines and summed (Figure 1). The lengths of sprouts from each MC were averaged in each well. The average lengths of sprouts (ALS) from 8 replicate wells of each testing group were analyzed and expressed as mean±SD. SPSS system for one-way ANOVA was used to compare the differences during the time courses and the General Liner Model (GLM) was used to determine the synergism. $P < 0.05$ was considered statistically significant.

Figure 1 Quantification of angiogenesis. Each MC in random photographed fields was overlaid with a grid that was equally divided around 360° at 10-degree intervals (original magnification $\times 100$). For each photographed microcarrier, the lengths of sprouts were measured on each of the grid lines and summed. The lengths of sprouts from each MC were averaged in each well. The average lengths of sprouts (ALS) from 8 replicate wells of each testing group were analyzed. Bar: 100 µm.

RESULTS

Sequential steps of capillary formation

In 1995, Nehls and Herrmann described a microcarrier-based *in vitro* model of angiogenesis^[9]. In their model, the endothelial cells coated on the microcarriers invaded the fibrin gel, forming elongated capillary-like structure in a response to angiogenic factors. However, this model was performed with large vascular endothelial cells of calf pulmonary artery origin. Although in later studies, they used human microvascular endothelial cells to investigate their response to the co-cultured tumor cells, but no positive result was found^[13]. In the present study, by modifying the system, we successfully established the microcarrier-based *in vitro* model of angiogenesis with human microvascular endothelial cells in fibrin.

In the early stages of capillary growth (about 16 h after polymerization of the fibrin gel), the HMVECs on microcarriers migrated into fibrin matrix to form sprouts without detectable lumina. At about 16-48 h, sprouts elongated, and small intracellular or intercellular lumina was formed. Usually, broad lumina developed at the base of the sprouts. The lumina frequently contained cellular debris, which could be seen to float by shaking the culture dishes, indicating that lumina contents had liquefied. The tips of capillary sprouts were generally solid or showed only primitive, slit-like lumina, which in later stages anastomosed to other sprouts, and finally formed capillary-like network (at about 5-7 d) (Figure 2). This result was not consistent with what was observed by Nehls and Herrmann, who assumed that due to the presence of serum, anastomosis of capillary sprouts occurred rarely^[14].

Capillary sprout formation induced by bFGF and VEGF

In the absence of growth factors, capillary sprout formation in our model was minimal. Both bFGF and VEGF induced obvious EC sprouting. The curves for both cytokines increase significantly with time. The angiogenic effects of both cytokines were dose-dependent over the range from 10 to 40 ng/mL. At d 1, 10 ng/mL

Figure 2 Sequential steps of capillary formation. During 3 d after polymerization of the fibrin gel, the HMVECs (bFGF 40 ng/mL) on microcarriers migrated into fibrin matrix to form sprouts, which elongated (A) with intracellular or intercellular lumina formed (bFGF 40 ng/mL). The lumina frequently contained cellular debris, which can be seen to float by shaking the culture dishes, indicating that lumina contents had liquefied (B, arrow). In the late stage (d 5), the capillary sprouts anastomosed to each other, and finally formed capillary-like network (C) (original magnification $\times 100$).

of bFGF and VEGF induced angiogenesis with an ALS of $32.13 \pm 16.6 \mu\text{m}$ and $43.75 \pm 27.92 \mu\text{m}$, respectively, which was significantly higher than that of the control ($5.88 \pm 4.45 \mu\text{m}$, $P < 0.01$). With the time going, on the difference became more significant (Figure 3). Within the dose range, angiogenesis increased correspondingly in both extent and rapidity as the concentration increased (Figure 4).

Exposure of ECs to both bFGF and VEGF in combination stimulated an angiogenic response that was greater than sum of their individual effects, and that occurred more rapidly than the response to either growth factor. The ALS induced by 10 ng/mL of bFGF plus 10 ng/mL of VEGF in combination was $590.75 \pm 289.15 \mu\text{m}$, which was greater than the total effects of 10 ng/mL of bFGF ($124.00 \pm 62.12 \mu\text{m}$) and 10 ng/mL of VEGF ($171.38 \pm 119.42 \mu\text{m}$) and also greater than that induced by 20 ng/mL of either bFGF ($187.25 \pm 98.14 \mu\text{m}$) or VEGF ($280.5 \pm 198.23 \mu\text{m}$) (Figure 5). The synergism of bFGF and VEGF was confirmed by the GLM test, which showed that the effect of the combination of bFGF plus VEGF was greater than the sum of the individual effects of bFGF and VEGF alone ($P = 0.011$) (Figure 5).

Figure 3 Time course of HMVEC angiogenesis in fibrin. Microcarriers coated with HMVECs were embedded in fibrin. The angiogenic effects of either bFGF or VEGF were dose-dependent over the range from 10 to 40 ng/mL. At day 1, 10 ng/mL of bFGF and VEGF induced angiogenesis with an ALS of $32.13 \pm 16.6 \mu\text{m}$ and $43.75 \pm 27.92 \mu\text{m}$, respectively, which were significantly higher than that of the control ($5.88 \pm 4.45 \mu\text{m}$, $P < 0.01$). The difference became more significant, as the time increased.

Figure 4 Dose responses of bFGF and VEGF on angiogenesis. Both bFGF and VEGF exhibited dose-dependent angiogenic effects in the range from 10 to 40 ng/mL. At d 1, 10 ng/mL of bFGF and VEGF induced angiogenesis with an ALS of $32.13 \pm 16.6 \mu\text{m}$ and $43.75 \pm 27.92 \mu\text{m}$, respectively, which were significantly higher than that of the control ($5.88 \pm 4.45 \mu\text{m}$, $P < 0.01$). With the concentration increasing, the difference became more significant.

Figure 5 Synergism of bFGF and VEGF. The samples were quantitated at d 3. The combination of 10 ng/mL bFGF and 10 ng/mL VEGF induced an angiogenic response that was greater than the sum of the effects by each cytokine alone at the same dose ($P = 0.011$).

DISCUSSION

Three-dimensional angiogenesis assays are based on the capacity of activated endothelial cells to invade 3-D substrates. The matrix may consist of collagen gels, plasma clot, purified fibrin, matrigel, or a mixture of these proteins with others. The culture medium may be added to the gel before polymerization or on top of the gel. Depending on the culture medium composition (percentage of serum, addition of cytokines), cells can be induced to sprout, proliferate, migrate, differentiate, and tubular endothelial cell phenotypes in the 3-D configuration. Thus, one can *in vitro* observe the morphogenic responses of isolated ECs, which characterize the *in vivo* angiogenesis. In fact, a variety of 3-D angiogenesis models have provided great advances in the understanding of angiogenesis and the investigation of angiogenic/anti-angiogenic factors^[2].

In 3-D angiogenesis models, the ECs were usually reorganized in the following ways: directly overlaid by gels^[15,16], sandwiched between two gel layers^[17], seeded dispersedly^[18] or clustered as spheroids in gels^[3,4], or attached onto microcarrier beads. Microcarrier-based angiogenesis model was firstly developed by Nehls and Drenckhan^[10], who suggested, in their later studies, that in the presence of serum, the anastomosis of capillary sprouts occurred only rarely^[14].

In this study, we also established an *in vitro* angiogenesis system based on microcarrier, but it was with human dermal microvascular endothelial cells (HMVECs). With this system, we observed all of the angiogenic steps that characterize the *in vivo* angiogenesis, including sprouting (16–24 h), branching (24–48 h), and capillary network formation (after 72 h), as described above. However, not in agreement with the observation by Nehls and Drenckhan, we found that the anastomosis of capillary sprouts occurred commonly in the later stage (3–5 d), even in the presence of up to 100 mL/L serum in our system (data not shown). After 5 d, the capillary-like network could be seen around/between MCs.

Since one of our goals was to characterize the gene expression patterns at the different steps of angiogenesis including sprouting, branching and networking, our 3-D angiogenesis model thus gave a good supporting. However, because of the morphological complexity, the capillary-like network at the late stage of the model was difficult to be quantified. So, we confined our observation to the first 3 d of the culture for the angiogenic quantification of the growth factors.

Angiogenesis in physiological conditions is characterized by strict regulation and occurs mostly through a collagen-rich extracellular matrix and leads to the formation of an organized capillary network. In contrast, in different pathological conditions as they are associated with tumor growth or wound healing, capillary sprouting processes are known to primarily occur in a

fibrin-rich matrix and the stimulation of new vessels is exaggerated, leading to the formation of a disorganized^[4,19], capillary network. As one of the native ECM components involved in angiogenesis, fibrin is formed by the polymerization of fibrinogen after the proteolytic cleavage by thrombin. This scenario naturally takes place at sites of wound healing and tumor under the stimulation of VEGF and other factors, and leads to the deposition and stabilization of local fibrin clots. These fibrin clots serve as a temporary matrix that provides a solid support for invading cells, such as fibroblasts and endothelial cells.

In vitro angiogenesis in fibrin is affected by EC fibrinolysis involving both plasmin and metalloproteinase systems and the spatial structure of the gel^[20,21]. Cell surface fibrinolytic activity is crucial for EC invasion and migration in fibrin^[22,23]. The presence of aprotinin is necessary to maintain the integrity of fibrin. In the absence of aprotinin, fibrin was unable to support EC angiogenesis because it would be degraded before capillary-like structure formation. The configuration and mechanical properties of fibrin were determined by the conditions in which it polymerized. Various factors, including pH, ionic strength, fibrinogen and thrombin concentrations could affect the structural feature of fibrin^[24]. It is thus important to prepare fibrin at a well-controlled condition when performing fibrin matrix-based angiogenic experiments, and to avoid any modification between the groups when comparing the potency of different angiogenic factors.

Many growth factors have been found to have angiogenic effects. FGFs and VEGFs are the best characterized among them. FGFs and VEGFs bind with high specificity to their cognate receptor tyrosine kinases, inducing activation of the intrinsic enzymatic activity of these receptors. This activity leads to tyrosine phosphorylation of the receptors, as well as of substrates for the kinases. In some cases, growth factors may induce angiogenesis by regulating the expression of some other growth factors and their receptors^[19]. It is noteworthy that FGF and VEGF may act synergistically in induction of angiogenesis. Synergy of these growth factors in *in vivo* angiogenesis has been reported^[25], and combination of the two factors also yielded a synergistic response in collagen-based *in vitro* system^[26,27]. The mechanisms responsible for this synergism are that these two growth factors closely interact with each other in angiogenic process. bFGF could induce expression of endogenous VEGF and its receptors in ECs^[28–30], and VEGF-receptor antagonists inhibited bFGF-induced angiogenesis in spite of its lack of activities against bFGF receptors^[31]. The capacity of VEGF to induce u-PA-plasmin activity and angiogenesis depended on endogenous bFGF produced by ECs^[32]. In our fibrin and microcarrier-based angiogenesis model, we also found that both bFGF and VEGF demonstrated angiogenic effects on HMVECs in a dose-dependent manner, and when applied in combination these two factors also acted synergistically.

In conclusion, we have successfully established a microcarrier-based *in vitro* three-dimensional angiogenesis model that offers a unique system for quantitative analysis of angiogenesis. The model is especially applicable to *in vitro* evaluation and screening of novel angiogenic or angiostatic factors. It may also shed light on the study of molecular mechanism of angiogenesis.

Abstract

AIM: The pathogenesis of hypogonadism in liver cirrhosis is not well understood. Previous results from our laboratory showed that IGF-1 deficiency might play a pathogenetic role in hypogonadism of cirrhosis. The administration of IGF-1 for a short period of time reverted the testicular atrophy associated with advanced experimental cirrhosis. The aim of this study was to establish the historical progression of the described alterations in the testes, explore testicular morphology, histopathology, cellular proliferation, integrity of testicular barrier and hypophyso-gonadal axis in rats with no ascitic cirrhosis.

METHODS: Male Wistar rats with histologically-proven cirrhosis induced with carbon tetrachloride (CCl₄) for 11 wk, were allocated into two groups ($n = 12$, each) to receive recombinant IGF-1 (2 µg/100 g·d, sc) for two weeks or vehicle. Healthy rats receiving vehicle were used as control group ($n = 12$).

RESULTS: Compared to controls, rats with compensated cirrhosis showed a normal testicular size and weight and very few histopathological testicular abnormalities. However, these animals showed a significant diminution of cellular proliferation and a reduction of testicular transferrin expression. In addition, pituitary-gonadal axis was altered, with significant higher levels of FSH ($P < 0.001$ vs controls) and increased levels of LH in untreated cirrhotic animals. Interestingly, IGF-1 treatment normalized testicular transferrin expression and cellular proliferation and reduced serum levels of LH ($P = ns$ vs controls, and $P < 0.01$ vs untreated cirrhotic group).

CONCLUSION: The testicular barrier is altered from an

early stage of cirrhosis, shown by a reduction of transferrin expression in Sertoli cells, a diminished cellular proliferation and an altered gonadal axis. The treatment with IGF-1 could be also useful in this initial stage of testicular disorder associated with compensated cirrhosis.

INTRODUCTION

Hypogonadism (characterized by low testosterone levels and relative hyperestrogenism, loss of libido, sexual impotence and feminine body features in men) is a common complication of advanced liver cirrhosis^[1]. Previous data demonstrated that rats with advanced cirrhosis showed reduced testicular size and weight and severe histopathological testicular abnormalities, including reduced tubular diameters, loss of the germinal line, and diminutions in cellular proliferation and spermatogenesis and testicular transferrin expression, a good marker of the integrity of blood-testis barrier^[2]. In addition, low serum testosterone and high serum LH were present in cirrhotic animals, as well as decreased levels of serum IGF-1. Interestingly, the administration of IGF-1 at low doses for a short period of time reverted the testicular atrophy and improved the altered pituitary-testicular axis in these animals^[2]. In cirrhotic patients, hypogonadism has been attributed to a variety of mechanisms including gonadal toxicities of alcohol, malnutrition and increased production of estrogens from androgens in peripheral tissues due to the existence of portal systemic shunting^[3-9].

Insulin-like growth factor-1 (IGF-1) is an anabolic hormone produced in different tissues although the liver accounts for 90% of the circulating hormone, which is synthesized in response to growth hormone (GH) stimulation^[10,11]. In cirrhosis the reduction of receptors for GH in hepatocytes and the diminished synthesizing ability of the liver parenchyma caused a progressive fall of serum IGF-1 levels^[11-14]. Although in an early stage of cirrhosis serum levels of IGF-1 were normal, its bio-availability seemed to be diminished^[15]. The clinical impact of the reduced production or availability of IGF-1 in cirrhosis was largely unknown^[11-14]. Recent studies from our laboratory have demonstrated that short courses of treatment with low doses of IGF-1 were able to induce marked improvements in nutritional state^[15], nitrogen retention^[16], intestinal absorption^[17-19], osteopenia^[20,21], liver function reducing fibrogenesis^[22,23], and restore the reduced somatostatinergic tone^[24] in rats with experimental cirrhosis. These data suggest that IGF-1 deficiency plays a pathogenetic role in several systemic complications occurring in cirrhosis.

It is well known that IGF-1 stimulates testosterone synthesis and spermatogenesis^[25-32]. Its deficiency could contribute to the development of hypogonadism associated with cirrhosis as

the previous data supported^[2]. Since the pathogenesis of hypogonadism in cirrhosis is not yet well understood, the aim of the present study was to study the chronological progression of the described alterations in testes^[2] in advanced cirrhosis, explore testicular morphology, histopathology, cellular proliferation, integrity of testicular barrier and hypophyso-gonadal axis in rats with cirrhosis in an early stage, without ascites.

MATERIALS AND METHODS

Induction of liver cirrhosis

All experimental procedures were performed in conformity with The Guiding Principles for Research Involving Animals^[33]. Cirrhosis was induced as previously described^[15,16]. Briefly, male Wistar rats (3-week-old, 130-150 g) were subjected to CCl₄ inhalation (Merck, Darmstadt, Germany) twice a week for 11 wk with a progressively increasing exposure time from 1 to 5 min. During the whole period of cirrhosis induction animals received Phenobarbital (Luminal, Bayer, Leverkusen, Germany) in the drinking water (400 mg/L). Both food (standard semipurified diet for rodents; B.K. Universal, Sant Vicent del Horts, Spain) and water were given *ad libitum*. Healthy, age and sex-matched control rats were maintained under the same conditions but receiving neither CCl₄ nor Phenobarbital.

Study design

The treatment was administrated for 2 wk after stopping of CCl₄ exposure. In the morning of d 0, animals were weighed and blood samples were drawn from the retroocular venous plexus from all rats with capillary tubes (Marienfeld, Germany) and stored at -20 °C until used for analytical purposes. Cirrhotic rats were randomly assigned to receive either vehicle (saline) (group CI, *n* = 12) or recombinant human IGF-1 (Pharmacia-Uppsala, Sweden) (2 µg/100 g·d in two divided doses, subcutaneously) (group CI+IGF, *n* = 12) for two weeks. Control rats (group CO, *n* = 10) received saline during the same period.

In the morning of the 15th d, rats were weighed, blood was obtained from the retroocular plexus and animals were killed by decapitation. After the abdominal cavity was opened, the liver and testes were dissected and weighed. Samples from the left major liver lobe and testes were processed for histological examination (fixed in Bouin's solution). The testicular diameters (AP and LM) were measured using a precision calliper, Mituyoto® (±0.05 mm). Ascites was ruled out by direct exploration of abdominal cavity in all cirrhotic animals.

Liver histopathology

Bouin-fixed tissues were processed and sections (4-µm) were stained with Haematoxylin and Eosin and Masson's trichrome. Livers were scored (1 to 4) as previously reported^[15,22]. Preestablished criteria for inclusion of cirrhotic (CI) animals in the final analysis were the presence of: (1) altered baseline biochemical data of liver function; and (2) in retrospect, histologically proven liver cirrhosis (scores 3 or 4 of the classification) in CCl₄-treated-animals. All animals had compensated cirrhosis without ascites.

Testicular histopathology and PCNA and transferrin immunohistochemistry

For histopathological evaluation of testes, 30 seminiferous tubules from each rat of the three groups were blindly evaluated by two observers and the arithmetic mean of the scores was taken as the final result. Transverse sections of seminiferous tubuli were examined and evaluation of histological changes was made using a light projection microscope (Micro Promar Leitz GMBH, Wetzlar, Germany) at 150× magnification. The following parameters were studied: tubular diameter, quantitation of the presence of different types of cells in tubuli,

presence of peritubular fibrosis, and the number of proliferating cells. For general purposes haematoxylin & eosin stain and Masson's trichrome stain were used. Specific techniques for other purposes are specified in the corresponding paragraphs.

Changes in tubuli were classified into 5 categories (Category I: highest damage to Category V: full normality). Category I: presence of only Sertoli cells; category II: Sertoli cells plus spermatids; category III: Sertoli cells, plus spermatides, and spermatocytes; category IV: presence of all kinds of cells but showing some morphological alterations (i.e.: severe vacuolization, aberrant cells); category V: presence of all kinds of cells without morphological alterations. The presence of peritubular fibrosis was evaluated in Masson's trichrome preparations according to the thickness of the staining of collagen deposition surrounding tubuli. Proliferating cells were identified by immunostaining of proliferating cellular nuclear antigen (PCNA) using an avidin-biotin peroxidase method^[34] with retrieval of antigen by means of microwave irradiation. Specific anti-PCNA antibody (mouse anti-PCNA, clone PC 10, DAKO, Denmark) biotinylated rabbit anti-mouse IgG (DAKO, Denmark) were used and the avidin-biotin complex technique (ABC, DAKO kit) was performed. The bound antibodies were visualized by means of 3,3'-diaminobenzidine tetrahydrochloride (Sigma Chemical Company, St. Louis, MO) with nickel enhancement^[34]. Finally, samples were slightly counterstained (10 s) in hematoxylin, dehydrated, and mounted in DPX. Controls were performed by substitution of the primary antibody by TBS. The number of PCNA positive cells was recorded. The result was expressed as stained cells per tubuli (arithmetic mean of 30 screened tubuli).

In addition, the expression of transferrin^[35] in tubuli was evaluated by immunostaining using similar technique as for PCNA with specific anti-transferrin antibody (obtained from rabbit, RARa/TRf, Nordic Immunological Laboratories, Teknovas, The Netherlands). Transferrin expression was scored from 0 to 4 points. If 30 tubuli expressed transferrin normally all over the germinal epithelium, it was scored 0 points. The remaining scores were obtained according to the following formula: (30-tubuli showing expression of transferrin all over the germinal epithelium) × 0.075.

Analytical methods

Serum levels of albumin, total proteins, glucose, cholesterol, bilirubin, alkaline phosphatase, transferrin and aminotransferases (AST and ALT) were determined by routine laboratory methods using a Hitachi 747 autoanalyzer (Boehringer-Mannheim, Germany). Serum levels of the different hormones were assessed by RIA in a GammaChen 9612 Plus (Serono Diagnostics, Roma, Italy) using specific commercial assay systems: total and free testosterone and estradiol-6, Coat-a-Count, DPC (Diagnostic Products Corporation, Los Angeles, CA); rat luteinizing hormone (rLH) and rat follicle stimulating hormone (rFSH) from Amersham International Plc (Little Chalfont Buckinghamshire, England HP7 9NA); IGF-1 by extraction (Nichols Institute Diagnostics, San Juan Capistrano, CA, USA).

Lipid peroxidation assessment of testicular homogenates

Malondyaldehyde (MDA) was assessed after heating samples at 45 °C for 60 min in acid medium. It was quantitated by a colorimetric assay using LPO-586 (Bioxytech; OXIS International Inc., Portland, OR, USA), which after reacting with MDA, generated a stable chromophore that could be measured at 586 nm (Hitachi U2 000 Spectro; Roche).

Statistical analysis

Data are expressed as mean±SE. To assess the homogeneity between the three groups of rats a Kruskal-Wallis test was

used, followed by multiple post-hoc comparisons using Mann-Whitney *U* tests (two tailed) with Bonferroni adjustment. A regression model was fitted considering histopathological score, PCNA or transferrin expression scores and IGF-1 plasma concentration as the dependent and independent variables respectively. Within group differences between pre-and post-treatment values were assessed by means of Wilcoxon matched pairs signed rank sum test. Any *P* value less than 0.05 was considered to be statistically significant. Calculations were performed by SPSS Win v.6.0. program.

RESULTS

At baseline, CI groups showed abnormal values compared to controls (CO) in serum levels of alanine aminotransferase (CO = 26±2; CI = 273±49 IU/L, *P*<0.01), aspartate aminotransferase (CO = 55±5; CI = 297±49 IU/L, *P*<0.001), cholesterol (CO = 82±4; CI = 115±5 mg/dL, *P*<0.05), alkaline phosphatase (CO = 310±43; CI = 701±146 IU/L, *P*<0.05), bilirubin (CO = 0.4±0.0; CI = 1.2±0.3 mg/dL, *P*<0.05), total proteins (CO = 6.9±0.1; CI = 6.4±0.2 g/dL, *P*<0.05) and albumin (CO = 3.6±0.1; CI = 3.1±0.2 g/dL, *P*<0.05). No differences were found between cirrhotic groups.

At the end of the experimental period, all rats from groups CI and CI+IGF showed established cirrhosis (mixed micro-macronodular cirrhosis in liver histopathology) with some signs of portal hypertension (spleen weight, g, CO = 0.8±0.0; CI = 1.4±0.2; CI+IGF = 1.4±0.1, *P*<0.001 both cirrhotic groups *vs* controls). Ascites was absent in all of the cirrhotic animals.

Testicular morphology and morphometry

The testicular size and volume were normal in the cirrhotic groups as compared to controls. Morphometric study showed reduction in testicular weight (in absolute values but not if it was corrected by body mass) in untreated cirrhotic group as compared to controls and CI+IGF group. Findings regarding longitudinal and transverse testicular diameters were similar to those in testicular weight. Morphometric data in the three groups are summarized in Table 1.

Testicular histopathology

Figure 1 shows testicular morphology in the three experimental groups. Testicular histological section of normal rat (CO) demonstrated active spermatogenesis in normal-size seminiferous tubuli with thin basement membranes and minimal

peritubular fibrosis. Leydig cells were scarce, being widely separated by seminiferous tubuli. No evidence of peritubular fibrosis and other alterations was found in cirrhotic groups. Cellular analyses (see Methods) in 30 seminiferous tubuli were performed in each preparation and summarized in Table 2. No relevant findings were obtained in this morphologic study.

Testicular cellular proliferation, as evaluated by PCNA^[35], was significantly reduced in CI rats while CI+IGF rats showed values similar to controls (CO: 66±2, CI: 57±1, CI+IGF: 61±1, *P*<0.001 untreated cirrhotic group *vs* controls and *P*<0.05 CI+IGF *vs* controls and CI group). Figure 2 shows PCNA immunohistochemistry (PCNA+cells) in the three groups.

Testicular transferrin, a marker of the integrity of hemato-testicular barrier^[36-38], was evaluated from 0 to 4 points by immunohistochemistry in testicular slices (see Methods). Transferrin expression was decreased in CI rats (3.40±0.03 points, *P*<0.001 *vs* CO and CI+IGF groups) as compared to controls (3.98±0.04 points) and to cirrhotic rats receiving IGF-1 (3.76±0.05 points). Figure 3 shows transferrin expression in the three experimental groups.

Testicular levels of MDA in order to study the likely direct damage of CCl₄ to testes, MDA levels, an index of lipid peroxidation^[39], were assessed in testicular homogenates. No differences were found between the three experimental groups in testicular MDA content (nmol/mg protein, CO = 9.1±0.8, CI = 13.0±3.2, CI+IGF = 8.9±1.6).

Pituitary-gonadal axis

Serum levels of sexual hormones are summarized in Table 3. No significant differences were found between groups, either in total and free testosterone, or estradiol, or in the ratio of estradiol/testosterone. However, a significant increase of FSH (*P*<0.001 *vs* controls) and also high levels of LH (*P* = 0.06 *vs* controls) were observed in untreated rats with compensated cirrhosis, suggesting an altered negative feed-back since this early stage of the cirrhosis. On the other hand, LH concentrations were moved towards normal values in IGF-1 treated cirrhotic group (*P* = ns *vs* controls, and *P*<0.01 *vs* untreated cirrhotic rats).

Serum levels of IGF-1

At the time of animal sacrifice (d 15), no significant differences between the three groups were found in serum levels of IGF-1 (CO: 1030±67, CI: 1165±58, CI+IGF: 1030±38 ng/mL), similar to those described previously in early stage of cirrhosis^[16-18,24].

Table 1 Body mass and parameters of testicular size and weight in the three experimental groups (d 15)

	Healthy control rats (CO, <i>n</i> = 12)	Untreated cirrhotic rats (CI, <i>n</i> = 12)	Cirrhotic rats treated with IGF-1 (CI+IGF, <i>n</i> =12)

Figure 1 Microscopy of testes (×150 magnification, Masson's stain). Testicular histological sections of normal rat (CO) demonstrated active spermatogenesis in normal-size seminiferous tubuli with thin basement membranes and minimal peritubular fibrosis. Leydig cells were scarce, being widely separated by seminiferous tubuli. No evidence of peritubular fibrosis and other alterations were found in testes from cirrhotic animals.

Figure 2 Study of proliferative activity, assessed by PCNA immunostaining. A significant reduction of cellular proliferation were observed in rats with compensated cirrhosis. This reduction was normalized in IGF-1 treated cirrhotic group (CI+IGF). (×200 magnification, in the three pictures).

Figure 3 Immunohistochemistry for testicular transferrin in seminiferous tubuli. Transferrin immunostaining was observed at the level of Sertoli cells and in germ cells in normal rats (CO) and in cirrhotic rats treated with IGF-1 (CI+IGF) but a lower or absent transferrin immunostaining was observed in several tubuli of untreated cirrhotic rats (CI) (score, CI: 3.40±0.03, CO: 3.98±0.04, CI+IGF-1: 3.76±0.05).

DISCUSSION

This study demonstrates that rats with compensated CCl₄-induced cirrhosis show some testicular alterations and gonadal dysfunction, from early stages of liver cirrhosis. The main finding of this study is that there is an altered hemato-testicular barrier,

probably responsible for the reduction of cellular proliferation, as well as a paradoxical response of pituitary-testicular axis.

The occurrence of testicular atrophy and gonadal dysfunction in advanced cirrhosis is a well known clinical event^[1,3-9]. Both testicular histopathological abnormalities and low levels of serum testosterone have been described in patients with

alcoholic and nonalcoholic cirrhosis several years ago^[3-9]. Previous experimental data^[2] showed that severe testicular atrophy and gonadal insufficiency treated with low doses of IGF-1 recovered to normal in a very short time (21 d). Data regarding experimentally induced cirrhosis are, however, scarce. Our previous data showed a severe testicular damage^[2] as manifested by macroscopic testicular atrophy and a variety of histopathological abnormalities including a reduction in tubular diameters, presence of aberrant cells in tubular lumen, peritubular fibrosis, loss of the germinal line and a marked reduction in cellular proliferation. These alterations resembled those found in necropsic studies in alcoholic cirrhotics^[1] and those reported in experimental models of testicular damage such as chronic testicular ischemia^[35].

The mechanisms responsible for the described alterations are not fully understood, although the relationship between IGF-1 deficiency and testicular damage in cirrhosis was demonstrated in the mentioned work^[2]. In cirrhotic rats included in the current work, no IGF-1 deficiency was present but there was a reduced availability of this hormone as it has been suggested previously^[16-18,22]. Moreover, we have previously demonstrated that the changes induced by cirrhosis in the serum profile of IGF-1 binding proteins further reduce bio-availability of IGF-1 in cirrhotic rats^[16]. In fact, exogenous administration of IGF-1 was able to reverse several abnormalities (decreased food utility and intestinal absorption of nutrients, and somatostatinergic tone and osteopenia) associated with cirrhosis in animals with normal serum levels of this hormone^[16-20,22-24].

On the other hand, a direct effect of IGF-1 on testes seemed to be the most important factor to explain previous findings^[2]. This idea is supported by the existence of receptors for IGF-1 in Sertoli cells, germ cells and Leydig cells^[25-27] and by findings demonstrating a direct effect of IGF-1 on testes^[27-31]. Since IGF-1 is a well recognized trophic factor for testis, its deficiency could be a contributing factor to testicular damage in cirrhosis.

The present work was designed in order to gain more insights into the mechanisms involved in the pathogenesis of hypogonadism associated with liver cirrhosis. In fact, many factors that have been involved in this process, such as portal systemic shunting^[1,39,40] or undernutrition^[1,41] were minimized in this early stage of the liver disease. Specifically, this study was targeted to establish the historical progression of the described testicular alterations^[2].

The blood-testis barrier is considered nearly as specific as the blood-brain barrier^[42]. Although all cells require irons from serum transferrin produced by hepatocytes, cells that create a blood barrier such as Sertoli cells in the testis and choroid plexus epithelium in the brain also express the transferrin gene to provide irons to cells sequestered within the serum-free environment. Testicular transferrin expression was a good marker of the integrity of the hemato-testicular barrier^[36,37]. A major finding of this work was that transferrin expression by Sertoli cells was reduced in untreated cirrhotic rats. The medical bioavailability of IGF-1 could be due to the mechanism of testicular transferrin reduction. IGF-1 treatment increased the expression of this protein in Sertoli cells of cirrhotic rats (Figure 3). This possibility seemed to be plausible since several metabolic functions of Sertoli cells were also influenced by IGF-1^[32,43-45]. Interestingly, the recovery of transferrin expression in Sertoli cells observed in our study suggested a role for IGF-1 in maintaining the integrity of the hematotesticular barrier^[2,33-38].

The first step of the pathogenesis of testicular atrophy occurring in advanced cirrhosis seems to be the decreased expression of transferrin, showing a dysfunction of Sertoli cells and consequently the disruption in blood-testis barrier integrity. Therefore, the observed reduction of cellular proliferation finally affecting spermatogenesis^[2,46] would be its logical consequence.

A question arises as to whether direct toxicity of CCl₄ on testicular tissue could contribute to testicular injury. Alcohol was known to produce oxidative damage and to be able to pass across testicular barrier^[47,48]. This toxic possibility has been reasonably ruled out by the presence of similar levels of MDA, a marker of lipid peroxidation^[39], in testicular homogenates from the three experimental groups. Certainly, a slight increase of testicular MDA was found in untreated cirrhotic rats, but this did not reach statistical significance.

In the early stage of cirrhosis, testosterone levels were normal. However, both FSH and LH were increased in untreated cirrhotic animals. This abnormal response of the negative feedback could be an initial hormonal reaction of primary hypogonadism. In advanced stages of cirrhosis, we found increased levels of serum LH associated with a significant reduction of total and free serum testosterone defining a picture of primary hypogonadism, thus ruling out hypothalamic-pituitary dysfunction as the responsible mechanism^[2]. Interestingly, LH levels were reduced by IGF-1 treatment in this series with compensated cirrhosis and an incipient gonadal dysfunction. The significant increase of FSH could be related to the observed reduction of cellular proliferation in cirrhotic rats. Since a close relationship has been reported between IGF-1 and gonadotropins^[49-51], our findings require further investigation.

In summary, this study shows an altered hemato-testicular barrier from an early stage of cirrhosis and suggests that the reduction of IGF-1 bioavailability may play a critical role in the beginning stage of testicular damage and hypogonadism associated with liver cirrhosis. In addition, these results support the conclusion that the exogenous administration of IGF-1 may be useful for the treatment of testicular alterations in cirrhotic patients.

ACKNOWLEDGEMENTS

The authors wish to express their gratitude to Dr. Bruce Scharschmidt, Chiron, for generously granting the rhIGF-1 used in this study. We are as well deeply indebted to the "Real Academia de Medicina de Cataluña" (Barcelona) and Mrs.C. Alonso-Borrás and Mr. J. Celaya for financial collaboration.

Abstract

AIM: To evaluate the relationships between the personal, sociocultural, and environmental characteristics, and the presence or absence of symptoms with the detection of *Enterobius vermicularis* (*E. vermicularis*) in a population sample in our region (General Mansilla, Province of Buenos Aires, Argentina), by individual and familiar analyses.

METHODS: *E. vermicularis* was diagnosed in 309 people from 70 family units residing in the urban area and the rural area of the city of General Mansilla. Each of them was surveyed so as to register personal, environmental and sociocultural data. Questions about the presence or absence of anal itch, abdominal pain and sleeping disorder were also asked. Significant associations were determined by square chi tests. Logistic regression models were adjusted by using a backward conditional stepwise method to determine the presence of this parasite in the individuals and in the families.

RESULTS: The parasites were found in 29.12% (90/309) of the individuals, with a frequency of 14.28% (20/140) among the heads of the families and of 41.42% (70/169) among the children. The only variables showing a significant association were affiliation, where the risk category was "being the son/daughter of", and the symptoms were abdominal pain, sleeping disorder, and anal itch. Families with a member infected with parasite were considered Positive Families (PF) and they were 40/70 (57.14%), only 5% (2/40) of the PF had 100% of their members infected with the parasite. The logistic regression models applied showed that the risk categories were mainly affiliation (son/daughter) and housing (satisfactory) among others.

CONCLUSION: The presence of *E. vermicularis* was proved in one third of the studied population. The frequency of families with all their members infected with the parasite was very low. Most of the studied personal, sociocultural, and environmental variables did not turn out to be significantly associated with the presence of the parasite. An association

with the category of "son/daughter" and housing classified as "satisfactory" was determined. The latter may be due to the fact that the people living in that category of housing have hygienic practices at home that favour the distribution of the eggs in the environment. The presence of the analysed symptoms was associated with the presence of the parasite, thus strengthening the need of periodical control of the population showing at least one of these symptoms.

INTRODUCTION

Enterobius vermicularis (*E. vermicularis*) is a small whitish nematode whose evolution cycle differs from other intestinal helminths in the biological peculiarities^[1].

Enterobiosis is a cosmopolitan parasitosis. The peculiar biology of *E. vermicularis* contributes to the creation of contamination foci around the infected resident and the re-infections. The intra-family or cohabitating members' infection is very frequent. The most important infection routes are through oral and respiratory tract. The oral infection included the anus-hand-mouth route, onychophagia and/or ingestion of contaminated food. The respiratory tract infection would be from inhaling dust contaminated with the parasite eggs^[2].

The main source of contamination inside the house is found in the environmental dust and carried by children. This would be one of the infection routes for the family units.

It has been reported that no sex difference existed in the infection rates. The teen-age, however, infection rates remain unchanged in boys but decrease among girls, since girls start observing hygienic practices with higher precocity than boys^[3,4]. Among adults, the infection frequency is similar in both sexes, but it was commonly observed that many adults seemed not to get infected even when subjected to contaminated environments due to personal hygiene^[1-5].

Waste disposal little affects the distribution of the infection, since the oxyurus eggs are not found in excrement. Several groups in the population may be infected without depending on the socioeconomic conditions and environmental hygiene due to the biological characteristics of this parasite^[6,7].

Generally, this parasitosis is an asymptomatic illness, and in those cases where clinical manifestations are present, anal itch is the most frequent symptom. Indirectly, and mainly in children, it produces insomnia, fatigue and irritability, and sometimes abdominal pain^[2-8,9].

The objective of this study was to evaluate the relationship between the personal, socio-cultural and environmental characteristics, presence or absence of symptoms, and the detection of *E. vermicularis* in a sample population in our region (Province of Buenos Aires, Argentina), through individual and family analysis.

MATERIALS AND METHODS

Study area

The city of General Mansilla is located in the northeast of the Province of Buenos Aires, in the central-western area of the Argentine Republic (South America), 96 km from the city of Buenos Aires. Population is 2 300 in the urban area and 1 700 in the rural area. The urban area covers 250 hectares and the rural population is settled in a 15 km range around it (Figure 1).

Population

A total of 309 people constituting 70 family units, made up by mother, father and children (1 to 6 per family), were studied. Fifty families were analyzed from the urban area (221 people) and 20 from the rural area (88 people). Each member of the family was surveyed to record personal, environmental and socio-cultural data. The following variables were assessed: a) personal: sex, age, affiliation of each member, and number of children in each family; b) socio-cultural and environmental: habitat (urban area - rural area), water supply (water pump - running water), disposal of waste (sewer - no sewer), housing (satisfactory - unsatisfactory), home garbage (collected - not collected), bathroom (existent - non-existent), and overcrowding (yes - no). Housing was considered satisfactory when built of masonry with cement floors, and unsatisfactory when built of wood and/or metal with dirt floors. Overcrowding was considered when more than three individuals slept together in the same room. Besides, questions were asked about the presence or absence of the following symptoms: anal itch, abdominal pain and sleeping disorders, since they are considered to be typical of this parasitosis.

Parasitological analysis

A perianal swab method was performed to each surveyed individual for the detection of *E. vermicularis*. Each surveyed person was given five 10 cm×10 cm gauze pads and a bottle of 5% formaldehyde. At the same time, they were explained the procedure for sample taking. In the case of minors, instructions were given to their parents. Each of the testee collected the sample before getting up for 5 consecutive days, each day rubbing a gauze pad previously imbibed in water, on the perianal margins. Then, they put the sample in the container with formaldehyde and sent it to the lab.

Statistical analysis

The association between each of the variables studied and the presence of *E. vermicularis* was analyzed by means of the chi square test. In the case of finding statistically significant associations, the odds ratio (OR) was calculated.

Logistic regression models were adjusted by using backward conditional stepwise method to determine the presence of *E. vermicularis* in individuals and in families. In the case of individuals (total, rural and urban), socio-cultural and environmental characteristics, symptoms, age and sex were used as (independent) explanatory variables. In the case of families, only socio-cultural and environmental characteristics and affiliation were used. The logistic regression model predicts the probability of being infected with *E. vermicularis* according to the explanatory variables. From this prediction, individuals are classified according to their risk of infection as: high risk (when the probability is higher than 0.5), and low risk (when the probability is lower than 0.5). For this classification, sensitivity (S), specificity (E), positive predictive value and negative predictive value, and global adjustment (total percentage of correct predictions) in each of the models were estimated. The model can be used to obtain OR estimators for each variable. SPSS (Statistical Package for the Social Sciences) software version 11.5 was used.

RESULTS

The frequency of infected people in the total studied population (309) was 29.12% (90/309). Among the parents, it was 14.28% (20/140) and 41.42% (70/169) among the children.

Families with at least one infected member were called positive families (PF) and the rest, negative families (NF). The number of PF was 40/70 (57.14%). Of these, 8 families presented less than 25% of their members with the parasite, 20 had 26-50%, 6 between 51% and 75%, 4 between 76% and 99% and only two had 100% of their members infected.

The mean age of parents from PF and NF was 32.3 and 33.6, respectively. The mean age for children from PF and NF was 8.48 and 7.71, respectively. The mean age of positive children was 6.85. Thirty percent (12/40) of the mothers from PF were infected while only 20% (8/40) of the fathers were infected. Prevalence for adults from PF was 25% (20/80).

The number of children from PF was 103. Of these, 67.96% (70/103) were positive and 52.85% (37/70) were male. The number of children from NF was 66, 48.48% (32/66) of which were male.

The results obtained from socio-cultural and environmental aspects both from PF and NF and their statistical analysis are shown in Table 1.

Table 1 Sociocultural and environmental factors studied in 70 *E. vermicularis* infected and non-infected families in General Mansilla, Province of Buenos Aires, Argentina (n, %)

Variable		PF (n = 40)	FN (n = 30)	P
Habitat	Urban	29 (72.5)	21 (70)	0.8188
	Rural	11 (27.5)	9 (30)	
Water supply	Water pump	12 (30)	13 (43.33)	0.2493
	Running water	28 (70)	17 (56.66)	
Disposal of waste	Sewer	14 (35)	8 (26.66)	0.4573
	No sewer	26 (65)	22 (73.33)	
Housing	Satisfactory	30 (75)	20 (66.66)	0.4450
	Unsatisfactory	10 (25)	10 (33.33)	
Garbage	Collected	28 (70)	21 (70)	1.0000
	Not collected	12 (30)	9 (30)	
Bathroom	Existent	25 (62.5)	22 (73.33)	0.3396
	Non-existent	15 (37.5)	8 (26.66)	
Overcrowding	Yes	17 (42.5)	9 (30)	0.2841
	No	23 (57.5)	21 (60)	

PF: Families with some member infected with *E. vermicularis*; NF: Families with no member infected with *E. vermicularis*.

¹Satisfactory housing: With cement floors and masonry walls; unsatisfactory housing: Dirt floors and wood or metal walls.

²Overcrowding: Yes: when more than three people sleep in a room; No: When less than three people sleep in a room.

When analyzing the association between the presence of *E. vermicularis* and each variable separately, the only one showing statistically significant association was affiliation, where the risk category was being the son/daughter ($P = 0.000$, $OR = 4.242$), and the symptoms of abdominal pain ($P = 0.001$, $OR = 2.680$), sleeping disorders ($P = 0.003$, $OR = 2.339$), and anal itch ($P = 0.001$, $OR = 2.662$).

Table 2 (a, b, c and d) shows the results from the logistic regression models built for the total of individuals, those residing in the urban area, those living in the rural area, and the families.

(1) In the whole population, the affiliation variable was the most significant, that is, children had greater probability of being infected than parents. In order of importance, the variables garbage collection and type of housing followed. Type of water supply and symptoms of abdominal pain and sleeping disorders

turned out to be of lesser importance. This model classified 22.2% of the infected individuals (S) and 92.2% of the non-infected individuals (E) correctly. Globally, it classified 71.8% of the individuals correctly.

(2) Among the rural population the affiliation variable had an even higher significance degree. It also turned out to be important age variable. This continuous variable had a positive coefficient, which implies that at an older age there is more risk to be infected. But being the affiliation variable present, older children are those with the higher risk of being infected. In order of importance, the symptom of sleeping disorders, type of housing and no bathroom available followed. This model classified 53.8% of the positive individuals (S), and 93.3% of the non-infected individuals (E) correctly. Globally, it classified 81.4% of the individuals correctly.

(3) Among the urban population, the affiliation variable was also the most significant. The symptom of abdominal pain, type of water supply and type of housing followed. This model classified 23.4% of the infected individuals (S) and 89.3% of the non-infected individuals (E) correctly. Globally, it classified 70.4% of the individuals correctly.

(4) Among the positive families, the variables of garbage collection, housing, water supply and bathroom had a similar degree of significance. This model classified 95% of the infected families (S) and 23% of the non-infected families (E) correctly. Globally, it classified 64.3% of the families correctly.

Table 2 Logistic regression models for the presence of *E. vermicularis* in 309 (88 rural and 221 urban) individuals, both individually and grouped into 70 families in General Mansilla, Argentina

Variable	Risk category	Coefficient	Odds Ratio
For the total of individuals, $n = 309$			
Affiliation	Son/daughter	1.267	3.550
Housing	Satisfactory	0.829	2.288
Garbage	Not collected	1.372	3.944
Water	Running	0.951	2.591
Abdominal pain	Present	0.555	1.742
Sleeping disorders	Present	0.561	1.752
Constant	-1.825		
For rural individuals, $n = 88$			
Affiliation	Son/daughter	10.246	28 167
Housing	Satisfactory	2.857	17.5
Age (yr)	Eldest son/daughter	0.316	1.372
Bathroom	Non-existent	2.160	8.670
Sleeping disorders	Present	1.967	7.151
Constant	-12.493		
For urban individuals, $n = 221$			
Affiliation	Son/daughter	1.176	3.241
Housing	Satisfactory	0.917	2.5
Water	Running	1.372	3.937
Abdominal pain	Present	0.690	1.993
Constant	-1.612		
For positive families, $n = 40$			
Housing	Satisfactory	2.749	15.625
Water	Running	2.614	13.699
Garbage	Not collected	2.75	15.636
Bathroom	Non-existent	2.403	11.056
Constant	0.338		

Regarding the three studied symptoms, the analysis showed anal itch in 19.41% (60/309) of the people. Of them, 27/60 (45%) were positive for *E. vermicularis* ($P = 0.0026$, $OR = 2.42$), 12/60 (20%) were negative but belonged to a PF, and 21/60 (35%)

were negative from NF. The presence of sleeping disorders was shown in 22.65% (79/309) of the studied population, 30/70 (42.85%) ($P = 0.0040$, $OR = 2.24$) of which were parasite infected, 17/70 (24.28%) showed no parasites but belonged to a PF, and 23/70 (32.85%) were negative from NF.

Abdominal pain was detected in 19.41% (60/309) of the testees, 28/60 (46.66%) ($P = 0.009$, $OR = 2.64$) of which were parasite infected individuals, 12/60 (20%) were negative for the parasite test but belonged to a PF, and 20/60 (33.33%) were negative from NF.

Figure 1 Geographical location of General Mansilla city in Argentina.

DISCUSSION

In the present study a high frequency of infection was found for *E. vermicularis*, going from 29.12% in the total population up to 41.42% if only the child population considered. These percentages are higher than those published in other countries. In Korea, a prevalence of this parasitosis was reported in 9.8% of school children^[10], 9.2% in pre-schoolers^[3], 14.8 in kindergarten children^[11], 12.6% in school children in the rural area^[4], and 9.8% in children of school age^[12]. In the town of Chennai, India, a prevalence of 0.50% was reported^[13] in school age children. In Thailand, in 5- to 10-year-old children, the prevalence was 21.91%^[7]. In Taiwan it was 11% in school age children^[14]. A prevalence of 10.5% was found for children between 7 and 13 years old in Turkey^[15]. A study carried out in 18- to 35-year-old adults in Malaysia, Kuala Lumpur, reported a frequency of 9.2%^[16,17]. In Poland, the frequency among 7-year-old children was 16.45%^[19]. And in Sweden, it was 21% in children from primary care centres^[18].

In America, a study carried out in New York (United States) on the prevalence of *E. vermicularis* in mentally and developmentally retarded children showed a prevalence of 4.5%^[19]. In Venezuela, the prevalence found in 5- to 14-year-old children was 19.1%^[20], and in Peru it was 1.1% in adults and children from different communities^[21]. In Argentina, a study carried out in two aboriginal communities from the province of Misiones, a prevalence of 0% and 5% for *E. vermicularis* was shown^[22]. In the Province of La Rioja, a percentage of 14.8% was reported in middle-class children^[23], and in the city of Buenos Aires, 20.50% was reported in hospital population^[24]. In Neuquen (Patagonia), 18.8% was reported in adults and children from deprived neighbourhoods^[25].

However, the high frequency shown in our study is similar to that reported by Norhayati *et al.*^[26] in 1994 in Malaysia (40.4%), Nithikathkul *et al.*^[6] in 2001 in Thailand (38.82%), Bahader *et al.*^[27] in 1995 in Egypt (43.8%), Gilman *et al.*^[28] in 1991 in Peru

(42.0%), and Mercado *et al.*^[29] in 1996 in Chile (35.2%) on studies done in diverse populations.

This study did not show significant sex and age differences regarding parasite infected parents, but there was a higher frequency among the mothers, probably due to the greater daily contact with their parasite infected children (regular behaviour among the inhabitants of this region).

The children had a higher probability of being infected than the parents. As to the infected children, no statistically verifiable differences could be found regarding sex or age but, unlike the parents, the highest level of infected people were male, probably in association with different hygienic practices for each sex. This difference agrees with Yoon *et al.*'s^[3] report about 10.1% of boys and 8.1% of girls with parasites, and Kim *et al.*'s^[10] about 10.8% in male and 8.7% in female schoolchildren. However, Kim^[10] reports 7.1% and 12.5% positive values for male and female kindergarten children, respectively. In our study, parasite infected kindergarten infantile population, sex distribution was 50% (13/26).

Among the PF there was a high percentage of non-infected parents and only 5% of these families had all of their members infected. With these results we could infer that when someone is detected to have parasites, the treatment of all the members of his/her family is not necessary, especially if we take into account that the cost of the treatment has to be afforded by each family in our region. This would make a regular control of the population so as to detect positive cases and treat them appropriately and thus reduce the prevalence of this parasitosis.

Socio-cultural and environmental factors studied in this study showed no statistically significant associations between PF and NF, which are in agreement with Nithikathkul *et al.*^[7] not with Kim *et al.*^[10].

Overcrowding was significantly associated for Acosta *et al.*^[1] ($P < 0.001$) with this parasitosis in children in Venezuela, but this association could not be shown in our study, in agreement with Norhayati *et al.*'s findings in children in Malaysia^[26].

In this study, a significant association was proved by the presence of anal itch, sleeping disorders and abdominal pain, and the detection of this parasite. But these symptoms were not exclusive for the parasite-infected population since 20% to 35% of the non-parasite infected people showed at least one of these symptoms. Venezuela^[1] reported that 53.9% of the parasite-infected population showed anal itch.

As a conclusion of this work we point out that enterobiosis was present in a percentage close to 30% of the general population and over 40% in children in our region (Province of Buenos Aires, Argentina).

Contrary to what was expected, the risk of getting this helminthosis was not related to age, sex, or most of the socio-cultural and environmental factors studied (habitat, consumption water, disposal of waste, garbage collection, bathroom characteristics and overcrowding). An association was determined between the variable affiliations, where the risk category was "being the son/daughter of".

The type of housing categorized as "satisfactory" was also related to this parasitosis. This contradictory situation could be due to the fact that people living in this type of housing show hygienic practices in the home favouring the distribution of eggs in the atmosphere (*e.g.*, shaking the sheets, using a feather dust for cleaning, *etc.*)

These results also strengthen the need of regular control of the population reporting at least one of these symptoms: anal itch, sleeping disorders, and/or abdominal pain.

ACKNOWLEDGEMENTS

The authors wish to thank Dr. Roberto Zungrí for his permanent "field work" contribution to this study.

Abstract

AIM: To sum up the clinical characteristics of patients with central pontine myelinolysis (CPM) after orthotopic liver transplantation (OLT) and to document the possible causes of CPM.

METHODS: Data of 142 patients undergoing OLT between January 1999 to May 2003 were analyzed retrospectively. Following risk factors during perioperation were analyzed in patients with and without CPM: primary liver disease, preoperative serum sodium level, magnesium level and plasma osmolality, fluctuation degree of serum sodium concentration, and immunosuppressive drug level, *etc*.

RESULTS: A total of 13 (9.2%) neurologic symptoms appeared in 142 patients post-operation including 5 cases (3.5%) with CPM and 8 cases (5.6%) with cerebral hemorrhage or infarct. Two patients developing CPM after OLT had a hyponatremia history before operation (serum sodium <130 mmol/L), their mean serum sodium level was 130.6 ± 5.54 mmol/L. The serum sodium level was significantly lower in CPM patients than in patients without neurologic complications or with cerebral hemorrhage/infarct ($P < 0.05$). The increase in serum sodium during perioperative 48 h after OLT in patients with CPM was significantly greater than that in patients with cerebral hemorrhage/infarct but without neurologic complications (19.5 ± 6.54 mmol/L, 10.1 ± 6.43 mmol/L, 4.5 ± 4.34 mmol/L, respectively, $P < 0.05$). Plasma osmolality was greatly increased postoperation in patients with CPM. Hypomagnesemia was noted in all patients perioperation, but there were no significant differences between groups. The duration of operation on patients with CPM was longer than that on others (492 ± 190.05 min, $P < 0.05$). Cyclosporin A (CsA) levels were normal in all patients, but there were significant differences between patients with or without neurologic complications ($P < 0.05$).

CONCLUSION: CPM may be more prevalent following liver transplantation. Although the diagnosis of CPM after OLT can be made by overall neurologic evaluations including magnetic resonance imaging (MRI) of the head, the mortality is still very high. The occurrence of CPM may be associated with such factors as hyponatremia, rapid rise of serum sodium concentration, plasma osmolality increase postoperation, the duration of operation, and high CsA levels.

INTRODUCTION

The morbidity and mortality of central nervous system (CNS) complications after orthotopic liver transplantation (OLT) was 19% and 47% respectively^[1]. Central pontine myelinolysis (CPM)^[2] is the most serious CNS complication that could be seen after OLT, and represents an important source of mortality early after OLT^[3]. CPM following liver transplantation was reported more and more in foreign literatures^[4,5], but it was rarely reported in our country^[6,7].

In this paper, we studied retrospectively 142 patients undergoing OLT in our center. Fifteen patients had CNS complications after OLT including 5 patients with CPM. The clinical features and possible causes of CPM after liver transplantation were analyzed.

MATERIALS AND METHODS

Clinical data

Between January 1999 to May 2003, consecutive OLT was performed on 142 patients at our center. Medical records and clinical data of the patients were retrospectively investigated. Of them 117 were males and 25 females, age from 19 to 65 years, their age was 45 ± 8.9 years. Indications for OLT included severe hepatitis 28 cases, hepatic cirrhosis (32 cases), liver carcinoma (53 cases), polycystic liver (3 cases), and others (24 cases). Operative procedures were performed with the standard technique and UW preservation solution. All patients had similar perioperative intensive care and received cyclosporin A (CsA) and methylprednisolone-based induction immunosuppression.

Observational indicators

Patients who developed posttransplant abnormal neurological symptoms underwent overall neurological evaluation. Magnetic resonance imaging (MRI) of head was performed in selected cases. CPM was diagnosed based on: (1) patients who had a variety of signs including mental status changes, quadriparesis, pseudobulbar palsy, and drowsiness, *etc*; (2) MRI showed a hypointense signal in T1-weighted images and a hyperintense signal in T2-weighted images in the central pontine. The signal of T2 was slightly increased after contrast administration.

Following risk factors during perioperation were analyzed between patients with and without CPM: age, gender, primary liver disease, pretransplant serum sodium, magnesium levels, plasma osmolality, fluctuation degree of serum sodium and plasma osmolality 48 h after transplantation, duration of operation, and CsA level. Hyponatremia was defined as serum sodium <130 mmol/L. Hypomagnesemia was defined as serum magnesium <1.5 mg/L.

Statistical analysis

Data were expressed as mean \pm SD. Comparisons of group

means were made with ANOVA for unpaired data, and Chi-Square test for enumeration data. $P<0.05$ and $P<0.01$ were considered statistically significant.

RESULTS

Clinical features of patients with CNS complications

Fifty-eight of 142 patients undergoing OLT developed abnormal neurological symptoms such as mania, tremor, confusion, drowsiness, and diminished state of responsiveness. Thirteen patients were diagnosed having CNS complications based on clinical features and MRI. The demographic characteristics of the patients are outlined in Table 1. There were 10 males and 3 females aged 40–55 years. Primary diseases included severe hepatitis in 6 cases; hepatic cirrhosis in 4 cases; liver carcinoma, drug liver failure, IgA nephropathy, and polycystic liver in 1 case, respectively. Patients developed neurological complications in the early postoperative period including cerebral hemorrhage/infarct in 8 cases, CPM in 5 cases. The incidence of cerebral hemorrhage/infarct and CPM was 5.6% (8/142) and 3.5% (5/142), respectively. The extent of CPM on MRI was variable, showing a hypointensity signal of T1-weighted images in the pontine without space occupying sign (Figure 1A), and increased signal intensity of T2-weighted images in central pontine (Figure 2A, 2B). None of the patients showed extrapontine myelinolysis. CNS complications occurred two weeks after liver transplantation, ranged from 2 to 18 d. The median time of survival of patients with CPM after OLT was 24 ± 16.1 d, ranged 7 to 48 d. The patients who were complicated with cerebral hemorrhage or infarct survived 2 to 96 d after transplantation, the mean time was 33 ± 30.7 d.

Comparison of clinical characteristics in patients with and without CPM (Table 2)

Pretransplant hyponatremia was present in all symptomatic patients with CPM. Two patients developing CPM after OLT had a severe hyponatremia history before operation (serum sodium level <130 mmol/L). The average serum sodium level was 130.6 ± 5.54 mmol/L. The serum sodium level was significantly lower in patients with CPM than in patients without neurologic complications or with cerebral hemorrhage/infarct ($P<0.05$). The average increase of perioperative serum sodium 48 h after OLT in patients with CPM, cerebral hemorrhage/infarct, and without CNS complications was 19.5 ± 6.54 mmol/L, 10.1 ± 6.43 mmol/L, 4.5 ± 4.34 mmol/L, respectively ($P<0.01$). Plasma osmolality was greatly increased 48 h postoperation in patients with CPM. Despite this, the plasma osmolality was normal in patients without CPM, but no significant difference was noted between patient who had complication of cerebral hemorrhage/infarct and patients who had no CNS complication. Hypomagnesemia was noted in all patients perioperation, but there were no significant differences between groups. The operation time for patients with CPM was longer than that for others ($P<0.05$). But no significant difference was found in operation time between patients who had complication of cerebral hemorrhage/infarct and those who had no CNS complication. Following transplantation, all patients received CsA-based induction immunosuppression. Though the mean CsA level in all patients was normal, the average CsA level was greatly higher in patients with CNS complications than in patients without CNS complications. Age, gender, primary liver disease were similar among three groups.

Table 1 Clinical characteristics of patients with CNS complications

Patient NO.	Hospital NO.	Age (yr)	Gender	Primary disease	CNS complication	Timing of onset (d)	Timing of survival (d)
1	287206	40	Male	Severe hepatitis	Cerebral hemorrhage	6	11
2	286967	48	Male	Severe hepatitis	CPM	10	15
3	291172	41	Female	Severe hepatitis	Cerebral hemorrhage	8	26
4	299921	54	Male	Severe hepatitis	CPM	6	23
5	306331	53	Female	polycystic liver	Cerebral infarct	4	28
6	312075	51	Male	Hepatic cirrhosis	Cerebral hemorrhage	2	9
7	314112	53	Male	Severe hepatitis	CPM	18	48
8	325113	49	Male	Liver carcinoma	Cerebral hemorrhage	2	2
9	315349	41	Male	Hepatic cirrhosis	CPM	3	20
10	328762	46	Male	Drug liver failure	CPM	5	7
				IgA nephropathy			
11	351480	55	Female	Hepatic cirrhosis	Cerebral hemorrhage	14	56
12	362960	52	Male	Hepatic cirrhosis	Cerebral hemorrhage	3	36
13	363980	46	Male	Severe hepatitis	Cerebral hemorrhage	14	96

Table 2 Comparison of Clinical characteristics in patients with and without CPM

Index	CNS Complications		NO CNS Complication
	CPM	Cerebral hemorrhage /cerebral infarct	
Preoperative serum sodium (mmol/L)	130.6 ± 5.54^{bc}	135.9 ± 2.61	137.4 ± 3.83
Preoperative serum magnesium (mg/L)	0.8 ± 0.19	0.9 ± 0.20	1.0 ± 0.21
Preoperative sosm (mOsm/kg H ₂ O)	274.3 ± 33.09	290.2 ± 22.12	292.5 ± 26.05
Change in serum sodium After 48 h (mmol/L)	19.5 ± 6.54^{bd}	10.1 ± 6.43^b	4.5 ± 4.34
Postoperative sosm (mOsm/kg H ₂ O)	341.6 ± 14.99^{bc}	317.9 ± 29.76	308.8 ± 16.89
Surgery time (min)	492.0 ± 190.05^a	450.0 ± 93.50	399.9 ± 76.07
CsA level (ng/dL)	301.3 ± 9.23^b	273.8 ± 28.55^a	247.2 ± 35.44

Abbreviations: Sosm: Serum Osmolarity ^a $P<0.05$ (0.016, 0.037), ^b $P<0.01$ (0.000, 0.001) compared with no CNS complications; ^c $P<0.05$ (0.017, 0.02), ^d $P<0.01$ (0.000) compared with cerebral hemorrhage/infarct.

Figure 2 A: T2-Weighted axial magnetic resonance imaging scan shows bilaterally symmetric high-signal intensity in the central pons. (arrow) B: T2-Weighted sagittal magnetic resonance imaging scan demonstrates hyperintensity in central pons. (arrow).

DISCUSSION

CPM was first described in 1959 by Adams. CPM after OLT was first reported by Starzl^[8] in 1978. CPM^[9,10] was characterized by symmetrical loss of myelin in the pontine basis, with relatively well-preserved axons and neuronal cell bodies. Acute CPM often occurred and had a variety of signs including quadriplegia, pseudobulbar palsy, and locked-in syndrome. As a severe neurological complication, the progress of CPM was usually dismal, with a high mortality rate^[11]. Most cases of CPM were diagnosed post-mortem. With the recognition of CPM and the development in MRI technology, more cases of CPM could be diagnosed while patients were alive. Liver transplant recipients constituted a high risk group for developing CPM. The incidence of CPM after OLT varied from 5-10%^[12-14], which was higher than that in other patients (0.16-5.8%)^[15]. The exact etiology of CPM is uncertain, the rapid correction of hyponatremia might be an important factor. However, controversy has been going on^[16-20].

Pathogenesis of CPM after OLT

End-stage hepatic insufficiency was a common feature of pretransplanted patients. Advanced liver failure was always associated with some degree of renal insufficiency. So almost all hyponatremic states associated with liver disease were chronic and difficult to be corrected^[21]. Input for patients after OLT was considerably increased as a consequence of bleeding during operation. The sodium content for fresh frozen plasma was around 165 mmol/L, 150 mmol/L for albumin solution, and 140 mmol/L for red blood cells, significantly higher than the serum sodium of patients with hyponatremia. Correction of blood loss would thus inevitably lead to a rapid rise in serum sodium concentration. A multicenter study showed^[22] that rapid correction of hyponatremia exceeding 18 mmol/L in the first 48 h was significantly associated with CPM. The present study

demonstrated that not all patients with hyponatremia developed CPM. But increase of serum sodium 48 h after OLT in patients with CPM was 19.5 ± 6.54 mmol/L, which was significantly higher than that in patients without CPM. Plasma osmolality was also greatly increased 48 h postoperation. The results of our study suggested that rapid correction of hyponatremia and abrupt change of plasma osmolality might account for the development of CPM. Liver failure might lead to disruption of astrocyte metabolism with resulting abnormalities of blood-brain barrier function and a decreased ability to generate new intracellular osmoles in response to osmotic changes. Thus, patients with liver transplantation were particularly susceptible to CPM^[23,24]. Lien *et al.*^[25] suggested that rapid correction of hyponatremia might produce acute dehydration of edematous brain, leading to high ion to organic osmolyte ratio, osmotic endothelial injury, and endothelial cell shrinkage with loosening of tight junctions. Subsequently, transvascular transport increased and myelinotoxic factors released. Because of an extensive gray-white matter admixture in the pontine, this anatomic arrangement could provide a suitable environment wherein myelinotoxic factors, chiefly derived from the richly vascular gray matter, could interact with surrounding bundles of myelin-containing white matter, then lead to demyelination viz development of CPM.

Dunn *et al.*^[26] demonstrated the neurotoxicity of CsA in transplanted patients. Three cases developing CsA associated akinetic mutism after liver transplantation were reported by Bird *et al.*^[27], two of three were identified by MRI. The CsA level in all patients was monitored and controlled in normal range. Although the mean in-hospital CsA level in CPM group was not different with that in cerebral hemorrhage/infarct group, the CsA levels in patients with CNS complications was higher than that in patients without CNS complications. In this study, pretransplant hypomagnesemia was noted in all patients after OLT. Previous study suggested^[28] that CsA neurotoxicity could lead to massive white matter lesions. Hypomagnesemia might contribute to CsA neurotoxicity and was associated with development of CPM after OLT, although the mechanism of CPM is unclear.

The results of our study also suggested that operation time in patients with CPM was significantly longer than that in patients without CNS complications. But there were no differences in operation time between patients with cerebral hemorrhage/infarct and without CNS complications, indicating that CNS lesions in liver transplant recipients may be related with intraoperative bleeding, prolonged low blood perfusion.

Prevention and therapy of CPM after OLT

To our knowledge, at present there is no definitive therapy for CPM. Therefore, prevention of this condition has become crucial^[29]. Slower correction of perioperative hyponatremia may be critical for patients undergoing OLT. The rate of correction should not exceed 15 mmol/L/24 h or 18 mmol/L/48 h. Major fluctuations in serum sodium during surgery should be avoided. Plasma osmolality level should be remained within normal reference, and aggressive magnesium replacement should be initiated for hypomagnesemia. To decrease the duration of operation and intraoperative bleeding, no venovenous bypass should be recommended. Immunosuppressive agent concentrations should be carefully monitored and controlled to avoid neurotoxicity^[30]. MRI of head should be performed when patients occurred neurologic and psychiatric symptoms after OLT^[31,32]. The best way of preventing CPM was to perform transplantation at an early stage of the disease. More recently, subclinical CPM after OLT was reported^[33], the patients were nearly asymptomatic, but MRI showed marked lesions in the pontine. According to these we suggest that the diagnosis of CPM should be considered in patients undergoing OLT with major electrolyte fluctuations, and high

immunosuppressive agent levels. MRI is currently the best modality available to identify CPM. Support treatment is very important for patients with CPM. It was reported that cortisol, vitamin, and serum replacement were used in CPM^[34]. Whether these therapies play a role in CPM remains to be determined.

Prognosis of CPM after OLT

A previous study showed^[35] that the occurrence of CPM after OLT varied from 2 to 11 d, average 7 d. The prognosis of CPM is usually dismal, with a high mortality rate. The results of the present study demonstrated that CPM occurred 3 to 18 d OLT. The median time of survival after OLT was 24.6±16.13 d, ranged 7 to 48 d, the mortality was 100%. These liver transplant recipients with CPM were associated with the following aspects. (1) Patients with CPM often had other complications^[36], such as infection, hemorrhage of digestive tract, and multi-organ failure. (2) Inadequate water intake and electrolyte derangements were not corrected due to CPM. (3) Venovenous bypass was used in part of transplantations^[37,38], which led to the increase in operation time, interoperative bleeding, time of low perfusion. The limited number of patients in this study may account for the high mortality of CPM after OLT.

Abstract

AIM: Both observational and experimental studies have shown that higher selenium status reduces the risk of upper gastrointestinal cancers in selenium deficient populations. Recent cancer registry data have shown very different rates of esophageal cancer (EC) and gastric cancer (GC) in four Provinces of Iran, namely Ardabil, Mazandaran, Golestan, and Kerman. The aim of this study was to have a preliminary assessment of the hypothesis that high rates of EC in Golestan and high rates of GC in Ardabil may be partly attributable to selenium deficiency.

METHODS: We measured serum selenium in 300 healthy adults from Ardabil ($n = 100$), Mazandaran ($n = 50$), Golestan ($n = 100$), and Kerman ($n = 50$), using inductively coupled plasma, with dynamic reaction cell, mass spectrometry (ICP-DRC-MS) at the US Centers for Disease Control (Atlanta, Georgia).

RESULTS: The median serum selenium concentrations were very different in the four Provinces. The medians (IQR) for selenium in Ardabil, Mazandarn, Golestan, and Kerman were 82 (75-94), 123 (111-132), 155 (141-173), and 119 (110-128) $\mu\text{g/L}$, respectively ($P < 0.001$). The results of linear regression showed that the Province variable, by itself, explained 76% of the variance in log selenium ($r^2 = 0.76$). The proportion of the populations with a serum selenium more than 90 $\mu\text{g/L}$ (the concentration at which serum selenoproteins are saturated) was 100% in Golestan, Kerman, and Mazandaran but only 29% in Ardabil.

CONCLUSION: Our findings suggest that selenium deficiency is not a major contributor to the high incidence of EC seen in northeastern Iran, but it may play a role in the high incidence of GC in Ardabil Province.

INTRODUCTION

Esophageal cancer (EC) and gastric cancer (GC), collectively known as upper gastrointestinal (UGI) cancers, constitute 16% of all cancer deaths worldwide and are responsible for approximately one million deaths each year^[1].

Both observational and experimental studies have shown that higher selenium status reduces the risk of UGI cancers in selenium deficient populations^[2-5]. In a large-scale, prospective cohort study conducted in Finland, a low selenium region prior to a current supplementation program, Knekt and colleagues found a lower risk of stomach cancer in individuals with higher baseline serum selenium concentrations^[3]. In another large cohort study, Mark and colleagues also found a reduced risk of esophageal cancer and gastric cardia cancer among individuals with higher initial serum selenium concentrations in a selenium deficient population in Linxian, China^[4]. A double-blind, randomized clinical trial in this same Chinese population showed a reduced risk of both cardia and non-cardia gastric cancers in individuals supplemented with a combination of selenium, beta-carotene, and alpha-tocopherol^[2].

Iran also has high rates of both EC and GC^[6-8], and these cancers are the two most common causes of cancer death in Iran^[9]. However, recent cancer registry data showed highly varying rates of EC and GC in four Provinces of Iran, namely Ardabil^[7], Mazandaran, Golestan, and Kerman (unpublished data). The annual age-standardized incidence rates (ASRs) for EC were 15, 19, 40, and 3 per 10⁵, and ASRs for GC were 38, 22, 18, and 8 per 10⁵ in these four Provinces, respectively.

We hypothesized that differences in serum selenium may partly explain the highly varying rates of EC and GC in Iran. Here, we present the results of an ecologic study that compared serum selenium concentrations in randomly selected healthy subjects from Ardabil, Mazandaran, Golestan, and Kerman Provinces.

MATERIALS AND METHODS

Serum samples from 300 healthy adults were selected for this study. These subjects had all been recruited for previous studies. Ardabil serum samples (100 samples) were selected from participants in an endoscopic survey of gastric precancerous lesions conducted among rural and urban subjects ≥ 40 years old^[10]. These subjects were selected using simple random sampling, and all resided in Meshkinshahr, a major city in Ardabil, or its surrounding villages. Mazandaran and Kerman serum samples (50 samples each) were selected from participants in a survey of the prevalence of celiac disease among urban inhabitants ≥ 18 years old in these two Provinces. These subjects were selected randomly from the entire urban

population of Sari and Kerman, the two major cities of these Provinces. In Golestan, 100 serum samples were selected from urban and rural individuals ≥ 40 years of age who were recruited during the pilot phase of a cohort study of UGI cancers. In all of these studies, the only inclusion criteria were residence, age, and lack of life-threatening conditions. All samples were collected in the years 2002 and 2003. From these subjects, we selected our study samples such that they represented male and female participants equally (Table 1). Samples from Ardabil and Golestan included both urban and rural populations, but samples from Kerman and Mazandaran represented only urban subjects.

A single blood sample was collected from each person. Serum was separated and frozen in -20°C freezers in plastic vials, and the samples were transported to the U.S. Centers for Disease Control (Atlanta, Georgia) on dry ice, where serum selenium was measured using inductively coupled plasma, with dynamic reaction cell, mass spectrometry (ICP-DRC-MS). The analytical limit of detection for assessment was $5.2\text{ }\mu\text{g/L}$ with a reference range of $80\text{--}300\text{ }\mu\text{g/L}$ ^[11]. We pooled samples to make an internal quality control serum, and 20 quality control samples were randomly inserted among the other serum samples. The coefficient of variation in these samples was 0.04.

The distribution of serum selenium in the four Provinces was not normal. Therefore we used medians and interquartile ranges (IQRs) to present the descriptive results and the Kruskal-Wallis test to test the differences in serum selenium ranks among provinces, between males and females, and between urban and rural participants. The distribution of the natural logarithm of selenium (log selenium) in each province did not deviate from normal. Therefore we used linear regression to test the effect of age on log selenium values. We also used linear regression to find the proportion of variance of log selenium that was explained by the province. All statistical analyses were done using STATA® Software, version 8 (Stata Corporation, Tx).

RESULTS

The median age of all the study subjects was 45 years. Half of the subjects from each area (a total of 150) were males (Table 1). Half of the subjects from Ardabil and Golestan ($n = 100$) and all of the subjects from Mazandaran and Kerman ($n = 100$) were from urban areas.

The median serum selenium concentrations were very different in the four Provinces. The medians (IQR) for selenium in Ardabil, Mazandarn, Golestan, and Kerman were 82 (75-94), 123 (111-132), 155 (141-173), and 119 (110-128) $\mu\text{g/L}$, respectively ($P < 0.001$). The results of linear regression showed that the province variable, by itself, explained 76% of the variance in log selenium ($r^2 = 0.76$). The proportion of these populations with serum selenium concentrations more than $90\text{ }\mu\text{g/L}$ (the concentration at which serum selenoproteins are saturated^[12]) was 100% in Golestan, Kerman, and Mazandaran, but only 29% in Ardabil.

The median (IQR) serum selenium concentrations in males

and females were 124 (95-145) and 116 (92-143) $\mu\text{g/L}$, respectively ($P = 0.49$).

Simple linear regression did not show a significant effect of age on log selenium in any of the four Provinces. The correlation coefficient between selenium and age in all samples combined was very low ($r = 0.006$).

Median (IQR) serum selenium concentrations in the urban and rural samples of Ardabil were 81 (76-86) and 83 (74-96) $\mu\text{g/L}$, respectively ($P = 0.57$). Median (IQR) serum selenium concentrations in urban and rural samples from Golestan were 150 (135-165) and 161 (144-183) $\mu\text{g/L}$ ($P = 0.003$).

DISCUSSION

Shamberger and Frost first suggested a role for selenium in the prevention of cancer in 1969, when they observed an inverse association between the geographic distribution of selenium in forage crops and cancer mortality rates in the United States^[13]. A growing body of evidence, from both laboratory and epidemiologic studies, has since shown that selenium may have anticarcinogenic effects, especially against cancers of the lung, prostate, skin, and gastrointestinal system^[14,15].

In this study, we measured serum selenium in 300 Iranian adults from four provinces with varying risks of EC and GC to have a preliminary assessment of the hypothesis that the high rates of EC in Golestan and GC in Ardabil may be partly attributable to selenium deficiency. The proportion of the populations with a serum selenium more than $90\text{ }\mu\text{g/L}$ (the concentration at which the serum selenoproteins are saturated) was 100% in Golestan, Kerman, and Mazandaran, and these three provinces had medium to high concentrations of serum selenium compared with the other areas of the world. Therefore, it is unlikely that high incidence of EC in Golestan and Mazandaran is due to selenium deficiency. This is consistent with a case-control study in Mazandaran that did not find any difference in hair selenium between EC cases and controls^[16]. In Ardabil, however, only 29% of the population had a serum selenium concentration above $90\text{ }\mu\text{g/L}$. This suggests that the high incidence of GC and pre-neoplastic gastric lesions in Ardabil^[10] could be partly due to selenium deficiency.

This is the first study that has examined serum selenium concentrations in different Iranian populations. Median serum selenium ranged widely, from $82\text{ }\mu\text{g/L}$ in Ardabil to $155\text{ }\mu\text{g/L}$ in Golestan. The median serum selenium concentration in these four provinces combined, weighted for the population of each province, was $123\text{ }\mu\text{g/L}$. For comparison, median serum selenium in other areas of the world varies from very low concentrations ($<50\text{ }\mu\text{g/L}$) in some parts of China and Serbia to very high concentrations ($>200\text{ }\mu\text{g/L}$) in parts of the USA and some other regions of China. However, the majority of median serum selenium concentrations in the world range from $80\text{--}120\text{ }\mu\text{g/L}$ ^[17].

The wide range of serum selenium concentrations among the four provinces and its small range within each province was an interesting finding. The major predictor of serum selenium is dietary intake^[14,17], and the observed differences

Table 1 Distribution of age, sex, location, and serum selenium in study sample

Province	Number of samples	Median age (yr)	Male (%)	Urban (%)	Annual incidence of EC/ 10^5	Annual incidence of GC/ 10^5	Median serum selenium (IQR) in $\mu\text{g/L}$
Ardabil	100	49	49 (49)	49 (49)	15	38	82 (75-94)
Mazandaran	50	35	24 (48)	50 (100)	19	22	123 (111-132)
Golestan	100	50	51 (51)	51 (51)	40	18	155 (141-173)
Kerman	50	33	26 (52)	50 (100)	3	8	119 (110-128)
Total	300	45	150 (50)	200 (67)	-	-	123 ¹

¹A weighted median based on the total population of each province.

among the provinces are most likely due to variation in the selenium content of their diets.

We plan to conduct further observational studies to confirm or refute the association of selenium intake and the risk of GC in Ardabil.

Abstract

AIM: To observe the changes of enkephalin mRNA and prodynorphin mRNA in hippocampus of rats induced by chronic immobilization stress.

METHODS: Thirty rats were randomly divided into three groups of 10 each: the normal control group (group A), the group induced by chronic immobilization stress for 7 d (group B) and the group induced by chronic immobilization stress for 21 d (group C). The changes of the enkephalin mRNA and prodynorphin mRNA in the rat hippocampus were detected by reverse transcription-polymerase chain reaction (RT-PCR).

RESULTS: Expression levels of enkephalin mRNA and prodynorphin mRNA in rat hippocampus were significantly increased under chronic immobilization stress, and the expression of prodynorphin mRNA in the rat hippocampus in group C was remarkably higher than that in group B (0.624 ± 0.026 ; $n = 5$; $P < 0.01$).

CONCLUSION: The increased enkephalin mRNA and prodynorphin mRNA gene expressions in rat hippocampus were involved in chronic stress.

INTRODUCTION

It is known that exposure to a variety of stressors can lead to the increase of plasma β -endorphin up to 10-15 times higher than normal. β -endorphin, enkephalin and dynorphin are termed as opioid peptides that are likely to exert influence on emotional and psychological state. Endogenous opioid peptides are extensively involved in the modulation of stress^[1] and regulation between central nervous system and immune system. We found that immune function was changed markedly (IL-1 β in serum was increased, while IL-2 and IL-6 in serum were decreased) in

rats under chronic immobilization stress^[2]. The average optical density of glucocorticoid receptor (GR) in hippocampus CA₁ and parietal lobe cortex was markedly increased after 7 d immobilization stress (180 min daily) exposure in comparison with normal control, but it was declined to the normal level after 21 d of stress exposure; the level of plasma adrenocorticotropin (ACTH) and serum cortisol had similar changes to that of GR^[3]. Are the opioid peptides in hippocampus implicated for the regulation of immune and internal secretion function under restrain stress? Here, we used animal models induced by chronic immobilization stress to observe the characteristic changes of expression of enkephalin mRNA and prodynorphin mRNA with reverse transcription-polymerase chain reaction (RT-PCR) in rat hippocampus.

MATERIALS AND METHODS

Subjects

Thirty male, Sprague-Dawley rats, weighing 180-220 g, were supplied by the Research Center of Experimental Animals "Weitong Lihua" in Beijing, with qualified certification No: SCXK-BJ2002-0003. They were randomly divided into three groups of 10 each: the normal control group (group A), the model group of 7 d (group B) and the model group of 21 d (group C). The rats were housed in groups of 5 rats in each cage and provided free access to food and water (20-24 °C, relative humidity of 30-40%).

All experiments conformed to the guidelines of NIH on the ethical use of animals. All efforts were made to minimize the animal suffering and maintain the number of animals necessary to produce reliable data.

Modeling methods

A T-form bound brace (self-made) was used: A frame with length of 20 cm and width of 10 cm and thickness of 2.8 cm was prepared. Its upper platform was of 22 cm in length and 6.6 cm in its widest part. A small frame for fixing the rat's head at the front end and grooves for rat's limbs were adapted. In the upper platform three adaptable soft bands, of which two are wide and one is thin, for fixing the rat in the head and neck, chest and loins, loins and back respectively were added. Means of chronic binding were applied in order to create stress models of rats. The rats were immobilized in the above-noted binding brace for 3 h daily and for either 7 or 21 consecutive days.

Extraction and measurement of total RNA

Extraction of total RNA of rat hippocampus: Rats were decapitated at the end of modeling and hippocampus tissues were rapidly taken bilaterally out and placed on the ice-plate. The tissues of 50-100 mg were mixed with 1 mL pre-cold TRIzol (Gibco) and were sufficiently ground in the appliance for grinding tissue. The homogenates produced were thereafter placed in ice for 5 min. Homogenates of hippocampus were added into 0.2 mL chloroform and drastically agitated for 15 s and placed in ice for 2-3 min. The resulting solution was then centrifuged at 12 000 g for 15 min. Supernatant was taken out and mixed with 0.5 mL isopropanol and placed for 5-10 min at room temperature. The resulting solution was then centrifuged at 12 000 g for 10 min at 4 °C and the supernatant produced was then removed. The

sediment was rinsed with 0.5 mL of 750 mL/L freshly made alcohol solution and centrifuged at 7 500 r/min for 5 min at 4 °C and the resulting supernatant was then removed. The sediment was dried at room temperature and then dissolved by 1 g/L diethyl pyrocarbonate (Sigma), in order to produce a concentration at which 1 µg RNA was resolved in 1 mL water.

Total RNA detection by electrophoresis

A 2-µL sample of the total RNA extracted was demonstrated by electrophoresis on 10 g/L agarose gel under constant voltage for 20 min. The strips of 28S, 18S and 5S were observed in the gel image system.

Quantification and purity identification of RNA

Certain amount of RNA sample was diluted (10- or 20- fold) and its concentration and purity were measured by ultraviolet spectrophotometer. Measurement of absorbance A_{260} was chosen to count the concentration of RNA (µg/µL) and ratios of A_{260}/A_{280} were chosen for its purity which was required as 1.8-2.0. Therefore, RNA with ratios less than 1.7 was deserted.

PCR primer design

Primers of β -actin, enkephalin and prodynorphin, of which β -actin was taken as inner-control of quasi-quantification PCR, were respectively designed by the software of Primer 5.0 according to the sequence of GenBank and synthesized by Sanboyuanzhi Company. Sequences of primers were as follows: β -actin: Primer of the upper stream: 5'-CATCTCTTGCTCGAAG TCCA-3', Primer of the down stream: 5'-ATCATGTTTGAGAC CTTCAACA-3'. Enkephalin: Primer of the upper stream: 5'-ATGGCGTTCCTGAGACTTTGA-3', Primer of the down stream: 5'-TAGAGTTTTGGCGTATTTTCGGAGGC-3'. Prodynorphin: Primer of the upper stream: 5'-ATGGCGTGGTCCAGGCTGATGC-3', Primer of the down stream: 5'-AGTTTGTTAGATTGA GAAGCCTTATCC-3'. Genes of enkephalin (810 bp) and prodynorphin (747 bp) were respectively amplified.

Reverse transcription reaction

A sample of RNA was kept at constant temperature of 70 °C for 10 min, centrifuged for several seconds and then placed in a water-bath. The following reaction (20 µL) happened in the centrifugal tube of PCR of 0.5 mL: 1 µL random primer 50 ng/µL; 1 µL dNTP (10 mmol/L) (Promega); 4 µL 5×RT buffer; 1 µL mixed solution of reverse transcriptase; 2 µL RNA sample; 1 µL DEPC-ddH₂O. The above-noted reaction system was placed at room temperature for 10 min and kept at constant temperature of 37 °C for 30 min, at 95 °C for 5 min, and then at 4 °C for 3 min prior to next procedures.

Amplification of target DNA by PCR

Enkephalin and prodynorphin were respectively amplified by PCR (PCT-100TM Programmable Thermal Controller, product of MJ RESEARCH, INC, America). The following materials were included in a 50 µL reaction system: 6 µL RT reaction product; 4.5 µL 10×PCR buffer; 1 µL dNTP (10 mmol/L); 1 µL (50 pmol) sense primer (enkephalin or prodynorphin); 1 µL (50 pmol) antisense primer (enkephalin or prodynorphin); 1 µL *Taq* DNA polymerase (Promega); 35.5 µL DEPC-ddH₂O. In the meantime, primer of enkephalin or prodynorphin was replaced by β -actin to perform PCR reaction with the rest reaction system noted above. The above systems were sufficiently mixed and centrifuged, then PCR reactions performed after adding 50 µL light mineral oil.

Temperatures of 46, 52 and 58 °C were respectively chosen as annealing temperature, so that three of them would be able to be used for amplification, while non-specific DNA segments would not occur. The last condition of optimized reaction was as follows: pre-degeneration at 94 °C for 3 min, tempering at

52 °C and extension at 72 °C, for 30 cycles, thereafter extension at 72 °C for another 15 min.

Amplified product was detected with 10 g/L agarose gel electrophoresis and analyzed with gel image analysis system FIT-5000 (Sweden). Ratio of optical density of the target genes and ratio of optical density of β -actin, which can be expressed as a stable value in the tissue (and it was therefore taken as interior control strip), were employed as data for quasi-quantified analysis.

Statistical analysis

Data were expressed as mean±SD and software of SPSS was applied for statistical analysis. ANOVA was performed for comparison among groups and followed by a post-hoc test. Significance was accepted at $P<0.05$.

RESULTS

General state of rats

Rats manifested symptoms such as lassitude, fewer activities, no gloss in hair, decreased food intake and loose stools.

Electrophoresis of total RNA

Three strips of 28S, 18S and 5S were observed after the extraction of the total RNA from the rat hippocampus with TRIzol RNA and electrophoresis.

Results of PCR amplification

Corresponding strips of target DNA were obtained via reverse transcription and PCR. The length of the strip of β -actin DNA was 300 bp, that of the enkephalin was 810 bp and that of the prodynorphin was 747 bp.

The expression of enkephalin mRNA was mildly increased in the rat hippocampus of group A, and significantly increased in the rat hippocampus of group C ($P<0.01$, $P<0.05$) when compared with rats in group A and B, respectively. The expression of prodynorphin mRNA was significantly increased in the rat hippocampus of group B and C when compared with rats in group A ($P<0.01$). The expression of prodynorphin mRNA in the rat hippocampus in group C was remarkably higher than that in group B ($P<0.01$). The results are shown in Table 1.

Table 1 Expression of enkephalin mRNA and prodynorphin mRNA in rat hippocampus ($n = 5$, mean ±SD)

Group	Enkephalin mRNA	Prodynorphin mRNA
A	0.284±0.013	0.360±0.017

DISCUSSION

Endogenous opioid peptides, which mainly include enkephalin family (methionine enkephalin and leucine enkephalin), endorphin family (α -endorphin, β -endorphin and γ -endorphin) and dynorphin family (dynorphin A and dynorphin B), are one class of matters with opioid action, naturally generated in the brain of mammals. It has been reported that endogenous opioid peptides are extensively involved in the regulation of stress and exert important effect on mediating the central nervous system and immune system^[4-7].

The increased expression of opioid peptides including enkephalin mRNA and prodynorphin mRNA in our study, may influence hippocampal function and facilitate long-term depression (LTD) of the Schaffer collateral input to CA1 pyramidal neurons^[8]. Chronic stress increased the synthesis

of opioid peptides in the nervous system and increased plasma glucocorticoid^[9].

Enkephalin is extensively distributed inside the brain as a kind of endogenous opioid peptides. It plays several roles in analgesia, cardiovascular, respiratory and body temperature regulation via receptors of endogenous opioid peptides including widespread immunity modulation after it is generated and released. In addition, enkephalin can exert its effect on regulating the immune functions of body under both normal and stress conditions. Both methionine enkephalin and leucine enkephalin can influence the activity and the formation rate of rosettes of T lymphocyte, as well as the activity of natural killer cells in the body under physiological conditions^[6,10]. The mechanism of enkephalin involved in regulating immunity under physiological conditions has yet to be clarified. More researches have focused on the mechanism of enkephalin in regulating immunity in different stress situations. Researches suggested that methionine enkephalin and leucine enkephalin could markedly inhibit the cytotoxic action that can be stopped by naloxone, a substance that is produced by the natural killer cells, under the stress induced by electric shock in rats. Therefore, endogenous opioid peptides played an important role in immune regulation stimulated by stress^[11,12].

Hippocampus is a crucial structure in which enkephalin can regulate immune function via IL-1 α . A spleen lymphocyte proliferation reaction stimulated by Canavalia protein A could be markedly reinforced by microinjection of methionine enkephalin and leucine enkephalin into rat hippocampus (similar result obtained in the experiment of mice)^[13]. The inhibitive effect of enkephalin on IL-1 gene expression of the glia cell in hippocampus may shed lights on the mechanisms involved in the immunological amplification by microinjection of enkephalin, which inhibits gene expression of IL-1 α via opioid receptors in glia cells of hippocampus or in certain nerve cell membranes that possess the capacity of generating IL-1 α , and result in decreased activating effect of IL-1 α on the hypothalamus-pituitary-adrenal axis together with decreased synthesis of IL-1 α inside the brain, and simultaneous strengthening of the immune function of body by decreasing the blood plasma corticoid^[14-16].

It was demonstrated in the present study that expression of enkephalin mRNA was mildly increased after 7 d and significantly increased after 21 d under the conditions of chronic immobilization. In general, increase of enkephalin will result in poorer immune function. In line with our former research^[2], the substantial decrease of the transforming function of the spleen lymphocytes in rats most likely originated from the indirect inhibitive action of enkephalin. It means that the increase of enkephalin would inhibit gene expression of central IL-1 α and is likely to result in lower IL-1 α inside the brain.

Prodynorphin, containing the sequence of leucine enkephalin at N-terminal which was considered as its precursor at first, is another member of the endogenous opioid peptides with analogous distribution inside the brain in striatum, hippocampus and hypothalamus. It also exists in adrenal glands and genital organs. The splitting process of prodynorphin is complicated and its main products include dynorphin A₁₋₁₇, dynorphin B₁₋₂₉, dynorphin A₁₋₈ and neo-endorphin. In addition, generation of prodynorphin mRNA is affected by multiple factors in many regions of brain. For instance, gamma-aminobutyric acid (GABA) can decrease its generation in neo-striatum.

With dual action, dynorphin can not only protect, but also damage the nerve cells in some cases. It was indicated that the expression of prodynorphin in rat hippocampus was significantly increased and its change was likely to be earlier than that of

enkephalin under the condition of chronic immobilization stress. Taken together our previous and current experiments, increase of dynorphin is likely to result in certain nerve damage as fewer numbers of brain-derived neurotrophic factors (BDNF) and neurotrophin 3 (NT₃) might exert fewer protective effects on the nervous system under chronic immobilization stress. Whether and how dynorphin correlates with neurotrophins have yet to be established.

ACKNOWLEDGEMENTS

Abstract

AIM: To observe the plasticity of whether dermis-derived multipotent cells to differentiate into insulin-producing pancreatic cells *in vitro*.

METHODS: A clonal population of dermis-derived multipotent stem cells (DMCs) from newborn rat with the capacity to produce osteocytes, chondrocytes, adipocytes and neurons was used. The gene expression of cultured DMCs was assessed by DNA microarray using rat RGU34A gene expression probe arrays. DMCs were further cultured in the presence of insulin complex components (Insulin-transferrin-selenium, ITS) to observe whether DMCs could be induced into insulin-producing pancreatic cells *in vitro*.

RESULTS: DNA microarray analysis showed that cultured DMCs simultaneously expressed several genes associated with pancreatic cell, neural cell, epithelial cell and hepatocyte, widening its transcriptomic repertoire. When cultured in the specific induction medium containing ITS for pancreatic cells, DMCs differentiated into epithelioid cells that were positive for insulin detected by immunohistochemistry.

CONCLUSION: Our data indicate that dermal multipotent cells may serve as a source of stem/progenitor cells for insulin-producing pancreatic cells.

INTRODUCTION

Organ-specific stem cells possess plasticity that can permit differentiation along new lineages and have significant implications for future therapies of diabetes. The production of endocrine pancreas and insulin-secreting beta cells from adult nonpancreatic stem cells and hepatic oval stem cell has been demonstrated^[1,2]. Zulewski *et al.* also showed that pancreatic islets contained a heretofore unrecognized distinct population of cells that expressed the neural stem cell-specific marker nestin. The nestin-positive islet-derived progenitor (NIP) cells are a distinct population of cells that reside within pancreatic islets and may participate in the neogenesis of islet endocrine

cells^[2]. According to this result, liver stem cells have been proved to differentiate into pancreatic islet-like cells^[3]. Dermis is a highly accessible tissue source for adult stem cells. Nestin-positive skin-derived stem cells have been isolated from dermis by Toma *et al.*^[4]. In our previous study, we isolated a clonal population of dermal multipotent cells by their adherence to tissue culture plastic (termed as plastic adherent DMCs) from newborn rat dermis. These cells showed the differentiation capacity to produce nestin-positive cells^[5]. In this study, we aimed to investigate whether plastic adherent DMCs had the differentiation capacity to produce insulin-producing pancreatic cells *in vitro*.

MATERIALS AND METHODS

Materials

A clonal population of dermis-derived multipotent stem cells (DMCs) was used in the experiments. The clonal population of DMCs were isolated and identified from primary dermal cells of male newborn Wistar rat as previously described^[5]. All tissue culture reagents, including Iscove's Modified Dulbecco's Medium (IMDM), ITS (insulin-transferrin selenium), epidermal growth factor, basic fibroblast growth factor, were purchased from Sigma (St. Louis, CA, USA). Fetal bovine serum (FBS) was purchased from Hyclone (Logan, UT, USA). The rat RGU34A gene expression probe arrays were purchased from Affymetrix (Santa Clara, CA). Mouse anti-insulin monoclonal antibody was purchased from Sigma (St. Louis, CA, USA). Horseradish peroxidase (HRP)-labeled goat anti-mouse IgG antibody was purchased from Boster (Wuhan, China).

Methods

Cell culture The DMCs were cultured in IMDM medium containing 10 mL/L fetal bovine serum and 100 U/mL penicillin and 100 µg/mL streptomycin. Cultures were maintained at 37 °C in a humidified atmosphere containing 50 mL/L CO₂. For differentiation induction, DMCs were transferred into specific inducing medium containing 10 µg/mL of keratocyte growth factor (KGF), 20 ng/mL of epidermal growth factor (EGF), 10 mmol/L of nicotinamide, and 1 mg/mL of ITS. The differentiated cells were examined for the insulin expression by immunohistochemistry.

DNA Microarray analysis Total RNA from cultured DMCs was isolated using QIAGEN's RNeasy total RNA isolation kit (Rneasy, Qiagen) following the manufacture's instructions, and quantified. Transcript profiling was conducted by means of rat RGU34A gene expression probe arrays, containing 8 799 probe sets, interrogating primarily annotated genes. The experiment was conducted according to the recommendations of the manufacturer (Affymetrix GeneChip expression analysis manual). The resulting "data-file" was processed further using the microarray analysis suite 5 software package (Affymetrix). According to the statistical expression analysis algorithm, the presence of a gene within a given sample was determined at a detection *P* value of <0.05 and was graded as absent (A), marginal (M), or present/positive (P).

Immunocytochemistry Immunocytochemistry study with peroxidase-labeled streptavidin biotin method was performed to detect the expression of insulin in differentiated cells. Before

detection, the cells were washed three times for 20 min with phosphate-buffered saline (PBS, PH = 7.2) to exclude the pollution of exogenous insulin in the culture medium. After washing, the cells were blocked for 30 min with 100 mL/L normal goat serum in PBS and were incubated with mouse anti-insulin antibody (1:100) at 4 °C for 24 h. Incubation at room temperature with anti-mouse secondary antibody and avidin-biotinylated peroxidase complexes was performed for 2 h. The specimens were washed for 15 min with 0.01 mol/L PBS between all steps. The reaction product was developed with 0.5 g/L 3'-diaminobenzine tetrahydrochloride (DAB). After staining, the result was observed microscopically. PBS was used as a substitute for primary antibody as negative control.

RESULTS

Biological properties of DMCs

Most adherent DMCs were of spindle-shaped cells (Figure 1). Phenotype analysis showed that DMCs were negative for some lineage-specific surface markers, including pan-cytokeratin, cytokeratin19, factor VIII, CD31, CD45, CD34, α -smooth muscle actin (α -SMA), desmin, collagen II and nestin, but were positive for CD59, CD90, CD44, vascular cell adhesion molecule-1 (VCAM-1) and intercellular adhesion molecule-1 (ICAM-1). The doubling time of cultured DMCs was about 40 h. Following induction, DMCs had the capacity to differentiate into cells with phenotypic characteristics of osteocytes (alkaline phosphatase activity and alizarin red staining), adipocytes (oil red staining), chondrocytes (collagen II and Alcian blue staining) and neurons (nestin and NF-200 staining) in specific induction media.

Figure 1 Morphology of cultured DMCs. (Inverted microscope, $\times 100$).

Gene expression profile of plastic-adherent DMCs

The gene expression of DMCs was assessed by DNA microarray analysis and the harbinger of a potential cell type was viewed by simultaneous expression of a panel of lineage-related genes. The result revealed that the cultured DMCs simultaneously expressed genes associated with pancreatic cells (Table 1). DMCs also simultaneously expressed transcripts for epithelial cell, neural cell, and hepatocyte as well (Table 1). These transcripts were developmentally related with pancreatic tissue and further widened the transcriptomic repertoire of DMCs. To confirm the data by DNA microarray, several genes were further tested by RT-PCR and the result was consistent with the result from microarray (data not shown).

Figure 2 Differentiation of DMCs into insulin-producing cells. A: After induction in the medium containing ITS for 4 wk, cells were positive for insulin; B: Negative control (SP, $\times 200$).

Table 1 DMC gene lists (partial) associated with diverse cellular lineages

Cell lineage	Representative examples of associated genes
A: Pancreatic cell	Pancreatic eukaryotic initiation factor 2 alpha-subunit kinase (PEK), pancreatic secretory trypsin inhibitor-like protein (PSTI), pancreatic islet cDNA Rattus norvegicus cDNA similar to rapamycin-binding protein FKBP-13, insulin II gene, IRS-1 mRNA for insulin-receptor, mRNA for glucose-dependent insulinotropic polypeptide
B: Neural cell	Neural visinin-like Ca ²⁺ -binding protein type 3, neuron-specific enolase, neuronal nitric oxide synthase, GABA receptor-associated proteins, NCAM, brain-derived neurotrophic factor (BDNF), syntaxin 7, glial fibrillary acidic protein (GFAP), adrenomedullin, myelin protein SR13 (growth-arrest-specific Gas-3 homolog), neurotrimin; secretogranin II, synapse-associated protein 102, latexin, kexin-like protease PC7A, N-methyl-D-aspartate (NMDA) receptor
C: Epithelial cell	Epithelial membrane protein 1, epithelial cell transmembrane protein antigen precursor, epidermal growth factor precursor, heparin-binding EGF-like growth factor, mucin, parathymosin and thy mosin 4 and 10
D: Hepatocyte	Liver glycogen phosphorylase enzyme, liver IL-6 receptor ligand binding chain, liver specific transcription factor LF-B, liver nuclear protein P47, liver α L-Fucosidase, hepatocyte nuclear factor 3 α (HNF-3beta)

Expression of a single gene can't define the phenotype of a particular cell type. Simultaneous expression of a panel of lineage-related genes in single isolated cell was viewed as the harbinger of a potential cell type. Representative examples of genes corresponding to each cell lineage are outlined in the above table.

Differentiation of DMCs into insulin-producing pancreatic cells

DMCs were further tested for their capacity to produce pancreatic cells in the inducing medium containing ITS. The morphology of DMCs were changed into epithelial cells-like cells when cultured in medium containing ITS for 2 wk and immunohistochemistry showed that a proportion of cells (less than 10 %) were positive for insulin when cultured in medium containing ITS for 4 wk (Figure 2). The negative control cells showed no positive staining for insulin. This result further indicated that DMCs could undergo differentiation to form insulin-producing cells.

DISCUSSION

Replacement of the insulin-producing pancreatic islet β cells represents the ultimate treatment for type I diabetes. Recent advances in islet transplantation underscore the urgent need for developing alternatives to human tissue donors, which are scarce. The generation of insulin-producing cells from adult stem cells is one possible approach^[6-9]. Recent studies have suggested that there are closely developmental relationship between the nestin positive progenitors and the pancreatic cells^[10-13]. In addition to liver stem cells and neural stem cells, multipotent stem cells from dermis have been proved to have the capacity to produce nestin positive cells^[4, 5]. In this study, we further reported that dermis-derived multipotent stem cells also showed a remarkable flexibility to differentiate into insulin-producing cells, when the appropriate stimuli were given. Since dermal cells are relatively easy to access and they also can be used for autologous use that may represent a safety advantage, dermis-derived multipotent cells may serve as a source of stem/progenitor cells for β cells.

Nevertheless, the efficiency of adult stem cells to differentiate into insulin-producing cells *in vitro* is low at present and expansion with large scale is needed for application. Genetic manipulation in tissue culture may be a choice and it is possible that new insights into endocrine pancreas development will lead to the manipulation of progenitor cell fate towards the β cell phenotype of insulin production, storage and regulated secretion^[14, 15]. If successful, these approaches could lead to widespread cell replacement therapy for type I diabetes.

Abstract

AIM: Microcirculatory disturbances are important early pathophysiological events in various organs during acute pancreatitis. The aim of the study was to evaluate changes in microperfusion of the pancreas, liver, kidney, stomach, colon, skeletal muscle, and to investigate the influence of heparin on the organ microcirculation in caerulein-induced experimental acute pancreatitis.

METHODS: Acute pancreatitis was induced by 4 intraperitoneal injections of caerulein (Cn) (15 µg/kg). The organ microcirculation was measured by laser Doppler flowmetry. Serum interleukin 6 and hematocrit levels were analysed.

RESULTS: Acute pancreatitis resulted in a significant drop of microperfusion in all examined organs. Heparin administration (2×2.5 mg/kg) improved the microcirculation in pancreas (36.9±4% vs 75.9±10%), liver (56.6±6% vs 75.2±16%), kidney (45.1±6% vs 79.3±5%), stomach (65.2±8% vs 78.1±19%), colon (69.8±6% vs 102.5±19%), and skeletal muscle (59.2±6% vs 77.9±13%). Heparin treatment lowered IL-6 (359.0±66 U/mL vs 288.5±58 U/mL) and hematocrit level (53±4% vs 46±3%).

CONCLUSION: Heparin administration has a positive influence on organ microcirculatory disturbances accompanying experimental Cn-induced acute pancreatitis.

INTRODUCTION

Pathophysiology of acute pancreatitis (AP) is heterogeneous and involves a complex cascade of events. Impaired tissue perfusion within the pancreatic gland is one of the early disorders accompanying the disease^[1,2]. Prolonged ischaemia and impaired tissue oxygenation, resulting from vasoconstriction, hemoconcentration, hypercoagulation, leukocyte adherence, increased vascular permeability, and interstitial oedema, play

an important role in the progression of the disease, leading to the development of pancreatic necrosis^[2-4]. Besides the pancreas, the microcirculatory disturbances, as a consequence of hypovolemia and systemic inflammatory response, are also observed in other organs^[1,5-8].

Although the hypovolemia and impairment of cardiac output can be normalized easily by vigorous fluid replacement, microcirculatory disturbances may be prevented merely by adequate fluid therapy, even though the cardiovascular parameters are stabilized at the baseline level^[9]. Various vasoactive mediators, as bradykinin, endothelin, thromboxan, platelet activating factor, and nitric oxide participate in the development of microcirculatory failure^[3,8]. In the last decade, the beneficial effect of therapeutic strategies in acute pancreatitis, affecting vasoactive mediators, is confirmed in several experimental studies.

One of the possible therapeutic agents, influencing microcirculatory disturbances by means of its anticoagulant and antiinflammatory properties, which could be applied in acute pancreatitis, is heparin. Some reports underlined beneficial impact of this well known polysaccharide on the course of the disease^[10-12]. In this study we examined whether heparin influenced splanchnic malperfusion in experimental caerulein-induced acute pancreatitis in rats.

MATERIALS AND METHODS

Animal models

The study was carried out on 34 male Wistar rats weighing 180-200 g. The rats were kept on a standard rat chow and fasted overnight before the experiment with water *ad libitum*. Acute pancreatitis was induced by four intraperitoneal injections of caerulein (Cn) (Sigma, St. Louis, USA) (15 µg/kg) in 1 mL of saline at 1h intervals: at the beginning, and consecutively after the first, second, and third hour of the experiment. Five hours after the first caerulein injection, rats were anaesthetized with pentobarbital sodium (40 mg/kg). Following the anaesthesia, a laparotomy was performed, and a fiberoptic probe of laser Doppler flowmeter (Periflux 4 001, Perimed Jarfalla, Sweden) was positioned against the surface of the pancreas, liver, kidney, stomach, colon, and skeletal muscle of thigh in order to estimate the organs' perfusion. Blood flow was measured in three different portions of each organ, the mean values were calculated, and presented as percent changes from basal values obtained in control rats (100%). After the measurements, blood was aspirated from the inferior caval vein for hematocrit and interleukin 6 tests, the pancreas was removed for microscopic evaluation, and the animals were exsanguinated.

The animals were randomly allocated into three groups: Group I (n=10), control; Group II (n=12), Cn-induced pancreatitis without treatment; and Group III (n=12), Cn-induced pancreatitis treated with heparin (Polfa, Warszawa, Poland) 2×2.5 mg/kg, given in the 3rd and 4th hafter the first Cn injection.

This study was approved by the Ethical Committee of the Medical University of Gdańsk.

Interleukin-6 functional assay

The IL-6 bioassay was performed using the IL-6 dependent

mouse hybridoma cell line B9 obtained from Dr. Lucien Aarden, Netherland Red Cross, Amsterdam. B9 cells were cultured in flat bottomed microtitre plates (10 000 cells/well) in the presence of serial dilutions of test sera. Starting serum dilutions were 1:10 for all specimens. After 48 h of incubation, proliferation of the B9 cells was measured using a rapid colorimetric MTT (tetrazolium) assay. The concentration of recombinant IL-6 producing half maximal proliferation was defined as one unit of activity, and the quantity of IL-6 in a serum sample was calculated by reference to a standard curve. Polyclonal anti-IL-6 antibody (Boehringer-Mannheim) was added into selected wells at concentrations: 1:10, 1:20, 1:50 in order to confirm the specificity of the assay. The antibody completely blocked IL-6 activity.

Statistical analysis

Data are presented as mean \pm SD. The differences between the groups were analysed by means of ANOVA test. Probability values less than 0.05 were considered significant.

RESULTS

Four intraperitoneal caerulein injections resulted in marked pancreatic oedema in all the rats. The microscopic examination revealed oedematous form of acute pancreatitis, with inter- and intralobular oedema, vacuolisation of parenchymal cells, and leukocyte infiltration within the pancreatic gland. No parenchymal necrosis was detected.

Microcirculatory values

Caerulein induced acute pancreatitis resulted in a significant drop of pancreatic microperfusion to 36.9 \pm 4% of basal values. Administration of heparin significantly improved the microcirculation of the pancreas up to 75.9 \pm 13%. Hepatic perfusion in rats with pancreatitis receiving no treatment was decreased to 56.6 \pm 6%, heparin injection raised this parameter to 75.2 \pm 16%. Renal blood flow in group II with pancreatitis was diminished to 45.1 \pm 6%, which was improved significantly with heparin treatment up to 79.3 \pm 15%. Microcirculatory values of stomach and colon wall in acute pancreatitis group were reduced to 65.2 \pm 8% and 69.8 \pm 6% respectively. Intraperitoneal injection of heparin caused improvement in the blood flow in stomach to 78.1 \pm 19%, and especially in colon to 102.55 \pm 19%. Similarly, skeletal muscle perfusion in rats with pancreatitis was significantly ameliorated after heparin administration from 59.2 \pm 3% to 77.9 \pm 13% (Figure 1).

Figure 1 Microcirculatory parameters of pancreas, liver, kidney, stomach, colon and muscle (Mean values). Legend: grey bars: - control, white bars: - AP, black bars: - AP+heparin, ^a P <0.05 vs control, ^c P <0.05 vs AP group.

Serum interleukin 6 assay

Cn-induced acute pancreatitis caused a significant increase of serum IL-6 activity from 37.7 \pm 21 U/mL up to 359.0 \pm 66 U/mL in control rats. The heparin administration significantly diminished

IL-6 level to 288.5 \pm 58 U/mL (Table 1).

Hematocrit measurements

The mean hematocrit level of the control group without pancreatitis was 41 \pm 3%. In group II with Cn-induced pancreatitis the hematocrit was significantly increased to 53 \pm 4%. Heparin administration in animals with pancreatitis of group III significantly reduced the hematocrit to 46 \pm 3% (Table 1).

Table 1 Interleukin 6 and hematocrit levels in the three groups

Group	Interleukin 6 (U/mL)	Hematocrit (%)
Control	37.7 \pm 21	41 \pm 3
Acute pancreatitis	359.0 \pm 66 ^a	53 \pm 4 ^a
Acute pancreatitis + heparin	288.5 \pm 58 ^c	46 \pm 3 ^c

^a P <0.05 vs control, ^c P <0.05 vs acute pancreatitis group.

DISCUSSION

Caerulein-induced experimental pancreatitis was adopted by many authors to investigate microcirculatory changes of AP. The present study indicated that in Cn-induced acute pancreatitis the microperfusion of the pancreas decreased to 36.9% of basal values. These observations are in accordance with other investigations, which revealed the drop of local pancreatic blood flow in Cn induced pancreatitis^[2,13,14], although a majority of microcirculatory studies did not report such an obvious deterioration of the pancreatic perfusion as observed in the current study. Such a sharp decline of the pancreatic microperfusion might be influenced by the fact that the animals did not receive i.v. fluid administration, and could be elucidated also by an additional stress resulted from six i.p. injections of the drugs in conscious animals. In Liu's study^[14], the water immersion stress in rats with Cn-induced pancreatitis caused further pancreatic ischemia, diminishing the pancreatic blood flow to 37% of the normal value, and was considered as an aggravating factor in AP.

In contrast to these observations, the Heidelberg group described increased pancreatic capillary flow in experimental oedematous pancreatitis^[15,16]. The discrepancy of the results may be explained by various techniques of microcirculatory measurements and i.v. fluid administration. On the other hand, in the model of necrotizing pancreatitis, the authors observed a significant decrease of the pancreatic capillary flow^[16].

The disturbances of microcirculation in acute pancreatitis were not only confined to pancreatic capillary bed but were also observed in other organs^[5-8]. It was suggested that diffused microcirculatory disorders might play a crucial role in the development of the pancreatitis-associated multiorgan dysfunction syndrome^[7], some authors even defined severe AP as a systemic dysfunction syndrome^[7,17].

The present study confirmed these data. Besides the pancreas, reduced capillary perfusion was observed in liver, kidney, stomach, colon, and skeletal muscles, however the drop in perfusion of other organs was not so remarkable as in the pancreas. This suggests that in pancreatitis, pancreatic gland is especially susceptible to microcirculatory disorders. Kinnala *et al.* found that splanchnic malperfusion seemed to begin with pancreatic hypoperfusion before disturbances in gut microcirculation^[1]. On the other hand, Hotz *et al.* noted that in mild pancreatitis, pancreatic capillary perfusion remained unchanged, whereas mucosal and subserosal colonic capillary blood flow was significantly reduced. It was also shown in their experiment that severe pancreatitis was associated with a marked reduction in both pancreatic and colonic capillary perfusion^[18].

Microcirculatory disturbances in AP comprised many

components: decreased capillary blood flow and capillary density, increased capillary permeability, and enhanced leukocyte-endothelial interaction^[7]. It still remains unclear which of these factors is the initiating one or the most important. It seems to be logical that any effort to improve the microcirculation may be beneficial for all organs, irrespective of the underlying initiating factors.

Many studies documented positive impacts of various treatments on improving microcirculation in acute pancreatitis. In studies by Konturek *et al.* and Liu *et al.* pancreatic microperfusion was ameliorated with L-arginine (nitric oxide donor) treatment^{[[13,14]}. Improvement of impaired pancreatic microcirculation by isovolemic hemodilution with dextran was observed by Klar *et al.*^{[[19]}. Rheologic properties of pentoxifylline, its antiinflammatory effect, reduction of thrombus formation, and lowering of blood viscosity had a positive influence on Cn-induced pancreatitis in study of Gomez-Cambronero *et al.*^{[[20]}. An advantageous effect of ICAM-1 antibodies on microcirculation in AP was shown by Foitzik *et al.*^{[[21]}, and Werner *et al.*^{[[22]}. A single i.v. injection of bovine hemoglobin in an experiment by Strate *et al.* reduced microcirculatory dysfunction and pancreatic tissue damage in rodent pancreatitis^{[[4]}. In a study by Zhao *et al.* Chinese natural medicines: Yuanhu (YHI) and Huoxuehuayu (HHI-I) had a positive impact on acute pancreatitis development, including pancreatic malperfusion and serum IL-6 level. Recently, it was shown that endothelin receptor blockade might be a promising therapeutic approach in AP, resulting in improvement of microcirculation, decreased capillary permeability and tissue injury^{[[7,23,24]}.

Intraperitoneal heparin administration in the current study significantly improved blood perfusion of examined organs. The beneficial effect of heparin on pancreatic microcirculation may in theory have an influence on severity of the disease, it could prevent or restrict the development of pancreatic necrosis. It was shown in our recent publication that heparin treatment in oedematous pancreatitis ameliorated the microscopic alterations of the pancreas: reduced leukocyte infiltration and diminished pancreatic oedema^{[[25]}.

By improving hepatic capillary blood flow, heparin could influence phagocytic Kupffer cell function in the liver which is important for eliminating antigens and toxic substances in acute pancreatitis. The study of Forgacs *et al.* showed a close relationship between liver phagocytic function and hepatic microperfusion in the early stage of experimental pancreatitis^{[[26]}. On the other hand, Chen *et al.* revealed that a significant number of adherent leukocytes was observed in hepatic microcirculation 2 h after the induction of AP^{[[27]}. This could impair hepatic perfusion, and might be a potential target for heparin treatment. In another study, Chen *et al.* observed beneficial effects of protease inhibitor gabexate mesilate on pancreatic and hepatic microcirculation^{[[8]}.

The pathophysiology of renal insufficiency, often observed as a complication of acute pancreatitis, is heterogeneous. The improvement of renal blood flow observed after heparin treatment in the rats with pancreatitis could also prevent this complication. Foitzik *et al.* using endothelin receptor blockers in severe acute pancreatitis, besides the enhancement of pancreatic perfusion, observed improved renal function^{[[7]}.

It was shown that decreased capillary blood flow in the colonic mucosa was associated with impaired gut barrier function and increased translocation of live bacteria through the morphologically intact colonic wall^{[[28]}. The present study revealed that heparin treatment in the group with pancreatitis led the altered microperfusion of the colonic wall to the normal level. It suggests that heparin administration may play a role in prevention of secondary pancreatic infection.

Besides the organ microcirculatory improvement, heparin administration significantly decreased interleukin 6 activity,

and reduced hematocrit level. IL-6 was a reliable predictor of acute pancreatitis severity^{[[29]}. Diminished IL-6 activity in the group with AP treated with heparin may indicate that this therapy could limit inflammatory response observed in AP. Beneficial influence of heparin on hematocrit level, observed in group III, may also suggest that heparin reduces capillary permeability, not just in the pancreatic gland, and prevent the fluid to the third space. Therefore heparin therapy may reduce the need for vigorous fluid resuscitation as applied in patients with AP.

The improvement of systemic microperfusion after heparin administration in rats with AP might be explained by its anticoagulatory effect which diminished blood viscosity and facilitated capillary blood flow. Besides its anticoagulant properties, heparin may play a positive role in AP treatment due to its antiinflammatory effects: TNF inhibition^{[[30]}, protection from oxygen free radicals^{[[31]}, the blockade of complement activity^{[[32]} and histamine release^{[[33]}. It was also shown that heparin prevented post-ischemic endothelial cell dysfunction^{[[34]}, neutrophil adhesion^{[[35]}, and had an inhibitory effect on the biosynthesis and release of endothelin-1, a very potent endogenous vasoconstrictor^{[[36,37]}.

In conclusion, heparin counteracts microcirculatory disorders, not only within the pancreas but also in other organs. The preservation of organ microperfusion with this treatment may be significant for diminishing and treating local and systemic complications in AP.

Abstract

AIM: To determine the long-term prevalence of *Helicobacter pylori* (*H. pylori*) gastritis in patients after partial gastric resection due to peptic ulcer, and to compare the severity of *H. pylori*-positive gastritis in the corpus mucosa between partial gastrectomy patients and matched controls.

METHODS: Endoscopic biopsies were obtained from 57 patients after partial gastric resection for histological examination using hematoxylin/eosin and Warthin-Starry staining. Gastritis was graded according to the updated Sydney system. Severity of corpus gastritis was compared between *H. pylori*-positive partial gastrectomy patients and *H. pylori*-positive duodenal ulcer patients matched for age and gender.

RESULTS: In partial gastrectomy patients, surgery was performed 20 years (median) prior to evaluation. In 25 patients (43.8%) *H. pylori* was detected histologically in the gastric remnant. Gastric atrophy was more common in *H. pylori*-positive compared to *H. pylori*-negative partial gastrectomy patients ($P < 0.05$). The severity of corpus gastritis was significantly lower in *H. pylori*-positive partial gastrectomy patients compared to duodenal ulcer patients ($P < 0.01$). There were no significant differences in the activity of gastritis, atrophy and intestinal metaplasia between the two groups.

CONCLUSION: The long-term prevalence of *H. pylori* gastritis in the gastric corpus of patients who underwent partial gastric resection due to peptic ulcer disease is comparable to the general population. The expression of *H. pylori* gastritis in the gastric remnant does not resemble the gastric cancer phenotype.

INTRODUCTION

Helicobacter pylori (*H. pylori*) is the major etiological factor for peptic ulcer disease and gastric MALT lymphoma, and is strongly

linked to the development of gastric carcinoma^[1-3]. Recently, a gastric cancer phenotype of *H. pylori* gastritis has been proposed, which is characterized by an increased inflammation of the corpus mucosa^[4]. This phenotype of *H. pylori* gastritis is significantly more common in patients with early gastric cancer, and also in those with advanced stages of gastric cancer^[4,5]. An increased severity of corpus inflammation has also been described in particular risk groups for gastric cancer, such as first-degree relatives of gastric cancer patients^[6]. In contrast, patients with duodenal ulcer disease are characterized by a severe gastritis in the antrum, but a mild gastritis in the corpus^[7]. The risk for gastric cancer in duodenal ulcer patients is low compared to the general population^[8].

Patients underwent partial gastric resection for peptic ulcer are at high risk for developing cancer in the gastric remnant^[9]. Several mechanisms have been proposed for this phenomenon. It has been suggested that stump cancers uniformly develop upon a background of chronic mucosal changes in the gastric remnant^[10-12]. Factors that may contribute to cancer of the gastric remnant include enterogastric pancreaticobiliary reflux, hypochlorhydria, microflora, and N-nitroso compounds^[13,14].

The role of *H. pylori* gastritis with respect to cancer risk in patients underwent partial gastric resection for benign peptic ulcer disease is not clearly defined. Assuming that the majority of peptic ulcer patients were *H. pylori*-infected at the time of surgery, persisting *H. pylori* infection and long-term inflammation of the gastric corpus mucosa might contribute to carcinogenesis in these patients.

The aim of our study was therefore to determine the prevalence of *H. pylori* gastritis in the gastric remnant of patients who underwent partial gastric resection, and to test the hypothesis that *H. pylori*-positive patients with partial gastric resection may have a more severe corpus gastritis resembling the gastric cancer phenotype of *H. pylori* gastritis.

MATERIALS AND METHODS

The study included consecutive patients who were admitted to our institution for surveillance endoscopy after partial gastric resection due to peptic ulcer disease. Exclusion criteria included previous surgery for gastric cancer, previous treatment for *H. pylori* infection, and a present ulcer or tumor under endoscopy. Further exclusion criteria included pretreatment with antibiotics, proton-pump inhibitors, non-steroidal anti-inflammatory within the 4 wk before study entry.

Endoscopic biopsies were routinely obtained in 4 quadrants from the anastomosis, or from any suspicious macroscopic lesion. In addition, 2 biopsies were obtained from the middle of the remnant corpus and 2 from the cardia for assessing prevalence, severity of *H. pylori* gastritis, and gastric atrophy. All biopsy specimens were fixed in 40 g/L formaldehyde and embedded in paraffin. Sections were stained with hematoxylin and eosin and Warthin-Starry. The presence of *H. pylori* colonization as well as intestinal metaplasia and atrophy were judged as positive or negative. The grade of gastritis (infiltration of lymphocytes and plasma cells), the activity of gastritis (infiltration of neutrophil granulocytes), and the replacement of foveolar epithelium by regenerative epithelium were assessed by a semiquantitative

scale (grade 0 = negative, grade 1 = mild, grade 2 = moderate, grade 3 = severe) in accordance with the updated Sydney system^[15].

The control group consisted of *H pylori*-positive patients with duodenal ulcer disease who participated in previous clinical trials^[7] and who were age- and gender-matched. In these patients, endoscopic biopsies have been obtained from the antrum and the corpus, and were processed as described above. All histological slides were assessed by a single pathologist.

Data analysis was performed using the statistical software package SPSS 10.0 for Windows. The Chi-square test or Fisher exact test was used when appropriate. $P < 0.05$ was considered statistically significant.

RESULTS

A total of 57 patients with partial gastric resection were included into the study (19 males and 38 females, median age 64 years, range 26-92 years). The time period between surgery and histology assessment ranged from 8 to 47 years with a median of 20 years. None of the intraepithelial neoplasia was detected at the gastric anastomosis. In 25 patients (43.9%) *H pylori* was detected histologically in the gastric remnant.

Table 1 summarizes the histological features in the corpus and cardia of partial gastrectomy patients. For analysis purposes, patients with grade 0 and 1, and patients with grade 2 and 3 were combined, respectively. There was a higher proportion of patients with moderate or severe activity of gastritis in the corpus ($P < 0.0005$) and cardia ($P = 0.007$) among *H pylori*-positive patients compared to *H pylori*-negative partial gastrectomy patients. In addition, the proportion of patients with atrophy in the corpus mucosa was significantly higher among *H pylori*-positive compared to *H pylori*-negative patients ($P = 0.047$). No significant differences were found with regard to grade of gastritis, regenerative epithelium and the presence of intestinal metaplasia between *H pylori*-positive and *H pylori*-negative partial gastrectomy patients.

The comparison of corpus gastritis between *H pylori*-positive partial gastrectomy patients and *H pylori*-positive duodenal ulcer patients is summarized in Table 2. The proportion of patients with moderate or severe grade of gastritis in the corpus ($P = 0.001$) and with moderate or severe regenerative epithelium ($P = 0.004$) was significantly lower in *H pylori*-positive partial gastrectomy patients than that in *H pylori*-positive duodenal ulcer patients, respectively. A similar trend was observed for the activity of gastritis in the corpus, however

the differences were not statistically significant. The prevalence of intestinal metaplasia in the corpus mucosa was similar in both groups. The prevalence of atrophy in the corpus mucosa was higher in partial gastrectomy patients, however the difference did not reach statistical significance.

Table 2 Severity of corpus gastritis in *H pylori*-positive partial gastrectomy patients and *H pylori*-positive duodenal ulcer patients matched by age and gender

DISCUSSION

In the present study the prevalence of *H pylori* gastritis in patients underwent partial gastrectomy was 43.9% which is comparable to the average population in Germany and which is within the range of other studies on the *H pylori* prevalence in partial gastrectomy patients^[16-20].

An association between *H pylori* infection and an increased acute and chronic inflammatory response and a higher prevalence of chronic atrophic gastritis and intestinal metaplasia in the gastric remnant mucosa has been described^[16,18] while others were non-confirmatory^[20]. Our study suggests that *H pylori* leads to a higher proportion of atrophy in the corpus of the gastric remnant compared to *H pylori*-negative partial gastrectomy patients.

Several studies have shown that a severe although non-atrophic gastritis in the corpus mucosa is a particular risk factor for gastric cancer among those individuals infected with *H pylori*^[4-7]. These findings were recently confirmed by a prospective observational study from Japan where gastric cancer developed only in those patients infected with *H pylori*^[21] and where a

No partial gastrectomy patient had a grade 2 or 3 regenerative type of epithelium in the corpus. Based upon this result a statistical analysis with regard to regenerative type of epithelium in the corpus was not appropriate.

corpus-dominant gastritis or pangastritis was associated with an 34-fold increased risk for gastric cancer. Based upon the increased risk for gastric cancer in the presence of severe corpus gastritis we hypothesized that patients with partial gastrectomy due to ulcer disease may develop a corpus-dominant phenotype of *H pylori* gastritis, which may contribute as a risk factor for cancer in these patients. Surprisingly, we found a significant lower grade of gastritis in the corpus of *H pylori*-positive partial gastrectomy patients compared to the control group consisting of *H pylori*-positive duodenal ulcer patients. Possible explanation for this finding might include that in some patients the infection may have disappeared spontaneously due to an altered gastric milieu, or that some of the patients may have been operated due to *H pylori*-negative ulcer caused by nonsteroidal anti-inflammatory drugs. Other patients may have received antibiotic therapy for other indications that *H pylori* infection potentially leads to coincident eradication of the bacteria. Nevertheless, we conclude that partial gastrectomy patients should be tested for *H pylori* infection, and, if diagnosed positive, eradication therapy should be initiated to reduce the risk of ulcer relapse^[22].

Other factors than *H pylori* have been implicated in the pathogenesis of the mucosa alterations in partial gastrectomy patients, including enterogastric reflux, achlorhydria and increased mucosal proliferation, effects of vagotomy and dietary factors^[23-26]. Bile reflux may play a promotional role by increasing permeability to initiating carcinogens. This enterogastric reflux has been reported to be more pronounced after a gastrojejunostomy than after a gastroduodenostomy, which may explain the higher stomach cancer risk after a Billroth II operation^[27-29].

