Abstract

Articles published in the *World Journal of Gastroenterology* (WJG) have been cited by 361 SCI covered journals, 44.59% of which are journals in the USA and 3.60% in China. Authors from 484 institutions have cited WJG, in which 22.58% of them are in the USA and 18.84% in China. The highest impact factor of SCI journals that have cited WJG is 28.740 (*Nature Medicine*), with 52.95% ($n=170$) of journals with an impact factor over 2.0. The total citation times of articles published in WJG during 1998-2003 were 484. The total citation times in 2003 were 2736 with 73.24% (2004) self-citation, 1486 in 2002 with 94.27% (1401) self-citation, 537 in 2001 with 92.92% (499) self-citation, 238 in 2000 with 92.43% (220) self-citation and 24 in 1999 with 33.33% (8) self-citation. Articles published in WJG in 2002 were cited 85 times by other SCI covered journals, and 82 articles were cited. The number was increased to 372 and 332 for articles published in 2003, respectively, with increase rates of 337.64% and 304.87%, respectively. Authors who have cited WJG are from 37 countries, and the journals that have cited WJG are from 21 countries. A total of 1 020 (57.46%) articles published in WJG were supported by international or national grants. Authors of WJG articles are from 40 countries. Articles published in issues 5-12 in 2003 have been downloaded 53 476 times online. In 2002, WJG was awarded a special grant from National Natural Science Foundation of China. Generally, the percentage of the self-citation times of articles published in WJG declined from 94.27% in 2002 to 73.24% in 2003. Meanwhile, article numbers and times cited by other SCI covered journals rose to 304.87% and 337.64% respectively. The above data suggested that the WJG underwent rapid development in 2003 with a significant increase in both numbers of cited articles and times of citation.

INTRODUCTION

World Journal of Gastroenterology (WJG ISSN-1007-9327) is an international academic journal in digestology published in China. The WJG was established in 1995 under the name

of China National Journal of New Gastroenterology, and adapted its present title in 1998^[1]. The WJG, now published semimonthly by the WJG Press, is a 210×297 mm-sized journal with 160 pages in each issue. The Journal is distributed by the Beijing Newspaper and Periodical Subscription and Distribution Bureau (Postal Issuance Code 82-261). In response to continuing growth in both basic and clinical studies on digestive diseases and the increasing demands for the international exchange in science and technology, the WJG will be published weekly from January 2005, with 160 pages in each issue. The publication dates are on the 7th, 14th, 21th and 28th of each month. Center for Information Analysis, Institute of Scientific and Technical Information of China conducted a general assessment on the SCI citation, source of manuscripts, and grant support of the articles published in the WJG during 1998-2004(issues 1-6), based on the information from ISI SCI, ISI JCR and Citation Report of Chinese Journals of Science and Technology. The assessment report is as follows.

CITATIONS OF ARTICLES PUBLISHED IN WJG BY SCI COVERED JOURNALS

Articles published in WJG have been cited 5 021 times, of which the total citation times in 2003 were 2 736 with 73.24% (2004) self-citation, 1 486 in 2002 with 94.27% (1 401) self-citation, 537 in 2001 with 92.92% (499) self-citation, 238 in 2000 with 92.43% (220) self-citation and 24 in 1999 with 33.33% (8) self-citation. Citations have been consistently increasing. However, the increase in self-citations is significantly lower than the increase in total citations (Figure 1).

Figure 1 Increase in self-citations is significantly lower than the increase in total citations.

CHANGING TREND IN OVERALL TIMES AND NUMBERS OF ARTICLES PUBLISHED IN WJG CITED BY SCI COVERED JOURNALS

Articles published in WJG in 2002 were cited by other SCI covered journals 85 times, and 82 articles were cited. The numbers were increased to 372 and 332 for articles published in 2003, respectively, with an increase rate of 338% and 305%, respectively (Figure 2, Table 1).

Figure 2 Changing trend in overall times and numbers of articles published in WJG between 1998 and 2003 cited by other SCI covered journals.

Table 1 Overall times and numbers of articles cited by other SCI covered journals

Year	2003	2002	2001	2000	1999	1998
Number of cited articles	332	82	38	17	16	0
Number of citations	372	85	38	18	16	0

GEOGRAPHIC DISTRIBUTION AND NUMBERS OF SCI COVERED JOURNALS THAT HAVE CITED ARTICLES PUBLISHED IN WJG

Overall, 361 SCI covered journals in 21 countries including 161 (44.59%) journals in the USA have cited articles published in WJG (Table 2).

Table 2 Geographic distribution and numbers of SCI covered journals that have cited articles published in WJG between 1998 and February 2004

List	Country	Number of journals
1	USA	161
2	UK	78

Of the 361 journals, 10 journals' publishing countries are unknown.

IMPACT FACTORS OF SCI COVERED JOURNALS THAT HAVE CITED ARTICLES PUBLISHED IN WJG

Overall, 361 SCI covered journals have cited articles published in WJG between 1998 and February 2004 (Table 3). Of these journals 321 (88.92%) with an impact factor ranged from 0.160 (*Progress in Biochemistry and Biophysics*) to 28.740

(*Nutare Medicine*). The impact factor was not available for other 40 journals. The impact factors of the 321 journals are shown in Figure 3.

GEOGRAPHIC DISTRIBUTION AND GRANT INFORMATION OF MANUSCRIPTS ACCEPTED FOR PUBLICATION IN WJG

Of the 1775 articles published from 1998 to issue 6, 2004, 1020 (57.46%) were supported by various international and national research grants (Figures 5-7).

DISTRIBUTION OF INSTITUTIONS OF AUTHORS WHO HAVE CITED ARTICLES PUBLISHED IN WJG

The authors who have cited articles published in WJG between 1998 and 2003 are from 484 institutions, including the world famous universities and institutes such as Washington University, Yale University, Cornell University, University of Minnesota, Stanford University, University of California, National Institute of Health and University of London (Table 5).

CITING STATUS OF ARTICLES PUBLISHED IN WJG

Self-citations have been decreased from 6.19 per article published in WJG in 2002 to 3.16 in 2003 and 3.15 in February 2004. The rate decreased from 12.68% in 2001 to 8.84% and 8.61%, respectively, in 2003 and 2004 (Figure 4 and Table 6).

ONLINE VISITING AND DOWNLOADING OF ARTICLES PUBLISHED IN WJG

A total of 436 articles published in issues 5-12, 2003 have been downloaded online with a total downloading number of 53 476 times. One article has been downloaded 2 255 times^[2] (Table 7).

GEOGRAPHIC DISTRIBUTION OF AUTHORS OF ARTICLES PUBLISHED IN WJG

Authors of WJG are from 40 countries (Table 8).

HONORS AWARDED TO WJG

The WJG is nationally recognized as a core journal in national natural science and an outstanding journal in science and technology, with an honor of the 2nd National Journal Award, and was listed as one of the 100 most important journals in China. In 2001, it was selected into the China Journal Square consisting of "200" journals. It was awarded a specific project grant as one of the key academic journals by the National Natural Science Foundation of China in 2002 (Project Grant No. 30224801).

OVERALL ASSESSMENT COMMENTS

- Total citation times of articles published in WJG in January and February 2004 by SCI covered journals were 560, in which self-citation rate was 77.67% (435). The total citation times in 2003 were 2736 with 73.24% (2004) self-citation, 1486 in 2002 with 94.27% (1401) self-citation, 537 in 2001 with 92.92% (499) self-citation, 238 in 2000 with 92.43% (220) self-citation and 42 in 1999 with 33.33% (8) self-citation. No data were available in 1998.
- Article number and times cited by other SCI covered journals were 82 and 85 in 2002, 332 and 372 in 2003, and 104 and 125 in January and February 2004, respectively.
- Overall, 361 SCI covered journals in 21 countries including 161 (44.59%) journals in the USA have cited articles published in WJG.
- Journals that have cited WJG include 11 SCI covered journals with a high impact factor; i.e. *Nature Medicine* (IF 28.740), *Cell* (IF 27.254), *Nature Reviews Neuroscience* (IF 24.047), *Nature Cell Biology* (IF 20.699), *Gene and Development* (IF 18.772), *Lancet* (IF 15.397), *Nature Neuroscience* (IF 14.857), *Neuron* (IF 13.846), *Nature Reviews*

Cancer (IF 13.625), *Gastroenterology* (IF 13.440) and *Hepatology* (IF 9.825). The impact factors of the journals that have cited WJG are as follows: 20.699-28.740 (4, 1.24%), 10.321-18.772 (12, 3.73%), 6.073-9.825 (20, 6.23%), 5.095-5.991 (14, 6.30%), 4.039-4.974 (19, 7.88%), 3.008-3.991 (46, 14.33%), 2.013-2.980 (55, 17.13%), 1.000-1.990 (78, 24.29%) and 0.160-0.996 (73, 22.74%).

- Overall, 484 articles by authors of SCI covered journals from 37 countries have cited articles published in WJG; 133 (22.58%) from the USA and 111 (18.84%) from China.
- The authors who have cited WJG are from 484 research institutions, including the world famous universities and institutes, such as Washington University School of Medicine, Yale University, Cornell University, University of Minnesota, Stanford University Center of Medicine, University of California at San Francisco, National Institute of Health and Imperial College, University of London.
- Self-citations have decreased from 6.19 per article published in WJG in 2002 to 3.16 in 2003 and 3.15 in February 2004.
- Of the 1 775 articles published from 1998 to issue 6, 2004, 1 020 (57.46%) were supported by various international

and national research grants.

- Authors of WJG are from 40 countries.
- A total of 436 articles published in issues 5-12, 2003 have been downloaded online with a total downloading number of 53 476 times. One article has been downloaded 2 255 times^[2].
- In 2002, WJG was awarded a special grant (No. 30224801) from National Natural Science Foundation of China.

In conclusion, WJG has been established its position as a regional and international English journal in gastroenterology, with increasing international influence. Despite high self citations over the past years, it appears that both self citations and self citation rate are rapidly decreasing.

Abstract

AIM: To review and summarize the current literature regarding M2A wireless capsule endoscopy.

METHODS: Peer reviewed publications regarding the use of capsule endoscopy as well as our personal experience were reviewed.

RESULTS: Review of the literature clearly showed that capsule endoscopy was superior to enteroscopy, small bowel follow through and computerized tomography in patients with obscure gastrointestinal bleeding, iron deficiency anemia, or suspected Crohn's disease. It was very sensitive for the diagnosis of small bowel tumors and for surveillance of small bowel pathology in patients with Gardner syndrome or familial adenomatous polyposis syndrome. Its role in celiac disease and in patients with known Crohn's disease was currently being investigated.

CONCLUSION: Capsule video endoscopy is a superior and more sensitive diagnostic tool than barium follow through, enteroscopy and entero- CT in establishing the diagnosis of many small bowel pathologies.

Eliakim R. Wireless capsule video endoscopy: Three years of experience. *World J Gastroenterol* 2004; 10(9): 1238-1239

INTRODUCTION

The M2A video capsule endoscope (CE) (Given Imaging LTD; Yokneam, Israel) is a wireless capsule (11 mm×27 mm) comprised of a light source, lens, CMOS imager, battery and a wireless transmitter. The slippery out side coating of the capsule allows easy ingestion and prevents adhesion of intestinal contents, while the capsule moves via peristalsis from mouth to anus. The battery provides 7-8 h of work in which the capsule photographs 2 images per second (between 50 000-60 000 images all together), which are transmitted to a recorder which is worn on the belt. The recorder is downloaded into a computer and seen as a continuous video film. Since its development additional support systems have been added- a localization system, a blood detector and a double picture viewer. All meant to assist the interpreter of the film and to shorten the reviewing period.

INDICATIONS

The full range of indications for CE became apparent with time. The initial device was invented to address a need for a better diagnostic tool for small bowel pathologies.

Obscure gastrointestinal bleeding

The most obvious and the first indication to be tested was obscure gastrointestinal bleeding (OGIB), which occurred in 5-10% of patients with any type of gastrointestinal (GI) bleeding. Several peer reviewed articles and many abstracts have compared the diagnostic yield of CE to push enteroscopy and other modalities in patients with OGIB^[1-4]. The added diagnostic yield of enteroscopy was in the range of 25-30%, while that of CE was significantly better (50-67%). This led Cave to propose an algorithm in which the first method to evaluate the small bowel in a patient with gastrointestinal bleeding with negative gastroscopy and colonoscopy would be CE, and then according to its results, the evaluation was continued with either push enteroscopy, angiography or intra-operative enteroscopy^[5]. Cave suggested that the closer the study was performed to the time of actual bleeding, the greater the diagnostic yield of CE.

Crohn's disease

The 2nd obvious indication was in patients with suspected Crohn's disease. Three peer reviewed studies published in journal and some more in abstract form demonstrated the superiority of CE compared to small bowel follow through and entero CT in these patients^[6-8]. The diagnostic yield of CE in these patients ranged between 43-71%, significantly better than small bowel follow through or entero CT (<30%). Moreover CE diagnosed Crohn's disease in 6-9% of patients that had OGIB^[9]. In patients with undetermined colitis the use of CE changed the diagnosis into Crohn's disease in 50% of patients (5/10)^[9].

Costamagna *et al.* compared CE and small bowel radiographs in patients with any suspected small bowel disease, another indication for CE^[10]. CE was diagnostic in 45% patients, and suspicious in another 40% patients, while X-ray was diagnostic in only 20% patients.

Other indications for CE

Diagnosis of celiac disease, extent of Crohn's disease, GI tumors, NSAID induced small bowel damage and surveillance of polyposis syndromes were currently investigated.

We have recently looked at CE in real life. We looked at the charts of the first 160 patients referred for CE by various doctors to 4 centers in Israel. We found that CE was of value in patients with OGIB (65%), Crohn's disease (55%) and chronic diarrhea (100%), but not in patients with chronic abdominal pain.

Future probable indications

These indications may include monitoring of small bowel damage due to drugs and chemicals (NSAID, *etc.*), monitoring of mucosal healing after various treatments (Crohn's for example), assessing the extent of diseases (Crohn's, celiac) and monitoring/surveillance of upper or lower GI damage (esophagitis, Barrett's, polyps).

CONTRAINDICATIONS

The only definite contraindication for CE was a patient with a history of intestinal obstruction or known stricture, or a patient who was a non surgical candidate.

Severe motility problems, or swallowing abnormalities could also preclude the use of CE. Initially patients with pacemakers were excluded from CE trials, but recent data mostly in abstract form, revealed that CE could be safely performed in patients with pacemakers.

COMPLICATIONS

The major complication with CE was capsule retention or non natural excretion (NNE) which was usually proximal to a stricture. This happened many times despite normal small bowel X-rays. History of NSAID usage, ischemic bowel event or known Crohn's disease, carried higher risk for NNE. NNE that necessitated surgery occurred in less than 1% of all patients and in 1.25% of patients with Crohn's disease^[9]. Usually, there were no clinical signs or symptoms and NNE was found when doing a plain abdominal film. Retrieval of the capsule and resection of narrowed segment via surgery, usually resolved the medical problem which was detected by the retained capsule.

CONCLUSIONS

M2A CE is a safe, valuable, non-invasive, innovative tool for the diagnosis and management of small bowel lesions like OGIB, Crohn's disease, chronic diarrhea and probably other small bowel diseases.

Newer versions of CE software allow us to get better localization and blood detection. Advanced versions will allow us to get therapeutic modalities and a shorter reading time.

Abstract

AIM: To test the hypothesis that, in the Southeastern Brazilian population, the *GSTT1*, *GSTM1* and *CYP2E1* polymorphisms and putative risk factors are associated with an increased risk for gastric cancer.

METHODS: We conducted a study on 100 cases of gastric cancer (GC), 100 cases of chronic gastritis (CG), and 150 controls (C). Deletion of the *GSTT1* and *GSTM1* genes was assessed by multiplex PCR. *CYP2E1*/PstI genotyping was performed using a PCR-RFLP assay.

RESULTS: No relationship between *GSTT1*/*GSTM1* deletion and the *c1/c2* genotype of *CYP2E1* was observed among the three groups. However, a significant difference between CG and C was observed, due to a greater number of *GSTT1*/*GSTM1* positive genotypes in the CG group. The *GSTT1* null genotype occurred more frequently in Negroid subjects, and the *GSTM1* null genotype in Caucasians, while the *GSTM1* positive genotype was observed mainly in individuals with chronic gastritis infected with *H. pylori*.

CONCLUSION: Our findings indicate that there is no obvious relationship between the *GSTT1*, *GSTM1* and *CYP2E1* polymorphisms and gastric cancer.

INTRODUCTION

In Brazil, gastric cancer occupies the fifth position, with an estimates of 20 640 new cases and 11 145 deaths in 2003, as a consequence of late diagnosis, and also of its high recurrence rate^[1]. Gastric carcinogenesis is a multi-step process, involving both genetic and environmental factors^[2]. Among the latter,

the most outstanding are dietary factors^[3], smoking^[4], drinking^[5], *Helicobacter pylori* infection^[6], and the occurrence of previous gastric injuries^[7]. Correa^[8] and Stemmermann^[9] suggested, in separate studies, a general hypothesis of pre-cancerous sequences for gastric carcinogenesis, especially for the intestinal types, namely superficial gastritis, chronic atrophic gastritis, intestinal metaplasia, dysplasia, and cancer.

Over the last decades, several studies have revealed the participation of polymorphisms in metabolic and DNA repair enzymes, that might confer different degrees of susceptibility to cancer. Among these metabolic enzyme polymorphisms, the most outstanding are those of cytochrome P-450 (CYPs), glutathione-S-transferases (GSTs), and N-acetyltransferases (NATs)^[10-12].

Concerning the superfamily of metabolic enzymes, both *CYP2E1* gene, a member of the cytochrome P-450 superfamily, and the *GSTT1* and *GSTM1* genes, that catalyze the conjugation reaction of glutathione with electrophilic compounds, exhibit polymorphisms which have been considered as potentially important modifiers of the individual risk for environmentally induced cancers, including cancer of stomach^[13-17]. Subjects with null *GSTT1* and *GSTM1* have a decreased capability of detoxifying some carcinogens, among which N-nitrosous compounds are involved in stomach carcinogenesis^[14].

Previous studies have shown inconclusive or controversial findings on associations between polymorphism of these genes and cancer susceptibility, due to the different types of cancer investigated and the diverse ethnic origin of the populations studied. Increased risk for oral^[18], nasopharyngeal^[19], and pulmonary^[20] cancer was observed in carriers of the rare allele *CYP2E1*, while an increased risk for esophageal cancer was observed in carriers of the common allele^[21]. On the other hand, *GSTT1* and *GSTM1* null genotypes have been linked to an increased risk for cancer of the lung, bladder and colon, and other specific sites^[11,17].

The relationship between *GSTT1*, *GSTM1* and *CYP2E1* gene polymorphisms and the risk for gastric cancer is not obvious. Many investigations were conducted on Asian populations^[22-36]. The Brazilian population is characterized by heterogeneous ethnic groups, emphasizing the need to investigate the frequency of these metabolizing genes and their association with gastric cancer.

We performed a case-control study to evaluate the association between the *GSTT1*, *GSTM1* and *CYP2E1* polymorphisms in patients from the Brazilian Southeast with gastric cancer or chronic gastritis, a lesion that increases the risk for gastric cancer by 10%^[37]. We also explored the potential interactions between the *GSTT1*, *GSTM1* and *CYP2E1* polymorphisms and demographic risk factors.

MATERIALS AND METHODS

Subjects

We conducted a simultaneous case-control study for gastric cancer and chronic gastritis. The case groups comprised 100 patients with histopathologically confirmed diagnosis of gastric

adenocarcinoma (73 men and 27 women) with a mean age of 60 years (ranging from 28 to 93 years), and 100 patients with histopathologically confirmed diagnosis of chronic gastritis (54 men and 46 women) with a mean age of 53 years (ranging from 19 to 86 years), respectively. These subjects were recruited from the "Hospital de Base", São José do Rio Preto, SP, and from the Pio XII Foundation, Barretos, SP, Brazil. The pathological diagnoses of gastric cancer and chronic gastritis were made according to criteria proposed by Lauren^[38] and the Sidney classification^[39], respectively. *H. pylori* infection was histologically established by Giemsa staining. The control group consisted of 150 healthy volunteers (90 men and 60 women), with a mean age of 54 years (ranging from 20 to 93 years), with no previous history of gastric disease, matched to the patients with respect to age, gender and ethnicity. Most controls were blood donors. Epidemiological data on the study population were collected through a standard interviewer-administered questionnaire, which included questions about current and past occupation, ethnicity, life-long smoking habits and alcohol consumption, and family history of cancer.

The human subject protocol was approved by the Research Ethics Committee of the IBILCE-UNESP, and written informed consent was obtained from all subjects.

Blood sampling and DNA extraction

Whole blood was collected and put into EDTA-coated tubes. Lymphocytes were isolated, transferred to tubes, and assigned a unique identifier code. DNA was then extracted using a non-organic extraction procedure, and stored at -20 °C until use for genotyping^[40].

Genotype analysis

The *GSTT1* and *GSTM1* genes were determined simultaneously in a single assay, using a PCR multiplex protocol, where part of exon 7 of the constitutional gene *CYP1A1* was co-amplified as an internal control.

PCR was performed in 25 µL reaction buffer containing 0.5 mmol/L of dNTPs, 2.0 mmol/L of MgCl₂, 12.5 pmol of each primer, about 150 ng DNA, and 1.25 U of thermostable Taq DNA polymerase, using a programmable thermocycler. The primers used for *GSTM1* were 5'-GAAGTCCCTGAAAAGCTAAGC and 5'-GTTGGGGCTCAAATATACGGTGG. The primers used for *GSTT1* were 5'-TTCCTTACTGGTCCTCACATCTC and 5'-TCACCGGATCAGGCCAGCA. The primers used for *CYP1A1* were 5'-GAAGTCCCTGAAAAGCTAAGC and 5'-GTTGGGGCTCAAATATACGGTGG.

PCR conditions were 94 °C for 5 min, followed by 40 denaturation cycles of 2 min at 94 °C, 1 min annealing at 59 °C, and 1 min extension at 72 °C. The PCR products were then analyzed by electrophoresis on ethidium bromide-stained 20 g/L agarose gel.

The presence or absence of *GSTT1* and *GSTM1* genes was detected by the presence or absence of a band at 480 bp and at 215 bp, respectively. A band at 312 bp (*CYP1A1*) was documented successful amplification^[41].

This technique could not distinguish between heterozygote and homozygote positive genotypes, but it could conclusively identify the null genotypes.

PCR-RFLP was performed to investigate the *CYP2E1**c2 allele. PCR was used to amplify the transcription regulation region of *CYP2E1* that includes the *Pst*I enzyme recognition site. PCR was performed in 25 µL reaction buffer containing 0.28 mmol/L of dNTPs, 1.5 mmol/L of MgCl₂, 10 pmol of each primer, about 200 ng DNA, and 1.5 units of thermostable Taq DNA polymerase, using a programmable thermocycler. The *CYP2E1* primers were 5'-CCAGTCGACTCTACATTGTCA and 5'-TTCATTCTGTCTTCTAACTGG. After 5 min of pretreatment

at 94 °C, 35 denaturation cycles of 1 min at 94 °C, 30 s annealing at 60 °C, and 1 min extension at 72 °C were performed. After amplification, the PCR products were subjected to restriction digestion by enzyme *Pst*I for 16 h at 37 °C. The PCR-RFLP fragments were then analyzed by electrophoresis on ethidium bromide-stained 20 g/L agarose gel^[42].

All the experiments included positive and negative controls for each studied polymorphism.

Statistical analysis

Statistical analyses were performed using Statdisk, Statistica, Minitab Release 10.1 computer software programs. The probability level (*P*) of 0.05 was used as significance criterion. Student's *t*-test and ANOVA *F*-test tests were used to compare continuous variables between the groups. Chi-square test or Fisher's exact test was utilized as appropriate to compare the groups with regard to genotype frequencies and putative risk factors such as gender, ethnicity, smoking, drinking, *H. pylori* infection, occupational pesticide exposure, and histological type of adenocarcinoma. In order to investigate gene-environment interactions, we also calculated the odds ratios (OR) and their 95% confidence intervals (95% CI), according to combinations of the *GSTT1*, *GSTM1* and *CYP2E1* polymorphisms with putative risk factors.

RESULTS

Figure 1 (PCR) and Figure 2 (PCR-PFLP) show the genotype analysis results. Table 1 shows the frequency distributions of the *GSTT1* and *GSTM1* genotypes among the groups. With respect to the genotype frequencies, considering the combinations between the *GSTT1*/*GSTM1* genes, no statistically significant differences were observed between the gastric cancer and chronic gastritis patients (*P*=0.189), nor between gastric cancer patients and controls (*P*=0.448). However, a significant difference (*P*=0.048) was observed between chronic gastritis patients and controls, due to a higher frequency of combination *GSTT1*/*GSTM1* positive genotypes in the chronic gastritis patients.

Figure 1 Polymerase chain reaction of the *GSTT1* and *GSTM1* genes. Lanes M: molecular weight maker; Lanes 1 and 4: patients homozygously null for *GSTT1*; Lanes 2, 3, 8 and 9: patients with positive *GSTT1* and *GSTM1* genotypes; Lanes 5 and 6: patients homozygously null for *GSTM1*; Lane 7: patient homozygously null for *GSTT1* and *GSTM1*; Lane 10 negative control.

The associations of the different genotypes with demographic risk factors (gender, ethnicity, smoking, drinking, pesticide-exposure, *H. pylori* infection and histological type of gastric cancer) in each group evidenced that the *GSTT1* null genotype occurred more frequently in Negroid controls (*P*=0.003), and

Table 2 Associations of *GSTT1* and *GSTM1* genotypes with demographic risk factors in gastric cancer (GC) and chronic gastritis (CG) cases and controls (C)

Groups	Categories	Genotype			
		<i>GSTM1</i> positive (%)	<i>GSTM1</i> null (%)	<i>GSTT1</i> positive (%)	<i>GSTT1</i> null (%)
C	Ethnicity				
	Caucasian	75 (55.6)	60 (44.4)	114 (84.4)	21 (15.6)
	Negroid	13 (86.7)	2 (13.3)	8 (53.3)	7 (46.7)
		<i>P</i> =0.020		<i>P</i> =0.003	
GC	Ethnicity				
	Caucasian	42 (46.3)	45 (51.7)	73 (83.9)	14 (16.1)
	Negroid	11 (84.6)	2 (15.4)	10 (76.9)	3 (23.1)
		<i>P</i> =0.017		<i>P</i> =0.690	
CG	<i>H. pylori</i> Infection				
	No	43 (71.7%)	17 (28.3%)	54 (90.0%)	6 (10.0%)
	Yes	19 (48.7%)	20 (51.3%)	34 (87.2%)	5 (12.8%)
		<i>P</i> =0.032		<i>P</i> =0.748	

the *GSTM1* null genotype in Caucasian controls (*P*=0.020) and gastric cancer patients (*P*=0.017). The *GSTM1* positive genotype was observed mainly in chronic gastritis cases with *H. pylori* infection (*P*=0.032) (Table 2).

The frequencies of the *GSTT1* and *GSTM1* polymorphisms were compared among the groups by χ^2 tests and estimated OR (data not shown), according to the pattern of the gastric cancer risk factors represented by gender, ethnicity, smoking, drinking, pesticide-exposure, and *H. pylori* infection. Thus, comparing the GC and CG groups, multivariate analysis revealed that smoking was not associated with increased OR's for stomach cancer in the *GSTM1* positive subjects (1.54, 95% CI=0.71-3.33), whereas it was associated with elevated OR's in the *GSTM1* null subjects (2.7, 95% CI=1.04-7.14).

Table 3 shows the frequency distributions of *CYP2E1* genotypes among the groups. The frequencies of *CYP2E1* (*c1/c2*) variant genotypes in the gastric cancer, chronic gastritis and control groups were 11.0%, 9.0% and 10.7%, respectively. The rare homozygous genotype (*c2/c2*) was not found. The results showed no statistical difference (*P*=0.878) between the groups, nor was there any relationship with the investigated etiological factors, according to the χ^2 test and estimated OR's (data not shown).

Table 3 *CYP2E1* genotype frequencies among gastric cancer (GC) and chronic gastritis (CG) patients and controls (C)

Groups	Genotype	
	<i>c1/c1</i> (%)	<i>c1/c2</i> (%)
GC	89 (89.0)	11 (11.0)
CG	91 (91.0)	9 (9.0)
C	134 (89.3)	16 (10.7)

c1/c1=homozygote for the common allele, *c1/c2*=heterozygote.

**Figure 2** PCR-RFLP of *CYP2E1*/PstI. Lanes M: molecular weight maker; Lanes 1, 2, 3, 4, 5, 6, 10, 12, 14, 15 and 16 patients homozygote for the common allele of *CYP2E1*/PstI; Lanes 7, 8, 9, 11 and 13 heterozygote for the rare allele of *CYP2E1*/PstI.

DISCUSSION

Interindividual differences in the cellular mechanisms of activation and detoxification of carcinogenic chemicals could confer different degrees of susceptibility to cancer^[43]. However, the results have not always been consistent, due to a number of possible reasons for anomalous findings, such as interaction between environmental and genetic factors, which is a complicating factor that needs to be taken into account^[32].

GSTT1, *GSTM1* and *CYP2E1* genetic polymorphisms have shown pronounced interethnic variations^[10]. Brazil is a large country with a very heterogeneous population, resulting from the cross-mating of the native population with immigrants from

Europe, Africa and Asia. Therefore, descriptive studies of the frequencies of genetic polymorphisms in the Brazilian population could be useful in verifying genetic variability in relation to xenobiotic metabolism, since this variability may influence cancer susceptibility. This is the first study that simultaneously evaluated the *GSTT1*, *GSTM1* and *CYP2E1* polymorphisms in Brazilian patients with gastric cancer and chronic gastritis.

The *GSTM1* genotype was absent in 35-65% of individuals^[44], while *GSTT1* was deleted in 10-65% of the human population^[17]. The prevalence of the *CYP2E1* c2 allele was shown to be 2-8% in both Caucasians and African Americans^[13], but higher in Asian populations, ranging from 17 to 26%^[45].

The frequencies of *GSTT1* (18.6%) and *GSTM1* (41.3%) null genotypes and the *CYP2E1/PstI* (10.7%) polymorphism observed in the control group were not different from other studies in Brazilian populations^[46-49]. We showed that the frequency of the *GSTT1* null genotype was higher in Negroid subjects, and that the *GSTM1* null genotype was higher in Caucasians. Other studies described similar results in Brazilian^[46,50] and also in American populations^[51].

Although studies of the *GSTT1* and *GSTM1* polymorphisms were performed previously, their association with gastric cancer susceptibility has not been established. Most of them showed no association between the *GSTT1* null genotype and risk for gastric cancer^[25,32,36,52,53]. However, two others suggested that the *GSTT1* null genotype might confer an increased risk for gastric cancer^[39,54].

The correlation between the *GSTM1* null genotype and gastric cancer appeared to be more consistent^[22,25,27,28,30,53]. On the other hand, other authors failed to demonstrate any statistically significant difference in the *GSTM1* polymorphism distribution of gastric cancer patients and controls^[24,26,32,36,52,55,56].

Several case-control studies also failed to find a significant association between the *CYP2E1/PstI* polymorphism and gastric cancer^[23,24,26,34]. However, while Nishimoto *et al.*^[51] observed that the rare variant c2/c2 was associated with a reduced risk for gastric cancer in non-Japanese Brazilians, Wu *et al.*^[35] observed that the distribution of the c2/c2 genotype, detected by *PstI* or *RsaI* digestion, differed significantly between gastric cancer cases and controls. These authors suggested that the *CYP2E1* genotype could be a determinant of gastric cancer. The reason for these inconsistent results is not clear, but one problem is the lack of sufficient investigation of the gene-environment interactions. Thus, Cai *et al.*^[31] and Gao *et al.*^[33] suggested that gene-environment interactions between the *CYP2E1* polymorphism and smoking might have the potential to alter the susceptibility for cancer development in the stomach.

Our current data corroborate the hypothesis of there being no association between *GSTT1* and *GSTM1* deletions and *CYP2E1/PstI* polymorphism with gastric cancer and chronic gastritis. However, smoking raised the OR's for stomach cancer in *GSTM1* null subjects. Our findings suggest that *GSTM1* null carriers may be more susceptible to the action of tobacco with regard to stomach cancer. Polycyclic aromatic hydrocarbons and N-nitrosamines found in cigarette smoke are potential human carcinogens. Thus, a deficiency of the detoxifying enzymes may affect the metabolic fates of these chemicals and raise cancer risk in subjects with a *GSTM1* null genotype. Cai *et al.*^[30] reported an increased frequency of the *GSTM1* null genotype in smokers with gastric cancer, that may modulate tobacco-related gastric carcinogenesis.

We also observed that a *GSTM1* positive genotype was more prevalent in chronic gastritis patients with *H pylori* infection. In the multi-step carcinogenesis of the stomach, chronic gastritis preceded the formation of gastric cancer, and a great proportion of the clinical tumors occurred in connection

with advanced forms of this pathology^[57]. *H pylori* has been reported to be a Class I human carcinogen^[58], and chronic *H pylori* infection was shown to increase the risk for gastric carcinoma from 2.8 to 9 fold^[59-64]. Ng *et al.*^[27] observed that the absence of the *GSTM1* enzyme might increase the risk of developing gastric cancer in patients with *H pylori* infection. Thus, chronic gastritis patients with *H pylori* infection, but with a *GSTM1* positive genotype, might benefit from a protective effect and exhibit a smaller predisposition to developing gastric cancer.

In this study, no association between the *CYP2E1/PstI* polymorphism and overall risk for gastric cancer was observed. Different from the study of Nishimoto *et al.*^[51] in a Brazilian population, the rare variant c2/c2 was not observed. Moreover, the risk for gastric cancer as related to demographic risk factors was also not affected by the *CYP2E1/PstI* polymorphisms.

In conclusion, the present work does not show any obvious relationship between *GSTT1*, *GSTM1* and *CYP2E1* polymorphisms and the development of gastric cancer in a Brazilian population. However, smoking and the *GSTM1* null genotype may be associated with an increased OR for stomach cancer. We emphasize that studies with negative findings also need to be reported, so as to avoid a publication bias leading to an overestimate of positive findings. We also suggest that the investigation of a greater number of biometabolism genes associated with DNA repair genes might bring a broader view of the process.

ACKNOWLEDGEMENTS

We wish to thank Dr. Adriana Barbosa Santos and Dr. Antônio José Manzato for their help in the statistical analysis.

Abstract

AIM: To examine the role of nucleostemin in the growth regulation of gastric cancer, liver cancer and other cancers.

METHODS: RT-PCR was used to clone the fragment of nucleostemin cDNA from HEK 293 cells. Eighteen kinds of malignant tumor tissues including gastric adenocarcinoma and liver cancer tissues, 3 kinds of benign tumor tissues, 3 kinds of benign hyperplastic tissues and normal tissues were employed to examine nucleostemin gene expression by RT-PCR, Slot blot, Northern blot and *in situ* hybridization.

RESULTS: We successfully cloned a 570 bp fragment of nucleostemin-cDNA from HEK-293 cells. All detected malignant tumor tissues, benign tumor tissues, and benign hyperplastic tissues had high levels of nucleostemin expression. Nucleostemin was also expressed in human placenta tissue at a high level. In terminally differentiated normal human adult kidney and mammary gland tissues, no nucleostemin expression could be detected.

CONCLUSION: Nucleostemin can help regulate the proliferation of both cancer cells and stem cells. It might play an important role in the growth regulation of gastric cancer, liver cancer and other cancers.

INTRODUCTION

Perhaps the most important and useful property of stem cells is self-renewal. Through this property, striking parallels can be found between stem cells and cancer cells: tumor may originate from the transformation of normal stem cells. Similar signaling pathways may regulate self-renewal in stem cells, and cancer cells^[1]. McKay and Tsai found a novel gene nucleostemin (NS) in rat embryo stem cells, the rat central nervous system (CNS)

stem cells and rat primitive bone marrow cells. NS gene was apparently involved in regulating the proliferation of both stem cells and at least some types of cancer cells^[2]. The protein encoded by NS was abundantly expressed while the cells were proliferating in an early multipotential state, but it abruptly and almost entirely disappeared at the start of differentiation. The fact that NS expressed in stem cells and several cancer cell lines, but not in the differentiated cells of adult tissues, suggested its role in maintaining self-renewal of stem cells and cancer cells. Our recent data also showed that NS expressed in human gastric cancer (SGC-7901) cells, human hepatocarcinoma (HepG2) cells, human cervical cancer (Hela) cells, human osteosarcoma (OS-732) cells, human mammary (MMK-7) cells and human embryo kidney (HEK-293) cells^[3]. Coordinated control of self-renewal and commitment to differentiation is key to maintaining the homeostasis of the stem cell compartment^[4,5], when deregulated it may contribute to cancer pathogenesis^[6,7]. The identification of stem-cell-specific proteins and the elucidation of novel regulatory pathways that ensure the integration of these processes, are therefore of fundamental importance^[8,9]. It seems that NS is involved in the regulatory pathways, but the fundamentals about NS are still unknown. For example, why does NS express in stem cells and cancer cells but not in differentiated cells? What are the tumor types that misexpress NS and the underlying mechanism? And what is the timing of NS reactivation in cancer cells.

Gastric cancer is common in China, and its early diagnosis and treatment are difficult^[10,11]. To investigate the mechanism of carcinogenesis of gastric cancer would facilitate its diagnosis and treatment. Therefore, NS may take part in the growth regulation of tumor tissues and hyperplastic tissues. So we employed a number of malignant tumor tissues, benign tumor tissues, benign hyperplastic tissues and normal tissues to examine the expression of NS gene by RT-PCR, Slot blot, Northern blot and *in situ* hybridization, which would help illuminate the mechanism of self-renewal of cancer cells.

MATERIALS AND METHODS

Materials

We collected tens of tumor tissue samples including gastric adenocarcinoma, liver cancer, bladder carcinoma, pancreatic cancer and esophagus squamous carcinoma samples. We also collected several kinds of normal tissue samples such as normal kidney tissues and muscle tissues. Human embryo kidney (HEK-293) cells were cultured in DMEM containing 100 mL/L FCS at 37 °C in 50 mL/L CO₂^[12,13]. The cells were kept in logarithmic growth phase by trypsin digestion and reinoculation every 2-4 d^[14,15]. DMEM cell culture medium was purchased from Gibco Corporation; fetal calf serum (FCS) and trypsin from Hyclone Corporation; restriction enzymes and T4 DNA ligase from Promega Corporation. PCR primers were synthesized by Shanghai Shenyong Company and DNA sequencing was also performed by this company.

Cloning of NS cDNA fragment

Total RNA in HEK 293 cells was isolated using total RNA

isolation kit (Promega Corporation). A 2 µg total RNA was used in reverse transcription (RT) reaction. Up-stream primer, 5' -ggatccatgaaaaggcctaagttaaagaaagc (*Bam*HI site underlined); Down-stream primer, 5' -aagcttgctctccaaattctccttggtga (*Hind*III site underlined). PCR protocol (94 °C 30 s→50 °C 30 s→72 °C 30 s) was run for 30 cycles and PCR product was about 570 bp. PCR product was separated by agarose gel electrophoresis, recovered with gel extraction kit (Omega Corporation), and ligated with pGEM-T vector. The ligate was transformed into competent *E.coli* JM 109 cells. The correct transformant was identified by restriction enzyme analysis and DNA sequencing.

Isolation of total RNA in tissue samples and RT-PCR

About 100 mg tissues of each sample was used to isolate total RNA using total RNA isolation kit (Promega Corporation). RT protocol and PCR protocol including PCR primers are the same as the above. GAPDH was used as a loading control, its up-stream primer, 5' -ggtggacctgacctgccgtctaga, and its down-stream primer, 5' -ttactccttgaggccatgtggg. PCR protocol (94 °C 30 s→55 °C 30 s→72 °C 20 s) was run for 25 cycles.

Analysis of slot blot

Twenty µg total RNA of each sample was added into slots, and transferred onto nylon membrane. Slot blot analysis was carried out using ³²P-labeled NS fragments and human 18S RNA as probes in the hybridization.

Analysis of Northern blot

Equal volume of total RNA of each sample was used in denaturing agarose gel electrophoresis, and after that RNA was transferred onto nylon membrane. Northern blot analysis was made using ³²P labeled NS fragments and human 18S RNA as probes in the hybridization.

Preparation of cRNA probes

Nucleostemin cDNA fragment was inserted into pGEM-T vector, and large quantities of plasmid was harvested with Plasmid Extraction Kit (Promega Corporation). After linearization by *Nco*I restriction enzyme, SP6 promoter was used to drive the transcription of NS-cRNA probes *in vitro* and in this system Biotin labeled rUTPs was introduced into NS-cRNA probes. In the same way, after linearization by *Not* I restriction enzyme, T7 promoter was used to drive the transcription of sense NS-cRNA probes *in vitro*, which acted as the negative control.

Detection of *in situ* hybridization histochemistry

The expression of NS mRNA was detected *in situ* by Biotin SP-HRP method^[16,17]. Pretreatment of paraffin-embedded specimens referred to the previously used methods^[13]. In brief, before *in situ* hybridization, sections were deparaffinized in xylene (7.5 min, twice) and rehydrated in graded ethanol. Sections were then rinsed in 2 changes of diethylpyrocarbonate-treated distilled water and rinsed in 10 mmol/L citrate buffer, pH 6.0. Sections were placed in glass racks (20 slides/rack) and submerged in approximately 250 mL citrate buffer in covered glass tubes. Sections were then microwaved in a 900-watt microwave (Panasonic Matsushita Electric, Danville, MA) 3 times for 5 min each time at full power, topped up with additional citrate buffer to compensate for evaporation. Slides were allowed to cool slightly, then were rinsed in 2 changes of diethylpyrocarbonate-treated distilled water, dehydrated in graded ethanol, and dried. Hybridization of the labeled probes to the tissue sections was carried out using a previously described method^[18]. Sense NS-cRNA probes and SP-HRP solution were used as negative controls. And the tissue sections were counterstained by hematoxylin.

RESULTS

Gain of NS-cDNA fragment

We successfully cloned a 570 nt fragment by RT-PCR in HEK-293 cells. Then the fragment was ligated with pGEM-T vector and the recombinant vector was named pGEM-T-NS. pGEM-T-NS was digested by *Bam*HI and *Hind*III enzymes, yielding a 3.0 kb fragment of vector and a 570 bp fragment of NS cDNA (Figure 1). The result of sequencing indicated our sequence of NS cDNA was completely identical to the sequence in Genebank. Sequencing revealed that no base mutation occurred in the sequence of our cloned NS-cDNA fragment.

Figure 1 Molecular cloning of nucleostemin cDNA fragment. 1. DNA marker: λDNA, *Eco*RI+ *Hind* III. 2. pGEM-T-NS, *Bam*HI+*Hind* III.

NS expression detected by RT-PCR

According to the results of RT-PCR, all above malignant tumor tissues, benign tumor tissues, and benign hyperplastic tissues had high levels of NS expression, so did the normal human placenta tissues. And a lower level of NS expression in normal human adult muscle tissues could also be detected. However, no NS expression could be detected in normal human adult kidney tissues and mammary gland tissues. Partial results of RT-PCR are shown in Figure 2.

Figure 2 Detection of NS expression in various tumor tissues and normal human adult kidney tissues using RT-PCR. 1. GAPDH cDNA-fragment sample. 2. NS-cDNA fragment sample. 3. Renal carcinoma tissue. 4. Normal human adult kidney tissue. 5. Bladder carcinoma tissue. 6. Liver cancer tissue. 7. Gastric adenocarcinoma tissue. 8. DNA marker: λDNA, *Eco*RI+*Hind* III.

NS expression by slot blot

Slot blot analysis indicated that NS expressed in all above malignant tumor tissues, benign tumor tissues, and benign hyperplastic tissues, which was in agreement with the results of RT-PCR. However, no NS expression could be detected in normal human adult kidney tissues, mammary gland tissues and muscle tissues. Partial results of Slot blot analysis are shown in Figure 3.

Figure 3 Detection of NS expression in various tumor tissues and normal human adult kidney tissues by Slot blot. 1. Liver cancer tissue. 2. Bladder carcinoma tissue. 3. Pancreatic cancer tissue. 4. Cardia adenocarcinoma tissue. 5. Gastric adenocarcinoma tissue. 6. Esophagus squamous carcinoma tissue. 7. Denatured NS-cDNA sample. 8. Ovary serous cystadenocarcinoma. 9. Ampulle carcinoma tissue. 10. Renal carcinoma tissue. 11. Normal human adult kidney tissue. 12. Benign hyperplasia tissue of prostate.

Figure 4 Detection of NS expression in various tumor tissues and normal human adult kidney tissues by Northern blot. 1. Gastric adenocarcinoma tissue. 2. Renal carcinoma tissue. 3. Normal human adult kidney tissue. 4. Liver cancer tissue. 5. Bladder carcinoma tissue.

Detection of NS expression by Northern blot

The results of Slot blot were further confirmed by Northern blot analysis. NS misexpressed in all these malignant tumor tissues, benign tumor tissues, and benign hyperplastic tissues. But the results of Northern blot analysis showed NS did not express in normal human adult kidney tissues, mammary gland tissues and muscle tissues. Partial results of Northern blot analysis are shown in Figure 4.

Figure 5 *In situ* hybridization detection of nucleostemin mRNA in invasive ductal breast carcinoma and normal mammary gland tissue by SP-HRP method. Counterstained with hematoxylin. A: Ductal carcinoma cells showed strong staining *in situ* (arrows). B: Normal mammary glandular epithelial cells showed no positive staining, only with azury nuclear counterstaining (arrows).

NS expression in tumor tissues confirmed by *in situ* hybridization

The Biotin SP-HRP (streptavidin-biotin-peroxidase-DAB) system reacted with 0.05% DAB (3-3', 4-4' -diaminobenzidine tetrahydrochloride) containing 0.1 mL/L H₂O₂, producing brown positive staining. And counterstain was performed by hematoxylin, producing azury nuclear staining. The results of *in situ* hybridization conformed to those of Slot blot analysis and Northern blot analysis. Positive staining was located in cytoplasm of cancer cells, but no positive staining in cytoplasm of normal adult tissue cells such as normal kidney cells and mammary gland cells. The results of *in situ* hybridization

detection of nucleostemin mRNA in invasive ductal breast carcinoma and normal mammary gland tissue are indicated in Figure 5. Ductal carcinoma cells showed strong staining in cytoplasm (Figure 5A), while normal mammary glandular epithelial cells showed no positive staining, only with azury nuclear counterstaining (Figure 5B).

DISCUSSION

Nucleostemin (NS) is a newly found p53-binding protein, which exists mainly in the nucleoli of stem cells and some various cancer cells, but does not express in committed and terminally differentiated cells^[2]. The expression level of NS declined obviously during embryo and adult development due to the differentiation of stem cells. For example, it was expressed preferentially in neuroepithelial precursors during embryogenesis and diminished during the central nervous system (CNS) differentiation. The expression of NS was also found in adult bone marrow hematopoietic stem cells, however could not be found in committed B-lymphocytes and granulocytes. *In vivo* experiments displayed that the NS expression could not even be detected after CNS stem cells were induced to differentiate. Recently, it was confirmed that NS expression also existed in ES cells and mesenchymal stem cells of mice^[19]. *In vivo*, NS expression disappeared before the changes of cell cycle markers during the development of CNS, which indicated the disappearance of NS expression induced the cell cycle arrest, but not the reverse. Moreover, non-cycling cells increased by silencing NS expression with small interfering RNA (siRNA) in CNS stem cells and U2OS cancer cells^[2].