In conclusion, our study suggests that the *H pylori* prevalence in partial gastrectomy patients (former peptic ulcer patients) is comparable to the general population. *H pylori*-positive partial gastrectomy patients appear not to develop a corpus-dominant gastritis resembling the gastric cancer phenotype of *H pylori* gastritis.

Abstract

AIM: To construct a recombinant strain which expresses BabA of *Helicobacter pylori* (*H. pylori*) and to study the immunogenicity of BabA.

METHODS: BabA₂ DNA was amplified by PCR and inserted into the prokaryotic expression vector pET-22b (+) and expressed in the BL21 (DE3) *E. coli* strain. Furthermore, BabA immunogenicity was studied by animal test.

RESULTS: DNA sequence analysis showed the sequence of BabA₂ DNA was the same as the one published by GenBank. The BabA recombinant protein accounted for 34.8% of the total bacterial protein. The serum from *H. pylori* infected patients and Balb/c mice immunized with BabA itself could recognize rBabA.

CONCLUSION: BabA recombinant protein may be a potential vaccine for control and treatment of *H. pylori* infection.

INTRODUCTION

Helicobacter pylori (*H. pylori*), a human-specific gastric pathogen, was first isolated in 1982 and has emerged as the causative agent of chronic active gastritis and peptic ulcer disease^[1-11]. Most infected individuals show no clinical symptoms, implicating additional factors, such as genetic predisposition and genotype of the infecting strain, are involved in disease pathogenesis. Chronic infection is associated with the development of gastric adenocarcinoma, one of the most common types of cancer in humans, and *H. pylori* was recently defined as a class I carcinogen. In addition, seroprevalence studies indicate that *H. pylori* infection is also associated with cardiovascular, respiratory, extra-gastrointestinal digestive, autoimmune disease. At present the main treatment to eradicate *H. pylori* is combined antibiotics, but the cost of combination therapy and the emergency of antibiotic resistance provide further incentives for vaccine development.

In the development of *H. pylori* vaccine, candidate vaccine antigens adopted currently such as urease, vacuolating cytotoxin, catalase, etc. basically focus on blocking toxicity factors of *H. pylori* while considerably few candidate vaccine antigens focus on adhesins which are closely associated with *H. pylori* colonizing human gastric mucosa by adhering to mucous epithelial cells and mucus layer lining the gastric epithelium. BabA is the only adhesin gene whose receptor has been confirmed. Studies indicate that BabA gene contains two alleles: BabA₁ and BabA₂. Gene BabA₁ is different from BabA₂ in the presence of a 10 bp repeat motif and in lack of Leb antigen-binding activity. No concerned study has been reported to date about BabA₂ in China. So in this study, recombinant plasmid of *H. pylori* BabA₂ gene was constructed and expressed for development of *H. pylori* vaccine.

MATERIALS AND METHODS

Materials

Bacterial strain BL21 (DE3) and plasmid pET-22b (+) were provided by Institute of Biotechnology, Academy of Military Medical Sciences. *H. pylori* SS1 was preserved in this research institute. Restriction enzyme *Not* I, *Nco* I and T4 DNA ligase, Vent DNA polymerase, isopropyl-β-D-thiogalactopyranoside (IPTG) were purchased from New England Biolabs Company. DNA molecular weight standard λ DNA/*Eco*RI/*Hind*III, goat anti-mouse and goat anti-human IgG-HRP were purchased from Huamei Bioengineering Company and His-Tag precolumn from Invitrogen Company. Specific-pathogen-free, female BALB/c mice were housed according to Health Research Council of China guidelines and allowed free access to food and water. Eight *H. pylori* positive sera (which were detected positive by the urease test, pathological dying and germiculture) and three *H. pylori* negative sera (which were detected negative by the above-mentioned three examinations) were from patients treated in the Endoscopy Center of this institute. Other reagents were analytically pure reagents produced in China.

Recombinant DNA techniques

Unless otherwise stated, plasmid and chromosomal DNA extractions, restriction enzyme digests, DNA ligations, transformations into *E. coli* and other common DNA manipulations were performed by standard procedures. Genome of *H. pylori* was prepared from the cells collected from the colonies on the agar plate. The gene of *H. pylori* BabA₂ was amplified from the genome of *H. pylori* by PCR using the primers BabA₂1 (5'-TG GCC ATG GAT AAA AAA CAC ATC CTT TCA-3') as upstream primer and BabA₂2 (5'-AG TGC GGC CGC ATA AGC GAA CAC ATA G-3') as downstream primer as described in the literature^[33]. BabA₂1 and BabA₂2 contained *Nco* I and *Not* I sites, respectively. PCR was performed with the hot start method. PCR condition was that after initial denaturing at 95 °C for 30 s, each cycle of amplification consisted of denaturing at 95 °C for 30 s, annealing at 55 °C for 30 s and polymerization at 72 °C for 60 s and further polymerization for 10 min after 35 PCR cycles. The PCR product was harvested from agarose gel, digested with *Nco* I and *Not* I, and inserted into the *Nco* I and *Not* I restriction fragment of the expression vector pET-22b(+) using T4 DNA ligase. The

resulting plasmid pET- BabA was transformed into competent *E.coli* BL21 (DE3) cells using ampicillin resistance for selection. The alkaline lysis method was chosen for large-scale preparations of recombinant plasmids which were identified by restriction enzymes. DNA sequence was performed with a DNA automatic sequencer.

Induced expression, purification and SDS-polyacrylamide gel electrophoresis

The recombinant strains were incubated overnight at 37 °C and shaken in 5 mL LB with 100 µg/mL ampicillin. A 50 mL LB was inoculated and the cells grew until the optical density at 600 nm reached 0.4-0.6. Isopropyl-β-D-thiogalactopyranoside (IPTG) was added to a final concentration of 0.1, 0.2, 0.4, 0.6, 0.8, 1.0 mmol/L, respectively. *E.coli* cells from a 50 mL growth 3 h or 5 h after induction were harvested by centrifugation at 12 000 g for 10 min and the pellet was resuspended in 1 mL 30 mmol/L Tris buffer (pH8.0) containing 1 mmol/L EDTA (pH8.0), 200 g/L sucrose. The suspension was put on ice for 10 min, and then centrifuged for 10 min at 12 000 g, and the resulting supernatant contained proteins from the periplasm. The resulting pellet was resuspended in 5 mL 50 mmol/L Tris buffer (pH8.0) containing 2 mmol/L EDTA, 0.1 mg/mL lysozyme and 10 g/L Triton X-100. The suspension was incubated at 30 °C for 20 min and then sonicated on ice until it became clarified. The lysate was centrifuged at 12 000 g for 15 min at 4 °C, then the resulting supernatant containing proteins from the cytoplasm was purified with Ni-NTA column. Whole-cell lysates, sonicated supernatant, osmotic shock liquid of recombinant strains expressing *H pylori* BabA2 genes and the purified rBabA were analyzed by electrophoresis analysis in a 100 g/L polyacrylamide gel.

Immunization of mice

Sixty-eight-week-old mice were immunized 4 times by hypodermic injection in the back of mice at weekly intervals. Each dose consisted of 20 µg of *H pylori* rBabA protein and 200 µg of adjuvant aluminum hydroxide gel. Age-matched control mice were not immunized. Four weeks after the last immunization, blood samples were taken from the retro-orbital sinus to measure the anti BabA systemic immune responses and stored at -20 °C until assay.

Serum antibody responses

Indirect ELISA as described previously evaluated serum samples from mice and patients for BabA-specific IgG. Purified *H pylori* rBabA was used as the coating antigen in ELISA immunoassays.

RESULTS

PCR amplification of *H pylori* BabA₂ gene

According to the literature, the gene encoding the BabA protein, was amplified by PCR with chromosomal DNA of *H pylori* Sydney strain (ss1) as the templates. The cloning products were electrophoresed and visualized on 8 g/L agarose gel (Figure 1). It revealed that BabA₂ DNA fragment amplified by PCR contained a gene of approximately 2 226 nucleotides, which was compatible with the previous reports.

Construction of recombinant plasmid and restriction enzyme confirmation

After the PCR products and pET-22 b (+) plasmid were cut by *Not* I and *Nco* I, directional cloning was performed, resulting in a recombinant plasmid named pET-22 b (+)/BabA. The recombinant plasmids pET-22 b (+)/BabA were all digested by *Not* I or *Nco* I, and by *Not* I and *Nco* I simultaneously, then digestive products were visualized on 8 g/L agarose gel electrophoresis (Figure 2). It demonstrated that recombinant plasmid contained the objective gene.

Figure 1 BabA₂ DNA fragment amplified by PCR from *Helicobacter pylori* electrophoresed on 8 g/L agarose gel. Lane 1: Nucleotide marker; Lane 2: PCR products.

Figure 2 Identification of recombinant plasmid by restriction enzyme digestion. Lane 1: Nucleotide marker; Lane 2: PCR products; Lane 3: Recombinant plasmid/*Not* I; Lane 4: Recombinant plasmid/*Not* I and *Nco* I; Lane 5: pET22b(+)/*Not* I.

Sequence analysis of cloned BabA₂ nucleotide

The nucleotide sequence of cloned genes inserted in pET22 b(+) was analyzed by automatic sequencing across the cloning junction, using the universal primer T7. The results showed that cloned genes contained 2 226 nucleotides with a promoter and a start codon coding a putative protein of 741 amino acid residues with a calculated molecular mass of BabA. As compared with previously reports, the homogeneity was 100% between them.

Expression and purification of BabA₂ gene in *Escherichia coli*

Whole-cell lysate, sonicated supernatant, osmotic shock liquid of recombinant strains expressing *H pylori* BabA₂ genes and the purified rBabA were analyzed by electrophoresis analysis in a 100 g/L polyacrylamide gel for detection of fusion proteins (Figure 3). The result showed that the clearly identifiable band was 78 000 u highly expressed fusion proteins, which was similar to that predicted. Gel automatic scan analysis showed that it was 0.6 at D value and the final concentration of IPTG was 0.1 mmol/L and the expression of BabA rose remarkably after 5 h of induction, which accounted for 34.8% of total bacterial proteins. Among them, soluble substance accounted for 15.0% of supernatant. BabA was further analyzed with Ni-NTA column and finally BabA whose purity was 90%.

Antigenicity study of recombinant fusion protein

The positive results by the test of ELISA had colours, but the negative results had no colours, or weak colours. Serum from the eight mice serums immunized with rBabA showed positive results. In contrast, serum from the eight mice in the control group showed negative results. At the same time, serums from patients also showed the same results. *H pylori* positive serum from the eight patients showed positive results and *H pylori* negative serum from the three patients showed positive results.

It showed that anti-BabA antibody existed in the serum of infected patients and rBabA could enable the organism to generate specific humoral immunity.

DISCUSSION

At first Wadstr *et al.* suspected that the resting or slow growing cells of *H pylori* could interact with Lewis blood group substances in gastric mucin layer and on epithelium to facilitate initial colonization. Afterwards liver *et al.* used receptor activity-directed affinity tagging to purify a kind of adhesin which mediated adherence of *H pylori* to human gastric epithelial cells by interacting with fucosylated Lewis b (Leb) histo-blood group antigen and named the adhesion BabA. Immunogold electron microscopy found BabA adhesin was located on the bacterial cell outer membrane by probing the Leb antigen. Receptor displacement analyses showed that receptor-adhesin complex was formed under conditions of equilibrium. Most of the cells (>90%) of the bacterial exhibited BAB activity, as determined by confocal microscopy and fluorescent Leb antigen. The K_a value for formation of the Leb antigen-BabA complex was -1×10^{10} mol/L. The number of Leb glycoconjugate molecules bound to BabA was calculated as -500 per bacterial cell. In addition, the prevalence of blood group antigen-binding activity was also assessed among 95 recent clinical isolates of *H pylori*, and 66% (63 isolates) were bound to the Leb antigen. Bosch *et al.* investigated the effects of acute stress on the salivary levels of the carbohydrate structure sulfo-Lewis (sulfo-Le). The results showed the stressor induced a strong increase in salivary sulfo-Le concentration (U/mL), sulfo-Le output (U/min), sulfo-Le/total protein ratio (U/mg protein), and saliva-mediated adherence (*ex vivo*) of *H pylori*. As expected, sulfo-Le concentration correlated with the adherence of *H pylori* ($r = 0.72$, $P < 0.05$). In a word, the adhesin BabA and its receptor Leb played an important role in the adherence mechanism of *H pylori*, especially when people were in the state of acute stress.

Isolates of *H pylori* differed in virulence and from individuals with peptic ulcers most often were type I strains that expressed vacuolating cytotoxin A (VacA) and cytotoxin-associated gene A (CagA) protein. By definition, type II strains could express neither marker. The bacterial Leb-binding phenotype was associated with the presence of the cag pathogenicity island among clinical isolates of *H pylori*. A vaccine strategy based on the BabA adhesin might serve as a means to target the

virulent type I strains of *H pylori*. So we selected *H pylori* ss1 chromosome DNA as a template, which has strong adhesin and is capable of colonizing firmly in the stomach of a mouse, designed specific primers and successfully screened the genes of BabA₂. To facilitate the expression and purification at the next stage, we cloned it into a fusion expression vector with 6 hercynine tails. The restriction enzyme digestion and the sequencing results showed that one open reading frame had the size of 2 226 bp. SDS-PAGE and scan analysis showed that the molecular mass of BabA was 78 ku and recombinant protein accounted for 34.8% of the total bacterial protein. Considering that the recombinant protein with bio-activity tended to preserve more integral and positive antigenicity, we selected supernatant of ultrasound disrupted live *E. coli* and performed repeated purification of rBabA with Ni-NTA resin, thus obtaining rBabA with activity whose purity was 90%. This has laid a foundation for further research on immune protection and molecular adhesin mechanism. In this study, serum from the mice immunized with purified recombinant protein BabA could be used to detect specific antibody against BabA, but serum from the mice in the control group could not. Serum from patients also showed the same results. These results suggest that BabA of *H pylori* maybe a good candidate as a vaccine component.

Abstract

AIM: To investigate the feasibility for antisense imaging of the colon cancer with liposome-entrapped ^{99m}Tc -labeled antisense oligonucleotides as tracers.

METHODS: Fifteen mer single-stranded aminolinked phosphorothioate antisense oligonucleotides of *c-myc* mRNA were labeled with ^{99m}Tc -pertechnetate, then purified and finally entrapped with liposomes to form the labeling compounds, liposome-entrapped ^{99m}Tc -labeled antisense oligonucleotides. The LS-174-T cells (colon of adenocarcinoma cell line) were incubated with the labeling compounds to test the uptake rates of LS-174-T cells. Later on, a model of 30 tumor bearing nude mice was constructed by inoculating with 5×10^6 of LS-174-T cells at right flank of each nude mouse. About 10 d later, the model were administered by intravenous injection of the liposome-entrapped ^{99m}Tc -labeled antisense oligonucleotides. Then some of the tumour bearing nude mice were sacrificed at 0.5, 1, 2, and 4 h after intravenous injection, and proper quantity of liver, spleen, tumor, etc. was obtained. The tissues were counted in a gamma counter, and after correction for decay and background activity, expressed as a percentage of the injected dose. The others whose anterior and posterior whole-body scans were obtained at 1, 1.5, 2, 4, 6 and 24 h with a dual-head bodyscan camera equipped with parallel-hole low-energy collimators. The ratios of radioactive counts in tumor to that in contralateral equivalent region of abdomen were calculated.

RESULTS: The uptake rates of LS-174-T cells for liposome-entrapped ^{99m}Tc -labeled antisense oligonucleotides increased as time prolonged and reach the peak ($17.77 \pm 2.41\%$) at 7 h. The biodistributions showed that the radioactivity in the tumor ($13.46 \pm 0.20\%$) of injected dose was the highest at 2 h of intravenous injection of liposome-entrapped ^{99m}Tc -labeled antisense oligonucleotides, and then decreased sharply to $4.58 \pm 0.45\%$ at 4 h. The tumor was shown clearly in the whole-body scan at 2 h of intravenous injection. The ratios, radioactive counts in tumor to that in contralateral equivalent region of abdomen (1.7332 ± 0.2537), was the highest one at 2 h after intravenous injection of liposome-entrapped ^{99m}Tc -labeled antisense oligonucleotides.

CONCLUSION: The liposome-entrapped ^{99m}Tc -labeled antisense oligonucleotides deserve being developed into radiopharmaceutics for the colon cancer imaging.

Zheng JG, Tan TZ. Antisense imaging of colon cancer-bearing nude mice with liposome-entrapped ^{99m}Tc -labeled antisense oligonucleotides of *c-myc* mRNA. *World J Gastroenterol* 2004; 10(17): 2563-2566

<http://www.wjgnet.com/1007-9327/10/2563.asp>

INTRODUCTION

Antisense imaging was referred to that antisense oligonucleotides of a gene were labeled with radionuclide, then administered to a organism to show its focus, especially the tumor^[1]. Colon cancer is a malignant tumor that seriously threatens human health. Its main oncogene, *c-myc*, whose overexpression can reach 30 times, is a target gene for antisense imaging^[2]. The oligonucleotides that are complementary to *c-myc* mRNA can prohibit many kinds of cancer cells from growing^[3]. Many nuclear medicine researchers are interested in this oncogene^[4,5]. At present, the antisense oligonucleotides of *c-myc* mRNA have been successfully labeled with ^{99m}Tc ^[6,7]. However, to the author's knowledge, their application in experimental researches on antisense imaging has not been reported as yet. Is the uptake rate of tumor tissue too small and the background too high to indicate the tumor? How can the uptake rates of tumor cells be increased? Do these limit the application of ^{99m}Tc -labeled antisense oligonucleotides? In order to explore the feasibility for antisense imaging of the colon carcinoma, develop a new radiolabeled-gene-pharmaceutics, and promote the progress in the molecular nuclear medicine, the primary experimental studies, antisense imaging, on liposome-entrapped ^{99m}Tc -labeled antisense phosphorothioate oligonucleotides as a tracer were carried out.

MATERIALS AND METHODS

Materials

Fifteen mer, single-stranded phosphorothioate oligonucleotides, aminolinked, antisense oligonucleotides targeted at the translation initiation codon of *c-myc* mRNA were purchased from Gibco-BRL, US. Their base sequences were 5'-NH₂-FACGTTGAGGGGCAT-3' (F stood for phosphorothioate A). The molecular mass of the chain was about 300 u. These oligonucleotides were used directly without further purification, and generally handled under sterile conditions. All solutions were sterilized by terminal filtration through a 0.22 μm filter. All pipettes and tubes were autoclaved prior to use. The oligonucleotides were dissolved at a concentration of 4 mg/mL in sterile water and stored at -20 °C.

The hydrazino nicotinamide derivatives were synthesized elsewhere. ^{99m}Tc -pertechnetate was obtained from a ^{99}Mo - ^{99m}Tc radionuclide generator made by the Chinese Atomic Energy Institute. Tricine, SnCl₂·2H₂O and Dimethyl sulfoxide were

supplied by Sigma Company, US, lipofectamin reagent by Gibco-BRL, US, EDTA by Boehringer Mannheim Company, Germany, and Sep-Pak (C₁₈) reverse column by Waters Company, US.

The oligonucleotides were bound to hydrazino nicotinamide derivatives and then labeled with ^{99m}Tc following the methods described by Hnatowich *et al*^[8]. The ^{99m}Tc-labeled oligonucleotides were entrapped with liposome according to the manufacturer's protocols.

The cellular uptake rates of oligonucleotides

The LS-174-T cells were grown by adherent culture in media (RPMI-1 640, Gibco-BRL, US), supplemented with 100 mL/L fetal bovine serum at 37 °C, 50 mL/L CO₂. Thirty-six culture plates with diameter of 33 mm each was inoculated with about 1×10⁵ LS-174-T cells and cultured at 37 °C for 48 h. After the cells were grown to about 50% confluence in regular culture media, they were transfected using lipofectamin with 2 μg of freshly prepared liposome-entrapped ^{99m}Tc-labeled antisense oligonucleotides with radioactivity of about 29.60 MBq according to the manufacturer's protocols. The cellular uptake rates were determined at 1, 2, 5 and 7 h, and the testing steps were as follows: The cells were detached by 2.5 g/L trypsin to form suspension, then washed three times with the media by centrifugation (2 500 r/min, 10 min). The supernatant was collected into a 50 mL volumetric cylinder and the precipitation remained in the centrifugation tube. Then the radioactive counts in the precipitation and supernatant were counted in an automatic gamma well counter after correction for decay and background activity separately, and the cellular uptake rates were expressed as a percentage of the total counts. The uptake rate = radioactive counts in precipitation/the total counts in precipitation and supernatant ×100%.

The biodistribution of the antisense oligonucleotides in tumor-bearing nude mice

At first, the tumor model was constructed. Large-scale of LS-174-T cells collected by digestion, centrifugation and washing, were diluted with culture medium without serum and antibiotic to the concentration of 5×10⁶ cells per 0.2 mL. Thirty male nude mice, aged about 2 mo, were purchased from Experimental Animal Center of Sichuan University. The mice were maintained in a specific pathogen-free environment and cared in accordance with the institutional guidelines. Each of them was inoculated with 5×10⁶ cells at right flank. The tumor was allowed to grow for 10 d until diameter reached about 1 cm. Thus the tumor model was constructed successfully.

Biodistribution of liposome-entrapped ^{99m}Tc-labeled antisense oligonucleotides was determined in the 20 tumor-bearing nude mice. Each mouse received 0.3 mL of saline containing 3 to 5 μg (0.259 MBq) of liposome-entrapped ^{99m}Tc-labeled antisense oligonucleotides by tail vein administration. Meanwhile, the same injected dose of liposome-entrapped ^{99m}Tc-labeled antisense oligonucleotides was stored in a tube as standard, and double assays were carried out. Five mice were used at each time point of 0.5, 1, 2 and 4 h. After being bled from eye, they were sacrificed by cervical dislocation, and proper quantity of liver, spleen, kidney, lung, heart, bone, muscle, stomach, intestines, brain and tumor obtained. The tissues were washed cleanly with cool physiological saline and weighted by electronic balance (Denver, US). The tissues were counted against appropriate standards of known dilution in an automatic gamma well counter, and after correction for decay and background activity, expressed as a percentage of the injected dose.

Antisense imaging

The liposome-entrapped ^{99m}Tc-labeled antisense oligonucleotides containing oligonucleotides from 30 to 90 μg at the concentration

of 37 MBq/mL were freshly prepared. The 6 tumor-bearing nude mice were administered with 0.3 mL of the above products through tail vein. When these mice anesthetized with pentobarbital, anterior and posterior whole-body scans were obtained at 1, 1.5, 2, 4, 6 and 24 h with a dual-head bodyscan camera (Elcint Apex Helix, Israel) equipped with parallel-hole low-energy collimators. The ratios of radioactive counts in tumor to that in the contralateral equivalent region of abdomen were calculated.

RESULTS

The cellular uptake rates of oligonucleotides

The most important thing for antisense imaging is how much oligonucleotides are able to enter cells. High uptake rate is the key to success. The cellular uptake rates are as follows: 7.21±1.23% at 1 h, 15.19±2.81% at 2 h, 16.13±2.54% at 5 h, and 17.77±2.41% at 7 h. Within 7 h, the cellular uptake rate increased as the time prolonged, and reached the peak at 7 h. It was significantly higher than that at 1 and 2 h. However, the uptake rate at 7 h was not significantly higher than that at 5 h.

The biodistribution of liposome-entrapped ^{99m}Tc-labeled antisense oligonucleotides

The biodistribution of liposome-entrapped ^{99m}Tc-labeled antisense oligonucleotides are shown in Table 1. The endothelial system played a main role in biodistribution, and accumulated the greater part of the injected dose. The radioactive counts in the tumor tissue increased within 2 h and gradually reached the peak at 2 h, then dropped down sharply.

Table 1 Course of biodistribution of liposome-entrapped ^{99m}Tc-labeled antisense oligonucleotides in tumor-bearing nude mice (mean±SD, percent of injected dose, *n* = 5 mice for each time)

Tissue	0.5 h	1 h	2 h	4 h

Antisense imaging

Anterior imaging at 1 h after intravenous injection of liposome-entrapped ^{99m}Tc-labeled antisense oligonucleotides showed that little accumulation of radioactivity might be seen in the right middle flank which was the place of tumor. Anterior imaging demonstrated a little accumulation of radioactivity in tumor site at 1.5 h (Figure 1), and a circular abnormal accumulation focus of radioactivity in the location of tumor at 2 h (Figure 2), but no accumulation of radioactivity in the location of tumor at 24 h.

The ratios of radioactive counts in tumor tissue to that in the contralateral equivalent region

The ratio was the highest one (1.7332±0.2537) at 2 h after intravenous injection of liposome-entrapped ^{99m}Tc-labeled antisense oligonucleotides. It was significantly higher than

that at 4 and 6 h ($P<0.05$). Although it was higher than that at 1.0 and 1.5 h, there was no statistical difference. These ratios are shown in Table 2.

Table 2 Ratios of the radioactive counts in tumor to that in the contralateral equivalent region of abdomen (mean \pm SD, $n = 5$ for each time point)

Time point (h)	Ratios
1.0	1.2266 \pm 0.1259
1.5	1.5597 \pm 0.0190
2.0	1.7332 \pm 0.2537
4.0	1.0182 \pm 0.0495 ^a
6.0	1.0199 \pm 0.0131 ^a

^a $P<0.05$ vs ratio of 2.0 h.

Figure 1 Anterior imaging at 1.5 h after intravenous injection of liposome-entrapped ^{99m}Tc -labeled antisense oligonucleotides. A little accumulation of radioactivity in tumor site, the right middle flank (arrow) could be observed.

Figure 2 Anterior imaging at 2 h after intravenous injection of liposome-entrapped ^{99m}Tc -labeled antisense oligonucleotides. A circular abnormal accumulation focus was observed in the location of tumor (arrow).

DISCUSSION

The possible advantages of delivering oligonucleotides into cells by liposomes are not only to increase the uptake rates of dividing and mitostatic cells, but also protect the oligonucleotides against degeneration by nucleases. It has been confirmed that the amount of oligonucleotides used can be decreased greatly as liposomes are adopted as vectors *in vitro*^[9-13].

The cellular uptake rates of the liposome-entrapped ^{99m}Tc -labeled antisense oligonucleotides are the key parameter to antisense imaging. The maximum cellular uptake rate of the LS-174-T (17.77 \pm 2.41%) was plenty enough for the experimental or clinical use, and could be applied for the following experiments: biodistribution and antisense imaging.

The biodistribution assay showed that the radioactive counts

per gram of the tumor tissue was in the middle level at 0.5 h after injection, increased as time prolonged within 2 h, and reached the peak at 2 h. The proportion of radioactive counts per gram of the tumor tissue to the total was 13.46 \pm 0.20%, which was significantly higher than that of the liver, spleen, kidney, blood, bone, muscle, intestines and brain. The ratio of radioactive counts in the tumor to that in the blood was 4.79, and to that in the muscle was 7.96. It was thus evident that enough liposome-entrapped ^{99m}Tc -labeled antisense oligonucleotides were accumulated in the tumor tissue. The tumor could be observed clearly so long as radioactivity in the tissues around it was comparatively low.

Delong *et al.*^[14] studied the biodistribution of ^{99m}Tc -labeled phosphorothioate oligonucleotides without using liposomes as carriers. Their investigation demonstrated that radioactivity in the tumor tissue was only 2% to 3%. However, in our study, liposomes were used as vectors, and 4.58% to 13.46% of the total radioactivity could be accumulated in the tumor. Radioactivity was 2.29 to 4.49 times higher than that reported by Delong *et al.*^[14]. Thus, the uptake rates of the tumor tissue can be increased greatly by using liposomes as carriers. Accordingly, liposome is an effective vector in antisense imaging.

The whole body scan in the tumor bearing nude mice showed that the tumor was observed clearly at 2 h after intravenous injection of the liposome-entrapped ^{99m}Tc -labeled antisense oligonucleotides. It was evident that the imaging of the liver above the tumor and the bladder below the tumor was more clear than that of the tumor. They could influence the imaging of the tumor. However, the interference of the bladder can easily be decreased by diuretic or drinking a certain quantity of water, which is a routine clinical method of whole body bone scan. But the influence of the liver needs further investigation.

Although the imaging of the liver will influence the quality of the antisense imaging, our primary success on the tumor-bearing nude mice with ^{99m}Tc -labeled antisense oligonucleotides may contribute to the molecular nuclear medicine progress.

In conclusion, liposome-entrapped ^{99m}Tc -labeled antisense oligonucleotides with high cellular uptake rates can be accumulated by tumor in the tumor bearing-nude mice, and be able to show the colon carcinoma accurately, was worthy of being developed into a new radiopharmaceuticals for diagnosis^[15]. This will provide a new strategy for the early diagnosis of the colon carcinoma.

Abstract

AIM: To investigate the effects of anti-Fas ribozyme on Fas expression and apoptosis in primary cultured mouse hepatocytes.

METHODS: Mouse hepatocytes were isolated by using collagenase irrigation. A hammerhead ribozyme targeting the Fas mRNA was constructed, and transfected into mouse hepatocytes via Effectene. Then Fas expression in mouse hepatocytes was detected by RT-PCR and western blotting. After being treated with anti-Fas antibody (JO₂), hepatocytes viability was measured with MTT assay. Caspase-3 proteolytic activity was detected, and cell apoptosis was measured according to Annexin V-FITC apoptosis detection kit.

RESULTS: Fas expressed in primary mouse hepatocytes. Fas expression in hepatocytes transfected with anti-Fas ribozyme was decreased remarkably and correlated with the resistance to Fas-mediated apoptosis as determined by flow cytometry and caspase-3 proteolytic activity.

CONCLUSION: Anti-Fas ribozyme can remarkably decrease the Fas expression in mouse hepatocytes, thus inhibit Fas-mediated apoptosis in hepatocytes. It is suggested that anti-Fas ribozyme could significantly increase the resistance of transplanted hepatocytes to apoptosis and improve the survival of transplanted hepatocytes.

INTRODUCTION

Liver transplantation is one of the efficient ways to treat liver function failure and liver necrosis induced by all kinds of diseases^[1,2]. But Fas expresses in hepatocytes and Fas-mediated apoptosis significantly impairs graft survival^[3-7]. Anti-Fas hammerhead ribozyme was designed and synthesized to target directly at position 596 of the Fas RNA, and cloned into a eukaryotic vector, which was transfected into primary cultured mouse hepatocytes via a vector named Effectene different from usual Lipofectamine reagents^[8]. Then the effects of anti-Fas ribozyme on Fas expression and apoptosis of mouse hepatocytes were investigated.

MATERIALS AND METHODS

Reagents and materials

E.coli DH-5 α was a kind gift from Department of Immunology, Tongji Medical College. Prokaryotic vector pBSKU6 and green fluorescent protein pEGFPC1 were given as presents by Dr. Kongxinjuan. All restriction endonucleases and T₄ DNA ligase were products of Promega Company. Mini plasmid DNA extraction kit, gel DNA purification kit and DL-2000 DNA marker were purchased from TaKaRa Company. Transfection reagent Effectene was purchased from Qiagen Company. Reverse transcriptional kit, dNTP, Taq DNA polymerase were products of MBI Company. Fluorescein isothiocyanate (FITC)-conjugated Annexin V kit was product of Bender Company (purchased from Jingmei Company). FITC-conjugated anti-mouse Fas antibody (JO₂) was product of PharMingen Company. Caspase-3 activity detection kit was product of Clontech Company. MTT reagent was purchased from Sigma Company.

Synthesis and cloning of ribozyme

GUA triplets located at 596 of the mouse Fas RNA were selected as the cleavage site of ribozyme^[9], two small nucleotide sequences complementary to flanks of the cleavage site of target RNA were located before and after hammerhead structure-the conservative core catalytic sequence of ribozyme, which can form typical active cleavage structure through complementation^[10]. The cDNAs encoding the anti-Fas ribozyme were composed of two complementary strands each about 50 nt, which were terminated with *Bam*H I and *Xba* I: a 5' TCTAGAGATATATAAACTGATGAGTCCGTGAGGACGAA ACAAGTG GATCC 3', b 5' GGATC CACTTGT TTC GTCCTCACGGACTCATCAG TTTATATATC TCTAGA 3'. All cDNAs were synthesized by Shanghai Sheng Gong Company. The ribozyme was cloned into the *Bam*H I and *Xba* I sites of the pBSKU6, which was named as U6-RZ596, and digested and sequenced to be correct. Then this recombinant plasmid was used as template to get a fragment including U6 promoter and ribozyme by using PCR. The fragment was subcloned into the *Mlu* I site of the pEGFPC1, which was named as pU6-RZ596, and testified to be correct.

Isolation, cultivation and transfection of primary mouse hepatocytes

Healthy adult mice were spiled via portal vein after being anaesthetized and irrigated with a constant flux at about 9 mL/min. First Hanks solution was used without Ca²⁺ and Mg²⁺, then 0.2 g/L collagenase solution for 8 min^[11,12]. At last liver tissues were lacerated bluntly and digested vibrantly for 15 min in 37 °C bath water, and filtrated through nylon net and washed with PBS twice. Cells were resuspended in RPMI 1640 supplemented with 100 mL/L FBS and counted. Cell viability was 90-92%. Cell count was adjusted to 2 \times 10⁶/mL and cells were cultured in a humidified 50 mL/L CO₂ atmosphere at 37 °C. Cells were collected and grouped as following: empty control; cells transfected with pEGFPC1; cells transfected with pU6-RZ596. Transfection was performed according to the instructions of Effectene reagent. Cells were cultured for 48 h, the stably transfected cells were selected by culturing in medium containing G418 (600 μ g/mL).

Detection of Fas mRNA expressed in hepatocytes by using RT-PCR

Total RNA was extracted from all above-mentioned groups by using TriZol reagent. After cDNA was synthesized, PCR reaction was performed, β -actin was used as control. The employed primers were as follows: Fas sense primer 5'-GCTGCAGACATGCTGTGGATC-3' and anti-sense primer 5'-TCACAGCCAGGA GAATCGCAG-3', β -actin sense primer 5'-GACGATGATATTGCCGACT-3' and anti-sense primer 5'-GATACCACGCTTGTCTGAG-3'. Reaction conditions for PCR were: pre-denaturation for 3 min at 95 °C, 30 cycles of denaturation for 30 s at 95 °C, annealing for 45 s at 58 °C, extension for 45 s at 72 °C, and extension for 3 min at 72 °C. PCR products were run on 15 g/L agarose gel.

Detection of Fas protein expressed in hepatocytes by western blot

Three groups of cells were collected regularly and lysed in soluble buffer, then the proteins were measured as 0.4 μ g/ μ L, and electrophoresed in 100 g/L SDS-polyacrylamide minigels. The first antibody was rabbit anti-mouse-Fas antibody (1:200). The second antibody was goat anti-rabbit-IgG (1:5 000). At last the color was developed by ECL system.

Detection of caspase-3 protease activity

Treated with JO₂ (5 μ g/mL) for 24 h under common growth condition, apoptosis of three-groups of cells were induced. Meanwhile the negative control without apoptosis and apoptosis cells treated with caspase-3 inhibitor (DEVD-fmk) were established. After being collected, cells were treated with cell lysis buffer sufficiently. The supernatant was retained (including protein needed), and then the procedure was performed according to the instructions of caspase-3 activity detection kit. The optical density (A) was measured at 405 nm.

Detection of cell viability via MTT assay

Grouped and treated as above, cells were inoculated into 96-well plates at a concentration about 10⁵/mL (100 μ L/well). After incubation with 10 μ L MTT(0.5 mg/mL) for 4 h at 37 °C, the formazan crystals were dissolved in 100 μ L DMSO, then the A was measured at 570 nm.

Detection of apoptosis through FACS

Three groups of cells treated with anti-Fas antibody JO₂ and the empty control were conjugated with Annexin V-FITC and PI respectively. Cell apoptosis was analyzed by flow cytometry.

RESULTS

Effects of ribozyme on Fas expression

Fas and β -actin PCR amplification generated amplicons of 419 bp and 186 bp respectively. Through scanning the luminescence, the ratio of Fas/ β -actin was analyzed by using gel image analysis system. The negative control was 1.1; mouse hepatocytes transfected with pEGFPC1 was 0.98; hepatocytes transfected with pU6-RZ596 was 0.43. It was clear that Fas mRNA expression in cells transfected with anti-Fas ribozyme was lower than that in control and cells transfected with empty vector (Figure 1).

Western blotting displayed Fas protein expressed in cells transfected with pU6-RZ596 was much lower than that expressed in control and cells transfected with pEGFPC1, which was consistent with the results of RT-PCR (Figure 2).

Effect of anti-Fas ribozyme on caspase-3 activity

After 24 h of stimulation with JO₂, caspase-3 activity of mouse hepatocytes was specifically inhibited by a caspase-3 inhibitor. Compared with negative control, caspase-3 activities of other groups transfected with pEGFPC1 and pU6-RZ596 were 95% and 45% respectively (Figure 3).

Effect of anti-Fas ribozyme on cell viability

After induction of apoptosis of mouse hepatocytes through stimulation with JO₂, cell viability was detected by MTT assay. Compared with negative control, cell viabilities of other groups transfected with pEGFPC1 and pU6-RZ596 were 98% and 208% respectively (Figure 4).

Inhibition of Fas-mediated apoptosis in mouse hepatocytes

Cell apoptosis was induced as the method mentioned above. Apoptosis rates of cells in control, mock-transfected and pU6-RZ596-transfected groups were 86%, 87% and 35%, respectively (Figure 5).

Figure 4 Stimulated with JO₂ for 24 h, cells viabilities of control, mock-transfected and pU6-RZ596-transfected groups were detected by MTT assay.

Figure 5 Detection of apoptosis of hepatocytes through cytometry. A: Apoptosis rate of control group was 86%; B: Apoptosis rate of mock-transfected cells was 87%; C: Apoptosis rate of pU6-RZ596-transfected cells was 35%.

DISCUSSION

Usually in clinic the hepatocytes of patients with acute or chronic liver failure show denaturation, necrosis and function failure. Existing pathogenic therapy and usual allopathy can not compensate functions of hepatocytes^[12,13]. Now, the most efficient way is liver transplantation, but grafts survival is one of the important factors to affect whether liver transplantation is successful.

Primary mouse hepatocytes were isolated through two-step irrigation method^[14], in which Fas expression was detected by RT-PCR and Western blotting. Treated with anti-Fas antibody JO₂, apoptosis of hepatocytes was induced with decreased viability. So hammerhead ribozyme targeting directly at 596 GUA triplets of Fas mRNA was constructed to efficiently block out Fas gene and decrease apoptosis of hepatocytes. As an RNA molecule with catalysis function^[15], ribozyme can bind and cleave target RNA to inhibit gene expression. Hammerhead ribozyme is widely used in gene therapy because of its many superiorities^[16], including small molecule weight, easy to design and synthesis, *etc.* Anti-Fas ribozyme was transfected into mouse hepatocytes by using Effectene reagent, then the stable clone was selected to investigate the inhibition action of ribozyme on Fas-mediated apoptosis. Results displayed that expression of Fas mRNA and protein in cells transfected with anti-Fas ribozyme was remarkably lower than that in control and mock-transfected cells. After stimulation with apoptosis inducer JO₂ (imitating the role of FasL *in vivo*) for 24 h, apoptosis rate of cells transfected with anti-Fas ribozyme was obviously lower than that of negative control and mock-transfected cells. Accordingly, caspase-3 activity of ribozyme-transfected cells was much lower than that of other groups, but cell viability was higher than the other two groups.

Apoptosis activates a series of proteases to induce programmed death of target cells through two ways including death receptor way and mitochondria way^[17,18]. The final effect of the two ways is activity of caspase-3, that is to say caspase-3 is the common channel of two apoptosis ways^[19]. Therefore, caspase-3 activity was increased in apoptosis and correlated with apoptosis rate positively. Anti-Fas ribozyme could not only decrease Fas expression but also weaken caspase-3 activity to reduce apoptosis induced by anti-Fas antibody. It is clear that hammerhead ribozyme targeting at 596 site of Fas RNA in this research can efficiently cleave Fas mRNA, which decreases not only the Fas expression but also its function. In existence of factors inducing apoptosis, ability of hepatocytes transfected with ribozyme against apoptosis was enhanced and cell viability was increased, which was coincident with study results of Dagmer about primary mouse islet β cells and insulinoma cells^[20,21].

In short, anti-Fas ribozyme not only prevents Fas expression in mouse hepatocytes but also inhibits Fas-mediated apoptosis to improve cell survival after being transfected into hepatocytes, which afford strong assurance for successful liver transplantation. Further research should be focused on clinical application of anti-Fas ribozyme and selection of more efficient, highly specific and low toxic vectors^[22-24].

Abstract

AIM: To develop a novel process for production of HAV in Vero cells grown on microcarriers in a bioreactor.

METHODS: Vero cells infected with HAV strain W were seeded at an initial density of 1×10^5 cells/mL into a 7-L bioreactor containing Cytodex-I microcarriers. During the stage of cell proliferation, the following conditions were applied: pH 7.2 ± 0.2 , temperature 37 ± 0.2 °C, dissolved oxygen 40% of air saturation and agitation rate 40 r/min. After the stage of virus culture started, the culture conditions were altered to pH 7.2 ± 0.2 , temperature 35 ± 0.2 °C, dissolved oxygen 25% of air saturation, agitation rate 50 r/min and perfusion of fresh medium at a flux of 20 mL/h. During the course of fermentation, cell density, HAV antigen titre, glucose, lactate and ammonia levels were monitored. A control experiment using conventional static culture was conducted in the T150 flask.

RESULTS: After a 28-d cultivation, cell density increased to 14.0×10^5 cells/mL in the bioreactor, 5.6×10^9 viable cells and 4 000 mL virus suspension with a titre of 1:64 were harvested. The viral antigen output per cell unit in the bioreactor was 3-fold higher than that in the T150 flask. Meanwhile the metabolic mode of Vero cells did not change after the infection with HAV strain W.

CONCLUSION: The process for production of HAV in Vero cells grown on microcarriers in a bioreactor is a novel, efficient and practical way to obtain virus antigen for vaccine purpose. This approach produces more cells and HAV antigen than the conventional static culture. With further improvement, it is possible to be used for the production of hepatitis A vaccine.

INTRODUCTION

Hepatitis A continues to be one of the most frequently reported infectious diseases with a worldwide distribution, and the

continued occurrence of extensive community wide outbreaks indicates that hepatitis A remains a major public health problem. The availability of hepatitis A vaccine provides the opportunity to substantially lower disease incidence and potentially eliminate infection^[1,2]. Several inactivated and live-attenuated hepatitis A vaccines have been developed. Due to the high protective efficacy, immunogenicity and safety, the inactivated vaccines are more favored^[3-6]. At present several inactivated hepatitis A vaccines such as HAVRIX[®], VAQTA[®], AVAXIM[®] and EPAXAL[®] are commercially available^[7-9]. Inactivated hepatitis A vaccine is prepared by methods similar to those used for inactivated poliovirus vaccines. Cell-culture-adapted virus is propagated in human fibroblast cells, usually in MRC-5 cells, purified from cell lysates by ultrafiltration and exclusion gel chromatography or other methods, inactivated with formalin, and absorbed to an aluminum hydroxide adjuvant. Compared with the production of live- attenuated vaccines, much larger quantities of HAV antigen are required for the production of inactivated vaccines. Thus the production of inactivated hepatitis A vaccines is usually hampered by the difficulty of preparation of large amounts of virus antigens in the conventional static flask or roller bottle cultures. The technique of microcarrier cell culture was first developed in the late 1960 s and has been used successfully for the production of rabies and poliomyelitis vaccines. One definite advantage of microcarrier cell culture is the ability to offer a high product output, which may help to solve the shortage of virus antigens for production of inactivated hepatitis A vaccines^[10-13].

As mentioned above, most hepatitis A vaccines are commonly prepared by cultivation of HAV in human fibroblast cells including MRC-5 cells. No vaccine is produced by microcarrier technology due to the unsuitability of growth for MRC-5 cells on microcarriers. For HAV production in a microcarrier system it is necessary to establish suitable cells on microcarriers. Vero cells can grow well on microcarriers. But HAV is very difficult to adapt to grow in Vero cells. There are few reports about the isolation and adaptation of HAV in Vero cells. Until recently, no report about the production of hepatitis A vaccines in Vero cells grown on microcarriers in bioreactor is available. To verify the feasibility of this approach, HAV strain W was isolated and adapted in Vero cells in our previous work. This study described the production of HAV strain W in Vero cells grown on Cytodex-I microcarriers in a 7-L bioreactor.

MATERIALS AND METHODS

Bioreactor

A 7-L cell bioreactor (Applikon. Co., Holland) was used. Its work volume is 4 L. The value of dissolved oxygen was regulated by importing air mixture with different ratios of O₂, N₂, CO₂ and air. The value of pH was controlled by addition of NaHCO₃.

Microcarrier

Cytodex-I microcarrier (Pharmacia Fine Chemicals, Uppsala, Sweden) was used.

Medium

Cells were grown in minimum essential medium (MEM; Gibco, Glasgow, UK) supplemented with 100 U/mL penicillin, 10 mmol/L

of glucose, 5 mmol/L of glutamine and 100 mL/L bovine calf serum. In both virus culture medium and the feeding medium, bovine calf serum was reduced to 2 %.

Cell line and virus

Vero cell line was obtained from ATCC and preserved at our laboratory. Vero cells were used between passages 142 and 146 in this study. HAV strain W was isolated and adapted in Vero cells at our laboratory. The antigen titre of HAV used for inoculation was 1:128.

Virus adsorption

Vero cells were seeded into the T150 flasks at the concentration allowing for the formation of a confluent monolayer in 4-5 d. The monolayer cells were trypsinized and collected to make cell suspension in a Bellco agitation bottle. The cell suspension was inoculated with HAV strain W and incubated at 35 °C with a stirring of 30 rpm for 6 h.

Bioreactor culture

Bioreactor culture was divided into two stages including cell proliferation and virus culture. Infected Vero cells were seeded into the 7-L bioreactor at an initial density of 1×10^5 cells/mL. During the stage of cell proliferation, the following conditions were applied: pH 7.2 ± 0.2 , temperature 37 ± 0.2 °C, dissolved oxygen 40% of air saturation and agitation rate 40 r/min. After the cell density reached to 1×10^6 cells/mL, stage of virus culture started and the used medium was replaced with maintenance medium. The culture conditions were altered to: pH 7.2 ± 0.2 , temperature 35 ± 0.2 °C, dissolved oxygen 25% of air saturation and agitation rate 50 r/min. Meanwhile, perfusion was started and the perfusion rate was modulated to 20 mL/h. After a 28-d culture, infected cells were trypsinized and collected for the harvest of HAV antigen.

In a further study, M199 medium was used instead of MEM during virus culture. A circulating equipment was used to increase the dissolved oxygen in the feeding medium.

Conventional static culture

Infected Vero cells were seeded at an initial density of 1×10^5 cells/mL into the T150 flask containing 150 mL MEM medium. The cultures were incubated at 35 °C and the medium was replaced each week. After a 28-d culture, infected cells were trypsinized and collected for the harvest of HAV antigen.

Metabolite analysis

Samples taken from the cultures in the bioreactor were centrifuged at 1 500 r/min for 10 min. The supernatants were stored at -20 °C until tested. Glucose, ammonia and lactate concentrations were monitored by enzymatic assays, using specific assay kits (16-UV, 171-UV and 826-UV for glucose, ammonia and lactate respectively; Sigma, St. Louis, USA).

HAV antigen titre assay

Harvested cells were applied to three cycles of freezing and thawing following ultrasonication. After centrifugation at 1 500 r/min for 10 min, HAV antigen titre in the supernatant was determined by ELISA.

RESULTS

Growth and metabolism of infected Vero cells in bioreactor

Seventy-eight hours after the seeding, infected Vero cell density increased from 1×10^5 cells/mL to 11.17×10^5 cells/mL. At this point, the mode of bioreactor culture was switched from cell proliferation to virus culture. During the stage of virus culture, the cell density was kept above 1×10^6 cells/mL, reaching a maximum

of 15.60×10^5 cells/mL at 402 h. It achieved 14.0×10^5 cells/mL at the end of virus culture, indicating a 14-fold increase over the initial cell density. The initial concentration of glucose was 7.8 mmol/L at the beginning of cell proliferation stage. As the cell density increased, the concentration declined. The rate of declination gradually became slow as a result of the feeding of fresh medium. The residual glucose concentration was 0.63 mmol/L at the end of virus culture. The initial concentrations of lactate and ammonia were 1.27 mmol/L and 0.18 mmol/L respectively at the beginning of cell proliferation and increased along with the increasing of cell density. The lactate level increased from 3.87 mmol/L to 12.68 mmol/L and ammonia level from 1.19 mmol/L to 2.68 mmol/L during the stage of virus culture. The rate of accumulation also became slow due to the feeding of fresh medium at the end of virus culture. Figure 1 shows the variations of cell density, glucose, lactate, and ammonia levels.

Figure 1 Growth and metabolism curves of Vero cells infected with HAV strain W. (●) Viable cell density (10^5 cells/mL), (□) Glucose (mmol/L), (■) Lactate (mmol/L), (○) Ammonia (mmol/L).

Figure 2 Production of HAV antigens by Vero cells grown on Cytodex-I microcarriers in a 7-litre bioreactor. (■) Viable cell density (10^5 cells/mL), (□) HAV antigen titre (1:).

Virus culture in bioreactor

No HAV antigen was detected during the stage of cell proliferation and at the early stage of virus culture. At 160 h, HAV antigen was first detected with a titre of 1:8 and achieved a maximum of 1:64 at 570 h (Figure 2). Four thousand millilitres of virus suspension with a titre of 1:64 was obtained at the end of virus culture.

Cell and antigen yields in flask

After a 28-d cultivation, 4×10^7 viable cells and 5 mL virus suspension with a titre of 1:128 were obtained from a T150 flask.

Improvement of virus culture in bioreactor

MEM medium was replaced by M199 medium, which contained richer nutrients and was more suitable for virus growth in cells. A circulating equipment was added to increase the dissolved oxygen in the feeding medium. With these

modifications, antigen titre achieved 1:128 in the harvested suspension.

DISCUSSION

In this study the growth kinetics and metabolic properties of Vero cells infected with HAV strain W were investigated. The results were similar to those of uninfected Vero cells in our previous work (Data not shown) and other studies^[14,15]. This indicated that the metabolic mode of Vero cells did not change after infection with HAV strain W.

The yield of viable cells was 5.6×10^9 in the bioreactor whereas 4×10^7 in the T150 flask. The former was 140-fold higher than the latter. The yield of HAV antigens was 4 000 mL with a titre of 1:64 in the bioreactor and equaled to the yield from 400 T150 flasks. Furthermore, per 10^5 cells produced 1 mL HAV antigens with a titre of 1:4.57 in a bioreactor compared with only a titre of 1:1.6 in the T150 flask, that is the antigen output per cell unit in the bioreactor was 3-fold higher than that in the T150 flask. The findings mentioned above demonstrated this process for the production of HAV in Vero cells grown on microcarriers in a bioreactor could provide much higher yields of viable cells and virus antigens than that in conventional static culture. The antigen output per cell unit was also apparently higher. The technique of microcarrier culture in a bioreactor could offer numerous advantages over traditional techniques, such as a high ratio of surface area to volume, an efficient monitoring and control of key process parameters including temperature, pH and dissolved oxygen. Moreover, the culture substrate conditions could be controlled exactly and regulated in batch or fed-batch operation. The optimal metabolism and physiological status of cells could be achieved through the feeding of fresh medium and removal of toxic metabolites. Thus a high cell density and product output rate could be easily achieved^[15-18].

In conclusion, the process for production of HAV in Vero cells grown on microcarriers in a bioreactor is a novel, efficient and practical way to obtain virus antigens for vaccine purpose. This approach produces more cells and HAV antigens than the conventional static culture. The optimal growth conditions for Vero cells and HAV strain W in a bioreactor are being further investigated to enhance the yield of virus antigens.

Abstract

AIM: To examine the expressions of matrix metalloproteinases-2 (MMP-2) and tissue inhibitor of metalloproteinases-1 (TIMP-1) in rat fibrotic liver and in normal rat hepatic stellate cells, and to investigate the changes in their expressions in response to treatment with interleukin-10 (IL-10) and platelet-derived growth factor (PDGF).

METHODS: Rat models of CCl₄-induced hepatic fibrosis were established and the liver tissues were sampled from the rats with or without IL-10 treatment, and also from the control rats. The expressions of MMP-2 and TIMP-1 in liver tissues were detected by S-P immunohistochemistry, and their expression intensities were evaluated in different groups. Hepatic stellate cells (HSCs) were isolated from normal rat and cultured *in vitro* prior to exposure to PDGF treatment or co-treatment with IL-10 and PDGF. MMP-2 and TIMP-1 levels were measured by semi-quantitative reverse transcriptional polymerase chain reaction (RT-PCR).

RESULTS: CCl₄-induced rat hepatic fibrosis models were successfully established. The positive expressions of MMP-2 and TIMP-1 increased obviously with the development of hepatic fibrosis, especially in untreated model group (84.0% and 92.0%, $P < 0.01$). The positive signals decreased significantly following IL-10 treatment (39.3% and 71.4%, $P < 0.01$ and $P < 0.05$) in a time-dependent manner. TIMP-1 mRNA in PDGF-treated group was significantly increased time-dependently in comparison with that of the control group, but PDGF did not obviously affect MMP-2 expression. No difference was noted in TIMP-1 and MMP-2 expressions in HSCs after IL-10 and PDGF treatment ($P > 0.05$).

CONCLUSION: MMP-2 and TIMP-1 expressions increase in liver tissues with the development of fibrosis, which can be inhibited by exogenous IL-10 inhibitor. PDGF induces the up-regulation of TIMP-1 but not MMP-2 in the HSCs. IL-10 inhibits TIMP-1 and MMP-2 expressions in HSCs induced by PDGF.

INTRODUCTION

Liver fibrosis and its end-stage sequelae cirrhosis represent a major worldwide health problem. By definition progressive fibrosis occurs when the rate of matrix synthesis exceeds matrix degradation^[1]. Considerable evidence suggests that the hepatic stellate cells (HSCs) are central to the fibrotic process. HSCs are normally located in the perisinusoidal space as quiescent vitamin A-storing cells secreting low levels of extracellular matrix (ECM). Following liver injury, increased synthesis of extracellular matrix constituents occurs in combination with other phenotypic changes (also called activation) of HSCs into myofibroblast-like cells. It has been demonstrated by the analysis of freshly isolated HSCs that a number of these phenotypic changes take place, including increased expression of extracellular matrix constituents and the expression of α -SMA^[2,3]. This activated phenotype of HSCs subsequently becomes the major source of the interstitial collagens^[4-6]. It has been suggested that HSCs are also a source of matrix-degrading metalloproteinases (MMPs), indicating their participation in matrix remodeling^[7-9]. As a family of neutral proteinases, MMPs act on a variety of substrates^[10]. Different expression profiles of MMPs influence the outcome of ECM components, resulting in preferential accumulation of interstitial collagens, type I in particular, in the fibrotic liver. MMPs are tightly regulated at the levels of transcription, secretion, and proteolytic activation, and their activities are governed by tissue-derived inhibitors^[11]. The expression of tissue inhibitors of MMPs (TIMP) has also been demonstrated in human fibrotic liver disease and animal models of liver fibrosis^[12]. At present, 4 TIMPs have been characterized^[13], all being low-molecular-weight proteins sharing structural similarities. Individual members of the TIMP family display selective affinities for different members of the MMP family^[14]. TIMP-1 controls mostly the activity of MMP, particularly MMP-1, whereas TIMP-2 is the major inhibitor of MMP-2^[15]. MMP/TIMP balance is thought to play a pivotal role in the development of liver fibrosis, but their direct interaction *in vivo* has not yet been clarified. In the present study, the expressions of MMP-2 and TIMP-1 in rat fibrotic liver and in HSCs were examined and their changes were investigated in the presence of interleukin (IL)-10 and PDGF.

MATERIALS AND METHODS

Materials

One hundred clean male Sprague-Dawley rats weighing 140-180 g

(provided by Shanghai Experimental Animal Center) were divided randomly into control group ($n = 24$), model group ($n = 40$) and IL-10 treatment group ($n = 36$). All the rats were bred under routine condition (room temperature of 22 ± 2 °C, humidity of $55 \pm 5\%$, with light/dark alternating every 12 h and free access to water and food. The feed was provided by BK Company in Shanghai, China).

Preparation of rats

Rats in control group were given intraperitoneal injection with saline at 2 mL/kg twice a week, and those in model and IL-10 treatment groups received intraperitoneal injection with 500 mL/L CCl_4 (dissolved in castor oil) at 2 mL/kg twice a week. From the third week, rats in treatment group were given intraperitoneal injection with IL-10 at 4 $\mu\text{g/kg}$ (dissolved in saline) 20 min prior to CCl_4 injection. All injections were performed on Mondays and Thursdays after measurement of the rats' body weight. In the 5th wk, 3 rats in model group and 2 in treatment group died; in the 7th wk, 8 and 4 rats in these two groups died, respectively, and in the 9th week, another 10 and 6 died. At this time point, 3 rats in control group also died. In the 5th, 7th and 9th wk, 7 to 10 rats in each group were sacrificed to collect their liver samples, which were fixed in 40 g/L formaldehyde and embedded with paraffin.

Immunohistochemistry

Rat liver tissues were sectioned at the thickness of 4 μm . After deparaffinization with xylene and dehydration with graded ethanol, the sections were incubated in PBS containing 30 mL/L H_2O_2 to remove endogenous peroxidases and then in PBS containing 0.1 mol/L citrate to saturate the nonspecific binding sites. After incubation with goat anti-rat MMP-2 and TIMP-1 monoclonal antibodies, the sections were treated with instant S-P immunohistochemical reagents (American Zymed Company) and then incubated in a buffer solution containing 3,3-diaminobenzidine tetrahydrochloride (DAB) and H_2O_2 for visualization, followed by dehydration and mounting procedures. Microscopic examination of the sections was then performed.

Result assessment

Reactions were graded and scored according to their intensities and percentage of the positive cells respectively as follows: Zero score for negative reaction, 1 score for pale yellowish staining, and 2 scores for dense yellow or brown staining; 0 score for a percentage of positive cells below 5%, 1 score for one between 6% and 25%, 2 scores for one between 26% and 50%, and 3 for one over 50%. The eventual score of the section was derived from the product of the 2 scores for staining intensity and positive cell percentage, and graded as negative (-) result for a score lower than 1, positive result (+) for one between 2 and 3, and strong positive result (++) for one over 4. Redit analysis was utilized to assess the difference between the groups.

Hepatic stellate cells isolation and culture

Male Sprague-Dawley rats weighing 450-500 g were used for isolation of HSCs. Rat liver nonparenchymal cells were isolated by means of sequential perfusion with collagenase and pronase E as described previously^[16]. Buoyant HSCs were separated from the resulted cell suspension by elutriation over a Nycodenz gradient centrifugation. Desmin immunocytochemistry demonstrated a purity of isolated HSCs over 95%. The HSCs were then seeded into plastic tissue culture flask at the density of $1 \times 10^6/\text{mL}$ in DMEM containing 100 mL/L fetal calf serum (FCS), and incubated at 37 °C with 50 mL/L CO_2 . The culture medium was replaced 24 h after plating and every 48-72 h thereafter. The subsequent passages of HSCs were diluted to

$5 \times 10^4/\text{mL}$ before seeded into 50 mL culture flask containing DMEM medium supplemented with FCS.

PDGF treatment of HSCs

The cultured HSCs were divided into 6 groups: the first and sixth groups serving as control were cultured in 3 mL DMEM medium for 2 and 24 h, respectively, with the second, third, fourth and fifth groups cultured in 3 mL DMEM medium in the presence of 20 ng/mL PDGF for 2, 4, 8 and 24 h, respectively. The cells were then harvested for reverse transcriptional-PCR (RT-PCR).

Co-treatment of HSCs with IL-10 and PDGF

Cultured HSCs were divided into 8 groups: the first and second groups (blank control) were cultured in 3 mL DMEM medium for 2 and 24 h, respectively, and the third, fifth and seventh groups (negative control) cultured in 3 mL DMEM medium containing 20 ng/mL PDGF for 2, 12 and 24 h, respectively, while the fourth, sixth and eighth groups were cultured in 3 mL DMEM medium containing both 20 ng/mL IL-10 and 20 ng/mL PDGF for 2, 12 h and 24 h, respectively. The cells were then harvested for RT-PCR.

RT-PCR for MMP-2 and TIMP-1

Total RNA was isolated from HSCs using Gentra reagent (USA) according to the protocol provided by the manufacturer. The A_{260}/A_{280} of total RNA ranged between 1.8 and 2.0. After treatment with Dnase-I (1-2 μg), total RNA was reversely transcribed into complementary DNA (cDNA) with oligo (dT) using cDNA synthesis kit, and 2 μL cDNA product was then used as the template to amplify specific fragments in a 25 μL reaction system. PCRs using *Taq* polymerase reaction were carried out with an initial denaturation at 95 °C for 5 min, followed by 25 cycles at 94 °C for 45 s, annealing at 60 °C for 30 s, at 72 °C for 60 s, with a final extension at 72 °C for 7 min. The primer sequences used for MMP-2 were 5'-GTGCTGAAGGACACCCTCAAGAAGA-3' (sense) and 5'-TTGCCGTCCTTCTCAAAGTTGTACG-3' (antisense), and those for TIMP-1 were 5'-GCCATGGAGAGCCTCTGTGG-3' (sense) and 5'-GCAGGCAGGCAAAGTGATCG-3' (antisense); the primers for β -actin as the internal control were 5'-GAGCTATGAGCTGCCTGACG-3' (sense) and 5'-AGCACTTGCGGTCCACGATG-3' (antisense).

Electrophoresis and semi-quantitative analysis

PCR products underwent 2% agarose gel electrophoresis and were visualized with ethidium bromide. The expected products' sizes were 604 bp for MMP-2, 310 bp for TIMP-1 and 410 bp for β -actin. Bio Imagine System was applied to detect the density of the bands of PCR products. The expression levels of MMP-2 and TIMP-1 were calculated by the ratio of their band densities of PCR products to that of β -actin. Semi-quantitative detection was repeated for 5 times. SPSS 10.0 software was used to analyze the difference between the groups.

RESULTS

MMP-2 and TIMP-1 expressions in liver tissues

The positive rate of MMP-2 in control group, model group and IL-10 treatment group was 9.5%, 84.0% and 39.3%, respectively, and that of TIMP-1 was 23.8%, 92.0% and 71.4%, respectively. The granular positive products were localized in the cytoplasm of hepatocytes and biliary epithelial cells. In control group, the positive expressions of MMP-2 and TIMP-1 were weak and found mainly in endothelial cells and hepatic cells. In model group, positive expressions increased obviously with the development of hepatic fibrosis, distributing in biliary epithelial cells, fibroblasts and muscular cells. In treatment group the

Intensities of MMP-2 and TIMP-1 immunoreactivities

Comparison of MMP-2 and TIMP-1 positive expression levels between the 3 groups is shown in Table 1. Redit analysis showed significant difference between the 3 groups ($P<0.01$). Higher expression levels of MMP-2 and TIMP-1 in model group were detected than in control group ($P<0.01$). In treatment group, IL-10 treatment resulted in decreased immunoreactivities for MMP-2 and TIMP-1 ($P<0.01$ and $P<0.05$ respectively). The expression levels of MMP-2 and TIMP-1 in different phases of hepatic fibrosis are listed in Table 2. With the development of hepatic fibrosis, the intensities of MMP-2 and TIMP-1 immunoreactivities increased gradually, and the difference was

significant ($P < 0.05$).

Relative quantities of MMP-2 and TIMP-1 mRNA in HSCs

Expression of TIMP-1 in PDGF-treated HSCs was significantly increased time-dependently as compared with that in control cells ($P < 0.01$). There was no difference in MMP-2 expression between PDGF-treated HSCs and control cells (Figure 5). After treatment with IL-10 and PDGF, expressions of TIMP-1 and MMP-2 in HSCs were similar to those in negative control groups ($P > 0.05$), without changes over time (Figure 6).

DISCUSSION

Liver fibrosis is thought to be a progressive pathological process that leads ultimately to deposition of excess matrix proteins in extracellular space^[17], and destroys normal liver architecture to finally result in cirrhosis. In extracellular space, matrix degradation occurs predominantly consequent to the action of a family of enzymes known as matrix metalloproteinases^[18]. These enzymes are secreted by cells into extracellular space as proenzymes, which are then activated by a number of specific mechanisms. MMP-2 (gelatinase A) produced by activated HSCs, as demonstrated by immunohistochemistry and *in situ* hybridization^[19,20], plays an important role in remodeling the basement membranes as it degrades several of the collagen components including collagen IV, laminin and fibronectin^[21]. In other tissues, such as lung, kidney and heart, MMP-2 expression is also increased during fibrogenesis^[22-25]. Recent studies showed that inhibition of MMP-2 activity^[26] or blockade of MMP-2 synthesis^[21] might effectively prevent mesangial cell proliferation and collagen I synthesis *in vitro*, indicating the possible role of MMP-2 as a growth factor and activator for mesangial cells, performed probably through an autocrine pathway^[27]. In human liver fibrosis or in rat models of CCl₄-induced liver fibrosis, the expression of MMP-2 mRNA was increased by several fold, and HSCs expressed MMP-2 when activated by *in vitro* culture^[27,28], as is consistent with our findings in this study.

TIMPs are the most important family of molecules involved in regulation of extracellular MMP activity^[29-32]. TIMPs are produced by a wide variety of cells and often cosecreted with MMPs, providing local autoregulation of MMP activity. Recognized now as a multifunctional protein, TIMP-1 has been reported to stimulate steroidogenesis, inhibit angiogenesis, and induce changes in cell morphology^[11,33]. It has been shown that TIMP-1, but not TIMP-2, can enter the nuclei of several types of cells, which further suggests that TIMP-1 may also act as a transcription factor^[34,35]. We found that during the development of liver fibrosis, TIMP-1 expression in the liver was markedly up-regulated. Increased serum TIMP-1 levels

have been documented in patients with chronic active liver disease in correlation with histological degree of human liver fibrosis^[36]. Liver TIMP-1 protein levels are also closely correlated with the histological degree of liver fibrosis. The above findings suggest that TIMP-1 plays an important role in the development of liver fibrosis^[12,30,37]. Recent findings indicate that HOE077, a prolyl-4-hydroxylase inhibitor, may prevent fibrosis by inhibiting the expression of liver type I procollagen and TIMP-1 mRNAs as well as proline hydroxylation and stellate cell activation, resulting in reduced expression of procollagen and TIMP-1 mRNAs^[38]. Experiments with liver-targeted TIMP-1 transgenic (TIMP-Tg) mouse have shown significantly attenuated ability of reversing spontaneous liver fibrosis in TIMP-Tg mice as compared with the control mice^[39]. But the exact role of TIMP-1 in liver fibrogenesis has not yet been clarified. In another experiment with TIMP-Tg mice, the direct effect of TIMP-1 overexpression on CCl₄-induced liver fibrosis was examined, it was found that TIMP-1 did not induce liver fibrosis by itself, but strongly promoted liver fibrosis development, in other words, TIMP-1 behaved not as the initiation factor, but as a strong promoter of liver fibrosis^[40].

PDGF is a major mitogen for connective tissue cells and some other cell types. This dimeric molecule consists of disulfide-bonded, structurally similar A- and B-polypeptide chains that combine to form homo- and hetero-dimers, and is involved in autocrine and paracrine stimulation of cell growth in several different pathological conditions. Evidence showed that recombinant PDGF stimulated proliferation of nonconfluent myofibroblasts and collagen production in confluent cultures of myofibroblasts without increasing cell number, demonstrating the importance of PDGF in pathogenesis of liver fibrosis^[41-45]. It has been established that human and rat HSCs are able to migrate according to the concentration gradients of chemotactic factors^[46-48]. The best characterized chemotactic factor for HSCs identified so far is PDGF-BB^[46,47,49], known also as the most potent mitogen for HSCs and overexpression during active hepatic fibrogenesis^[50]. Our findings in this study showed that after PDGF treatment, the expression of TIMP-1 increased significantly in HSCs possibly because PDGF-promoted HSC proliferation and activation, indicating the importance of PDGF in pathogenesis of liver fibrosis. We also found that the expression of MMP-2 did not increase in HSCs after PDGF treatment, which is suggestive of the irrelevance of MMP-2 in fibrogenesis induced by PDGF.

IL-10, originally isolated from mouse helper T cells, is a cytokine that regulates a number of interleukins. It inhibits synthesis of several cytokines by T lymphocytes and activates monocytes, and was therefore originally named cytokine synthesis inhibitory factor^[51]. Recent studies showed that IL-10 also acted on connective tissue cells such as fibroblasts, inducing, for instance, transcriptional inhibition of the expression of type I collagen, which is the major component of extracellular matrix^[52]. IL-10 also possesses antifibrogenic properties by down-regulating profibrogenic cytokines like TGF-β₁ and TNF-α^[53,54]. Our previous studies indicated that IL-10 could produce antifibrogenesis effect on CCl₄-induced rat hepatic fibrosis. In this study, we found that IL-10 down-regulated expression of MMP-2 and TIMP-1 in rat fibrotic liver, possibly another way that IL-10 exerts its effect of antifibrogenesis. In our previous study, PDGF was found to markedly promote the contraction and proliferation of HSCs and expressions of collagen type I and III as well as TGF-β₁ in HSCs, which was significantly inhibited by IL-10^[55]. But results of the present experiment showed that at the dose of 20 ng/mL, IL-10 did not inhibit TIMP-1 and MMP-2 expressions in PDGF-treated HSCs, indicating that the inhibitory effects of IL-10 on HSCs may not involve TIMP-1 and MMP-2.

In summary, the present study demonstrates that positive

expressions of MMP-2 and TIMP-1 in rat liver tissue increase with the development of hepatic fibrosis, and MMP-2 and TIMP-1 play an important role during the development of liver fibrosis. Exogenous IL-10 decreases the expression of MMP-2 and TIMP-1 in liver tissues. PDGF increases the expression of TIMP-1 in HSCs, possibly through promoting HSC proliferation and activation, and this effect is not inhibited by IL-10.

Abstract

AIM: To investigate the protective effect of ischemic preconditioning (IPC) on hepatocellular carcinoma (HCC) patients with cirrhosis undergoing hepatic resection under hepatic inflow occlusion (HIO) and its possible mechanism.

METHODS: Twenty-nine consecutive patients with resectable HCC were randomized into two groups: IPC group: before HIO, IPC with 5 min of ischemia and 5 min of reperfusion was given; control group: no IPC was given. Liver functions, hepatic Caspase-3 activity, and apoptotic cells were compared between these two groups.

RESULTS: On postoperative days (POD) 1, 3 and 7, the aspartate transaminase (AST) and alanine transaminase (ALT) levels in the IPC group were significantly lower than those in the control group ($P < 0.05$). On POD 3 and 7, the total bilirubin level in the IPC group was significantly lower than that in the control group ($P < 0.05$). On POD 1, the albumin level in the IPC group was higher than that in the control group ($P = 0.053$). After 1 h of reperfusion, both hepatic Caspase-3 activity and apoptotic sinusoidal endothelial cells in the IPC group were significantly lower than those in the control group ($P < 0.05$).

CONCLUSION: IPC has a potential protective effect on HCC patients with cirrhosis. Its protective mechanism underlying the suppression of sinusoidal endothelial cell apoptosis is achieved by inhibiting Caspase-3 activity.

INTRODUCTION

Hepatic inflow occlusion (HIO), also called Pringle's maneuver^[1], is an effective and simple technique to control blood loss from the raw surface during hepatic parenchymal transaction, and

has been widely used during hepatectomy. However, HIO could also result in hepatic ischemic-reperfusion (I/R) injury, especially in case of cirrhosis. It is generally accepted that cirrhotic liver is particularly sensitive to ischemia. Although warm ischemia for cirrhotic liver should not exceed 30 min^[2], prolonged HIO might cause dysfunction of the remnant liver, which was a major risk factor associated with postoperative morbidity and mortality^[3]. Therefore, therapeutic modalities to ameliorate this injury are critically important in liver surgery.

Ischemic preconditioning (IPC), defined as giving a short period of ischemia and reperfusion and subsequently sustaining a prolonged ischemic insult, was first described by Murry *et al.*^[4] in 1986, and then this protective phenomenon was found in various visceral organs including the liver^[5-9].

However, up to now, the data of IPC available were most focused on animal models. Recently, Clavien *et al.*^[10] reported the first clinical trial, suggesting a beneficial effect of IPC during major hepatectomy on patients who were subjected to 30 min of ischemia. But there was no cirrhotic case in Clavien's series. In China and other Asia areas, more than 80% of hepatocellular carcinoma (HCC) patients had underlying cirrhosis or hepatitis due to hepatitis B virus infection^[11]. Whether IPC has the similar protective effect on I/R injury encountered in hepatectomy for cirrhotic liver is unclear. Hence, we conducted this prospective randomized clinical trial on cirrhotic HCC patients to test whether IPC could protect cirrhotic liver against I/R injury during tumor resection under HIO, and to explore its possible protective mechanism.

MATERIALS AND METHODS

Patients

Fifty-six consecutive patients with HCC were treated at the Department of Hepatobiliary Surgery, the First Affiliated Hospital of Sun Yat-Sen University between January 1, 2001 and April 30, 2001. Among them, 29 patients whose tumors were considered to be resectable after preoperative investigations, including liver function tests, liver function reserve (oral glucose tolerance test, OGTT)^[12], abdominal ultrasound, CT assessment and laparotomy, were recruited in this study. The resectable criteria we used were as follows. (1) The general condition of the patients was good and they could tolerate hepatectomy. (2) The tumor did not extend beyond half of the liver and had no distant metastasis. (3) Liver function belonged to Child A or B and liver function reserve was type P₁ or P₂ according to OGTT, which is a test widely used to evaluate liver function reserve^[12]. Briefly, patients were fasted overnight, and the fast blood glucose (FBS) was measured next morning, then 75 g of glucose diluted in pure water was given to the patients orally. One and 2 h after glucose solution was drunk, blood glucose concentration (BGC) was measured respectively. If BGC after 2 h was still higher than that after 1 h, it was the linear type (L type). If BGC after 2 h was between the FBS and that after 1 h, it was the parabolic type 2 (P₂ type). If BGC after 2 h was lower than 7.3 μmol/L, it was parabolic type 1 (P₁ type). P₁ type indicated the best liver function reserve, and patients could tolerate right

or left hepatectomy. P₂ type was moderate, and patients could tolerate segmentectomy or irregular hepatectomy. L type indicated the poor liver function reserve, and patients could only tolerate local tumor resection. The other 27 unresectable cases were excluded.

Then 29 resectable cases were randomized into IPC group ($n = 14$) and control group groups ($n = 15$) by permuted block without stratification. Our previous study indicated that IPC with 5 min of ischemia and 5 min of reperfusion produced the best protection on cirrhotic rat liver I/R model^[13]. Therefore, IPC with these time intervals was applied in these patients. Prior to liver parenchymal transection under HIO, IPC with 5 min of ischemia and 5 min of reperfusion was conducted in the IPC group. No IPC was given prior to liver parenchymal transection performed under HIO in the control group.

This protocol was performed under the consent of patients approved by the Ethical Committee of Sun Yat-sen University.

Procedures and biopsy

General anesthesia was performed. Bilateral subcostal incision was made. A further abdominal exploration was conducted to exclude intra-abdominal metastasis. After mobilization of the liver prior to parenchymal transection, HIO was achieved by clamping the portal pedicles using a tourniquet. Blood inflow was initiated when hemostasis was achieved after removal of the tumor. The procedures available in these patients included irregular hepatectomy, segmentectomy and right/left hepatectomy according to the tumor's location and liver function tests. Liver parenchyma was transected by diathermy and crushing hepatic tissue with an artery forceps. Tubular structures on the raw surface were divided and ligated. All hepatectomies were finished within one time of HIO in our series, and the time of HIO not including the ischemic phase of IPC in the IPC group were recorded. Intraoperative blood loss was accurately calculated from the suction bottles and surgical pads. No cell saver was used in our series. Before HIO and 1 h after reperfusion, a small piece of liver tissue was harvested by wedge resection in remnant liver. The procedures were performed by the same surgical team.

Liver function test

Peripheral blood was sampled before operation and on postoperative days (POD) 1, 3, 7. Aspartate transaminase (AST), alanine transaminase (ALT), total bilirubin (TBIL), albumin (ALB) were measured using an auto biochemical analyzer (HITACHI 7170A, Japan).

Hepatic Caspase-3 activity assay

Caspase-3 activity was quantified by proteolytic cleavage of the fluorogenic substrate 7-amino-4-trifluoro-methylcoumarin-conjugated Asp-Glu-Val-Asp tetrapeptide (AMC-DEVD)^[14]. Briefly, fresh liver tissue (20 mg) was homogenized in a lysis buffer at 4 °C. After 4 times of freezing and thawing, lysates were centrifuged at 15 000 *g* for 10 min, supernatants were collected. Then Caspase-3 activity was measured using a fluorescence spectrophotometer (HITACHI F-3 010, Japan) and a Caspase-3 fluorescent kit (Sigma Co. USA) according to the manufacturer's instructions. Caspase-3 activity was expressed as nmol AMC release per hour per mg liver tissue.

TUNEL assay

Apoptosis was detected by terminal deoxynucleotidyl mediated nick end labeling (TUNEL) assay^[15]. Paraffin-embedded liver tissue was cut into 5- μ m thick sections. After deparaffinized in series of alcohol solutions, a TUNEL kit (Boehringer Mannheim Co. Germany) was used according to the manufacturer's protocols. Five high power fields ($\times 400$) were selected randomly in each specimen, for which apoptotic cells were calculated by a pathologist.

Statistical analysis

Data are expressed as mean \pm SD. Means were compared between these two groups by *t* test (continuous data) or chi-square test (categorical data). *P* value less than 0.05 was considered statistically significant.

RESULTS

Clinical characteristics of these two groups

The clinical characteristics (Table 1) including age, gender, Child's classification, tumor size, operation procedure, operation time, liver ischemic time and blood loss were compared between these two groups, and there was no statistical significance, indicating that the characteristics of the two groups were homogeneous and comparable.

Table 1 clinical characteristics of these two groups

Data	IPC group	control group	<i>P</i> value
Age (yr)	50.4 \pm 10.7	49.5 \pm 10.3	0.605
Gender			0.684
Male	12	12	
Female	2	3	
Child's classification			0.684
Grade A	12	12	
Grade B	2	3	
Grade C	0	0	
OGTT			0.867
P ₁ type	3	4	
P ₂ type	8	9	
L type	4	3	
Cirrhosis ¹			0.316
(+)	13	12	
(-)	1	3	
Tumor size (cm)	7.1 \pm 3.6	7.9 \pm 2.9	0.544
Procedures			0.971
Right/left hepatectomy	2	2	
Segmentectomy	4	4	
Irregular hepatectomy	8	9	
Operation times (min)	191.3 \pm 74.9	208.2 \pm 45.3	0.485
Ischemic times (min)	18.0 \pm 3.6	17.4 \pm 2.3	0.602
(Range)	(15-25)	(13-22)	
Blood loss (mL)	469.2 \pm 292.6	602.0 \pm 310.6	0.257

¹Cirrhosis: (+) refers to macroscopic cirrhosis, which was diagnosed during surgery, (-) refers to that we could not diagnose cirrhosis during surgery by naked eyes, however, it was diagnosed mild cirrhosis and hepatitis by microscopic pathology. The etiology of cirrhosis was hepatitis B virus infection in our series.

IPC protected cirrhotic liver from I/R injury

Serum AST and ALT levels were sensitive parameters to assess the severity of liver injury. As shown in Table 2, on postoperative d 1, 3, 7, the AST and ALT levels in the IPC group were significantly lower than those in the control group ($P < 0.05$). On postoperative d 3, 7, the TBIL levels in the IPC group were also lower than those in the control group ($P < 0.05$). On postoperative d 1, the ALB level in the IPC group was higher than that in the control group, but it did not reach statistical significance. These data suggest that IPC could effectively protect cirrhotic liver from I/R injury. I/R injury could inhibit albumin synthesis, however IPC could ameliorate this albumin-synthesis inhibition.

Table 2 Comparison of liver functions between two groups before and after operation

Date	AST (U/L)		ALT (U/L)		TBIL ($\mu\text{mol/L}$)		ALB (g/L)	
	Control	IPC	Control	IPC	Control	IPC	Control	IPC
Preop	64.7 \pm 39.2	60.1 \pm 55.4	56.7 \pm 53.9	54.8 \pm 45.0	22.6 \pm 13.1	18.9 \pm 7.4	41.2 \pm 5.6	40.6 \pm 3.7

POD 7	85.3 \pm 45.5	56.5 \pm 18.9 ^a	130.1 \pm 49.0	89.9 \pm 42.8 ^a	39.7 \pm 29.3	22.8 \pm 8.0 ^a		

Note: preop = preoperation. ^a $P < 0.05$, vs control (independent t test); ^b $P < 0.01$, vs control (independent t test).

Postoperative mortality, morbidity and hospitalized days

There was no operative and hospital mortality in both groups. The common postoperative morbidity was pleural effusion and liver failure. Pleural effusion was confirmed by chest X-ray. Postoperative liver failure was defined as the total bilirubin was higher than 2 times of its normal level, and massive ascites occurred. Pleural effusion occurred in 2 cases (14.3%) of the IPC group, and in 5 cases (33.3%) of the control group ($P = 0.390$), who needed repeated pleural tapping. No in the IPC group was complicated with liver failure after surgery. However, liver failure occurred in 3 cases of the control group after operation. These 3 patients recovered after conservative treatment. Other postoperative complications including subphrenic collection were found in 2 cases of the control group, who were treated by fine needle aspiration guided by ultrasound. Bile leakage from the transection surface was found in 1 case of the IPC group, who was cured by local drainage. No wound infection occurred in both groups. The mean hospitalized time of the IPC group was 12.8 d, which was significantly shorter than that of the control group (12.8 \pm 3.1 d vs 18.6 \pm 9.1 d, $P = 0.034$).

Figure 1 Comparison of Caspase-3 activity and SEC apoptosis between control group and IPC group ^a $P = 0.047$, vs control, ^c $P = 0.002$, vs control, (t test) (caspase-3 activity unit: nmol AMC · h⁻¹ · mg⁻¹ (tissue)) hpf: high power field.

Effect of IPC on Caspase-3 activity and apoptosis

To investigate the effect of IPC on Caspase-3 activity and apoptosis, 5 cases in each group were selected prospectively, whose hepatic Caspase-3 activity and apoptotic cells were detected respectively. One hour after reperfusion, the hepatic Caspase-3 activity in the IPC group was significantly lower than that in the control group ($P < 0.05$), and subsequently, the apoptotic sinusoidal endothelial cells (SECs) in the IPC group were also less than those in the control group ($P < 0.05$) (Figures 1, 2). Only few hepatocytes underwent apoptosis in the control group in this checking time point (Figure 2). These data indicated that IPC inhibited Caspase-3 activity and subsequently SEC apoptosis in the remnant liver.

DISCUSSION

Hemorrhage is the major lethal factor during hepatic resection. Hemostasis can be achieved by HIO or total vascular occlusion. The latter nevertheless was the safe choice for patients whose tumor involved major hepatic veins and inferior vena cava^[16]. But clinically, the vast majority of liver resections do not need this method for its detrimental effect of systemic circulation disturbance. HIO or Pringle's maneuver, which has the least hemodynamic effect, has been widely used in liver surgery^[17]. However, HIO could also result in liver I/R injury, which is one of the major factors leading to postoperative liver dysfunction. Cirrhotic liver is very vulnerable to ischemic injury. Though warm ischemia for cirrhotic liver should not exceed 30 min, and the majority of liver resections could be finished within this limit interval by using diathermy and crushing hepatic tissue with an artery forceps, the deleterious effect of ischemia could not be neglected. In order to minimize liver I/R injury, intermittent hepatic inflow occlusion (iHIO) has been used in HCC resection^[18,19]. However, massive bleeding might result from iHIO during reperfusion interval, which might increase blood transfusion and the possibility of postoperative morbidity and tumor recurrence^[20].

Our results demonstrated that HIO could cause massive

Figure 2 Typical features of apoptosis after 1 h of reperfusion (TUNEL assay, $\times 200$). Bold arrows show the SEC apoptosis and the black arrows indicate scanty of hepatocyte apoptosis. A: IPC group, B: control group.

liver injury and inhibit albumin synthesis in cirrhotic patients. However, IPC could significantly protect cirrhotic liver from I/R injury during hepatic resection under hepatic inflow occlusion in cirrhotic HCC patients. These were represented by a dramatically decrease in postoperative AST, ALT and TBIL levels; a relatively higher serum albumin level; an uneventful postoperative course and a relatively short hospital stay in the IPC group.

IPC is a simple procedure, which can produce dramatic protective effect on I/R injury. However, its clinical application is rare.

The protective mechanism of IPC has not been fully understood. Intrinsic nitric oxide (NO) synthesis, adenosine release^[18] and decreasing leukocyte/endothelial cell interactions^[21] have been reported to be the protective mechanisms underlying I/R injury.

Apoptosis, or programmed cell death, which is a distinct form of cell death from necrosis, has been documented to be a pivotal mechanism responsible for I/R injury encountered in liver surgery and liver graft preservation^[22-25]. However, this cell pathology was challenged by other authors, who documented that cell necrosis was the major cell death in rat liver I/R model subjected to 60 or 120 min of ischemia^[26]. Jaeschke *et al.*^[27], believed that both apoptosis and necrosis occurred in liver I/R. Actually, in our previous cirrhotic rat liver I/R model, we used H&E staining, TUNEL assay and electron microscope to investigate the cellular pathology, and found that there was no obvious necrosis but massive hepatocyte apoptosis mediated by Fas apoptotic pathway subjected to 30 min of liver ischemia and 6 h of reperfusion^[28]. This discrepancy might be due to the different time of ischemia and reperfusion used in each experiment.

In this clinical trial, we found that the major cell type undergoing apoptosis in the control group was SECs subjected to 1 h of reperfusion, only a few apoptotic hepatocytes were found at this checking time point. However, in our previous animal model^[28], after 6 h of reperfusion, massive apoptotic hepatocytes were seen, indicating that the cell type undergoing apoptosis might be time dependent. In the rat liver cell apoptosis model induced by intraperitoneal injection of Fas antibody^[29] and liver graft cold I/R model^[25], 1 h after antibody administration or reperfusion, SEC apoptosis was predominant. However, 2 to 6 h after antibody administration or reperfusion, hepatocytes were the major cell type undergoing apoptosis. Though we did not check apoptosis after 6 h of reperfusion in this clinical trial, we believed that during this period of time, hepatocytes might undergo apoptosis predominantly, thus subsequently resulting in liver injury and clinical manifestations.

As to the cellular mechanism of IPC related to apoptosis, Yadav *et al.*^[30], reported that the protective mechanism of IPC underlying hepatocyte and SEC apoptosis was achieved by inhibiting Caspase-3. It has been found that caspase-3 is a cysteine specific protease, an "executor" leading to DNA fragmentation in apoptotic signal cascades^[31]. We demonstrated that IPC could protect cirrhotic liver from I/R injury by inhibiting hepatocyte and SEC apoptosis through down-regulation of Fas expression and suppression of Caspase-3 activity in cirrhotic rat liver I/R model^[13]. In this study, we demonstrated again that the protective mechanism of IPC against liver I/R injury in cirrhotic patients was achieved by inhibiting Caspase-3 activity and subsequently apoptosis.

Why IPC down-regulates Caspase-3 activity is still under investigation. IPC could result in inhibition of intrinsic NO synthesis. *In vitro* and *in vivo* studies indicated that NO could inhibit Caspase-3 by S-nitrosation in Cys-163 residue of Caspase-3^[32].

In conclusion, IPC can protect potentially cirrhotic liver against I/R injury when hepatic resection is performed under hepatic inflow occlusion in HCC patients with cirrhosis. Its protective mechanism underlying SEC apoptosis is achieved

by inhibiting caspase-3 activity. IPC is a simple procedure with a potential protective effect, and it is recommended for clinical application.

Abstract

AIM: To evaluate the major clinical symptom, etiology, and diagnostic method in patients with primary small intestinal disease in order to improve the diagnosis.

METHODS: A total of 309 cases with primary small intestinal disease were reviewed, and the major clinical symptoms, etiology, and diagnostic methods were analyzed.

RESULTS: The major clinical symptoms included abdominal pain (71%), abdominal mass (14%), vomiting (10%), melaena (10%), and fever (9%). The most common disease were malignant tumor (40%), diverticulum (32%) and benign tumor (10%). Duodenal disease was involved in 36% of the patients with primary small intestinal diseases. The diagnostic rate for primary small intestinal diseases by double-contrast enteroclysis was 85.6%.

CONCLUSION: Abdominal pain is the most common clinical symptom in patients with primary small intestinal disease. Malignant tumors are the most common diseases. Duodenum was the most common part involved in small intestine. Double-contrast enteroclysis was still the simplest and the most available examination method in diagnosis of primary small intestinal disease. However, more practical diagnostic method should be explored to improve the diagnostic accuracy.

Zhan J, Xia ZS, Zhong YQ, Zhang SN, Wang LY, Shu H, Zhu ZH. Clinical analysis of primary small intestinal disease: A report of 309 cases. *World J Gastroenterol* 2004; 10(17): 2585-2587 <http://www.wjgnet.com/1007-9327/10/2585.asp>

INTRODUCTION

Clinically, primary small intestinal disease is relatively rare. Accounting for only 1-4% of digestive diseases^[1]. In spite of the development of techniques in endoscopy and the innovation of equipments, such as capsule endoscopy^[2,3] and double-balloon push enteroscopy^[4,5], diagnosis of primary small intestinal disease is still difficult. For example, uncontrollability in the movement of endoscopic capsule, the influence of fluid inside gastrointestinal tract, poor discrimination in images and unavailability of biopsy decrease the practicability of capsule endoscopy in clinical practice^[6]. Theoretically, there is no blind region in total small intestine for double-balloon push enteroscopy, as the new instrument has been put into practice recently. However, it is almost impossible for double-balloon

push enteroscopy to search all small intestines through either mouth or anus. Furthermore, double-balloon push enteroscopy has other limitations, such as long time of examination and patients' prolonged endurance^[7]. Therefore, the diagnosis of primary small intestinal disease is still difficult. In this study, by clinical analysis of 309 cases of patients with primary small intestinal disease, we aimed to investigate clinical symptoms, etiology, and diagnostic methods in primary small intestinal disease in order to increase the knowledge in primary small intestinal disease and improve the diagnosis.

MATERIALS AND METHODS

Criteria for selected patients

All selected patients had clinical symptoms or signs of the digestive system. The diagnosis of small intestinal disease was confirmed by means of laparotomy, pathology and other examinations. Primary small intestinal disease included duodenal disease, jejunal disease and ileal disease. However, duodenal bulb ulcer was not included. Secondary small intestinal diseases were also excluded.

Method of analysis

A total of 309 cases with primary small intestinal disease were reviewed, and the major clinical symptoms, etiology, and diagnostic methods were analyzed.

RESULTS

From January 1976 to July 2003, 309 cases with primary small intestinal disease were collected. Among them, there were 167 males, 142 females, with age ranging from 2 to 87 years old, and an average age of 51.2 years.

Among the 309 cases, 216 cases were confirmed by surgical operations, 53 by double-contrast enteroclysis, 24 by gastric endoscopy or enteroscopy and biopsy and 16 by a combination of clinical and other examinations. Among the 216 cases with surgical operations, diagnosis could not be definitely made in 142 cases until laparotomy was performed. Lesions were found in 89 of 104 cases examined by double-contrast enteroclysis, giving a positive rate of 85.6%. The major clinical symptoms were abdominal pain, abdominal mass, vomiting, melaena, fever, hematochezia and diarrhea. Some cases had two or more symptoms (Table 1). The most common diseases were malignant tumor (40%), diverticulum (32%) and benign tumor (10%). Duodenal disease was involved in 36% of the patients with primary small intestinal diseases. The distribution of the major diseases of 309 cases is listed in Table 2.

Table 1 Major clinical symptoms of 309 cases with primary small intestinal disease

Symptom	n (%)	Symptom	n (%)
Abdominal pain	218 (71)	Hematochezia	19 (6)
Abdominal mass	44 (14)	Diarrhea	14 (5)
Vomiting	32 (10)	Jaundice	13 (4)
Melaena	30 (10)	Haematemesis	3 (1)
Fever	27 (9)	Others	8 (3)

Table 2 Distribution of major diseases in 309 cases with primary small intestinal disease

Disease	n (%)
Small intestinal diverticulum	100 (32)
Small intestinal adenocarcinoma	35 (11)
Small intestinal leiomyosarcoma	34 (11)
Small intestinal lymphoma	29 (9)
Crohn's disease	15 (5)
Small intestinal leiomyomas	13 (4)
Hemorrhagic necrotizing enteritis	13 (4)
Ampullar carcinoma	11 (4)
Small intestinal malignant mesenchymoma	11 (4)
Small intestinal polyp	10 (3)
Small intestinal twist	8 (3)
Small intestine multiple perforation	4 (1)
Terminal ileal ulcer	3 (1)
Small intestinal cavernous hemangioma	2 (1)
Small intestinal malabsorption syndrome	2 (1)
Small intestinal internal hernia	2 (1)
Small intestinal fistula	2 (1)

¹Including jejunal malignant melanoma, jejunal malignant angioendothelioma, ileal liposarcoma, small intestinal malignant reticulosis, small intestinal fibrosarcoma, jejunal lipoma, jejunal fibroma, jejunal neurofibroma, ileal neurilemmoma, small intestinal benign mesenchymaloma, small intestinal teratoma, small intestinal inflammatory pseudotumor, terminal ilealitis, eosinophilic enteritis and idiopathic small intestinal obstruction which had 1 case respectively.

DISCUSSION

Distribution of major diseases in patients with primary small intestinal disease

In this study, 216 (70%) of 309 cases were diagnosed as having primary small intestinal disease by a combination of surgical operations and pathology. In addition, 24 of 309 cases were diagnosed by a combination of gastric endoscopy or enteroscopy and biopsy. Therefore, a total of 240 (78%) cases were diagnosed by pathology. Based on the analysis of the characteristics of the diseases, we found that malignant tumor was the most common disease in primary small intestinal disease. Overall, 125 patients had malignant tumors, 35 (11%) with adenocarcinoma, 34 (11%) with leiomyosarcoma, 29 (9%) with small intestinal lymphoma, and 11 (4) with ampullar carcinoma. These patients accounted for 40% of the cases with primary small intestinal disease. There were only 32 (10%) cases with small intestinal benign tumor, mainly including 13 (4%) cases of small intestinal leiomyomas, and 10 (3%) with small intestinal polyps. The ratio of small intestinal benign over malignant tumors was almost 1:4 (32:125), which indicates that most of small intestinal neoplasms are malignant, and thus small intestinal malignant tumors contribute significantly to small intestinal disease. This finding is consistent with previous domestic reports by Liu *et al.*^[8] and Shi *et al.*^[9], but different from the overseas reports that small intestinal benign tumor is more common than small intestinal malignant tumor^[10]. Our observations suggest that malignant tumors should be considered if small intestinal disease is under consideration, and further examinations should be taken as soon as possible to assure or exclude small intestinal malignant tumor. In this way, patients with small intestinal malignant tumor would receive optimum management through the early diagnosis and early treatment strategy, and thus prognosis would be significantly improved.

Among the 309 cases, 100 had small intestinal diverticulum, which contributed to 32% of cases and was the second common diagnosis in small intestinal disease. Among patients with small intestinal diverticulum, 72 (72%) had duodenal diverticulum, and 28 (28%) had jejunal or/and ileal diverticulum, which indicates that duodenal diverticulum is much more common than jejunal or/and ileal diverticulum. The data suggest that more attention should be paid to duodenal diverticulum, especially diverticulum of descending part of duodenum because diverticulum in this site is not only common but also detectable easily by gastric endoscopy or barium meal examination.

In addition, 84 cases had other small intestinal benign disease, which contributed to 27% of patients with small intestinal diseases, mainly including 32 (10%) with small intestinal benign tumor, 15 (5%) with Crohn's disease, 13 (4%) with hemorrhagic necrotizing enteritis and 8 (3%) with small intestinal twist. These data indicate that small intestinal benign tumor is the most common disease among small intestinal non-diverticular benign disease. It is also noticed that 111 cases with duodenal diseases contributed to 36% of the 309 patients with primary small intestinal disease. There were 72 cases with diverticulum accounting for 65% of patients with duodenal disease, 37 with malignant tumor accounting for 33% of patients with duodenal disease, and 2 with duodenal polyps. Since the human small intestine is 5 to 6 meters long, and duodenum is only 0.25 meter long, which is not longer than 1/20 of full length of small intestine. However, more than one third of small intestinal diseases were duodenal diseases. Therefore, duodenum is the most common part involved in small intestinal disease, and special attentions should be paid to duodenal disease, especially between descending part and ascending part of duodenum when small intestinal disease is under consideration, because duodenum is not only commonly involved but also shallow enough to be easily detected by gastric endoscopy or a barium meal examination without need for other complex examinations.

Major clinical symptoms in patients with primary small intestinal disease

Clinical symptoms of primary small intestinal disease in this study included abdominal pain, abdominal mass, vomiting, melaena, fever, hematochezia, diarrhea, jaundice, haematemesis, marasmus, abdominal distension, and constipation. Among these symptoms, abdominal pain was the most common clinical symptom as 218 cases had abdominal pain, which contributed to 71% of cases with primary small intestinal disease. The site of abdominal pain was mainly located around the navel. The second common symptom was abdominal mass. Altogether 44 cases had abdominal mass, which contributed to 14% of cases with primary small intestinal disease. The other common symptoms were vomiting, melaena and fever. Fever was caused mostly by small intestinal lymphoma and hemorrhagic necrotizing enteritis. However, hematochezia, diarrhea, jaundice, haematemesis were less common. Hematochezia was often characterized by dark-red stool and negative findings by enteroscopy. Haematemesis was a rare symptom, but if it occurred, then the volume of bleeding would be enormous. Therefore, the symptoms of patients with primary small intestinal disease are lacking of specificity as these symptoms may occur in patients with upper digestive disease and colon disease. So small intestinal disease could not be diagnosed only by symptoms, which is also one of the reasons for the difficulty in the diagnosis of primary small intestinal disease. However, when patients had above mentioned symptoms, especially melaena, hematochezia, haematemesis and enteremphraxis, but no positive findings were found by gastric endoscopy and enteroscopy at the same time, further examinations should be

given to patients to verify or exclude small intestinal disease. These examinations include double-contrast enteroclysis, selective arteriography, small intestinal endoscopy, capsule endoscopy, and double-balloon push enteroscopy.

Examinations methods for the diagnosis of primary small intestinal disease

In spite of so many examination methods, how to select appropriate examinations is a question to be often asked in clinical work. We found that some patients were finally definitely diagnosed as having primary small intestinal disease through almost all the examinations, which not only put heavy economical burden on patients, but also increased suffering of patients, and especially delayed the diagnosis of disease. However, if an examination was correctly selected, the diagnosis could be easily achieved. Capsule endoscopy is nontraumatic method for the examination of small intestinal disease, however, uncontrollability in movement of capsule endoscopy, poor discrimination in images and unavailability of biopsy, expensive price, and time-consuming decrease the practicability of this method in clinical practice. The traditional enteroscopy can only observe the digestive tract 1 meter above jejunum to Treitz ligament due to itself limitation, which means that most of small intestinal could not be diagnosed by the traditional enteroscopy. Radiography includes selective arteriography and double-contrast enteroclysis. Selective arteriography is a useful examination for patients with main clinical symptoms of melaena, hematochezia or haematemesis. The diagnosis rate of selective arteriography is increased especially when a patient is bleeding^[11]. Otherwise, double-contrast enteroclysis is a very valuable examination for patients with main clinical symptoms of abdominal pain, abdominal mass, vomiting, or diarrhea. In this study, among the 309 cases with primary small intestinal disease, 104 cases were examined by double-contrast enteroclysis, and 89 cases were found lesion in small intestine, with a positive rate of 85.6%, which was similar to report by Wang *et al*^[12]. This positive rate is significantly higher than that (70%) reported by Zhan *et al*, based on the hospitalized patients in our hospital before 1997^[13]. The improvement of diagnosis accuracy may be related to the better choice made by doctors for examinations, the improved experience of examiners and more attention paid to small intestinal disease over the past 6 years. Unfortunately, only one third of cases with primary small intestinal disease were examined by double-contrast enteroclysis in this study. The reasons for this included unawareness of double-contrast enteroclysis by physicians, emergency that did not allow patient for double-contrast enteroclysis but for laparotomy and situations that patients had a complete or incomplete intestinal obstruction. In fact, patients with incomplete intestinal obstruction can be examined by double-contrast enteroclysis with meglucamine diatrizoate instead of barium by placing a tube into duodenum during gastric endoscopy, which could not only increase the diagnosis rate, but also be more available and safer for patients^[14]. Because some endoscopic capsules can not move out of body in some patients until laparotomy was performed, it is suggested that double-contrast enteroclysis should be performed before capsule endoscopy. By this way, doctors not only obtain primary knowledge if there is a matter

with patient, but also obtain the information of the intestinal movement, which would help determine whether capsule endoscopy is suitable for the patient and thus avoid the situation which endoscopic capsule can not naturally move out of the body^[15]. Double-balloon push enteroscopy has been applied recently to provide a powerful tool for diagnosis of small intestinal disease. Therefore, we would draw a conclusion from what mentioned above that as a traditional nontraumatic or microtraumatic examination, double-contrast enteroclysis has advantages in simplicity and availability, little torment, high diagnosis accuracy and low price. Therefore, at present, double-contrast enteroclysis still plays an important role in diagnosis of small intestinal disease. We are hoping that double-balloon push enteroscopy and other newer and more practical examinations could aid in diagnosis of small intestinal disease with the development of technology in endoscopy and general use of endoscopic equipment.

Abstract

AIM: To determine the effects of total parenteral nutrition and somatostatin on patients with chylous ascites.

METHODS: Five patients were diagnosed with chylous ascites on the basis of laboratory findings of ascites sample from Nov 1999 to May 2003. Total parenteral nutrition and somatostatin or its analogue was administered to 4 patients, while the other one only received total parenteral nutrition. All the patients had persistent peritoneal drainage, with the quantity and quality of drainage fluid observed daily. Necessary supportive treatments were given to the patients individually during the therapy.

RESULTS: Two of 4 patients who received somatostatin therapy obtained complete recovery within 10 d without any recurrence while on a normal diet. In these 2 patients, the peritoneal drainage reduced to zero in one and the other's decreased from 2 000 mL to 80 mL with a clear appearance and negative qualitative analysis of chyle. Recurrent chylous ascites, though relieved effectively by the same method every time, developed in one patient with advanced pancreatic cancer. The other patient's lymphatic fistula was blocked with the fibrin glue after conservative treatment. The patient who only received total parenteral nutrition was cured 24 d after therapy.

CONCLUSION: Total parenteral nutrition along with somatostatin can relieve the symptoms and close the fistula in patients with chylous ascites rapidly. It appears to be an effective therapy available for the treatment of chylous ascites caused by various disorders.

INTRODUCTION

Chylous ascites, an uncommon disease usually caused by obstruction or rupture of the peritoneal or retroperitoneal lymphatic glands, is defined as the accumulation of chyle in the peritoneal cavity^[1]. It is a difficult disorder due to the serious mechanical, nutritional and immunological consequences of the constant loss of protein and lymphocytes^[2]. Morton's dramatic and detailed account in 1694 of a 2-year-old boy with tuberculosis who died of chylous ascites was the first clear report of chyloperitoneum.

Many pathological conditions can result in this disease, including congenital defects of the lymphatic system, nonspecific bacterial, parasitic and tuberculous peritoneal infection, liver cirrhosis, malignant neoplasm, blunt abdominal trauma and surgical injury^[1]. Over all, the most common cause in adults is believed to be abdominal malignancy, while congenital lymphatic abnormalities in pediatric population. Press *et al.* reported an incidence of 1 per 20 464 admissions at the Massachusetts General Hospital during a 20-year period^[3]. They found, however, a 1 per 11 589 incidence in the last years of their study. Most investigators believe that the incidence of chylous ascites is increasing because of more aggressive thoracic and retroperitoneal surgery and with the prolonged survival of patients with cancer^[4-8]. Some new techniques, such as laparoscopic surgery and transplantation, also lead to postoperative chylous ascites^[9-11]. Kaas *et al.* found that 12 (7.4%) of 163 patients with complex surgical procedures developed chylous ascites^[12].

Though the incidence of chylous ascites has increased in recent years, the treatment remains unsatisfactory in some cases because of prolonged duration of disease. Conservative treatment of chylous ascites, recommended in most patients, involves paracentesis, a medium chain triglyceride (MCT) based diet, total parenteral nutrition (TPN), recently used somatostatin and so on. Surgery is only recommended when conservative treatment fails^[2]. In a review of 156 patients with chylous ascites resolved after intervention, 51 patients were successfully treated surgically; 105 patients were treated conservatively^[13]. Usually the MCT based diet is the first choice, TPN is recommended after dietary manipulation has failed, and somatostatin therapy is attempted only if chylous ascites has been refractory to all conservative measures. It will take several weeks to 2 mo to close the lymphatic fistula adequately with routine conservative regimens^[13].

Here we report on our successful use of persistent peritoneal drainage, TPN as well as somatostatin in treatment of 5 cases of chylous ascites.

MATERIALS AND METHODS

Five adult patients with chylous ascites were admitted to our hospital from November 1999 to May 2003. On admission, computerized tomography (CT) examination was performed to reveal the etiology, and the diagnosis was confirmed by analyzing the cloudy ascites fluid obtained through paracentesis or peritoneal drainage. Table 1 shows the clinical features, CT findings and laboratory findings of ascites samples from 5 patients.

As soon as the diagnosis was confirmed, every patient was put in fasting state and received fluid replenishment until disturbance of water, electrolytes and acid-base was corrected. A single lumen central venous catheter was inserted into the peritoneal cavity for continuous drainage in 3 patients, while peritoneal cavity drainage tubes inserted during the operation were reserved in patient 4 and 5. The quality and quantity of drainage fluid were monitored daily. Then TPN (non-protein calorie 25 kcal/(kg·d), nitrogen 0.2-0.25 g/(kg·d), glucose: fat ratio 6:4) via central vein was administered to patients at gradually increasing dose. Somatostatin (Stilamin, Laboratoires Serono S. A.) was administered to patient 2 and 4 through continuous intravenous infusion at a dose of 3 mg per 12 h.

Patient 3 and 5 received subcutaneous administration of the somatostatin analogue, octreotide (Sandostatin, Novartis Pharma AG), at a dose from 100 µg to 200 µg 3 times daily. Necessary supportive treatments, such as albumin, diuretics and antibiotics, were given to the patients individually during the therapy. In addition, patient 5 received abdominal cavity and peripheral venous chemotherapy at the same time.

RESULTS

Figure 1 shows the change of drainage volume, the duration of TPN and somatostatin therapy of 5 patients. Once the peritoneal

drainage was zero (in patient 1 and 4) or was proved non-chylous ascites (in patient 2 and 3), TPN and somatostatin dose would diminish gradually along with the recovery of oral low fat diet. Patient 3 and 4, who received somatostatin therapy, obtained complete recovery within 10 d, while patient 1 who only received TPN was cured 24 d after therapy. The drainage of patient 3 decreased from 2 000 mL to 80 mL within 10 d with a clear appearance and negative qualitative analysis of chyle, and the volume remained unchanged when she received normal diet. Then patient 3 was referred to department of gastroenterology for further treatment of the established liver cirrhosis, which caused the remaining ascites. All these 3 patients' drainage

Table 1 Clinical features, CT and laboratory findings for 5 patients with chylous ascites

Patient	Age in yr/Sex	Medical/Surgical condition	CT findings	Laboratory findings of ascites			
				Qualitative analysis of chyle	Leukocyte count (/mm ³)/Lymphocyte (%)	Total protein/Albumin (g/L)	Cholesterol/Triglyceride (mmol/L)
1	48/M	Two wk after radical distal subtotal gastrectomy for gastric cancer	Large volume of ascites	+	1 600/95	49.4/30.9	1.92/7.14
2	50/M	Five mo after pancreaticoduodenectomy for pancreatic cancer	Large volume of ascites, multiple metastases involving liver and lymph nodes	+	120/95	15.0/10.1	1.59/2.41

Figure 1 Change of drainage volume and the duration of TPN and somatostatin therapy in 5 patients. ↓The beginning and the end of TPN, ↓the beginning and the end of somatostatin therapy, ↓the beginning of food intake, ↓blockage of the fistula. A: Patient 1 who only received TPN recovered fully after 24 d of therapy; B: Patient 2 suffered from repeated recurrence though the drainage volume decreased from 2 000 mL to 100 mL within 11 d; C: Chylous ascites never recurred in patient 3 after the drainage volume decreased to 80 mL within 10 d with negative qualitative analysis of chyle; D: Patient 4 recovered fully within 9 d; E: Chylous fistula of patient 5 showed refractory to therapy and was sealed with fibrin glue.

catheters were removed after they had normal diet for 3 d. The drainage volume of patient 5, though dropped from 600 mL to 200 mL within 10 d, remained unchanged for 11 d with positive qualitative analysis of chyle. Then we successfully used fibrin glue to block up the lymphatic fistula that was proved mature with X-ray fistulography. CT follow-up examinations did not reveal the presence of ascitic fluid. The nutritional status of them was well maintained during therapy. Follow-up study found no recurrence in these 4 patients while on normal diet after 6 mo. Though the drainage decreased from 2 000 mL to 100 mL within 11 d and was proved non-chylous ascites, repeated recurrences developed in patient 2 who died of advanced pancreatic cancer 3 mo later.

DISCUSSION

Our results showed that TPN along with somatostatin appears to be an effective therapy available for the treatment of chylous ascites caused by various disorders.

There are multiple causes of chylous ascites. The most common ones in Western countries are abdominal malignancy and cirrhosis, which account for over two thirds of all cases. In contrast, infectious etiologies, such as tuberculosis and filariasis, account for the majority of cases of chylous ascites in Eastern and developing countries^[14]. Previous studies showed the effect of some regimen in the treatment of chylous ascites caused by one kind of pathological condition. In the present series, various etiological factors including surgical injury (patient 1 and 5), pancreatic cancer (patient 2), liver cirrhosis (patient 3) and idiopathic cause (patient 4) demonstrate the wide indications of our treatment. It also indicates the change of etiology spectrum in China, operation and cancer have become the common causes now.

Treatment of the underlying cause of chylous ascites is of pivotal importance in managing patients with chylous ascites, especially those having an infectious, inflammatory, or hemodynamic cause. But conservative treatment is usually vital for most patients to relieve the symptoms and restore nutritional deficits. Paracentesis is not only a diagnostic but also therapeutic method in the management of chylous ascites. Despite several definite drawbacks and complications, repeated paracentesis is commonly included in the nonoperative treatment regimens to relieve abdominal distention^[13]. In three patients of this series, repeated paracentesis was replaced by persistent peritoneal drainage with a single lumen central venous catheter, which permitted us to monitor the quality and quantity of drainage daily. In patient 4 and 5, peritoneal drainage tube inserted during the operation was reserved until recovery. No tube blockage, catheter-related sepsis or any other complications developed in all patients. So persistent peritoneal drainage may be a much better and accepted choice than repeated paracentesis.

Fasting, together with TPN, can decrease the lymph flow in thoracic duct dramatically from 220 mL/(kg·h) to 1 mL/(kg·h)^[13]. Furthermore, TPN restores nutritional deficits and balances metabolic impairments imposed by long-standing chylous ascites and repeat sessions of paracentesis. So fasting and TPN are essential in nonoperative management of chylous ascites. In the past, however, TPN was usually recommended as the second line treatment when enteral dietary manipulation failed^[13]. Routine conservative treatment, using TPN only or combined with an MCT diet, needed 2 to 6 wk to cure 60% to 100% of cases^[14,15]. In our study, patient 1 who only received fasting and TPN recovered completely after 24 d.

Initial experience with continuous intravenous high dose somatostatin for the closure of postoperative lymphorrhagia was reported in 1990 by Ulibarri *et al.* The exact mechanisms of somatostatin on drying lymphatic fistulas are not completely understood. It has been previously shown to decrease the

intestinal absorption of fats, lower triglyceride concentration in the thoracic duct and attenuate lymph flow in the major lymphatic channels^[16]. In addition, it also decreases gastric, pancreatic and intestinal secretions, inhibits motor activity of the intestine, slows the process of intestinal absorption and decreases splanchnic blood flow, which may further contribute to decreased lymph production. It has also been speculated that somatostatin improves chylous ascites by inhibition of lymph fluid excretion through specific receptors found in the normal lymphatic vessels of intestinal wall^[17,18]. Shapiro *et al.* reported rapid resolution of chylous ascites after liver transplantation within 2 d after administration of the octreotide combined with total parenteral nutrition^[17]. Satisfactory results were also achieved by others^[16,19-23]. To our knowledge, however, most of these articles included just one case. Somatostatin therapy also remains an indefinite or second-line method in treatment of chylous ascites. The recommended algorithm for the management of chylous ascites in a review in 2000, only regarded somatostatin in combination with TPN as an unproved alternative method^[13]. Another algorithm in 2002 recommended somatostatin therapy only after a period of combined dietary intervention and TPN had failed^[14]. Our results showed that 2 of 4 patients treated with somatostatin or its analogue recovered completely within 10 d with well maintained nutritional status and no significant side effect, while the symptoms of patient 2 relieved despite of relapse. As to patient 5, the conservative treatment decreased the fistula drainage greatly and paved the way for the subsequent management. In this case we are inclined to surmise that chemotherapy may affect the closure of lymphatic fistula. These results suggest that somatostatin along with TPN can close the lymphatic leakage or relieve the symptom effectively and rapidly, in comparison with conventional regimens.

The outcome of chylous ascites mostly depends on the underlying pathological condition causing lymphatic leakage. The mortality of chylous ascites, especially those caused by surgery, has decreased much than before^[15], but that caused by malignancy remains high. In our study, TPN and somatostatin could not control the chylous ascites completely in patient 2, so necessary adjustment of this regimen or more aggressive therapy should be applied to stop the lymphatic leakage in these patients. Peritoneovenous shunt has been proved to be a valuable method especially for those cancer patients who are refractory to conservative treatment^[24-26].

We conclude that TPN with somatostatin should be the first-line therapy for chylous ascites caused by various disorders, and started as soon as possible. Some other methods should also be attempted to close the fistula that is refractory to conservative treatment. Further studies of multicenter clinical trials involving more patients to compare the efficacy and cost between this regimen and the others are suggested.

Abstract

AIM: To examine whether glutamine prevents the injury to the intestinal mucosa after intestinal ischemia-reperfusion (I/R) in rats.

METHODS: Thirty male Sprague-Dawley rats were randomly divided into 3 groups: a standard parenteral nutrition (PN) group ($n = 10$); an I/R-PN group ($n = 10$); an I/R-glutamine enriched PN (I/R-Gln) group ($n = 10$). The superior mesenteric artery (SMA) was clamped. After 60 min of ischemia, reperfusion was initiated and infusion was started. All rats received isocaloric and isonitrogenous nutritional support for 48 h. Spleen, liver, mesenteric lymph nodes (MLN), and intestinal segments were removed for morphological and biochemical analyses, and blood samples were collected for bacterial culture and measurement of endotoxin levels. The permeability of intestinal mucosa was assayed by measurement of D-(-)-lactate levels in plasma.

RESULTS: In I/R-PN group, extensive epithelial atrophy was observed, mucosal thickness, villous height, crypt depth and villous surface area were decreased significantly compared with PN group, whereas these findings did not occur in the I/R-Gln group. The incidence of intestinal bacterial translocation to spleen, liver, MLN, and blood was significantly higher in I/R-PN group than that in other groups. Plasma endotoxin levels significantly increased in the I/R-PN group compared with the I/R-Gln group. Remarkably higher values of D-(-)-lactate were also detected in PN group compared with that in I/R-Gln group.

CONCLUSION: Glutamine protects the morphology and function of intestinal mucosa from injury after I/R in rats.

INTRODUCTION

Ischemia-reperfusion (I/R) of the gut is a common event in a variety of clinical conditions, such as trauma, burn, septic shock, heart or aortic surgery, and liver or small bowel transplantation^[1,2]. Intestinal I/R results in many adverse events to the small intestine such as edema and disruption of the structural and

functional mucosa. This injury includes mucosal and vascular permeability, change bacterial translocation, and a high death rate^[3,4]. It has been proposed that most of the mucosal injury resulted from I/R are mediated by reactive oxygen derived free radicals produced and released when hypoxic tissues are reoxygenated during reperfusion. Clinical and experimental studies suggest that I/R-induced intestinal injury play a role in the pathogenesis of systemic inflammation, respiratory failure, and multiple-organ failure (MOF)^[5].

Glutamine (GLN) is the primary metabolic fuel of small intestinal enterocytes, and has been shown to be an essential metabolic component of the proliferative response of enterocytes. Studies have shown that glutamine reduced atrophy of intestinal mucosa in rats on total parenteral nutrition (TPN), prevented intestinal mucosal injury accompanying small bowel transplantation, chemotherapy, and radiation. It was also reported that glutamine supplemented TPN prevented intestinal I/R injury, and improved survival after intestinal I/R in animal models^[6,7]. Thus, GLN treatment seems to be a preventive and therapeutic method for gut I/R-induced organ injury. However, despite the positive result from previous studies, glutamine has not been used extensively to treat preexisting intestinal I/R injury. The purpose of this study was to examine whether glutamine prevented damage to the intestinal mucosa after intestinal I/R in rats.

MATERIALS AND METHODS

Experimental protocol/procedures

Thirty male Sprague-Dawley rats weighing 350 to 450 g were employed after a period of acclimatization. After an overnight fast, the rats were anesthetized with sodium pentobarbital 25 mg/kg intraperitoneally. Through a midline laparotomy, the superior mesenteric artery (SMA) was carefully isolated and clamped at its origin from the abdominal aorta. After 60 min of ischemia, the clamp was removed from the SMA and reperfusion was initiated. The abdominal incision was closed and infusion was started immediately. A silastic catheter was inserted through the right jugular vein, tunneled subcutaneously, and brought out through the skin of midscapular region. The rats were randomly divided into 3 groups: a standard parenteral nutrition (PN) group ($n = 10$); an I/R-PN group ($n = 10$); an I/R-glutamine enriched PN (I/R-Gln) ($n = 10$). The SMA of sham rats in PN group was isolated but not clamped. All rats were maintained in individual metabolic cages, and received parenteral nutritional support for 48 h. The composition of the TPN solution is shown in Table 1. Both solutions were isocaloric (174.3 kcal/kg·d) and isonitrogenous (1.0 g/kg·d). After 48 h' nutritional support, a 20-cm long intestinal segment was obtained from a point 10 cm distal to the ligament of Treitz for morphological and biochemical analysis. Spleen, liver, MLN, and blood samples were collected for bacterial culture and measurement of endotoxin levels.

Histologic evaluation and biochemical analysis

Intestinal samples corresponding to the first 5 cm of the resected intestinal segment were fixed in 40 g/L formaldehyde. All samples were embedded in paraffin and stained with hematoxylin and eosin. Three paraffin sections were prepared from each fixed tissue sample, and each slide was analyzed. A blinded

observer performed the histologic analyses using the histologic scoring system. Mucosal wall thickness, villous height, crypt depth and villous surface area were measured under light microscope. All measurements were made in triplicate, and mean values were obtained. The 15 cm of the intestinal segment left was sampled, and the mucosal sample was immediately scraped from the underlying muscular layer with a glass slide. The mucosa was weighed and stored at -70 °C until analysis. DNA and RNA content was measured by the fluorometric method. Protein content was determined by the bicichoninic acid method.

Intestinal permeability

The permeability of intestinal mucosa was assayed by measurement of D-lactate levels in plasma. The procedure used a glycine-hydrazine buffer at pH 9.5 and 25 °C. The assay was based on the enzymatic oxidation of D-lactate with a specific D-lactic dehydrogenase coupled to reduction of NAD⁺ with the spectrophotometric measurement of NADH at 340 nm. Plasma was separated from the blood sample by centrifugation and stored at -70 °C until analysis. Quantification of D-lactate was performed by fluorescence spectrometry as described by Shimojo *et al.*^[8]. The measurements were made with a Beckman DU fluorescence spectrophotometer at 340 nm. D-lactate standard stock solution was 0.47 mg/mL Li lactate (0.44 mg/mL D-lactic acid) and was diluted for standard curves. D-lactic dehydrogenase was from Sigma Biochemicals and was diluted with water to about 600 U/mL. Sigma assay kit 826-UV was used for D-lactate analysis.

Bacterial translocation measurements

Rats were killed, and their mesenteric lymph nodes, spleens and livers were removed. The tissues were transferred to grinding tubes containing sterile BHI to detect aerobic bacteria or sterile 10 A broth to detect lactobacilli. The tissues were homogenized, and BHI tubes were incubated aerobically, whereas the 10 A broth tubes were incubated in 100 mL/L carbon dioxide at 37 °C. After incubation, 0.2 mL of the tissues homogenates was spread on blood agar plates to detect aerobic bacteria, *E. coli* or lactobacilli. The tissues homogenates were Gram- stained to confirm that bacteria present in the homogenates grew on the agar plates.

Statistical analysis

Data were analyzed using standard statistical software (SPSS 10.0). For normally distributed data, a paired Student's *t* test was used for statistical analysis. A probability value less than or equal to 0.05 was considered statistically significant. All data were expressed as mean±SE.

RESULTS

The mortality rate was 0% (0/10), 28.6% (4/14), and 16.7% (2/12) in the PN, I/R-PN, and I/R-Gln groups, respectively. It was significantly higher in I/R-PN group compared with that in the PN group and I/R-Gln group ($P<0.05$).

In the I/R-PN group, extensive mucosal damage characterized by extensive edema, leukocytic infiltration, epithelial sloughing, mucosal ulceration of villous tips, and mucosal atrophy was observed. This did not occur in the PN group and I/R- Gln group, and no histologic difference was noted between the PN group and I/R- Gln group. Mucosal wall thickness, villous height, crypt depth and villous surface area decreased significantly in the I/R-PN group compared with those in the PN group and I/R-Gln group ($P<0.05$; Table 2). Mucosal wet weight, protein, DNA content and RNA content decreased significantly in the I/R-PN group compared with those in the PN group and I/R- Gln group ($P<0.05$; Table 3).

Plasma D-lactate levels significantly increased in the I/R-PN group (0.15 ± 0.04 mmol/L) compared with those in the PN group (0.08 ± 0.02 mmol/L; $P<0.05$) and I/R- Gln group (0.10 ± 0.02 mmol/L;

$P<0.05$). No significant difference was observed between PN group and I/R- Gln group.

The incidence of intestinal bacterial translocation to MLN, spleen, liver, and blood was significantly higher in I/R-PN group compared with that in PN group and I/R- Gln group. There was no significant difference between PN group and I/R- Gln group ($P<0.05$; Table 4). The plasma endotoxin levels increased in I/R-PN group (14.5 ± 0.12 pg/mL) compared with PN group (9.2 ± 0.8 pg/mL; $P<0.05$) and I/R- Gln group (10.5 ± 0.9 pg/mL; $P<0.05$).

Table 1 Composition of parenteral nutrition solutions (per 100 mL)

	PN	I/R- Gln
Glucose (g)	17.9	17.9
Fat emulsion (g)	5.6	5.6
Amino acid (g)	5.8	2.2
Ala-Glu (g)	0.0	3.6
Nitrogen (g)	0.93	0.93
NPC (kcal)	122.0	122.0
NPC/N	131.2	131.2

Table 2 Morphologic parameters

	PN (n = 10)	I/R-PN (n = 10)	I/R- Gln (n = 10)
Mucosal wall thickness (μm)	566.5±37.4 ^a	418.2±39.6	564.4±59.3 ^a
Villous height (μm)	404.2±39.1 ^a	290.8±48.8	396.4±60.5 ^a
Crypt depth (μm)	214.5±29.4 ^a	136.6±20.2	204.9±38.6 ^a
Villous surface area (mm ²)	0.118±0.010 ^a	0.065±0.006	0.112±0.012 ^a

^a $P<0.05$ vs I/R-PN; PN: parenteral nutrition; I/R: ischemia-reperfusion Gln: glutamine.

Table 3 Mucosal wet weight and biochemistry

	PN (n = 10)	I/R-PN (n = 10)	I/R- Gln (n = 10)
Mucosal wet weight (mg/cm)	74.6±16.3 ^a	55.2±12.0	82.8±18.2 ^a
Protein content (mg/cm)	3.25±0.92 ^a	1.73±0.60	3.16±0.47 ^a
DNA content (mg/cm)	1.42±0.20 ^a	0.64±0.12	1.33±0.17 ^a
RNA content (mg/cm)	4.53±0.58 ^a	3.26±0.78	4.45±0.84 ^a

^a $P<0.05$ vs I/R-PN; PN: parenteral nutrition; I/R: ischemia-reperfusion Gln: glutamine.

Table 4 Bacterial translocation measurements

	PN (n = 10)	I/R-PN (n = 10)	I/R- Gln (n = 10)
Rate of BT	10% (1/10)	100% (10/10)	20% (2/10)
MLN	1	9	2
Blood	1	7	1
Liver	0	5	0
Spleen	0	4	1

BT: bacterial translocation, MLN: mesenteric lymph node.

DISCUSSION

Ischemia of the gut is a common event after trauma and a significant predisposing factor of MOF. Intestinal I/R injury results in

many adverse events to the small intestine such as interstitial edema and disruption of the structural and functional mucosa. These increase the permeability of the intestinal mucosa and promote bacterial translocation. Clinical and experimental studies suggest that I/R-induced intestinal injury plays a role in the pathogenesis of systemic inflammation, respiratory failure, and MOF^[9,10]. Glutamine is the primary metabolic fuel of small amino acid pool in the body, and has been shown to be an essential metabolic component of the proliferative response of enterocytes. Studies showed that glutamine supplementation of TPN improved survival after gut I/R injury^[6,11], reduced atrophy of intestinal mucosa in rats on total parenteral nutrition^[12], prevented intestinal mucosal injury accompanying short bowel, small bowel transplantation, chemotherapy, and radiation^[13-17]. In the present study, the mortality rate was 28.6% in the I/R-PN group and apparent mucosal damage, such as epithelial sloughing and mucosal ulceration was observed histologically. A 100% survival was achieved in the PN group, 16.7% in I/R-Gln group, and only minor histologic changes of the small intestine were observed in PN and I/R-Gln groups. The I/R-Gln rats had a greater villous height, more mucosal protein, DNA and RNA content, and a lower degree of intestinal permeability compared with the I/R-TPN rats. This suggests that Gln supplemented TPN plays an important role in the maintenance of intestinal structure and barrier function in I/R-injured rats.

The intestinal mucosa, especially in the region of villi, is especially susceptible to hypoxia because of the microvascular architecture and its high energy demand. Intestinal ischemia perpetuates the bacteremic condition by promoting translocation of bacteria into the circulation. Several experimental and clinical studies have shown that intestinal ischemia decreases barrier function of the gut and enhances translocation of bacteria and toxin^[18,19]. In our I/R model, the SMA of rats was clamped for 60 min, and the rats were killed 48 h after intestinal I/R. Mesenteric lymph nodes, spleens, livers and blood were then cultured quantitatively. Almost all MLN had positive cultures and grew significantly great numbers of enteric bacteria, spread to the blood, liver and spleen in I/R-PN group. The most common bacterium discovered from solid viscera was *E. coli*, other species included *enterococcus*, *pseudomonas*, *proteus*, and *staphylococcus*. While, only 20% MLN cultures were positive, less than 10% spread to blood and spleen in I/R-Gln group. Additionally, plasma D-lactate and endotoxin levels increased significantly in I/R-PN group compared with that in I/R-Gln group. These findings indicated that the increase of intestinal permeability and the incidence of bacterial translocation in the intestinal I/R rats were prevented by glutamine supplementation.

In conclusion, the present study demonstrates that glutamine supplemented TPN protects rat intestine from morphologic and functional mucosal injury after intestinal I/R. These results suggest that glutamine would be clinically useful in the treatment of intestinal I/R injury.

Abstract

AIM: To investigate the effects of dendritic cells (DCs) transfected with full-length wild-type *p53* and stimulated by gastric cancer lysates on immune response.

METHODS: The wild-type *p53* was transduced to DCs with adenovirus, and the DCs were stimulated by gastric cancer lysates. The surface molecules (B7-1, B7-2, MHC-I, MHC-II) of all DCs were detected by FACS, and the ability of the DCs to induce efficient and specific immunological response in anti-⁵¹Cr-labeled target cells was studied. BALB/c mice injected with DCs and Mk28 were established, and CTL response in mice immunized with Lywt-*p53*DC was evaluated. Tumor-bearing mice were treated with Lywt-*p53*DC.

RESULTS: The surface molecules of Lywt-*p53*DC had a high expression of B7-1 (86.70±0.07%), B7-2 (18.77±0.08%), MHC-I (87.20±0.05%) and MHC-II (56.70±0.07%); T lymphocytes had a specific CTL lysis ability induced by Lywt-*p53*DC; the CTL lysis rate was as high as 81%. The immune protection of Lywt-*p53*DC was obvious, the tumor diameter in Lywt-*p53*DC group was 3.10±0.31 mm, 2.73±0.23 mm, 3.70±0.07 mm on d 13, 16 and 19, respectively, which were smaller than control, DC, wtp-*p53*DC and LyDC group ($P<0.05$). Tumor growth rate in Lywt-*p53*DC group was slower than that in other groups ($P<0.05$).

CONCLUSION: DCs transfected with wild-type *p53* and stimulated by gastric cancer lysates have specific CTL killing activity.

INTRODUCTION

Dendritic cells (DCs) are the most potent antigen-presenting cells and are actively used in cancer immunotherapy. The wild-type *p53* can be recognized as an antigen and can induce specific CTLs in the host body. It is an effective method to immunize body with *p53* in *p53*-overexpressing tumor cells. *p53*-based

immunization is an attractive approach to cancer immunotherapy due to the accumulation of *p53* protein in gastric cancer. We detected the effects of DCs transfected with full-length wild-type *p53* and modified by gastric cancer lysates on immune response and tried to make DC induce efficient and specific anti-tumor immunological response.

MATERIALS AND METHODS

Animals and cell lines

Eight-week-old female BALB/c mice were purchased from Hubei Animal Center and housed in pathogen-free units of Tongji Hospital experiment center.

Gastric cancer cells (Mk28) were obtained from Hubei cell culture center and cultured in complete culture medium (CCM) containing RPMI 1640 supplemented with 25 mL HEPES, 100 mL/LFCS, and antibiotics (100 U/mL penicillin, 100 µg/mL streptomycin, 0.25 µg/mL amphotericin B). It is a relatively immunogenic tumor that carries a mutant endogenous *p53* gene. P815 mastocytoma cells were obtained from ATC Company and cultured in CCM. The cell cultures were maintained at 37 in 50 mL/L CO₂ humidified atmosphere.

Reagents

Ad-mp53 was constructed by cloning the 1.5-kb murine *p53* cDNA (obtained from Sigma, Wuhan, China) into pAd1/CMV that contains CMV promoter and bovine growth hormone polyA signal sequence. This plasmid was co-transfected with pBHG10 into 293 cells. Recombinant adenovirus was selected based on PCR analysis of individual plaques. Control adenovirus (Ad-c) was prepared by deletion of E1 region from adenovirus serotype.

FITC-labeled mouse anti-mouse *p53* antibody and isotype mouse IgG2a were purchased from Serotec Company (New York, USA). FITC-labeled anti-mouse CD11c antibody and isotype mouse IgG2a, k, PE-labeled anti-mouse I-Ad, anti-mouse B7-1, B7-2, MHC-I, MHC-II antibody and isotype mouse IgG2a, k, as well as hamster anti-mouse CD40 (HM40-3) monoclonal antibody and anti-hamster IgM were purchased from Sigma Company.

Generation of DCs

DCs were generated from bone marrow of naive syngeneic mice in CCM supplemented with 20 ng/mL murine GM-CSF, 10 ng/mL IL-4, and 50 µmol/L 2-mercaptoethanol. The cells were maintained at 37 in a 50 mL/L CO₂ humidified atmosphere. Half of the medium was replaced on d 3. After 5-6 d in culture, cells were collected and enriched by centrifugation over a 135 g/L metrizamide gradient. The purity of DCs fraction was higher than 80% as determined by FACS analysis of surface molecules expression (B7-1, B7-2, MHC-I, MHC-II).

Infection of cells with adenovirus

DCs were infected with Ad-c or Ad-*p53* (10 000 viral particles per cell) for 90 min in 0.5 mL serum-free RPMI 1 640 medium supplemented with 20 ng/mL GM-CSF and 10 ng/mL IL-4 in 24-well plates followed by culturing in CCM with the same cytokines for 48 h. This dose was selected after some preliminary

experiments, and did not affect cell viability (95% viable after trypan blue staining).

Preparation of lysates and DCs loaded with tumor cell lysates

DCs were washed twice in PBS and incubated with 14 $\mu\text{g/mL}$ hamster anti-mouse CD40 monoclonal antibody for 25 min on ice, then washed in RPMI 1640 twice and cultured in 1 mL CCM supplemented with 3.5 $\mu\text{g/mL}$ anti-hamster IgM, 20 ng/mL GM-CSF and 10 ng/mL IL-4 overnight. Four kinds of DCs such as DC, wtp53DC, LyDC, and Lywtp53 were collected and loaded with tumor cell lysates.

FACS analysis of four kinds of DCs surface molecules expression

DCs were estimated by intracellular staining followed by flow cytometry. Cells were washed in PBS twice, fixed by 2.5 g/L paraformaldehyde solution for 30 min on ice, washed in PBS, permeabilized by 2 g/L Tween 20 for 15 min at 37 $^{\circ}\text{C}$, washed in PBS, incubated with FITC-labeled mouse anti-mouse p53 antibody or isotype mouse IgG2a for 25 min on ice, washed twice in PBS and analyzed by FACScalibur low cytometer.

To study the expression of surface molecules, DCs were washed twice in PBS, incubated with 1 $\mu\text{g}/10^6$ cells FITC-labeled anti-mouse CD11c antibody and PE-labeled anti-mouse I-Ad or anti-mouse B7-1, B7-2, MHC-I, MHC-II antibody for 25 min on ice, washed twice in PBS and analyzed by flow cytometry. Non-specific binding was estimated using FITC-labeled isotype mouse IgG2a, k and PE-labeled isotype mouse IgG2b, k.

Immune protection effect of Lywtp53 and treatment in mice

DCs were generated from bone marrow of BALB/c mice and infected with adenovirus as described above. Forty-eight hours later cells were washed 3 times in PBS and injected to BALB/c mice (2×10^5 /mouse) 3 to 4 times with a 10-14 d interval. Seven days after the last immunization Mk28 tumor cells (3.5×10^5 /mouse) were inoculated s.c. and the size of the tumor was observed.

The same tumor model was used to evaluate the effectiveness of treatment. Five hundred thousand Mk28 cells were inoculated s.c. shaved backs of BALB/c mice. The treatment was started when tumors reached 4-6 mm in diameter (d 7). Mice were treated with DCs prepared as described above. The treatment was repeated 4 times with 5- to 6-d intervals. Tumor sizes were measured every 3-5 d for 4 wk.

CTL assay

Splenocytes (effector cells) freshly isolated or restimulated for 7 d with 4 kinds of DCs were mixed with different ^{51}Cr -labeled target cells: Mk28 cells pre-incubated for 48 h with 5 ng/mL murine IFN- γ or p815 cells infected with Ad-p53 or Ad-c. After 6-h incubation and harvesting of supernatants, the radioactivity was measured by gamma-counter. To estimate the maximum ^{51}Cr -release, 10 g/L triton X-100 was used. The percentage of cell lysis was calculated as follows: (experimental release-spontaneous release)/(maximum release-spontaneous release) $\times 100\%$.

RESULTS

DCs surface molecules expression

Surface molecules of lywt-p53DC highly expressed were detected by FACS: B7-1 ($86.70 \pm 0.07\%$), B7-2 ($18.77 \pm 0.08\%$), MCH-I ($87.20 \pm 0.05\%$), MCH-II ($56.70 \pm 0.07\%$).

Induction of CTL response in mice immunized with DCs

To induce an immune response against wild-type p53, we started with three immunizations of BALB/c mice with DCs generated from bone marrow progenitors of syngeneic mice and transduced with Ad-p53 loaded with lysates as described

in MATERIALS AND METHODS. We found statistically significant differences in tumor formation between mice immunized with Lywtp53 DCs and control groups (9 mice per group), and no differences between wtp53DC and LyDC.

The presence of Mk28-specific CTLs was evaluated in mice immunized with activated Ad-p53-transduced DCs. Six-hour standard CTL assay was performed 1 mo and 1 wk after the last immunization (1 mo after inoculation of Mk28 cells into immunized mice). Freshly isolated splenocytes were mixed with ^{51}Cr -labeled Mk28 cells at different ratios. Splenocytes from mice injected with Ad-c-infected DCs demonstrated no ability to lyse target cells, whereas splenocytes from mice immunized with Ad-p53-transduced DCs demonstrated low, but clearly significant cytotoxicity against Mk28 cells (Figure 1).

Table 1 Surface molecules expression of 4 kinds of DCs stimulated with lysates ($n = 10$, mean \pm SD, %)

Surface molecules	DC	Wtp53DC	LyDC	Lywtp53
B7-1	36.70 \pm 0.07	61.77 \pm 0.08	67.20 \pm 0.05	86.70 \pm 0.07 ^a
B7-2	5.27 \pm 0.01	9.90 \pm 0.04	9.13 \pm 0.03	18.77 \pm 0.08 ^a
MHC-I	44.03 \pm 0.04	69.13 \pm 0.05	68.10 \pm 0.03	87.20 \pm 0.05 ^a
MHC-II	17.13 \pm 0.12	31.10 \pm 0.31	32.73 \pm 0.23	56.70 \pm 0.07 ^a

^a $P < 0.05$ vs any group of DC, wtp53DC and LyDC.

Table 2 Immune protection of DCs (mean \pm SD, $n = 10$)

Group	Tumor diameter after inoculation (mm)			
	d 10	d 13	d 16	d 19
Control	3.72 \pm 0.01	6.70 \pm 0.02	7.10 \pm 0.09	9.90 \pm 0.02
DC	3.70 \pm 0.01	5.70 \pm 0.08	6.10 \pm 0.04	9.70 \pm 0.08
Wtp53DC	3.07 \pm 0.01	6.90 \pm 0.04	7.13 \pm 0.03	8.22 \pm 0.08
LyDC	4.03 \pm 0.04	6.13 \pm 0.05	7.10 \pm 0.03	8.77 \pm 0.05
Lywtp53	3.13 \pm 0.02	3.10 \pm 0.31 ^a	2.73 \pm 0.23 ^a	3.70 \pm 0.07 ^a

^a $P < 0.05$ vs control, DC, wtp53DC and LyDC group.

Table 3 Immune treatment of DCs (mean \pm SD, $n = 10$)

Group	Tumor diameter after inoculation (mm)			
	d 7	d 12	d 15	d 18
Control	5.72 \pm 0.02	7.88 \pm 0.09	9.20 \pm 0.11	11.90 \pm 0.09
DC	4.70 \pm 0.03	7.71 \pm 0.08	9.02 \pm 0.04	10.70 \pm 0.68
Wtp53DC	5.03 \pm 0.09	6.90 \pm 0.09	7.13 \pm 0.11	8.29 \pm 0.05
LyDC	5.06 \pm 0.01	6.13 \pm 0.08	7.10 \pm 0.05	8.77 \pm 0.03
Lywtp53	5.19 \pm 0.09	5.10 \pm 0.39	6.73 \pm 0.66 ^a	6.79 \pm 0.77 ^a

^a $P < 0.05$ vs control, DC, wtp53DC and LyDC group.

The immune protection of Lywtp53DC group was obvious, the tumor size of Lywtp53DC group was smaller than control, DC, wtp53DC and LyDC group on d 13, 16 and 19 (Table 2).

Treatment of tumor-bearing mice with Ad-p53-transduced DCs and CTL response are shown in Table 3. On d 15 and 18, the growth rate of tumor in Lywtp53DC group was slower than any of the other group (Table 3).

DISCUSSION

p53 protein is an attractive target for immunotherapy of cancer. Normal cells have very low levels of p53, whereas accumulation of this protein because of mutations or functional inactivation is observed in 50% of human malignancies. This provides, in theory, potential targets for CTLs that recognize class I MHC-bound epitopes^[1-3].

In this study we have demonstrated that activated DCs transduced with full-length wild-type p53 loaded with lysates are able to break tolerance to this self-protein and induce potent antitumor response with no detectable autoimmune abnormalities. Wild-type, p53-derived, self-MHC-self-peptide complexes expressed by bone marrow-derived cells in the thymus cause negative selection of immature thymic T cells with a high avidity for such complexes^[4,5]. These results in deletion of T cells with sufficient avidity to recognize natural wild-type p53 epitopes presented by MHC class I molecules on tumor cells and thus prevent immune response. Only low avidity CTLs survive during the induction of self-tolerance^[6-8].

We suggest here another method of immunotherapy based on the use of full-length wild-type p53. This approach may be devoid of many limitations of peptide-based immunization and would provide a valuable option for clinical trials. Overexpression of wild-type p53 in antigen-presenting cells would allow presentation of several different epitopes. The feasibility of such an approach was shown previously in model experiments in which each of the different minimal epitopes combined to a single fusion protein can be presented separately on the cell surface and be recognized by specific CTLs^[9,10].

The study demonstrated that the wild type p53 was transduced to DCs with adenovirus, and the DCs were stimulated by gastric cancer lysates. The T lymphocytes had specific CTL lysis ability induced by Lywt-p53DC loaded with lysates, the CTL lysis rate was as high as 81%. The surface molecules of Lywt-p53DC showed a high expression of B7-1 (86.70±0.07%), B7-2 (18.77±0.08%), MHC-I (87.20±0.05%), MHC-II (56.70±0.07%); There were significant differences in tumor sizes between Lywtp53DC group and any other group. In Lywtp53DC group, the growth rate of tumor was slower than any one of the other group ($P<0.05$). These studies showed that Lywtp53 DC had immune protection effect on mice, especially loaded with lysates^[11-14].

Because of a polyclonal nature of T cells generated after two rounds of stimulations with p53 DCs, it is possible that some level of cytotoxicity against tumor cells could be mediated by alloreactivity. When the DCs were loaded with lysates of tumor, the lysates will be presented to APC, and the process can increase immunogenicity in the body. DCs were recognized; the specificity of CTLs was enhanced^[15,16].

In conclusion, these data indicate that DCs transduced with full-length wild-type p53 loaded with lysates are able to generate a CTL response specifically for tumors with p53 overexpression. These findings demonstrate that this approach may overcome tolerance to self-protein and may serve as a valuable option in cancer immunotherapy.

Abstract

AIM: To evaluate the immediate and long-term results in a series of patients with highly symptomatic polycystic liver disease (PLD) treated by combined hepatic resection with cystic fenestration.

METHODS: We reviewed our recent experience with a combined hepatic resection-fenestration procedure in seven highly symptomatic patients with PLD. Clinical data, liver manifestation of computed tomography (CT), and morbidity were recorded pre- and post-operation. Follow-up was made by clinical and CT examinations in all patients.

RESULTS: Symptomatic relief and reduction in abdominal girth were obtained in all patients during an average follow-up period of 20.4 mo. CT scans confirmed post-resection hypertrophy of the spared liver and lack of significant cyst progression. All patients had mild to severe ascites. Two patients were complicated with pleural effusion.

CONCLUSION: Some highly symptomatic patients with massive PLD may benefit from combined hepatic resection and fenestration at acceptable risk. To stitch the dissected hepatic ligaments could prevent the instable remnant liver from kinking and collapsing.

INTRODUCTION

Polycystic liver disease (PLD) is a rare, benign inherited condition, frequently associated with polycystic disease of the kidney^[1]. Unusually as liver failure appears, some patients may be highly symptomatic due to the compression of liver enlargement or liver complications, therefore requiring treatment.

Highly symptomatic patients with PLD almost exhaust all conservative therapeutic options, and surgery is considered as the best possible procedure^[2]. The purpose of this study was to evaluate the immediate surgical results and the short- and long-term outcome in patients treated with hepatic resection combined with cyst fenestration on the basis of our preliminary understanding and experience.

MATERIALS AND METHODS

From October 1995 to September 2002, we examined and operated on 6 women and 1 man with highly symptomatic PLD at our hospital. All operations were performed by a single surgeon (G.S. Yang). In this retrospective study, the medical records were reviewed. The mean interval from diagnosis of PLD to surgical treatment was 4.3 years, ranging from 2 to 11 years. Patient age ranged from 36-54 years, averaging 44.1 years. Specific symptoms included pain, massive abdominal distention, early satiety, regurgitation and supine dyspnea. Six patients were complicated with polycystic kidney disease but had no clinical evidence of abnormal renal function. Four patients had undergone percutaneous cyst aspiration with alcohol sclerotherapy before operation.

Preoperative workup included hematologic, hepatic and renal laboratory tests, and determinations of both respiratory and cardiovascular performance. CT scan was performed to delineate cyst distribution to assess portal vein patency and to serve as a baseline for follow-up comparison in each patient. No patient underwent angiography. The clinical features of these patients are summarized in Table 1.

Preoperative preparations of each patient were an overnight lavage bowel preparation and venous catheterization. The abdomen was explored through a bilateral subcostal incision. The hepatoduodenal ligament was exposed to provide access to a vascular clamping and identification of major vascular and biliary structures. The liver was mobilized by the division of hepatic peritoneal attachments, which was facilitated by sequential fenestration of accessible cysts according to the Lin technique^[3]. Liver segments spared of cystic involvement were identified to define limits to resection. Non-anatomic segmental or lobar resection was executed due to cystic distortion of normal anatomy. Significant islands of functional liver parenchyma were preserved as many as possible. After resection of major cystic segments, extensive fenestration of residual cysts was performed by excision of the cyst walls. Finally, cyst cavities exposed to the peritoneum were fulgurated by argon beam coagulation (Bard Electromedical Systems, USA) in an attempt to ablate secretory epithelium and reduce postoperative peritoneal fluid losses. Cholecystectomy in conjunction with hepatectomy was performed in three patients. The hepatic resection bed was drained by two large closed suction drains. After operation, patients were sent to the surgical intensive care unit for close monitoring.

All patients were followed up through telephone calls or at clinic. Special data included hepatic and renal function, symptomatic relief, the patients' working capacity and CT scans.

RESULTS

The surgical outcome of our patients is presented in Table 2. The histologic examination showed von Meyenburg's complexes in all cases. There was no hospital death. All patients had ascites, the majority of them were successfully managed with diuretics and drainage within one week. The average duration of drainage was 11 d, with a range of 5-26 d. Drainage

was continued by needle aspiration in Patients 5 and 6 immediately after a two-week closed suction drainage. The change was an attempt to prevent ascites from infection. Furthermore Patient 5 required thoracentesis due to left pleural effusion.

All patients experienced relief of abdominal symptoms and had normal hepatic and renal laboratory tests. Abdominal

girth was reduced markedly in six patients and moderately in one. Repeated abdominal CT scans in these patients failed to show significant development of cysts in the previously spared liver segments during a mean follow-up period of 20.4 mo, with a range from 2 to 86 mo. Indeed, as shown in Figure 1, CT scans confirmed post-resection hypertrophy of the spared liver and lack of clinically significant cyst progression.

Figure 1 CT scans of livers in PLD patients before (left panels) and 3 mo (right panels) after operation, show that hypertrophy of spared liver and lack of clinically significant cyst progression, and that operative methods totally depend on cystic distribution in different patients, e.g., lateral segment removal from A to B, right semi-hepatectomy resection from C to D, whereas extensive fenestration of posterior and interior cysts from E to F.

DISCUSSION

PLD is a rare disorder usually associated with autosomal dominant polycystic kidney disease, with an increasing prevalence associated with age and female sex^[4]. Symptoms arise from liver enlargement and compression of adjacent structures. Most symptomatic patients complained of increasing abdominal girth and a chronic dull abdominal pain. Liver enlargement may cause early satiety, weight loss, respiratory compromise, and physical disability. Complications such as ascites, esophageal varices, jaundice and hepatic failure, are rare^[5-7].

A variety of treatment have been advocated for the few patients with incapacitating symptoms. Percutaneous aspiration with alcohol sclerotherapy seems valuable for solitary cysts but does not provide relief for patients with PLD because cyst collapse may not be sufficient^[8]. Cyst fenestration with internal drainage into the peritoneal cavity, described by Lin in 1968, may fail to achieve long-term favorable outcome^[9]. In practice, the efficacy of the Lin decompression for PLD is limited by extent of cysts, access to central cysts, postoperative walling off of cysts, and the rigid architecture of the fenestrated liver, which does not completely collapse^[2]. Liver transplantation might be considered for patients with a “syndrome of lethal exhaustion” from PLD^[7,10,11].

Armitage and Blumgart^[12] described in 1984 a patient with PLD who underwent partial hepatic resection and cyst fenestration. This procedure allowed the excision of most prominent cysts with minimal resection of liver tissue; liver parenchyma was preserved despite the polycystic disease. Other reports have shown the feasibility of such an approach (Table 3)^[1,2,8,12-18]. We reported a similar favorable outcome. During a mean follow-up of 20.4 mo, six of seven patients were symptom free. Herein, we emphasize that the result might be achieved by a careful selection of patients and by an experienced surgeon. The head surgeon of our surgical team

has abundant experiences of more than 1400 hepatectomies for liver tumors during the same study period.

The postoperative morbidity rate in reviewed reports was 54.3%. The majority of immediately postoperative complications in our series were ascites and transient pleural effusion. Ascites was easily treated by diuretics and effective drainage or followed by needle aspiration. None of our patients had kidney failure requiring dialysis before or after operation. Ascites occurred in the patients with renal dysfunction may be refractory and even increased the chance to be infected or bring forth malnutrition^[17]. The elucidation for the mechanism of hepatic cystic epithelium secretion may be a key to solve this problem^[19].

The literature review showed an overall mortality rate of 4.3%. There is only one report that the cause of death was related to this procedure for patients with PLD^[15]. Acute Budd-Chiari syndrome developed shortly after fenestration of posterior cyst, which provoked a liver collapse. In practice, to stitch on the dissected triangular, falciform and round ligaments easily kept the stability of the remnant liver, which was weakened by extensive fenestration of posterior and interior cysts. Patient 6 is a good example in our series. In patients 3 and 4, we found that the left lobes twisted towards right due to gravity after right semi-hepatectomy in operation. Connecting the falciform and round ligaments easily enabled the remnants fixed, avoiding occurrence of kinking. It may be unnecessary to avoid fenestration of posterior cysts and propose a frontal hepatectomy. Two patients in literature died from postoperative intracerebral bleeding, suggesting that evaluation of selected patients' cerebral vasculature to detect aneurismal disease is essential^[2,16].

Our follow-up duration is limited and our preliminary study includes just seven selected patients. Therefore, the long-term benefit of combined hepatic resection and fenestration should be further evaluated. On the basis of our experience and review of the available literature, however, this approach

could be feasible, with an acceptable risk as well as a favorable long-term outcome at follow-up. To stitch the dissected hepatic ligaments could prevent the instable remnant liver from kinking and collapsing.

Abstract

A 59-year-old woman was admitted to our hospital because of recurrent follicular lymphoma (FL). Colonoscopic examination revealed a rectal submucosal tumor (SMT) without any erosions and ulcers. In this patient, it was difficult to distinguish non-Hodgkin's lymphoma (NHL) invasion from other disorders of the colon including carcinoid tumor merely based on endoscopic findings. Histopathologic and immunohistochemical studies on biopsy specimens showed an infiltration of atypical lymphocytes that were positive for CD20 and BCL2 but negative for UCHL-1. Fluorescence *in situ* hybridization on paraffin-embedded tissue sections (T-FISH) identified a translocation of *BCL2* with *IGH* gene. Based on these findings, the tumor was defined as an invasion of FL. T-FISH method is useful for the detection of a monoclonality of atypical lymphocytes in an SMT of the gastrointestinal tract, and particularly for the detection of chromosomal translocations specific to lymphoma subtypes.

INTRODUCTION

Primary gastrointestinal (GI) lymphomas are uncommon tumors, constituting less than 2% of all GI malignancies^[1]. The stomach, however, is the most frequent site of extranodal NHL. Of all GI NHLs, the incidence of gastric lymphomas ranged from 51% to 86%^[2,3], while that of colonic lymphomas ranged from 1.6% to 16.2%^[4,5]. Diagnosis of GI lymphomas may be complicated due to difficulties in pathological diagnosis and in staging with

endoscopic biopsies. In fact, it is occasionally difficult not only to distinguish NHL from other tumors but also to define subtypes of NHL on the basis of endoscopic and histological findings of biopsy specimens^[6,7]. Although flowcytometric analysis is efficient for differential diagnosis of lymphomas, obtaining a diagnostic biopsy may sometimes be difficult because GI lymphomas spread submucosally and have normal surface qualities; therefore, a number of specimens are required for an accurate diagnosis.

On the other hand, chromosomal translocations are closely associated with distinctive subtypes of malignant lymphoma^[8]. Both chromosomal banding and fluorescence *in situ* hybridization (FISH) are used for the detection of specific translocation. In addition, we have developed a procedure using FISH directly on paraffin embedded tissue sections (T-FISH), enabling us to perform cytogenetic analyses on both archival and small biopsy specimens^[9,10].

In the current study, using T-FISH we detected rearrangement of the *BCL2* with immunoglobulin heavy chain (*IGH*) gene on biopsy specimens obtained from a small rectal submucosal tumor (SMT), thereby differentiating follicular lymphoma (FL) from other neoplastic tumors of colon as well as other types of lymphoma.

CASE REPORT

A 59-year-old woman was admitted to our hospital because of the swelling of multiple cervical lymph nodes. The patient had suffered from stage IV disease of FL since 1997. Although multiple chemotherapies including high dose regimen supported by autologous hematopoietic stem cell transplantation were administered, complete remission has not been achieved. At the current hospitalization, the patient showed elevated soluble interleukin-2 receptor (1 024 U/L), while no abnormal cells were detected in both the peripheral blood and bone marrow. Gallium-scintigraphy showed abnormal accumulation at cervical and supra-clavicular lesions. Gastroscopic examination revealed no remarkable abnormalities, whereas colonoscopic examination detected a small elevated lesion (7 mm×8 mm in size) on the rectum.

The surface of tumor was slightly reddish, but no erosions and ulcers were noted (Figure 1). No definitive deformity of colonic wall was detected with double-contrast barium enema (Figure 2). The tumor invasion was confined to the second layer of colonic wall based on the endoscopic ultrasonographic findings (Figure 3). Flowcytometric analyses were not able to be performed because of small specimens obtained from diagnostic biopsies. Histopathologic and immunohistochemical studies on biopsy specimens showed the aggregation of atypical medium-sized lymphocytes having irregularly enlarged nuclei that were positive for CD20, CD10 and BCL2, but negative for UCHL-1 and CD5 (Figures 4A-C).

Using DHAP regimen (cisplatin 70 mg/m², Ara-C 1.4 g/m²×2, dexamethasone 40 mg×4), the patient achieved a partial response, followed by the administration of rituximab. The rectal lesion disappeared on d 120.

In order to confirm a diagnosis of lymphoma and define specific chromosomal abnormalities, we performed T-FISH analyses on the sample obtained from a rectal SMT according to the protocol already described elsewhere^[9,10]. Briefly, sections from paraffin-embedded tissues were placed on slides, and then deparaffinized in xylene. Each slide was dehydrated in ethanol and treated with 0.2 mol/L HCl and 0.05 mg/mL proteinase K in TEN (0.05 mol/L tris-HCl, pH 7.8, 0.01 mol/L EDTA, and 0.01 mol/L NaCl buffer) for 10 min at 37 °C. FISH probes and samples were denatured simultaneously for 10 min at 90 °C, and were hybridized overnight at 42 °C. LSI IGH/BCL2, IGH/BCL1 and MALT1 probes (Vysis, CA, USA) were used for the detection of t (14; 18), t (11; 14), and 18q21 translocations, respectively. Images of signal were captured by a CCD camera. T-FISH detected fusion signals of *BCL2* and *IGH* genes on 75 of 100 nuclei (Figure 5), defining the invasion of FL with t (14; 18) (q32; q21). On the other hand, 95 of 100 nuclei showed negative results for both t (11; 14) and 18q21 translocations.

Figure 1 Endoscopic examination revealed a small submucosal tumor on rectum.

Figure 2 Double-contrast barium enema revealed no definite deformity of the GI wall at the lesion.

Figure 3 Endoscopic ultrasonography showed that the tumor was confined at the second layer of the colonic wall.

Figure 4 Histopathological studies showed aggregated atypical lymphocytes (A). Immunohistochemical analysis revealed that these lymphocytes were positive for CD20 and BCL2 (B and C).

Figure 5 T-FISH detected fusion signals of IGH and BCL2 genes in nuclei as indicated by arrows.

DISCUSSION

We demonstrated rearrangement of *BCL2* with *IGH* gene on a small rectal SMT in a patient with recurrent lymphoma using T-FISH, thereby defining colonic involvement of FL. It is difficult to discriminate NHL from other disorders of the GI tract only based on endoscopic and histological findings^[11]. Although endoscopic procedures are important not only in the detection of other disorders involving GI tract, but also in providing a means for pathologic diagnosis through biopsy, it should be noted, however, that obtaining a diagnostic biopsy may be difficult because GI lymphomas spread submucosally and have normal surface qualities. Since most GI lymphomas and other malignancies including adenocarcinoma and carcinoid tumor frequently display a polypoid growth pattern involving the mucosa, submucosa and muscularis^[12], it is sometimes difficult to make differential diagnosis based on the histological findings.

In the current patient, immunohistochemical studies defined a diagnosis of lymphoid lesion of a rectal SMT, although flowcytometric analysis was not successful because of small specimens obtained from diagnostic biopsy. There are many kinds of SMTs originating in the colon, for example, lipoma, malignant lymphoma, carcinoid tumor, *etc*^[13]. Flowcytometric and immunocytochemical studies are useful for demonstration of a monoclonal population of lymphocytes of a lesion of interest, since most GI lymphomas are virtually always of the B-cell type. However, it should be noted that there are certain subtypes preferentially involving GI tract including mantle cell lymphoma, and mucosa-associated lymphoid tissue (MALT) lymphoma^[14]. In this respect, cytogenetic study is necessary for the determination of these subtypes, since chromosomal translocations are closely associated with distinctive subtypes of NHL^[14]. More than 90% of mantle cell lymphoma was related to the translocation of *IGH* with *BCL1* gene^[15]. MALT lymphoma

was related to the translocation of *API2* with *MALT1* at frequencies of 18.8%^[9]. Approximately 60% of FL showed the translocation of *BCL2* with *IGH* (Matsumoto *et al.* in press). Hence, T-FISH is a useful method not only to make definitive diagnosis of NHL but also to define its subtypes. In addition, a few biopsy samples are enough for T-FISH analysis when compared with flowcytometric analysis and polymerase chain reaction (PCR). Furthermore, the tissues embedded for a period of 15 years were available for T-FISH analysis^[9,10].

At present there is considerable controversy concerning the treatment of primary and secondary GI lymphomas. Rituximab has recently included in treatment option^[16]. In our patient with recurrent FL, salvage therapy including high-dose Ara-C with rituximab was performed. Because *API2-MALT1*-positive lymphoma has demonstrated a more aggressive subgroup^[17], T-FISH will provide novel information for the selection of treatment for GI lymphomas.

In conclusion, our results indicate that T-FISH is a promising procedure for the routine detection of genetic alterations in GI lymphomas, it enables us to not only make definitive diagnosis of NHL but also to define its subtypes.

Abstract

Chronic mesenteric ischemia is an uncommon condition associated with a high morbidity and mortality. We reported a 36-year old woman with postprandial abdominal pain due to chronic mesenteric ischemia caused by a fistula between superior mesenteric and common hepatic artery.

INTRODUCTION

Chronic mesenteric ischemia (CMI) is an uncommon condition associated with a high morbidity and mortality and the symptoms may be nonspecific until late in the course of disease^[1,2].

The most common cause of CMI is atherosclerosis. Involvement of the celiac, superior mesenteric, and inferior mesenteric arteries at their origins is typical^[3]. We reported an abnormal communication between the superior mesenteric artery (SMA) and common hepatic artery (CHA) which caused splanchnic hypoperfusion. To our knowledge, this entity has not been reported previously in the literature.

CASE REPORT

The patient was a 36-year old woman who had complained of severe postprandial abdominal pain and abdominal distention for 9 mo. The pain was described as a severe, poorly localized one radiating to the back. No fever, nausea or vomiting, hematochezia, or weight change was reported. She had no history of previous trauma, abdominal surgery, hepatic or pancreatic disease. Hematological and biochemical test results on admission were as follows: white blood cell count, 7 000/mm³ (normal, 4.0-10.0); hemoglobin, 13.4 g/dL (normal, 12.1-17.2); platelets, 177 10³/uL (normal, 150-400); total bilirubin, 0.36 mg/dL (normal, 0.1-1.3); albumin, 4.6 g/dL (normal, 3.5-5.2); aspartate aminotransferase, 29 u/L (normal, 10-31); alanine aminotransferase, 30 u/L (normal, 10-31); amylase, 74 u/L (normal, 0-90); lactate dehydrogenase, 335 u/L (normal, 220-450).

On physical examination, pulse rate was 84/min and arterial blood pressure was 110/70 mm Hg. Rectal examination revealed no mass and the stool was hemoccult negative. Computerized

tomography of the abdomen, plain abdominal radiography and upper endoscopy were normal. Abdominal ultrasonography showed a slightly enlarged liver with normal echo pattern and communication between the common hepatic artery and superior mesenteric artery (Figure 1). On Doppler ultrasound, arterial flow was observed within this fistula (Figure 2). We suspected CMI and consequently performed angiography. Celiac arteriogram revealed an abnormal fistula from the SMA to the CHA and not any other arterial communications (Figure 3).

Figure 1 Sonogram showing a fistula (thin arrow) between superior mesenteric artery (arrowhead) and common hepatic artery (thick arrow).

Figure 2 Color doppler sonogram of fistula revealing arterial flow.

Figure 3 Selective superior mesenteric artery angiography showing a fistula between superior mesenteric artery and common hepatic artery.

A small quantity diet with low fat content was advised to the patient who responded well to this measure and after one month she was free of abdominal pain, and also of abdominal distension, hence we did not plan to perform surgery or interventional radiology.

DISCUSSION

The major vascular supply of the bowel depends on the celiac, superior mesenteric and inferior mesenteric arteries. The superior mesenteric artery is the largest of all the aortic branches and carries over 10% of the cardiac output. Splanchnic circulation was about 30% of the circulating blood volume^[4,5].

CMI is a disputatious diagnostic problem. Most patients do not develop ischemic symptoms because of the abundant collateral circulation of these intestines. Usually at least two of the three mesenteric arteries must be significantly stenotic before symptoms developed^[6,7].

Classically, postprandial abdominal pain, known as "intestinal angina", was almost invariably the principal symptom. Other less consistent symptoms included bloating, flatulence, nausea, and variable changes in bowel habit^[2,8,9]. Superior mesenteric artery blood flow increased after ingestion of meals with a high fat content^[5]. Our patient reported significant crampy abdominal pain after heavy meal, meanwhile consuming small and low fat meal did not cause pain. The pathophysiological mechanism in this case was an arterial abnormality which was an abnormal communication between SMA and CHA. Under such a condition blood perfusion became impaired. A higher blood pressure in SMA could force flow towards CHA. Blood flow might be sufficient to sustain resting metabolic needs, but after a heavy meal, however, splanchnic blood flow did not increase because of this steal phenomenon.

A diagnosis of vasculogenic mesenteric ischemia was made on the basis of the clinical history and duplex ultrasonography findings. Other causes of abdominal pain were excluded. Large majority of cases of colonic ischemia were due to non-occlusive diseases^[10]. Other less common causes of CMI were vasculitis, SLE, sick cell disease, hypercoagulable states, medications (estrogen, danazol, vazopressin, gold, psychotropic drugs), and cocaine abuse^[1,11].

Clinical presentations of the patient might depend on the size and amount of blood flow through the fistula, ranging from asymptomatic cases to overt intestinal ischemia.

We suggested nutritional measures aiming at avoiding large meals and reduction of long-chain fat content.

In a patient with an unexplainable chronic abdominal pain, after exclusion of common reasons, vascular abnormalities must be suspected. Like in our case, there might be other abnormal vascular communications, thus even in a young patient vascular examinations might be necessary.

Abstract

A 44-year-old woman developed jaundice and was diagnosed as stage II of primary biliary cirrhosis (PBC). She showed a severely high total cholesterol level. This article focuses on atypical presentations of PBC and the need to test the total cholesterol level of PBC patients.

<http://www.wjgnet.com/1007-9327/10/2607.asp>

CASE REPORT

A 44-year-old gentlewoman was admitted in August 1996 due to a feeling of itching and jaundice. She had no special past history, such as operation, blood transfusion, tattooing or illicit drug use. She did not drink or smoke. There were no particular familial histories such as liver disease or hyperlipidemia. The patient had been on medication for hyperlipidemia, with a daily intake of 10 mg of pravastatin sodium, 12 g of cholestyramine, and 600 mg of ursodeoxycholic acid since one month earlier.

On admission, her height, body mass and body mass index (BMI) were 154.5 cm, 46.0 kg and 19.3 kg/m², respectively. Her physical examination revealed mild anemia and jaundice. Xanthoma was noticed around her eyes, but thickened Achilles tendon was not seen on X-ray examination. Her liver and spleen were not enlarged. There was no pretibial edema in her feet.

Blood test results were compatible with the picture of primary biliary cirrhosis (PBC). The serum bilirubin level was 57 mg/L (normal 2-12 mg/L), direct bilirubin was 42 mg/L (normal <3 mg/L), alkaline phosphatase was 2 362 IU/L (normal 115-359 IU/L), and alanine aminotransferase was 105 IU/L (normal 8-42 IU/L). Prothrombin time was within normal limits at 11.8 seconds. Platelet count was 277×10⁹/L. Renal function was normal. Ultrasound scan showed normal liver size and biliary trees were normal. There were no gallstones or ascites. Intimal medial thickness (IMT) of the right common carotid artery did not show any increase on high-resolution B mode ultrasonography.

Serology tests for hepatitis B and C viruses were negative. Anti-mitochondrial antibody (AMA) and anti-mitochondrial M2 antibody were positive (×320) and 41.5 (normal <7). Anti-

nuclear antibody (ANA) and anti-smooth muscle antibody were both negative. IgG and IgM were 27.42 g/L (normal 8.7-17 g/L) and 11.89 g/L (normal 0.35-2.20 g/L), respectively. Thyroid gland functions were within normal limits at this time.

Her serum total cholesterol level was 13.90 g/L (normal 1.25-2.20 g/L), triglyceride 1.12 g/L (normal 0.35-1.50 g/L), high-density lipoprotein (HDL) cholesterol 1.03 g/L (normal >0.40 g/L), and blood glucose 1.03 g/L. She was positive for lipoprotein X. LCAT was not detectable, compatible with Frederickson type V hypercholesterolemia [apolipoprotein A-I 0.48 g/L (normal 1.26-1.65 g/L), A-II 0.24 g/L (normal 0.246-0.333 g/L), B 1.44 g/L (normal 0.66-1.01 g/L), C-II 333 mg/L (normal 15-38 mg/L), C-III 3.42 g/L (normal 26-46 mg/L) and E 450 mg/L (normal 29-53 mg/L)].

Liver biopsy showed no cirrhosis but revealed compatibility with PBC stage II (according to Ludwig). She was re-started on ursodeoxycholic acid at 900 mg/d and probucol at 500 mg/d. She was diagnosed as subclinical hypothyroidism [TSH 11.5 μIU/mL (normal 0.35-4.94 μIU/mL), free T3 1.45 pg/mL (normal 1.71-3.71 pg/mL) and free T4 8.2 ng/L (normal 7.0-14.8 ng/L)] in April 1999 and 0.05 mg/d of levothyroxine sodium was begun. However, her total cholesterol level remained quite similar to that before treatment as in October 2000 it was still high (10.11 g/L).

DISCUSSION

In PBC patients, a hyperlipidemic state is often observed; however, this case illustrated an unusual presentation of severe hypercholesterolemia. According to Talwalkar and Lindor^[1], up to 85% of patients presented with hypercholesterolemia at diagnosis. However, such a degree of hypercholesterolemia was not observed in many cases. In fact, our survey of more than 100 cases of PBC who visited our clinic revealed only this one case with a level of hypercholesterolemia higher than 10 g/L.

Earlier cross sectional studies reported higher levels of total cholesterol and lower levels of HDL cholesterol in patients with advanced disease compared with those in the earlier stages^[2,3]. On the other hand, Nikkila *et al.*^[4] reported that reduced hepatic synthesis and internal absorption in the terminal stage of PBC might lead to decreased total cholesterol levels. Although high levels of lipoprotein X, comprised of nonesterified cholesterol and phospholipids, were present in the serum of patients with PBC^[5], our patient was at stage II of early PBC, even if her serum bilirubin level was 57 mg/L. Hypothyroidism and subclinical hyperthyroidism often caused hyperlipidemia^[6,7]. In our patient, hypercholesterolemia did not improve after thyroid hormone therapy.

In PBC, marked hypercholesterolemia was not associated with an excess risk of cardiovascular disease, whereas less advanced patients with moderate hypercholesterolemia were exposed to an increased cardiovascular risk^[8]. There is no doubt that a reduction in serum cholesterol levels in PBC patients could be achieved with medical therapy^[9,10], so our patient continued to be observed with medical therapy.

In conclusion, we report a case of severe hypercholesterolemia, not familial, but associated with early-stage PBC. Further studies of severe hypercholesterolemia are warranted.

Abstract

Cystic dystrophy of the duodenal wall is a rare condition characterized by the development of cysts in heterotopic pancreatic tissue localized in the duodenal wall. A 38-year-old man was admitted to the hospital for abdominal pain and vomiting after food intake. The diagnosis of acute pancreatitis was initially suspected. Abdominal ultrasound examination revealed thickening of the second portion of duodenal wall within which, small cysts (diameter, less than 1 cm) were present in the vicinity of pancreatic head. The head of pancreas appeared enlarged (63 mm×42 mm) and hypoechoic. Upper endoscopy and barium X-ray series were performed revealing a severe circumferential deformation, as well as 4 cm long stenosis of the second portion of the duodenum. CT examination revealed multiple cysts located in an enlarged, thickened duodenal wall with moderate to strong post-contrast enhancement. We suspected that patient had cystic dystrophy of duodenal wall developed in the heterotopic pancreas and diagnosis was confirmed by endoscopic ultrasound (EUS). Endoscopic ultrasound (EUS) revealed circular stenosis from the duodenal bulb onwards. A twenty megaHertz mini-probe examination further showed diffuse (intramural) infiltration of duodenal wall limited to the submucosa and muscularis propria of the second portion of duodenum with multiple microcysts within the thickened mucosa and submucosa. Patient was successfully surgically treated and pancreatoduodenectomy was performed. The pathological examination confirmed a diagnosis of cystic dystrophy of a heterotopic pancreas. Endoscopic ultrasonography features allow preoperative diagnosis of cystic dystrophy of a heterotopic pancreas in duodenal wall, with intraluminal 20 MHz mini probe sonography being more efficient in cases of luminal stenosis.

Jovanovic I, Knezevic S, Micev M, Krstic M. EUS mini probes in diagnosis of cystic dystrophy of duodenal wall in heterotopic pancreas: A case report. *World J Gastroenterol* 2004; 10 (17): 2609-2612

<http://www.wjgnet.com/1007-9327/10/2609.asp>

INTRODUCTION

The most common type of heterotopic tissue in the gastrointestinal tract is pancreas. Pancreatic heterotopia is defined as the

presence of abnormally located (aberrant) pancreatic tissue with no contact (vascular, neural, and anatomical) with the normal pancreas, and possesses its own duct system and vascular supply^[1,2]. Heterotopic pancreatic tissue has been found in several abdominal and intrathoracic locations, most frequently in the stomach (25-60%) or duodenum (25-35%)^[3].

Cystic dystrophy of the duodenal wall in heterotopic pancreas is a relatively rare clinical disorder affecting young men in particular^[4]. Diagnosis is usually suspected during initial investigation of non-specific clinical symptoms such as abdominal pain, duodenal obstruction and weight loss and finally confirmed by imaging techniques, mainly endoscopic ultrasound which localizes precisely cysts in duodenal wall.

The purpose of this report was to present a case with this anomaly and provide up-to-date literature review on this topic.

CASE REPORT

A 38-year-old man who was admitted for clarification of several months of upper abdominal pain, vomiting after food intake accompanied by a weight loss. The patient had no history of alcohol abuse, and smoked 20 cigarettes per day. Physical examination revealed tachypnea and tachycardia, and a blood pressure 100/70 mmHg. There was abdominal tenderness in upper abdomen. Hematological and blood bio-chemical tests were performed (Tables 1, 2) showing a sevenfold increased level of serum amylase (625 U/L, range 20-90 U/L) accompanied by an elevated alkaline phosphatase, and markers of acute hepatocyte injury such as alanine (AST) and aspartate aminotransferase (ALT) and gamma GT. Bilirubin levels remained normal. The urine had a pH 6.5 and a specific gravity of 1.010. The sediment contained 3-5 red cells and 0-2 white cells per high-power field. A diagnosis of acute pancreatitis was initially suspected.

Ultrasonographic examination revealed an enlarged steatotic liver, no stones in gall bladder, and a common bile duct diameter of 8 mm with no signs of stone obstruction. Second portion duodenal wall appeared thicker within which, small cysts (diameter, less than 1 cm) were present in the vicinity of pancreatic head. The head of pancreas appeared enlarged (63 mm×42 mm) and hypoechoic.

An upper GI endoscopy also revealed a severe semispherical deformation of second portion of duodenum without mucosal lesions. Due to the stenosis the endoscope could not be passed distal to upper duodenal flexure. Biopsy of the duodenal mucosa detected moderate inflammatory changes (Figure 1).

A barium meal revealed a severe circumferential deformation, as well as 4 cm long stenosis of the second portion of the duodenum (Figure 2).

We suspected that the patient had cystic dystrophy of duodenal wall developed in the heterotopic pancreas which was highly indicated by computed tomography and endoscopic ultrasound (EUS).

CT examinations revealed multiple cysts located in an enlarged, thickened duodenal wall with moderate to strong post-contrast enhancement.

Endoscopic ultrasound (EUS) revealed circular stenosis from the duodenal bulb onwards. Twenty megaHertz mini-probe

examinations further showed diffuse (intramural) infiltration of duodenal wall limited to the submucosa and muscularis propria of the second portion of duodenum with multiple, very small anechoic spots, like microcysts (Figure 3A, B). EUS did not reveal any tumors of the pancreas.

MRI examinations showed a suspicious 6 cm×4 cm solid and partly cystic tumor of processus uncinatus of pancreas.

The patient was successfully surgically treated and pancreatoduodenectomy was performed (Figure 4). Pathological examinations confirmed a diagnosis of cystic dystrophy of a heterotopic pancreas (Figure 5).

Table 1 Hematologic tests

Variable	Value	Initial tests	Repeated tests
Hematocrit (%)	35-54	43	49.7
White cell count ($\times 10^9$)	4.0-10.0	12.0	17.7
Differential count ($\times 10^9$)			
Neutrophils	1.4-6.5	4.3	2.8
Lymphocytes	1.2-3.4	5.6	2.8
Monocytes	0.1-0.6	2.1	1.1
Prothrombin time (% quick)	75-120	114	115

Table 2 Blood bio-chemical tests

Variable	Initial test	Repeated test
Sodium (mmol/L)	132	148
Potassium (mmol/L)	2.5	4.6
Chloride (mmol/L)	75	107
Urea nitrogen (mmol/L)	9.4	2.8
Creatinine ($\mu\text{mol/L}$)	80	57
Glucose (mmol/L)	8.5	4.3
Bilirubin ($\mu\text{mol/L}$)	13	13
AST (U/L)	50	153
LT (U/L)	93	217
Alkaline phosphatase (U/L)	361	980
Alpha amylase (U/L)	627	354

Figure 5 Irregular pseudocystic change in myofibroblastic stromal proliferation is considered as common histological findings in this lesion (HE, 112 \times).

DISCUSSION

The pancreas develops from two primitive diverticula, dorsal and ventral, that arise from the duodenum and the base of the liver, respectively, in the fifth week of gestation. During the seventh week, the two primordia fuse. The ventral portion gives rise to part of the head of the pancreas and the uncinate process,

and the dorsal portion becomes the body. In more than half the cases of pancreatic heterotopia, pancreatic tissue has been located in the duodenum or the pylorus but other sites have also been involved^[2].

Pancreatic heterotopia can develop due to either metaplasia of multipotent endodermal cells in situ or transplantation of embryonic pancreatic cells to adjacent structures^[2]. Heterotopic pancreatic tissues may be found in the mucosa or the muscularis or may be attached to the serosa of the gastrointestinal tract. Heterotopic pancreatic tissues that lack both acinar and endocrine cells have been called myoepithelial hamartoma, adenomyosis, or adenomyoma. Despite its congenital origin, pancreatic heterotopia was usually discovered in adults due to its complications^[5]. Most frequently it was found incidentally during autopsies, operations or during endoscopic examinations of the upper GI tract^[6]. The occurrence rate of heterotopic pancreas in autopsy series was estimated to be about 0.55% to 13.7%^[4,7].

Despite many advances of new diagnostic tools and methods, the diagnosis of heterotopic pancreas prior to surgery is still difficult. Heterotopic pancreas is usually asymptomatic and does not require treatment (i.e. surgical excision). However, sometimes, there were evident clinical symptoms^[8]. The most common symptoms attributed to heterotopic pancreas were: abdominal pain, nausea, vomiting, anemia, weight loss and melena^[9]. Rare manifestations and complications of heterotopic pancreas included acute and chronic pancreatitis^[10], biliary obstruction, intestinal obstruction, cystic dystrophy and malignant degeneration^[5,11,12].

The differential diagnosis of a cystic dystrophy of heterotopic pancreas includes disorders in three broad categories: inflammatory lesions, neoplasms, and congenital anomalies.

Complications of pancreatic heterotopia usually include inflammation with a formation of an inflammatory mass, ulceration, bleeding and obstruction with clinical manifestations of acute and chronic pancreatitis. Chronic pancreatitis with mucinous metaplasia of the ductal epithelium can further be complicated by prominent exudation of mucin into the stroma, mimicking mucinous carcinoma^[13].

The most challenging differential diagnosis of cystic dystrophy of heterotopic pancreas is cystic (mucinous) neoplasms. It has been demonstrated that pancreatic carcinomas or endocrine tumors can also develop in heterotopic pancreatic tissue^[14,15]. In this case, CT findings are non-specific. Endoscopic and upper GI barium X-ray series can reveal duodenal stenosis and submucosal masses if there are no mucosal lesions and biopsies from the lesions cannot always provide a representative tissue specimen. The introduction of endoscopic ultrasonography (EUS) makes the diagnosis of cystic dystrophy of the duodenal wall in heterotopic pancreas easier^[16]. Furthermore, endoscopic ultrasonography is a reliable method providing precise localization, extent and characteristics of the submucosal mass, making possible to differentiate it from all other causes of stenosis such as tumor and pancreas annulare^[17].

However, although there is good correlation between EUS^[16], computer tomography (CT) and nuclear magnetic resonance (NMR) findings with histological changes^[17,18], the definite diagnosis is often made only from surgical excision.

The treatment of this disease is controversial. There are reports of successful treatment with long-acting somatostatin synthetic stable analog^[19]. In some 40% of patients reduction in cyst size could be accomplished after three months of treatment^[16]. But, on the other hand, octreotide/analog treatment was of a limited value regarding already formed stenosis of the duodenum (in regards to persistent duodenal stenosis)^[20,21]. Furthermore, the necessary duration of treatment has not been established yet.

Ponchon *et al.* offered an alternative to surgical treatment for endoscopic fenestration of cysts, but that approach was feasible only for cases where cysts were fewer, not dispersed and relatively larger in size^[22].

Despite the encouraging attempts to treat cystic dystrophy of duodenal wall in heterotopic pancreas with conservative approaches, the treatment is still primarily surgical^[20,21,23,24].

Moreover, there is a difficult therapeutic dilemma: if such a lesion should be treated by duodenopancreatectomy or limited local excision?

Regarding the surgical procedures, there were data that conservative surgical procedures including segmental duodenal resection could be an alternative approach to the Whipple procedure^[25], but in other cases of pancreatic surgery, they were associated with a considerable morbidity and mortality^[26-28], and should be reserved for specialized centers^[29].

In conclusion, we demonstrated a rare case of cystic dystrophy of heterotopic pancreas in duodenal wall. Cystic dystrophy of aberrant pancreatic tissue can be either isolated or as in our case associated with acute pancreatitis and duodenal stenosis. Although the condition is benign, clinical symptoms vary and patients are usually referred for suspected pancreatic neoplasms or acute pancreatitis. Endoscopic ultrasonographic features allow preoperative diagnosis of cystic dystrophy of a heterotopic pancreas in duodenal wall, with intraluminal 20 MHz mini-probe sonography being more efficient in cases of luminal stenosis.

Abstract

AIM: To assess CT and MR manifestations and their diagnostic value in splenic hamartoma with review of literatures.

METHODS: We described a woman who was accidentally found to have a splenic tumor by ultrasound of the abdomen. CT and MR findings of this splenic hamartoma were proved by pathology retrospectively.

RESULTS: The CT and MR findings in this case included a ball-like mass with homogeneous mild-hypodensity lesions on non-enhanced CT scans or isointensity on T₁-weighted images and mild hypointensity on T₂-weighted images, progressive homogeneous enhancement on multiple-phase spiral CT and MR enhanced scans, and isodense enhancement on delayed post-contrast CT scans and obvious hyperintensity relative to the spleen on delayed MR images.

CONCLUSION: Splenic hamartoma has some specific radiological features. However, the diagnosis of this disease must be based on clinical features and confirmed by pathology.

INTRODUCTION

Splenic hamartoma is a rare benign vascular tumor^[1]. Up to now,

less than 50 cases in Chinese literature or about 160 cases in the world have been reported after the first description by Rokitansky in 1861.

Imaging features of splenic hamartoma have been described by several researchers at computed tomography (CT), magnetic resonance imaging (MRI) and sonography^[2-8] and the imaging appearance of these lesions is considered as nonspecific and a histopathological confirmation is often required^[9-11].

This paper described the CT and MRI features of splenic hamartoma in a 40-year-old patient with review of the literature.

CASE REPORT

A 40-year-old woman was accidentally diagnosed having a splenic tumor by ultrasound of the abdomen. She did not complained about fever, fatigue, abdominal pain, or weight loss was complained. She denied any history of hepatitis or tuberculosis. Physical examination was entirely normal. There was no evidence of jaundice, peripheral lymphadenopathy or hepatosplenomegaly. Her hemoglobin was 125 g/L, the number of white blood cells was $7.3 \times 10^9/L$ and the number of platelets was $176 \times 10^9/L$. Both stool and urinate routine tests and hepatic and renal function tests were normal. Chest x-ray was also normal.

Spiral CT of the abdomen before contrast medium administration revealed a 3.8-cm diameter, homogeneous mild-hypodensity lesion within the spleen (Figure 1A). During hepatic artery phase following bolus injection of intravenous contrast, the lesion showed a slightly homogeneous enhancement (Figure 1B). During the portal venous phase and hepatic parenchymal phase, the lesion showed a progressively homogeneous enhancement. On delayed images up to 5 min after-contrast injection, the tumor was isodense with the spleen (Figure 1C). CT diagnosis was a splenic hemangioma.

MRI of the abdomen showed a 3.6 cm×3.8 cm×4.2 cm ball-like mass with isointensity on T₁-weighted images (Figure 2A) and mild hypointensity on T₂-weighted images (Figure 2B). The lesion demonstrated a diffuse heterogeneous enhancement on images obtained early after contrast medium administration (Figure 2C) and became more uniformly enhanced on the portal venous phase and hepatic parenchymal phase. It was hyperintense compared to the spleen on the delayed images (Figure 3). The MR examination yielded a diagnosis of splenic hemangioma. A 4.0-cm diameter tumor was found in the spleen during operation. The pathologic diagnosis was a splenic hamartoma (Figure 4).

Figure 1 CT scans of splenic hamartoma. A: Homogeneous mild hypodensity lesion within the spleen found by unenhanced CT scan, B: Mild-homogeneous enhancement of the mass found by enhanced CT scan on hepatic artery phase, C: Isodense tumor with normal spleen on delayed enhanced CT images.

Figure 2 MR images of splenic hamartoma. A: Round-like mass with isointensity relative to the spleen on MR T₁-weighted images, B: Mild-hypointense mass on MR T₂-weighted images, C: Diffuse heterogeneous enhancement of mass by enhanced MR scan on early portal venous phase.

Figure 3 Obviously hyperintense tumor with normal spleen on delayed enhanced MR images.

Figure 4 Red marrow tissue and some blood sinusoid structures with lymphocytes and macrophages in hamartoma. Fibrosis was remarkable. (HE, original magnification×100).

DISCUSSION

Hamartoma of the spleen is a rare benign lesion and the diagnosis is difficult to make preoperatively. Histologically it is composed of an aberrant mixture of the normal tissue components of the spleen, so hamartoma of the spleen is often called splenoma, splenadenoma or nodular hyperplasia^[2,3].

Splenic hamartoma occurs most commonly in adults. About 14.3% of the reported cases of splenic hamartoma occurred in pediatric patients^[12]. Most patients were asymptomatic, they were incidentally found during imaging studies, laparotomy or autopsy^[2,3]. Our case was accidentally discovered by ultrasound examination of the abdomen. Symptomatic splenic hamartoma was rare but nearly half of splenic hamartoma pediatric patients had symptoms^[12]. A minority of these lesions had hematologic symptoms such as pancytopenia, anemia, and thrombocytopenia^[12-16]. Spontaneously ruptured splenic hamartoma has been reported^[17,18]. Symptomatic splenic hamartoma with renal, cutaneous abnormalities or portal hypertension and

heterotopic ovarian splenoma were described accidentally^[19-21].

A few radiological findings in splenic hamartoma have been described^[2-8]. Sonography was a more sensitive modality than CT in demonstrating the lesion, which showed hyperechoic masses with cystic components occasionally^[2]. But hypoechoic splenic mass was found and color Doppler sonography showed blood-flow signals inside the mass in a recent report^[4]. CT could reveal splenomegaly and homogeneous or heterogeneous low-density or isodense masses with calcification^[2,5,6] or fatty components, which are characteristic CT findings. Dense spreading enhancement on dynamic CT and prolonged enhancement on delayed post-contrast scans were noted in singular mass^[5]. But low-density masses relative to the spleen were seen in multiple splenic hamartomas after contrast medium administration^[2]. The CT findings in this case were similar to those in Ohtomo's report^[5], which included a homogeneous mild-hypodensity lesion on non-enhanced scans, a progressive homogeneous enhancement on multiple-phase spiral CT enhanced scans and an isodense enhancement on delayed post-contrast scans.

There were two types of MRI findings in splenic hamartomas, fibrous and non-fibrous splenic hamartomas. Histopathologically, fibrous splenic hamartomas had a dominant fibrous tissue and MRI showed isointensity or hyperintensity on T₁-weighted images, hypointensity on T₂-weighted images^[3,7]. We consider hypointensity on T₂-weighted images is one of the common MRI findings in splenic hamartomas. Non-fibrous splenic hamartomas are more common and MRI showed isointensity on T₁-weighted images, hyperintensity on T₂-weighted images^[6,8]. Both of the tumors demonstrated diffuse heterogeneous enhancement on the hepatic artery phase or early dynamic contrast-enhanced scans, which became more uniformly enhanced on delayed images^[3,5,8]. This case belonged to fibrous type and the MRI findings were similar to those in Fernandez-Canton's report besides obvious hyperintensity relative to the spleen on delayed images^[3]. We agree with that diffuse progressive enhancement and prolonged enhancement were the characteristic radiological findings^[5].

In short, the following clinical features and radiographic findings may suggest the diagnosis of splenic hamartomas: (1) asymptomatic and incidental findings in adults; (2) possible association with hematologic symptoms such as pancytopenia, anemia, and thrombocytopenia or spontaneous rupture of splenic mass; (3) splenic mass with calcification or fatty components on plain CT, and isointensity on T₁-weighted images, heterogeneous hyperintensity or hypointensity on T₂-weighted images; (4) dense spreading enhancement and obviously prolonged enhancement on postcontrast CT and MRI. Though splenic hamartomas have some clinical and CT features, the final and exact diagnosis depends on histopathologic examination.

Splenic haemangioma should be differentiated from splenic hamartomas^[8]. They have similar clinical and radiological findings. But the latter is manifested by splenic mass with calcification or fatty component on plain CT. The lesions appear isointense on T₁-weighted images, heterogeneous hyperintense or hypointense on T₂-weighted images. CT and MRI can demonstrate diffuse enhanced lesions on the hepatic artery phase or early dynamic contrast-enhanced scans. The typical CT and MRI features of the former include early peripheral nodular enhancement, hypointensity on T₁-weighted images and homogeneous hyperintensity on T₂-weighted images. Rare calcification and no fatty component of splenic haemangioma are seen on plain CT. In addition, splenic lymphoma and metastases were also considered to be different from splenic hamartomas^[5,8]. Most of splenic lymphomas are multiple, secondary lesions and often have extra-splenic lymphoma. Splenic metastases usually have a history of primary extra-splenic malignant neoplasms and hepatic metastases. Both splenic lymphoma and metastases seldom have dense spreading enhancement or prolonged enhancement on post-contrast CT and MRI.

Abstract

AIM: To analyze the clinicopathological features of Brunner's gland adenoma of the duodenum.

METHODS: A rare case of Brunner's gland adenoma of the duodenum was described and related literature was reviewed.

RESULTS: Brunner's gland adenoma of the duodenum appeared to be nodular hyperplasia of the normal Brunner's gland with an unusual admixture of normal tissues, including ducts, adipose tissue and lymphoid tissue. We suggested that it might be designated as a duodenal hamartoma rather than a true neoplasm.

CONCLUSION: The most common location of the lesion is the posterior wall of the duodenum near the junction of its first and second portions. It can result in gastrointestinal hemorrhage and duodenal obstruction. Endoscopic polypectomy is a worthy treatment for benign Brunner's gland adenomas, as malignant changes in these tumors have never been proven.

Gao YP, Zhu JS, Zheng WJ. Brunner's gland adenoma of duodenum: A case report and literature review. *World J Gastroenterol* 2004; 10(17): 2616-2617

<http://www.wjgnet.com/1007-9327/10/2616.asp>

INTRODUCTION

Brunner's gland adenoma, also known as Brunneroma or polypoid hamartoma, is a rare, benign, proliferative lesion arising from the Brunner's glands of the duodenum, accounting for 10.6% of benign tumors of the duodenum. The time patients are usually asymptomatic and lesions are discovered incidentally. These lesions manifest occasionally as a rare cause of duodenal obstruction or upper gastrointestinal hemorrhage, and require surgical excision^[1]. This article reports a case of Brunner's gland adenoma, and reviews briefly its clinical presentations, pathological features and therapy.

CASE REPORT

A 32-year-old Chinese man complained of two episodes of melena and a two-month history of vague epigastric discomfort. The patient had in October 2001 his first tarry stool episode without nausea, vomiting and epigastralgia. Endoscopic examination revealed a mild ulcer in the duodenal bulb. The

symptoms were relieved by antacids and H₂ blockers. He reported however another tarry stool in September 2002 and complained about epigastric pain without nausea and vomiting during the preceding 2 mo. Antacids were taken and the pain was relieved. Vital signs were normal and no anemia was reported when he was admitted. The physical examination had no unremarkable finding. The abdomen was soft without palpating pain and jumping pain.

However, X-rays barium radiological examination of the upper gastrointestinal in October 2002 revealed a nodular, polypoid-filling defect mass measuring 3 cm×2.5 cm with a smooth surface and no ulceration in the duodenal bulb. A tumor was suspected. Follow-up endoscopy disclosed a lobulated, red-color tumor, occupying the anterior wall of the bulb. The surface of the tumor was smooth with mild depression at the top. The mucosa had no erosions and ulcers. Multiple biopsy specimens were taken and interpreted as "mucosal mild-medium atypia." CT scan was negative. A preoperative diagnosis of malignant tumor was made and the patient prepared for operation. On October 25, 2002, at the time of operation, a pedunculated polyp on a short broad-based stalk, 3.5 cm×3 cm×2 cm in size, was found in the anterior wall of the duodenal bulb. The common bile duct was normal. The lesion was amputated at the base of the stalk.

The resected specimen showed a lobulated, polypoid mass measuring 3.3 cm×2.5 cm×2.5 cm projecting into the duodenum. The stalk was measured 1.8 cm in diameter and 0.5 cm in length. The tumor was completely enveloped by the intact thin duodenal mucosa. The surface of the tumor was smooth without erosions and ulcers. The cut surface of tumor had a gray-red or gray-yellow color, revealing lobules. The consistency was moderate. On microscopic examination, the tumor was composed of hyperplasia of Brunner's glands. The hyperplasia formed lobules that were separated by intervening bands of fibrous tissue, adipose tissue, ducts and well developed aggregated lymphoid. No sign of malignancy was found in the hyperplasia, Brunner's glands as well as the surrounded duodenal mucosa. The frozen sections and the final pathologic diagnosis were assessed as Brunner's gland adenoma. The patient had an uneventful postoperative course and was discharged on the tenth postoperative day. He has remained symptom free ever since and no episode of recurrent melena has been reported.

DISCUSSION

Besides the duodenal gland, the duodenum has Brunner's glands under the mucin. Its structure and function are similar to glands of the pylorus. Brunner's glands secrete an alkaline fluid composed of viscous mucin, whose function appears to protect the duodenal epithelium from acid chyme of the stomach. Brunner's glands consist of submucosal mucin-secreting glands located exclusively in the duodenum. They extend from the pylorus distally for a variable distance, usually stopping at the first and second portions of the duodenum, and less often stopping at the third and fourth portions.

In 1688 Brunner gave a precise anatomic description of the duodenal submucosal glands and coined the term "pancreas secundarium." In 1846 Middeldorpf correctly identified these glands as a separate entity, which he proposed be named Brunner's

glands. Salvioli reported the first adenoma of Brunner's gland in 1876. Since then, 150 cases or so have been reported in literature of English language^[2].

The etiology of Brunner's gland adenoma remains obscure. It tends to present predominantly in the fifth and sixth decades of man's life with no sex predominance. It has been found although the size of adenoma might extend from 1-12 cm, it is generally 1-2 cm in diameter^[3]. The most common location for the lesion is the posterior wall of the duodenum near the junction of its first and second portions. Brunner's gland adenoma was rarely found extending to the proximal jejunum^[4].

Brunner's gland adenoma has fallen into two categories: symptomatic tumors and asymptomatic ones that are only found incidentally. Symptomatic tumors can further be divided into hemorrhagic and obstructive tumors. The clinical manifestations of the former are gastrointestinal hemorrhage, due to ulceration or erosion of the tumor. Obstructive tumors occur when hyperplasia diffuses or a single adenoma grows too large, causing epigastric bloating, discomfort, vomiting or weight loss. Duodenal intussusception has been reported only in two patients^[2], probably because of the fixation of duodenum to the posterior abdominal wall. There are also reports about patients who complained of diarrhea owing to duodenal motor disturbances^[5].

Preoperative histological diagnosis at present is not always easy. In X-rays barium examination, the findings are often nonspecific because there is usually a sessile or pedunculated polypoid-filling defect in the duodenal bulb. Some doctors hold that hypotonic duodenography should play a vital role in establishing the diagnosis and should be treated as the best method to check the surface of the lesion. Endoscopy has an additional function in diagnosing and treating Brunner's gland adenoma, since it can verify the histological diagnosis and remove the tumor simultaneously. Endoscopic pinching biopsy however usually gave a negative result because the tumor was almost covered entirely with thick intact duodenal mucosa in the biopsy sites and the biopsy was often not deep enough to reach the submucosal tumor tissue^[6]. In our case, the endoscopic biopsy was negative, and the condition was diagnosed as chronic gastritis, although the final pathologic diagnosis indicated that the patient suffered from Brunner's gland adenoma. CT examination appeared to be unrevealing.

Pathomorphological features of Brunner's gland are characterized by the presence of nondysplastic, lobulated

Brunner's glands. Its hyperplasia is divided into diffuse hyperplasia, nodular hyperplasia and adenomatous hyperplasia with or without erosion or ulcer. In our opinion, the unusually admixture of normal tissues, including Brunner's glands, ducts, adipose tissue, and lymphoid tissue, supports the designation of these lesions as a hamartoma or nodular hyperplasia rather than a true neoplasm. It is a tumor without malignant predisposition. The malignant type is rare. Fujimaki *et al.* reported recently one patient with a focus atypical gland^[7].

It is still controversial whether asymptomatic Brunner's gland adenoma found incidentally needs surgical removal. Some people think that it needs no treatment, whereas others hold that it should undergo endoscopic excision in order to prevent complications. There have been several reports^[2,4] that Brunner's gland adenoma could give rise to acute profuse bleeding, which results in shock of patients. Symptomatic Brunner's gland adenoma, in our point of view, usually needs surgical treatment. When the tumor is small or pedunculated, endoscopic polypectomy is the first choice. Open surgical excision is reserved for cases where snaring has failed or when tumor is too large. The outcome of operation is usually excellent and there is no recurrent ever reported.

Abstract

AIM: To construct a phage display library of human single-chain variable fragment (scFv) antibodies associated with esophageal cancer and to preliminarily screen a scFv antibody against esophageal cancer.

METHODS: Total RNA extracted from metastatic lymph nodes of esophageal cancer patients was used to construct a scFv gene library. Rescued by M13K07 helper phage, the scFv phage display library was constructed. esophageal cancer cell line Eca 109 and normal human esophageal epithelial cell line (NHEEC) were used for panning and subtractive panning of the scFv phage display library to obtain positive phage clones. Soluble scFv was expressed in *E.coli* HB2151 which was transfected with the positive phage clone, then purified by affinity chromatography. Relative molecular mass of soluble scFv was estimated by Western blotting, its bioactivity was detected by cell ELISA assay. Sequence of scFv was determined using the method of dideoxynucleotide sequencing.

RESULTS: The size of scFv gene library was approximately 9×10^6 clones. After four rounds of panning with Eca109 and three rounds of subtractive panning with NHEEC cells, 25 positive phage clones were obtained. Soluble scFv was found to have a molecular mass of 31 ku and was able to bind to Eca109 cells, but not to HeLa and NHEEC cells. Variable heavy (V_H) gene from one of the positive clones was shown to be derived from the γ chain subgroup IV of immunoglobulin, and variable light (V_L) gene from the κ chain subgroup I of immunoglobulin.

CONCLUSION: A human scFv phage display library can be constructed from the metastatic lymph nodes of esophageal cancer patients. A whole human scFv against esophageal cancer shows some bioactivity.

INTRODUCTION

Esophageal cancer is one of the most common malignancies in China with a relatively high mortality rate. In recent years, antibody-mediated tumor immunoscintigraphy and immunotherapy have been used in the diagnostic and therapeutic approaches of cancers^[1,2]. However, most antibodies are of murine origin, and repeated administration can induce human anti-mouse antibodies (HAMA). In addition, intact antibody is too large to penetrate into tumor masses, its application is limited. To overcome such deficiencies, many kinds of humanized antibodies including human-murine chimeric antibody and small molecular antibodies have been developed, but they are still of murine origin.

Recently, the emergence of genetically engineered antibodies and phage display libraries of human antibody fragments from immune or naïve donors has enabled the production of human antibody fragment targeting cancers^[3]. In the present study, phage antibody library techniques were used to construct a human phage single-chain Fv antibody library from metastatic lymph nodes of esophageal cancer patients. To obtain a single chain Fv AD09, panning and subtractive panning were performed with human esophageal cancer cell line (Eca109) and normal human esophageal epithelial cell line (NHEEC) respectively. Soluble AD09 was expressed in *E.coli* HB2151 and purified by affinity chromatography using anti-E tag antibody, its bioactivity was then detected by cell ELISA assay.

MATERIALS AND METHODS

Cell culture

Human esophageal carcinoma cell line Eca109 (Cytology Institute of Chinese Medical Academy, Beijing) and HeLa cell line (Shanghai Cytology Institute, China) were cultured at 37 in RPMI1640 medium supplemented with 100 mL/L fetal calf serum (Hyclone, USA) in a humidified atmosphere of 50 mL/LCO₂. Normal human esophageal epithelial cell (NHEEC) line was a primary cell line from a 20-wk conception fetus cultured in RPMI1640 with 200 mL/L fetal calf serum.

Primer design

Primer sequences were created as previously described^[4] with some modifications in PCR assembly part (Table 1B). We designed complementary coding sequences for a peptide linker at the 5'-end of J_H forward primers and the 3'-end of human V kappa (or lambda) back primers to optimize the diversity and efficiency of ligation. The primers were synthesized by Sunbiotech Company (Beijing, China) and the sequences are shown in Table 1. Sequences were given using the IUPAC nomenclature of mixed base (R = A or T, K = G or T, Y = C or T, S = G or C, H = A or C or T, N = A or C or G or T).

Library construction

Metastatic lymph nodes of 5 esophageal cancer patients were

collected for total RNA extraction (TRizol, Gibco BRL, UK). First-strand cDNA synthesis was performed in the presence of 40 U RNase inhibitor, 200 U Superscript II transcriptase (Gibco BRL, UK). The sample was finally treated with 2 U RNase H for 30 min at 37 °C and stored at -20 °C until use.

IgG-specific variable heavy (V_H) and light (V_L) chain gene fragments were amplified using Pyrobest PCR system (TarkaRa Biotechnology, Dalian, China) for 30 cycles (at 94 °C for 30 s, at 55 °C for 30 s and at 72 °C for 1 min), with each forward oligonucleotide primer and one of the back primers (Table 1A). The fragments were isolated from a 15 g/L agarose gel with the QIAex kit (QIAGEN, Germany). Then fragments were used as templates for PCR amplification to extend a linker, V_H fragments used human J_H -linker primers and human V_H back primers, V_L fragments used linker-human V_k primers (or linker-human V_l primers) and human J_k forward primers (or human J_l forward primers), respectively.

The amplified V_H -linker and V_L -linker PCR products were combined in a SOE-PCR reaction mixture. First, approximately 100 ng each of V_H -linker and V_L -linker was assembled by PCR without primers in which the short regions of complementarities built into the ends of primers drove hybridization of various fragments. An initial denaturation step (at 94 °C for 5 min) was followed by five cycles (at 94 °C for 1 min, at 60 °C for 1 min and at 72 °C for 1.5 min) in the absence of primers. After the outer primers containing restriction sites (Table 1C) were added, 30 cycles (at 94 °C for 30 s, at 60 °C for 1 min and at 72 °C for 1.5 min) were performed. These were gel-purified, digested with *SfiI* and *NotI* (TarkaRa Biotechnology, Dalian), cloned into the vector pCANTAB 5E (Amersham Pharmacia Biotech, Sweden) and transformed into electrocompetent *E.coli* TG1 (Amersham Pharmacia Biotech, Sweden). After electroporation, cells were plated on SOBAG medium (containing 20 g/L glucose and 100 mg/mL ampicillin) in 20 dishes and incubated overnight at 30 °C. The clones were scraped off the plates in 50 mL 2×YT medium with 100 mL/L glycerol and subsequently stored at -70 °C. Plasmid DNA was prepared from 10 randomly selected clones using Qiagen plasmid minikit (Qiagen, Germany). PCR and a *SfiI/NotI* double digestion reaction were performed to identify the positive insert clones.

Rescue of phagemid libraries

Ampicillin-resistant colonies were scraped into 2×YT medium and superinfected by M13K07 (Amersham Pharmacia Biotech, Sweden) helper phage. After an overnight induction in 2×YTAK medium without glucose, the phage preparation was precipitated in 40 g/L PEG/0.5 mol/L NaCl and resuspended in 10 g/L PBS.

Panning and subtractive panning of phage antibody library

To screen the positive phage clones, live Eca109 cell line as the antigen was used for panning. Live NHEEC was used for subtractive panning. The panning procedure was carried out essentially as described previously^[5]. After four rounds of panning and three rounds of subtractive panning, the unabsorbed phages were amplified.

Cell ELISA assay with phage

To detect the scFv-phage recombinant antibody, cell ELISA was performed. Eca109 cells (5×10^4) as antigens were grown in 96-well plates at 37 °C for 24 h, then fixed with 25 g/L glutaraldehyde and blocked with 10 g/L BSA. This was followed by incubation with scFv-phage at 37 °C for 2 h. After washed three times with PBS, HRP/anti-M13 monoclonal conjugate (1:5 000) (Amersham Pharmacia Biotech, Sweden) was added into wells with scFv-phage and they were incubated for 1 h at 37 °C. After washed again as above, 1×ABTS substrate solution was added, and incubated in darkness for 30 min and the reactions were read at 405 nm. PBS was used as negative control. The absorbance

reading for the positive was 0.2 or above at least three times higher than that for the negative control.

Expression and purification of soluble scFv

To produce soluble scFvs, strongly positive recombinant phage clones were used to infect log-phage *E.coli* HB2151 (Amersham Pharmacia Biotech, Sweden). Expression of soluble scFv was induced by adding isopropyl β -D-thiogalactopyranoside (IPTG) to a final concentration of 1 mmol/L and the cultures grown overnight at 30 °C. The induced culture was centrifuged at 1 500 r/min for 20 min. Cell pellets were resuspended in 2% of culture volume ice-cold 1×TES. Subsequently, 3% of culture volume ice-cold 0.2×TES was added, the mixture was incubated on ice for 30 min to induce a mild osmotic shock. The contents were centrifuged at 12 000 g for 10 min. The supernatant, containing the soluble antibodies from the periplasm, was transferred to the clean tubes and stored at -20 °C.

Soluble scFvs from periplasm were purified by affinity chromatography. Anti-E tag antibody (Amersham Pharmacia Biotech, Sweden) was covalently coupled to a protein G column (Amersham Pharmacia Biotech, Sweden) and soluble scFvs were selected by binding to anti-E tag antibody. After washed with 20 mmol/L phosphate buffer, pH 7.0, +0.5 g/L Na₂SO₄, scFvs were eluted from the column with 0.1 mol/L glycine-HCl, pH 3.0, and neutralized immediately with 1 mol/L Tris/HCl, pH 8.2, +0.5 g/L Na₂SO₄. Column fractions were assayed and positive fractions were pooled and stored at -70 °C. The expressed soluble scFv proteins were analyzed by 120 g/L sodium dodecyl sulfate (SDS)-polyacrylamide gel electrophoresis (PAGE), and confirmed by Western blotting. Purity and concentration of proteins were determined with Bradford assay.

Cell ELISA assay for activity of soluble scFv

To detect the activity of soluble scFv, HRP/anti-E tag antibody (Amersham Pharmacia Biotech, Sweden) was used. Eca109 cells, HeLa cells and NHEEC cells (5×10^4) were used as antigens. The cell ELISA assay procedure was performed as described above.

Sequencing

Plasmid DNA was prepared from recombinant clones using the Qiagen plasmid minikit (Qiagen, Germany). Nucleic acid sequencing was carried out on the ABI PRISM 377 DNA sequencer by the method of dideoxynucleotide sequencing. DNA and deduced amino acid sequence were compared with NCBI database.

RESULTS

Library construction and panning

The presence of V_H and V_L gene fragments obtained by RT-PCR was confirmed by electrophoresis, with their sizes being approximately 350 bp (Figure 1 A). The scFv genewas assembled successfully. Its size was about 750 bp (Figure 1B).

Figure 1 V_H and V_L and scFv fragments in 20 g/L agarose gel electrophoresis with staining of ethidium bromide (EB). (A) V_H and V_L fragments, (B) scFv fragment, M: DGL 2 000 marker.

After the scFv gene repertoires were transformed into *E. coli* TG1 cells, approximately 9×10^6 ampicillin-resistant clones grew. PCR and *SfiI/NotI* double digestion reactions showed the positive insert ratio was about 95% (19/20). Rescued by M13K07 helper phage, the recombinant phage antibody library (about 9×10^{11} cfu/mL) was constructed.

Four rounds of panning with Eca109 cells resulted in a 130-fold enrichment of tumor cell binding scFv-phage. After three rounds of subtractive panning with NHEEC cells, individual phage-displayed scFv fragments were tested for reactivity with Eca109 cells by cell ELISA. Of the 95 clones screened, 25 were positive. The highest A_{405} nm value was found in AD09 clone.

Expression and purification of soluble scFv

The soluble scFv was stably expressed in *E. coli* HB2151 transfected with AD09 positive phage clone. In pCANTAB 5E, the pel B signal peptide upstream from the scFv directed the expression to periplasmic compartment. The periplasmic extract of AD09 was run through anti-E tag antibody affinity chromatography column and soluble AD09 was eluted from the column as a single peak (data not shown). The expressed and purified AD09 was loaded on 120 g/L SDS-PAGE and analyzed by Western blot. This protein migrated with a molecular mass approximately 31 ku (Figure 2). The overall yield of soluble AD09 in *E. coli* flask culture was more than 0.55 mg/L. The purity was about 90%.

Figure 2 Expression and purification of AD09. A: SDS-PAGE. Lane 1: Markers (Amersham Pharmacia Biotech, Sweden). Lane 2: Product of *E. coli* HB2151 without scFv gene. Lane 3: Expression of AD09 in *E. coli* HB2151 with induction of IPTG. Lane 4: Purified AD09 protein. B: Western blot. Lane 1: Markers. Lane 2: Purified AD09 protein.

Determination of immunoreactivity of soluble scFv

The immunoreactivity of purified soluble AD09 was determined by ELISA. The result revealed that AD09 was highly specific and could bind to Eca109 cells, but not to HeLa and NHEEC cells (Table 2).

Table 2 Immunore activity of soluble scFv determined by ELISA

Sample	$A_{405\text{nm}}$ (mean \pm SD)		
	Eca109	HeLa	NHEEC
Soluble scFv	0.78 \pm 0.12	0.21 \pm 0.09 ^d	0.23 \pm 0.07 ^b
PBS	0.14 \pm 0.04	0.13 \pm 0.08	0.15 \pm 0.02

^d $P < 0.001$, ^b $P < 0.01$ vs Eca109 group.

Sequence analysis

Sequencing of six randomly selected antibodies from the positive clones was performed with an ABI PRISM 377 DNA sequencer using pCANTAB5 sequencing primer set (Amersham Pharmacia Biotech, Sweden). The sequence of AD09 clone is shown in

Figure 3. Compared using BLAST, both V_H and V_L had sequence similarities to the variable fragments of some known human antibodies. Alignment with the V_H and V_L sequences of Ig, blast analysis of immunoglobulin sequences showed that V_H was the γ chain subgroup IV of human immunoglobulin and V_L was the κ chain subgroup I of human immunoglobulin.

DISCUSSION

The discovery of hybridoma technology by Kohler and Milstein in 1975^[6] has heralded a new era in antibody research and clinical development. However, until recently, there were few antibody-based products suitable for clinical trial. This delay can be largely explained by the fact that murine antibodies could trigger a human anti-mouse antibody response^[7-9]. Human monoclonal antibodies seldom triggered a harmful immune response and have been used in cancer immunotherapy^[10]. However, there are many difficulties in making human monoclonal antibodies by hybridoma technology. Phage display antibody library technique provides a powerful tool to produce human antibody. In this study, we selected a human single chain antibody against esophageal cancer from a phage displayed antibody library. It confirmed that this technique was feasible.

Since scFv could penetrate faster and deeper in solid tumors, scFv format of monoclonal antibody was selected. ScFv is a small antigen-binding antibody fragment consisting of V_H and V_L joined together by a flexible peptide linker. The main advantage of scFv over intact whole IgG or Fabs was its small size (one sixth of intact IgG), making it penetrate a solid tumor mass more rapidly and evenly^[11,12]. In addition, the lack of constant regions decreased retention by Fc receptors found in most tissues and organs, which further reduced the side effects^[13,14]. These characteristics rendered scFv an ideal vector for delivery of

agents such as radionuclide, enzyme, drugs or toxin *in vivo*^[14,15].

Normally, peripheral blood lymphocytes were the main source for the construction of antibody libraries^[16]. However, it was inconvenient to isolate at least 200 mL of peripheral blood to obtain 10^7 B-lymphocytes for constructing a large antibody library^[3]. There are thousands of B cells in metastatic peritumor lymph nodes which may be preimmunized by tumor-associated antigens in esophageal cancer patients. The preimmunized B cells are sufficient to construct a library, and can be directly used for screening recombinant antibodies, since the heavy and light chain genes have been rearranged and ligated to specific targets of tumor antigens. Therefore, it has become a better source of B cells for human antibody library construction^[17].

Recombinant antibodies in phage antibody library could be best captured with purified tumor antigens^[18]. Unfortunately, esophageal cancer associated specific antigens have not yet been identified. Human esophageal cancer cell line, Eca109 could express human esophageal cancer-associated specific antigens^[19]. In addition, live cells could facilitate the identification of antibodies better than fixed cells^[5,20] since the antibodies bound to native rather than denatured antigens. Moreover, using live cancer cells to screen phage antibody library was a feasible method^[20,21]. So we used live Eca109 as antigens to screen the phage antibody library, and live NHEEC cell line was used for subtractive panning to obviate the cross-reaction with normal human esophageal epithelial cells. This was done to facilitate subsequent expression cloning of corresponding antigens, as well as to enhance the therapeutic potential of the antibodies obtained.

Generation of large repertoires of scFv genes is a crucial step during phage antibody display. To construct a large scFv gene repertoire, a number of methods were used. (1) Multiple primers covering most of the immunoglobulin heavy and light chain variable genes were used. (2) To optimize the diversity and efficiency of ligation, linker sequences were designed in PCR assembly primers. These made the linker easily synthesized and increased the diversity of scFv genes. (3) Electroporation transformation was used to obtain an efficiency of 10^9 cfu/ug for pUC18 and 3×10^7 cfu/ug for ligation products. (4) The quality of mRNA appeared essential in the PCR amplification step and in subsequent construction of the library. To preserve intact mRNA, DEPC and RNase inhibitor were used during total RNA extraction and cDNA synthesis.

To further identify the bioactivity of scFv, soluble scFv protein was expressed in *E. coli* HB2151 induced by IPTG. SDS-PAGE and Western blot showed that the molecular mass was about 31 ku, which was consistent with the theoretically predicted product. The soluble expression level of scFv in *E. coli* HB2151 was still low, but it was sufficient for bioactivity detection. Cell ELISA assays showed that the soluble scFv had esophageal cancer associated antigen-binding activity. Whether this scFv shows affinity and specificity for tissue *in vivo* remains to be determined. Finally, DNA sequencing determined that scFv had common characteristics shared by other known scFvs^[3].

Our study demonstrated that specific human antibodies against tumor-associated antigens could be selected from a phage library constructed from the metastatic lymph nodes of esophageal cancer patients. The approach did not depend on immunization procedures. Since the antibody is entirely of human origin, it is expected to be much less immunogenic than murine antibodies and more efficient in targeting tumor cell surface. It may also be used as research reagents or a starting point for the development of therapeutic antibodies.

Abstract

AIM: To investigate the correlation between expression of vascular endothelial growth factor (VEGF) and cell differentiation, invasion, metastasis and Maspin expression in gastric carcinoma.

METHODS: Formalin-fixed paraffin-embedded tissue specimens from 73 cases of gastric carcinoma were studied with SP immunohistochemistry, using anti-VEGF monoclonal antibody, and thirty-nine of them were studied using anti-Maspin monoclonal antibody. VEGF expression was compared with the clinical stage, lymph node metastasis, and Borrmann's and WHO's classification of gastric carcinoma.

RESULTS: The positive rate of VEGF expression was significantly higher in adjacent non-carcinoma epithelia (ANCE) than in non-metaplastic, non-carcinoma gastric epithelia (NMNCE), which were at least 4 cm distant from the primary tumor ($P = 0.000$, $\chi^2 = 73.03$). The positive rate of VEGF expression was significantly higher in advanced gastric carcinoma (AGC) than in early gastric carcinoma (EGC) ($P = 0.032$, $\chi^2 = 4.62$). The positive rate of VEGF expression in gastric carcinomas with lymph node metastases was significantly higher than that in those without metastasis ($P = 0.006$, $\chi^2 = 7.47$). Maspin was weakly expressed in 16 out of 39 cases of NMNCE, and the positive immunoreaction was limited to gland cells of the stomach body. There was no significant correlation between the expression of VEGF and histological or gross classifications, and correlation between the expressions of VEGF and Maspin in gastric carcinoma ($P = 0.648$, $\chi^2 = 0.21$).

CONCLUSION: Expression of VEGF is significantly correlated to the malignant biological behaviors of gastric carcinoma, but there is no significant correlation between the expression of VEGF and Maspin.

INTRODUCTION

Tumor angiogenesis is one of the most important biological features. It has been shown that tumor angiogenesis plays an important role in its growth, invasion, metastasis and recurrence^[1-3]. Among the factors contributing to angiogenesis, VEGF is recognized as one of the most important molecules in the formation of new blood vessels. There is clinical and experimental evidence that VEGF plays a role in the progression of solid tumors, and its clinical significance in solid tumors has been demonstrated both immunohistochemically and quantitatively^[4]. Many studies demonstrated that over-expression of VEGF participated the growth and metastasis of malignant tumors depended on angiogenesis^[2,5]. VEGF increased the incidence rate of tumor metastasis by inducing tumor angiogenesis^[5]. Some studies demonstrated that the level of VEGF expression was of prognostic value in predicting metastasis of various malignant solid tumors and the level of VEGF expression correlated with tumor progression in human brain cancers and experimental tumor models^[6,7]. Hence, most studies in the field have focused on the regulation and inhibition of angiogenesis. The tumor suppressor gene Maspin, a unique member of the serpin super family, could inhibit cell motility, invasion, and metastasis in some cancers^[8-10]. Although at present the molecular and biological mechanisms of the function of Maspin remain unknown, there is evidence that Maspin interacts with the p53 tumor suppressor pathway and may function as an inhibitor of angiogenesis *in vitro* and *in vivo*^[11]. Pemberton *et al.*^[12] demonstrated the presence of Maspin in epithelia of several normal human organs (such as prostate, thymus, testis, small intestine, and colon). We are interested whether the tumor suppression function of Maspin in mammary or pancreatic carcinoma can be also detected in gastric carcinoma.

In this study, VEGF expression was immunohistochemically investigated in non-metaplastic, non-carcinoma gastric epithelia (NMNCE), which were at least 4 cm distant from the primary tumor, adjacent non-carcinoma epithelia (ANCE) and gastric carcinoma, and compared with the pathobiological behaviors of gastric carcinoma in order to clarify the clinical and pathobiological significance of the expression of VEGF. The relationship between the expressions of VEGF and Maspin was also explored.

MATERIALS AND METHODS

Tissue specimens

Seventy-three surgically removed specimens of gastric carcinoma were collected from Cancer Institute, China Medical University. The age of patients ranged from 32 to 80 years, mean age was 55.2 years; Forty-eight were males and 25 females. Carcinomas were staged according to pathological characteristics including depth of tumor invasion, tumor location, Borrmann's classification, and status of lymph node metastasis. According to clinical staging, 24 cases were in early stage (early gastric carcinoma, EGC), 49 cases in advanced stage (advanced gastric carcinoma, AGC). According to metastasis status, 40 cases had lymph node metastasis, of them 1 had ovary metastasis, 1 had liver metastasis (without lymph node metastasis), and 32 had not any metastasis. Seventy-three cases of gastric carcinoma were

studied with SP immunohistochemistry, using anti-VEGF monoclonal antibody, and thirty-nine of them were studied using anti-Maspin monoclonal antibody. Each specimen was classified according to the Borrmann's classification and WHO's histological classification criteria.

Immunohistochemistry

All specimens were fixed in 40 g/L formaldehyde solution and embedded in paraffin. Five μ m Sections were cut and mounted onto glass slides. Mouse anti-human monoclonal antibody against VEGF (ready to use) was from Maixin Biotech (Fuzhou, China) and mouse anti-human monoclonal antibody against Maspin was from Novo Castro (Newcastle, England). Immunohistochemical staining was performed using SP method. For control, sections were proceeded with PBS (0.01 mol/L, pH 7.4) instead of the primary antibodies. Counterstaining was performed with haematoxylin.

Evaluation of VEGF and Maspin expression

Clearly brown staining restricted to cytoplasm was considered as positive reaction for VEGF or Maspin. Two experienced pathologists assessed the positive rate according to the percent of positive cells in counted cells from 5 randomly selected representative fields. To evaluate the expression of VEGF and Maspin, immunostaining was classified into two groups, corresponding to the percentage of immunoreactive cells. The cut-off point to distinguish negative from positive VEGF or Maspin expression was 20% of positive cells.

Statistical analysis

Statistical evaluation was performed by χ^2 -test to differentiate the rates between two groups. $P < 0.05$ was considered statistically significant.

RESULTS

None of NMNCE expressed VEGF. VEGF expression was significantly higher in ANCE than in NMNCE ($P = 0.000$, $\chi^2 = 73.03$) (Table 1). Immunohistochemically, VEGF expression was significantly higher in AGC than in EGC ($P = 0.032$, $\chi^2 = 4.62$). There was no correlation between expression of VEGF and histology typing or gross typing (Table 2). VEGF expression in gastric carcinoma with lymph node metastases was significantly higher than that in those without metastasis ($P = 0.006$, $\chi^2 = 7.47$) (Table 3). Sixteen (41.0%) out of thirty-nine cases of NMNCE showed a weak Maspin expression that was limited to gland cells of the stomach body, while all gastric normal epithelia with intestinal metaplasia (GNEIM) strongly expressed Maspin (14/14) (Table 4). The positive rate of Maspin was 53.6% (15/28) in specimens of positive VEGF expression, whereas the positive rate of Maspin was 45.5% (5/11) in specimens of negative VEGF expression (Table 5). There was no significant correlation between the expressions of VEGF and Maspin in gastric carcinoma ($P = 0.648$, $\chi^2 = 0.21$) (Table 5).

Table 1 VEGF expression in NMNCE, ANCE and gastric carcinoma ($n = 73$)

Tissue origin	<i>n</i>	VEGF expression		Positive rate (%)
		-	+	
NMNCE	73	73	0	-
ANCE	73	23	50	68.5 ^b
Gastric carcinoma	73	14	59	80.8 ¹

^b $P = 0.000$ vs NMNCE (Yates corrected: $\chi^2 = 73.03$), ¹ $P = 0.086$ vs ANCE (Yates corrected: $\chi^2 = 2.93$).

Table 2 Relationship between VEGF expression and gross and histological types of gastric carcinoma ($n = 73$)

Type	<i>n</i>	VEGF expression		Positive rate (%)
		-	+	
Gross types				
EGC ^a	24	8	16	66.7
I	4	0	4	100.0
II	12	6	6	50.0
III	7	2	5	71.4
SS ¹	1	0	1	100.0
AGC	49	6	43	87.8
Bor. 0	3	0	3	100.0
Bor. I	1	0	1	100.0
Bor. II	6	0	6	100.0
Bor. III	36	5	31	86.1
Bor. IV	3	1	2	66.7
Histological type				
Papillary adenocarcinoma	8	1	7	87.5
Well-differentiated adenocarcinoma	3	2	1	33.3
Moderately-differentiated adenocarcinoma	11	3	8	72.7
Poorly-differentiated adenocarcinoma	30	5	25	83.3
Undifferentiated carcinoma	3	1	2	66.7
Signet-ring cell carcinoma	10	1	9	90.0
Mucinous adenocarcinoma	7	0	7	100.0
Carcinoid	1	1	0	-

^a $P = 0.032$ vs AGC ($\chi^2 = 4.62$), There was no correlation between the expression of VEGF and histology typing or gross typing ($P > 0.05$).

¹EGC SS (early gastric carcinomas of superficial spreading type).

Table 4 VEGF and Maspin expressions in NMNCE, GNEIM and gastric carcinoma

Histological type	n	VEGF		+ %	Maspin		+ %
		+	-		+	-	
NMNCE	39	0	39	0	16 ^a	23	41.0
GNEIM	14	-	-	-	14	0	100.0
Gastric carcinoma							
Papillary adenocarcinoma	3	3	0	100.0	2	1	66.7
Well-differentiated adenocarcinoma	3	2	1	66.7	2	1	66.7
Moderately-differentiated adenocarcinoma	6	5	1	83.3	2	4	33.3
Poorly-differentiated adenocarcinoma	21	14	7	66.7	11	10	52.4
Undifferentiated adenocarcinoma	3	2	1	66.7	1	2	33.3
Signet ring-cell carcinoma	3	2	1	66.7	2	1	66.7
Total of gastric carcinoma	39	28	11	71.8	20	19	51.3

Maspin was weakly expressed in gland cells of the stomach body, while it was not expressed in superficial epithelial cells and pyloric gland of the stomach.

Table 3 Relationship between VEGF expression and metastasis of gastric carcinoma ($n = 73$)

Metastasis status	n	VEGF expression		Positive rate (%)
		-	+	
No metastasis	32	12	20	62.5 ^b
Lymph node metastasis	39	4	35	89.7
Liver metastasis	1	1	0	0
Ovary metastasis	1	0	1	100.0

^b $P = 0.006$ vs lymph node metastasis ($\chi^2 = 7.47$).

Table 5 Relationship between VEGF and Maspin expressions in gastric carcinoma

Gastric carcinoma	Maspin +	Maspin -	Total
VEGF +	15	13	28
VEGF -	5	6	11
Total	20	19	39

There was no significant correlation between the expression of VEGF and Maspin in gastric carcinoma ($P = 0.648$, $\chi^2 = 0.21$).

DISCUSSION

Ferrara^[13] and his colleagues found that bovine pituitary follicular cells secreted a novel heparin-binding growth factor specific for vascular endothelial cells in 1989 and named it VEGF. VEGF is known to be a highly specific mitogen for endothelial cells which is almost specifically expressed in endothelial cells. VEGF might act as an autocrine and paracrine growth factor to induce the proliferation of tumor cells as well as tumor angiogenesis of tumor cells^[14].

Tumors require blood vessels for nutrient and oxygen supply to maintain their viability. In the first stage of growth, cloning proliferative phase does not need angiogenesis. To continue tumor expansion, additional blood supply was prerequisite, which was significantly correlated to tumor invasion, metastasis and recurrence^[15-18]. It has been widely accepted that tumor angiogenesis was one of the most crucial steps in tumor invasion and metastasis. There was a close relationship between VEGF expression and depth of invasion, lymph node metastasis and five-year survival rate of patients, which was an independent prognostic factor. Our study showed that there was no significant relationship between VEGF expression and histological or gross types of gastric carcinomas.

Yonemura further demonstrated the correlation between VEGF-C expression and lymphatic invasion or lymph node

metastasis^[19]. Tumors with high expression of VEGF-C had more remote lymph node involvement than those with low VEGF-C expression^[7,19,20]. These results strongly suggested that cancer cells producing VEGF-C might induce proliferation and dilation of lymphatic vessels, resulting in the development of invasion of cancer cells into lymphatic vessels and lymph nodes. These results were consistent with recent reports that showed a positive correlation of VEGF-C levels with lymph node metastasis in gastric carcinoma.

A number of observations and animal trials have spurred extensive investigations of VEGF inhibitors as possible therapies for cancer. In tumor cell lines VEGF was an autocrine growth factor, so that inhibitors of VEGF or VEGF receptors (VEGFR) compromised the viability of tumor cells. Lastly, inhibition of VEGF or VEGFR signaling would inhibit both tumor angiogenesis and tumor cell growth and viability when there was evidence that VEGFR was expression in tumor cells^[21,22].

Our study showed that VEGF was positively expressed in 76.7% of gastric carcinomas, which was significantly higher than that in NMNCE. The result indicated that VEGF was up-regulated and there might exist an autocrine mechanism of VEGF in gastric carcinoma. VEGF could promote tumor growth and metastasis by both direct and indirect pathways^[23].

Maspin, a member of the serpin family of protease inhibitors, is expressed in normal human mammary and prostate epithelial cells, and down-regulated during cancer progression. Biological studies demonstrated a tumor-suppressive role of Maspin, acting at the levels of tumor invasion and metastasis^[8,12]. Maass^[24] did not detect Maspin expression in any of 6 gastric cancer cells. Son^[25] studied Maspin expression in 30 cases of human gastric adenocarcinoma using immunohistochemistry and reverse transcripted-polymerase chain reaction. Twenty-seven cases (90%) of gastric adenocarcinoma, regardless of histological type, and all cases of GNEIM showed diffuse and strong immunoreactivity to Maspin. Eighteen of 26 cases (69.2%) of NMNCE showed weak and focal immunoreactivity. The level of Maspin expression was higher in GNEIM and lower in NMNCE than in adenocarcinoma cases. Akiyama^[26] examined Maspin expression and/or allele-specific methylation status in four gastric cancer cell lines, as well as normal, metaplastic, and carcinoma epithelia obtained from 50 gastric cancer patients. Three gastric cancer cell lines exhibiting Maspin overexpression showed hypomethylation on both alleles or a haploid allele. Dense and diffuse immunoreactivity to Maspin was observed in 40 (80%) of 50 gastric carcinomas and all GNEIM, but not in GNE without IM. Maspin gene promoter region of all GNE without IM was hypermethylated on both alleles whereas those with IM frequently represented the haploid type of hypomethylation

status. Maspin mRNA was amplified from GNEIM and cancerous crypts but not from GNE without IM. These results suggested that demethylation at the Maspin gene promoter disrupted the cell-type-specific gene repression in both GNE and gastric cancer. In our study, 41.0% (16/39) of NMNCE showed a weak Maspin expression that was limited to gland cells of the stomach body, and 51.3% (20/39) of gastric carcinomas expressed Maspin. The positive rate of Maspin expression in NMNCE and in gastric carcinoma in our study was significantly lower than that in Son and Akiyama's study. We considered that the cut-off point made the different results. The reason why all GNEIM showed immunoreactivity to Maspin in all studies should be studied further. In addition, the role of Maspin gene and its encoding protein in tumorigenesis and progression of gastric cancer need to be investigated further.

In our study, Maspin and VEGF showed no correlation in gastric carcinomas. The precise roles of VEGF and Maspin in cancer tumorigenesis, invasion, and metastasis should be studied further. The relationship between expression of VEGF and Maspin in gastric cancer needs to be proved by amplifying samples.

Abstract

AIM: To explore the effects of mifepristone, a progesterone receptor (PR) antagonist, on the proliferation of human gastric adenocarcinoma cell line SGC-7 901 *in vitro* and the possible mechanisms involved.

METHODS: *In situ* hybridization was used to detect the expression of PR mRNA in SGC-7 901 cells. After treatment with various concentrations of mifepristone (2.5, 5, 10, 20 $\mu\text{mol/L}$) at various time intervals, the ultrastructural changes, cell proliferation, cell-cycle phase distribution, and the expression of caspase-3 and Bcl-X_L were analyzed using transmission electron microscopy (TEM), tetrazolium blue (MTT) assay, ³H-TdR incorporation, flow cytometry, and reverse transcription-polymerase chain reaction (RT-PCR).

RESULTS: Mifepristone markedly induced apoptosis and inhibited cell proliferation of PR- positive SGC-7 901 cells revealed by TEM, MTT assay and ³H-TdR incorporation, in a dose- and time-dependent manner. The inhibitory rate was increased from 8.98% to 51.29%. Flow cytometric analysis showed mifepristone dose-dependently decreased cells in S and G₂/M phases, increased cells in G₀/G₁ phase, reduced the proliferative index from 57.75% to 22.83%. In addition, mifepristone up-regulated the expression of caspase-3, and down- regulated the Bcl-X_L expression, dose-dependently.

CONCLUSION: Mifepristone effectively inhibited the proliferation of PR-positive human gastric adenocarcinoma cell line SGC-7 901 *in vitro* through multiple mechanisms, and may be a beneficial agent against human adenocarcinoma.

INTRODUCTION

Gastric adenocarcinoma is the second most common cancer with the second highest mortality rate^[1,2]. Presently, there is still no effective treatment means for patients with advanced

gastric adenocarcinoma^[3,4]. Chemotherapy or radiation therapy has generally shown some clinical response but little survival advantage and is not tolerated in many patients^[5,6]. Therefore, there is a need to identify other therapeutic agents against the tumor.

Mifepristone is a progesterone receptor (PR) antagonist that has been widely used as the first- line drug for the termination of early pregnancy^[7]. Interestingly, recent studies have proved that mifepristone could effectively inhibit the proliferation of PR-positive breast cancer^[8-10], ovarian cancer^[11,12], endometrial cancer^[13], and prostate cancer^[14] cells without serious side effects and drug resistance. However, the effects of mifepristone on gastric adenocarcinoma are still unknown. Therefore, the present study was undertaken to explore the effects of mifepristone on the proliferation of human gastric adenocarcinoma cell line SGC-7 901 *in vitro*. Results showed that mifepristone effectively inhibited the proliferation of cultured SGC-7 901 cells *in vitro* through multiple mechanisms.

MATERIALS AND METHODS

Cell culture and treatment

Human gastric adenocarcinoma cell line SGC-7 901, obtained from Wuhan University Type Culture Collection (Wuhan, China), was routinely maintained in phenol red-free RPMI1640 (Gibco BRL, Grand Island, NY) containing 100 mL/L fetal bovine serum (Hyclone, Logan, UT), 10⁵ U/L penicillin and 100 mg/L streptomycin at 37 °C in a humidified atmosphere with 50 mL/L CO₂ in air. When cells were grown to approximately 50% confluence, medium was replaced with serum-free RPMI1640. After 24 h, fresh media containing 2.5, 5, 10, 20 $\mu\text{mol/L}$ mifepristone (Sigma Chemical Co., St Louis, MO) were added, respectively. Control cells were treated with the same volumes of vehicle (ethanol). Unless otherwise indicated, the cells were harvested after 96 h of incubation.

In situ hybridization analysis of PR

The expression of PR mRNA in SGC-7 901 cells was detected by *in situ* hybridization (ISH) using an ISH detection kit for PR (Boster, Wuhan, China) according to the manufacturer's instructions. Unless otherwise stated, all steps were performed at room temperature. Briefly, after 24 h of culture on the RNase-free slides, cells were washed 3 times with phosphate buffered saline (PBS, pH7.4), fixed with 40 g/L paraformaldehyde in PBS containing 0.1 g/L diethylpyrocarbonate (DEPC-water) for 30 min, washed 3 times with 0.01 mol/L PBS, and then incubated with 5 mL/L hydrogen peroxide in methanol for 30 min to block endogenous peroxidase activity. After being rinsed with 0.01 mol/L PBS, cells were digested with proteinase K (10 g/mL in 0.01 mol/L PBS) at 37 °C for 15 min. Further washes with 0.5 mol/L PBS were performed before pre-hybridization for 3 h at 37 °C in the pre-hybridization solutions in a humidified environment. Hybridization was then performed with digoxigenin-labeled cRNA antisense probe (5 g/mL) overnight at 37 °C in a moist chamber. Subsequently cells were washed for 10 min with 2 SSC (1 SSC = 150 mmol/L NaCl, 15 mmol/L sodium citrate, pH7.0), followed by 0.5 SSC for 15 min, and finally 0.2 SSC for

15 min. After treatment with blocking reagent for 30 min, cells were incubated with biotin-labeled mouse anti-digoxigenin antibody at 37 °C for 1 h, washed 4 times, for 5 min each time, with 0.5 mol/L PBS, and then treated with SABC solutions at 37 °C for 20 min. Then cells were washed 3 times, for 5 min each time, with 0.5 mol/L PBS, incubated with biotin-labeled peroxidase (POD) at 37 °C for 20 min, washed three times with 0.5 mol/L PBS. Finally, cells were visualized with 3,3'-diaminobenzidine (DAB), counterstained with hematoxylin, dehydrated, cleared, mounted with neutralgum, and examined under a microscope. Brown-yellow deposits indicated the sites of hybridization. PR-positive breast cancer tissues were used as positive control, and probes were replaced by PBS as negative control.

Ultrastructural analysis

Harvested cells were washed 3 times with PBS, fixed for 2 h with 2.5 g/L glutaraldehyde in PBS, and then post-fixed for 2 h at 4 °C with 1 g/L OsO₄ in PBS. Cells were dehydrated using gradually increasing concentrations of ethanol from 50% to 100%, and then embedded in Epon 812. The ultra-thin sections (60 nm) were stained with uranyl acetate and lead citrate prior to examination at 50 kV with a Hitachi 600 transmission electron microscope (Hitachi Corp., Tokyo, Japan).

MTT assay

SGC-7 901 cells were seeded into 96-well plates at a density of 1×10^5 /mL in RPMI1640. After 96 h of incubation with various concentrations of mifepristone, cell proliferation was measured by MTT (Sigma) reduction assay as described previously^[15]. Absorbance at 570 nm (A_{570nm}) was assayed. The inhibitory rate (IR) of SGC-7 901 cells was calculated according to the equation as following: $IR (\%) = (A_{570nm} \text{ in control group} - A_{570nm} \text{ in mifepristone-treated group}) / A_{570nm} \text{ in control group} \times 100\%$.

³H-thymidine (³H-TdR) incorporation

Cells were incubated at various time intervals without or with various concentrations of mifepristone, followed by treatment with 10 μ Ci ³H-TdR (Amersham, Arlington Heights, IL) for an additional 6 h. Then, cells were washed twice with 100 mL/L trichloroacetic acid by centrifugation and resuspension, and were continuously incubated for 30 min at 60 °C with 0.5 mL of NaOH (0.3 mol/L). Finally, the cell lysates were collected, and the radioactivity was measured by a liquid scintillation counter (Beckman LS1 801, USA).

Cell cycle analysis by flow cytometry

The harvested cells were fixed with 700 mL/L ethanol at -20 °C for 30 min, and then stained with propidium iodide (Sigma) for 30 min in the dark. The stained cells were analyzed in a FACS Calibur flow cytometer (Becton Dickinson Labware, Lincoln Park, NJ) with excitation wavelength of 488 nm. The resulting histograms were analyzed by program MODFIT for cell distribution in cell cycle phase. Proliferative index (PI) was calculated according to the formula: $PI (\%) = (S + G_2/M) / (G_0/G_1 + S + G_2/M) \times 100\%$.

Measurement of caspase-3 activity

Total proteins were extracted from harvested cells as described previously^[16], and protein concentrations were determined using the Bio-Rad protein assay (Bio-Rad Laboratories, Hercules, CA). An equal amount of cellular protein from extract of each group was added to a final volume of 100 μ L of reaction mixture containing 0.2 mmol/L of a colorimetric caspase-3 substrate, acetyl-Asp-Glu-Val-Asp-p-nitroaniline (Ac-DEVD-pNA; Calbiochem, San Diego, CA), followed by incubation at 30 °C for 10 min. Free p-nitroaniline (pNA) released upon enzymatic cleavage was detected at 405 nm using a microplate reader (Bio-Rad). Caspase-3 activity correlated with the concentration of free

pNA generated in the reaction. Purified caspase-3 (Calbiochem) was used as positive control, whereas caspase-3 inhibitor I (Ac-DEVD-CHO, Calbiochem) was used as negative control.

RT-PCR analysis for Bcl-X_L

Total RNA was extracted from the cells using TRIzol reagent (Gibco BRL) according to the manufacturer's protocol. Two milligrams of total RNA were used for reverse transcription in a total volume of 20 μ L with the SuperScript preamplification system (Promega, Madison, MI). Aliquots of 2 μ L cDNA were subsequently amplified in a total volume of 50 μ L using the GeneAmp PCR kit (Promega) following conditions recommended by the manufacturer. The sense and antisense primers for Bcl-X_L were 5'-AGGCAGGCGATGAGTTTGAAC-3' and 5'-GAACCACACC AGCCACA GTCA-3', respectively. The sense and antisense primers for α -actin used as an internal control were 5'-ATCTGGCACC ACACCTTCTACAATGAGCT GCG-3' and 5'-CGTCA TACTCCTGCTTGCTGATCCACAT CTGC-3', respectively. The cycling conditions were 94 °C for 2 min, followed by 30 cycles of 92 °C for 30 s, at 62 °C for 30 s, and at 72 °C for 1 min and a final extension of 72 °C for 5 min. PCR products were separated on the 15 g/L agarose gel stained with ethidium bromide (EB) and viewed under ultraviolet light.

Statistical analysis

Data were expressed as mean \pm SD. Statistical analysis was performed using the Student's *t* test and the chi-square test. $P < 0.05$ was considered statistically significant.

RESULTS

Expression of PR mRNA

In situ hybridization analysis showed that PR mRNA was highly expressed in the cultured SGC-7 901 cells, which was mainly localized in the cytoplasm of the cells (Figure 1).

Figure 1 *In situ* hybridization (ISH) analysis of progesterone receptor (PR) expression in human gastric adenocarcinoma cell line SGC7 901 (ISH, $\times 1000$).

Morphological changes

To assess the effect of mifepristone on the ultrastructural changes of SGC-7 901 cells, transmission electron microscopic analysis was performed. Results revealed that mifepristone dose-dependently induced apoptosis, which was especially remarkable at the 20 μ mol/L concentration (Figure 2B). However, the irregular and enlarged nuclear, multiple nucleoli and increased nucleus-to-cytoplasm ratio were clearly seen in the cells of control group (Figure 2A).

MTT assay and ³H-TdR incorporation

After 96 h of incubation with 2.5, 5, 10, 20 μ mol/L mifepristone, MTT assay revealed A_{570nm} was markedly decreased in a dose-dependent manner, and the inhibitory rate (IR) of SGC-7 901

Table 1 Effects of mifepristone on cell proliferation, cell-cycle phase distribution and caspase-3 activity of SGC7 901 cells *in vitro* (mean±SD)

Concentration (μmol/L)	A_{570nm} (MTT)	Cell cycle phase distribution (%)			Caspase-3 activity (U)
		G ₀ /G ₁	S	G ₂ /M	
0	1.125±0.048	42.25±4.20	35.68±3.98	22.07±3.01	1.28±0.28
2.5	1.024±0.030	49.47±5.68	30.82±4.36	19.71±2.41	2.79±0.36
5	0.896±0.035	52.23±6.22	28.68±3.64	19.01±1.36	5.04±0.29
10	0.678±0.026	65.80±5.63	25.93±3.01	8.27±1.10	9.46±0.20

cells by mifepristone was 8.98%, 20.36%, 39.73% and 51.29%, respectively (Table 1). Figure 3 shows that ³H-TdR incorporation into DNA of SGC-7 901 cells was significantly decreased in a dose- and time-dependent manner.

**Figure 2** Transmission electron microscopic photographs of the SGC7901 cells cultured for 96 h in the absence(A) or the presence of 20 μmol/L mifepristone (B) *in vitro* (TEM, ×2000). Arrows indicate apoptotic bodies which were formed in the cells of mifepristone-treated group.**Figure 3** Effect of various concentrations of mifepristone on the ³H-TdR incorporation of SGC7 901 cells at various time intervals *in vitro*.

Cell-cycle phase distribution

The effect of mifepristone on the cell-cycle phase distribution of SGC-7 901 cells was determined by flow cytometry. After treatment with mifepristone, there was a strong dose- dependent decrease in the percentage of S- and G₂/M-phase cells, and with a concomitant increase in the percentage of cells in the

G₀/G₁ phases of the cell cycle (Table 1). Additionally, there is a significant decrease in the proliferative index (PI) of the mifepristone-treated cells (50.53%, 47.69%, 34.20% and 22.83%) as compared with control group (57.75%, $P<0.01$).

Expression of caspase-3 and Bcl-X_L

As shown in Table 1, mifepristone significantly up-regulated the activity of caspase-3 as compared with that in control group. Figure 4 shows the results of RT-PCR analysis for Bcl-x_L mRNA expression. Results indicated that mifepristone dose-dependently inhibited the expression of Bcl-X_L in the SGC-7 901 cells.

**Figure 4** RT-PCR analysis of Bcl-X_L mRNA expression in the SGC7 901 cells cultured for 96 h in the absence or the presence of various concentrations of mifepristone *in vitro*. Lanes 1-5: Marker (bp), contro l, 5, 10, 20 μmol/L mifepristone, respectively.

DISCUSSION

Accumulating evidence demonstrates that PR level is closely associated with proliferation, invasion and metastasis of human gastric adenocarcinoma, as well as prognosis of patients^[17-19]. Therefore, there has been increasing interest in the development of antiprogesterins for tumor treatment. Mifepristone has been proved to be a potent and effective PR antagonist by competing with progesterone for PR binding, followed by binding to progesterone response element (PRE)^[20]. In the present study, we proved that mifepristone effectively inhibited the proliferation of human gastric adenocarcinoma cell line SGC-7 901 *in vitro* through induction of apoptosis and arresting the cell cycle progression.

Previous studies^[21] found that the determination of PR levels was primarily used as a marker of a tumor's responsiveness to mifepristone. To determine the expression of PR mRNA in the SGC-7 901 cells, *in situ* hybridization was performed. We found that PR mRNA was highly expressed in cultured SGC-7 901 cells. Meanwhile, the result is in agreement with the work of Cui *et al.*^[22], who reported that the concentrations of PR protein in the cytoplasm and nuclei of cultured SGC-7901 cells were 20.3 fmol/mg and 22.7 fmol/mg, respectively, revealed by dextran-coated charcoal (DCC) assay. Thus, we speculate that the growth inhibitory effects of mifepristone in our study might be mediated, at least in part, by PR.

In our study, TEM, MTT assay and ^3H -TdR incorporation were used to evaluate the effect of mifepristone on the proliferation of SGC-7901 cells *in vitro*. We found that mifepristone exerted significantly anti-proliferative effect on cultured SGC-7901 cells *in vitro* in a dose- and time-dependent manner. The results are in agreement with those of previous studies on other tumor cell lines *in vitro*^[9-11,23].

Although a number of studies have proved that mifepristone has the growth inhibitory effects on tumor cells, but the mechanisms remain unknown. These theoretically could be related with the changes of the dynamics of cell proliferation. The hypothesis was demonstrated by the work of Thomas *et al.*^[24], who proved that mifepristone inhibited the proliferation of the MCF-7 human breast cancer cells by arresting them in the G₀/G₁ phase of the cell cycle. Recently, Peters *et al.*^[25] reported that mifepristone up-regulated the expression of cell cycle protein p21^{WAF/cip1} in medroxyprogesterone acetate-induced ductal mammary adenocarcinoma. Thus, we further explored the effects of mifepristone on the cell cycle of SGC-7901 cell using flow cytometry. Results showed that mifepristone markedly increased the proportion of cells in G₀/G₁, and simultaneously decreased the percentage of cells in S- and G₂/M-phase. Taken together, it seems reasonable to conclude that the growth inhibitory effects of mifepristone on SGC-7901 cells is partially due to an accumulation of cells in G₀/G₁ phase.

To explore whether or not the apoptosis-related genes contributed to the inhibitory effect of mifepristone on the SGC-7901 cells, we assessed the activity of caspase-3, an executioner of apoptosis^[26,27], and mRNA level of Bcl-X_L, an anti-apoptotic gene. Our findings showed that mifepristone dose-dependently up-regulated caspase-3 activity and down-regulated Bcl-X_L mRNA expression. This result is supported by previous studies on prostate cells. El Etreby *et al.* reported that mifepristone significantly induced apoptosis in LNCaP prostate cancer cells in a time- and dose-dependent manner through down-regulation of Bcl-2 protein and induction of caspase-3 activity. Collectively, it is possible that the activation of caspase-3 and the degradation of Bcl-X_L are partially responsible for the antiproliferative effects of mifepristone on cultured SGC-7901 cells.

In conclusion, the study demonstrated that mifepristone exerted marked antiproliferative effect on the PR-positive SGC-7901 cells by inducing apoptosis, arresting cell cycle progression, up-regulating caspase-3 activity and down-regulating Bcl-X_L mRNA expression. These results indicate that mifepristone may be a useful agent against human gastric adenocarcinoma although further studies are clearly needed to prove the possibility.

Abstract

AIM: Mitotic cell death has been focused on in tumor therapy. However, the precise mechanisms underlying it remain unclear. We have reported previously that enediyne antibiotic lidamycin induces mitotic cell death at low concentrations in human epithelial tumor cells. The aim of this study was to investigate the possible link between centrosome dynamics and lidamycin-induced mitotic cell death in human hepatoma BEL-7402 cells.

METHODS: Growth curve was established by MTT assay. Cell multinucleation was detected by staining with Hoechst 33342. Flow cytometry was used to analyze cell cycle. Aberrant centrosomes were detected by indirect immunofluorescence. Western blot and senescence-associated β -galactosidase (SA- β -gal) staining were used to analyze protein expression and senescence-like phenotype, respectively.

RESULTS: Exposure of BEL-7402 cells to a low concentration of lidamycin resulted in an increase in cells containing multiple centrosomes in association with the appearance of mitotic cell death and activation of SA- β -gal in some cells, accompanied by the changes of protein expression for the regulation of proliferation and apoptosis. The mitochondrial signaling pathway, one of the major apoptotic pathways, was not activated during mitotic cell death. The aberrant centrosomes contributed to the multipolar mitotic spindles formation, which might lead to an unbalanced division of chromosomes and mitotic cell death characterized by the manifestation of multi- or micronucleated giant cells. Cell cycle analysis revealed that the lidamycin treatment provoked the retardation at G2/M phase, which might be involved in the centrosome overduplication.

CONCLUSION: Mitotic cell death and senescence can be induced by treatment of BEL-7402 cells with a low concentration of lidamycin. Centrosome dysregulation may play a critical role in mitotic failure and ultimate cell death following exposure to intermediate dose of lidamycin.

INTRODUCTION

Liver cancer is one of the most malignant tumors in the world^[1,2]. Surgical resection is considered the most effective but not the most popular method for the treatment of hepatocellular carcinoma (HCC). Chemotherapy is indicated for a large member of HCC patients. Mitotic cell death is a cell death form different from apoptosis, on which has been focused in tumor therapy. It is also known as mitotic catastrophe or delayed reproductive death, and can be activated by radiation or antitumor agents at low doses or concentrations^[3-5]. Mitotic cell death is frequently characterized by enlargement of cell volume, appearance of multi- or micronucleation, and arrest in G2/M phase of cell cycle. Finally, these cells underwent death. Thus far, little is known about the mechanism responsible for mitotic cell death. Some researchers considered that defects in mitotic machinery, such as multiple rounds of DNA synthesis without an intervening cytokinesis, and chromosome missegregation, might play a key role in the process of lethal nuclear fragmentation^[6]. Previous reports have suggested that the absence or delay of the G1/S checkpoint and the subsequent absence of interphase apoptosis coupled to this checkpoint contribute to mitotic cell death^[7,8].

The centrosome, representing the major microtubule organizing centre in eukaryotic cells, contains a pair of centrioles surrounded by pericentriolar material. The centrosome duplicates once during each cell cycle. To complete the normal cell cycle, the centrosome duplication cycle and the centrosome quantity must be precisely regulated to couple the other events of cell cycle^[9]. If centrosome replication deviates from cycles of DNA synthesis and mitotic division, an unsuccessful mitosis will come out with the features associated with the formation of aberrant centrosomes and multiple mitotic spindles, and unbalanced chromosome segregation^[10].

Enediyne antibiotics have been focused on their potent antitumor activity due to their unique ability to damage the DNA of tumor cells by inducing single strand (SSB) and/or double strand (DSB) breaks through free radical attacks on the deoxyribose moieties in DNA^[11]. Lidamycin (also designated as C1027) is a member of the enediyne antibiotic family, which was isolated from a *Streptomyces globisporus* C1027 strain in China^[12,13]. Lidamycin consists of a chromophore and an apoprotein, and the former has the ability to attack DNA, whereas the latter plays the role as a protecting protein^[14]. The biological effects induced by lidamycin and ionizing radiation are similar^[11]. Previous reports have shown that lidamycin is highly cytotoxic toward tumor cells^[14-16]. As an attempt to investigate the mechanisms of lidamycin-induced mitotic cell death in human hepatoma BEL-7402 cells, we treated cells with lidamycin at low concentrations, and discovered centrosome overduplication, multipolar mitotic spindle formation, multinucleation, delayed reproductive death and changed patterns of protein expression associated with the regulation of proliferation and apoptosis.

These results indicate that mitotic cell death in BEL-7402 cells induced by lidamycin is associated with centrosome overduplication independently of mitochondria pathway.

MATERIALS AND METHODS

Chemical

Lidamycin was generously provided by Professor Lian-Fang Jin from our institute, and stored at -20°C as a $100\text{ }\mu\text{mol/L}$ stock solution in 9 g/L NaCl solution.

Cell culture

Human hepatoma BEL-7402 cells (obtained from the Key Laboratory of Cell Proliferation and Regulation Biology of the Ministry of Education, Beijing Normal University) were cultured in DMEM (Gibco BRL) supplemented with 100 mL/L fetal bovine serum (HyClone), 100 U/mL penicillin and $100\text{ }\mu\text{g/mL}$ streptomycin at 37°C in the presence of 50 mL/L CO_2 .