We successfully cloned a 570 bp fragment of NS-cDNA from HEK-293 cells. The full length of NS-cDNA was 1 650 bp and the cloned fragment was located in the 5' -terminal of the full length. The fragment had high specificity and non-homology with other genes by BLAST analysis, so it was equal to probes in the screening of gene expression. From the results of RT-PCR, Northern blot and Slot blot analysis, we found that all these malignant tumor tissues, benign tumor tissues, and benign hyperplastic tissues had high levels of NS expression, which indicated that NS played an important role in the self-renewal of these cancer cells and hyperplastic cells. At the same time, NS expressed in human placental tissues also at a high level, possibly due to the existence of a mass of placental stem cells^[20-23]. A small quantity of NS expression could be found in normal human muscle tissues by RT-PCR, however no expression could be detected by Slot blot and Northern blot analysis. The reason might be that a few of myoblasts with the characteristic of stem cells existed in muscle tissues^[24,25], so only by the sensitive RT-PCR technique could a very small volume of NS expression be detected (figures not provided). In terminally differentiated normal human adult kidney tissues and mammary gland tissues, no NS expression could be detected as no cells possess the characteristics of stem cells or cancer cells in these tissues. The analysis of *in situ* hybridization indicated that NS gene expressed in cancer cells, but not in normal adult tissue cells, such as normal kidney cells and mammary gland cells. These results were in agreement with McKay's^[2].

All these results displayed that NS might play an important role in the proliferation regulation of cancer cells and stem cells. A working hypothesis of NS deduced from all information involved displayed that NS accumulated predominantly in the nucleolus and NS localized into nucleoplasm after binding with GTP^[26]. In the nucleoplasm, NS and p53 existed in a protein complex, and subsequently the growth-suppressive function of p53 was inhibited. During cell differentiation, when NS expression was downregulated, p53 was released from the protein complex, which allowed the stabilization or activation of p53 and induction of target genes critical for cell cycle exit

and differentiation, such as p21^{CIP}. Members of the E2F family of transcription factors play a crucial role in cell proliferation control by regulating the expression of genes important for DNA synthesis and cell cycle progression^[27]. A functional E2F factor is composed of a heterodimer between an E2F polypeptide (E2F1- E2F6) and a DP polypeptide (DP1 and DP2). The transcriptional activities of E2F factors are regulated through association with the Rb (retinoblastoma) tumor suppressor protein and the other pocket proteins, p107 and p130. Binding of a pocket protein inhibits the transcriptional activation capacity of E2F factors and, in at least some cases, can convert E2F to repressors of transcription. The activity of Rb is regulated during the cell cycle by cdks (cyclic dependent kinase), primarily by cdk4 and cdk6, in association with D-type cyclin and cyclin E in association with cdk2. Phosphorylation of Rb by these cdks results in the dissociation of Rb from E2F and the depression/activation of E2F-regulated genes. The E2F-DP transcription complex determined the start of S phase and induced the expression of some genes which were necessary to the progress of S phase, such as Cyclin E, Cyclin A, proliferating cell nuclear antigen (PCNA) and dihydrofolate reductase (DHFR). The product of Cip1, p21^{CIP}, blocked the process of phosphorylation of Rb by cdks and Cyclin complex, so E2F-DP in non-phosphorylation state still bound with RB and could not be freed. Only freed E2F-DP could gain its activity to promote the expression of these genes, and as a result, DNA synthesis was carried out and cells would pass through S phase.

Our results were in agreement with the working hypothesis mentioned above. There were high levels of NS expression in cancer cells, hyperplastic tissue cells and stem cells, so NS inhibited the p53-induced cell differentiation or apoptosis and these cells could easily pass through cell cycles. NS helped regulate the proliferation of both cancer cells and stem cells, although the precise mechanism was not yet clear. The focus on NS has potential therapeutic implications. For example, the growth of gastric cancer may be suppressed by silencing the NS expression with some molecular techniques, which would greatly improve the validity of its treatment.

ACKNOWLEDGEMENT

We want to thank Dr. Hong Gao and Dr. Siguo Liu in our group for their helpful discussions and research suggestions. We also thank Ms. Lin Hou from pathological center of Peking University for her help with *in situ* hybridization experiments and Professor. Hongwei Zhang and her colleagues from Beijing Haidian Hospital for their help with the pathological analysis.

Abstract

AIM: To investigate the clinical significance of the expression of VEGF₁₆₅mRNA and the correlation with vascular endothelial growth factor (VEGF) protein and inducible nitric oxide synthase (iNO) in human gastric cancer.

METHODS: We tested VEGF₁₆₅mRNA expression in 31 cases of resected gastric cancer specimens and normal paired gastric mucosae by RT-PCR. Total RNA was extracted with TRIzol reagents, transcribed into cDNA with oligo (dT)₁₅ priming, inner controlled with β -actin expression and agarose gel isolated after PCR. VEGF expression was quantitated with IS1000 imaging system. Meanwhile we also examined expression levels of VEGF protein and iNOS in 85 cases of gastric cancer. All paraffin-embedded samples were immunohistochemically stained by streptavidin-peroxidase method (SP).

RESULTS: The mean expression of VEGF₁₆₅mRNA in gastric cancer was 1.125 ± 0.356 , significantly higher than that of normal paired mucosae, which was 0.760 ± 0.278 . The data indicated that the expression level of VEGF₁₆₅mRNA was well related to lymph node metastasis and TNM stages of UICC. The expression levels in patients with lymph node metastasis and without lymph node metastasis were 1.219 ± 0.377 and 0.927 ± 0.205 respectively ($P < 0.05$). The expression in stages I, II, III, IV was 0.934 ± 0.194 , 1.262 ± 0.386 respectively ($P < 0.01$). Further analysis showed the lymph node metastasis rate in the group with over-expression of VEGF was higher than that in the group with low expression of VEGF (83.3% vs 46.2%), and the ratio of stage III+IV in the group with over-expression of VEGF was also higher than that in the group with low expression with VEGF (77.8% vs 33.8%) ($P < 0.05$). The positive rates of expression of VEGF protein and iNOS in 85 cases of gastric cancer were 75.4% and 58.8% respectively, and 50.1% of the patients showed positive staining both for iNOS and VEGF, the correlation with the two factors was significant ($P = 0.018$). But more intensive

INTRODUCTION

Many observations have shown that angiogenesis plays an important role in the growth, progression and metastasis of solid tumors. Several potential angiogenic factors have been identified, vascular endothelial growth factor (VEGF) is known as one of the most powerful and specific molecules in vascularization. VEGF₁₆₅ is the major isoform among the five different VEGF species^[1,2]. Studies have demonstrated that tumor cells could produce and secrete VEGF periodically by themselves, which binding with the VEGF receptor in the vascular endothelial cells and then promote the angiogenesis in tumors^[3]. Inducible nitric oxide synthase (iNOS) is one of the isoforms of nitric oxide synthase that catalyzes the formation of nitric oxide, a regulator of vascular permeability. Expression of VEGF protein and iNO has been shown by immunohistochemistry in gastric cancer^[4-8]. However, the relationship has not been well evaluated between the VEGF₁₆₅mRNA and the clinical pathological features, and between VEGF and iNO, the two angiogenic regulators in gastric cancer.

The present study detected the expression of VEGF₁₆₅mRNA by RT-PCR and the expression of VEGF protein and iNO by immunohistochemistry in surgically resected human gastric cancer specimens, and characterized the correlation that mentioned above.

MATERIALS AND METHODS

Materials

Specimens of cancer tissue from 85 cases of gastric cancer were confirmed pathologically and at the second Affiliated Hospital of Medical College of Zhejiang University from August 1998 to January 2002. Of these, 54 patients were male, and 23 female, with a median age of 54 (31-77) years. All the cases were classified by WHO criteria histologically and TNM staging of UICC. Fresh cancerous and normal paired gastric mucosae obtained from 31 cases of them were frozen quickly by liquid nitrogen and stored at -80 °C until used for RT-PCR. All the specimens from 85 cases were fixed in 40 g/L buffered formaldehyde and embedded in paraffin for immunohistochemistry.

RT-PCR

Total RNA was extracted from 100 mg each frozen tissue using TRIzol reagents according to the manufacturer's instructions (GIBCO BRL) and the purity and quality were identified by an ultraviolet spectrometer and denatural gel electrophoresis.

First-strand cDNA was synthesized from 2 µg of total RNA in a 40 µL reaction volume by reverse transcription (RT) using 50 pmol oligo (dT)₁₅ 2 µL, RNasin 40 U, 10 mmol/L dNTP 2 µL, M-MLV reverse transcriptase 10 U (PROMEGA). The RNA template and oligo (dT)₁₅ were incubated at 65 °C for 10 min first, and were then added to the total reaction system at 37 °C for 1 h, stored at -20 °C for PCR. cDNA of 5 µL was amplified by PCR in a 25 µL reaction volume, containing 10 mmol/L dNTP 0.5 µL, Taq 1.5 U, per primer 10 pmol, and was inner controlled with β-actin. VEGF primers according to Tishcer's design^[9] were the upper primer: 5'-CAAGGATCCATGAAC TTTCTGCTGCTT-3', the lower primer: 5'-CTTAAGCTTGC TCCTTCC TCCTGCCCCGCG-3'. The upper primer of β-actin: 5'-TCGACAACGGCTCCGGCA-3', the lower primer of β-actin: 5'-CGTACATGGCTGGGGTGT-3'. The recombinant plasmid pGEM- T-VEGF₁₆₅ was used as positive control (provide by the Surgery Laboratory in our hospital). PCR condition of VEGF₁₆₅: pre-denaturation 94 °C for 5 min, then 30 cycles of amplification at 94 °C for 45 s, at 60 °C for 45 s, and at 72 °C for 45 s, extension at 72 °C for 10 min.

Aliquots of the PCR products (10 µL) were separated and visualized with ethidium bromide staining after electrophoresis in a 15 g/L agarose gel in Tris acetate ethylenediaminetetraacetic acid buffer at 100 V for 20 min, and quantitated with IS 1000 imaging system (Alpha Inotech). The expression of VEGF₁₆₅mRNA was expressed as follow: numeral value of VEGF₁₆₅=scanning data of VEGF₁₆₅ band/ scanning data of β-actin band. The value greater than 1 was regarded as higher expression of VEGF₁₆₅mRNA, and the value less than 1 was regarded as lower expression of VEGF₁₆₅mRNA. Statistical analysis was performed by means of SPSS10.0.

Immunohistochemical analysis

Paraffin-embedded samples were serially sectioned at 4 µm, and mounted onto the histosticked-coated slides. Sections were dewaxed in xylene, and dehydrated in ethanol, and then heated at 98 °C in EDTA retrieved solution for the antigens. Endogenous peroxidase was blocked by incubation of samples in hydrogen peroxide blocking reagent (Maixin Bio, Fuzhou). After washed with phosphate-buffered saline solution, the samples were incubated for 60 min with the primary antibodies. The anti-VEGF antibody is a polyclonal mouse anti-serum against VEGF of human origin and recognizes an amino-terminal epitope found in VEGF_{121,165,189}, and the anti-iNOS antibody is a monoclonal mouse anti-serum against the C-terminal domain of iNOS of human origin (The two antibodies were from Santa Cruz Biotechnology, Inc., CA). Location of the primary antibodies was achieved by subsequent application of a biotinylated anti-primary antibody, an avidin-biotin complex conjugated to horseradish peroxidase. The reaction products were visualized with diaminobenzidine. The slides were counter-stained by hematoxylin. Negative controls were established by replacing the primary antibody with PBS and normal rabbit serum. Known immunostaining-positive slides were used as positive controls. Immunoreactivity was diagnosed depending on the shade of cells staining assigned to 0-3 scores (0: negative reaction, 1: weak brown-color staining, 2: moderate brown-color staining, 3: strong brown-color staining), and the percent of positive staining cells, the average percentage of positive cells was determined in at least 5 areas

at ×400 and assigned to 0-3 scores (0: negative or equivocal staining, 1: weakly positive expression, cells were staining in 1-25%, 2: moderately positive expression, cells were staining in 25-50%, 3: strongly positive expression, the cells were stained over 50%). The diagnosed grades accorded to the sum of two scores, -: 0-1, +: 2, ++: 3-4, +++: >5. Statistical analysis was performed by means of SPSS10.0.

RESULTS

Expression of VEGF₁₆₅mRNA in gastric cancer

As shown by RT-PCR, the amplification products of VEGF and β-actin were 655 bp and 370 bp, respectively. Over-expression of VEGF₁₆₅ was detected in gastric cancer mucosae, and the over-expression rate was 58%, whereas 16% in normal paired mucosae. The mean value of the VEGF₁₆₅mRNA expression in gastric cancer tissues was significantly higher than that in normal paired tissues, which was 1.125 ± 0.356 and 0.760 ± 0.278 respectively (Figure 1 and Table 1).

Figure 1 RT-PCR products of VEGF₁₆₅mRNA by 20 g/L agarose gel electrophoresis. M, marker; P, recombined plasmid of VEGF₁₆₅; T, gastric cancer mucosae; N, non-gastric cancer mucosae; ', β-actin. The product of VEGF₁₆₅ mRNA was 655 bp, and the product of β-actin was 370 bp.

Relationship between expression of VEGF₁₆₅mRNA and clinical pathological features of gastric cancer

As shown in Table 2, the expression level of VEGF₁₆₅mRNA in the group of positive lymph node metastasis was higher than that in the group of negative lymph node metastasis ($P < 0.05$), and the expression level in stages III and IV was also higher than that in stages I and II ($P < 0.05$). The expression levels had no correlation with age, sizes of tumors and degree of histological differentiation.

Another observation shown in Table 3 and Table 4 was that the rate of lymph node metastasis and the ratio of stages III and IV in the group with over-expression of VEGF₁₆₅ mRNA were also higher than those in the group with low-expression of VEGF₁₆₅ mRNA (83.3% vs 46.2%, 77.8% vs 30.8% respectively, $P < 0.05$).

Correlation between VEGF and iNOS in gastric cancer

Positive immunostaining for iNOS and VEGF was observed in cancer cells, and weakly positive or negative staining was observed in the normal gastric epithelial tissues. VEGF and iNOS immunoreactivity was located mainly in the cytoplasm and cell membrane (Figure 2). The positive expression rate of iNOS was 58.8% (50/85), and that of VEGF was 75.4% (64/85). There were 50.1% (43/85) patients showing positive staining both for iNOS and VEGF, 16.5% (14/85) showing negative staining both for iNOS and VEGF. Correlation with the two factors was significant ($P < 0.05$). But more intensive analysis by Kendall test showed that the immunoreactive grades of VEGF had no association with that of iNOS ($P > 0.05$, see Table 5).

DISCUSSION

VEGF is well characterized by its potent, specific angiogenesis-promoting effect. Native VEGF is a basic, heparin-binding, homodimeric glycoprotein of M_r 43 000–46 000. Five human VEGF mRNA species encoding VEGF isoforms of 121, 145, 165, 189, and 206 amino acids have been identified by alternative splicing of VEGFmRNA. An important biological property that distinguishes the different VEGF isoforms is their heparin and heparin-sulfate binding ability. VEGF₁₆₅ is the predominant form. VEGF has been found to be a highly specific mitogen for endothelial cells, and a prime regulator of angiogenesis and vasculogenesis, and could also contribute to the development of tumors because of its ability to induce permeabilization of blood vessels^[1,2,10,11]. Numerous studies have demonstrated that the high expression level of VEGF in many kinds of tumor cells^[12–14]. The same observations have also been seen in gastric cancer cells by *in vitro* and *in vivo*^[3–6,15,16]. We tested VEGF₁₆₅mRNA expression in 31 cases of resected gastric cancer specimens and normal paired gastric mucosae by RT-PCR, the results showing that the mean expression of VEGF₁₆₅mRNA in gastric cancer was significantly higher than that of normal paired mucosae. VEGF in high expression could combine with its receptors Flt-1 or KDR to exert its powerful function of promoting angiogenesis^[1,2,10]. Furthermore, some studies showed the high expression of Flt-1 and KDR in gastric tumor specimens by RT-PCR and immunohistochemistry, and exogenous VEGF₁₆₅ stimulated the growth of KDR positive carcinoma cells^[17,18]. These findings indicate there is a possible autocrine pathway for VEGF in gastric cancer, which is very important in the development of gastric cancer.

VEGF induces the formation of fenestrations in blood vessels and vesiculo-vacuolar organelles that form channels through which blood-borne proteins can extravasate. This could lead to the formation of an extravascular fibrin gel, which provides a matrix that supports the growth of endothelial cells and tumor cells and allows invasion of stromal cells into the development of tumors^[2]. A substantial number of studies have demonstrated a strong association between elevated tumor

expression of VEGF and advanced disease or poor prognosis in various cancers^[1,2]. In our study, the expression of VEGF₁₆₅mRNA was well related with lymph node metastasis and TNM stage, VEGF₁₆₅mRNA elevated in lymph node positive or stages III and IV patients, and was consistent with many immunohistochemical results. Kakeji *et al.*^[4] also revealed VEGF to be an independent prognostic factor and independent risk factor for liver metastasis. Karayiannakis *et al.*^[19] showed there was a significant association between serum VEGF levels and disease stage, as well as invasion depth of the tumor and the presence of distant metastasis. It was concerned with the invasiveness and metastasis of gastric cancer, and might be predictive of tumor status and prognosis in advanced gastric cancer patients, and could provide new prognostic information not afforded by conventional clinicopathologic prognostic indicators^[20-24].

Early gastric cancer patients have high survival rates, but there is lymph node metastasis in early gastric cancer, especially in submucosa, the rate of lymph node metastasis was about 20%, resulting in the decrease of 5-year survival of early gastric cancers. In our study, the expression of VEGF₁₆₅mRNA in the 5 cases of early gastric cancer had no difference with the normal paired mucosae, which the mucosae or submucosae were invaded, and lymph node metastasis was negative in the 5 cases. Recently Amioka *et al.* demonstrated VEGF was associated with lymphatic invasion and lymph node metastasis in early gastric cancer^[25-27]. The clinical significance of VEGF expression in early gastric cancer should be intensively studied.

VEGF production has been found to be regulated by growth factors, cytokines, oncogenes, anti-oncogenes and other extra cellular molecules, such as hypoxia, p53 gene, TGF- α ^[28-32]. But few investigations have been concerned with relationship between VEGF and iNOS. Nitric oxide produced through iNOS induction could enhance vasodilation, increase vascular permeability and accelerate nutrient supply of tumor tissues and promote neovascularization, thereby facilitating tumor growth^[7,8]. It has been shown that the expression of iNOS in most tumor tissues was higher than that in normal tissues. There were many reports concerning the high expression of iNOS in gastric cancer, which increased with the stage of the cancer and lymph node metastasis^[7,8,33]. We found the expression rate of iNOS in gastric cancer was 58.8%, and iNOS and VEGF had co-expressions in 50.1% of the patients, there was a correlation between the two factors. According to some reports^[34], VEGF could induce the release of NO from endothelial cells, on the other hand, endogenous NO enhanced VEGF synthesis in rat vascular smooth muscle cells; Host expression of NOS could contribute to induction of NOS in tumor and melanoma growth in mice, possibly by regulating the amount and availability of VEGF. The positive interaction between endogenous NO and VEGF might have implications for endothelial regeneration^[35]. Kisley *et al.*^[36] examined the effect of iNOS deficiency on VEGF protein concentration in mouse lung tumors, and showed VEGF concentration was lower than 54% in lung tumors isolated from iNOS(-/-)mice versus controls(wild-type +/+). NO enhanced the transcription of VEGF gene by inducing HIF-1 (hypoxia -inducible factor-1) binding activity in glioblastoma A-172 cells and hepatoma Hep3B cells. HIF was the best-characterized regulator of VEGF gene transcription^[37]. The high coincidental expression of iNOS and VEGF protein accumulation may be important events to enhance gastric carcinogenesis and poor clinical features. But in our present work, more intensive analysis showed that the immunoreactive grades of VEGF were no association with that of iNOS, indicating that many other factors may induce the production and angiogenesis of VEGF besides iNOS in gastric cancer.

Abstract

AIM: To investigate the association of TNF polymorphisms with chronic atrophic gastritis (CAG) and gastric adenocarcinoma in Chinese Han patients.

METHODS: The TNF- α 5 microsatellites and 3 RFLP sites were typed using PCR technique, followed by high-voltage denaturing PAGE with silver staining and restriction enzyme digestion respectively in specimens from 53 patients with CAG and 56 patients with gastric adenocarcinoma and 164 healthy controls. The PCR products were cloned and sequenced.

RESULTS: The frequency of TNF- β NcoI*1/2 genotype was higher in patients with chronic atrophic gastritis than in healthy controls, but no significant difference was observed (60.38% vs 46.34%, $P=0.076$). The frequency of TNF- α 10 allele was significantly higher in patients with chronic atrophic gastritis than in healthy controls (19.81% vs 11.89%, $P=0.04$). However, it did not relate to age, gender, atrophic degree or intestinal metaplasia in patients with chronic atrophic gastritis. The frequency of TNF- β NcoI*1/2 and d2/d6 genotypes were significantly higher in patients with gastric adenocarcinoma than in healthy individuals ($P>0.05$). However, TNF- β NcoI*1/2 and d2/d6 genotypes did not relate to age, gender, grade of differentiation and clinicopathologic stage in patients with gastric adenocarcinoma. The frequency of TNF- α 6b5c1 haplotype homozygote was significantly lower in patients with gastric adenocarcinoma than in healthy controls (1.79% vs 15.85%, $P=0.006$).

CONCLUSION: TNF- α 10 allele may be a risk factor for chronic atrophic gastritis. TNF- β NcoI*1/2 and d2/d6 genotypes are associated with the susceptibility to gastric adenocarcinoma, whereas TNF- α 6b5c1 haplotype homozygote may contribute to the resistance against gastric adenocarcinoma.

INTRODUCTION

Gastric adenocarcinoma is one of the most frequent malignant diseases in the world, but the causes of gastric cancer remains unclear. The crude mortality rate of stomach cancer in China was 25.2 per 10⁵ (32.8 per 10⁵ for males and 17.0 per 10⁵ for females), which comprised 23.2% of the total death of cancer from 1990 to 1992, making stomach cancer the leading cause of the death among cancers^[1].

Tumor necrosis factor (TNF) is a multifunctional cytokine and its anti-tumor effect has attracted particular attention. TNF was found at a higher concentration in patients with malignant tumor. Forones *et al.*^[2] reported increased TNF- α expression in the sera of patients with advanced gastric cancer. TNF- α mRNA was markedly increased in gastric carcinoma tissue^[3]. Recombinant TNF has been demonstrated to have considerable treatment effect on gastric cancer *in vitro*^[4,5].

The gene for TNF- α and lymphotoxin- α (TNF- β), referred to as the TNF locus, are tandemly arranged within a 7-kilobase region in the HLA on the short arm of chromosome 6. HLA has recently been found to contribute to cancer development^[6-9]. Several RFLP sites and 5 microsatellites within the TNF gene have been identified. Some studies have shown that TNF individual alleles were correlated to secretion from activated monocytes^[10-13]. Furthermore, some experiments found that TNF secretion was also associated with TNF haplotypes, not only individual alleles^[14]. These findings suggest that TNF polymorphisms may play a role in the pathogenesis of several autoimmune, infectious and neoplastic diseases.

Chronic atrophic gastritis (CAG) is believed to be the precancerous lesion of gastric adenocarcinoma. In the present study, we examined whether TNF genetic polymorphisms were associated with CAG and gastric adenocarcinoma in Chinese Han population. Additionally, we determined whether the associations between TNF genetic polymorphisms and CAG and gastric adenocarcinoma varied with clinicopathologic features of the 2 diseases.

MATERIALS AND METHODS

Patients and genomic DNA extraction

The subjects of this study included 56 patients with gastric adenocarcinoma (43 males, 13 females; mean age 55.6 \pm 12.2 years), 53 patients with CAG (32 males, 21 females; mean age 53.5 \pm 11.4 years), and 164 unrelated healthy individuals (113 males, 51 females; mean age 52.5 \pm 11.3 years) from Chinese Han population in Hubei province of China. The diagnoses of gastric adenocarcinoma and CAG were confirmed by histopathology examinations. Genomic DNA was extracted

from venous blood by a salting out procedure with minor modifications.

TNF polymorphism typing

Five microsatellites were amplified using a single step PCR reaction with primers described by Pociot *et al.*^[15]. TNF microsatellite alleles were typed by a 60 g/L polyacrylamide, 0.4-mm sequencing gel, followed by silver nitrate staining. Fragments were sized using DNA markers and simultaneously typed with known alleles derived from the cloned PGEM-T vector.

The sites in the first intron of TNF- β marked by AspH1 and *Nco*I were analyzed using PCR and endonuclease digestion. BSIHKA1, an isoschizomer of AspH1 (New England Biolabs, Beverly, MA) was used instead of AspH1. The digested products were electrophoresed in 1 g/L ethidium bromide-stained 15 g/L agarose gels. Similarly, the TNF-308 polymorphism was examined by PCR amplification and *Nco*I digestion. The digested products were separated on a 100 g/L non-denaturing polyacrylamide gel. Alleles were visualized as described for TNF microsatellite typing.

Cloning and sequencing

The PCR products of 5 microsatellites were purified and ligated with PGEM-T vector. High efficiency JM 109 competent cells were used in the process of transformation. Needed transformants were obtained by blue/white color screening and standard ampicillin selection. Recombinant plasmid DNA were isolated and identified. Sequencing was done on ABI 377 DNA sequencer.

Statistical analysis

Allele frequencies in patients and control groups were calculated by direct counting. The Chi-square test and Fisher's exact test were used for statistical analysis. Hardy-Weiberg equilibrium was tested in a 2 \times n analysis using Chi-Square.

RESULTS

The frequencies of the various alleles at 8 TNF polymorphic sites in 3 groups are shown in Table 1. The frequency of TNFa10 allele was significantly higher in patients with CAG than in healthy controls (19.81% vs 11.89%, $P=0.04$, OR=1.83, 95%CI

1.02-3.27). However, it was not related to age, gender, atrophic degree and intestinal metaplasia in patients with CAG (Table 2). The frequency of TNF- β NcoI*1/2 genotype was higher in patients with chronic atrophic gastritis than in healthy controls (Table 3). However no significant difference was observed (60.38% vs 46.34%, $P=0.076$).

The frequency of TNF- β NcoI*1/2 genotype was significantly higher in patients with gastric adenocarcinoma than in healthy controls (64.29% vs 46.34%, $P=0.020$, OR=2.08, 95%CI 1.12-3.86). The frequency of d2/d6 genotype was also significantly higher in patients with gastric adenocarcinoma than in healthy individuals (10.71% vs 2.44%, $P=0.028$, OR=4.8, 95%CI 1.18-19.47). However, TNF- β NcoI*1/2 and d2/d6 genotypes were not related to age, gender, grade of differentiation and clinicopathologic stage in patients with gastric adenocarcinoma (Table 4).

Based on maximum likelihood estimate, 4 most frequent 3-locus haplotypes have been described in 4 European

populations: TNFa11b4c1, TNFa2b1c2, TNFa6b5c1, TNFa10b4c1. These haplotypes have also been observed in our study. By analysis of 2 locus association, we established 5 extended haplotypes which integrated alleles across the TNF locus in our population: TNFa6b5c1d8e4TNF308-1TNF β NcoI-1TNFAspH1-2, TNFa2b1c2d5e1TNF308-1TNF β NcoI-2TNFAspH1-2, TNFa11b4c1d4e3TNF308-1TNF β NcoI-2TNFAspH1-1, TNFa10b4c1d4e3TNF308-1TNF β NcoI-2TNFAspH1-1, TNFa2b3c1d2e3TNF308-2TNFAspH1-2. There were no significant differences in haplotype frequencies between CAG, gastric adenocarcinoma, and control groups for these haplotypes. However the frequency of TNFa6b5c1 haplotype homozygote was significantly lower in patients with gastric adenocarcinoma than in healthy individuals (1.79% vs 15.85%, $P=0.006$). It was not related to age, gender, grade of differentiation and clinicopathologic stage in patients with gastric adenocarcinoma.

Figure 1 Nucleotide sequence of the cloned PGEM-T vector comprising TNFa6 allele (135→241) and TNFb5 allele (29→157), 150→179 fragment is 15 (AC/GT) repeats, 107→127 fragment is 10.5 (TC/GA) repeats.

Figure 2 Nucleotide sequence of the cloned PGEM-T vector comprising TNFc1 allele (35→193), 59→76 fragment is 9 (TC/GA) repeats.

Figure 3 Nucleotide sequence of the cloned PGEM-T vector comprising TNFd4 allele (34→163), 64→85 fragment is 11 (TC/GA) repeats.

Figure 4 Nucleotide sequence of the cloned PGEM-T vector comprising TNFe3 allele (29→131), 47→62 fragment is 8 (TC/GA) repeats.

Table 2 Association between TNFa10 allele and clinical features of CAG

Groups	Age (yr)	Gender		Atrophic degree			Intestinal metaplasia	
		M	F	Mild	Moderate	Severe	Positive	Negative
TNFa10+	53.9±9.6	13	8	3	12	6	14	7
TNFa10-	53.2±12.5	19	13	6	18	8	22	10

Table 3 Distribution frequency of TNF TNF-β Ncol*1/2 and TNFd2/d6 genotypes in CAG, gastric adenocarcinoma and healthy controls

Group	TNF-β Ncol*1/2		TNFd2/d6	
	+	-	+	-
Controls	76	88	4	160
CAG	32	21	2	51
Gastric adenocarcinoma	36 ^a	20	6 ^c	50

^aP<0.05 vs compared with control group of TNF-β Ncol*1/2, ^cP<0.05 vs compared with control group of TNFd2/d6.

Table 4 Association between d2/d6 and TNF- β Ncol*1/2 genotypes and clinical features of gastric adenocarcinoma

Group	Age (yr)	Gender		Grade of differentiation		Clinicopathologic stage	
		M	F	High and moderate	Low	I-II	III-IV
d2/d6+	59.7 \pm 9.5	5	1	0	6	4	2
d2/d6-	55.1 \pm 12.5	38	12	13	37	21	29
1/2+	56.7 \pm 12.2	26	10	9	27	15	21
1/2-	53.6 \pm 11.5	17	3	4	16	10	10

The sequences of five TNF microsatellites (Figures 1-4) were consistent with that from a GeneBank database. However, several base exchanges were noted as following: TNFa at position 218 T \rightarrow G, TNFc at 129 G \rightarrow C, 170 A \rightarrow G, TNFd at 87 G \rightarrow A, 91 A \rightarrow G, and TNFe at 81 C \rightarrow T.

DISCUSSION

Genetic predisposition appears to be important in the pathogenesis of gastric adenocarcinoma. Genetic factors determining cancer risk have been postulated for the last decades and seem to be more apparent for gastric adenocarcinoma^[16-21]. The relevant genes mediating the risk of gastric adenocarcinoma have not been identified until now. Progress of CAG towards gastric adenocarcinoma seems to be influenced by genetic factors^[22,23].

A diallelic TNF- β polymorphism detected using the enzyme Ncol influences the TNF- α and/or - β secretion of peripheral blood mononuclear cells^[24]. Park *et al.*^[25] found that TNF- β Ncol*1/1 genotypes showed an increased risk for colorectal cancer, and that TNF- β *1 allele played some role in the initial step of tumorigenesis or activation of dormant tumor cells, whereas TNF- β *2 allele mediated some functions associated with cytotoxicity of tumor cells. Our result showed that the frequency of TNF- β Ncol*1/2 genotype was significantly higher in patients with gastric adenocarcinoma than in healthy individuals. It suggested that TNF- β Ncol*1/2 genotype was related to the pathogenesis of gastric cancer. At the same time we found the frequency of TNF- β Ncol*1/2 genotype was also high in patients with CAG. However, the association between TNF- β Ncol*1/2 genotype and CAG did not show a significant difference. Further studies are necessary to elucidate if TNF- β Ncol*1/2 genotype is a risk factor for CAG. The frequency of d2/d6 genotype was also significantly higher in patients with gastric adenocarcinoma than in healthy individuals. It indicated that d2/d6 genotype might have some effect on pathogenesis of gastric adenocarcinoma.

Azuma *et al.*^[23] reported that the DQA1*0102 might contribute to resistance against *H. pylori* associated gastric atrophy and immunogenetic factors were important in the etiology of *H. pylori* associated gastric atrophy. Proinflammatory IL-1 β polymorphisms are associated with hypochlorhydria and atrophic gastritis in Japan^[24]. The presence of the IL-1*C allele may also indicate a risk of mucosal atrophy of the stomach in the Japanese population^[26]. Our study has shown an association between TNFa10 allele and CAG, but not between TNFa10 allele and gastric adenocarcinoma. It suggested that TNFa10 allele might be a host risk factor for CAG. However, it was not related to age, gender, atrophic degree and intestinal metaplasia in patients with CAG.

A significant reduction in high expressing haplotypes was found in patients with follicular lymphoma^[27]. Hajeer *et al.*^[28] reported the TNF a2-b4-d5 haplotype was significantly associated with the number of basal cell carcinoma (BCC) lesions. It provides the evidence that TNF microsatellite haplotype may influence the pathogenesis of multiple BCC. We found negative association between TNFa6b5c1 haplotype homozygote and gastric adenocarcinoma. The frequency of

TNFa6b5c1 haplotype homozygote was lower in patients with gastric adenocarcinoma. It suggested that TNFa6b5c1 haplotype homozygote might contribute to the resistance against gastric adenocarcinoma. The absence of TNFa6b5c1 haplotype homozygote might increase the risk of gastric adenocarcinoma.

The TNF- α 308A allele has been associated with enhanced TNF- α expression^[10]. Machado *et al.* proposed that individuals carrying TNF- α 308A allele had an increased risk for gastric cancer with an OR of 1.9^[29]. However our results showed that there was no association between TNF- α 308 allele and gastric adenocarcinoma. Similarly, Wu *et al.* reported no association was noted between gastric cancer and controls in the distribution of TNF- α genotypes in Taiwanese Chinese population^[30]. The discrepancy may be attributable to ethnic difference.

Onishi *et al.*^[31] demonstrated a significantly favorable prognosis in the renal carcinoma patients with TNF- β 1/1 homozygote compared with other zygotes of TNF-beta polymorphism. The patients with TNF- β 1/1 homozygote showed much lower stage and/or grade than those of other zygotes. TNF polymorphisms TNF-488A and TNF-859T were associated with grade of tumour in patients with bladder cancer^[32]. However, in our study TNF- β Ncol*1/2 and d2/d6 genotypes and TNFa6b5c1 haplotype were not related to age, gender, grade of differentiation and clinicopathologic stage in patients with gastric adenocarcinoma. Patients with d2/d6 genotype were present with a lowly differentiated tumor, however the difference did not reach statistical significance. Larger sample studies are needed.

The association between TNF genetic polymorphisms and CAG and gastric adenocarcinoma is not clear. However, 2 distinct potential mechanisms can be proposed. First, TNF alleles may be involved in genetically controlled variations in TNF production as previously described. Another possible explanation is that these genes are not responsible for the pathophysiological mechanisms but are linked closely to other responsible genes. TNF has been reported to be in linkage disequilibrium with HLA genes^[33-35]. The negative association of TNFa3-e1 with rheumatoid arthritis may be secondary to the negative linkage disequilibrium between TNFa3-e1 and HLA-DR4^[36]. Additional studies will be necessary to investigate whether TNF genes are independent of other linked genes to play a role.

With regard to several base exchanges in our sequencing result, more studies should be done to verify whether they are caused by ethnic difference or other factors.

Abstract

AIM: To investigate the expression of effector protease receptor-1 (EPR-1), proliferative index ki-67 and apoptosis index in patients with primary advanced gastric adenocarcinoma and to clarify the significance of EPR-1 expression and its correlation with the proliferation and apoptosis indexes.

METHODS: Using immunohistochemical staining and terminal deoxynucleotidyl transferase mediated nick end labelling (TUNEL) technique, we determined the expression of EPR-1, proliferative index (Ki-67) and apoptotic index (AI) in 120 paraffin-embedded specimens of primary advanced gastric adenocarcinoma as well as lymph node metastasis and adjacent normal tissues.

RESULTS: EPR-1 expression was distributed in the cytoplasm of normal gastric mucosa, carcinoma cells and smooth muscle cells. The positive rate of EPR-1 expression in the primary gastric adenocarcinomas, invasion tumor node and lymph node metastasis was 65.83%, 55.29% and 68%, respectively. While the positive rate in normal gastric mucosa and smooth muscle cells was 46.7% and 53.3%, respectively. The average positive rate of ki-67 in EPR-1-positive tumors was 7.00% which was significantly lower than that of 8.53% in EPR-1-negative tumors, but the average AI in EPR-1-positive tumors was 1.25%, which was significantly higher than that of 1.00% observed in EPR-1-negative tumors. On the other hand, the average positive labeling index for Ki-67 (ki-67) in EPR-1-positive lymph node metastasis was 7.65%, which was significantly lower than that of 9.44% observed in EPR-1-negative lymph node metastasis. However, the average AI in EPR-1-positive lymph node metastasis tumors was 0.99%, which was significantly higher than that of 0.67% observed in EPR-1-negative lymph node metastasis.

CONCLUSION: The frequency of EPR-1 expression was significantly higher in primary gastric adenocarcinoma and in its lymph node metastasis than that in normal gastric mucosa. Expression of EPR-1 was significantly correlated with tumor histological subtypes and tumor differentiation. Weighted EPR-1 Score is positively correlated with apoptosis

index, but is negatively related with proliferative index. Thus, Weighted EPR-1 Score and EPR-1 expression in gastric adenocarcinoma cells maybe a potential marker in clinical setting.

INTRODUCTION

Gastric cancer is the second most common malignancy worldwide. Approximately 95% of all malignant gastric neoplasms are adenocarcinoma. This study aimed to investigate the correlation among expression of EPR-1, proliferative index (PI, also referred to as ki-67) and apoptosis index (AI) in patients with primary advanced gastric adenocarcinoma and to clarify the significance of EPR-1 expression in human primary gastric adenocarcinoma, its lymph node metastasis and adjacent non-tumor tissues.

MATERIALS AND METHODS

Patients and tissue samples

Primary gastric adenocarcinoma specimens from 120 patients who had undergone gastrectomy in the period of January 1991 and December 1995 were selected from the files of the Pathology Department, Nanjing Jinling Hospital. None of the patients had received chemotherapy or radiotherapy before surgery. There were 72 males and 48 females, with a median age of 64.8 years (range, 45-78 years). Samples were taken from the representative cancerous lesions as well as lymph node metastasis and adjacent non-cancerous mucosa.

Specimens of the adenocarcinoma were classified into papillary adenocarcinoma, tubular adenocarcinoma, mucinous adenocarcinoma and signet-ring cell carcinoma. Each subclass had 30 cases.

For formalin-fixed and paraffin-embedded tissue specimens, consecutive 4- μ m thick sections were cut and representative sections were used for immunohistochemistry (IHC) and haematoxylin-eosin (H&E) staining as well as the terminal deoxynucleotidyl transferase (TdT)-mediated dUTP-biotin nick end-labeling (TUNEL) for apoptotic index. Using the H&E-stained sections, the tumor histology according to Lauren's grade of tumor differentiation and criteria of the World Health Organization were reassessed. Tumors were staged according to TNM classification.

Immunohistochemistry

The deparaffinized and rehydrated slides were boiled in a 10 mmol/L EDTA buffer (pH 8.0) for 5 min in an autoclave at 121 °C. The sections were immunohistochemically stained by

the labeled streptavidin-biotin peroxidase method (LSAB2 Kit; Dako Japan Inc., Kyoto, Japan) with the following primary antibodies: monoclonal antibodies EPR-1 (ADI, Alpha Diagnostic International, dilution 1:100), and Ki-67 (Maxim, China, dilution 1:50). The slides were immersed for 10 min in 3 mL/L hydrogen peroxide/methanol to deplete endogenous peroxidase. Then, nonspecific binding sites were blocked with 3 mL/L normal goat serum for 10 min. The primary antibody was then applied, and the sections were incubated overnight at 4 °C. After washed with PBS (0.01 mol/L pH7.4), biotinylated goat antimouse IgG was applied onto the tissue sections and incubated at room temperature for 10 min. After washed with PBS, a streptavidin peroxidase reagent was applied and incubated at room temperature for 10 min. Finally, the reaction product was visualized using developing color by incubating the slides in a solution of 3 mL/L hydrogen peroxide and AEC chromogen. The sections were counterstained slightly with hematoxylin. Negative controls included parallel sections treated without the primary antibody, in addition to negat an adjacent section of the same block in which the primary antibody was replaced by phosphate-buffered saline (PBS).

TUNEL staining

For detection of apoptotic cells, apoptotic index was examined by the terminal deoxynucleotidyl transferase-mediated deoxyuridine triphosphate fluorescence nick end labeling (TUNEL) method. TUNEL: *In situ* cell death detection kit POD (ISCCD, Boehringer Mannheim, Germany) was used to detect the apoptotic cell. The procedures was according to the protocol of the kit and other references. Briefly, the sections were deparaffinized, rehydrated, and washed in distilled water (DW). The tissues were digested with 20 g/mL proteinase K (Boehringer Mannheim, Mannheim, Germany) at room temperature for 15 min. Endogenous peroxidase activity was blocked by incubating it in 3 mL/L hydrogen peroxide/methanol in PBS at 37 °C for 30 min. The sections then were incubated with terminal deoxynucleotidyl transferase at 37 °C for 60 min, and dioxigenin-conjugatd dUTP was added to the 3' -OH ends of fragmented DNA. Anti-dioxigenin antibody peroxidase was applied to the sections to detect the labeled nucleotides. The sections were stained with DAB and counterstained slightly with hematoxylin. The positive cells were identified, counted and analyzed under the light microscope.

Evaluation of EPR-1 expression

Two experienced pathologists in a blinded fashion (without knowledge of the clinico-pathological features of the tumors) examined the expression of EPR-1 and Ki-67 independently in terms of intensity and positive rate of the immunostaining in each specimen tissue section. The positive staining for EPR-1 protein was expressed as red brown granules, which were mainly located in cell cytoplasm at microscopy. At least 5 high-power ($\times 400$ field) fields were chosen randomly and 1 000 cells were counted. The ratio of EPR-1-positive cells was calculated by dividing the number of positive cells over the total number of cells, and was expressed as percentage.

For quantitation of the EPR-1 expression in various samples examined, a semi-quantitative scoring system was used as previously described^[1]. An average percentage of positive tumor cells was determined in at least five areas at $\times 400$ magnification and assigned to one of the five categories: (a) $0 \leq 5\%$, (b) $1 = 5-25\%$, (c) $2 = 25-50\%$, (d) $3 = 50-75\%$, and (e) $4 \geq 75\%$. The intensity of EPR-1 immunostaining was scored on a scale of 1-3 as following: (a) weak, 1+; (b) moderate, 2+; and (c) intense, 3+. The percentage of positive tumor cells and the staining intensity were multiplied to produce a weighted score for each case. The case with the weighted score less than 1 was defined as negative, otherwise as positive.

Ki-67-positive cells showed a distinct brown staining of the nuclei with strong intratumoral heterogeneity (Figure 1). The percentages of Ki-67-positive tumor cells were evaluated with a light microscope holding a $\times 100$ oil immersion objective by scoring a minimum of 1 000 tumor cells in randomly selected fields.

Figure 1 Immunohistochemical staining patterns of Ki-67 in gastric adenocarcinomas. Positive nuclear staining in LSAB, $\times 200$. Poorly-differentiated adenocarcinoma, demonstrated cell proliferative activity.

The percentage of apoptotic cells was calculated as the number of TUNEL-positive cancer cells per 1 000 cancer cells in the most frequently identified areas, and determined as the apoptotic index (AI). Under microscopy, morphological evidences of cell shrinkage, nuclear chromatin condensation, formation of cytoplasmic blebs and apoptotic bodies were frequently observed as the characteristic changes of apoptosis cells (Figure 2).

Figure 2 Apoptotic cancer cells in well-differentiated adenocarcinoma detected by TUNEL method. LSAB, $\times 200$.

Statistical analysis

Data were expressed as mean \pm SD. The two-tailed χ^2 test was used to examine the correlation between various clinical or pathologic parameters and the expression of EPR-1. Statistical significance between different groups was determined by independent Student's *t*-test (two-tailed). The Pearson test was used to examine linear correlation between Weighted EPR-1 Score and proliferative or apoptotic indexes. A *P* value less than 0.05 was considered statistically significant. All the calculations were performed by SPSS 10.0 for windows.

RESULTS

Correlation between EPR-1 protein expression and clinicopathological parameters

No significant relation was found between the expression of EPR-1 and patient age, sex, tumor location, lymph node metastasis or depth of invasion (Table 1, *P* > 0.05).

Table 1 No Correlation between EPR-1 protein expression and clinicopathological parameters

Clinico-pathological parameters	Cases	EPR-1 positive cases (%)	P value

**Figure 3** Strong Positive cytoplasm staining of EPR-1 in gastric adenocarcinomas (LSAB×400).**Figure 4** Positive staining of EPR-1 in signet-ring cell carcinoma invasion in smooth muscle and smooth muscle cells (LSAB×200).**Figure 5** Moderate positive nuclear staining in benign gastric adenocytes (LSAB×200).**Figure 6** Positive cytoplasm staining in well-differentiated lymph node metastasis (LSAB×200).

Expression of EPR-1 between histological subtypes

There were a variety of positive rates of EPR-1 protein in different histological subtypes (Figures 3, 4, 5, 6 and Table 2). The positive rate of EPR-1 expression nodes was significantly different in the invasive tumor ($P=0.007$), while it was differently expressed among the 4 subtypes and adjacent non-tumor tissues in the primary carcinoma and its lymph node metastasis ($P<0.05$). But there was no difference of EPR-1 expression in the adjacent normal gastric mucosa cells and smooth muscle cells among the 4 histological subtypes ($P=0.849$ and 0.720).

Expression of EPR-1 in the highly-differentiated adenocarcinomas

The positive rate of EPR-1 expression in the primary gastric adenocarcinoma was significantly higher than that in normal gastric mucosa (Table 3, $P=0.006$), while no significant difference was found in the invasion tumor nodes, lymph node metastasis and smooth muscle ($P=0.20$, 0.632 , 0.088), respectively. However, in the primary highly-differentiated gastric adenocarcinomas, the positive expression rate of EPR-1 was significantly different from that of normal gastric mucosa, invasive tumor node, lymph node metastasis and smooth muscle while no significant difference was found in the poorly-differentiated adenocarcinomas.

Relation of EPR-1 expression with AI and PI in primary adenocarcinoma

The apoptotic index for EPR-1 positive in primary adenocarcinoma group was 1.25% and was 1.00% for EPR-1 negative group, while the proliferative index for the two group was 7.00% and 8.53%, respectively. The difference of the two indexes between the EPR-1 positive and negative groups was statistically significant (Table 4, $P<0.05$). The relation of EPR-1 score with AI and PI is shown in Figure 7.

Figure 7 Significant difference of AI and PI with EPR-1 score in primary adenocarcinoma. A: The results of Pearson correlation coefficient, $r=0.296$, $P=0.001<0.05$; B: The results of Pearson correlation coefficient, $r=-0.204$, $P=0.025<0.05$. Weighted EPR-1 Score was positively correlated with apoptotic index, but negatively related with proliferative index in primary adenocarcinoma.

Figure 8 Significant difference of AI and PI with EPR-1 score in lymph node metastasis. A: The results of Pearson correlation coefficient, $r=0.332$, $P=0.019<0.05$. B: The results of Pearson correlation coefficient, $r=-0.336$, $P=0.017<0.05$. Weighted EPR-1 score is positively correlated with apoptosis index, but negatively related with proliferative index in lymph node metastasis.

Table 2 Different expression of EPR-1 between histological subtypes

Subtypes	Primary carcinoma	<i>P</i> value	Normal gastric mucosa	<i>P</i> value	Invasion node	<i>P</i> value	Lymph node metastasis	<i>P</i> value	Smooth muscle cell	<i>P</i> value

DISCUSSION

Effector cell Protease Receptor-1 (EPR-1) has been recognized as a receptor of the transmembrane glycoprotein coagulation factor Xa and its transcripts are present in terminally differentiated adult tissues^[2-9]. Survivin gene was identified by Ambrosini *et al.* during hybridization screening of a human EPR-1 genomic library with the cDNA of EPR-1^[10,11]. The gene spanned nearly 15 kb and was co-located at 17q25 with EPR-1^[12]. Survivin has been found to be a new member of the inhibitors of apoptosis proteins (IAP) family^[13-16], and is selectively overexpressed in common human cancers but not in normal adult tissues.