Growth curve assay

Growth curves establishments were performed at a 5-d interval as previously described^[17] with some modifications. Totally 2.0×10^3 cells were seeded into 96-well plates and then treated with lidamycin for 2 h. A $12\text{ }\mu\text{L}$ MTT (5 mg/mL) was added to each well before assay and incubated for an additional 4 h at 37°C , followed by treatment with $100\text{ }\mu\text{L}$ of 0.01 mol/L HCl- 100 g/L SDS overnight. The value at each time point was read on a Microplate Reader (Model 550, Bio-Rad) at $\lambda_{570\text{ nm}}$.

Cell multinucleation shown by staining with Hoechst 33342

Subconfluent cells were continuously incubated for 72 h after exposure to lidamycin for 2 h, and then were stained by the DNA-specific fluorescent dye Hoechst 33342 ($2\text{ }\mu\text{g/mL}$) (Sigma) for 15 min at 37°C . Next, cells were washed once, kept in PBS, and observed using a fluorescence microscope (BH2 system, Olympus) equipped with a $\lambda_{455\text{ nm}}$ filter.

Flow cytometry

Cells were exposed to 0.5 nmol/L lidamycin for 2 h and then incubated in fresh, drug-free medium. Following a 3-d incubation, cells including the floating and the attached were harvested and washed with cold PBS twice. Cell suspensions were fixed in 700 mL/L ethanol at 4°C overnight. Next, the fixed cells were washed twice in PBS and incubated with $50\text{ }\mu\text{g/mL}$ RNase (Sigma) for 30 min at 37°C . Samples were then stained with $50\text{ }\mu\text{g/mL}$ propidium iodide (Sigma) in the dark at 4°C for 30 min, and analyzed on a fluorescence-activated cell sorter (EPICS XL, Coulter).

Indirect immunofluorescence

Cells were grown on coverslips. After 3 d following 2-h lidamycin treatment, the cells were washed in PHEM buffer (60 mmol/L PIPES, 25 mmol/L HEPES, 10 mmol/L EGTA and 2 mmol/L MgCl_2) twice briefly, and incubated with a permeabilization buffer (5 mL/L Triton X-100 in PHEM buffer) for 90 s. Then, the cells were fixed in 37 g/L paraform in PHEM buffer for 15 min at room temperature. After washed in PBS 3 times, the cells were incubated with a blocking solution (50 g/L defatted dry milk and 0.5 mL/L Tween-20 in PBS) for 30 min and used for indirect immunofluorescence. The primary antibodies included anti- α -tubulin monoclonal antibody (Zymed) and anti-centrin polyclonal antibody^[18] (kindly provided by Professor Da-Cheng He, the Key Laboratory of Cell Proliferation and Regulation Biology of the Ministry of Education, Beijing Normal University). Rhodamine-labeled goat anti-mouse antibody (Zymed) and Fluorescein isothiocyanate-labeled goat anti-rabbit antibody (Zymed) were used as second antibodies. The microscope slides were mounted with glycerol mounting medium (900 mL/L glycerol and 100 mL/L PBS) and observed under a laser-scanning

microscope (IX-70 system, Olympus). The cell with three or more centrosomes was considered aberrant.

Senescence-associated β -galactosidase (SA- β -gal) staining

Cells were treated with 0.1 nmol/L or 0.5 nmol/L lidamycin for 2 h and continuously maintained for 72 h. The attached cells were fixed in 5 mL/L glutaraldehyde and stained for SA- β -gal activity using X-gal at pH 6.0 as previously described^[19].

Western blot analysis

Cells incubated with lidamycin at 37°C for 2 h and then allowed to recover for 72 h at 37°C were harvested and washed in PBS. The cells were lysed on ice in lysis buffer (100 mmol/L Tris, pH 6.8, 25 g/L SDS, 100 mL/L β -mercaptoethanol, 1 mmol/L phenylmethylsulfonyl fluoride, and 100 mL/L glycerol) for 10 min, followed by ultrasonication. The cell lysates were cleared by centrifugation, and the protein concentration was estimated using the Bradford method with bovine serum albumin as a standard. Western blot analysis was performed as a protocol described previously^[20]. In brief, equal amounts of protein were electrophoresed on SDS-polyacrylamide gel (Fluka) and transferred onto a nitrocellulose membrane (Hybond-P, Amersham Pharmacia) for blotting with primary antibodies including anti-Bax (N-20, Santa Cruz), anti-Smac (a kind gift from Dr. Xiao-Dong Wang, University of Texas Southwestern Medical Center, Dallas, USA), anti-cyclin B1 (GNS-1, Santa Cruz), anti-p16 (16P04, NeoMarkers), anti-Rb (C-15, Santa Cruz), anti-p53 (DO-1, Santa Cruz), anti-p21 (F-5, Santa Cruz), and anti-actin (I-19, Santa Cruz) antibodies. Secondary antibodies conjugated with horseradish peroxidase (Amersham Pharmacia). Enhanced chemiluminescence (ECL Western Blot Kit, Amersham Pharmacia) was used according to the manufacturer's instructions.

RESULTS

Growth inhibition induced by lidamycin in BEL-7402 cells

Inhibition of cell growth and proliferation was measured by the MTT test. Exposing BEL-7402 cells to 0.1 and 0.5 nmol/L lidamycin resulted in a dose-dependent inhibition of cell growth (Figure 1).

Figure 1 Effects of lidamycin treatment on BEL-7402 cells growth. Cells were seeded in 96-well plates and treated with 0.1 nmol/L or 0.5 nmol/L lidamycin for 2 h. Growth curves were established indirectly by detecting reactions with MTT. The value of each time point was derived from three samples.

Atypical chromatin condensation and multinucleation induced by lidamycin in BEL-7402 cells

With 0.1 nmol/L lidamycin for 2 h, followed by a 72-h incubation in drug-free medium, the treated BEL-7402 cells displayed a unique and atypical chromatin condensation characterized by appearance of small "dots" representing segregated condensed chromatin without apoptotic bodies (Figure 2B). Moreover, we did not observe detachment of these cells from the monolayer during the process of chromatin condensation. After 72-h incubation, multinucleation (three or more nuclei), one of the

Figure 2 Induction by lidamycin of atypical chromatin condensation and multinucleation in BEL-7402 cells, determined by staining with the fluorescent dye Hoechst 33342 at 72 h after exposure to 0.1 nmol/L and 0.5 nmol/L lidamycin for 2 h. A: Untreated BEL-7402 cells; B: 0.1 nmol/L lidamycin treated BEL-7402 cells; C: 0.5 nmol/L lidamycin treated BEL-7402 cells.

Figure 3 Effects of lidamycin on cell cycle. BEL-7402 cells were treated with 0.5 nmol/L lidamycin for 2 h, then washed and fed with fresh medium. After 72 h of incubation, the cells were stained with propidium iodide and sorted by flow cytometry. A,B: Untreated BEL-7402 cells; C, D: 0.5 nmol/L lidamycin treated BEL-7402 cells. The changes indicated in dot density maps were in accordance with those displayed in histograms.

Figure 4 Immunofluorescence analysis of centrosomes and mitotic spindles in BEL-7402 cells at 72 h after treatments with 0.5 nmol/L lidamycin for 2 h. Cells grown on coverslips were fixed in paraform and doubly labeled with antibodies to α -tubulin (red) and centrin (green). Localization of centrosome on superimposed image showed yellow. A: Untreated BEL-7402 cells; B,C: 0.5 nmol/L lidamycin treated BEL-7402 cells. Arrows in B,C indicated the cells with multiple centrosomes, multipolar mitotic spindle or chromosome missegregation.

Figure 5 Phase contrast images of SA- β -gal stained BEL-7402 cells. At 72 h after incubation with lidamycin for 2 h, attached cells were fixed with 5 mL/L glutaraldehyde and stained for SA- β -gal activity for 16 h. A: Untreated BEL-7402 cells; B: 0.1 nmol/L lidamycin treated BEL-7402 cells; C: 0.5 nmol/L lidamycin treated BEL-7402 cells. The photographs were taken at 200-fold magnification (25 μ m scale bars).

main features of mitotic cell death, occurred at 0.5 nmol/L lidamycin-treated BEL-7402 cells (Figure 2C).

Changes of cell cycle progression and DNA polyploidy induced by lidamycin in BEL-7402 cells

The biochemical and cytological changes of multinucleated

giant cells remain poorly understood. To further characterize the etiology of mitotic cell death, we analyzed the cell cycle and DNA content of the lidamycin-treated BEL-7402 cells by flow cytometry. The cells were exposed to a low concentration of lidamycin for 2 h. At 72 h after treatment, ~23.7% of BEL-7402 cells arrested in G2/M phase, and the cells with >4N DNA

content were detected at 32.0% (Figure 3C).

Centrosome overduplication, multipolar spindle formation and unbalanced division induced by lidamycin in BEL-7402 cells

Immunofluorescence microscopy revealed that the abnormalities of multiple centrosomes and multipolar mitotic spindles markedly increased in BEL-7402 cells induced by lidamycin at a low concentration. Co-staining with antibodies to centrin and α -tubulin indicated that the increased centrosomes were localized at each pole of the multiple spindles, and the cells not deriving from equal division appeared (Figure 4B, C). However, to untreated cells, these defects rarely displayed (Figure 4A).

Induction by lidamycin of senescence-like phenotype in BEL-7402 cells

The induction of SA- β -gal activity and mitotic cell death were thought to be independent events^[21]. To investigate the effects of mitotic cell death on senescence-like phenotype of the lidamycin-treated cells, we observed SA- β -gal expression, a senescence marker, at 72 h after lidamycin treatment. The treated cells showed phenotypic changes that resembled features of normal senescence, including enlarged and flattened morphology, increased granularity, vacuolization, and enhanced SA- β -gal-positive cells (Figure 5). Moreover, the induction of senescence-like phenotype in BEL-7402 cells was increased dose-dependently.

Alterations of cell cycle related proteins in lidamycin-treated BEL-7402 cells

To understand some molecular changes that led to mitotic cell death, cell cycle proteins were analysed by Western blot analysis in lidamycin-treated cells. In BEL-7402 cells, lidamycin induced an increase in the levels of cyclin B1, p16 and pRb, meanwhile a decrease in expression of p53 and p21 (Figure 6).

Figure 6 Western blot analysis of BEL-7402 cells. Cells were harvested at 72 h after 2-h lidamycin treatment, and total proteins (30 μ g/lane) were resolved by 8 to 15% SDS-PAGE and transferred onto nitrocellulose, and Western blot was performed using the indicated antibodies. Lane A, untreated BEL-7402 cells; lane B, 0.1 nmol/L lidamycin treated BEL-7402 cells; lane C, 0.5 nmol/L lidamycin treated BEL-7402 cells.

Alterations of apoptosis related proteins in lidamycin-treated BEL-7402 cells

To confirm that mitotic cell death induced by lidamycin was distinguished from typical apoptosis, and detect the correlation between them, proteins associated with apoptosis were examined. Bax is a regulator of apoptosis^[20]. Smac, an inhibitor of caspase suppressors, promotes cytochrome c-induced activation of caspases by sequestering the inhibitor of apoptosis protein family^[22]. As is shown in Figure 6, the protein levels of Bax and Smac declined in lidamycin-treated BEL-7402

cells. We were unable to detect the proteolytically activated caspase-3 and caspase-9, and found no significant alterations of the blots representing caspase-3 precursor and caspase-9 precursor after exposure to low concentrations of lidamycin in BEL-7402 cells (data not shown).

DISCUSSION

HCC is one of the most common malignant neoplasms in the world^[1]. The incidence of HCC in China exceeds 100 000 per year, and at least 110 000 HCC-related deaths occur every year. Lidamycin is a highly potent cytotoxic antitumor agent. We treated human hepatoma BEL-7402 cells with lidamycin at concentrations in the nanomolar range, and assessed the potential role of centrosome in lidamycin-induced mitotic cell death. The results indicated a series of abnormal events including centrosome overduplication, formation of multipolar mitotic spindles, multinucleation, and eventual mitotic catastrophe. In this study, we have described for the first time the association between centrosomes and enediyne antibiotics-induced cell death in human hepatoma cells.

Thus far, the modes of cell death induced by lidamycin can be divided into two classes, one is apoptosis, and the other is mitotic cell death^[5,23]. It has been reported that lidamycin can act directly as an endonuclease without dependence on caspase activities and is considered as an apoptosis-mimetic agent, at high concentrations^[24]. Cells exposed to low concentrations of lidamycin lost reproductive integrity due to inappropriate entry into mitosis, and apparently exhibited the morphological and biochemical changes associated with mitotic cell death: enlarged cell shape, multi- or micronucleation, accumulation of karyotypic abnormalities, and a G2/M arrest^[5]. Apoptosis, mitotic cell death and irreversible cell cycle arrest may all contribute to cell death after lidamycin treatment. The exact mechanism of mitotic cell death is unclear, and only a few studies have attempted to elucidate the effects of lidamycin on cells at moderate concentrations^[5,11]. In the present study, we used low-dose lidamycin to treat BEL-7402 cells, and mitotic cell death was observed predominantly after treatment. We demonstrate that lidamycin can induce multiple centrosomes which may be responsible for the assembly of multipolar mitotic spindles and the chromosomes missegregation. Most of the cells containing multiple nuclear fragments were temporarily viable but reproductively dead. However, in some cases, the cells undergoing mitotic death initiated endocycles, restituted mitosis and finally survival^[8]. We plan to continue this study to confirm the link between lidamycin-induced mitotic cell death and centrosome overduplication by using centrosome inhibitors and vectors containing antisense mRNAs to centrosome related proteins.

Because centrosome duplication was closely associated with DNA replication, cytokinesis and cell cycle regulation^[25,26], we analyzed the cell cycle progression of lidamycin-treated BEL-7402 cells to detect relationship between centrosome dysregulation and cell cycle distribution as well as to confirm the appearance of multinucleated cells, which is one of the main features of mitotic cell death. We found that lidamycin induced centrosome overduplication associated with induction of G2/M arrest. Previous reports showed that centrosome replication could dissociate from DNA synthesis cycle and mitotic division^[27], and cell cycle block in G2/M phase might be related to abnormal centrosome accumulation^[10], and endocycles starting from G2/M arrest could produce endopolyploid cells^[7]. We suppose that lidamycin-induced DNA replication cycle retardation in BEL-7402 cells could be helpful to trigger centrosome overduplication.

Analysis of gene expression may provide further insights into the molecular mechanisms mediating mitotic cell death. Cyclin B1, a component of the mitosis-promoting factor, plays an important role in G2/M regulation by forming a complex with

p34cdk1 to phosphorylate various substrates necessary for mitosis. The cells with the morphological features of mitotic catastrophe frequently undergo up-regulation of cyclin B1 level^[28,29], which is consistent with our results. Bax expression is a regulator of apoptosis. Ordinarily action of Bax facilitates apoptosis^[30]. However, our present study demonstrated that the levels of Bax and Smac both decreased along with no proteolytic activation of caspase-3 and caspase-9, and no DNA ladder was obtained (data not shown) after lidamycin treatments, which suggested that the mitochondrial apoptosis pathway might not be activated. The undetectable typical apoptosis is not caused by Bcl-2 involvement in BEL-7402 cells exposed to low concentrations of lidamycin (data not shown) and some other genes might play an essential role in this response. p21 is a p53-regulated protein. p53 inhibition was shown to increase mitotic death^[31]. We noticed decreased levels of p53 and p21 in BEL-7402 cells after lidamycin treatment. However, the expression of p16 and pRb proteins was upregulated in BEL-7402 cells, which might explain the increased intensity of staining for SA- β -gal in lidamycin-treated cells, since p16 is closely related to induction of senescence-like phenotype^[32]. Based on data presented here, we propose that the G2/M arrest of BEL-7402 cells may not be mediated by a classically driven cell cycle checkpoint mechanism correlated with p53. From a therapeutic standpoint, centrosome dysregulation might provide a valuable anticancer target. Further study to identify signaling pathways to mitotic cell death in tumor cells and normal somatocytes would help to improve the efficacy of HCC therapy with a low systemic toxicity.

ACKNOWLEDGMENTS

We thank Drs. Lian-Fang Jin, Da-Cheng He and Xiao-Dong Wang for providing lidamycin and antibodies to centrin and Smac. We thank Wei-Li Cai for technical assistance. Hong-Bin Deng, Jian-Ming Jiang and Guo Li are acknowledged for their helpful discussions.

Abstract

AIM: To evaluate the safety of *Curcuma aromatica* oil gelatin microspheres (CAO-GMS) infused via hepatic artery against primary liver cancer.

METHODS: The safety of CAO-GMS was evaluated in view of its acute toxicity in rats, long-term toxicity in Beagle dogs and general pharmacology in rats and mongrel dogs.

RESULTS: The 50% lethal dose (LD₅₀) of CAO-GMS infused via the hepatic artery was 17.19 mg/kg, and the serum biochemical indices of dying rats after the administration changed markedly while those of survived rats did not. Subsequent pathological examination of the tissues from the dead rats indicated improper embolism. Similar edema and small necrotic foci in the hepatic lobule were found in the hepatic tissue of rats receiving 10 and 5 mg/kg CAO-GMS and GMS 60 d after the last administration, while not in the rats of the blank control group, indicating that microspheres infused via the hepatic artery may induce irreversible liver damage dose-dependently. General pharmacological study showed that the activities (posture and gait), respiration frequency, blood pressure or heart rate of the dogs were not affected by CAO-GMS, nor were salivation, tremor or pupil changes of the rats observed or their balancing ability compromised, suggesting CAO-GMS infused via the hepatic artery did not significantly affect the nervous, respiratory and cardiovascular systems.

CONCLUSION: CAO-GMS embolization administered via the hepatic artery is safe but undesired embolization induced by vascular variation should be given due attention in its clinical application. Individualized embolization dosage and super-selective catheterization technique are recommended to avoid undesired embolism and reduce complications.

INTRODUCTION

Curcuma aromatica oil (CAO) is the oil mixture extracted from

Curcuma aromatica consisting of multiple effective ingredients, such as β -elemene and curcumol^[1-7]. Researchers have demonstrated that CAO, with relatively low toxic effects, is the main anti-neoplasm ingredient of *Curcuma aromatica*^[8-12], which can be used for therapy against neoplastic diseases, especially liver neoplasm^[13-19]. Clinically, CAO has been applied in interventional therapy administered via the hepatic artery, and produced favorable effects in patients with primary liver cancer^[20-24] and experimentally, in rats with transplanted liver tumor as well^[25]. As an oil preparation, CAO is often difficult to achieve total embolization in interventional therapy with far too short retention time in the neoplastic lesions. CAO microsphere is suggested to be ideal for increasing the retention time, enhancing the inhibitory effects on cancer cells, and also for blocking the trophic vessels for the hepatoma, so to produce dual effects of chemotherapy and embolization. Therefore, we employed the microsphere degradation technique to entrap the CAO into the gelatin medium and prepared CAO-GMS^[26], which has shown potent therapeutic efficacy against transplanted liver cancer in rats^[27-29] and from which the released CAO exhibited marked dose-dependent inhibition of the growth of human hepatoma cell line SMMC-7721^[30].

CAO-GMS is a preparation of traditional Chinese herbal drugs possible for quality control^[26]. Considering its special pharmaceutical form and administration route, we adopted the interventional procedures described by Lindell *et al.*^[31] similar to clinical situations, so as to study CAO-GMS in view of its acute toxicity, long-term toxicity and general pharmacology in rats and dogs. The results may help evaluate the safety of the interventional therapy with CAO-GMS embolization administered via the hepatic artery in the treatment of primary liver cancer and provide experimental evidence for its potential clinical application.

MATERIALS AND METHODS

Drugs and reagents

CAO-GMS (50-100 μ m in diameter, Batch No.: 971006), 8% CAO and blank gelatin microspheres (50-100 μ m in diameter, Batch No.: 97050) were provided by the Department of Pharmaceutics, Shenyang Pharmaceutical University. Sodium carboxymethyl cellulose (CMC-Na) was purchased from Guangzhou Chemical Reagents and Glassware Co. (Batch No.: 950808). The microspheres were suspended in 3 g/L CMC-Na solution for use.

Animals

A total of 104 SD rats (clean animals, including 52 males and 52 females weighing 220-300 g, Certification No.: 152) used in this study were purchased from Shanghai Sino-British SIPPR/BK Lab Animal Co. Ltd. Twenty-one mongrel dogs (conventional animals, 11 males and 10 females, weighing 13.5-21.0 kg, Certification No.: 19980610) were purchased from Guangzhou Shima Experimental Animal Company and guaranteed by the Experimental Animal Center of Guangzhou University of Traditional Chinese Medicine. Eighteen Beagle dogs (specific pathogen-free animals, 9 males and 9 females, weighing 12.5-13.1 kg, Certification No.: 97A025) were purchased from the Experimental Animal Center of Guangzhou Medicine Industry Institute.

Six-channel physiological recorder (Plugsys, Hugo Sachs Elektronik, Germany), blood pressure sensor (Isotec, Hugo Sachs Elektronik, Germany), thermosensitive recorder (WR500, Isotec, Hugo Sachs Elektronik, Germany), digital subtraction angiography-interventional therapy apparatus (DSA, Siemens, Germany), automated blood analyzer (Counter-5, Japan), automated blood coagulation analyzer (ACT-3000 plus, Germany), clinical biochemical analyzer (CL-7200, Japan) and electrocardiograph (ECG-6511, Japan) were used in this study.

Acute toxicity in rats

Seventy-four SD rats were randomly divided into 7 groups including CAO-GMS-1 group ($n = 10$) receiving CAO-GMS 5 mg/kg, CAO-GMS-2 group ($n = 12$) receiving CAO-GMS 10 mg/kg, CAO-GMS-3 group ($n = 14$) receiving CAO-GMS 20 mg/kg, CAO-GMS-4 group ($n = 12$) receiving CAO-GMS 40 mg/kg, GMS control group ($n=10$) receiving gelatin microspheres 40 mg/kg, blank control group ($n = 8$) receiving 3.5 mL/kg CMC-Na (3 g/L) in a volume equivalent to that of injected microspheres and ZT group ($n = 8$) receiving 3.2 mg/kg CAO. All rats were anesthetized with 45 mg/kg intraperitoneal pentobarbital injection prior to drug administration following the method described by Lidell *et al.*^[31] (Figure 1). In brief, a catheter was inserted through the gastroduodenal artery to the proper hepatic artery, the distal end of the gastroduodenal artery was ligated, and the common hepatic artery as well as the right branch of the proper hepatic artery was temporarily blocked to receive the agents through the left branch of the proper hepatic artery. The general activities, mortality and survival time of the rats were consecutively observed and recorded for 14 d after drug administration. Blood samples of the dying rats were collected and determined for ALT, AST, total bilirubin (T-BIL), direct bilirubin (D-BIL), blood creatinine (BCr) and blood urea nitrogen (BUN). Blood samples were also taken from the survived rats on d 14 for determination of the above indices. Autopsy was performed on the dead rats and the vital organs such as the liver, spleen, lung and kidney *etc.* were pathologically examined.

Figure 1 Administration method (from Lindell^[31]).

Long-term toxicity in Beagle dogs

Eighteen Beagle dogs were randomly divided into 4 groups including CAO-GMS high-dose group (CAO-GMS-H, 5 dogs) receiving 15 mg/kg CAO-GMS every 4 wk, CAO-GMS low-dose group (CAO-GMS-L, 5 dogs) receiving 7.5 mg/kg CAO-GMS every 4 wk, GMS control group (4 dogs) receiving 15 mg/kg gelatin microspheres every 4 wk, blank control group (4 dogs) receiving 10 mL/kg saline in the same volume as that of the microspheres every 4 wk. Each dog was anaesthetized with 30 mg/kg pentobarbital, and a catheter was super-selectively inserted into the hepatic artery through the femoral artery puncture under perspective monitor. The hepatic artery was examined by intra-arterial digital subtraction angiography with

the injection of 8 mL meglumine diatrizoate (760 g/L) at the rate of 2 mL/s, 150 Psi by a high-pressure syringe. The microspheres of specified doses were mixed with the contrast media and slowly injected. To prevent improper embolism due to reflux of the liquid, the injection rate was strictly controlled. The catheter was washed with saline after the injection, and angiography of the hepatic artery was performed for confirmation of the range and degree of embolization. The catheter was withdrawn after the surgery, and the puncture pressed for 15 min and bandaged with pressure. The procedures were repeated twice every 4 wk. Half of the dogs in each group were sacrificed on d 30 after the last treatment and the other half on d 60. The tissue samples were fixed in 40 g/L neutral formaldehyde, processed by the standard histological techniques, and stained with hematoxylin and eosin (HE) for light microscopic examination. The liver, kidney, lung, adrenal, pancreas, stomach, duodenum, ileum, colon, prostate, brain, spinal cord, heart, spleen, sternum (bone and marrow), bladder, uterus, ovary, thyroid, thymus and testis of the dogs were all examined pathologically to assess the long-term toxicity, reversible toxicity and delayed toxicity of CAO-GMS.

General effect on nervous system of rats

Thirty rats were randomly divided into 3 groups including high-dose CAO-GMS group (CAO-GMS-H, 12 rats) receiving 10 mg/kg CAO-GMS, low-dose CAO-GMS group (CAO-GMS-L, 10 rats) receiving 5 mg/kg CAO-GMS, and blank control group (8 rats) receiving 3.5 mL/kg CMC-Na (3 g/L, in equivalent volume). The administration of the agents followed the procedures described above. The general activities (posture and gait), salivation, tremor or pupil changes of rats were recorded. Balance test of rotarod model was performed on d 3, 5, 7 and 14, respectively, in which the rats were put on a 90-cm-long rod 2.5 cm in diameter to observe the dropping frequency. The rats dropping more than 3 times were defined to have incoordination with nervous system impairment.

General effect on respiratory and cardiovascular systems of dogs

Twenty-one mongrel dogs were randomly divided into 4 groups, namely high-dose CAO-GMS group (CAO-GMS-H, 6 dogs receiving 0.10 g CAO-GMS), low-dose CAO-GMS group (CAO-GMS-L, 6 dogs receiving 0.03 CAO-GMS), CAO group (4 dogs receiving 6.4 μ L/kg CAO) and blank control group (5 dogs) receiving 10 mL/kg CMC-Na (3 g/L, in equivalent volume). Under anesthesia with pentobarbital, the blood pressure of the dogs was measured with catheterization through the common carotid artery (connected by Isotec blood pressure sensor). Two-lead electrocardiogram and respiratory frequency were also recorded. Thirty minutes later, the dogs were given specified agents with the method described above. The respiratory frequency, blood pressure and electrocardiogram of the dogs before and 30, 60, 120, 180 min after administration were measured using six-channel physiology recorder.

Statistical analysis

Data were expressed as mean \pm SD. The 50% lethal dose (LD_{50}) was calculated with Bliss method. The biochemical indices were assessed by multiple ANOVA. Changes in blood pressure, respiratory frequency and heart rate before and after administration of the agents within the same group were assessed by paired *t* test using SPSS 10.0 statistical software. The difference was considered significant when *P* value was less than 0.05.

RESULTS

Acute toxicity in rats

All rats in CAO-GMS-4 group fell in a state of drowsiness with

hair erection and died within 24 h after administration of the agent. Death of the rats in CAO-GMS-3 group occurred 24–48 h after the administration, with the survived rats exhibiting signs of fatigue, hair erection, and emaciation accompanied by reduced activity and anorexia; 2 rats developed ascites and survived until d 14. The rats in CAO-GMS-2 group also showed fatigue within the first 2 d after administration of the agent but resumed normal condition on d 3. The rats in CAO-GMS-1, blank control and CAO group did not show signs of discomfort. The rats of GMS group exhibited changes similar to those of CAO-GMS-4 group. LD₅₀ of CAO-GMS embolization via the hepatic artery was 17.19 mg/kg, with the 95% confidential interval of 13.08–23.67 mg/kg (Table 1).

Compared with those of the blank control group, all the dying rats of the CAO-GMS groups showed marked increase in ALT, AST, T-BL, D-BL, BCr and BUN (Table 2), but none of the survived rats showed marked changes in these indices (Table 3).

The tissue samples of the rats in CAO-GMS and GMS groups showed damage of hepatic tissues, as were mostly manifested in CAO-GMS-3, 4 groups and GSM group. The rats in CAO-GMS-3 and -4 groups were found to have hemorrhagic damage in lung tissues and necrosis of renal tubules, indicating dose-dependent damage of the kidney and lung by CAO-GMS. We identified traces of the microspheres in a tissue sample of CAO-GMS-2 group, suggesting that the toxic effects on kidney tissues in CAO-GMS-1, -2, -3, -4 groups arose from improper

embolization of the renal artery. The tissue samples from the 4 groups showed dose-independent damage of the spleen tissues. Abnormal changes were not observed in vital organs in blank control and CAO groups.

We found that CAO-GMS induced untoward responses and death of the rats dose-dependently. Since the rats in blank control and CAO groups showed no untoward response as those in GMS group did, we presumed that GMS, instead of CAO, caused renal and hepatic injuries. The most probable cause of the renal damage might be undesired embolization of the renal artery by GMS.

Long-term toxicity in Beagle dogs

The dogs of CAO-GMS-H, CAO-GMS-L and GMS groups showed necrotic foci in the hepatic tissue with color attenuation 1–2 mm in diameter. The blank control group showed no marked change in the color and texture of the hepatic tissue.

Figure 2 displays the pathological changes in hepatic tissues of the dogs. Two dogs in CAO-GMS-H group exhibited whole lobule coagulation necrosis in the hepatic tissue with total destruction of the normal structures. The remaining hepatic tissue exhibited extensive moderate cellular edema with occasional cellular inflammatory edema in the necrotic region. In a dog died during the experiment, whole lobule coagulation necrosis was observed in the hepatic tissue, which was also seen in two dogs sacrificed on d 30 with mild cellular edema in the remaining hepatic tissue and destruction of normal structures.

Table 1 Deaths of the rats after administration of CAO-GMS

Group	Number of rats	Dosage (mg/kg)	Number of dead rats	Mortality (%)	Peak time of death occurrence (h)
CAO-GMS-1	10	5	0	0	-
CAO-GMS-2	12	10	4	33.33	24–48
CAO-GMS-3	14	20	8	57.14	24–48
CAO-GMS-4	12	40	12	100	<24
GMS	10	40	7	71.42	24–48
Blank control	8	3.5 ¹	0	0	-
CAO	8	3.2	0	0	-

¹Measured in mL/kg.

CAO-GMS-3	6	39.0±10	314±59	7.4±4.7	4.5±2.9	39.0±13	9.20±2.9
CAO-GMS-4	0	-	-	-	-	-	-
GMS	3	46.0±6.5	265±114	4.0±1.5	2.9±1.6	35.0±1.4	7.60±1.4
Blank control	8	38.0±11	278±114	4.5±1.3	3.2±1.6	38.7±3.5	8.60±1.8
CAO	8	36.0±7	307±84	4.8±1.9	3.2±1.7	39.4±2.4	8.00±1.6

Figure 2 Long-term toxicity of CAO-GMS on the liver of dogs. A: CAO-GMS-H group receiving 15 mg/kg CAO-GMS every 4 wk; B: CAO-GMS-L group receiving 7.5 mg/kg CAO-GMS every 4 wk; C: GMS group receiving 15 mg/kg GMS every 4 wk; D: Blank control group receiving 10 mL/kg saline every 4 wk.

Two dogs of CAO-GMS-L group developed extensive moderate to severe hepatic cellular necrosis. The central region of the liver lobules showed moderate cellular edema with fatty degeneration and foci of coagulation necrosis, where neutrophilic leukocyte infiltration could be seen. Two dogs sacrificed on d 30 had extensive moderate cellular necrosis in the hepatic tissue and small necrotic foci, with ruptured normal structure.

In GMS group, two dogs were found to have whole lobular coagulation necrosis in the hepatic tissue where normal structure was disrupted. The other regions of the liver lobules showed moderate cellular edema with lymphocyte infiltration in the necrotic region. Two dogs sacrificed on d 30 exhibited extensive mild cellular necrosis in the hepatic tissue and spotty necrosis of the hepatic cells.

In the blank control group, mild cellular edema in the hepatic tissue was found in 2 dogs, with disrupted normal structure. Two dogs sacrificed on d 30 exhibited mild cellular necrosis in the hepatic tissue.

Pathological examination of the other vital organs showed no abnormal changes in the morphology of the kidney, lung, adrenal, pancreas, stomach, duodenum, ileum, colon, prostate, brain, spinal cord, heart, spleen, sternum (bone and marrow), bladder, uterus, ovary, thyroid, thymus and testis.

The above results demonstrated that CAO-GMS infused via the hepatic artery may cause irreversible ischemic necrosis

of the liver without visible damage on other organs. Delayed toxic response was not evident. The toxic effects on liver were identical with those observed in study of the acute toxicity. Partly due to the super-selective catheterization technique employed in this study, no improper embolization was found, indicating the importance of the technique in the clinical application for reducing complications.

Effects on nervous system of rats

The rats receiving 5 or 10 mg/kg CAO-GMS or 3 g/L CMC-Na showed emaciation, reduced activity and anorexia in the first 2 postoperative days, but resumed normal conditions on d 3, probably due to operative injury. No pupil abnormality or tremor was observed. All rats dropped less than 3 times in the balance test of rotarod model, indicating that CAO-GMS did not affect the balancing ability of the rats.

Effects on respiratory and cardiovascular systems of dogs

The effects of CAO-GMS on respiratory frequency, blood pressure and heart rate are shown in Table 4. CAO infused via the hepatic artery produced no marked effects on blood pressure and heart rate of the dogs ($P>0.05$). The respiratory frequency of the dogs within 3 h after administration of the agent was lowered, but not statistically ($P>0.05$ vs indices before embolization).

CAO-GMS or blank GMS produced no marked effects on blood pressure and heart rate of the dogs ($P>0.05$, Tables 5, 6).

Table 4 Changes in respiration, rates blood pressure and ECG in dogs at different time points after CAO (6.4 μ L/kg) interventional therapy (mean \pm SD)

The respiratory frequency of the dogs within 3 h after the administration was lowered, but not significantly ($P>0.05$ vs indices before embolization).

Effects on respiratory blood pressure and heart rate graphs

The recorded graphical data also indicated the same results (Figure 3) as above.

**Figure 3** Effects of CAO-GMS infused via the hepatic artery on respiration, blood pressure and heart rate of dogs. A: Blank control group (with 3 g/L CMC-Na, 10 mL/kg); B: CAO-GMS group (with CAO-GMS, 0.1 g); C: CAO-GMS group (with CAO-GMS, 0.03 g); D: CAO group (with CAO, 6.4 μL/kg); 1: Before administration; 2: 60 min after administration; 3: 180 min after administration.

DISCUSSION

Transarterial chemoembolization (TACE) is most commonly adopted for palliative treatments in patients with hepatocellular carcinoma (HCC)^[32,33], but the shrinkage of neoplasm comes at the price of sacrificing the hepatic function and in the long-term effects, it does not significantly differ from conservative therapy^[34]. Improvement in the operative technique and in the agents used for interventional therapy is therefore much desired to produce better anti-tumor effect with low toxicity and liver

protection. By producing CAO-GMS, we take full advantage of CAO of its anti-tumor, immune-enhancing effects with low-toxicity^[12-26]. To enhance the effect of embolizing the trophic vessels for hepatoma, CAO was coupled with biodegradable microsphere (50-100 μm in diameter).

Previous studies demonstrated that CAO-GMS exhibited marked inhibitory effects on transplanted liver cancer in rats, which were attributed to the blocking of trophic vessels of the hepatoma by the microspheres and the therapeutic effects of CAO released slowly from the degraded microspheres^[27-30].

In this study, CAO-GMS was not found to affect respiration, blood pressure and heart rate, *etc.*, nor did it elicit acute or long-term toxic response, but at high doses, CAO-GMS embolization via the hepatic artery might induce significant increase in AST and ALT as well as irreversible ischemic necrosis of the liver. This was a sign of hyperreactive acute liver injury, as was similar to the clinical effect of other chemotherapeutic microspheres at high doses^[35,36], and predominantly responsible for its untoward, or even lethal effects.

CAO-GMS or blank GMS administered via the hepatic artery in normal animals caused embolization in the kidney and untargeted liver lobes, leading to the death of animals, which, however, did not happen with CAO or saline. This result indicates that CAO alone normally does not induce the adverse effects, which arise from undesired embolization of CAO-GMS as with other chemotherapeutic microspheres^[36,37]. Based on these facts, we concluded that the most probable reason for the acute hyperreactive response was the sudden accumulative embolization in the liver or undesired embolization as in the renal artery.

The dose adopted for embolization and the operation technique are crucial for clinical application of CAO-GMS. Most researchers preferred the use of computed tomography (CT) to determine individualized dosage rather than a conventionally fixed dosage, along with super-selective catheterization techniques to reduce reflux embolization of the microspheres. These techniques were believed to enhance the safety of the CAO-

GMS interventional therapy.

In general, the results of this study demonstrated that CAO-GMS is fairly safe for interventional therapy but individual difference should be fully considered in its clinical application. Clinicians are advised to determine the embolization dosage and interventional method individually to avoid the undesired embolization caused by the microspheres. We propose the use of superselective catheterization technique to precisely block the trophic artery of the hepatoma, and the exact dosage of CAO-GMS should be determined according to the size, location and trophic vessels of the tumors to prevent undesired embolization or complications after the interventional therapy.

Abstract

AIM: To investigate the effect of histone acetylation on regulation of $p21^{WAF1}$ gene expression in human colon cancer cell lines.

METHODS: Two cell lines, Colo-320 and SW1116 were treated with either trichostatin or sodium butyrate. Expressions of $p21^{WAF1}$ mRNA and protein were detected by real-time RT-PCR and Western blotting, respectively. Acetylation of two regions of $p21^{WAF1}$ gene-associated histones and total cellular histones were examined by chromatin immunoprecipitation assay and Western blotting.

RESULTS: Trichostatin or sodium butyrate re-activated $p21^{WAF1}$ transcription resulted in up-regulated $p21^{WAF1}$ protein level in colon cancer cell lines. Those effects were accompanied by an accumulation of acetylated histones in total cellular chromatin and $p21^{WAF1}$ gene-associated region of chromatin.

CONCLUSION: Histone acetylation regulates $p21^{WAF1}$ expression in human colon cancer cell lines, Colo-320 and SW1116.

INTRODUCTION

Cell cycle progression is controlled by various cyclin-dependent kinases (CDKs), whose activation is carefully regulated at multiple levels including the induction and degradation of cyclin protein, CDKs phosphorylation by cyclin-activating kinase, and the induction of CDK inhibitors (CDKIs)^[1]. CDKI $p21^{WAF1}$ was first cloned and characterized as an important effector that acts to inhibit CDK activity in p53 mediated cell cycle arrest in response to various agents^[2]. Increased expression of $p21^{WAF1}$ may play a crucial role in the G₁/S phase arrest induced in transformed cells, and may prevent the progression of neoplasia^[3].

Histone acetylation is emerging as a major regulatory mechanism thought to modulate gene expression by altering the accessibility of transcription factors to DNA and recent studies suggest that these alterations may also be important in the process of neoplasia formation^[4]. The level of histone acetylation depends on the activity of histone acetyltransferases (HATs) and histone deacetylases (HDACs). An important approach that has been used to study the function of chromatin acetylation is the use of specific inhibitors of HDAC. Trichostatin A^[5,6] (TSA, a hybrid polar compound of specific inhibitor) and sodium butyrate^[4] (a short chain fatty acid produced in human colon by bacterial fermentation of carbohydrate) were reported to inhibit HDAC activity.

Previously it was revealed that acetylation of gene-associated histone or total cellular histone alone regulated $p21^{WAF1}$ expression in colon cancer cell lines^[7,8]. We have shown^[9] that TSA or sodium butyrate induced G₁ phase cell cycle arrest was linked to increased expression of $p21^{WAF1}$. However, little is known about the regulation of acetylation of both gene-associated histone and total cellular histone on $p21^{WAF1}$ expression in human colon cancer. It is as yet not clear about the effect of histone acetylation on $p21^{WAF1}$ protein in Colo-320 and SW1116 cell lines. Therefore, in the present study, we further investigated whether TSA and sodium butyrate induced overexpression of $p21^{WAF1}$ resulted from hyperacetylation of gene-associated histones and histones in total cellular chromatin in two human colon cancer cell lines, Colo-320 and SW1116.

MATERIALS AND METHODS

Cell culture

Human colon cancer-derived cell lines Colo-320 and SW1116 were obtained from Shanghai Institute of Biochemistry and Cell Biology, SIBS, China and Shanghai Second Medical University Ruijin Hospital, respectively. Colo-320 and SW1116 cells were maintained in RPMI 1640 supplemented with 100 mL/L heat-inactivated fetal bovine serum, 2 mmol/L L-glutamine, 100 U/mL penicillin and 100 µg/mL streptomycin at 37 °C in a 50 mL/L CO₂ incubator.

Treatment of cells with TSA or sodium butyrate

Colon cancer cell lines were exposed to 1 µmol/L TSA or 5 mmol/L sodium butyrate (Sigma, St. Louis, MO) alone for 24 h, as described by Siavoshian *et al.*^[10]. The control cultures were treated simultaneously with phosphate-buffered saline (PBS) or alcohol (control for TSA treatment, because TSA can only be dissolved in alcohol).

Western blotting of acetylated histones and $p21^{WAF1}$

Colo-320 cells were cultured as described below with or without treatment. Cells were recovered by centrifugation, washed twice with ice-cold PBS, and resuspended for lysis in 1 mL buffer A (10 mmol/L HEPES, pH 7.4, 10 mmol/L KCl, 1.5 mmol/L MgCl₂, 0.5 mmol/L DTT, 0.2 mmol/L PMSF, 1 µg/mL protease inhibitors, 0.25 g/L NP40) for 15 min with rotation at 4 °C and the nuclear pellet was resuspended in 100 µL buffer B (20 mmol/L HEPES, pH 7.4, 420 mmol/L NaCl, 1.5 mmol/L MgCl₂, 0.2 mmol/L EDTA,

250 mL/L glycerol, 0.5 mmol/L DTT, 0.2 mmol/L PMSF, 1 µg/mL protease inhibitors) for 30 min, then the soluble nuclear protein was collected by centrifugation. Fifty µg (for acetylated histone H3 and H4) or 150 µg (for p21^{WAF1} protein) of nuclear extracts was boiled in loading buffer (125 mmol/L Tris-HCl, pH 6.8, 40 g/L SDS, 200 g/L glycerol, 0.05 g/L bromophenol blue) for 5 min and then loaded onto a 150 g/L SDS-polyacrylamide gel. After electrophoresis, proteins were transferred onto nitrocellulose membrane (0.45 µm). The following antibodies were used: rabbit polyclonal antibody against acetylated histone H3 or H4 (Upstate Biotechnology, Lake Placid, NY) and goat polyclonal antibody against p21^{WAF1} (C19, Santa Cruz, California). The bindings of antibodies were detected using ECL-system (Amersham Pharmacia Biotech, Piscataway, NJ, USA) and membranes were then exposed to Kodak BioMax film for 1 min. Antibody against β-actin (Sigma) in Western blot was used as a control for protein concentration.

Real-time RT-PCR for p21^{WAF1} mRNA

mRNA level of p21^{WAF1} was measured using a real-time quantitative PCR system. Total RNA samples from SW1116 and Colo-320 cells with or without treatment were prepared by TriZol Reagent. Gene-specific TaqMan probes and PCR primers were designed using Primer Express software (PE Biosystems, Foster City, CA). The sequence for forward and reverse primers and the probe are shown in Table 1. Triplicate PCR reactions were prepared for each cDNA sample. PCR consisted of 40 cycles of 95 °C denaturation (15 s) and 60 °C annealing/extension (60 s). Thermal cycling and fluorescent monitoring were performed using an ABI 7 700 sequence analyzer (PE Biosystems). The point at which the PCR product is first detected above a fixed threshold, termed cycle threshold (Ct), was determined for each sample, and the average Ct of triplicate samples was calculated. To determine the quantity of gene-specific transcripts present in treated cells cDNA relative to untreated cells, their respective Ct values were first normalized by subtracting the Ct value obtained from the β-actin control ($\Delta Ct = Ct_{FAM} - Ct_{VIC}$). The concentration of gene-specific mRNA in treated cells relative to untreated cells was calculated by subtracting the normalized Ct values obtained with untreated cells from those obtained with treated samples ($\Delta \Delta Ct = \Delta Ct_{treated} - \Delta Ct_{untreated}$), and the relative concentration was determined ($2^{-\Delta \Delta Ct}$). Altered mRNA expression was defined as 3-fold difference in the expression level in cells after the treatment relative to that before treatment^[11].

Chromatin immunoprecipitation (ChIP) assay

A ChIP assay kit from Upstate Biotechnology was used

according to the manufacturer's protocol and Richon's report^[12]. Colo-320 cells that were either treated with 1 µmol/L TSA or 5 mmol/L sodium butyrate for 24 h or untreated were plated at a density of 10×10^6 /T25 flask. Formaldehyde was then added to the cells to a final concentration of 10 g/L, and the cells were incubated at 37 °C for 10 min. The medium was removed, and the cells were suspended in 1 mL of ice-cold PBS containing protease inhibitors [1 mmol/L phenylmethylsulfonyl fluoride (PMSF), 1 µg/mL aprotinin and 1 µg/mL pepstatin A, Boehringer Mannheim]. Cells were pelleted, resuspended in 0.2 mL of SDS lysis buffer, and incubated on ice for 10 min. Lysates were sonicated. The majority of DNAs ranged from 200 bp to 1 000 bp. Debris was removed from samples by centrifugation for 10 min at 15 000 g at 4 °C in a microcentrifuge. An aliquot of the chromatin preparation (200 µL) was set aside and designated as the input. Supernatants were 10-fold diluted in ChIP dilution buffer containing the protease inhibitors as above, and 80 µL of a salmon sperm DNA/protein A-agarose beads was added and incubated for 30 min at 4 °C with rocking. Beads were pelleted by centrifugation, and supernatants were placed in tubes with 10 µg of antibody against acetylated histone H3 or H4, or normal rabbit IgG, and incubated overnight at 4 °C with rotation. Salmon sperm DNA/Protein A-agarose beads (60 µL) was added, and samples were rocked for 1 h at 4 °C. Protein A complexes were centrifuged and washed 5 times for 5 min each with low salt buffer, high salt buffer, LiCl buffer and TE buffer, respectively. Immune complexes were eluted twice with 250 µL of elution buffer (10 g/L SDS/0.1 mol/L NaHCO₃) for 15 min at room temperature. NaCl (5 mol/L, 20 µL) was added to the combined eluate, and the samples were incubated at 65 °C for 4 h. EDTA, Tris-HCl, pH 6.5, and proteinase K were then added to the samples at a final concentration of 10 mmol/L, 40 mmol/L, and 0.04 µg/µL, respectively, and the samples were incubated at 45 °C for 1 h. Immunoprecipitated DNA (both immunoprecipitation samples and input) was recovered by phenol/chloroform extraction and ethanol precipitation and analyzed by PCR. p21^{WAF1}-specific primers were used to carry out PCR. Sequences of two sets of primers for p21^{WAF1} PCR and PCR condition are shown in Table 2. The first set primer was used to amplify -576 to -293 and the second set primer was used to amplify -51 to +77 of p21^{WAF1} promoter and exon 1, which contained the transcription factor E2A binding sites.

RESULTS

HDAC inhibitors resulted in accumulation of acetylated core histones H3 and H4

Western blotting showed that before incubation with TSA or

sodium butyrate, the levels of acetylated H3 and H4 in colo-320 cells were low. Incubation with HDAC inhibitors resulted in the accumulation of acetylated histones H3 and H4 (Figure 1).

Figure 1 Western blotting of acetylated histones H3, H4 and $p21^{WAF1}$ protein in Colo-320 cells. Lane 1: Control (PBS); lane 2: Control (alcohol); lane 3: TSA 1 μmol/L, 24 h; lane 4: NaBu 5 mmol/L, 24 h.

Either TSA or sodium butyrate induced re-expression of $p21^{WAF1}$ mRNA and protein

To understand the change of $p21^{WAF1}$ expression level following HDAC inhibitors treatment, we examined accumulation of mRNA and protein by RT-PCR and Western blotting. As shown in Figures 1 and 2, $p21^{WAF1}$ mRNA and protein were activated after treatment of TSA and sodium butyrate. In addition, Colo-320 cells had an initial increase in $p21^{WAF1}$ expression to a higher level than that in SW1116 cells.

Figure 2 RT-PCR showed either TSA or sodium butyrate induced overexpression of $p21^{WAF1}$ mRNA in human colon cancer cell lines Colo-320 and SW1116. Lane 1: Control (PBS); lane 2: Control (alcohol); lane 3: TSA 1 μmol/L, 24 h; lane 4: NaBu 5 mmol/L, 24 h.

Figure 3 HDAC inhibitors induced accumulation of acetylated histones H3 and H4 in chromatin associated with $p21^{WAF1}$

gene. A: PCR products for the 1st set primer of $p21^{WAF1}$; B: PCR products for the 2nd set primer of $p21^{WAF1}$; C: The figure in A and B was scanned and quantified by using IMAGE analysis software. The ratio between input DNA and precipitated DNA was calculated for each treatment and primer set. The increase after treatment with either TSA or sodium butyrate was calculated from indicated ratios. PCR products of the 2nd primer were not visualized on agarose gel before treatment with HDAC inhibitor, so it could not be calculated. Input DNA, lanes 1-4: Soluble chromatin was immunoprecipitated with antiacetylated histone H3 antibody; lanes 5-8: Soluble chromatin was immunoprecipitated with antiacetylated histone H4 antibody; lanes 9-12: Normal rabbit serum as negative control; lanes 13-16, 1, 5, 9, 13: PBS control; lanes 2, 6, 10, 14: Alcohol control; lanes 3, 7, 11, 15: TSA 1 μmol/L, 24 h; lanes 4, 8, 12, 16: NaBu 5 mmol/L, 24 h.

$p21^{WAF1}$ gene-associated histone H3 was hyperacetylated in colon cancer cells treated with TSA or sodium butyrate

To determine whether histone acetylation reflected $p21^{WAF1}$ transcription and the functional interaction between $p21^{WAF1}$ and TSA or sodium butyrate treatment, ChIPs-PCR was performed. As shown in Figure 3, the densities of bands of $p21^{WAF1}$ gene-associated acetylated histones H4 and H3 were higher in chromatin extracted from Colo-320 cells treated with either TSA or sodium butyrate than that from cells mock treated, either the first or the second set PCR primer.

Taken together, TSA or sodium butyrate activated the transcription of $p21^{WAF1}$ through acetylation of histones H4- and H3-associated $p21^{WAF1}$ promoter.

DISCUSSION

Several lines of evidence suggest that histone acetylation plays a role in transcriptional regulation, probably by altering chromatin structure^[13]. Acetylation of core nucleosomal histones is regulated by the opposing activities of HATs and HDACs. The latter catalyze the removal of an acetyl group from the ε-amino group of lysine side chains of histones H2A, H2B, H3 and H4, thereby reconstituting the positive charge in lysine. Transcriptionally silent chromatin is composed of nucleosomes in which the histones have low levels of acetylation of lysine residues at their amino-terminal tails^[14,15]. Acetylation of histone neutralizes the positive charge in lysine residues and disrupts nucleosome structure, allowing unfolding of the associated DNA, access by transcription factors, and changes in gene expression. Chromatin fractions enriched in actively transcribed genes are also enriched in the more highly acetylated isoforms of the core histones^[16]. HDAC inhibitors appear to be selective with regard to the genes whose expression is altered^[17].

Total cellular histone acetylation is also involved in the regulation of gene expression. Several studies^[18] indicated that the effect of HDAC inhibitors on gene transcription was associated with an increased accumulation of acetylated histones H3 and H4 in total cellular chromatin. However, Lee's group^[19] showed an accumulation of acetylated histones H3 and H4 in total cellular chromatin after treatment with HDAC inhibitor (MS-275), but no change in the level of histone acetylation in chromatin-associated TGF-β I receptor gene. Therefore, we wanted to know whether HDAC inhibitor affected the acetylation level of histones in both gene-associated and total cellular chromatin. The data from ChIP and Western blotting suggested that $p21^{WAF1}$ transcription was dependent upon acetylation at the level of chromatin, since the level of $p21^{WAF1}$ promoter amplified from acetylated histone H3- or H4-associated chromatin was greater in chromatin isolated from HDAC inhibitor-treated cells than that from untreated cells. Accumulation of acetylated $p21^{WAF1}$ -associated histones induced by HDAC inhibitors was higher than that in total cellular chromatin, although there was accumulation of

acetylated histones H3 and H4 in total cellular chromatin.

It is noteworthy that, the level of acetylated histones H3 and H4 at the domain containing the transcriptional start site in *p21^{WAF1}* promoter and the binding sites of E2A was significantly higher than that at another domain or total cellular chromatin analyzed. The result of our observations suggested that *p21^{WAF1}* expression could be activated by histone acetylation of its transcription start domain in promoter. Therefore, a possible mechanism involved the binding of transcription factor E2A to *p21^{WAF1}* promoter at transcription start site of acetylated *p21^{WAF1}* gene-associated histones H3 and H4, and the enhancement of *p21^{WAF1}* gene transcription. It is known that histone acetylation can be targeted to specific promoters by gene-specific activator. E2A transcription factor belongs to the basic helix-loop-helix family of proteins^[20], which contains a conserved basic region responsible for DNA binding and a helix-loop-helix domain for dimerization^[21]. E2A binds *p21^{WAF1}* at the domain nearby TATA box in the promoter. TATA box-independent transcription of the *p21^{WAF1}* promoter has been previously reported^[22]. The proximal *p21^{WAF1}* promoter contains a TATA box^[23]. Some reports indicated that *p21^{WAF1}* was up-regulated by E2A binding to HTLV-1-infected T cells^[20]. Moreover, overexpression of E2A proteins, such as E47 has been shown to induce *p21^{WAF1}* promoter activity independent of p53 binding sites^[24,25].

Also, we showed that the levels of *p21^{WAF1}* mRNA and protein in colon cancer cells were very low, even difficult to detect before treatment. In Colo-320, *p21^{WAF1}* mRNA was increased by 27.1-fold and 17.15-fold after 1 μ mol/L TSA and 5 mmol/L sodium butyrate treatment, respectively. Accordingly, the protein level of *p21^{WAF1}* was elevated. Similar effects were shown in SW1116 cells (data not shown). Our data about TSA or sodium butyrate inducing *p21^{WAF1}* mRNA and protein expression are consistent with previous reports^[12].

In summary, this study demonstrated that HDAC inhibitor, TSA or sodium butyrate, activated the expressions of *p21^{WAF1}* mRNA and protein, and this increased expression was associated with an accumulation of acetylated histones in total cellular chromatin and the chromatin of *p21^{WAF1}* gene in these two colon cancer cell lines. It has been shown that *p21^{WAF1}* expression is reduced in adenomas and colorectal carcinomas. Our observations support the claim for the therapeutic potential of HDAC inhibitors in the treatment of colorectal carcinoma, because there is probably no mutation of the *p21^{WAF1}* gene in colorectal cancer.

Abstract

AIM: Hereditary nonpolyposis colorectal cancer (HNPCC) is an autosomal dominantly-inherited cancer-susceptibility syndrome that confers an increased risk for colorectal cancer and a variety of other tumors at a young age. It has been associated with germline mutations in five mismatch repair (MMR) genes (hMSH2, hMLH1, hPMS1, hPMS2, and hMSH6/GTBP). The great majority of germline mutations were found in hMSH2 and hMLH1. The purpose of this study was to analyze the clinical features of Chinese HNPCC patients and to screen hMSH2 and hMLH1 gene mutations.

METHODS: Twenty-eight independent Chinese families were collected, of which 15 met Amsterdam criteria I and 13 met the Japanese clinical diagnosis criteria. The data were recorded including sex, site of colorectal cancer (CRC), age of diagnosis, history of synchronous and/or metachronous CRC, instance of extracolonic cancers, and histopathology of tumors. Peripheral blood samples were collected from all pedigrees after formal written consents were signed. PCR and denaturing high-performance liquid chromatography (DHPLC) were used to screen the coding regions of hMSH2 and hMLH1 genes. The samples showing abnormal DHPLC profiles were sequenced by a 377 DNA sequencer.

RESULTS: One hundred and seventy malignant neoplasms were found in one hundred and twenty-six patients (multiple cancer in twenty-three), including one hundred and twenty-seven CRCs, fifteen gastric, seven endometrial, and five esophageal cancers. Seventy-seven point eight percent of the patients had CRCs, sharing the features of early occurrence (average age of onset, 45.9 years) and of the right-sided predominance reported in the literature. In Chinese HNPCC patients, gastric cancer occurred more frequently, accounting for 11.9% of all cancers patients and ranking second in the spectrum of HNPCC predisposing cancers. Synchronous CRCs occurred less frequently, only accounting for 3.1% of the total CRCs. Twenty percent of the colorectal patients had metachronous CRCs within 10 years after operation. Eight hMSH2 or hMLH1 gene sequence variations were found in twelve families, including the first Mongolian kindred with a hMSH2 gene mutation.

CONCLUSION: HNPCC is characterized by an early-age

onset, proximal predominance of CRC, multiple metachronous CRCs, and an excess of extra-colonic cancers. Frequent gastric cancer occurrence and less synchronous CRCs are the remarkable features in Chinese HNPCC patients. DHPLC is a powerful tool in hMSH2 and hMLH1 gene mutation screening. hMLH1 gene mutations, especially of the first nine exons, have been found more common than hMSH2 gene mutations in Chinese patients. Three of seven mutations have been found to be novel, and the germline G204X nonsense mutation in the third exon of hMSH2 has become the first MMR gene mutation found in Chinese Mongolian people.

INTRODUCTION

Hereditary nonpolyposis colorectal cancer (HNPCC, or Lynch syndrome) is an autosomal dominantly-inherited cancer-susceptibility syndrome. It is estimated that HNPCC may account for 5-10% of the total colorectal cancers (CRC) worldwide^[1]. In Western countries, patients inheriting this predisposition are at a particularly high risk of developing CRC and endometrial cancer at a young age, and also at an increased risk of developing various other types of tumors, such as ovarian, uroepithelial, small intestine, biliary tract, stomach, brain, and skin cancers^[2]. Five mismatch repair (MMR) genes (hMSH2, hMLH1, hPMS1, hPMS2, and hMSH6/GTBP^[3-8]) have been known to be involved in this cancer susceptibility. Currently, more than 300 different mutations have been described in these genes, which account for approximately 500 HNPCC kindreds in the world^[9]. hMSH2 and hMLH1 germline mutations were found to be responsible for more than 90% of the HNPCC families^[10] (<http://www.nfdht.nl/>). Therefore, identification of the mutational incidence and spectrum of hMSH2 and hMLH1 genes is important. Identifying the clinical features of HNPCC in China, which might have some differences from those reported in Western countries, will facilitate its diagnosis and treatment. We described the clinical features and the results of mutation screening of both hMSH2 and hMLH1 genes in 28 HNPCC families registered in our hospital. We think that Chinese HNPCC patients have some unique clinic features and MMR gene defects.

MATERIALS AND METHODS

Clinical Data

Subjects were selected from 28 independent Chinese families from January 1992 to August 2003. Among these families, 15 met the Amsterdam criteria I^[11]. The criteria were as follows: (1) Three or more relatives had histologically-verified CRC, one of them was a first degree relative to the other two relatives; (2) At least two successive generations were affected; (3) One or

more CRC cases were diagnosed under 50 years of age; and (4) Familial polyposis of the colon was excluded. The Japanese clinical diagnosis criteria for HNPCC^[12] were used for the other 13 highly-suspected families that did not fully meet the Amsterdam criteria I. Families that met the following A or B were also clinically diagnosed as having HNPCC: A: a case with three or more CRCs within the first-degree relatives; B: a case with two or more CRCs within the first-degree relatives meeting one of the following criteria: age at onset of CRCs being under 50 years, right colon involvement, synchronous or metachronous multiple CRCs, or associated with synchronous or metachronous extracolorectal malignancies.

Detailed family and medical histories were obtained through interview with the proband, and a home visit to extended family members and an extensive review of medical records if available. Peripheral blood samples were collected from all participants after formal written consents were signed.

Eligible HNPCC families were registered and family members were followed up intensively. All patients were reviewed by telephone or outpatient visit at regular intervals. Data concerning sex, site of CRC, age of diagnosis, history of synchronous and/or metachronous CRC, instance of extracolonic cancers, and histopathology of tumors were documented and thoroughly verified.

DNA extraction and PCR amplification

Genomic DNA was isolated from peripheral blood lymphocytes according to the salting-out procedure^[13]. The entire hMLH1 and hMSH2 coding region and the splice junctions were amplified by PCR according to Weber methods^[14] with minor modifications.

DHPLC analysis

DHPLC analysis was performed on a Transgenomic WAVE system (Transgenomic Inc.) identical with that described previously^[15]. Briefly, PCR products (25 µL) were denatured for 5 min at 95 °C and then gradually reannealed by decreasing sample temperature from 95 °C to 45 °C over a period of 30 min to form homo- and/or heteroduplexes. Crude PCR product (7-10 µL) was loaded on the DHPLC column and eluted with a linear acetonitrile gradient at a flow rate of 0.9 mL/min. Gradient parameters were determined based on size and G-C content of the amplicon. Generally, an analysis took approximately 7 min, including column regeneration and re-equilibration to starting conditions. The column mobile phase consisted of a mixture of 0.1 mol/L triethylammonium acetate pH 7.0 (TEAA) with (buffer B) or without (buffer A) 250 mL/L acetonitrile. The temperature for heteroduplex analysis was primarily established by using the DHPLC melting algorithm WAVE MakerTM of the WAVETM instrument. The final temperature and denaturing condition for optimal resolution of homoduplexes and heteroduplexes of each fragment were experimentally determined.

DNA sequencing

PCR products displaying a double DHPLC peak indicating existence of heteroduplex were purified with micron microconcentrator filters (Amicon, Beverly, MA) to remove unwanted reagents from the PCR reaction and to concentrate the final products, which were then sequenced by a 377DNA sequencer. All mutations were sequenced in both directions and confirmed in other family members.

RESULTS

Statistics on patients and tumors

A total of 28 kindreds were studied, all of them met the Japanese clinical diagnosis criteria and 15 of them met the Amsterdam I criteria. There were 9 Lynch syndrome I families, in which only colorectal cancers were found, and 19 Lynch syndrome II families, which were characterized by concurrent extracolonic malignancies.

One hundred and seventy malignant neoplasms were found in 126 patients (multiple cancer in twenty-three), including 127 CRCs; 15 gastric, 7 endometrial, 5 esophageal, 2 skin, 2 pancreatic, 2 lung, 1 breast, 1 cervical, 1 ovarian, 1 hepatic, and 1 biliary cancers; 1 gastric leiomyosarcoma, 1 liposarcoma, 1 bone sarcoma, 1 leukemia, and 1 brain glioblastoma. In the present group, 77.8% of the patients had CRCs and 74.7% of the cancers were colorectal ones. There were 45 metachronous CRCs and 4 synchronous CRCs, accounting for 35.4% and 3.1% of the total CRCs, respectively. Right-sided colon cancers constituted 52.9% of the total tumors, and 70.9% of CRCs. Individuals suffering from gastric cancer amounted to 11.9% of total patients.

The average age of malignant neoplasm onset in all the patients was 47.0 years and the ratio of males to females was 1.2:1. Individuals developed CRCs at an average age of 45.9 years. Sixty-two point seven percent of colorectal tumors developed under 50 years of age, 33.3% under 40 years of age and less than 4% occurred above the age of 70 years. In the 28 pedigrees, the average age of tumor occurrence in the first, second, third, and fourth degree was 59.6, 50.0, 44.0, and 31.8 years, respectively.

Eighty-five percent of the patients received radical operations. The remaining patients received chemotherapy, irradiation, and traditional Chinese medicine treatment. Twenty percent of colorectal patients had metachronous CRCs within 10 years after the first operation and required re-operations.

hMSH2 and hMLH1 mutation results

Thirteen double peak profiles displayed in DHPLC were found among 28 probands of all the pedigrees. Finally, 12 probands were identified with a varying DNA sequence by sequencing, of which 7 developed different mutations and 5 had the same hMSH2 polymorphism (Table 1 and Figure 1). We also examined the relatives of affected probands for the same mutations, and found that cancers and mutations were co-segregated in all affected pedigrees.

Table 1 hMSH2/hMLH1 gene sequence variations identified by sequencing

Sample No.	Gene/Exon	Point of mutation	Mutation result	Reported previously by
23 ¹	hMSH2/3	g. ² 610G>T,GGA→TGA	G204X, Truncated protein (nonsense mutation)	None
10,12,15,16,28	hMSH2/10	g.1661+12A>G	In intron, polymorphism	Scott <i>et al.</i> ^[16]
26	hMSH2/14	g.2211-2 A>C	Truncated protein (splice point mutation)	None

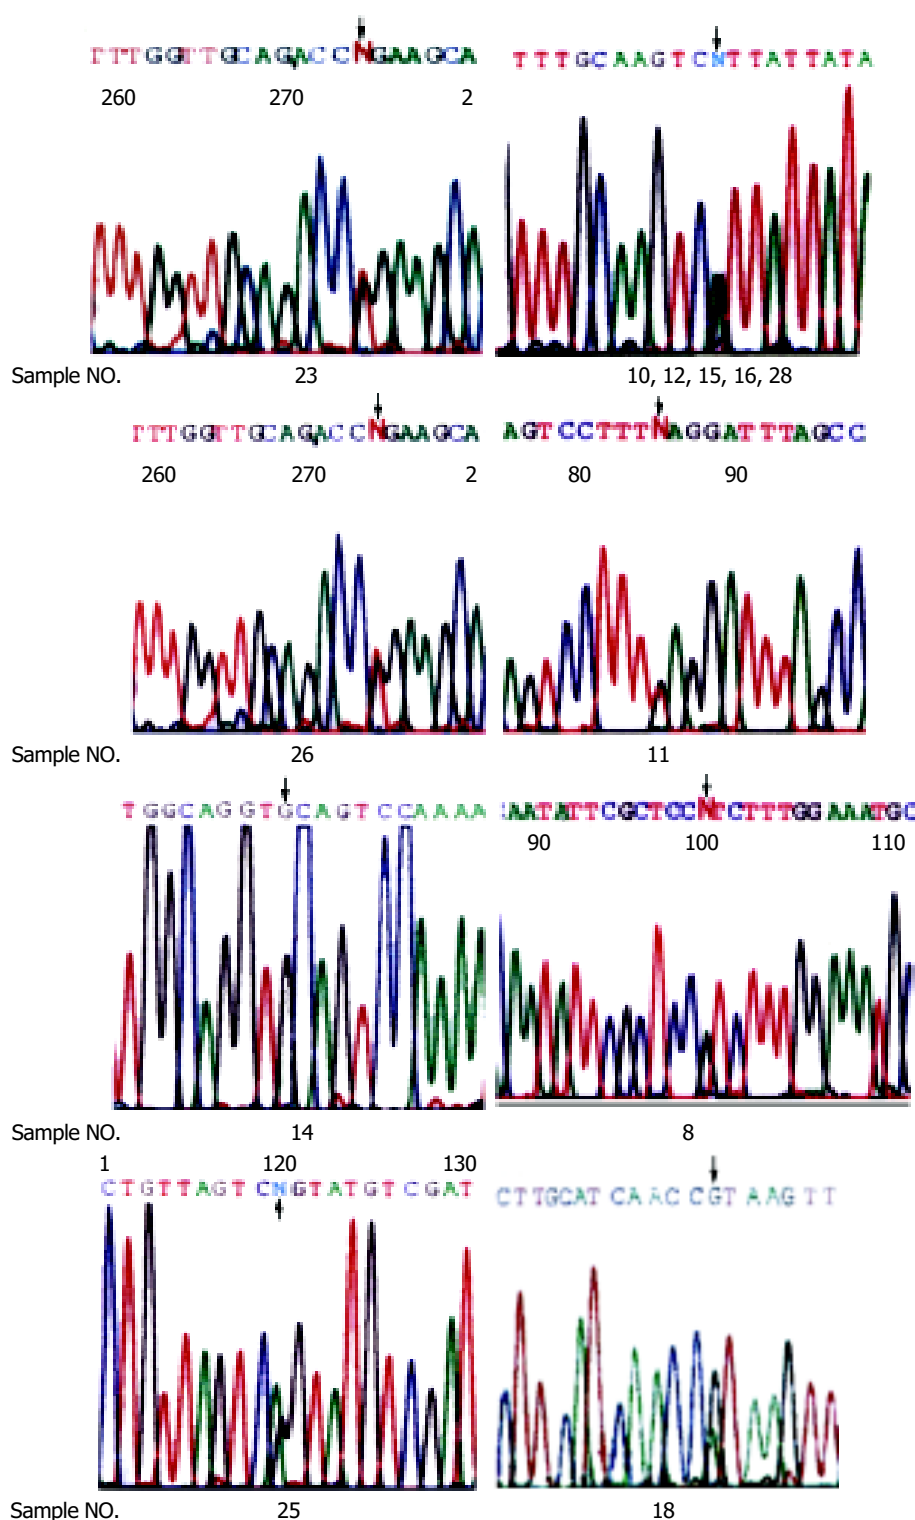

Figure 1 Sequencing graphs of mutations.

DISCUSSION

HNPCC was characterized by an early onset of colorectal cancers (proximal predominance, with 70% proximal to the splenic flexure), multiple synchronous and metachronous CRCs (about 18.1% and 24.2% respectively^[21]), and an excess of certain extracolonic cancers^[22]. In our study, patients with HNPCC developed CRC at an average age of 45.9 years, much earlier than the general population in China. According to our data, right-sided colon cancers amounted to 52.9% of the total cancers, and 70.9% of CRCs, similar to those reported in Western countries. Moreover, we also found the phenomenon of “generation anticipation”, that is, the later the generation was, the earlier the CRC developed. The fact that the family members

tended to be diagnosed early in the follow-up was an explanation for this phenomenon. Another reason for this phenomenon might be that there were carriers who harbored mutated MMR genes but did not become penetrant. Further studies should be carried out.

We found that the following two features were different from those reported in Western countries. Though Chinese patients had a high incidence of metachronous CRCs, synchronous cancer occurred quite rarely, only 3.1% in this study. Our previous studies also had a similar conclusion^[20], and the reason for the rare incidence of synchronous cancer in Chinese HNPCC patients remains unclear. The other striking feature was that gastric cancer was the second most common

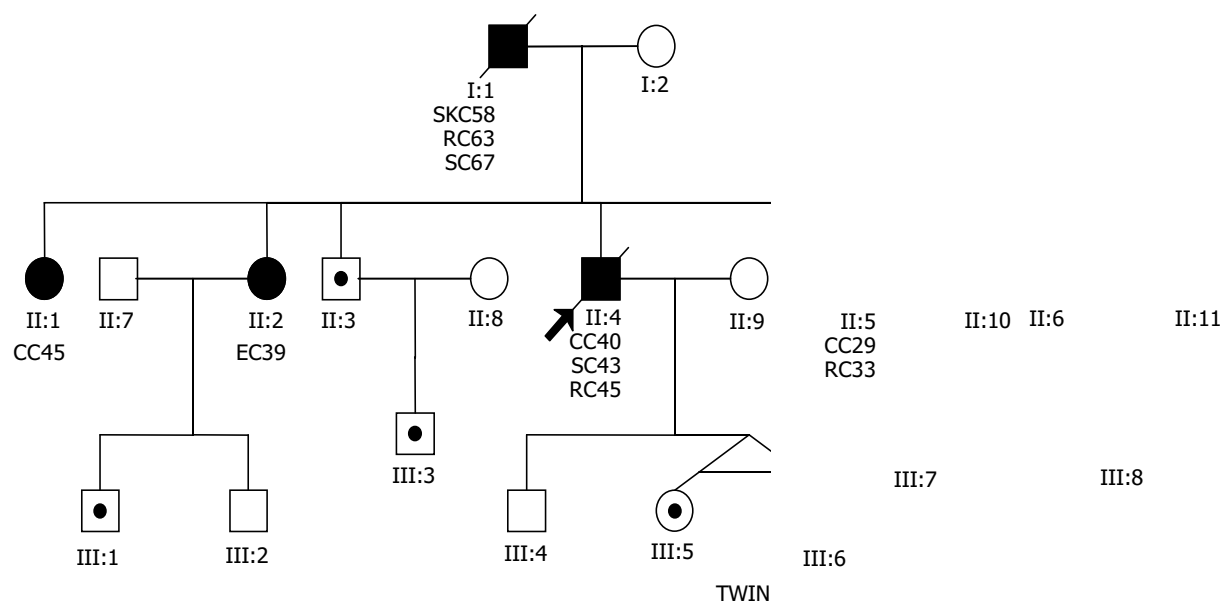

Figure 2 Pedigree of the first Mongolian family with hMSH2 gene mutation in China. ● Cancer patient, ○ Normal person, ⊙ Mutational gene carrier, SKC: skin cancer, RC: rectal cancer, CC: colonic cancer, EC: endometrial cancer, SC: stomach cancer.

cancer in Chinese HNPCC families, amounting to 11.9% of all cancers patients, much higher than the reported incidence in Western countries^[23,24]. Endometrial cancer ranked third, amounting to only 5.6%, and was followed by esophagus carcinoma. In Western countries, however, the second most commonly-seen tumor was endometrial cancer^[22,25]. In Japan and Korea, gastric cancer also occurred more frequently^[26]. We suppose that these features may represent the ethnic and geographical characteristics that may have some diagnostic significance in China and/or Asia.

The diagnosis of HNPCC depends on the detection of MMR genes. Single-strand conformation polymorphism (SSCP), denaturing gradient gel electrophoresis (DGGE), and direct sequencing have been used in MMR gene defect screening. Using DHPLC, we found a specificity of 92.3%, and recommended it as a hMSH2 and hMLH1 gene mutation screening method. In our study, 5 of 15 families (proband sample NO. 23, 11, 14, 8, 25), who met the Amsterdam I criteria, were found to have mutations and its mutation detection rate is 33.3%. But these criteria could only identify large families where the gene defect was highly penetrant and many small families were inappropriately excluded. In this study, 2 of 13 families (proband sample NO. 26, 18), which did not meet Amsterdam I criteria but fulfilled the Japan criteria, were also found to have mutations. Though the MMR gene defect rate of the latter is comparatively low (only 25%), it has been recommended as the clinical diagnosis criteria in HNPCC patients.

The mutations found in these families were compared with those described already in the human gene mutation database (HGMD) (<http://www.uwcm.ac.uk/uwcm/mg/hgmd0.html>). To our knowledge, apart from mutation of sample 11 (hMLH1, g. 265 G>T, GAG> TAG, E89X) reported before^[17], mutations of samples 14, 8, and 18 and the polymorphism of hMSH2 (g.1661+12A>G) were also reported previously^[18-20]. The other three mutations are novel. All the seven mutations resulted in an impaired capacity in MMR, which were consistent with their associations with penetrant tumors in the families. The probability of polymorphism of hMSH2 (g.1661+12A>G) being pathogenic was very small. Though there were no distinct "hot spot" mutations, we still noticed that hMLH1 gene mutations, especially of the first nine exons, were more common than hMSH2 gene mutations in China. Similarly, Baba^[12] and Yuan *et al.*^[27] described that hMLH1 gene mutations were more

frequently seen in Asia. So, it is worthwhile to initiate MMR gene mutation screening from the first nine exons of hMLH1 gene.

In this study, we identified the first Mongolian family with hMSH2 gene mutation in China. The pedigree is shown in Figure 2. In the large family, the nonsense alteration 610 (genomic DNA) G→T at codon 204 in exon3 of hMSH2 resulted in the substitution of stop codon TGA for glycine codon GGA. This mutation co-segregated with the disease in the family. In five phenotypic normal family members, the same mutated gene was found in the germline. These carriers remain to be followed up intensively.

Abstract

AIM: To identify the differential proteins associated with colorectal cancer genesis and hepatic metastasis.

METHODS: Hydrophobic protein samples were extracted from normal colorectal mucosa, primary cancer lesion and hepatic metastatic foci of colorectal cancer. With two-dimensional electrophoresis and image analysis, differentially expressed protein spots were detected, and the proteins were identified by matrix assisted laser desorption/ionization-time of flight-mass spectrometry and peptide mass fingerprint analysis.

RESULTS: Significant alterations of the proteins in number and expression levels were discovered in primary cancer and hepatic metastatic foci, the expression of a number of proteins was lost in 25-40 ku, but protein spots was increased in 14-21ku, compared with normal mucosa. Nine differentially expressed protein spots were identified. Three proteins expressed in normal mucosa, but lost in primary cancer and hepatic metastasis, were recognized as calmodulin, ribonuclease 6 precursor and mannosidase- α . Proapolipoprotein was expressed progressively from normal mucosa to primary cancer and hepatic metastasis. The differentially expressed protein of beta-globin was found in normal mucosa and hepatic metastatic tumor, but lost in primary cancer lesion. Cdc 42, a GTP-binding protein, was identified in hepatic metastasis. The protein spots of C4 from primary cancer, M7 and M9 from hepatic metastasis had less homology with the proteins in database.

CONCLUSION: Variations of hydrophobic protein expression in colorectal cancer initiation and hepatic metastasis are significant and can be observed with two-dimensional electrophoresis. The expression of calmodulin, ribonuclease 6 precursor and mannosidase- α is lost but the expression of proapolipoprotein is enhanced which is associated with colorectal cancer genesis and hepatic metastasis. Cdc 42 and beta-globin are expressed abnormally in hepatic metastasis. Protein C4, M7 and M9 may be associated with colorectal cancer genesis and hepatic metastasis.

INTRODUCTION

Colorectal cancer genesis and metastasis are complex processes involving multiple changes in gene and protein expression^[1-5]. The liver is a common site of metastasis from colorectal cancer^[6-8]. Hepatic metastasis caused severe and fatal effects on patients who underwent radical excision for large intestine primary carcinoma^[9-12]. The success of metastatic hepatic cancer treatment is strongly dependent on early diagnosis and understanding of the molecular mechanisms and biological behaviors of colorectal cancer, especially its infiltration and metastasis. To unravel these alterations, genome and proteome approaches for the identification of qualitative and quantitative changes in gene and protein compositions provide theoretic and technical support^[13-16]. Our study was focused on the identification of differential expression proteins between primary colorectal cancer foci and hepatic metastasis with proteome approach. Hydrophobic proteins including membrane proteins play important roles in cellular signal transduction. Identification of the proteins is helpful to understand the molecular biological mechanisms of colorectal carcinogenesis and hepatic metastasis and to select tumor markers for colorectal cancer.

MATERIALS AND METHODS

Tissue sample collection

Samples of normal colorectal mucosa, primary cancer lesion and hepatic metastasis were collected from 12 colorectal cancer patients aged 36-68 years including 6 males and 6 females. The samples were stored in liquid nitrogen. Pathology examination was performed for all the specimens and the histological types consisted of moderately and poorly differentiated adenocarcinoma, signet-ring cell carcinoma and undifferentiated carcinoma, 4 cases in each type.

Protein sample preparation

A set of samples were taken from the same patient, 0.9 g of each, including normal colorectal mucosa, primary cancer and hepatic metastatic tumor. The samples were washed with PBS and then immediately ground by a liquid nitrogen cooled mortar, and homogenized in protease inhibitor buffer (cocktail formula: phenylmethylsulfonyl fluoride 40 μ g/mL, ethylenediamine tetraacetic acid 1 mmol/L, peptide inhibitor 0.7 μ g/mL, leupeptin 0.5 μ g/mL). Protein extraction was performed with Molloy procedure. Lysis buffer I (Tris 40 mmol/L, pH8.8) was added, stirred and mixed by an ultrasonic disintegrator. The mixture was centrifuged at 105 000 g for 1 h. Yellow lipids were discarded from the supernatant and the middle layer liquid was transferred and dried with a freezing dryer. The pellet was solubilized in lysis buffer II (Urea 8 mol/L, Tris 10 mmol/L, CHAPS 40 g/L, DTT 65 mmol/L) and centrifuged. The supernatant was dried and stored as *idem*. The pellet was solubilized in lysis buffer III (urea 5 mol/L, thiocarbamate 2 mol/L, SB3-10 20 g/L, 0.2 g, CHAPS 20 g/L, TBP 2 mmol/L), then the procedure was repeated once more. The proteins extracted with fractional procedure were stored at -20 °C.

Two-dimensional gel electrophoresis and image analysis

The first dimension of isoelectric focusing (IEF) was performed

in immobilized pH gradient (IPG) gel strips with nonlinear immobilized pH 3-10 gradient. Three hundred μg of protein sample from each tissue specimen of normal mucosa, primary cancer and hepatic metastatic tumor was loaded respectively. IPG strips were placed onto the rehydration buffer (urea 8 mol/L, CHAPS 40 g/L, TBP 2 mmol/L, IPG buffer 3 g/L) and added into the sample solution without trapping air bubbles. IEF with a low voltage (30 V, followed by 60 V and 200 V) was carried out according to the programmed settings. After IEF was terminated, the IPG strips were equilibrated for 20 min in equilibration buffer. The second dimension of SDS-PAGE was performed on vertical systems. IPG strips were loaded and run on a 125 g/L acrylamide SDS-PAGE gel in electrode buffer (Tris 0.025 mol/L, glycine 0.192 mol/L, SDS 1 g/L, pH 8.3). Electrophoresis was performed with a current of 30 mA/gel for 15 min, then at maximum settings of 60 mA/gel for 4 h. The temperature of the cooling plate was set at 20 °C. After SDS-PAGE, the gels were stained with silver nitrate. Proteins were visualized by silver-staining and then scanned using Scan Prisa 640 UT. Two DE image computer analysis was carried out with Melanie 3.0 software (GeneBio, Geneva). Isoelectric points and molecular weights of individual proteins were evaluated with polypeptide SDS-PAGE-standards. Differential protein spots among normal colorectal mucosa, primary cancer lesion and hepatic metastasis were picked out by comparison of 2-DE images with Melanie 3.0 analysis.

Mass spectrometry and peptide mass fingerprint analysis

Selected differential protein spots were excised from 2-DE gels and transferred to a 96-well plate ready for trypsin digestion. The gel pieces were washed successively in water, Tris-HCl (20 mmol/L pH 8), Tris-HCl (20 mmol/L pH 8)/500 g/L acetonitrile and finally 1 000 g/L acetonitrile, and dried. The dried gel pieces were incubated in trypsin solution for 16 h at 37 °C. The resultant peptide mixture was extracted with 20 μL 5 g/L TFA/300 g/L

acetonitrile, followed by extraction with 20 μL 5 g/L TFA/600 g/L acetonitrile. α -cyano-4-hydroxycinnamic acid was used as matrix solution. Matrix assisted laser desorption/ionization-time of flight-mass spectrometry analysis were performed with MALDI-TOF mass spectrometer (Bruker, USA). The spectrum was obtained and recorded. Proteins were identified by searching NCBI and SwissProt databases using ProFound peptide mass fingerprinting retrieval software (http://129.85.19.192/profound_bin/WebProFound.exe?FORM=1). Protein identities were assigned if at least four peptide masses were matched within a maximum of 100 ppm error spread across the data set and the candidate agreed with the estimated pI and molecular weight from the 2-DE gel.

Statistical analysis

Experimental data were analysed statistically with Crosstab chi-Square test and Student's *t*-test using SPSS 10.0. $P < 0.05$ was considered statistically significant.

RESULTS

2-DE image analysis of protein spots in matched sets of colorectal cancer

The hydrophobic protein profiles including partial membranous proteins from colorectal normal mucosa, primary cancer and metastatic foci in liver are displayed in Figures 1A-C. Comparing the 2-DE protein images of the three tissues, we found that the number of protein spots and protein expression level were significantly changed in primary cancer and hepatic metastatic lesion. Under the same experimental conditions, 390 ± 28 protein spots and 206 ± 22 , 236 ± 19 spots were found in normal colorectal mucosa and in primary cancer and hepatic metastasis, respectively. Compared with normal colorectal mucosa, the number of protein spots in primary cancer and metastatic tumor was significantly different $t = 53.116$, $t = 33.399$,

Figure 2 MALDI-TOF mass spectrometry and peptide mass fingerprint analysis of the differential protein spots (A) N2 protein spot from normal colon mucosa, (B) M6 protein spot from hepatic metastasis.

Table 1 Identification of nine differentially expressed proteins by peptide mass fingerprint and matching with proteins in databases

Spot No.	Accession (NCBI nr)	Theoretical pI	Theoretical M_r	Length (AA)	Protein name
N1	1CDL_B	4.0	16.56	147	Calmodulin complexed with calmodulin-binding peptide
N2	NP_003721	6.7	29.46	256	Ribonuclease 6 precursor
N3	XP_040720	8.4	32.76	287	Hypothetical protein XP_040720
C4		4.5	22.48	217	
C5	AAA51747	5.4	28.94	249	Proapolipoprotein
M6	AAA88054	6.8	15.96	147	Beta-globin
M7		5.5	22.57	203	
M8	XP_010554	6.8	21.25	191	Similar to cell division cycle 42
M9		4.5	14.72	127	

The difference of protein spot number between hepatic metastatic tumor and primary cancer was also significant ($t = 24.407$, $P < 0.01$).

Peptide mass fingerprinting of differential protein spots from 2-DE gels

Nine differential protein spots of the 2-DE gels were analysed using mass spectrometry. Three protein spots, N1, N2, N3, were taken from normal colorectal mucosa. C4 and C5 spots were from primary cancer lesions and four spots, M6, M7, M8, M9, from hepatic metastatic cancer. Molecular weight and isoelectric points of the nine protein spots were determined according to the standard molecular markers and peptide mass fingerprint analysis, and the data are shown in Table 1 and Figure 2.

Identification of differential expression proteins of colorectal cancer and hepatic metastasis

The peptide mass fingerprints obtained from the nine differential protein spots were compared to fingerprints obtained by theoretical cleavage of protein sequences in databases and the protein identities were assigned. Protein spots of N1, N2 and N3 from normal colorectal mucosa represented calmodulin, ribonuclease 6 precursor and hypothetical protein XP_040720, respectively. The expression of three proteins was lost in primary cancer and hepatic metastatic foci. Protein C5, matching to proapolipoprotein, expressed progressively from normal mucosa to primary cancer and hepatic metastatic tumor. Protein spot M6 was observed in normal mucosa and in hepatic metastatic cancer, but lost in primary carcinomas, being recognized as beta-globin. Expressed in hepatic metastasis, M8 was identified with cell division 42 (GTP-binding protein), but not found in normal mucosa and primary cancer lesion. Differential protein spots of C4 from primary carcinomas, M7 and M9 from hepatic metastasis were not identified by peptide mass fingerprint analysis because their peptide mass fingerprints had less homology with the known proteins in databases.

DISCUSSION

The initiation and hepatic metastasis of colorectal cancer involved multiple gene and protein alterations^[17-19]. Understanding the molecular basis of the disease is of great significance for its early detection and treatment. In this study, the proteome approach was applied to the identification of differential proteins between primary colorectal cancer lesion and its hepatic metastasis. We used 2-DE to isolate and analyze the set of hydrophobic proteins from normal colorectal mucosa, primary

cancer and hepatic metastatic tumor. It was of clinical importance to identify the differential expression proteins that had potentiality of being tumor markers and anticancer targets.

By comparison with 2-DE images, significant differences of protein expression were found in normal mucosa, primary cancer and hepatic metastasis, and the number and distribution of protein spots changed noticeably in the range of pH 4.0-9.0. Compared with normal mucosa, a number of protein spots with a molecular weight of 25-40 ku were lost in primary cancer and hepatic metastasis, but proteins with a molecular weight of 14-21 ku were observed in the same pH range. What the differential proteins were and what functions they performed in colorectal carcinogenesis and in hepatic metastasis attracted our attention. We identified nine protein spots and studied their roles in the course of initiation and hepatic metastasis of colorectal cancer.

Proteins of calmodulin (N1), ribonuclease 6 precursor (N2) and hypothetical protein XP_040720 (N3) were expressed in normal colorectal mucosa, but lost in primary cancer lesion and in hepatic metastasis. It indicated the loss of proteins was associated with colorectal carcinogenesis and hepatic metastasis. Calmodulin could regulate the concentration of calcium ions in cells and had important effects on normal cellular functions. Ca^{2+} regulation was necessary for cell differentiation and apoptosis. Combination of calcium ions and the receptors could influence cell signal transduction that controls cell differentiation and division. Low concentration of calcium ions made cell division easily, and the high concentration was advantageous to cell differentiation. Calcium ions promoted cancer cells into apoptosis. Thus, calcium was regarded as a chemoprophylaxis agent for colorectal cancer^[20,21]. We propose loss of calmodulin expression is connected with initiation and hepatic metastasis of colorectal cancer.

Ribonuclease 6 precursor protein belongs to the Rh/T2/S-glycoprotein class of extracellular ribonucleases and the gene is present in a single copy in the human genome and has been mapped to 6q27. This has been found to be a region of the human genome prone to rearrangements associated with several human malignancies^[22]. The family of the proteins possesses the function of ribozyme and self-splicing. They catalyze breaking of RNA, synthesis of polypeptide bonds and nucleotides. The protein can disintegrate DNA fragments, regulate cell biological behaviors and cell division. Loss of ribonuclease 6 precursor expression would facilitate carcinogenesis and infiltration. Ribozyme has been found useful in anticancer therapy^[23]. The loss of ribonuclease 6 precursor expression in primary colorectal cancer and hepatic metastasis could provide an experimental interpretation of ribozyme treatment.

XP_040720, a hypothetical protein is now defined as a

member of mannosidase- α class 1A. The protein is located in Golgi complex and participates in N-glycoprotein synthesis and oligosaccharide processing. It could play an important role in synthesis of membranous proteins and receptor proteins^[24]. But we do not know what functions the protein performs in colorectal carcinogenesis and metastasis. It could be regarded as a differentiation-related protein in normal mucosa cells, and loss of the protein expression is a dedifferentiation phenotype in the primary cancer lesion and hepatic metastasis, which is still lack of evidence.

Loss of the three protein expressions was considered to be connected with colorectal cancer initiation and hepatic metastasis. However proapolipoprotein expression was found stepwisely increased from normal mucosa to primary cancer and hepatic metastasis, and enhanced expression of the protein was in association with colorectal cancer. Proapolipoprotein was hydrolyzed by the signal peptidase and propeptidase, through which apolipoprotein was generated^[25]. Apolipoprotein is a carrier of lipids and regulates many cellular functions. It was found that apolipoprotein had an antiapoptosis effect and was related with carcinogenesis and progression. Enhanced expression of apolipoprotein has been reported in hepatoma^[26]. Our study provided an evidence of apolipoprotein in colorectal cancer.

A differentially expressed protein in our study was beta-globin. Its expression was found in normal mucosa and hepatic metastasis, but lost in primary cancer lesion. We suggested beta-globin was an associated protein with hepatic metastasis. The gene family of beta-globin consists of five functional genes and is located on chromosome 11. The family members expressed in order of the genes as they were arranged on the chromosome during various developmental stages. Beta-globin gene was activated and expressed continuously in late stage of pregnancy^[27,28]. Study on regulation of beta-globin showed that the variations of transcription frequency and cycle of phasic and specific expression of beta-globin family genes in developmental regulation were more important than changes of the gene transcription speed and expression quantity^[29]. Understanding the mechanisms of beta-globin regulation is helpful to researches on cell growth, carcinogenesis and progression. The cycle variation of beta-globin expression from the normal mucosa to primary cancer and hepatic metastasis implied genetic recombination and regulation changes in hepatic metastasis of colorectal cancer. It was reported that beta-globin expression was induced by treatment of chemotherapy agents in some cancer cells. This might indicate that the expression of beta-globin increased drug resistance of cancer cells and facilitated hepatic metastasis.

It has been found that Cdc 42, a differential protein expressed in hepatic metastasis, is a Rho-related member of the Ras superfamily, and acts as a GTP-binding protein^[30,31]. The protein performs the function of a molecular switch to control a diversity of cellular processes, and regulates cytoskeleton actin recombination, cell polarity and cell movement. Enhanced expression of Cdc 42 might facilitate cell division and accelerate cancer cell growth and proliferation, as well as interrupt signal transduction of apoptosis^[32]. Invasive behavior of cancer cells was reinforced by enhanced Cdc 42 expression through regulating cellular skeleton, cell adhesiveness and neovascularization. Therefore, Cdc 42 has been regarded as an associated protein in hepatic metastasis of colorectal cancer.

C4 expressed in primary cancer, M7 and M9 in hepatic metastasis, had low homology with the proteins known in database, and the three proteins were not identified. They manifested the possibility to be new proteins associated with colorectal cancer. Sequencing of the proteins and study of their functions are needed to help understand the mechanisms

of colorectal carcinogenesis and hepatic metastasis.

In summary, we identified 9 differentially expressed proteins that were associated with colorectal cancer genesis and hepatic metastasis. Relations of these proteins with colorectal cancer were not or seldom reported before. The differential proteins will help understand the mechanism of colorectal cancer genesis and hepatic metastasis. The results prove that proteome study represents a very useful and promising tool in discovering new tumor markers and anticancer targets of colorectal cancer.

Abstract

AIM: To synthesize three small-interference RNAs (siRNAs) by T₇ RNA polymerase-catalyzed reaction, and to investigate their efficacy on modulating the expression of serine/threonine kinase Pim-2 in human colon cancer cell line.

METHODS: siRNA I, II and III were synthesized by T₇ RNA polymerase-directed *in vitro* transcription, then transfected into human colon cancer cells SW-480. After incubation for 6 h at 37 °C, 100 mL/L FBS in RPMI 1640 was substituted in each well. After the transfection was repeated twice to three times in each kind of siRNA, hPim-2 mRNA and protein expression were measured by RT-PCR and Western blotting, respectively.

RESULTS: Compared to the control group, after transfected for 48 h with hPim-2 siRNA I, II and III, the relative inhibition rates of hPim-2 mRNA expression in colon cancer cells were 65.4% ($P < 0.05$), 46.2% ($P < 0.05$) and 56.1% ($P < 0.05$), respectively. The protein level of hPim-2 was decreased at 72 h compared to the untransfected cells. The relative inhibition percentages of hPim-2 protein by siRNA I, II, III were 61.6% ($P < 0.05$), 45.8% ($P < 0.05$) and 55.6% ($P < 0.05$), respectively.

CONCLUSION: The *in vitro* transcribed siRNAs can be useful for silencing oncogene hPim-2 expression specifically and efficiently. This may open a new path toward the use of siRNAs as a gene-specific therapeutic tool.

INTRODUCTION

RNAi is an evolutionarily conserved mechanism known to control insects, plants, and mammalian cells^[1-4]. In this process, introduced double-stranded RNAs (ds-RNAs) silence gene was expressed through specific degradation of their cognate mRNAs^[5,6]. Importantly, RNAi can be achieved in mammalian cells following transfection of synthetic 21- and 22-nucleotide (nt) small interfering (si) RNAs, indicating that RNAi may serve as a powerful tool to block the expression of target genes

specifically^[7-11].

Pim-2 is a member of a family of serine/threonine protein kinases that consists of two other members, Pim-1 and Pim-3, and it exists at high concentrations in many tumor cells^[12,13]. Though it was identified 20 years ago, its function that maintains the cell size and its role in the survival of cancer cells have been just determined recently^[14,15]. It is believed to be a cancer-causing gene, or oncogene. Here, we sought to use siRNA-targeting hPim-2 to determine whether this technique could be used to specifically inhibit hPim-2 expression.

MATERIALS AND METHODS

T₇ siRNA synthesis

siRNAs selection was based on the characterization of siRNA by Elbashir *et al.*^[16]. Three hPim-2 siRNA sequences are given in Figure 1. For *in vitro* transcription, 40-nt DNA template oligonucleotides were designed to produce 21-nt siRNAs. siRNA sequences of the form GN₁₇CN₂ were selected for each target. Uridines in the last two nt form the 3' overhang of the siRNA duplex. The template and a 19-nt T₇ promoter (GGT AAT ACG ACT CAC TATA) were synthesized by Applied Biosystems 393 DNA synthesizer and purified by OPC (Perkin-Elmer, Foster city, CA). The oligonucleotide-directed mutagenesis of small siRNA transcription with T₇ polymerase is as follows: for each transcription reaction, 1 nmol of each oligonucleotide was annealed in 50 µL of TE buffer (10 mmol/L Tris-HCl pH 8.0, and 1 mmol/L EDTA) by heating at 95 °C; after 5 min, the heating block was switched off and allowed to cool down slowly to obtain dsDNA. Transcription was performed in 50 µL of transcription mixture: 1×T₇ transcription buffer (40 mmol/L Tris-HCl pH 7.9, 6 mmol/L MgCl₂, 10 mmol/L DTT, 10 mmol/L NaCl and 2 mmol/L spermidine), 1 mmol/L rNTPs, 0.1 U yeast pyrophosphatase (Sigma), 40 U RNase (Life Technologies) and 100 U T₇ RNA polymerase (Fermentas) containing 200 pmol of the dsDNA as template. After incubation at 37 °C for 3 h, 1 U RNase free-DNase (Promega) was added at 37 °C for 30 min. Sense and antisense 21-nt RNAs (single strand RNA, ssRNA) generated in separate reactions were annealed by mixing both crude transcription reactions, incubating at 37 °C overnight to obtain "T₇ RNA polymerase synthesized small interfering double-strand RNA (T₇ siRNA, dsRNA)". The mixture (100 µL) was then extracted with TE-saturated (pH 4.5) phenol:chloroform:isoamyl alcohol (25:24:1), purified with chloroform:isoamyl alcohol (24:1), isopropanol and 0.2 mol/L sodium acetate (pH 5.2). The pellet was washed once with 750 mL/L ethanol, dried, and resuspended in 50 µL of water.

Cell culture

Human colon cancer cell line SW-480 was obtained from Chinese National Cancer Institute. The cells were grown in RPMI 1640 medium (Invitrogen) supplemented with 100 mL/L fetal bovine serum (GIBCO BRL, Grand Island, NY), 100 U/mL penicillin and 100 µg/mL streptomycin at 37 °C with 50 mL/L CO₂.

Transfection with siRNA oligonucleotides

Cells were seeded the day before the experiment in 6-well plates at a density of 1.5×10^5 per well to be 50% confluent on the day

Figure 1 Sequences of 21-nt siRNA duplex that were used to target at hPim-2.

of the experiment. Transfection of the RNA oligonucleotides was performed using Lipofectamine 2000 (Invitrogen) as directed by the manufacturer to result in a final RNA concentration of 50 nmol/L. After transfection (incubation for 6 h at 37 °C), cells were washed with PBS and incubated in fresh culture medium until additional analyses.

Analysis of hPim-2 mRNA by RT-PCR

After transfection, total RNA was isolated using TRIZOL (Invitrogen) by a single-step phenol-extraction. Subsequent RT-PCR was performed (RT-PCR kit, Promega, Madison, WI.). Briefly, first strand cDNA was synthesized using an Oligo (dT)₁₅ primer at 42 °C for 30 min. PCR for hPim-2 and β -actin was performed in a single reaction of 20 μ L volume. The latter served as a control following 28 cycles of denaturing at 95 °C for 45 s, annealing at 58 °C for 40 s, and extending at 72 °C for 40 s. Under this PCR condition, the amplification showed linearity as was determined experimentally (data not shown). PCR products were run on a 30 g/L agarose gel and visualized by ethidium bromide staining, and the intensities were then measured by scanning the gel with Gel Doc 1000 (Bio-Rad, Hercules, CA). Inhibition of hPim-2 mRNA was calculated according to the following formula:

$$\text{Inhibition percentage} = \frac{(1 - A_{\text{sample}} \times A_{0\text{control}})}{A_{\text{control}} \times A_{0\text{sample}}} \times 100\%.$$

A_{sample} : the intensity of hPim-2 PCR product in cells transfected with siRNA and Lipofectamine; $A_{0\text{sample}}$: the intensity of hPim-2 PCR product in cells transfected with Lipofectamine alone; A_{control} : the intensity of β -actin product in cells transfected with siRNA and Lipofectamine; $A_{0\text{control}}$: the intensity of β -actin product in cells transfected with Lipofectamine alone.

Analysis of hPim-2 protein

The expression levels of hPim-2 protein in cells transfected with siRNAs were measured by scanning the density of bands on Western blotting. The expression level of hPim-2 mRNA was analyzed by the method described above. After 72 h of transfection, cells were lysed in RIPA buffer [10 mmol/L Tris-HCl (pH 7.4), 10 g/L deoxycholate, 10 g/L NP40, 150 mmol/L NaCl, 1 g/L SDS, 0.2 mmol/L phenylmethyl sulfonyl fluoride, 1 μ g/mL aprotinin and 1 μ g/mL leupeptin] for 30 min on ice. The lysates were centrifuged at 15 000 r/min for 15 min to remove debris. Equal amounts (30 μ g) of proteins were separated by 120 g/L SDS-PAGE and transferred onto PVDF membrane (Hybond-polyvinylidene difluoride membranes, Amersham Biosciences). The transferred membrane was incubated with anti-hPim-2 goat polyclonal or anti- β actin rabbit polyclonal antibodies (Santa Cruz Biotechnology, Santa Cruz, CA) and followed with peroxidase-linked secondary antibody. Finally, the

immunoreactive proteins were detected by an ECL-plus detection kit (Amersham Biosciences) and scanned by Gel Doc 1000 (Bio-Rad), and the inhibition percentage (%) was calculated according to the following formula: inhibition percentage = $(1 - A_{\text{sample}}/A_{\text{control}}) \times 100$.

Statistics

The data were expressed as mean \pm standard deviation (mean \pm SD). Statistical analysis was performed by Student's *t*-test (two tailed). All data represented at least two independent experiments.

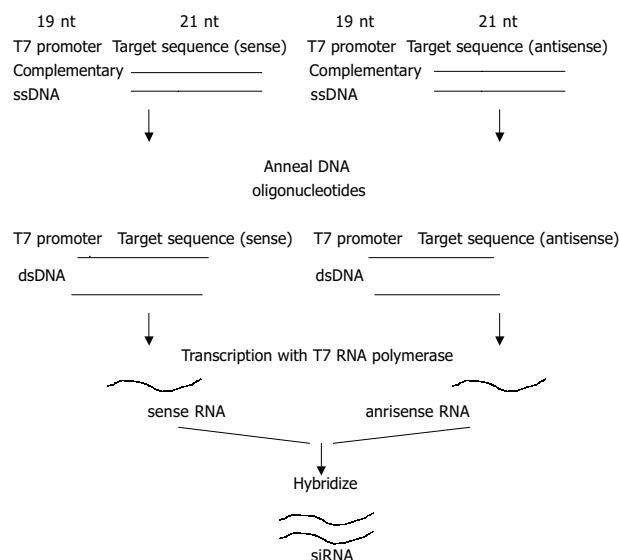

Figure 2 Strategy to generate T7 siRNA.

RESULTS

Synthesis of siRNA by *in vitro* transcription

To generate siRNAs by *in vitro* transcription, we designed the strategy presented in Figure 2. Target sequences for siRNA were identified by scanning the length of the hPim-2 gene with AA sequences. The AA and downstream 19 nucleotides were recorded and compared to an appropriate genome database to eliminate any sequences with significant homology to other genes. Those sequences that appear to be specific are the potential siRNA target sites. Besides, it is noteworthy that T₇ RNA polymerase can transcribe a template efficiently if only the first nucleotide of the RNA transcript is G. Thus, the design of T₇ siRNAs requires that the sequence starts with a G and has a C at position 19 (GN₁₇CN₂) to allow annealing with the complementary RNA, which also starts with a G^[17,18]. The T₇ promoter oligonucleotide is invariant and common to any target gene. A 40 mer DNA oligonucleotide template was synthesized

by a 21 mer oligonucleotide encompassing the T₇ promoter with complementary sequence preceded by two additional nucleotides (reading the sequence 5'---3'). Following transcription reactions, sense and antisense transcriptions were annealed, ethanol precipitated and yielded what we refer to as T₇siRNAs. The integrity of the transcriptions was checked on a 30 g/L agarose gel (Figure 3).

Figure 3 Lane 1: T7 *in vitro* transcribed single-strand RNA. Lane 2: annealed double-strand DNA template. Lane 3: hybridized double-strand small interference RNA.

Effect of siRNAs on hPim-2 expression

The mRNA level of hPim-2 was determined by semi-quantitative RT-PCR. A 237-bp DNA fragment of hPim-2 gene and a 317-bp DNA fragment of β -actin gene were amplified by RT-PCR with specific primers, respectively. As shown in Figure 4A, mRNA expression level of hPim-2 was decreased when compared to the uninduced cells, while the mRNA level of β -actin as the control was almost unchanged. As shown in Figure 4B, after transfection with hPim-2 siRNA I, II and III and compared with the

levels of β -actin, the relative inhibition rates of hPim-2 mRNA expression were 65.4% ($P<0.05$), 46.2% ($P<0.05$) and 56.1% ($P<0.05$) in colon cancer cells, respectively.

In order to verify the decrease in mRNA expression, which corresponded to the decreases at protein levels, Western blotting was performed. Figure 5A shows that the protein level of hPim-2 was decreased at 72 h compared to the uninduced cells. The relative inhibition percentages of hPim-2 protein by siRNA I, II and III were 61.6% ($P<0.05$), 45.8% ($P<0.05$) and 55.6% ($P<0.05$), respectively (Figure 5B).

DISCUSSION

Oncogene overexpression has been implicated in the development and progression of a variety of human cancers and, therefore, provides a potential target for cancer gene therapy^[19-22]. For years, research has been focused on effective tools to specifically down-regulate oncogene overexpression such as antisense oligonucleotide strategy. However, there has been only limited success because of the lack of specificity and potency for this method. For example, screening of more than 20 oligomers is usually required before identifying one antisense that functions effectively, and the dose required for inhibiting gene expression is often not much different from the doses that lead to nonselective toxicity^[23-25].

Recent progress of RNAi techniques has demonstrated the potential to overcome those limitations. The selection of targeting sequences of RNAi is less restricted, once the site is identified, sense and antisense oligonucleotides with 3'-UU overhangs can be designed, so the success rates of producing effective duplexes are higher. Just like in this experiment, siRNAs were designed complimentary to three different regions of the corresponding Pim-2 mRNA, and each of them has different level of inhibition efficacy, the suppression of hPim-2

Figure 4 Inhibitory effects of siRNA on mRNA level of hPim-2. A: Electrophoresis of RT-PCR products of hPim-2 gene and β -actin gene in colon cancer cells transfected with siRNA I, II, III. B: Quantitation of inhibitory percentage of hPim-2 mRNA in transfected cells. Each level of PCR product of hPim-2 gene was quantitated and normalized to the level of β -actin. Inhibitory rate was calculated by comparing to the control cells. The results were expressed as mean \pm SD from independent experiments. $P<0.05$ vs the cells transfected with lipofectamine alone.

gene expression by these siRNAs directed at different sites varied from 45-65%. This indicates that screening potential target of RNAi is much more easy.

Besides, our results demonstrate that *in vitro* transcribed siRNA can effectively down-regulate oncogene expression with great efficiency. It has been suggested that siRNA may inhibit gene expression through diverse effects, inhibition of mRNA can occur through the formation of a nuclease complex called RISC (RNA-induced silencing complex) that targets and cleaves mRNA which is complementary to the siRNA. The damaged mRNA may deteriorate through the action of the RNA-dependent RNA polymerase (RdRP), producing new siRNAs to target other mRNA. This incessant waterfall-like amplification can produce RNA interference effect at a very small dose, and inhibit the protein translation quickly and efficiently^[26-30]. In our experiment, the dose required for inhibiting Pim-2 gene expression was 50 nmol/L, far below the dose required for the antisense oligonucleotide^[31], indicating that siRNA synthesized by the *in vitro* transcription strategy can suppress the hPim-2 gene expression sensitively.

Here, we used the *in vitro* transcription method for the synthesis of siRNAs by T₇ RNA polymerase and transferred them into cells. The main advantage of this technique is its simplicity. It provides a reproducible and highly efficient means to inhibit the target gene expression. Human Pim-2 gene, a regulated transcriptional apoptotic inhibitor, has a novel role in promoting cell autonomous survival. Over-expression of Pim-2 allows the tumour cells to ignore or become insensitive to boosters of the immune system^[14]. Application of Pim-2-directed siRNA can significantly reduce Pim-2 mRNA and protein levels efficiently. Our next step is to try to manipulate the action of Pim-2 with siRNA, so that we can interfere with the survival of cancer cells.

Abstract

AIM: Transforming growth factor (TGF)- β_1 , metalloproteinase (MMP)-1 and its tissue inhibitor (TIMP)-1 are considered predictive biomarkers of chronic hepatitis activity and fibrosis. The aim of this study was to evaluate the effect of lamivudine treatment on the plasma levels of these peptides in patients with chronic hepatitis B.

METHODS: TGF- β_1 , MMP-1 and TIMP-1 plasma concentrations were measured with an enzyme immunoassay in 40 patients treated with lamivudine for 48 wk. Elimination of HBV-DNA and HBV antigens was evaluated 24 wk after treatment completion.

RESULTS: Baseline TGF- β_1 (29.6 ± 2.2 ng/mL) and TIMP-1 ($1\ 578 \pm 93$ ng/mL) significantly exceeded normal values (18.3 ± 1.6 ng/mL and $1\ 102 \pm 67$ ng/mL respectively). Lamivudine treatment resulted in a significant decrease of TGF- β_1 and TIMP-1 during treatment with an increase after 24 wk of treatment. Pretreatment MMP-1 levels (6.7 ± 0.7 ng/mL) were significantly lower than normal values (11.9 ± 0.9 ng/mL) and increased during treatment and follow-up. A significant correlation was noted between TGF- β_1 or TIMP-1 and aminotransferases as well as fibrosis scored in liver biopsy specimens. There were no statistically significant differences of TGF- β_1 , TIMP-1 and MMP-1 between four groups at baseline, 24 and 48 wk of treatment. TGF- β_1 and TIMP-1 levels increased significantly in non-responders and normalized in responders at wk 72. MMP-1 also normalized in responders and decreased to values significantly lower than normal in non-responders.

CONCLUSION: These findings support the role of TGF- β_1 , TIMP-1 and MMP-1 in the pathogenesis of chronic hepatitis B. Because of their association with hepatic injury and antiviral treatment efficacy, determination of these peptides may be useful in disease management.

INTRODUCTION

Transforming growth factor- β_1 (TGF- β_1) is considered a pivotal inducer of liver fibrosis, acting mostly through activation of hepatic stellate cells (HSCs), which are the main source of extracellular matrix (ECM) proteins^[1-3]. The effect of TGF- β_1 on liver fibrosis is at least in part related to stimulation of the tissue inhibitor of metalloproteinases-1 (TIMP-1), which affects metalloproteinases (MMP) activity and is responsible for inhibition of ECM proteins breakdown^[4]. Apart from a profibrogenic role, TGF- β_1 inhibits DNA synthesis serving as a terminator of regenerative cell proliferation and induces apoptosis of hepatocytes in normal liver and during regression of liver hyperplasia^[5]. On the other hand, TGF- β may inhibit stellate cells apoptosis and promote their survival, which are at least in part a result of anti-apoptotic effect of TIMP-1^[6]. Additionally TGF- β_1 exerts regulatory, mostly immunosuppressive effects on the immune system. Since hepatitis B virus (HBV) infection is related to an immune response, cell proliferation and fibrosis, modulation of TGF- β_1 might affect the course of chronic viral hepatitis B^[7,8]. The possible role of TGF- β_1 , TIMP-1 and MMP-1 as predictive biomarkers of chronic hepatitis activity and progression was supported by recent clinical studies^[9-16], which demonstrated their association with hepatic function impairment or fibrosis, but did not evaluate their effect of antiviral treatment. We undertook this study to evaluate the effect of lamivudine, the most widespread antiviral medication for chronic HBV infection, on plasma TGF- β_1 , TIMP-1 and MMP-1 levels in patients with chronic hepatitis B.

MATERIALS AND METHODS

Patients

Ethical approval for the study was obtained from the Bioethical Committee of the Medical Academy of Bialystok. Informed consent was obtained from 40 patients (13 females and 27 males, mean age: 45 ± 3 years) with chronic hepatitis B, who were included into the protocol of lamivudine (ZeffixTM, Glaxo-Smith-Kline) treatment. Normal values of TGF- β_1 , TIMP-1 and MMP-1 were collected from 13 healthy volunteers (5 females and 7 males, mean age: 47 ± 2 years). The diagnosis of chronic hepatitis B was confirmed by the presence of HBs and HBe antigens with stable elevated alanine aminotransferase (ALT) activity for at least 6 mo. Additionally the disease activity was confirmed by the presence of viral replication and evaluation of liver biopsy specimens performed by means of the Hepafix System (Braun, Melsungen, Germany). Paraffin-embedded biopsy specimens were stained and evaluated using the Scheuer scoring system^[17]. Patients received 100 mg of lamivudine daily for 48 wk. Plasma levels of TGF- β_1 , TIMP-1 and MMP-1 were measured before treatment and at wk 24, 48 (end of the treatment) and 72. These results were compared to standard laboratory indices of liver injury. To evaluate treatment efficacy patients were divided into four groups with respect to elimination of HBV antigens and HBV-DNA at week 72 (24 wk after

completion of treatment). Criteria for inclusion into particular groups were as follows: group I (complete response): HBsAg (-), HBeAg (-), HBV-DNA (-); group II: HBsAg (+), HBeAg (-), HBV-DNA (-); group III: HBsAg (+), HBeAg (-), HBV-DNA (+); group IV (no response): HBsAg (+), HBeAg (+), HBV-DNA (+).

Methods

Venous blood for plasma TGF- β_1 , TIMP-1 and MMP-1 was collected on ice using tubes with EDTA. Samples for TGF- β_1 were immediately activated with acetic acid and urea and assayed with ELISA using recombinant human TGF- β soluble receptor type II (T β RII) as a solid phase precoated onto a microplate (Quantikine[®], R&D Systems Inc., Minneapolis, USA) as we described previously^[18]. TIMP-1 and MMP-1 were assayed by the two-site ELISA sandwich technique (Amersham Pharmacia Biotech, Little Chalfont, Buckinghamshire, England) using specific antibodies as a solid phase. MMP-1 assay recognises total human MMP-1, ie. free and complexed with TIMP-1. TIMP-1 assay recognises total human TIMP-1, including free and complexed with any metalloproteinases bound to the solid phase. TIMP-1 or MMP-1 bound to the solid phase, were detected by peroxidase labelled antibodies. There is no cross-reactivity between TIMP-1 and MMP-1 in these assays.

Liver function tests: ALT, aspartate aminotransferase (AST), alkaline phosphatase (ALP), gamma glutamyltranspeptidase (GGT) activity and bilirubin concentration were measured using a Cobas Mira instrument (Roche) and the prothrombin index (PI) was determined using Kselmed K-3002 (Poland).

Statistics

Values were expressed as the mean \pm SE. The significance of the difference was calculated by two-tailed Student's *t* test. For correlation analysis the Pearson product moment correlation was performed. Values of $P < 0.05$ were considered as statistically significant.

RESULTS

Plasma concentrations of TGF- β_1 and TIMP-1 were determined before lamivudine treatment (mean: 29.6 \pm 2.2 ng/mL and 1 578 \pm 93 ng/mL respectively) and significantly exceeded mean normal values (18.3 \pm 1.6 ng/mL and 1 102 \pm 67 ng/mL respectively). Treatment resulted in a significant decrease by wk 24 and a further decline at the end of the treatment. However 24 wk after treatment completion mean values of both TGF- β_1 and TIMP-1 increased (Table 1). In contrast, mean MMP-1 baseline level (6.7 \pm 0.7 ng/mL) was almost half the normal value (11.9 \pm 0.9 ng/mL) and increased during treatment. After completion of treatment the levels still remained lower than normal (Table 1). There was a significant positive correlation between TGF- β_1 , TIMP-1 and ALT or AST (Table 2). A significant correlation was also demonstrated between TIMP-1 and ALP or GGT, but there was no association between MMP-1 and the biochemical indices of liver injury (Table 2). As demonstrated in Figure 1 a significant positive correlation ($r = 0.435$; $P < 0.01$) was observed between TGF- β_1 and TIMP-1. There was no correlation between TGF- β_1 and MMP-1 ($r = 0.069$), or between TIMP-1 and MMP-1 ($r = -0.143$).

As demonstrated in Table 3 scored degree of hepatic inflammation and fibrosis was similar before and after the treatment. Histologic observations in biopsies performed before the treatment showed a significant correlation between the degree of fibrosis and plasma TGF- β_1 or TIMP-1 levels (Table 4). There was no association between scored inflammation or fibrosis and classical biochemical parameters of liver injury.

Table 1 Plasma concentrations of TGF- β_1 , TIMP-1 and MMP-1 during treatment with lamivudine (mean \pm SE)

	Normal values	Time since treatment beginning (wk)			
		0	24	48	72
TGF- β_1 (ng/mL)	18.3 \pm 1.6	29.6 \pm 2.2 ¹	22.6 \pm 1.2 ²	21.9 \pm 1.5 ²	24.1 \pm 2.4
TIMP-1 (ng/mL)	1 102.0 \pm 67	1 578.0 \pm 93 ¹	1 235.0 \pm 67 ²	927.0 \pm 50 ²	1 215.0 \pm 98 ²
MMP-1 (ng/mL)	11.9 \pm 0.9	6.7 \pm 0.7 ¹	8.3 \pm 0.5 ¹	9.6 \pm 0.5 ¹	9.7 \pm 0.7 ²

Statistical significance in comparison with normal ¹ and baseline ² values.

Table 2 Correlation expressed by *r*-value and its significance between analyzed biochemical indices and TGF- β_1 , TIMP-1 or MMP-1 in chronic hepatitis B patients treated with lamivudine

	mean \pm SE	TGF- β_1	TIMP-1	MMP-1
Bil (mg%)	1.02 \pm 0.06	0.049	0.119	-0.059

Table 3 Values of scored degree of hepatic inflammation and fibrosis in liver biopsy specimens obtained from patients before and after lamivudine treatment (mean \pm SE)

	Before the treatment	After the treatment
Portal inflammation	2.6 \pm 0.1	2.5 \pm 0.2
Lobular inflammation	1.9 \pm 0.1	1.8 \pm 0.1
Fibrosis	2.0 \pm 0.2	1.8 \pm 0.2

Table 4 Correlation expressed by *r*-value and significance between scored degree of hepatic inflammation or fibrosis and plasma levels of TGF- β_1 , TIMP-1 and MMP-1 in patients with chronic hepatitis B before lamivudine treatment

	Inflammation		Fibrosis
	Portal	Lobular	
TGF- β_1	0.207	0.179	0.391 ^a
TIMP-1	0.224	0.319	0.620 ^a
MMP-1	0.009	-0.094	-0.135

^a $P < 0.05$ vs others.

The majority of patients (23-57.5%) did not respond to treatment and were classified into group IV. A complete response (group I), with elimination of HBs and HBe antigens as well as HBV-DNA, was observed in 5 patients (12.5%). Six patients (15%) demonstrated a partial response (group II), and another six eliminated HBeAg with detectable viral replication (group III). Evaluation of baseline liver function tests and efficacy of treatment showed no statistically significant differences between the four groups. As demonstrated in Table 5, at the end of the treatment, patients in groups III and IV had significantly higher ALT activities than patients in group I. This difference was statistically significant in respect to both ALT and AST activities, 24 weeks after the treatment completion (Table 5). Histologic pictures did not demonstrate significant differences between groups in liver biopsies performed before

Table 5 Activities of alanine and aspartate aminotransferases during the treatment (0, 24 and 48 wk) and 24 wk after its completion (week 72) in four groups (mean \pm SE)

	ALT (U/l)				AST (U/L)			
	0	24	48	72	0	24	48	72
Group I	87.0 \pm 24.5	25.2 \pm 5.0	23.0 \pm 4.8	23.2 \pm 4.9	79.8 \pm 15.9	30.2 \pm 6.7	28.0 \pm 6.4	27.0 \pm 6.1
Group II	108.5 \pm 53	32.5 \pm 9.5	31.9 \pm 7.5	31.7 \pm 5.7	66.7 \pm 24.8	44.2 \pm 12.7	32.1 \pm 4.8	29.8 \pm 3.8
Group III	127.0 \pm 43.4	38.7 \pm 8.2	78.0 \pm 30.1 ^a	88.2 \pm 34 ^b	117 \pm 47.2	39.2 \pm 8.8	60.5 \pm 15.9	63.5 \pm 22 ^a

and after the treatment. During treatment TGF- β_1 , TIMP-1 and MMP-1 plasma levels were similar among all patients before divided into the response-related groups (Figures 2, 3, 4). And there were no statistically significant differences in their concentrations between groups at baseline, 24 and 48 weeks of treatment, either. Although at week 48 the mean TGF- β_1 in the non-responder groups (III and IV) tended to increase, whereas in groups I and II normalized, the difference was not significant (Figure 2). However 24 weeks after treatment completion (wk 72), the difference between TGF- β_1 levels in groups I and IV (17.5 \pm 0.6 and 26 \pm 1.8 ng/mL respectively) became significant ($P = 0.04$). Moreover the concentration in group IV was significantly ($P = 0.009$) higher than normal values. TIMP-1 mean concentrations were similar among all groups during the treatment period and normalized at week 48 (Figure 3). However 24 wk later, values in group IV (1 350 \pm 70 ng/mL) were significantly higher than normal, as well as that in group I (900 \pm 131 ng/mL). MMP-1 levels increased in all groups during the treatment. At wk 72, MMP-1 almost normalized in responders and slightly decreased in non-responders (Figure 4). The difference between MMP-1 concentrations in group IV after treatment completion (9.1 \pm 0.8 ng/mL) and normal values was statistically significant ($P = 0.037$).

DISCUSSION

The pivotal role of TGF- β_1 in fibrogenesis was finally proved in transgenic mice with an overexpression of TGF- β_1 , which caused an increase of TGF- β_1 plasma levels up to 700 ng/mL and a marked upregulation of TIMP-1 gene expression^[19-21]. Chronic liver injury leading to fibrosis displayed diminished ECM degradation mainly through TIMP induction and consequent MMP inhibition^[4]. As demonstrated recently by Nie *et al.* in the process of hepatic fibrosis, fibroblasts and myofibroblasts are the major cells that express TIMP-1 and TIMP-2, and their gene expressions correlate with degree of hepatic fibrosis.

The most important factor that affects the measurement of TGF- β_1 in human is the preparation of samples with minimal contamination from platelets which are an important source of this cytokine^[22]. The Quantikine ELISA System is recommended because of the relatively quick and simple activation with acid and urea, which disrupt the majority of TGF- β_1 complexes.

As we have demonstrated previously, TGF- β_1 correlates significantly with the degree of liver insufficiency in humans with liver cirrhosis^[18]. Moreover both TGF- β_1 and TIMP-1 measured in plasma of patients with chronic hepatitis B demonstrate a significant correlation with the degree of hepatocyte injury and fibrosis in liver biopsy specimens^[10]. We confirmed these observations in the present study. As demonstrated by Yoo *et al.*^[7] HBV antigens induce expression of TGF- β_1 in the early stages of infection. According to Lee *et al.*^[8] HBV encoded pX protein enhances transcriptional activity and response to TGF- β by amplification of Smad-mediated signaling, which can also contribute to HBV-associated liver fibrosis. Therefore the stimulatory effect of HBV antigens on TGF- β_1 seems to be an important mechanism of liver fibrosis in addition to TGF- β release caused by hepatocyte injury.

Association between circulating or tissue TGF- β and liver fibrosis has also been confirmed in HCV infection^[10,11]. Recent studies of Neuman *et al.*^[23], Chen *et al.* and Lu *et al.*^[16] demonstrated a similar relationship between different chronic liver diseases including primary biliary cirrhosis and alcoholic liver disease and TGF- β_1 . Our previous study showed that the positive predictive value of TGF- β_1 plasma levels exceeding the upper normal range reached 96% for liver cirrhosis^[18]. As demonstrated recently by Zhang *et al.* serum level of TIMP-1 and TIMP-1/MMP-1 could be used as the indices for the diagnosis of hepatic fibrosis in chronic hepatitis B. According to Boeker *et al.*^[9], measurement of plasma TIMP-1 detected cirrhosis with a 100% sensitivity but lower specificity. These observations were also confirmed by the association between hepatic fibroproliferation and expression of hepatic TIMP and MMP mRNA^[12]. Walsh *et al.*^[15], who studied liver histology in patients with chronic hepatitis C, underlined the high sensitivity of TIMP-1 and TIMP-2 in detecting advanced liver disease. According to Nie *et al.*, there was a significant correlation between circulating and liver levels of TIMP-1 in cirrhotics, so its measurement in plasma might be useful in fibrosis management. These observations indicate the usefulness of both TGF- β_1 and TIMP-1 as possible early non-invasive biomarkers for liver fibrosis.

The rate of HBeAg seroconversion in our study (27.5%) was in range (18-32%) demonstrated by numerous authors in previous research with lamivudine treatment^[24-26]. In this study we confirmed the association between the degree of hepatocyte injury or liver fibrosis and plasma TGF- β_1 or TIMP-1 levels in patients with chronic hepatitis B. Aminotransferases, which are classical surrogate markers of hepatic injury, demonstrated similar association with the outcomes of the treatment. However, in contrast to TGF- β_1 and TIMP-1 their activities were not related to liver fibrosis. As the levels of TGF- β_1 , TIMP-1 and MMP-1 showed a similar change in all groups during therapy, it was unclear whether this was a direct effect of lamivudine on their expressions or an effect caused by HBV inhibition. However, their levels at 24 wk after therapy completion demonstrated their association with infection activity. This relationship was noted in respect to TGF- β_1 , which increased in group IV (non-responders) at the end of treatment. The effect on TIMP-1 was probably secondary to TGF- β_1 . The inhibitory activity of excessive TIMP-1 accumulation might be the reason for the decreased MMP-1 plasma concentration. These results are in accordance with our previous findings, demonstrating the strong association between TGF- β_1 or TIMP-1 plasma levels and scored hepatic fibrosis evaluated in biopsy specimens of patients with chronic hepatitis B and C^[10]. The findings of increased TGF- β_1 and TIMP-1 accompanied by an elevation in plasma carboxyterminal cross-linked telopeptide of type I procollagen (ICTP), indicative of type I collagen degradation. We suggested that collagenolytic mechanisms preceded TGF- β_1 /TIMP-1

dependent stimulation of liver fibrosis^[10]. Low MMP-1 plasma levels before treatment in the present study is consistent with this observation. It is also in accordance with the report by Murawaki *et al.*^[13], who demonstrated a decrease in MMP-1 concentration during histological progression of chronic hepatitis. Moreover, a significantly decreased baseline plasma MMP-1, followed by an increase during treatment, supports the role of TGF- β_1 /TIMP-1 dependent mechanism of liver fibrosis in patients with active chronic hepatitis B. Similar effects on MMP-1 and TIMP-1 were observed by Ninomiya *et al.*^[14] in patients with chronic hepatitis C who showed improvement of liver histology after treatment with interferon- α . Reduced progression of liver fibrosis during treatment of chronic hepatitis B with lamivudine has been demonstrated in numerous trials^[24-28]. Downregulation of TGF- β_1 /TIMP-1 causing an increase of MMP-1 activity should be considered as the probable mechanism underlying this effect of lamivudine. However, to confirm this hypothesis further research should be focused on the MMP-1 activity measurement.

These findings support the role of TIMP-1 and MMP-1 balance in the TGF- β_1 dependent mechanism of liver fibrosis related to HBV infection. The association of TIMP-1, MMP-1 and TGF- β_1 with hepatic injury and antiviral treatment efficacy suggest their possible usefulness in chronic hepatitis B management. Elevated TGF- β_1 plasma concentrations during antiviral therapy may indicate medication failure.

Abstract

AIM: To establish and assess the methods for quantitative detection of serum duck hepatitis B virus (DHBV) DNA by quantitative membrane hybridization using DHBV DNA probe labeled directly with alkaline phosphatase and fluorescence quantitative PCR (qPCR).

METHODS: Probes of DHBV DNA labeled directly with alkaline phosphatase and chemiluminescent substrate CDP-star were used in this assay. DHBV DNA was detected by autoradiography, and then scanned by DNA dot-blot. In addition, three primers derived from DHBV DNA S gene were designed. Semi-nested primer was labeled by AmpliSensor. Standard curve of the positive standards of DHBV DNA was established after asymmetric preamplification, semi-nested amplification and on-line detection. Results from 100 samples detected separately by alkaline phosphatase direct-labeled DHBV DNA probe with dot-blot hybridization and digoxigenin-labeled DHBV DNA probe hybridization. Seventy samples of duck serum were tested by fluorescent qPCR and digoxigenin-labeled DHBV DNA probe in dot-blot hybridization assay and the correlation of results was analysed.

RESULTS: Sensitivity of alkaline phosphatase direct-labeled DHBV DNA probe was 10 pg. The coincidence was 100% compared with digoxigenin-labeled DHBV DNA probe assay. After 30 cycles, amplification products showed two bands of about 180 bp and 70 bp by 20 g/L agarose gel electrophoresis. Concentration of amplification products was in direct proportion to the initial concentration of positive standards. The detection index was in direct proportion to the quantity of amplification products accumulated in the current cycle. The initial concentration of positive standards was in inverse proportion to the number of cycles needed for enough quantities of amplification products. Correlation coefficient of the results was (0.97, $P < 0.01$) between fluorescent qPCR and dot-blot hybridization.

CONCLUSION: Alkaline phosphatase direct-labeled DHBV DNA probe in dot-blot hybridization and fluorescent qPCR can be used as valuable means to quantify DHBV DNA in serum.

INTRODUCTION

Duck hepatitis B virus (DHBV) infection model is an important referenced animal model for studying HBV infection and viral replication and evaluating antiviral agents^[1-8]. HBV DNA level in serum is an important evidence for assessing antiviral effect. At present, it is difficult to accurately define the quantity of HBV DNA, though many methods^[9-15] such as competitive PCR, Chiron Quantiplex branched DNA (bDNA) assay, Abbott Genostics solution hybridization assay and Digene Hybrid Capture System have been reported which are not suitable for clinical application because of time- and cost-consuming process. HBV DNA quantitative PCR has been used in clinical detection^[16-18], but no reports were presented about DHBV DNA quantitative PCR. With the development of non-isotope-labeled nucleic acid probes, especially chemiluminescent-labeled probes^[19-21], the probe-sensitivity has been improved obviously. In order to establish a quick, sensitive and specific method for quantitative detection of DHBV DNA in serum, we detected DHBV DNA in serum sample with alkaline phosphatase direct-labeled DHBV DNA probe with dot-blot hybridization and fluorescent qPCR.

MATERIALS AND METHODS

Materials

DHBV serum was obtained from Institute of Viral Hepatitis, Chongqing University of Medical Sciences, Chongqing, China. pBR325 containing DHBV DNA sequence was extracted, digested with *EcoRI* and recovered according to the kit protocol. Then quantification was made with DU^R Series 600. DNA fragment diluted with water to a series concentrations of 2.76×10^6 to 2.76×10^1 copies/ μ L was used as positive standard. Reagents and instruments such as alkaline phosphatase direct-labeled kit (Amersham Pharmacia Biotech), Wizard Plus Midipreps DNA purification system (Promega), agarose gel DNA extraction kit (Roche), DU^R Series 600 (Beckman), scanning apparatus (Vuego Scan, Brisa-620ST), AmpliSensor kit (Biotronics), *Taq* DNA polymerase (Roche), AG-9 600 Analyzer and Amplicor monitor (Biotronics) were used in the study. Primers derived from DHBV DNA S gene were 5'-TGGCCTAATCGGATTACTGG-3' (Limited primer, 20 bp), 5'-CCTGGGCATCCCCACGGGCAGG-3' (Excess primer, 22 bp) and 5'-GGGACGCGCTTTCCAAGATACTG-3' (Semi-nested primer, 25 bp). The three primers were synthesized by Seagon, Shanghai.

Methods

Detection of serum DHBV DNA with a membrane hybridization assay using alkaline phosphatase direct-labeled DHBV DNA probe DHBV DNA fragment was diluted to a concentration of 10 ng/ μ L and labeled referring to alkaline phosphatase direct-labeling protocol. The probe can be stored in 50 mL/L glycerol at -20 °C for up to six months. DHBV DNA in the concentration series (100 ng, 10 ng, 1 ng, 100 pg, 10 pg) was dotted on nitric fibrous membrane in order to determine the probe sensitivity. The specificity was detected with human serum, duck serum and rat serum. The serum sample (40 μ L) was dotted on nitric fibrous membrane and 1 mol/L NaOH was used for DNA

degeneration. The membrane was baked at 80 °C for 2 h and prehybridized for at least 15 min, then 100 ng of the labeled probe was added to the buffer used for the prehybridization stage to hybridize at 55 °C overnight in a shaking water bath. The membrane was washed with the primary wash buffer for 20 min at 55 °C and with secondary wash buffer for 10 min at room temperature. The excess secondary wash buffer was drained from the blots and the membrane was placed on a clean, flat surface. Detection reagent was piped onto the blots (30–40 $\mu\text{L}/\text{cm}^2$) for 2–5 min. The DNA blots were placed side up in the film cassette and a sheet of autoradiography film was placed on top of the blots. The cassette was closed and exposed for 1 h at room temperature. The blots on the film were scanned with scanning apparatus and analysed with Discovery Series Quantity One [BioRad, volume (mm^3) = intensity \times Area].

Fluorescent qPCR for serum DHBV DNA ligation Five \times coupling reagent 10 μL , 5 \times AmpliSensor 10 μL , semi-nested primer 0.5 μg , water 30 μL were added to a microcentrifuge tube at room temperature. The tube was incubated for 90 min at 37 °C, then the reaction was terminated by adding 50 μL of deionized water and heating to 90 °C for 5 min to denature the enzymes. The ligated product was labeled as 5 \times AmpliSensor primer stock.

Ligation efficiency Two of the sample wells (5 \times AmpliSensor primer 1 μL , 1 \times PCR buffer 4 μL and PCR extension mixture 5 μL per well), two for negative control and two for standard (5 \times AmpliSensor primer 0.1 μL , 1 \times PCR buffer 4.9 μL and PCR extension mixture 5 μL per well), two for blank control (water 5 μL , PCR extension mixture 5 μL per well) were designated. The negative control served as a control of baseline signal, whereas the standard was a reference of maximum energy transfer. The reaction mixture was heated to 94 °C for 20 s, 55 °C for 20 s, 72 °C for 30 s, and then 20 °C for 30 s to equilibrate the signal. The fluorescence was read under the coupling mode using AG-9 600 Analyzer. Upon finishing, data were saved as baseline reading. One unit of *Taq* DNA polymerase was added to both the sample and standard wells and the reactions were subjected to three additional thermal cycles. Each cycle consists of 20 s at 94 °C, 20 s at 55 °C and 30 s at 72 °C. At the end of the cycling, reactions were cooled down to 20 °C for 30 s. The fluorescence reading was repeated under the same mode. When the data were saved, the coupling efficiency was displayed on the screen.

Asymmetric preamplification Length of amplification fragment was 182 bp. Ten \times PCR buffer 110 μL , 40 mmol/L MgCl_2 110 μL , 10 \times dNTP 110 μL , 10 \times primer 110 μL , 10 \times terminal primer 110 μL , H_2O 330 μL were added. PCR master mix is intended for 100 reactions. The wells for negative (addition of 5 μL H_2O), Apex, standards (addition of 5 μL positive standards), sample (addition of 5 μL sample) were designated. PCR master mix 5 μL was added into each well except the well designated as Apex, to which 10 μL of 1 \times PCR buffer instead of 0.5 U *Taq* DNA polymerase was added. PCR cycle was repeated for 25 times: 20 s at 94 °C, 20 s at 55 °C and 30 s at 72 °C. At the end of the cycle, the reaction was at 72 °C for 30 s and cooled down to 4 °C for 2 min.

Semi-nested PCR and on-line detection A 700-bp fragment was amplified as follows: The 5 \times AmpliSensor primer stock 66 μL , 10 \times PCR buffer 33 μL , 40 mmol/L MgCl_2 33 μL and H_2O 198 μL were added into a 0.5 mL microcentrifuge tube to make the AmpliSensor mix. AmpliSensor mix 5 μL was aliquoted to each reaction. PCR cycles were: At 94 °C for 20 s, at 55 °C for 30 s and at 72 °C for 30 s. The reaction was cooled for 30 s at 20 °C to

establish a signal equilibrium, and then fluorescence reading was acquired under the standard mode using an AG-9 600 Analyzer. Data were saved as a baseline reading. Thermal cycling was resumed for a defined number of cycles. Fluorescence reading was repeated under the same mode, and data were saved as an assay reading. A detection index calculated by APAS software was derived from each reading. The magnitude of the detection index was directly proportional to the quantity of amplification product accumulated at the current cycle. The report window was activated to reveal the quantitative data of each sample.

Assessment of the two methods Alkaline phosphatase direct-labeled DHBV DNA probe with dot-blot hybridization was compared with digoxigenin-labeled DHBV DNA probe with dot-blot hybridization for 100 samples, and then the correlation of 70 samples between fluorescent qPCR and dot-blot hybridization with digoxigenin-labeled probe was analysed.

RESULTS

DHBV DNA fragment

The recovered DHBV DNA fragment after digestion of *Eco*RI was about 3.0 kb and the concentration was 28 $\mu\text{g}/\text{mL}$ ($A_{260}/A_{280} = 1.9$) (Figure 1).

Figure 1 Detection of *Eco*RI-digested pBR325 and recovered long fragment by 10 g/L agarose gel electrophoresis. Lane 1: Molecular marker; lane 2: pBR325 digested with *Eco*RI; lane 3: Long fragment of pBR325 (DHBV DNA).

Sensitivity and specificity of alkaline phosphatase direct-labeled probe

Sensitivity of alkaline phosphatase direct-labeled probe was 10 pg without nonspecific signs (Figure 2, Table 1).

Figure 2 Sensitivity of alkaline phosphatase direct-labeled probe.

Comparison of alkaline phosphatase direct-labeled probe and digoxigenin-labeled DHBV DNA probe

Compared with digoxigenin-labeled DHBV DNA probe, the detection sensitivity of alkaline phosphatase direct-labeled probe was 100% (60/60), the specificity was 100% (40/40) and the coincidence was 100% (80/80) (Table 2).

Table 1 Results of serum samples from different genera detected by alkaline phosphatase direct-labeled probe

Genera	Samples (n)	DHBV DNA positive samples (n)	DHBV DNA negative samples (n)
Duck serum	20	10	10
Human serum	20	0	20
Rat serum	20	0	20

Ligation efficiency of semi-nested PCR and AmpliSensor assay

The detection indices of semi-nested PCR and AmpliSensor assay for sample wells were 424.79 and 551.28, respectively. A “+” status was assigned to samples with ligation efficiency greater than 70. The primer could be used in asymmetric preamplification.

Table 2 Comparison of the results of 100 serum samples detected with different probes

Probe	Positive samples (n)	Negative samples (n)
Digoxigenin-labeled probe	60	40
Alkaline phosphatase direct-labeled probe	60	40

Detection of DHBV DNA positive standard with qPCR

After 30 cycles, amplification products showed two bands of about 180 bp and 70 bp by 2% agarose gel electrophoresis. The concentration of amplification products was in direct proportion to the initial concentration of the positive standards (Figure 3).

Figure 3 Detection of products of DHBV DNA positive standard with qPCR by 20 g/L agarose gel electrophoresis. Lane 1: Negative control; lanes 2-7: DHBV DNA positive standard (2.76×10^6 – 2.76×10^1 copies/ μ L); lane 8: DNA marker.

Figure 4 Amplification index standard curves of DHBV DNA positive standard.

Figure 5 Concentration standard curve of DHBV DNA positive standard.

Standard curves of DHBV DNA positive standards with qPCR

The detection index curves Std1–Std5 showed that the detection index was in direct proportion to the quantities of amplification products at the current cycle (Figure 4). The concentration curve showed that the initial concentration of the positive standards was in inverse proportion to the number of cycles needed for enough quantities of amplification products and the correlation coefficient between initial concentration and number of cycles was 0.992 (Figure 5).

Detection of serum DHBV DNA

Seventy serum samples of ducks were tested by fluorescent qPCR and digoxigenin-labeled DHBV DNA probe with dot-blot hybridization, and the correlation of results was analysed. Correlation coefficient of the results was 0.97 ($P < 0.01$) between the two methods. DHBV DNA could not be found by dot-blot hybridization, but it could be detected by qPCR when DHBV DNA loads $< 10^2$ copies/mL (Table 3).

Table 3 Correlation analyses of DHBV DNA quantitative results of 70 serum samples detected by two methods

Serum samples (n)	qPCR (mean \pm SD) (copy/mL)	Dot-blot hybridization using digoxigenin-labeled probe (mean \pm SD) (volume, mm ³)
10	(2.37 ± 1.70) $\times 10^2$	-
10	(2.44 ± 1.71) $\times 10^3$	1 155 \pm 25
10	(4.47 ± 1.96) $\times 10^4$	1 241 \pm 32
10	(5.02 ± 2.14) $\times 10^5$	1 353 \pm 27
10	(1.83 ± 1.03) $\times 10^6$	1 428 \pm 25
10	(4.81 ± 2.61) $\times 10^7$	1 550 \pm 40
10	(5.16 ± 2.72) $\times 10^8$	1 748 \pm 118

DISCUSSION

Though probes labeled with radioisotope are still used to detect nucleic acids because of its high sensitivity and complete operation rule established many years ago, the safety and half-life of radioisotope must be taken into account. At present, labeling and detecting with non-radioisotope have made significant progress, and the sensitivity of the probe labeled with chemiluminescence has reached 50 fg. Two methods of labeling with non-radioisotope were available in the present study: non-direct-labeling such as random primed DNA-labeling with digoxigenin-dUTP^[22] and direct-labeling such as DNA-labeling with alkaline phosphatase^[23]. DNA-labeling with alkaline phosphatase is a new method with advantages of quickness, convenience and high sensitivity. Some procedures such as long time incubation with antibody and blocking reagent and elution can be omitted. The probe can be detached from hybridizing membrane and therefore the membrane can be used to hybridize with another probe sensitively and conveniently. Furthermore, alkaline phosphatase may be detected with chemiluminescence (dioxetane) and autoradiography or photoscanning apparatus. Chen *et al.*^[21] reported that the sensitivity of dot-blot hybridization with Epstein-Barr virus probe coupled with alkaline phosphatase was 4 pg, which is similar to our results that the sensitivity of dot-blot hybridization with DHBV probe labeled by alkaline phosphatase was 10 pg. It is necessary to optimize labeling method of alkaline phosphatase for improving the sensitivity of the probe. This study showed that the alkaline phosphatase direct-labeled probe could be used to evaluate antiviral activity in DHBV infection animal model.

AmpliSensor-PCR is a real-time, quantitative tool for PCR-based detection. The assay is based on the principle that fluorescence resonance energy transfer can be used to detect duplex formation between complementary nucleic acid strands. If the two complementary strands are labeled with donor and

acceptor fluorophores, respectively, fluorescence resonance energy transfer between the fluorophores is facilitated when the strands are base-paired, or eliminated when the base-pair is disrupted. In this way, the extent of energy transfer can be used to measure the amount of duplex formation between the fluorophore-labeled oligonucleotide duplexes, thereby the extent of duplex formation mediated DNA polymerase. The measured fluorescence intensity is in proportion to the quantity of AmpliSensor duplex left at the end of each amplification cycle. The decrease in the fluorescence intensity correlates proportionately to the initial target dosage and the extent of amplification. The signal-generating mechanism of AmpliSensor assay is tightly linked to the priming event. However, unlike typical PCR, where single-stranded primers are constantly subject to the possibility of nonspecific priming, the AmpliSensor primer is sequestered in a double-stranded form and stabilized against random priming. The AmpliSensor is a quasi-stable signal duplex of two oligonucleotides each labeled with an energy donor and acceptor fluorophore, respectively. Two strands of the AmpliSensor are unequal in length with the long strand 5' overhanging the short one by 7 nucleotides (5'-GCGTCCC-3'). For effective ligation, the semi-nested primer should encompass at its 5' end a "hook" sequence, that is, 5'-GGGACGC-3', complementing the overhang of the AmpliSensor. The fluorescence signal correlates to the overall energy transfer efficiency in a predictable, sequence-specific manner, and the amplified product can be monitored directly. As a simple, homogeneous assay for PCR quantification, AmpliSensor technology is target-specific, and it is amenable to the normalization of signal loading and sample loading. Thus it can reliably count the amplified product while it accounts for the efficiency difference among reactions.

At present, fluorescence quantitative PCR has been applied in the fields of clinical diagnosis for hepatitis B and C, evaluating and monitoring of antiviral effect, prediction of interferon effect, *etc.*^[24,25].

DHBV and HBV are two members of the hepadnavirus family of viruses. They both display similar molecular biological character and 40% nucleic acid sequence homology. We usually make use of DHBV model to learn human hepatitis B about its infection and replication strategies or antiviral effect and to screen new anti-HBV drugs. In previous studies, dot-blot hybridization, Southern blotting and *in situ* hybridization with digoxigenin-labeled probe were used to detect DHBV DNA in serum or liver, but the advanced AmpliSensor-PCR and a membrane hybridization assay with alkaline phosphatase direct-labeled DHBV DNA probe could provide more objective, more valuable experimental data for developing new anti-HBV drugs and elucidating pathogenesis of hepatitis B.

Abstract

AIM: To develop a cell culture system capable of producing high titer hepatitis C virus (HCV) stocks with recombinant vaccinia viruses as helpers.

METHODS: Two plasmids were used for the generation of recombinant HCV: one containing the full-length HCV cDNA cloned between T7 promoter and T7 terminator of pOCUS-T7 vector, and the other containing the HCV polyprotein open reading frame (ORF) directly linked to a vaccinia late promoter in PSC59. These two plasmids were co-transfected into BHK₂₁ cells, which were then infected with vTF7-3 recombinant vaccinia helper viruses.

RESULTS: After 5 d of incubation, approximately 3.6×10^7 copies of HCV RNA were present per milliliter of cell culture supernatant, as detected by fluorescence quantitative RT-PCR (FQ-PCR). The yield of recombinant HCV using this cell system increased 100- to 1 000- fold compared to *in vitro*-transcribed HCV genomic RNA or selective subgenomic HCV RNA molecule method.

CONCLUSION: This cell culture system is capable of producing high titer recombinant HCV.

INTRODUCTION

Hepatitis C virus (HCV) is a causative agent of acute and chronic liver diseases that infect millions of people worldwide^[1]. There is no vaccine for prevention of HCV infection, and interferon is the only known therapeutic drug, yet it is only 10-20% effective alone and less than 50% effective when used in combination with ribavirin^[2]. Overall, despite the epidemic significance of HCV infection, the development of anti-HCV drugs and vaccines has been impeded by the lack of functional cell culture systems capable of growing the virus on a large scale.

Several approaches have been taken for the propagation of HCV in cell cultures. One approach focuses on the identification of primary cells or cell lines that support replication of the virus. It has been reported that HCV isolated from infected patients is capable of infecting human primary hepatocytes^[3-5],

peripheral blood mononuclear cells^[6], and cell lines such as human T cell line HPBMa10-2, Daudi B cell line^[7-9] and various hepatocyte cell lines^[10-12]. However, HCV replication in these cell culture systems is generally transient and very inefficient. A second approach is to transfect *in vitro*-transcribed HCV genomic RNA into human hepatoma cell line, Huh7^[13]. Although it was reported that the transfected cells produced infectious viral particles, the replication efficiency of this method was very poor, and moreover, many research groups have reported failure to generate detectable HCV virions using this method. Recently, Lohmann *et al.* recovered high levels of selective subgenomic HCV RNA molecules from transfected Huh-7 cells. These replicons were derived from a cloned full-length HCV (genotype 1b) consensus sequence with the C-p7 or C-NS2 regions removed and a neomycin phosphotransferase gene (neo) inserted downstream of the HCV internal ribosome entry site IRES^[14-17]. However, HCV particles generated by this system may differ from the native virions, due to the alteration of full-length HCV genomic RNA. Thus, researchers continue to search for a HCV replication system that will produce large-scale quantities of native virions.

Compared to the infection of cell lines with HCV-containing patient serum, the introduction of cloned viral genomes was superior because the inoculum was well-defined and could be generated in high quantities^[18]. Here, we used recombinant vaccinia viruses as helper viruses to produce high-titer cloned HCV stocks in a cell culture system. This method has the advantages of being simple, highly efficient, and capable of producing large quantities of high-fidelity HCV particles.

MATERIALS AND METHODS

Plasmid construction

Plasmid pBRT703'X (NIHJ1) (generously provided by T. Suzuki), containing the full-length HCV cDNA, was cut with Hind III and inserted into vector pOCUS-T7 (plasmid pOCUS containing a T7 terminator) between *EcoR* I and Hind III sites, resulting in insertion of the HCV sequence between bacteriophage T7 promoter and terminator sequences to create plasmid pT7HCV. Next, plasmid O. pMKC1A (HCV) was cut with *EcoR* I and Hind III and inserted into PSC59 between *EcoR* I and Stu I sites to generate plasmid pVHCV, which contained the HCV polyprotein open reading frame (ORF) linked to a vaccinia late promoter. The correct sequences of pT7HCV and pVHCV were confirmed by restriction enzyme digestion and DNA sequencing.

HCV production

One day prior to use, BHK₂₁ cell cultures (5×10^5 cells per well) were seeded in 6-well plates and incubated in Dulbecco's modified Eagle's medium (DMEM) with high levels of glucose (4.5 g/L) supplemented with 100 mL/L fetal calf serum and antibiotics (100 U/mL penicillin and 100 U/mL streptomycin). Cultures were incubated overnight in a 37 °C CO₂ incubator. Cells were then transfected with either 5 µg pT7HCV, 5 µg pT7HCV plus 5 µg pVHCV, 5 µg pVHCV or control plasmid (pOCUS-T7) using the LIPOFECTAMINE™ 2000 reagent (Invitrogen) followed by infection with vTF7-3 vaccinia viruses^[19].

Two hours after inoculation, the inoculum was removed and the cells were cultured in a fresh medium in a 30 °C CO₂ incubator for 2–5 d.

Determination of HCV virions in cell culture supernatants

HCV virion RNA was used as an indicator for HCV virion production. Accordingly, cell culture supernatants were filtered through a 0.22 µm filter to remove residual cells and vaccinia viruses. Ten units of RNase A and 20 units of DNase I were added to 200 µL of each filtrate, and samples were incubated at 37 °C for 1 h for complete digestion of RNA and DNA. Protease K was then added to a final concentration of 100 µg/mL, and extraction of HCV genomic RNA was carried out using the high pure viral RNA kit (Roche). The resultant RNA was treated with DNase I and used as a template for RT-PCR (GIBCO BRL). For detection of positive strand HCV genomic RNA, a 416 bp fragment of the 5' region (nt 346 to 761) and a 488 bp fragment of the 3' region (nt 9378 to 8891) were amplified by RT-PCR. The primers used for reverse transcription and 5' and 3' region PCR reactions are shown in Table 1.

PCR amplification consisted of 30 cycles of denaturation at 94 °C for 30 s, annealing at 55 °C for 30 s, and extension at 72 °C for 30 s. Amplified fragments were confirmed by 10 g/L agarose gel electrophoresis, ethidium bromide staining and visualization under UV light.

Immunofluorescence and Western blot analysis of HCV proteins

For immunofluorescence, BHK₂₁ cells were grown on glass coverslips for 48 h and fixed after washed 3 times with PBS in an ice-cold mixture of 9:1 acetone and methanol. After 10 min of incubation at -20 °C, the cells were washed 3 times with PBS and incubated for 1 h in 1F buffer (PBS, 30 g/L bovine serum albumin and 1 g/L Triton X-100) at 4 °C. A mixture of NS3- and NS5a-specific mouse monoclonal antibodies (Bioscience) was added at a dilution of 1:100 in 1F buffer. After 1 h, the cells were washed 3 times with PBS followed by incubation with a mouse-specific antibody conjugated with fluorescein isothiocyanate (Sigma) in 1F buffer. Coverslips were washed 3 times with PBS and mounted on glass slides, and the cells were examined under a fluorescence microscope.

For Western blot analysis, cells were lysed with a buffer containing 10 g/L sodium deoxycholate, 1 g/L sodium dodecyl sulfate (SDS), 10 g/L Triton X-100, 10 mmol/L Tris, 140 mmol/L NaCl, 1 mmol/L phenylmethylsulfonyl fluoride (PMSF), 2 µg of aprotinin per mL, and 2 µg of leupeptin per mL (pH 8.0). The cell lysate was cleared of cell debris and nuclei by low-speed centrifugation (15 min at 15 000 g, 4 °C). A fraction of the supernatant was denatured by heating for 4 min at 100 °C in SDS sample buffer. The samples were electrophoresed on SDS-100/L polyacrylamide gels and transferred to nitrocellulose membranes. The membranes were then incubated overnight in blocking buffer (PBS containing 5 mL/L Tween 20 and 50 mL/L milk powder), and the mixture of NS3- and NS5a-specific mouse monoclonal antibodies was added at a dilution of 1:100 in blocking buffer for 1 h. After washed 3 times with 5 mL/L Tween 20 in PBS, the membranes were then incubated with a mouse-specific antibody conjugated with peroxidase (Sigma) in blocking buffer for 1 h, washed 3 times as described above, and bound antibodies were detected by DAB.

Immunoelectron microscopy

Transfected cells were grown in 6-well plates for 48 h. After washed 2 times with ice-cold PBS (pH 7.4), the cells were fixed in Petri dishes for 30 min in a mixture of 40 g/L formaldehyde, 2.5 g/L glutaraldehyde, and 2 mL/L picric acid in PIPES buffer. The fixed cells were washed 3 times with PBS, then cell pellets were embedded in 40 g/L melted agarose and cut into small blocks, which were stained in 10 g/L uranyl acetate dissolved in water for 30 min at 4 °C. The blocks were further dehydrated in ethanol and embedded in Epon-Araldite. Ultrathin sections were mounted on nickel grids without supporting films. All labeling was conducted on grids according to the method of Sparkman and White^[20]. Grids were etched with 10 g/L sodium periodate in water for 15 min, washed 3 times with PBS, and incubated with 30 g/L BSA in PBS for 30 min. The grids were then incubated for 1 h with a mixture of NS3- and NS5a-specific mouse monoclonal antibodies (diluted 1:100 in 10 g/L BSA-PBS) or in 10 g/L BSA-PBS only. After washed 5 times with PBS, the sections were treated for 1 h with goat anti-mouse antibody conjugated with colloidal gold (10-nm diameter, diluted 1:100 in PBS). Samples were rinsed five times with PBS. After counterstained with uranyl acetate and lead citrate, the sections were examined with an electron microscope.

Quantification virion RNA copy numbers

Fluorescence quantitative RT-PCR (FQ-PCR) was used to determine the amount of HCV virion RNA in cell culture supernatants treated with RNase A and DNase I as described above. Hepatitis C virus fluorescence polymerase chain reaction (PCR) diagnostic kit (Da Am Company, China) was used as directed to quantify virion RNA. Samples from ten transfections were detected by FQ-PCR.

RESULTS

Recombinant plasmids pT7HCV and pVHCV were confirmed by restriction endonuclease digestion. As expected, pT7HCV generated two fragments of 6.7 kb and 4.6 kb when digested with *Eco*R I, and pVHCV generated two fragments of 8 kb and 4.4 kb when digested with *Xho* I. DNA sequencing confirmed that the 3' and 5' sequences were as expected.

RT-PCR was used to detect HCV virion RNA in the cell culture supernatant as a measure of virion production. To ensure that the detected HCV RNA was the product of virions, we used RNase A treatment to remove HCV RNA that might release into the culture medium, as the virion envelope could protect the desired HCV RNA from digestion. To ensure that the fragments detected by RT-PCR did not come from the HCV DNA, the cell culture supernatants were also treated with DNase I. To ensure that the detected HCV RNA included the entire genome, the 5' and 3' ends of HCV genome were both amplified by RT-PCR. Positive samples amplified a 416 bp DNA fragment from the 5' UTR and a 488 bp DNA fragment from the 3' UTR. Transfection of BKH₂₁ cells with either pT7HCV or pT7HCV plus pVHCV resulted in samples that were positive for both the 3' and 5' fragments amplified by RT-PCR but not PCR alone. HCV RNA was not detected following transfection with pVHCV alone or with the control plasmid. These results confirmed that HCV virions existed in the culture supernatant of BKH₂₁ cells.

Table 1 Primers for RT-PCR

Oligodeoxynucleotide	5' region	3' region
Reverse transcription primers	agccctggcagcgcgccctagggggcgcc (nt 791 to 762)	gggggatggcctattggcctggagtgt (nt 9414 to 9388)

Figure 1 Immunofluorescent analysis of HCV nonstructural proteins expressed in BHK₂₁ cells using a mixture of NS3- and NS5a-specific mouse monoclonal antibodies. A: cells transfected with pT7HCV; B: cells cotransfected with pT7HCV and pVHCV; C: cells transfected with pVHCV.

transfected with pT7HCV or pT7HCV plus pVHCV.

Expression of HCV nonstructural proteins in the infected cells was detected by immunofluorescence and Western blot analysis using NS3- and NS5a-specific mouse monoclonal antibodies. BHK₂₁ cells transfected with pT7HCV, pT7HCV plus pVHCV or pVHCV were positive for immunofluorescence, though to varying degrees. Cells transfected with pVHCV showed the strongest signal, and cells transfected with pT7HCV showed the weakest (Figure 1). Expression of HCV nonstructural proteins in BHK₂₁ cells was further confirmed by Western blot analysis. Nonstructural proteins NS3 and NS5a were detected as bands of ~70 and 56 ku, respectively. Western blot analysis also showed that the expression of nonstructural proteins was highest in cells transfected with pVHCV and lowest in cells transfected with pT7HCV (Figure 2).

Figure 2 Western blotting of HCV gene products expressed in BHK₂₁ cells probed with a mixture of NS3- and NS5a-specific mouse monoclonal antibodies. 1: cells transfected with control plasmid (pOCUS-T7); 2: cells transfected with pVHCV; 3: cells cotransfected with pT7HCV and pVHCV; 4: cells transfected with pT7HCV.

NS3- and NS5a-specific mouse monoclonal antibodies were used to determine the subcellular localization of HCV proteins in cells transfected with pT7HCV plus pVHCV. Specific, though weak, signals were found in cytoplasm and vesicles (Figure 3), which were consistent with the results of Pietschmann *et al.*^[16], who reported that antisera monospecific for NS3, NS4b, NS5a or NS5b resulted in weak specific signals that were difficult to interpret. Our immunoelectron microscopy results identified positively stained small particles, about 40 to 60 nm in diameter, in cytoplasm and vesicles (Figure 3). The morphology and size of these particles were consistent with previous predictions regarding the HCV particles^[21-24]. No virion-like structures were identified in cells transfected with control plasmid and/or infected with vTF7-3 vaccinia alone.

Next, FQ-PCR was used to quantify the virion production in supernatants of cells transfected with pT7HCV, pT7HCV

plus pVHCV, pVHCV or the control plasmid. The copy number of HCV RNA per milliliter of culture supernatant 2, 3, 4 and 5 days after inoculation are shown in Table 2.

Figure 3 Immunoelectron microscopy of HCV-like virions in BHK₂₁ cells cotransfected with pT7HCV plus pVHCV and stained with mixed NS3- and NS5a-specific mouse monoclonal antibodies. Virions about 40 to 60 nm in diameter (arrows) were identified in cytoplasm and vesicles. Bar: 500 nm (A) and 200 nm (B). c: cytoplasm; lu: lumen; n: nucleus.

Table 2 Virion RNA quantitation in cell culture supernatants as measured by fluorescence quantitative RT-PCR (RNA copies per mL)

Culture time	RNA copies			
	PT7HCV	PT7HCV+ PvHCV	PvHCV	Control plasmid
48 h	1.12±0.18×10 ⁵	3.76±0.22×10 ⁵	0	0
72 h	4.08±0.20×10 ⁵	8.00±0.28×10 ⁵	0	0
96 h	1.28±0.27×10 ⁶	7.68±0.22×10 ⁶	0	0
120 h	3.24±0.25×10 ⁶	3.60±0.18×10 ⁷	0	0

DISCUSSION

Since HCV virions contain only genomic RNA and structural proteins, transfecting host cells with *in vitro* synthesized HCV viral genomic RNA could result in generation of HCV virions if the host cells were able to translate mRNA and properly processed the resulting polyprotein^[13]. However, because of low transfection efficiency, the short lifetime of viral RNA in the cytoplasm, and poor translation efficiency, viral production was generally very low by the RNA transfection method.

In this study, we used the vaccinia viral replication machinery to produce HCV virions in cell culture. The vaccinia expression system was previously tried for the production of HCV virions in cell culture. Selby *et al.* transfected Ost7-1 cells with a plasmid containing a cDNA of HCV genomic RNA downstream of a T7 promoter. The transfected cells were then infected with a recombinant vaccinia virus containing a T7 polymerase gene. Although HCV polyprotein was synthesized in Ost7-1 cells and correctly processed into individual viral proteins, no HCV virions were generated^[25], perhaps because the researchers did not place a T7 terminator downstream of HCV cDNA. Without terminator, transcripts synthesized by T7 RNA polymerase were heterogeneous concatemers that were too large to be packaged into a HCV virion. To correct this problem, Mizuno *et al.* cloned HCV cDNA between a T7 promoter and a T7 terminator^[21], resulting in the expression of both structural and nonstructural proteins in HeLa G cells, and the appearance of HCV core antigen-positive particle-like structures in cytosol and cisternae of the endoplasmic reticulum (ER). However, these particles were not tested for the presence of HCV RNA.

For identification of recombinant HCV virions, we detected the expression of HCV nonstructural proteins NS3 and NS5a in the supernatant of transfected cells. This has been reported by Mizuno *et al.* who detected the expression of structural proteins in HeLa G cells transfected with the full-length HCV genome sequence^[21]. Next, we used RT-PCR to detect the presence of positive strand HCV genomic RNA. Following digestion of HCV RNA from blocked cells, and residual plasmid DNA, RT-PCR of fragments from the 5' (nt 346 to 761) and 3' (nt 9378 to 8891) regions of HCV RNA showed that virions contained the entire sequence. This was in contrast to the report of Baumert *et al.*, who reported that HCV-like particles produced in insect cells using a recombinant baculovirus containing cDNA of HCV structural proteins contained various shortened HCV RNAs^[22]. Finally, we observed the expression of HCV proteins and virion-like structures using immunoelectron microscopy.

In this new culture system, cells were transfected with two plasmids. One contained the HCV genomic RNA-coding region between upstream T7 promoter and downstream T7 terminator, transcripts synthesized by bacteriophage T7 RNA polymerase would have a defined size. The other plasmid contained the open reading frame (ORF) of HCV polyprotein directly linked to a vaccinia late promoter. The doubly transfected cells were subsequently infected with vTF7-3 recombinant vaccinia viruses containing a T7 RNA polymerase gene under the control of a vaccinia promoter. Thus, T7 RNA polymerase was synthesized in the infected cells and in turn transcribed plasmid DNA encoding HCV genomic RNA. Meanwhile, vaccinia RNA polymerase transcribed DNA encoding HCV polyprotein. After polyprotein was processed, the resulting viral proteins packaged HCV genomic RNA and assembled it into virions, which were then released from cells via the secretory pathway. In the system, we took the advantage of the unique properties of vaccinia viruses. Vaccinia virus replicates entirely in cytoplasm and uses its own enzymes to replicate DNA and synthesize 5' capped and 3' polyadenylated mRNA. Vaccinia DNA polymerase is able to replicate plasmid DNA in cytoplasm, increase the number of DNA copies, and transcribe cytoplasmic DNA that is linked to a vaccinia promoter. Meanwhile, the viral capping enzyme

and poly(A) polymerase add a 5' cap and 3' poly(A) tail to the transcribes. The resulting mRNA can be translated by the host cell translation machinery. Because HCV genomic RNA is synthesized by T7 RNA polymerase of vaccinia while mRNA for the viral proteins is synthesized by vaccinia enzymes, RNA synthesis will not be restricted as RNA replication that is catalyzed by HCV enzymes.

For practical examination of this new system, we transfected BHK₂₁ cells with pT7HCV and pVHCV respectively, or cotransfected the cells with pT7HCV plus pVHCV for comparison. After 5 d of culture, we detected approximately $3.24 \pm 0.25 \times 10^6$ copies of HCV RNA per mL of supernatant from cells transfected with pT7HCV and $3.60 \pm 0.18 \times 10^7$ copies of HCV RNA per mL from cells cotransfected with pT7HCV plus pVHCV. HCV RNA was not detected in cells transfected with pVHCV alone. These results suggest that cotransfection with pT7HCV plus pVHCV could increase virion production. Evidence from a previous study with *in vitro*-transcribed HCV RNA showed that although transfection of cells with genomic HCV RNA could result in the production of HCV virions, cotransfection with both genomic RNA and 5' capped RNA in which 5' UTR is deleted could increase virion production^[13]. We hypothesize that it may be possible to further increase the production of viral particles by slight alterations of pT7HCV, including addition of mutations in the NS5a or NS3 regions (*e.g.*, serine to isoleucine at NS5 position 1179) to enhance replication^[26-29], or addition of a hairpin-ribozyme cassette right after the end of the 3' untranslated region^[30-32], which may also increase the titer of the resulting viral particles. However, the experimental benefits of these changes have yet to be determined.

Indeed, it also remains to be seen whether recombinant HCV virions identified in the present study are infectious. Evidence from a study with *in vitro*-transcribed full-length and subgenomic HCV RNA showed that recombinant viral particles were infectious and replication competent^[13]. To determine whether the virions produced by our new method are infectious, future work may include purification of the particles by sucrose and CsCl gradient centrifugation according to Baumert *et al.*^[22], to rule out interference by residual vaccinia viruses. Alternatively, we might generate a defective vaccinia virus that lacks D13L gene, which is essential for HCV production. Repression of D13L gene expression had no effect on viral replication and viral protein expression but could block formation of progeny virions^[33].

In conclusion, the yield of recombinant HCV using our cell system increased 100- to 1000-fold compared to *in vitro*-transcribed HCV genomic RNA method or selective subgenomic HCV RNA molecule method. This culture system may enable us to provide academic and medical researchers with high quality HCV preparations as well as to generate attenuated HCV for vaccine development. Furthermore, it may be useful as a system for future drug screening and vaccine selection.

Abstract

AIM: To construct *ltB-ureB* fusion gene and its prokaryotic expression system and identify immunity and adjuvant activity of the expressed recombinant protein.

METHODS: The *ureB* gene from a clinical *Helicobacter pylori* (*H pylori*) strain Y06 and the *ltB* gene from *Escherichia coli* (*E. coli*) strain 44851 were linked into *ltB-ureB* fusion gene by PCR. The fusion gene sequence was analyzed after T-A cloning. A prokaryotic recombinant expression vector *pET32a* inserted with *ltB-ureB* fusion gene (*pET32a-ltB-ureB*) was constructed. Expression of the recombinant LTb-UreB protein (rLTb-UreB) in *E. coli* BL21DE3 induced by isopropylthio- β -D-galactoside (IPTG) at different concentrations was detected by SDS-PAGE. Western blot assays were used to examine the immunoreaction of rLTb-UreB by a commercial antibody against whole cell of *H pylori* and a self-prepared rabbit anti-rUreB serum, respectively, and determine the antigenicity of the recombinant protein on inducing specific antibody in rabbits. GM₁-ELISA was used to demonstrate the adjuvant activity of rLTb-UreB. Immunoreaction of rLTb-UreB to the UreB antibody positive sera from 125 gastric patients was determined by using ELISA.

RESULTS: In comparison with the corresponding sequences of original genes, the nucleotide sequence homologies of the cloned *ltB-ureB* fusion gene were 100%. IPTG with different dosages of 0.1-1.0 mmol/L could efficiently induce *pET32a-ltB-ureB-E.coli* BL21DE3 to express the rLTb-UreB. The output of the target recombinant protein expressed by *pET32a-ureB-E.coli* BL21DE3 was approximately 35% of the total bacterial proteins. rLTb-UreB mainly presented in the form of inclusion body. Western blotting results demonstrated that rLTb-UreB could combine with the commercial antibody against whole cell of *H pylori* and anti-rUreB serum as well as induce rabbit to produce specific antibody. The strong ability of rLTb-UreB binding bovine GM₁ indicated the existence of adjuvant activity of the recombinant protein. All the UreB antibody positive sera from the patients (125/125) were positive for rLTb-UreB.

CONCLUSION: A recombinant prokaryotic expression

system with high expression efficiency of the target fusion gene *ltB-ureB* was successfully established. The expressed rLTb-UreB showed qualified immunogenicity, antigenicity and adjuvant activity. All the results mentioned above laid a firm foundation for further development of *H pylori* genetically engineered vaccine.

INTRODUCTION

In China, gastritis and peptic ulcer are the most prevalent gastric diseases and gastric cancer is one of the malignant tumors with high morbidities^[1]. *Helicobacter pylori* (*H pylori*), a microaerophilic, spiral and Gram-negative bacterium, is recognized as a human-specific gastric pathogen that colonizes the stomachs of at least half of the world's populations^[2]. Most infected individuals are asymptomatic. However, in some subjects, *H pylori* infection causes acute, chronic gastritis or peptic ulceration. Furthermore, the infection is also a high risk factor for the development of peptic ulcer and gastric adenocarcinoma, mucosa-associated lymphoid tissue (MALT) lymphoma and primary gastric non-Hodgkin's lymphoma^[3-8]. Recently, direct evidence of carcinogenesis of the microbe in an animal model has been presented^[9-11]. Immunization against the bacterium represents a cost-effective strategy to prevent *H pylori*-associated common peptic ulcer diseases and to reduce the incidence of global gastric cancers^[12]. However, no vaccines preventing *H pylori* infection have been commercially available so far.

Previous studies revealed many protective protein antigens of the microbe such as UreB, HpaA, FlaA, CagA, VacA *etc*^[13-18]. Among these protein antigens, UreB, one of the four subunits of an urease produced by almost all the isolated strains of *H pylori*, has been demonstrated to have the strongest antigenicity and protection in all known proteins of *H pylori*^[13,19,20]. *ureB* gene, responsible for encoding UreB with 569 amino acid residues, is a highly conserved nucleotide sequence with a similarity of approximately 95% in different *H pylori* isolates^[21-23]. These data strongly indicate that UreB can be used as an excellent antigen candidate for *H pylori* vaccine.

Since a genetically engineered vaccine composed of a single protein antigen usually showed a low immunization effect, it is necessary to increase immunogenicity of the antigen by co-administration with an appropriate adjuvant. *Escherichia coli* (*E. coli*) heat-labile toxin B subunit (LTB) and cholera toxin B subunit (CTB) were well-confirmed mucosal adjuvants^[24-28]. However, some of the previous studies demonstrated that the mucosal adjuvant activity of LTB was stronger than that of CTB^[26,29]. Furthermore, CTB activates Th2 pathway, and induces IL-4, a

cytokine closely related to IgE-mediated allergic reaction, but LTb mainly stimulates Th1 pathway^[26,30].

In order to simplify the procedure steps and further reduce cost in *H. pylori* vaccine production, we constructed *ltB-ureB* fusion gene and its recombinant prokaryotic expression system. The immunogenicity, antigenicity and adjuvant activity of the expressed target recombinant protein (rLTB-UreB) were examined. The results of this study would benefit the mass production of *H. pylori* UreB-associated genetically engineered vaccine at a lower cost.

MATERIALS AND METHODS

Materials

Both the *ureB* gene from a clinical *H. pylori* strain Y06 and the *ltB* gene from *E. coli* strain 44851 (offered by National Institute for the Control of Pharmaceuticals and Biological Products of China) was cloned by our laboratory^[31]. A plasmid *pET32a* (Novagen, Madison, USA) and *E. coli* BL21DE3 (Novagen, Madison, USA) were used as the expression vector and host cell, respectively. Primers for PCR amplification were synthesized by BioAsia (Shanghai, China). *Taq*-plus high fidelity PCR kit and restriction endonucleases used were purchased from TaKaRa (Dalian, China). The T-A Cloning Kit, DNA Agarose Gel Purification Kit and sequencing service were provided by BBST (Shanghai, China). DAKO (Glostrup, Denmark) and Jackson ImmunoResearch (West Grove, USA) supplied rabbit antiserum against whole cell of *H. pylori*, HRP-labeling sheep anti-rabbit IgG and anti-human IgG antibodies, respectively. The UreB antibody positive serum samples from 125 *H. pylori* infected patients with gastritis or ulcer were stored at -70 °C in our laboratory^[31].

Methods

Extraction of DNA templates *E. coli* DH5 α strains respectively containing plasmid *pUCm-T-ureB*, *pUCm-T-ltB* were cultured in LB medium. The two plasmids were extracted by alkaline-denature method and then purified by DNase-free RNase treatment and routine phenol-chloroform method described by Sambrook *et al.*^[32]. The obtained DNA extracts were dissolved in TE buffer and their concentrations as well as purity were measured by ultraviolet spectrophotometry^[32]. The *pUCm-T-ureB* DNA was further digested with restriction endo- nucleases *EcoR* V and *Xho* I at 37 °C for 3 h. The target fragment of *ureB* gene was separated by agarose gel electrophoresis and then recovered by DNA Agarose Gel Purification Kit.

Amplification of *ureB* and *ltB* gene The sequence of *ltB* sense primer was: 5'-CCGGATATCATGAATAAAGTAA AATGTTA-3' (*EcoR* V). The sequence of antisense primer linking the 3'-end of *ltB* gene and the 5'-end of *ureB* gene was: 5'-AGAAACATATTCTTTTCTGCTAATGTTTCCATA CTGATTGCCGC-3'. Total volume per PCR was 100 μ L containing 2.5 mol/L each dNTP, 250 nmol/L each of the two primers, 15 mol/L $MgCl_2$, 2.5 U *Taq*-plus polymerase, 100 ng *pUCm-T-ltB* DNA template and 1 \times PCR buffer (pH8.3). Parameters for PCR of *ltB* gene were: at 94 °C for 5 min, \times 1; at 94 °C for 30 s, at 48 °C for 30 s, at 72 °C for 45 s, \times 10; at 94 °C for 30 s, at 48 °C for 30 s, at 72 °C for 50 s (an addition of 5 s for each of the following cycles), \times 20; finally at 72 °C for 7 min, \times 1. The results of PCR were observed under UV light after electrophoresis in 15 g/L agarose pre-stained with ethidium bromide. The expected size of target amplification fragment from *ltB* gene was 375 bp. The target fragment in the gel was recovered by using DNA Agarose Gel Purification Kit.

Construction of *ltB-ureB* fusion gene by PCR Total volume per tube was 90 μ L containing all the PCR reagents mentioned above but not the primers, 100 ng of the recovered *ltB* DNA fragment with a cohesive end and 400 ng of the recovered *ureB*

DNA fragment were added. Parameters for the following PCR were : at 94 °C for 5 min, \times 1; at 94 °C for 30 s, at 45 °C for 30 s, at 72 °C for 150 s, \times 10; at 72 °C for 10 min, \times 1. After this PCR, the two fragments of *ureB* and *ltB* produced a complex fragment of *ureB-ltB* dependent on the cohesive end in the *ltB* fragment, which would be used as a template for the next PCR. The sense primer for *ureB-ltB* amplification was as previously mentioned. The sequence of antisense primer was: 5'-CGACTCGAGGAA AAT GCTAAAGAGTTGTGC-3' (*Xho* I). The 250 nmol/each of the two primers was added into each of the tubes. Parameters for *ltB-ureB* amplification were: at 94 °C for 3 min, \times 1; at 94 °C for 30 s, at 50 °C for 30 s, at 72 °C for 180 s, \times 10; at 94 °C for 30 s, at 50 °C for 30 s, at 72 °C for 195 s (an addition of 15 s for each of the following cycles), \times 15; at 72 °C for 12 min, \times 1. Examination of the results of this PCR and recovery of the target fragment were the same as described above. The expected size of target amplification fragment from *ureB-ltB* fusion gene was 2 070 bp.

T-A cloning, sequencing and subcloning of *ureB-ltB* fusion gene The *ltB-ureB* amplification DNA fragment was cloned into plasmid vector *pUCm-T* (*pUCm-T-ltB-ureB*) by using T-A Cloning Kit according to the manufacturer's instruction. The recombinant plasmid was amplified in *E. coli* DH5 α and then extracted by Sambrook's method^[32]. A professional company (BBST) was responsible for nucleotide sequence analysis of the inserted fragment. Two plasmids *pUCm-T-ltB-ureB* and *pET32a* in two different strains of *E. coli* DH5 α after amplified in LB medium were extracted and then digested with *EcoR* V and *Xho* I, respectively^[32]. The fragment *ltB-ureB* and *pET32a* were recovered and then ligated. The recombinant expression vector *pET32a-ltB-ureB* was transformed into *E. coli* BL21DE3, and the expression system was named as *pET32a-ltB-ureB-E. coli* BL21DE3. The *ltB-ureB* fragment inserted in *pET32a* was sequenced again.

Expression of the target recombinant protein *pET32a-ltB-ureB-E. coli* BL21DE3 was rotatively cultured in LB medium at 37 °C induced by isopropylthio- β -D-galactoside (IPTG) at different concentrations of 1.0, 0.5 and 0.1 mmol/L. The supernatant and precipitate were separated through centrifugation after the bacterial pellet was ultrasonically broken (300 V, 3 \times 5 s). The molecular mass and output of the target recombinant protein (rLTB-UreB) were measured by SDS-PAGE.

Identification of immunoreactivity and antigenicity of rLTB-UreB The expressed rLTB-UreB was collected by Ni-NTA affinity chromatography. The commercial rabbit antiserum against whole cell of *H. pylori* or rabbit anti-rUreB serum prepared in our previous study and HRP-labeling sheep anti-rabbit IgG were used as the first and second antibodies, respectively, to determine the immunoreactivity of rLTB-UreB by Western blot. Rabbits were immunized with rUreB to prepare the antiserum and Western blot was applied again to determine the antigenicity of rLTB-UreB.

GM₁-ELISA GM₁-ELISA was used to demonstrate the adjuvant activity of rLTB-UreB. Briefly, 40-well plates were coated by bovine GM₁ (Sigma) and then added with rLTB-UreB. The rabbit anti-rLTB-UreB serum was used as the first antibody (1:100 dilution) and the commercial HRP-labeling sheep anti-human IgG (1:4 000 dilution) was applied as the second antibody. Each of the first antibody dilutions contained four wells. Negative controls without addition of rLTB-UreB with four repeated wells were set up and their mean A_{490} value plus 3-fold *SD* values were used as the positive standard for each of the tested wells^[33].

ELISA By using rLTB-UreB as coated antigen at the concentration of 20 μ g/mL, each of the UreB antibody positive serum samples from the 125 patients (1:400 dilution) as the first antibody and HRP-labeling sheep anti-human IgG (1:4 000 dilution) as the second antibody, the immunoreaction of rLTB-UreB to the specific antibody in the sera were detected by

ELISA. In this assay, six UreB antibody negative serum samples were used as the control and the positive standard was similar to that in the GM₁-ELISA.

Statistical analysis

The nucleotide sequence of the cloned *ltB-ureB* fusion gene was compared for homologies with the original sequences^[31] by using a molecular biological analysis software.

RESULTS

PCR

The target fragments of *ureB*, *ltB* and *ltB-ureB* genes with the expected sizes are shown in Figure 1.

Figure 1 Target amplification fragments of *ltB* and *ureB* genes and *ltB-ureB* fusion gene. Lane 1: 250 bp DNA marker (BBST); Lanes 2, 4 and 6: Blank controls; Lanes 3 and 5: Target amplification fragments of *ltB* gene and *ltB-ureB* fusion gene, respectively; Lane 7: Target recovered fragment of *ureB* gene from *pUCm-T-ureB* after digestion with both *EcoR V* and *Xho I*.

Nucleotide sequence analysis

The homologies of the nucleotide sequences of the cloned *ltB-ureB* fusion gene compared with the original *ltB* and *ureB* gene sequences were 100%^[31]. The nucleotide and putative amino acid sequences of the *ltB-ureB* fusion gene are shown in Figure 2.

Expression of target fusion protein

IPTG at concentrations of 1.0, 0.5 and 0.1 mmol/L could efficiently induce the expression of rLTB-UreB in *pET32a-ltB-ureB-E.coli* BL21DE3 system. The product of rLTB-UreB was mainly presented in the ultrasonic precipitate and the output was approximately 35% of the total bacterial proteins (Figure 3).

Immunoreactivity and antigenicity of rLTB-UreB

Commercial rabbit antibody against the whole cell of *H pylori* could combine with rLTB-UreB and induce rabbit to produce specific antibody as confirmed by Western blotting (Figure 4), respectively.

GM₁-ELISA

Since the mean±SD of A_{490} of the negative control in the four repeated wells was 0.28 ± 0.09 , the positive reference value was 0.55. The mean±SD of A_{490} of the tested wells was 1.29 ± 0.10 , indicating that rLTB-UreB had the ability of binding to bovine GM₁.

ELISA

Since the mean±SD of A_{490} values of the six UreB antibody negative serum samples was 0.17 ± 0.03 , the positive reference value for the specific antibody detection in patients' sera was 0.26. According to the reference value, 100% (125/125) of the tested patients' sera were positive for the antibodies against rLTB-UreB with an A_{490} value ranging from 0.37-1.98.

Lanes 1, 3 and 5: rLTB-UreB with rabbit antibody against whole cell of *H. pylori*, and rUreB- and rLTB-UreB-immunized rabbit antisera, respectively; Lanes 2, 4 and 6: Corresponding blank controls.

DISCUSSION

The selection of antigenic targets is critical in the design of *H. pylori* vaccine. A large number of published data showed that UreB might be the most definitive antigen candidate for *H. pylori* vaccine^[13,19-23]. On the other hand, LTB is found to be the most efficient mucosal adjuvant with few possibility of inducing allergic reaction^[24-30]. So UreB and LTB should be the optimal antigen and adjuvant for developing orally taken *H. pylori* vaccine, respectively.

In the present study, *ltB-ureB* fusion gene was obtained by using three PCRs and the nucleotide sequence of the gene showed absolutely the same as the corresponding ones. This data indicated that the method used for constructing fusion gene was highly efficient and of high fidelity.

SDS-PAGE performed in this study confirmed that the constructed prokaryotic expression system *pET32a-ltB-ureB-E.coli* BL21DE3 could produce rLTB-UreB with high efficiency even when the concentration of IPTG was as low as 0.1 mmol/L. The inclusion body as a major form of rLTB-UreB and higher output (35% of the total bacterial proteins) of the recombinant protein was beneficial to industrial production.

The results of Western blotting in this study demonstrated that the rLTB-UreB could combine with both the commercial antibody against whole cell of *H. pylori* and rabbit anti-rUreB serum. And this recombinant protein was able to efficiently induce rabbit to produce specific antibody. Furthermore, all the UreB antibody positive serum samples from 125 patients confirmed by our previous studies could recognize rLTB-UreB.

In the reports, the adjuvanticity of LTB was based on the binding ability to GM₁ receptor on the surface of cell^[27-33]. In this study, the strong binding to GM₁ receptor of rLTB-UreB was confirmed by GM₁-ELISA. Therefore, rLTB-UreB with qualified immunoreactivity, antigenicity and adjuvanticity could be used to develop *H. pylori* genetically engineered vaccine at lower costs.

Abstract

AIM: To identify the genes expressed differentially in the regenerating rat liver in a short interval successive partial hepatectomy (SISPH), and to analyze their expression profiles.

METHODS: Five hundred and fifty-one elements selected from subtractive cDNA libraries were conformed to a cDNA microarray (cDNA chip). An extensive gene expression analysis following 0-36-72-96-144 h SISPH was performed by microarray.

RESULTS: Two hundred and sixteen elements were identified either up- or down-regulated more than 2-fold at one or more time points of SISPH. By cluster analysis and generalization analysis, 8 kinds of ramose gene expression clusters were generated in the SISPH. Of the 216 elements, 111 were up-regulated and 105 down-regulated. Except 99 unreported genes, 117 reported genes were categorized into 22 groups based on their biological functions. Comparison of the gene expression in SISPH with that after partial hepatectomy (PH) disclosed that 56 genes were specially altered in SISPH, and 160 genes were simultaneously up-regulated or down-regulated in SISPH and after PH, but in various amount and at different time points.

CONCLUSION: Genes expressed consistently are far less than that intermittently; the genes strikingly increased are much less than that increased only 2-5 fold; the expression trends of most genes in SISPH and in PH are similar, but the expression of 56 genes is specifically altered in SISPH. Microarray combined with suppressive subtractive hybridization can in a large scale effectively identify the genes related to liver regeneration.

INTRODUCTION

In the liver regeneration (LR) after partial hepatectomy (PH), a great deal of genes is involved, and varied in the different phases of LR^[1-5]. Peak of DNA synthesis appears at 24 h and two small peaks occur at 36 h and 48 h after PH^[6]. Despite numerous related papers, the molecular mechanism of LR has not been thoroughly elucidated^[7-16]. To explore the hepatic regeneration mechanism, a 0-36-72-96-144 h short interval successive partial hepatectomy (SISPH) model was established in 2001, and has been proved an important tool for studying specific gene expression at various crucial points of LR^[17-19]. To uncover unknown differential display genes relevant to LR, the method of subtractive suppression hybridization (SSH) was used, and a bulk of up-regulated and down-regulated expressed sequence tags (ESTs) in the regenerating rat liver of 0-36-72-96-144 h SISPH were obtained. With development of cDNA microarray technology, genomewide expression of thousands of genes can be simultaneously analyzed facilitating differential expression monitoring of a large number of activated or suppressed genes under various biological conditions. To further display their expression variation in the LR, an in-house cDNA microarray was successfully performed to identify gene expression profiles in regenerating liver following the SISPH. Relevant information was achieved by data analysis of Microsoft Excel and GeneSpring.

MATERIALS AND METHODS

Short interval successive partial hepatectomy of rats

Male and female Sprague-Dawley (SD) rats, aged 10-12 wk and weighing 200-220 g, were raised in Experimental Animal Center of Henan Normal University. According to Xu *et al.*, lobule external sinister and lobus centralis sinister, lobus dexter, lobus centralis, and lobus caudatus were removed subsequently at four time points of 0, 36, 72, 96 h of 0-36-72-96-144 h SISPH^[20].

Sample preparation and RNA extraction

The removed liver lobes were rinsed in cold 1×PBS and immersed in -80 °C refrigerator for RNA and protein extraction. Total RNA was isolated from frozen liver lobes according to the manual of Trizol kit of Invitrogen. In brief, 50-100 mg liver tissue was homogenized in 1 mL Trizol reagent containing phenol and guanidinium isothiocyanate/cationic detergent, followed by phenol-chloroform extraction and isopropyl alcohol precipitation. The quantity and integrity of total RNA were examined by ultraviolet spectrometer and denaturing formaldehyde agarose electrophoresis stained by ethidium bromide (EB).

Subtracted cDNA library construction and screening

cDNA subtractive libraries were generated from total RNA by PCR-Select TM cDNA Subtraction kit (Clontech) following the manufacturer's instruction. Briefly, total RNA was reverse transcribed to double cDNA strands and digested with restriction enzymes, followed by subtractive hybridization with drivers and testers. Finally with suppression PCR, differential expression sequence tags were performed to construct

subtractive cDNA library, which was cloned into T-vector (Promega) and screened by PCR with nest primer 1 and 2.

Sequence analysis

The base sequence assay of ESTs was carried out according to the current protocols in molecular biology. All sequences were determined for both strands. Comparison analysis of the selected sequences was conducted with the DNAMAN and the National Center for Biotechnology Information (www.ncbi.nlm.nih.gov) GenBank database.

cDNA microarray construction

cDNA fragments amplified by polymerase chain reaction (PCR) with nested PCR primer 1 and primer 2, and purified by NaAc/isopropanol were spotted onto glass slides (Biostar) with the help of ProSys-5 510A spotting machine according to designed project. Then the gene chips were ready by hydrating, blocking and drying. Totally 1 152 elements (double spot chip) including 50 control systems (8 negative control, 12 blank control, 30 internal control) and 551 target genes to be studied comprised 8 submatrixes (12*12) occupying 9 mm*18 mm (Biostar).

Fluorescence-labeled cDNA preparation

RNA isolated from rat livers before SISPH served as a reference for all cDNA microarray analyses. Total denatured RNA was reverse transcribed with Cy3-conjugated dCTP (control group) and Cy5-conjugated dCTP (test group) (Amersham-Pharmacia Biotech) using MMLV reverse transcriptase (Promega) with olig (dT) primer. After bath incubation for 2 h, labeled buffer I and II were subsequently added to the reaction. The control group and test group were mingled together symmetrically and stored in the dark for use.

Hybridization and scanning

The glass slices were prehybridized at 42 °C for 5-6 h in hybridization buffer containing freshly cooked shared salmon sperm DNA. The labeled denatured probe was hybridized against cDNA microarrays with an overnight (16-18 h) incubation at 42 °C. The slides were then washed twice with 2×SSC containing 5 g/L SDS for 5 min at room temperature, once with 0.2×SSC containing 5 g/L SDS at 60 °C for 10 min, and finally with 0.2×SSC at 60 °C for 10 min. After that, the slices were photographed. Hybridized images were scanned by a fluorescence laser scanning device, Gene Pix 4 000 A (Axon Instruments, Inc., Foster City, CA). At least two hybridizations were performed at each time point. In addition, a semiquantitative inspection of the hybridization results was performed for (1) green signal (down regulation); (2) yellow signal (no obvious regulation); and (3) red signal (up regulation).

Data analysis

The cy3 and cy5 signal intensities were quantified by Gene Pix Pro 3.0 software (Axon Instruments, Inc., Foster City, CA). Subsequently, we normalized the obtained numerical data with classical linear regression techniques. In brief, quantified cy3 and cy5 signal intensities were obtained when foreground signal intensities were deducted by background signal intensities and cy5 signal intensities were replaced by 200 when it was <200. When R_i ($R_i = \text{cy5}/\text{cy3}$) was between 0.1 and 10, R_i was taken logarithms base natural to generate R_i' [$\log(R_i)$] and ND was taken by EXP (R_i') (averaged R_i'). The modified cy3^* was generated when ND was multiplied by cy3, and was replaced by 200 when it was <200. The ratio was expressed as $\text{cy5}/\text{cy3}^*$. Therefore, we selected genes whose ratio was more than 2 or less than 0.5 representing a 2-fold difference in expression level. To analyze the selected gene expression data, we applied κ -means cluster analysis, and performed

GeneMaths hierarchical clustering to appraise the number of groups. Whole analyses were executed with Microsoft Excel (Microsoft, Redmond, WA) and GeneSpring (Silicon Genetics, San Carlos, CA).

RESULTS

Category and expression changes of genes related to rat liver regeneration

Among the tested 551 genes, 216 were identified to be altered by more than 2-fold in intensity at least at one time point in the 0-36-72-96-144 h SISPH. Of the 216 identified genes, 111 were up-regulated and 105 were down-regulated. Ninety-nine of these 216 genes were unreported genes and the other 117 were reported, of which quite a few genes had not been reported to be involved in LR. Based on the functions and the time points at which they showed maximum up- or down-regulation, those reported genes were respectively involved in stress response, glycometabolism, fat and stearyl metabolism, oxidation and reduction response, regulation-proteins, glycoproteins, lipid-proteins, nucleolar proteins, receptors, factors, hemoglobins, immunological proteins, chaperonins, cytoskeletons, marker proteins, amino acid enzymes, proteolytic enzymes, proteinase inhibitors, phosphorylases, phosphatases, synthases and transferases (Table 1).

Gene expression differences at various time points of the 0-36-72-96-144 h SISPH

The gene expression profiles at different time points were generalized at 36, 36-72, 36-96, 36-144, 72, 72-96, 72-144, 96, 96-144, 144 h, and it was found that at 36 h of SISPH, 17 genes were up-regulated and 2 were down-regulated; at the time points of 36 h and 72 h of SISPH, 3 genes were up-regulated and 3 down-regulated; at the time points of 36 h and 96 h of SISPH, only 2 genes were up-regulated; at the time points of 36 h and 144 h of SISPH, 32 genes were up-regulated and 23 genes down-regulated, which is the largest group at all time points of SISPH; at 72 h of SISPH, 13 genes were down-regulated and 12 up-regulated. At the time points of 72 h and 96 h of SISPH, 5 genes were down-regulated and 4 up-regulated; at the time points of 72 h and 144 h of SISPH, 14 genes were up-regulated and 21 down-regulated; at 96 h of SISPH, one gene were up-regulated and 6 down-regulated; at the time points of 96 h and 144 h of SISPH, 10 genes were down-regulated and 7 up-regulated; at 144 h of SISPH, 11 genes were up-regulated and 31 down-regulated. Briefly, the LR of 0-36-72-96-144 h SISPH involved 216 elements, of which, 111 were up-regulated and 105 were down-regulated (Figure 1).

Gene expression level in the regenerating rat liver of 0-36-72-96-144 h SISPH

According to the up-regulated and down-regulated intensity of genes in the 0-36-72-96-144 h SISPH, we categorized the genes into 3 groups: (1) 105 genes were down-regulated by less than 50%; (2) 93 genes were up-regulated by 2-5 fold; (3) 18 genes were strongly up-regulated by more than 5-fold (Figure 2).

Hierarchical cluster analysis of genes expressed in the liver regeneration

The expression profile of the 216 genes altered by more than 2-fold in intensity at least at one time point in the 0-36-72-96-144 h SISPH was emanative to the last time point, indicating that at 144 h of SISPH, the liver regeneration has not been completed yet (Figure 3A). We undertook hierarchical clustering of 5 time points (0, 36, 72, 96 and 144 h) of SISPH using GeneSpring software and discovered that gene expression profiles had no similarity at the four time points (Figure 3B).

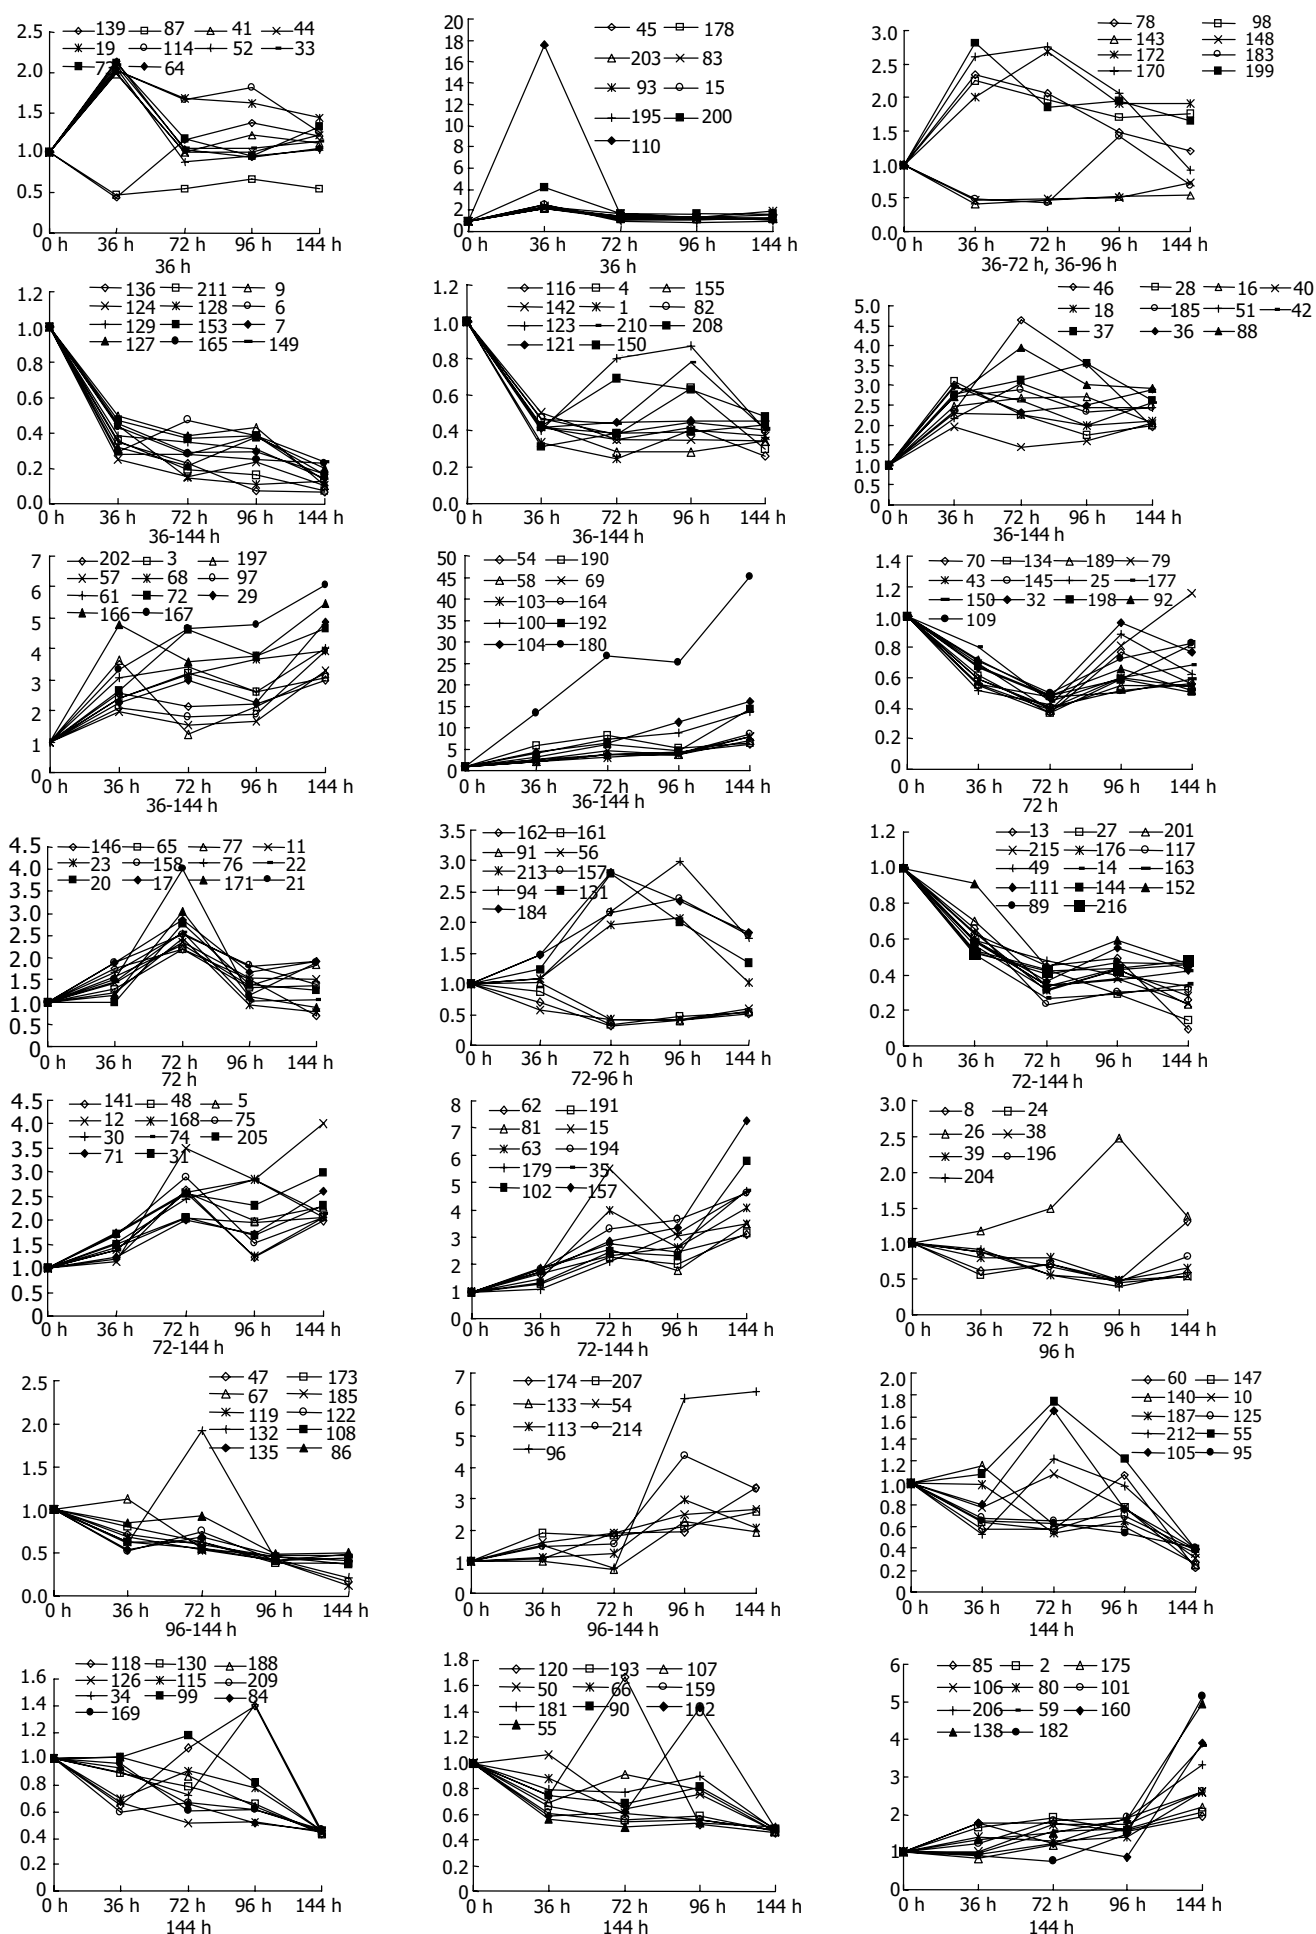

Figure 1 Gene expression differences in the regenerating rat liver of 0-36-72-96-144 h SISPH.

Figure 2 Expression level of genes in the regenerating rat liver of 0-36-72-96-144 h SISPH.

Figure 3 Cluster analysis of 216 elements. A: The difference of their intensity was identified more than two-fold at least at one time point. B: A hierarchical clustering of five time points indicated that the genes at these time points hardly had a common expression profile.

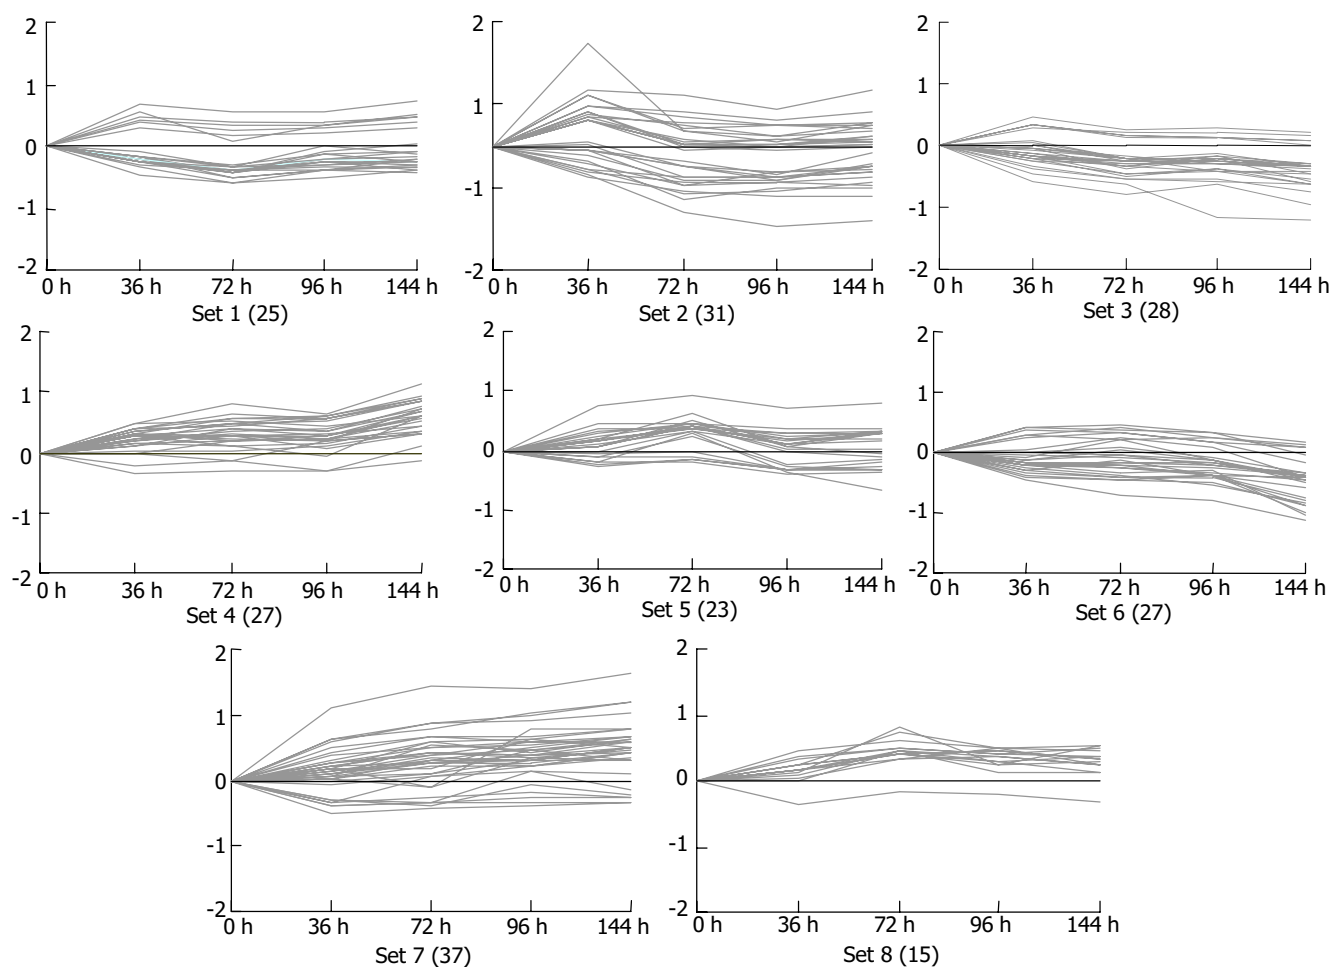

Figure 4 Cluster analysis of gene expression profiles identified by cDNA microarray. These genes were classified into 8 clusters by the κ -means method.

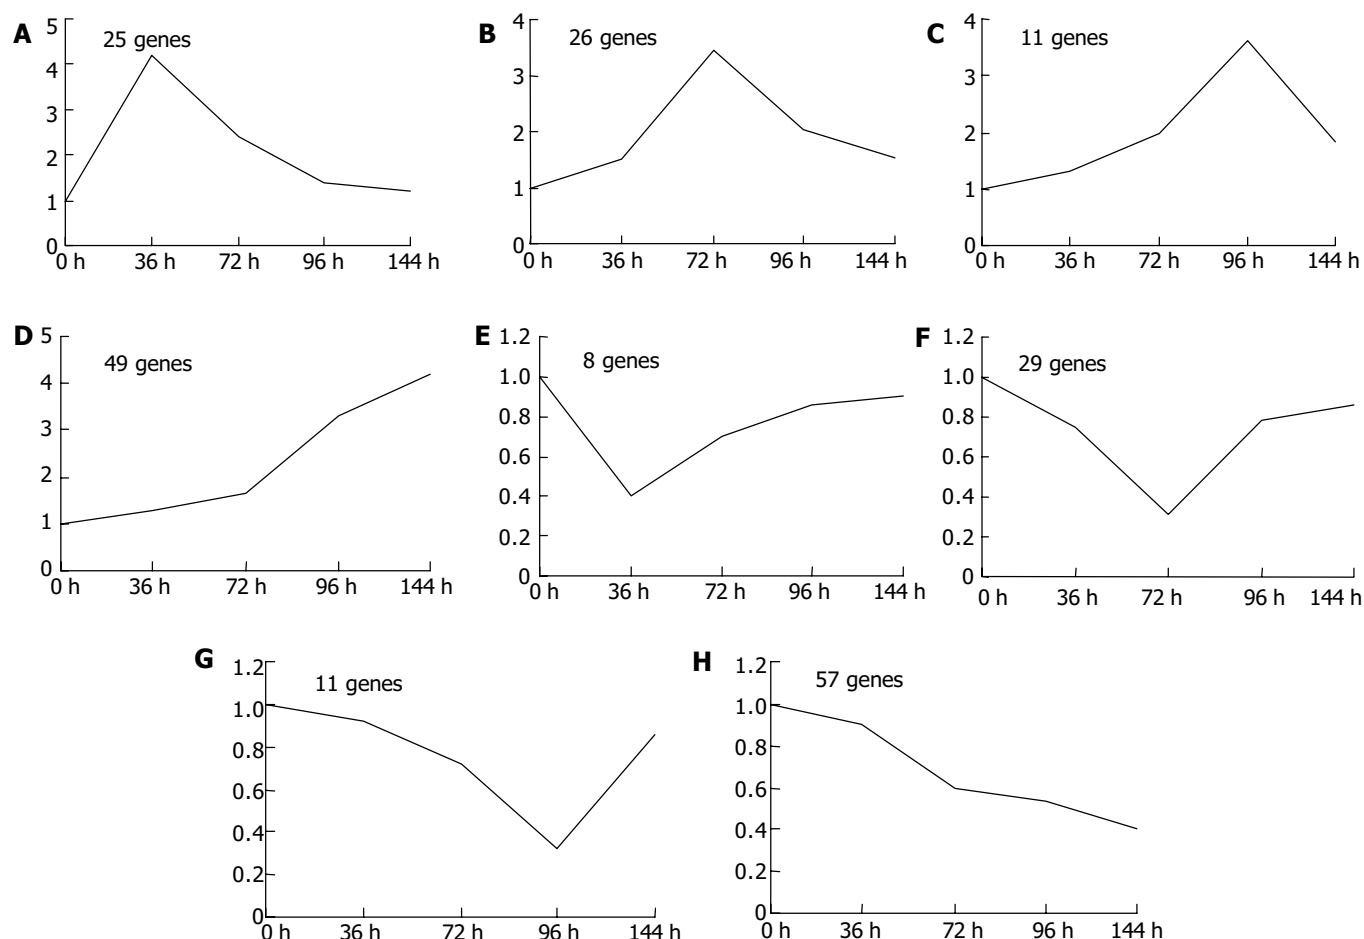

Figure 5 Category of the 216 elements. Based on the results of the cluster analysis, eight distinct temporal patterns were designated. A: Immediate induction, B: Middle induction, C: Late induction, D: Consistent induction, E: Immediate suppression, F: Middle suppression, G: Late suppression, H: Consistent suppression.

To facilitate the visualization and interpretation of the gene expression program presented in this very large body of data, we used the method of κ -means to order genes on the basis of similarities in their expression patterns and displayed the results in a compact graphical format, generating 8 kinds of ramose gene expression clusters (Figure 4). We then categorized the selected elements into 8 distinct temporal induction or suppression patterns: immediate induction, middle induction, late induction, consistent induction, immediate suppression, middle suppression, late suppression, consistent suppression (Figure 5).

Comparison of gene expression in SISPH with that after PH

Comparison of gene expression profile in SISPH with that after PH revealed that 56 genes were specially induced by SISPH, and the expression of 160 genes was altered simultaneously with the same trend in both SISPH and PH, but the time points of their expression and degree of up-regulation and down-regulation were different (Table 2).

DISCUSSION

This study found that 111 genes were up-regulated in the 0-36-72-96-144 h SISPH, suggesting that they could promote the liver growth, development and regeneration. It was also found that a large number of genes were related to positive and negative acute phase reaction to the successive hepatectomy, which suggests that these genes might regulate the balance of cell proliferation and death in the acute-phase response.

In the 25 genes up-regulated to reach the highest level at 36 h

of 0-36-72-96-144 h SISPH, 20 genes were decreased immediately to control level after the peak of 36 h, but 5 kept a high level until 144 h of SISPH. Among them, 3-phosphoglycerate dehydrogenase (PGDH) was reported to catalyze the first step in serine biosynthesis and was increased in regenerating liver^[21-23]. Prostaglandin D2 synthase 2 was confirmed to play an important role in reproduction as a PGD2-producing enzyme and a retinoid transporter^[24,25]. Phosphoprotein 1 was involved in regulation of hepatocyte proliferation in LR^[26]. The maximum expression of these genes at 36 h of SISPH showed that they could regulate hepatocyte multiplication after the peak of DNA replication in LR.

In the 27 genes up-regulated to reach the highest level at 72 h of 0-36-72-96-144 h SISPH, 12 of them declined gradually to control level at 96-144 h, and 6 did not decline until 144 h of SISPH, of which *eIF4A1* was reported to control melanoma cell proliferation by over expression^[27], whose up-regulation was assumed to accelerate protein synthesis at 72 h of SISPH. Actin γ played specific roles in the growth of liver parenchymal cells in the LR of SISPH^[28]. Cocoa extract could protect against early alcohol-induced liver injury in the rat^[29], whose conduction at 72 h was presumed to be involved in relieving hepatocytes from alcohol damage in LR of SISPH. Alpha-2-macroglobulin (A2M) was confirmed to reduce paracrine- and autocrine-stimulated extracellular matrix synthesis by scavenging TGF- β ^[30]. The successive induction of alpha 2-macroglobulin, a multifunctional binding protein with protease and cytokine scavenging properties^[31], may restrain protein degradation and termination of TGF- β in LR. The increase of HSP40 at 72 h means that lots of newly synthesized proteins need to correctly

fold with help of HSP40 in LR of SISPH.

In the 11 genes up-regulated to reach the highest level at 96 h of 0-36-72-96-144 h SISPH, cytochrome P450 cholesterol 7- α -hydroxylase (CYP7) is confirmed to regulate the protein modeling and the mRNA level in response to multiple physiological activities, including liver cholesterol synthesis, bile acid feedback inhibition, and diurnal rhythm^[32,33]. The conduction of CYP7 at 96 h is supposed to relate with cholesterol synthesis and hormone regulation in LR of SISPH.

In the 48 genes up-regulated to reach the highest level at 144 h of 0-36-72-96-144 h SISPH, plasma fibronectin was decreased in favor of LR impairment^[34-36], its expression at 144 h indicated that fibronectin-mediated function between the cells and the extracellular matrix was active in LR of SISPH. α -1-macroglobulin, serine protease inhibitor 1, angiotensinogen (Agt), fibrinogen γ , pregnancy-zone protein (Pzp) were always up-regulated from 36 h to 144 h of 0-36-72-96-144 h SISPH, suggesting that they are necessary for inhibiting proteolysis and facilitating cell growth and connection at these time points of SISPH. α -1 major acute phase protein (alpha 1-MAP) is one of the cysteine protease inhibitors^[37]. Complement component 5 can increase hepatic glycogenolysis by a prostanoid-mediated intercellular communication between Kupffer cells and hepatocytes^[38]. Fc- γ receptor III is responsible for IgG-dependent cell cytotoxicity and production of several cytokines and chemokines and involved in macrophage inflammatory protein 1 α (MIP-1 α) and neutrophil influx^[39-41]. JE/MCP-1 is known as a CC chemokine attracting monocytes, basophils and T-lymphocytes^[42,43]. Serum amyloid A-5 (SAA-5) is a major acute-phase protein synthesized and secreted mainly by the liver^[44], and is increased in response to acute inflammation in LR of SISPH. T-kininogen and kininogen are promoters to IL-6 as LR signal. These genes were always up regulated from 36 h to 144 h of 0-36-72-96-144 h SISPH, suggesting that they are necessary for relinquishing inflammation and promoting growth in whole SISPH.

This study found that 105 genes were suppressed in 0-36-72-96-144 h SISPH and a large number of them were related to energy metabolism, suggesting that they restrain LR by various paths, and that the need for energy in LR of SISPH is not as important as for other demand, which is different after PH.

Eight genes were suddenly down-regulated at 36 h after SISPH, including histidine-rich glycoprotein (HRG), apolipoprotein C-I (Apo C-I), retinol-binding protein (PRB), cytochrome P450 3A1 (Cyp3A1), RNase A family 4, carnitine O-octanoyltransferase (Crot), cytochrome b5 (Cyb5), *etc.* Histidine-rich glycoprotein (HRG) is confirmed an abundant serum exhibit protein in diverse biological systems, whose combination with zinc could be used as an antidote for heparin^[45,46]. Therefore, the down-regulation of HRG at 36 h indicated that the increased activity of heparin is essential for LR of SISPH. Apo C-I is known associated with the lipid surface of the plasma chylomicron, VLDL, and HDL subfractions, and reverse transfer from VLDL to HDL and to SBV^[47], acting as a major plasma inhibitor of cholesteryl ester transfer protein and phospholipase inhibitor^[48,49]. From the above evidence, a low level of Apo C-I at 36 h is supposed to facilitate lipoprotein linkage to LDL receptor, LDL receptor-related protein, and VLDL receptor, as well as fatty acid uptake of hepatocytes in LR of SISPH. Cyp3A1 enzymes belong to the most abundant subfamily of the cytochrome P-450 system that is predominantly found in the liver where they metabolize numerous drugs and endogenous substances such as oestrogens^[50]. The down-regulation of cyp 3A1 suggested that the harm induced by hepatectomy was presumably distinct from that by drugs and endogenous substances in rat liver.

Twenty-nine genes were suppressed and had a minimum expression at 72 h in after SISPH. Among them, angiopoietin-like protein 3 (Angptl3) is reported to activate lipolysis in adipocytes

as a vascular endothelial growth factor by response to the liver X receptor (LXR)^[51]. The extensive suppression of angiopoietin-like protein 3 mRNA at 72 h suggested that the activity of lipolysis of hepatocytes was very low in LR of SISPH. Acyl-CoA can play many important roles in numerous biochemical reactions, such as tricarboxylic acid cycle, glycoxylate bypass, fatty acid synthesis. The mRNA level of acyl-coA oxidase was first dropped to meet the condition and later increased to eliminate over expressed acyl-CoA in LR of SISPH.

Hpcl 2 was expressed at 96 h in SISPH, and involved in the carbon-carbon bond cleavage as peroxisomal pyrophosphate-dependent enzyme during α -oxidation of 3-methyl-branched fatty acids^[52,53]. Down-regulation of Hpcl 2 can protect phytanic acid against being broken down, which may store energy during LR of SISPH. Fmo1 can lead to the decrease of cytochrome P-450^[54], which was repressed at 96 h to accommodate electronic environment for hepatocyte multiplication in LR of SISPH.

Retinoic acid is known necessary for the maintenance of many lining epithelia of the body, whereas retinol dehydrogenase can catalyze the first step in retinoic acid biosynthesis^[55]. Its suppression at 144 h after SISPH demonstrates that retinoic acid is not necessary in late phase of LR. In normal liver the activity of ADH is in excess, while in regenerating rat liver, the rate of ethanol elimination may be limited by the activity of alcohol dehydrogenase in SISPH^[56]. Cathepsin C (Ctsc) and dipeptidyl aminopeptidase I are regarded to play an important role in protein degradation and the activation of proenzyme in rat liver^[57]. The down-regulation of cathepsin C may be due to the indispensability of peptide for protein construction in LR of SISPH. Hepatectomy is reported to decrease liver cytochrome P450 levels by inducing heme oxygenase and inhibiting ALA synthase activities^[58], which was inhibited at 144 h to regulate the oxidation reaction of hepatocytes in LR of SISPH. Glutathione S-transferase (GST) is a family of conjugative enzymes that catalyze nucleophilic addition of tripeptide glutathione to xenobiotics carcinogens and endogenous lipophilic compounds^[59]. It was manifested that xenobiotics carcinogens and endogenous lipophilic might produce some uncertain toxic effect on LR of SISPH. Glutathione S-transferase type 3 (Yb3) mRNA was always hampered, implying that over accumulation of Yb3 could lead to contrary reaction. Fatty binding protein is well known to transfer fat from cytoplasm to nuclear or membrane, and fatty acid elongase 1 (rELO1) catalyzes short chain fat transition to long chain fat. The repression of its mRNA in SISPH indicates that long chain fatty acid was not in badly need until 144 h in LR of SISPH. Leuserpin-2 (Sperpin1) was confirmed to participate in complement activation in fibrinolysis and inflammatory response^[60], which was continuously repressed in SISPH, suggesting that it can regulate inflammatory response to improve severely injured hepatocytes in LR of SISPH. Myelin-associated glycoprotein (MAG)-binding activity of novel sulfated GM1b, high-affinity ligands for neural singes is important to nervous system regeneration^[61]. The repression of MAG at 144 h of SISPH may result in mild damage of hepatocytes and nerve system in late phase of LR.

In conclusion, further experiments will be done by using sham surgical rats as control, so as to confirm which genes reported in this paper are related to surgical operation, and which are really related to liver regeneration.

ACKNOWLEDGEMENTS

Abstract

AIM: To investigate the effects and mechanisms of melatonin on immunological liver injury in mice.

METHODS: A model of liver injury was induced by tail vein injection of *Bacillus Calmette Guerin* (BCG) and lipopolysaccharide (LPS) in mice. Kupffer cells and hepatocytes were isolated and cultured according to a modified two-step collagenase perfusion technique. Levels of alanine aminotransferase (ALT), aspartate aminotransferase (AST) and nitric oxide (NO), content of malondialdehyde (MDA), activity of superoxide dismutase (SOD), were measured by biochemical methods. Tumor necrosis factor- α (TNF- α) activity was determined by RIA. Interleukin (IL)-1 activity was measured by thymocyte proliferation bioassay. Hepatic tissue sections were stained with hematoxylin and eosin and examined under a light microscope.

RESULTS: Immunological liver injury induced by BCG+LPS was successfully duplicated. Serum transaminase (ALT, AST) activities were significantly decreased by melatonin (0.25, 1.0, 4.0 mg/kg bm). Meanwhile, MDA content was decreased and SOD in liver homogenates was upregulated. Furthermore, pro-inflammatory mediators (TNF- α , IL-1, NO) in serum and liver homogenates were significantly reduced by melatonin. Histological examination demonstrated that melatonin could attenuate the area and extent of necrosis, reduce the immigration of inflammatory cells. In *in vitro* experiment, TNF- α was inhibited at the concentrations of 10^{-8} - 10^{-6} mol/L of melatonin, while IL-1 production of Kupffer cells induced by LPS (5 μ g/mL) was decreased only at the concentration of 10^{-6} mol/L of melatonin, but no effect on NO production was observed. Immunological liver injury model *in vitro* was established by incubating hepatocytes with BCG- and LPS-induced Kupffer cells. Activities of ALT, TNF- α , IL-1, and MDA in supernatant were significantly increased. Melatonin had little effect on the level of ALT, but reduced the content of TNF- α and MDA at concentrations of 10^{-7} - 10^{-5} mol/L and decreased the content of IL-1 at concentrations of 10^{-6} - 10^{-5} mol/L.

CONCLUSION: Melatonin could significantly protect liver injury in mice, which was related to free radical scavenging, increased SOD activity and pro-inflammatory mediators.

INTRODUCTION

Viral infection, alcoholic or drug toxicity, or any other factors that cause damage to hepatocytes elicit an inflammatory reaction in the liver. The damaged hepatocytes, their membrane components, metabolites of toxic agents, and infiltrating inflammatory cells are the activators of Kupffer cells. Kupffer cells, the resident macrophages in the sinusoids of the liver, play significant roles in immunomodulation, phagocytosis, and biochemical attack^[1,2]. It has been reported that Kupffer cells to be activated are considered the key evidence in the pathophysiology of many animal models of hepatic injury^[3-8]. Activated Kupffer cells contribute to the onset of liver injury by producing and releasing cytotoxic agents such as pro-inflammatory cytokines including tumor necrosis factor alpha (TNF- α)^[9,10], interleukin-1 (IL-1)^[9], interleukin-6 (IL-6) and active oxygen^[11], nitric oxide (NO)^[8] which damage sinusoidal endothelial cells and hepatocytes. Previous studies have shown that elimination of Kupffer cells by gadolinium chloride^[5] and TNF- α antibodies are effective on reducing hepatic damage *in vivo*.

Ferluga *et al.* first reported the *P. acnes*-primed LPS-induced hepatic shock model in mice in 1978^[12], and three years later Ferluga also reported that LPS injection subsequent to the priming of *Bacillus Calmette-Guerin* (BCG) provoked the same hepatic injury in mice^[13]. Since then, many investigators have tried to explain the mechanism of the above two similar models^[14,15]. It is known that *P. acnes* or BCG priming and LPS challenge in mice cause massive liver injury, which consists of priming and eliciting phases. *P. acnes* or BCG priming induces mononuclear cell infiltration into the liver lobules and granuloma formation^[16]. The subsequent LPS injection elicits acute and massive hepatic injury, with a concomitant release of various cytokines and active free radicals^[17-21]. Thus, in immunological liver injury model induced by BCG and LPS, hepatocyte damage is presumably caused by immunological mechanisms. Pro-inflammatory cytokines and active free radicals produced by activated Kupffer cells play an important role in the progress of the resulted liver injury. This experimental immunological liver injury has frequently been used as a model for testing and developing new drugs^[12,13,22-24].

The hormone melatonin (N-acetyl-5-methoxytryptamine) is synthesized by pineal gland. Melatonin participates in many important physiological functions, including anti-inflammation^[25] and immunoregulation^[26,27], as well as acting as a broad spectrum antioxidant^[28-30]. In addition, melatonin protects against liver injury induced by endotoxin shock^[31,32] and ischemia/reperfusion^[33,34] in rats through its antioxidant action. The purpose of this study was to investigate whether exogenous melatonin would protect against BCG- and LPS-induced immunological liver injury in mice via antioxidative and immunoregulatory mechanisms. Meanwhile, the direct effect of melatonin on isolated Kupffer cells or co-cultured Kupffer cells and hepatocytes *in vitro* was studied.

MATERIALS AND METHODS

Materials

Melatonin, purchased from Sigma Chemical Co. (St Louis, Mo, USA), was dissolved in 9 g/L saline with absolute ethanol (≤ 0.1 mL/L) and stored at -20°C . 3-[4,5-dimethylthiazol-2-yl]-2,5-diphenyltetra-zolium bromide (MTT), RPMI 1640, Hepes buffer, collagenase IV, Pronase E, DNase, Nycodenz and LPS from *Escherichia coli* were obtained from Sigma Chemical Co (St Louis, Mo, USA). Commercial kits used for determining lipid peroxidation and superoxide dismutase (SOD) activity were obtained from the Jiancheng Institute of Biotechnology (Nanjing, China). Other chemicals used in these experiments were of analytical grade from commercial sources.

Animals

Male Sprague-Dawley (SD) rats (300 ± 20 g), C57BL/6J mice (18 ± 2 g) and male Kunming mice (20 ± 2 g), obtained from the Animal Department of Anhui Medical University, were maintained on a 12 h light/ dark cycle from 6AM to 6PM in a controlled environment ($20 \pm 1^{\circ}\text{C}$). Animals were housed in plastic cages with free access to food and water. All experimental protocols described in this study were approved by the Ethics Review Committee for Animal Experimentation of Institute of Clinical Pharmacology, Anhui Medical University.

Establishment of immunological liver injury model^[8,13]

A 2.5 mg dose of BCG (viable bacilli) suspended in 0.2 mL saline was injected via the tail vein into each animal, and 10 d later, 7.5 μg LPS dissolved in 0.2 mL saline was injected. Mice were anesthetized with ether, then sacrificed by cervical dislocation 16 h after LPS injection and trunk blood was collected into heparinized tubes (50 U/mL) and centrifuged (1 500 r/min, 10 min, 4°C). Serum was aspirated and stored at -70°C until assayed as described below. The liver was also removed and stored at -70°C until required.

Drug treatment

In vivo experiment, the animals were equally divided into 5 groups randomly, including normal, model control and melatonin groups (3 different doses). Mice in melatonin groups were received daily doses of 0.25, 1.0 or 4.0 mg/kg bw of melatonin using an 18-gauge stainless steel animal feeding needle for 10 d prior to LPS injection. Mice in normal and model control group were only fed the same volume of vehicle.

In *in vitro* experiment, after Kupffer cells were isolated from normal rat, the cells were divided into 7 groups randomly, including control cells, cells added with LPS (5 $\mu\text{g}/\text{mL}$) alone, cells added with LPS (5 $\mu\text{g}/\text{mL}$) simultaneously with melatonin (5 different concentrations including 10^{-9} , 10^{-8} , 10^{-7} , 10^{-6} , 10^{-5} mol/L). Every group had triplicate wells and the experiment above was repeated twice.

In another *in vitro* experiment, after Kupffer cells were isolated from BCG priming rat and hepatocytes isolated from normal rat, the two types of cells were divided into 7 groups randomly, including control cells, cells added with LPS (5 $\mu\text{g}/\text{mL}$) alone, cells added with LPS (5 $\mu\text{g}/\text{mL}$) simultaneously with melatonin (5 different concentrations including 10^{-9} , 10^{-8} , 10^{-7} , 10^{-6} , 10^{-5} mol/L). Every group had triplicate wells and the experiment above was repeated twice.

Isolation and culture of Kupffer cells and hepatocytes

In vitro experiment, the direct effect of melatonin on Kupffer cells was studied by isolating Kupffer cells from the livers of normal rat. Rat liver perfusion was performed using a modification of the two-step collagenase perfusion technique introduced by previous studies^[35,36].

In brief, the rat liver was perfused through the portal vein with D-Hank's until blood free, and then with Hank's containing 0.5 g/L collagenase IV. The latter was administered by recirculation until the vessels were digested (up to 20 min). The liver was then scraped using a cell scraper, filtered through a 100- μm filter, and stirred in Hank's containing 2.5 g/L pronase and 0.05 g/L DNase for 20 min at 37°C . After three times of centrifugation and washing at $300 \times g$ for 10 min at 4°C in Gey's balanced salt solution (GBSS), cells were centrifuged in an 180 g/L Nycodenz gradient at $2\,500 \times g$ for 20 min. Kupffer cells were carefully sucked by cusp-straws at the pearl layer interphase. At last, purified Kupffer cell fractions were obtained by centrifugal elutriation. The viability of Kupffer cells prepared was more than 95% as determined by trypan blue exclusion. The purity of Kupffer cells was greater than 90% based on a peroxidase activity assay^[37].

Kupffer cells, obtained as described above, were washed with Hanks' and resuspended in RPMI 1640 medium containing antibiotics (penicillin, 100 U/mL; streptomycin, 100 mg/mL), 2 mmol/L glutamine, and 100 mL/L fetal calf serum. One-milliliter aliquots containing 1×10^6 cells were added to 24-well culture plates. The cells were incubated for 60 min in a humidified atmosphere containing 50 mL/L CO_2 at 37°C . Nonadherent cells were removed, and adherent cells were washed twice with PBS. The cells at a density of $1 \times 10^6/\text{mL}$ were incubated with different concentrations of melatonin (10^{-9} , 10^{-8} , 10^{-7} , 10^{-6} , 10^{-5} mol/L). They ($1 \times 10^6/\text{well}$) were cultured for 48 h with 5 $\mu\text{g}/\text{mL}$ LPS and the supernatants were collected and TNF- α and NO concentration measured with the methods described below.

In *in vitro* liver injury model, BCG induced Kupffer cells were isolated from the livers of the rats which were injected via the tail vein with 3 mg of BCG 10 d before, at the same time hepatocytes isolated from normal rat. The hepatocytes at a density of $1 \times 10^9/\text{mL}$ were incubated with different concentrations of melatonin (10^{-9} , 10^{-8} , 10^{-7} , 10^{-6} , 10^{-5} mol/L) and BCG-induced Kupffer cells ($1 \times 10^6/\text{well}$). They were co-cultured for 48 h with 5 $\mu\text{g}/\text{mL}$ LPS and the supernatants were collected.

Measurement of serum ALT and AST

Serum ALT and AST were determined using commercial kits produced by Jiancheng Institute of Biotechnology (Nanjing, China). Their activities were expressed as an international unit (U/L).

Measurement of NO in serum and cell culture supernatants

Nitric oxide (NO) in Kupffer cells was measured by a microplate assay using Griess reagent, which produces a chromophore with the nitrite^[38]. Briefly, 100 μL of cell culture supernatants was removed and incubated with 100 μL of Griess reagent (10 g/L sulfanilamide and 1 g/L N-1-naphthylethylenediamine dihydrochloride in 25 mL/L phosphoric acid) in a 96-well plate. The plate was incubated for 10 min at room temperature. Nitrite production was quantified spectrophotometrically using an automated colorimetric procedure. Absorbance at 540 nm was measured using a microplate reader (Bio-Tek, USA). The nitrite concentration was calculated by comparing samples with standard solutions of sodium nitrite produced in the culture medium. All samples were assayed in triplicate. Results were expressed as $\mu\text{mol}/\text{L}$.

Measurement of MDA and SOD in liver homogenates

Livers were thawed, weighed and homogenized with Tris-HCl (5 mmol/L containing 2 mmol/L EDTA, pH 7.4). Homogenates were centrifuged (1 000 r/min, 10 min, 4°C) and the supernatant was used immediately for the assays of MDA and SOD. MDA and SOD were determined following the instructions of the kit. In brief, MDA in liver tissue was determined by the thiobarbituric

acid method^[39]. All samples were assayed in triplicate. The content of MDA was expressed as nmol per gram liver tissue. The assay for total SOD was based on its ability to inhibit the oxidation of oxyamine by the xanthine-xanthine oxidase system. The red product (nitrite) produced by the oxidation of oxyamine has an absorbance at 550 nm. One unit (U) of SOD activity was defined as the quantity that reduced the absorbance at 550 nm by 50%. All samples were assayed in triplicate. Results were expressed as U per gram liver tissue.

Measurement of TNF- α in serum and cell culture supernatants

Serum was assayed according to procedures described by the instruction of the commercial kits. The standard curve of TNF- α measured was between 2 and 160 pg/mL.

Bioassay of IL-1 activity in serum and cell culture supernatants

IL-1 activity was measured by mouse thymocyte activation assayed by MTT (Sigma) reduction^[40]. MTT was dissolved in sterile PBS to a concentration of 5 mg/mL and stored in the dark at 4 °C for up to 1 wk. Immediately before use, stock MTT was filtered (0.22 μ m) to remove any formazan precipitate. Thymocytes (2×10^6 /well) from mice were cultured for 48 h in 96-well plates containing RPMI 1640 medium supplemented with 5 μ g/mL concanavalin A and 0.1 mL collected supernatants in triplicate. Three hours before the termination of culture, cells were pulsed with MTT stock (20 μ L/well), returned to 37 °C and incubated for another 3 h. The plates were centrifuged for 10 min at 1 000 g to cell pellets and MTT formazan products. The supernatant was carefully aspirated without disturbing the pellets, and formazan was solubilized by addition of isopropanol (100 μ L/200 μ L supernatant). Insoluble material was then removed by centrifugation for 10 min at 1 000 g. The solubilized formazan in isopropanol was collected and distributed into 12-well flat-bottom ELISA plates at a final volume of 100 μ L/well. Plates were read at 570 nm in EL 301 Strip Reader (Bio-Tek, USA) within 1 h of addition of isopropanol. Values were expressed as mean absorbance (A) of triplicate wells.

Histological analysis

Formalin-fixed specimens were embedded in paraffin and stained with hematoxylin and eosin for conventional morphological evaluation. After decapitation of rats, small liver specimens were placed in 100 mL/L formalin solution and processed routinely by embedding in paraffin. Tissue sections (4-5 μ m) were stained with hematoxylin and eosin and examined under light microscope (Olympus). An experienced histologist who was unaware of the treatment conditions made histological assessments.

Statistical analyses

All values were presented as mean \pm SE. Statistical analysis of the data for multiple comparisons was performed by one-way analysis of variance (ANOVA) followed by Duncan's test. For a single comparison, the significance of differences between means was determined by the *t*-test. A level of $P < 0.05$ was accepted as statistical significant.

RESULTS

Effect of melatonin on serum ALT and AST

Activities of both serum AST and ALT, indices of hepatic cell damage, were significantly higher in BCG- and LPS-induced group than in the control group. Melatonin (0.25, 1.0, 4.0 mg/kg bm) significantly reduced the activities of serum AST and ALT (Table 1).

Effect of melatonin on liver homogenate MDA and total SOD

Liver homogenate malondialdehyde (MDA) content in BCG-

and LPS-induced group was significantly higher than that in the control group while liver total SOD activity was lower. Melatonin (0.25, 1.0, 4.0 mg/kg bm) significantly attenuated MDA generation and increased liver total SOD activity (Table 2).

Table 1 Effects of melatonin on serum ALT and AST activities in immunological liver injury in mice ($n = 10$, mean \pm SE)

Group	Dose (mg/kg bm)	ALT (U/L)	AST (U/L)
Normal	---	28.2 \pm 8.8	26.8 \pm 8.5
Model	---	224 \pm 40 ^d	205 \pm 40 ^d
Melatonin	0.25	187 \pm 21 ^a	129 \pm 13 ^b
	1.0	119 \pm 41 ^b	124 \pm 36 ^b
	4.0	163 \pm 44 ^b	162 \pm 33 ^a

^a $P < 0.05$, ^b $P < 0.01$ vs model group; ^d $P < 0.01$ vs normal control group.

Table 2 Effects of melatonin on MDA level and SOD activity of liver homogenates of immunological injury mice ($n = 10$, mean \pm SE)

Group	Dose (mg/kg bm)	MDA (nmol/g tissue)	SOD (U/g tissue)
Normal	---	92 \pm 26	297 \pm 22
Model	---	439 \pm 25 ^d	202.46 \pm 26 ^d
Melatonin	0.25	335 \pm 37 ^b	266 \pm 71 ^b
	1.0	332 \pm 28 ^b	273 \pm 31 ^b
	4.0	346 \pm 17 ^b	244 \pm 27 ^b

^a $P < 0.05$, ^b $P < 0.01$ vs model group; ^d $P < 0.01$ vs normal control group.

Effect of melatonin on serum and liver homogenate TNF- α , IL-1 and NO concentration

As shown in Table 3, when mice were first injected with BCG and then challenged with LPS, the levels of TNF- α , IL-1 and NO were elevated significantly. Melatonin (0.25, 1.0 and 4.0 mg/kg bm) obviously reversed these effects. Similarly, in liver homogenates of immunological injury mice the levels of above three indices increased and melatonin (0.25, 1.0 and 4.0 mg/kg bm) significantly inhibited the production of TNF- α and NO while melatonin (4 mg/kg bm) inhibited IL-1 (Table 4).

Table 3 Effects of melatonin on serum TNF- α , IL-1 and NO levels in immunological liver injury mice ($n = 10$, mean \pm SE)

Group	Dose (mg/kg bm)	TNF- α (ng/L)	IL-1 ($A_{570\text{ nm}}$)	NO (μ mol/L)
Normal	---	1.61 \pm 0.76	0.107 \pm 0.001	9.82 \pm 1.92
Model	---	4.80 \pm 1.61 ^d	0.242 \pm 0.03 ^d	73 \pm 19 ^d
Melatonin	0.25	3.42 \pm 1.08 ^a	0.183 \pm 0.07 ^a	55 \pm 18 ^a
	1.0	3.26 \pm 0.73 ^a	0.131 \pm 0.04 ^b	28 \pm 14 ^b
	4.0	2.64 \pm 1.19 ^b	0.158 \pm 0.04 ^b	56 \pm 19 ^a

^a $P < 0.05$, ^b $P < 0.01$ vs model group; ^d $P < 0.01$ vs normal control group.

Effect of melatonin on NO, TNF- α and IL-1 production of isolated Kupffer cells

In vitro, melatonin at the concentrations of 10^{-8} - 10^{-6} mol/L was able to inhibit directly the production of TNF- α while only at the concentrations of 10^{-6} mol/L decreased IL-1 production of Kupffer cells co-cultured with LPS (5 μ g/mL). However, melatonin had no effect on NO production (Table 5).

Table 4 Effects of melatonin on TNF- α , IL-1 and NO levels of liver homogenates in immunological injury mice ($n = 10$, mean \pm SE)

Group	Dose (mg/kg bm)	TNF- α (ng/L)	IL-1 ($A_{570\text{ nm}}$)	NO ($\mu\text{mol/L}$)

Effect of melatonin on liver injury in mice *in vitro*

Immunological liver injury model *in vitro* was established by hepatocytes incubated with BCG- and LPS-induced Kupffer cells. Activities of ALT, TNF- α , IL-1 and MDA in supernatant

were significantly increased. Melatonin had little effect on the level of ALT, but at concentrations of 10⁻⁷-10⁻⁵ mol/L it reduced the content of TNF- α and MDA while at concentrations of 10⁻⁶-10⁻⁵ mol/L it decreased the content of IL-1 (Table 6).

Histological results

In normal group, there was no pathological abnormality. Liver parenchyma was in good morphology and hepatocytes were arranged around the central vein. No congestion and inflammation were observed in the sinusoids (Figure 1A).

In model group, there was a severe pathological abnormality. Hepatocytes were with marked vacuolization, moreover, hepatocytes dot necrosis, striped necrosis, bridging necrosis appeared and inflammatory cells arranged around the necrotic tissue. Congestion in liver sinusoids was significant with scattered infiltration of inflammatory cells (Figure 1B).

In melatonin-treated group, the area and extent of necrosis attenuated and the immigration of inflammatory cells reduced. Liver parenchyma was well preserved with radially arranged hepatocytes around the central vein. Regular sinusoidal structures were seen without congestion (Figure 1C).

DISCUSSION

Injection of BCG followed by LPS is useful for the creation of experimental models of acute hepatic damage^[13,16,22,41]. In the present study, immunological liver injury in mice was successfully induced by BCG and LPS and the model *in vitro* also duplicated. On this basis, administration of melatonin *in vivo* resulted in marked reduction of acute liver injury, as demonstrated by significant reduction of serum transaminase concentration and amelioration of severe hepatic pathological abnormalities. Meanwhile, melatonin decreased MDA content and increased total SOD activity in liver homogenates. Furthermore, melatonin significantly reduced TNF- α , IL-1 and NO production in serum and liver homogenates. The *in vitro* experiment also supported

the direct protective role of melatonin in suppression of Kupffer cell function. Although melatonin had no direct protection on hepatocytes injury *in vitro* induced by BCG and LPS, it could inhibit the production of MDA and pro-inflammatory cytokines such as TNF- α and IL-1. Based on the current results, we propose that the mode of melatonin's hepatic protective action is, at least in part, related to its antioxidative and immunoregulatory properties.

As it is well known, melatonin, the chief secretory product of the pineal gland, was found to be a multi-faceted free radical scavenger and antioxidant. It detoxifies a variety of free radicals and reactive oxygen intermediates, including the hydroxyl radical, singlet oxygen, peroxynitrite anion and nitric oxide^[29,30]. In both *in vitro* and *in vivo* experiments, melatonin has been found to protect cells, tissues, and organs against oxidative damage induced by a variety of free-radical-generating agents and processes, *e.g.*, the carcinogen safrole, LPS, carbon tetrachloride, ischemia-reperfusion, amyloid-protein, and ionizing radiation^[42,43]. Melatonin also has been reported to stimulate the activities of enzymes and increase gene expression that improves the total antioxidative defense capacity of the organism, *i.e.*, SOD, glutathione peroxidase, glutathione reductase^[44,45]. Moreover, recent studies indicate that melatonin is effective on inhibiting oxidative liver damage. Calvo *et al.* found that melatonin protected against ANIT-induced liver injury with cholestasis in rats, and suggested that this protective effect was likely due to its antioxidative properties and above all to its capacity to inhibit liver neutrophil infiltration, a critical factor in the pathogenesis of ANIT-induced liver injury^[46]. Melatonin also could dose-dependently reduce liver lipid peroxide content in CCl₄ treated rats. This indicated that melatonin exerted a therapeutic effect on CCl₄-induced acute liver injury in rats, possibly through its antioxidant action. Melatonin plays a cytoprotective role in the liver insulted by ischemia and reperfusion by virtue of its ability to prevent hepatic malfunction and inhibit the generation of free radicals and accumulation of neutrophils in the damaged hepatic tissue^[35]. In the present study, the effects of melatonin on immunological liver injury model were firstly investigated. The results showed that melatonin decreased MDA content in liver homogenates, meanwhile, SOD activity rose significantly. Those results are in accordance with the findings of melatonin's antioxidative properties.

A growing body of evidence suggests that nitric oxide (NO) may also modulate different experimental liver injuries. The role, that NO plays in the process of liver injury has been the subject of active debate. *In vitro* and *in vivo* data suggest that NO may act to protect tissue by virtue of its ability to react with and decompose superoxide radical^[47-49]. It has also been suggested that NO may act to modulate the activity of certain transcription factors such as NF- κ B^[50]. Although some studies demonstrate that NO may act to limit or down-regulate liver injury, there are other reports suggesting that NO may actually promote hepatocellular damage possibly due to the formation of strongly oxidizing species peroxynitrite^[51]. Much of the controversy may be related to the use of non-specific inhibitors of different NOS isoforms and the concentration of NO^[52]. Melatonin is reported to inhibit peroxynitrite induced oxidative reactions. Additionally, melatonin under or near physiological concentration inhibits the prooxidative enzyme nitric oxide synthase (NOS) activity^[14,49] and thereby influences NO production. It was also reported that melatonin had protective effect in an endotoxic and non-septic shock partly related to prevention of NO overproduction. The present study showed that melatonin significantly inhibited serum NO and did not directly inhibit Kupffer cells and generate NO *in vitro*. The results demonstrated that melatonin might modulate the generation of NO at a whole body level but had no direct effect on Kupffer cells. It seems

likely that melatonin regulated NO production to a certain extent, but more studies should be carried out to clarify it.

As it is well known, TNF- α is a multifunctional cytokine mostly secreted by inflammatory cells and is involved in numerous pathological states. TNF- α is considered to be a common early effector molecule for liver injury, in addition to its direct cytotoxic effects, this cytokine is able to induce chemokines, macrophage chemotactic protein-1 and adhesive molecules, vascular-cell adhesion molecule-1, which are key to inflammation and consequent liver damage^[9-11]. Prevention of liver injury has been observed upon neutralization of TNF- α with anti-TNF- α antibody, prevention of translation of primary RNA transcript of TNF- α by antisense oligonucleotide and interaction of TNF- α with soluble TNF- α receptors^[53]. Although IL-1 itself does not exert damage on liver, its elevation could stimulate inflammatory cells to excrete many other cytokines including TNF- α , IL-6 and IL-8. Our results suggest that the elevation of inflammatory cytokines including TNF- α and IL-1 in serum, liver homogenates and Kupffer cell culture supernatants contributes to the mechanisms of immunological liver injury.

It is now well recognized that melatonin plays an important immunoregulatory role. Shin *et al.* found that low levels of *Bacillus anthracis* were known to induce release of cytokines such as TNF- α , and thereby exposure of melatonin (10^{-7} - 10^{-6} mol/L) to anthrax lethal toxin-treated macrophages also decreased the release of TNF- α to extracellular medium as compared to the control^[54]. Sacco found that administration of melatonin to mice (5 mg/kg bm, s.c. 30 min before or simultaneously with LPS) inhibited serum TNF- α levels by 50-80% and improved survival of mice treated with a lethal dose of LPS. Melatonin did not increase serum corticosterone and did not modify the elevation of serum corticosterone levels by LPS or by IL-1. Furthermore, it exerted its inhibitory effect in adrenalectomized or hypophysectomized mice also, indicating that its effect is independent of the hypothalamus-pituitary-adrenal axis^[55]. It was previously reported melatonin had a protective role in LPS-induced septic shock by suppressing pro-inflammatory cytokines, prostaglandins and NO production^[31,32]. However, other studies indicated melatonin did not alter cytokines including TNF- α and IL-1 secretion by LPS-stimulated macrophages^[56]. The inconsistencies in the literature suggested that the effect of melatonin on macrophages was complex. In our experimental condition, we found that in *in vitro* experiments melatonin at the concentrations of 10^{-8} - 10^{-6} mol/L directly inhibited production of TNF- α while only at the concentrations of 10^{-6} mol/L decreased IL-1 production of Kupffer cell co-cultured with LPS (5 μ g/mL). In *in vitro* liver injury model, we also found that melatonin at the concentrations of 10^{-7} - 10^{-5} mol/L reduced the content of TNF- α while at concentrations of 10^{-6} - 10^{-5} mol/L decreased the content of IL-1. Even more, *in vivo* experiment showed that melatonin at the dose between 0.25 mg/kg bm and 4.0 mg/kg bm significantly inhibited serum TNF- α and IL-1 level. Thus suppression of TNF- α and IL-1 could be one of the means by which melatonin attenuated immunological liver injury in mice.

Therefore, the protective effects of melatonin on immunological liver injury might relate to free radical scavenging, increased content of SOD, decreased expression of procytokines.

Abstract

AIM: To explore the effects of endothelin-1(ET-1) on hepatic stellate cells (HSCs) DNA uptake, DNA synthesis, collagen synthesis and secretion, inward whole-cell calcium concentration ($[Ca^{2+}]_i$) as well as the blocking effect of verapamil on ET-1-stimulated release of inward calcium (Ca^{2+}) of HSC *in vitro*.

METHODS: Rat hepatic stellate cells (HSCs) were isolated and cultivated. 3H -TdR and 3H -proline incorporation used for testing DNA uptake and synthesis, collagen synthesis and secretion of HSCs cultured *in vitro*; Fluorescent calcium indicator Fura-2/AM was used to measure $[Ca^{2+}]_i$ inward HSCs.

RESULTS: ET-1 at the concentration of 5×10^{-8} mol/L, caused significant increase both in HSC DNA synthesis ($2\ 247 \pm 344$ cpm, $P < 0.05$) and DNA uptake ($P < 0.05$) when compared with the control group. ET-1 could also increase collagen synthesis ($P < 0.05$ vs control group) and collagen secretion ($P < 0.05$ vs control group). Besides, inward HSC $[Ca^{2+}]_i$ reached a peak concentration (422 ± 98 mol/L, $P < 0.001$) at 2 min and then went down slowly to 165 ± 51 mol/L ($P < 0.01$) at 25 min from resting state (39 ± 4 mol/L) after treated with ET-1. Verapamil (5 mol/L) blocked ET-1-activated $[Ca^{2+}]_i$ inward HSCs compared with control group ($P < 0.05$). Fura-2/AM loaded HSC was suspended in no Ca^{2+} buffer containing 1 mol/L EGTA, 5 min later, 10^{-8} mol/L of ET-1 was added, $[Ca^{2+}]_i$ inward HSCs rose from resting state to peak 399 ± 123 mol/L, then began to come down by the time of 20 min. It could also raise $[Ca^{2+}]_i$ inward HSCs even without Ca^{2+} in extracellular fluid, and had a remarkable dose-effect relationship ($P < 0.05$). Meanwhile, verapamil could restrain the action of ET-1 ($P < 0.05$).

CONCLUSION: Actions of ET-1 on collagen metabolism of HSCs may depend on the transportation of inward whole-cell calcium.

INTRODUCTION

Hepatic fibrosis associated with the activation of hepatic stellate cells (HSCs), the major source of extracellular matrix (ECM) proteins^[1]. It is generally believed that HSCs are the main cells producing ECM, from resting state to active myofibroblasts, which is the key point of formation and development of hepatic fibrosis^[2-6]. Endothelin-1(ET-1) is currently known as a polypeptide with a stronger activity to contract blood vessel. So, based on prophase researches^[7-9], we chose ET-1 to observed its direct effect on DNA ingestion and synthesis as well as collagen synthesis and secretion of HSCs in cultivating. Meanwhile, as we know that Ca^{2+} is an important intracellular messenger, relate to HSC proliferation and ECM synthesis^[10-13]. The effects of ET-1 on regulation and intracellular $[Ca^{2+}]_i$ of HSCs isolated and cultivated *in vitro* were studied.

MATERIALS AND METHODS

MATERIALS

Animals Wistar male rats, weighting (450 ± 50) g, were provided by Shanghai Experimental Animals Center of Chinese Academy of Sciences.

Reagents ET-1, calcium fluorescence probes Fura-2/AM, Triton X-100, pronase, trypsin, DMEM, DAB- H_2O_2 were from Sigma; verapamil from Knoll; collagenase from Medical Industry Academy of Shanghai; RPMI 1640 from Gibco; HEPES from EMK; 3H -L-proline from Academy of Atomic Energy in China (66.6 GBq/mmol, radioactivity purity $> 90\%$). 3H -TdR was from Institute of Atomic Energy in Shanghai (814 GBq/mmol, radioactivity purity $> 95\%$).

Methods

Isolation and cultivation of rat HSCs Rat HSCs were isolated referring to Knook^[14-17]. Rats were anaesthetized with pentobarbitone (200 mg/kg) by abdominal injection, then heparin sodium (10 mg/kg) was injected into the caudal vein. The abdominal cavity was opened and portal vein and dorsal vein were exposed. Blood was released through vein and D-Hank's solution was perfused (20-25 mL/min) until pale yellow appeared. Liver was taken out and undergone extracorporeal circulation when perfusion fluid was changed to GBSS containing 0.5 g/L pronase E, 0.5 g/L collagenase and 10 mmol/L HEPES. Circle perfusion was performed for 30 min (15 mL/min). Liver was taken out and cut to pieces, then put into GBSS containing 0.25 g/L pronase E, 0.25 g/L collagenase and 10 mmol/L HEPES, shocked at $37^\circ C$ for 30 min, little suspended deposit was put in culture media on the top of three-layer density gradient centrifugation fluid containing 80 g/L and 130 g/L metrizamide, 2 800 r/min centrifugation for 20 min. Cells were sucked between top layer and 80 mL/L density layer. DMEM containing 200 mL/L calf serum was used to regulate the number of cells to 1×10^5 /mL.