Transfecting with EPR-1 mRNA into cells could inhibit endogenous expression of survivin gene and induce apoptosis as well as inhibit cell proliferation^[17]. Shinozawa *et al.*^[18] used RT-PCR method to detect the expression of Survivin and EPR-1 in leukemia and lymphoma, and found that the abnormality of the expression ratio of EPR-1 and Survivin might exert anti-colon tumor proliferation functions. Yamamoto *et al.*^[19] reported that EPR-1 in a human colon cancer cell line downregulated survivin expression, with a similar decrease in cell proliferation and an increase in apoptosis. This antitumor efficacy was further enhanced in combination with anticancer agents 5-Fu and CDDP. These findings suggest that regulation of survivin by induction of EPR-1 may have a significant potential as a therapy for human cancer. But to our knowledge, EPR-1 expression in gastric adenocarcinoma has not been reported.

In order to gain insight into the role of EPR-1 in gastric adenocarcinoma, we investigated the expression of EPR-1 in a group of gastric adenocarcinomas, and examined the relationship of its expression with cell proliferation and apoptosis index. By immunohistochemical analysis performed in 120 cases, our study shows that positive staining for EPR-1 protein was expressed as red brown granules, which were mainly located in cell cytoplasm. There was no significant relationship between the expression of EPR-1 and patient age, sex, tumor location, lymph node metastasis or depth of invasion. However, a significantly different expression of EPR-1 was found between histological subtypes.

Our study also explored the potential relationship between the Weighted EPR-1 expression score and apoptotic, proliferative indexes. Ki-67 has been regarded as a parameter of tumor proliferation^[20-29] and the TUNEL method has become a popular way to detect apoptotic cells^[30-32]. Using these two reliable methods, we found that the positive rate of EPR-1 expression in the primary gastric adenocarcinoma was significantly higher than that in normal gastric mucosa and in terms of degree of differentiation, the positive expression rate of EPR-1 was significantly different among the primary gastric adenocarcinoma, normal gastric mucosa, tumor invasive node, lymph node metastasis and smooth muscle in the highly-differentiated adenocarcinomas while no significant difference was found in the poorly-differentiated adenocarcinomas.

In conclusion, EPR-1 can influence the biological behaviors of tumor cells not only by inducing their apoptosis, but by inhibiting their proliferation. Whether EPR-1 can be used as a new anti-cancer therapeutics strategy is still waiting for more evidence.

Abstract

AIM: To investigate the chemopreventive effects of 1 α , 25-dihydroxyvitamin D₃ in diethylnitrosamine induced, phenobarbital promoted rat hepatocarcinogenesis.

METHODS: The rats were randomly divided into 6 different groups (A-F). Groups A, C and E rats received a single intraperitoneal (i.p) injection of diethylnitrosamine (DEN) at a dose of 200 mg/kg body mass in 9 g/L NaCl solution at 4 wk of age, while group B served as normal vehicle control received normal saline once. After a brief recovery of 2 wk, all the DEN treated rats were given phenobarbital (PB) at 0.5 g/L daily in the basal diet till wk 20. Group A was DEN control. Treatment of 1 α , 25-(OH)₂D₃ in group C was started 4 wk prior to DEN injection and continued thereafter till wk 20 at a dose of 0.3 μ g/100 μ L propylene glycol per one single dose (os) twice a week. Group E received the treatment of 1 α , 25-(OH)₂D₃ at the same dose mentioned as above for 15 wk. The rats in group D and F received 1 α , 25-(OH)₂D₃ alone as in group C without DEN injection.

RESULTS: The comet assay showed statistically higher mean values for length to width ratios (L: W) of DNA mass and tailed cells ($P < 0.01$; $P < 0.01$ respectively) in DEN treated rats as compared to their normal controls. Continuous supplementation of 1 α , 25-dihydroxyvitaminD₃ showed a significant ($P < 0.01$) decrease in L:W ratio of DNA mass tailed cells. Furthermore, 1 α , 25-(OH)₂D₃ supplementations elevated the super oxide dismutase (SOD) activity, hepatic malondialdehyde (MDA) level, reduced glutathione (GSH) and glutathione S-transferase (GST) activity ($P < 0.01$, $P < 0.05$, $P < 0.05$ and $P < 0.05$ respectively). As an endpoint marker histological changes were observed to establish the chemopreventive effects of 1 α , 25-dihydroxyvitaminD₃.

CONCLUSION: Supplementations of 1 α , 25-(OH)₂D₃ has

a marked protection against hepatic nodulogenesis, antioxidant enzymes and DNA damages in DEN induced rat hepatocarcinogenesis promoted by phenobarbital.

INTRODUCTION

1 α , 25dihydroxyvitaminD₃ plays an important role in reducing the incidence of carcinomas of breast, prostate and colon in human as well as in experimental animals^[1,2]. 1 α , 25(OH)₂D₃ has been shown to promote the differentiation of cancer cells and cell lines *in vitro*^[3,4]. Little information is available for the antioxidant property of 1 α , 25(OH)₂D₃ in the inhibition of chemical rat hepatocarcinogenesis^[5]. A number of micronutrients, macronutrients and non-nutrients have been reported as the chemopreventive agents in the carcinogenesis^[6]. Vitamin D₃ treatment of mice with GM-CSF-secreting tumors can interrupt the myelopoiesis-associated immunosuppressor cascade and reduce tumor metastasis^[7]. Various new vitamin D analogues are developed with increased growth inhibitory and reduced calcemic activity, but significant antiproliferative and differentiation-inducing agents have now been synthesized and may be used as anticancer drugs^[8,9]. Polychlorinated biphenyls, phenobarbital and many other compounds that induce hepatic biotransformation enzymes promote experimental hepatocarcinogenesis in rodents previously exposed to initiating carcinogens^[10]. Several mechanisms for liver tumor promotion by PB and other inducing xenobiotics have been documented^[11].

Number of methods are available for detecting DNA damage, as opposed to the biological effects of DNA damaging agents (e.g., micronuclei, mutations, structural chromosomal aberrations) have been used to identify substances with genotoxic activity. The alkaline elution assay ignores the critical importance of intercellular differences in DNA damage and requires relatively large numbers of cells. The full approach for assessing DNA damage is the single-cell gel electrophoresis (SCG) or comet assay^[12]. Identification of different cell populations can be made by a modified alkaline comet assay^[13,14]. Comet assay can be used to identify possible human mutagens and carcinogens^[15] and DNA damage of human hepatoma cells irradiated by heavy ions^[16]. The alkaline comet assay has been very popular for the analysis of DNA damage caused by various chemical and physical agents^[17-20]. The genetic damages in leprosy patients undergoing multidrug treatment are also measured by comet assay^[21].

Free radical species are involved in carcinogenesis, superoxide dismutases catalyze the dismutation of super-oxide

radical to hydrogen peroxide and oxygen^[22]. Chemical induction of liver carcinoma is associated with changes in the oxygen radical metabolism in liver. The changes in hepatic oxygen radical metabolism were demonstrated by measurement of the antioxidant enzymes SOD. Tumour cells have abnormal activities of antioxidant enzymes, and decreased activities of SOD in tumour cells^[23,24]. The influence of oxygen-derived free radicals on survival in advanced colonic cancer was assessed in a prospective randomized controlled double-blind trial using the radical scavengers^[25]. Compounds that can scavenge excessive free radicals in the body are suggested to hinder the process of carcinogenesis.

The present study was undertaken to investigate the effectiveness of 1 α , 25(OH)₂D₃ on the development of hepatic nodules, the cytogenetic effects of DEN induced rat hepatocarcinogenesis determined by comet assay and the antioxidant enzymes in diethylnitrosamine induced rat hepatocarcinogenesis promoted by phenobarbital.

MATERIALS AND METHODS

Chemicals

All the reagents and biochemicals, unless otherwise mentioned, were obtained from Sigma Chemical Co. (St. Louis, MO, USA).

Animals

Male Sprague-Dawley rats (80–100 g) were purchased from the Indian Institute of Chemical Biology (CSIR), Kolkata, India. They were given the standard laboratory diet purchased from Lipton, India. The animals were housed in an air-conditioned room (22±1 °C, relative humidity 50±10%) with a 12-h light/dark cycle in Tarson cages (4 rats per cage) and were acclimatized for 1 wk before the start of the experiment. Guidelines for the care and use of the laboratory animals (National Institute of Health, USA) were followed during the experiment and approved by the Institutional Animal Ethics Committee (IAEC), Jadavpur University, Kolkata.

Experimental regime

The rats were randomly divided into 6 different groups with 10 rats in each as illustrated in Figure 1. Groups A, C and E rats received a single intraperitoneal (i.p.) injection of DEN (Sigma) at a dose of 200 mg/kg body mass in 9 g/L NaCl solution at 4 wk of age while group B served as normal vehicle control (received normal saline once). After a brief recovery of 2 wk, all the DEN treated rats were given PB at 0.05% daily in the basal diet till wk 20. Group A was DEN control. Treatment of 1 α , 25(OH)₂D₃ in group C was started 4 wk prior to DEN injection and continued thereafter till wk 20 at a dose of 0.3 µg/100 µL propylene glycol *per os* (*opus sit*) twice a week. In group E 1 α , 25(OH)₂D₃ treatment at the same dose mentioned as above was started 1 wk after DEN injection and continued thereafter till the completion of the experiment. The animals of groups D and F served as 1 α , 25(OH)₂D₃ controls for groups C and E that received 1 α , 25(OH)₂D₃ (Sigma, MO, USA) at a dose of 0.3 µg/100 µL propylene glycol *per os* twice weekly for 20 wk. All the treatments were withdrawn at wk 20 and the rats were sacrificed at wk 21 under proper ether anaesthesia.

Comet assay

Comet assay was performed on liver tissue under alkaline conditions following the procedure of Ward *et al.*^[26], with minor modifications. All the steps of comet assay were conducted under yellow light to prevent the occurrence of additional DNA damage. After sacrifice, liver of either lobe was excised, minced and homogenized in 50 µL of phosphate-buffered saline (PBS; pH 7.5). Briefly, 4 µL of homogenized tissue samples was diluted

with 50 µL of PBS and mixed with 150 µL of 10 g/L low melting point agarose (37 °C) prepared in PBS and pipetted onto an 10 g/L normal melting agarose precoated slide, which had been dried overnight, and covered with a coverslip. After the slide was kept on a chilled plate for 10 min, the coverslip was removed and the slide was lowered into freshly made ice-cold lysis solution (2.5 mol/L NaCl, 100 mmol/L EDTA, 10 mmol/L Tris, 100 g/L DMSO, 10 g/L Triton X-100, pH 10) and kept at 4 °C in the dark for 60 min. After draining the lysis solution, the slide was rinsed with distilled water for 15 min. After washed twice in the prepared distilled water, the slide was placed in a horizontal electrophoresis tank containing freshly made buffer (300 mmol/L NaOH and 1 mmol/L EDTA, pH>13) for 30 min. Electrophoresis was performed in the same buffer for 20 min by applying an electric field of 25 V (0.8 V/cm) and adjusting the current to 300 mA by slowly changing the buffer level in the tray. After electrophoresis the slide was rinsed gently with 0.4 mol/L Tris-Hcl buffer (pH 7.5) for 5 min, this step was again repeated. Then the slide was dried at room temperature and kept in a refrigerator in a sealed container until analysis. Duplicate slides were prepared for all the samples.

The slides were immersed in distilled water for 30 min, then stained with 100 µL of ethidium bromide (5 µg/mL) and read at 250× using a Zeiss fluorescence microscope equipped with a green excitation filter and a 590 nm barrier filter. All slides were coded and examined blindly. Routinely 100 cells (50 cells/slide) were screened per sample. In selecting cells for measurements, straight line scanning of a slide was begun at an arbitrary point and cells were measured as they came into the field, provided there was no overlap with patterns from other cells. The length and width of the DNA mass were measured using an ocular micrometer disk. Under these conditions a DNA pattern with a ratio of one had a DNA length of -25 µm and a ratio of four had a DNA length of -100 µm. The length: width ratios of the DNA mass and the frequency of tailed (damaged) cells were used in all comparisons.

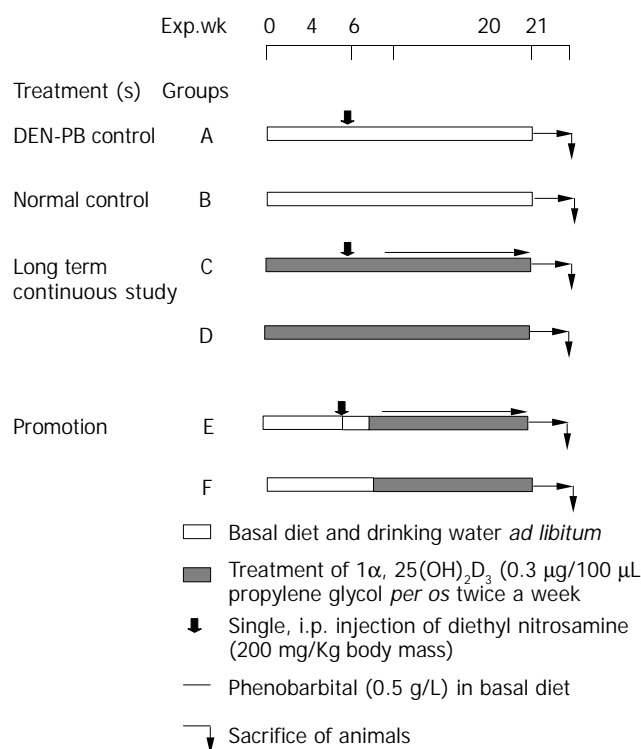

Figure 1 Basic experimental protocol.

Morphology and morphometry of liver tissue

After the rats were sacrificed, their livers were excised from all

treated and control rats, weighed and examined on the surface for subcapsular macroscopic lesions (hyperplastic nodules; HNs). The nodules with approximate spheres were measured in 2 perpendicular directions to the nearest millimeter into three categories namely ≥ 3 , $< 3 - > 1$ and ≤ 1 mm^[27].

Histopathological examination

For histopathological examination and morphometric analysis, tissues were fixed in 40 g/L buffered formaldehyde and the fixed paraffin embedded sections were stained with hematoxylin and eosin (H&E).

Histochemical detection of γ -glutamyl transpeptidase-positive foci

After sacrifice of the rats, each liver was examined of the right, left and caudate lobes. They were fixed in an ice-cold mixture of dehydrated ethanol and glacial acetic acid (19:1) for 4 h followed by an overnight incubation in 995 mL/L ethanol at 4 °C and then embedded in soft paraffin (melting point 47 °C). Two contiguous paraffin sections were made from each liver section for γ -glutamyl transpeptidase (GGT) histochemistry according to the method of Rutenberg^[28]. Quantitative evaluation of GGT-positive foci (lesions smaller than a liver lobule mainly visible microscopically) was performed according to the method of Campbell^[29].

Biochemical assays

The animals were sacrificed with proper anaesthesia. Liver of either lobes was minced and homogenized with 0.25 mol/L sucrose and the homogenate was centrifuged at 9 000 g (33 000 r/min) for 15 min in refrigerated centrifuge (Megafuge 1.0R). The pellet was discarded and an aliquot of supernatant was kept for the assay of cytosolic enzyme activities. The left portion was recentrifuge at 105 000 g for 90 min in refrigerated centrifuge (Megafuge 1.0R). The microsomal fraction was prepared separately from hyperplastic nodule (HNs) and non-nodular surrounding parenchyma (NNSP) liver area and untreated normal control liver. All the operations were done at 0-4 °C.

The activity of superoxide dismutase (SOD) was measured by following the method of Beyer and Fridovich^[30]. Hepatic cytosolic enzymatic lipid peroxidation was estimated according to the method of Okhaw *et al.*,^[31] based on the formation of malondialdehyde (MDA). The reduced glutathione (GSH) level was quantified by the method of Ellman^[32]. Hepatic cytosolic glutathione S-transferase (GST) activity was determined with 1-chloro 2,4-dinitrobenzene as the substrate according to the method of Habig *et al.*^[33].

Statistical analysis

Data were analyzed statistically for differences between the means using Dunnett's *t*-test when more than one group was compared against a control group. *P*-value < 0.05 was considered statistically significant.

RESULTS

Dietary intake

Daily food and water intake of all the groups of rats was same. Daily intake of water was measured with a measuring cylinder and it was found that each rat took on an average of 8-10 mL water per day.

Body and liver mass

The effect of $1\alpha, 25(\text{OH})_2\text{D}_3$ on body and liver mass of different group of rats sacrificed after 20 wk is shown in Table 1. Body mass of DEN control group rats (group A) were slightly lower ($P < 0.05$) than that of the normal control rats (group B). Treatment with $1\alpha, 25(\text{OH})_2\text{D}_3$ increased the final body mass of

the animals in groups C, D, E and F which received $1\alpha, 25(\text{OH})_2\text{D}_3$ as compared with group A carcinogen control. This suggested that treatment with $1\alpha, 25(\text{OH})_2\text{D}_3$ had no adverse effect on the growth response of rats. Liver masses of rats in various groups showed no significant differences. The relative liver mass of DEN control group rats (group A) was found to be significantly increased ($P < 0.01$) than that of normal control rats (group B). Treatment with $1\alpha, 25(\text{OH})_2\text{D}_3$ significantly ($P < 0.05$) reduced the relative liver masses of rats in groups C, D, E and F compared with group A. $1\alpha, 25(\text{OH})_2\text{D}_3$ supplied rats showed a better resistance against hepatocarcinogenesis.

Table 1 Body and liver masses in each group of rats at end of the study (after 20 wk) (mean \pm SE)

Group	No of rats	Body mass (g)	Liver mass (g)	Relative liver mass (g) (Liver/100 g body mass)
A	6	282.5 \pm 15.8 ^a	14.6 \pm 2.6	5.16 \pm 0.47 ^b
B	10	338.0 \pm 18.3	10.8 \pm 1.9	3.19 \pm 0.21
C	8	334.3 \pm 13.8 ^c	12.3 \pm 1.8	3.67 \pm 0.36 ^e
D	10	348.9 \pm 21.6	11.9 \pm 1.5	3.41 \pm 0.29
E	8	308.1 \pm 19.1	13.1 \pm 2.2	4.25 \pm 0.45
F	10	336.6 \pm 22.2	12.1 \pm 1.8	3.59 \pm 0.42

Statistical level of significance by using Dunnett's *t*-test. ^a $P < 0.05$,

^b $P < 0.01$, significantly different from normal control (group B),

^c $P < 0.05$, ^e $P < 0.05$, significantly different from DEN control (group A).

Effect of $1\alpha, 25(\text{OH})_2\text{D}_3$ on induction of GGT-positive foci

Table 2 shows that GGT-positive foci developed in all the DEN treated groups (Groups A, C and E), while the livers of rats in normal as well as $1\alpha, 25(\text{OH})_2\text{D}_3$ control groups (groups B, D and F respectively) were found to be normal in terms of histochemical observations of GGT-positive foci. In group E supplementation of $1\alpha, 25(\text{OH})_2\text{D}_3$ inhibited the appearance of GGT-positive foci (45.25%). But $1\alpha, 25(\text{OH})_2\text{D}_3$ treatment which was started 4 wk before DEN administration and continued till the end of the experiment minimized the appearance of GGT-positive foci most significantly in group C (68.80%) than in DEN treatment. Thus $1\alpha, 25(\text{OH})_2\text{D}_3$ decreased significantly ($P < 0.01$) GGT-positive foci in group C compared to the DEN control (group A).

Table 2 Effect of $1\alpha, 25(\text{OH})_2\text{D}_3$ on inhibition of GGT-positive foci in DEN induced rat hepatocarcinogenesis promoted by phenobarbital (mean \pm SE)

Effect of $1\alpha, 25(\text{OH})_2\text{D}_3$ on hepatic histopathology

Histopathological examination of liver sections from normal untreated group B (Figure 5) revealed normal liver parenchymal cells with granulated cytoplasm and small uniform nuclei radially arranged around the altered cell foci with granulated cytoplasm and small uniform nuclei radially arranged around the central vein. In the DEN treated groups A, C and E, phenotypically altered hepatocytes in altered liver cell foci and nodules at varying extent were noticeable throughout the hepatic parenchyma. The hepatocellular architecture of DEN control (group A) was found to be grossly altered and the hepatocytes became oval

in shape. The altered liver cells in foci and nodules were considerably enlarged, vesiculated and binucleated (Figure 4). A substantial irregularity (enlargement) in the shape of nucleus and chromatin pattern (chromatin condensation) were also observed. The nucleocytoplasmic ratio was increased in sinuses and greatly dilated with hyperplastic Kupffer cells. The cytoplasm was extensively vacuolated, continued masses of acidophilic material were observed. Supplementation of $1\alpha, 25(\text{OH})_2\text{D}_3$ for the entire period study (group C) elicited a maximum protection against DEN induced hepatocarcinogenesis, which was reflected in almost normal hepatocellular architecture. In group C liver cells were found to contain compact cytoplasmic material with only clear cell foci (Figure 6). The nucleocytoplasmic ratio was decreased considerably as compared to group A. The configuration of sinuses appeared normal with normal Kupffer cells. The size of nuclei resembled that of normal cells and binucleated cells were extremely less. A moderate improvement of hepatic histological picture was observed in $1\alpha, 25(\text{OH})_2\text{D}_3$ supplemented group C in comparison to group E. A considerable vacuolation was still observed in the cytoplasm and the compactness of hepatocytes was somewhat disturbed in group C. The liver sections from these groups presented a predominance of clear cell foci rather than eosinophilic or basophilic foci. There was a slight decrement in nucleocytoplasmic ratio in the cells with respect to group A with slightly dilated sinuses. The number of binucleated cells was less as compared to group A with normal size nuclei.

Effect of $1\alpha, 25(\text{OH})_2\text{D}_3$ on incidence, number and size of hepatocellular lesions

The carcinogen treated rats showed 100% nodule incidence in group A as compared to the normal control rats (group B). The incidence of HNs was lower in the rats that received $1\alpha, 25(\text{OH})_2\text{D}_3$ and DEN in groups C and E (Table 3). The average number of nodules/nodule-bearing livers (nodule multiplicity) was also found to be less in $1\alpha, 25(\text{OH})_2\text{D}_3$ supplemented group C (60%) as compared to group A. The result was statically significant ($P<0.01$) in group C compared with group A. The total number of nodule 22 and the average nodule bearing livers (3.66 ± 0.68) in group C were compared with the DEN control (group A). Group C rats showed the lowest value in each range compared with the other groups (groups A and E). In the present study the relative size distribution of nodules revealed that supplementation of $1\alpha, 25(\text{OH})_2\text{D}_3$ characteristically reduced the appearance of HNs more than 3 mm in size in group C compared to group A.

Effect of $1\alpha, 25(\text{OH})_2\text{D}_3$ on comet Assay

The results of comet assay based on mean tailed cells (TC) (%) and mean length: width ratios (L: W) in hepatic cells of rats treated with DEN are shown in Table 4. The mean length to width ratio of the DNA mass observed in DEN control rats (group A) was significantly greater ($P<0.01$) compared with the normal control group B. Similarly, the mean frequency of tailed cells was (84 ± 0.020) in DEN control rats and significantly different ($P<0.01$) from the normal control (29 ± 0.008). Figures 2 and 3 illustrate the distribution of L: W and TC in DEN control

(group A), normal (group B), long term study (group C), and promotion study (group E). For length: width ratio and tailed cells, the median values were higher in DEN control (group A) compared with the normal control (group B). The distribution of damage cells was also wider and the lengths of the boxes were greater in DEN control rats, indicating larger interquartile ranges than that of the normal controls rats. The median line in normal control rats (group B) were tailing towards smaller values. In group C and group E the median lines were in the middle of the boxes, the distribution of TC was more or less symmetrical. In group C $1\alpha, 25(\text{OH})_2\text{D}_3$ offered more than 54.09% in the length and width ratio and 53.37% of tailed cells compared to group A.

Table 4 Effect of $1\alpha, 25$ dihydroxyvitamin D₃ on DNA damage [based on mean tailed cells (%) and mean length: width ratios \pm SEM of DNA pattern] in hepatic cells of rats during DEN induced rat hepatocarcinogenesis promoted by phenobarbital (mean \pm SE, $n=100$)

Effect of $1\alpha, 25(\text{OH})_2\text{D}_3$ on hepatic super oxide dismutase activity

Table 5 depicts the SOD activity. A significant decrease ($P<0.01$) was found in SOD activity in HNs and NNSP tissues in DEN control (group A) compared with the normal control (group B). A significant increase ($P<0.05$) in SOD level was observed in both HNs and NNSP tissues in group C rats, where $1\alpha, 25(\text{OH})_2\text{D}_3$ treatment started 4 wk before DEN administration and continued till the end of the experiment. In group E $1\alpha, 25(\text{OH})_2\text{D}_3$ was supplemented only for 15 wk, starting the treatment 1 wk after DEN administration showed no statistical significance in SOD activity.

Effect of $1\alpha, 25(\text{OH})_2\text{D}_3$ on hepatic cytosolic lipid peroxidation

$1\alpha, 25(\text{OH})_2\text{D}_3$ had effect on hepatic cytosolic lipid peroxidation (Table 6) in different groups of rats treated with DEN, which was promoted by phenobarbital. A significant increase in the total content of MDA ($P<0.01$) was observed in DEN control rats (group A), both HNs and NNSP liver area in group A were compared with normal control. A significant decrease ($P<0.05$) in elevated hepatic MDA level was found in group C when compared with DEN control. Supplementation of $1\alpha, 25(\text{OH})_2\text{D}_3$ led to a significant reduction in total MDA production in DEN treated rats. The maximum effect was observed in group C rats whose $1\alpha, 25(\text{OH})_2\text{D}_3$ treatment was started 4 wk before DEN administration and continued till 20 wk, which offered a better protection in group E, in which $1\alpha, 25(\text{OH})_2\text{D}_3$ was supplemented for only 15 wk, starting 1 wk after DEN administration.

Table 6 Changes in total hepatic lipid peroxidation (nmol MDA/100 mg protein) level in different groups of rats treated with $1\alpha, 25(\text{OH})_2\text{D}_3$ during DEN induced rat hepatocarcinogenesis promoted by phenobarbital (mean \pm SE, $n=5$)

Groups	Nodules	Surrounding	Control

Figure 6 Shows section of rat liver (group C) initiated with DEN and supplemented with $1\alpha, 25(\text{OH})_2\text{D}_3$ [0.3 μg /100 μL propylene glycol per os twice a week for 20 wk] showing almost normal hepatic architecture (HE $\times 325$).

Effect of 1 α , 25(OH)₂D₃ on 1-chloro-2, 4-dinitro benzene (CDNB) conjugated hepatic cytosolic glutathione S-transferase (GST) activity in different groups

Table 8 depicts the GST activity with CDNB in different experimental groups. DEN control rats showed (group A) a significantly increase ($P < 0.01$) more than 2-fold in NNSP compared with the normal control, but HNs showed a significantly decrease in value. Altered activity of 1 α , 25(OH)₂D₃ was found in group B. Groups C and E also showed higher altered activity of 1 α , 25(OH)₂D₃ than the normal control rats. 1 α , 25(OH)₂D₃ was found to be more effective in the inhibition of rat liver carcinogenesis ($P < 0.05$) in abating the GST activity. 1 α , 25(OH)₂D₃ control groups (groups D and F) had no statistical significance in the GST activity when compared with normal control.

Table 8 Changes in activity of 1-chloro-2, 4-dinitro benzene (CDNB) conjugated (μmol CDNB conjugated/ mg protein/ mL) hepatic cytosolic glutathione S-transferase (GST) in different groups of rats treated with 1 α , 25(OH)₂D₃ during DEN induced rat hepatocarcinogenesis promoted by phenobarbital (mean \pm SE, $n=5$)

DISCUSSION

The results of our present investigation clearly demonstrated that long term supplementation of 1 α , 25(OH)₂D₃ (at a dose of 0.3 $\mu\text{g}/100 \mu\text{L}$ propylene glycol twice a week) greatly reduced the incidence of hepatic nodulogenesis, antioxidant enzymes and genetic damage in DEN induced rat hepatocarcinogenesis promoted by phenobarbital. Previous studies in our laboratory have shown that long term supplementation of 1 α , 25(OH)₂D₃ in combination with vanadium could effectively inhibit DEN-induced rat liver carcinogenesis^[34-36].

DEN is a well-known hepatocarcinogen in rats, forming DNA-carcinogen adducts in the liver and inducing hepatocellular carcinomas without cirrhosis through the development of putative preneoplastic enzyme-altered hepatocellular focal lesions^[37]. After limited treatment with DEN, the rats ended up with a large benign hepatomas^[35,38], which were equivalent to neoplastic nodules and highly differentiated hepatocarcinomas. The preneoplastic lesions were thought to be the possible precursors of hepatic cancer in experimental animals and humans^[39]. Treatment with hepatocarcinogen could result in the proliferation of oval cells. These cells have been shown to have the ability to differentiate into hepatocytes^[40]. The results of our present investigation clearly indicated that long term supplementation of 1 α , 25(OH)₂D₃ could reduce the incidence, multiplicity and size of visible HNs more than 3 mm in size. Preneoplasia (γ -glutamyl transpeptidase -positive and glucose 6-phosphate negative) appeared in 1 α , 25(OH)₂D₃ treated animals 1 wk after carcinogen withdrawal, but livers from 1 α , 25(OH)₂D₃ depleted rats exhibited an increase in the number of GGT-positive foci. There was no change in the body masses among the groups under study. This is particularly important because nutritional deprivation causing body mass loss might result in a decrease in tumor volume^[41]. Thus 1 α , 25(OH)₂D₃ had the maximum effect in reducing the number and nodule growth, which were not mediated through the impairment of nutritional status in the experimental animals. 1 α , 25(OH)₂D₃ effect

observed in this study might be important for cancer prevention.

Comet assay is sensitive, a small number of cells and substances are required. It is inexpensive, and easy to apply to any tissues. The tissue selection in our study was based on a recent data analysis of the mice and rats^[42]. Comet assay can be applied to any tissues *in vivo*. In comet assay DNA is organized as loops, retaining the super coils and circular structure that are contained in the nucleosome. Epidemiological studies showed that comet tail was made up of relaxed loops and that the number of loops in the tail could indicate the number of DNA damages and tailed cells consisting of fragments of DNA^[43]. This study indicated a significantly higher incidence of DNA damage in the DEN-PB control compared with the normal control. In the present investigation, 1 α , 25(OH)₂D₃ protected against the DNA damage in DEN induced rat hepatocarcinogenesis.

SOD is the first line of defense of the cellular antioxidant system against the oxidative damage mediated by superoxide radicals. Life is continuously exposed to oxidative stress, cells are equipped with gene regulatory mechanism that can sense a high oxidative stress potential and consequently induce higher levels of several enzymes capable of reducing reactive oxygen species and repairing oxidative damage. The antioxidant enzymes are thus a major cell defense against acute oxygen toxicity. Their function is to protect membrane and cytosolic components against damage caused by free radicals. SOD, catalase and glutathione peroxidase (GPx) exemplify some of the most important ones. SOD, catalase could convert oxygen into hydrogen peroxides and water, SOD could diminish the damage caused by superoxide-producing agents as long as the generated hydrogen peroxide was removed by glutathione peroxidase and catalase does not become rate limiting^[44,45]. The enzyme GPx and glutathione reductase were then destroyed either by catalase or by enzyme system, these 2 systems could convert hydrogen peroxide into water at the expense of NADPH, using reduced GSH as an electron donor^[46]. Differences were found between normal and cancer cell superoxide dismutase activity in the treatment of cancer^[47]. The SOD ratio was lower in liver cells, and this might provide an explanation for the higher susceptibility of tumor cells to treatments likely to involve oxygen radicals^[48,49]. Our present results showed that 1 α , 25(OH)₂D₃ supplementation in group C inclined towards normal and in group E no change was found. Decreased antioxidant activity could cause the accumulation of free radicals. However, there was no change in SOD activities in group E rats, which might be due to the inactivated gene not reactivated by 1 α , 25(OH)₂D₃ supplementation, the physiological characterization and the genetic mapping of the mutant should identify the gene.

Lipid peroxidation plays an important role in carcinogenesis, treatment with inhibitors of lipid peroxidation, such as vitamins D, E, C, as well as selenium and vanadium and beta-carotene are protective agents^[36,50-52]. Stimulation of NADPH-dependent microsomal lipid peroxidation was proposed to be mediated by ADP/Fe²⁺, NADPH-cytochrome P-450 reductase and cytochrome P-450^[53]. Therefore, the increase of one of these modulators in the liver could explain the reduced lipid peroxidation. Previous studies in our laboratory showed that a significant increase in the total content of MDA was observed in DEN control compared to normal control^[50,54]. In our present study a significant increase in lipid peroxidation was observed in DEN PB-treated rats (group A) when compared with normal control rats (group B). But it was found in group C most significant ($P < 0.05$) compared to DEN-PB control. Treatment with 1 α , 25(OH)₂D₃ abated the production of MDA in different DEN-PB treated rats (groups C and E). The ability of 1 α , 25(OH)₂D₃ to inhibit iron dependent lipid peroxidation in liposomes might be important in protecting the membranes of normal cells against free radical induced oxidative damage^[55]. Thus, the oxygen

radical formation and detoxification, which result in lipid peroxidation and tissue damage, may be prevented.

GSH occurred primarily in the soluble phase, part of it conjugated with foreign compounds or their metabolites for detoxification and transport from body in the precancerous stage, GSH concentration in rat liver increased^[56-58]. From our study increased level of GSH in DEN control rats (group A), might be that GGT catalysed the degradation of extracellular GSH that can be used in the intracellular GSH synthesis^[59]. $1\alpha, 25(\text{OH})_2\text{D}_3$ supplemented groups C and F rats showed decrease in GSH levels. The significantly decreased GSH level in group C reflected the chemopreventive mechanism, by promoting the formation of additional pyridine nucleotides to provide hepatocytes with reduced properties and to inhibit the growth and spread of neoplastic nodules.

GST catalyzes the reaction of compounds with -SH group and thus neutralizes their electrophilic sites and produces more water soluble products. The evolution of thiol dependent detoxification pathways was initially the result of the availability of molecular oxygen^[60]. The cellular defence against oxygen free radicals and peroxides is of considerable importance to cell survival. Since the initial report of elevated expression of GST activity in nitrogen mustard resistant cell line^[61], a number of different tumors have been found to overexpress GST isoenzymes. In MCF-7 human breast cancer cell line, there appeared to have a coordinately increased expression of both GST- π and other enzymes including selenium dependent glutathione peroxidase and SOD^[62]. An increased GST activity was observed in metabolic inactivation and resistance to several anticancer drugs^[63]. In the present study, an increased activity of GST was observed in DEN control rats (group A). Decreased activity of GST was observed in groups C and F. But the significant decrease ($P < 0.05$) in GST activity was found in group C supplemented with $1\alpha, 25(\text{OH})_2\text{D}_3$. The increased anti-cancer drug resistance of one or more of the GST isoenzymes in resistant cells was compared with normal cells^[64].

$1\alpha, 25(\text{OH})_2\text{D}_3$ is very much effective in preventing DEN-PB induced changes in hepatocytes possibly through the inhibition of nodular growth, GGT-positive foci development, normalization of DEN induced changes in enzyme activities and prevention DNA damages in DEN-induced rat hepatocarcinogenesis. The results of our present study strongly suggest that $1\alpha, 25(\text{OH})_2\text{D}_3$ may be important for cancer prevention.

Abstract

AIM: To study the significance of p16 and p15 transcription suppression with hypermethylation of their genes' 5' CpG islands during human hepatocellular carcinogenesis.

METHODS: The mRNA expression levels of p16 and p15 genes were evaluated in cancerous, para-cancerous and non-cancerous tissues of 20 HCC, 3 normal liver tissues from 3 accidentally died healthy adults using semi-quantitatively Northern blot. The methylation status was also assessed with methylation specific PCR.

RESULTS: p16 mRNA expression level was decreased in the cancerous tissues in 60% (12/20) of HCC patients, of which 2 cases had no p16 mRNA detected, 5 cases (25%) displayed variation in the order of cancerous<para-cancerous<non-cancerous liver tissues. p15 mRNA expression level was decreased in the cancerous tissues in 50% (10/20) HCC patients, of which one case had no p15 mRNA detected, 4 cases (20%) displayed variation in the order of cancerous<para-cancerous<non-cancerous liver tissues. In cancerous, para-cancerous and non-cancerous tissues, p16 promoter CpG islands hypermethylation occurred 65%, 60% and 35%, while p15 promoter CpG islands hypermethylation occurred 50%, 40% and 25%. Of 12 HCCs with lower p16 mRNA expression level, 11 cases showed p16 promoter CpG islands methylation (91.6%). Hundred percent (10/10) HCCs with lower p15 mRNA expression level showed p15 promoter CpG islands methylation. Significant correlation between 5' CpG islands methylation and p16/p15 mRNA expression suppression was found. The decreased expression of p16/p15 mRNA or methylation of p16/p15 promoters 5' CpG island was significantly correlate with poor differentiation of HCC ($P=0.0083$, 0.0102 , 0.00271 , 0.0218 , respectively, $P<0.05$).

CONCLUSION: p16 and p15 genes transcriptional inactivation might play an important role in hepatocarcinogenesis. 5' CpG islands methylation might be the major mechanism of p16 and p15 genes inactivation in primary HCC in the studied

population. 5' CpG islands methylation of p16 and p15 genes might be an early event in hepatocarcinogenesis.

INTRODUCTION

Hepatocellular carcinoma (HCC) is one of the most common causes of death from cancer in China. The mechanisms of hepatocellular carcinogenesis are not yet expounded although alterations of some cell cycle tumor suppressor genes have been revealed to be involved in hepatocellular carcinogenesis. p16INK4a and p15INK4b are homologous cell cycle tumor suppressors, which are within 30 kb of one another on chromosome 9p21 region and in the same transcription orientation. p16INK4a has 3 exons whereas p15INK4b is encoded by 2 exons. They act as competitive inhibitors by binding directly to CDK4 and CDK6 and prevent their association with a cyclin, which in turn arrest the cells in late G1 phase of the cycle with pRB in a hypophosphorylated state^[1-4].

Although the high frequency of P16 protein expression deficiency or low expression in HCC was reported, the rate of p16 gene homozygous deletion and mutation is much lower than P16 protein expression deficiency. This suggested that there might be another mechanism inactivating p16 and p15 genes in human primary hepatocarcinoma^[5-9].

It has been demonstrated that aberrant methylation of CpG islands, which are CpG dinucleotide rich region located mainly in the promoter regions of many gene, serves as an alternative mechanism for inactivation of the tumor suppressor gene in cancers^[10]. Recently, aberrant methylation of the p16 and p15 promoters has been reported^[11-16]. The discordant events in which low P16 protein expression was not accompanied with deletion or mutation could be resulted from the low mRNA expression level of p16 gene due to hypermethylation of its CpG islands. To further study the association of hypermethylation of CpG islands in p16 and p15 genes with disrupted transcription of the corresponding genes in hepatocarcinogenesis, and to address the question whether the expression of p16 and p15 genes, as well as CpG island methylation of p16 and p15 genes is related to the differentiation degrees of HCC, the mRNA expression of p16 and p15 genes, as well as their CpG island methylation status in 20 HCCs was studied.

MATERIALS AND METHODS

Samples and extraction of total RNA and DNA

With informed consent of patients and ethics committee approval, surgically resected tumor, adjacent cancerous as well as non-cancerous tissue samples from 20 HCC patients, and

normal liver tissues from 3 accidentally died healthy adults were collected in West China Hospital of Sichuan University. The diagnosis of HCC was confirmed histologically in all cases.

Total RNA was extracted from 100 mg frozen tissue specimen with one-step guanidine thiocyanate-phenol method and dissolved in 5 g/L SDS solution. Genomic DNA was isolated from 100 mg frozen tissue specimen by digestion with proteinase K, followed by standard phenol-chloroform extraction and ethanol precipitation. The concentration of RNA and DNA was calculated according to their A_{260} values.

The genomic DNA of human plasmacytoma cell line HS-Sultan, which had p16 and p15 CpG islands methylation, was kindly gifted by Dr. Lo YM in Chinese University of Hong Kong. It was used as a methylation control for methylation specific PCR.

Northern blot hybridization

The plasmid that contained complete sequences of p16 cDNA or p15 cDNA was kindly gifted by Dr. D Beach in Cold Spring Harbor Laboratory. The 0.8 kb cDNA fragment of p16 and 2 kb cDNA fragment of p15 were nick translated with non-radiated digoxin using Boehringer Mannheim random primer DNA labeling kit. A 0.9 kb cDNA fragment of γ -actin was used as control probe. The total RNA (20–30 μ g) was fractionated on 1% agarose-formaldehyde gel and blotted onto nylon membrane (Bio-Rad) by capillary transfer. The hybridization was carried out in a solution containing 70 g/L SDS, 500 g/L formamide, 20 mL/L blocking reagent, 50 mmol/L sodium phosphate, pH7.0, 1 g/L sarcosyl, 5 \times SSC, 80 ng/mL probe. The hybridization and the subject signal chemiluminescent imaging were performed according to the manufacturer's manual. Every membrane was sequentially hybridized with p16, p15 and γ -actin cDNA probe after the bound probe was washed with 5 g/L SDS.

The intensity of the hybridization signal was scanned with UVP GDS8000 and quantited with Gelworks of UVP. To calculate the relative expression level of p16 or p15 gene, the hybridization signal intensity of γ -actin was employed as internal control to correct the unidentical amount of RNA loaded in electrophoresis, because γ -actin gene has a stable expression in various tissues.

Bisulfite conversion of DNA

Bisulfite modification and methylation specific PCR were conducted based on the principle that bisulfite treatment of DNA would convert unmethylated cytosine residues into uracil, whereas methylated cytosine residues would remain unmodified. Thus, the sequence-specific primers would distinguish the bisulfite converted unmethylation sequences and the unmodified methylation sequences by U and C.

The chemical modification was performed essentially as described previously with minor modification^[17]. DNA (1–2 μ g) in a volume of 50 μ L was denatured by NaOH (final concentration, 0.2 mol/L) for 10 min at 37 °C. Totally 520 μ L of 3 mol/L sodium bisulfite at pH5.0 and 30 μ L of 10 mmol/L hydroquinone, both freshly prepared, were added. After being mixed, the samples were incubated under the cover of mineral oil at 56 °C for 16 h. The modified DNA was desalted with the Wizard DNA purification resin and eluted in 50 μ L of water. For alkali desulphonation, an equal volume of 0.6 mol/L NaOH was added to an eluted DNA and incubated for 5 min at room temperature, modified DNA was precipitated with sodium acetate and ethanol and resuspended in 30 μ L of water. The DNA was stored at -70 °C.

Methylation specific PCR

The primers were designed for the CpG islands in promoter

and the first exon region of both p16 and p15 genes. All bisulfite-converted DNA samples were amplified with primers specific for methylated p16 or p15 sequence, and also amplified with primers specific for unmethylated p16 or p15 sequence. The sense and antisense primers for methylated p16 sequence were 5' TTATTAGAGGGTGGGGCGGATCGC3' and 5' GACCCGAACCGCGACCGTAA3'. The sense and antisense primers for unmethylated p16 sequence were 5' TTATTAGAGGGTGGGGTGGATTGT3' and 5' CAACCCCAAACCACAACCATAA3'. The sense and antisense primers for methylated p15 sequence were 5' GCGTTCGTATTTTGCGGTT3' and 5' CGTACAATAACCGAACGACCGA3'. The sense and antisense primers for the unmethylated p15 sequence were 5' TGTGATGTGTTTGTATTTTGTGGTT3' and 5' CCATACAATAACCAAACAACCAA3'. The 25 μ L of PCR mixture contained 50 ng of modified DNA, 200 μ mol/L each dATP, dGTP, dCTP and dTTP, 1 μ mol/L each primer, 50 g/L DMSO, 2.5 mmol/L MgCl₂, 1 \times reaction buffer and 1.5 U Taq polymerase. The PCR conditions were as follows: one cycle of at 95 °C for 5 min, 35 cycles of at 95 °C for 30 s, at 65 °C for 30 s (p16 methylation primers) or at 60 °C for 30 s (p16 unmethylation primers, p15 methylation and unmethylation primers), at 72 °C for 45 s, and 1 cycle of at 72 °C for 7 min. A 10 μ L of PCR products was then electrophoresed on a 25 g/L agarose gel, stained with ethidium bromide, and visualized under UV illumination in UVP GDS8000 gel imaging system^[17].

Statistical analysis

The difference in the p16 and p15 mRNA expression between cancer and noncancer tissue was analyzed using *t* test. The correlation of p16 or p15 gene mRNA expression level with its corresponding methylation of CpG islands was analyzed using Fisher's exact test. The correlation of between mRNA expression, and methylation of p16 and p15 genes with pathologic characteristics was also analyzed with Fisher's exact test. A *P* value <0.05 was considered statistically significant.

RESULTS

p16 and p15 mRNA expression in human hepatocarcinoma

After Northern blot hybridization, the 1.3 kb transcript of p16 mRNA, 3.8 kb transcript of p15 mRNA, 2.1 kb transcript of γ -actin mRNA were detected.

As shown in Figure 1, there was a decrease in p16 mRNA expression level in the cancerous tissues in 60% (12/20) of HCC compared with their corresponding para-cancerous and non-cancerous liver tissues, and p16 mRNA signal was not detected in 2 cases (10%). Five cases (25%) displayed variation in the order of cancerous <para-cancerous <non-cancerous tissues. The mRNA expression level of p16 gene in cancerous tissues was significantly lower than that of non-cancerous liver tissues (*P*<0.05).

p15 mRNA expression level was decreased within the cancerous tissues in 50% (10/20) of HCC, and p15 mRNA was not detected in 1 case. Four cases displayed variation in the order of cancerous <para-cancerous <non-cancerous tissue. The mRNA expression level of p15 gene in cancerous tissues was significantly lower than that of non-cancerous liver tissues (*P*<0.05).

Methylation status of the 5'CpG islands of p16 and p15 genes

Hypermethylation of p16 promoter CpG islands occurred in cancerous tissues (65%, 13/20), and also in para-cancerous tissues (60%, 11/20,) and non-cancerous tissues (35%, 7/20). Four cancerous tissues exhibited only the methylation band,

while the others showed methylation and unmethylation bands, suggesting partial methylation (Figure 2)^[11,13,18].

Aberrant promoter methylation of p15 gene was detected in 50%(10/20) of patients with HCC. Among them, the methylation was found only in cancerous tissues in 2 cases, in both cancerous and para-cancerous tissues in 3 cases, in all of cancerous, para-cancerous and non-cancerous tissues in 5 cases. The partial methylation occurred in all of the non-cancerous tissues. None of the 3 healthy subjects displayed p16 or p15 methylation, whereas they displayed unmethylated p16 and p15 alleles (Figure 3).

Reciprocal relationship between mRNA expression of p16/p15 and their promoter methylation status

Significant correlation between 5' CpG island methylation and low mRNA expression of p16/p15 was found in the 20 HCCs ($P<0.05$). Among 12 HCCs, which displayed lower p16 mRNA expression level in cancerous tissue, 11 cases showed p16 promoter 5' CpG island methylation (91.6%). Similar event took place in p15 gene. All of 10 HCCs with decreased p15 mRNA expression in cancerous tissue had 5' CpG island hypermethylation (100%), while unmethylation occurred in non-cancerous liver tissue. Interestingly, 1 case displayed no detectable transcript p15 gene in cancerous tissue with hypermethylation (Table 1).