DNA and collagen synthesis of HSCs HSCs in 2 to 4 th generation were digested by pancreatin and cultured with DMEM supplemented with 100 g/L calf serum and 100 mL/L horse serum. Cells were adjusted to 1×10^5 /mL and inoculated on a 48-well plate, cultured for 24 h, then different concentration of ET-1 and the same dosage of drug was added, respectively

and triplicated for each concentration. ^3H -TdR and ^3H -proline were used to assay the incorporation.

HSC ingestion of DNA ^3H -TdR 18.5 GBq/mmol was added at 10, 20, 30 and 60 min respectively, washed 3 times with PBS of 1×10^5 mmol/L, centrifuged 1000 r/min 10 min, the top layer fluid was removed, 2 mL of 100 g/L TCA was added and centrifuged 1000 r/min 10 min again. Top layer fluid was collected and deposited, washed 3 times with 800 mL/L ethanol at 4 °C. The top layer fluid was removed and dried in vacuum. 1 mol/L NaOH was added to lyse the deposit and 1N HCl was used to adjust pH to 7.0 Radioactivity of specimens was measured on Beckman scintillation counter.

Collagen secretion of HSC In experiment of ^3H -TdR, before transferred to F_{49} filter paper, 1 mL culture media was taken out and put into a tube. A 5 mmol/L acetic acid was used to adjust pH to 2 to 3, then 25 μL of 2.5 g/L pepsin was added to digest. A 50 μL of proline was added at 4 °C for 3 h, 1, 1.2 mol/L trichloroacetic acid was fixed for 2 h, transferred to F_{4a} filter paper, closed with saline, 0.6 mol/L trichloroacetic acid was used again, then bleached with anhydrous alcohol, baked at 80 °C. Radioactivity of specimens was measured on YSJ-75 liquid scintillation counter.

$[\text{Ca}^{2+}]_i$ in Fura-2/AM loaded HSC HSCs were cultured on a rectangle glass when HSCs grew and covered the glass. Then cells were taken out of the glass and RPMI 1640 containing Fura-2/AM (10 nmol/L) was added to incubate at 37 °C for 50 min, D-Hank's solution was used to wash extracellular free Fura-2/AM and incubated for another 30 min, 1 g/L trypsin was used to digest the cells and the number of cells was adjusted to $10^6/\text{mL}$ by buffer.

Fluorescence spectrum About 2 mL of Fura-2/AM loaded HSCs was suspended for the test with a fluorescence spectrophotometer. Raster (EX) 5 nm, radiate raster (EM) 10 nm were excited at a middle scan speed (32 mm/min), excitation light scan ranged 300-400 nm, emission light scan ranged 440-540 nm.

Intracellular fluorescence intensity Fluorescence intensity F was detected first (laser wave-length 340 nm, EX 5 nm, emission wave-length 510 nm, EM 10 nm), then different concentrations of ET-1 and verapamil and EGTA (last concentration 8 mmol/L) were added for the detection of minimum fluorescence intensity (F_{\min}).

Calculation of $[\text{Ca}^{2+}]_i$ Intracellular $[\text{Ca}^{2+}]_i$ (nmol/L) = $\text{kd} (F - F_{\min}) / (F_{\max} - F)$. Kd is a dissociation constant to Fura-2/ Ca^{2+} compound which equals to 224 nmol/L.

Statistical analysis Variance homogeneity tests were used to make comparisons.

RESULTS

HSC activity

Trypan blue staining revealed an activity above 90% for HSCs. The purity of HSCs was more than 80% assessed by fluorescence microscope. The nuclei of HSC were stained blue among the desmin-positive satellite cells.

Effect of ET-1 on HSC DNA synthesis

As shown in Table 1, ET-1 could accelerate ^3H -TdR incorporation into HSCs and HSC DNA synthesis and proliferation ($P < 0.05$), in a concentration-dependent manner.

Effect of ET-1 on HSC ingested ^3H -TdR

ET-1 could accelerate the rate of HSC ingested DNA, the rate increased with the time prolonged ($P < 0.05$ or $P < 0.01$, Figure 1).

Effect of ET-1 on HSC collagen synthesis

ET-1 could accelerate ^3H -Proline incorporation into HSCs and

collagen synthesis at the concentration of 5×10^{-8} mol/L ($P < 0.05$), in a concentration-dependent manner.

Figure 1 Effect of ET-1 on HSC ingested ^3H -TdR.

Table 1 Effects of ET-1 on HSC DNA synthesis, collagen synthesis and secretion (cpm, mean \pm SD)

Group	DNA synthesis	Collagen Synthesis	Collagen secretion
Control	1 370 \pm 113	2 167 \pm 454	1 431 \pm 389
ET 10 ⁻⁹ mol/L	1 489 \pm 305	2 206 \pm 725	1 528 \pm 242
ET 5 \times 10 ⁻⁸ mol/L	1 986 \pm 457 ^a	2 698 \pm 304 ^a	1 903 \pm 552 ^a
ET 10 ⁻⁸ mol/L	2 247 \pm 344 ^a	2 876 \pm 396 ^a	2 087 \pm 128 ^a
ET 10 ⁻⁷ mol/L	4 015 \pm 102 ^a	3 056 \pm 401 ^a	2 794 \pm 397 ^b

^a $P < 0.05$, ^b $P < 0.01$ vs control group.

Effect of ET-1 on HSC collagen secretion

As shown in Table 1, ET-1 could remarkably accelerate HSC collagen secretion compared with the control group ($P < 0.05$).

Effect of ET-1 (10⁻⁸ mol/L) on intracellular $[\text{Ca}^{2+}]_i$

As shown in Figure 2, when ET-1 was added to the suspension of Fura-2/AM loaded HSCs and kept for 25 min ($n = 3$), $[\text{Ca}^{2+}]_i$ in HSCs rose from (39 ± 4) mol/L (resting state) to (165 ± 51) mol/L ($P < 0.01$) and rose to peak (422 ± 98) mol/L ($P < 0.001$) after another 2 min, then it began to go down slowly and remained a higher concentration even after another 18 min compared with the resting $[\text{Ca}^{2+}]_i$ ($P < 0.01$). It suggested that the effect of ET-1 on $[\text{Ca}^{2+}]_i$ in HSCs could be divided into 2 phases, a fast phase (I P) and a slow phase (II P).

Figure 2 Effect of ET-1 on $[\text{Ca}^{2+}]_i$ peak value in HSCs.

Effect of ET-1 on peak concentration of $[\text{Ca}^{2+}]_i$ in HSCs

As shown in Figure 3, $[\text{Ca}^{2+}]_i$ in HSCs was in a ET-1 concentration-dependent manner. No change of $[\text{Ca}^{2+}]_i$ occurred in HSCs when ET-1 was less than 10^{-11} mol/L. $[\text{Ca}^{2+}]_i$ reached its peak in a ET-1-dose-dependent manner when ET-1 was greater than 10^{-9} mol/L.

Figure 3 Effect of ET-1 on $[Ca^{2+}]_i$ in HSCs (10^{-10} mol/L).

Blocking effect of verapamil

As shown in Figure 4, calcium channel blocking agent verapamil (5 μ mol/L) could significantly restrain I P and II P effects on $[Ca^{2+}]_i$ in HSCs excited by ET-1 compared with control group ($P < 0.05$). Fura-2/AM loaded HSCs suspended in Ca^{2+} -free buffer containing 1 mol/L EGTA made $[Ca^{2+}]_i$ in HSCs raise from resting state to peak (399 ± 123) mol/L, then go down to (49 ± 17) mol/L at the time of 20 min when first treated with 10^{-8} mol/L of ET-1, suggesting that Ca^{2+} -free buffer had no remarkable effect on I P of $[Ca^{2+}]_i$ in HSCs excited by ET-1 but completely blocked II P.

Figure 4 Effect of ET-1 increase $[Ca^{2+}]_i$ in HSCs.

DISCUSSION

HSCs were first detected by Ito and Nemoto in 1952, which provided a new way to study episode mechanism of hepatic fibrosis and deepened the cognition of hepatic fibrosis from an angle of source cells of collagen production^[2-6,15,16]. HSCs are also named Ito cell, VitA storing cell, liver antrum around cell, fat-storing cell, and is one of the liver interstitial cells. The main function of HSC is to store and metabolize VitA. It has been found to be able to synthesize and secrete ECM and synthesize collagenase^[2-6]. When hepatic fibrosis occurred, HSC turned into fibroblasts or myofibroblasts that were the cause of liver synthesis of ECM. This change of HSC was called activation or conversion^[2,3]. It has been certificated that interstitial cells especially HSCs are the main cells which product collagen when hepatic fibrosis occurs. So it has become a central link in hepatic fibrosis occurrence mechanism.

ET distributes widely in liver and portal vein system, and has important biological effects on liver^[18-24]. This experiment showed that ET could remarkably accelerate HSC proliferation, DNA synthesis, collagen synthesis and secretion. It is thus clear that ET-1 had double roles during hepatic fibrosis, accelerating not only HSC synthesis of collagen but also selective excretion of collagen. Besides^[25,26], endothelial cells in hepatic sinusoid secrete endothelins that can activate HSCs. It has been reported that ET could raise $[Ca^{2+}]_i$ in smooth muscle cells^[27-29]. This study showed that ET-1 could raise $[Ca^{2+}]_i$ in

HSCs and appeared double phase reaction, fast phase and slow phase. Both phases had a dose-dependent manner. It turns out that when the cells are at resting state, if there is extracellular Ca^{2+} , the $[Ca^{2+}]_i$ in HSCs will be higher than that without extracellular Ca^{2+} . ET-1 can remarkably raise $[Ca^{2+}]_i$ in HSC with or without extracellular Ca^{2+} . It implies that ET-1 can accelerate HSC release of intracellular Ca^{2+} .

Three different ways have been found to elevate $[Ca^{2+}]_i$ ^[30-33]. Plenty of calcium flows into cell through Ca^{2+} channel, Ca^{2+} -ATP enzyme or Na^{+} - Ca^{2+} changing system is restrained which can transfer Ca^{2+} out of cells; Ca^{2+} storing systems such as mitochondrion and endoplasm increase Ca^{2+} . We used Ca^{2+} -free buffer and found it had no effect on $[Ca^{2+}]_i$ in I P in HSC excited by ET-1 but could block $[Ca^{2+}]_i$ in II P. It implies that elevated $[Ca^{2+}]_i$ in I P is caused by increased Ca^{2+} stored in cells, while elevated $[Ca^{2+}]_i$ in II P is caused by Ca^{2+} flowing out of cells. It has been currently accepted by some of scholars that the raise of Ca^{2+} in HSC is through the way of phospholipase C (PLC)-inositol triphosphate (IP_3)-diacylglycerol (DAG)^[34-51]. ET-1 excites PLC on cell membrane through G protein that makes 4,5-biphosphate inositol divide into IP_3 and DAG- IP_3 . Mitochondrion, endoplasm and sarcoplasm that make Ca^{2+} in cell release to cytoplasm and increase free $[Ca^{2+}]_i$ in cells. IP_3 works only a very short time, and is quickly converted to IP_4 by special enzymes. So peak I P lasts for a very short time, but IP_4 can accelerate the opening of Ca^{2+} channel on cell membrane, which makes an increase of calcium flowing out of cells and at last results in a fast raise of $[Ca^{2+}]_i$ in cells.

Physiological and pathological significance of elevated free Ca^{2+} in HSCs excited by ET is still not clear. Maybe it could participate the series of signals in cells and physiological effect of ET^[25,27]. In conclusion, ET-1 can remarkably accelerate HSC proliferation, collagen synthesis and secretion, increase of $[Ca^{2+}]_i$ in HSC and of release of Ca^{2+} in cells, thus accelerating proliferation of fibrous tissues and repair of injury tissues.

Abstract

AIM: To examine the protein expression alterations in liver injury/repair network regulation as a response to gut-derived lipopolysaccharide (LPS) treatment, in order to anticipate the possible signal molecules or biomarkers in signaling LPS-related liver injury.

METHODS: Male BALB/c mice were treated with intra-peritoneal (i.p.) LPS (4 mg/kg) and sacrificed at 0, 6, 24 and 30 h to obtain livers. The livers were stained with hematoxylin and eosin for histopathologic analyses. Total liver protein was separated by two-dimensional gel electrophoresis (2-DE). The peptide mass of liver injury or repair related proteins were drawn up and the protein database was searched to identify the proteins.

RESULTS: Observations were as follows: (1) TRAIL-R2 was down regulated in livers of LPS-treated mice. TNFAIP1 was significantly up regulated at 6 h, then down-regulated at 24, 30 h with silent expression during senescent stage. (2) The amount of metaxin 2 and mitochondria import inner membrane translocase subunit TIM8a (TIMM8A) was increased upon treatment with LPS. (3) P34 cdc2 kinase was significantly up-regulated 30 h after LPS administration with silent expression during senescent, 6, 24 h treated stage. (4) The amount of proteasome activator 28 alpha subunit (PA28), magnesium dependent protein phosphatase (MDPP) and lysophospholipase 2 was decreased 6 h after LPS treatment but recovered or up-regulated 24 and 30 h after LPS treatment.

CONCLUSION: LPS-treated mouse liver displaying a time-dependent liver injury can result in expression change of some liver injury or repair related proteins.

INTRODUCTION

Human intestinal tract accumulates Gram-negative bacteria that supply lipopolysaccharide (LPS). Gut-derived LPS reaches the first target organ liver through portal venous flow and results in hepatic clearance or tissue damage. Recent studies have shown that peritoneal macrophages in cirrhotic patients may secrete angiogenic products when stimulated by LPS and accumulate in liver injury^[1-3]. *In vivo* experiments also indicate LPS may cause liver injury in normal subjects and exaggerate liver injury in alcoholic liver disease^[4-7]. That is, chronic liver diseases suffering from subsequent LPS attack would result in much severer clinical findings. The precise mechanisms underlying LPS-treated liver injury remain unclear. Several studies of liver protein expression exposed to some hepatotoxic agents have revealed certain changes which illustrated the pathogenesis of liver injury in some extent^[2,4,8,9]. However, most reported researches focused only on some partial signaling or effector molecules on a limited view^[4,5,7]. Protein expression changes of liver exposed to LPS remains to be established.

The goal of the present study was to dynamically examine protein expression alterations in liver tissues from mice exposed to LPS administration, in order to anticipate of the possible signal molecules or biomarkers in signaling LPS-related liver injury.

MATERIALS AND METHODS

Reagents

Ultra pure reagents for polyacrylamide gel preparation were obtained from Bio-Rad. Eighteen cm immobilized pH gradient (IPG) strips (pH3-10 L), IPG buffer and dry strip cover fluid were purchased from Amersham Pharmacia Biotech (Uppsala, Sweden). 3-[(3-cholamidopropyl) dimethylammonio]-propanesulfonate (CHAPS), glycine, ammonium persulphate (APS), TEMED, trifluoroacetic acid were obtained from Amresco (Solon, OH, USA). Dithiothreitol (DTT), PMSF, Iodoacetamide, urea, thiourea, α -cyano-4-hydroxycinnamic acid (CCA), TPCK-Trypsin, *E. Coli* LPS 0111:B4 were purchased from Sigma Chemical (St Louis, MO, USA). Acetonitrile was HPLC grade. Ten μ L ZipTipTMC18 tip were purchased from Millipore Company (USA).

Animal treatment protocol

Male BALB/c mice (supplied by Laboratory Research Animal Center, 2nd Xiangya Hospital, Central South University), 6 wk of age and weighing 19-21 g, were used. The animals were housed individually in mouse gang cages in cleaning-grade controlled room. The Hunan Association accredited the house facility for Accreditation of Laboratory Animal Care, and all animal handling procedures were in conform to the Guide for the Care and Use of Laboratory Animals. Four groups of five mice each received intra-peritoneal (i.p) RPMI-1640 medium treatment (control) and LPS (diluted in RPMI-1640 medium) 4 mg/kg for 6, 24, 30 h, respectively. Mice were killed by decapitation, liver samples were removed and flash-frozen in liquid nitrogen and kept at -70 °C until proteomics analysis. For histopathologic research, liver slices from the right lateral lobes were immersion-fixed in 40 g/L neutral buffered formaldehyde,

routinely processed to 5- μ m thick paraffin sections, stained with hematoxylin and eosin (HE) and examined by light microscopy.

Sample preparation^[10]

Liver samples were homogenized in eight volumes of 8 mol/L urea, 2 mol/L thiourea, 40 g/L CHAPS, 20 g/L Triton X-100, 5 g/L DTT, 1 mmol/L PMSF, 1 mmol/L EDTA, 40 mmol/L Tris. Homogenates were centrifuged at 42 000 g at 20 °C for 1 h (LE-80 K ultracentrifuge, Type 90 rotor, Beckman). Supernatant was removed, divided into several aliquots and stored at -70 °C until to be used. Protein concentration of each sample was measured by Bradford method^[11].

Two-dimensional gel electrophoresis^[11,12]

The first-dimensional isoelectrical focus (IEF) was performed on precast 18 cm IPG strips at 20 °C with a maximum current setting of 50 μ A/strip using an Amersham Pharmacia IPGphor IEF unit. The strips were rehydrated at 30 V for 16 h in 350 μ L samples containing 8 mol/L urea, 20 g/L CHAPS, 20 mmol/L DTT, 5 g/L IPG buffer. Eight hundred μ g proteins was applied to each IPG strip. After rehydration, IEF run was carried out using the following conditions: 500 V, 500 Vh; 1 000 V, 1 000 Vh; 8 000 V, 40 000 Vh. Then, the strips were subjected to a two-step equilibration. The first was with an equilibration buffer consisting of 6 mol/L urea, 300 g/L glycerol, 20 g/L SDS, 50 mmol/L Tris (pH8.8) and 10 g/L DTT. The second equilibration buffer was the same, only with DTT substituted by 25 g/L iodoacetamide. After the strips were transferred onto the second-dimensional 0.75 mm thick 125 g/L sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE) gel, the strips were sealed in place with 7.5 g/L agarose. Electrophoresis was carried out at a constant current of 25 μ A/gel at 12 °C until bromophenol blue reached the edge of gels.

Silver staining

Gels were fixed in 400 mL/L ethanol, 100 mL/L acetic acid in water for 30 min, and then sensitized with 2 g/L sodium thiosulfate for 30 min. After the gels were rinsed twice with water for 5 min each, they were incubated in 2.5 g/L silver nitrate for 20 min. After the silver nitrate was discarded and rinsed with three changes of distilled water for 5 min each, the gels were visualized in 25 g/L sodium carbonate in 0.004% formalin until the desired intensity was attained. Then the gels were incubated with 14.6 g/L EDTA disodium dihydrate for 10 min to stop the development. The staining procedure was performed by three rinses with water for 5 min each.

Quantitative gel pattern analysis

Stained 2-D gels were scanned on a UMAX powerLook III scanner (Amersham Biosciences). Image analysis and Group Wise statistical comparisons were performed using the Image Master 2D v3.01 software (Amersham Pharmacia). The protein spot intensity was arbitrarily calculated by integrating the optical density over the spot area to search for treatment-related protein change. The amount of protein was marked by volumes ($A \times \text{area}$) and expressed as mean \pm SD. Statistical difference was analyzed by analysis of Variance (ANOVA). The cutoff of quantitative protein changes between control and treated groups was made at $P < 0.05$.

Protein digestion and protein identification by MALDI-TOF-MS^[10,12]

Destaining Protein spots of interest were excised from the 2-D gels and washed 3 times in distilled water, destained with 15 mmol/L potassium ferricyanide in 50 mmol/L sodium thiosulfate, dehydrated in acetonitrile and finally dried in a centrifugal vaporizer.

Reduction and alkylation Gel pieces were incubated in 100 mmol/L

NH_4HCO_3 by adding 10 mmol/L DTT at 57 °C for 1 h. After they were cooled, 100 mmol/L NH_4HCO_3 with 55 mmol/L iodoacetamide was added and incubated at room temperature in dark for 30 min. Supernatant was removed and samples were washed twice in 100 mmol/L NH_4HCO_3 and dehydrated in 1 000 g/L acetonitrile, finally dried in a centrifugal vaporizer.

In-gel digestion Gel pieces were rehydrated in a digestion buffer containing 0.1 mg/mL TPK-trypsin for 30 min. After excess buffer was discarded, the gel pieces were covered with digestion buffer and proteins were in-gel digested for 24 h at 37 °C.

Deionization Digested peptides were pipetted out and into to make them attached in a 10 μ L ZipTipTMC18 tip, washed twice with 1 mL/L trifluoroacetic acid.

MALDI-TOF-MS for protein identification The matrix solution was saturated in 500 g/L acetonitrile, 1 g/L TFA in water. Peptides were eluted with 5 μ L MALDI matrix, 2.0 μ L mixed solution was loaded to the sample plate target and allowed to air-evaporate. MALDI experiments were performed on a Perspective Biosystem Voyager-DE STR time-of-flight mass spectrometer (Applied Biosystems Voyager system 4307, USA) equipped with delayed ion extraction. Data were acquired in the delayed ion extraction mode using a 20 KV accelerating voltage and a 100 ns extraction delay time. Dual microchannel plate detection was utilized in the reflector mode with the ion signal recorded using a transient digitizer. The performance of the mass spectrometer produced sufficient mass resolution to produce isotopic multiplet for each ion species below a mass-to-charge (m/z) of 3 000. All MALDI mass spectra were internally calibrated using masses from two trypsin autolysis products (monoisotopic masses 2163.05 and 2273.15). The software package Protein Prospector (*prospector.ucsf.edu*) was used to identify protein spots. The mouse nonredundant (NR) database Genpept.5.1.2002 was used in searches. The search parameters used were as follows: Cysteines modification mode as carbamidomethylation, maximum allowed peptide mass error 50 ppm, more than four peptide mass hits required for protein match, up to one enzymatic missed cleavage. A restriction was placed on species of origin, pI (experimental pI \pm 1.00 pH unit) and protein mass (experimental molecular mass \pm 50%).

RESULTS

General health and histopathology

All subjects were inspected for general health before, during and after LPS exposure. Throughout the study, no animal experienced mortality that was determined to be related to the exposure. Nine of 10 animal that were treated by exposure to LPS for 24, 30 h experienced visible signs of laziness and retardation. Light microscopic examination of HE sections from LPS-treated mice revealed that a large number of inflammatory cells infiltrated portal areas with additional focal hepatocellular necrosis 24, 30 h after i.p. LPS (4 mg/kg)^[13].

Table 1 Relative amount of 8 injury/repair related liver proteins in response to LPS treatment (mean \pm SD)

Liver protein	Control	LPS

**Figure 1** Partial 2-D images of mouse liver proteins from (a₁, a₂) a control animal and animals treated with 4 mg/kg i.p LPS (b₁, b₂) 6 h, (c₁, c₂) 24 h, (d₁, d₂) 30 h. The spots representing proteins whose levels changed following LPS treatment are shown. a₁, b₁, c₁, d₁ represent the relative same partial map after different LPS-treated onset. a₂, b₂, c₂, d₂ represent another relative same partial map.**Figure 2** Peptide mass fingerprint of MDPP (spot 447). The spot was in-gel digested with trypsin. After desalted, the peptide mixture was analyzed by MALDI-TOF-MS. All MALDI mass spectra were internally calibrated using masses from two trypsin autolysis products (monoisotopic masses 2 163.05 and 2 273.15).

2-DE and relative abundance change

The resolution in 2-DE silver-stained gels resulted in approximately 1000 spots. The volumes ($A \times \text{area}$) and coordinates of each spot (pI and MW) were determined to select the fine right proteins

among candidates. There were significant alterations in 40 protein spots following LPS treatment when compared with each other, $P < 0.01$. These 40 proteins were identified by MALDI-TOF-MS (data not shown). Figure 1 (A-D) shows the location of 8 injury/repair related proteins in illustrated partial 2-DE maps of control and LPS-treated mice, respectively. Table 1 summarizes the relative amount of these considered proteins. The amount of protein 1 was 9 800 in the control and down-regulated to 1 130 in 6-h group, absent in 24-, 30-h group. Protein 5 was significantly up-regulated 6 h after LPS treatment, then down-regulated 24 h and 30 h after LPS treatment with silent expression in the control. Proteins 2 and 13 were increased upon treatment with LPS. Protein 9 was significantly up-regulated 30 h after LPS treatment with silent expression in control, 6, 24 h treated stage. Proteins 6, 447 and 524 were decreased in amount 6 h after LPS treatment, recovered and up-regulated 24 and 30 h after LPS treatment.

Identity of injury/repair related proteins

The proteins were cut from 2-DE gels and subjected to tryptic digestion. The 8 proteins analyzed by peptide mass fingerprinting yielded searchable masses and resulted in the identification (Table 2). Figure 2 indicates the peptide mass fingerprint of MDPP (spot 447) as a representative.

DISCUSSION

It has been proved that gut-derived LPS provokes liver inflammation

with focal hepatocyte injury and increases the sensitivity of hepatotoxicity to carbon tetrachloride, concanavalin A, D-galactosamine and ethanol induced liver damage^[4-6,14]. The role of LPS signaling pathway in the initiation and early propagation of immune response has been deeply demonstrated^[8,9,15]. In this study, liver injury occurred apparently 24 h after LPS administration. It indicated that LPS could promote hepatotoxicity by indirect mechanisms. Some immediate signaling or effector molecules may play a pivotal role in this delayed injurious response.

In our research, TNF-related apoptosis-inducing ligand receptor 2 (TRAIL-R2), TNF- α inducible endothelial protein 1 (TNFAIP1) and mitochondria apoptosis signaling related proteins metaxin 2, mitochondria import inner membrane translocase subunit TIM8a (TIMM8A) were demonstrated to be involved in the initiation of liver injury of LPS-treated mice and consistent with the histological change of liver tissue.

A recent research showed that LPS administration could result in elevated circulating TNF- α and up-regulation of gene transcription for TNF- α as early as 2 h after administration^[16]. Then, TNF- α related apoptosis pathway played a control role in mediating the tissue injury. TRAIL was recently reported to promote apoptosis of carcinogenic cells by binding to the transmembrane receptors. The resulting death-inducing signaling complex consisting of TRAIL, TRAIL-R2 and caspase-8, initiated the subsequent cascade of Caspases mediating apoptosis^[17,18]. The down-regulation of TRAIL-R2 in livers of LPS-treated mice could result in rather a protective mode of normal hepatocytes. The induction of TNFAIP1 has been shown to be apoptosis-specific, suggesting that TNF- α related apoptosis is triggered in liver cells of LPS-treated mice at earlier stage^[19].

Metaxin 2 is bound to the cytosolic face of mitochondria outer membrane by its interaction with membrane-bound metaxin 1, and this complex may play a role in protein import into mammalian mitochondria. The requirement of metaxin in TNF-induced cell death has been confirmed by *in vitro*^[20,21]. It has been found that TIMM8A exists in the mitochondria intermembrane space which mediates the import and insertion of inner membrane proteins^[22-24]. These two mitochondria proteins are required for normal physiological balance. Treatment-mediated changes of these proteins were likely to associated with mitochondria apoptosis. How mitochondria related pro- or anti-apoptotic proteins are involved in liver injury needs to be further demonstrated.

Tissue repair associated proteins, p34 cdc2 kinase and proteasome related proteins, showed some controversial expression in response to LPS-treated liver injury. p34 cdc2 kinase belongs to the Ser/Thr family of protein kinases. The sequential activation and inactivation of p34 cdc2 kinase of eukaryotic cells are required for it to entry into mitosis and to exit from it. In addition, a sustained activation of it during mitotic arrest has been associated with anti-microtubule agents-induced apoptosis^[25,26]. In this study, we found significant histopathological changes in mice livers 24 h after LPS treatment. p34 cdc2 kinase of mice livers was significantly up-regulated 30 h after LPS administration with silent expression during senescent, 6-, 24-h treated stage. It indicated that the enhanced expression of p34 cdc2 kinase was subsequently present to severe hepatic damage. It is likely that up-regulation of p34 cdc2 kinase in LPS-treated mice was more reflective of mitogenic response rather than antimitogenic activities. That is, cell division and tissue repair occurred as events opposing to tissue injury and could limit the extent of liver injury. It seemed possible that p34 cdc2 kinase could act by promoting mitosis and tissue repair, thus contributing to tissue repair response to LPS-treated liver injury.

The biological implications of amount in abundance of proteasome related proteins in mice liver response, including

proteasome activator 28 alpha subunit (PA28), magnesium dependent protein phosphatase (MDPP) and lysophospholipase 2, which decreased in amount 6 h after LPS treatment but recovered or up-regulated 24 and 30 h after LPS treatment, were even less clear. Previous study demonstrated that PA28 could bind to and activate the proteasome by the alpha subunit^[27]. MDPP is a new member of the halo acid dehalogenase family which has been found to be competent to catalyzing dephosphorylation of tyrosine-phosphorylated proteins^[28]. Lysophospholipase 2 was implicated in the initiation of inflammatory response by mediating cell division and differentiation^[1,29].

It is concluded that proteasome related proteins play a major role in the initiation of tissue repair program opposing to tissue damage. While the function, pathway interactions and ultimate biological outcomes of these changes in protein expression remains to be explained by further research.

In summary, the current investigation used 2-DE to characterize the proteome of LPS-treated mice liver that displayed a time-dependent liver injury in some liver injury or repair related proteins. In this study, 8 liver injury or repair related proteins were identified whose expression levels were altered at different time points after LPS treatment. TNF related apoptosis induced by LPS treatment could provoke an initiation response in tissue repair.

Abstract

AIM: To investigate the effects of platelet-derived growth factor(PDGF) and interleukin-10 (IL-10) on Fas/Fas-ligand and Bcl-2/Bax mRNA expressions in rat hepatic stellate cells.

METHODS: Rat hepatic stellate cells (HSCs) were isolated and purified from rat liver by *in situ* digestion of collagenase and pronase and single-step density Nycodenz gradient. After activated by culture *in vitro*, HSCs were divided into 4 groups and treated with nothing (group N), PDGF (group P), IL-10 (group I) and PDGF in combination with IL-10 (group C), respectively. Semi-quantitative reverse-transcriptase polymerase chain reaction (RT-PCR) analysis was employed to compare the mRNA expression levels of Fas/FasL and Bcl-2/Bax in HSCs of each group.

RESULTS: The expression levels of Fas between the 4 groups had no significant differences ($P>0.05$). FasL mRNA level in normal culture-activated HSCs (group N) was very low. It increased obviously after HSCs were treated with IL-10 (group I) (0.091 ± 0.007 vs 0.385 ± 0.051 , $P<0.01$), but remained the low level after treated with PDGF alone (group P) or PDGF in combination with IL-10 (group C). Contrast to the control group, after treated with PDGF and IL-10, either alone or in combination, Bcl-2 mRNA expression was down-regulated and Bax mRNA expression was up-regulated, both following the turn from group P, group I to group C. Expression of Bcl-2 mRNA in group C was significantly lower than that in group P (0.126 ± 0.008 vs 0.210 ± 0.024 , $P<0.01$). But no significant difference was found between group C and group I, as well as between group I and group P ($P>0.05$). Similarly, the expression of Bax in group C was higher than that in group P (0.513 ± 0.016 vs 0.400 ± 0.022 , $P<0.01$). No significant difference was found between group I and group P ($P>0.05$). But compared with group C, Bax expressions in group I tended to decrease (0.449 ± 0.028 vs 0.513 ± 0.016 , $P<0.05$).

CONCLUSION: PDGF may promote proliferation of HSCs but is neutral with respect to HSC apoptosis. IL-10 may promote the apoptosis of HSCs by up-regulating the expressions of FasL and Bax and down-regulating the expression of Bcl-2, which may be involved in its antifibrosis mechanism.

INTRODUCTION

Liver fibrosis is a progressive pathological process involving multi-cellular and molecular events that ultimately lead to deposition of excess matrix proteins in the extracellular space. It is generally accepted that hepatic stellate cells (HSCs) are central to the process of fibrosis as the major source of extracellular matrix (ECM) components^[1-10]. Following acute or chronic liver tissue injury, HSCs undergo a process of activation towards a phenotype characterized by increasing proliferation, motility, contractility and synthesis of ECM components. Cytokines play an important role in the formation, development and reversibility of fibrosis^[9-14]. Activated HSCs secrete many important cytokines through autocrine and paracrine, of which platelet-derived growth factor (PDGF) can activate secretory cells and those quiescent HSCs around^[15,16] and promote the proliferation of HSCs^[17]. IL-10 is a potent anti-inflammatory cytokine that inhibits the synthesis of pro-inflammatory cytokines by T helper type 1 T cells and mono/macrophages. Previous studies have shown that endogenous IL-10 has the ability to inhibit the inflammation in injured liver and block the advance of fibrosis^[18-21]. Previous works by our group have demonstrated that exogenous IL-10 has an anti-fibrogenic function^[22]. But the underlying mechanism remains obscure. In this study, in order to investigate the effects of IL-10 and PDGF on the proliferation and apoptosis of rat HSCs, culture-activated HSCs were treated with IL-10 and PDGF. Fas/FasL and Bcl-2/Bax mRNA expressions in each group were assayed by semiquantitative reverse-transcriptase polymerase chain reaction (RT-PCR) analysis.

MATERIALS AND METHODS

Materials

Male Wistar rats, weighing 450-500 g, were provided by Shanghai Center for Laboratory Animals. Total RNA isolation kit was obtained from Jingmei Biotechnology Company of Shenzhen. Moloney murine leukemia virus (M-MLV) reverse transcriptase was purchased from Promega. PCR reagent and Dulbecco's modified Eagle's medium (DMEM) were respectively provided by Shanghai Biotechnology Company and GibcoB. PCR primers were synthesized by Shanghai Biotechnology Company.

Isolation, culture and evaluation of HSCs

HSCs were isolated from normal male Wistar rats by *in situ* digestion of collagenase and pronase and single-step density Nycodenz gradient as Ramm GA^[23] and Friedman SL^[24] previously described, and cultured in DMEM supplemented with 100 mL/L FBS. Desmin immunocytochemistry was employed to determine the

isolated HSCs' purity. HSCs were subcultured 4 d after primary culture. Alpha smooth muscle actin (α -SMA) immunocytochemistry and electron microscope were employed to confirm that HSCs were activated by culture *in vitro* and transformed into myofibroblasts.

Intervention and division of HSCs

The subcultured HSCs were diluted to a concentration of $5 \times 10^4/\text{mL}$ with DMEM containing 100 mL/L FBS and seeded onto the 24-well plastic tissue culture plates. When HSCs spread the plate fully, the culture medium was replaced with DMEM containing 10 mL/L FBS. After incubated for 24 h, HSCs were divided randomly into 4 groups: one as control group cultured in 1 mL DMEM containing 10 mL/L FBS, the other three were cultured in the same medium and treated with 20 ng PDGF or 20 ng IL-10, either alone or in combination, respectively. We named them group N, group P, group I and group C, respectively. Each group included 5 wells.

RNA extraction

Total RNA was extracted from the above treated HSCs after incubated for 24 h according to the RNA isolation kit instructions. The content and purity of total RNA were determined by spectrophotography. A_{260}/A_{280} of total RNA was between 1.8-2.0.

RT-PCR for Fas/FasL and Bcl-2/Bax

For RT-PCR, total RNA was reverse-transcribed using M-MLV reverse transcriptase and oligo (dT) at 37 °C for 60 min, followed by at 70 °C for 10 min. Approximately 2 μg total RNA was used in each reverse transcription reaction and the final volume was 25 μL . β -actin was used as internal control. The PCR reaction volume was 50 μL , including 5 μL 10 \times PCR buffer, 2 mmol/L MgCl_2 , 1 μL 10 mmol/L dNTP, 1 μL 20 pmol/ μL target gene sense and anti-sense primers, 1 μL 20 pmol/ μL β -actin primer pair, 2 μL RT product, 1.5 U Tag DNA polymerase. The specific sets of primers and the target gene amplification conditions are shown in Table 1.

Result determination

PCR products were run on 20 g/L agarose gel eletrophoresis and visualized with ethidium bromide staining. Bio imagine system was used to detect the densities of bands of the PCR products. The ratio of target gene density to β -actin density was used to represent the relative levels of Fas/FasL and Bcl-2/Bax mRNA expressions. The semi-quantitative detection was analyzed 5 times repeatedly.

Statistical analysis

All data were expressed as mean \pm SE. The significance for the

difference between the groups was assessed with SPSS 10.0 by one-way ANOVA. $P < 0.05$ was considered statistically significant.

RESULTS

Evaluation of HSCs

Freshly isolated HSCs were round-shaped with many yellow droplets in cytoplasm. After cultured for 5-6 d, the spread cells showed a typical 'star'-like configuration. Desmin immunocytochemistry showed that the positive percentage was about 95% (Figure 1A), indicating that 95% of the isolated cells were HSCs. α -SMA immunocytochemistry showed that 98% of the cells were α -SMA positive (Figure 1B), indicating that most of the cells were activated. The myofilament could be seen in cytoplasm under the electron microscope, confirming that HSCs were activated and transformed into myofibroblasts after cultured *in vitro* (Figure 2).

Table 1 Primer sequences for PCR and amplification conditions for each target gene

Primer (base)	Sequence	Amplification conditions
Fas 414	5'-GAATGCAAGGGACTGATAGC-3' 5'-TGGTTCGTGTGCAAGGCTC-3'	Denaturation at 94 °C for 45 s, Annealing at 55 °C for 30 s and synthesizing at 72 °C for 1 min for 25 cycles
FasL 239	5'-GGAATGGGAAGACACATATGGAAGTGC -3' 5'-CATATCTGGCCAGTAGTGCAGTAATTC-3'	Denaturation at 94 °C for 45 s, Annealing at 55 °C for 30 s and synthesizing at 72 °C for 1 min for 33 cycles
Bcl-2 525	5'-TATGATAACCGGGAGATCGTGATC-3' 5'-GTGCAGATGCCGGTTCAGGTACTC-3'	Denaturation at 94 °C for 45 s, Annealing at 60 °C for 30 s and synthesizing at 72 °C for 1 min for 33 cycles
Bax 310	5'-GACACCTGAGCTGACCTTGG-3' 5'-GAGGAAGTCCAGTGTCAGC-3'	Denaturation at 94 °C for 45 s, Annealing at 60 °C for 30 s and synthesizing at 72 °C for 1 min for 30 cycles
β -actin 660	5'-CCAACCGTGAAAAGATGACC-3' 5'-CAGGAGGAGCAATGATCTTG-3'	Changed according to different target genes

All initial denaturations were at 94 °C for 5 min. Finally an additional extension step at 72 °C for 7 min was done.

M: 100 bp DNA ladder (upper to lower: 1 000, 900, 800, 700, 600, 500, 400, 300, 200, and 100 bp); Lane 1: Normal group as control; Lane 2: PDGF treatment group; Lane 3: IL-10 treatment group; Lane 4: Combined PDGF and IL-10 treatment group.

Effects of PDGF and IL-10 on Fas and FasL expressions in HSCs

Fas mRNA was expressed in HSCs of each group and the expression levels had no significant difference among the 4 groups, as shown in Figures 3A, 4A, indicating that neither PDGF nor IL-10 had effect on Fas mRNA expression in HSCs. As it could be informed from Figures 3B, 4B, FasL mRNA level in normal culture-activated HSCs (group N) was very low. It increased obviously after HSCs were treated with IL-10 (group I) (0.091 ± 0.007 vs 0.385 ± 0.051 , $P<0.01$), but remained the low level after treated with PDGF alone (group P) or PDGF in combination with IL-10 (group C) (0.085 ± 0.006 , 0.101 ± 0.008 , respectively). The data suggested that IL-10 could improve FasL mRNA expression in culture-activated HSCs and PDGF could not. Furthermore, PDGF tended to abolish this effect of IL-10.

Effects of PDGF and IL-10 on Bcl-2 and Bax expressions in HSCs

Bcl-2 and Bax mRNA were expressed in normal culture-activated HSCs. Both of their expression levels were significantly changed after treated with PDGF and IL-10, either alone or in combination. Bcl-2 mRNA expression was down-regulated and Bax mRNA expression was up-regulated, following the turn from group P, group I to group C. The expression of Bcl-2 in group C was significantly lower than that in group P (0.126 ± 0.008 vs 0.210 ± 0.024 , $P < 0.01$). But no significant difference was found between group C and group I, as well as between group I and group P (0.210 ± 0.024 vs 0.166 ± 0.017 , 0.166 ± 0.017 vs 0.126 ± 0.008 , $P > 0.05$) (Figures 5A, 6A). Similarly, the expression of Bax in group C was higher than that in group P (0.513 ± 0.016 vs 0.400 ± 0.022 , $P < 0.01$). No significant difference was found between group I and group P (0.400 ± 0.022 vs 0.449 ± 0.028 , $P > 0.05$). But compared with combined treatment group, Bax expressions in group I tended to decrease (0.449 ± 0.028 vs 0.513 ± 0.016 , $P = 0.045 < 0.05$) (Figures 5B, 6B). These results showed that both PDGF and IL-10 promoted the Bax mRNA expression in HSCs and inhibited the Bcl-2 expression, but the differences of their effects were not significant. Intervention with PDGF and IL-10 seemed to be able to manifest effects on Bax expression than intervention alone. IL-10 showed similar influences on culture-activated HSCs and reactivated HSCs by PDGF.

DISCUSSION

It is generally accepted that hepatic stellate cells (HSCs) are central to the process of hepatic fibrosis. They are the major source of extracellular matrix and during fibrogenesis undergo an activation process characterized by increased proliferation and collagen synthesis^[1-10,24]. So the activation, proliferation and apoptosis of HSCs have close relationship with the formation and development of liver fibrosis. To inhibit the activation and proliferation of the HSCs and promote their apoptosis has become the most important therapeutic approach for liver fibrosis^[7-10,14,25-28].

There is evidence that HSCs can be successfully isolated by *in situ* digestion of collagenase and pronase and single-step density Nycodenz gradient^[23,24,29]. Desmin is a marker for muscle cells and expressed by all muscle lineages including HSCs (either quiescent or activated) in the liver. Alpha smooth muscle actin (α -SMA) is an intermediate filament protein that is expressed by activated HSCs and is widely accepted to be a marker of activation. Both of them were used to identify and quantify HSCs and their activation. The desmin immunocytochemistry result showed that the purity of the isolated HSCs by this method was satisfying (Figure 1A). The results of α -SMA immunocytochemistry (Figure 1B) and electron microscope (Figure 2) confirmed that HSCs were activated and transformed into myofibroblasts after cultured *in vitro*.

PDGF, which is produced by HSCs, Kuffer cells and platelets, is a major mitogen for connective tissues and certain other cells. It was viewed as one of the most important growth factors serving as the matrix-bound cytokines^[11] and plays an important role in the pathogenesis of liver fibrosis via promoting the activation and proliferation of HSCs^[12,15,25,30-32]. The best characterized chemotactic factor for HSCs identified so far is the PDGF-BB^[33-35] which is also known as the most potent mitogen for HSCs over-expressed during active hepatic fibrosis^[36]. But there is also evidence that PDGF is proapoptotic for fibroblasts in conditions of low serum^[37]. Saile B^[38] reported that resting HSCs displayed no sign of apoptosis and spontaneous apoptosis became detectable in parallel with HSCs activation, suggesting that apoptosis might represent an important mechanism terminating proliferation of activated HSCs. He also found that Fas and Fas-ligand in HSCs became increasingly expressed during the course of activation. But our data demonstrated that PDGF

alone had no effect on the expression of Fas and FasL during further activating the culture-activated HSCs, which was supported by Issa R^[39]. Bax and Bcl-2 are known as the representatives of proapoptotic factor and contra-apoptotic factor of Bcl-2 family, respectively^[40,41]. In our study, evidences showed that PDGF could promote Bax mRNA expression in HSCs and inhibited Bcl-2 mRNA expression as well, resulting in the apoptosis of HSCs^[41]. All the above data demonstrated that PDGF can accelerate the apoptosis of HSCs through Bcl-2/Bax pathway in parallel with their proliferation^[42]. In other words, PDGF may promote proliferation but is neutral with respect to HSCs apoptosis. But the proportion of apoptosis-inducing forces and apoptosis-inhibiting forces would determine that PDGF-activated HSCs tend to proliferate and increase^[22].

Cytokine interleukin-10 (IL-10), produced by lymphocytes and macrophages as well as cells within liver such as Kuffer cells, hepatocytes and HSCs, has profound inhibitory actions on macrophages and inflammation. The present studies showed that IL-10 had additional effects on connective tissue cells, such as HSCs and fibroblast. IL-10 could inhibit the activation of HSCs by inflammatory cells^[43], relieve the inflammation of liver^[18,19,44], suppress the function of NF- κ B^[45] and affect the expression of collagen I and collagenase^[20], thus exerting an antifibrogenesis effect^[46]. Failure for HSCs to sustain IL-10 expression might underlie pathologic progression to liver cirrhosis^[18,20]. Our previous studies also implied that IL-10 had an antagonism on CCL₄-induced rat hepatic fibrosis^[22]. But the underlying mechanism remains obscure. In this study, our results showed that IL-10 could promote the expression of FasL and Bax mRNA in culture-activated HSCs and meanwhile could inhibit Bcl-2 mRNA expression, implying that IL-10 may induce the apoptosis of HSCs through binding FasL to Fas on the cell membranes of HSCs and increasing the proportion of Bax and Bcl-2. Saile B^[38] found that apoptosis could be fully blocked by Fas-blocking antibodies in normal cells and HSCs already entering the apoptotic cycle, implying that Fas/FasL system is the key pathway for the apoptosis of HSCs. Our data, however, showed that Bax/Bcl-2 system was another important pathway involving in HSCs' apoptosis^[40,41]. In short, IL-10 could promote the apoptosis of HSCs, which may be related to its mechanism of antifibrosis.

There is evidence that activated-HSCs could express IL-10 as well as its receptor^[20,47]. In this study, PDGF had a similar effect to IL-10 on Bax/Bcl-2 mRNA expression in HSCs. This promotes us to hypothesize that PDGF may regulate the expression of Bax and Bcl-2 mRNA by affecting the expression of IL-10 in HSCs. But PDGF in combination with IL-10 did not show a satisfying synergistic action, thus we can not exclude the possibility that PDGF and IL-10 affect in different ways, and further works are demanded.

Abstract

AIM: To analyze detailed changes in hematology and biochemistry tests parameters before and after a long-distance race in ultramarathon runners.

METHODS: Blood samples of 11 participants were obtained for standard analysis before, immediately after, two days after and nine days after the 2002 International Ultramarathon 24 h Race and the International Association of Ultrarunners (IAU) Asia 24 h Championship.

RESULTS: Total bilirubin (BIL-T), direct bilirubin (BIL-D), alkaline phosphatase (ALP), aspartate aminotransferase (AST), alanine aminotransferase (ALT) and lactate dehydrogenase (LDH) increased statistically significantly ($P<0.05$) the race. Significant declines ($P<0.05$) in red blood cell (RBC), hemoglobin (Hb) and hematocrit (Hct) were detected two days and nine days after the race. 2 d after the race, total protein (TP), concentration of albumin and globulin decreased significantly. While BIL, BIL-D and ALP recovered to their original levels. High-density lipoprotein cholesterol (HDL-C) remained unchanged immediately after the race, but it was significantly decreased on the second and ninth days after the race.

CONCLUSION: Ultra-marathon running is associated with a wide range of significant changes in hematological parameters, several of which are injury related. To provide appropriate health care and intervention, the man who receives athletes on high frequent training program high intensity training programs must monitor their liver and gallbladder function.

INTRODUCTION

Numerous reports have been published on the effects on the body of endurance sports such as the 5 000 m, the 10 000 m, the marathon, cross-country running, rowing and cycling^[1-14]. In recent years, more athletes have become involved in ultra-endurance races, such as the iron-man triathlon, the 100 km race and the 24 h marathon, and a few investigations have addressed the related hematological and biochemical changes. Strenuous physical activities are becoming increasingly popular around the world, and this work may benefit participants in future competitions.

Some of these previous studies have involved staged races with long rest periods; while others made comparisons before and after competition. This study examines, athletes who have completed a long-distance run lasting 24 h, and detailing the related hematological and biochemical changes before, immediately after, two days after and nine days after the race.

MATERIALS AND METHODS

Anthropometric data

A 24 h ultra-marathon was held at Soo-Chow University on March 2, 2002. The runners ran around a 400 m oval track for 24 h, covering a distance of at least 100 km. The runners changed direction every 4 h. The temperature during the 24 h race ranged from 19.0 to 26.8 °C and the relative humidity ranged from 63 to 91%. The runners were permitted to rest and to ingest water and food freely. Ten males (10/36) and one female (1/1) participated in this study, having previously given their informed consent. Table 1 lists the anthropometric data.

Table 1 Anthropometric data of the study population ($n = 11$)

	Range	Mean	Standard Deviation
Age (yr)	26.00-55.00	45.10	±2.64
Height (cm)	155.00-177.00	166.80	±6.23
Body weight (kg)	47.00-69.30	60.60	±9.69
Distance completed (km)	106.70-194.40	158.60	±26.78
BMI(body mass index)	19.56-22.12	21.79	±0.24

Parameter of blood tests

20 mL blood samples were obtained from the antecubital vein 24 h before the race, immediately after the race, two days after the race and nine days after the race. The blood was analyzed in 1 h using an ABBOTT CELL DYN 3 000 autoanalyser (Abbott Diagnostics, Mountain View, CA., USA) and HITACHI 7150 autoanalyser (Hitachi High Technologies, Tokyo, Japan).

Statistical significance of paired differences in means and standard deviations of the related hematological and biochemical changes among pre-race, immediately post-race, two days post-race, and nine days post-race values were calculated using by one-way ANOVA analysis. The level of significance was set at $P<0.05$.

RESULTS

Hb. Hct. platelet data

The pre-race red cell count, Hb and Hct levels were not significantly

immediately after the race, but were significantly reduced two and nine days after the race, being lowest at two days after the race. The mean cell volume was not significantly changed immediately after the race or on day two post-race, but was significantly increased by day nine post-race. Mean cell Hb concentration was significantly lower on day two than before the race, but had recovered on day nine.

Mean cell Hb and red cell distribution width remained unchanged at all times. The platelet concentration immediately after the race and on day nine following the race was increased significantly compared to pre-race values, but had decreased significantly on day two. (Table 2).

Total WBC and differential count

The white blood cell count was significantly increased at the end of the race and remained high until day nine. Moreover, the number of neutrophils was increased at the end of race but recovered two days later. Furthermore, the lymphocytes, eosinophils and basophils were decreased immediately after the race but recovered two days later. Finally, the number of monocytes was increased immediately after the race and on day two post-race, but returned to the pre-race level by day nine post-race. (Table 3).

Ferritin, TIBC

The ferritin level, total iron binding capacity (TIBC) and transferring saturation rose significantly immediately post-race along with ferritin level, and remained at the end higher on day two and nine. All of the parameters remained normal

mean values. (Table 4).

Liver function tests

The BIL-T and BIL-D concentrations were significantly raised immediately after the race and normalized two days later. TP, albumin and globulin concentrations were unchanged immediately after the race but were significantly reduced on day two, recovering gradually after day nine, though TP and albumin remained below pre-race levels.

ALP, AST and ALT had increased significantly by the end of the race. ALP returned to its pre-race level after day two. Moreover, AST declined by day two and resumed its pre-race level by day nine. Furthermore, ALT continued to rise until day two and had recovered by day nine. Gamma glutamyl transferase (γ -GT) remained unchanged until the end of race and beyond the end of the event. Finally, LDH was significantly raised by the end of the race and was decreased on day two post-race, but remained above their pre-race level on day nine. (Table 5).

Lipid metabolism

Triglyceride (TG), cholesterol/low-density lipoprotein cholesterol (CHO/LDL-C) ratio and LDL-C were lower immediately after the race had finished. TG level and CHO/LDL-C ratio recovered by day two post-race, while LDL-C recovered by day nine. Cholesterol was not significantly changed at the end of the race, but was significantly lower on day two.

HDL-C was highest immediately after the race but had reduced by day two and nine post-race. (Table 6).

DISCUSSION

Few studies have extensively addressed the hematological and biochemical changes in endurance runners. This investigation elucidates the effects of intensive exercise on athlete health and the findings can be used to help participants in future competitions.

Red cell count, Hb and Hct, three indicators of anemia, were normal before the race. Significant decreases was found by day two, consistent with the accelerated destruction of RBC in endurance athletes. The three indicators remained reduced between days two and nine; so-called sports anemia^[15], is not only caused by hemolysis owing to mechanical trauma but also by oxidative injuries of the red cells^[16]. Under normal conditions, red cells with a mean life of 120 d are renewed at approximately 1% daily. However, this turnover rate increases following endurance training, as reflected in the participants in this study. The increased turnover rate is good for the athletes as the young red cells can carry oxygen more efficiently than the older cells.^[17,18] The mean cell volume, mean cell hemoglobin and mean cell hemoglobin concentration remained normal throughout. The transient sports anemia was caused by reduced red cell numbers rather than red cell size or amount of Hb^[19,20]. The change in platelets number was inconsistent with previous studies. The platelet count was higher at the end of the race and on day nine, but remained within the normal range, and no coagulopathy was detected. Further study can clarify the significance of the increase. The white cell count increased markedly race and subsequently declined. The initial increase followed from to a rise in peripheral reserves and was mostly associated with neutrophils. Neutrophilia and numbers of lymphocytes were related to catecholamine, cortisol and some chemotactic factors: transient immunological dysfunction may occur under such conditions^[21,22]. This study found on decrease in absolute lymphocyte count and no signs of infection in a follow-up questionnaire administered 2 wk after the race.

The concentration of serum ferritin was significantly increased immediately after the race and on day nine post-race, owing to the acute phase response of the destruction of red cells, consistent with previous reports. Total iron binding capacity and transferrin saturation were markedly increased by

the end of race, reflecting the acute release of iron.

BIL and BIL-D increased at the end of the race and normalized after day two, associated with hemolysis that follows from ultra-long running. The hemolysis was related to a decline in haptoglobin concentration and structural changes in the red cell membranes^[23,24]. AST, ALT, γ -GT, LDH and ALP all increased by the end of the race, implying damage to the skeletal muscle cells and hepatic cells. Serum BIL normalized by day two as red cell turnover reduced, but AST, ALT and LDH continued to exceed pre-race levels, representing a continued release of enzymes from the muscles and liver^[25-27].

Albumin is involved in protein synthesis by the liver. Albumin reduced significantly by day two, reflecting damage to the anabolic functioning of hepatic cells. TP fell after day two, mainly owing to the decrease in albumin and had not recovered by day nine. Despite the reduced protein level, no clinical pitting edema was found. The pre-race mean AST, ALT and LDH exceeded the normal range, possibly indicating chronic damage to the liver following long-term strenuous exercise.

Most hepatic function parameters displayed no correlation with age, except for negatively correlated globulin, reflecting the lower immunological functioning of older runners following endurance exercise^[28,29]. AST, ALT and LDH were positively correlated with runner performance and unrelated to BIL and ALP, implying that changes in hepatobiliary parameters resulted mainly from damage to hepatic cells. Long-term regular exercise has been recognized to contribute to reducing cholesterol^[30-32], triglyceride and LDL-C and increasing HDL-C. In this study the lipid parameters of all of the participants were in the normal ranges, supporting the beneficial effect of rhythmic aerobic exercise. However, the effects of long-term ultra-endurance activities deserve further investigation.

Most fat is stored as triglyceride in fat and muscle cells. Plasma and muscular triglyceride were consumed equally during the first stage of endurance exercise, and subsequently the free fatty acid became the major source of energy explaining the reduction in triglyceride at the end of the race^[33,34]. The TG and LDL-C were significantly lower at the end of the race and on day agreeing with previous reports. Cholesterol is a major

risk factor for coronary artery disease and deserves extensive investigation. Cholesterol levels were not significantly changed at the end of the race, and were decreased by day two, but the cholesterol/HDL-C ratio, which is not affected by plasma volume, was significantly reduced by the end of the race. This phenomenon may result from the increase in HDL-C and the decrease in LDL-C.

Ultramarathon running is associated with numerous changes in hematological parameters, many of which are injury related. These changes should not be confused with indicators of disease. Increasing liver enzyme levels in runners indicated damage to liver cells, but increased BIL resulted from higher clearance rates of RBC. The liver damage was directly proportional to workload. Acute reduction of TG might result from the use of body fat as the major energy source. An ultra-long endurance run effectively reduced LDL-C for two days post-race, but did not significantly change HDL-C.

Safety guidelines, protective equipment and prevention education are crucial to reducing sports injuries. Then, preventing liver and gall bladder injuries and ensuring safe health management program are necessary for ultramarathon athletes. In summary, efforts to minimize these injuries are warranted both to ensure the long-term health of runners and to reduce medical costs. The key to management of ultramarathon runner osteoporosis involves identifying the potential risk for osteoporosis and osteoporotic fracture, followed by measures that focus on reducing modifiable risk factors through health management program^[33-34].

Abstract

AIM: Some recent studies showed that alteration of upper-gut motility in coeliac disease may be related to dysfunction of autonomic nervous system. The aim of our study was to investigate whether autonomic nervous system was altered in untreated and unselected coeliac disease patients.

METHODS: We studied 8 untreated and consecutive coeliac disease patients (2 males and 6 females, age range 37 ± 14.5 years). Histological evaluation of duodenal mucosa, anti-gliadin antibodies (AGA), antiendomysial antibodies (EMA) and anti-tTG antibodies and sorbitol H2 breath test were performed in all patients. Extrinsic autonomic neuropathy was assessed by the standardized measurement of cardiovascular reflexes (lying-to-standing, Valsalva manoeuvre, deep breathing, sustained handgrip). The results obtained were compared with a healthy, asymptomatic control group (6 males and 7 females, age range 42.3 ± 13.5 years).

RESULTS: Coeliac patients exhibited a lower increase of PAS as a response to isometric effort, a reduction of spectral power LF as a response to clinostatic position, but without statistical significance. Also they showed a lower tolerance to orthostatic position, associated with a latent disequilibrium of sympathetic-vagal balance, a relative prevalence of parasympathetic component of the autonomic function. However, these results were not statistically significant when compared with control group ($P = \text{n.s.}$). And they were unchanged after 6 and 12 mo of gluten-free diet.

CONCLUSION: This study failed to confirm a significant correlation between autonomic dysfunction and coeliac disease, yet we could not exclude a role of autonomic dysfunction in the genesis of systemic symptoms in some coeliacs.

INTRODUCTION

Coeliac disease (CD) is the most common severe food intolerance in the Western world^[1]. It is a clinical syndrome of intestinal malabsorption, a characteristic though not specific histological lesion involving total, subtotal or partial small bowel villous atrophy (predominating in its proximal segments). It is the result of sensitiveness to ingested gluten in genetically susceptible people with the subsequent immune reaction leading to small bowel inflammation^[2]. The classical malabsorptive symptoms of diarrhoea and weight loss are only one aspect of the spectrum of manifestations of this relatively common disease^[3,4], since symptoms may be subtle and many patients have subclinical or silent disease^[5,6]. A proper gluten-free diet (GFD) would lead to a clinical and histological improvement^[7-9]. In particular, GFD played a key role in preventing nutritional deficiency, especially of micronutrients, and in reducing the risk of the development of intestinal malignancies^[10].

It is quite frequently seen in clinical practice that coeliac patients present gastrointestinal motor abnormalities^[11]. It has been recently shown that alteration of upper-gut motility may be related to dysfunction of autonomic nervous system^[12]. The aim of our study was to investigate whether autonomic nervous system (ANS) was altered even in untreated and unselected coeliac patients and to assess the effect of GFD on ANS dysfunctions.

MATERIALS AND METHODS

Patients

We studied 8 untreated, consecutive and unselected coeliac disease patients (2 males and 6 females, age range 37 ± 14.5 years). Both the original^[13] and revised^[14] criteria for the diagnosis of CD were used in this study. CD was defined as a permanent gluten-sensitive enteropathy, primarily manifested by the presence of characteristic small intestinal lesions^[15]. Small-bowel biopsy was performed in all patients, as well as esophagogastroduodenoscopy (Fujinon EG300 videogastroscope; Fujinon, Omiya, Japan). At least six small-bowel biopsies were obtained from the second part of the duodenum using a disposable biopsy forceps with spike (U.S. Endoscopy Inc., Mentor, Ohio, U.S.A.) and evaluated by haematoxylin/eosin staining. Histopathology was expressed according to the Marsh classification of 1992^[16]: "infiltrative" lesions with >30 lymphocytes/100 epithelial cells were defined as Marsh type I, "infiltrative/hyperplastic" lesions as Marsh II and "partial (sub)total villous atrophy (VA) as type III. We subdivided the Marsh III type into partial VA (Marsh IIIa), subtotal VA (Marsh IIIb) and total VA (Marsh IIIc), according to Oberhuber's modified classification^[17].

Other possible causes of villous atrophy or duodenal damage, such as *Giardia Lamblia* infection, tropical sprue, collagenous sprue, food protein hypersensitiveness (cow's milks, eggs, fish, rice, chicken) were excluded, as well as other causes of inflammatory infiltration of duodenum, such as peptic duodenitis^[17].

Methods

IgA and IgG anti-gliadin antibodies (AGA) were measured in all patients by enzyme-linked immunosorbent assay (kit Alfa-gliatest, Eurospital, Trieste - Italy); the lower limit of positivity

of IgA-class was 0.2 EU/mL and of IgG-class 10.0 EU/mL. IgA antiendomysial antibodies (EMA) were screened by the indirect immunofluorescent method on monkey oesophagus (kit Antiendomysium, Eurospital, Trieste - Italy). IgA anti-tissue transglutaminase antibodies were also screened by enzyme-linked immunosorbent assay using human recombinant tTG (kit Eu-tTG, Eurospital, Trieste - Italy); the lower limit of positivity of these antibodies was 7 UA/mL.

Also sorbitol H₂ breath test (H₂-BT) was performed. All patients were studied after an overnight fasting having been instructed to consume a meal of rice and meat; they were also requested not to smoke on the morning of the test day. End expiratory samples were collected before the patients drank the test solution (5 g of sorbitol in 150 mL of tap water) and every 30 min for 4 h. Hydrogen concentrations in each collected sample were measured with a breath-hydrogen analyzer (EC60 Gastrolyzer Breath Hydrogen Monitor, Bedford Scientific Ltd, Upchurch - Kent, England [U.K.]). An increase in H₂ concentration of at least 20 ppm over fasting baseline was considered positive for sorbitol malabsorption. The cut-off for calculating the validity of the test was shifted every 30 min, and a response operating characteristics (ROC) curve was plotted on the basis of the obtained results.

The clinical, endoscopic, histological and serological pattern of the studied coeliacs are described in Tables 1, 2.

5	+	+	+	+	+
6	+	+	-	+	+
7	-	-	+	-	+
8	+	-	-	+	+

Abbreviations: AGA: Anti-gliadin antibodies; EMA: anti-endomysium antibodies; anti-tTG: anti-tissue transglutaminase; H₂-BT: Hydrogen₂-breath test.

No patient had other associated organic (such as hereditary, toxic, infectious, inflammatory) or metabolic diseases.

Extrinsic autonomic neuropathy was assessed by the standardized measurement of cardiovascular reflexes. Tests were performed in the morning and at constant temperatures. Autonomic function was evaluated by means of electrocardiograph Personal 120 (Esaote Biomedica, Firenze, Italy) and a Finapres set (Ohmeda, Louisville, Colorado, USA). We evaluated the heart rate variation (R-R interval) and systolic (SBP) and diastolic (DBP) blood pressures in response to a variety of stimuli: lying-to-standing (evaluation of R-R variation with a 30.15 ratio); Valsalva manoeuvre (forced expiration for 15 s with a 40 mm Hg pressure); deep breathing (6 expiratory cycles throughout one minute, evaluating the average of differences between the maximal and minimal duration of R-R interval during three subsequent deep breath [DB3]); sustained handgrip (performing isometric sub-maximal work for 3 min and evaluating blood pressure and heart rate variations); and tilt tests. The results of each test were scored according to Ewing's modified criteria^[18,19].

The results obtained were compared with a healthy, asymptomatic control group (13 people, 6 males and 7 females, age range 42.3±13.5 years). All coeliac patients were re-evaluated about the autonomic function 6 and 12 mo after GFD has started.

Statistical analysis

The Student's *t*-test for unpaired data was used, and data are presented as mean±SD. *P*<0.05 was considered as statistically significant.

RESULTS

We noted that coeliac patients showed a lower increase of PAS in response to isometric effort. Moreover, they showed a reduction of spectral power LF in response to clinostatic position, but without statistical significance (Tables 3, 4).

Only one female patient (Table 5, patient number 8) showed symptomatic orthostatic hypotension (defined as SBP decrease ≥/ = 20 mm Hg and DBP ≥/ = 10 mmHg within 3 min in orthostatic position) as responsiveness to orthostatic position.

The overall results of ANS in coeliacs showed a tendency

to lower systolic-diastolic values of blood pressure both in clinostatic position and in active and passive orthostatic positions. However, these results had no statistical difference compared with those of control group (Table 4).

The spectral analysis of heart rate variance (HRV), performed with autoregressive method, confirmed these findings. The autoregressive analysis of HRV showed an important, but not significant, reduction of the power LF according to a considerable reductive activity of sympathetic tone at rest with a relative prevalence of parasympathetic tone. Passive orthostatic, evaluated by tilt tests, induced a marked sympathetic response (with increase of spectral power LF) (Table 5).

All patients were re-evaluated about the autonomic function 6 and 12 mo after GFD has started. In none of them we noted change of the results, and the symptomatic orthostatic hypotension persisted in patient number 8 despite strict adherence to GFD.

DISCUSSION

In recent years a discrete frequency of autonomic neuropathy has been disclosed in coeliac patients^[12,20], similar to that reported in other functional gastrointestinal disorders, but lower than that described in diabetic subjects^[21]. Pathogenetic factors involved in autonomic dysfunction in coeliac disease were unknown, and autoimmune damage or metabolic derangement have been hypothesized^[22-24].

We investigated our coeliac patients, exploring their autonomic function using the cardiovascular tests because they were easily available reproducible, and not very expensive^[25,26]. Our study showed quite different results from those recent studies about autonomic function in coeliacs. In particular, they differed from Usai's study, which reported ANS abnormalities in 45% of coeliacs affected by upper gastrointestinal symptoms^[12]. Thus, we can hypothesize that ANS abnormalities may play a role in upper gastrointestinal symptoms rather than in systemic symptoms. In fact we recorded ANS abnormalities only in 1/5 patient without gastrointestinal symptoms. On the other hand, it is noteworthy that we did not find ANS abnormalities in any of the 3 patients complaining about gastrointestinal symptoms (Table 5). However, a role of ANS dysfunction in some coeliac patients cannot be excluded, since the patient No. 8 of our studied population (a 32-year-old

female), the only one with ANS dysfunction, did not show dyspeptic symptoms but only systemic symptoms.

What a role could then the autonomic neuropathy play? Can it really play a role in the systemic symptoms in coeliac disease? We knew that several coeliac patients experienced weakness or chronic fatigue in clinical practice. In most cases it was related to malabsorption (such as iron-deficiency anaemia or folic acid deficiency), but in some cases autonomic neuropathy might be suspected. Our study unfortunately failed to demonstrate a significant autonomic dysfunction in CD; however, we cannot exclude that in some patients ANS dysfunction might play a role in the genesis of some systemic symptoms, such as weakness or chronic fatigue. In fact we noted that coeliac patients showed a lower tolerance to orthostatism, associated with a latent disequilibrium of sympathetic-vagal balance, ie, a relative prevalence of the parasympathetic component of the autonomic function. These alterations, and in particular the reduced tolerance to orthostatism, may explain the above mentioned symptoms in some cases, as we noted in patient No. 8 (Table 5).

But another very finding was that ANS dysfunction did not improve in this patient after GFD. It is difficult to explain why ANS did not improve after gluten withdrawal. We speculate that ANS dysfunction may be a two step process. In the first phase it may be gluten-related, and may improve after GFD. This phase may have a variable length, probably related to age, gender and time to gluten exposure. In the second phase it may be gluten - independent, probably related to autoimmune axonal aggression to autonomic nervous system, in which autoimmunity may perpetuate the neurological damage. Recent studies of Luostarinen *et al.*^[27] may in part confirm this hypothesis. They showed that axonal neuropathy in CD might be also subclinical without any sign of malabsorption and it often persisted despite good compliance to GFD^[27]. This hypothesis may justify the persistence of the orthostatic hypotension in patient 8 after six and twelve months of GFD, and it may also explain why some coeliacs experienced persistence or recurrence of chronic fatigue despite GFD. We consider that the recurrence of systemic symptoms is related to incidental gluten ingestion from unknown sources: the autonomic neuropathy, with consequent disequilibrium of sympathetic-vagal balance may be the cause of these systemic symptoms.

Abstract

AIM: To study the frameshift mutations of the retinoblastoma protein-interacting zinc finger gene *RIZ* in gastric cancer with microsatellite instability, and to identify two coding polyadenosine tracts of *RIZ*.

METHODS: Frameshift mutations at (A)₈ and (A)₉ tracts of *RIZ* were detected in 70 human gastric cancer (HGC) specimens by DHPLC and DNA sequencing. Microsatellite instability (MSI) status was assessed by two mononucleotide markers, BAT26 and BAT25, by means of denaturing high-performance liquid chromatography (DHPLC).

RESULTS: In 70 HGC samples, 8 (11.4%) were found positive for instabilities at BAT26 and BAT25. In 7 of the 8 cases with instabilities at both BAT26 and BAT25 (MSI-H), 1 was unstable at BAT26 but stable at BAT25. Frameshift mutations were identified in 4 (57.1%) of the 7 samples with MSI-H in the (A)₉ tract of *RIZ* without mutations in the (A)₈ tract. In contrast, frameshift mutations were found in neither of the polyadenosine tracts in 63 samples of MSI-L or MSI stable tumors. Pro704 LOH detection in 4 cases with frameshift mutations did not find LOH in these cases.

CONCLUSION: Frameshift mutations of *RIZ* may play an important role in gastric cancers with MSI.

INTRODUCTION

Two major pathways of genomic instabilities have been recently recognized, namely the chromosomal instability pathway (CIN) and the microsatellite instability (MSI) pathway (MIN), the

former is characterized by the loss of heterozygosity (LOH) whereas the latter by MSI^[1]. Some genes contain repetitive regions in their coding sequences that are often targets of MSI. Gastrointestinal tumors with DNA mismatch repair (MMR) defects often present MSI and harbor frameshift mutations in coding mononucleotide repeats of cancer-related genes. MSI (+) tumors arise from the defects in the MMR system through the mechanism presumably involving frameshift mutations of the microsatellite repeats within the coding regions of the affected target genes, whose function loss is believed to contribute to tumorigenesis^[2-5].

The retinoblastoma protein-interacting zinc finger gene *RIZ* is a candidate tumor suppressor gene locus on 1p36, a region that commonly harbors alterations in many types of human cancers^[6]. The interaction of *RIZ* with the retinoblastoma protein (Rb) suggests its involvement in the control of proliferation by an alternative mechanism. *RIZ* gene encodes two protein products, RIZ1 and RIZ2, which differ for a motif present in the N-terminal domain, defined as the PR domain that was previously identified as a common motif in several transcription factors. RIZ1 contains a PR domain indicative of tumor suppressor function, whereas RIZ2 does not contain this motif^[7,8]. RIZ1 has the capacity to induce cell cycle arrest at G₂/M phase and cell apoptosis, and suppresses tumorigenicity in nude mice^[9-11]. A role for *RIZ* has been recently proposed in cell cycle arrest and cell apoptosis through a transcriptional repression mechanism^[7,12].

In MSI(+) tumors, *RIZ* was found to be affected by frequent frameshift mutations of one or two coding poly(A) tract, an (A)₈ tract at the coding nucleotide sequence 4273-4280 and an (A)₉ tract at 4462-4471 in exon 8. These mutations generate truncated RIZ1 proteins lacking the COOH-terminal PR-binding motif and are expected to have serious deleterious effects on the PR domain-specific function of RIZ1. *RIZ* plays an important role in hereditary tumors of the MIN pathway as suggested by the frequent frameshift mutations in HNPCC tumors^[11]. The role of *RIZ* in gastric MSI(+) tumors remains to be investigated. In this study, we used denaturing high-performance liquid chromatography (DHPLC), a highly productive method, to rapidly detect frameshift mutations of (A)₈ and (A)₉ tracts and LOH of pro704 in gastric cancer specimens and to explore the role of *RIZ* gene in gastric carcinogenesis.

MATERIALS AND METHODS

Tissue specimen and DNA extraction

Gastric cancer samples and matched adjacent normal gastric tissues were obtained from 41 male and 29 female patients during surgical resection of the tumors with informed consent from the patients at Beijing Institute for Cancer Research, Beijing Cancer Hospital. The fresh samples were collected at the time of surgery and frozen at -80 °C. The sections from each specimen were examined by a pathologist. There were 39 intestinal-type tumors and 31 diffuse-type tumors. High-molecular weight genomic DNA was extracted by standard proteinase K digestion and phenol/ chloroform extraction^[13].

Primers and PCR

Primers used for (A)₈ tract and (A)₉ tract in the *RIZ* gene amplification

were as follows: *RIZ*A8-F5'-GAGCTCAGCAAAATGTCGTC-3', *RIZ*A8-R5'-CAAGTCGGCCTTCTGCTTTG-3'; *RIZ*A9-F5'-TCTCACATCTGCCCTTACTG-3', *RIZ*A9-R5'-GTGATGAGTGTCCACCTTTT-3'. The *RIZ* Pro704 deletion polymorphism was assayed by PCR followed by DHPLC. The PCR primers were: RP145 5'-CCCAAGATAAACTAAGTCTCT-3', RP105 5'-ACTCCATGCTGGTGAGTC-3'.

The samples used for mutation screening and sequencing were amplified in 25 μ L reaction solution containing 50 ng genomic DNA, 0.4 μ mol/L sense and antisense primers for each tract, 200 μ mol/L dNTPs (Perkin-Elmer, Foster City, CA, USA), 0.2 μ L Taq polymerase (Ampli Taq Gold; Perkin-Elmer), and 2.0 mmol/L $MgCl_2$. After an initial activation of the enzyme by denaturation at 95 °C for 9 min, PCR amplification was performed for 35 cycles in the following sequence: at 94 °C for 30 s, at optimized annealing temperature for 45 s, and at 72 °C for 45 s, with a final extension at 72 °C for 10 min. The annealing temperature for various primer sets was: 58 °C for *RIZ* A₈ tract, 60 °C for *RIZ* A₉ tract, and 55 °C for pro704.

Mutation analysis

For examining the heteroduplex content, 50-100 ng of the PCR products were subjected to DHPLC (WAVE™ system, Transgenomic, USA) under partial denaturation condition. The mobile phase consisted of a mixture of 0.1 mol/L triethylamine acetate (TEAA, pH 7.0) with or without 25% acetonitrile. The flow rate used in this study was 0.9 mL/min. The column temperatures for the PCR products were 57 °C for *RIZ* (A)₈ tract and 56 °C for *RIZ* (A)₉ tract. The PCR products were heated to 95 °C for 3 min followed by cooling to 25 °C over 45 min. Homozygous mutant DNA must be combined with the wild

type at the ratio of approximately 1:1 prior to hybridization.

LOH analysis

The pro704 PCR products were directly used without a denaturation and reannealing process under non-denaturing conditions on the WAVE™ system. The gradient of buffer B from 1 to 7 min was 49-55%. The column temperature was 50 °C and flow rate was 0.75 mL/min.

DNA sequencing

The PCR product was treated with exonuclease and shrimp alkaline phosphatase based on the protocol provided by the United States Biochemical and sequenced by the Mayo Clinic DNA sequencing facility. Sequencing reactions were performed in the GeneAmp PCR System 9600 with fluorescent terminations, and the products were analyzed on an ABI 377 sequencer (Perkin-Elmer, Foster City, CA, USA). All sequence alterations were confirmed by bidirectional sequencing of the PCR products generated by at least two independent reactions.

MSI analysis by DHPLC

MSI analysis by DHPLC was performed as described previously^[14]. Briefly, the PCR products were examined by DHPLC under fully denaturing conditions. The flow rate used in this study was 0.9 mL/min, with the column temperature of 80 °C. The gradient of buffer B from 0.1 to 7.1 min was 30-51%.

RESULTS

A total of 70 HGC samples and their matched normal tissues were analyzed for MSI status by two mononucleotide markers,

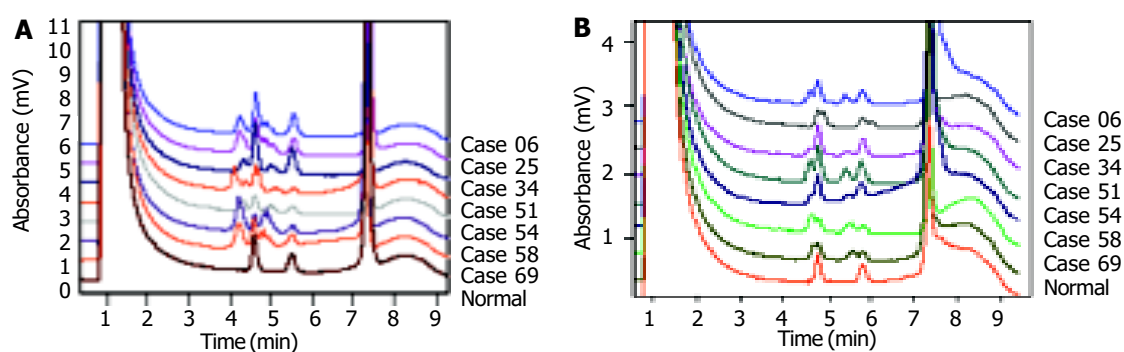

Figure 1 MSI analysis of 70 paired HGCs by DHPLC. Curves at the bottom in both Panels A and B represent normal DNA as indicated by the specification on the bottom right, and the rest curves represent tumor DNA in specified cases. Column: DNASEp™; mobile phase: 0.1 mol/L TEAA (pH 7.0); linear gradient: 30-51% B in 7 min; flow rate: 0.9 mL/min; temperature: 80 °C; detection: UV at 260 nm. Panel A: DHPLC chromatograms of HGCs at BAT26; Panel B: DHPLC chromatograms of HGCs at BAT25.

Figure 2 Typical elution profiles of DHPLC analysis and sequencing. Panel A: DHPLC elution profiles for *RIZ*(A)₉ tract, column temperature: 56 °C, flow rate: 0.9 mL/min, mobile phase: 0.1 mol/L TEAA (pH 7.0), linear gradient: 51-60% B in 4.5 min, detected with UV at 260 nm; Panel B: Sequence tracings for the same samples. The upper panel is a normal control, and the lower is a frameshift mutation (1-bp deletion). The arrow indicates the mutant nucleotide; Panel C: DHPLC elution profiles for pro704 LOH, column temperature: 50 °C, flow rate: 0.75 mL/min, mobile phase: 0.1 mol/L TEAA (pH 7.0), linear gradient: 49-55% B in 7 min, detected with UV at 260 nm.

BAT26 and BAT25, by means of DHPLC. In 70 HGC samples, 8 (11.4%) were found to contain sequence variation at BAT26 and BAT25 and 7 of them were shown to be unstable at both BAT26 and BAT25 (Figure 1), classified as MSI-H. One was unstable at BAT26 but stable at BAT25.

Frameshift mutations of *RIZ* (A)₉ and (A)₈ tract were identified. HCT-116 cell line had been studied previously and frameshift mutations were identified in the polyadenosine tracts^[11], which served as the positive control in this study. In 7 samples with MSI-H, 4 (57.1%) were found to have mutations in the (A)₉ tract of *RIZ* by DHPLC and DNA sequencing, including 3 intestinal-type tumors and 1 diffuse-type tumor. All of them had a 1-bp deletion (Figure 2A, B). No mutations were detected in the (A)₈ tract. No mutations in the (A)₉ or (A)₈ tract were found in the 63 MSI-L or MSI stable samples.

To determine whether *RIZ* was also affected by chromosomal deletion in MSI(+) tumors, pro704 LOH studies were performed on 4 samples with frameshift mutations for which the matched normal DNAs were available. We observed that both the PCR products of the tumor DNA and matched normal DNA resulted in the same peak chromatogram on DHPLC under the condition used for DNA sizing at 50 °C. LOH was not found at the *RIZ* locus in these tumors (Figure 2C).

DISCUSSION

Approximately 10-15% of gastrointestinal tumors are caused by defective MMR^[15], characterized by the presence of tumor MSI (MSI-H) and the absence of protein expression for any of the various genes involved in DNA MMR including hMLH1, hMSH2, hMSH6 or hPMS2^[16]. Gastric cancer with an MSI-H phenotype often harbors somatic frameshift mutations in the coding mononucleotide repeats of cancer-related genes. Frameshift mutations in *TGFβRII*, *BAX*, *IGFIR* and *E2F4* genes are often observed in cancers exhibiting a high frequency of MSI^[17]. Recently, the new candidate tumor suppressor gene, *RIZ*, which may be targeted for deletion, was identified. *RIZ* is a protein with two alternative forms of RIZ1 and RIZ2, which differ for a PR domain present in the N-terminal domain. The PR domain is necessary for the negative regulatory function of *RIZ*. Frameshift mutations in either (A)₈ or (A)₉ tract are thought to lead to C-terminal domain loss of the *RIZ* protein involved in PR binding. In this study, we detected frameshift mutations in *RIZ* (A)₉ tract, whereas no mutation was found in (A)₈ tract. All of the frameshift mutations here found in *RIZ* are assumed to lead to the production of the COOH-terminal domain-truncated protein, which is likely to seriously affect RIZ1 functions.

Frameshift in short mononucleotide tracts is common in gastrointestinal tumors of the microsatellite mutator phenotype (MMP). MSI is considered a hallmark of the mutator phenotype, and determination of MSI is critical for understanding tumor biology. Separation of HGCs based on their mutator phenotypes is an effective first step to allow the distinction of these two different pathways of carcinogenesis. In the present study, we analyzed MSI status by two mononucleotide markers, and detected *RIZ* mutations in 4 (57.1%) of the 7 MSI-H tumors but in none of the 63 MSI-L or MSI stable gastric cancers, indicating that these mutations are specific for MSI-H tumors that exhibit a tendency to accumulate frameshift mutations in reiterated sequence of the coding regions of cancer-related genes known to facilitate cancer development and progression. These mutations may contribute to cancer progression either by inactivating their tumor suppressor functions or acting as secondary mutator mutations in MMP(+) gastric tumors^[18]. Our study has shown that MSI-H gastric cancers accumulate frameshift mutations in the *RIZ* gene. On the basis of our findings, we suppose that *RIZ* is a candidate target gene in MSI tumorigenesis.

Two kinds of genetic instability, MIN and CIN, have been

documented in colorectal cancers. To determine whether *RIZ* is also affected by chromosomal deletion in MSI-H cancers, we detected the pro704 LOH in the 4 cases with frameshift mutations but failed to find LOH at the *RIZ* locus in these tumors, suggesting that *RIZ* frameshift mutations are common in MSI(+) gastric cancers, whereas LOH is not. More extensive studies on gastric cancers are needed to clarify whether *RIZ* is affected by two different ways. In MSI(+) tumors (MIN pathway), frameshift mutations in the COOH-terminal interfere with the interactions between the C terminus of the protein and its PR domain. In MSI(-) tumors (CIN pathway), mutations or deletions of the PR domain of *RIZ1* may have similar effects.

In this study, we detected MSI status and LOH by DHPLC analysis. DHPLC has been described as a novel technology for the detection of gene mutations in inherited diseases or cancers and for the identification of single nucleotide polymorphisms (SNPs)^[19]. The present study demonstrates the efficacy of DHPLC in analysis of the MSI status and LOH, which allows automated examination of MSI and LOH with considerable precision at relatively low cost, without any special labeling procedure.

Abstract

AIM: To examine the effects of ovarian hormone on the expression of 5-hydroxytryptamine 3 receptors (5-HT₃R) in rat colon of restraint stress-induced bowel dysfunction.

METHODS: Twenty-four female Sprague-Dawley rats were randomly divided into three groups of 8 each: sham operation, ovariectomy (OVX) and ovariectomy with estrogen (E₂) and progesterone (P) replacement therapy (OVX+E₂+P). The rats were subjected to 1-h restraint stress 4 wk after operation. The changes of defecation were monitored by collection of fecal pellets. The gonadal steroids were measured in duplicate by radioimmunoassay (RIA). The expression of 5-HT₃R mRNA in the colon was studied by RT-PCR.

RESULTS: Compared with sham group and OVX+E₂+P group, OVX group showed increase in fecal pellets and decrease in the time of vitreous pellets excretion ($P < 0.01$). Serum levels of E₂ and P were suppressed in OVX group and restored following treatment with ovarian steroids ($P < 0.01$), and the levels of 5-HT₃R mRNA in the colon of ovariectomized rats were significantly increased, the expression of 5-HT₃R mRNA was significantly decreased in hormone replacement therapy group ($P < 0.01$).

CONCLUSION: Ovarian hormone plays a role in the regulation of 5-HT₃R expressions in restraint stress-induced bowel dysfunction of rats. The interactions between ovarian steroids and gastrointestinal tract may have major pathophysiological implications in 5-HT-related disorders, such as irritable bowel syndrome (IBS).

INTRODUCTION

IBS is characterized by intermittent or continuous abdominal pain and alterations in bowel patterns^[1,2]. The syndrome is one of the most common gastrointestinal (GI) disorders seen in primary care and specialist practices^[3,4]. There is a female-to-male ratio of 2/1 in North American population studies of IBS^[5],

and epidemiologic surveys indicate that women seek health care services for IBS more frequently than men^[4,6]. In menstruating women, symptoms are influenced by menstrual cycle. Peri- and postmenopausal women have a high prevalence of altered bowel function and IBS-like gastrointestinal complaints^[7]. For many women, symptoms become amplified around the time of menses^[8]. However, the exact mechanism (e.g. ovarian hormones, stress response) accounting for these cyclic changes is still unknown.

Studies suggested that the female sex steroid hormones, including estrogen and progesterone, could affect the myoelectric and mechanical activity of colonic smooth muscle *in vitro*. By geometric center method, estrogen and progesterone pretreatment of ovariectomized rats resulted in a significant decrease in colonic transit compared with untreated ovariectomized rats^[9].

5-HT₃R is a ligand-gated ion channel and probably involved in the modulation of colonic motility and visceral pain in the gut^[10]. Clinically, 5-HT₃R antagonists are important in the treatment of symptoms in IBS and more effective on diminishing bowel pattern symptom in women as compared to men^[11]. Rat with wrap restraint stress is an appropriate animal model to study stress-related colonic dysfunction like IBS^[12]. Previous studies have suggested that restraint stress results in an increase of fecal pellet output in rats via peripheral 5-HT₃ receptors^[13].

Earlier research has shown that E₂ can suppress gastric motility response to thyrotropin-releasing hormone (TRH) and restraint stress in conscious rats^[14], low dose of P (1 mg/kg) increased intestinal transit while higher dose (10-20 mg/kg) had no effect. Recently, it has been demonstrated that both forskolin and 17-beta-estradiol inhibit the function of 5-HT₃R in a noncompetitive manner and that this inhibition is independent of cAMP levels^[15]. Based on the research mentioned above, we suggested that this change, in part, be due to the increased activity of 5-HT₃R innervating these organs. Therefore, we decided to assess whether both of these sex steroids could modulate mRNA expression of 5-HT₃R in rat colon with restraint stress-induced colonic dysfunction and the potential mechanisms involved. Ovariectomized rats were treated with or without E₂ and P in combination, after that changes in fecal pellets and the time of vitreous pellets output were assessed. Furthermore, we used RT-PCR to determine whether there was a decrease in 5-HT₃R mRNA expression after treatment with sex steroids.

MATERIALS AND METHODS

Animals

Twenty-four adult female Sprague-Dawley rats (weighing 220-250 g), purchased from the Animal Department of Tongji Medical College, Huazhong University of Science and Technology were housed individually in a light and temperature controlled room with light-dark cycles of 12:12 h, where the temperature (24±2 °C) and relative humidity (65-70%) were kept constant. The animals were fed on a standard pellet diet, and food was withdrawn overnight before surgery and emptying experiments, but free access to water was allowed *ad libitum*. Experimental protocols followed standards and policies of the Animal Care and Use Committee, School of Medicine, Wuhan University.

Surgical procedures

Rats were housed for 7 d before experiments. At 6 wk of age, rats were randomly divided into three groups of eight each: sham-operated group, OVX group and OVX+E₂+P group. Under aseptic conditions, bilateral ovariectomy or sham operation was performed under general anesthesia with ketamine (100 mg/kg, ip). For OVX, two dorsolateral incisions, in the skin and the peritoneum, were made and the ovaries and uterine horn removed. Sham operations consisted of skin and peritoneum incisions. After operation, animals were housed four per cage under previous conditions. On the same day, rats in OVX+E₂+P group were subcutaneously injected a mixture of estradiol benzoate (E₂, 5 µg/d) and progesterone (P, 0.2 mg/d). Four weeks after E₂ and P combination treatment, wrap restraint stress experiments were performed in the three groups.

Restraint stress-induced bowel dysfunction

The method described by Williams *et al.*^[16] was used with slight modifications. Rats were acclimated to metal mesh cage placed on a tray for 5 h (9:00-14:00). After the acclimation, they were lightly anesthetized with ether. Then, their forelimbs were restrained with adhesive tapes (12.5 mm in width). The restrained limbs and thoracic trunk were wrapped with other adhesive tapes (50 mm in width). Immediately after those rats were returned to the cages, the number of feces dropped on the tray was counted 1 h after the wrapping. Test compounds were administered 1 h or 30 min before the restraint.

Hormone assays

The blood was collected from the heart of anesthetized animals and serum was separated by centrifugation at 1 500 r/min for 20 min and kept at -70 °C until assayed for E₂ and P. The gonadal steroids were measured in duplicate by radioimmunoassay using kits (Tianjin Depu Biotech). Aliquots of serum were added to tubes that had been coated with antibodies to steroid hormone followed by addition of ¹²⁵I-hormone. Mixtures were vortexed gently and incubated for 2-3 h at room temperature. Incubation was terminated by aspirating excess of ¹²⁵I-hormone and tubes were counted.

RNA extraction and RT-PCR

Distal colon tissues were harvested from animals in various treatment groups and frozen in liquid nitrogen. Total RNA from the frozen tissues was extracted using TRIzol as described by the manufacturer's protocol (Invitrogen). RNA was dissolved in RNase-free water and the concentration was determined by measuring the optical density (A) at 260 nm. The purity of the RNA was assessed by the ratio of A₂₆₀/A₂₈₀. Two micrograms of total RNA from each sample was transcribed into cDNA using M-MLV reverse transcriptase (Promega). Briefly, total RNA was mixed with M-MLV reverse transcriptase (200 U/µL), oligo (dT)₁₈ (50 µmol/L, Sangon, Shanghai), RNase inhibitor (40 U/µL), and dNTPs (1.25 mmol/L each, TaKaRa, Dalian) in a buffer containing 37.5 mmol/L KCl, 25 mmol/L Tris-HCl, and 1.5 mmol/L MgCl₂ (pH 8.3) in a total volume of 25 µL. The mixture was incubated at 42 °C for 90 min, heated to 95 °C for 5 min and cooled to 58 °C for 5 min. The resulted cDNA samples were amplified by PCR using Biometra PCR machine (Standard Power Pack P25, Germany) and the following specific primer pairs were used (SBS Genetech, Beijing): rats 5-HT₂R sense, 5'-GAG ACC ATC TTC ATT GTG CAG CTG GTG CA-3'; antisense, 5'-ACA GCA GCG TGT CCA GCA CAT ATC CCA CC-3', for the 397-bp product^[17]. Amplification of the rat β-actin gene transcript was used to control the efficiency of RT-PCR among the samples, β-actin sense, 5'-GTC ACC CAC ACT GTG CCC ATC T-3'; antisense, 5'-ACA GAG TAC TTG CGC TCA GGA G-3' for the 542-bp product^[18]. PCR mixes contained 25 pmoL each of sense

and antisense primers, 2.0 U Taq DNA polymerase (Biostar), the buffer supplemented with 1.5 mmol/L MgCl₂, 0.2 mmol/L dNTPs and 1 µL cDNA in 25 µL. The amplification cycles were carried out under the following conditions: first denaturing at 94 °C for 3 min, then denaturing at 92 °C for 45 s, annealing at 55 °C for 45 s, and extension at 72 °C for 45 s for a total of 35 cycles, finally a 7 min extension at 72 °C was conducted. The resulted PCR products were analyzed on 20 g/L agarose gels in TBE buffer (40 mmol/L Tris-acetate, 1 mmol/L EDTA, pH 8.3) containing 0.05 µg/mL ethidium bromide. Appropriate molecular weight markers (100 bp ladder, MBI) were used to verify the required size of the final PCR product. The gels were scanned and the mean density of the products were visualized and photographed under the BIO-PROFIL (VILBER LOURMAT, France).

Statistical analysis

Results are expressed as mean±SD. The statistical significance of difference was evaluated with one-way analysis of variance (ANOVA), and analyzed by SPSS 10.0. A confidence level of P<0.05 was considered significant.

RESULTS

Fecal pellets output

Table 1 shows the effects of E₂+P combination and blank control on restraint stress-induced fecal pellet output in rats. The number of fecal pellets counted during observation period was negligible in unrestrained normal rats. In the restraint stress rats, fecal pellet output was measured with pellet counts of 5.6±0.5 for ovarian hormone-induced sham group. The number of fecal pellets was significantly increased in OVX vehicle-treated group compared with sham and E₂+P-treated group (vehicle-treated, 8.6±0.6; sham group, 5.6±0.5; E₂+P-treated, 4.1±0.5; P<0.01). Meanwhile, the time of vitreous pellets output was significantly decreased (P<0.01). The number of fecal pellets was significantly decreased (E₂+P-treated, 4.1±0.5; sham group, 5.6±0.5; P<0.01) and the time of vitreous pellets output was significantly increased in E₂+P-treated group (P<0.01).

Table 1 Effects of ovarian hormone on fecal pellets output in the ovariectomized restraint stress rats (mean±SD, n = 8)

Group	Fecal pellets (number)	Time of vitreous pellet output (min)
Sham-operated	5.6±0.5	4.8±0.26
OVX	8.6±0.6 ^d	1.3±0.22 ^f
OVX+E ₂ +P	4.1±0.5 ^{db}	5.8±0.29 ^f

^bP=0.000 vs OVX group; ^dP = 0.000 vs sham-operated group; ^fP = 0.000 vs sham-operated group.

Table 2 Serum concentration of estrogen and progesterone (mean±SD, n = 8)

Group	E ₂ (pmol/L)	P (nmol/L)
Sham-operated	104±6	26±1
OVX	15.7±0.8 ^d	3.2±0.6 ^b
OVX+E ₂ +P	168±8 ^d	44±2 ^b

^bP = 0.000 vs sham-operated group; ^dP = 0.000 vs sham-operated group.

Serum concentration of estrogen and progesterone

As expected, serum levels of E₂ were suppressed in OVX rats and restored after treatment with ovarian steroids (sham-operated, 104±6; OVX: vehicle-treated 15.7±0.8; E₂+P-treated 168±8; P<0.01, Table 2). Serum levels of P were also decreased

Figure 1 A: 5-HT₃R mRNA expression in the colon of restraint stress rats. Lane 1: Markers, 100-bp ladder; lane 2: sham-operated group; lane 3: OVX group; lane 4: OVX+E₂+P group. B: 5-HT₃R mRNA expression in the colon of restraint stress rats. The bar shows the relative optical density of 5-HT₃R band obtained from different groups. Values were reported as the ratio of 5-HT₃R to β-actin signals and normalized by the corresponding RT-PCR products for β-actin, used as the internal control. PCR was carried out for 35 cycles. Amplified cDNA products were separated by 20 g/L agarose gel electrophoresis. ^d $P = 0.000$ vs sham-operated group; ^b $P = 0.000$ vs OVX group; ^{bd} $P = 0.000$ vs sham-operated group.

in OVX rats and increased following treatment with E₂+P (sham-operated, 26±1; OVX: vehicle-treated, 3.2±0.6; E₂+P-treated, 44±2; $P < 0.01$).

Expression of 5-HT₃R in the colon of restraint stressed rats

Effects of ovarian hormone on the expressions of 5-HT₃R mRNA in colon tissues of restraint stress-induced rats were examined by RT-PCR as shown in Figure 1, which revealed a marked increase in OVX vehicle-treated group (relative optical density: 1.12±0.07). The expression of 5-HT₃R mRNA in colon was increased to a maximum in OVX vehicle-treated group (sham: 0.85±0.06, $P < 0.01$) and significantly decreased after E₂+P-treatment (0.65±0.05, $P < 0.01$, Figure 1B). Furthermore, 5-HT₃R mRNA expression was decreased by 1.3-fold in E₂+P-treated group ($P < 0.01$ compared with sham group, Figure 1B). However, there was a trend of lower expression of 5-HT₃R mRNA in colon with the increasing serum levels of E₂ and P.

DISCUSSION

IBS is a complex GI disorder with a poorly understood pathophysiology in which three major mechanisms interact: altered gastrointestinal motility, increased sensory function of the intestine and psychosocial factors^[19]. Various observations suggested that fluctuations in sex hormones in women might have an influential role in IBS: for many women, symptoms became amplified around the time of menses^[8]. In menstruating women, symptoms are influenced by menstrual cycle and bloating, abdominal pain, and diarrhea tend to be amplified during the late luteal and early menses phases^[20,21]. GI symptoms increase and intestinal transit decreases during pregnancy (a time of high E₂ and P levels)^[22], and rectal sensitivity is greater during menses compared with other menstrual-cycles in women with IBS^[8]. The precise mechanism responsible for the changes in gastrointestinal motility is still unknown. Earlier research has shown that E₂ can delay gastric emptying and GI transit in rats^[23], low dose of P (1 mg/kg, i.p.) enhanced the gastric emptying and high dose of P (5 mg/kg, i.p.) inhibited it. P (1 mg/kg) increased the intestinal transit while higher dose (10–20 mg/kg) had no effect. E₂ suppresses gastric motility response to thyrotropin-releasing hormone (TRH) and restraint stress in conscious rats^[14]. The precise sex steroid that is responsible for these changes is controversial. It appears that sex steroids play an important role in modulating these effects as postmenopausal women being treated with sex hormone-replacement therapy (HRT) had a decreased rate of gastric emptying of solids compared with men. In contrast, postmenopausal women without hormone replacement had rates of solid emptying similar to those of men^[24]. Results in pre- and postmenopausal women taking sex HRT showed they had slower gastric emptying than men^[25]. Whereas

recent studies have also confirmed that HRT is associated with an increased risk of IBS^[26].

Stress is known to be an important factor in causing IBS, since it significantly alters bowel functions. Several rodent models of bowel dysfunction caused by restraint stress have been investigated for pharmacological analysis of a stress-related bowel disorder like IBS^[12,13,27]. There were similarities between the intestinal effects of wrap restraint stress in rats and IBS in human. Therefore, wrap restraint stress rat is an appropriate animal model to study stress-related intestinal dysfunction. The role of sex hormones in the development of IBS is the subject of ongoing study. Our results indicate that in the restraint stress rats, serum levels of E₂ and P were suppressed in OVX rats and restored following chronic treatment with ovarian steroids. Meanwhile, OVX vehicle-treatment significantly increased the number of fecal pellets, moreover, the time of vitreous pellets output was significantly decreased. E₂+P treatment significantly decreased the number of fecal pellets and increased the time of vitreous pellets output. Our study indicated that E₂ and P could relieve the rat colon contractile response to restraint stress, thus decrease the number of fecal pellets and increase the number of fecal pellets output.

5-HT₃R is expressed by most myenteric neurons, including those that excite gastrointestinal muscle^[28–30]. In contrast to other serotonin receptor subtypes, these receptors are ligand-gated ion channels involved in rapid excitatory responses in peripheral and central nervous system^[31]. 5-HT₃R mediates a fast inward current in myenteric neurons^[29,30], and their activation is thought to enhance cholinergic transmission via the release of acetylcholine from parasympathetic nerve terminals^[13], thus resulting in an increase in gastrointestinal motility, fluid secretion and pain. Clinically, 5-HT₃R antagonists are important in the treatment of symptoms in IBS^[32].

Previous studies demonstrated that restraint stress resulted in an increase in fecal pellet output in rats fed the diet, as well as diarrhea in food-deprived rats, which are equally mediated through the endogenous activation of the 5-HT₃R^[13,14]. Clinically, 5-HT₃R antagonist drugs appeared to more effectively diminish bowel pattern disruption in women with IBS as compared to men^[11]. Recently, it has been demonstrated that both forskolin and 17-beta-estradiol inhibit the function of 5-HT₃R in a noncompetitive manner and that this inhibition is independent of cAMP levels^[15]. Because 5-HT₃R plays a role in the pathogenesis of IBS, it is possible that the attenuated development of IBS in female rats might be related to the modulation of gonadal hormones on 5-HT₃R and GI system. This study focused on the effects of gonadal steroid hormones on 5-HT₃R mRNA expression in colon of wrap restraint stress rats. We observed an increase in 5-HT₃R gene expression in OVX rats. The increase in 5-HT₃R gene

expression was prevented by treating the OVX rats with a combination of E₂ and P. These results suggest that 5-HT₃R mRNA expression is sensitive to the absence of E₂ and P. Their roles in regulation of 5-HT₃R mRNA expression deserve further study. If the increase in the density of 5-HT₃R gene expression induced by E₂ and P deficiency reflects overactivity of 5-HT₃R, then such changes may be relevant to hormone- and age-related GI dysfunction.

In conclusion, we suggest that female gonadal hormones may play an important role in regulation of colon 5-HT₃R. Exploration of 5-HT₃R expression by gonadal steroid hormones could contribute to a better understanding of the interactions between ovarian steroids and GI and may have major pathophysiological implications for 5-HT-related bowel disorders, such as IBS.

Abstract

AIM: To assess the efficacy and safety of intraperitoneal chemotherapy in patients undergoing curative resection for gastric cancer through literature review.

METHODS: Medline (PubMed) (1980-2003/1), Embase (1980-2003/1), Cancerlit Database (1983-2003/1) and Chinese Biomedicine Database (1990-2003/1) were searched. Language was restricted to Chinese and English. The statistical analysis was performed by RevMan4.2 software provided by the Cochrane Collaboration. The results were expressed with odds ratio for the categorical variables.

RESULTS: Eleven trials involving 1 161 cases were included. The pooled odds ratio was 0.51, with a 95% confidence interval (0.40-0.65). Intraperitoneal chemotherapy may benefit the patients after curative resection for locally advanced gastric cancer, and the combination of intraperitoneal chemotherapy with hyperthermia or activated carbon particles may provide more benefits to patients due to the enhanced antitumor activity of drugs. Sensitivity analysis and fail-safe number suggested that the result was comparatively reliable. However, of 11 trials, only 3 studies were of high quality.

CONCLUSION: Intraperitoneal chemotherapy after curative resection for locally advanced gastric cancer may be beneficial to patients. Continuous multicenter, randomized, double blind, rigorously designed trials should be conducted to draw definitive conclusions.

INTRODUCTION

Gastric cancer is the second most common cause of cancer death worldwide. Surgery is the main choice of radical treatment, however, even for patients with apparently completely resection, the five-year survival rate is about 30-60%, which has been disappointing. Peritoneal metastasis is the most common type of recurrence after surgery and has the worst prognosis in

patients with advanced stomach cancer. To improve the survival of the patients with gastric cancer, intraperitoneal chemotherapy (IPT) as a possible effective treatment for peritoneal dissemination in locally advanced gastric cancer has been investigated clinically, but the results among these studies are still different and disputed. To evaluate whether IPT benefited the patients undergoing radical resection for locally advanced gastric cancer, we summarized all the available randomized trials and combined the results for meta-analysis.

MATERIALS AND METHODS

Materials

Medline (PubMed) (1980-2003/1), Embase (1980-2003/1), Cancerlit Database (1983-2003/1) and Chinese Biomedicine Database (1990-2003/1) were searched. Languages were restricted to Chinese and English.

Inclusion and exclusion criteria

To be included, trials had to be randomised and controlled. Trials could be single-blind, double-blind or not blind. Chemotherapy groups were treated intraperitoneally, including intraperitoneal chemotherapy with or without activated carbon particles (CH), intraperitoneal hyperthermic perfusion. No oral or intravenous chemotherapy, chemoimmunotherapy, or radiotherapy were used. Those receiving gastrectomy alone were included in control group. All patients must have had a potential curative surgery for locally advanced gastric cancer.

Data extracted included the baseline data of intraperitoneal chemotherapy group and control group, assessments of eligibility and trial quality, number of survival and death and the statistical consideration.

Methods

Data collection The content terms of stomach neoplasms, intraperitoneal chemotherapy and surgery, and the methodological terms of clinical trial, phase III, randomized trial, double blind method were used. These searches were supplemented by hand searching of the reference lists of identified trials and review articles. Two reviewers assessed independently the outcome data using a pre-designed strategy. They also evaluated study quality using Jadad-scale^[1] plus allocation concealment. Intention-to-treat analyses were also performed. Agreement was achieved through discussion when they have different evaluations.

Statistical analysis

The results of eligible trials were pooled using RevMan4.2 software provided by the Cochrane Collaboration. The result was expressed with odds ratio (OR) for the categorical variables. *Q* statistic test was used for gross statistical heterogeneity. Sensitivity analysis was performed by excluding the trials in which Jadad-scale was low. Publication bias was assessed by calculating the Rosenthal's fail-safe number. Subgroup analysis was performed by collecting summaries for subsets of studies with different characteristics.

RESULTS

Study selection

There was good agreement between the two reviewers on the eligibility, quality scores and data extraction of analysis. Eighteen

Compariso: 01 chemotherapy vs surgery

Outcome: 01 OR

Figure 3 Sensitivity analysis 2 (by excluding the low quality trials).

random trials including surgery plus intraperitoneal chemotherapy, preliminary surgery alone were analysed, from which 7 reports were excluded for repetitive studies. Table 1 shows the details of the 11 trials^[2-12] included in the analysis with a total enrollment of 1 161 patients, in which 609 patients were assigned to the treatment group and 552 to the control group. The average sample size was 106 patients. Of 11 trials, three studies were of high quality according to the Jadad-scale (with three scores), one trial mentioned double-blind design and sample-size calculation, and two studies described intention-to-treat analysis. The fail-safe number of 104 suggested that no important publication bias existed in this meta-analysis.

Meta-analysis

Figure 1 shows the result of the meta-analysis. There was no statistically significant heterogeneity in our analysis, so a fixed effect model was used and the odds ratio was 0.51 (95% CI 0.40 to 0.65). The sensitivity analysis was performed by excluding trials with Jadad-scale scores between 1 and 3 and revealed the same difference between intraperitoneal chemotherapy and surgery alone (odds ratio 0.51, 95% CI 0.36 to 0.71; odds ratio 0.54, 95% CI 0.31 to 0.93) (Figures 2, 3).

Subgroup analysis

As shown in Table 2, intraperitoneal hyperthermic chemoperfusion (IHCP) or chemotherapy with activated carbon particles (CH) produced more benefits to patients than those without hyperthermia or CH; the group of trials from Asian countries exhibited a trend towards a more significant effect than those from non-Asian countries, which showed no effect with IPT; for trials with more than 5 years of follow-up, the effects were less obvious than those of shorter follow-up, if indicated that IPT might afford long-term survival by delaying relapse and recurrence.

Table 2 Subgroup analysis

Characteristic	No. of trials	OR	95% CI
IPT (without CH and IHCP)	2	0.57	(0.35-0.92)
IPT (only with CH)	2	0.52	(0.29-0.94)
IHCP	7	0.48	(0.35-0.67)
Follow-up time (mo) <60	6	0.40	(0.27-0.59)
Follow-up time (mo) ≥60	5	0.60	(0.44-0.82)
Asia	9	0.49	(0.38-0.64)
Non-Asia (Austria)	2	0.67	(0.32-1.41)

IPT: intraperitoneal chemotherapy; CH: carbon particles; IHCP: intraperitoneal hyperthermic chemoperfusion.

Side effect analysis

All studies described the side effects of medicine, including anastomotic leakage, leukocytopenia, fever, intestinal obstruction, fistula, intraabdominal bleeding, and prolonged abdominal pain, *etc.* Of 11 trials, 5 had mild complications; 3 had no significant differences in adverse effects between the surgery group and the chemotherapy group; 2 trials produced complications in the chemotherapy group: one was bowel fistula, the other was intraabdominal abscess which turned better after effective treatment. One trial from Austria reported serious side effects by IPT, the complications of the treatment group and control group were respectively 35% and 16%, the death rates, 11% and 2%, which terminated the trial ahead of schedule.

DISCUSSION

IPT is applied to kill residual tumor cells left behind during surgery, which can not be achieved by the intravenous approach, especially for stage 3 and 4 gastric carcinomas. It is of much importance to extirpate the free tumor cells in the abdominal cavity and micrometastases on the peritoneal surface to attain longer survival. Animal trials and phase II clinical trials have revealed that IPT could be effective to prevent peritoneal dissemination and liver metastasis^[13].

The aim of meta-analysis is to provide a comprehensive, up-to-date summary of average effect of all the relevant randomized controlled trials, to provide reliable guidance for clinical practice and future research^[14]. Based on our results, IPT may benefit the patient after curative resection for locally advanced gastric cancer, and the combination of IPT with hyperthermia or activated carbon particles may provide more benefit to patients due to the enhanced antitumor activity of drugs^[15]. Sensitivity analysis and fail-safe number suggested that the results were comparatively reliable.

Two trials from Austria showed that intraperitoneal chemotherapy was not beneficial to patients, one of them terminated ahead of time because of serious adverse effects. Nine Asian studies (from China, Japan, Korea) confirmed a significant survival benefit for patients with tolerable side effects of antitumor drugs. Considering the difference between western studies and Asian studies^[16,17], we speculate that they may have different aetiology or biology methods^[18].

The adverse effect was an important factor to influence the result of intraperitoneal chemotherapy. However, only 4 trials described the side effects of medicine on the basis of World Health Organization classification, and the different forms of illustration made it difficult to analyze the effect according to evidence based medicine. There fore, we should observe and

describe the toxicity of medicine by WHO standard in future clinical research.

Of included 11 trials, only 3 trials were of high quality (Jadad-scale with 3 scores) and the other 8 trials were of low quality, which weakened our evidence. On the other hand, reliance on published trials alone might distort the outcome of meta-analysis, because positive studies were more likely to be published than negative ones.

At present, the treatment effect of gastric cancer is still disappointing. Many surgeons hold that the stomach cancer patients cannot benefit from IPT, which is different from our meta-analysis results. To draw definitive conclusions, more effective multicenter, randomized, double blind, rigorously designed trials are needed.

Abstract

AIM: To determine the role of p38 MAP kinase signal transduction pathways in diallyl disulfide (DADS)-induced G2/M arrest in human gastric cancer MGC803 cells.

METHODS: MGC803 cell growth inhibition was measured by MTT assay. Phase distribution of cell cycle was analyzed by flow cytometry. Expression of Cdc25C, p38, phosphorylation of p38 (pp38) were determined by Western blotting.

RESULTS: MTT assay showed that SB203580, a specific p38 MAPK inhibitor blocked DADS-induced growth inhibition. Flow cytometry analysis revealed that treatment of MGC803 cells with 30 mg/L DADS increased the percentage of cells in the G2/M phase from 9.3% to 39.4% ($P<0.05$), whereas inhibition of p38 activity by SB203580 abolished induction of G2/M arrest by DADS. Western blotting showed that phosphorylation of p38 was increased 3.52-fold following treatment of MGC803 cells with 30 mg/L DADS for 20 min ($P<0.05$), whereas Cdc25C was decreased 68% following treatment of MGC803 cells with 30 mg/L DADS for 24 h ($P<0.05$). Decreased Cdc25C protein expression by DADS was attenuated by SB203580 ($P<0.05$).

CONCLUSION: DADS-induced G2/M arrest of MGC803 cells involves activation of p38 MAP kinase pathways. Decreased Cdc25C protein expression by p38 MAPK played a crucial role in G2/M arrest after treatment with DADS.

INTRODUCTION

Unlimited and uncontrolled cell proliferation is obviously characteristics of tumor cells^[1,2]. Given that disruption of cell cycle plays a crucial role in cancer progression^[3], its modulation

by phytochemicals seems to be a logical approach in controlling carcinogenesis. Thus cell cycle regulation and its modulation by various natural (plant-derived) and synthetic agents are gaining widespread attention in recent years^[4-18]. Most of the plant products with anticancer activity are strong antioxidants and some of them are effective modulators of protein kinase/phosphatases that are associated with cell cycle regulation. DADS is a major component of cooked garlic and oil-soluble organosulfur compound in processed garlic, which inhibits the proliferation of human breast, hepatoma, lung, bladder, colon cancer cells and human leukemia HL-60 cells^[19-25]. Previous studies showed that the ability of DADS to suppress HCT-15, HT-29 cell proliferation was related to its propensity to induce a G2/M arrest^[23,24]. However, the molecular mechanisms by which DADS exerts its effects on tumor cells leading to inhibition of cell growth and induction of G2/M arrest are largely unknown. p38 MAP kinase (p38) is a member of the mitogen-activated protein (MAP) kinase signaling cascade which has been shown to regulate a variety of cellular events such as cell proliferation, differentiation, and apoptosis^[26-28], and may therefore be a potential target of DADS action. Gastric cancer is one of the most common malignant tumors in China^[29-30]. Our previous studies showed that DADS could inhibit human gastric cancer MGC803 cell growth^[31]. In this study, signaling pathways of p38 MAPK-induced G2/M arrest in DADS treated MGC803 cells were investigated for their involvement in the mechanisms of DADS-induced growth inhibition.

MATERIALS AND METHODS

Materials

Human gastric cancer cell line MGC803 was purchased from Cancer Research Institute of Hunan Medical University. DADS was purchased from Fluka Chemika (Ronkonkoma, NY). Monoclonal anti-p38, anti-pp38 antibodies and SB203580 were purchased from Cell Signaling (Beverly, MA). Polyclonal anti-Cdc25C antibody was purchased from Santa Cruz Biotechnology (Santa Cruz, CA).

Methods

Cell culture and MTT assay MGC803 cells were cultured in RPMI 1640 medium (Gibco) supplemented with 100 mL/L fetal bovine serum (Sijiqing Co.1 Hangzhou) with addition of 100 U/mL penicillin, 100 U/mL streptomycin. Cells in suspension (50 μ L) were added to each well of a 96-well culture plate and incubated for 24 h at 37 °C in a humidified atmosphere of 50 mL/L CO₂ in air. The 96-well culture plate was divided into 4 sections, with one section being treated by culture media, the others were treated by one of the followings at 50 μ L: culture media containing 2 \times reagents (10 μ mol/L SB203580, 30 mg/L DADS, 30 mg/L DADS+10 μ mol/L SB203580). In the latter group, SB203580 was added 1 h prior to DADS. The cultures were again incubated as above. After 72 h, 20 μ L 5 g/L MTT solution was added to each well, and the cultures were further incubated in 100 μ L DMSO solution. A microplate reader was used to measure absorbance at 570 nm for each well. Growth inhibition rate was calculated as follows: growth inhibition rate = $(1 - A_{570nm} \text{ of treated cells} / A_{570nm} \text{ of control cells}) \times 100\%$.

Cell cycle analysis Cells were incubated in culture media alone or culture media containing reagents (10 μ mol/L SB203580, 30 mg/L DADS, 30 mg/L DADS+10 μ mol/L SB203580), at 37 °C for 24 h. In the latter group, SB203580 was added 1 h prior to DADS. Cells were harvested in cold PBS, fixed in 700 mL/L ethanol, and stored at 4 °C for subsequent cell cycle analysis. Fixed cells were washed with PBS once and suspended in 1 mL of PI staining reagents (20 mg/L ribonuclease and 50 mg/L propidium iodide). Samples were incubated in the dark for 30 min before cell cycle analysis. The distribution of cells in the cell cycle was measured by a flow cytometer.

Western blotting MGC803 cells treated with different reagents were harvested, rinsed twice with cold PBS, and incubated in the lysis buffer containing 50 mmol/L Tris (pH7.5), 150 mmol/L NaCl, 10 mL/L NP-40, 1 g/L SDS, 10 g/L sodium deoxycholate, 1 mmol/L DTT, 1 mmol/L PMSF, 2.5 mg/L leupeptin, 25 mg/L aprotinin on ice for 20 min. Following the centrifugation at 12 000 g for 30 min at 4 °C. The amount of protein in the supernatant was determined using BCA protein assay reagent. Equal amount of protein sample was completely vortexed with 2 \times SDS-gel buffer, and boiled for 5 min at 100 °C to dissolve the bound proteins. The samples were segregated on 100 g/L SDS-acrylamide gel, transferred onto a nitrocellulose membrane and blocked with 50 g/L defatted milk, then probed with different primary antibodies. Anti-mouse or anti-rabbit IgG conjugated peroxidase was as a secondary antibody. The filters were then incubated in SuperSignal ECL-HRP detection reagent for 1 min followed by exposure to X-ray film.

Statistical analysis

Results were analyzed by SPSS10.0 statistical software. Data were expressed as mean \pm SD. Comparisons between different groups were made by one-way ANOVA (with LSD for post hoc analysis) or χ^2 test. $P < 0.05$ was taken as statistically significant.

RESULTS

Effect of reagents on growth inhibition of MGC803 cells

As shown in Table 1, 30 mg/L DADS suppressed MGC803 growth by 58.6% ($P < 0.05$). SB203580 10 μ mol/L alone slightly reduced cell growth. In contrast, SB203580 blocked DADS-induced growth inhibition ($P < 0.05$). Thus, addition of SB203580 to the cells decreased the inhibitory ability of DADS to MGC803 cells growth.

Table 1 A_{570nm} of MGC803 cells exposed to reagents

<i>n</i> = 12	Control	SB203580 (10 μ mol/L)	DADS (30 mg/L)	DADS (30 mg/L) +SB203580 (10 μ mol/L)
χ	0.78	0.076	0.32	0.53
<i>S</i>	0.038	0.035	0.028	0.024
IR (%)		3.4	58.6 ^a	31.7 ^a

^a $P < 0.05$ vs control; IR: inhibition rate.

Table 2 Distribution of MGC803 cells in cell cycle (%)

	Control	SB203580 (10 μ mol/L)	DADS (30 mg/L)	DADS (30 mg/L) +SB203580 (10 μ mol/L)
G1	62.5 \pm 0.9	62.8 \pm 1.3	33.7 \pm 1.2	54.0 \pm 1.5
S	28.2 \pm 1.2	27.3 \pm 0.8	27.9 \pm 0.8	24.8 \pm 1.1
G2	9.3 \pm 0.8	9.9 \pm 1.1	39.4 \pm 1.3 ^a	21.2 \pm 0.9 ^a

^a $P < 0.05$ vs control.

Effect of reagents on cell cycle distribution of MGC803 cells

Flow cytometry revealed that the proportion of cells in the G2/M phase after treatment with 30 mg/L DADS for 24 h was 39.4%, three times more than that in untreated cells (9.3%). SB203580 10 μ mol/L alone had no effect on cell growth ($P > 0.05$). But inhibition of p38 activity by SB203580 abrogated induction of G2/M arrest by DADS. MGC803 cells treated with DADS in the presence of SB203580 decreased the G2/M phase to 21.2%, compared to 39.4% by DADS alone ($P < 0.05$).

Expression of p38, pp38, and Cdc25C after reagents treatment of MGC803 cells

Western blotting revealed that phosphorylation of p38 was increased 3.52-fold following treatment of cells with 30 mg/L DADS for 20 min. At the same time, the total p38 amount did not change. Furthermore, DADS-induced-phosphorylation of p38 was completely inhibited by SB203580 (10 μ mol/L) (Figure 1).

Figure 1 Expression of p38, phosphorylation of p38 proteins in MGC803 cells following treatment of reagents for 20 min.

DADS treatment for 24 h decreased the level of Cdc25C by 68%, and pretreatment of MGC803 cells with SB203580 partially reversed the down-regulation of Cdc25C level by DADS. In contrast, SB203580 alone had no significant effect on Cdc25C expression (Figure 2).

Figure 2 Expression of Cdc25C protein in MGC803 cells following treatment of reagents for 24 h.

DISCUSSION

Mitogen-activated protein kinase (MAPK) pathway has a central role in transducing extracellular signals into cellular responses. p38 kinase is a member of the mitogen-activated protein kinase family that is activated by a variety of environmental stress. Rapid initiation of G2 arrest after UV radiation is mediated by p38 kinase^[32]. Inhibition of p38 blocks the rapid initiation of G2 delay in both human and murine cells after ultraviolet radiation. p38 kinase is responsible for rapid initiation of the G2 delay in IME cells after the hypertonic stress created by addition of NaCl^[33]. Inhibition of p38 kinase blocks the rapid initiation of this checkpoint both in an immortalized cell line (mIMCDs) and in second-passage IME cells from mouse inner medulla. Genistein-induced G2/M arrest is associated with the activated p38 mitogen-activated protein kinase^[34]. Thus p38 is a critical event for initiating the G2/M checkpoint and inducing G2/M arrest. Our research showed that DADS-induced MGC803 cells

G2/M arrest and growth inhibition correlated with increased p38 phosphorylation. We used SB203580, a specific inhibitor of p38 to address the potential role of p38 kinase in the regulation of cell-cycle progression. Inhibition of p38 activity by SB203580 abolished induction of G2/M arrest by DADS. Therefore, our research data demonstrated that DADS-induced G2/M arrest of MGC803 cells involved activation of p38 MAP kinase pathways.

p34^{cdc2} is the key regulator of cell-cycle progression through G2-M^[35]. In particular, activation of p34^{cdc2} kinase activity is required for progression from G2 to M. phosphorylation of the inhibitory residues Thr14/Tyr15 of p34^{cdc2} leads to decreased kinase activity and subsequent arrest at the G2/M phase^[36]. The Cdc25C protein phosphatase is a key regulator of p34^{cdc2} phosphorylation status and kinase activity by dephosphorylating Thr14/Tyr15 residues^[37]. *In vitro*, p38 binds and phosphorylates Cdc25C at serine 216^[32]. Phosphorylation of Cdc25C triggers cell-cycle arrest by the sequestration of Cdc25C by 14-3-3^[38]. Frey *et al.* found that p38 was involved in genistein-induced G2/M arrest and down-regulation of Cdc25C expression in immortalized human mammary epithelial cell line MCF-10F^[35]. Hepatitis B virus X protein (pX) is implicated in hepatocarcinogenesis by an unknown mechanism. Research data^[39] showed that pX-dependent activation of p38 MAPK inactivated Cdc25C by phosphorylation of Ser216, thus initiating activation of the G2/M checkpoint, resulting in 4pX-1 cell growth retardation. These data suggest that p38 participation in down-regulation of the Cdc25C level may be an important way to impair its actions and an important event in G2/M checkpoint regulation. In the present studies, decreased Cdc25C protein phosphatase by DADS was attenuated by SB203580. Thus it indicates that regulation of Cdc25C protein expression by p38 is a critical event for G2/M arrest after treatment with DADS.

In summary, DADS-induced G2/M arrest and growth inhibition of MGC803 cells involves activation of p38 MAP kinase pathways. Decreased Cdc25C protein expression by p38 is a critical event for G2/M arrest by DADS. However, it should be noted that although p38 inhibitor SB203580 abrogated DADS-induced G2/M arrest, the reversal was not total. SB203580 could not completely abolish induction of G2/M arrest by DADS. This implies that p38 activation is not the sole prerequisite for DADS induced G2/M arrest, other mechanisms may be involved in G2/M arrest. Additional studies are needed to clarify these mechanisms. A deeper understanding of the molecular mechanisms involved in the regulation of cell cycle control is very important for the development of novel anticancer strategies.

Abstract

AIM: To study the expression of a disintegrin and metalloproteinase 17 (ADAM17) mRNA in hepatocellular carcinoma (HCC) and to evaluate the relationship between ADAM17 mRNA expression and clinicopathological features of HCC.

METHODS: Hepatocellular carcinomas (HCC) from 31 cases were divided into small HCC (SHCC), nodular HCC (NHCC) and solitary large HCC (SLHCC) according to tumor diameter and the number of nodes. ADAM17 mRNA expressions were compared among those groups by means of semi-quantitative reverse transcription polymerase chain reaction (RT-PCR). The relationship between ADAM17 mRNA expression level and clinicopathological features of HCC was evaluated.

RESULTS: NHCC had lower differentiation and was more frequently of microvascular invasion (10/12) than SHCC (3/11) and SLHCC (3/8) ($P < 0.05$), but no statistical difference was observed between SHCC and SLHCC comparing their clinicopathological features. ADAM17 mRNA expression was detected in 77.4% (24/31) of HCC tissues and was significantly higher than that in paired non-cancerous liver tissues in which only 35.5% (11/31) of the samples were detected of the expression ($P < 0.05$). The expression of ADAM17 mRNA was much higher in NHCC than in SHCC and SLHCC ($P < 0.05$), while no significant difference was discovered between SHCC and SLHCC. The quantities of ADAM17 mRNA were significantly higher in poorly differentiated HCC than in well or moderately differentiated HCC, but no statistical difference was found concerning liver cirrhosis, tumor capsule formation or microvascular invasion of the cancer.

CONCLUSION: The increased expression of ADAM17 may play a key role in the development of HCC. The expression levels of ADAM17 mRNA varied among different pathological types of HCC. Lower mRNA expression of ADAM17 mRNA in SLHCC may be associated with the better molecular pathological features of SLHCC.

INTRODUCTION

Hepatocellular carcinoma (HCC) is one of the most common malignant diseases in the world. Approximately 560 000 new cases of HCC are diagnosed each year, constituting 6% of all new human cancers^[1]. The HCC mortality rate in China is approximately 20.4/100 000 and is the second leading cause of cancer death among Chinese males^[2]. The prognosis of large hepatocellular carcinoma (LHCC) is generally considered to be worse than small hepatocellular carcinoma (SHCC), but long-term survival of some LHCC, especially solitary large hepatocellular carcinoma (SLHCC), could be frequently observed after curative resection^[3-5]. From the clinical observation and our research, we hypothesized that SLHCC was of relatively better biological behavior^[2]. Furthermore, we have preliminarily proved our hypothesis in a series of researches by showing that SLHCC was of relatively better pathological features and surgical prognosis^[2,3,6]. Although many systemic studies have been performed, the unique clinical and molecular pathological features of SLHCC are still far from a clear deep understanding and need further investigation.

A disintegrin and metalloproteinase 17 (ADAM17) is a kind of transmembrane metalloproteinase^[7], which can cleave the ectodomain of many transmembrane proteins. The substrates of ADAM17 mediated cleavage include tumor necrosis factor- α (TNF- α), tumor necrosis factor receptor type I (TNFR I) and tumor necrosis factor receptor type II (TNFR II), interleukin1 receptor type II (IL1R II), Notch receptor, L-selectin, mucin1 (MUC1), CD30, tumor necrosis factor-related activation-induced cytokine (TRANCE) and many ligands of epidermal growth factor receptor (EGFR), such as transforming growth factor- α (TGF- α), heparin-binding epidermal growth factor-like growth factor (HB-EGF), amphiregulin and so on^[8-19]. Hassan reported that the oxygen radicals generated by smoke stimulated ADAM17 to cleave transmembrane amphiregulin. The binding of amphiregulin to EGFR then promoted proliferation of lung cancer cells^[20]. The cleavage function of ADAM17 was required for the activation of EGFR by TGF- α in Hela cells, and the high expression level of ADAM17 in mammary tumors was correlated with high activation rate of EGFR^[21]. Another experiment showed that single metastatic lung cancer cell in bone marrow presented overexpression of ADAM17^[22]. All these suggested that ADAM17 played a key role in the development of some cancers. It is well known that the EGFR mediated pathway played an important role in HCC development^[23,24]. The overexpression of EGFR and its ligands were observed in HCC tissue and were related to the prognosis of HCC patients^[25,26]. However, much less is known about the mechanisms involved in signal transduction, which activate the EGFR in HCC. It is even not sure whether there is an increased activation rate of EGFR in HCC besides the overexpression of EGFR and its ligands. As ADAM17 played an important role in the activation of EGFR^[27] and up to now, there is no report about the expression and function of ADAM17 in HCC, so to have a better understanding of the molecular mechanisms involved in HCC development and the unique molecular pathological features of SLHCC, we studied the expression of ADAM17 in HCC and paired non-cancerous liver tissues.

MATERIALS AND METHODS

Materials

Thirty-one fresh HCC specimens (26 from males and 5 from females) were obtained by surgical resection in Xiangya Hospital, Central South University between May 2002 and February 2003. Tissues 1 cm away from the edge of the cancer were used as the paired non-cancerous control. The tissues used for RNA extraction were immediately snap-frozen in liquid nitrogen and stored at -70 °C. The specimens used for pathological study were fixed with 10% formalin, dehydrated by conventional methods, embedded in paraffin, cut into slices of 5 µm thick and stained by haematoxylin and eosin.

The specimens were divided into SHCC group (largest diameter less than 5 cm for single tumor nodule or the sum of diameters less than 5 cm for two tumor nodules, $n = 11$), SLHCC group (single tumor nodule with largest diameter more than 5 cm, $n = 8$) and NHCC group (two or more tumor nodules in the liver, only two tumor nodules and the sum of diameters less than 5 cm were excluded, $n = 12$).

Clinicopathological study

All specimens were examined under a microscope after haematoxylin-eosin staining by two pathologists. Four aspects of clinicopathological features including liver cirrhosis, Edmondson classification, capsule formation and microvascular invasion were studied.

RT-PCR

The total RNA was extracted from HCC tissue and paired non-cancerous liver tissue by using the TRIzol (Invitrogen, USA). The quality of RNA was checked through the ribosomal RNA bands on the gel. Two µg of each intact total RNA sample was reverse-transcribed to complementary DNA (cDNA) by using RT-PCR kit (MBI, USA). The PCR primer sequences used were as follows: sense: 5'-GCACAGGTAATAGCAGTGAGTGC-3' and antisense: 5'-CACACAATGGACAAGAATGCTG-3' for ADAM17; sense: 5'-TTCCAGCCTTCCTTCCTGG-3' and antisense: 5'-TTGCGCTCAGGAGGAGC AAT -3' for β-actin. The sizes of PCR products were 440 bp for ADAM17 and 218 bp for β-actin. The procedure was as follows: denaturation at 94 °C for 5 min, then 40 cycles of denaturation at 94 °C for 50 s; annealing at 52 °C for 1 min and extension at 72 °C for 1 min. The PCR products were electrophoresed in 20 g/L agarose gels, and visualized under ultraviolet light. The expression ratio of ADAM17 mRNA to β-actin was determined by Eagle Eye II photo-analysis system.

Statistical analysis

The χ^2 test was used for quantitative enumeration data. The student's t test and one-way analysis of variance were used for qualitative data. The statistic analysis was performed by statistical software SPSS11.0. P value less than 0.05 was considered significant.

RESULTS

Clinicopathological features of HCC in three groups

According to the results of pathological study (shown in Table 1), the NHCC group had higher incidences of microvascular invasion (10/12) compared with SLHCC (3/8) and SHCC (3/11) ($P < 0.05$). Only 8.3% NHCC (1/12) was classified as Edmondson I-II, while 62.5% SLHCC (5/8) and 63.6% SHCC (7/11) were classified as Edmondson I-II. The differentiation of NHCC was significantly poorer than SLHCC and SHCC ($P < 0.05$). The other two pathological features of SLHCC and SHCC were also better than NHCC but the difference did not reach statistical significance. No statistical difference of the four pathological features was observed between SLHCC and SHCC.

Table 1 Pathological features of HCC in three groups

Pathological features	SHCC ($n = 11$)	SLHCC ($n = 8$)	NHCC ($n = 12$)

^a $P < 0.05$ vs NHCC.

Expression of ADAM17 mRNA in HCC and paired non-cancerous liver tissue

As shown in Figure 1, RT-PCR products of ADAM17 and β-actin presented at the same site as previously designed. The expression of ADAM17 mRNA was detected in 77.4% (24/31) of HCC tissues, much higher than that in paired non-cancerous liver tissues in which only 35.5% (11/31) tissues were detected of the expression ($P < 0.05$).

Figure 1 ADAM17 transcription was detected in HCC but no obvious transcription was observed in paired non-cancerous tissues.

Transcription level of ADAM17 in SLHCC, SHCC and NHCC

As shown in Figures 2, 3, the transcription level of ADAM17 was 0.8 ± 0.7 (mean \pm SD) in SLHCC and 0.9 ± 0.6 in SHCC. Both were significantly lower than that in NHCC (1.6 ± 0.5) ($P < 0.05$). No statistical difference in transcription level of ADAM17 was observed between SLHCC and SHCC.

Figure 2 The expression of ADAM17 mRNA was higher in NHCC compared with SHCC and SLHCC.

Figure 3 Transcription level of ADAM17 in three groups of HCC.

Relationship between transcription level of ADAM17 and clinicopathological features of HCC

The transcription level of ADAM17 was compared between different pathological types of HCC. The ADAM17 transcription level was much higher in HCC samples classified as Edmondson I-II compared with those classified as Edmondson III-IV ($P<0.05$). While no statistical difference in transcription level of ADAM17 was observed when capsule formation, liver cirrhosis, and microvascular invasion were concerned (Table 2).

Table 2 Relationship between ADAM17 transcription and pathological features of HCC

	Sample (n)	Transcription level of ADAM17 (mean±SD)	P
Liver cirrhosis			
Present	22	1.141±0.743	>0.05
Absent	9	0.996±0.662

I-II	13	0.768±0.204	<0.05
III-IV	18	1.349±0.157	

DISCUSSION

HCC ranks fifth in frequency worldwide among all malignancies^[1]. Surgery is the only potential curative treatment of HCC^[28]. The post-operative survival of SHCC was generally considered to be better than LHCC, but long-term disease-free survival of some LHCC was also frequently observed after curative resection. Furthermore, some clinical investigation showed that the 5-year survival rate of LHCC after curative resection was not statistically different from SHCC^[4,5]. This kind of LHCC was named SLHCC because it was of some unique characters such as: isolated lesion, expanding growth and relatively integrated fibrous capsule formation *et al.*^[2]. Previous studies showed that SLHCC had relative better prognosis after curative resection^[2,3,6]. Consistent with this, the relatively better pathological features of SHCC were found in this study. The differentiation of SLHCC was much better than that of NHCC, and NHCC was more frequently of microvascular invasion compared with SLHCC. No statistic difference in pathological features was observed between SHCC and SLHCC.

ADAM17 is a sheddase of many transmembrane proteins. The substrates of ADAM17 mediated shedding include many

ligands of EGFR such as TGF- α , HB-EGF, amphiregulin *et al.*^[14]. It has been well known that the activation of EGFR is essential for the carcinogenesis and metastasis of many cancers, while ADAM17 mediated shedding is a key mechanism of sending signals to activate EGFR^[19-21]. Overexpression of ADAM17 has been observed in gastric tumor, mammary cancer, leukemia cell lines and prostate cancer cell lines^[20,21,29-32]. In this study the transcription of ADAM17 was detected in 77.4% (24/31) HCC samples and was statistically higher than that in paired non-cancerous samples in which only 35.5% (11/31) were detected ($P<0.05$). This suggests that ADAM17 may play a key role in HCC development.

Previous studies showed that SLHCC had relative better prognosis after curative resection. To understand the underlying molecular mechanism, the transcription levels of ADAM17 in SLHCC, SHCC and NHCC were also studied. As expected, the transcription level of ADAM17 was much higher in NHCC than in SLHCC and SHCC, while no statistical difference was observed between SLHCC and SHCC. The transcription level of ADAM17 mRNA was also detected to be statistically higher in samples classified as Edmondson III-IV compared with those classified as I-II. The higher expression of ADAM17 mRNA in NHCC as well as in poorly differentiated HCC suggested that it might facilitate tumor invasiveness. The lower transcription level of ADAM17 in SLHCC was probably associated with the relatively better molecular pathological features of SLHCC.

The relationship between ADAM17 mRNA expression and the other two tumor features: microvascular invasion and tumor capsule formation was also studied in this study. Although much higher ADAM17 mRNA level was detected in tumors with microvascular invasion and those without integrated capsule formation, the difference did not reach statistical significance. This maybe due to the relatively small sample size in this study. As only 31 samples were used in the study, especially after the samples were divided into three groups, the significance of the research results may be impaired. The role of ADAM17 in HCC invasiveness needs further investigation with a larger sample size.

The increased transcription of ADAM17 may facilitate the growth and invasiveness of HCC in several ways. (1) Overexpressions of EGFR and its ligands were observed in HCC and were related to the prognosis. However, ADAM17 mediated shedding is a key mechanism of sending signals to activate EGFR. ADAM17 is required for the activation of EGFR by TGF- α or amphireglin in several cancer cells and the high expression of ADAM17 in mammary tumors was correlated with a high activation rate of EGFR^[20,21]. As ADAM17 regulates the ligands production and activity of EGFR, the overexpression of ADAM17 is probably as important as the increased expression of EGFR and its ligands for HCC development; (2) ADAM17 can function as an effector of G protein-coupled receptor (GPCR)-mediated signaling. Activation of GPCR specifically results in ADAM17 cleavage and release of amphiregulin, which could activate EGFR and regulate the proliferation and motility of squamous cell carcinoma^[32]. Overexpression of GPCR was also observed in HCC and was strongly correlated with carcinogenesis of HCC^[33]. ADAM17 may be a key element of communication between GPCR and EGFR in HCC and facilitates HCC development; (3) TRANCE could activate osteoclast and help cancer cells metastasize to bones. Overexpression of TRANCE was found in bone metastatic lesion of several cancers^[34]. ADAM17 may play a role in the bone metastasis of HCC by cleaving TRANCE; (4) The shedding of TNFR by ADAM17 may cause disorder of host immune system as the soluble form of TNFR could bind to the TNF and block its attack to cancer cells^[35].

Other transmembrane proteins associated with HCC

metastasis such as Fas ligand, CXCL12, E-cadherin, interleukin-6 α ^[36-39] were also the suspected substrates of ADAM17 mediated shedding, so it is of particular significance to study the sheddase role of ADAM17 in HCC development. The ADAM metalloproteinase family includes more than 30 members by now^[40]. Many of them not only function as metalloproteinases to shed transmembrane proteins^[41-43] in cancer but also can work as adhesion molecules^[44,45]. In contrast to the matrix metalloproteinases, relatively few data on expression of ADAMs in cancer tissue are available. The expression of ADAM12 and ADAM9 were recently studied in HCC tissue and were of particular importance^[46]. To study the role of other ADAM family members may help us better understand HCC development.

Abstract

AIM: To investigate the relationship between insulin-like growth factor-I, -II (IGF-I and IGF-II), IGF-binding protein 3 (IGFBP-3) and Child-Pugh score in patients with liver cirrhosis, and to search for potential clinical markers of liver function.

METHODS: Forty-four patients with advanced liver cirrhosis of viral origin were divided into 3 groups according to severity of cirrhosis (Child-Pugh score) and 38 healthy subjects served as controls. Serum levels of IGF-I, IGF-II and IGFBP-3 were measured by immunoradiometric assay.

RESULTS: Serum IGF-I, IGF-II and IGFBP-3 levels were significantly lower in patients with cirrhosis than in controls, and serum concentrations of IGF-I, IGF-II and IGFBP-3 were associated with the severity of liver dysfunction, and dropped sharply during the progression of liver failure. Among these 3 parameters, serum IGF-II was the most sensitive and effective indicator for liver dysfunction. Concentrations of IGF-I <30 ng/mL, IGF-II <200 ng/mL and IGFBP-3 <6 ng/mL implied a negative prognosis for patients with liver cirrhosis.

CONCLUSION: Serum IGF-I, IGF-II and IGFBP-3 may provide a new dimension in the assessment of liver dysfunction. Combined detection of serum IGF-I, IGF-II and IGFBP-3 with Child-Pugh score is more effective in predicting prognosis than Child-Pugh score alone.

INTRODUCTION

Insulin-like growth factor-I and II (IGF-I, IGF-II), two major forms of insulin-like growth factors (IGFs) family, are single-chain molecules with three intrachain disulfide bridges consisting of 70 (M_r 7 646) and 67 (M_r 7 471) amino acid residues respectively^[1,2]. Both of them may be considered as important anabolic hormones which are active throughout one's life, inducing anabolic metabolism and stimulating DNA synthesis, cell proliferation and meiotic division^[3,4]. Compared with IGF-I, IGF-II is more well-known as a tumor genesis marker^[5]. As serum IGF-II may be produced and secreted by hepatoma cells, the hormone

could accelerate or magnify its function of continuously stimulating cell growth by directly or indirectly combining with its receptor in neighboring cells or hepatoma cells themselves to form intracellular shortcuts^[6,7].

Insulin-like growth factor binding protein-3 (IGFBP-3) consisting of 264 amino acid residues binds nearly 95% circulating IGFs in the human body, forming a stable ternary complex (M_r 150 000) with the acid-labile subunit (ALS). The complex is believed to serve as a reservoir in circulation to prolong half-lives of both IGF-I and IGF-II^[8,9]. Since most circulating IGF-I, IGF-II and IGFBP-3 are synthesized by hepatocytes, lower levels of the above three parameters should be found in patients with liver diseases^[10]. This study was designed to clarify the influences of associated liver cirrhosis as assessed by Child-Pugh score (CP score) on these parameters, to determine whether measurement of these three parameters could reflect the severities of cirrhosis and liver dysfunction, to reveal whether the combination of these three parameters with CP score could be a more reasonable clinical option for evaluating liver function.

MATERIALS AND METHODS

Patients

From February to September 2001, 44 patients with hepatitis B-induced liver cirrhosis (30 males and 14 females with a mean age of 57.41 years, ranging from 38 to 83) were studied. Patients with liver cirrhosis were diagnosed by liver biopsy and/or by computerized tomography, ultrasonography and clinical biochemical examinations, according to Chinese diagnostic criteria of liver cirrhosis set up in 1995. Patients were divided into 3 groups by CP score: Fifteen people in the group of CP A (scored 5-6), 19 in the group of CP B (scored 7-10) and 10 in the group of CP C (scored 11-15). A total of 38 healthy subjects were served as controls (23 males and 15 females, mean age of 49.97 years, ranging from 35 to 82). After detection of serum IGF-I, IGF-II and IGFBP-3 levels, patients were followed-up in the liver clinic for a period of 6 mo.

Study protocols

Serum IGF-I was quantified by immunoradiometric assay kit (Immunotech A BECKMAN Company). Serum levels of IGF-II and IGFBP-3 were detected by DSL-2 600 ACTIVETM immunoradiometric assay kits (Diagnostic System Laboratories Inc, USA).

Sample collection, procession and storage were referred to the following: A 6 mL venipuncture blood was collected into a dry, heparinized tube in the morning from every subject. Then serum or plasma was separated from cells by centrifugation. Samples should be kept at below -30 °C after aliquoting so as to avoid repeated freezing and thawing.

Assay procedures were firmly accorded to instructions of the kits. Briefly, taking protocol of IGF-II for example, first, 100 μ L of the reconstituted standards, controls and pretreated samples were added to appropriate tubes. Then all the tubes were mixed and incubated at room temperature for 3 h, centrifuged at 180 r/min, and decanted except for total count tubes by simultaneous inversion. The tubes were shaken violently to facilitate complete drainage and allowed to drain on absorbent for 1-2 min. Two

milliliters of deionized water was added to all tubes, except total count tubes, and the tubes were decanted. After 100 μ L of anti-IGF-II [125 I] reagents was added, all tubes were mixed by shaking and were incubated at room temperature for 1 h on a shaker at 180 r/min, then were decanted except for total count tubes by simultaneous inversion. The tubes were struck sharply on absorbent material for 1-2 min and analyzed, after 2 mL of wash solution being added to each tube except for total count tubes. All tubes were counted in a gamma counter for 1 min after decantation.

Statistical analysis

Data were listed as mean \pm SD. Comparison between means was tested by Student's *t* test, Friedman's ANOVA and Duncan test in SAS. *P* value less than 0.05 was considered significant.

RESULTS

Serum IGF-I, IGF-II and IGFBP-3 in cirrhotic liver tissues and matched controls

The mean values for IGF-I, IGF-II and IGFBP-3 in 44 cirrhotic patients (66 \pm 58, 367 \pm 193 and 12.0 \pm 7.6 ng/mL, respectively) were significantly lower than those in 38 healthy subjects (260 \pm 74, 1 094 \pm 119 and 39 \pm 7 ng/mL, respectively, *P*<0.001, Table 1). Since mean values of the three parameters were negatively correlated to age according to our statistical show (*r* = -0.646, -0.612, -0.609), data were revised with covariance analysis to obviate age-related effect on three parameters, and similar result was obtained (*P*<0.001).

Serum IGF-I, IGF-II and IGFBP-3 levels in patients with different CP scores

The mean values for IGF-I, IGF-II and IGFBP-3 were 119 \pm 67, 507 \pm 185 and 19 \pm 8 ng/mL, respectively, in CP A; 45 \pm 29, 343 \pm 154 and 10 \pm 5 ng/mL, respectively, in CP B. The mean values for IGF-I, IGF-II and IGFBP-3 in patients classed as Child-Pugh C stage, the worst stage of liver dysfunction with incurable ascites and elongation of APTT (activated partial thromboplastin time), were 27 \pm 11, 201 \pm 115 and 6 \pm 3 ng/mL, respectively. Significant difference of the three parameters was found between control group and any stage of cirrhosis (*P*<0.001). These three parameters gradually diminished, along with disease progression. Statistic analysis also showed that the mean levels for IGF-I and IGFBP-3 in CP A were significantly higher than those in CP B/C (*P*<0.001), and these values were a little higher in CP B than in CP C, however no significant difference of the two parameters was observed between these 2 categories (*P*>0.05). Only mean levels of IGF-

II showed clear statistical difference in patients between CP B and CP C (*P*<0.05), suggesting that IGF-II reduced significantly due to the severity of liver dysfunction (Table 2, Figure 1). Thus serum IGF-II was a more sensitive and effective indicator than IGF-I and IGFBP-3. Furthermore, the depressed IGF-II level was significantly correlated with the IGF-I variation, as well as with CP score (*P*<0.001).

Figure 1 Serum IGF-I, IGF-II and IGFBP-3 levels in patients with different Child-Pugh scores.

DISCUSSION

Low levels of circulating IGF-I in cirrhosis have been described^[11]. In recent studies, Assy *et al*^[12] confirmed that basal IGF-I and IGFBP-3 levels were significantly lower in patients with liver cirrhosis in their pilot study of IGF-I generation test, in which the two parameters were observed before and after stimulation with recombinant human growth hormone (rhGH). It was also approved by Donaghy *et al*^[13] that basal IGF-I and IGFBP-3 levels dropped markedly in cirrhosis due to severe GH resistance in these patients, caused by the feedback maladjustment of GH-IGF-I-IGFBP-3 axis. He considered that the fact of impaired IGF-I and IGFBP-3 production and the severity of GH resistance seen in cirrhosis likely reflected the effect of injury to the liver, the central organ of the endocrine GH-IGF-I-IGFBP-3 axis. GH resistance, an increasingly recognized feature related to the reduction of IGF-I, IGF-II and IGFBP-3 in liver dysfunction, may have been further pathogenically effected by the severity of liver dysfunction, disorder of portosystemic shunting and malnutrition of hepatic storage. In addition, the production/secretion of GH receptor was also markedly reduced due to severely damaged hepatocytes, thus leading to the disturbance of feedback maladjustment and GH resistance^[14,15].

¹*P* represents the statistical comparison in columns between healthy subjects and patients with different Child Pugh scores (A: scored 5-6; B: scored 7-10; C: scored 11-15). *P*<0.001 vs between different groups of the same parameter.

Our data confirmed that serum IGF-I, IGF-II and IGFBP-3 levels were significantly lower in patients with liver cirrhosis than those in control group. Circulating concentrations of IGF-I, IGF-II and IGFBP-3 were decreased in patients with liver cirrhosis and apparently correlated with the degree of liver dysfunction. These lines of evidence indicate that impaired hepatic IGF-I, IGF-II and IGFBP-3 levels may be the real potential indicators for evaluation of liver dysfunction and clinical outcome.

Though no significant difference of serum IGF-I and IGFBP-3 was observed between CP B and CP C in our study, serum IGF-II responded comparably lower in patients with CP C than with CP B, confirming that fluctuation of serum IGF-II level remained statistically significant even in patients with severe liver dysfunction assessed by CP score, and the range of serum IGF-II concentrations was much more clearly delineated from normal to excessively low in patients with severe dysfunction than the case for serum IGF-I and IGFBP-3. With regards to the facts above, serum IGF-II concentration could be an important indicator for hepatic dysfunction and clinical prognosis, and was more sensitive and effective than serum IGF-I and IGFBP-3. The assumption was also supported by Nicolici^[16], who recently reported that serum IGF-II was lower in patients of cirrhosis than in healthy subjects, and that serum IGF-II was markedly lower in patients with Child-Pugh B/C score ($P < 0.05$). Moreover, he found that serum IGF-II was significantly correlated with IGF-I and CP score ($P = 0.007$). So Nicolici suggested that single IGF-II determination, a safe, reliable and convenient measurement, may be applicable for the assessment of patients with liver cirrhosis instead of GH stimulated IGF-I generation test and combined measurement of serum IGF-I, IGF-II and IGFBP-3. Other studies showed that both IGF-II and IGF-I were synthesized by hepatocytes, however, specific IGF-II mRNA has been found in hepatocytes, which indicated the impaired serum IGF-II production was the direct effect of decreased liver function, while baseline IGF-I and IGFBP-3 levels were decreased under other circumstances, besides liver dysfunction, such as low serum albumin, malnutrition and glucose metabolic abnormality, most of which are the complications of cirrhosis^[17-19].

Our research confirmed that serum concentrations of IGF-I, IGF-II and IGFBP-3 were correlated with CP scores ($P < 0.001$), which is consistent with previous studies^[20,21]. Thus, we investigated serum levels of IGF-I, IGF-II and IGFBP-3 that had similar effects on evaluation of hepatic dysfunction and proposed that the combined detection of serum IGF-I, IGF-II and IGFBP-3 effectively predicted functional liver reserve, prognostic and clinical states of the patients. More relation has been found between IGF-I and the degree of portal hypertension and portosystemic shunting compared with the degree of liver function impairment^[22,23]. In agreement with our results, IGFBP-3 has been reported suitable to predict liver synthetic capacity, because IGFBP-3 uniquely reflects GH activity, so it is down-regulated during depletion of either GH or its receptor, and diminished even in the presence of rebounded GH concentration^[24,25]. Biological functions of IGF-I and IGF-II are modulated by specific high-affinity IGFBP-3. IGFBP-3 level might be less age-dependent than IGF-I level^[26-28]. The significance of IGF-II detection has been described above.

Assy *et al*^[29] measured serum levels of IGF-I and IGFBP-3 before and 24 h after a single subcutaneous injection of rhGH (0.14 U/kg bw). IGF-I level below 10 nmol/L was considered indicative of a poor prognosis with 15% survival at one year, whereas above 10 nmol/L indicated a 100% survival rate in 1-2 years. He then concluded that stimulated IGF-I of less than 10 nmol/L might be a true predictor of a negative prognosis in patients with liver cirrhosis. Castilla-Cortazar *et al*^[30-32] obtained similar results in their study.

In our research, all patients were followed up in the liver clinic for a period of 6 months after the measurement, among

which 6 patients' levels were below the specific levels (IGF-I < 30 ng/mL, IGF-II < 200 ng/mL and IGFBP-3 < 6 ng/mL), and 5 (83%, 4 in CP C, 1 in CP B) of them died of liver failure or bleeding in less than half a year. It is suggested that hepatic cirrhosis patients with low baseline IGF-I, IGF-II and IGFBP-3 levels have a lower survival rate than those with high levels. In agreement with our result, Assy^[12] also speculated that CP score alone could not be regarded as an ideal predictive method for patients with liver cirrhosis.

So, combined evaluation of baseline IGF-I, IGF-II and IGFBP-3 with CP score gives better prediction than CP score alone of patients' liver function. It appears to be a good predictor of survival and an early indicator of liver dysfunction. However, long-term follow-up with multi-center and large sampled studies are expected.

Abstract

AIM: To explore the expression of triggering receptor expressed on myeloid cells (TREM-1) mRNA in acute pancreatitis (AP).

METHODS: Using the reverse transcription polymerase chain reaction (RT-PCR), we examined the expression of TREM-1 mRNA in 10 cases of mild acute pancreatitis (MAP), 8 cases of severe acute pancreatitis (SAP), and 10 cases of healthy control subjects. And we also examined the expression of TREM-1 mRNA in 14 cases of AP (including 10 MAP and 4 SAP) before treatment, after successful therapy and clinically cured.

RESULTS: The expression of TREM-1 mRNA in the groups of MAP, SAP patients and healthy control subjects was 0.771 ± 0.274 , 1.092 ± 0.331 and 0.459 ± 0.175 , respectively; there was a significant difference among the three groups ($P < 0.05$). And there was also a significant difference between the AP patients (0.914 ± 0.341) and healthy control subjects (0.459 ± 0.175) ($P < 0.05$). Moreover, in the 14 cases of AP, before treatment, after successful therapy and clinically cured, the expression of TREM-1 mRNA was 0.905 ± 0.226 , 0.739 ± 0.169 and 0.633 ± 0.140 , respectively, and there was a significant difference among the three stages ($P < 0.05$).

CONCLUSION: The expression of TREM-1 mRNA in the patients with AP increases obviously, and correlates with the degree of AP. Furthermore, the expression of TREM-1 mRNA is distinctly different at the different stages of AP. It indicates TREM-1 may play an important role in the occurrence and development of AP.

INTRODUCTION

TREM-1 is a new activating receptor of the Ig superfamily expressed on human myeloid cells. And it is selectively expressed on blood neutrophils and a subset of monocytes and up-regulated by bacterial lipopolysaccharide (LPS)^[1]. Researchers have demonstrated that TREM-1 mediates activation of neutrophil and monocytes, and may have a predominant role in inflammatory responses such as septic shock and systemic inflammatory response syndrome (SIRS)^[1,2]. In this study, we aimed to explore the expression of TREM-1 mRNA in AP and

tried to reveal etiology of AP and underlying mechanism.

MATERIALS AND METHODS

Patients and specimens

Data obtained from 18 AP patients without any treatment during 48 h of the onset of the disease and 10 healthy control subjects were explored. According to the standards of diagnosis and classification of AP proposed at the Sixth National Conference on Pancreatic Surgery of China in 1996^[3], we divided the AP patients into two groups: 10 cases of MAP, and 8 of SAP. Among the AP patients, we examined the expression of TREM-1 in 14 patients at different stages of the disease (before treatment, after successful therapy and clinically cured). We collected 2 mL of blood from the patients and controls before breakfast in the morning and stored them in the EDTA tube. The total leucocytes in the blood were separated by centrifugation at 1 200 r/min for 15 min.

Reagents and primers

Trizol reagents, Oligo (dt) 15, M-MLV reverse transcriptase and DEPC were the products of Promega Co. (USA). Taq DNA polymerase were purchased from Sangon Co. (Shanghai). The RNase inhibitor was from Takara Co. (Japan). According to the human TREM-1 and β -actin cDNA sequence reported in GeneBank, we designed two sets of primers: TREM-1 sense 5'-GTG TGT GAT CTA CCA GCC T-3', antisense 5'-TTC AGA GTC AGG AGT GGA G-3' (amplified fragment length: 232 bp); β -actin sense 5'-GTG CGT GAC ATT AAG GAG-3', antisense 5'-CTA AGT CAT AGT CCG CCT-3' (amplified fragment length: 520 bp).

Total RNA extraction

The total RNA was extracted from the leucocytes by Trizol reagent. The extracted RNA concentrations and purity were determined at A_{260} and A_{280} spectrophotometrically (Beckman DU650, USA). Then 750 mL/L ethanol was used to preserve total RNA at -20 °C.

Reverse transcription polymerase chain reaction

The total RNA was denatured by incubation for 5 min at 70 °C and rapidly cooled on ice for about 2-3 min. Single-stranded cDNA was synthesized by mixing 1-2 μ g denatured RNA with 0.5 μ L (40 u/ μ L) RNase inhibitor, 1 μ L (200 u/ μ L) M-MLV reverse transcriptase, 4 μ L reaction buffer, 1 μ L Oligodt (15), 1 μ L (10 mmol/L) dNTP, and adding DEPC-treated water up to 20 μ L. The RT reaction mixture was incubated at 37 °C for 60 min, followed by 95 °C for 5 min to inactivate M-MLV reverse transcriptase, and stored at 4 °C for use. A 5 μ L of the cDNA was used as template in PCR amplification for TREM-1. The mixture (50 μ L) consisting of 1 μ L of primers (p1/p2 of TREM-1 and β -actin) each, Taq DNA polymerase (0.5 μ L (5 U/ μ L)), 10 \times PCR buffer 5 μ L, $MgCl_2$ 3 μ L (25 mmol/L), by addition of deionised water up to 50 μ L, was reacted on a programmable thermocycler (Perkinelmer 9600). The DNA was predenatured at 95 °C for 5 min, followed by 35 cycles of denaturation (45 s at 95 °C), annealing (45 s at 56 °C), and extension (45 s at 72 °C). Then the mixture was finally extended for 10 min at 72 °C, and stored at -20 °C. β -actin was served as internal control in each experiment under the same conditions.

Electrophoresis identification and quantitative scanning

PCR products (7-9 μ L) with DL 2 000 marker were electrophoresed through 10 g/L agarose gel in 1 \times TBE at 70 V for 30 min. The samples were stained with ethidium bromide (0.5 mg/L) and observed by ultraviolet illumination and photographed. Each lane was scanned longitudinally. The A values of TREM-1 and β -actin bands were measured by a gel imaging analysis system (GELWORKS 1D advanced v4.01). The A ratios of TREM-1/ β -actin representing the relative levels of the expression of TREM-1 mRNA were calculated for semi-quantitative analysis.

Statistical analysis

Results were presented as mean \pm SD. Statistical comparisons were analyzed through the SAS 8.1 software. Analysis of variance was used. $P < 0.05$ was considered statistically significant.

RESULTS

Expression of TREM-1 mRNA and semi-quantitative analysis

The expression of TREM-1 mRNA in the groups of MAP, SAP patients and healthy control subjects were 0.771 ± 0.274 , 1.092 ± 0.331 and 0.459 ± 0.175 , respectively. There was a significant difference among the three groups ($P < 0.05$). The difference was also significant ($P < 0.05$) (Figures 1, 3) between the AP patients (0.914 ± 0.341) and healthy control subjects (0.459 ± 0.175). In AP patients of before treatment, after successful therapy and clinically cured, the expression of TREM-1 mRNA was 0.905 ± 0.226 , 0.739 ± 0.169 and 0.633 ± 0.140 , respectively. There was a significant difference among the three stages ($P < 0.01$ or $P < 0.05$). And the expression of TREM-1 mRNA was higher in clinically cured group than in healthy control subjects ($P < 0.05$) (Figures 2, 4).

Figure 1 Electrophoresis of the PCR products. M: DL2000 marker; 1: the PCR product of normal subject; 2: the PCR product of MAP; 3: the PCR product of SAP. The amplified fragment lengths of β -actin and TREM-1 are 520 bp and 232 bp respectively.

Figure 2 Electrophoresis of the PCR products. M: DL2 000 marker; 1: the AP patient before treatment; 2: the same patient after successful therapy; 3: the same AP patient after clinically cured; 4: negative control. The amplified fragment length of β -actin is 520 bp, of TREM-1 is 232 bp. 10 g/L agarose gel.

Figure 3 The A ratios of TREM-1/ β -actin in different degree of AP: There was a significant difference among the three groups in the expressions of TREM-1 mRNA ($P < 0.05$). And between the AP patients and healthy control subjects, the difference was significant ($P < 0.05$).

Figure 4 The A ratios of TREM-1/ β -actin in different stage of AP: 1, the group in the stage of before treatment. 2, the group in the stage after successful therapy. 3, the group in the stage of clinically cured. 4, the group of normal subject. There was a significant difference among the three stages in the expression of TREM-1 mRNA (groups 1, 2 and 3. $P < 0.05$). And in the group of clinically cured the ratio was higher than in healthy control subjects ($P < 0.05$).

DISCUSSION

AP is a disease of self-digestive chemical inflammation with unclear etiology. In most cases, they present a self-limited course. Twenty percent of patients with AP have a severe form of the disease. SAP is such a severe disease that it may be associated with both systemic and local complications, such as respiratory insufficiency with adult respiratory distress syndrome (ARDS), renal failure, the development of pancreatic and peripancreatic infection. The mortality of SAP is higher than 40%^[4,5]. Even now, there are no efficient and sensitive methods to treat AP successfully because the pathogenesis of AP still remains obscure^[6]. Recent studies^[7] show that factors like the pancreatic enzymes activated abnormally lead the body to secrete and amplify large quantities of cytokines. Finally, the cytokines increase vascular permeability, activate complement components, resulting in microcirculatory impairment and imbalance of thrombo-fibrinolytic system. Many of these events occur not only in the pancreas itself, but also in the other vital organs and tissues, leading to SAP and complications^[8,9]. Generally, there are three phases of AP progression: local acinar injury, systemic response, and general sepsis^[7]. Moreover, some data suggest that the changes in concentration of proinflammatory cytokines can be an early diagnostic criterion for AP^[10,11]. Most authors have realized that the pathogenesis of SAP is very complicated. It is a multifactorial as well as multifaceted disease. First of all, the etiologic agents initiate the pancreatic acinar injury by release of pancreatic enzymes and over-stimulation of

macrophages and neutrophils, and then the cytokines and inflammatory mediators are delivered^[12,13].

In 2000, Bouchon *et al.* had identified a new activating receptor of the Ig superfamily expressed on human myeloid cells, called triggering receptor expressed on myeloid cells (TREM). TREM-1 is selectively expressed on blood neutrophils and a subset of monocytes and up-regulated by bacterial LPS. Engagement of TREM-1 triggers secretion of IL-8, monocyte chemoattractant protein-1, and TNF- α and induces neutrophil degranulation. Intracellularly, TREM-1 induces Ca²⁺ mobilization and tyrosine phosphorylation of extracellular signal-related kinase 1 (ERK1), ERK2 and phospholipase C- γ . To mediate activation, TREM-1 associates with the transmembrane adapter molecule DAP12^[14]. Furthermore Bleharski *et al.*^[15] suggested that activation of TREM-1 on monocytes participated in the early induced and adaptive immune responses involved in host defense against microbial challenges. Thus, TREM-1 was considered mediating the activation of neutrophil and monocytes, and might have a predominant role in inflammatory responses.

Wilson *et al.*^[16] discovered that SAP had many similarities to sepsis syndrome and septic shock. The haemodynamic features of cardiovascular instability, reduced ejection fraction and decreased systemic vascular resistance were indistinguishable in each of these conditions. In addition, there are many striking similarities in the cytokine and inflammatory mediator profiles, suggesting that the haemodynamic abnormalities may result from the same pathogenic mechanisms, albeit as a result of different inflammatory stimuli.

In 2001 through their experiments, Bouchon *et al.*^[2] believed that inflammatory responses to microbial products were amplified by a pathway mediated by TREM-1. TREM-1 was an activating receptor expressed at high levels in neutrophils and monocytes that infiltrate human tissues infected with bacteria. Furthermore, it was up-regulated in peritoneal neutrophils of patients with microbial sepsis and mice with experimental LPS-induced shock. Notably, blockade of TREM-1 protected mice against LPS-induced shock, as well as microbial sepsis caused by live *Escherichia coli* or caecal ligation and puncture. Their results demonstrate a critical function of TREM-1 in acute inflammatory responses to bacteria and implicate TREM-1 as a potential therapeutic target for septic shock. A recent study shows that TREM-1 amplifies Toll-like receptor-initiated responses against microbial challenges and potentiates the secretion of proinflammatory chemokines and cytokines in response to bacterial and fungal infections. Blockade of TREM-1 reduced inflammation and increased survival in animal models of bacterial infections that caused systemic hyper-inflammatory syndromes^[17]. But nobody knows how TREM-1 expressed in AP as yet. According to the theory mentioned above, we carried out a study of the expression of TREM-1 in AP.

We demonstrated that the expression of TREM-1 in leucocytes of patients with AP was much higher than that in healthy control subjects and correlated with the degree of AP. Furthermore, significant differences in the expression of TREM-1 mRNA were found at the different stages of AP. The expression of TREM-1 decreased gradually with the improvement of severity of the AP patients. This experiment indicates that the expression of TREM-1 is relevant to progression of AP. Because of lack of

relevant data about the patients after they were discharged from the hospital, we only compared the expression of TREM-1 between the cured group and healthy control subjects and found that there was still a significant difference between them. Therefore, we suggest that the pathological changes of the pancreas continued even after the patients were cured clinically.

This study may help reveal the etiology of AP and the mechanism of its progression. It may provide a new standard for the diagnosis and classification of AP as well as an efficient method to cure AP by blocking the expression of TREM-1.

Abstract

AIM: To establish an ELISA kit using monoclonal antibodies against *Clostridium difficile* (*C. difficile*) toxin A.

METHODS: An indirect sandwich ELISA was described using the purified rabbit monospecific antiserum as capturing antibody. After the polystyrene microtitre plates with 96 flat-bottomed wells were coated with rabbit antiserum, the wells were blocked with 100 g/L BSA in PBS-T. *C. difficile* toxin A or culture filtrates were added to each well and then monoclonal antibodies IgG-horseradish peroxidase conjugate was added as detecting antibody, tetramethylbenzidine was used as substrate and A_{450} of the stopped reacting product was recorded in an automated plate reader.

RESULTS: The tested specimens included culture filtrates of 2 strains of toxigenic *C. difficile*, 2 strains of non-toxigenic *C. difficile*, 26 strains of *E. coli*, 2 strains of *S. dysenteriae*, 1 strain of *Bif. infantis*, 5 strains of *V. cholera*, 2 strains of *S. typhi*, 7 strains of *C. botulinum*, 1 strain of toxigenic *C. sordellii*, and 1 strain of *C. butyricum*. A total of 47 strains of culture filtrates were all negative except for 2 strains of toxigenic *C. difficile*. The detective limitation of toxin A was 0.1 ng/mL.

CONCLUSION: An ELISA kit with high specificity and excellent sensitivity for the rapid detection of *C. difficile* toxin A was established. It will be a useful tool for diagnostic test of *C. difficile* toxin A.

INTRODUCTION

Clostridium difficile (*C. difficile*), which has been reported as the major cause of antibiotic-associated colitis (AAC) and pseudomembranous colitis (PMC) in humans and experimental animals, produces at least two toxins, named toxin A and B. Toxin A, a tissue-damaging enterotoxin, can lead to hemorrhagic fluid accumulation in rabbit ileal loops and is cytotoxic for cultured fibroblasts. Toxin B is an extremely potent cytotoxin for many cultured cells^[1,2].

Polyclonal antibodies are used in immunoassays and detection for *C. difficile* toxin in many clinical researches. They

are against toxin A and toxin B, and may be against other antigens at the same time, causing false positive results^[3-5]. The problem may be solved when monoclonal antibodies were used. They can not only improve the specificity of the method, but also decrease the false positive results as well. The present report describes an enzyme-linked immunosorbent assay (ELISA) which used monospecific antibody as a capture antibody, and monoclonal antibody as a detection antibody, for detection of *C. difficile* toxin A in clinical specimens.

MATERIALS AND METHODS

Bacterial strains and culture filtrates

The 49 strains of bacteria included 2 strains of toxigenic *C. difficile*, 2 strains of non-toxigenic *C. difficile*; 26 strains of *E. coli*, 2 strains of *S. dysenteriae*; 1 strain of *Bif. infantis*; 5 strains of *V. cholera*; 2 strains of *S. typhi*; 7 strains of *C. botulinum*; 1 strain of *C. sordellii*; and 1 strain of *C. butyricum*. All strains were cultured with proper medium separately and the culture filtrates were used for the assay.

Purification of *C. difficile* toxin A

Toxigenic *C. difficile* VPI 10463 was grown anaerobically at 37 °C for 72 h in brain heart infusion (Difco) by the dialysis bag methods. Toxin A was purified by precipitation with 500 g/L $(\text{NH}_4)_2\text{SO}_4$ and acid precipitation at pH5.5, then by ion-exchange chromatography on DEAE-Toyopearl 650 mol/L.

Preparation of monospecific toxin A antiserum

Purified toxin A was inactivated with 4 g/L formaldehyde at 37 °C for 72 h, mixed with SEPPIC adjuvant (5.41:4.6 v/v, Montanide ISA206, France), and then injected in to a New Zealand white male rabbit of 2 kg weight every 2 wk over a period of 4 wk. Booster injections of 0.2 mg of toxoid A were prepared with adjuvant and injected subcutaneously at 4 wk intervals over a period of 32 wk, and antiserum was collected 1 wk after the final booster dose.

Production of monoclonal antibody

Purified toxin A of *C. difficile* (100 µg) was inactivated with 4 g/L formaldehyde at 37 °C for 72 h, and mixed with SEPPIC adjuvant, BALB/c mice were injected intraperitoneally with 0.5 mL of toxoid A at 2 wk intervals over a period of 8 wk. Three days before fusion, one mouse was boosted with the same quantity of toxoid A without the adjuvant. The splenocytes from immunized mice were fused with myeloma cells Sp2/0. The hybridoma cells were screened by indirect ELISA and cloned by limiting dilution method.

Purification of antibodies

Antibodies were purified by precipitation with 400 g/L $(\text{NH}_4)_2\text{SO}_4$ followed by precipitation with 330 mL/L $(\text{NH}_4)_2\text{SO}_4$ for 3 times, centrifuged at 6 000 r/min for 30 min, and then loaded on Sephacryl-300 chromatography column.

Conjugate of monoclonal antibody to horseradish peroxidase^[6]

Sodium periodate solution (0.3 mL, 0.1 mol/L) and 5 mg horseradish peroxidase dissolved in 1 mL of water, the mixture was stirred

for 30 min at 4 °C and dialyzed at 4 °C against 0.01 mol/L sodium acetate buffer (pH4.4) overnight, followed by addition of 0.5 mL of 0.16 mol/L ethylene glycol, stirred for 1 h at 4 °C. Monoclonal IgG of 5 mg in 1 mL of 0.05 mol/L sodium carbonate buffer (pH9.6) was added immediately, stirred and dialyzed at 4 °C with same buffer overnight before any unconjugated enzyme was removed by addition of 0.2 mL sodium borohydride solution (5 mg/mL, 4 °C, 3 h), then precipitated by addition of equal volumes of 100% ammonium sulfate (4 °C, 2.5 h), centrifuged (6 000 r/min, 15 min), dialyzed against 0.01 mol/L PBS (pH7.4) at 4 °C overnight, and stored at 4 °C after diluted with 500 mL/L glycerol (1:1).

Indirect sandwich ELISA

Ninety-six-well polystyrene flat-bottomed microtitre plates were coated with 100 µL of purified rabbit monospecific antitoxin (8 µg/mL, capture antibody) in 0.05 mol/L carbonate buffer (pH9.6) and incubated overnight at 4 °C, the plates were washed once in PBS-T (0.01 mol/L PBS containing 0.5 g/L Tween-20, pH7.4). After 200 µL of 100 g/L BSA in PBS-T was added to the wells and incubated at 37 °C for 2 h, washed 5 times in PBS-T with 3 min incubation at room temperature between each wash, 100 µL of *C. difficile* toxin A or test samples in PBS-T were added to each well and incubated for 1 h at 37 °C, washed for 5 times. Then 100 µL of 1:1 000 diluted monoclonal antibodies IgG-horseradish peroxidase conjugate (detecting antibody) was added for 1 h at 37 °C, wells were washed 5 times with PBS-T, and 0.1 mL of TMB(3,3',5,5'-tetramethylbenzidine) substrate was added to each well. After 15 min at 37 °C in the dark, the reaction was stopped by the addition of 1 drop of 2 mol/L sulfuric acid and A_{450} was measured. ELISA titers of positivity were expressed as $A_{450} \geq 0.10$. Non. toxigenic *C. difficile* culture filtrate was used as negative control.

Protein determination

Protein concentration was determined by the method of Coomassie brilliant blue G-250, and bovine serum albumin was purchased from Sigma Company of USA.

RESULTS

Properties of the antibodies

Six hybridoma cell lines (2H7, 3E9, 4B5, 5C10, 6G8 and 8A1) secreting mAbs against *C. difficile* toxin A were produced. The Ig subclasses of mAbs 2H7, 3E9 and 6G8 were IgM, mAbs 4B5 and 8A1 were IgG1, mAb 5C10 was IgG2a. All 6 mAbs had no neutralization activity. Epitope recognized by 5 mAbs (2H7, 4B5, 5C10, 6G8 and 8A1) differed from mAb 3E9. Relative affinities of mAbs 8A1 and 4B5 were all above 10^5 , and those of the other 4 mAbs were 10^4 . mAbs 8A1 were conjugated to horseradish peroxidase for ELISA, A_{403}/A_{280} was 0.40 and the optimal dilution was 1:1000. The monospecific antiserum could neutralize all activities of *C. difficile* toxin A. The ELISA titer was 10^6 /mL.

Figure 1 Detection of *C. difficile* toxin A with ELISA.

Sensitivity of ELISA

Purified *C. difficile* toxin A was detected with ELISA and a high sensitivity of 0.1 ng/mL was found.

Specificity of ELISA

The tested specimens were from culture filtrates of 49 strains. Forty-seven strains were all negative except that 2 strains were positive. Table 1 illustrates the ELISA results with a high specificity.

Table 1 Detection of *C. difficile* toxin A in culture filtrates by ELISA

Strain	Number	Culture supernatant	
		Positive (n)	Negative (n)
<i>C. difficile</i> toxigenic	2	2	0
<i>C. difficile</i> non-toxigenic	2	0	2
<i>E. coli</i>	26	0	26
<i>S. dysenteriae</i>	2	0	2
<i>Bif. infantis</i>	1	0	1
<i>V. cholera</i>	5	0	5
<i>S. typhi</i>	2	0	2
<i>C. botulinum</i>	7	0	7
<i>C. sordellii</i>	1	0	1
<i>C. butyricum</i>	1	0	1

Stability of the ELISA kit

Ninety-six-well polystyrene flat-bottomed microtitre plates were coated with 100 µL of purified rabbit monospecific antitoxin (8 µg/mL) in carbonate buffer (pH9.6) and incubated overnight at 4 °C, the plates were washed once in PBS containing 0.5 g/L Tween-20, pH 7.4 (PBS-T). After 200 µL of 100 g/L BSA in PBS-T was added to the wells and incubated at 37 °C for 3 h, and then vacuumed and kept in plastic bag at 37 °C for 6 d, the titer was detected, indicating that the kit can be kept at 4 °C for at least 1 year.

DISCUSSION

A number of rapid (enzyme immunoassay and latex agglutination) and conventional (direct plating and tissue culture) tests have been developed as aids in the diagnosis of *C. difficile* infection: (1) Tissue culture cytotoxicity assay is the best available laboratory test for determination of the role of *C. difficile* in the pathology of a given patient diarrhea, it has an excellent sensitivity and specificity, but its utility is limited because of its inherent technical complexity, time requirement, specimen-handling requirements, and high costs; (2) Latex agglutination test was found to be nearly as sensitive as the cytotoxicity assay and it did not detect toxin A but a *C. difficile* cell-associated protein; (3) Organism culture: first, the asymptomatic carriage rate of this organism may be as high as 20% in patients receiving antibiotics making interpretation of positive culture data difficult. Second, organisms that do not produce toxin are thought to be avirulent. Isolates must be proved to produce toxin to be considered pathogenic; (4) ELISA. ELISA has the potential of greatly simplifying and improving the efficiency of the laboratory diagnosis of *C. difficile* associated diseases. It has the high sensitivity and excellent specificity comparable with tissue culture cytotoxicity assay. Using the commercial enzyme immunoassays for the detection of toxin A or toxin B, the results could be available in 2-4 h. ELISA was a perfect method to detect toxin A in feces^[7,8].

The advantage of ELISA for detection is that: first, as a clinical expression of *C. difficile* infection, toxin A was more stable than toxin B. Second, toxin A was easy to be purified and its antibodies were easy to produce. Third, the monoclonal antibodies can be prepared in unlimited quantities and are more reproducible reagents than other antibodies. After comparing

the antibody preparations by indirect ELISA, Lyster *et al.* reported that ELISA with monoclonal antibodies could detect 4 ng of toxin A, but the polyclonal antibodies purified by affinity chromatography and monospecific antiserum could detect 1 ng of toxin A^[8]. Laughon *et al.* reported that they could detect 0.1 ng (1.0 ng/mL) of toxin A with a monospecific antiserum^[9]. In this study we present ELISA kits which used the purified rabbit monospecific antitoxin as capturing antibody and monoclonal antibodies IgG-horseradish peroxidase conjugate as detecting antibody, the detection limit of toxin A was 0.1 ng/mL.

Antibiotic-associated diarrhea and PMC are the major problems in a variety of health care settings. Requests for the laboratory diagnosis of *C. difficile*-associated diseases are frequently made, but there have been no diagnostic reagents in China until now. Thus, rapid diagnosis of *C. difficile* in patients with PMC and antibiotic-associated diarrhea is very important and guides both the treatment and control of nosocomial spread of infection. The ELISA kits with a high specificity, sensitivity and stability for the rapid detection of *C. difficile* toxin A are presented here. The usefulness of the ELISA kits awaits further studies in clinic.

Abstract

AIM: To investigate the relationship of urokinase type plasminogen activator receptor (uPAR) and vascular endothelial growth factor (VEGF) expression with clinical and pathological characteristics of human gallbladder cancer.

METHODS: uPAR and VEGF expressions in 68 gallbladder cancer tissues were detected with anti-receptor immunohistochemical stain.

RESULTS: Expression rate of uPAR was 57.4% (39/68), and VEGF 51.5% (35/68) in gallbladder cancer tissues. Expression of both uPAR and VEGF was significantly related to metastasis, but not significantly correlated with differentiation stage and size of gallbladder cancer.

CONCLUSION: Expression of uPAR and VEGF may be an invasive phenotype of gallbladder cancer and indicator for predicting prognoses, and uPAR expression is significantly correlated with the expression of VEGF.

INTRODUCTION

The main lethal cause of patients with malignant tumor is the invasion and metastasis of tumor cells. Tumor blood vessels can not only get rich nutrient from hosts, but also spread many malignant cells to hosts. And all these result in unceasing tumor growth and metastasis^[1-4]. Urokinase-type plasminogen activator (uPA) is a kind of serine protease, which can activate plasminogen to fibrinolysin, the latter can degrade most kinds of extracellular matrix, which then form extracellular local lysis region, thus constructing the path for metastasis. The role of uPA *in vivo* is dependent on the expression of corresponding receptor (uPAR) in cell membrane. The conjugation of uPA and uPAR can reinforce tumor cells' infiltration ability^[5,6]. Formation of tumor blood vessels is a very complicated process. Vascular endothelial growth factor (VEGF) has an important role in the formation of tumor blood vessels, as well as in growth and metastasis of tumor, because it can adjust angiogenesis and is specific^[7-9]. Prognosis

of operation of gallbladder cancer is poor, and its relapse rate is very high. So investigation of metastasis and recurrence of gallbladder cancer has great clinical significance. We made use of immunohistochemistry to detect the expression of uPAR and VEGF in gallbladder cancer, and investigated the relationship between the expression of uPAR and VEGF and pathologic characteristics, invasion and metastasis of gallbladder cancer. Image analyses were also used to quantitatively analyze the relationship between them.

MATERIALS AND METHODS

Materials

Sixty-eight specimens of gallbladder cancer resected or biopsied from 1990 to 2001 were pathologically diagnosed. Retrospective analyses were performed on these routine paraffin embedded sections of 4 μ m thick. According to WHO classification standard of gallbladder cancer differentiation, 21 cases were in grade I, 27 cases grade II, 20 cases grade III. Twenty-six cases had a diameter of tumor \leq 2 cm, 23 cases 2-4 cm, 19 cases $>$ 4 cm. Metastasis was found in 31 cases by clinic examination and in surgical operation. Murine anti-uPA, -VEGF and -SABC monoclonal antibodies were purchased from Wuhan Bosted Co, and uPA from Guangdong Tipus Co.

Methods

Anti-ligand antibodies were used to determine uPAR^[10-13]: routine de-waxing, trypsin digestion, non-specific antigen blocking. A 1 mg/L of urokinase was used to saturate receptors; anti-uPA monoclonal antibody was added; the rest procedures were according to routine SABC. The procedures of VEGF mAb staining was according to instruction of SABC test kit. There were blank, substitute and normal controls. Positive cells were defined as cytoplasm and/or cell membrane stained clearly buffy or brown. Samples were analyzed by image analyzer. Firstly, strong positive expression regions were selected under low power visual field, then, 10 high power visual fields (400 times) were randomly selected, their grey scales were detected, the average value was used as average expression intensity of the sample.

Statistics

Analyses were performed by χ^2 -test, *t*-test and correlation-test. *P* < 0.05 was considered significant.

RESULTS

Results of immunohistochemistry

Positivity rates of uPAR and VEGF expressions in tissue of gallbladder cancer were 57.4% (39/68) and 51.5% (35/68), respectively. uPAR and VEGF were negatively stained in corresponding noncancerous tissues, including relatively normal liver tissue and normal mucosa tissue of gallbladder.

Expression of uPAR and VEGF and clinical pathological stages

Analysis of the relationship between expression rate and

intensity of uPAR and VEGF and clinical features revealed that expression of uPAR and VEGF was closely correlated to metastasis of gallbladder cancer, but not significantly correlated to the differentiation stage and size of gallbladder cancer (Tables 1, 2).

Table 1 Relationship between uPAR expression and clinical pathological stages of gallbladder cancer

Tumor	Patients (n)	uPAR-positive patients (n)	Positive rate (%)
Diameter of tumor			
</=2 cm	26	15	57.7
2-4 cm	23	11	47.8

Negative	37	11	29.7

^bP<0.01 vs others.

Image analysis of expression of uPAR and VEGF

Grey scales for positively expressed uPAR and VEGF were 238.4±6.2 and 231.2±4.1, respectively, that for negative expression were 32.1±4.3 and 36.2±3.7, respectively. Correlation analysis showed that the expression intensity of uPAR was significantly positively correlated to that of VEGF ($\gamma = 0.671$).

DISCUSSION

Human uPAR is composed of 313 amino acid residues. The binding site for uPAR and its ligand-uPA is domain I which is close to N-terminal. Amino acid residues involved in the interaction with ligand are mediated by hydrophobic interaction^[14-17]. uPAR and its ligand-uPA's binding is highly specific. Moreover, this kind of highly effective binding ($K_d = 0.1-1.0$ nmol/L) makes uPA strongly gather on cell surface, thus activating plasminogen to fibrinolysin locally, leading to extracellular matrix hydrolyzing^[18-21]. On the other hand, uPAR also has high avidity to pro-uPA. After pro-uPA binding to its membrane receptor, pro-uPA is easily activated into uPA by fibrinolysin around, then pre-fibrinolysin is activated into fibrinolysin by uPA, forming positive feedback enlargement effect. In addition,

fibrinolysin on cell membrane is not easily hydrolyzed to inactive form by its inhibitor- α_2 anti-fibrinolysin^[22-25]. Furthermore, uPAR also activates pre-fibrinolysin by taking part in complex formation of pro-uPA and pre-fibrinolysin on cell surface. Therefore, expression of uPAR in tumor cells has an important localizing role in process of local extracellular matrix hydrolysis, and closely correlates to metastasis^[26-30].

VEGF is a kind of specific vascular endothelial cell stimulating factor. It high-effectively and specifically acts on vascular endothelial cells, and intensively promotes splitting and chemotaxis by: (1) increasing microvessel permeability, leading to plasm fibrous protein exosome, thus providing a fiber network for cell migration during the process of vascularization^[31-34]; (1) directly stimulating endothelial cell proliferation by acting on two special receptors flt and flk (kdk) of endothelial cell, and producing plasminogen activator (tissue-type and urokinase-type) and collagenase^[35-37]. It not only promotes endothelial cell movement, which is in favor of vascularization, but also benefits cancer cells shedding and entrance to blood vessel or infiltrating to neighboring fibrous protein and connective tissue matrix. This specificity provides conditions for tumor invasion and metastasis.

Our results display that expression of uPAR and VEGF is closely correlated to invasion and metastasis of gallbladder cancer, but not significantly correlated to the differentiation stage and size of gallbladder cancer. uPAR and VEGF can be regarded as an invasive phenotype of gallbladder cancer and used for predicting the prognoses, and as evaluation marker for therapeutic efficacy as well. The results also revealed the correlation between the incidence of gallbladder cancer and expression of uPAR and VEGF. On the one hand, extracellular matrix hydrolysis by uPAR provides advantages over vascularization; on the other hand, plasminogen activator induced by VEGF stimulates endothelial cell growth and increases microvascular permeability by interacting with uPAR, herein, extracellular matrix hydrolysis is reinforced by uPAR^[38-40]. The regulatory mechanism between uPAR and VEGF, and effective gene therapy methods need further investigation.

Abstract

AIM: To work out an individualized lipiodol dose in transcatheter arterial chemoembolization (TACE) for large hepatocellular carcinoma (HCC) according to its blood supply evaluated by CT.

METHODS: One hundred patients with large HCC (more than 8 cm in diameter) were studied by multidetector helical CT. Patterns of blood supply of HCC were divided into sufficient blood supply, poor blood supply, mixed blood supply and arteriovenous (A-V) shunt. The dose of ultra-fluid lipiodol was determined by diameter and blood supply type of HCC. Patients were divided into two groups (50 cases each): lipiodol perfusion group and iodized oil perfusion group according to tumor diameter and the blood supply type of tumor.

RESULTS: The confirmation and effective rates were 82%, 84% in the first group and 36%, 46% in the second group ($P < 0.01$).

CONCLUSION: A relatively individualized lipiodol dose may be determined according to the blood supply pattern and the tumor diameter by CT imaging.

INTRODUCTION

A critical issue in treating large hepatocellular carcinoma (HCC) is determining the optimum lipiodol and antitumor drug dose before transcatheter arterial chemoembolization (TACE). Over-dose will damage hepatic function and inadequate dose will lead to poor treatment effect. Tumor blood supply is the crucial factor for determining lipiodol dose. Lipiodol dose was worked out according to the HCC blood supply check by CT scan, then the actual perfusion dose and curative effect were compared in order to assess the therapeutic efficacy.

MATERIALS AND METHODS

Patients

One hundred patients (91 male and 9 female, age range 20-72 years,

mean age 48 years) with large HCC (diameter larger than 8 cm) were prepared for TACE. All HCC cases were confirmed by clinic, laboratory and image examinations.

Methods

CT scan CT scan patterns were as follows: multi-slice helical CT (Lightspeed QX/I, GE Corporation); 5 mm-thick-section; Pitch 3:1; non-enhanced scanning performed along with arterial phase, portal-venous phase and delayed-phase at 20-25 s, 45-50 s and 2-3 min, respectively; at 120 kV; 270-300 mA; high pressure injector as well as nonionic-contrast media injected at a rate of 3 mL/s (standard 1.2-1.5 mL/kg). The images were obtained by picture archiving and communication system (PACS) and relevant diagnostic reports writing workstation (DELL 21 in monitor, resolving power 1 920 × 1 920). Radiologists analyzed the CT images by using analysis software on Radworks 5.1 to determine the tumor contrast features and confirm the blood supply patterns and further work out the lipiodol dose.

DSA examination DSA (Advantx TC, GE Corporation) was selected and the hepatic artery, coeliac artery and mesenteric artery were detected; the contrast media was injected to reveal the tumor blood supply; the correlation between CT and DSA images was analyzed. Catheter was put into nourishing artery with super-selection skill and anti-carcinoma drug and iodine oil were perfused.

Perfusion dose All cases were randomly divided into two groups. In testing group, dose was determined based on maximum tumor diameter along with the pattern of blood supply. When the sufficient blood supply was concerned, lipiodol dose would be 2-3 times tumor's diameter (If tumor diameter of sufficient blood supply was about 10 cm, the lipiodol dose would be about 20-30 mL). As for the poor blood supply, the dose would be equal to its diameter; lipiodol was perfused till tumor volume was filled completely. To mixed blood supply, the dose was adjusted according to its sufficient blood supply area. When A-V shunt existed, lipiodol amount was determined according to actual condition during TACE. In control group dose was determined based on tumor size (If tumor was about 10 cm, lipiodol dose would be 10 mL accordingly).

Reference standard of lipiodol congregration In CT film, we took the area which lipiodol actually occupied within tumor as a criterion after first TACE: over 75% area as complete filling, area between 50-74% as relatively complete filling, below 49% area as partial filling. Through CT scanning, complete filling and relatively complete filling accorded with pre-operation criterion and partial filling did not.

Evaluation criterion for curative effect With short term follow-up of 6 mo, according to evaluation criterion established by WHO, curative effect could be divided into: complete response (CR), partial response (PR), no change (NC), and progressive deterioration (PD). The three former items were regarded as effective and PD ineffective.

Statistics Confirmation rate and effective rate were assessed by χ^2 test.

RESULTS

Four types of blood supply patterns of large HCC

Type I, abundant blood supply, which could be further divided into Ia and Ib subtype. Ia subtype: Tumor displayed obviously homogeneous or non-homogeneous hyper-dense contrast in arterial phase after enhancement in which broadened nourishing vessels were like radiated, piebald, petal or tuberous shape, and were still in enhancement at portal-venous phase and tailed off at delayed-phase. In DSA, tumor's nourishing arteries broadened and small vessel was hyperplasia in radiated and clasp shape. Ib subtype: Compared with surroundings of hepatic parenchyma in CT, tumor presented slight enhancement and were still in relative hypodense in arterial and portal-venous phases where slightly broadened or nodular arteries at arterial phase could be seen. And palisade shape enhancement could be found at portal-venous phase. Many small vessels showed in DSA film.

Type II, poor blood supply, tumor showed no or mild enhancement during arterial phase, portal-venous phase or delayed phase. In DSA, the nourishing arteries presented no or slight widening and small vessels were in absence; during parenchyma phase, the tumor showed slightly staining.

Type III, mixed blood supply, tumor consisted of sufficient blood supply areas and poor blood supply areas, some areas took on apparent contrast while others did slightly. In DSA, sufficient blood supply areas and poor supply areas co-existed in a tumor.

Type IV, A-V shunt portal vein showed at arterial phase in advance while tumor rarely contrasted at arterial or portal venous phase. In DSA, the normal hepatic artery evidently enlarged rather than tumor arteries. A great amount of contrast media could flow into fistula existed in tumor through portal vein or hepatic vein so that involved veins visualized.

From Tables 1, 2, types I-III in CT scan accorded to that in DSA, and the type of A-V shunt in CT scan is very different from that in DSA. The confirmation rate of lipiodol perfusion was 82% in testing group and 36% in control group. In terms of the effective rate, the difference was significant between testing group (84%) and control group (46%).

Table 1 Blood supply of 100 cases large HCC classified in CT and DSA

Item	Case	Sufficient blood supply		Poor blood supply		Mixed blood supply		A-V shunt	
		Case	%	Case	%	Case	%	Case	%
CT	100	75	75	14	14	7	7	4	4
DSA	100	72	72	12	12	6	6	10	10

Table 2 Curative effects in two groups

Group	Case	PR	NC	PD	Effective rate (%)
Testing group	50	24	18	8	84.0
Control group	50	7	16	27	46.0

CP: Complete response; PR: Partial response; NC: No change; PD: Progressive deterioration.

DISCUSSION

Lipiodol dose is determined by tumor blood supply, patients' general conditions, tolerance to operation, catheter position, etc., of which tumor blood supply plays a crucial role. CT and DSA can display the tumor blood supply well. With sufficient blood supply, tumors in CT scan show apparent enhancement and in DSA display a large amount of inordinately dilated vessels, even "blood lake". With poor blood supply, tumors

reveal little enhancement as well as a small number of vessels. The display rate and staining extent of the vessels were different when the catheter ends reached coeliac trunk, common hepatic artery or proper hepatic artery. Tumor staining extent was significantly higher in latter two because most of blood stream could flow back to splenic artery when catheter was in coeliac trunk. In addition, display rate and staining extent of small vessels were in direct proportion to contrast media amount and injection rate. Two cases revealing no classical trabecula and roundish contrast features in CT were misdiagnosed as poor blood supply type, but the nourishing arteries were presented in arterial phase and a large amount of small vessels appeared in portal venous phase and in DSA lipiodol filled in the tumor completely.

It is of great significance to work out a set of individualized therapy before TACE. Previously, lipiodol dose was determined by tumor's size^[1]. In another word, lipiodol dose should correspond to tumor size and if lipiodol dose is equal to tumor diameter or 1.5 times the diameter, it will produce good curative effect, and if dose is beyond twice the diameter, it will have fewer effects and even damage the hepatic function, leading to cirrhosis. Matsuo^[2] believed that in conventional TACE, lipiodol should be over 5 mL if tumor diameter is less than 5 cm, and the maximum dose will be 10 mL when the tumor develops to more than 5 cm in diameter. With the improvement of the catheter quality and the development of the superselective skills, the catheter can be superselected directly into tumor supply arteries with ease, and lipiodol dose can rise up to 20 mL to fill the tumor less than 10 cm in diameter and 30 mL or more to the tumor more than 10 cm. But in poor blood supply cases, the lipiodol dose should not be over its necessity because lipiodol can flow back and disperse into the normal liver parenchyma. As for mixed blood supply, the dose will rely on the sufficient blood supply area in tumor. Tumor has its shape and volume, supposing to make the lipiodol fill in the tumor as much as possible, it is not enough to inject lipiodol dose into tumor just as its maximum diameter, especially in sufficient blood supply tumor. The tumor will survive if lipiodol dose is not sufficient. Theoretically, tumor cell can be killed only when lipiodol has obstructed all supply vessels and drug flows completely into the tumor. Over dose of drug and lipiodol will make hepatic function get worse in the case of the liver cirrhosis. For these reasons above, to make the drug and lipiodol fill as completely in the tumor as possible, lipiodol dose ought to be based not only on tumor diameter but also on individual blood supply.

CT film can reflect tumor's position, shape, size, quantity as well as blood supply, thus providing guidance for therapy. Patterns of tumor blood supply can be divided into 3 types at arterial phase in CT scan: sufficient blood supply, poor blood supply and mixed blood supply. The survival rate of sufficient blood supply is obviously higher than that of poor blood supply^[3,4]. Vogl^[5] held that lipiodol filling over 75% area of tumor was complete filling and 50-70% area was comparatively complete filling, and the survival rate was encouraging in these two circumstances.

Chung suggested that over-dose lipiodol injection could lead to pulmonary artery embolism when obvious artery-vein shunt exists, especially in hepatic arterial-venous fistula of large HCC. CT can illustrate obvious A-V shunt and provide guidance for therapy. In such cases, lipiodol dose should be decreased and fistula embolized by gelfoam, then correct dose of lipiodol injected to perfuse tumors.

In the first time of therapy, lipiodol dose should be relatively excessive to completely fill in the tumor, because tumor cells can produce the drug resistance with the increase of TACE operation, the artery will be impaired more or less by lipiodol even produce stenosis or obstruction, and finally, the sufficient blood supply of tumor may turn into poor blood supply, meanwhile, the normal hepatic parenchyma may gradually

become cirrhosis, or deteriorated from intrinsic cirrhosis, which would bring side effects and even interrupt the treatment.

Abstract

AIM: To establish the purification method for *Clostridium difficile* (*C. difficile*) toxin A.

METHODS: *C. difficile* VPI 10463 filtrate was cultured anaerobically by the dialysis bag methods. And then the toxin A was purified by precipitation with 500 g/L $(\text{NH}_4)_2\text{SO}_4$ and acid precipitation at pH 5.5, followed by ion-exchange chromatography on DEAE-Toyopearl.

RESULTS: Purified toxin A exhibited only one band on native polyacrylamide gel electrophoresis (native-PAGE) and Ouchterlony double immunodiffusion. The molecular weight of toxin A was estimated to be 550 000. The purified toxin A had a protein concentration of 0.881 mg/mL. The minimum lethal dose was 1×10^6 MLD/mL (i.p.mice). The cytotoxic titer was 10^7 CU/mg. The haemagglutinate activity was at a concentration of 1.72 $\mu\text{g/mL}$. The ratio of fluid volume (mL) accumulated to the length (cm) of the loop was 2.46.

CONCLUSION: The modified method for purification of toxin A of *C. difficile* was simple and convenient. It may be even more suitable for purification of toxin A on large scales.

INTRODUCTION

Clostridium difficile (*C. difficile*) is one major causative agent of pseudomembranous colitis (PMC) and a large number of antibiotic-associated diarrhea in humans and animals. It has been reported that this organism produces at least two toxins, designated A (enterotoxin) and B (cytotoxin). Toxin A, a tissue-damaging enterotoxin, causes hemorrhagic fluid accumulation in rabbit ileal loops and is cytotoxic to cultured fibroblasts. Toxin B is an extremely potent cytotoxin for many cultured cells^[1]. The importance of toxin A in the pathogenesis of *C. difficile* enteritis has been documented and several investigators have established the purification method of enterotoxin^[2]. In this report, we presented a simple method for purification of toxin A. The highly purified toxin A was obtained and analyzed for its biological and immunological properties.

MATERIALS AND METHODS

Bacterial strains and culture filtrates

C. difficile VPI 10463 was grown anaerobically at 37 °C for 72 h

in Brain Heart Infusion (Difco) by the dialysis bag methods.

Purification of toxin A

C. difficile VPI 10463 culture filtrates were centrifuged at 8 000 r/min for 20 min and filtrated through a 0.45 μm membrane filter. The culture supernatant of 200 mL was precipitated by 500 g/L saturated $(\text{NH}_4)_2\text{SO}_4$ overnight at 4 °C, centrifuged at 8 000 r/min for 15 min. The precipitation was dissolved in 50 mmol/L Tris-HCl buffer (pH7.5) and dialyzed in 10 mmol/L acetic buffer (pH5.5) at 4 °C for 24 h, centrifuged twice. The precipitate was dissolved in 50 mmol/L Tris-HCl (pH7.5) and dialysed against the same buffer, concentrated by PEG 10000 at 4 °C. The sample was then loaded onto anion-exchange DEAE-Toyopearl 650 mol/L chromatography column, the sample was equilibrated by 300 mL of 50 mmol/L Tris-HCl buffer (pH7.5, containing 50 mmol/L NaCl), and then eluted first with 200 mL of a linear NaCl gradient (50-250 mmol/L NaCl), followed by 200 mL of 50 mmol/L Tris-HCl buffer (pH7.5) containing 300 mmol/L NaCl. A second elution using 200 mL of a linear gradient (300-600 mmol/L NaCl) in the same buffer was performed. The toxins that eluted in the first NaCl gradient were designated toxins A. The toxin was pooled and concentrated, and analyzed for its biological and immunological properties.

Tissue culture assay

Cytotoxic activity was determined by using African green monkey kidney (Vero) cells as previously described by Kamiya *et al.*^[3]. For the analysis, tenfold dilutions of test samples were prepared and assayed for activity. The cytotoxic titer, which was expressed as the reciprocal of the highest dilution that caused 100% rounding of the cells by 24 h, was determined by serially diluted 100 μL samples transferring to microtiter wells containing Vero cells ($10^5/\text{mL}$) in 100 μL of MEM medium. The specific activity, which was determined from the cytotoxic titer, was defined as the number of cytotoxic units per microgram.

Haemagglutinate activity

In reference to the methods described by Meng *et al.*^[3], rabbit blood cells were washed 3 times with PBS (0.15 mol/L, pH7.2) and then diluted to 25 mL/L suspension. $2 \times$ serial dilution of specimens (50 μL) was performed with PBS buffer in microplate wells and 50 μL of blood cells were added to each well. The HA titer was expressed as the highest dilution that agglutinated rabbit blood cells at 4 °C for 3 h.

Rabbit ileal loop assay

Enterotoxic activity was determined by the rabbit ileal loop assay as previously described^[3]. Results were obtained approximately 18 h after injection of 1 mL of test samples and expressed as the ratio of the accumulated fluid (volume) to the length (centimeters) of the loop. Heat-inactivated toxin preparations were used as negative controls.

Determination of lethal activity

The minimum lethal dose was determined by intraperitoneally injecting mice (14-16 g) with 0.5 mL aliquots of tenfold serial dilutions of test samples and observing the mice over 72 h for toxicity. Two mice were used for each dose of toxin.

Polyacrylamide gel electrophoresis (PAGE)

Native polyacrylamide gel electrophoresis was performed in 75 g/L and 40-300 g/L gel. Samples were electrophoresed at 120 V for 15 h after initial electrophoreses at 70 V for 30 min. After electrophoresis, gels were stained with Coomassie brilliant blue R-250 and destained. Molecular weights were estimated by comparison with high molecular weight standards (Pharmacia).

Immunological methods

Ouchterlony double immunodiffusion was done in 10 g/L agarose. Crossed immunoelectrophoresis (CIP) was performed as previously described^[3]. Goat antiserum against toxin A used in the analyses was prepared in our laboratory.

Protein assay

Protein concentration was determined by the method of Coomassie brilliant blue G-250. Bovine serum albumin was purchased from Sigma Company of USA.

RESULTS

High purified toxin A was obtained by precipitation with 500 g/L $(\text{NH}_4)_2\text{SO}_4$ and acid precipitation at pH5.5, followed by DEAE-Toyopearl 650 mol/L column chromatography. The elution profile of toxin A by DEAE-Toyopearl 650 mol/L column chromatography is shown in Figure 1. The purified toxin A exhibited only one band on 40-300 g/L native polyacrylamide gel electrophoresis, the molecular mass of toxin A was estimated to be 550 000 (Figure 2). The toxin preparation also gave a single component when analyzed by Ouchterlony double immunodiffusion (Figure 3) and cross immunoelectrophoresis.

The purified toxin A had a protein concentration of 0.881 mg/mL, the cytotoxic titer was 10^7 CU units per mg. The HA activity was at a concentration of 1.72 $\mu\text{g/mL}$, the ratio of fluid accumulated volume (mL) to the length (cm) of the loop was 2.46. The minimum lethal dose was 1×10^6 MLD/mL (Table 1). All biological properties of purified toxin A were neutralized by the antiserum of *C. difficile* toxin A.

Figure 1 Purification of *Clostridium difficile* toxin A by DEAE-Toyopearl 650 mol/L chromatography. Fractions 1-34 were eluted with 50 mmol/L Tris-HCl buffer (pH7.5) containing a linear NaCl gradient (50 mmol/L-250 mmol/L), then fractions 35-50 were eluted with 300 mmol/L NaCl and fractions 51-75 were eluted with linear gradient (300 mmol/L-600 mmol/L NaCl) in the same buffer.

Table 1 Purification of *C. difficile* toxin A

Purification step	Vol (mL)	Protein(mg/mL)	Lethal dose(Mice, MLD/mL)	Cytotoxicity (CU/mg)
Crude culture supernatant	200	1.86	6×10^4	10^{10}
50% $(\text{NH}_4)_2\text{SO}_4$ precipitation	10	ND	ND	ND
Acid precipitation	10	6.15	2×10^6	10^{10}
DEAE-Toyopeal 650 mol/L	6	0.881	1×10^6	10^7

ND: not detected.

Figure 2 Analysis of toxin A preparations by native-PAGE (4-30%). Line 1: Purified *C. difficile* toxin A; Line 2: High molecular mass markers, thyroglobulin (M_r 669 000), ferritin (M_r 440 000), catalase (M_r 232 000), lactate dehydrogenase (M_r 140 000), bovine serum albumin (M_r 67 000).

Figure 3 Analysis of toxin A by Ouchterlony double immunodiffusion. Well 3 contained 20 μL of antiserum against strain 10463 culture filtrate, well 1 and well 2 contained 20 μL of purified toxin A by acid precipitation and DEAE-Toyopeal 650 mol/L chromatography respectively.

DISCUSSION

Affinity chromatography used to purify toxin A in the present study was first described by Krivan *et al.* The methods using bovine thyroglobulin for purification of *C. difficile* toxin A which depends on the temperature was dependent on binding between toxin A and thyroglobulin. A change of the temperature from 4 to 37 $^{\circ}\text{C}$ toxin A was released from the glycoprotein molecule^[2]. In addition to toxin A, there were trace amounts of toxin B and a few other proteins at low level. As thyroglobulin is an expensive biological reagent, this method might not be suitable for purification of toxin A in some laboratories.

Sullivan *et al.* (1982) described a procedure for preparing milligram amounts of homogeneous toxin A from culture filtrate^[4]. The method consisted of ultrafiltration through an Amicon XM100 membrane filter, anion-exchange chromatography on DEAE-Sephacel CL-6B, and precipitation at pH5.5. We purified toxin A from culture filtrate with the method and found that except for a major protein band, there was a faint band as well on native PAGE. High purified toxin A was obtained by precipitation with 500 g/L $(\text{NH}_4)_2\text{SO}_4$ and acid precipitation at pH5.5, followed by DEAE-Toyopearl 650 mol/L column chromatography.

In the studies on the toxins of *C. difficile*, researchers have reported the cytotoxicity of *C. difficile* toxin A for human colonic and pancreatic carcinoma cell lines^[5]. Although there are a lot

of problems to be solved before the toxin being used in clinic, the modified method for purification of toxin A of *C. difficile* was simple and convenient, it may be even more suitable for purification of toxin A on large scale.

Abstract

AIM: To investigate the expression of Survivin in pancreatic cancer and its correlation to the expression of Bcl-2.

METHODS: Survivin and Bcl-2 expressions were examined by immunohistochemistry in 42 tissue samples from pancreatic cancer and 10 from normal pancreas.

RESULTS: No survivin expression was detected in the tissue samples from normal pancreas, while it was detected in 34 of 42 tissue samples from pancreatic cancer (81.95%). There was a correlation between survivin expression and differentiation and stages of pancreatic cancer. Survivin positive cases were strongly correlated to Bcl-2 expression (28/30 vs 6/12, $P < 0.05$).

CONCLUSION: Overexpression of survivin plays an important role in the development and progression of pancreatic cancer, and correlates to the expression of Bcl-2. Survivin expression can be used as a prognostic factor.

INTRODUCTION

The inhibitor of apoptosis protein (IAP) is a member of the widely-expressed gene family of apoptosis inhibitors. It can inhibit apoptosis induced by a variety of stimuli and plays a critical role in the physiologic activities of cells. Survivin is a recently-characterized gene, a member of the IAP family, and has a close relation between anti-apoptosis and tumors. Overexpression of survivin has been reported to play an important role in the development and progression of pancreatic cancer^[1-5]. In this study, we investigated the relationship between the expression of survivin in patients with pancreatic cancer and the expression of Bcl-2 in order to provide a theoretical basis for the prevention, diagnosis, and treatment of pancreatic cancer.

MATERIALS AND METHODS

Materials

Ten samples from normal pancreatic tissue and 42 samples from

pancreatic cancer were collected. Normal pancreatic tissues were obtained from autopsy specimens in Department of Anatomy, Medical College, Wuhan University, and their mean age was 49.3 years (range, 33-78). Pancreatic cancer samples were obtained from surgically-resected specimens in Zhongnan Hospital, Wuhan University. All these cancers were diagnosed pathologically.

Reagents

Primary antibody for survivin was purchased from Novus Co., Ltd (USA) and Bcl-2 was purchased from Boster Biological Technology Ltd (Wuhan). SP kit was purchased from Zhongshan Biotechnology Co., Ltd (Beijing).

Methods

Fixed in routinely-processed formalin and then embedded in paraffin, 4- μ m thick sections were prepared from the cut surface of blocks at the maximum cross-section. For morphological analysis, the sections were routinely stained with hematoxylin and eosin. Immunohistochemical staining for survivin and Bcl-2 antigen was made by the standard streptavidin/peroxidase (SP) technique. The positive section was used as a positive control. As a negative control, PBS was used instead of the primary antibody for survivin and Bcl-2.

Scoring criteria

Cytoplasm staining with light yellow or brown was defined as a marker of positive cells. All sections were analyzed by an image analysis system. The mean percentage of positive cells for the expression of survivin and Bcl-2 was determined in at least 10 areas at 400-fold magnification, and the cases with less than 5% positively-stained cells were defined as being negative. The cases with 5% to 10% positively-stained cells were defined as having a positivity rate of "+", 11% to 60% as "++", and more than 60% as "+++".

Statistical analysis

All statistical analyses were performed with SPSS 11.0 software. Difference and correlation were analyzed by χ^2 test. $P < 0.05$ was considered statistically significant.

RESULTS

Immunohistochemistry

With immunohistochemical staining, we examined the expression of survivin in pancreatic cancer. The results are shown in Figure 1. The expression of survivin was localized in cytoplasm of tumor cells, which are shown as brown granules in Figure 1 (SP), and in Figure 2 (HE). Survivin was expressed in 34 of 42 pancreatic cancer samples, but not expressed in the 10 samples from normal pancreatic tissue. The expression rate was 81.95%.

To study the relationship between the expressions of survivin and Bcl-2, 42 cases were analyzed. The results are shown in Table 2.

Figure 1 Expression of survivin in poorly and well differentiated pancreatic cancer. A: Expression of survivin in poorly differentiated pancreatic cancer (SP×400). B: Expression of survivin in well differentiated pancreatic cancer (SP×200).

Figure 2 Poorly and well differentiated pancreatic cancer. A: poorly differentiated pancreatic cancer (HE×400). B: well differentiated pancreatic cancer (HE×400).

Table 1 Relationship between survivin expression in pancreatic cancer and clinicopathologic parameters

		Survivin expression		P	r
		(-,+)	(++,+++)		
Sex	Male	11	7	>0.05	
	Female	13	11		
Location	Head	16	14	>0.05

Stage	I-II	18	8	<0.05	0.311
	III-IV	6	10		

Table 2 Correlation between expressions of survivin and Bcl-2

		Survivin expression		P	r
		(+)	(-)		
Bcl-2 (+)	28	2		<0.01	0.499
Bcl-2 (-)	6	6			

DISCUSSION

Survivin, a recently-characterized member of IAP family, was isolated from the human gene bank by Altieri *et al.* in 1997 using effector cell protease receptor-1(EPR-1) cDNA^[6]. Recently, great progress has been made in the structure and function of survivin and its correlation to malignant tumors.

Many findings have suggested that survivin may express selectively in different tissues. Survivin was max expressed or poorly expressed in normal terminally-differentiated tissues, whereas it was extensively expressed in many kinds of human tumor tissues^[7-14].

Studies have shown that Caspase is responsible for apoptosis, which can activate in cascade and lyze protein, thus determining the pattern of apoptosis. Survivin could directly inhibit the activities of Caspase-3 and 7 and block the process of apoptosis and indirectly inhibit Caspase through P21. Therefore survivin would bind to cell cycle apoptosis factor CDK4 to form survivin-CDK4 complex, and then release of P21 from CDK4 complex. When P21 was bound to mitochondrial Caspase-3, it could inhibit its activity, thus preventing apoptosis^[15-17].

The results of our study showed that survivin was highly expressed in pancreatic tumor tissues, but not in normal pancreatic tissues, suggesting that it might play a critical role in the development and progression of pancreatic cancer. Furthermore, there was a positive correlation between survivin expression and tumor TNM staging and differentiation grade. It can be concluded that survivin expression is indicative of higher invasiveness or poor prognosis in pancreatic cancer.

Bcl-2 was the first characterized anti-apoptotic gene with an inhibiting apoptotic pathway different from that of survivin. Bcl-2 could regulate apoptosis by preventing cytochrome C release from mitochondrion to cytoplasm. Whereas, survivin acted by direct inhibition of the terminal effector proteases of apoptosis, i.e., Caspase-3 and Caspase-7.

Our study demonstrated that the expression of survivin was positively correlated with that of Bcl-2. It might be caused by the same transcription and activation mechanism of survivin and Bcl-2, or both might be regulated by GC-rich promoters, and were then transcribed and activated to enhance cell proliferation, acting synergistically to inhibit apoptosis^[18-29].

Asanuma *et al.*^[2,5] investigated whether survivin expression could directly regulate cancer sensitivity to radiotherapy using gene-transduced pancreatic cancer cell strain (MIAPaCa-2). Their results showed that survivin expression could directly down-regulate pancreatic cancer sensitivity to radiotherapy.

In addition, Rohayem *et al.*^[12,30,31] observed that specific anti-survivin antibody could be detected in serum of patients with cancers of the lung and colon, suggesting that this antibody could be used as a new diagnostic marker for cancers of the lung and colon. Furthermore, Smith *et al.*^[32], Moore *et al.*^[33], and Swana *et al.*^[34] found that survivin levels in urine could be used to diagnose primary and recurrent bladder carcinomas, thus providing a new idea for the diagnosis of pancreatic cancer^[35-39].

In conclusion, Survivin can be used as a cancer therapeutic target because of its selective expression in the tissue concerned. Moreover, natural antisense nucleic acid for Survivin-endogenous EPR-1 has become a new hot issue for the tumor gene therapy.

Abstract

AIM: To observe effects of ACOL on fibrinogen (FIB), fibrin degrading products (FDP) and changes of FIB and FDP concentration in rabbits with intra-abdominal exudates during 7 d after major abdominal surgery.

METHODS: Sixty New Zealand rabbits were randomly divided into 4 groups: ACOL group, the control group, DCT group and the normal group. After being modeled, except the normal group, the other 3 groups were treated with different ways for a week; the intra-abdominal exudates of rabbits in the 4 groups were drawn for FIB and FDP measurement once daily during 7 d after major abdominal surgery.

RESULTS: FIB and FDP in the intra-abdominal exudates altered in a regular way and ACOL could change the concentration of FIB and FDP in the intra-abdominal exudates after major abdominal surgery.

CONCLUSION: ACOL can prevent intestinal adhesion by reducing the concentration of FIB and raising that of FDP in the intra-abdominal exudates after major abdominal surgery.

INTRODUCTION

With a high incidence of 90%^[1-2], intra-abdominal adhesions are the most common complications after major abdominal surgery, and overall 70% patients of intra-abdominal adhesion have the history of previous laparotomies^[3]. The exact mechanisms about this complication have widely been explored. The damage of peritoneum and its base during laparotomies leads to intra-abdominal traumatic inflammation, and thus the normal intra-abdominal physical condition is destroyed, inflammatory cells and medias are released. Coagulation, kinin

peptide, fibrinolysis, arachidonic acid (AA) participate in this process. The activity of plasminogen activator (t-PA), matrix metalloproteinase (MMP) and their inhibitor changes accordingly^[4-8]. The related factors of adhesion, such as TNF- α , TGF- β , and VEG-F, are involved in regulations of the whole process^[9-11], which results in the abnormally higher concentration of free FIB and FDP in the intra-abdominal exudates. The disturbance of the intra-abdominal homeostasis among secreting, dissolving and absorbing together with over-deposition of fibrin in the abdominal cavity finally leads to fibrous adhesion^[12]. In this research, occurrence and development of intra-abdominal adhesions will be discussed by observing the dynamical changes of FIB and FDP in rabbits' intra-abdominal exudates continuously during 7 d postoperatively. Antiadhesion concentrated oral liquid (ACOL) was used as soon as possible to improve the intra-abdominal physical condition and help to regain the homeostasis of internal environments to prevent the formation of the fibrous jelly in the abdominal cavity. This experiment provided evidence for the punctual and strategic prevention and treatment of the postoperative intra-abdominal adhesion.

MATERIALS AND METHODS

Experimental animal

Sixty healthy New Zealand rabbits of both sexes, weighing from 2.5-3.5 kg, were purchased from Laboratory Animal Center, Medical College of Xi'an Jiaotong University.

Drugs, reagents and instruments

ACOL consisted of Rubarb, Cotex Magnoliae Officinalis, Fructus Auvantii Immature, Caucklandiu Lappal, Folium Raphani Radish Seed, Radix Aucklandiae, Radix Astragali, Cortex Cinnamomi, Fructu Amomi, Radix Angelicae Cinensis, Rhizoma Zingiberis and Radix Salvia Miltiorrhiza. Da-Cheng-Qi Tang (DCT) consisted of Rubarb, Ctex Magnoliae Officinalis, Fructus Aurantii Immature and Natrli Sulfas. Both were provided by Shaanxi College of TCM, and decocted with water and concentrated through reflux with distillatory and water bath to extract the decoction containing 1.0 g crude /mL. FIB test kit was purchased from Changzheng Medical Scientific Limited Company, Shanghai, (batch number f4900704). FDP test kit was purchased from Institute of Microbiology and Epidemiology, Academy of Military Medical Sciences, (batch number 900325). Automatic Biochemical Analyzer 7170 type was from Hitachi, Tokyo, Japan.

Animal models

The experiment was carried out in the clean but not sterile condition under 30 g/L procaine anesthesia (0.5 mL/kg, iv). After shaving and skin-disinfecting, the laparoscopy was performed through a 4 cm vertical midline incision to enable the following performances: (1) appendectomy, (2) perforation of an incision (1 cm in diameters) at 5 cm off pylorus on the lesser curvature with punching device, then repair of the perforation, (3) 2×2 cm² area of the cecal parietal peritoneum being carefully stripped, (4) injection of the solution of Talc powder 1mL/kg and 5 mL distilled water into the abdominal cavity prior to skin closure, (5) splenectomy, and (6) leaving a tube for drainage in the

spleen pit because all the animals were fasted for 8 h after operation. The study protocol was in accordance with the guideline for animal research and was approved by the Research Committee of the hospital.

Grouping and medication

The 60 New Zealand rabbits were randomly divided into 4 groups: normal group, ACOL group, control group and DCT group, with 15 rabbits in each group. From the second day postoperation, rabbits in ACOL group were administered ACOL (5 mL/kg) gastrogavage twice daily, the DCT group was administered DCT, the control group was given normal saline (NS) instead, while the normal group had none treatment. The medication was carried out from the second day of modeling and lasted for 1 wk. 15 mL NS was injected through the drainage tube into the abdominal cavity of each model animal once daily, and 5 min later the abdominal exudates was drawn for FDP and FIB detection.

Statistical analysis

All data were expressed as mean \pm SD, and statistical analysis were performed by Student-Newman-Keuls test, ANOVA analysis, Difference between groups were compared by SNK-*q* test, with $P<0.05$ considered to have statistical significance.

RESULTS

Concentration curves of FIB and FDP in rabbits abdominal exudates during the 7 d postoperatively

The concentration curve of FIB in the rabbits' intra-abdominal exudates showed an increasing trend in the initial 5 d, and reached its peak on the 5th d. After that, it showed a decreasing trend, while on the 7th d still above the preoperative value (0.1 \pm 0.017) g/L. (Figure 1). At the same time, the concentration curve of FDP in the exudates showed increase in the first 4 d, arriving at its peak on the 3rd or the 4th d. After that, it showed decrease, while the value of the 7th d was also still above the preoperative value (0.3 \pm 0.012) μ g/mL. (Figure 2). In comparison with the concentration curve of FIB and FDP in the exudates during the 7 d postoperatively, the DCT group was similar to the ACOL group while the normal group similar to the control group. (Figure 1, 2). In comparison with the average concentration

of FIB and FDP in intra-abdominal exudates during 7 d postoperatively, there was remarkable difference among the DCT group, normal group, and control group ($P<0.05$). The ACOL group showed a remarkable difference ($P<0.05$), compared with the other three groups. (Tables 1, 2).

($P<0.05$); while in comparison with the other 3 groups, those of the ACOL group showed a significant difference ($P<0.05$).

DISCUSSION

So far, there is no safe and effective prophylaxis available for intra-abdominal adhesions. Scientists try to find the answer from studying the exact mechanism of intra-abdominal adhesions, thus various experiments have been conducted to elaborate the exact mechanism of intra-abdominal adhesions and its prevention. The theory of traumatic inflammation is prevalent in elucidating the mechanism of intra-abdominal adhesions^[14]. Actually, multiple factors are involved in the development of postoperative intra-abdominal adhesions, such as operative injury, tissue ischemia and foreign materials left during operation^[14-15]. Any damage to the peritoneum and its base can lead to the release of inflammatory exudates, which contained FIB that causes fibrous adhesion and eventually results in the following two consequences: First, the fibrin is eliminated through the phagocytosis and endogenous fibrinolysis system, and the regeneration of mesothelial cell will cover the wound surface thus to get it repaired physiologically. Second, the wound is not covered by the regenerated mesothelial cells and no physiological repair occurs. Instead, fibrous adheres to other serosa in 12-24 h after operation, and then fibroblasts forms in place of the fibrous matrix, which causes the production of the fibrous collagen and eventually leads to fibrous adhesion. The adhesion can be absorbed completely if mesothelial cells are intact, but when the mesothelial cells are seriously destroyed, its plasminogen activator activity (PAA) is depressed, and with the depression value to that low as 60% or less, the fibrous adhesion will form as a consequence^[16-19].

In this experiment, the postoperative concentration levels of FIB and FDP in the rabbits' intra-abdominal exudates were constantly observed during the postoperative period of 7 d. The values of both FIB and FDP in intra-abdominal exudates increased considerably after 24 h postoperatively, arrived at its peak on the 4th or 5th d after operation, and then started to decrease till the 7th d, but still not being able to recover to the its normal preoperative level. The whole process is rather similar to the traumatic inflammation process. Giving the experimental animals some drugs which had been proved effective in promoting the ability of intestinal movement, the incidence of intestinal adhesion decreased remarkably, which indicates that the intestinal adhesion is related to traumatic inflammation, intestinal movement, and intra-abdominal physical conditions.

Under normal condition, there is a little serous fluid in the peritoneal cavity, which, on one hand, is necessary to keep the surface of the viscera moist and reduce the friction among the viscera, and on the other hand, functions to help recover the viscera and defend it against damage. Normally, the omentum, parietal and visceral peritoneum keeps a balance between releasing and absorbing serous fluid in the peritoneal cavity. Maintenance of this balance depends upon the normal sequential movement of intestines and the unobstructed movement of intestinal contents. After abdominal surgery, ileus paralysis and the retention of the intestinal contents can effect the normal sequential movement of intestines and the smooth movement of intestinal contents. With intestines paralyzed postoperation, the contents are retained in the intestinal cavity. Endotoxin and bacteria in the stool are absorbed from intestines, which results in the abnormally high level endotoxin in the blood, which, in turn, stimulates intestines and worsens their paralysis, thus weakening the intestines' sequential movement and obstructing the smooth movement of their contents. Inflammatory reaction is indispensable to the healing of gastrointestinal and peritoneal damage in operation.

Tissue injury, local hemorrhage, cell inactivity and coagulation will call for the inflammation response, which originates from the following vascular reaction: the inflammatory mediums such as histamine, 5-HT, bradykinin, and prostaglandin. cause small blood vessels to first contract transiently, then dilate with congestion, and thus increase the permeability of blood vessels, which enables water, electrolyte, serum proteins, neutrophils and monocytes to enter tissue inter-space, so traumatic inflammatory reaction happens to help heal the damage. The FIB that has permeated into the wound gaps can turn into fibrin and fill the gaps to function as the network for cells to proliferate. However these inflammatory exudes can also enter peritoneal cavity from the wound, and the homeostasis of intra-abdominal serous postoperation is destroyed. During the damage, the serous secretion is far beyond the absorbing capability of peritoneal cavity. At the same time, high concentration of FIB in the wound exudes increases the concentration of FIB in peritoneal cavity. With the weakened movement of intestines in the early stage of postoperation and the temporarily destroyed normal physical condition, the exudes among viscera containing higher concentration of FIB easily constitute early fibrous adhesion, which is although still fragile at its early stage. Such traumatic inflammatory response arrives at the climax around 48 to 72 h postoperation, then disappears gradually. The early fragile adhesion can turn into tight one through endometrial stage and mould stage. We can see that the early recovery of the intestinal movement and abdominal physical condition postoperation is vital for prevention of the intestinal adhesion^[20-23].

The present study also indicates the traumatic inflammation caused by major abdominal surgery can cause the release of cytokines, the subsequent effects on endothelial cells, inflammatory cells and mesothelial cells, which produce and release plasminogen activator activity inhibitor I or II (PAI1, PAI2). Previous research showed TNF- α , IL-1, TGF β , alone or combined, can stimulate the cultured mesothelial cells to produce plasminogen activator activity inhibitor I or II (PAI1 and PAI2), which ultimately causes the disturbance of homeostasis between FIB and FDP intra-abdominal exudes. Consequently fibrin depositing on the surface of intra-abdominal viscera constitutes adhesion^[24-27].

In essence, intestinal adhesion is that the normal physical condition of peritoneum and the homeostasis between secreting and absorbing sera is destroyed, with higher FIB concentration in the peritoneal cavity, the weakened sequential movement of intestines and the dysfunctional movement of the intestinal contents, so that the wound healing appears among intestine, peritoneal and other viscera. The incidence of intestinal adhesion is related to the degree of the completeness of the peritoneal mesothelial cells in that when mesothelial cells are destroyed seriously, the fibrous adhesion forms. The damage of peritoneal mesothelium cannot be avoided in laparoscopy no matter how gentle the operation is. Since intestinal adhesions postoperation are almost inevitable to some extent^[28], recovery of the physical condition in abdominal cavity after operation as soon as possible can reduce the incidence and the adventure of intestinal adhesion^[29].

Now we can see, how to shorten the time of traumatic inflammation caused by major abdominal surgery, how to recover the normal physical condition of intra-peritoneum, and how to recover the homeostasis between FIB and FDP, is the vital to prevent the intra-abdominal adhesion postoperatively. The pharmaceuticals of laxative remedies represented by Rhubarb start with purgation of intestinal contents, improve the early recovery of intestinal movement as soon as possible. The pharmacologic research of Rhubarb develops quickly, clinic application is wider and wider. The main components of Rhubarb include: Anthraquinones (emodin, rhein, aloe-emodin),

Polysacchavide from *Rheum palmatum* (DHP₁, DHP₂) Tannins (hydrolysates type, condensed type), Modern pharmacology finds the effective component in Rhubarb of purgation is Anthraquinone, which effects on colon and increases the tension of the middle and far parts of colon to make them move faster, while no affection on the function of small bowels to absorb the nutritions. experiments reported: if vasectomy the part between colon and small bowels, then inject Anthraquinone into small bowels, but the medicine affects on the colon. Emodin combines with the muscle albumen of affected organ, then behavior cholinergic reaction, which can excite the M receptors of intestinal smooth muscle, increasing intestinal movement, inhibiting Na⁺ K⁺ ATP enzyme in intestinal cell membrane. It also can hinder the absorption and transportion of Na⁺, increase osmotic pressure of intra-intestines, keep lots of water, promote intestinal movement to defecate.^[30] On one hand through relieving the temporary enterogenic bacterial translocation caused by intestine paralyzed. Rhubarb prevent intestines from ischemia-reperfusion injury, protect gut barrier function, lower the level of endotoxin in blood to demodulate the releasation of cytokine and inflammatory mediums intra-peritoneum. on the other hand, it can lower the ability of endotoxin in blood which stimulates the target cells such as mesothelial cell, platelet *et al*, Lower the sensitivity of these target cells to the stimulus of endotoxin in blood, make the injurys caused by cytokine, inflammatory mediums easy to be controled. It also can reduce the level of PGE and CAMP in cerebrolate. Lots of experiments prove: Rhubarb remarkably inhibits the functions of cytokine secreted by Macrophage cells which are stimulated by endotoxin. emodin strongly inhibits proliferations of T lymphocyte. Perhaps it is realized through reducing the expression of inflammatory mediums IL-2mRNA and concentration of Ca²⁺ in cell membrane^[31], emodin has excellent Antagonism to early inflammatory exudes, increasing penetration of microvascular, and leucocytes migration^[32]. In the condition of injures, such as tissue ischemia, endometrial injury, leucocytes Infiltration, and platelet aggregation, lots of free radicals are brought out, which cause pathologic lipidoxidation and induce production of cytotoxic lipid free radical and lipid peroxides malondialdehyde (MDA). Rhubarb can inhibit the production of MDA, relieve the injure of tissue and organ. Rhubarb is a kind of strongly free radical scavengers, and an inhibitor of lipidoxidation, it has function to remove most of free radicals^[33]. Rhubarb can remove O₂, H₂O₂ and other peroxides, inhibit lipid oxidation, Rhubarb themselves on pharmacology have the function of immune regulate two-wayly. emodin improve Indraft of Ca²⁺ outside of leucocytes, this function have some relations with improving immune of leucocytes; while Polysacchavide from *Rheum palmatum* inhibits Indraft of Ca²⁺ outside of leucocytes and releasation of Ca²⁺ inside of leucocytes, and the degree of inhibition have some relations with its dosage, so for leucocytes it has inhibit function^[34], Rhubarb can inhibits the production of red blood corpuscles antibody, and inhibit the function of T cell, improve phagocytosis of macrophage, it is benefit to regulate immunation. It also can inhibits synthetic of germ's protein and nucleic acid, ACOL adds some medicine such as Radix Astragali, Radix Salvia Miltiorrhiza, Rhizoman Zingiberis to DCT. Those functions lie in invigorating qi and strengthening asthenia, activating blood to resolve stagnation, and improving the whole condition of patiences postoperatively. They also can enhance the resistance of human being, improve the microcirculation. It is benefits to the recovery of the normal physical condition of intra-peritoneum postoperatively. Altogather, ACOL can suppress bacterial and anti-inflammation, protect organs, improve microcirculation through exclude from accumulating. It relieves the accumulation of excrement and bacterial through improving intestinal movement, so it can lower temporary high level toxin in blood, reduce the release and

production of histamine, bradykinin, 5-HT, prostaglandin, *et al*, improve the perfusion of blood, relieve the traumatic inflammation intra-peritoneum postoperatively, recover the homeostasis between FIB and FDP as soon as possible, reduce the incidence of adhesion intra-peritoneum.

Abstract

We presented a 20-year-old patient with Crohn's disease (CD). Colonoscopy revealed longitudinal ulceration in the terminal ileum and rectal aphthoid ulcers. After treatment with mesalamine and total parenteral nutrition, repeat colonoscopy revealed a granular elevated area in the terminal ileum, which appeared as an irregular dome-like elevation with irregularly arranged villi on magnifying endoscopy. Biopsy specimens taken from the region showed microgranulomas and lymphoid hyperplasia. Scanning electron microscopy revealed the presence of M cells, confirming that the area corresponded to Peyer's patches. Peyer's patches by magnifying endoscopy and electron microscopy may provide insights into the pathogenesis of CD.

INTRODUCTION

The gut-associated lymphoid tissue (GALT) is composed of Peyer's patches, peripheral lymphoid tissues and appendix and plays an important role in the immune system of the gastrointestinal tract^[1]. The importance of Peyer's patches in the development of Crohn's disease (CD) is generally accepted^[1-8], but there have been only a few reports focusing on the endoscopic appearance of Peyer's patches of the terminal ileum in CD^[3-5].

We presented a patient with CD in whom specific CD lesions were found in the Peyer's patches of the terminal ileum by magnifying endoscopy, histopathology and scanning electron microscopy. We also discussed the importance of endoscopic observation of the Peyer's patches of the terminal ileum in the diagnosis and assessment of the pathogenesis of CD.

CASE REPORT

A 20-year-old man was admitted to our hospital with right lower abdominal pain, diarrhea and anal fistula for 4 wk. Physical examination revealed localized guarding with tenderness in the right lower quadrant of the abdomen as well as anal discharge. Laboratory analysis showed leukocytosis (10 700/ μ L), elevated C-reactive protein (27 mg/L) and slight hypoproteinemia, while other biochemical and serological data were within normal limits. Repeated stool cultures yielded no enteric pathogens including *Yersinia* and *tubercle* bacilli. Colonoscopy showed longitudinal ulcers in the terminal ileum (Figure 1A), ileocecal valve, hepatic flexure, and anal canal. A subsequent radiological examination of the small bowel disclosed three discrete longitudinal ulcers with cobblestone appearance in the ileum. After treatment with a total of 2 250 mg of mesalamine for 2 wk under total parenteral nutrition, repeat colonoscopy revealed improvement of the above lesions, leaving deformity of the ileocecal valve and anal stenosis. In addition to multiple aphthoid ulcers in the rectum, a granular elevated area was noted in the terminal ileum, which corresponded to the lymph follicle type of the Peyer's patches according to a classification proposed by Fujikura (Figure 1B)^[9]. On magnifying endoscopy, the surface of the Peyer's patches appeared as an irregular dome-like elevation with irregularly arranged villi (Figure 1C). Histopathological examination of the biopsy specimens taken from the region and rectal aphthoid ulcers disclosed the presence

Figure 1 Endoscopic findings. A: Endoscopic view showing an ulceration of the terminal ileum. B: Endoscopic view showing granularly elevated mucosa consistent with the lymphoid follicle type of the Peyer's patches. C: Magnifying endoscopy showing the irregular villi and the dome.

of microgranulomas and lymphoid hyperplasia (Figure 2). Scanning electron microscopy of the specimen taken from the Peyer's patch revealed the presence of M cells (Figure 3).

Figure 2 Histological finding of a biopsy specimen obtained from the Peyer's patches in the terminal ileum disclosing the presence of a microgranuloma and lymphoid hyperplasia.

Figure 3 Scanning electron microscopy of the Peyer's patches demonstrating M cells with microfolds.

DISCUSSION

Major advances have been made in every aspect of CD and ulcerative colitis (UC), but several problems in the etiology and pathogenesis of inflammatory bowel diseases (IBD) remain unresolved^[1-8]. It has been recognized that the disorder of GALT plays a crucial role in the development of IBD^[1-8]. Peyer's patches and related lymphoid follicles have specialized follicle-associated epithelia (FAE) which serve as sites for the induction of mucosal immune responses^[4,5]. In particular, it has been found that M cells serve as an important first step in this process^[1,4,5], and Peyer's patches are abundantly distributed in the terminal ileum^[7,9], an area predisposed to CD. However, little attention has been paid to endoscopic observation of Peyer's patches, and therefore, only a few studies^[3-5] have described endoscopic appearance of Peyer's patches in the terminal ileum. In this regard, Fujikura^[9] examined the terminal ileum by colonoscopy in 110 normal cases and grossly in 48 autopsy cases, and classified Peyer's patches into three categories as follows; lymph follicle, lymph border and lymphocyte aggregation types^[9]. Macroscopically, the lymph follicle type appeared as granular or convolute elevation and was associated with lymphoid hyperplasia. The lymphocyte aggregation type appeared as a flat area associated with mild lymphocytic infiltration and few lymphoid follicles^[9]. Recently, Van Kruiningen *et al.*^[7] examined 55 adults without intestinal disease and reported that Peyer's patches were concentrated in the distal 25 cm of ileum but extended proximally to 200 cm from the ileac end.

In the present case, magnifying endoscopy identified the irregular surface of Peyer's patches, which harbored microgranulomas and lymphoid hyperplasia when examined histopathologically. Scanning electron microscopy identified the presence of M cells, confirming that the specimens were taken from the Peyer's patches.

Our findings pose an important question: does the CD lesion

selectively originate from the Peyer's patch? In this regard, Lockhart-Mummery and Morson^[2] reported in 1960 that the earliest microscopic change in CD was ulceration of the lymphoid follicles and Peyer's patches in the terminal ileum. Since then, several investigators have reported that CD initially occurs as tiny aphthoid lesions at the sites of mucosal lymphoid follicles in the gastrointestinal tract^[3-5]. Recently, Fujishima *et al.*^[3-5] investigated ultrastructurally the epithelium covering solitary lymphoid nodules using biopsy samples obtained from the colorectum during colonoscopy, and indicated that the red halo appearance of such epithelia seemed to precede visible aphthoid ulcers. They suggested that ulcerations in CD might originate from the follicle-associated epithelium (FAE), possibly related to its role as a portal entry for potentially pathogenic agents. These studies have led to the concept that CD could originate from GALT including Peyer's patches and lymphoid follicles in the terminal ileum^[3-8]. With this concept^[3-7], one can explain the reason for the occurrence of the skip lesions and the frequent involvement of the terminal ileum in CD.

Fujikura^[9] showed that M cells of the Peyer's patches were more frequently seen in the dome area of the lymph follicle and lymph border types than in that of the lymphocyte aggregation type, emphasizing its pathogenetic functions. Further studies of the ultrastructure of M cells should enhance our understanding of their role in the development of IBD. However, it is difficult to obtain M cells by conventional endoscopic biopsy because they are located in the dome area (FAE), but not in the villi of Peyer's patches^[9]. Our experience indicates that biopsy using magnifying endoscopy is beneficial for accurate biopsy sampling to obtain tissue segments containing M cells, because this tool allows us to clearly recognize the dome area.

In conclusion, we identified CD-specific lesions in the Peyer's patch of the terminal ileum by endoscopy and histopathological examination. Although the pathogenic role of M cells in the development of IBD is still unknown, examination of the Peyer's patches by magnifying endoscopy and electron microscopy may provide insights into the pathogenesis of CD.

Abstract

AIM: To highlight the intestinal perforation (IP), an uncommon and catastrophic complication after combined liver-kidney transplantation.

METHODS: Combined liver-kidney transplantation (LKTx) with left kidney excision and a cyst fenestration procedure on the right kidney were performed on a case of 46-year-old female with congenital polycystic disease (CPCD).

RESULTS: Two sites of IP were noted 40-50 cm proximal to ileocecal area during emergent laparotomy 10 d postoperatively. Despite aggressive surgical and medical management, disease progressed toward a fatal outcome due to sepsis and multiple organ failure 11 d later.

CONCLUSION: Long duration of operation without venovenous bypass, overdose of steroid together with postoperative volume excess may all contribute to the risk of idiopathic multiple IPs. Microbiology and pathology inspections suggested that the infected cyst of the fenestrated kidney might be one reason for the fatal intra-peritoneal infection. Thus for the CPCD patients who seem to be very susceptible to infectious complications, any sign of suspected renal-infection found before or during LKTx is indication for the excision of original kidney. And the intensity of immunosuppression therapy should be controlled cautiously.

<http://www.wjgnet.com/1007-9327/10/2769.asp>

INTRODUCTION

Intestinal perforation (IP) is a catastrophic complication after

liver or kidney transplantation and well documented in literatures separately^[1,2]. Herein we report a case of IP after combined liver-kidney transplantation (LKTx).

CASE REPORT

The recipient was a 46-year-old female who had a history of 6-year aggravating abdominal girth and pain, with symptoms of gross hematuria, intermittent fever and anorexia in the recent one and a half year. The above symptoms severely affected her daily life as well as her profession. She had obvious abdominal protuberance with a liver palpable 5 cm below the right costal margin, the lower edge of left kidney aligned with the navel level and the right kidney 3 cm lower. Percussion tenderness was found in bilateral areas of kidney. Her liver function was Child B. Her serum creatinine was 132 $\mu\text{mol/L}$ and the glomerular filtration rate was 19.3 mL/min. In urine sediment Gram-negative bacillus was found (1/hpf). ABO typing was "O". HLA typing results were: A3, 26 (10); B39 (16), 54 (22); Bw6; DR4, 8; DRw53; DQw7 (3), 8 (3). Preoperative diagnosis was congenital polycystic disease (CPCD) with chronic renal failure and urinary tract infection.

Allografts came from an "O" type, 23-year-old male cadaver. HLA typing results were: A203 (2), 1102 (11); B27, 38 (16); Bw4; DR15 (2), 16 (2); DRw51; DQw5 (1), 6 (1); DTT-PRA negative; lymphocytotoxic crossmatch negative. Liver and kidney were harvested and preserved routinely.

Bacillus in urine sediment and culture turned negative after therapy whereas WBC counting was $4.1 \times 10^9/\text{L}$ (neutrophils 80.5%) before operation. Left kidney excision + right kidney fenestration + combined liver-kidney transplantation were performed on June 23, 2000. About 1 000 mL ascites was found in laparotomy. The fluid in the cysts of right kidney and liver was clear, in contrast to those muddy yellow-white liquids in the cysts of left kidney. Culture of the fluid from left cysts showed Gram-negative bacilli. The recipient hepatectomy and graft liver implant (Piggyback) were done routinely with modification (the hepatic artery and portal vein anastomosis was performed subsequently and revascularized simultaneously). No venovenous bypass was done. The left kidney resection, right kidney depression and graft kidney implantation (in right iliac fossa) were performed in the usual manner. Totally 650 mL urine was collected from recipient's kidneys but no urine drainage was found from the implanted kidney. The whole operation lasted 18 h and 47 min (anhepatic period 2 h 7 min; warm ischemic 0 min, cold ischemic 794 min for liver and 1 143 min for kidney). Bleeding during operation (about 7 000 mL) mainly came from the right kidney. The haemodynamic was stable.

Immunosuppression regimen was initially based on cyclosporine. Oral cyclosporine 500 mg was given the night before operation and 1 000 mg methylprednisolone was given intravenously before revascularization. However, due to the delayed recovery of function of the implanted kidney, postoperative immunosuppression protocol shifted to methylprednisolone + mycophenolate mofetil (MMF, Roche Corp.). The dosage of methylprednisolone during the 8-d post transplantation were 200, 160, 260, 220, 160, 100, 40, 20 mg separately and, maintained

at a dosage of prednisolone 20 mg/d. MMF 2 g/d was given orally until the 16th d, when bone marrow suppression was manifested. Sandostatin (somatostatin, Sandoz Corp.) and Losec (Astra) were given daily after operation. Beta-lactam antibiotics, ganciclovir (Cymevene, Roche Corp.) and injection fluconazole (Diflucan, Pfizer Corp.) were used for prophylaxis of bacterial, cytomegalovirus (CMV) and fungus infections separately.

The patient woke up 2 h after returning to ICU. Due to transfusion overload (6 000 mL positive balance in the first 24 h) and retention of sodium and water, acute left heart failure, pulmonary edema and ARDS presented in turn. All were reversed 6 d later. The liver function recovered well. Drainage from left side subdiaphragmatic location increased continuously. Its creatinine concentration was 2-fold higher than that of blood (1 114 $\mu\text{mol/L}$ vs 586 $\mu\text{mol/L}$), which indicated urine leakage from the right kidney. Since d 5 postoperatively (POD), daily urine decreased from 900 mL to 40 mL, and serum creatinine peaked to 626 $\mu\text{mol/L}$ (glomerular rate 22.6 mL/min). Haemodialysis was performed daily since d 8 postoperatively. Passage of flatus and green stools began from d 6 postoperatively, and changed to water like, with frequent discharge and urgency to defecate. Temperature mounted since d 7 postoperatively. Obvious abdominal pain and distention with lower abdominal tenderness presented on d 10 postoperatively. White blood cell count rose to $17.35 \times 10^9/\text{L}$. No vascular problem of implanted liver and kidney was found in real-time ultrasound examination. In emergent exploration on d 10, two sites of bowel perforation at a diameter of 1.2 cm and 0.6 cm were noted 40-50 cm proximal to ileocecal area; and multiple ulcerative lesions with purulence were scattered on the serosa of terminal ileum. Postoperative pathology found no sign of rejection in the implanted liver and kidney except that, acute tubular necrosis in the graft kidney; acute purulence with multiple acute perforations on the ileum wall; and especially, the inflammation on the serosa side was more severe than that of the mucosa side (Figure 1). Ileum of 60 cm (30 cm proximal to the ileocecal) long was resected and an end-to-end anastomosis was done. Distention and abdominal pain were not relieved after laparotomy. And multiple ulcers appeared on the buccal mucosa, with skin rash on the forehead and chest. The temperature rose to 39.5°C on d 15 postoperatively, accompanied with decreased counting of WBC and PLT ($1.3 \times 10^9/\text{L}$, $1.8 \times 10^9/\text{L}$ separately). A bone marrow aspiration showed severe marrow suppression that was not ultimately reversed by granulocyte macrophage colony stimulating factors. Culture findings included: *Pseudomonas cepacia* (blood, urine, secretion from trachea, and abdominal drainage), *Staphylococcus haemolyticus* (abdominal drainage and wound secretion), *Klebsiella pneumoniae*, *Acinetobacter junii* (secretion from trachea), *Candida parapsilosis*, *Candida sake* (urine). Serology supervision of CMV, herpes simplex virus and EB virus were always negative. No reperforation was found except multiple superficial ulcers scattered on the

whole bowel wall and mesentery in reexploration on d 20 postoperatively. Biopsy of graft liver/kidney and chest rash indicated no evidence of rejection and GVHD. The case progressed to death on d 21 for multiple organ failure (Data shown in Figure 2).

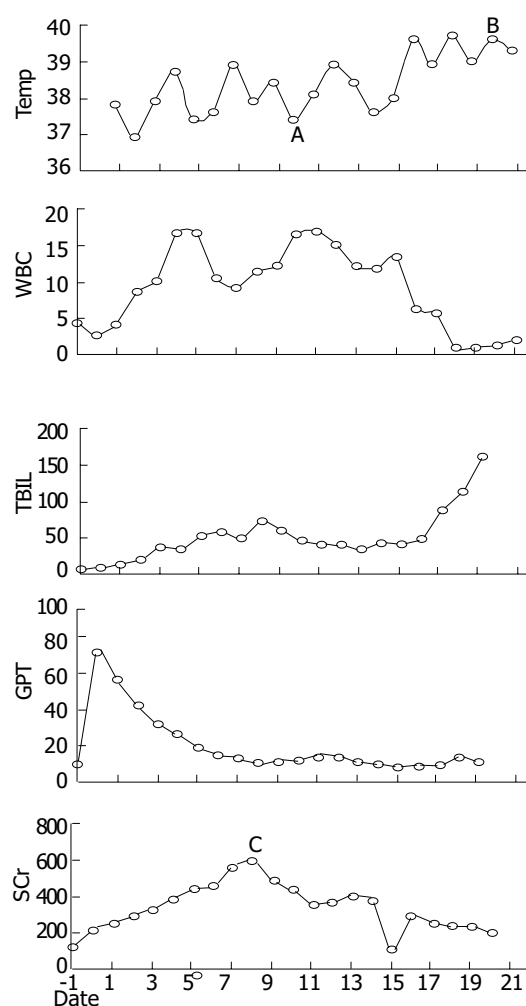

Figure 2 Alterations of body temperature, white blood cell count, liver and renal function after combined liver-kidney transplantation. Temperature ($^\circ\text{C}$) = daily maximum of body temperature; WBC = white blood cell count ($\times 10^9/\text{L}$); TBIL = total bilirubin ($\mu\text{mol/L}$); GPT = glutamic pyruvic transaminase (IU/L); SCr = serum creatinine ($\mu\text{mol/L}$); DATE = date posttransplant; Point A: the first emergent laparotomy on the 10th d posttransplantation; Point B: the second laparotomy on the 20th d; Point C: inception of haemodialysis on the 8th d.

Figure 1 A: Lesions of bowel perforation and multiple ulcerative lesions 40-50 cm proximal to ileocecal area; attached with purulent secretion scattered on the serosa of terminal ileum. B: Photomicrograph of mucosal ulceration in ileum wall (HE staining, original magnification: $\times 100$).

DISCUSSION

For liver transplantation, postoperative IP mostly happens among pediatric recipients (6.4-20%)^[1,3], especially in those who have had previous abdominal surgery but rarely seen in adults. The median delay between transplantation and perforation was 13 d, according to Soubrane O.^[3] The sites tended to locate in small intestine^[4,5] and, according to Marujo, the typical intraoperative findings in whom developed the syndrome of multiple bowel perforations were pinpoint perforations in areas of normal bowel^[6]. The cause remains obscure and is probably of multifactorial origin. Risk factors have been implicated as following: a previous history of abdominal operation (especially those who received Kasai operation for congenital biliary atresia), steroid therapy, CMV infection, long time duration of operation, relaparotomy for postoperative bleeding, early portal vein embolism and venovenous bypass^[3,6,7]. Incidence of reperforation was as high as 31-53%^[7,8]. Even though there was report of 100% success rescue^[6] and 70% 3-year survival^[3], we noticed Shaked's report of 50% (12/24) mortality in primary perforation and 78% (7/9) in reperforation group^[4].

The incidence of IP in renal transplant recipients ranged from 0.62% to 3.4%^[9,10] or, in reports of larger sample, differed from 1.1% to 2.1%^[11,12]. Most perforations occurred within a few weeks or months after engraftment, the period of most intense immunosuppression^[9,12]. The pathogenesis was related to a high incidence of diverticular disease in patients with polycystic kidneys and/or chronic renal failure^[11]. Other risk factors included overimmunosuppression^[9,12], CMV infection^[13], and the transplant procedure^[11]. The average mortality rate was 56.5%^[14]. This high mortality appeared to be related to the effects of immunosuppression and associated response to sepsis^[9]. Clinical findings in these patients, such as fever or leucocytosis, might be masked by the immunosuppressive agents^[12]. And pneumoperitoneum on abdominal roentgenograms was not necessarily positive^[1,4]. Therefore, prompt diagnosis, aggressive surgical care consisting of resectional therapy, broad-spectrum antibiotics, and a reduced immunosuppressive protocol are crucial to outcome^[2].

In our case, without a previous history of abdominal surgery and consequent adhesion, resections of the original liver and left kidney as well as implantation of graft liver and kidney were smooth, although the whole duration of operation lasted 18 h due to the limitation of personnel in the renal transplantation group. Diverticulosis and CMV infection were also cautiously excluded by inspection during operation and postoperative supervision separately. Furthermore, no pathologic evidence of GVHD was found in the examinations of either the perforated ileum or biopsy skin rash in this case. In our case, it is hard to blame just the absence of venovenous bypass during the anhepatic phase as the only risk factor in inducing gastrointestinal congestion thus responsible for the perforation^[6]. But the postoperative sodium and water retention aggravated the bowel edema and stasis authentically. In addition, an obvious risk factor herein, is the relatively high dose of steroid that has not tapered down routinely because of the withdrawal of cyclosporine. Overimmunosuppression may increase risk of IP through inducing damage to the barrier of intestinal mucosa^[9,12]. Thus we propose that, the long duration of operation without venovenous bypass, overdose of steroid together with postoperative volume excess may all contribute to the risk of idiopathic multiple IPs in the present case.

Also, we suggest that intraperitoneal infection in this case might originate first from the infected cyst of the fenestrated kidney and might be prior to the occurrence of IP, based on the following evidences: (1) Neutrophils counting was above normal before operation. (2) *G. bacillus* was found in the fluid

from left cysts during operation. (3) Evidence of urine leakage from the right kidney was present. (4) The inflammation on the serosa side was more severe than that of the mucosa side under pathologic inspection. This supports Jeyarajah's observation in 6 cases of CPCD who received liver and kidney transplantation and that, possibly due to overimmunosuppression or the presence of infectious foci in residual cysts, these patients seemed to be very susceptible to infectious complications after transplantation^[15]. Unfortunately, the intraperitoneal infection of this case was masked and deteriorated by the post-transplant leukopenia. The cause of marrow suppression in this case might be multifactorial but most likely to be drug-induced. Leukopenia and/or thrombocytopenia, the frequent side effects of MMF, ganciclovir and beta-lactam antibiotics that had been applied in this case, might be accentuated by her renal dysfunction.

In summary, the lesson we learn from this particular case is, for the CPCD, any sign of suspect renal infection found before or during LKTx is indication for the excision of original kidney and, the intensity of immunosuppression therapy should be controlled with caution.

Correa P. Why a *World Journal of Gastroenterology*? *World J Gastroenterol* 2004; 10(19): 2773-2774

<http://www.wjgnet.com/1007-9327/10/2773.asp>

When a new medical journal is launched, the reaction is frequent: Why? Do we have already so much to read that we feel overwhelmed? But, the litmus test of a good new journal is: Does it find its way into the reading time of physicians and medical scientists? The new *World Journal of Gastroenterology* has the opportunity to pass that litmus test.

We already have excellent journals of gastroenterology. All have originated as local publications. Some have reached an international status because of the quality of the published materials. Clear examples in the Western world are journals originated in Great Britain, Scandinavia and the United States of America. But they all keep their original flavor which permeates their published materials and reflects mostly the experience and the interest of physicians in the countries they represent.

Gastroenterologists, as most clinicians, tend to draw conclusions from their own experience, which they tend to generalize to "the world". That experience represents the pattern of diseases in their community. But gastrointestinal diseases display radically different patterns in different populations. In the case of cancer, for instance, the incidence of cancers of the colon, liver, biliary system, and stomach displayed rates in some populations that were several times higher than in other populations, as regularly published and illustrated by the International Agency for Research on Cancer^[1].

The phenomenon is well illustrated by gastric cancer and its precursor lesions. Their morphologic characteristics were first masterfully described and illustrated by European pioneers such as Faber, Fenwick, Magnus and Kupfer approximately a century ago^[2-5]. In those days pernicious anemia was a major medical problem in Europe and was, with good reasons, linked to gastric carcinogenesis. At the present time pernicious anemia has drastically decreased in frequency perhaps due to improved nutrition and sanitation. However, the genes for the predisposition to the syndrome remain in the population. The type of gastric adenocarcinoma originally described in association with pernicious anemia (the papillary type, located in the corpus) has become very rare^[6]. But it is entirely possible that the genes that predispose to pernicious anemia in one set of environmental conditions may manifest themselves as a different disease in another set of conditions. It has been suggested in populations susceptible to pernicious anemia, the initial trigger for chronic gastritis may be *Helicobacter pylori* infection. In such populations gastritis may be severe in the corpus leading to atrophy of the oxyntic mucosa^[7].

Most clinicians attending only populations of non-European

extraction have never seen a case of pernicious anemia. The genes linked to that disease are either rare or not present in their population and gastritis associated with *Helicobacter pylori* in their patients is multifocal but antral predominant, with minimal or absent corpus involvement. Some medical writers concentrated on corpus atrophy as a cancer precursor and ignore the gastric antrum^[8]. They might not appreciate that outside Europe, most gastric cancer precursors were predominantly in the antrum, not in the corpus.