The relationship between mRNA expression, or methylation and pathologic characteristics

Significant correlation either between decreased p16/p15 mRNA expression and poor cellular differentiation of HCC, or between p16/p15 promoters 5' CpG islands methylation and poor differentiation of HCC was found ($P=0.0083$, 0.0102 , 0.00271 , 0.0218 , respectively, $P<0.05$). However, there was no significant correlation between p16/p15 mRNA expression and HBV infection or cirrhosis, or between their promoter methylation and HBV infection or cirrhosis (Table 1).

DISCUSSION

Our study showed that a decreased p16 mRNA expression level was detected within cancerous tissues in 60% of HCCs compared with their corresponding non-cancerous tissues, 5 of which displayed in turn variation in cancerous tissue less than in para-cancerous tissue, then in non-cancerous liver tissues. It was interesting that among the 12 cases with lower p16 mRNA expression, 9 cases were accompanied with p16 gene promoter partial methylation in cancerous tissues, while 2 cases were accompanied with complete methylation. In contrast, methylation was not detected in normal liver tissues from 3 accidentally died subject. The partial methylation of p16 gene promoter may explain why the p16 mRNA expression just decreased but not loss in majority of HCCs. It has been reported that partial loss of expression of p16 was associated with low level of methylation rather than complete loss^[11,19,20]. The relationship between p16 mRNA expression and its promoter CpG island methylation has been demonstrated in other studies. Kaneto *et al.*, using methylation specific PCR and immunohistochemistry, had detected methylation of p16 promoter in HCC (72.6%, 16/22) and loss of expression in all methylation positive HCC^[13]. Roncalli *et al.* reported that methylation of p16 promoter with complete loss of immunoreactivity occurred in 27 of 33 HCC (82%)^[15]. Thus, our result, which was consistent with other reports, suggested that association of p16 gene 5' CpG island methylation with transcription inactivation might play an important role in hepatocarcinogenesis, and 5' CpG island methylation was the major mechanism of p16 gene inactivation.

Like the alteration of p16 gene, a decreased p15 mRNA expression level was found within cancerous tissue in 50% of HCC compared with their corresponding non-cancerous liver tissues. All cases that had a lower transcription level of p15 were in conjunction with the hypermethylation of p15 promoter CpG island. Roncalli *et al.* detected methylation of p15 islands in 42% of HCC (14/33), and methylation positive HCC had a

complete loss of immunocytochemical expression of p15. Wong *et al.* reported a high frequency of p15 methylation (64%, 15/25) in HCC. Yang *et al.* showed methylation of p15 in 49% of HCC^[14-16]. Based on Northern blot analysis, our study found that a complete loss of p15 mRNA expression accounted for a small portion of the p15 methylation positive cases, while the majority had decreased transcription level. This discrepancy of our result with other studies might be due to the high sensitivity of Northern blot analysis. Nevertheless, our result provided further evidence from different aspect for the contribution of the epigenetic alteration to inactivation of p15 gene in hepatocarcinogenesis.

In our present study, partial methylation of p16 and/or p15 promoter was detected in 50% of non-cancerous liver tissues (10/20). However, the p16/p15 positive liver tissue still expressed mRNA of p16/p15 genes. It was very interesting to note that a complete methylation of p16 promoter CpG island was present in cancerous tissue while partial methylation in non-cancerous tissues. A similar phenomenon of p15 gene alteration occurred in 2 cases. This supported the hypothesis that methylation of cell cycle inhibitor gradually accumulate in the transition from cirrhosis or chronic hepatitis to HCC^[13,15]. Yu *et al.* detected that hypermethylation of the p16 promoter CpG islands occurred overwhelmingly in HCC samples (56.6%, 17/29) and less frequently in adjacent non-cancerous tissues (21.9%, 6/29) after analyzing the methylation profiling of 20 promoter-CpG islands of genes in human primary hepatocellular carcinoma. Therefore, they thought that hypermethylation of p16 promoter CpG islands may occur at very late stage of the hepatocarcinogenesis^[21]. Edamoto *et al.* showed that higher rate of promoter methylation of p16 in HCCs (59%) than in cirrhotic liver (21%) or chronic hepatitis lesions (0/10)^[22].

Our study also showed that in the non-cancerous liver tissues, the frequency of p15 partial methylation was higher in cirrhosis (44%, 4/9) than non-cirrhosis (9%, 1/11). Also the rate of p16 partial methylation was higher in cirrhosis (44%, 4/9) than non-cirrhosis 27%, 3/11), although these results had no statistical significance probably due to the few studied cases (Data not shown). The percentage of p16 methylation in cirrhosis was reported 29.4% by Kaneto *et al.*, and 39% by Roncalli *et al.*^[13,15]. The frequency of p15 methylation reported by Roncalli *et al.* was 33%^[15]. Roncalli *et al.* noted that p15 was responsible for the early methylation pattern in cirrhosis but not in HCC. They proposed that p15 but not p16 was necessary for the inactivation of other genes in the transition from cirrhosis to HCC^[15]. Nevertheless, the methylation of p16 and p15 might be the major mechanism to inactivate cell-cycle inhibitor in preneoplastic stage.

The correlation between either decreased p16/p15 mRNA expression or p16/p15 promoter CpG island methylation and poor differentiation of HCC was determined in our present study. Interestingly, the correlation of loss of p16 protein expression with the cellular differentiation of HCC and gastric cancer has been reported^[23,24]. Park *et al.* also noted that inactivation of p16 exon 1 by DNA hypermethylation occurred during the progression of tumor cells to poorly differentiated HCC, which was induced by diethylnitrosamine plus thioacetamide in Fischer 344 rats^[25]. These studies suggested that the aberrant alteration of mRNA expression and methylation of p16 and p15 genes might be not only involved HCC carcinogenesis but also associated with its progress.

Although the mechanism of methylation in cancers remains to be explained clearly, it has been generally recognized that two methyltransferases, Dnmt1 and Dnmt3b cooperatively maintain DNA methylation and gene silencing in human cancer cells^[26-28]. It has been reported that higher expression of methyltransferases was associated with methylation of p16

and p15 genes in HCC^[29]. It has been noted that either the inhibitors of methyltransferase, such as 5-aza-2'-deoxycytidine and tea-polyphenol (-)-epigallocatechin-3-gallate or antisense inhibitors of DNA methyltransferases, reactivated silenced tumor suppressor genes and inhibited the growth of cancer cells^[30-33].

Thus, methylation of 5' CpG islands of p16 and p15 genes might be an early event in hepatocarcinogenesis. The methylation of p16 and p15 genes could be a biomarker for monitoring HCC and other tumors, which was demonstrated by recent studies^[14,34,35,36]. It also provides an insight into therapy of the high risky patients and prevention of HCC.

Abstract

AIM: To explore whether P-glycoprotein (Pgp) and other pumps, multidrug resistance-associated protein (MRP) and lung resistance protein (LRP), could affect tumor accumulation and efflux of ^{99m}Tc -MIBI in liver cancer.

METHODS: Surgically treated 78 liver cancer patients were included in this study. Before surgery, ^{99m}Tc -MIBI SPECT was performed 15 min and 120 min after injection of 20 mCi ^{99m}Tc -MIBI, respectively. Early uptake, delayed uptake (L/Nd), and washout rate (L/Nwr) of ^{99m}Tc -MIBI were obtained. Expressions of Pgp, MRP and LRP were investigated with Western blotting and immunohistochemistry. Messenger RNA (mRNA) level of Pgp, MRP and LRP was determined by RT-PCR.

RESULTS: No ^{99m}Tc -MIBI uptakes in tumor lesions of 68 of 78 (87.2%) patients with hepatocellular carcinoma were found on ^{99m}Tc -MIBI SPECT. P-gp expression was observed in tumor tissues of the patients with no uptake of ^{99m}Tc -MIBI ($P < 0.017$). No appreciable correlation was found between liver cancer ^{99m}Tc -MIBI images and expression of MRP or LRP on the level of protein or mRNA.

CONCLUSION: ^{99m}Tc -MIBI SPECT is noninvasive, and useful in predicting the presence of MDR1 gene-encoded Pgp in patients with hepatocellular carcinoma.

INTRODUCTION

Multidrug resistance (MDR) is the main barrier to efficient chemotherapy of human malignancies. MDR has been closely associated with overexpression of multidrug resistance genes (MDR1)^[1] and has been observed in hepatocellular carcinomas (HCC)^[2]. The MDR phenotype has been defined on the basis

of cellular drug targets involved Pgp, MRP, LRP and atypical MDR (mediated through altered expression of topoisomerase type II)^[3-6]. Pgp, encoded by MDR1 gene, is a 170-ku transmembrane glycoprotein and acts as an adenosine triphosphate (ATP)-driven drug efflux pump to reduce drug accumulation^[7]. MRP is a 190-ku membrane-bound glycoprotein and can act as a glutathione S-conjugate efflux pump by transporting drugs that are conjugated or cotransported with glutathione^[8,9]. Both Pgp and MRP are integral membrane proteins belonging to the ATP-binding cassette (ABC) superfamily of transporter proteins, which appear to confer resistance by decreasing intracellular drug accumulation^[10]. In contrast, LRP is not an ABC transporter protein. LRP has recently been identified as a vault protein, which is a typical multisubunit structure involved in nucleocytoplasmic transporter^[11]. Determination of these MDR proteins at the time of diagnosis is imperative to the development of rational therapeutic strategies for preventing drug resistance.

^{99m}Tc -MIBI is a cationic lipophilic agent, widely used for myocardial perfusion imaging to detect various tumors^[12-18]. Recent evidence has shown that ^{99m}Tc -MIBI is a suitable transport substrate for Pgp and may provide additional information about the Pgp status of tumor cells^[19,20]. It has been reported that MIBI is accumulated within mitochondria and cytoplasm of cells based on transmembrane electrical potentials. Malignant tumors show increased transmembrane potential as a result of increased metabolic requirements that induce increased accumulation of MIBI in tumors^[21]. The potential advantage of ^{99m}Tc -MIBI imaging lies in its superiority in detecting the presence of Pgp overexpression *in vivo* noninvasively^[22,23]. Recently, ^{99m}Tc -MIBI efflux has been shown to be a substrate for MRP *in vivo*^[24].

^{99m}Tc -MIBI imaging or SPECT was performed in various cancers^[25,26], but no clinical studies in HCC have been found. The aim of this study was to determine whether Pgp and other pumps, MRP and LRP, could affect tumor accumulation and efflux of ^{99m}Tc -MIBI in hepatocellular carcinoma.

MATERIALS AND METHODS

Patients

Seventy-eight patients (30 women, 48 men, aged 24-71 years, mean 54 ± 1.6 years) with HCC were enrolled in the study, 70 of 78 (89.7%) patients were hepatitis B surface antigen positive, 2 (2.6%) were anti-hepatitis C virus positive, and the remaining had no known cause of HCC. No patients previously received chemotherapy. All patients underwent ^{99m}Tc -MIBI SPECT prior to surgery. All tumor samples were analyzed with RT-PCR, Western blotting and immunohistochemistry.

^{99m}Tc -MIBI SPECT

Liver imaging was performed with a double-head gamma camera equipped with a high-resolution parallel-hole collimator (PRISM 2000; Marconi Medical Systems, Cleveland, OH). Images were obtained 15 and 120 min after injection of 20 mCi ^{99m}Tc -MIBI, respectively. Early and delayed SPECT of the liver was performed

on all patients. For SPECT of the liver, 72 projections were obtained using 64×64 matrix at 45 s per view. Image reconstruction was performed using filtered back projection with Butterworth and ramp filters. Transverse, coronal, and sagittal sections were reconstructed. Attenuation correction was not applied.

SPECT images were compared with liver CT images, and accumulation in liver tumors was interpreted by nuclear medicine physicians. The findings on ^{99m}Tc-MIBI livers were measured semiquantitatively. Regions of interest (ROIs) were manually defined on the transaxial tomograms showing the lesion's highest uptake in center of the tumor. ROIs placed on the lesions (L) encompassed all pixels that had uptake values of >90% of the maximum uptake in that slice, and the average rate in each ROI was calculated. Another ROI of the same size was then drawn over the normal lung (N) on the same transverse section. The early uptake (L/Ne) and the delayed uptake (L/Nd) were obtained. The washout rate (L/Nwr) was calculated using the following formula: $L/Nwr = (L/Ne - L/Nd) \times 100 (L/Ne)$.

Immunohistochemical study

After resection of HCC, immunohistochemical study of the biopsy or resected tumor tissues and surrounding nontumorous liver parenchyma was performed. Four-micrometer-thick, formalin-fixed, paraffin-embedded tissue sections were cut from the specimens and mounted on poly-L-lysine-coated glass slides (Sigma Chemical Co., St. Louis, MO). The standard avidin-biotin-peroxidase complex (ABC) technique was used for immunostaining using a LSAB kit (Dako Co., Carpinteria, CA).

After deparaffinization and rehydration, the sections were treated with 1 mL/L methanol hydrogen peroxide for 20 min to block endogenous peroxidase activity, incubated with normal horse serum for 30 min at 37 °C, and with primary antibody, JSB-1 (1:20), MRP1 (1:10), LRP-56 (1:10) overnight in a moist chamber at 4 °C. The tissue sections were incubated with avidin-biotin-peroxidase complex. The final reaction product was

revealed by exposure to 0.3 g/L diaminobenzidine, and the nuclei were counterstained with Mayer's hematoxylin.

A negative control was obtained by staining the sample with secondary antibody and a positive control by inclusive of a normal liver. The results of immunostaining were interpreted independently by two pathologists who were unaware of the imaging studies. Expressions of Pgp, MRP and LRP were scored as follows: -, negative; +, ≤10% positive tumor cells; ++, ≤30% positive tumor cells; +++, >30% positive tumor cells.

Quantitative RT-PCR

RT was performed with random primers with a complementary DNA (cDNA) synthesis kit (Promega, Madison, WI). RT-reaction reagents were added as follows: 2 μL of MgCl₂ (50 mmol/L), 2 μL of reverse transcription buffer (Tris-HCL [PH8.3], 100 mmol/L, KCL 500 mmol/L and Triton X-100 10 g/L), 2 μL of deoxynucleotide mixture (10 mmol/L), 0.5 μL of RNase inhibitor (20U), 2 (15U) of avian myeloblastoma virus reverse transcriptase, 1 μL of random primers (500 μg/mL) and 5 μg substrate RNA. The final volume of the reaction (20 μL) was completed with RNase free water. First strand cDNA synthesis was carried out at 42 °C for 30 min in the DNA thermal cycler (PTC-100, MJ Reserch Inc., Watertown, MA). Afterwards, the tubes were incubated at 99 °C for 5 min to stop the reaction. Then each tube was kept at 4 °C until PCR was performed. Expression of the target genes (MDR1, MRP and LRP) and endogenous reference β-actin was quantified using the primers and standards. The primers were designed using the software Primer Express (Applied Biosystems) (Table 1).

RT-PCR

Expressions of the target genes (MDR1, MRP and LRP) and GAPDH gene were quantified using the primers and standards. The primers were designed using the software Primer Express (Applied Biosystems) (Table 2).

RT-PCR was performed according to the TaqMan 2-step

Table 1 MDR1, MRP, LRP primers for RT-PCR amplifications

method using the ABI PRISM 7 700 sequence detection system (Applied Biosystems). The nontemplate controls, standard dilutions, and samples were assayed. A 25- μm volume of PCR reaction mixture was used, containing 200 ng of the sample cDNA, TaqMan buffer, 200 mmol/L deoxy-ATP, deoxycytidine triphosphate, and deoxy-guanosine triphosphate, 400 mmol/L deoxyuridine triphosphate, 5.5 mmol/L magnesium chloride, 0.025 U/mL AmpliTaq Gold DNA polymerase (Applied Biosystems), 0.01 U/mL AmpErase uracil N-glycosylase (Applied Biosystems), 200 nmol/L forward and reverse primers, and 100 nmol/L probe. PCR cycling conditions included an initial phase at 50 °C for 2 min, followed by at 95 °C for 10 min for AmpErase, 40 cycles at 95 °C for 15 s, and at 60 °C for 1 min. Quantification of the PCR products was based on the TaqMan 5' nuclease assay using the ABI PRISM 7 700 sequence detection system. The starting quantity of a specific mRNA in an unknown sample was determined by preparing a standard cDNA. The standard curve was generated on the basis of the linear relationship between CT value (corresponding to the cycle number at which a significant increase in fluorescence signal was first detected) and logarithm of the starting quantity. The unknown samples were quantified by the software of the ABI PRISM 7 700 sequence detector system, which calculated the CT value for each sample and then determined the initial quantity of the target using the standard curve. The amount of expressed target gene was normalized to that of GAPDH.

Western blotting

Liver cancer samples were analyzed for the presence of Pgp, MRP and LRP protein. Samples were washed in PBS and homogenized in a lysis buffer^[27]. Protein supernatants were quantitated using the Lowry assay, and equal amounts of protein from each sample were separated by SDS-PAGE and electroblotted onto nitrocellulose membranes. Membranes were probed with mAb recognizing Pgp, MRP and LRP (Sigma, Co), respectively. Enhanced chemiluminescence was used for protein detection.

Statistical analysis

The results of L/Ne, L/Nd, and L/Nwr were expressed as mean \pm SD. The differences in L/Ne, L/Nd, and L/Nwr between patients with (-), (+), and (++) Pgp, MRP, and LRP expressions were determined using Student *t* test. The differences in L/Ne, L/Nd, and L/Nwr between patients with high and low Pgp mRNA, MRP mRNA, and LRP mRNA expressions were determined using Student *t* test. If *P* was <0.05, the difference was considered statistically significant.

RESULTS

All the 78 surgically obtained tissue samples were assessed to estimate the levels of Pgp, MRP, and LRP expression on protein and mRNA. Table 3 summarizes the immunohistochemical results and RT-PCR data.

Correlation of ^{99m}Tc -MIBI results with immunohistochemical results

Significant MIBI uptake on ^{99m}Tc -MIBI SPECT was noted in tumor lesions of 10 (12.8%) patients with HCC, but not in tumor lesions of 68 (87.2%) patients with HCC. In patients with MIBI uptake, immunohistochemical analysis of tumor tissues showed no detectable P-glycoprotein-positive cells. But immunohistochemical analysis of tumor lesions in patients without MIBI uptake revealed uniformly distributed P-gp-positive cells. We noted a significant correlation between ^{99m}Tc -MIBI SPECT findings and P-gp expression in tumors of patients with HCC.

MRP and LRP protein expression was found in tumor lesions of 7 and 4 patients, respectively, and no correlation was found with ^{99m}Tc -MIBI.

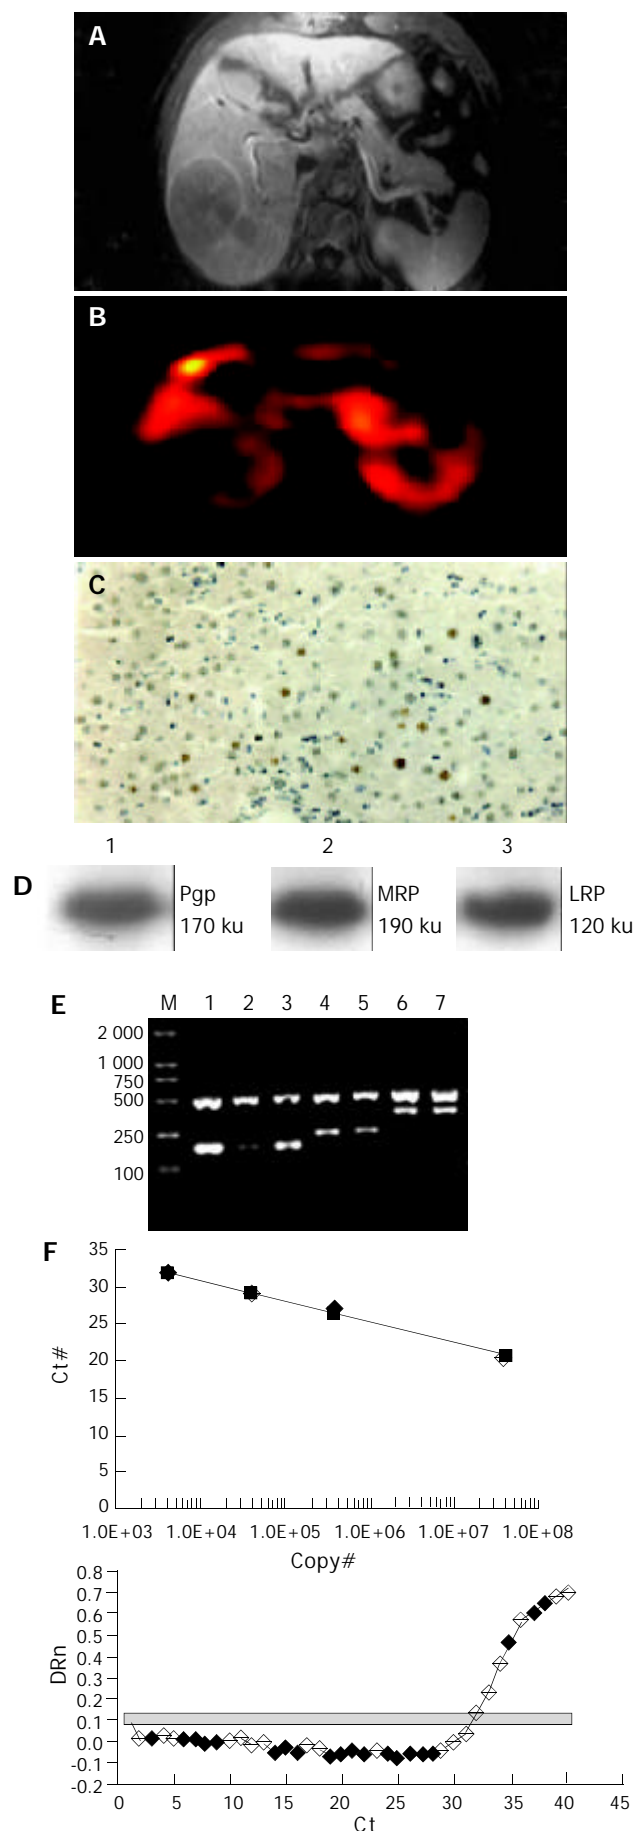

Figure 1 A: CT image of one patient with liver carcinoma. B: ^{99m}Tc -MIBI SPECT Liver image of the patient. C: Immunohistochemical expression of Pgp. D: Western blotting images of Pgp, MRP and LRP. E: MDR1 176 bp, MRP 358 bp, LRP 492 bp shown by RT-PCR image. F: Real time RT-PCR image of Pgp.

Table 3 Patient characteristics and radionuclide imaging

Group	Cases	Tumor size (cm)	^{99m} Tc-MIBI SPECT			Immunohistochemistry			RT-PCR		
			L/Ne	L/Nd	L/Nwr(%)	Pgp	MRP	LRP	mdr1	MRP	LRP
I	68	2.5-15	2.09±0.67	1.25±0.42	54.94±10.23	68 (+)	4 (+)	3 (+)	0.38±0.16	0.04±0.02	0.02±0.01
II	10	1.5-7	1.98±0.56	2.78±0.53	3.07±0.57	10 (-)	3 (+)	1 (+)	0	0.06±0.03	0.03

Correlation of ^{99m}Tc-MIBI with RT-PCR results

No correlation was found between L/Ne and the level of Pgp mRNA, MRP mRNA, and LRP mRNA. The mean L/Nd (2.78±0.64) of the Pgp mRNA low expression group was significantly higher than that (1.25±0.43) of the Pgp high-expression group ($P=0.0115$, Figure 1). L/Nd was not related to the level of MRP mRNA or LRP mRNA. Statistical support was found toward a significant difference in L/Nwr between the Pgp mRNA high-expression group and the Pgp mRNA low-expression group. L/Nwr was not related to the level of MRP mRNA or LRP mRNA.

The grouping was according to the positive immunohistochemistry of Pgp, there were 4 cases positive of MRP and 3 cases positive of LRP in group I, there were 3 cases positive of MRP and 1 case positive of LRP in group II.

DISCUSSION

The resistance of tumors to multiple drugs is a major problem in cancer chemotherapy. Pgp, a transmembrane ATP-dependent efflux pump encoded by MDR1 gene, has a central role in multidrug resistance. Increased amounts of Pgp may confer multidrug resistance to cells by preventing intracellular accumulation of a variety of cytotoxic drugs. A unique feature of multidrug resistance is the apparent capacity of Pgp for recognizing and transporting a large group of cytotoxic compounds sharing little structural or functional similarity other than being relatively small hydrophobic and cationic agents, including anthracyclines, Vinca alkaloids, and actinomycin D. Evidence has shown that Pgp as a drug efflux pump extrudes ^{99m}Tc-MIBI and other drugs from cells and that Pgp expression and enhanced efflux of ^{99m}Tc-MIBI from these cells are closely connected^[28,29]. In animal models, faster clearance of ^{99m}Tc-MIBI was observed in tumors with or without Pgp expression^[30,31]. Our study revealed that the mean L/Nd in Pgp (-) patients was significantly higher than that in Pgp (++) patients ($P=0.035$). Pgp (++) patients had a higher L/Nwr than Pgp (-) patients ($P=0.027$). No correlation was found between L/Ne and Pgp expression. The same results were obtained from mRNA level. Moreover, no correlation was found between MRP and ^{99m}Tc-MIBI SPECT. The same result was obtained from LRP protein and mRNA level. ^{99m}Tc-MIBI uptake by tumor is associated with many factors, including direct mechanisms such as negative transmembrane potential and drug efflux pump and indirect mechanisms such as blood flow and capillary permeability. We considered L/Ne to be more affected by blood flow. In contrast, L/Nd and L/Nwr clearly reflected Pgp expression of intrinsic properties of the tumor.

Until now, there have been some reports about the expression of Pgp in tumor tissues of patients with HCC^[32,33]. Resistance to cancer chemotherapy in HCC resulted from Pgp expression. The specific localization of Pgp and the incidence of Pgp expression in each histological type of HCC were observed. The analysis indicated that the incidence was the lowest in the compact type of HCC, and it was significantly lower than that in the pseudo glandular and trabecular types^[34]. But in our study, mRNA and protein level of Pgp revealed no significant difference in the incidence of Pgp expression in each histological type.

It has been established that MRP belongs to the superfamily of ABC transmembrane transporter proteins and can act as a glutathione S-conjugate efflux pump^[35]. ^{99m}Tc-MIBI was shown

to be a substrate for MRP *in vitro*^[36]. The abilities of Pgp and MRP transporters to wash out ^{99m}Tc-MIBI have been reported to be similar in cell lines, in spite of different possible mechanisms of transport^[37]. However, cardiac muscle showed a low L/Nwr of ^{99m}Tc-MIBI and a low level of Pgp expression but a high level of MRP expression^[38]. In our study, we did not observe any correlation between tumor accumulation or efflux of ^{99m}Tc-MIBI and expression of MRP on protein level or mRNA level in liver cancer. The mechanisms are also unclear.

LRP has been identified as the vault protein involved in nucleocytoplasmic transport. Recently, subcellular accumulation of drugs was found to be localized in cytoplasm and minimally in nuclei in LRP overexpression cells^[39]. As increased cytoplasm concentration of the drug could intensify its contact with the membrane, we proposed that efflux of the drug might be enhanced in LRP overexpression cells. However, we did not find a correlation between tumor accumulation or efflux of ^{99m}Tc-MIBI and expression of LRP. Subcellular accumulation of ^{99m}Tc-MIBI within mitochondria and cytoplasm of cells has been reported to be based on transmembrane electric potentials^[40]. Therefore, efflux of ^{99m}Tc-MIBI was rarely affected by expression of LRP.

Until now, there have been few clinical studies on the relation between Pgp expression and ^{99m}Tc-MIBI uptake in HCC. As ^{99m}Tc-MIBI is cleared through the liver, and it is not easy to detect liver tumors. To the best of our knowledge, our study was the first to show an inverse correlation in MDR1/Pgp expression and ^{99m}Tc-MIBI uptake in HCC. But ^{99m}Tc-MIBI SPECT has some limitations, because it depends on the optimal perfusion of tumor tissues. Poor MIBI penetration could be attributable to poor tumor perfusion in tumors larger than 2.5 cm, where tumor necrosis would be expected. Therefore, perfusion studies such as a Tl-201 scan could be used to eliminate the possibility of poor penetration.

In conclusion, our results suggest that L/Nd and L/Nwr of ^{99m}Tc-MIBI are noninvasive and useful in detecting the expression of Pgp in patients with HCC

Abstract

AIM: Bcl-2/adenovirus E1B 19 ku interacting protein 2-like (BNIP-2) is a novel protein recently identified in our laboratory. BNIP-2 is homologous to human BNIP-2, a potentially proapoptotic protein, and can interact with Bcl-2 and Cdc42GAP and promote apoptosis in BEL-7402 cells. Here we report the gene-expression profile regulated by BNIP-2 in human hepatocarcinoma Hep3B cells and the analysis of its potential roles in cell apoptosis.

METHODS: BNIP-2 was overexpressed in Hep3B cells using tetracycline inducible or Tet-on system. Screened by Western blot, the cells with low background and high induction fold of BNIP-2 were obtained. We performed Atlas human cDNA expression array hybridization on these cells and analyzed the data with Quantarray® software to identify BNIP-2-regulated genes and their expression profile. RT-PCR was used to confirm the altered expression level of part of genes identified by the Atlas array hybridization.

RESULTS: Fifteen of 588 genes spotted on the Atlas membrane showed altered expression levels in BNIP-2-transfected Hep3B-Tet-on cells, in which 8 genes involved in cell apoptosis or growth inhibition were up-regulated and 7 genes involved in cellular proliferation were down-regulated following overexpression of BNIP-2.

CONCLUSION: cDNA array is a powerful tool to explore gene expression profiles under inducible conditions. The data obtained using the cDNA expression microarray technology indicates that BNIP-2 may play its roles in apoptosis through regulating the expression of genes associated with cell apoptosis, growth inhibition and cell proliferation.

INTRODUCTION

Bcl-2/adenovirus E1B 19 ku interacting protein 2-like (BNIP-2) is recently identified and characterized as an apoptosis-associated protein^[1-3]. BNIP-2 shares 72% homology (46% identity) with BNIP-2^[4] and has 2 variants BNIP-1 and BNIP-2. Full-length amino acid sequence of BNIP-1 is shorter by 82 amino acids at N-terminus than that of BNIP-2. Our previous experiment showed that BNIP-1 could inhibit MIF-mediated proliferation of BEL-7402 cells and BNIP-2 could inhibit cell growth and promote apoptosis in BEL-7402 cells. However, the molecular mechanisms by which BNIP-1 suppresses the cell growth and BNIP-2 commits the cell to die are not known^[1,2].

In 1992, Gossen and Bugard developed the tetracycline (or doxycycline)-induced gene expression (Tet-on) system, which is useful for controlling the expression of targeted genes in a quantitative manner and for determining the roles of gene products in cellular functions^[5,6]. In the present study, Hep3B-Tet-on cells were transfected with *BNIP-2* using lipofectamine transfection reagent. In order to obtain cells with low background and high induction fold of *BNIP-2*, transfected cells were screened by Western blot. Using this system, we established Hep3B cell line with doxycycline-regulated BNIP-2 expression.

The microarray technique was first reported in 1995 by Schena *et al.*^[7] and allows simultaneous parallel expression analysis of thousands of genes. Information provided by cDNA microarray analysis might be useful for tumor classification, elucidation of key factor in tumors, and identification of genes which might be applied to diagnostic purposes or as therapeutic targets^[8,9]. The Atlas human cDNA expression system provides a convenient and quick method for profiling the expression of 588 genes at the same time. In this study, we used cDNA expression microarray technology to analyze the differentially expressed genes regulated by cell apoptosis-related gene *BNIP-2*.

MATERIALS AND METHODS

Materials

cDNA microarray Atlas human cDNA expression array membranes (#7740-1) were purchased from Clontech Laboratories Inc (Palo Alto, California, USA). The membrane contained 10 ng of each gene-specific cDNA from 588 known genes and 9 housekeeping genes. Several plasmid and bacteriophage DNAs and blank spots were also included as negative and blank controls to confirm hybridization specificity. The 588 known genes spotted on the Atlas membrane consist of cDNAs for cell-cycle control proteins, stress response proteins, apoptosis-associated proteins, DNA transcription factors, cell receptors, extracellular cell signaling and communication proteins, *etc.* A complete list of the genes with the array positions and GeneBank accession numbers spotted on the array is available at Clontech's web site (<http://www.clontech.com>).

Enzyme and other reagents

Restriction endonucleases *Bam*HI and *Cla*I were purchased from New England Biolabs Inc (Beverly, Maryland, USA).

Lambda DNA/*Hind*III Markers were from Sino-American Biotechnology Company (Shanghai, China). Tet system approved fetal bovine serum, doxycycline, hygromycin, pTRE2hyg, and Atlas human cDNA expression array trial kit were from BD Biosciences Clontech (Palo Alto, California, USA). Lipofectamine and SuperScript™ first strand synthesis system for RT-PCR were from Invitrogen™ Life Technologies (Carlsbad, California, USA). High glucose Dulbecco's modified Eagle's medium (DMEM) was from Gibco/BRL (Carlsbad, California, USA). Monoclonal antibody actin pan Ab-5, horseradish peroxidase-coupled second antibodies anti-rabbit IgG, and anti-mouse IgG were from Santa Cruz Biotechnology (Santa Cruz, California, USA). SuperSignal west femto maximum sensitivity substrate and T-PER™ tissue protein extraction reagent was from Pierce Chemical Company (Rockford, Illinois, USA). PROTRAN nitrocellulose transfer membrane was from Schleicher & Schuell (Keene, New Hampshire, USA). Hep3B-Tet-on cell line was constructed by Wang *et al.*^[10].

Methods

Plasmid construction For construction of plasmid pTRE2hyg-BNIP-2, human *BNIP-2* DNA fragment encoding the full-length protein was amplified by PCR using the primers containing *Bam*HI and *Cla*I restriction sites and HA-tag sequence (Table 1). The PCR product was subcloned into the Tet-on expression vector pTRE2hyg which contains hygromycin-resistance gene. The recombinant plasmid construct, pTRE2hyg-BNIP-2, was confirmed by *Bam*HI/*Cla*I digestion and DNA sequencing.

Cell culture and transfection

Hep3B-Tet-on cells were cultured in DMEM containing 150 mL/L tetracycline-free fetal bovine serum at 37 °C in a 50 mL/L CO₂ incubator. They were grown in 6-well plates to 70% confluence and transfected with pTRE2hyg-BNIP-2 plasmid DNA using lipofectamine reagents under conditions recommended by the manufacturer. After 48 h, the medium was replaced with fresh DMEM containing 100 mg/L hygromycin to select the stable cell lines. Two weeks later, hygromycin-resistant clones were obtained. Thirty-seven clones were selected and cultured continuously. After further selection in the medium containing 25 mg/L hygromycin for more than 3 wk, they were analyzed by Western blot using anti-BNIP-2 polyclonal antibody (the rabbit anti-BNIP-2 polyclonal antibody was prepared by National Laboratory for Oncogenes and Related Genes, Shanghai Cancer Institute, Shanghai, China). BNIP-2 expression in the cell line was induced by incubating cells with doxycycline (Dox), which is a tetracycline analogue.

Western blot

Cells were washed twice with ice-cold PBS and lysed with T-PER™ tissue protein extraction reagent. Equal amounts of protein (10 µg) were electrophoresed on 100 g/L SDS-PAGE and blotted to PROTRAN nitrocellulose transfer membrane by a semi-dry transfer unit (Amersham Pharmacia Biotech AB, Piscataway, New Jersey, USA). The transferred membranes were blocked with 50 g/L non-fat milk in PBST buffer (20 mmol/L Tris-HCl, pH 7.6; 130 mmol/L NaCl, 1 g/L Tween 20) for 1 h at room temperature and subsequently incubated with the primary antibody anti-BNIP-2 at 1:500 dilutions in PBST containing 40 g/L non-fat milk for 2 h. After several washes with PBST, the membranes were incubated with the corresponding horseradish peroxidase-coupled secondary antibody anti-rabbit IgG in the same buffer. The immunocomplexes were visualized using SuperSignal west femto maximum sensitivity substrate. For standardization and quantification, β-actin was used as an internal control.

cDNA synthesis, labeling and purification

Hep3B-Tet-on-BNIP-2/13 cells were cultured in DMEM containing 150 mL/L tetracycline-free fetal bovine serum at 37 °C in a 50 mL/L CO₂ incubator. They were grown in 4 10-cm dishes to 80% confluence and 2 dishes were treated with Dox (2 mg/mL) for 24 h. Then total RNA samples were extracted from 1×10⁷ cells using TRIzol reagent. They were reverse-transcribed into cDNA and labeled with [α-³²P] dATP. Before labeling, total RNA of each sample was treated with DNase I (TaKaRa, Dalian, Shenyang, China) at 37 °C for 30 min to remove contaminated DNA. For each labeling, the treated 5 µg of total RNA was dissolved in 2 µL of diethyl pyrocarbonate (DEPC)-treated H₂O, incubated with 1 µL CDS Primer Mix at 70 °C for 2 min, and continued to incubate at 50 °C for 2 min. Then, 2 µL 5×reaction buffer, 0.5 µL 0.1 mol/L DTT, 1 µL dNTP mixture (containing dCTP, dGTP, and dTTP), 3.5 µL [α-³²P] dATP (10 µCi/µL), and 1 µL MMLV reverse transcriptase were added to each sample and incubated at 50 °C for 25 min. The reaction was stopped by adding 1 µL of 10× Termination Mix. The labeled first strand cDNA probes were purified by NucleoSpin extraction spin column to remove the unincorporated nucleotides. After purification, labeled cDNAs were denatured before use.

Membrane hybridization and exposure

Five milliliters ExpressHyb hybridization solution and 0.5 mg heat-denatured sheared salmon testes DNA were added to the tube containing Atlas human cDNA expression array membrane, which was pre-hybridized at 68 °C for 3 h. The different probes were then added to different tubes and hybridization was performed at 68 °C for 18 h in a rolling bottle. The membrane was washed twice at 68 °C in 2×SSC, 10 g/L SDS for 20 min, once at 68 °C in 0.1×SSC, 5 g/L SDS for 20 min, and once at room temperature in 2×SSC for 5 min, followed by exposure to x-ray films at -70 °C for 2-5 d.

Image analysis

The images were scanned with Cyclone™ storage phosphor system (Packard Bioscience Company, Meriden, Connecticut, USA) and saved as TIFF format files. The TIFF images were imported into the Quantarray® image system (Packard Bioscience Company) and analyzed. Housekeeping genes *ubiquitin* and *b-actin* were selected for normalization. The normalized intensity of each spot representing a unique gene expression level was acquired. Genes were considered to be up-regulated when the intensity ratio was >2 and down-regulated when the intensity ratio was <0.5.

Semi-quantitative RT-PCR

To confirm the cDNA array results, semi-quantitative RT-PCR was performed for 4 genes (*Rad*, *CLK-1*, *p38 MAP Kinase* and *p21*) that displayed expression alterations. Five micrograms of total RNA was reverse-transcribed into 20 µL of the first strand cDNA with SuperScript™ first strand synthesis system, then 2 µL of the product was used as the template to amplify each specific gene fragment in a 25 µL reaction mixture with corresponding primers (Table 1) under the following conditions: denaturation at 94 °C (3 min); 26 cycles at 94 °C (30 s), at 60 °C (30 s), and at 72 °C (30 s); then extension at 72 °C (3 min). In each PCR reaction, primers for the human *b-actin* gene were used as an internal control. PCR primer pairs were designed using Primer3 Internet software program. Their specificity was confirmed by a BLAST Internet software assisted search for a nonredundant nucleotide sequence database (National Library of Medicine, Bethesda, Maryland, USA). Ten microliters PCR reaction product was analyzed by electrophoresis on a 20 g/L agarose gel and visualized by ethidium bromide staining.

Table 1 Gene specific primers for PCR

Table 2 Up-regulated genes in BNIPL-2-transfected Hep3B-Tet-on cells

Location	Gene description	Induction-fold
C5n	Rad (Ras associated with diabetes)	5.886
F3e	Insulin-like growth factor binding protein 1 (IGFBP-1)	2.594
D6f	p21; Cdk-interacting proteins (Cip1); mda-6/WAF1/SDI1	2.574
E2m	Interleukin-2 receptor	2.5
D3n	Transcription factor (E2A)	2.115
F7m	Estrogen sulfotransferase (EST)	2.112
F1e	Transforming growth factor-beta (TGF-beta)	2.018
E7k	Ifa-1 alpha subunit	2.012

RESULTS

Construction and identification of pTRE2hyg-BNIPL-2 plasmid

Tet-on expression plasmid pTRE2hyg-BNIPL-2 was successfully constructed. Restriction endonucleases *Bam*HI and *Cla*I digestion showed that *BNIPL-2* gene was correctly inserted into the multicloning site. The *BNIPL-2* fragment and pTRE2hyg vector were about 1.1 kb and 5.3 kb, respectively (Figure 1).

Figure 1 Agarose gel (10 g/L) electrophoresis analysis of recombinant pTRE2hyg-BNIPL-2 digested with *Bam*HI and *Cla*I. Lane 1: Lambda DNA/*Hind* III markers, Lane 2: SD 006 markers, Lane 3: pTRE2hyg-BNIPL-2 digested with *Bam*HI and *Cla*I.

Screening of stable Hep3B-Tet-on-BNIPL-2 cell line

After screening in the medium containing hygromycin for more than 8 wk, a total of 37 independent Hyg-resistant cell lines were obtained from the Hep3B-Tet-on cells, transfected with pTRE2hyg-BNIPL-2. Of the 37 clones, clone Hep3B-Tet-on-BNIPL-2/13 showed a low background and high induction fold expression of BNIPL-2 by Dox and was selected as the cell line for further investigations. The amount of BNIPL-2 induced in the Hep3B-Tet-on-BNIPL-2/13 cells treated with Dox (2 000 µg/L) was 12-fold higher than that in the cells without Dox treatment (Figure 2A).

Figure 2 Western blot analysis of BNIPL-2 expression after Dox induction, A: Different cell protein was gotten from 37 clones after hygromycin selection. The clone Tet-on-BNIPL-2/13 showed a low background and high induction fold of BNIPL-2 regulated by Dox. The intensity of each band was quantified by densitometry. Lane 1: lysate of Tet-on-BNIPL-2/13, Lane 2: lysate of Tet-on-BNIPL-2/13+Dox, Lane 3: lysate of Tet-on-BNIPL-2/17, Lane 4: lysate of Tet-on-BNIPL-2/17+Dox, Lane 5: lysate of Tet-on-BNIPL-2/21, Lane 6: lysate of Tet-on-BNIPL-2/21+Dox, Lane 7: lysate of Tet-on-BNIPL-2/28, Lane 8: lysate of Tet-on-BNIPL-2/28+Dox.

8: lysate of Tet-on-BNIP1-2/28+Dox. B: Hep3B-Tet-on-BNIP1-2/13 cells were treated with Dox at different concentrations (0, 500, 1 000, 2 000 $\mu\text{g/L}$) for 24 h. C: Hep3B-Tet-on-BNIP1-2/13 cells were treated with Dox (2 000 $\mu\text{g/L}$) for different time as indicated (0, 12, 24, 48 h). Equal amount of total cell protein was analyzed using BNIP1-2 antibody. β -actin was used as an internal control.

Hep3B-Tet-on-BNIP1-2/13 cells were amplified and passaged (1.0×10^5 cells) into 35-mm dishes, and treated with varying amounts of Dox for different times. Equal amounts of total cell protein were detected by Western blot with BNIP1-2 antibody. The level of BNIP1-2 expression increased significantly after exposing the cells to Dox for 24 h over a range of Dox concentrations from 500 $\mu\text{g/L}$ to 2 000 $\mu\text{g/L}$ (Figure 2B). However, the level of BNIP1-2 expression did not increase when Dox concentration was over 2 000 $\mu\text{g/L}$ (data not shown). On the other hand, after the cells were treated with Dox (2 000 $\mu\text{g/L}$) for 0, 12, 24, or 48 h, the level of the induction

increased with the treatment time and apparent increased induction was seen at 24 h (Figure 2C). Therefore, there was a direct correlation between the concentrations of Dox added to the cells or the time of treatment with Dox and the level of BNIP1-2 induction. The above results obtained by Western blot screening with anti-BNIP1-2 polyclonal antibody were confirmed by anti-HA McAb (data not shown).

Microarray analysis

Using a cDNA expression microarray technique we established the expression profile of 588 genes regulated by *BNIP1-2* (Figure 3) in Hep3B-Tet-on-BNIP1-2/13 cells. No signals were visible in the blank spots and negative control spots, indicating that Atlas human cDNA array hybridization was highly specific. The density of housekeeping genes was very similar between samples, indicating that the results were reliable. We used the housekeeping genes *Ubiquitin* and *b-actin* to normalize the intensities. The comparison results analyzed by Quantarray®

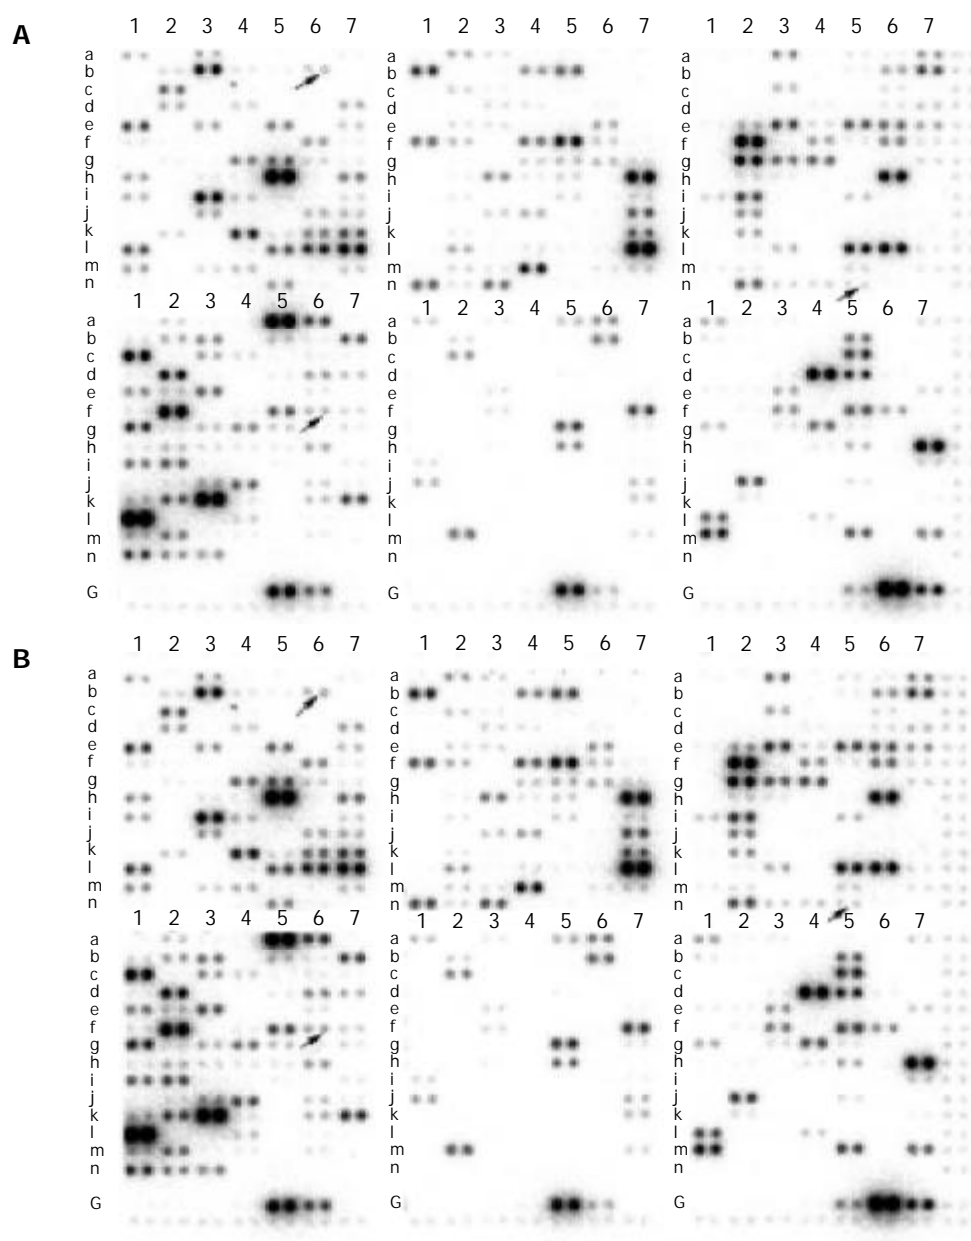

Figure 3 Parallel analysis of gene expression profiles in Hep3B-Tet-on-BNIP1-2/13 cells before or after BNIP1-2 overexpression. Total RNA samples were purified from 1×10^7 cells using TRIzol reagent before (A) or after (B) BNIP1-2 overexpression. They were reverse-transcribed into cDNA, labeled with [α - ^{32}P] dATP, and hybridized to Atlas human cDNA expression array (#7740-1) according to the manufacturer's protocol. Notes: The genes in the row G are housekeeping genes. Arrows indicate the three examples of differentially expressed genes (*A6b*, *p120 antigen*; *C5n*, *Rad*; *D6f*, *p21*).

image system showed that there were 15 genes altered in terms of their expression levels, of which 8 were up-regulated (Table 2) and 7 were down-regulated (Table 3) following overexpression of BNIP-2 in Hep3B cells.