Some publications insist that the high cancer risk gastritis phenotype depends on the grade and activity of gastritis in the corpus. The general experience presently showed that the antrum and the antrum-corpus transition zones (mostly the area of the incisura) were the sites of the most advanced lesions, including intestinal metaplasia, dysplasia and carcinoma^[9].

The Jarvi-Lauren classification of tumors as "intestinal" or "diffuse" has been challenged. Some reports have concluded that gastric carcinomas may arise as "gastric type" and later convert to a mixed type, expressing gastric and intestinal mucins. It has been suggested that stem cells, from which carcinomas are supposed to arise, are "primarily gastric type" (meaning they encode for gastric mucins only)^[10]. Normal stem cells have a minimal amount of acid (intestinal) mucins, indicating repressed genes and explaining their multi-potential characteristics^[11]. Obviously the ultimate mechanism of carcinogenesis is not well understood. An attractive hypotheses has been recently discussed by Kirchner *et al.*^[12]. They presented scientific evidence in support of a mechanism of carcinogenesis based on atrophy (loss of differentiated cells) followed by re-differentiation of stem cells, which may be abnormal. This would explain the carcinogenic process of the gastric and cardiac mucosae. After atrophy, the so-called complete intestinal metaplasia expresses preferentially small intestinal (sialic) mucins. Later the so called "incomplete" metaplasia appears and expresses several types of mucins, including gastric MUC-5AC and MUC-6, small intestinal MUC-2 and large intestinal DAS-1^[13]. These findings do not support gastric carcinoma classification based on mucin expressions as "gastric", "intestinal" or "mixed". Mucins expressed by pre-neoplastic and neoplastic cells represent abnormal re-differentiation which is not a permanent but rather a represent dynamic expression of mucin genes present in stem cells.

We hope that the *World Journal of Gastroenterology* will minimize the "provincial" bias and inspire the authors to be less dogmatic and more eclectic. We also hope that future authors adopt some of the basic teachings of epidemiology. For example, (1) Disease patterns are strongly influenced by the geographic and demographic characteristics of the populations under study. The local experience may not be applicable to all populations. Frequently, more than one demographic group share the same geography, comparison of such groups offers opportunities for etiologic research. (2) Disease frequency determines population risk and there are clear rules to assign causality. As an example, cancer frequency is often measured in the number of cases per 100 000 populations. Invasive gastric carcinoma is the final stage of a prolonged precancerous process involving chronic gastritis, atrophy, metaplasia and dysplasia. As in precancerous processes in other organs, the earlier stages are very frequent but less predictive of eventual neoplastic outcomes. Later stages have a lower prevalence in the population but are better indicators of cancer risk. Let us

remember that the skin of all people is exposed to the effects of sun rays which may lead to several degrees of actinic damage. But very few develop skin cancer. Large cohorts observed for many years may provide more valid data than small cohorts followed-up for a few years. Large cohorts have been reported in Finland, Yugoslavia and Japan^[14-16]. (3) As in all medical sciences, epidemiologic observations may be biased. But epidemiologists have figured out how to deal with bias. Causal vs non-causal associations are distinguished by epidemiologic criteria such as strength, consistency, temporality, and plausibility of the associations.

Recent advances in medicine and biology have made it possible to depend less on experimental animals to test causality. Molecular changes can be traced in human cells, tissues and fluids, but molecular techniques are not an end in themselves. Clinicians and medical scientists should remember that these new techniques are merely tools to explore causality in human beings. The new science of molecular epidemiology in some way should make molecular biologists use the epidemiologic techniques to analyze their findings. Similarly, classical epidemiologists need to become acquainted with the new powerful tools provided by molecular biologists. More than ever, multidisciplinary teams are needed to make real progresses in our understanding of the complex processes of carcinogenesis.

Abstract

AIM: To investigate the relationship between *p53* codon 72 polymorphism and human papillomavirus (HPV) type 16 infection in Kazakh's esophageal cancer (EC) in Xinjiang, China.

METHODS: Encoding regions of *p53* codon 72 and HPV-16 *E6* were amplified by polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP) and polymerase chain reaction (PCR) methods using pairs of primary esophageal squamous cell carcinoma (SCC) tissue and corresponding normal mucosa, which were collected from 104 patients of Kazakh in Xinjiang, China.

RESULTS: Only arginine allele was detected in 70.1% (39/55) of HPV-16-*E6*-positive cases but only in 40.8% (20/49) of HPV-16-*E6*-negative cases ($P < 0.05$; OR, 3.53; 95% CI, 1.57-7.98). In contrast, such a significant correlation between *p53* polymorphism and HPV infection was not evident in corresponding normal mucosae. The allele frequency of *Arg* allele in cancer cases (0.68) was higher than that in normal mucosa samples (0.54) ($P < 0.05$; OR, 1.80; 95% CI, 1.21-2.69).

CONCLUSION: *p53* codon 72 *Arg* homozygous genotype is one of the high-risk genetic factors for HPV-associated SCC of Kazakh. Individuals carrying *Arg* allele compared to those with *Pro* allele have an increased risk for esophageal SCC.

<http://www.wjgnet.com/1007-9327/10/2775.asp>

INTRODUCTION

Esophageal cancer is common in several areas of central Asia, including Xinjiang Uygur Autonomous Region, China. The incidence of Kazakh's EC is the highest among population in Xinjiang and its age-adjusted mortality rate up to 91/100 000

has been reported in Kazakh's population^[1]. The population size of Kazakh was estimated to be 13 million around the world and 10 million Kazakh distributed in Kazakhstan and 2 million in Xinjiang, China. The population in the present study was a Kazakh isolated community located at the Northeast of Xinjiang. The genetic homogeneity and geography stability of the population, along with shared exposure to common environmental variables, provide an excellent opportunity for the study of genetic influence on EC. These cancers are mostly SCC, and show a high frequency of mutation in the *p53* tumor suppressor^[2]. Epidemiological studies have suggested that a number of risk factors are involved in the carcinogenesis of Kazakh's SCC, including deficiencies in vitamins and minerals, consumption of pickled foods and environmental exposure to specific nitrosamines, etc^[3,4]. Viral infections, in particular HPV infection, have been reported in esophageal cancers from China, and HPV DNA has been detected in 0-60.0% of cancer tissues by polymerase chain reaction analysis^[5,6]. HPV is implicated in the pathogenesis of squamous cell carcinoma of the cervix and esophagus. HPV-16 encodes *E6* protein, which binds to cellular tumor-suppressor protein *p53* and directs degradation through the ubiquitin pathway^[7]. This event is mediated by another cellular protein termed *E6-AP*, a component of the ubiquitin pathway^[8,9]. The arginine allele at codon 72 of *p53* was found to be more susceptible to degradation by HPV *E6* protein than the proline allele *in vivo*, thus resulting in a high frequency of esophageal SCC in individuals homozygous for arginine at the codon^[8]. On the basis of these experiments, it has been widely assumed that *p53* is functionally inactivated by the viral *E6* protein in HPV-associated cancer cells and that infection with high-risk HPV types leads to the same phenotype as a loss of *p53* function because of *p53* gene mutations or direct degradation^[9]. The association of *p53* codon 72 polymorphism with HPV-16-associated esophagus SCC risk has been studied by several groups but with inconsistent results. Kawaguchi *et al.*^[10] reported that the form of *p53* protein carrying an *Arg* residue at this position in HPV-16/18 positive samples was found to be significantly more susceptible to degradation by *E6* protein than that in HPV-16/18 negative samples. There are controversial results from several clinical studies of esophagus SCC^[11,12]. A part of Kazakh's esophageal SCC correlated with the presence of HPV-16/18^[13]. To our knowledge, *p53* polymorphism in Kazakh's esophageal SCC has apparently not been documented. In this study, we investigated the genotypic frequency of *p53* codon 72 polymorphism and HPV-16 *E6* in Kazakh's esophageal SCC patients in Xinjiang, China. The data we obtained seemed to be the first regarding the association of this polymorphism with HPV-associated risk for cancer of the esophagus.

MATERIALS AND METHODS

Tissue specimens

Pairs of primary Kazakh's esophageal SCC tissue and corresponding normal mucosa were obtained from 63 patients who underwent surgery in the Department of Surgery, 1st Teaching Hospital of Xinjiang Medical University, from 1999 to 2003, and from 41 patients who underwent surgery in

Department of Surgery, the People's Hospital of Xinjiang Uygur Autonomous Region, China, between 1998 and 2000. No patient had been given treatment prior to the study. In all cases the histopathological type of tumors was squamous cell carcinoma. Cancer tissues and well-separated normal esophageal mucosae obtained from surgically resected esophageal SCC patients were fixed in 40 g/L formaldehyde and embedded in paraffin. Genomic DNA was prepared by proteinase K digestion and phenol/chloroform extraction, followed by ethanol precipitation, as described by Greer *et al.*^[14].

HPV detection and identification

First, as a control, purified genomic DNA was successfully amplified by PCR using primers specific for the β -globin gene, indicating a suitable quality and quantity of DNA. PCR analysis was then performed using HPV-16 *E6* oligodeoxynucleotide primers as follows: HPV-16 *E6* forward, 5'-GCAAGCAACAGTTACTGCGA-3' and reverse, 5'-CAACAAGACATACATCGACC-3'. Amplified PCR products were then determined by electrophoresis on 15 g/L agarose gels stained with ethidium bromide. Finally, the gels were analyzed by DC-2000 image system (Bio-Rad, USA).

Analysis of codon 72 polymorphism

p53 exon 4 (codons 33-125) containing codon 72 was amplified by PCR using oligodeoxynucleotide primers 5'-TGAGGACC TGGTCTCTGAC-3' (forward) and 5'-AGAGGAATCCCAA GTTCCA-3' (reverse), under the following conditions: denaturation at 94 °C for 30 s, primary annealing at 54 °C for 30 s, and extension at 72 °C for 30 s for 35 cycles. PCR products (412 bp) were digested overnight at 37 °C with *Acc* II, which was cut within the sequence corresponding to the *Arg* codon (CGC) at position 72 to generate two fragments of 252 bp and 160 bp^[15]. The DNA fragments were then resolved by electrophoresis on 30 g/L agarose gels stained with ethidium bromide. Presence of uncut (412 bp) DNA was indicative of the *Pro* allele and heterozygous for *Arg/Pro* genotypes showed three fragments of 412, 252 and 160 bp.

Statistical analysis

Chi-square test was used to examine the correlation between the *p53* codon 72 polymorphism of the esophageal SCC patients and the presence of HPV-16 *E6* by SPSS software (12.0).

RESULTS

Frequency of HPV-16 *E6* among Kazakh's esophageal SCC patients

Pairs of 104 DNA sample from primary Kazakh's esophageal SCC tissues and corresponding normal mucosae were analyzed for the presence of oncogenic HPV-16-*E6* using PCR methods (Figure 1). The frequency of HPV-16-*E6* gene in cancer cases (52.9%) was higher than that in corresponding normal mucosae (39.4%) (Tables 1, 2). These results were similar to previous reports^[16].

Table 1 *Arg* and *Pro* alleles of *p53* in SCCs of Kazakh's esophagus (n, %)

	<i>Pro</i>	<i>Pro/Arg</i>	<i>Arg</i>
Esophageal SCC (n = 104)	21 (20.2)	25 (24.0)	58 (55.8)
HPV16 <i>E6</i> positive (n=55)	8 (14.5)	8 (14.5)	39 (71.0) ^a
HPV16 <i>E6</i> negative (n=49)	13 (26.5)	16 (32.7)	20 (40.8)

^a*P* < 0.05 vs negative.

Arg allele at the codon 72 in HPV-associated esophageal SCC
PCR-RFLP was carried out on 104 DNA samples from primary

Kazakh's esophageal SCC tissues and corresponding normal mucosae to analyze the association between the *p53* codon 72 polymorphism and HPV-associated esophageal SCC by DC-2000 image system (Figure 2). It showed a typical pattern of codon 72 evaluated by restriction analysis. Presence of the *Pro* allele resulted in resistance of the PCR amplified DNA fragment to digestion by *Acc* II. The comparison between the distribution of *p53* alleles at codon 72 in HPV-positive esophageal SCC with the HPV-negative group is shown in Table 1. The frequency of presence of *Arg* allele alone from the Kazakh's esophageal cancer specimens was similar (55.8%, 58 of 104) to other population cases of esophageal cancer^[10]. Moreover, there was a marked difference in the frequency of *Pro/Arg* alleles between HPV-positive and HPV-negative groups. *p53 Arg* allele alone was detected in 71.0% (39/55) in the HPV-positive group, whereas in 40.8% (20/49) in the HPV-negative group (*P* < 0.05; *OR*, 3.53; 95% *CI*, 1.57-7.98) (Table 1). The allele frequency of *Arg* alleles in cancer cases (0.68) was higher than that in normal mucosa samples (0.54) (*P* < 0.05; *OR*, 1.80; 95% *CI*, 1.21-2.69).

Figure 1 Agarose gel electrophoresis of HPV-16 *E6* PCR-amplified fragments. Lane M: 100 bp DNA ladder marker; Lane 1: negative sample; and Lane 2: positive sample.

Table 2 *Arg* and *Pro* alleles of *p53* in normal mucosae of Kazakh's esophagus (n, %)

	<i>Pro</i>	<i>Pro/Arg</i>	<i>Arg</i>
Normal mucosa (n = 104)	28 (26.9)	40 (38.5)	36 (34.6)
HPV16 <i>E6</i> positive (n = 41)	10 (24.4)	18 (43.9)	13 (31.7)
HPV16 <i>E6</i> negative (n = 63)	10 (15.9)	30 (47.6)	23 (36.5)

Figure 2 Restriction analysis of *p53* codon 72 polymorphism. The PCR product from the proline alleles had a single band with a fragment of 412 bp in length. The arginine was cleaved by *Acc* II, yielding two small fragments (252 and 160 bp). Lane M: 100 bp DNA ladder marker; Lane 1: homozygous for arginine; Lane 2: homozygous for proline; and Lane 3: digested sample, heterozygous for the polymorphism.

Arg allele at the codon 72 in surrounding normal mucosae in HPV-associated esophageal cancer

Differences in *p53* polymorphism in the corresponding normal mucosae were not significant between HPV-positive and -negative tissues (*P* > 0.05; *OR*, 0.81; 95% *CI*, 0.35-1.86) (Table 2).

DISCUSSION

Infection with human papilloma virus is an important etiological factor in the development of SCC and it has been proposed that individuals homozygous for *Arg/Arg* at codon 72 of *p53* are several times more susceptible to HPV-mediated cancer^[10,17]. In agreement with the result, studies in India and Mexico also found a strong increase in SCC risk associated with *p53* polymorphism and the presence of HPV infection^[18,19]. In China similar research has been carried out on esophageal SCC, ovarian carcinoma, and breast carcinoma^[20]. However, several studies conducted in different countries failed to reproduce this observation^[21-25]. This polymorphism has been shown to vary with ethnic and geographical distribution. However, its influence has not been elucidated in the Kazakh population.

In the present study, the frequency of HPV-16-*E6* gene in Kazakh's esophageal SCC cases was higher than that in corresponding normal mucosae, suggesting that there is a trend towards an association between the carcinogenesis of Kazakh's esophageal SCC and the presence of HPV-16 infection. These results were similar to previous report^[16], which suggested that infection with HPV-16 might be involved in carcinogenesis of Kazakh's esophageal SCC. In addition, the distribution of *p53* codon 72 *Arg* homozygous genotype in Kazaks's esophageal SCC was significantly higher than that in corresponding normal mucosae, indicating that an individual homozygous for *p53 Arg* would be more likely to develop esophageal SCC than a *Pro/Arg* heterozygote or a *Pro* homozygote. Furthermore, it is noteworthy that the distribution of *p53* codon 72 *Arg* homozygous genotype in HPV positive samples of Kazakh's esophageal SCC was at a 3.53-folds higher risk for the development of esophageal SCC compared with HPV negative samples. In contrast, such a significant correlation between *p53* polymorphism and HPV infection was not evident in corresponding normal mucosae. From the above analyses, when stratified with HPV infection, the frequency of *p53* codon 72 *Arg* homozygous genotype was at a 1.48-folds increased risks for developing Kazakh's esophageal SCC compared with *p53 Arg* homozygosity (*Arg/Arg*) solely. Therefore, this implied *p53* codon 72 *Arg* polymorphism in combination with HPV infection could increase the risk of development of SCC in Kazakhs.

p53 tumor-suppressor protein accumulates rapidly through post-transcriptional mechanisms and is also activated as a transcriptional factor, thus leading to growth arrest or apoptosis when DNA damage has occurred^[26]. The ubiquitin-dependent proteolytic pathway plays a major role in selective protein deregulation. *E6* oncoprotein of oncogenic HPV-16/18 might use this cellular proteolytic system to target *p53* protein^[7] and bind to a cellular protein of *E6-AP*, and the *E6-AP* complex might interact with *p53*, resulting in the rapid ubiquitin-dependent degradation of *p53*^[27]. The level and half-life of *p53* in *E6* immortalized cell lines or in HPV-positive cervical carcinoma cells have been reported to be generally decreased^[28,29]. Certain HPV types such as HPV-16/18 found in SCC of esophagus suggested a model by which *E6* degraded cell growth control by elimination of the *p53* tumor suppresser protein and led to HPV-associated esophageal SCC^[10,30].

In conclusion, the current study reveals the potential role of the polymorphism of *p53* at codon 72 in HPV-associated carcinogenesis of esophageal SCC in Kazakh population. Individuals carrying *Arg* alleles compared to those with *Pro* alleles have an increased risk for esophageal SCC.

ACKNOWLEDGMENTS

We thank Professor Zhen-Zhu Sun (Department of Pathology, the People's Hospital of Xinjiang Uygur Autonomous Region, China) for providing the samples of Kazakh's esophageal SCC.

Abstract

AIM: To investigate the inhibitory effect of ubiquitin-proteasome pathway (UPP) on proliferation of esophageal carcinoma cells.

METHODS: Esophageal carcinoma cell strain EC9706 was treated with MG-132 to inhibit its UPP specificity. Cell growth suppression was evaluated with 3-(4,5-dimethylthiazole-2-yl)-2,5-diphenyl tetrazolium bromide (MTT) assay. DNA synthesis was evaluated by ³H-thymidine (³H-TdR) incorporation. Morphologic changes of cells were observed under microscope. Activity of telomerase was examined by telomeric repeat amplification protocol (TRAP) of PCR-ELISA. Cell cycle and apoptosis were detected by flow cytometry (FCM). DNA fragment analysis was used to confirm the presence of apoptosis. Expression of p27^{kip1} was detected by immunocytochemical technique.

RESULTS: After exposed to MG-132, the growth and value of ³H-TdR incorporation of EC9706 cells were obviously inhibited. Cells became round, small and exfoliative under microscope. TRAP PCR-ELISA showed that light absorption of cells gradually decreased after exposed to 5 μmol/L of MG-132 for 24, 48, 72 and 96 h ($P < 0.01$). The percentage of cells at G₀/G₁ phase was increased and that at S and G₂/M was decreased ($P < 0.01$). The rate of apoptotic cells treated with 5 μmol/L of MG-132 for 48 and 96 h was 31.7% and 66.4%, respectively. Agarose electrophoresis showed marked ladders. In addition, the positive signals of p27^{kip1} were located in cytoplasm and nuclei in MG-132 group in contrast to cytoplasm staining in control group.

CONCLUSION: MG-132 can obviously inhibit proliferation of EC9706 cells and induce apoptosis. The mechanisms include upregulation of p27^{kip1} expression, G₁ arrest and depression of telomerase activity. The results indicate that inhibiting UPP is a novel strategy for esophageal carcinoma therapy.

INTRODUCTION

Esophageal carcinoma is common in China. Previous studies have shown that its occurrence and progression are complicated, and are associated with the changes of multi-genes and molecules^[1-3]. The ubiquitin-proteasome pathway (UPP) is the major system employed by eukaryotes for the selective degradation of cellular proteins that play key roles in cellular processes such as cell cycle regulation, differentiation, signal transduction, gene transcription, antigen presenting and transmembrane localization of proteins^[4,5]. In this study, we investigated the inhibitory effect of UPP on proliferation of esophageal carcinoma cells by using specific ubiquitin proteasome to find a new strategy for esophageal carcinoma therapy.

MATERIALS AND METHODS

Materials

Esophageal carcinoma cell strain EC9706 was presented by professor Ming-Rong Wang, China Academy of Medical Sciences. MG-132 was purchased from Calbiochem Co. Ltd (USA), and dissolved in dimethylsulfoxide (DMSO) as a 40 mmol/L stock solution and stored at -20 °C. 3-(4,5-dimethylthiazole-2-yl)-2,5-diphenyl tetrazolium bromide (MTT) and DMSO were bought from Sigma Co. Ltd (USA). ³H-thymidine (³H-TdR) was provided by Beijing Atomic Power Research Institute. Telomeric repeat amplification protocol (TRAP) ELISA telomerase detection kit was obtained from Intergen Company (USA). Monoclonal mouse antibody of p27^{kip1}, ultra sensitive S-P kit, and 3,3-diaminobenzidine (DAB) kit were purchased from Fuzhou Maixin Biotechnology Co. Ltd. RPMI 1640 medium was obtained from GIBCOBRL Company (USA). Low melting-temperature agarose was obtained from Promega Company (USA). DNA-PREP™ LPR and DNA-PREP™ stain were obtained from America Beckman Coulter Company.

Cell culture

Human esophageal carcinoma cell strain EC9706 was maintained in RPMI 1640 medium supplemented with 100 mL/L fetal calf serum (FCS), 100 kU/L penicillin, 100 mg/L streptomycin and 2 mmol/L L-glutamine in a humidified incubator containing 50 mL/L CO₂ at 37 °C, the medium was changed every 2-3 d.

MTT assay

EC9706 cells growing exponentially were chosen. Cell density in the suspension was adjusted to 2×10⁵ cells/mL. After addition of 200 mL/well of the final cell suspension, 96-well plates were incubated for 24 h. Then the cells were treated with 0.5, 1.0, 2.5, 5.0, 10, 15, 20 μmol/L (DMSO ≤ 0.5 g/L) of MG-132, respectively, as the different observation groups. The cells treated with an equal amount of DMSO instead of MG-132 served as the control. The background was conducted using only cell-free culture medium. After cultivated for 24, 48, 72 and 96 h, 10 μL of stock MTT solution (5 g/L) was added to the cells in each well, followed by a further incubation at 37 °C for 4 h. The culture medium was carefully removed, 100 μL of DMSO was added to each well and culture was vibrated for 20 min. The absorbance

of samples was measured three times for each group with three wells at a wavelength of 550 nm with the enzyme linked immunosorbent assay meter (PR 2100, SANOFI company, France). The inhibitory rate (IR) was calculated according to the formula: $IR = [1 - (\text{absorbance of MG-132 group} - \text{absorbance of background group}) / (\text{absorbance of control group} - \text{absorbance of background group})] \times 100\%$.

Incorporation test of ^3H -TdR

As described above, experimental group and control group were cultured for 3 h with 100 mL/L FCS RPMI 1640, and then for 12 h with FCS-free RPMI 1640. MG-132 and 1 μCi ^3H -TdR were added to each group, which was rinsed with PBS after 24, 48, 72 and 96 h and fixed with methyl alcohol and absolute ethyl alcohol for 10 min each. Finally, 200 μL of 0.1 mol/L NaOH was added, then 200 μL of each was taken after blowing, and mixed in 5 mL scintillation liquid for overnight. On the following day, the count per minute (CPM) of ^3H was tested three times for each group with three wells.

Morphologic changes of cells

Morphologic changes of EC9706 cells were observed under microscope 24, 48, 72 and 96 h after treated with MG-132 (5 $\mu\text{mol/L}$).

Telomerase assay

The cells (10^5 - 10^6) treated with MG-132 (5 $\mu\text{mol/L}$) for 24, 48, 72 and 96 h were collected, respectively. After addition of 300 μL telomerase assay lysis buffer (1 \times CHAPS), the cells were lysed on ice. The lysate was incubated on ice for 30 min and then centrifuged at 13 000 g for 25 min at 4 $^{\circ}\text{C}$. The supernatant (2 μL) was added to reaction solution containing 10 μL of TRAP buffer, 2 units of Taq polymerase and 48 μL of DH_2Oqs . PCR was carried out through 33 amplification cycles, each cycle consisting of denaturation at 94 $^{\circ}\text{C}$ for 30 s, primer annealing at 55 $^{\circ}\text{C}$ for 30 s, and extension at 72 $^{\circ}\text{C}$ for 30 s. The amplified product was added to block/dilution buffer (250 μL), and incubated at 37 $^{\circ}\text{C}$ for 30 min, and 5 μL of TRAP reactant was then added and mixed. After incubated at 37 $^{\circ}\text{C}$ for 60 min, 100 μL working solution of anti-DNP Ab was added and incubated for 30 min, then 100 μL of 3,3',5,5'-tetramethylbenzidine (TMB) substrate solution and 100 μL of stop reagent were added. The absorbance value in each well was read at the wave lengths of 450 nm and 690 nm on an enzyme linked immunosorbent assay meter. Telomerase activity was considered positive when the absorbance value of a sample was at least 0.8 units. When those were lower than 0.2 units, they were regarded as negative.

Flow cytometry detection

After cell cycle was synchronic, the cells of experiment group were treated with MG-132 (5 $\mu\text{mol/L}$) for 48 h and 96 h. The collected cells were added with DNA-PREPTM LPR and DNA-PREPTM stain, respectively, after they were washed with PBS and centrifuged. Cell cycle and apoptosis were detected by

flow cytometry (Epics XL, Beckman Coulter Company, USA) and SYSTEM IITM software was used to dispose the data.

DNA ladder demonstration

As described above, the cells (7×10^6 /sample, both attached and detached cells) were lysed with hypotonic lysis buffer (10 mmol/L edetic acid, 5 g/L Triton X-100, Tris-HCl, pH 7.4) for 15 min on ice and precipitated with 25 g/L polyethylene glycol and 1 mol/L NaCl for 15 min at 4 $^{\circ}\text{C}$. After centrifugation at 16 000 g for 10 min at room temperature, the supernatant was treated with proteinase K (0.3 g/L) at 37 $^{\circ}\text{C}$ for 1 h and precipitated with isopropanol. After centrifugation, each pellet was dissolved in 10 μL of Tris-EDTA (pH 7.6) and electrophoresed on a 17 g/L agarose gel containing ethidium bromide. DNA ladder pattern was identified under ultraviolet light.

Immunocytochemical staining

EC9706 cells cultured with MG-132 (5 $\mu\text{mol/L}$) for 48 h were fixed with dimethyl ketone at 4 $^{\circ}\text{C}$. The cells carrying the detected antigen were stained following SP immunocytochemical staining method using anti-p27^{kip1} as primary antibody^[6]. PBS was substituted for primary antibody as negative control.

Statistics

The data were expressed as mean \pm SD. The difference between each group was analyzed by *t*-test. $P < 0.05$ was considered statistically significant.

RESULTS

Inhibitory effect of MG-132 on EC9706 cell growth

The growth of EC9706 cells treated with 0.5-20 $\mu\text{mol/L}$ of MG-132 was significantly inhibited compared with that of control group. While the cells exposed to MG-132 for 24 h produced a certain inhibitory effect, but only exceeding 48 h did MG-132 show significant effect. When the dose of MG-132 exceeded 5 $\mu\text{mol/L}$, only slight increases in IR of the cells were observed (Figure 1).

Figure 1 MTT assay of EC9706 cells after exposed to MG-132.

Figure 2 Morphologic changes of EC9706 cells observed under microscope after treated with 5 $\mu\text{mol/L}$ of MG-132. A: control group; B: EC9706 cells treated with MG-132 for 24 h; C: EC9706 cells treated with MG-132 for 48 h; D: EC9706 cells treated with MG-132 for 72 h; E: EC9706 cells treated with MG-132 for 96 h ($\times 200$).

Inhibition of DNA synthesis

The values of ^3H -TdR incorporation of MG-132 group were decreased compared with the control group (Table 1).

Morphologic changes of cells

EC9706 cells became round, small and exfoliative after exposed to MG-132 under microscope (Figure 2).

Inhibition of telomerase activity

After treated with MG-132 (5 $\mu\text{mol/L}$) for 24, 48, 72 and 96 h, respectively, EC9706 cells showed a gradual decrease in values of A compared with the control group ($P<0.01$). Furthermore, telomerase activity was negative (Table 2).

Table 2 Effect of MG-132 on telomerase activity of EC9706 cells (mean \pm SD)

Groups	Light absorption (A)			
	24 h	48 h	72 h	96 h
Control	1.871 \pm 0.061	2.234 \pm 0.092	2.907 \pm 0.113	3.025 \pm 0.120

^b $P<0.01$ vs control group.

DNA ladder

Agarose electrophoresis showed marked ladders in MG-132 group, while the ladder was not detected in control group. Furthermore, DNA fragmentation was more apparent at 96 h (Figure 4).

Figure 4 Results of DNA agarose electrophoresis. Lane1: control group; Lane 2: EC9706 cells exposed to 5 $\mu\text{mol/L}$ of MG-132 for 48 h; Lane 3: EC9706 cells exposed to 5 $\mu\text{mol/L}$ of MG-132 for 96 h; Lane 4: 200, 400, 600, 800, 1 000, 1 200, 1 400, 1 600, 1 800, 2 000 bp ladder markers.

Figure 5 Results of immunohistochemical staining of EC9706 cells. A: control group. Immunohistochemical staining of p27^{kip1} protein located in cytoplasm of EC9706 cells; B: MG-132 group.

Immunohistochemical staining of p27^{kip1} protein located in cytoplasm and nuclei ($\times 200$).

Expression of p27^{kip1}

In the control group, the cytoplasm was stained in brownish yellow and the nuclei were stained in blue. In the experiment group, both the cytoplasm and nuclei were stained in brownish yellow, indicating that the expression of p27^{kip1} in EC9706 cells was increased after treated with MG-132 (Figure 5).

DISCUSSION

Proteolytic degradation by ubiquitin-proteasome system involves ATP-dependent covalent attachment of a macromolecular chain of ubiquitin (Ub) molecules to the target protein, followed by degradation through the multicatalytic 26S proteasome. The conjugation of Ub, a highly conserved 8.6 kDa protein, to its target protein is mediated by the serial actions of three enzymes. E1, the Ub-activating enzyme, activates Ub in an ATP-dependent manner. E2, the Ub-conjugating enzyme, catalyzes the attachment of Ub to the substrate protein. E3, the Ub-ligase, serves as a scaffold between E2 and the substrate and provides recognition specificity of the substrate^[7-10]. A protein tagged with a polyubiquitin chain is recognized and degraded by the 26S proteasome complex. This complex is composed of a 19S regulatory subcomplex and two 20S catalytic subcomplexes. UPP is extensively involved in physiological and biochemical processes. Some experiments showed that the low expression of some anti-oncogene including p53, p27^{kip1} in tumor cells was associated with the increasing activity of ubiquitin proteasome which leads to degradation of expression products of anti-oncogene, and have proved that deubiquitination of p53 is an important pathway for p53 stabilization^[11,12]. Moreover, the degradation accommodation of some transcription factors was regulated by UPP, such as NF- κ B, c-fos, c-jun, c-mos, c-myc and MATA^[13-17]. So UPP is closely associated with the occurrence and development of malignant tumor.

Ubiquitin proteasome inhibitors include peptide aldehyde, borofax peptide and 3, 4-dichloro isocoumarin. MG-132, also known as carbobenzoxy-L-leucyl-L-leucyl-L-leucinal, a reversible, effective and specific peptide aldehyde inhibitor of ubiquitin-proteasome, could block UPP through inhibiting ubiquitin-mediated proteolysis by binding to and inactivating 20S and 26S proteasomes^[18-22].

In our study, esophageal cancer cell line EC9706 was exposed to MG-132 to observe whether UPP could be inhibited. We found that the proliferation of cells was obviously inhibited in a dose- and time-dependent manner. The results also revealed some anti-tumor mechanisms of MG-132. First, MG-132 could up-regulate the expression of p27^{kip1}. p27^{kip1} was recently found^[23] as a anti-oncogene with function of negative regulation of cell cycle, getting involved in the inhibitive reaction of cytokines, inducing cell differentiation and apoptosis, enhancing cell's adherence and regulating the resistance to medicines for noumenal tumors. p27^{kip1} protein is a cyclin dependent kinase inhibitor (CDKI) that could block G₁/S transition of cell cycle by inhibiting the action of cyclin E-CDK2 complex and cyclin D-CDK4 complex^[24-26]. p27^{kip1} expression decreases in esophageal cancer and it may correlate with the histologic differentiation. Reduction of p27^{kip1} has been considered to be an independent prognostic indicator of esophageal cancer^[27-30]. The nuclear localization signal of p27^{kip1} contains a protein kinase B (PKB/Akt) consensus site at threonine 157, and phosphorylation of p27^{kip1} by PKB/Akt has been found to impair its nuclear import^[31,32], which is a key procedure to play its functional role^[33]. We found that p27^{kip1} protein localized in cytoplasm of EC9706 cells showed low expression, but that localized both in cytoplasm

and nuclei of EC9706 cells showed high expression after treated with MG-132. Our previous studies^[6,34] demonstrated that the growth of EC9706 cells and tumors implanted in nude mice was obviously inhibited, apoptosis was induced and cell cycle was arrested in G₁ phase by up-regulating p27^{kip1}. Second, MG-132 could depress telomerase activity. The activation of telomerase was closely associated with cyclin. It has been reported that inhibition of UPP could not only increase the expression of p27^{kip1}, but also increase the expression of p53^[35]. Moreover p27^{kip1} and p21 regulated by p53 could inhibit cyclin and result in decreased telomerase activity^[36,37]. Third, MG-132 could cause G₁ arrest, which may be involved in changes of cell cycle regulatory factors such as p27^{kip1}. Fan *et al.*^[38] obtained the same results as ours. But Ling *et al.*^[39] tended to consider ubiquitin proteasome inhibitors to cause G₂ arrest. The difference may be involved in the different types of cells. The last, MG-132 could induce apoptosis, which may be closely associated with the functions mentioned above.

In conclusion, MG-132 can obviously inhibit proliferation of EC9706 cells and induce apoptosis. The mechanisms include upregulation of p27^{kip1} expression, G₁ arrest and depression of telomerase activity. The results indicate that inhibiting UPP is a novel strategy for esophageal carcinoma therapy.

Abstract

AIM: To investigate the prognostic value of the expression of connexin (Cx) 26, 32 and 43 messenger RNA (mRNA) in hepatocellular carcinoma (HCC) tissues.

METHODS: Using a reverse-transcriptase polymerase chain reaction (RT-PCR), Cx 26, Cx 32 and Cx 43 mRNAs were determined in the liver tissues of 15 controls and in HCC tissues of 25 patients undergoing curative hepatic resection. The patients were followed up clinically.

RESULTS: Cx 26 and Cx 32 mRNAs were significantly lower in HCC tissues compared with controls (both $P < 0.01$). By multivariate analysis, a lower level of Cx 26 and Cx 32 mRNA correlated significantly with a risk of HCC recurrence ($P = 0.033$) and recurrence-related mortality ($P = 0.031$, $P = 0.031$). Cx 43 mRNA was higher in HCC tissues compared with controls but did not correlate with postoperative recurrence or recurrence-related mortality. Other significant predictors of HCC recurrence included cellular dedifferentiation ($P = 0.033$), less encapsulation ($P = 0.050$), vascular permeation ($P = 0.046$), and daughter nodules ($P = 0.046$). Significant variables related to recurrence-related mortality consisted of cell dedifferentiation ($P = 0.031$), vascular permeation ($P = 0.048$), and daughter nodules ($P = 0.048$). The levels of Cx 26 and Cx 32 mRNAs correlated significantly with cell differentiation ($P = 0.031$).

CONCLUSION: A low expression of Cx 26 and Cx 32 mRNAs in HCC tissues is predictive of postoperative recurrence of HCCs.

INTRODUCTION

Hepatocellular carcinoma (HCC) is a leading cause of death in Taiwan and many Asian countries, where hepatitis B and C have a high prevalence. During the last 10 years, efforts have been made worldwide toward early detection and curative surgical resection of HCC. However, despite diagnostic and therapeutic advances, postoperative recurrence is still common^[1-7]. Predicting which patients are likely to have a recurrence is a challenge.

Gap junctional intercellular communication (GJIC) occurs via intercellular hemichannels, which are formed by six basic protein subunits expressed in neighboring cells. These subunits are called connexins (Cx)^[8]. Six connexins locate around a central pore, through which adjacent cells directly exchange low weight molecules providing information or energy. GJIC plays important roles in embryonic development, metabolic cooperation, growth control, cell proliferation, and differentiation^[9-12]. Many authors believed that disorders of GJIC were involved in carcinogenesis^[12-21].

Connexin 32 (Cx 32) and connexin 26 (Cx 26) are the major gap junction proteins in hepatocytes. Some authors have reported that Cx 32 and Cx 43 mRNAs and their proteins were significantly decreased in HCC tissues and cell lines. In contrast, Cx 43 protein was increased in the hepatoma cell line SMMC-7721^[22-25].

To the best of our knowledge, little is known about the prognostic significance of connexin mRNA expression in the prediction of postresection recurrence of HCCs. We conducted this prospective study to investigate the correlation between connexin mRNA expression in HCC tissues and postoperative recurrence of the tumor.

MATERIALS AND METHODS

Study population

From July 1999 to August 2000, 25 (18 men and 7 women, with a mean age of 56.4 ± 12.6 years) of 34 consecutive patients with HCC undergoing curative hepatectomy were enrolled in this prospective study. The 9 patients who were excluded had a previous hepatectomy, preoperative neoadjuvant ethanol injection, hepatic arterial chemoembolization (TACE), or surgical morbidity. The surgical procedures performed included 23 major resections (6 extended right lobectomies, 10 right lobectomies, 3 left lobectomies and 4 double segmentectomies) and 2 minor resections (single segmentectomy). Clinical details were available from medical records on all patients (Table 1). Connexins were assayed in both cancerous and noncancerous liver tissues obtained at the time of resection. A control group including 5 healthy volunteers, 5 individuals with chronic active hepatitis without HCCs, and 5 individuals with liver cirrhosis but no HCC also underwent liver biopsies during exploratory laparotomies for other reasons. The surgically removed liver samples were immediately transferred to the pathology laboratory, dissected, frozen in liquid nitrogen, and stored at -80°C until RNA extraction. Frozen and formalin-fixed samples of the dissected tumor and surrounding tissues were also studied by routine pathology. No obvious ischemic change

was observed in the surrounding tissues, suggesting that the time between removal and freezing of samples did not result in problematic artifacts.

After discharge, the patients were assessed regularly to detect tumor recurrence with abdominal ultrasonography (every 2-3 mo during the first 5 years, then every 4-6 mo thereafter), serum alpha fetoprotein (AFP) and liver biochemistry (every 2 mo during the first 2 years, then every 4 mo during the following 3 years, and every 6 mo thereafter), abdominal computed tomography (CT) (every 6 mo during the first 5 years, then annually), and chest X-ray and bone scans (every 6 mo). Hepatic arteriography was obtained if the other studies suggested possible recurrences. A recurrence was defined as detection of a tumor on any imaging study.

Clinicopathologic parameters analyzed included sex (male vs female), age, presence of liver cirrhosis, hepatitis B virus (HBV) infection (hepatitis B surface antigen-positive), hepatitis C virus (HCV) infection (anti-hepatitis C virus antibody-positive), serum AFP level (<20 ng/mL vs 20 to 1 000 ng/mL vs >1 000 ng/mL), cirrhosis, Child-Pugh class of liver functional reserve (A vs B), tumor size (<3 cm vs 3 to 10 cm vs >10 cm in diameter), tumor encapsulation (complete vs incomplete or absent), presence of daughter nodules, vascular permeation (including vascular invasion and/or tumor thrombi in either the portal or hepatic vein), and cell differentiation grade (Edmondson and Steiner grades I to IV) (Table 1).

Table 1 Demographic, clinical and pathological variables in patients with HCC undergoing curative resections (n = 25)

Variables	Patients (n, %)
Age (mean, yr)	56.4±12.6
Male	18 (72)
Child- Pugh class A	
Serum AFP <20 ng/mL	3 (12)
20-10 ³ ng/mL	10 (40)
>10 ³ ng/mL	12 (48)
HBsAg (+)	12 (48)
Anti-HCV (+)	10 (40)
Diameter of HCC <3 cm	2 (8)
3-10 cm	10 (40)
>10 cm	13 (52)
Cirrhosis	20 (80)
Edmondson-Steiner's grade I	11 (44)
grade II	
grade III	14 (56)
grade IV	
Complete capsule	9 (36)
Vascular permeation	14 (56)
Daughter nodules	13 (52)
Multinodular HCC	5 (20)
Tumor necrosis	5 (20)
Tumor hemorrhage	1 (4)

AFP: serum alpha fetoprotein; HBsAg (+): positive hepatitis B surface antigen; Anti-HCV(+): positive hepatitis C virus antibody; Edmondson Steiner grade: differentiation grade.

Detection of connexin mRNA in liver tissues

We chose measuring connexin mRNA instead of measuring protein because RT-PCR was thought to provide better quantification method than immunohistochemistry.

Extraction of RNA Resected tissues were completely homogenized in 1 mL of RNA-bee™ (Tel-Test, Protech Technology Enterprises

Co., Ltd, Friendswood, TX, USA), 0.2 mL chloroform was added, and the mixture was shaken vigorously for 15 to 30 s. The samples were stored on ice for 5 min and then centrifuged at 12 000 g for 15 min. The supernatant was transferred to a new 1.5 mL Eppendorf tube, precipitated with 0.5 mL of isopropanol for 5 min at 4 °C, and centrifuged at 12 000 g for 5 min at 4 °C. The supernatant was removed and the RNA pellet was washed with 1 mL of isopropanol and shaken to dislodge the pellet from the side of the tube. The pellet was centrifuged again at 12 000 g for 5 min at 4 °C, the supernatant was removed, and the RNA pellet was washed once again with 750 mL/L ethanol. The pellet was resuspended in at least 1 mL of 750 mL/L ethanol and centrifuged at 7 500 r/min for 5 min at 4 °C, after which the ethanol was carefully removed. The RNA was allowed to dry in air and then dissolved in DEPC-H₂O (50 to 100 µL) and stored at -80 °C.

Reverse transcription The RNA sample was heated at 55 °C for 10 min and chilled on ice. The following reagents were then added: (1) 4 µL 5×RT buffer containing Tris-HCl (pH 8.3), 75 mmol/L KCl, 3 mmol/L MgCl₂, and 10 mmol/L DTT (dithiothreitol), (2) 3 µL 10 mmol/L dNTP (deoxyribonucleoside triphosphate), (3) 1.6 µL Oligo-d(T)₁₈ and 0.4 µL random hexamers (N) 6 (1 µg/µL), (4) 0.5 µL RNase inhibitor (40 U/µL), (5) 3 µL 25 mmol/L MnCl₂, (6) 6 µL RNA in DEPC-H₂O, and (7) 0.5 µL DEPC-H₂O. The mixture was incubated at 70 °C for 2 min and then chilled to 23 °C to anneal the primer to the RNA. We then added 1 µL of M-MLV RTase (moloney murine leukemia virus reverse transcriptase, 200 U/µL, Promega) and the mixture was incubated for 10 min at 23 °C followed by 60 min at 40 °C. It was heated at 94 °C for 5 min, then chilled on ice. The cDNA was stored -20 °C.

Amplification of connexins 26, 32, 43, and GAPDH cDNA by PCR First-strand cDNA synthesis was carried out using 2 µg of total RNA purified from 50 mg tissue. Reverse transcription was performed in a final volume of 20 µL containing 2 µg of random hexamer (Gene Tek Bioscience Inc., Taipei), and 1.5 mmol/L each of dATP, dCTP, dGTP, and dTTP. Each reaction mixture was incubated for 8 min at 23 °C with 20 U of rRNasin (RNase inhibitor; Promega, Madison, WI) followed by incubation with 200 U of moloney murine leukemia virus reverse transcriptase (Gibco-BRL, Paisley, UK) for 60 min at 40 °C, followed by 5 min at 94 °C. PCR was performed in a final volume of 50 µL, by using 2 µL of cDNA solution in a mixture containing 0.4 mmol/L deoxynucleotide triphosphates, 40 pmol/L of both sense and antisense oligonucleotide primers for Cx 26, Cx 32 or Cx 43, 2.5 mmol/L MgCl₂, 2.5U of Taq DNA polymerase (Promega) and 5 µL of 10x Taq DNA polymerase reaction buffer (500 mmol/L KCl, 100 mmol/L Tris-HCl (pH9.0), 10 g/L Triton-X-100). PCR primer sequences of the sense and antisense oligonucleotides for Cx 26, Cx 32 and Cx 43 as well as the direction, size and reaction conditions are shown in Table 2. For example, Cx 26 anti-sense oligonucleotide (5'-CCGAAGTTCATGAAGGGAGA GAT-3') and its related scrambled sequence (5'-GGTCTTTTGG ACTTCCCTGAGCA -3') were synthesized (by Sigma-Genosys Ltd, Woodlands, TX, USA). GAPDH was used as a control, with the quantities of the other mRNA products reported as their intensity as a fraction of that of GAPDH mRNA. To eliminate any possibility of genomic DNA contamination, PCR amplification reaction was carried out on each sample from the RNA extraction. As another internal contamination control, PCR amplification was also carried out on a sample of reaction mixture in the absence of cDNA.

The intensity of bands was measured using Fujifilm Science Lab 98 (Image Gauge V3.12). The sensitivity of our assay was assessed using human hepatocytes. A HepG2 (hepatoblastoma) cell line served as a positive control for connexin mRNA expression. For negative controls, we used EDTA-treated water (filtered and vaporized).

Statistical analysis

A statistical software package (SPSS for windows, version 8.0, Chicago, Illinois) was used. Student's *t*-test was used to analyze continuous variables and chi-square or Fisher's exact test was used for categorical variables. A Cox proportional hazards model was used for multivariate stepwise analysis to identify the significant factors predicting recurrence and mortality. Significance was taken as a *P* value <0.05.

Table 2 Nucleotide sequences of the primer sets and specific oligonucleotide probes to each type of connexin 5'-noncoding mRNA

Type of connexin mRNA	Primer probes	Nucleotide sequences
Cx 26	Sense	5' CCGAAGTTCATGAAGGGAGAGAT
	Antisense	5' GGTCTTTTGGACTTCCCTGAGCA
Cx 32	Sense	5' CTGCTCTACCCGGGCTATGC
	Antisense	5' CAGGCTGAGCATCGGTGCTCTT
Cx 43	Sense	5' TACCATGCGACCAGTGGTGCGCT
	Antisense	5'GAATTCTGTTATCATCGTCGGGGA

RESULTS

RT-PCR analysis of connexin transcripts in liver and HCC tissues

The mean values of Cx 26 mRNA and Cx 32 mRNA in HCC tissues were significantly lower than those in the control samples ($P < 0.01$, $P < 0.01$ respectively). There was no significant difference in Cx 43 mRNA between cancerous and control tissues (Table 3).

Table 3 Correlation of Cx 26, Cx 32, and Cx 43 mRNAs in cancerous and noncancerous liver tissues of 25 patients with HCC and liver tissues of 15 control patients

Tissues	mRNA (mean value)		
	Connexin 26	Connexin 32	Connexin 43
HCC patients			
Cancerous liver ¹	0.745	0.775	0.241
Controls ²	1.205	1.225	0.100

$P < 0.01$ for connexin 26 mRNA; $P < 0.01$ for connexin 32 mRNA; $P > 0.05$ for connexin 43 mRNA.

Correlation of connexin mRNA expression and tumor recurrence

Patients were followed up for a median of 45 mo (range 38 to 51 mo). Fourteen (56%) had clinically detectable recurrences, of whom 6 died. A low Cx 26 mRNA correlated significantly with tumor recurrences by both univariate ($P < 0.001$, $P < 0.001$) and multivariate analyses ($P = 0.033$, $P = 0.033$). No such correlation was found with Cx 43 mRNA. By multivariate analyses, other significant predictors of recurrences included poor cell differentiation ($P = 0.033$), less encapsulation ($P = 0.050$), vascular permeation ($P = 0.046$) and the presence of daughter nodules ($P = 0.046$) (Table 4).

Correlation of connexin mRNA expression and recurrence-related death

A low level of Cx 26 mRNA and Cx 32 mRNA in HCC tissues was significantly correlated with death from recurrent tumors by both univariate ($P < 0.001$, $P < 0.001$) and multivariate analyses ($P = 0.031$, $P = 0.031$) (Table 5). By multivariate analyses, poor cell differentiation, vascular permeation, and daughter nodules correlated significantly with mortality ($P = 0.031$, 0.048, and 0.048

respectively), and less encapsulation correlated with mortality with a marginal significance ($P = 0.053$).

Table 4 Predictors of HCC recurrence

Variable	<i>P</i> values	
	UV	MV
Sex	1.000	-
Age (yr)	0.030	0.071

Correlation between connexin mRNA expression and clinical and histopathologic features

Cx 26 and Cx 32 mRNAs were significantly correlated with cell differentiation but not with gender, age, serum AFP level, chronic HBV or HCV carriage, tumor size, coexisting cirrhosis, encapsulation, vascular permeation, daughter nodules, tumor necrosis, or tumor hemorrhage (all $P > 0.05$).

DISCUSSION

Our study showed that a low value of Cx 26 and Cx 32 mRNAs in resected HCC tissues was significantly associated with an increased risk of postoperative recurrences and death. While increased Cx 43 mRNA was not significantly predictive of outcomes.

Most tumors studied had a reduction in either homologous or heterologous GJIC. This presumably contributed to neoplastic progression by allowing tumor cells to escape intercellular signals involved in regulation of cell proliferation, differentiation, and apoptosis^[8,10,12,13]. Cx 32 and Cx 26, the components of hepatocyte gap junctions, were also found in a variety of other cell types. Cx 43 (or $\alpha 1$) was prominent in the liver capsule and between other types of liver cells, including Ito (fat-storing) cells, cholangiocytes, and endothelial cells lining the venules. We speculated that, because the Cx 32 and Cx 26 genes were expressed in normal liver tissues, they might serve as tumor suppressor genes. Other authors have suggested Cx 32 and Cx 43 for this role^[16]. Eghbali *et al.*^[18] found that transfection of tumor cells with Cx 32 cDNA retarded tumor growth *in vivo*. They demonstrated that the growth rate of tumor cells correlated negatively with the strength of intercellular communication.

Since Lowenstein *et al.*^[12] used electrophysiologic techniques to demonstrate a lack of communication between rat liver cancer cells, an interest has been attracted to changes in cell-to-cell communications in carcinoma tissues. In studies of rat hepatocarcinogenesis, several laboratories have found that a significant decrease in the major liver gap junction protein Cx 32 at the mRNA or protein level occurred in preneoplastic nodules and HCCs induced by chemicals^[14,17,19,21]. Loss of GJIC due to down-regulated expression of Cx genes appears to be an important event in cell transformation and is associated with uncontrolled tumor cell growth. Transformed cells *in vitro* and *in vivo* had a decreased GJIC capacity between themselves or with surrounding normal cells^[18,20]. Disruption of GJIC activity could contribute to the multi-step process of carcinogenesis.

Oyamada *et al.*^[25] reported that GJIC was altered in human HCCs by molecular mechanisms different from those in rat hepatocarcinogenesis. It is possible that defects in post-translational processing of Cx 32 and Cx 43 proteins may be an obstacle in their transportation to cell membranes. Some studies suggested that multiple mechanisms could likely contribute to block of GJIC, including decreased expressions of gap junction proteins and abnormal pathways of signal transduction resulted from decreased levels of intracellular Ca^{2+} , phosphorylation of the tyrosine of Cx proteins^[19]. Other potential mechanisms included control of cell recognition and gating of established gap junctions^[19,20,24].

Different authors have proposed various mechanisms by which changes in connexin mRNA might contribute to the biological behaviors of HCC. These include rapid proliferation of tumor cells, changes in the interaction between host and tumors, aberrant localization of connexins, and change in connexin expression during tumor differentiation. Whether the rapid growth of preneoplastic tissues is the cause or the effect of a decrease in connexin mRNA remains unknown.

Some authors have found a great decrease in the number of gap junctions after partial hepatectomy. A reciprocal correlation between the expression of Cx32 and the mitotic activities of hepatocytes during liver regeneration was noted. Based on their findings of a significant reduction of Cx 32 expression in S-phase cells, it seems that quantitative changes in gap junction expression may play an important role in the control of proliferation of liver cells. Since neoplastic liver tissues had a higher proliferation rate than the surrounding tissues, it might have fewer gap junctions. It was found that the partial loss of gap junctions provided a selective advantage for those preneoplastic liver cells which developed into rapidly proliferating tumor cells. It is possible that preneoplastic cells with a reduced number of gap junctions might have an increased capability of proliferating and are therefore more likely to develop into HCC^[14].

With regard to changes in the interaction between host and tumors, Krutovskikh *et al.*^[24] highlighted the role such an interaction might play in natural host resistance against neoplastic growth, with an emphasis on the underlying mechanisms of both connexin function and impairment.

Some other authors attributed the possible contribution of connexins to aberrant localization of the gap junction proteins. Some studies showed that the levels of Cx 32 and Cx 43 mRNAs were not decreased in HCCs compared with normal liver tissues, but the proteins were aberrantly located in HCCs^[25]. Krutovskikh *et al.*^[26] thought abnormal location of Cx 32 was more important than its translational dysregulation. Omori *et al.*^[17] drew a similar conclusion regarding Cx 32.

Another mechanism leading to a loss of heterologous host-cancer cell coupling is a change in the expression of connexin species in tumors during differentiation. According to Markert *et al.*^[27] three important characteristics of cell differentiation were the rate of cell division, the adhesive properties of the cell membrane that determine the capacity of the cell of migrating or metastasizing, and specific patterns of cell metabolism. Connexins are likely related to adhesive properties. An altered pattern of adhesion molecules on the surface of tumorigenic hepatocytes may influence the distribution of gap junctions in neoplastic tissues.

A characteristic feature of a cancerous phenotype is dedifferentiation. In some tissues, cells at different stages of differentiation express different sets of connexin proteins. HCC cells may express the same connexins as surrounding normal hepatocytes and therefore adhere well to each other. However, because of the inability of Cx 32 hemichannels expressed by normal hepatocytes to assemble functional gap junctional channels with Cx 43 hemichannels in neoplastic cells, they failed to communicate with each other^[28,29].

The high recurrence rate after resection is the main cause of the poor outcomes of HCC. Variables correlated with tumor recurrence included high serum AFP, hepatitis, vascular permeation, grade of cell differentiation, infiltration or absence of capsule, tumor size, coexisting cirrhosis, presence of daughter nodules, and multiple lesions^[1-7, 30-33]. According to our study, connexin was significantly correlated with the grade of cell differentiation. In our series, tumors with higher levels of Cx26 and Cx32 mRNAs, that were closer to normal, were more likely to be well-differentiated (Edmondson and Steiner grade I) and less likely to recur than those tumors of grade II to IV. The association between the grade of anaplasia and connexin positivity also varied in other reports. We attribute these differences to the possibility that different histologic grades may coexist within a particular HCC. Additionally, the regulation of connexin may be complex, particularly at different grades of dedifferentiation.

There is also discrepancy in the expression of Cx 43 in human HCCs. Ma *et al.*^[34] suggested that decreased expression of Cx 32 and Cx 43 might be closely related to liver carcinogenesis.

We found a similar decrease in Cx32 mRNA, but Cx 43 mRNA was increased. The discrepancy might be due to a difference in study samples and examination methods, as well as the background liver diseases. Furthermore, it should be noted that the benign liver tissue surrounding HCC was not normal. Oyamada *et al.*^[25] studied 6 patients with HCC and found various abnormalities in the surrounding tissues, including cholestasis in 2, fatty liver in 1, chronic persistent hepatitis in 1, cirrhosis in 1, and possible hemochromatosis in 1. In our 25 patients, we found a different distribution of background liver diseases, including cirrhosis in 20 (80%), hepatitis B virus hepatitis in 12 (48%) and hepatitis C virus hepatitis in 10 (40%); 3 patients had both hepatitis B and C hepatitis. We used RT-PCR and Northern and Southern blot analyses. Oyamada *et al.*^[25] found no decrease in Cx 32 mRNA, while the level of Cx 43 mRNA was higher than that in the surrounding nontumorous tissues but without any amplification of Cx 43 gene. They attributed the increased expression of Cx 43 to a large amount of connective tissues in HCC.

However, another possible explanation for elevated expression of Cx 43 is the stem cell concept of tumor cell origins. This theory proposes that the target cells in carcinogenesis are stem cells present in normal tissues. Assuming that a stem cell that expresses Cx 43 is the target cell in human hepatocarcinogenesis, the resulting neoplasm would be expected to express connexin 43. The mechanism of switching on the Cx 43 gene in human HCC remains to be investigated, which may include DNA methylation, a stabilization of RNA, or positive or negative trans-acting factors^[25].

Carcinogenesis is believed to result from block, arrest, or derangement in differentiation. Based on this concept, we could explain the increased expression of Cx 43 by the appearance of isozymes, for example, aldolase and γ -glutamyl transpeptidase, in human HCC.

We proposed that not all HCCs contained connexin mutations, in another word, there might be both connexin-dependent and connexin-independent pathways leading to liver cancer. The selective advantage conferred on liver cells by a mutant connexin gene seems to be significant in later steps of tumorigenesis, after the accumulation of additional genetic changes. The identification of genetic alterations related to connexin changes remains a considerable challenge in the field of liver cancer research.

Surgery remains the best possible therapy for patients with HCC. Examination of connexin mRNA in HCC tissues may provide information about the risk of postoperative recurrences, and our results support this hypothesis. Addition of neoadjuvant therapy after surgery, might be considered for the risk patients. Furthermore, serial measurement of circulating connexin mRNAs after surgery to monitor the effects of therapy or screen for recurrences needs further investigation.

Abstract

AIM: To evaluate the effect of postoperative adjuvant transcatheter arterial chemoembolization (TACE) on the prognosis of hepatocellular carcinoma (HCC) patients with or without risk factors for the residual tumor.

METHODS: From January 1995 to December 1998, 549 consecutive HCC patients undergoing surgical resection were included in this research. There were 185 patients who underwent surgical resection with adjuvant TACE and 364 patients who underwent surgical resection only. Tumors with a diameter more than 5 cm, multiple nodules, and vascular invasion were defined as risk factors for residual tumor and used for patient stratification. Kaplan-Meier method was used to analyze survival curve and Cox proportional hazard model was used to evaluate the prognostic significance of adjuvant TACE.

RESULTS: In the patients without any risk factors for the residual tumor, the 1-, 3-, 5-year survival rates were 93.48%, 75.85%, 62.39% in the control group and 97.39%, 70.37%, 50.85% in the adjuvant TACE group, respectively. There was no significant difference in the survival between two groups ($P = 0.3956$). However, in the patients with risk factors for residual tumor, postoperative adjuvant TACE significantly prolonged the patients' survival. There was a statistically significant difference in survival between two groups ($P = 0.0216$). The 1-, 3-, 5-year survival rates were 69.95%, 49.86%, 37.40% in the control group and 89.67%, 61.28%, 44.36% in the adjuvant TACE group, respectively. Cox proportional hazard model showed that tumor diameter and cirrhosis, but not the adjuvant TACE, were the significantly independent prognostic factors in the patients without risk factors for residual tumor. However, in the patients with risk factors for residual tumor adjuvant TACE, and also tumor diameter, AFP level, vascular invasion, were the significantly independent factors associated with the decreasing risk for patients' death from HCC.

CONCLUSION: Postoperative adjuvant TACE can prolong the survival of patients with risk factors for residual tumor, but can not prolong the survival of patients without risk factors for residual tumor.

INTRODUCTION

Hepatocellular carcinoma is the fifth most common malignant death in the world and is estimated to cause half a million deaths annually^[1]. In China, primary liver cancer mortality ranked second after stomach cancer. The age-standardized mortality rate (adjusted by the world population) was 33.7 per 100 000 in male Chinese and 12.3 per 100 000 in female Chinese^[2]. Surgical resection is a major treatment for hepatocellular carcinoma (HCC)^[3]. However, postoperative recurrence is still high and the main death cause after resection of HCC^[4]. The overall recurrence was 30.1%, 62.3% and 79.0% in 1, 3, 5 years after resection of HCC, respectively^[5]. Adjuvant therapies were used to prolong the survival and decrease the recurrence of HCC in different centers, such as transcatheter arterial chemoembolization (TACE)^[6-13], polyprenic acid^[14], adoptive immunotherapy^[15], interferon^[16], and iodine-131-labeled lipiodol^[17-19]. TACE was one of the most commonly used adjuvant managements for preventing recurrence and prolonging the survival of patients postoperatively. However, the benefits of adjuvant TACE were controversial. From January 1995 to December 1998, a consecutive series of 549 HCC patients with partially hepatectomy were included in this study. Of them, 185 patients received adjuvant TACE and 364 patients received surgical resection only. The aim of this research was to evaluate the benefits of adjuvant TACE in our series and to determine whether the characteristics of HCC such as diameter of tumor size, tumor nodules and vascular invasion could affect the benefits of adjuvant TACE to the patients' survival.

MATERIALS AND METHODS

Patients

This study included 549 patients with HCC who underwent partial hepatectomy. The entry criteria included: 1) All the tumor lesions were removed, which were judged by surgeon's gross inspection; 2) no lymphnode involvement; and 3) no distant metastasis. For all the 549 patients, hepatectomy was performed in Liver Cancer Institute, Zhongshan Hospital, Fudan University from January 1995 to December 1998. There were 465 males and 84 females with a median age of 50 years. According to the UICC TNM classification, 48 patients were in stage I, 382 in stage II, 86 in stage IIIA, and 33 in stage IVA. For their liver function defined by Child-Pugh classification, 539 patients were in class A, 10 in class B, and no patients in class C.

Adjuvant TACE

In the entire series, 185 patients underwent adjuvant TACE and 364 patients who did not undergo adjuvant TACE were assigned as control. Adjuvant TACE was performed 2 mo after hepatectomy. Hepatic arterial angiography was performed and then preventive or therapeutic chemoembolization was done depending on the patients with or without tumor stain in the remnant liver, respectively. The regimen for preventive adjuvant TACE consisted of 5-fluorouracil (5-FU) 0.75 g, cisplatin (DDP) 60 mg, and the emulsion mixed with mitomycin C (MMC) 16 mg and lipiodol 5 mL. Two months later a repeated preventive adjuvant TACE was performed and the regimen was finished. For therapeutic adjuvant TACE, the regimen consisted of 5-FU 1.0 g, DDP 80 mg, and the emulsion of MMC 20 mg and lipiodol 5-10 mL (the volume of lipiodol used for a patient depending on the tumor volume in the patient). TACE was repeated every one and a half month. The interval and times of repeated TACE depended on the response of the patients.

Patient stratification and grouping

The patients were retrospectively stratified into patients without risk factors for the residual tumor and patients with any risk factors for the residual tumor. These risk factors were evaluated according to preoperative ultrasonography, CT scan and postoperative pathological examination. Risk factors were defined as tumor diameter >5 cm, multiple nodules or vascular invasion. These factors were reported to have a close relation with residual tumor or recurrence in the remnant liver of HCC patients^[4,20-23]. After stratification, there were 251 patients without risk factors for the residual tumor and 298 patients with risk factors for the residual tumor. After stratification, the patients were further grouped as the adjuvant TACE group and the control group.

Follow-up and statistics

The patients were followed up every 2 to 3 mo with ultrasonography and alpha-fetoprotein (AFP) during the first 2 years after HCC resection and every 3-6 mo afterwards. If the patients were unable to undergo this procedure, they were followed up with telephone or letter every year. The follow-up termination time for all patients was December 31, 2002. The significance of differences in clinical and pathological characteristics between groups was examined with Chi-square test and Student *t* test. Cumulative survival rates were obtained by the Kaplan-Meier method. Cumulative survival comparison between groups was performed with log-rank test. Multivariate analysis for the independent prognostic factors was determined by Cox proportional hazards model. *P* values <0.05 were considered statistically significant.

RESULTS

Clinical and pathological characteristics of adjuvant TACE and control groups

Clinical and pathological characteristics of the patients with or without risk factors for residual tumor in adjuvant TACE and control groups were summarized in Tables 1 and 2, respectively. There were no significant differences in their age, HBsAg positive rate, Child-Pugh class, AFP level, TNM class between two groups, except that the ratio of female vs male patients was lower in the adjuvant TACE group than that in control group (*P* = 0.005) without risk factor for residual tumor.

Survival of patients in adjuvant TACE group and control group

Figure 1A presents the Kaplan-Meier survival analysis comparing the patients in control group and adjuvant TACE group without risk factors for the residual tumor. There were

no differences in their survival curves between two groups (*P* = 0.3956). The 1-, 3-, 5-year survival rates were 93.48%, 75.85%, 62.39% in the control group and 97.39%, 70.37%, 50.85% in the adjuvant TACE group, respectively. However, for the patients with risk factors for the residual tumor improved survival rates were observed in the adjuvant TACE group, as showed by Figure 2B. There were significant differences between two groups (*P* = 0.0216). The 1-, 3-, 5-year survival rates were 69.95%, 49.86%, 37.40% in the control group and 86.67%, 61.28%, 44.36% in the adjuvant TACE group.

Multivariate analysis

Cox proportional hazards models were constructed to predict the survival of the patients with adjuvant TACE and other variables including sex, age, HBsAg, cirrhosis, Child-Pugh class, AFP levels, tumor diameter, tumor nodules, and vascular invasion. In the patients without risk factors for residual tumor, the tumor diameter and cirrhosis were statistically significant independent factors associated with an increased risk of death from HCC, but adjuvant TACE had no effect on the survival of patients (Table 3). However, in the patients with risk factors for residual tumor, adjuvant TACE was statistically significant independent factor associated with a decreased risk of the death of patients with HCC. Tumor diameter, AFP level and vascular invasion were significantly independent factors associated with death of patients with HCC (Table 4). These results indicated that adjuvant TACE could improve the survival of patients with risk factors for residual tumor, but did not affect the survival of patients without risk factors for residual tumor.

DISCUSSION

The frequent postoperative recurrence was a main obstacle for long survival after resection of HCC and intrahepatic metastasis was thought to have a close relation with the postoperative recurrence^[24]. However, it is difficulty to detect the minimal intrahepatic metastasis before or during operation and the existence of this minimal intrahepatic metastasis contributes to intrahepatic recurrence. Theoretically, treatment of this minimal intrahepatic metastasis should play an important role in preventing of postoperative recurrence of HCC. However, though TACE has been widely used in unresectable HCC patients^[25-27], the clinical trial showed there was no confirmed evidence supporting the benefits of adjuvant TACE to patients with resectable HCC^[6]. Tanaka and Izumi showed that postoperative adjuvant TACE improved the survival of HCC patients^[28,29]. The patients selected in their clinical trials had advanced stages (TNM III or TNM IV) or characteristics of uncompleted encapsulated, intrahepatic metastasis, or vascular invasion which was thought to have a close relation with residual tumor and earlier massive recurrence^[22,30]. For these patients postoperative adjuvant TACE played a role in earlier therapy of the residual tumor and could decrease the earlier recurrence and prolong survival. However, TACE has been known to damage remnant liver and deteriorate liver function. This adverse impact is possible to affect long survival of patients with resectable HCC if the resection is truly curative. One of the clinical trials showed that adjuvant chemembolization using the regimen of intravenous epirubicin in combination with transarterial infusion of an emulsion of iodized oil and cisplatin, was even associated with more frequent extrahepatic recurrences and a worse outcome in their group of patients^[31]. In that clinical trial, all the patients had no demonstrable evidence of residual disease on ultrasonography and hepatic angiography 1 mo after surgery. These evidences suggested that the benefits of adjuvant TACE depended on the selection of patients. In patients who had high risks of residual tumor or intrahepatic metastasis in remnant liver, adjuvant TACE could improve their survival due to therapeutic actions on the residual tumor. However, in patients with lower risks of residual tumor or intrahepatic metastasis, adjuvant TACE might have less usefulness or even worse actions due to deterioration of remnant liver function.

Our results showed that postoperative adjuvant TACE could improve the survival of patients with risk factors for the residual tumor but not the survival of patients without risk factors for the residual tumor. For further evaluation of the effect of adjuvant TACE on patients with resectable HCC, Cox proportional hazards models were constructed to study if adjuvant TACE was the significantly independent factor associated with the survival. The results showed that in patients without risk factors for residual tumor, the significantly independent prognostic factors

Figure 1 Survival curves of patients in control group and adjuvant TACE group without or with risk factors for residual tumor. A: Survival curve of patients in control group and adjuvant TACE group without risk factor for residual tumor. B: Survival curve of patients in control group and adjuvant TACE group with risk factors for residual tumor.

were tumor diameter and cirrhosis but not the adjuvant TACE. However, in patients with risk factors for residual tumor, adjuvant TACE was the significant prognostic factor. This result suggested that the benefits of adjuvant TACE to patients with resectable HCC depended on the selected patients with or without risk factors for the residual tumor. Therefore adjuvant TACE should be used in patients with higher risks of residual tumor but not in patients with lower risks of residual tumor.

Abstract

AIM: To explore the expression of heparanase mRNA and point mutation in hepatocellular carcinoma (HCC).

METHODS: Reverse transcription polymerase chain reaction was used to measure the expression of heparanase mRNA in the primary tumor tissues and surrounding liver tissues of 33 HCC patients. T-A cloning and sequencing were used to detect whether there was any mutation in the amplified PCR products.

RESULTS: The expression of heparanase mRNA was positive in 16 primary tumor tissues of HCC, and the positive rate was 48.5%, which was significantly higher than that in the surrounding liver parenchyma ($P < 0.01$). The positive rate for heparanase gene in high-tendency to metastatic recurrence group (71.4%, 10/14) was obviously higher than that in low-tendency to metastatic recurrence group (31.6%, 6/19) ($P = 0.023$). The positive rate for heparanase gene in patients with metastatic recurrence during postoperative follow-up (78.6%, 11/14) was also significantly higher than that in those without metastatic recurrence (21.4%, 3/14) ($P = 0.003$). Sequence analysis of the HPA PCR products was made in 7 patients, and 2-point mutations were found in 4 patients, one of which was sense mutation, neither base insertion nor deletion was detected. The mutation rate was 57.1% (4/7).

CONCLUSION: The expression rate of heparanase mRNA increases in HCC, and HPA mRNA may be one of the reliable markers for the metastatic activity gained by the liver tumor cells and could be used clinically in predicting metastatic recurrence of HCC. Point mutation may be one of the causes for enhanced heparanase mRNA expression.

INTRODUCTION

Primary hepatocellular carcinoma (HCC) is a common malignant

tumor, especially in China and southeast Asia. Although the resection rate of HCC has improved in recent 20 years, the general therapeutic efficacy is still not satisfactory yet. The death rate of HCC ranks second in all malignant tumors in China, due to postoperative metastatic recurrence as the main cause. Tumor invasion and metastasis can break through the tissue barriers, which are formed of extracellular matrix (ECM) and basement membranes (BMs) and are composed of structural proteins, including collagen, laminin and vitronectin, etc. and glycosaminoglycans (GSGs). The chief components of GSG are heparan sulfate proteoglycans (HSPGs) that are principally composed of a core protein covalently linked to several heparan sulfate side chains^[1]. Over the past ten years, most studies about neoplasm metastasis including HCC, focused on some proteases, such as matrix metalloproteinases (MMPs)^[2-4], u-PA^[5,6], serine and cysteine protease^[7,8] whose substrates were structural proteins, but heparanase (HPA), whose substrate was GSGs, was ignored. In recent years, mammalian HPA gene has successfully been cloned and sequenced in Israel and U.S.A^[9-13], and HPA was found to play an important role in tumor invasion and metastasis. El-Assal *et al.*^[14] found that HPA mRNA expression in HCC patients was related to the tumor sizes, staging, classification, infection of hepatitis C virus (HCV), vascularization, postoperative metastasis and prognosis. However, in their studies, over half of HCC patients (52.7%, 29/55) were accompanied with HCV infection, and few were associated with hepatitis B virus (HBV). Ikeguchi *et al.*^[15] found that relative heparanase mRNA expression level in HCC was significantly lower than that in noncancerous liver tissues ($P < 0.001$), and that tumor heparanase expression did not correlate to tumor differentiation, tumor stage, or patient prognosis. They concluded that enhanced heparanase mRNA expression might not be a good biological marker for HCC. In addition, the possible mechanism of HPA expression has not been explored in both studies. It is well known that most HCCs in China are HBV-associated, which is different from the HCCs reported in Japan, but whether there is some difference of HPA expression in HCCs between in China and Japan or other regions is still unknown. In the present study, we tried to find out whether HPA mRNA expression was related to the clinicopathological indexes, including infection of HBV and postoperative metastatic recurrence of Chinese HCC patients, whether there was mutation in HPA gene, and whether the mutation of HPA gene was associated with HPA mRNA expression.

MATERIALS AND METHODS

Patients

Thirty-three patients (28 men and 5 women) undergoing curative hepatic resection for HCC between October 2000 and April 2001, were included in the present study. None of the patients received preoperative chemo- or embolic therapy. The patients' ages ranged from 27 to 73 years (49 ± 7 years, mean \pm SD). Among the 33 patients, the biggest diameter of tumors was > 5 cm in 25 cases and ≤ 5 cm in 8. Tumor capsules were integrated in 14 and disintegrated in 19 cases. Serum AFP was positive in 21 and negative in 12; HBsAg was positive in 24 and negative in 9. Liver cirrhosis was detected in 18 cases. Thirteen patients

belonged to Edmondson grade I or II, and the remaining 20 patients to Edmondson grade III or IV. Eighteen patients belonged to TNM staging I or II, and 15 to TNM staging III or IV. According to the operative records and postoperative pathologic data, 14 HCC patients with cancer emboli, intrahepatic dissemination (satellite foci or multiple nodules) and/or lymph node metastasis were demarcated to high-tendency to metastatic recurrence group, and the other 19 patients without emboli, dissemination and/or metastasis belonged to low-tendency to metastatic recurrence group. A total of 28 patients were followed up 6-16 mo after operation, during which neoplasm metastasis or recurrence was found in 14 patients.

Tissue selection

After the neoplasm was resected, HCC tissues from all the patients were selected from the most viable areas of the tumors immediately. This aimed at excluding areas of tissue necrosis and hemorrhages, which might influence the quality and the quantity of the extracted RNA. For selection of surrounding non-tumor liver tissues, specimens were obtained from tissues at a clear distance from the edge of tumors (>1cm), if there was no evidence of nearby tumor invasion. Tissues were at once preserved in liquid nitrogen after the resection and kept at -80 °C until the experiment began.

RNA extraction and cDNA synthesis

About 100 mg tumor or liver tissue was used for total RNA isolation using TRIzol reagent (Gibco-BRL), according to the instructions of the manufacturer. First-strand cDNA was synthesized using 5 L total RNA with oligo (dT)₁₆ primer in a 50-L reverse transcription mixture containing 10 L of 5× first-strand buffer, 2.5 L dNTP mixture containing 25 mmol/L each deoxynucleotide triphosphate base (Pharmacia Biotech, Tokyo, Japan), 2.5 L ribonuclease inhibitor (TaKaRa Biochemicals, Ohotsu, Japan), 25 L ddH₂O (managed with DEPC in advance), and 2.5 L avian myeloblastosis virus reverse transcriptase (TaKaRa Biochemicals, Ohotsu, Japan).

PCR amplification of HPA and β -actin genes

The resulting cDNA was used for PCR amplification using Taq polymerase (TaKaRa Biochemicals, Ohotsu, Japan). The primers for HPA PCR amplification were designed according to the literature^[9]. The sequences of the oligonucleotides were: forward, 5'-TTCGATCCCAAGAAGGAATCAAC-3'; and reverse, 5'-GATTCACTTACATGGCATCACTAC-3'. The first and final bases of the amplified HPA segment were at the 409th and 993rd positions of the HPA cDNA, respectively, and the amplified segment should be 585 bp in length. The primers used for β -actin had the following sequences: forward, 5'-TTCCAGCCTTCCTTCCTGG-3', and reverse, 5'-ATTGCTCCTCCTGAGCGCAA-3', as generated by Oligo 4.0 S computer software. The amplified β -actin segment was 224 bp in length. The PCR conditions included initial denaturation at 94 °C for 4 min, followed by 35 cycles of amplification with subsequent denaturation at 94 °C for 30 s, annealing at 57 °C for 45 s, and extension for 1 min at 72 °C. Ten μ L PCR products underwent electrophoresis using 12 g/L agarose and was visualized by UV absorption and ethidium bromide.

T-A cloning and sequencing

By using *Escherichia coli*, competent cell DH5 α was routinely prepared and stored at -80 °C. One hundred μ L liquid HPA PCR products was used for purification. Five liters of purified preparation, 1 L pGEM-Teasy vector (3 015 bp in length) and 1 L T4-DNA ligase (Promega, New York, U.S.A) were mixed and incubated overnight at 4 °C for ligation reaction. After 200 L competent cell suspension was thawed at room temperature, 5 L

ligated products was added for transformation test. The recombinant plasmid was screened, and the plasmid DNA was extracted by the alkaline lysis method. Five liters plasmid DNA was digested with 0.5 L restriction endonuclease *EcoR* I for 2-3 h at 37 °C, then the enzyme digestion products were identified by electrophoresis. Results of enzyme digestion analysis were essentially identical with expected ones. Using the recombinant plasmid DNA as a template, DNA sequencing for both strands was performed on an ALF express DNA automatic sequencer (Pharmacia Co.) by the dideoxy terminal termination method. The sequenced HPA segment was 585 bp in length. The sequence of amplified HPA segment was compared with the gene bank database and analyzed for homogeneity using BLAST program at NCBI.

Statistical analysis

The significance of difference between two groups was tested with Chi-square analysis or exact probabilities in fourfold table. A *P* value less than 0.05 was considered statistically significant.

RESULTS

Expression of HPA mRNA in HCC

HPA mRNA was amplified in the tumor tissues from 16 patients. Electrophoretic analysis showed a bright band about 550-600 bp in length in these patients. No amplification strand was found in the other 17 patients (Figure 1). The HPA mRNA expression rate in the tumor tissues of HCC was 48.5% (16/33) and significantly higher than that in the surrounding non-tumor liver tissues (*P*<0.01) in which HPA mRNA was positive in only one patient.

Figure 1 Expression of HPA mRNA in HCC. M: molecular mass markers (DL2 000); lanes 1 and 3: the noncancerous liver tissue; lanes 2 and 4: the HPA positive samples of cancer tissues both with a bright band at 585 bp.

Relationship between HPA expression and clinicopathological indexes

By statistical analysis, no significant difference in HPA mRNA expression was found among the tumor size, capsule, AFP, HBsAg and liver cirrhosis groups (*P*>0.05) (Table 1). HPA expression rate in Edmondson grade I or II group was significantly lower than that in Edmondson grade III or IV group (*P* = 0.019), and the rate in TNM staging I or II group was also obviously lower than that in TNM staging III or IV group (*P* = 0.047) (Table 1).

Relationship between HPA expression and metastatic recurrence of HCC

HPA mRNA expression rate in high-tendency to metastatic recurrence group was obviously higher than that in low-tendency to metastatic recurrence group (*P* = 0.023), and the rate in metastatic recurrence group was also significantly higher than that in non-metastatic recurrence group (*P*=0.003) (Table 2).

Point mutation

After the recombinant plasmid DNA was digested by *EcoR* I and run in 10 g/L agarose gel electrophoresis, 2 bright bands could be seen, which were about 750 and 2 900 bp in length, respectively, according to the markers. The recombinant plasmid that was not digested by the enzyme showed only one band about 3 600 bp in length, and the pure HPA RT-PCR products only produced one strip about 550-600 bp in length

in the same agarose gel. These results proved that it was successful to purify HPA RT-PCR products, ligate them with plasmid DNA to be digested by restriction endonuclease (Figure 2). Seven samples of HPA mRNA positive PCR products were cDNA sequenced, and the results confirmed that the target gene segment in all the 7 samples of PCR products was human HPA cDNA. Two point mutations (at the 513th and 878th base of the HPA cDNA, respectively) were observed in 4 samples, and no insertion or deletion was found. The mutation rate was 57.1% (4/7). One of the point mutations of G to A transversion was at the third base position of codon 138. Because the varied codon was still translated to glutamic acid resulting in no alternation of amino acid residues, the mutation belonged to nonsense mutation. The other point mutation of A to G transversion at nucleotide 878 corresponded to the second base position of codon 260. After transversion, the codon became AGU from AAU, resulting in alternation of amino acid residues (asparamide to serine), it was therefore sense mutation (Table 3, Figure 3).

DISCUSSION

Mammalian genes including human HPA gene have been cloned and identified in recent years^[9-13]. It is known that the gene is on chromosome 4q22^[16] and includes 14 exons separated by 13 introns. The complete cDNA of HPA is 1 758^[9] or 1 629 bp in length^[10], and contains an open reading frame encoding a polypeptide of 543 amino acids, with a calculated molecular weight of 61 192 daltons. The HPA enzymes of about 50 ku isolated from human placenta and hepatoma cell line (SK-hep-1) may represent a processed or mature form of the native protein. In normal state, HPA is mainly identified in placenta, fetus liver, thymus gland, spleen, platelets, neutrophils, and activated T- and B-lymphocytes. HPA plays important physiological roles in embryonic morphogenesis, wound healing, inflammatory and autoimmune conditions by degrading GAGs. Many tumors and their stroma cells also produce or secrete HPA and use the same molecular machinery to induce neoplasm metastasis. RT-PCR analysis showed that most highly metastatic tumor cells expressed higher levels of HPA mRNA or HPA activity, but nonmetastatic carcinoma cells and low metastatic cells expressed no or only very weak HPA activity. HPA expression correlates with the metastatic potential of breast cancers^[17], and antisense-mediated suppression of human heparanase gene expression may inhibit pleural dissemination of human cancer cells^[18]. It has been found that high levels of HPA can be detected in a variety of malignant tissues or cells with high malignance or powerfully metastatic potential, among which are lymphoma, fibrosarcoma^[9,19], oral cancer cell lines and oral cancer^[20], esophageal carcinomas^[21], lung cancer^[18,22], malignant melanoma^[19,23,24], breast cancer^[9,25], gastric carcinoma and carcinoma of colon^[26,27], pancreatic carcinoma^[28,29], prostate cancer^[30], bladder carcinoma^[31], pheochromocytoma and ovarian cancer, and that no or only very weak HPA could be observed in some tumor cells with low or no metastatic potential. We detected the HPA mRNA expression of cancerous tissues in 33 HCC patients, and found that it was positive in 16 HCC samples (48.5%, 16/33). The expression rate of HPA mRNA in our study was similar to that of El-Assal *et al.* (47%)^[14]. In addition, we detected the HPA mRNA expression in the surrounding non-tumor liver tissues, and found that it was positive in only one sample. These results showed that about half of HCC tissues could

synthesize or secrete HPA, and the surrounding non-tumor liver tissues could hardly produce the enzyme on the whole.

HPA could degrade HSPG by cleaving the glycosidic linkages^[24] with a hydrolase mechanism, destroy and degrade the ECM and BM barricade in coordination with other proteases to promote the invasion and metastasis of tumor cells^[9,24]. Moreover, HPA could not only activate plasminogen and MMPs by means of promoting the release of urokinase-type plasminogen activator (u-PA) and tissue-type plasminogen activator (t-PA) but also facilitate the release of HS-binding active basic fibroblast growth factor (bFGF) and vascular endothelial growth factor (VEGF) to deliver its effect of enhancing cell metastasis and angiogenesis. It has been proved that HPA in cancerous tissues is closely related to tumor invasion, metastasis and angiogenesis^[9,10]. Both metastatic recurrence and tumor microvessel density (MVD) in tumors might significantly increase with high levels of HPA. By analyzing statistically the relationship between HPA mRNA and clinicopathological parameters in HCC patients, El-Assal *et al.*^[14] found that HPA mRNA expression was related to the tumor size, staging, classification, infection of HCV, vascularization, postoperative metastasis and prognosis, but was not related to other clinicopathological parameters. In this study, the expression rate in HCC was 48.5%, and HPA expression was associated with the pathological classification and TNM staging, which were similar to the conclusions drawn by El-Assal *et al.*^[14] The obvious difference in HPA expression between low- and high-tendency to metastatic recurrence groups in our study preliminarily indicated that HPA was associated with the invasion and metastasis of HCC. The significant difference between metastatic recurrence group and nonmetastatic recurrence group in our study was also similar to that of El-Assal^[14], and further proved that HPA expression was associated with metastatic recurrence, and that there were stronger invasiveness and tendency of postoperative recurrence in patients with positive HPA compared with HPA negative patients, and that HPA might provide a potential and valuable index to predict clinically postoperative metastatic recurrence.

No relationship was found between HPA expression and the integrity of tumor size or capsule in this study, which was different from the study of El-Assal *et al.*^[14]. We speculate that the probable cause is that there were relatively fewer patients with tumors ≤ 5 cm in diameter (only 8 cases). In addition, HPA expression was not found to be associated with AFP, HBsAg and liver cirrhosis in this study perhaps because the types of causative viruses were different. Patients in the study of El-Assal *et al.*^[14] were mainly infected with HCV, but most HCCs in China were related to HBV infection and posthepatitic cirrhosis, few were infected with HCV. In addition, our conclusions are different from those of Ikeguchi *et al.*^[15], in which relative heparanase mRNA expression level in HCC was significantly lower than that in noncancerous liver tissues, and tumor heparanase expression did not correlate with tumor differentiation, tumor stage, or patient prognosis. Both the discrepancy of hepatitis virus and experimental methods could contribute to the different results. The surrounding non-tumor liver tissues in our study were at a clear distance from the edge of tumors (>1 cm), but they could be close to the tumor tissues in the study of Ikeguchi *et al.*

Both the positive rates of HPA mRNA in the study of El-Assal *et al.*^[14] and ours were close to 50% (47% and 48.5%, respectively), but very few HPAs were expressed in the surrounding non-tumor liver tissues. To our knowledge, no concrete mechanism of enhanced HPA mRNA expression in tumor tissues has been evaluated so far. To explore the probable mechanism of enhanced HPA expression in cancerous tissues, the positive PCR products of 7 patients were randomly selected and sequenced by T-A cloning. Two-point mutations including

a G to A transversion at nucleotide 513 and a A to G at nucleotide 878 of the HPA cDNA were found in 4 cases. By sequence analysis, we did not find base insertion and deletion, and the mutation rate was 57.1%. The point mutation of G to A transversion at nucleotide 513 resulting in GAG to GAA at codon 138 was a nonsense mutation because the amino acid residue was still glutamic acid after translation. The other point mutation of A to G transversion at nucleotide 878 leading to AAU to AGU at codon 260 belonged to sense mutation because it resulted in the alteration of amino acid residue (asparamide to serine), which may cause HPA structure to change and HPA activity to increase, resulting in the acceleration of ECM and BM barrier degrading and the final metastasis of tumor cells. Therefore, we guess that the point mutation at HPA gene might be one of the important mechanisms of increased HPA expression and enhanced metastasis of carcinoma cells, and it deserves further study.

Abstract

AIM: To investigate the pathogenic mechanism of colon cancer at the molecular level and to elucidate the relationship between intercellular adhesion molecule-1 (ICAM-1) and nm23H₁ genes and Chinese patients with colon cancer.

METHODS: DNA was extracted from paraffin-embedded materials. Polymerase chain reaction-single strand conformation polymorphism (PCR-SSCP) was used to analyze MSI and LOH. Expression of ICAM-1 was detected by Envision immunohistochemistry. Experimental results were analyzed with Leica-Qwin computer imaging techniques and SPSS software of statistics.

RESULTS: ICAM-1 expression of lymphatic endothelium was negative in normal colon and positive in colon cancer respectively. The number of lymphatics positive for ICAM-1 was gradually increased with degree of cancer invasion ($P < 0.01$). In the group with metastasis of colon cancer, the number of lymphatics positive for ICAM-1 in lymph nodes was more than that in the group with no metastasis ($P < 0.01$). The frequency of MSI, LOH and nm23H₁ protein was 26.67%, 20.00% and 53.33% in colon cancer, respectively. In TNM staging, MSI (43.75%) and nm23H₁ protein (81.25%) in stages I+II were detected more easily than the corresponding indexes (MSI: 7.14%, $P < 0.05$ and nm23H₁: 21.43%, $P < 0.01$) in stages III+IV. By comparison, the frequency of LOH (35.71%) in stages III+IV was more than that of LOH (6.25%, $P < 0.05$) in stages I+II. LOH exhibited a rising trend along with the Duke's staging. nm23H₁ protein in the group of tubular adenocarcinoma (60.00%) was higher expressed than that in the group of mucoid adenocarcinoma (20.00%) ($P < 0.01$), and exhibited a rising trend with the differentiation degrees of tubular adenocarcinoma. nm23H₁ protein in MSI positive group was higher expressed (75%) than that in MSI negative group (45.45%, $P < 0.05$).

CONCLUSION: The expression of ICAM-1 in lymphatic vessels is beneficial to the judgement of the invasion and metastasis ability of colon cancer and the anti-tumor immunity function, and shows an important clinical significance in predicting lymphatic metastasis of colon cancer. MSI and LOH may separately control the development of sporadic colon cancer with different pathways. LOH mostly arises in the late period of sporadic colon cancer and endows a high aggressive and poor prognostic phenotype. By compassion, MSI may be an early period molecule marker for sporadic colon cancer,

enhanced expression of nm23H₁ protein can effectively inhibit colon cancer metastasis and improve prognosis of sporadic colon cancer patients.

INTRODUCTION

Colon cancer is one of the common malignant tumors. A series of investigations have revealed that the main reason why it gives rise to death of patients lies in its invasiveness and metastasis^[1]. Therefore, preventing colon deterioration and decreasing the death rate of colon cancer is of great significance. So far, it has been known that many factors may have an influence on colon cancer, such as anti-oncogenes, adhesion molecular E-selectin and E-cadherin, vascular endothelial growth factor and matrix metal protein (MMP-2)^[2-5]. Among these factors, anti-oncogene and adhesion molecules have become the "hot spots" in research of colon cancer^[6-8].

Intercellular adhesion molecule-1 (ICAM-1), an important transmembrane glycoprotein, is negatively expressed on endothelial cells of lymphatic vessels in normal conditions^[9,10]. ICAM-1 could induce attachment of cells such as lymphocytes to endothelial cells of blood vessels, and traverse blood vessels, aggregate antigens and take part in immune and inflammatory reactions. When tumors appeared in the body, lymphatic vessels became the main pathway for tumor cells to be transferred as a result of their own permeability^[11]. In the process, recognition, adhesion, morphologic change and penetration between cells were involved. Vasse *et al.*^[12], reported that breast cancer cells could over-express the specific ligands of ICAM-1 (lymphocyte function associated antigen 1, LFA-1). With the development of cancer, the expression of LFA-1 went to an ascending trend on cancer cells. All the results indicated that ICAM-1 might take part in the metastasis. How endothelial cells of lymphatic vessels express ICAM-1? Few reports are available about whether endothelial cells of lymphatics express ICAM-1 or not in cancer tissue and whether ICAM-1/LFA-1 take part in the process of cancer cells attached to endothelial cells of lymphatics and metastasis.

nm23H₁ is one of the main anti-oncogenes. A great number of experiments indicated that inactivation of these genes, that is, genetic instability, resulted in metastasis^[13,14]. However, there were few researches of these genes on colon cancers^[15]. In order to further investigate the pathogenic mechanism of colon, we examined the instability of D17S396 of nm23H₁ in unrelated patients with the single strand conformation polymorphism analysis of polymerase chain reaction products (PCR-SSCP).

MATERIALS AND METHODS

Case selection and extraction of DNA

Thirty-two specimens were obtained during 2000 to 2002. There were 21 males and 11 females, aged 27-77 years. Twenty-seven cases were patients with tubular adenocarcinoma, 5 cases were

patients with mucoid adenocarcinoma in histological types. A senior pathologist made the final diagnosis on the basis of histological examination. No patient received radioactive therapy, chemotherapy before operation. Fresh surgical tissue samples were fixed immediately in formaldehyde solution for 12-24 h and paraffin-embedded for PCR-SSCP and immunohistochemical assay.

DNA extraction

DNA was extracted according to the standard protocols.

PCR amplification

Designed primers were synthesized by Shanghai Shengyou Biology Company. The primer sequences were (sense) 5'-TTGACCGGGGTAGAGAACTC-3', (antisense) 5'-TCTCAGTACTTCCCGTGACC-3'. PCR mixture contained 200 ng of template-DNA and PCR reaction buffer containing 50 mmol/L KCl, 10 mmol/L Tris-HCl (pH 8.4), 1.5 mmol/L MgCl₂, 0.5 μmol/L each of two fragment-specific primers, 100 μmol/L each of dATP, dGTP, dTTP and dCTP, and 2 units of Taq DNA polymerase (Shanghai Shengyou Biology Company) for a reaction volume of 50 μL. The conditions for all PCR amplifications were at 94 °C for 5 min for pre-denaturation, at 94 °C for 45 s, at 62 °C for 45 s and at 72 °C for 45 s. Amplification was carried out for 35 cycles with a final extension for 10 min at 72 °C. The amplified fragments were run in 1% agarose gel.

SSCP analysis

SSCP analysis of fragments was performed on a mini electrophoresis Unit (Bio-Rad Company, USA). Ten microlitre of the PCR product was diluted with 10 μL of sample buffer containing 90% formamide, 0.05% bromphenol blue dye and 0.05% xylene cyanol. The samples were heated at 100 °C for 8 min, transferred into an ice-cold water bath for 3 min, and analysed by 8% PAGE in 45 mmol/L-Tris-borate (pH8.0)/1 mmol/L-EDTA (TBE) buffer under 13 v/cm at 10 °C.

DNA silver staining

Gels were stained with silver as follows. Gels were firstly fixed in 100 mL/L alcohol for 10 min and then oxidized in 100 mL/L nitric acid for 3 min. After washed for 1 min with double distilled water, they were stained in 2 g/L silver nitric acid for 5 min and washed for 1 min with double distilled water. Gels showed appropriate color in 15 g/L anhydrous sodium carbonate and 4 mL/L formalin and then the reaction was terminated by 7.5 mL/L glacial acetic acid. Finally they were washed with double distilled water.

Immunohistochemical assay

Immunohistochemical study was performed using Envision method. Briefly, 5 μm thick sections of the tissue were deparaffinized and rehydrated. Endogenous peroxidase activity was blocked with 3% hydrogen peroxide for 20 min. After three times of rinsing with 0.01 mol/L phosphate-buffered saline (PBS) (pH = 7.4), the slides were incubated with 10% normal goat serum

at room temperature for 10 min to block the nonspecific reaction, and incubated for two hours with anti-ICAM-1 antibody. After rinsed in PBS for five min, they were incubated with Envision complex for two hours at room temperature, and stained with DAB after washed in PBS.

Statistical analyses

The experimental results were expressed as mean±SD. The correlation was analyzed with SPSS 8.0 software. *P* value less than 0.05 was regarded as statistically significant.

RESULTS

Expression of ICAM-1 in lymphatic endothelial cells

In the submucosa of normal colon, there existed a few lymphatic vessels with large, irregular cavities and thin walls. Simple squamous epithelia lined on them had no expression of ICAM-1 (Figure 1A). But in the submucosa and peripheral area of colon cancer, the number of lymphatic vessels was increased. Significant differences existed between them (*P*<0.01) (Table 1). The expression of lymphatic endothelial cell was positive for ICAM-1 in colon cancer (Figure 1B). With the degree of cancer invasion, lymphatic vessels positive for ICAM-1 showed an increasing trend (*P*<0.01) (Table 2). When cancer metastasis appeared in the peripheral lymph node, ICAM-1 was strongly expressed in endothelial cells of their peripheral lymphatic vessels, and the number of lymphatic vessels positive for ICAM-1 was to the highest (Table 2).

Genetic instability at D17S396 of nm23H1

Microsatellite fragments of D17S396 were amplified. The positive rate of D17S396 MSI (Figures 2A, B), LOH (Figure 2C) and nm23H₁ protein (Figure 2D) was 26.67%, 20.00% and 53.33% respectively in 30 cases of colon cancer (Table 3).

MSI and LOH were independent of the histological type of colon cancer, the degree of differentiation and Duke's stage were related to the clinical TNM stage. In TNM staging, the frequency of MSI (43.75%) in stages I+II was more than that in stages III+IV (7.14%, *P*<0.05). In contrast, LOH (35.71%) in stages III+IV was detected more easily than that (6.25%, *P*<0.05) in stages I+II. In addition, LOH exhibited an ascending trend with the Duke's stage (*P*<0.01).

Expression of nm23H₁ protein

The positive rate of nm23H₁ protein was related with the histological type of colon cancer, differentiation degree and

Figure 1 Expression of ICAM-1 in lymphatic endothelial cells. A: Negative expression of ICAM-1 in the lymphatic endothelium (L) of normal colon and positive expression of ICAM-1 in blood vessel endothelium (arrow) (Envision, original magnification ×400); B: Positive expression of ICAM-1 in the lymphatic endothelium (arrow) of colon cancer (Ca) (Envision, original magnification ×400).

Figure 2 Positive D17S396 MSI, LOH and nm23H₁ in 30 cases of colon cancer. A: Positive MSI (arrow-headed) with an additional allele band (1C) compared with normal tissue (1N); B: Positive MSI (arrow-headed) with a removed allele band (4C) compared with normal tissue (4N); C: Positive LOH (arrow-headed) with a lacked allele band (9C) compared with normal tissue (9N); D: Positive nm23H₁ protein (arrow-headed) in cytoplasm, and nucleoli and membranes (Envision, original magnification ×200).

clinical stage. The expression of nm23H₁ protein in the group of tubular adenocarcinoma (60.00%) was apparently higher than that in the group of mucoid adenocarcinoma (20.00%, *P*<0.01), and exhibited a rising trend with the differentiation degrees of tubular adenocarcinoma (*P*<0.01). The positive rate of nm23H₁ in stages I+II (81.25%) was greater than that in stages III+IV

(21.43%) (*P*<0.01). The same phenomenon occurred between the group positive for MSI (75%) and the group negative for MSI (45.45%) (*P*<0.05) (Table 4). However, LOH had no effect on the expression of nm23H₁ protein (Table 4). Computer imaging analysis showed that there was a difference among the groups in nm23H₁ protein expression level.

Table 4 Relationship between LOH, MSI and nm23 protein expression (mean±SD)

Groups	Cases	Expression of nm23 protein(%)	Intensity of nm23 protein
Positive to MSI	8	6/8 (75.00)	39.06±2.14
Negative to MSI	22	10/22(45.45)	41.14±2.36
Positive to LOH	6	2/6 (33.33)	41.23±2.27
Negative to LOH	24	14/24 (58.33)	39.44±2.52

DISCUSSION

Metastasis, the spread of cells from primary neoplasms to distant sites and their growth at that location, is the most harmful aspect of cancer. Despite great improvements in early diagnosis, surgical techniques, general patient care, local and systemic adjuvant therapies, most deaths from cancer are attributable to metastases that are resistant to conventional therapies. During metastatic cascade, tumor cells interact with various host cells as well as extracellular matrices and basement membrane components including laminin, fibronectin, and type I collagen through certain adhesion molecules such as integrins. Such adhesive interactions may lead to the enhancement of survival, arrest, or invasiveness of tumor cells and is one of the most important events in the metastatic process^[14-17].

Intercellular adhesion molecule-1 (ICAM-1) is a single transmembrane glycoprotein and has two patterns in the body. One is located on the endothelial cells of blood vessels and is consisted of outmembrane region, transmembrane region and cytoplasmic region. The other (sICAM-1) is soluble in serum and is consisted of extracellular domains and originates from leucocytes, endothelial cells and hepatocytes^[18-20]. The specific ligand of ICAM-1, LFA-1, can be expressed on the surfaces of leucocytes and lymphocytes. In normal conditions, ICAM-1/LFA-1 plays an important role in various immune responses.

How ICAM-1 expresses when tumors appear in the body? In the present case, ICAM-1 was expressed on endothelial cells of lymphatic vessels in colon cancer. With the degree of cancer invasion, lymphatic vessels positive for ICAM-1 showed an increasing trend. When cancer metastasis appeared in peripheral lymph nodes, ICAM-1 was strongly expressed on endothelial cells of peripheral lymphatic vessels, and the number of lymphatic vessels positive for ICAM-1 was the highest. The results might give a hint that cancer cells can be transferred into lymphatic vessels in combination with LFA-1. Furthermore, sICAM-1 transformed from ICAM-1 could inhibit natural killer cells, which could activate lymphocytes and restrict major histocompatibility complex (MHC) to react with T cells and tumor cells, thus promoting tumor cells to escape^[21-23]. Therefore, sICAM-1 could strengthen and promote cancer cells to survive and transfer in lymphatic vessels when tumor metastasis occurred.

Genetic instability is the main reason why tumors appear and transfer^[24-31]. MSI and LOH could induce canceration in the body. MSI was firstly found in hereditary non-polyposis colorectal cancer (HNPCC), and then in some kinds of sporadic tumors such as colon cancer, gastric cancer, uterus cancer, breast cancer, prostate cancer and pancreatic cancer. Our results showed that DNA from thirty Chinese patients at the site of D17S396 appeared microsatellite instability, the incidence was 26.67%. Subsequent experiments indicated that the incidence of MSI at the site of D17S396 in the stage of TNM I+II was greater than that in the stage of TNM III+IV, suggesting that MSI might be one of the markers for early colon cancer.

In contrast to MSI, the incidence of LOH at the site of D17S396 increased with the degree of Duke stage. Therefore, our results made it clear that LOH of nm23H₁ appeared at the later stage of colon cancer, which endowed colon cancer with

a high invasiveness and a poor prognosis.

The expression of nm23H₁ has a negative relationship with tumor metastasis. Leone *et al.*^[32] found that nm23H₁ had a function on the prevention of tumor metastasis by inhibiting the ability of cancer cells to clone. With the degree of tumor stage, the expression of nm23H₁ decreased. Our results indicate that with the development of colon cancer, the expression of nm23H₁ decreases.

Abstract

AIM: To screen and identify the proteins which interact with hepatitis B virus (HBV) X protein in hepatocytes by yeast two-hybrid system and to explore the effects of X protein in the development of hepatocellular carcinoma (HCC).

METHODS: With HBV X gene amplified by polymerase chain reaction (PCR), HBV X bait plasmid, named pAS2-1-X, was constructed by yeast-two hybridization system³ and verified by auto-sequencing assay. pAS2-1-X was transformed into the yeast AH109, and X-BD fusion protein expressed in the yeast cells was detected by Western blotting. The yeast cells cotransformed with pAS2-1-X and normal human liver cDNA library were grown in selective SC/-trp-leu-his-ade medium. The second screen was performed with β -gal activity detection, and false positive clones were eliminated by segregation analysis, true positive clones were amplified, sequenced and analyzed with bioinformatics. Mating experiment was performed to confirm the binding of putative proteins to X protein in the yeast cells.

RESULTS: Bait plasmid pAS2-1-X was successfully constructed and pAS2-1-X correctly expressed BD-X fusion protein in yeast AH109. One hundred and three clones grew in the selective SC/-trp-leu-his-ade medium, and only one clone passed through β -gal activity detection and segregation analysis. The inserted cDNA fragment showed high homology with Homo sapiens cytochrome C oxidase III (COXIII). Furthermore, mating experiment identified that the binding of COXIII to X protein was specific.

CONCLUSION: COXIII protein is a novel protein that can interact with X protein *in vivo* by yeast two-hybrid system, and may contribute to the development of HCC through the interaction with X protein.

INTRODUCTION

Hepatitis B virus (HBV) belongs to the family hepadnaviridae which replicate their genome by reverse transcription, and causes acute and chronic hepatitis and is strongly associated with the development of primary hepatocellular carcinoma (HCC)^[1,2]. HBV has a unique open reading frame, with the sequence being highly conserved among different mammalian hepadnaviruses, coding for a 16.5 kDa protein known as hepatitis B virus X protein (HBx). X gene is a multifunctional regulatory factor which has been identified as a potential oncogene. Transcriptional activation of diverse cellular genes by the HBx has been suggested as one of the mechanisms for HBV-associated HCC^[2]. HBx has been shown to activate a wide variety of cellular and viral genes in trans activation including the HBV enhancers, tumor suppressor p53^[3,4], and proto-oncogenes *c-jun*, *c-fos* and *c-myc*^[5,6]. HBx-responsive elements also include nuclear factor kappa B (NF- κ B), activator protein-1 (AP-1), activator protein-2 (AP-2) and cAMP-response element (CRE)^[7,8]. Since HBx has no ability to bind to dsDNA, protein-protein interaction seems to be crucial for HBx transactivation. The interaction of HBx with cellular proteins may trigger a cascade of phosphorylation and dephosphorylation events which might lead to a general up-regulation of gene expression^[9]. Identification of cellular X-interactive proteins would provide insights into the mechanism of HBV cellular effects. Several techniques have been used to study possible protein-protein interaction with HBx. Using these approaches, HBx has been discovered to interact with many proteins^[9]. Nonetheless, to the author's knowledge, the functional significance of these interactions has not yet been elucidated. In the present study, we screened a clone encoding a novel X-interactive protein which was homologous to Homo sapiens cytochrome C oxidase III (COXIII) from normal human liver cDNA library by the *Saccharomyces cerevisiae* two-hybrid system.

MATERIALS AND METHODS

Plasmids and cells

Plasmids pAS2-1, PCL1, PLAM5'-1, normal human liver pACT2-cDNA library and *Saccharomyces cerevisiae* AH109 were purchased from Clontech, USA. *Saccharomyces cerevisiae* AH109 was grown in YPD medium (10 g/L yeast extract, 20 g/L peptone, 20 g/L dextrose). This yeast strain carried LacZ, HIS3 and ADE2 reporter genes under the control of Gal4-binding site and was used to screen the liver cDNA library. *Escherichia coli* JM105 was provided as a gift from Research Institute of Hepatology, Beijing University, China.

Reagents

Restriction enzymes (*Eco*RI and *Pst* I), TaqDNA polymerase and T4 DNA ligase were purchased from Promega, USA. DNA gel extraction kit was provided by Jingmei Company, China. Gal4 DNA-BD monoclonal antibody, matchmaker AD LD-insert screening amplimers and yeast culture medium were purchased from Clontech, USA. Glass beads (acid-washed) were purchased from Sigma, USA. Alkaline phosphatase-conjugated goat anti-mouse IgG was purchased from Wuhan Boster Biological Technology Company, China.

pAS2-1-X construction

The X region of the HBV genome was amplified by PCR with XF and XR as forward and reverse primers which contained an *EcoRI* site and a *PstI* site, respectively, for convenience of cloning. The sequences of the primers with the restriction enzyme sites underlined were: XF, 5'-ACGGAATTCATGGCTGCTAGGCTGTG-3'; XR, 5'-ATCCTGCAGAGGTGAAAAAGTTGCAT-3'. The fragment amplified was from nucleotides 1 374 to 1 838 on HBV genome. The template for this reaction was extracted from sera of HBV DNA-positive patients. The reaction mixture was subjected to 30 cycles of PCR amplification. Each cycle included denaturation at 94 °C for 30 s, annealing at 58 °C for 1 min, and extension at 72 °C for 30 s, and a final extension for 7 min at 72 °C. The approximate 464 bp fragment was digested by *EcoRI* and *PstI*, and recombined into the plasmid pAS2-1 by T4 DNA ligase. The reconstructed plasmid was subsequently named pAS2-1-X and identified by PCR and auto-sequencing assay. Auto-sequencing assay was performed in Bioasia Biologic Technology Company and the resulting sequence was analyzed in the database of EMBL/GenBank by the BLAST program.

Transformation of pAS2-1-X into AH109

Yeast AH109 was transformed with pAS2-1-X by lithium acetate-mediated method demonstrated by Gietz *et al.*^[10] and plated in selective SC/-trp medium. Plasmids were isolated from transformants and X gene was amplified. Filter assay was used to exclude the auto-activation function of pAS2-1-X in AH109. Expressed X-BD fusion protein in yeasts transformed with pAS2-1-X was detected by Western blotting. The cells were collected by centrifugation and yeast protein extract was prepared according to urea/SDS method. SDS-polyacrylamide gel electrophoresis was performed and protein extracts were electroblotted onto nitrocellulose membrane. After being blocked with nonfat milk, the membrane was added to 1:3 000 diluted Gal4 DNA-BD monoclonal antibodies and incubated for 1 h, after washed with TBST. Then, the secondary alkaline phosphatase-conjugated goat anti-mouse IgG was added and incubated for 2 h. The proteins were visualized with 5-bromo-4-chloro-3-indolyl phosphate and nitro blue tetrazolium. Protein extracts of untransformed yeast cells were used as negative control.

Screening of human liver cDNA library by the yeast two-hybrid system

The screening procedure used here was a modification of the method described by Gietz *et al.*^[10]. Yeast cells were transformed with pAS2-1-X and pACT2-cDNA library by lithium acetate-mediated method, plated in selective SC/-trp-leu-his-ade medium, incubated at 30 °C for 7 d and selected for histidine, leucine and tryptophan prototrophy. The freshly growing clones were assayed for β -gal activity by replicating the yeast transformants onto Whatman filter paper. The filters were then snap frozen twice in liquid nitrogen for 10 s and incubated in a buffer containing 5-bromo-4-chloro-3-indolyl- β -D-galactopyranoside solution at 30 °C for 1-8 h. Positive interactions were detected by appearance of blue clones. Plasmids PCL1 and PLAM5'-1 were transformed into AH109 as positive and negative controls, respectively. Segregation analysis was performed to eliminate false positive clones and thus true positive clones were obtained.

Analysis of positive clones

pACT2-cDNA plasmid genome was isolated following the method described by Gietz *et al.*^[10]. Briefly, the true positive clones were incubated with SC/-leu liquid medium at 30 °C overnight, followed by spinning down the cells by centrifuging at 14 000 g for 5 min, and resuspension of pellets in lysis buffer

(20 g/L Triton 100, 10 g/L SDS, 10 mmol/L NaCl, 10 mmol/L Tris-HCl, pH8.0, 1 mmol/L Na₂EDTA) was added with phenol, chloroform and isoamyl alcohol (volume fraction 25:24:1). Then the suspension was vortexed vigorously with acid-washed glass beads, lysate was centrifuged and plasmid DNA was harvested. The pACT2-cDNA plasmid was purified by CsCl gradient centrifugation to permit PCR using the matchmaker AD LD-insert screening amplimers which annealed to GAL4-AD. The PCR reaction consisted 30 amplification cycles, each cycle included denaturation at 94 °C for 30 s, annealing at 68 °C for 3 min, and a final extension for 7 min at 72 °C. Auto-sequencing assay was performed in Shanghai Sangon Biological Engineering Technology and Service Corporation, the resulting sequences were compared against the databases of EMBL/GenBank by the BLAST program.

Mating experiment

pAS2-1-X, pAS2-1, pLAM5'-1 transformed yeasts in SC/-trp medium and positive clones were incubated in SC/-leu medium at 30 °C for 2 d, respectively, then removed. Two types of transformants were incubated into YPD medium at 30 °C for 4 h. Finally, transformants were subcultured in SC/-leu-trp medium, incubated at 30 °C for 2 d and assayed for β -gal activity.

RESULTS

Identification of the pAS2-1-X

The fragment of approximately 460 bp was amplified from the reconstructed plasmid pAS2-1-X, and auto-sequencing assay confirmed the fragment inserted into plasmid pAS2-1 had a high identity (99.9%) with X gene.

Detection of the transformed yeast AH109

X gene was amplified from the plasmid isolated from the transformed yeast cells (Figure 1). Filter assay excluded the auto-activation function of pAS2-1-X in the cells. Staining for X-BD was obtained in yeast cells transformed with pAS2-1-X (Figure 2). pAS2-1-X could be used as a bait plasmid in yeast two-hybrid system.

Figure 1 Result of detection of X gene in yeasts transformed with pAS2-1-X. M: PCR marker; lanes 1 and 2: transformed yeasts; lanes 3: untransformed yeasts; N: negative control.

Figure 2 Western blot analysis of expressed fusion protein in yeasts transformed with pAS2-1-X. Lane 1: protein molecular weight standard; lane 2: protein extracted from transformed yeasts; lane 3: protein extracted from untransformed yeasts.

Screening of the liver cell cDNA library

Of the 5×10^6 transformants screened, 103 were grown in the selective SC/-trp-leu-his-ade medium, 19 were positive for β -gal activity, and only 1 clone passed through the segregation analysis.

Analysis of positive clones

The fragment of approximately 900 bp was amplified from the true positive clones (Figure 3). DNA sequence analysis of the fragment revealed that the yeast plasmid insert had a high identity (98%) with the Homo sapiens COXIII gene (GeneBank ID:BC013930).

Mating experiment

The transformants containing pAS2-1-X and positive pACT2-cDNA gave a blue colour by filter assay, whereas the transformants containing pAS2-1 or pLAM5'-1 and positive pACT2-cDNA gave a white colour. Mating experiment confirmed the specific interaction between positive clones and HBx (Figure 4).

Figure 3 Results of amplification for cDNA fragment by PCR from the positive clones. M: 100 bp DNA ladder; lane1: positive clone; N: negative control.

DISCUSSION

Chronic HBV infection is strongly associated with the development of HCC, but the mechanisms by which HBV induces events leading to the genesis of HCC remains unclear. Several studies have suggested a possible role of HBx in the process of HCC, a few studies have reported transformation of certain cell types *in vitro* by HBx^[11] and initiation of HCC in HBx transgenic mice^[12,13], but its direct oncogenicity seems to depend on the strength, and duration of protein expression and the genetic background of mice and cells. It is more likely that HBx causes transactivation of cell regulatory genes or interacts with one or more cellular proteins to initiate the development of human HCC through upregulation of cell growth and mutagenesis. The transactivation function of HBx has been shown to involve both direct interaction with transcriptional factors, such as RPB5 of RNA polymerases^[14], TATA-binding protein^[15] or activating transcription factor (ATF)/CRE-binding protein (CREB)^[16] and activation of signal transduction pathways, such as ras/raf/MAP-kinase^[17], protein kinase C (PKC)^[18] and SAPK/JNK^[19,20]. HBx is predominantly localized in the cytoplasm with a low level of nuclear distribution, whereas recent findings from two independent laboratories

indicated that HBx could localize at the mitochondria. Confocal laser microscopy of hepatoma cells transfected with respective expression vectors showed colocalization of the third member of the family of human genes that encode the voltage-dependent anion channel (HVDAC3) and HBx in mitochondria. Moreover, stable cationic fluorophore dye showed that HBx expression in hepatoma cells led to alteration of mitochondrial transmembrane potential, an abnormal aggregation of mitochondrial structures, release of cytochrome C from mitochondria, decrease of mitochondrial membrane potential and membrane blebbing of cells, which are characteristics of cell death. These functional roles of HBx in affecting mitochondrial physiology are associated with HBV-induced liver injury and development of HCC^[21,22].

Since HBx seems to accomplish its functions via protein-protein interaction, identification of the HBx-interactive cellular proteins represents a major goal in order to define the function of HBx in HBV replication and liver carcinogenesis. The yeast two-hybrid system using a genetic approach, offers a way to clone and identify genes that interact with a protein of interest through *in vivo* complementation in yeast cells^[23,24]. In the present study, we screened and cloned a novel HBx-interactive protein from a normal human liver cDNA library. Sequence analysis revealed it was the homolog of Homo sapiens COXIII. The interaction of HBx with COXIII was confirmed by yeast-two hybridization system 3. The growth of yeast cells harboring both pAS-1-X and pACT2-COXIII recombinant plasmids in His-independent medium, formation of blue-colonies detected by the β -gal assay, and the behaviors of the cells in false-positive elimination tests suggested that the binding of COXIII was HBx specific. Mating experiment further identified the interaction between COXIII and HBx in yeast cells.

Cytochrome C oxidase (COX), the terminal enzyme of the mitochondrial respiratory chain, catalyzes the transfer of electrons from reduced cytochrome C to molecular oxygen. COXIII, which is encoded by the mitochondrial DNA and synthesized within the mitochondria, represents one of the large subunits of COX and acts as the catalytic core of the enzyme^[25]. Defective COX activity resulting in deficient adenosine triphosphate generation may contribute to the development of Alzheimer's disease^[26], cardiomyopathy^[27], neonatal giant cell hepatitis^[28] and other clinically heterogeneous diseases^[29,30]. Incorrect assembly of the critical subunits including COXI, COXII and COXIII, is a major mechanism leading to COX deficiencies. COX also plays a key role in inducing apoptosis in multiple cell types through transcriptional activation of the respective genes^[31]. Mitochondrial dysfunction and transcriptional function changes have been identified to be associated with chronic liver disease and oncogenic processes^[32]. Kuo *et al.*^[33] reported the integration of HBV with human hepatoma cells might cause mitochondrial defects in the ATP synthase 6 and COXIII genes. Studies on the effects of HBx on apoptotic pathways indicated that HBx blocked the activation of caspases 8, 9 and 3 and the release of cytochrome c, it also upregulated PKC, extracellular signal-regulated kinase (ERK), phosphatidylinositol-3-kinase (PI-3-K) and NF- κ B activity^[34]. The study of NF- κ B and HBx expression in human HCC tissues detected by immunohistochemistry SP method strongly suggested that NF- κ B was abnormally activated in HCC, which was probably related to HBx. The ability of HBx to induce the activation of NF- κ B has been demonstrated by mobility shift and reporter gene expression assays with lysates from HBx-transfected HepG2 cells^[35]. Furthermore, HBx was shown to bind to a voltage-dependent anion channel and alter the mitochondrial transmembrane potential and consequently induce activation of transcription factors, which include STAT-3 and NF- κ B^[21]. Cogswell *et al.*^[36] reported that the NF- κ B regulatory pathway existed in mitochondria and NF- κ B could negatively regulate the expression of both COXIII and cytochrome B mRNAs. Whether and how the interaction of HBx with COXIII

regulates the activity of transcription factor NF- κ B has remained obscure. However, based on our data, we hypothesize that HBx might impair mitochondrial respiration chain and energy metabolism by combining COXIII.

Future investigations will focus on the identification of COXIII properties and physiological significance of interaction of HBx with COXIII and probably with other mitochondrial proteins. Further inquiries in this area may pave the way for investigation of possible mechanisms leading to chronic infection and subsequent progression to HCC in the context of mitochondrial association of HBx.

Abstract

AIM: Cyclooxygenase (COX)-2 is over expressed in gastrointestinal neoplasm. *Helicobacter pylori* (*H pylori*) infection is causally linked to gastric cancer. However, the expression of COX-2 in various stages of *H pylori*-associated gastric carcinogenesis pathway has not been elucidated. Therefore, the aim of this study was to clarify the role of *H pylori* induced COX-2 expression during carcinogenesis in the stomach.

METHODS: Gastric biopsies from 138 subjects [30 cases of chronic superficial gastritis (CSG), 28 cases of gastric glandular atrophy (GA), 45 cases of gastric mucosal intestinal metaplasia (IM), 12 cases of moderate gastric epithelial dysplasia and 23 cases of gastric cancer] were enrolled. *H pylori* infection was assessed by a rapid urease test and histological examination (modified Giemsa staining). The expression of COX-1 and COX-2 in human gastric mucosa was detected by immunohistochemical staining.

RESULTS: *H pylori* infection rate was 64.3% in GA and 69.5% in gastric cancer, which was significantly higher than that (36.7%) in CSG ($P < 0.05$). The positive expression rates of COX-2 were 10.0%, 35.7%, 37.8%, 41.7% and 69.5% in CSG, GA, IM, dysplasia and gastric cancer, respectively. From CSG to GA, IM, dysplasia and finally to gastric cancer, expression of COX-2 showed an ascending tendency, whereas COX-1 expression did not change significantly in the gastric mucosa. The level of COX-2 expression in IM and dysplasia was significantly higher in *H pylori*-positive than in *H pylori*-negative subjects ($P < 0.01$).

CONCLUSION: COX-2 expression induced by *H pylori* infection is a relatively early event during carcinogenesis in the stomach.

INTRODUCTION

Gastric cancer remains the world's second, and the Chinese first, commonest cause of cancer related deaths^[1]. There is epidemiological evidence that *Helicobacter pylori* (*H pylori*) infection is causally linked to gastric cancer^[2,3]. It has been classified as a class I biological carcinogen by the World Health Organization^[4]. However, the exact mechanism responsible for the development of gastric cancer in *H pylori*-infected patients still remains obscure. According to Correa's^[5] model, gastric cancer develops in a multistep process from chronic active gastritis, gastric glandular atrophy (GA), intestinal metaplasia (IM), dysplasia, and finally to gastric cancer. Recent studies have shown that *H pylori* infection induces cyclooxygenase-2 (COX-2) expression in human gastric mucosa^[6-8]. COX-2, an inducible isoform of cyclooxygenase enzyme, which converts arachidonic acid to prostanooids, is strongly expressed in colorectal cancer^[9,10], pancreatic cancer^[11], hepatocellular carcinoma^[12,13], esophageal cancer^[14,15], and gastric cancer^[16,17]. Several studies have also shown that COX-2 expression is increased in premalignant lesions including colonic adenoma^[9], Barrett's esophagus^[18,19], and gastric adenomas^[20], indicating that this enzyme may be involved in the early process of carcinogenesis.

It is well known that *H pylori* infection causes inflammation, and COX-2 is involved in inflammatory responses and also related to carcinogenesis. However, COX-2 expression in various stages of *H pylori*-associated gastric carcinogenesis pathway has not been elucidated. To clarify the role of *H pylori* induced COX-2 expression during carcinogenesis in the stomach, COX-1 and COX-2 expression at different stages of gastric carcinogenesis from inflammation, premalignant lesions, to gastric cancer was investigated by using immunohistochemical analysis in the present study.

MATERIALS AND METHODS

Patients

A total of 138 patients were studied. Of these, 78 were males and 60 were females. The mean age was 52 years (range, 19-74). Endoscopies with biopsy were performed in all patients. Patients who took non-steroidal anti-inflammatory drugs (NSAIDs), H₂ receptor antagonists, proton pump inhibitors, antimicrobials, bismuth compounds, over last 4 wk prior to the examination, were excluded. The Medical Ethics Committee of Nanjing Medical University approved this study and written informed consent was obtained from all patients.

Endoscopy and histological assessment

All endoscopic examinations were performed under local anesthesia with lidocaine. Four biopsy specimens, 2 from the antrum within 2 cm of the pyloric channel and 2 from the corpus, were taken during the procedure. When lesions suspected to be cancerous were noted, additional biopsies were taken from the site of lesions. Of these specimens, 2 (each from antrum and corpus) were submitted to a rapid urease test (RUT), and the others were processed for hematoxylin and eosin (H&E) stain and modified Giemsa stain. The pathologic assessment

was performed by one pathologist according to the updated Sydney system^[21]. GA was defined as loss of glandular tissue and fibrous replacement of lamina propria. IM or exchange of crypts by intestinal epithelium was recognized by the presence of goblet cells and absorptive cells.

Detection of *H pylori* infection

H pylori infection was identified by histological examination using modified Giemsa stain and RUT (CLO test, Delta West, Bentley, Australia). Patients were classified as *H pylori* positive if any of the two examinations yielded a positive result. Subjects were considered to be *H pylori* negative only when both assays were negative for the organism.

Immunohistochemistry

Immunohistochemical staining for COX-1 and COX-2 was performed by the avidin-biotin-peroxidase complex (ABC) method using a Vectastain kit (Vector Laboratories, Burlingame, CA). In brief, paraffin-embedded blocks were sectioned at about 4-μm thickness, deparaffinized, and rehydrated. After microwave pretreatment in citrate buffer (pH 6.0) for antigen retrieval, slides were immersed in 3 mL/L H₂O₂ in methanol for 30 min to block the endogenous peroxidase activity. Nonspecific binding was blocked with 50 mL/L rabbit serum (DAKO, Glostrup, Denmark) in phosphate-buffered saline (PBS), and the tissues were then incubated with goat polyclonal antibody against COX-1 or COX-2 (1:200, Santa Cruz Biotechnology, Inc. Santa Cruz, CA) in PBS containing 20 mL/L rabbit serum and 1 mL/L Triton 100 overnight at 4 °C in a humidity chamber. After being rinsed with PBS, the sections were subsequently incubated with biotinylated secondary rabbit anti-goat immunoglobulins (1:400) for 45 min and then with avidin-biotin-peroxidase complex for another 45 min. The color was developed in 3,3'-diaminobenzidine tetrahydrochloride (Sigma Chemical Co., St. Louis, MO) solution containing 0.3 mL/L H₂O₂. Nuclei were counterstained with Mayer's hematoxylin (Merck, Darmstadt, Germany). Tissues of part sections were incubated with PBS containing 20 mL/L rabbit serum and 1 mL/L Triton 100 without the primary antibody as a negative control.

Evaluation of COX-1 and COX-2 immunostaining

In each section, 5 high-power fields were selected, and a total of at least 1 000 cells were calculated. The percentage of positive staining cells was graded semiquantitatively, and each sample was assigned to one of the following categories: - (negative, 0% to 4%); + (weak, 5% to 29%); ++ (moderate, 30% to 59%); or +++ (strong, more than 60%). All immunostained sections were evaluated independently by two investigators who were blind to the pathological and clinical data. Evaluations were similar among assessors, with less than 10% disagreement. A final consensus was achieved between the 2 assessors using a multihead microscope.

Statistical analysis

Expressions of COX-1 and COX-2 between the 5 study groups (CSG, GA, IM, dysplasia and gastric cancer) were compared by Kruskal-Wallis nonparametric analysis of variance test, using Dunn's multiple comparison tests for *post hoc* comparison. The association between COX-2 expression and *H pylori* infection was analyzed using Fisher's exact test. Statistical significance was taken at $P < 0.05$.

RESULTS

Histopathologic characteristics and the prevalence of *H pylori* infection

Of the 138 patients, 63 were *H pylori*-positive and 75 were *H pylori*-

negative. Table 1 shows the histopathologic characteristics and *H pylori* status. Histopathologic diagnosis in this population included CSG ($n = 30$), GA ($n = 28$), IM ($n = 45$), moderate dysplasia ($n = 12$) and gastric cancer ($n = 23$). The rates of *H pylori* infection in GA and gastric cancer were significantly higher than that in CSG.

Table 1 Rates of *H pylori* infection in various gastric mucosal lesions

Pathological diagnosis	<i>n</i>	<i>H pylori</i> rate (%)
CSG	30	36.7
GA	28	64.3 ^a
IM	45	31.1
Dysplasia	12	33.3
Gastric cancer	23	69.5 ^a

^a $P < 0.05$ vs CSG.

Expression of COX-1 and COX-2 in human gastric mucosa with various lesions