Table 3 Down-regulated genes in BNIP-2-transfected Hep3B-Tet-on cells

Location	Gene description	Induction-fold
B4f	Transducin beta-1 subunit 3' end	0.429
B1b	MAL protein	0.431
B5f	p38 MAP kinases/CSBP/Mxi2	0.442
A7e	Tob	0.447
A7h	CLK-1	0.457
B4b	GTP binding protein (RAB5)	0.48
A6b	p120 antigen	0.496

Semi-quantitative RT-PCR

Four genes were measured for their transcript levels by RT-PCR to verify the accuracy and universality of the hybridization data. The RT-PCR results were consistent with hybridization data in each of the genes measured (Figure 4), *i.e.* *Rad* and *p21* were up-regulated, *p38 MAPK* and *CLK-1* were down-regulated in BNIP-2 overexpressed cells.

Figure 4 Semi-quantitative RT-PCR assays of *Rad*, *CLK-1*, *p21*, and *p38 MAPK* before or after BNIP-2 overexpression. β -actin was also amplified as an internal control. The figure was consisted with the hybridization results. Lane 1: Before BNIP-2 inducible expression, Lane 2: After BNIP-2 inducible expression.

DISCUSSION

The Tet-on system, which utilizes an *E. coli* gene regulatory system^[11], has been found to have several advantages^[12-14]. Namely gene expression is easily regulated by administration of Dox, Dox is minimally toxic, and Dox acts specifically on the target gene, and does not activate other cellular genes. In the present study, we established a cell line Hep3B-Tet-on-BNIP-2/13 in which *BNIP-2* gene could be expressed conditionally by Dox treatment. Dox activated the Tet-response element and significantly enhanced the expression of *BNIP-2* gene in Hep3B cells in a dose-dependent manner. The strategy used here, by which a stable cell line with a low background and high fold Dox-induced expression of *BNIP-2* was generated, seemed to be more efficient and rapid for regulating *BNIP-2* gene expression.

The cDNA array technology was used to examine simultaneously the expression of specific genes on a single hybridization. Although expression analysis techniques such as differential display polymerase chain reaction (DD-PCR), Northern blot, serial analysis of gene expression (SAGE), and RT-PCR have been widely used, these studies are time-consuming and can only be used to deal with a limited number of genes. Thus a systematic approach to the examination of a large number of genes simultaneously is required. We therefore explored the gene expression profiles in human hepatocarcinoma

cell line Hep3B regulated by BNIP-2 overexpression using Atlas human cDNA array.

Following overexpression of BNIP-2 in Hep3B cells, the expression level of 15 genes was altered, of which 8 were up-regulated and 7 were down-regulated. Genes involved in growth inhibition (*IGFBP-1*, *TGF- β*) or cell apoptosis (*p21*, *E2A*) were up-regulated. IGFBP-1 is thought to be the major short-term modulator of IGF bioavailability. In most clinical studies, circulating IGFBP-1 has been associated with growth inhibition^[15]. Insulin-like growth factor I promotes muscle cell survival as an early event in differentiation through a pathway that involves Akt-dependent induction of *p21*^[16]. Transforming growth factor- β (TGF- β) is a potent growth inhibitor for a wide variety of cells, controlling growth, differentiation and apoptosis of cells, and having important functions during embryonic development^[17]. It has been found that Cdk inhibitor *p21* is often responsible for stress-induced *p53*-dependent and *p53*-independent cell cycle arrest, and *p21* plays an essential role in growth arrest after DNA damage and its overexpression leads to G1 and G2 or S-phase arrest. In addition, *p21* is a negative regulator of *p53*-dependent apoptosis^[18]. Human gastric cells were initially arrested in G1 by TGF- β and then driven to apoptosis after caspase-3-induced cleavage of *p21*^[19]. Overexpression of *E2A* protein activity has been shown to induce either growth arrest or apoptosis, indicating that these proteins may regulate cell proliferation and survival^[20,21]. Genes involved in cellular proliferation (*p38 MAPK*, *Tob*, *CLK-1*) were down-regulated in Hep3B cells when BNIP-2 was overexpressed. *P38 MAPK* participates in not only inflammatory responses but also stress-induced signaling, cell proliferation and apoptosis. The *p38 MAPK* pathway participates in *p21* induction, which consequently leads to decrease of cyclin D1/cdk4 and cyclinE/cdk2 complexes^[22]. *Tob* is a member of the *Tob* and *BTG* anti-proliferative protein family. Recently, one report indicated that *Tob* functioned as a molecular switch that regulates cell cycle progression through early G1^[23]. In *CLK-1* mutants, the affected features included cell cycle, embryonic and post-embryonic development, rhythmic behaviors, reproduction, and life span, all of which were lengthened or slowed down on average^[24,25].

In conclusion, cDNA array is a powerful tool to explore gene expression profiles and the present results provide the basis for elucidating previous findings that BNIP-2 might inhibit cell growth and promote apoptosis in BEL-7402 cells^[2]. Although the mechanism of this interaction between BNIP-2 and other proteins is not clear, we suggest that BNIP-2 maybe inhibited growth by inducing cell cycle arrest at the G1 phase by TGF- β and *p21* and affecting G2/M checkpoint through the *p38 MAPK* kinase pathway.

Abstract

AIM: To explore the effects of recombinant human growth hormone (rhGH) on the remnant liver after hepatectomy in hepatocellular carcinoma with liver cirrhosis.

METHODS: Twenty-four patients with hepatocellular carcinoma who underwent hepatectomy were randomly divided into 2 groups: parenteral nutrition (PN) group ($n=12$) and rhGH+PN group ($n=12$). Liver function, blood glucose, AFP, serum prealbumin and transferrin were detected before operation, at post-operative d 1 and d 6. Albumin (ALB) mRNA in liver biopsy specimens was detected by RT-PCR at post-operative d 6. Liver Ki67 immunohistochemical staining was studied.

RESULTS: On post-operative d 6, compared with PN group, the levels of blood glucose, serum prealbumin, transferrin, the expression of hepatic ALB mRNA and liver Ki67 labeling index were higher in rhGH+PN group.

CONCLUSION: rhGH can improve protein synthesis and liver regeneration after hepatectomy in hepatocellular carcinoma with liver cirrhosis.

INTRODUCTION

Hepatocellular carcinoma (HCC) is one of the most common malignant tumors of mankind. Since 1990s HCC has become the second killer among various cancers in China^[1]. Surgical resection of the tumor is considered the only potentially curative therapy, and is regarded as the first choice of treatment of HCC. However, 80% of HCC are complicated with liver cirrhosis in China. After partial hepatectomy, the risk of hemorrhage, infection, and liver failure is very high, as the liver function is usually impaired before surgery in patients with cirrhosis. For safer hepatic resection in patients with cirrhosis, the reserve of hepatic function and rapid regeneration of the remnant liver are crucial. Because liver function is usually impaired in patients with cirrhosis, and because cirrhotic livers are less able to regenerate, it is important to

stimulate both the regeneration and function of the remnant cirrhotic liver after hepatectomy.

The prognosis of severe liver failure depends on the ability of the remaining hepatocytes to regenerate. Improvement of hepatic tissue repair can increase the survival rate of patients suffering from acute hepatic failure and reduce the recovery period after massive liver resection. Nutritional support is undoubtedly the most physiologic manner of treatment and it is clear that adequate nutrition should significantly speed up liver regeneration and patient recovery. The composition of parenteral nutrition (PN) for the postoperative nutritional management of patients with liver cirrhosis might be extremely important because of their metabolic disorders and hemodynamic disturbance following surgical intervention.

Considering that the provision of branched-chain amino acids (BCAA) may improve nutritional status and liver regeneration and ameliorate hepatic encephalopathy, increased provision of BCAA in patients with liver disease seems to be a reasonable approach to various forms of liver injury^[2-4]. While a decline in liver protein synthesis was induced by the surgical procedure^[5]. In patients given short-term PN, plasma insulin concentrations were increased 5-fold compared with control, but no effect on liver protein synthesis rates was observed^[6]. Growth hormone (GH) has important direct and indirect effects on protein, carbohydrate and lipid metabolism. Potential areas of further research may include the combination of BCAA supplements with other anabolic factors (e.g. GH) in managing patients with catabolic disease states^[7]. The aim of this study was to investigate the effects of treatment with amino acids enriched BCAA and recombinant human GH (rhGH) for 5 d on the remnant liver after hepatectomy in HCC with liver cirrhosis.

MATERIALS AND METHODS

Patients

All the patients were from our department who underwent curative resection for HCC with liver cirrhosis between September 2002 and June 2003. Curative resection was defined as complete resection of all macroscopically detectable tumors with histological tumor clearance (the entire tumor mass was included in the surgical specimen without exposure of tumor cells on the cut edge). At the time of entry, the inclusion criteria were no evidence of endocrine disease. The study protocol conformed to the ethical guidelines and the patients were enrolled after informed consent was obtained. Twenty-four patients were recruited and were randomly using sealed envelopes divided into 2 groups: PN group ($n=12$) and rhGH+PN group ($n=12$) using sealed envelopes. Between the 2 groups, there were no differences in age, sex, body mass, operative methods, operation time, intraoperative blood loss and intraoperative blood transfusion (Table 1). At the same time, 12 patients with cholelithiasis or hemangioma who underwent operation served as normal controls. None had liver cirrhosis or endocrine disease.

Nutritional support and rhGH administration

Nutritional support and rhGH administration were started on the first day after surgery and continued until d 5. PN was

initiated through a percutaneously placed subclavian vein catheter threaded into the superior vena cava. The formula provided non-protein calorie 25 kcal/kg·d. Each patient was provided 250 mL 200 mL/L MCT/LCT lipid emulsion (Guangzhou Qiaoguang Pharmaceutical Co. Ltd) and 750 mL 100 g/L aminoplasmal Hepa (Braun Co. Ltd) containing 20 kinds of amino acids, 330 g/L branched-chain amino acids and 15.3 g/L nitrogen. Nonprotein calories were provided 310 mL/L as lipid emulsion. The formula provided nitrogen 0.19 g/kg·d. The ratio of nonprotein calories to nitrogen was 132:1. The ratio of glucose (g) to insulin (IU) was 6:1. Vitamins, trace minerals, and electrolytes were supplied according to the daily requirement. This parenteral nutrition was tolerated by all patients without complications, and no patient showed symptoms of sepsis during the treatment period.

Patients in the rhGH+PN group received 10 U rhGH (Saizen, Sero Biotech&Beyond) additionally per day subcutaneously.

Table 1 Patient characteristics

	PN group (n=12)	rhGH+PN group (n=12)
General conditions		
Age (years)	46.1±13.6	50.3±10.6
Sex (M/F)	11/1	10/2
Body weight (kg)	59.7±9.3	64.3±7.7
Operative methods		
Hepatic left lateral lobectomy	0	1
Left hemihepatectomy	2	2
Right hemihepatectomy	1	1
Tumor or segmentectomy	9	8
Intraoperative information		
Operation time (min)	250.8±126.4	203.3±73.2
Intraoperative blood loss (mL)	1 331.7±1 704.8	966.7±1031.4
Intraoperative blood transfusion (mL)	1 100.0±1 334.2	408.3±609.7

Collection of samples

Blood samples were collected from antecubital veins in the morning after an overnight fast prior to operation in the normal, PN and rhGH+PN groups, on postoperative day (POD) 1 and 6 in the PN and rhGH+PN groups. Aliquots were transferred into different tubes placed for the determination of liver function, blood glucose, prealbumin, transferrin and α -fetoprotein (AFP). Blood samples were centrifuged at 4 °C and then frozen at -70 °C until assay.

Liver specimens from PN and rhGH+PN group, including hepatocellular carcinomas and adjacent non-tumor tissues were excised at the operation and percutaneous liver biopsies were taken on d 6 after operation in the PN group and rhGH+PN group, immediately frozen with liquid nitrogen, and stored at -70 °C for analysis of ALB mRNA. Liver biopsy specimens were obtained with Tru-Cut biopsy needles. The needle-biopsy specimens ranged in length from 15 to 20 mm. For histological examination, some liver specimens were fixed in 40 g/L neutrally-buffered formaldehyde and embedded in paraffin.

Biochemical examinations

Liver function, including serum aspartate aminotransferase (AST), alanine aminotransferase (ALT), alkaline phosphatase (ALP), total bilirubin (TBIL), albumin (ALB) and blood glucose were analyzed by an autoanalyzer. Serum prealbumin and transferrin were detected quantitatively by immunoturbidity assay. Serum AFP was detected quantitatively by microparticle enzyme immunoassay. The normal values were <20 μ g/L.

Measurement of ALB mRNA in liver tissue

RT-PCR was performed to measure the expression levels of

ALB mRNA in liver tissue. The primers used were deduced from the cDNA sequence. The sequences of the primers for ALB sense and antisense were as 5' -CCCAAGTGTCAACTCCAACCT-3' (sense) and 5' - GCAGGTCTCCTTATCGTCAG-3' (antisense), a 456-bp long fragment was amplified. The sequences of the primers for β -actin sense and antisense were as 5' -ACTCTTCCAGCCTTCCTTCCT-3' (sense) and 5' -TCACCTTCACCGTTCAGTTT-3' (antisense), a 513-bp long fragment was amplified.

Total RNA was extracted from frozen liver specimens by the guanidinium isothiocyanate method. The RNA was quantified and checked for purity by spectrophotometry at 260 and 280 nm. Aliquots of total RNA were reversely transcribed using SperSriptII Reverse Transcriptase (Invitrogen Corp) and subsequently amplified by PCR using the Taq DNA polymerase (Promega).

The PCR was carried out in 25 mL of reaction mixture containing 0.5 μ L cDNA template, 2.5 μ L 10 \times PCR-Buffer, 1.5 μ L 25 mmol/L MgCl₂, 0.5 μ L 10 mmol/L dNTPs, 0.5 μ L 10 μ mol/L ALB, 0.15 μ L 10 μ mol/L β -actin primers, 0.5 μ L 5 U/ μ L Taq DNA polymerase. The mixture was heated for 5 min. at 94 °C for initial DNA denaturation, followed by 30 cycles of denaturation at 94 °C for 45 s, annealing at 50 °C for 45 s, polymerization at 72 °C for 1 min. and then a final extension of 10 min at 7 °C. PCR reactions were stored frozen until analysis by agarose gel electrophoresis.

PCR reactions were electrophoresed on 15 g/L agarose gel, stained with ethidium bromide and quantitated using the interactive build analysis system (IBAS). The band intensity of the ALB was compared with the band intensity of the β -actin, and the amount of ALB mRNA was estimated.

Immunohistochemical staining of Ki67 in liver tissue

Two-step immunohistochemical staining technique was used. Main reagents included rabbit polyclonal antibody Ki67 Ab-4 (Neomarkers) and PV-6000 PicTure™ kits. Briefly, sections were deparaffinized, rehydrated, and then immersed in 0.1 mol/L citric acid buffer (pH 6.0) and boiled for 5-10 min in a microwave oven. The slides were then rinsed gently with phosphate buffered saline (PBS) at pH 7.2-7.4, and treated with 3 mL/L hydrogen peroxide in absolute methanol for 1 h at room temperature (RT) to remove endogenous peroxidase. The sections were then incubated with the primary antibody Ki67 Ab-4 (1:200 dilution) for 30 min at 37 °C. After rinsed with PBS for 3 times, each for 2 min, the sections were incubated with PV-6000 for 30 min at 37 °C. They were then rinsed 3 times with PBS for 2 min each and visualized with DAB. Finally, the sections were counterstained with hematoxylin.

On each slide, Ki67-positive nuclei were estimated by means of light microscopy at 400 magnifications. At least 1 000 cells were evaluated in 5 different fields each containing a minimum of 200 cells. The Ki67 labeling index (Ki67 LI) is the percentage (%) of positive cells.

Recording doses of albumin infusions within 5 d after operation

Plasma contained 4.5 g/L albumin. Doses of plasma infusion were converted into doses of albumin.

Statistical analysis

Data were expressed as mean \pm SD. The statistical software SPSS 10.0 was used. Statistical significance was set at $P<0.05$.

RESULTS

Surgery outcome and albumin doses within 5 d after operation

There was no surgical mortality in this series. The postoperative

hospital stay showed no difference between the PN group and rhGH+PN group (14.7 ± 6.2 d vs 13.5 ± 4.5 d, $P > 0.05$). In the PN group, 2 patients had right pleural effusion. In the rhGH+PN group, 1 patient had right pleural effusion, another patient had subcutaneous fat liquefaction. The postoperative complication related morbidity was not different between the 2 groups ($P > 0.05$). Albumin doses within 5 d after operation were not different between the PN and rhGH+PN group (57.0 ± 48.8 g vs 52.4 ± 24.4 g, $P > 0.05$).

The decreased percentage of serum AFP within 5 d after operation

The decreased percentage of serum AFP within 5 d after operation were calculated by (POD 1 serum AFP- POD 6 serum AFP)/POD 1 serum AFP. In the PN group, 6 patients had preoperative serum AFP < 20 μ g/L. In the rhGH+PN group, 3 patients had preoperative serum AFP < 20 μ g/L and at POD 6, 3 patients whose preoperative serum AFP were < 50 μ g/L had their serum AFP < 20 μ g/L. Those patients were excluded from the statistics. For the other 6 patients in the 2 groups, the decrease percentage of serum AFP within 5 d after operation was not different between the PN group and rhGH+PN group (0.536 ± 0.182 vs 0.579 ± 0.193 , $P > 0.05$).

The changes of liver function and blood glucose

Compared with normal control group, serum AST, ALT of HCC patients with cirrhosis were significantly increased, while serum ALP, TBIL, ALB, blood glucose were not different. Serum AST, ALT, ALP, TBIL, ALB, blood glucose on preoperative day and POD 1 were not different between the PN group and rhGH+PN group. Compared with PN group, serum AST, ALT, ALP, TBIL, ALB on POD 6 in the rhGH+PN group were not different, but blood glucose was significantly increased (Table 2).

The changes of serum prealbumin and transferrin

In HCC patients with cirrhosis, serum prealbumin and

transferrin were lower than the normal control group. Serum prealbumin and transferrin on preoperative day and POD 1 were not different between PN group and rhGH+PN group, but serum prealbumin and transferrin on POD 6 in the rhGH+PN group were significantly increased compared with the PN group (Table 2).

The changes of hepatic ALB mRNA and liver Ki67 labeling index

In HCC patients with cirrhosis, hepatic ALB mRNA of tumor tissues was lower than in adjacent non-tumor tissues, while in adjacent non-tumor tissues it was lower than the normal liver tissues. Compared with the PN group, hepatic ALB mRNA on POD 6 was significantly increased in the rhGH+PN group. Liver Ki67 labeling index in tumor tissues was higher than adjacent non-tumor tissues. Liver Ki67 labeling index on POD 6 in the rhGH+PN group was higher than the PN group (Table 3).

DISCUSSION

The prevalence of malnutrition in patients with liver cirrhosis is high^[8]. Nutritional status affects prognosis, and cirrhotic patients with malnutrition are prone to develop major complications and infections. A poor nutritional status negatively influences survival, while appropriate nutritional intervention has been found to improve liver function and survival. Because the liver is the metabolic workhouse of the body, alteration in liver function clearly affects the whole body metabolism. In addition, the goals of nutritional support should include maintenance of adequate nutrition and prevention and/or amelioration of liver damage. Major resection of portions of the liver for primary hepatic or metastatic malignancy and the repair of hepatic injury associated loss of liver tissue are performed with such a frequency as to require careful consideration of the consequences of the postoperative nutritional care of the patients. Often, the recovery from such surgery involves a prolonged period of delayed oral intake.

Table 2 Comparison of liver function, blood glucose, serum prealbumin and transferrin

	Normal control group (n=12)	PN group (n=12)			rhGH+PN group (n=12)		
		Preoperative	POD 1	POD 6	Preoperative	POD 1	POD 6
AST (IU/L)	26.0 \pm 5	56.0 \pm 27 ^a	761.0 \pm 578	62.0 \pm 32	55.0 \pm 25 ^a	578.0 \pm 206	56.0 \pm 25

Although the liver normally has considerable reserve function and regeneration potential, an acute reduction in hepatic mass can significantly affect liver function, its metabolic activity, and substrate metabolism. The trauma caused by moderate or large operation may result in disturbance of glucose, lipid and protein metabolism including hypermetabolism and increased catabolism, which may lead to acute protein malnutrition, decline of immunological function and dysfunction of multiple organs^[9-11]. Postoperative maintenance of protein synthesis is one measure to preserve a satisfactory quality of life after hepatectomy^[12].

The amino acids that comprise the various parenteral feeding formulations are the important components of these regimens, because they provide the precursors for the synthesis of numerous structural and functional body proteins. BCAA appears to act favorably in albumin metabolism. Early oral supplementation of BCAA for HCV-related cirrhosis with serum albumin level between 3.5 and 3.9 g/dL and branched-chain tyrosine ratio (BTR) less than 4.0, improves serum albumin levels and thus might improve prognosis^[13].

Liver protein synthesis is usually estimated in humans by measuring the synthesis rates of major exported liver proteins. Albumin is a ubiquitous protein synthesized only by hepatocytes. Albumin is a polypeptide chain of 580 amino acids that is produced by hepatocytes^[14]. The expression of ALB gene is reduced in various liver diseases and the degree of reduction in the hepatic ALB mRNA level is generally correlated with the severity of the disease^[15]. This study showed that hepatic ALB mRNA in tumor tissues was lower than in adjacent non-tumor tissues, and it was lower in adjacent non-tumor tissues than normal liver tissues. Serum ALB whose long half-life of approximately 20 d makes it a late index of nutritional status, and its exclusive use may delay implementation of appropriate nutritional interventions. Serum prealbumin and transferrin have been proposed as earlier nutritional markers. Clinically significant changes in albumin can be reliably predicted by earlier changes in serum transferrin and prealbumin^[16]. In this study, serum AST, ALT, ALP, TBIL, ALB on POD 6 were not different between the PN group and rhGH+PN group, but blood glucose, serum prealbumin, transferrin, hepatic ALB mRNA, and liver Ki67 labeling index were significantly increased in the rhGH+PN group. Thus, rhGH can promote liver protein synthesis and liver regeneration. Moreover, liver function recovered faster in the rhGH+PN group. It has been demonstrated that PN is not able to support protein synthesis sufficiently in patients with or without malnutrition^[17]. Long-term conventional PN is unable to increase or even maintain body protein; the anabolic response to PN is often suboptimal because of the concomitant presence of catabolism and/or alterations in the hormonal regulation of metabolism^[18,19]. GH is anabolic in protein metabolism. Gu and Wu also demonstrated that the administration of rhGH could result in significant anabolic effects on body growth and improve the efficiency of PN^[20].

An important but unresolved question is intrahepatic recurrence after resection of HCC^[21-26]. Metastasis and recurrence of HCC after surgical removal is still high. The frequency of 5-year recurrence after radical resection was 61.5% overall^[27]. The recurrence, especially at an early period after hepatectomy, is the major cause of poor prognosis in patients with HCC^[28]. This is of relevance in determining preventive and therapeutic strategies for recurrence. Although all patients in this study underwent curative tumor resection, the potential tumor-promoting effect of GH must be addressed. This study showed that the decreased percentage of serum AFP within 5 d after operation was not different between the PN group and rhGH+PN group. Furthermore, liver function recovered faster in the rhGH+PN group. However, hepatic

functional damage immediately after hepatectomy is a significant risk factor for early intrahepatic recurrence in cirrhotic HCC. Careful perioperative management of hepatic function may therefore be important in preventing early recurrence and prolonging survival^[29]. Tacke *et al* demonstrated no evidence for an increased risk of tumor recurrence after rhGH treatment for a short period of time after removal of a gastrointestinal adenocarcinoma^[30]. Moreover, rhGH attenuated the depression in cellular immunity following surgical stress^[31]. Therefore, short-term use of rhGH in HCC patients with cirrhosis after operation may be safe.

In conclusion, rhGH+PN can promote liver recovery, liver protein synthesis and liver regeneration after hepatectomy in HCC with liver cirrhosis. It may not promote HCC recurrence, but may increase blood glucose.

Abstract

AIM: To investigate the difference of amino acid uptake between normal and cancerous colon tissues.

METHODS: Sixteen patients with colon cancer were enrolled in our study. Blood samples were taken during operations, serum amino acid concentrations of blood from cancerous or normal colon were analyzed. Amino acid uptake rate was calculated by the A-V difference and evaluated statistically.

RESULTS: Except for methionine, the uptake rate of amino acids in cancer was higher than that in normal colon (25.01% vs -2.29%, $P < 0.01$). The amino acid uptake rate did not correlate to the size of tumor mass ($P > 0.05$). There was no statistical significance in the amino acid uptake rate according to the Dukes stage, though it was higher in patients with Dukes stage C or D than that with Dukes stage B ($P > 0.05$).

CONCLUSION: Abnormal synthetic metabolism of colon cancer may contribute to its higher amino acid uptake rate than that of normal colon.

INTRODUCTION

Studies note the significance of amino acid metabolism in neoplasms, though there are lots of questions that remain to be answered^[1-5]. It is helpful to improve the life quality if we take patients' nutrition into account according to their characteristic amino acid metabolism before we treat cancer patients. Studies^[6,7,8,9] demonstrated that the amino acid concentrations in serum, especially essential amino acids (EAAs) but not leucine, were decreased in colon cancer patients with weight loss, but not in patients without weight changes, of which the non-essential amino acids (NEAAs), like asparagic

acid, glutamine, glycine, alanine, taurine and ornithine, were slightly elevated in serum. Zheng^[10] studied the changes of free amino acids in colon cancer tissue and revealed that the serum concentration of most EAAs (leucine, isoleucine, phenylalanine, threonine, lysine) and some NEAAs (tyrosine, proline, glutamine) in cancer tissue were obviously higher than those in normal tissue ($P < 0.01$), while the serum concentration of most NEAAs and some EAAs (methionine, valine, histamine) was slightly elevated. There was no statistical significance. The ammonia serum concentration in cancer tissue decreased significantly ($P < 0.05$). To make further investigations of the amino acid metabolism in colon cancer, we analyzed the arterial and venous (A-V) serum free amino acid uptake rates in tumor region, and tried to find the difference of amino acid metabolism between normal and cancerous colon tissue.

MATERIALS AND METHODS

Clinical materials

Sixteen patients were enrolled in this study from Department of Surgical Oncology, Sir Run Run Shaw Hospital, Zhejiang University Medical College. Patients with a median age of 57 years (range from 37 to 77) were diagnosed having colon cancer pathologically. Nine (66.7%) patients were males and in 9 patients, the mass was larger than 5 cm in size. According to Dukes stage, 10 patients were in stage B, 5 in stage C, and 1 in stage D. Before operation, hormone, blood, albumin and amino acid intake were prohibited. Five-day doses of sulfaguanidine and metronidazol were given for bowel preparations.

Sample collection and processing

A 3 mL arterial blood as sample A was collected before making division of the mesentery vessels during laparotomy, and 3 mL reflux venous blood from the tumor region was collected as sample C, another 3 mL mesentery venous blood in normal colon tissue, which was about 7 cm from the tumor margin, was collected as sample E. After incubation at 37 °C for an hour, the serum was collected by centrifugation, and 1mL serum mixed with 50 mg sulfosalicylic acid was placed for an hour at 4 °C, then centrifuged at 16 000 g for 6 min. The supernatant was diluted with 0.02 mol/L hydrochloric acid before analysis. Each sample was analyzed twice with automatic amion-acid analyzer (Japan 835-50) 18 standard amino acids including ammonia were placed as control.

Statistical analysis

The A-V amino acid uptake rate in colon cancer (R1) was calculated by the following formula ($R1 = (A - C) / A \times 100\%$) and that in normal tissue (R2) was calculated as the following: $R2 = (A - E) / A \times 100\%$ [A, C and E refer to the amino acid concentrations of samples A, C and E]. The rate was compared by means of *t* test, statistical significance was defined as $P < 0.05$.

RESULTS

We measured 16 patients with 48 samples. The uptake rates of amino acids in normal and cancerous colon tissue were calculated. As is shown in Table 1, except for methionine, the uptake rates of all amino acids in cancer were higher than those

in normal colon (25.01% vs -2.29%, $P < 0.01$). The EAAs uptake rates in cancer tissue were between 25.44% and 39.75% with a mean of 31.7% and between -8.01% and 13.5% in normal colon tissue ($P < 0.01$). Methionine was 11.55% in cancer tissue but -0.13% in normal tissue. The ketogenic or ketogenic and glucogenic amino acid uptake rates had a mean of 30.86%, which was higher than that of glucogenic acids (18.7%). Sulfur-bearing amino acid uptake rates in colon cancer tissue, which were comparatively lower than the other amino acids, were higher than those in normal tissue, though there was no statistical significance. The uptake rates of some amino acids (lysine, arginine, proline, glutamine, glycine, alanine, cystine, methionine and ammonia) were negative in normal tissue, and the serum concentration of asparagic acid could not be detected in more than 10 patients.

Table 1 A-V amino acid uptake rates in normal and cancerous colon tissue

Amino acid	Sample number	R2 (%)	R1 (%)	P value
Threonine ^{1,3}	16	13.50±3.76	39.25±7.59	<0.01
Phenylalanine ^{1,3}	16	6.37±1.77	26.26±4.31	<0.01
Leucine ^{1,4}	16	8.21±2.13	36.55±6.11	<0.01
Isoleucine ^{1,3}	15	11.39±3.55	30.63±5.50	<0.01
Methionine ¹	16	-0.13±1.20	11.55±5.22	>0.05
Valine ¹	16	7.67±2.42	33.46±5.56	<0.01

Relationships between the uptake rates of amino acids and the size of tumor mass or the Dukes stage are shown in Table 2 and Table 3.

DISCUSSION

Studies have noted the amino acid uptake changes in blood and tumor tissue, but the results were controversial^[8,11-13]. More factors, such as ages, food intake, consumption and digestion, liver and kidney functions, could influence the amino acid concentrations in serum, and different sample treatment was also confirmed as an important factor^[14-17]. In our study, we compared the amino acid concentrations in cancer tissue with those in normal colon as self-control to eliminate the factors that influenced the results.

Tumor cells needed more glucose and amino acids than normal body cells^[1]. Limited data were found in *in vivo* studies. We analyzed the amino acid uptake rates in cancer tissue and revealed that the uptake rates of amino acids, especially EAAs, ketogenic, ketogenic and glucogenic amino acids, but not methionine, were significantly higher than those in normal tissue, suggesting that colon cancer might need more of these amino acids.

Protein synthesis was more active in tumor tissue^[18-21], and enzymes such as protein kinase were more active in hepatic cancer cells than those in normal cells. Michael *et al.* demonstrated that the protein concentration in cancer tissue (hepatic cancer, digestive cancer and breast cancer) was elevated continuously with tumor progression. Hagmuller *et al.*^[22] revealed that, not only the protein synthesis, but the uptake of EAAs and branched-chain amino acids (BAAs) in cancer tissue were more significant than those in arm tissue, as in our study. Khirallah *et al.* suggested that the sources of amino acids in cell protein synthesis came from the plasma and cell protein degradation, though it was not clear which would be the major source. According to our study, amino acids, especially EAAs, might come from the plasma because colon cancer cells were inadequate to synthesize EAAs.

Asparagic acid, glycine, glutamine, folinic acid and ammonia were the basic substrates in pyrimidine and purine nucleosides

synthesis^[23]. Our data showed that asparagic acid was too low to be detected in most patients, which might be due to its total utilization in nucleosides synthesis, as was reported by Norton^[6]. Methionine is one of the important amino acids in cancer metabolism, and total parenteral nutrition (TPN) with cystine and methionine deficiency has been shown to decrease the tumor growth by inhibiting DNA and RNA synthesis in cancer cells^[24,25]. Our data showed that the cystine and methionine uptake rates in cancer tissue were not higher than those in normal tissue, it might be resulted from its repetitive utilization in methylation by S-adenomethionine circulation. On the other hand, lower methylation in nucleosides metabolism might also decrease the cystine/methionine requirement in tumor.

Tumor growth consumes a large amount of energy. Glycolysis was ascertained as the major source of energy especially in archaeocytes and poorly differentiated cells because the enzymes in glycolysis in tumor tissue were elevated, which increased the lactic acid concentration and reduced the pH value. Because a little adenosine triphosphate (ATP) could be released by glycolysis, a lot of glucose should be consumed to get adequate energy. Most studies showed that alanine, glycine and glutamine might be involved in glyconeogenesis for their concentrations in blood were higher than the other amino acids. On the other hand, liver glyconeogenesis increased in tumor tissue, and the enzymes involved in glyconeogenesis were more activated, though they were lower in liver cancer than in normal tissue in some studies^[1,26]. The glucogenic amino acid concentrations were not obviously changed in tumor tissue in our study, though the uptake rates were higher than those in normal tissue, suggesting these amino acids were utilized during glyconeogenesis.

Aerobic metabolism was present in tumor tissue. Whether any enzyme deficiency occurs in tumor aerobic metabolism is still controversial. Kern *et al.*^[27] reported that the fat, but not the liver starch, was the primary substrate in energy metabolism when fasting. Compared with anaerobic metabolism, it could produce eighteen to nineteen times of ATP. The amino acid concentrations in colon cancer tissue (threonine, isoleucine, leucine, phenylalanine, proline, tyrosine and lysine) were higher than those in normal tissue in our study, suggesting that tumor colon tissue utilized these amino acids as a fuel to get more energy in Krebs cycle. There might be a more active and flawless aerobic metabolism in colon cancer tissue, and further studies should be conducted.

It seems that the poorer the cell differentiation, the more elevated ability the more amino acid uptake in tumor. The samples we selected in our study were moderately differentiated globular adenocarcinomas. It was difficult to reveal the differences according to their differentiation, and more samples are needed in further study. Several studies^[28-32] demonstrated that there was a correlation between the amino acid concentrations and the tumor volume. On the contrary, in our study, there was no obvious correlation between the size of tumor and the uptake rates of amino acids in tumor tissue, which might probably due to tumor necrosis or lower metabolism. The amino acid uptake rates of patients in Dukes stage C or D were higher than those in Dukes stage B, but only methionine had statistical significance.

The uptake rates of EAAs (methionine and lysine) and NEAAs (glutamine, glycine, alanine, cystine, arginine, proline and ammonia) were negative in normal colon tissue, suggesting that normal colon tissue has the ability to synthesize these amino acids or produce them by tissue protein degradation. Studies^[26,33] demonstrated that malignant neoplasms had the ability to enhance the degradation of proteins in surrounding normal tissue or muscles and absorb some part of amino acids to glyconeogenesis, though its function was ignored in general

conditions. Whether it is significant in short gut patients needs further studies.

Abstract

AIM: To construct a differentially-expressed gene subtracted cDNA library from two colorectal carcinoma (CRC) cell lines with different metastatic phenotypes by suppression subtractive hybridization.

METHODS: Two cell lines of human CRC from the same patient were used. SW620 cell line showing highly metastatic potential was regarded as tester in the forward subtractive hybridization, while SW480 cell line with lowly metastatic potential was treated as tester in the reverse hybridization. Suppression subtractive hybridization (SSH) was employed to obtain cDNA fragments of differentially expressed genes for the metastasis of CRC. These fragments were ligated with T vectors, screened through the blue-white screening system to establish cDNA library.

RESULTS: After the blue-white screening, 235 white clones were picked out from the positive-going hybridization and 232 from the reverse. PCR results showed that 200-700 bp inserts were seen in 98% and 91% clones from the forward and reverse hybridizations, respectively.

CONCLUSIONS: A subtractive cDNA library of differentially expressed genes specific for metastasis of CRC can be constructed with SSH and T/A cloning techniques.

INTRODUCTION

CRC is one of the most common malignant tumors in the world and its metastasis is the major cause of mortality in patients with colorectal carcinoma. More than hundreds of genes have been reported to be involved in the regulations of metastasis in colorectal carcinoma. However, they are still not sufficient for

fully explaining the complexity and diversity of metastasis. Besides, current investigations of these genes that mostly focused on the expression analysis of one or several genes make it difficult to understand the genes' interactions and find the new genes. Cloning and identification of metastasis-associated genes have been hypothesized to be beneficial to the elucidation of the molecular mechanisms underlying the metastasis and finding gene targets for metastatic forecast, therapy and prognosis of CRC patients. In our study, SSH and bacterial culture PCR screening were used to construct a differentially-expressed gene subtracted cDNA library specific for metastasis of human CRC with the hope to screen new metastasis associated genes.

MATERIALS AND METHODS

Cell lines

Highly metastatic cell line SW620 and lowly metastatic cell line SW480 from human colorectal carcinoma were purchased from ATCC with the number of CCL-227 and CCL-228 respectively. Both of the paired cell lines were from one colonic adenocarcinoma patient and had the same genetic backgrounds. Cell lines were routinely cultured with DMEM supplemented with 10% bovine serum under the atmosphere containing 50 mL/L CO₂ at 37 °C.

PCR primers and adaptors

cDNA synthesis primer (5' -TTTTGTACAAGCTT₃₀N₁N-3') was used for the first-strand cDNA synthesis. Adaptor1 (5' -CTAATACGACTCACTATAGGGCTCGAGCGGCCGCCGGG CAGGTACCTGCCCGG-3') and adaptor2R (5' -CTAATACGAC TCACTATAGGGCAGCGTGGTCGCGGCCGAGGTACCTCGGC CG-3') have the same sequence of the 5' region and the different palindromic structures in the 3' end. Only the differentially expressed fragments digested by RsaI restriction enzyme could be ligated with two adaptors. Primary PCR was performed to amplify these fragments with primer1 (5' -CTAATACGACTCAC TATAGGGC-3') that corresponds to the outer common sequence of the adaptors. After that, nested primer1 (5' -TCGAGCGGCC GCCCGGCCAGGT-3') and nested primer2R (5' -AGCGTGG TCGCGGCCGAGGT-3') designed from the inner sequences of the adaptors respectively were used for the further enrichment of these fragments in secondary PCR. The underlines in the sequences indicated the sites of RsaI restriction enzyme. The above primers and adaptors were provided by PCR-Select™ cDNA Subtraction Kit (Clontech Laboratories Inc, USA).

mRNA isolation

Total mRNA was isolated from the two cell lines respectively using QuickPrep micro mRNA purification kit (Pharmacia, USA) following the recommendations of the manufacturer.

Suppression subtractive hybridization

SSH was performed by using PCR-Select™ cDNA subtraction kit (Clontech Laboratories Inc, USA) according to the

recommendations of the manufacturer. The highly metastatic cell line SW620 was used as the tester while the lowly metastatic cell line SW480 was used as the driver in the forward hybridization, and vice versa in the reverse hybridization.

Double strand cDNA synthesis

A total of 2 μg (4 μL) mRNA with 1 μL oligo (dT₃₀) primer was heated to 70 °C for 2 min and rapidly cooled on ice. The reaction mixture was made up to 10 μL by adding 1 μL cDNA synthesis primer (10 $\mu\text{mol/L}$), 2 μL 5 \times the first strand reaction buffer, 1 μL dNTP mix (10 mmol/L each) and 1 μL sterile H₂O. Reverse transcription was started by adding 1 μL AMV reverse transcriptase (20 U/ μL). The reaction mixture was incubated at 42 °C for 1.5 h to synthesize the first strand cDNA. The second strand cDNA synthesis was performed by immediately adding 48.4 μL sterile H₂O, 16 μL 5 \times the second strand buffer, 1.6 μL dNTP mix, 4 μL 20 \times the second strand enzyme cocktail. The reaction mixture was incubated at 16 °C for 2 h. Double strand cDNA was blunted by adding of 2 μL T4 DNA polymerase and incubated at 16 °C for 20 min. The reaction was stopped by adding 20 \times EDTA/glycogen mix into the reactive mixture. cDNAs were then extracted, precipitated, and resuspended in 50 μL of deionized water.

Ligation of cDNA fragments

For the ligation of cDNA fragments, 43.5 μL of ds cDNA from the tester and driver was digested respectively with 1.5 μL of RsaI (10 U/ μL) at 37 °C for 1.5 h. The reaction was terminated by adding 20 \times EDTA/glycogen mix. The resulting fragments of cDNAs were extracted, precipitated and finally resuspended in 5.5 μL of deionized water. Adaptor1 and adaptor2R were ligated separately to 2 μL of RsaI digested tester cDNA with 1:6 dilution in the presence of T4 DNA ligase at 16 °C overnight followed by heating at 70 °C for 5 min to inactivate the ligase. In order to determine whether the ligation efficiency was high or not, 1 μL of adaptor1-ligated and adaptor2R-ligated cDNAs of the tester was diluted into 200 μL H₂O respectively and amplified in two separate 50 μL reactions. One reaction used G3PDH3' , 5' primer, while the other used G3PDH3' primer and PCR primer1. PCR parameters were as follows: 30 cycles at 94 °C for 30 s, at 65 °C for 30 s and at 68 °C for 2.5 min. The products were examined by electrophoresis on a 20 g/L agarose/EB gel.

Two subtractive hybridizations

In the first hybridization, 1.5 μL of RsaI digested driver cDNA was mixed with 1.5 μL of diluted adaptor1- or adaptor2R-ligated tester cDNA. The samples were denatured at 98 °C for 1.5 min and immediately incubated in a thermal cycler at 68 °C for 8 h. In the second hybridization, two kinds of sample resulting from the first hybridization were mixed in the presence of a freshly denatured driver cDNA. The samples were incubated at 68 °C for 18 h. After 200 μL of dilution buffer was added, the samples were incubated for an additional 7 min. Analysis of the subtraction efficiency was carried out using PCR amplification of G3PDH in diluted subtracted cDNA versus unsubtracted cDNA. PCR was performed for 33 cycles at 94 °C for 30 s, at 60 °C for 30 s and at 68 °C for 2 min. The products were monitored on a 20 g/L agarose/EB gel for an aliquot which was removed from each reaction after 18, 23, 28, 33 cycles.

Two suppression PCRs (nested PCR)

A 1 μL of diluted subtraction mixture was amplified with PCR primer1 in the primary PCR. The reaction mixture was incubated at 75 °C for 5 min to extend the adaptors and followed in turn at 94 °C for 25 s, 30 cycles at 94 °C for 10 s, at 64 °C for 30 s and at 71 °C for 1.5 min. The primary PCR mixture was diluted 10-fold and 1 μL from that was used in secondary PCR with nested

PCR primer1 and primer2R. The conditions of the reaction were 15 cycles at 94 °C for 10 s, at 68 °C for 30 s and at 72 °C for 1.5 min. Eight μL products from each PCR reaction of the secondary PCR was analyzed on a 20 g/L agarose/EB gel.

Screening for subtraction library

The second PCR products were purified and their concentrations were measured by a spectrophotometer. The T/A cloning method was performed by using pGEM-T vector system I (Promega, USA) according to the recommendations of the manufacturer. The PCR product was cloned into the vector with a molar ratio of 6:1(insert: vector). A 2 μL purified PCR products(25 ng/ μL) was used in a 10 μL -ligation-reaction system including 5 μL 2 \times Rapid ligation buffer, 1 μL pGEM-T Easy Vector (50 ng/ μL), 1 μL T4 DNA ligase (3 Weiss units/ μL) and 1 μL deionized water. The mixture was incubated at 4 °C overnight. The positive control was made by using the control insert DNA from the kit instead of the PCR products. The background control was made without inserting any fragments. The recombinant plasmids were transformed respectively into the competent JM109 E-coli cell with the CaCl₂ method. A 100 μL of transformants was grown on 8 cm \times 8 cm agar plates containing 100 $\mu\text{g/mL}$ ampicillin, 100 $\mu\text{mol/L}$ IPTG and 100 $\mu\text{g/mL}$ X-gal at 37 °C for 20 h when the blue/white staining could be clearly distinguished. White clones were counted, inoculated into 3 mL of LB liquid medium containing ampicillin and shaken overnight at 37 °C. The resulting bacterial culture was directly used as PCR templates to amplify the inserts in 50 μL reaction mixture containing 10 \times PCR buffer 5.0 μL , Mg²⁺ (25 mmol/L) 3 μL , nested primer 1 (20 $\mu\text{mol/L}$) 1 μL , nested primer 2R (20 $\mu\text{mol/L}$) 1 μL , dNTP mix (10 mmol/L) 1 μL , Taq enzyme mix (5 U/ μL) 0.5 μL and bacterial culture 0.5 μL . PCR consisted of an initial denaturation step at 94 °C for 5 min, followed by 25 cycles at 94 °C for 30 s, at 68 °C for 30 s and at 72 °C for 2 min each. The PCR products were analyzed on an 10 g/Lagarose/EB gel.

RESULTS

Quality identification of extracted mRNA

The extracted mRNA that was electrophoresed on 10 g/L agarose gel exhibited as a clear smear with over 0.5 kb length (Figure 1). Their absorbances($A_{260}/A_{280}>1.8$) in spectrophotometry suggested that extracted mRNAs were in a highly purified quality.

Figure 1 Quality identification of mRNA extracted from two cell lines, Lane 1: SW480 cell line, Lane 2: SW620 cell line.

RsaI digestion analysis of synthesized cDNA

The results of 10 g/L agarose electrophoresis showed that cDNA before digested with RsaI, displayed a zonal smear with a length from 0.5 kb to 10 kb. After the digestion, the cDNA length became shorter with fragments from 0.1 kb to 2 kb, suggesting that cDNAs were completely digested (Figure 2).

Analysis of ligation efficiency

The high ligation efficiency was the most important factor for

success of SSH. Figure 3 shows that the intensity of band 2/ band1, band4/ band3 was over 80%, indicating that subtracted cDNA library had the high ligation efficiency, 80% of the tester's ds cDNA fragments were ligated with adaptors1 or 2R.

Figure 3 Ligation efficiency analysis of ds cDNA, Lane 1: PCR products using tester1-1 (adaptor1-ligated-cDNA fragment) as the template and the G3PDH3', 5' primer; Lane 2: PCR products using tester1-1 as the template and the G3PDH3' primer, PCR primer1; Lane 3: PCR products using tester1-2 (adaptor2R-ligated-cDNA fragments) as the template and the G3PDH3', 5' primer; Lane 4: PCR products using tester1-2 as the template and the G3PDH3' primer, PCR primer1; Lane M: Marker DGL2000.

Analysis of secondary PCR products

Nested primers from the inner sequences of adaptors were used to amplify the primary PCR products, and the smear was increased obviously after 15 cycles, in which some obscure bands with the lengths between 0.2 and 1.5 kb were observed (Figure 4).

Figure 4 Electrophoresis of secondary PCR products, Lane C: Positive control cDNA supplied with the kit, Lane 1: Unsubtracted cDNA, Lane 2: Subtracted cDNA.

Subtractive efficiency

Figure 5 shows that obvious bands were seen after 23 cycles in

unsubtracted cDNA and after 33 cycles in diluted subtracted cDNA. The amount of G3PDH was significantly decreased after subtraction, indicating that the subtracted cDNA library had the high subtraction efficiency.

Figure 5 Reduction of G3PDH by PCR subtraction, Lanes 1-4: Unsubtracted secondary PCR products, Lanes 5-8: Subtracted secondary PCR products, Lanes 1, 5: 18 cycles, Lane 2, 6: 23 cycles, Lanes 3, 7: 28 cycles, Lane 4, 8: 33 cycles, Lane M: Marker DGL2000.

Screening for subtraction cDNA library

On the agar plates with 100 μ L of transformants, 235 white clones were obtained in the forward hybridization (group A) while 232 white clones were obtained in the reverse hybridization (group R) (Figure 6). White clones accounted for more than 80% of the total clones. Ninety-eight percent and 91% of the white clones were demonstrated by PCR having the inserts with a length of 200-700 bp in groups A and R, respectively (Figure 7), indicating that a subtracted cDNA library specific for metastasis in CRC was successfully constructed.

Figure 6 Blue/white screening for target clones, Two hundred and thirty-five white clones (86%) and 37 blue clones were seen on the agar plates in group A, and 232 white clones (91%) and 21 blue clones were seen in group R.

DISCUSSION

Metastasis is the major cause of mortality in CRC patients. The molecular basis for metastasis has not been fully elucidated yet. Available studies have shown that many specific genes are involved in the process of metastasis, which may accelerate or suppress metastasis by a mechanism of cooperative or inhibitive interactions between genes^[1]. Till now hundreds of genes have been reported to be involved in the regulation of metastasis in colorectal carcinoma. However, the existent methods for investigating the molecular mechanism of metastasis are mostly limited to the analysis of expressions of only one or several genes, which makes it difficult to understand the genes' interactions and their relations to the metastasis.

One of the most important ways to understand the carcinogenesis and development of tumors is to clone and identify the differentially expressed genes. In recent years several cloning techniques for the differentially expressed genes have been established, including differential display PCR (DD-PCR), representational difference analysis (RDA), SSH and cDNA microarray. Until now, these techniques have been widely applied in the study of pathology^[2], immune^[3], embryo development^[4], as well as the specific expression of tissue protein^[5]. Although it is rapid, easy to perform and sensitive, DD-PCR has also some limitations, such as the higher false positive rate and the truncated length of obtained specific cDNA that is usually located in non-translated regions of 3' poly(A). Likewise, RDA needs less amount of mRNAs samples and has lower false positive rate. But it is troublesome to perform more complicated steps of hybridization or PCR. Microarray-based methods have the potentials to revolutionize the study of differential gene expression under parallel conditions with higher automation. While a number of drawbacks of this approach have been found such as the higher expense and less sensitive than that of PCR-based techniques.

SSH was first put forward by Diatchenko *et al.* in 1996. The basic principle was that common cDNAs in the paired materials were subtracted by subtractive hybridization and then suppressive PCR was carried out to amplify cDNA fragments specially expressed in tester. The advantage of SSH was the design of two different adaptors and the introduction of suppression PCR with the result that the differentially expressed cDNA fragments were amplified. It allows two subtractive hybridizations in the forward or reverse direction. Some mRNA expressed with low abundance could be detected, which provided clues for the further gene sequencing and identification^[6-9]. With the development and improvement of SSH technique, it has become one of the most effective techniques for cloning differentially expressed genes. Since it was established, more than two hundred papers have been published concerning about carcinogenesis^[10], tumor metastasis^[11], signal transduction^[12], apoptosis^[13] and tumor therapy^[14]. Combined with other molecular biological techniques such as DNA chip, it could clone tumor associated genes^[15] and metastasis-associated genes in lung carcinoma, breast carcinoma and other malignancies^[16-20]. Zhang *et al.*^[21] carried out SSH in human NCI-H69 cell line and its variant, a more aggressive NCI-N417 SCLC cell line, to characterize the variable expression of genes between the two cell lines, in which 42 genes were screened by the forward and reverse hybridizations. Wang *et al.*^[22] have identified five cDNA fragments with SSH that were expressed at much higher levels in the poorly metastatic cancer cell clone than in the highly metastatic variety. Until now studies on separating metastasis-associated genes in human CRC have not been reported.

In our study, SSH and bacterial culture PCR were performed to construct a subtracted cDNA library specific for the metastasis-related genes of human CRC, in which a pair of

human colorectal carcinoma cell lines SW620 and SW480 was used. The SW480 cell line was derived from a Dukes' stage B colon carcinoma that arose in a 50-year-old male patient with liver and mesenteric lymph node metastases. The SW620 cell line was derived from one of the lymph node metastases. The monoclonal origin of the two cell lines that was confirmed by the presence of shared marker chromosomes on cytogenetic analysis makes it suitable to study the genetic basis of their phenotypic differences. Hewitt *et al.*^[23] have also found that the phenotypic differences of both SW620 and SW480 cell lines were retained, despite long-term culture *in vitro*.

Both the forward and reverse hybridizations were performed in this study. In the forward hybridization (group A), the highly metastatic cell line SW620 was treated as the tester, while the lowly metastatic cell line SW480 was treated as the driver in the reverse hybridization (group R). As a result, the total cDNAs in the tester and driver were subtracted efficiently. cDNA fragments appearing only in SW620 cells were amplified specially in group A and those only in SW480 cells were amplified in group R. After that, the second PCR products were inserted into T vectors and then screened by the blue/white screening system. Two hundred and thirty-five or 232 white clones were obtained in group A or group R respectively. The resultant subtractive cDNA library that was rich in metastasis-associated gene fragments of CRC was superior to that obtained by other methods for 4 reasons: (1) High specificity. Two subtractive hybridizations and two suppressive PCR were carried out to amplify the differentially expressed cDNA fragments, and suppress the amplification of unspecific cDNA fragments. Thus, the specificity of the subtractive library was greatly increased. (2) High sensitivity. The normalization of tester ss cDNA by SSH could make the differentially expressed genes with high or low abundance separated efficiently. (3) High efficiency. One SSH reaction could separate hundreds and thousands differentially expressed genes simultaneously. (4) More information. The differentially expressed fragments in the forward hybridization might have a role in accelerating metastasis, and those in the reverse hybridization might be metastasis suppressor genes. The forward and reverse hybridizations could provide more information of the screening results.

However, the subtracted cDNA library constructed by SSH had some limitations. One of them was the requirement of large quantities of mRNA samples. The other was that differentially expressed cDNAs obtained from SSH were cDNA fragments digested by restrictive enzyme and needed to be amplified to get the full length. These drawbacks could be overcome by other methods such as the multi-cycle linear amplification based on cDNA synthesis and template-guided *in vitro* transcription, in which enough mRNA for the continual research could be amplified with less than 1-50 ng RNA samples^[24]. Thus, it is especially suitable for tissues that are hard to get or too little to provide enough RNAs. In addition, the full length of differential fragments could be obtained by the rapid amplification of cDNA ends (RACE)^[25].

After the blue/ white screening, bacterial culture PCR was used in the present study to screen the positive recombinants. Compared with the routine methods, bacterial culture PCR was not only simple but also helpful for the further identifications. Our results showed that there were 98% clones with 200-700 bp inserts in group A and 91% positive clones of recombinants in group R, suggesting that these clones may contain metastasis-related cDNA fragments. The construction of this library is therefore of significance in screening and identifying the genes associated with metastasis of CRC, which would be beneficial to the elucidation of the molecular mechanism of metastasis and provide new gene targets for metastasis forecast, gene therapy and prognosis estimation in clinical practice.

Abstract

AIM: To study the relationship between infection with *Helicobacter pylori* L-forms and chronic gastritis and its association with possible changes of cellular immune function.

METHODS: Gastric mucosal biopsies were taken from 428 patients with chronic gastritis to detect *H pylori* L-form by Gram staining and immunohistochemistry staining. Peripheral venous blood samples of patients were taken to detect the percentage of CD3+, CD4+ and CD8+ by the biotin-streptavidin (BSA) assay and the levels of IL-2, IL-6 and IL-8 by ELISA.

RESULTS: The rate of infection with *H pylori* L-forms was 48.83% (209/428). The rate was 50.47% (216/428) and 52.80% (226/428), respectively, as detected by immunohistochemistry staining and Gram staining ($P>0.05$). The rate of *H pylori* L-forms in males and females was 57.8% (136/235) and 37.28% (73/193), respectively, ($\chi^2=17.05$, $P<0.01$). Furthermore, the rate increased with age, with the rate being significantly greater in patients ≥ 40 years old than in those <40 years old ($P<0.01$). The percentage of CD3+, CD4+, CD8+, the ratio of CD4+ / CD8+, and the levels of IL-2, IL-6, IL-8 in *H pylori*-positive patients were $47.58\pm 4.44\%$, $25.51\pm 4.74\%$, $22.77\pm 7.46\%$, $1.44\pm 0.51\%$, 1.56 ± 0.47 mg/L, 103.62 ± 5.85 ng/L, and 109.79 ± 7.18 ng/L, respectively. Compared with *H pylori*-negative patients, the percentage of CD3+, CD4+ and the ratio of CD4+ / CD8+ and the IL-2 level decreased, but the levels of IL-6, IL-8 increased ($P<0.001$ - $P<0.01$). Moreover, the percentage of CD3+, CD4+, CD8+, the ratio of CD4+ / CD8+, and the levels of IL-2, IL-6 and IL-8 in patients infected with both *H pylori* L-forms and vegetative forms were $46.67\pm 5.21\%$, $30.75\pm 4.89\%$, $22.15\pm 6.45\%$, $1.32\pm 0.47\%$, 1.16 ± 0.38 mg/L, 116.45 ± 5.44 ng/L, and 118.64 ± 6.24 ng/L, respectively. Compared with patients infected with only vegetative forms, the percentage of CD4+, the ratio of CD4+ / CD8+ and IL-2 level decreased, but the levels of IL-6 and IL-8 increased ($P<0.001$ or $P<0.01$).

CONCLUSION: L-form variation often occurs in patients with chronic gastritis and is commonly found in male patients and associates with ages. The L-form variation may be an important factor causing disorder of cellular immune function in the patients with *H pylori*-induced chronic gastritis.

INTRODUCTION

Helicobacter pylori infection of the gastric mucosa can be found in approximately 50% of the world's population, and is associated with a range of pathologies, including chronic gastritis, peptic ulcer, atrophic gastritis, and gastric cancer^[1-6]. Infection of *H pylori* is life-long that elicits a marked host inflammatory response^[7-9]. However, natural infection fails to yield protective immunity^[10,11]. *H pylori* is a gram-negative, spiral and microaerophilic bacterium that colonizes the gastric epithelium of humans^[12-15]. Under some hostile conditions, *H pylori* changes from vegetative forms into L-forms by which *H pylori* can escape the body's immune response and live in the body for a long time. Once conditions return to normal *H pylori* reverts into vegetative forms, which further deteriorates the pathological changes. Therefore, *H pylori* L-forms appear to be more pathogenic and virulent than vegetative forms^[16-18]. Animal experiments and clinical studies have demonstrated that damages induced by *H pylori* are associated with Th1 cell-mediated immune response^[19-23]. The aim of this study was to confirm the occurrence of L-forms variation of *H pylori* vegetative forms, and to determine the relationship between *H pylori* L-form infection and chronic gastritis, and its association with possible changes of cellular immune function in the patients. In the study, gastric mucosal biopsies were taken from 428 patients with chronic gastritis to detect *H pylori* L-form by Gram staining and immunohistochemistry staining, and T lymphocyte subsets and serum levels of IL-2, IL-6 and IL-8 of patients were also detected.

MATERIALS AND METHODS

Patients

A total of 428 patients (aged from 14 to 67 years, 235 males and 193 females) with chronic gastritis diagnosed in our affiliated hospital from September 2000 to December 2002 were included in this study. Patients with other diseases were excluded.

Reagents

Gram staining and immunohistochemistry staining were used in this study. The biotin-streptavidin (BSA) reagents for T lymphocyte subset classification were provided by Jin'an Medical Laboratory Institute in Shanghai. Separating medium for lymphocyte was supplied by The Second Biochemical Reagent Factory in Shanghai (batch No.011215), and the test kits for IL-2 (batch No.1002-21), IL-6 (batch No.1006-32) and IL-8 (batch No.1008-25), were offered by Besancon Company (France).

Detection of *H pylori* L-forms

Biopsies of gastric antrum and gastric corpus were taken from 428 patients during upper endoscopy, fixed in 40 g/L formaldehyde, then embedded in paraffin and cut into section in 4 μ m thickness. The sections were used for Gram staining and immunohistochemistry staining separately. Gram stained slide was observed under oil lens (10 \times 100), and a total of 10-15

fields were randomly counted for *H pylori* L-forms. We regarded it as positive only when the average number was greater than 20. The antigen and antibody used in immunohistochemistry staining for *H pylori* L-forms were made in our laboratory, and the concentration of first antibody is 1:80. Other steps were performed according to the instruction of manufacturer (Dako company), using the known positive slide as a positive control and using PBS instead of first antibody as a negative control. A specimen was defined to be infected with *H pylori* L-forms when both staining methods produced a positive result.

Detection of cellular immune function

To investigate the possible changes of cellular immune function in *H pylori*-infected individuals, including the patients infected by *H pylori* L-forms and vegetative forms, the percentage of CD3+, CD4+, CD8+, ratio of CD4+/CD8+, and the levels of IL-2, IL-6, IL-8 in peripheral blood of *H pylori*-positive individuals were tested with the biotin-streptavidin (BSA) method. The peripheral venous blood of the subjects was taken, anticoagulated with heparin, and diluted with a solution free of Ca²⁺, Mg²⁺. Then, peripheral blood mononuclear cells were separated with lymphocytes separating medium and cleaned, and the number of cells was adjusted to (1-3)×10⁹/L of which 10 µL was taken and smeared in an acidproof varnish circle on the surface of a slide. When it dried naturally, McAb of anti-CD3+, anti-CD4+ and anti-CD8+, and sheep anti-guinea pig IgG, and SA-HRP. Cells was regarded as positive when the membrane was stained in brown color. A total of 200 cells were counted, and the positive percentages of cells were calculated. In addition, the serum levels of IL-2, IL-6 and IL-8 were detected by ELISA following the procedures detailed in the product instructions.

Statistical analysis

Data were expressed as mean±SD. Multiple comparison tests were performed with the χ^2 test and *t*-test.

RESULTS

Examination of *H pylori* L-forms with gram staining

Of the 428 patients studied, 226 (52.80%) were positive for both *H pylori* vegetative forms and L-forms, and other 17 (3.97%) were positive for vegetative forms only by Gram staining. The morphology of *H pylori* L-forms was highly variable, such as spheroid, coccoid form, big body, elementary body, long filament body, as seen on the smears under microscope.

Comparison between gram staining and immunohistochemistry staining

H pylori L-forms was detected in 216 (50.47%) patients by immunohistochemistry staining, of whom 209 (48.83%) were also detected *H pylori* L-forms by Gram staining. There was no significant difference in detection rate of *H pylori* L-forms between the 2 methods ($P>0.05$) (Table 1).

Relationship between infection of *H pylori* L-forms and gender as well as age of patients with chronic gastritis

H pylori L-forms were present in 57.87% (136/235) of males and 37.82% (73/193) of females ($\chi^2=17.05$, $P<0.01$). Furthermore, the rate of *H pylori* L-forms was significant difference between patients <40 years old and those ≥ 40 years old ($P<0.01$) (Table 2).

Detection of cellular immune function

The percentages of CD3+, CD4+ and the ratio of CD4+/CD8+ and IL-2 decreased, but the levels of IL-6 and IL-8 increased in *H pylori*-positive patients, compared with *H pylori*-negative patients, (Tables 3 and 4). In addition, the percentage of CD4+, the ratio of CD4+/CD8+ and the levels of IL-2 decreased, but

the levels of IL-6 and IL-8 increased in the patients infected by both L-forms and vegetative forms of *H pylori*, compared with those only infected by vegetative forms (Tables 3, 4).

Table 1 Comparison of Gram staining and immunohistochemistry staining in detection of *H pylori* L-forms

Gram staining (n)	Immunohistochemistry staining (n)		Total (n)
	Positive	Negative	
Positive	209	17	226
Negative	7	195	202
Total	216	212	428

$\chi^2=0.46779$, $P>0.05$ between the 2 methods.

Table 2 Relationship of infection of *H pylori* L-forms with gender and age of patients with chronic gastritis

Age(yr)	Male		Female		Total	
	n	Detection rate (%)	n	Detection rate (%)	n	Detection rate (%)
14-	62	31 (50.00)	75	17 (22.67)	137	48 (35.04) ^b
30-	37	14 (37.84)	48	18 (37.50)	85	32 (37.65) ^b
40-	55	35 (63.64)	23	12 (52.17)	78	47 (60.26) ^b
50-	81	56 (69.14)	47	26 (55.32)	128	82 (64.06) ^b

DISCUSSION

Helicobacter pylori was first isolated by Warren and Marshall in 1983 from gastric mucosa of patients with gastritis. It is now accepted to be an etiological agent of chronic gastritis, peptic ulcer and gastric cancer. It is a Gram-negative, spiral-shaped, microaerophilic bacterium that colonizes human gastric epithelium, with a curved, S or arc-like appearance in the stomach. When exposed to factors such as gastric juice, bile,

antibiotics and other hostile conditions, some bacterial cells turn into pleomorphic variations^[24-26] of which L-forms (spheroid) is the most common one^[27-30]. In this study, gastric mucosal biopsy specimens from 428 patients with chronic gastritis were taken for the detection of *H pylori* L-forms. Gram staining showed that 226 patients were infected with both *H pylori* L-forms and vegetative forms, and 17 patients were infected with *H pylori* vegetative forms only. This indicates that L-forms variation of *H pylori* is common in patients with chronic gastritis. Due to the loss of cell walls, or certain components and antigens of cell walls, *H pylori* L-forms differ from the vegetative forms in antigenicity, which may affect the result of serology diagnoses and, more importantly, enables the bacteria to live in the stomach for a long time by escaping the body's immunity. Moreover, when conditions improve, L-form can revert to typical vegetative forms, which may be an important factor leading to deterioration and relapse of infection. Therefore, *H pylori* L-forms are more adhesive, invasive and pathogenic, and the variation of *H pylori* results in the deferment and recurrence of chronic gastritis^[9,31].

In this study, the detection rate of *H pylori* L-forms was significantly greater in males than in female (57.87% vs 37.82%). This may be related to some male habits, such as smoking, drinking, irregular diets that might damage gastric mucosa and change the gastric internal environment^[9,30-35]. In addition, the presence of *H pylori* L-forms seems to be related to patients' ages, as the detection rate of *H pylori* L-forms increases with age.

Cellular immune function of patients with *H pylori* has been described in recent years. The chronic inflammatory responses associated with natural infection do not provide protection, but contribute to tissue damages and pathogenesis of gastroduodenal diseases, including atrophic gastritis, peptic ulcer, and gastric cancer. These immune responses are likely to attribute to a subject of T helper lymphocytes, so-called Th1 cells, which enhance cell-mediated immunity and induce damage to the gastric epithelium. To investigate the mechanisms for Th1 immune response caused by *H pylori* based on the variation of L forms, T lymphocyte subsets and the levels of IL-2, IL-6, and IL-8 in peripheral blood of the patients were detected. The results showed that in *H pylori*-positive patients, CD3+, CD4+, CD4+/CD8 and IL-2 decreased, but IL-6 and IL-8 increased, compared with those in *H pylori*-negative, indicating that *H pylori* infection may weaken the immune function of the host and cause a predominant Th1 cellular response. Moreover, the percentage of CD4+, the ratio of CD4+/CD8 and the level of IL-2 were lower but the levels of IL-6 and IL-8 were higher in the patients infected with both L-forms and vegetative forms, compared with those infected with vegetative forms only. Thus, *H pylori* L-forms infection may be closely related to disorder of the immune function, and may be one of the crucial factors causing Th1 immune response. We postulate that *H pylori* L-forms may invade into the host cells where they may serve as a pronounced inducer for Th1-type CD4 (+) T cell response, leading to the decrease in the percentage of CD4+ and the ratio of CD4+/CD8. Active CD4+-T cell may also inhibit the activation of Th1 cells cytokines, and the outcome of IL-2 is a risk factor of cellular immune response.

In addition, in this study, the levels of IL-6 and IL-8 in peripheral blood of the patients increased significantly, which is likely to be associated with ulceration inflammation, blood macrophage stimulation and active secretion by the neutrophils and vascular endothelial cells. Once attached to the gastric epithelial cells, *H pylori* incites an immune response characterized by the increased pro-inflammatory cytokine of IL-8, IL-12 and TNF-alpha. Activated inflammatory and immunologically competent cells such as neutrophils, lymphocytes and monocytes release cytokines such as IL-6, IL-8 and IFN-gamma. As a result, the serum levels of IL-6 and IL-8 increase^[18].

In conclusion, Co-infection with both *H pylori* vegetative forms and L-forms is common in patients with chronic gastritis. The rate of infection with *H pylori* L-forms in males is higher than in females, and the rate increases with age. Once *H pylori* L-forms occurs, the morphology and microstructure of the organisms change, i.e., the cell walls of the L-forms are partly or completely lost, the charge of the bacterial surface increases, and the adherence and invasiveness of the bacteria become more powerful. All of these changes may play an important role in the deferment and relapse of chronic gastritis and in the disordered cellular immune function in patients with *H pylori* infection.

Abstract

AIM: To investigate the significance of c-kit gene mutation in gastrointestinal stromal tumors (GIST).

METHODS: Fifty two cases of GIST and 28 cases of other tumors were examined. DNA samples were extracted from paraffin sections and fresh blocks. Exons 11, 9 and 13 of the c-kit gene were amplified by PCR and sequenced.

RESULTS: Mutations of exon 11 were found in 14 of 25 malignant GISTs (56%), mutations of exon 11 of the c-kit gene were revealed in 2 of 19 borderline GISTs (10.5%), and no mutation was found in benign tumors. The mutation rate showed significant difference ($\chi^2=14.39$, $P<0.01$) between malignant and benign GISTs. Most of mutations consisted of the in-frame deletion or replication from 3 to 48 bp in heterozygous and homozygous fashions. None of the mutations disrupted the downstream reading frame of the gene. Point mutations and frame deletions were most frequently observed at codons 550-560, but duplications were most concentrated at codons 570-585. No mutations of exons 9 and 13 were revealed in GISTs. Neither c-kit gene expression nor gene mutations were found in 3 leiomyomas, 8 leiomyosarcomas, 2 schwannomas, 2 malignant peripheral nerve sheath tumors, 2 intra-abdominal fibromatoses, 2 malignant fibrous histiocytomas and 9 adenocarcinomas.

CONCLUSION: C-kit gene mutations occur preferentially in malignant GISTs and might be a clinically useful adjunct marker in the evaluation of GISTs and can help to differentiate GISTs from other mesenchymal tumors of gastrointestinal tract, such as smooth muscle tumors, schwannomas, etc.

INTRODUCTION

GISTs are the most common mesenchymal tumors of the human

gastrointestinal tract, previously uniformly classified as smooth muscle tumors. Recently, GISTs have been defined as cellular spindle cell, epithelioid, or occasionally pleomorphic mesenchymal tumors of the gastrointestinal tract (GI) that express the c-kit protein (CD117), as detected using immunohistochemistry. GISTs are strongly and nearly uniformly CD117 positive^[1-4].

Recently, the c-kit mutations in GISTs have been shown to lead to ligand-independent activation of the tyrosine kinase of c-kit^[5]. So several questions were suggested: what are the possible relationship of c-kit expression and mutations, the relationship of mutations and malignancy, and the possible specificity of the mutations for GISTs?

A study of larger series of GISTs, revealed that these tumors had a spectrum of clinical behaviors at all sites of their occurrence^[6]. Some GISTs are typical benign tumors, and most of them are found incidentally in other conditions, for example, during gall bladder or gynecologic surgery. In contrast, other GISTs metastasize to the liver and disseminate in the peritoneal cavity. Large tumor size, presence of intratumoral necrosis, infiltrative growth pattern in muscularis propria, invasion of mucosa, and high mitotic figures are considered as malignant. However, there is a definite percentage of mitotically inactive tumors that subsequently metastasize, emphasizing the fact that low mitotic count does not rule out a malignant behavior. Therefore, the designation "uncertain malignant potential" applies to a significant number of GISTs.

In this study, we further explored whether the c-kit gene mutations were valuable as an adjunct malignant marker in GISTs and could help to differentiate GISTs from other tumors.

MATERIALS AND METHODS

Cases

Archival paraffin-embedded and frozen tissue samples of 52 GISTs were immunohistochemically analysed for CD117 and CD34. They were mainly obtained from the Department of Pathology, Zhongshan Hospital, Fudan University, and from other pathology departments in Cancer Hospital, Huadong Hospital, and Chongming Center Hospital, etc. Additionally, 28 other tumors were investigated, including 8 leiomyosarcomas of retroperitoneum, 3 leiomyomas of esophagus, 2 schwannomas of stomach, 2 malignant peripheral nerve sheath tumors of intra-abdomen, 2 intra-abdominal fibromatoses of intestine, 2 malignant fibrous histiocytomas of intra-abdomen, and 9 adenocarcinomas of GI (of which, 4 were accompanied by GISTs).

Histologic evaluation

One to 14 hematoxylin and eosin-stained slides (median, 4 slides) were reviewed for each case. The following features were recorded in all cases: type of the majority cells (spindle vs epithelioid), skeinoid fibers (extracellular collagen globules), mucosal ulceration. Additionally, other important features included mitoses counted from 50 consecutive high-power fields (HPFs), coagulation necrosis, infiltrative growth pattern, and lymph node involvement. According to the histologic observation, GISTs were divided into 3 groups: small incidental tumors with less 5 cm in diameter or fewer mitoses per 50 HPF

were designated as benign, mitotically inactive tumors larger than 5 cm or cellular tumors which had no necrosis and infiltration were designated as uncertain malignant potential, and tumors with active mitotic counts over five per 50HPF or with necrosis, infiltrative growth pattern were designated as malignant.

Immunohistochemistry

Antibodies to the following antigens were used. CD117 (c-kit protooncogene product, polyclonal, 1:70) was purchased from Santa Cruz Biotechnology, Santa Cruz, CA, USA, CD34 (QBEND-10, monoclonal, 1:150, DAKO), α -SMA (1A4 monoclonal, 1:200), MSA (HHF35 monoclonal, 1:200), desmin (D33, monoclonal, 1:150), S-100 protein (polyclonal, 1:300), and protein gene product 9.5 (PGP9.5, polyclonal, 1:300) were purchased from Dako Corp. Epitope retrieval was used for antibodies. The slides were immersed in 10 mmol/L citrate buffer, pH 6.0 and heated in a microwave oven at a high setting for 5 min. The EnVision staining technique was used followed by incubation with 3,3'-diaminobenzidine tetrahydrochloride and counterstained with hematoxylin.

DNA extraction

Ten micrometers of tissue sections were cut from freshly frozen tumors or paraffin embedded, and then incubated in extraction buffer (50 mmol/L KCl, 10 mmol/L Tris[pH8.3], 2.5 mmol/L MgCl₂) containing 60 μ g/mL proteinase K overnight at 55 °C. The proteinase K was inactivated by a 10-min incubation at 95 °C. The resulting lysate was spun in a microcentrifuge for 5 min to pellet debris, and then stored at -20 °C.

PCR amplification of exons 11, 9, and 13 of c-kit gene

PCR assays were developed to amplify exons 11, 9, and 13. The 3 primer pairs were designed based on the human c-kit gene. Exons 9, 11 and 13 of the c-kit gene were amplified by PCR using the following oligonucleotide primer pairs: for exon 9, 5'-TCCTAGAGTAAGCCAGGGCTT-3' / 5'-TGGTAGACAGAGCCTAAACATCC-3'; for exon 11, 5'-CCAGAGTGCTCTAATGACTG-3' / 5'-TGACATGGAAGCCCCTGTT-3'; and for exon 13, 5'-GCTTGACATCAGTTTGCCAG-3' / 5'-AAAGGCAGCTTGGACACGGCTTTA-3'. The lengths of PCR products were

261 bp, 225 bp, and 193 bp, respectively. The PCR reaction conditions were the standard ones recommended by Perkin Elmer. The annealing temperature was 55 °C. The PCR products were size fractionated on 50 g/L polyacrylamide gels and stained with ethidium bromide.

DNA sequencing

Direct sequencing was performed on the ABI Prism 310 DNA sequencer, using the same primers as were used for amplification. Sequencing reactions were conducted with the big dye terminator sequencing ready reaction kit (Perkin-Elmer) according to the manufacturer's instructions.

Statistical analysis

χ^2 test was used.

RESULTS

Clinicopathological features of GISTs

There were 27 gastric, 7 small intestine, 6 rectal, 5 extra-GI, 2 abdominal disseminated primary tumors, with 5 intraabdominal recurrences. Of these tumors, 8 were classified as histologically benign, 19 as histologically uncertain malignant potential of borderline tumor, and 25 as malignant based on high mitotic activity, coagulative necrosis, infiltrative growth pattern. These tumors displayed a wide variety of cell types and histologic patterns, of which, 34 tumors had a predominant spindle cell pattern, 8 were epithelioid, and 10 were spindle/epithelioid mixed. The spindle cells were most often arranged in interlacing fascicles. The epithelioid cells were characterized by sheets. However, they often showed focally a storiform pattern, mimicked large rosettes, or palisaded the nuclei.

Immunohistochemical findings

CD117 positivity was detected in 50 of 52 cases (96.2%), typically in most of tumor cells in a strong membrane of apparently diffuse cytoplasm. CD34 positivity was seen in 38 of 52 cases (73%), including focal reactive cases. Two CD117-negative cases were CD34 positive. A small number were focal positive for α -SMA (10 of 52), MSA (9 of 52), desmin (2 of 52). Additionally, 6 and 3 cases were reactive for S-100 and PGP9.5.

Figure 1 Exon 11 of c-kit mutations in 16 GIST samples. The wild-type sequence of amino acids encoded by exon 11 is shown at the top. The sequence starting at codon 550 and ending at 590. The wild-type sequence is shown above, the numbers are shown at the left. Point mutation is shown in black type, deletion is shown in thin line indicates heterozygote mutation and thick line indicates homozygote ones. the shaded areas correspond to insertion or duplication mutations.

Evaluation of mutations in exons 11, 9, and 13 of *c-kit* gene

PCR amplification and DNA sequencing revealed exon 11 mutation in 14 malignant GISTs, in 2 borderline GISTs, and in no benign GISTs. Sequence analysis showed in-frame deletions of 3 to 48 bp, point mutations, and duplications. Point mutations and deletions were most frequently observed at codons 550-560, but duplications were most concentrated at codon 570-585. Of the 16 mutated GISTs, 2 had a homozygous mutation and 14 heterozygous mutation, which did not result in any amino acid change. The sequence corresponding to these mutations are shown in Figure 1. Figure 2 shows a case of duplication by DNA direct sequencing.

Five non-tumor tissue samples from the stomach or intestine adjacent to mutation-bearing GISTs demonstrated neither deletions nor point mutations.

The conservation of *c-kit* mutation pattern was observed in a relapse lesion from the same patients (Figure 3).

No exon 9 and exon 13 mutation were detected.

χ^2 test showed that the *c-kit* mutation of GISTs demonstrated a statistical ($\chi^2=14.39$, $P<0.01$) significance between the malignant group and the borderline and benign groups.

Figure 2 Duplication of codons from 581 to 584 (PYDH) in one case of GIST by direct sequencing of *c-kit* exon 11.

Figure 3 Deletion of codon from 553 to 557 (YEVQW) by direct sequencing of *c-kit* exon 11.

Other tumors

The three esophageal leiomyomas were histologically paucicellular spindle cell neoplasms with distinctly eosinophilic cytoplasm, and lack of mitotic activity. All cases were positive for α -SMA, MSA and desmin, and negative for CD117 and CD34, and only mast cells in the stroma showed positive CD117.

The 8 retroperitoneal leiomyosarcomas were spindle cell tumors that resembled smooth muscle tumor with oval to mildly elongated nuclei and variably eosinophilic cytoplasm. Four tumors showed focal pleomorphism and high mitotic activity ($>50/50$ HPF). Coagulation necrosis was present in 4 tumors. All cases were positive for α -SMA, MSA, and 7 cases positive for desmin. All cases were negative for CD34 but 1 case was focal weak positive for CD117.

The 2 cases of schwannomas showed slender spindle cells

and a characteristic lymphoid cuff. Two cases were diffusely and strongly positive for S-100 and 1 case was positive for PGP9.5. Both of them were negative for CD117 and CD34. The 2 cases malignant peripheral nerve sheath tumor showed spindle cells and active mitosis. Two cases were positive for S-100 and weak positive for PGP9.5 and negative for CD117 and CD34.

The 2 cases of intro-abdominal fibromatosis of intestine and 2 cases of malignant fibrous histiocytoma were negative for all antigens but 1 case of intro-abdominal fibromatosis was focal positive for α -SMA.

There were no mutations of the *c-kit* gene in the above 28 control tumors and one case of adenocarcinoma accompanied by mutation-bearing GIST also had wild-type *c-kit* gene.

DISCUSSION

Most of the GISTs examined expressed both CD117 and CD34, which was consistent with the literature reports^[7-12]. The rates of CD117 and CD34 expression had no difference between benign, borderline, and malignant GISTs, so the expressions were not useful markers for evaluating malignancy.

In this study, we examined the sequence and expression of *c-kit* gene in the spectrum of GISTs, including benign, borderline, and malignant variants from different sites. The sequences of *c-kit* gene were also evaluated in typical smooth muscle tumors, schwannomas and other tumors, especially in 4 adenocarcinomas accompanied by GISTs.

Our series of 52 benign, borderline, and malignant GISTs showed that 96.2% of the GISTs expressed CD117 and only some of the GISTs had mutations. The results indicated a considerable proportion of GISTs expressed CD117 with no mutation. In other words, most of *c-kit* mutations did not affect the proportion of GISTs with CD117 expression. Mutations in exon 11 of the *c-kit* gene were observed in 56% of malignant cases. In contrast, only 2 borderline GISTs (10.5%) showed mutations, and no benign GISTs showed mutations, suggesting that the mutations of exon 11 of the *c-kit* gene may represent a genotypic marker with a correlation to malignancy.

Lasota and colleagues^[13] reported the mutation of exons 9 and 13, but the mutation rate seemed to be very low, and they only detected the small portion (8%) of mutations of GISTs in exons 9 and 13, which did not have mutations in exon 11 of the *c-kit* gene. In our series, no mutations were detected. The result also indicated the rates of mutations in other regions of the *c-kit* gene were very low.

Our present results were in accordance with those previously reported^[14-16]. In hot spot region of exon 11 involving codons 550-560, point mutation and frame deletion were mainly detected at these codons, and 2 cases showed homozygous deletions.

In addition to the change at codons of 550-560, however, the duplication mutation fashion was found in 3 cases to cluster at codons 570 to 585, which was rarely detected in the previously reports.

Analysis of *c-kit* mutation pattern in relapse lesions showed the persistence of the mutation that remained identical in the primary lesion. Therefore, the *c-kit* mutation pattern could be tumor-specific.

C-kit mutations were never observed in smooth muscle tumors or nerve sheath tumors or other soft tissue tumors. Furthermore, one adenocarcinoma accompanied by mutation-positive GIST was the wild-type *c-kit* gene. Therefore, *c-kit* mutations may also represent a genotypic lineage marker for GISTs.

Previous and present molecular studies have revealed the gain-of-function mutations of the *c-kit* gene could be observed in mast cell neoplasms^[17,18], human germ cell tumors^[19] and GISTs, but the location of *c-kit* mutations differs in them. The particular aspartic acid in the tyrosine kinase domain would

changes into valine in mast cell neoplasms, The aspartic acid at amino acid position 816 would change into histidine, whereas deletion, point mutation, or both in the juxtamembrane domain were observed in GISTs mutations. Specially, the mutations were located within codons 550 to 560 in exon 11, and rare mutations are detectable in other domains of the c-kit gene, such as exons 9, 13. Clustering of c-kit mutations in the same region of GISTs and in different region with mast cell neoplasm supported their specific biological significance.

The occurrence of activating mutations involving exon 11 of the c-kit gene in sporadic GIST and the association of exon 11 germline mutations in familial GISTs indicated they were important in GIST's tumorigenesis^[20]. Especially, c-kit mutations could be detected only in some of GISTs^[21,22], so the value of the c-kit gene mutation in GISTs inspired the researchers, but there are no concordant conclusions, reports regarding the frequency of mutations in exon 11 varied widely, and prognostic significance of c-kit mutations with respect to the association between exon 11 mutations and malignant histology and/or aggressive malignant behavior were conflicting, and the reported frequency of these mutations varied over a wide range^[23-29]. Taniguchi and colleagues^[23] found that c-kit mutation-positive GIST were worse than c-kit mutation-negative GISTs. But other studies showed that c-kit exon 11 mutation analysis did not correlate well with histological assessment of malignant potential, and could not be regarded as a reliable objective marker for poor prognosis in GISTs.

Some malignant GISTs lack of exon 11 mutation suggested that mutations in exon 11 of c-kit gene were not the only mechanisms related to malignancy and there must exist other molecular mechanisms^[30-33], which may include mutations in other regions of the c-kit gene. But previous report and our study indicated other region mutation of the c-kit gene was few. Recently, Heihrich and colleagues^[34] have made an important finding in GISTs, they reported that 35% (14/40) of GISTs lacking c-kit mutations had intragenic activation mutations in tyrosine kinase, platelet-derived growth factor (PDGFRA). C-kit gene and PDGFRA mutations appeared to be alternative and mutually exclusive in GISTs, further study is needed to understand the role of PDGFRA in GISTs.

In summary, the results showed a consistent c-kit expression in GISTs with or without detectable mutations. The mutations occurred more preferentially in malignant GISTs than versus in benign GISTs, but not in smooth muscle tumor and other tumors. These observations suggest that mutations in exon 11 of the c-kit gene might represent useful molecular genetic markers for malignant GISTs and help to differentiate GIST from other tumors. Whether the c-kit gene mutation can indicate bad prognosis of malignant GISTs needs to be further studied.

ACKNOWLEDGMENTS

We thank Dr. Lu X,Y. and Dr. Yu M. for kindly providing the cases.

Abstract

AIM: To investigate the pathway via which 17 β -estradiol (β -Est) exerts suppressive effects on rat hepatic fibrosis.

METHODS: *In vivo* study was done in CCl₄-induced female hepatofibrotic rats. Fibrosis-suppressive effect of β -Est (20 μ g/kg·d) was evaluated in intact and ovariectomized rat models. Six weeks after the treatment, all the rats were sacrificed and specimens of serum or liver tissue were collected for the studies. Serum liver enzymes, fibrosis markers and estradiol levels were determined by standard enzymatic methods, ELISA and RIA, respectively. Degrees of fibrosis and areas of hepatic stellate cells (HSCs) positive for α -smooth muscle actin (α -SMA) in the liver were determined by van Gieson (VG) stain and immunohistochemistry. *In vitro* studies, HSCs were isolated by a combination of pronase-collagenase perfusion and density gradient centrifugation. First-passage HSCs were randomly divided into 10 groups, and different concentrations of β -Est, 2-hydroxyestradiol (2OHE) or 2-methoxyestradiol (2MeOE) were separately added to the cell groups. After incubation for 72 h, the degree of cell proliferation, collagen production, α -SMA or estrogen receptor (ER) expression was determined by MTT assay, ELISA and immunohistochemistry, respectively.

RESULTS: β -Est treatment reduced aspartate aminotransferase (AST), alanine aminotransferase (ALT), hyaluronic acid (HA) and type IV collagen (C IV) in sera, suppressed hepatic collagen content, decreased the areas of HSCs positive for α -SMA significantly in both intact and ovariectomized female hepatofibrotic rats. There was a negative correlation between the percentage of fibrotic area of liver tissue and the serum estradiol level; the calculated correlation coefficient was -0.57 ($P < 0.01$). β -Est and its metabolites concentration-dependently (10^{-9} mol/L- 10^{-7} mol/L) inhibited HSC proliferation and collagen synthesis. At the concentration of 10^{-7} mol/L, they could inhibit α -SMA expression. The order of potency was 2MeOE > 2OHE > β -Est.

CONCLUSION: β -Est may suppress hepatic fibrosis probably via its biologically active metabolites.

INTRODUCTION

Several epidemiological studies demonstrated a lower incidence of hepatic cirrhosis and its complications in women than in men^[1-3]. But as menopause comes, the morbidity of the disease increases gradually. So, endogenous estrogen may take part in the protective effects on hepatic fibrosis. *In vivo*, 17 β -estradiol (β -Est) is the most active estrogen and can be converted to several metabolites, some of which are known to possess biological activities. Of the various metabolites, 2-hydroxyestradiol (2OHE) and 2-methoxyestradiol (2MeOE) are the biologically active substances, which have been investigated in depth^[4,5]. 2OHE is one of the hydroxylated metabolites of β -Est converted by cytochrome P-450 enzymes (CYP450) and can be rapidly catalyzed by enzyme catechol-O-methyl-transferase (COMT) to 2MeOE^[6-8]. Recent studies have shown that 2OHE and 2MeOE could inhibit DNA synthesis, cell proliferation, collagen synthesis and mitogen activated protein kinase activity in vascular smooth muscle cells (VSMCs), cardiac fibroblasts (CFs) and glomerular mesangial cells (GMCs) with the potency stronger than β -Est^[9-13]. Hence, the fibrosis-suppressive effects of β -Est not only reflect the biological effects of β -Est per se but also those of its biologically active metabolites.

Hepatic stellate cells (HSC), the key cells responsible for hepatic fibrogenesis, are VSMC, CF or GMC analogs and belong to the pericytes generically^[14]. So, they may have many properties in common, including a prominent role in fibrosing injury and the same reaction to metabolites of β -Est.

The present study was initiated to investigate the role of β -Est in the female rat model of carbon tetrachloride (CCl₄)-induced hepatic fibrosis. Moreover, the effects of β -Est, 2OHE and 2MeOE on the first-passage rat HSCs were assessed.

MATERIALS AND METHODS

In vivo study

Fifty female Sprague-Dawley rats aged 10 wk (Laboratory Animal Center affiliated to Chinese Academy of Sciences, Shanghai, China) were divided into 5 groups ($n=10$). All the rats were initiated with either a bilateral ovariectomy (Ovx) or a sham operation 3 wk before the studies. Control group received subcutaneous injection of olive oil (3 mL/kg every 3 d and first dosage doubled), CCl₄ group was given the same dose of 400 g/L CCl₄, OvX+CCl₄ group was treated with the same dose of 400 g/L CCl₄ after ovariectomy, β -Est+CCl₄ group along with CCl₄ injection described above was treated with 0.002% β -Est (1 mL/kg·d, Sigma-Aldrich Corporation, St Louis, Missouri, USA), OvX+ β -Est+CCl₄ group was treated the same as β -Est+CCl₄ group with the addition of ovariectomy.

At the end of 6 wk, the number of alive rats in the groups was 10, 7, 8, 10, 9 respectively. Several rats died of infection at the site of injection or hepatic crack by unsuitable handling.

After an overnight fast, all the rats were sacrificed. Serum samples obtained were treated with proteinase inhibitor and stored at -20°C . Liver tissue specimens were rinsed with normal saline containing 0.1 g/L DEPC, some were stored at -80°C , and the others were fixed in neutral formalin and embedded in paraffin.

Serum activities of aspartate aminotransferase (AST) and alanine aminotransferase (ALT) were assayed by standard enzymatic methods, hyaluronic acid (HA) and type IV collagen (C IV) concentrations were measured by enzyme-linked immunosorbent assay (ELISA) using a commercial kit (Navy Medical Institute, Shanghai, China).

The embedded liver specimens were sliced 5 μm in thickness, mounted on slides, deparaffinised in xylene, and dehydrated in alcohol. For histopathological studies, the liver sections were stained with van Gieson (VG). For alpha-smooth muscle actin (α -SMA) immunohistochemistry, the sections were incubated with 3% (v/v) hydrogen peroxide in methanol for 15 min to block endogenous peroxidase, and then with 1 g/L Triton-X plus 1 g/L BSA in phosphate-buffered saline (PBS) to block non-specific antigens. After absorption of surplus liquid, the samples were incubated with a 1:100 dilution of a polyclonal antibody against α -SMA (Boster Biological Technology Corporation, Wuhan, China) at 37°C for 2 h. Then the samples were rinsed and incubated with a 1:100 dilution of biotin-conjugated goat anti-rabbit IgG (Boster Biological Technology Corporation, Wuhan, China) at 37°C for 30 min. Finally, the antigen-antibody complexes were visualized with 3,3'-diaminobenzidine (DAB).

For morphometric analysis, the mean value of collagen content or α -SMA positive cells in six ocular fields per specimen was used as the percentage area at 100x magnification using Zeiss KS400 image analysis system (Kontron Electronics, Eching, Germany).

Serum estradiol concentrations were measured with radioimmunoassay (RIA) using a commercial kit (Diagnostic Products Corporation, Tianjin, China).

In vitro study

HSCs were isolated and purified from the livers of normal female rats weighing about 400 g to 450 g by a combination of pronase-collagenase perfusion and density gradient centrifugation^[15-19]. Briefly, the liver was perfused *in situ* through the portal vein, first with $\text{Ca}^{2+}/\text{Mg}^{2+}$ -free Krebs-Ringer (KR) solution at a flow rate of 20 mL/min, followed by pronase and then with collagenase (Sigma-Aldrich Corporation, St Louis, Missouri, USA) in KR solution. The digested liver was excised, minced with scissors, and incubated in KR solution containing pronase and DNase (Sigma-Aldrich Corporation, St Louis, Missouri, USA) for 30 min. The resulting suspension was filtered through nylon mesh (200 μm in diameter) and then washed 3 times by centrifugation in D-Hanks solution at 1 700 r/min for 7 min. An HSC-enriched fraction was obtained by centrifugation of the filtrate in an 180 g/L nycodenz (Sigma-Aldrich Corporation, St Louis, Missouri, USA) solution with the volume ratio of 1:2 at 3 200 r/min for 17 min. The cells in the upper layer were washed by centrifugation at 1 700 r/min for 7 min and suspended in Dulbecco's modified Eagle medium (DMEM, GIBCO BRL Life Technologies Incorporation, USA) supplemented with 200 mL/L fetal bovine serum (FBS, GIBCO BRL Life Technologies Incorporation, USA). Both cell viability and purity were over 90%, examined by trypan blue (Sigma-Aldrich Corporation, St Louis, Missouri, USA) exclusion and autofluorescence respectively.

Cells were plated at a density of 1×10^6 cells in 1 mL culture medium on uncoated plastic culture dishes. The culture medium was changed after 24 h and then every 3 d. After cultured for 14 d, the cells were passaged.

The first-passage HSCs were plated at a density of 2×10^5

cells in 1 mL DMEM supplemented with 100 g/L FBS on an uncoated plastic culture dish. Subconfluent HSCs were divided into 10 groups, and different concentrations of β -Est, 2OHE, 2MeOE (Sigma-Aldrich Corporation, St Louis, Missouri, USA) or vehicle were added to the cells. After incubated for 24 h, experiments were done to assess the functional state of HSCs.

HSC proliferation was measured by MTT assay. The cells were continually cultivated with 3-(4,5-dimethylthiazol-2yl)-2,5-diphenyl tetrazolium bromide (MTT, Sigma-Aldrich Corporation, St Louis, Missouri, USA) in a 96-well plate for 4 h. After the supernatant in each well was aspirated and discarded, the cells were agitated with dimethylsulfoxide (DMSO, Sigma-Aldrich Corporation, St Louis, Missouri, USA) 150 μL for 10 min. Finally, the optical density of each well was read in an auto reader using a 492 nm filter with a reference at 630 nm.

The levels of HA and C IV in the supernatants of cell were measured as afore-mentioned.

For immunohistochemical examination of α -SMA, estrogen receptor (ER) α and ER β , the cells were mounted on slides and fixed with 40 g/L paraformaldehyde for 5 min at 4°C . Following incubation with 30 mL/L H_2O_2 for 15 min, the cells were blocked by 1 g/L Triton-X plus 1 g/L BSA in PBS for 15 min at room temperature. They were incubated for 2 h at 37°C with a 1:100 dilution of polyclonal antibody against α -SMA, ER α or ER β (Santa Cruz Biotechnology Incorporation, California, USA) in a humid chamber. After the samples were rinsed, they were incubated with a 1:200 dilution of biotin-conjugated goat anti-rabbit IgG, and then visualized with DAB. Integral light density (ILD) analysis was performed on 20 cells in up, down, left, right quadrant of each section, data were calculated from average of 4 ILDs.

Statistical analysis

Data are presented as mean \pm SE unless otherwise indicated. Parametric data were compared using one-way analysis of variance, followed by multiple pair-wise comparisons according to the least-significant difference *t*-test. Pearson's analysis was performed to compare the correlation between serum estradiol and fibrotic area percentage. A *P* value less than 0.05 was accepted as statistically significant.

RESULTS

In vivo effect of β -Est on hepatic fibrosis

Table 1 shows the liver enzymes and fibrosis markers in CCl_4 -treated female rats. Treatment with CCl_4 caused a significant increase in the activities of serum ALT and AST compared with the control animals. The enzyme levels in ovariectomized model rats were higher than those in CCl_4 model group, whereas CCl_4 plus β -Est group showed a significant decrease in enzyme levels compared with CCl_4 group. There was no significant difference between CCl_4 group and OvX+ β -Est+ CCl_4 group.

The changes of fibrosis markers, HA and C IV, were in parallel with those of the enzyme levels in all groups.

The control livers showed a distinct lobular architecture with collagens only surrounding the central and portal veins (Figure 1A). Administration of CCl_4 induced inflammation, necrosis and collagen deposition in the livers. Ovariectomy significantly increased hepatic fibrosis induced by CCl_4 (Figure 1B), whereas β -Est had the opposite effect. The fibrotic area percentage of OvX+ CCl_4 + β -Est group was similar to that of CCl_4 group (Figure 1C).

Immunohistochemistry of α -SMA, an activation marker of rat HSC^[20-22], showed strong staining around vascular wall, but not the sinusoids in control female rat livers (Figure 2A). After administration of CCl_4 , fibrotic change was evident with significant increases of α -SMA positive cells in centrilobular

and periportal fibrotic bands. Ovariectomy significantly increased the percentage area of staining (Figure 2B), whereas β -Est had the opposite effect. There was no significant difference in the fibrotic area percentage of staining between CCl₄ and Ov_x+CCl₄+ β -Est groups (Figure 2C).

Figure 3 summarizes the histopathological and immunohistochemical changes in CCl₄-treated female rats.

Figure 4 shows the serum estradiol levels in the rats. The levels did not change in animals treated with CCl₄ alone. Ovariectomy produced significantly lower serum estradiol levels. In rats model treated with exogenous β -Est, the levels increased significantly as compared with those of control or CCl₄ model groups. Twenty μ g/kg·d β -Est could rectify the low serum estradiol levels in ovariectomized rats.

Table 1 Change of liver enzymes and serum fibrosis indicators

	ALT (nkat/L)	AST (nkat/L)	HA (μ g/L)	C IV (μ g/L)
Control	275.50 \pm 32.05	84.80 \pm 11.83	155.50 \pm 10.41	17.10 \pm 1.77
CCl ₄	1 070.71 \pm 82.95 ^b	806.00 \pm 82.43 ^b	481.43 \pm 24.68 ^b	49.57 \pm 2.47 ^b
Ov _x +CCl ₄	1 403.88 \pm 120.30 ^{ab}	1 102.88 \pm 84.91 ^{bd}	583.75 \pm 37.50 ^{ab}	61.00 \pm 3.30 ^{ab}

Figure 4 Serum estradiol levels in CCl₄-treated female rats, ^b P <0.01 vs control, ^d P <0.01 vs CCl₄.

In 34 CCl₄-treated rats, there was a negative correlation between the fibrotic area percentage and serum estradiol level, the calculated correlation coefficient was -0.57 ($P < 0.01$, Figure 5).

Figure 5 Negative correlation between fibrotic area percentage and serum estradiol level ($r = -0.57$, $P < 0.01$).

In vitro effect of β -Est and its metabolites on activation of rat HSCs
 β -Est, 2OHE and 2MeOE (10^{-9} - 10^{-7} mol/L) inhibited HSC proliferation (Figure 6A) and ECM secretion (Figures 6B and

6C) in a dose-dependent manner. Only the high concentration ($\geq 10^{-7}$ mol/L) of β -Est exerted inhibitory effects, while a concentration of 2MeOE as low as 10^{-9} mol/L had a similar effect. The order of potency was 2MeOE > 2OHE > β -Est. At a concentration of 10^{-7} mol/L, β -Est, 2OHE and 2MeOE all could inhibit HSCs in expressing α -SMA, and the potency of 2MeOE was significantly stronger than that of β -Est (Figure 6D).

A representative immunohistochemistry showed the expression of ER- β (Figure 7B) but not ER- α (Figure 7A) on rat HSCs.

DISCUSSION

Hepatic fibrosis, which is often associated with hepatocellular necrosis and inflammation, occurs as a repair process in many chronic liver diseases and is considered to be a forerunner of cirrhosis. HSCs are regarded as the primary target cells for inflammatory stimuli in the injured liver. Once activated, HSCs would be transformed into α -SMA positive myofibroblast-like cells, which are responsible for much of the collagen hypersecretion during hepatic fibrogenesis^[23-28].

In vivo study showed that β -Est at physiological doses could suppress the development of hepatic fibrosis in CCl₄-

Figure 6 Effects of estradiol metabolites on function of HSCs proliferation (A), HA (B) and CIV (C) secretion in HSCs, effects of 10^{-7} mol/L estradiol metabolites on α -SMA expression (D) of HSCs, Values for each point represent mean \pm SD from 5 separate experiments, ^a $P < 0.05$ vs control, ^d $P < 0.05$ vs 10^{-7} mol/L β -Est.

Figure 7 Representative immunohistochemistry showing expression of ER on HSCs used for studies, original magnification $\times 200$, No expression of ER- α (A) but ER- β (B) was observed.

induced hepatofibrotic rat models along with decreased serum liver enzymes, reduced collagen content and smaller areas of fibrosis in the liver. There was a negative correlation between the percentage of fibrotic area and the serum estradiol level with a calculated correlation coefficient of -0.57. Additionally, in cultured rat HSCs, β -Est inhibited cell proliferation, ECM secretion and α -SMA expression in a dose-dependent manner. These findings support β -Est as a potent inhibitor of HSCs transformation, thus, playing an antifibrogenic role in the progression from hepatic fibrosis to cirrhosis.

The pathway by which β -Est inhibits HSC activation is not clear. As HSCs contain ERs, it is presumed that ERs mediate the fibrosuppressive effects of β -Est. However, several lines of evidence do not support the hypothesis. In this regard, high levels of ER β but low or no levels of ER α expression were observed in normal and fibrotic livers and also in quiescent and activated HSCs from both male and female rats^[29], but β -Est in physiological doses was unable to suppress hepatic fibrosis in male rats following dimethylnitrosamine or pig serum administration^[30-32]. Our preliminary studies also suggested a sexually dimorphic response pattern of the injured liver to β -Est. Besides, the male patients expressed high serum levels of estradiol parallel to the stage of liver cirrhosis.

HSCs are VSMC, CF or GMC analogs that belong to the pericytes generically, so they may have many properties in common including a prominent role in repairing fibrosis against injury and similar reactions to β -Est. Recent studies by Iafrati *et al.*^[33] and Karas *et al.*^[34, 35] showed that β -Est inhibited injury-induced VSMC proliferation in arteries of mice that lacked either ER α or ER β as well as in double knockout mice that lacked both ER α and ER β , suggesting that the effects might be mediated via an ER-independent pathway. Furthermore, 2OHE and 2MeOE, the biologically active metabolites of β -Est, could inhibit DNA synthesis, cell proliferation, collagen synthesis and mitogen activated protein kinase activity in VSMCs, CFs or GMCs with a potency stronger than β -Est^[9-13, 36, 37]. Liver is the main locus where β -Est metabolizes, so it is possible that the antifibrogenic actions of β -Est are mediated in part by local conversion of β -Est to biologically active metabolites.

In the present study, we attempted to testify this hypothesis by comparing the inhibitory effects of β -Est and its metabolites on the activation of rat HSCs *in vitro*. We found that treatment of HSCs with β -Est or its metabolites differentially inhibited FCS-induced cell proliferation, ECM secretion and α -SMA expression in the following order of potency: 2MeOE > 2OHE > β -Est. Only the pharmacological concentration ($>10^{-7}$ mol/L) of β -Est could significantly inhibit HSC proliferation and collagen synthesis, while the concentration of 2MeOE or 2OHE as low as 10^{-9} mol/L gave similar effects. β -Est, 2OHE and 2MeOE at a concentration of 10^{-7} mol/L each inhibited α -SMA expression by 24%, 30% and 47%, respectively.

The findings of this study provided evidence in rat HSC experiments that the metabolites of β -Est with little or no affinity for ERs could mediate the fibrosuppressive effects of β -Est via an ER-independent pathway. The results suggest that β -Est metabolism in the liver may be an important determinant of fibrosuppressive effects of circulating estradiol and that sexual differences in the liver metabolism of β -Est could determine a sexually dimorphic response pattern of liver cirrhosis. Moreover, genetic or acquired differences in β -Est metabolism may determine the fibrosuppressive benefits a patient receives from β -Est replacement therapy. Finally, the results also imply that nonfeminizing β -Est metabolites may afford antifibrogenic protection regardless of gender.

Abstract

AIM: To study the blood-brain barrier integrity, brain edema, animal behavior and ammonia plasma levels in prehepatic portal hypertensive rats with and without acute liver intoxication.

METHODS: Adults male Wistar rats were divided into four groups. Group I: sham operation; II: Prehepatic portal hypertension, produced by partial portal vein ligation; III: Acetaminophen intoxication and IV: Prehepatic portal hypertension plus acetaminophen. Acetaminophen was administered to produce acute hepatic injury. Portal pressure, liver serum enzymes and ammonia plasma levels were determined. Brain cortex water content was registered and trypan blue was utilized to study blood brain barrier integrity. Reflexes and behavioral tests were recorded.

RESULTS: Portal hypertension was significantly elevated in groups II and IV. Liver enzymes and ammonia plasma levels were increased in groups II, III and IV. Prehepatic portal hypertension (group II), acetaminophen intoxication (group III) and both (group IV) had changes in the blood brain-barrier integrity (trypan blue) and hyperammonemia. Cortical edema was present in rats with acute hepatic injury in groups III and IV. Behavioral test (rota rod) was altered in group IV.

CONCLUSION: These results suggest the possibility of another pathway for cortical edema production because blood brain barrier was altered (vasogenic) and hyperammonemia was registered (cytotoxic). Group IV, with behavioral altered test, can be considered as a model for study at an early stage of portal-systemic encephalopathy.

INTRODUCTION

Portal hypertension (PH) is a major syndrome that frequently accompanies chronic liver diseases such as cirrhosis. Prehepatic

PH creates a splanchnic hyperdynamic circulation and hyperemia with increased splanchnic resistance and production of collateral vessels that drive splanchnic blood flow to systemic circulation^[1].

Portal-systemic encephalopathy (PSE), the most commonly encountered form of hepatic encephalopathy (HE), describes a wide spectrum of reversible and irreversible neuropsychiatric abnormalities that appear as a complication in patients with acute or chronic liver disease. HE is usually found as an overt form or in a mild form with lesser neuropsychiatric symptoms, which can be misdiagnosed^[2].

Acetaminophen (APAP) is a non-steroid anti-inflammatory drug (NSAID), frequently used in adults and children. At high concentration of APAP, the glutathione-dependent conjugation system generates a toxic metabolite that binds covalently to cellular proteins and macromolecules followed by cell destruction^[3,4].

Finally, ammonia originated from the gut protein metabolism has been implicated as an important factor in the production of HE. In chronic liver disease, ammonia evades liver catabolism to urea through portal systemic shunts and collaterals, and reaches the brain in high blood concentration^[5].

In previous experiments we documented different aspects of the relationship between prehepatic PH in rats and central nervous system: alterations in uptake and release of norepinephrine and modification and tyrosine hydroxylase activity in discrete regional mesencephalic nucleus^[6,7]. Furthermore, we considered that PH rats underwent a subclinical HE^[8].

The aim of this experiment was to study the blood-brain barrier (BBB) integrity, brain cortical edema, ammonia plasma levels and behavior in rats with different liver injuries.

MATERIALS AND METHODS

Animals and surgical procedures

Male Wistar rats (240-260 g of body mass, 12 h of light cycle: 8 a.m.-8 p.m.) were used and animal welfare was in accordance with guidelines of the Faculty of Pharmacy and Biochemistry of Buenos Aires and approved by ethical committee according to Helsinki's Declaration. Animals were placed in individual cages and allowed to recover from surgery. Rats were fed standard laboratory chow and water *ad libitum*.

Group II (chronic PH): Portal hypertensive (PH) animals were obtained by calibrated stenosis of the portal vein according to Chojkier *et al.*^[11]. Rats were lightly anesthetized with ether and then midline abdominal incision was made. The portal vein was located and isolated from surrounding tissues. A ligature of 3.0 silk suture was placed around the vein, and snugly tied to a 20-gauge blunt-end needle placed along the side of the portal vein. The needle was subsequently removed to yield a calibrated stenosis of portal vein, after which the abdomen was sutured. Operations were performed at 2 p.m. to obey circadian rhythm and fourteen days later the animals developed PH.

Group III (acute intoxication): Acetaminophen was injected i.p. at a dose of 750 mg/kg.d per rat on the 13th and 14th day, considering as the start day or day zero, the day of the surgical procedure of group II.

Group IV (chronic PH plus acute intoxication): Rats underwent partial portal vein ligation as in group II and then

received acetaminophen the same dose as in group III.

Group I: Shamly operated rats underwent the same experimental procedure like group II, except that portal vein was isolated but not stenosed.

All groups received a subcutaneous injection (25 mL/Kg of body mass) of a 50 g/L dextrose, 4.5 g/L saline solution, containing 20 mEq/L of potassium chloride, every 12 h after the first injection of APAP, as a supportive therapy to prevent hypoglycemia and renal failure^[9]. Rats were sacrificed on d 14, 6 to 8 h after the last acetaminophen injection.

Experimental procedures

Following experiment were performed in four groups of animals (I: SHAM, II: HP, III: APAP and IV: HP+APAP, $n=6/8$ per group).

Portal pressure measurement

Rats were anesthetized with sodium pentobarbital (40 mg/kg, ip). The spleen was cannulated with a polyethylene cannula (PE 50) filled with heparinized saline solution (25 U/mL) to measure portal pressure by Statham Gould P23ID pressure transducer (Statham, Hato Rey, Puerto Rico) coupled to a Grass 79 D polygraph (Grass Instruments, Quincy, MA).

Biochemical determination

Blood samples were obtained by abdominal aortic artery puncture for the determination of biochemical parameters. Plasma aminotransferase activity was determined using standardized and optimized commercial Boehringer-Mannheim kits (Germany). Ammoniac Enzymatique UV kits (Biomerieux-France) were used to determine plasma ammonia concentration. Plasma levels of urea, glucose and creatinine were measured by current biochemical colorimetric UV methods (Wiener, Argentine).

Microscopy

High resolution optical microscopy (HROM): sections of liver were fixed in buffered formalin and embedded in paraplast. Routine stains were used: hematoxylin-eosin, PAS and Masson's trichrome for light microscopy and toluidine blue stain for HROM.

Brain water content

Rats were sacrificed by exsanguination under complete ether anesthesia, their brains cortex water content was measured to quantify possible brain edema according to Marmorou^[10].

One cerebral hemisphere was quickly removed after rats were sacrificed and stored at 4 °C to be processed within 30 min. The hemisphere was cut into coronal slices and eight samples taken from the cerebral cortex, approximately 10 mg in weight, was placed in a bromobenzene-kerosene density gradient column to measure brain water^[10]. The column was previously calibrated with varying concentrations of potassium sulfate to ensure a linear relation (>0.997) between the K₂SO₄ and readings in the density gradient. The equilibration point of the samples was read at 2 min and averaged, conversion from specific gravity to brain water was done as previously reported^[10].

Trypan blue transcardial perfusion

Rats were perfused with trypan blue (TB) solution and then fixed in paraformaldehyde. TB solution (5 g/L) was made by dissolving 1 g of TB in 200 mL of PBS with gentle heat. The solution was allowed to cool room temperature and then added to the filtrate, then the solution was placed on ice and used immediately. The temperature of TB solution was 10-12 °C at the time of perfusion. Rats were anesthetized with ethyl urethane (1 mg/kg) and perfused transcardially with 200 mL of TB solution, followed by 300 mL of ice-cold paraformaldehyde (20 g/L in PBS), the low rate of perfusate was maintained at 25 mL/min. Brains were dissected and post-fixed overnight in

0.3 Kg/L sucrose for 2 d. Subsequently, brains were frozen in powdered dry ice and stored at -80 °C until processed for microscopic studies. Slices of brain hippocampus were obtained with cryostat in sections of 300 microns according to Watson and Paxinos (Hippocampus fig 24, bregma 4.8, interneuron 4.2). Hippocampal slices were evaluated under light microscopy and the results were expressed as positive (+) or negative (-) for TB staining. Medial eminence and choroids plexus staining were used as control of TB appropriated perfusion^[11].

Pharmacological and behavioral test

Corneal, pain-response and right reflexes were performed. Automated open field (Animex) and rota-rod tests (to study motor coordination) were realized. Rota-rod speed was fixed at 25 turns/min. Rats were trained 48 h before the experiment until they fell down less than 3 times in 5 min. The number of falls during the experiment and time elapsed to the first fall were recorded^[12,13].

Statistical methods

Results were expressed as mean±SE. Statistical analysis was performed by means of repeated measurement analysis of variance (ANOVA) followed by Newman-Keuls' s test. Dunn' s test was used for non-parametric data, *P* values less than 0.05 were considered statistically significant.

RESULTS

Portal pressure (PP) was significant higher in groups II and IV ($^aP<0.01$) when compared to control group. There was no significant difference when compared PP of group I (Sham) with group III (APAP) (Table 1).

Table 1 Portal pressure (PP) and plasma aminotranferase levels

	Sham (I)	PH (II)	APAP (III)	PH+APAP (IV)
PP (mmHg)	8.5±0.5	12.1±1 ^a	8.1±0.2	11.9±0.9 ^a
AST (UI/L)	155±25	316±23 ^b	426±36 ^b	380±34 ^b
ALT (UI/L)	39±4	63±9	134±20 ^a	308±27 ^b

PP was significantly increased in groups II and IV ($^aP<0.05$ vs control and APAP group). AST plasma levels were significantly increased in groups II, III and IV ($^bP<0.001$ vs sham group). ALT was significantly increased in groups III and IV ($^aP<0.05$ and $^bP<0.001$ vs sham group, respectively).

AST plasma levels were significant increased in groups II, III and IV when compared with group I ($^bP<0.001$). ALT plasma levels were significant increased in groups III and IV when compared with control group (Table 1).

Plasma levels of urea, glucose and creatinine were normal in all groups of rats (data not shown).

Ammonia blood concentrations (μmol/L) showed significant increase in PH rats, APAP group and PH plus APAP ($P<0.05$ and $P<0.001$ respectively) (Figure 1).

Light microscopy and HROM showed normal histology in liver parenchyma in group I, minimal focal necrosis in group II; diffuse hemorrhagic necrosis in group III and focal hemorrhage and confluent necrosis in group IV. (Figure 2 A-D).

Brain cortical water content (H₂O/ g brain weight %) showed significant increase in rats injected with APAP ($P<0.001$) and in those with PH+APAP ($P<0.01$) (Figure 3).

In Groups II, III and IV trypan blue was positive in the perivascular space in the hippocampus area (Figure 4).

All reflexes studied including the Animex were normal for all groups except for rota-rod test that showed in group IV a significant difference at the time elapsed to the first fall (not in number of falls), when compared to shamly operated animals (Table 2).

Figure 1 Significantly increased ammonia plasma levels in all groups of rats ^a $P < 0.05$ and ^b $P < 0.01$ when compared with sham group.

Figure 3 Significantly increased brain water content in groups III and IV ^d $P < 0.01$, ^b $P < 0.001$ when compared with sham group.

Figure 2 Liver Microscopy. A: Shows a normal liver histology corresponding to a rat in sham group (HE, 100×), B: Minimal focal necrosis in group II (HE, asterisk, 500×), C: Diffuse hemorrhagic necrosis in group III (HE, arrows, 400×), D: Focal hemorrhagic confluent necrosis in group IV (HE, asterisk, 400×).

Figure 4 Trypan blue and BBB. A: Trypan blue dye in hippocampus of a sham rat. No breakdown of BBB was observed. Trypan blue was only positive in vascular space (100×), B: Trypan blue dye diffusion due to the breakdown of BBB as an example of what was observed in hippocampus in groups II, III and IV (100×).

Table 2 Rota rod test: First fall time

	Sham (I)	PH (II)	APAP (III)	PH+APAP (IV)

¹: expressed in seconds. Rota rod test was significantly different in group IV compared with all the others groups (^a $P < 0.05$ Dunnett's test).

DISCUSSION

Experimental prehepatic portal hypertension produces a hyperdynamic redistribution of splanchnic circulation and minimal liver damage. It could be considered that prehepatic PH is a subclinical PSE stage^[8]. In this study APAP was used to produce liver injury because of its aggressive effect on liver parenchyma^[3,4]. It was administered to two groups that reflected different situations, namely an acute form of liver injury (group III) and a chronic liver PH group plus an acute liver intoxication.

Portal pressure (PP) was significantly increased in group II, as it was described elsewhere^[8] and in group IV. PP in group III (APAP) had normal values. This agreed with acute intoxications

and specifically with acute APAP intoxication^[14]. Group IV and group II had similar PP values, and it might be due to a chronic PH induced shunt (groups II and IV).

Liver enzymes reflected hepatocyte damage. When liver parenchyma was injured, the enzymes increased as it could be seen in early stages of PSE. Plasma enzyme levels were higher in group III than those in APAP induced acute liver damage. In addition, liver histopathology was concordant with these data as a diffuse hemorrhagic necrosis was observed in group III^[14].

Ammonia plasma level data showed normal values in group I and significantly increased values in groups II, III and IV. The values registered were remarkably lower than those observed in different models of acute liver failure (ALF). It is important to point out that in group II hyperammonemia was produced by opened shunts due to the splanchnic blood flow redistribution^[15]. It is also interesting that in this experimental model the hepatic blood flow was reduced, but not completely shunted as in other models (e.g. porto-caval shunts, PCS). Ammonia was markedly increased as the major responsible molecule related to HE^[16] had several pathways, lately the cGMP-NO-glutamate that leads to cytotoxic brain edema characterized by swelling of astrocytes and their processes, raised intracranial pressure and as a consequence, to brain herniation^[5]. This was the main cause of mortality in ALF and it could be predicted by increased arterial ammonia plasma levels^[17]. Besides this, PSE could lead to increased nNOS activity^[18], associated with L-arginine uptake in a PCS model^[19].

In this model of PH, brain edema was not correlated with ammonia increase. Furthermore brain edema was documented in group III and ammonia level was lower than that in group II and no cerebral edema was observed. Besides this, brain edema was lower in group IV than in group III and the highest recorded ammonia was recorded. What is the major mechanism involved in the development of brain edema in this experiment? One of the pathways of brain edema is the vasogenic and if that mechanism was involved in groups III and IV, why in group II BBB integrity was broken-down and ammonia plasma levels were increased, and no cortical brain edema was documented? Although a mixed mechanism (vasogenic and cytotoxic) was proposed for brain edema in ALF^[20], in this experiment no brain edema was present in the chronic group without acute hepatocyte injury. In the chronic group plus acute liver injury brain edema was registered and the cytotoxic mechanism could be mostly responsible. Under these experimental conditions another mechanism of brain edema might involve aquaporins. The aquaporin-type water channels are integral membrane proteins that have been found to function as conduits for osmotically driven transport of water across cell plasma membranes^[21]. In this experiment BBB integrity was altered and thus endothelial cells were involved. AQP4 presented in both, endothelia and astrocytes might play an active role in regulation of astrocyte swelling and the presence of brain edema^[22].

TB demonstrated altered integrity of the BBB at the hippocampus areas involved in learning and memory consolidation in groups II, III and IV. Furthermore, the only group with an altered behavioral test, at first fall in rota rod test, was group IV. These might be related with the observation in the only group with PH, elevated enzymes, hepatocyte injury, hyperammonemia, brain edema, positive TB and altered rota rod test. Dixit^[23] demonstrated that in rats with galactosamine-induced ALF BBB breakdown evidenced by TB dye infusion studies began in grade III coma. Despite this, under the present experimental conditions no clinical evidence of coma could be registered in any group. Therefore, group IV can be considered as an experimental model of subclinic PSE.

Abstract

AIM: To observe the effects of Kupffer cells on hepatic drug metabolic enzymes.

METHODS: Kunming mice were ip injected with GdCl_3 10, 20, 40 mg/kg to decrease the number and block the function of kupffer cells selectively. The contents of drug metabolic enzymes, cytochrome P450, NADPH-cytochrome C reductase (NADPH-C), aniline hydroxylase (ANH), aminopyrine N-demethylase (AMD), erythromycin N-demethylase (EMD), and glutathione s-transferase (mGST) in hepatic microsome and S9-GSTpi, S9-GST in supernatant of 9 000 g were accessed 1 d after the injection. The time course of alteration of drug metabolic enzymes was observed on d 1, 3, and 6 treated with a single dose GdCl_3 . Mice were treated with *Angelica sinensis* polysaccharides (ASP) of 30, 60, 120 mg/kg, ig, qd \times 6 d, respectively and the same assays were performed.

RESULTS: P450 content and NADPH-C, ANH, AMD, and EMD activities were obviously reduced 1 d after Kupffer cell blockade. However, mGST and S9-GST activities were significantly increased. But no relationship was observed between GdCl_3 dosage and enzyme activities. With single dose GdCl_3 treatment, P450 content, NADPH-C, and ANH activities were further decreased following Kupffer cell blockade lasted for 6 d, by 35.7%, 50.3%, 36.5% after 3 d, and 57.9%, 57.9%, 63.2% after 6 d, respectively. On the contrary, AMD, EMD, mGST, and S9-GST activities were raised by 36.5%, 71.9%, 23.1%, 35.7% after 3 d, and 155%, 182%, 21.5%, 33.7% after 6 d, respectively. Furthermore, the activities of drug metabolic enzymes were markedly increased after 30 mg/kg ASP treatment, and decreased significantly after 120 mg/kg ASP treatment. No change in activity of S9-GSTpi was observed in the present study.

CONCLUSION: Kupffer cells play an important role in the modulation of drug metabolic enzymes. The changes of drug metabolic enzyme activities depend on the time of kupffer cell blockade and on the degree of Kupffer cells activated. A low concentration of ASP increases the activities of drug metabolic enzymes, but a high concentration of ASP decreases the activities of drug metabolic enzymes.

INTRODUCTION

Drug metabolic enzymes can detoxify endogenous and exogenous compounds and also generate potentially carcinogenic or toxic compounds in the process of catalyzing the metabolism of xenobiotics, and inhibition and induction of their activities are also the key mechanisms in drug-drug interactions^[1,2]. The induction or inhibition of metabolizing enzyme activities by a great deal of substances (including drugs, foods, inflammatory factors, etc.) influences their toxicological or pharmacological outcomes as well as those of other xenobiotics or drugs^[3-5].

The role of sinusoidal cells in hepatic metabolism has been greatly underestimated until now. However, Kupffer cells, despite their size represents 80% to 90% of all fixed macrophages in the body and approximately 14% of the hepatic cellular mass, the function in hepatic metabolism of Kupffer cells is unknown. Some reports suggested that Kupffer cells might play an important role in xenobiotic-induced hepatotoxicity, which is often dependent on their metabolism. Although hepatocytes are the major site of xenobiotic metabolism, several enzymatic activities such as glutathione s-transferase, UDP-glucuronosyltransferase and cytochrome P450-dependent oxidase have been found in nonparenchymal cells (mainly Kupffer cells) and may play an important role in the metabolism and cellular effects of paracetamol^[6,7]. Only a small number of reports demonstrated the relationship between drug metabolic enzymes and activities of Kupffer cells. The aim of this work was to investigate the effects of kupffer cell mediated metabolism as demonstrated by hepatic drug metabolic enzymes.

MATERIALS AND METHODS

Reagents

Gadolinium chloride (GdCl_3), glutathione (GSH), erythromycin, aniline, NADPH, aminophenazone, isocitric acid, isocitric acid dehydrogenase, 1-chloro-2,4-dinitrobenzene (CDNB), ethacrynic acid (EA) were purchased from Sigma, USA. All other reagents used in this study were of AR grade.

Animals and treatment

Kunming strain male mice (aged 4-6 wk) weighing 18-24 g were obtained from the Experimental Animal Center, Wuhan University School of Medicine. The animals were fed with a standard diet in pellets, and allowed free access to water. The mice were randomly divided into 9 groups, 10 per group: control group; GdCl_3 10-1d group; GdCl_3 20-1d group; GdCl_3 40-1d group: mice received ip injection of GdCl_3 10, 20, 40 mg/kg, respectively, and killed after 1 d; GdCl_3 20-3 d group; GdCl_3 20-6 d group: mice were treated with GdCl_3 at a single dose of 20 mg/kg, and killed after 3 d, and 6 d, respectively; ASP1 group; ASP2 group; ASP3 group: mice were given ASP 30, 60, and 120 mg/kg, respectively, i.g, qd \times 7 d, and were then killed on the 7th d. The livers were collected for the assay of drug metabolic enzyme activities.

Preparation of liver sample S9 and microsomal fractions

Microsomal fractions were prepared as previously described^[8]. Total protein concentration in mice liver microsomes was determined by the method of Lowry *et al.*^[9] (1951) using BSA as the standard. All operations were performed at 4 °C.

Assays for metabolic enzyme activities

Total cytochrome P450 (P450) content was based on the use of the extinction coefficient of 105 mmol/L·cm for reduced cytochrome P450 minus oxidized P450 with a UV-1601 spectrophotometer^[10].

NADPH-cytochrome C reductase (NADPH-C) activity was determined with a spectrophotometer at 550 nm by monitoring the reduction of cytochrome C (0.5 mg/mL) at 37 °C in an incubation mixture containing potassium phosphate (300 mmol/L, pH7.7) EDTA (0.1 mmol/L), liver microsomes (20 µg/mL) and NADPH (2 mg/L)^[11].

Aminopyrine N-demethylase (AMD) and erythromycin N-demethylase (EMD) were detected by measuring the production of formaldehyde. Its reaction system contained Tris-HCl 50 mmol/L, MgCl₂ 10 mmol/L, KCl 50 mmol/L and an NADPH-generating system (including NADP⁺ 0.4 mmol/L, isocitric acid 10 mmol/L, and isocitric acid dehydrogenase 0.6 units). Erythromycin 0.4 mmol/L or aminopyrine 8 mmol/L was added, the reaction was initiated by the NADPH-generating system, the supernatant was incubated with the Nash reagent at 60 °C for 20 min and the color absorbance was measured at 415 nm with a UV-1601 spectrophotometer^[12].

Aniline hydroxylase (ANH) was assessed with aniline as substrate as previously described^[13].

Microsome glutathione s-transferase (mGST) and S9 glutathione s-transferase (S9-GST) activities were measured with CDNB as substrate ($\epsilon=9.6$ mmol/L·cm)^[14]. The assay mixture contained 850 µL of 0.1 mol/L sodium phosphate-1 mmol/L EDTA (pH6.5), 50 µL of 20 mmol/L GSH, 50 µL of 50 mmol/L CDNB, and 50 µL of sample. The absorbance at 340 nm was continuously recorded for 1 min^[15]. S9-GSTpi was determined

with EA and GSH as substrates ($\epsilon=5.0$ mmol/L·cm)^[14]. The assay mixture contained 850 µL of 0.1 mol/L sodium phosphate, 1 mmol/L EDTA (pH6.8), 50 µL of 50 mmol/L GSH, 50 µL of 50 mmol/L EA, and 50 µL of sample. The absorbance at 340 nm was continuously recorded for 1 minute.

Statistical analysis

The data were presented as mean±SD. Comparisons were performed using one-way analysis of variance (ANOVA) followed by the *posteriori* Student-Newman-Keuls' *t*-test. *P*<0.05 was considered statistically significant.

RESULTS

Influence of different dose of GdCl₃ on P450 content and P450 isoform activities

The content of P450 and the activities of NADPH-C, ANH, AMD, and EMD were obviously reduced after 1 d after GdCl₃ treatment, and no relationship was found between the enzyme activities and the dose of GdCl₃ (Table 1).

Time course of alterations of P450 content, activities of P450 isoforms, S9-GSTpi, S9-GST and mGST by Kupffer cell blockade

The content of P450 and activities of NADPH-C and ANH were reduced by 35.7%, 50.3%, 36.8% after Kupffer cell blockade for 3 d, and 57.9%, 57.9%, 63.2% for 6 d, respectively. However, the activities of AMD, EMD were raised by 36.5%, 71.9% after 3 d, and 155%, 181% after 6 d, respectively. S9-GST, mGST were markedly increased by Kupffer cell blockade. However, the changes were not related with the time of Kupffer cell blockade. No changes in S9-GST were observed (Table 2).

Influence of ASP on P450, activities of P450 isoforms, S9-GSTpi, S9-GST and mGST

The content of P450 and the activities of NADPH-C, ANH,

ASP1, ASP2, ASP3: Mice were given 30, 60, and 120 mg/kg ASP, ig, qd×7 d, respectively and sacrificed on day 7. The hepatic microsome was prepared to assay the content of P450, and activities of P450 isoforms, S9-GSTpi, S9-GST and mGST. (n=8, mean±SD, ^aP<0.05, ^bP<0.01 compared with control group).

AMD, EMD were obviously increased by 50.0%, 35.9%, 18.4%, 34.4%, and 46.1% after 30 mg/kg ASP treatment, and obviously decreased by 57.1%, 47.6%, 73.7%, 36.5%, and 53.9% after 120 mg/kg ASP treatment, respectively. Thirty and 60 mg/kg of ASP could increase the activity of S9-GST by 26.5%, 42.3%, respectively. The alterations of mGST activity were similar to those of S9-GST. The activities of S9-GST and mGST were reduced by 4.8%, 38.0% after administration of 120 mg/kg ASP, respectively. No changes in S9-GSTpi were observed (Table 3).

Influence of different dose of GdCl₃ on activities of S9-GSTpi, S9-GST and mGST

S9-GST activity was increased by 18.1%, 22.9% after 10 mg and 20 mg/kg of GdCl₃ treatment, respectively, and the alterations in mGST activity were similar to those of S9-GST. No changes in S9-GSTpi were observed (Table 4).

GdCl ₃ 20-1d	0.93±0.17	10.2±1.5 ^a	0.28±0.06
GdCl ₃ 40-1d	0.91±0.12	7.9±0.8	0.264±0.012

The administration of GdCl₃ and the treatment of animals were the same as described in Table 1. S9-GST: glutathione s-transferase in S9; S9-GSTpi: glutathione s-transferase pi in S9; mGST: glutathione s-transferase in microsome. (n=8, mean±SD, ^aP<0.05 compared with control group).

DISCUSSION

Neyrinck *et al.*^[16,17] reported that Kupffer cells might play a role of xenobiotic metabolism in hepatocytes *in vitro*, and treatment of GdCl₃ could decrease the total hepatic content of cytochrome P450. Kupffer cells were involved in some liver diseases in which the activities of drug metabolic enzymes changed^[18,19]. Few studies until now have reported an effect of GdCl₃ injection on the activities of specific CYP isoforms and GST, and on the time course of developmental changes of their activities after Kupffer cells blocked by GdCl₃ *in vivo*. The present study showed that Kupffer cell blockade indicated a tendency to decrease cytochrome P450 content and its isoform activities, and to increase GST (including S9-GST, and mGST) activities. However, CYP isoforms and GST activities showed different changes following different time of Kupffer cell blockade. The total cytochrome P450 content, NADPH-C and ANH (as marker of CYP2E1) activities had a sustained decrease following

prolonged Kupffer cell blockade, but AMD, EMD (as marker of CYP3A) activities obviously raised 3 d after Kupffer cell blockade, and GST activities kept a high level 6d after Kupffer cell blockade. Some authors have already reported that the treatment of GdCl₃ causing inactivation of Kupffer cells could protect liver against damage induced by some toxic chemicals (such as ethanol, CCl₄, *etc.*) through inhibiting CYP2E1^[20, 21]. The present study offered further support for a relevant role of Kupffer cells through the control of hepatocyte metabolism mediated liver injury. CYP3A contributed significantly to the biotransformation of xenobiotic chemicals such as drugs, and toxic chemicals^[22]. GSTs constitute a multigene family of phase II conjugating enzymes broadly distributed phylogenetically. Detoxification of electrophilic compounds by GSTs may occur via catalytic conjugation of electrophilic intermediates with GSH, via GSH-dependent reduction of organic peroxides, or via direct binding to lipophilic compounds. GST might have an important cytoprotective function^[23]. The current study showed CYP3A and GST activities were rapidly recovered, which might be a self-regulated and self-protected mechanism of the body.

The changes in CYP and GST activities were related with the state of Kupffer cells activated by Angelica sinensis polysaccharides (ASP). Now, some new functions of ASP have been reported. ASP could promote ulcer healing, protect hepatic injury and might have antitumor effects^[24-26]. Immunoactivity is the most important function of ASP. It could enhance the proliferative response of lymphocytes *in vitro* and differential expression of genes in the liver of immunological injury mice^[27,28]. In the present study, 30 mg/kg ASP could increase cytochrome P450 content, P450 isoform activities and GST activities. However, 120 mg/kg ASP could obviously decrease the activities of these enzymes. This phenomenon might be concerned with the immunoactivity of ASP. Its mechanism remains to be further studied.

GSTpi, a glutathione s-transferase of placenta type, often presented high expression in tumor tissues related with drug resistance^[29]. The present study indicated that GSTpi activity was not influenced by Kupffer cell blockade or activated, suggesting that GSTpi activity is not easily induced in normal tissues.

In conclusion, Kupffer cells and their adjacent hepatocytes capable of regulating interactions could be demonstrated^[30], suggesting that Kupffer cells may mediate hepatic functions including drug metabolism.

Abstract

AIM: To study the expression of peroxisome proliferator activated receptor- γ (PPAR γ) in the liver of rats with fatty liver disease (FLD) and to explore the role of PPAR γ in the pathogenesis of FLD to provide the basis for using PPAR γ ligand to treat patients with FLD.

METHODS: Forty Wistar rats were divided into 4 groups of ten rats each randomly: normal group (group A), alcohol group (group B), fat-rich diet group (group C), alcohol and fat-rich diet group (group D). The rats were sacrificed at the end of the 16th week from the feeding day. Alanine aminotransferase (ALT), tumor necrosis factor- α (TNF α) in serum and malondialdehyde (MDA) in liver homogenate were determined; livers were collected for observing pathologic changes by HE, Sudan IV, Masson stain under microscope. The morphologic results were analyzed by picture quantitative analysis technique. The changes of ultrastructure were also examined under electron microscope. The expression of PPAR γ in liver was detected by immunohistochemistry and RT-PCR. The correlations between the expression of PPAR γ and biochemical indexes, and liver histology were analyzed.

RESULTS: The steatosis, inflammation, necrosis and fibrosis were present in livers of different experimental groups, especially in livers of alcohol and fat-rich diet group. The content of immunodetectable PPAR γ was decreased remarkably in the livers of model rats (group B-D); the level in alcohol and fat-rich diet group (3.43 ± 1.48) was significantly lower than that in normal group (18.34 ± 3.73), alcohol group (8.82 ± 2.52) and fat-rich diet group (11.73 ± 2.51) (all $P < 0.01$). The level of PPAR γ mRNA was also lower in the livers of model rats (group B-D) than in livers of controls. The expression of PPAR γ in rat liver correlated negatively with the degree of its inflammation, necrosis and fibrosis, as well as the level of serum TNF α and the content of MDA in liver homogenates, but not with steatosis or serum ALT.

CONCLUSION: Decreased expression of PPAR γ may play an important role in the development of hepatocellular inflammation, necrosis and fibrosis of rats with FLD. Thus, activating PPAR γ by its ligand can be anticipated to provide a therapy target for FLD.

INTRODUCTION

Fatty liver disease (FLD) includes alcoholic liver disease (ALD) caused by alcohol and non-alcoholic fatty liver disease (NAFLD) due to obesity, hypertriglyceridemia and other factors. The pathogenesis is not clear now. Some scholars put forward the tale of two or multiple "hits"^[1]. The first hit is steatosis by ethanol or insulin resistance which offers substrates for lipid peroxidation. The second hit is alcoholic hepatitis or nonalcoholic steatohepatitis (NASH) caused by oxidative stress and lipid superoxidation. The release of the inflammation mediator, inflammation and necrosis can be found in hepatocytes^[2-6]. Liver fibrosis or cirrhosis is the third hit because the synthesis of extracellular matrix exceeds the decomposition of it or inflammation is continuous. Why excess hepatocellular fat can induce inflammation or even fibrosis in the liver? The pathogenesis is not clarified up now. Peroxisome proliferator-activated receptor-gamma (PPAR γ), is one member of the nuclear hormone receptor superfamily that can be activated by various ligands. Recent studies showed that this transcription factor associated not only with adipocyte differentiation, insulin resistance, sugar and lipid metabolism^[7-10], but also with the regulation of inflammation, hepatocyte proliferation and the apoptosis in human liver cancer cells^[11-17]. The role of PPAR γ in FLD has not been well addressed and some studies even showed contrary results. The present study was designed to characterize PPAR γ activity in liver of rats with FLD so to explore whether PPAR γ ligand could be used as a potential therapeutic agent for FLD.

MATERIALS AND METHODS

Rat model of fatty liver disease

Forty female Wistar rats (from the Animal Center of Hebei Medical University) were divided into 4 groups of ten rats each randomly. Rats in normal group (group A) received standard diet and intragastric saline (1.5 mL/100 g body mass) twice daily. Rats in alcohol group (group B) were intragastrically fed twice a day initially with 400 mL/L ethanol (1.5 mL/100 g body weight) for 4 wk, with 500 mL/L ethanol for 4 wk and then with 60% ethanol for 8 wk on the basis of standard diet. Rats in fat-rich diet group (group C) were fed with high fat diet (standard diet with 10% lard and 2% cholesterol) and given intragastrically with saline twice a day. Rats in alcohol and fat-rich diet group (group D) had the same high fat diet as rats in group C and took the same ethanol as rats in group B.

Preparation of samples

Serum from rats fasted for 12 h was isolated and stored at -70 °C for alanine aminotransferase (ALT) and tumor necrosis factor α (TNF α) determination. Liver was homogenized in 10 volumes of 0.01 mol/L sucrose containing 10 mmol/L Tris-Cl, pH 7.4, and 0.1 mmol/L ethylenediaminetetraacetic acid and

centrifuged at 3 000 r/min for 10 min at 4 °C and the supernatant was stored at -70 °C for MDA assay. A small sample of liver was stored in liquid nitrogen for isolation of total RNA. The others were fixed in 40 g/L formaldehyde for light microscopy or in 40 g/L paraformaldehyde for immunohistochemistry and in 40 g/L glutaraldehyde for electron microscopy.

Biochemical indexes

Serum ALT, TNF α were measured using an auto-biochemical analyzer (Olympus AU 2700) and radio-immuno- assay (Beijing Furui) respectively. MDA in liver homogenates was detected using TBA kit (Nanjing Jiancheng).

Liver histology

Livers were fixed in 40 g/L buffered formaldehyde, embedded in paraffin, sectioned, and stained with hematoxylin-eosin for routine examination and with Sudan IV for steatosis or with Masson for fibrosis. The steatosis and collagen were quantified as the percentage of positive area by multifunctional pathological image analyzer (Beijing Aerospace University). The activity of necro- inflammation was scored between 1 to 4 blindly by an independent pathologist. The ultrastructure of the livers was observed by HITACHI H7500 transmission electron microscope (TEM) after the samples underwent 40 g/L glutaraldehyde-osmic acid fixation, epoxy resin embedding and ultrathin section.

Immunohistochemistry

In brief, paraffin-embedded tissue specimens and controls were sectioned at a thickness of 4 μ m, deparaffinized, and rehydrated. The slides were incubated with 30 mL/L hydrogen peroxide in methanol for 10 min to block endogenous peroxidase activity and then washed twice in phosphate -buffered saline (PBS) for 5 min. Antigen in sections was retrieved by microwave. Sections were then blocked with 10% goat serum and incubated (12 h at 4 °C) with the primary antibody (mouse anti-rat monoclonal antibody of PPAR γ , E-8, 1:100, Santa Cruz). After being washed twice for 15 min in PBS, sections were incubated (30 min at 37 °C) with the secondary antibody (goat anti -mouse IgG marked by biotin), with streptavidin marked by horseradish peroxidase, and then with DAB (Beijing Zhongshan). Then, 0.01 mol/L PBS was substituted for primary antibody as the negative control. The positive cells presented brownish yellow. Quantitative analysis was done by a multifunctional pathological image analyzer. Ten high power fields were examined randomly per sample.

Reverse transcriptase-polymerase chain reaction

Total RNA was isolated from liver using a modification of the single -step guanidinium-phenol-chloroform method. cDNA was obtained by reverse transcription (Promega kit) and then subjected to PCR amplification with GAPDH as standard reference (452 bp). A 403 bp PPAR γ gene fragment was amplified with the following primers: up 5' -TATCATAAATAAGCTT CAATCGGATG GTTC -3' and down 5' -ACCACAGTCCATG CCATCAC -3'. The primers were designed according to the published sequences^[18] and synthesized by Shanghai Biology Engineering Corporation. Thirty-two cycles of amplification were performed at 94 °C for 5 min, then at 94 °C for 30 s, at 57 °C for 45 s, and at 72 °C for 1 min, with a final extension at 72 °C for 5 min. The PCR reaction mixture was electrophoresed in 5% SDS-polyacrylamide gel, and observed by EB staining under UV light. The optical density of EB-stained DNA bands was analyzed by BIO-PROFIL picture analysis system and the ratio of PPAR γ to GAPDH was calculated.

Statistical analysis

SAS8.0 package was used to process all data. Results were

expressed as mean \pm SD. Student's *t*-test was used for the comparison between two groups. Group means were compared by ANOVA followed by the Student-Newman-Keuls test if the former was significant. Differences were considered significant when $P < 0.05$. Linear regression analysis was used for relativity analysis.

RESULTS

Biochemistry

The biochemical features are outlined in Table 1. Serum ALT, TNF α and MDA in liver homogenates were elevated significantly, particularly in group D.

Table 1 Biochemical features of rats with fatty liver disease

Group	n ¹	ALT (U/L)	TNF α (μ g/L)	MDA (μ mol/g)
A	10	34 \pm 9.02	1.36 \pm 0.35	5.71 \pm 0.25
B	9	119 \pm 17.15 ^a	3.39 \pm 0.42 ^a	7.26 \pm 0.32 ^a
C	10	103 \pm 17.24 ^a	3.02 \pm 0.37 ^a	6.72 \pm 0.31 ^a
D	9	125 \pm 16.51 ^a	5.01 \pm 0.52 ^{a,b,d}	9.12 \pm 0.42 ^{a,b,d}

^a $P < 0.05$ vs the normal control; ^b $P < 0.01$ vs the alcohol group;

^c $P < 0.01$ vs the fat-rich diet group, ¹ One rat died in groups B, D respectively in the process of experiment.

Figure 1 Swelling, diffusive steatosis of hepatocytes (SudanIV 40 \times).

Figure 2 Central vein fibrosis (Masson 40 \times).

Liver histology

The quantitative evaluation of the liver histology of rats in each group is shown in Table 2. The livers of model rats (group B-D) were engorged with microvesicular and macrovesicular fat, particularly in alcohol and high-fat group (group D) (Figure 1). The hepatocytes of rats in alcohol group presented inflammation, and centrilobular (zone 3) cloudy swelling, ballooning degeneration, spotty necrosis with either pericellular fibrosis or Mallory body. The hepatic sinusoids became narrowed significantly. The infiltration of inflammatory cells, especially

neutrophilic granulocytes could be seen in the portal areas, and there was fibrosis around the hepatic sinusoids. Focal necrosis or piecemeal necrosis (PN) even bridge necrosis (BN) in alcohol and fat-rich diet group could be found. Around these areas there were a large number of inflammatory cells. Perisinusoid fibrosis and central vein fibrosis could be seen (Figure 2) and the vein wall became thick even occluded. The portal area was enlarged, the fibrous tissue proliferated and extended to interlobular area. Under TEM, the nuclear membrane was tortuous, the nuclear chromatin agglutinated into blocks in hepatocytes of the model rats (groups B-D). The cytoplasm was loose and had more or less fat. The mitochondria swelled and proliferated and sometimes huge mitochondria could be seen. Some of the sinusoids were capillarized. Activated stellate cells and perisinusoid fibrosis could be observed distinctly (Figure 3).

Figure 3 Activated stellate cells and perisinusoid fibrosis (TEM $\times 8\ 000$).

Table 2 Quantitative evaluation of liver histology of rats (%)

Groups	<i>n</i>	Steatosis	Inflammation and necrosis	Collagen
A	10	1.34 \pm 0.33	0.67 \pm 0.66	2.03 \pm 0.87
B	9	12.79 \pm 2.73 ^a	4.35 \pm 0.56 ^a	11.85 \pm 3.89 ^a
C	10	35.82 \pm 8.52 ^{a,b}	3.05 \pm 0.72 ^a	7.90 \pm 2.79 ^{a,b}
D	9	37.97 \pm 11.48 ^{a,b}	5.71 \pm 1.03 ^{a,c}	19.02 \pm 4.01 ^{a,b,c}

^a $P < 0.01$ vs the normal control; ^b $P < 0.05$ vs the alcohol group; ^c $P < 0.05$ vs the fat-rich diet group.

Expression of PPAR γ

The level of PPAR γ protein and mRNA in rat livers detected by immunohistochemistry and RT-PCR respectively is shown in Table 3. The levels of PPAR γ expression were decreased significantly in model groups (groups B-D), especially in group D (Figure 4).

Table 3 Level of PPAR γ protein and mRNA in rat livers (%)

Group	<i>n</i>	PPAR γ protein	PPAR γ mRNA
A	10	18.34 \pm 3.73	0.8097 \pm 0.098
B	9	8.82 \pm 2.52 ^a	0.2530 \pm 0.072 ^a
C	10	11.73 \pm 2.51 ^a	0.3647 \pm 0.084 ^a
D	9	3.43 \pm 1.48 ^{a,b,d}	0.1226 \pm 0.054 ^{a,b,d}

^a $P < 0.05$ vs the normal control; ^b $P < 0.01$ vs the alcohol group; ^d $P < 0.01$ vs the fat-rich diet group.

Relationship between levels of PPAR γ protein and biochemical and histological parameters

The correlation analysis showed that the expression of PPAR γ protein in the liver of model rats (group B-D) was associated negatively with the level of serum TNF α , the content of MDA in the liver, the degree of liver inflammation, necrosis, and

fibrosis, but not associated with the degree of liver steatosis and the level of serum ALT (Table 4).

Figure 4 Expression of PPAR γ mRNA and GAPDH mRNA in the liver of rats with FLD (Note: from left to right M: PCR marker; lane A: normal control; lane B: alcohol group; lane C: fat-rich diet group. Lane D: alcohol and fat-rich diet group). A: Expression of PPAR γ mRNA in the liver of rats with FLD, B: Expression of GAPDH mRNA in the liver of rats with FLD.

Table 4 Correlation between levels of PPAR γ protein and biochemical, histological parameters in model rats (*r* value)

^a $P < 0.05$ vs the normal control the alcohol group ^b $P < 0.01$.

DISCUSSION

It is well known that PPAR γ is one of the nuclear transcription factors activated by ligands and belongs to type II nuclear receptor superfamily. It includes 3 subtypes as PPAR α , PPAR δ and PPAR γ . PPAR α is expressed abundantly in liver associated with lipid deposition and certain amount of PPAR γ could be found in liver possibly related to the inflammation^[19-30]. The experiment *in vitro* proved that the activation of PPAR γ could inhibit the secretion of cytokines and chemokines. For example, the activation of PPAR γ could inhibit the secretion of IL-6, IL-1 and TNF α induced by lipopolysaccharide (LPS)^[31]. Kon proved that pioglitazone (1 mg/kg body weight), the ligand of PPAR γ could prevent liver from inflammation, necrosis and increase of serum TNF α caused by carbon tetrachloride. At the same time pioglitazone could inhibit the expression of α -SMA and type I procollagenin of primary cultured hepatic stellate cells (HSCs)^[11,32]. The activation of HSC was the basis of liver fibrosis. Everett's research also proved that activation of PPAR γ could inhibit the activation of cultured HSC *in vitro*^[19]. We speculated that decreased expression and dysfunction of PPAR γ might correlate with the release of inflammatory mediator and fibrosis during the process of liver injury due to alcohol and high fat diet.

Our data showed that there were steatosis, inflammation and centrolobular ballooning degeneration, necrosis with fibrosis in the livers of rats fed with either alcohol or high fat diet, especially in the rats fed with both alcohol and high fat. The expression of PPAR γ in the liver of rats with FLD (groups

B, C, D) decreased significantly particularly in group D compared to the normal control ($P < 0.05$). The correlation analysis indicated that except for steatosis, the expression of PPAR γ correlated negatively with the levels of liver MDA, serum TNF α and the degree of inflammation and fibrosis in livers of rats with FLD. These suggested that the weaker the PPAR γ expressed, the more severe the liver would be damaged. High-fat diet could deteriorate liver damage and promote liver fibrosis by increasing the lipid deposition, lipid peroxidation and inhibiting PPAR γ expression in the liver. It proved that PPAR γ played a very important role in the cascade reaction of lipid peroxidation - release of inflammation cytokines - damage of liver - liver fibrosis of rats with FLD. It might be one of the initiation factors. Therefore, the ligand of PPAR γ might block the development of inflammation, necrosis and fibrosis of FLD and be potentially used for FLD treatment.

Abstract

AIM: Based on the pathogenesis of severe acute pancreatitis and our experimental studies, to investigate the effect of dexamethasone and dextran in treatment of patients with severe acute pancreatitis.

METHODS: Thirty-two patients with severe acute pancreatitis were treated with 0.5-1 mg/kg per day dexamethasone for 3-5 d, and 500-1 000 mL/d of dextran 40 for 7 d, besides the routine therapy.

RESULTS: After 4-8 h of treatment, abdominal pain began to be relieved; range of tenderness began to be localized in 27 patients. They were cured with nonsurgical treatment. Five of them were deteriorated, and treated with surgery. Four patients in this group died.

CONCLUSION: Dexamethasone and dextran 40 block the pathologic process of severe acute pancreatitis through inhibition of inflammatory mediators and improvement of microcirculation disorders respectively.

INTRODUCTION

Acute pancreatitis (AP) is usually mild and self-limiting. However, 15-20% of cases deteriorate and develop organ failure or local complications (including necrosis, pseudocyst and abscess)^[1]. Many patients with severe AP develop organ failure during the first few days of illness, and this accounts for the majority of early deaths^[2]. The rate of severe AP approaches 40 per cent^[3]. Although a number of treatments are currently available to treat AP, they have failed to have a significant impact on the overall disease progression^[1,4-6]. It is known that the activation of trypsin is the trigger of AP. The key to understand the pathophysiology of AP lies in discovering why a proportion of patients progress from a limited local inflammation to a potentially dangerous systemic inflammatory response. Recent studies^[6-21] showed that inflammatory

mediators and microcirculation disorders (MCD) play very important roles in the pathogenesis of severe acute pancreatitis. It has been proposed that the systemic sequelae of AP arise from excessive leukocyte activation with the release of secondary inflammatory mediators, such as interleukin (IL)-1 α , IL-6, IL-8, IL-10; tumor necrosis factor- α (TNF- α); platelet-activating factor (PAF); nitric oxide (NO); and phospholipase A₂^[6-14]. Excessive production of these mediators contributes to the induction of the systemic inflammatory response syndrome, acute phase response, and multiple organ failure^[7,14]. On the other hand, the pancreatic microcirculation is impaired in acute pancreatitis^[15]. Local release of acinar enzyme, vasoactive mediators, vasoconstriction, increase in vascular permeability, ischaemia, intravascular coagulation, and capillary stasis result in pancreatic edema and hemoconcentration, and impaired capillary and venous drainage consequently lead to hemorrhagic pancreatic necrosis^[16-21]. Furthermore, MCD in severe AP are not confined to the pancreas but can also be found in the colon, liver, and lungs; they extend beyond the early stage of AP and persist for 48 h or longer. They not only affect capillary blood flow but also involve prolonged changes of capillary permeability and leukocyte endothelial interaction^[22]. There is no strict correlation between necrosis and organ failure in AP. Patients with pancreatic necrosis are not necessarily at risk of having initial organ failure or later organ failure during the total hospital stay and *vice versa*^[23].

Therefore, the therapeutic strategy for severe AP should focus on inhibiting inflammatory mediators and improving systemic MCD. Based on our previous experimental studies^[24,25], 32 patients with severe AP were treated with the new therapeutic approach.

MATERIALS AND METHODS

General data of patients

According to the definition of the International Symposium on Acute Pancreatitis held in 1992 in Atlanta^[26], 32 patients with severe AP were treated in our hospital. Eighteen of them were males and fourteen females. The mean age was 42.8 (range 26-63) years. The treatment began from 8 h to 4 d after the symptoms onset.

Diagnosis

The patients had an epigastric pain of visceral nature that radiated to the back. The pain was constant and at times could be poorly localized. Other clinical findings included fever, nausea, vomiting, ileus, and abdominal distention, hyperamylasemia, and hypotension. Ultrasonography demonstrated edema of the pancreas, retroperitoneal edema, and pancreatic ascites. Sixteen patients represented biliary systemic problems (cholecystitis, cholelithiasis or biliary ductal dilatation). Findings on CT (or contrast-enhanced dynamic CT) included edema of the pancreas, peripancreatic fluid collections, and edema of the surrounding viscera and pancreatic necrosis. Twelve patients had abnormal findings on chest radiographs at the time of diagnosis, including segmental atelectasis, an elevated hemidiaphragm, pleural effusions, or the presence of

early pulmonary parenchyma infiltrates.

Treatment

After severe AP was diagnosed, the patients were treated with following routine methods: (1) Nasogastric tube decompression; (2) Supplemental oxygen, mechanical ventilation instituted in the event of respiratory insufficiency, (3) Aggressive fluid and electrolyte resuscitation to prevent hypovolemia and prerenal azotemia; and (4) Prophylactic antibiotics (Imipenem).

Besides above routine therapy, 0.5-1.0 mg/kg of dexamethasone was administered daily for 3-5 d, and 500-1 000 mL of dextran 40 was daily administered for 7 d.

RESULTS

After for 4-8 h of treatment, the abdominal pain began to be relieved, and the range of tenderness began to be localized in 27 patients. They were cured with nonsurgical treatment. Five patients were deteriorated, and 4 patients were treated with surgery (necrosectomy). The necrotic peripancreatic and pancreatic tissues were removed, and the lesser sac was drained with multiple drains (closed drainage), or lavaged with a large volume of dialysate (closed lavage). Cholecystectomy was performed in 21 patients with biliary pancreatitis, after pancreatitis was completely relieved. Operative cholangiography was performed in 18 patients. Gallstone was found in 5 cases of them, and their common bile ducts were explored. Four cases died, and 2 of them died from acute respiratory distress syndrome, 1 died from postoperative intraabdominal hemorrhage and sepsis and, 1 died from severe intraabdominal infection and organ failure.

DISCUSSION

It is now becoming much better understood that inflammatory mediators and MCD play a dominant role in the pathogenesis of systemic inflammatory response syndrome and organ dysfunction of AP. In addition, there is little doubt that inhibition or blockage of the inflammatory mediators or improvement of MCD can dramatically alter the expected course of experimental AP^[30-33]. In our observation, the patients were treated with dexamethasone and dextran 40 for 4-8 h, then, their symptoms and signs began to be improved. Twenty-seven out of 32 patients were cured with this non-surgical approach. The mortality rate was lower (12.5%) compared with literature (40%)^[3].

It has been shown in recent studies that inflammatory mediators, including IL-1, IL-6, PAF, and arachidonic acid metabolites were excessively produced during AP. These mediators play an active role in initiating or amplifying the cytokines cascade^[9,10], and a central role in the progression of AP from a local to a systemic disease^[11,27-29]. It is the cumulative effect of each of these mediators that eventually leads to vascular leakage, hypovolemia, systemic inflammatory response syndrome, shock, and organ failure^[27,28]. Therefore, recent advances in understanding of the pathophysiology of the early systemic illness have led to the development of a new therapeutic approach in AP. Many specific inhibitors of these mediators have beneficial effects in experimental AP^[33-40]. However, few specific inhibitors can be used in clinic. A recent randomized, controlled study showed that antagonist of PAF activity is not sufficient to ameliorate systemic inflammatory response syndrome in severe AP^[41]. One of main reasons is that many inflammatory mediators may be involved in the pathophysiology of AP, and any one specific antagonist can not successfully down-regulate this inflammatory response, systemic effects, and organ failure. Dexamethasone is a non-specific anti-inflammatory agent, can inhibit or block several

inflammatory mediators' production, including inhibition of synthesis of TNF- α , IL-1 α , IL-6, IL-8, and prostaglandins^[42-44]. In our previous study, we found that dexamethasone attenuated the inflammatory mediators, 6-keto-PGI $_2$, TXB $_2$, and cytokine IL-6, and then improved the survival rate of experimental AP^[24]. The mechanism by which dexamethasone inhibits arachidonic acid and its metabolites is that dexamethasone can induce phospholipase A $_2$ inhibitor lipocortin. Other studies also indicated that exogenous glucocorticoids have beneficial effects in experimental AP^[42-47]. Now it is also clear that, the earlier glucocorticoids used, the better the results obtained. However, the optimal dose of glucocorticoids is not known. We used a high dose of dexamethasone short time interval, and found significant results. Although glucocorticoids have a positive impact on AP, Gomez *et al*^[48] found that survival rate decreased and pancreatic necrosis increased in mice after 7 d of pretreatment with hydrocortisone. Therefore, in our clinic, dexamethasone was used for 3-5 d to prevent its potential side reactions.

MCD is another important factor in the pathogenesis of multiple organ dysfunction syndromes in AP^[49,50]. MCD involve a series of changes including vasoconstriction, ischaemia, increased vascular permeability, impairment of nutritive tissue perfusion, ischaemia/reperfusion, leukocyte adherence, hemorrhheological changes and impaired lymphatic drainage. In addition, MCD in AP is not confined to the pancreas but appear to be a systemic disorder. Increased capillary permeability results in ascites and/or pleural effusion. Above mentioned ultrasonography demonstrated ascites in all patients with severe AP. In our previous experimental study, we found that blood viscosity, plasma viscosity, hematocrit, erythrocyte osmotic fragility elevated, while erythrocyte sedimentation rate and fibrinogen decreased significantly in AP^[25]. MCD affect organs other than the pancreas and persist after pancreatic necrosis is manifested and enzyme levels have returned to normal values^[22]. Therefore, MCD are not only an initiating or aggravating factor to pancreatic injury, but considered as a systemic reaction that contributes to pancreatitis-associated multiple organ dysfunction syndrome. Dextran 40 has numerous pharmacologic effects when infused intravenously: anti-platelet activity, anti-fibrin activity, and plasma volume expansion in hypovolemia, improvement of microcirculation by decreasing blood viscosity and impeding erythrocyte aggregation. The principal effect of dextran 40 is plasma volume expansion, resulting from the drug's colloidal osmotic effect in the drawing fluid from the interstitial to the intravascular spaces. Plasma volume expansion is accompanied by an increase in central venous pressure, cardiac output, stroke volume, blood pressure, urinary output, capillary perfusion, and pulse pressure, and by a decrease in heart rate, peripheral resistance, blood viscosity, and mean transit time. Dextran 40 also enhances blood flow through correction of hypovolemia and improved microcirculation. Dextran 40 may coat erythrocytes, thus reducing bonding forces and maintaining the erythrocytes in a state of electronegativity, and mutual repellancy; dextran 40 may also coat other formed elements. In addition, the drug may decrease erythrocyte rigidity, thereby facilitating passage of erythrocytes through small blood vessels^[51]. In experimental studies, it has been shown that dextran not only limited the progression of pancreatic necrosis by improving pancreatic microcirculation, reduced trypsinogen activation, prevented acinar necrosis, and improved survival in necrotizing rodent pancreatitis^[52-56], but also reduced blood viscosity, hematocrit and erythrocyte osmotic fragility, and elevated fibrinogen significantly^[25]. The colon, liver, and lungs affected by the AP associated systemic inflammatory response may still benefit from improved microcirculation at a time when pancreatic necrosis can no longer be reversed^[22].

In conclusion, treatment of severe AP with dexamethasone and dextran is an effective and practical approach. Dexamethasone can inhibit multiple inflammatory mediators and dextran can improve MCD. We emphasize that high dose of dexamethasone should be used in a short time interval to ensure the pharmacological effect and avoid its potential side reactions. Of course, when patients represent acute respiratory distress syndrome or severe intraabdominal infection, other therapeutic approaches, such as, mechanical ventilation, surgery should be considered.

Abstract

AIM: To study the value of monitoring K-ras point mutation at codon 12 and telomerase activity in exfoliated cells obtained from pancreatic duct brushings during endoscopic retrograde cholangiopancreatography (ERCP) in the diagnosis of pancreatic cancer.

METHODS: Exfoliated cells obtained from pancreatic duct brushings during ERCP were examined in 27 patients: 23 with pancreatic cancers, 4 with chronic pancreatitis. K-ras point mutation was detected with the polymerase chain reaction and restriction fragment-length polymorphism (PCR-RFLP). Telomerase activity was detected by PCR and telomeric repeat amplification protocol assay (PCR-TRAP-ELISA).

RESULTS: The telomerase activities in 27 patients were measured in 21 exfoliated cell samples obtained from pancreatic duct brushings. D_{450} value of telomerase activities in pancreatic cancer and chronic pancreatitis were 0.446 ± 0.27 and 0.041 ± 0.0111 , respectively. Seventy-seven point eight percent (14/18) of patients with pancreatic cancer and none of the patients with chronic pancreatitis showed telomerase activity in cells collected from pancreatic duct brushings when cutoff value of telomerase activity was set at 2.0. The K-ras gene mutation rate (72.2%) in pancreatic cancer was higher than that in chronic pancreatitis (33.3%) ($P < 0.05$). In considering of both telomerase activities and K-ras point mutation, the total positive rate was 83.3% (15/18), and the specificity was 100%.

CONCLUSION: Changes of telomerase activities and K-ras point mutation at codon 12 may be an early event of malignant progression in pancreatic cancer. Detection of telomerase activity and K-ras point mutation at codon 12 may be complementary to each other, and is useful in diagnosis of pancreatic cancer.

INTRODUCTION

Pancreatic cancer has a poor prognosis, its early diagnosis remains unsatisfactory. Even serum tumor markers, such as CA19-9, are associated with pancreatic cancer, but lack sensitivity and tumor specificity. Recent studies have shown that K-ras oncogene is often activated by specific point mutations restricted to codon 12 in human pancreatic ductal adenocarcinoma. In pancreatic adenocarcinoma, K-ras mutations were found in 75% to 100% of the cases^[1-8]. We and others previously showed that k-ras analysis from specimens obtained during ERCP was a sensitive (around 80% to 85%) and specific (close to 100%) method in differentiating benign from malignant pancreatic diseases. Therefore, k-ras mutation identification has been claimed as an useful and early marker in diagnosis of pancreatic cancer^[9-12]. Telomerase is a key enzyme with regard to immortalization of cancer cells and increased activity has been demonstrated in various human malignant neoplasms^[13-16]. We previously detected telomerase activity in 87% of surgically resected human pancreatic cancers. While in adjacent tissues, the positive rate of telomerase activity was only 10%. Detection of telomerase activity was useful in diagnosis of pancreatic cancer^[17].

In the present study, we evaluated the diagnostic role of K-ras mutation and telomerase activity in exfoliated cells obtained from pancreatic duct brushings alone and in combination, in differentiating chronic pancreatitis from pancreatic cancer.

MATERIALS AND METHODS

Patients

From April 1999 to December 2000, 27 patients undergoing ERCP were prospectively investigated at Changhai Hospital, 23 of them were patients with pancreatic cancer, 4 were patients with chronic pancreatitis. There were 17 men, 10 women with a mean age of 58.5 years (range: 22 to 75). The diagnosis of pancreatic cancer was confirmed histologically. The locations of the cancer were pancreatic head ($n=13$), body ($n=5$) and tail ($n=1$), and diffusion over the pancreas ($n=4$). Chronic pancreatitis was diagnosed by clinical history, ERCP and CT findings. All patients with chronic pancreatitis were followed up clinically and radiologically for at least six months.

Sampling technique

ERCP was performed using Olympus JF-240, 230 and TJF200 duodenoscope (Olympus, Japan). Lesions were identified after injection of iodinated contrast agent, a wire (0.035 inch in length) was introduced carefully into the main pancreatic duct and advanced to the suspected abnormal areas under guidance of fluoroscopic monitoring. Then a pancreatic duct brush (BC-24Q, Olympus) was introduced through the guide wire to the suspicious lesion, and the guide wire was withdrawn. The brush was moved rigorously back and forth across the suspicious lesion, brushes were retracted into the guiding catheter tip and removed together with the catheter to avoid losing a portion of the specimen inside the catheter. Specimens were immediately

collected in 5 mL of sterile saline solution at 4 °C for analysis of telomerase activity and DNA or smeared on glass slides, fixed in 95% alcohol and stained by HE for cytological examination, the order of brushing samples studied was always kept consistent.

Detection of K-ras point mutations at codon 12

Samples were centrifuged at 2000 r/min for 15 min and the pellet was collected. Genomic DNA was isolated using DNA lysis buffer and proteinase K digestion, followed by extraction with phenol and chloroform. K-ras point mutations were detected using PCR and restriction fragment-length polymorphism (PCR-RFLP). Primers were synthesized and supplied by Shanghai Bio-Engineering Research Center. The sequences of primers were: P1=5'-CTTGTGGTAGTTGGACCT-3' containing a mismatched base indicated by the underline, P2=5'-GTCAGAGAAACCTTTATCTG-3', P3=5'-TGCACCAAGTAATATG-CATAT-3'. The reaction volume was 50 µL containing 5 µL of 10×Ex Taq buffer, 4 µL of dNTP mixture, 0.5 µL of each primer, 0.25 µL (5 U/µL) of Taq DNA polymerase. The primers for the first PCR were P1 (sense) and P2 (antisense) that flanked codon 12 of the K-ras gene. The first PCR amplification was performed for 30 cycles using a DNA thermal cycler, and each cycle consisted of denaturation at 94 °C for 30 s, annealing at 52 °C for 30 s, and extension at 72 °C for 45 s. A 5 µL sample of the first PCR product was digested with 1 µL (10 U/µL) of Mva I at 37 °C for 1 h under the conditions recommended by the supplier of mismatched sense primer described above. Subsequently, 5 µL of the reaction mixture was subjected to a second round of PCR and amplified for 30 cycles under the same conditions using the following primers: sense: P1; antisense: P3. The second PCR products were also digested with 1 µL (10 U/µL) of Mva I for 1 h. Mutations were confirmed by electrophoresis of 10 µL of the second digested sample on a 20 g/L agarose gel.

Detection of telomerase activity

Telomerase activity was detected with telomerase PCR-ELISA (Boehringer Mannheim, Germany). Exfoliated cells obtained from pancreatic duct brushings were collected and washed with PBS, and centrifuged at 10 000 g for 10 min. Then the cells in PBS containing 200 µL Lysis reagent were incubated on ice for 30 min, and centrifuged at 16 000 g for 20 min at 4 °C. Next, the supernatants (175 µL) were transferred to a Eppendorf tube, and tested for telomerase activity assay. Protein concentration was determined by Coomassie protein assay. Each of TRAP reactions contained 2 µL of cell extract (5-6 µg total protein) and sterile water with a final volume of 50 µL. The reaction mixture was incubated at 25 °C for 30 min, heated at 94 °C for 5 min. Then PCR amplification was performed for 33 cycles using a DNA thermal cycler, and each cycle consisted of denaturation at 94 °C for 30 s, annealing at 50 °C for 30 s, and extension at 72 °C for 90 s followed by 72 °C for 10 min. After PCR, 5 µL of the PCR products was dispensed into a reaction tube and incubated with 20 µL of denaturation reagent at room temperature for 10 min, and then mixed thoroughly by overtaking briefly with 225 µL hybridization buffer per tube. By transferring 100 µL of the mixture per well of percolated MTP modules, MTP modules were incubated at 37 °C on a shaker (300 r/min) for 2 h and washed 3 times with PBS, and enzyme reactions were incubated at room temperature on a shaker (300 r/min) for 30 min by addition of 100 µL anti-Dig-POD per well. After washed 5 times with PBS, 100 µL TMB substrate solution was added to each well and incubated for color development at room temperature for 20 min while shaking at 300 r/min. Using a ELISA reader, the absorbance value of samples was measured at 450 nm within 30 min after termination of reaction.

Statistical analysis

Statistical analysis was performed using the unpaired *t* test and χ^2 test or Fisher's exact test. $P < 0.05$ was considered statistically significant. Data were expressed as mean±SD.

RESULTS

Detection of K-ras point mutations at codon 12

K-ras point mutations at codon 12 were detected in 21 exfoliated cell samples obtained from pancreatic duct brushings by PCR-RFLP. Normal DNA had a 114 base pair (bp) band and k-ras DNA mutation remained as a 131 bp band since it was not digested by MvaI (Figures 1,2). K-ras gene mutation rate in pancreatic cancer was 72.2%, which was higher than that of chronic pancreatitis (33.3%, $P < 0.05$).

Figure 1 PCR products after restriction enzyme digestion, M: Marker; 1: Positive control; 2-7: Pancreatic cancer.

Detection of telomerase activity

Telomerase activities in 27 patients were measured in 21 exfoliated cell samples obtained from pancreatic duct brushings. D450 values of telomerase activity in carcinoma and chronic pancreatitis were 0.446 ± 0.27 and 0.041 ± 0.0111 , respectively. Seventy-seven point eight percent (14/18) of the patients with pancreatic cancer and none of patients with chronic pancreatitis showed telomerase activity in cells from pancreatic duct brushings when cutoff value of telomerase activity was set at 2.0. Both telomerase activity and cytological examination were detected in 66.7% (12/18) of patients.

Table 1 Location of pancreatic cancer and K-ras mutation or telomerase activity

Location	<i>n</i>	K-ras mutation		Telomerase activity	
		(+)	%	(+)	%
Head	11	8	72.7	9	81.8
Body	3	2	66.7	2	66.7
Tail	1	1	100	1	100
Diffuse	3	2	66.7	2	66.7
Total	18	13	72.2	14	77.8

Table 2 Comparison of K-ras point mutations and telomerase activity

	K-ras mutation	Telomerase	Both
Pancreatic cancer (<i>n</i> =18)	13	14	12
Chronic pancreatitis (<i>n</i> =3)	1	0	0
Sensitivity (%)	72.2	77.8	66.7
Specificity (%)	66.7	100	100

Relationship between K-ras gene or telomerase activity and location of tumors

No significant correlation of positivity of K-ras gene or telomerase activity with tumor location was observed (Table 1).

Comparison of K-ras point mutations with telomerase activity

The total rate of positive telomerase activity and K-ras mutation was 83.3% (15/18). The sensitivity and specificity of K-ras mutation and telomerase in differential diagnosis of pancreatic cancer and chronic pancreatitis was compared (Table 2).

Figure 2 Agarose gel of PCR products, P1, P2, P3 : after restriction enzyme digestion; P1a, P2a, P3a: before restriction enzyme digestion, P1 and P1a, P2 and P2a, P3 and P3a represent same samples, respectively.

DISCUSSION

Recent application of molecular biologic techniques, such as detection of K-ras mutation, has been proposed for the diagnosis of pancreatic cancer^[18-22]. K-ras gene mutation was found in greater than 90% of pancreatic cancers, and detection of K-ras gene mutation-positive cells in pure pancreatic juice or duodenal juice were reported to be useful in the diagnosis of pancreatic cancer^[23-26]. K-ras mutation was detected in ERCP brush samples. We used the sensitive RFLP method and found 72.2% of patients with pancreatic cancer had K-ras mutation, which was relatively higher than that in other reports. K-ras mutation was also detected in 1 patient with chronic pancreatitis. Although K-ras mutation has been detected mainly in malignancy, it could be detected in nonmalignant pancreatic lesions^[27-29]. However, a recent long-term follow-up report suggested that K-ras mutation in chronic pancreatitis might represent false-positive results^[30]. Studies including ours showed that this mutation could also occur in benign condition. Queneau *et al.*^[31] found 27.8% (10/36) chronic pancreatitis patients had k-ras mutations. Recently, several investigators failed to detect K-ras mutations in chronic pancreatitis even though they used highly sensitive methods^[32,33] and suggested that K-ras mutation was an extremely specific event in pancreatic cancer. Unfortunately, the reason for this discrepancy is not clear.

Telomerase is an enzyme that was found containing an RNA template complementary to the short DNA sequence repeats at chromosomal ends^[34]. Telomerase activity has been found in the majority of malignant tissues, such as pancreatic cancers, but not in somatic tissues except for reproductive and hematopoietic cells. Moreover, telomerase activity was detected in an extremely early stage of pancreatic cancer when the tumor could not be detected by other diagnostic methods^[35]. Hiyama *et al.*^[36] reported that 95% of pancreatic carcinomas but none of 11 benign pancreatic tumors showed telomerase activity. Suehara *et al.*^[37] reported that 100% of pancreatic carcinomas had high levels of telomerase activity. None of pancreatitis or normal pancreas extracts had detectable telomerase activity. However, some pancreatic adenomas demonstrated weak telomerase activity. Telomerase activity in pancreatic juice reflected the activity of the enzyme in tissue specimens^[38,39]. The telomerase activity in pancreatic juice from patients with pancreatic ductal carcinomas was lower than that in resected tissues. It is possible that various digestive enzymes in pancreatic juice might disturb telomerase assay by inhibiting Taq polymerase^[40]. Myung *et al.*^[41] and Uehara *et al.*^[42]. Have reported their study results in the diagnosis of pancreatic cancer by detecting K-ras mutations and telomerase activity alone

and in combination in pancreatic juice. We compared these two methods and evaluated their usefulness alone and in combination for the differentiation of pancreatic cancer from chronic pancreatitis. Using PCR-TRAP-ELISA method, we could give a more accurate diagnosis of pancreatic cancer by evaluating both K-ras mutations and telomerase activity in cells obtained from pancreatic duct brushings, and found that K-ras mutations in cells obtained from pancreatic duct brushings were useful for detecting neoplastic lesions and that telomerase activity was useful for differentiating malignancy from benign lesions of the pancreas, when telomerase activity cutoff was set at 2.0. The sensitivity and specificity of K-ras mutations for the diagnosis of pancreatic cancer were 72.2% and 66.7%, respectively, whereas those of telomerase activity were 77.8% and 100%, respectively. By combining these two methods, the sensitivity was 66.7% and the specificity was 100%.

In conclusion, detection of K-ras mutation and telomerase activity in cells obtained from pancreatic duct brushings may be complementary to each other, and may prove to be a potent tool for the diagnosis of pancreatic cancer.

Abstract

AIM: To know the epidemiology and outcome of Crohn's disease at King Khalid University Hospital, Riyadh, Saudi Arabia and to compare the results from other world institutions.

METHODS: A retrospective analysis of patients seen for 20 years (between 1983 and 2002). Individual case records were reviewed with regard to history, clinical, findings from colonoscopy, biopsies, small bowel enema, computerized tomography scan, treatment and outcome.

RESULTS: Seventy-seven patients with Crohn's disease were revisited, 13% presented the disease in the first 10 years and 87% over the last 10 years. Thirty-three patients (42.9%) were males and 44 (57.1%) were females. Age ranged from 11–70 years (mean of 25.3 ± 11.3 years). Ninety-two (92%) were Saudi. The mean duration of symptoms was 26 ± 34.7 mo. The mean annual incidence of the disease over the first 10 years was 0.32:100 000 and 1.66:100 000 over the last 10 years with a total mean annual incidence of 0.94:100 000 over the last 20 years. The chief clinical features included abdominal pain, diarrhea, weight loss, anorexia, rectal bleeding and palpable mass. Colonoscopic findings were abnormal in 58 patients (76%) showing mostly ulcerations and inflammation of the colon. Eighty nine percent of patients showed nonspecific inflammation with chronic inflammatory cells and half of these patients revealed the presence of granulomas and granulations on bowel biopsies. Similarly, 69 (89%) of small bowel enema results revealed ulcerations (49%), narrowing of the bowel lumen (42%), mucosal thickening (35%) and cobblestone appearance (35%). CT scan showed abnormality in 68 (88%) of patients with features of thickened loops (66%) and lymphadenopathy (37%). Seventy-eight percent of patients had small and large bowel disease, 16% had small bowel involvement and only 6% had colitis alone. Of the total 55 (71%) patients treated with steroids at some point in their disease history, a satisfactory response to therapy was seen in 28 patients (51%) while 27 (49%) showed recurrences of the condition with mild to moderate symptoms of abdominal pain and diarrhea most of which were due to poor compliance to medication. Seven patients (33%) remained with active Crohn's disease. Nine (12%)

patients underwent surgery with resections of some parts of bowel, 2 (2.5%) had steroid side effects, 6 (8%) with perianal Crohn's disease and five (6.5%) with fistulae.

CONCLUSION: The epidemiological characteristics of Crohn's disease among Saudi patients are comparable to those reported from other parts of the world. However the incidence of Crohn's disease in our hospital increased over the last 10 years. The anatomic distribution of the disease is different from other world institutions with less isolated colonic affection.

INTRODUCTION

Crohn's disease is a chronic recurrent inflammatory disorder of the bowel of unknown cause that can affect any gastrointestinal site from mouth to the anal canal. It results in long-term morbidity and the need for medical treatment and surgical interventions with resection of bowels. Slight increase in mortality plays significant demands upon healthcare resources^[1,2]. Epidemiological studies have shown that Crohn's disease tends to increase^[3-5]. These may be due to improvement of diagnostic procedures and practices and increasing awareness of the disease. Crohn's disease varies with geographical location^[6-15]. Diet and genetic predisposition triggered by environmental factors may play a significant role^[16].

The aim of this study was to know the epidemiology and outcome of Crohn's disease at our institution and to compare the results with reports from other world institutions.

MATERIALS AND METHODS

All patients attending the Gastroenterology Unit of King Khalid University Hospital, Riyadh, Saudi Arabia with a diagnosis of Crohn's disease between 1983 and 2002 were enrolled into the study. Seventy-seven patients with Crohn's disease were qualified (based on completeness of the data). The files of these patients were thoroughly reviewed from the time when the diagnosis of Crohn's disease was made based on history, colonoscopic findings, colonic biopsies, small bowel enema and CT scan of abdomen up to the date of each patient's last follow-up. Significant data collected included epidemiological points of Crohn's disease patients, age and gender at presentation, smoking history, the common clinical features of the disease, diagnostic modalities used for confirmation of the disease and their corresponding results, laboratory tests at initial and last visits, current status of the patient, treatment protocols used, their responses to treatment and outcome of management.

Data were entered systematically into computer with Microsoft Excel. Statistical analyses and correlations were done

using Stat Pac Gold analysis software. *P* values less than 0.05 were considered statistically significant.

RESULTS

A total of 77 patients with Crohn's disease over the last 20 years were reviewed. Ten (13%) patients presented the disease in the first 10 years and 67 (87%) patients over the last 10 years (Figure 1). Thirty-three (42.9%) patients were males and 44 (57.1%) were females. Age ranged from 11 to 70 years with a mean age of 25.3 ± 11.3 years. Seventy-one (92%) were Saudi nationals (Figure 2). The mean duration of symptoms was 26 ± 34.7 mo (range 1-180 mo). Table 1 shows the demographic characteristics of all patients with Crohn's disease.

Figure 1 Number of patients with Crohn's disease over the last 20 years.

Figure 2 Age of patients at presentation.

Table 1 Demographic characteristics of patients with Crohn's disease in KKHU, Riyadh, Saudi Arabia (*n*=77)

	All patients	Active	On remission
Number	77	34 (44%)	43 (56%)
Total males	33 (42.9%)	15 (44%)	18 (42%)
Total females	44 (57.1%)	19 (56%)	25 (58%)
Age (range)	11-70 years	11-55 years	11-70 years
Mean age	25.3 ± 11.3 years	22.9 ± 8.3 years	27.3 ± 13.2 years
Nationality (Saudi/non-Saudi)	71/6	32/2	39/4

The mean annual incidence of the disease in the first 10 years was 0.32:100 000 and 1.66:100 000 in the last 10 years with total a mean annual incidence of 0.94:100 000 in the last 20 years.

Table 2 illustrates the chief clinical features of patients with Crohn's disease, showing abdominal pain in 67 patients (87%), diarrhea in 60 (78%), weight loss in 41 (53%), anorexia in 22 (29%) and rectal bleeding in 19 patients (25%). Fifty eight percent of patients had abdominal tenderness and 10% had palpable mass while 42% had negative physical examination findings.

Table 2 Clinical features of Crohn's disease in KKHU

	All patients <i>n</i> =77 (%)	Active Crohn's <i>n</i> =34 (%)	Remission <i>n</i> =43 (%)
Abdominal pain	67 (87)	29 (85)	38 (88)
Diarrhea	60 (78)	27 (79)	33 (77)
Weight loss	41 (53)	23 (68)	18 (42)
Anorexia	22 (29)	10 (29)	12 (28)
Fever	20 (26)	8 (24)	12 (28)
Rectal bleeding	19 (25)	5 (15)	14 (32)
Normal physical examination	32 (42)	10 (29)	22 (51)
Abdominal tenderness	45 (58)	24 (71)	21 (49)
Palpable mass	8 (10)	3 (9)	5 (12)

Table 3 shows the colonoscopic, biopsy results, enteroclysis findings and CT scan results. Colonoscopy was abnormal in 58 patients (76%) showing features of ulcerations in 40 patients (52%), inflammation in 25 (33%), thickened mucosa in 18 (24%), pseudopolyps in 13 (17%) and nodularity in 8 (11%). Biopsy showed abnormal results in all patients with chronic inflammatory cell infiltration in 69 patients (90%), ulceration and granuloma in 31 patients (40%), crypt abscess in 19 (25%), edema in 15 (19.5%), granulations in 11 (14%) and goblet cell depletion in 10 (13%). Small bowel enema showed abnormal findings in 69 patients (89%) with ulceration in 34 (49%), narrowed lumen in 29 (42%), mucosal thickening in 24 (35%), nodularity in 18 (23%), loop separation in 15 (19%) and filling defect in 6 (8%). CT scan results showed abnormal findings in 68 patients (88%) with thickened loops in 45 patients (66%), small mesenteric nonspecific lymphadenopathy in 25 (37%), hypervascularity in 18 (23%) and presence of mass in 15 (19%).

Table 3 Colonoscopic, biopsy, small bowel enema findings and CT scan results of Crohn's disease in KKHU

	All patients <i>n</i> =76	Active Crohn's <i>n</i> =33	Remission <i>n</i> =43
Colonoscopy			
Normal	18 (24%)	8 (24%)	10 (23%)
Abnormal	58 (76%)	25 (76%)	33 (77%)
Biopsy	<i>n</i> =77	<i>n</i> =34	<i>n</i> =43
Normal	0	0	0
Abnormal	77 (100%)	34 (100%)	43 (100%)
Enteroclysis	<i>n</i> =77	<i>n</i> =34	<i>n</i> =43
Normal	8 (11%)	5 (15%)	3 (7%)
Abnormal	69 (89%)	29 (85%)	40 (93%)
CT scan	<i>n</i> =77	<i>n</i> =34	<i>n</i> =43
Normal	9 (12%)	9 (26%)	0
Abnormal	68 (88%)	25 (74%)	43 (100%)

The anatomic distribution of Crohn's disease in our patients was as follows, namely 16% had small bowel disease without colonic involvement, 78% had both small and large bowel disease and 6% had colitis alone.

Of the 77 patients, 55 were treated with steroids. A satisfactory response was seen in 28 patients (51%) while 27 (49%) showed recurrences of the condition, most of which were due to poor compliance to medication. Twenty-one (27%) patients however, did not receive steroids, of them seven (33%) remained with active Crohn's disease.

Nine (12%) patients underwent surgery with resections of parts of their bowel, two (2.5%) with steroid side effects, 6 (8%) with perianal disease (*e.g.* fissure, sinuses or fistulae), and 3 (4%) with fistulae between the bowel and 2 (2.5%) with perianal fistulae.

Table 4 Initial laboratory results of Crohn's disease patients at KKHU (all patients vs active vs on remission)

	All patients	Active Crohn's	Remission
WBC count	9.06±3.95	8.57±4.43	9.42±3.58
Hemoglobin	10.8±1.89	10.97±1.61	10.72±2.12
Platelets	429.9±161	422.5±145.2	435.4±176.1
ESR	42.8±27.8	34.4±22.9	49.5±26.6
Albumin	30.7±8.9	30.4±9.9	30.97±8.21

Table 5-A Comparison of initial and last follow-up laboratory results of Crohn's disease patients who went into remission

	Initial visit	Last follow-up	P value
WBC count	9.42±3.58	8.36±3.4	0.1629
Hemoglobin	10.72±2.12	12.4±1.78	0.0001
Platelets	435.4±176.1	396.4±132.02	0.2485
ESR	49.5±26.6	29.9±26.01	0.0009
Albumin	30.97±8.21	33.5±7.97	0.1508

Table 5-B Comparison of initial and last follow-up laboratory results of Crohn's disease patients who remained active

	Initial visit	Last follow-up	P value
WBC count	8.57±4.43	8.35±3.04	0.8120
Hemoglobin	10.97±1.61	11.2±2.3	0.6344
Platelets	422.5±145.2	388.5±122.5	0.3005
ESR	34.4±22.9	33.05±24.4	0.8148
Albumin	30.4±9.9	30.55±7.67	0.9445

Table 4 illustrates the comparison of the initial laboratory results in all patients with active Crohn's disease and those with remission. Of these initial laboratory results, the hemoglobin level in patients with remission was statistically significantly higher than those patients with active Crohn's disease (P value = 0.0118). Table 5-A shows the comparison of initial and last follow-up laboratory results of 43 patients with remission. In patients with remission, the hemoglobin level was significantly increased from an initial level of 10.72±2.12 g/L to 12.4±1.78 g/L at the last follow-up (P value = 0.0001). Furthermore, erythrocyte sedimentation rate (ESR) of 49.5±26.6 on the initial visit was significantly dropped to 29.9±26.01 at the last follow-up (P value 0.0009). Whereas, in patients with active Crohn's, there was no significant change in their laboratory results from initial to last follow-up (Table 5-B).

DISCUSSION

Before 1982, Kirsner and shorter observed that inflammatory bowel disease was rare or non existent in Saudi Arabia and Morocco^[16]. In 1982 Mokhtar and his group from King Abdul-Aziz University in Jeddah reported the first two cases of Crohn's disease in Saudi's^[6]. In 1984 Al-Nakib et al in Kuwait reported 14 patients with Crohn's disease and suggested that inflammatory bowel disease was uncommon in our population was wrong^[17]. El Sheik et al from Riyadh Armed Force Hospital reported three cases of Crohn's disease between 1979 and 1985^[18]. In 1990 Hossain and his group from King Khalid University Hospital in Riyadh reported seven cases of Crohn's disease, three patients were Saudis and the remaining were of different Arab nationalities and concluded that Crohn's disease did exist among Arabs^[7]. Hubler and Isbister from King Faisal Specialist and Research Hospital in Riyadh reported 28 patients with Crohn's disease between 1976 and 1994^[19]. From the previous reports we noticed that Crohn's disease was present among Saudi nationals in the 1980s but in a few numbers.

The present study was a retrospective study done in a referral, teaching hospital where we noticed an increase in the number of patients with Crohn's disease over the last a few years (Figure 1).

The total number of patients with Crohn's disease in KKHU from 1983 till 2002 was seventy-seven. Some of them were diagnosed after admission to the hospital for investigation and management of acute problems and the remaining as outpatients for investigations of chronic problems, *e.g.* diarrhea, abdominal pain and loss of weight.

There was an increase in the number and incidence of patients with Crohn's disease over the last 10 years in comparison to the first 10 years of the study. This is not definitely related to the accuracy of diagnostic tools because the same investigations were applied to all patients, *e.g.* colonoscopy and radiological investigations from the start of the study. These may reflect an actual increase in the number of patients since 1993.

The mean annual incidence of the disease over the last 20 years was 0.94: 100 000 and this is more than that in Japan and some other Far East countries, less than that of Western countries and similar to that in the Province of Granada in Spain^[8-13,20].

It appeared that there was a slight female preponderance to the disease and the female to male ratio was 1.33. This is similar to that of North American population and some European countries, while in some studies from various areas of Asia and Europe suggested that there was a marked male preponderance, *e.g.* 1.6:1-2.2:1 in Japan and Korea respectively and 1.3:1 in Italy^[1,8-14].

In many European studies, the age distribution showed a bimodal pattern, with peaks at the ages of 20-29 and 60-69 years^[12]. Many other studies, however, have demonstrated a unimodal distribution and some a trimodal distribution^[15]. The peak age at diagnosis in our study was between 20 and 30 years and this is similar to the results of other institutions (Figure 3).

The clinical manifestations of Crohn's disease are variable depending on the involved part of the bowel and the extent of disease. In our center more than two thirds of our patients presented had abdominal pain and diarrhea, half of all our patients had weight loss and tenderness, less than one third had fever and rectal bleeding and a few percent had a palpable mass. These presentations were investigated and the diagnosis of Crohn's disease was confirmed by endoscopies, biopsies and radiological investigations. The above presentations are the usual manifestations of Crohn's disease in most of the communities.

The worldwide anatomic distribution of Crohn's disease ranged from 30-40% in those with small bowel disease, 40-55% in those with both small and large intestine involvement and 15-25% in those with colitis alone^[20,21]. In our study the distribution of the disease was different, most of the patients had small and large intestinal involvement and less than a quarter of patients had small bowel disease, while colonic disease alone represented only 6%.

It is difficult to predict which patients with Crohn's disease will go into remission. Localization of the disease, age, sex or even clinical symptoms did not significantly correlated with outcome of the treatment. Prolonged steroid response could occur in nearly half of patients receiving steroid^[22]. In this review, 55 patients (71%) received steroids and 28 of them (51%) went into remission with good response to therapy while the remaining did not, mainly due to poor compliance to treatment. During the long-term follow-up of this study, 42 patients (54.5%) were in remission at any time.

It was estimated that 75% of patients with Crohn's disease require surgery within the first 20 years after onset or appearance of symptoms. The most common operation performed is a resection of a diseased segment of small intestine and colon^[23,24]. Only 12% of our patients had surgeries with resections of parts

of their colon and small bowel.

In general, perianal Crohn's disease is present in as many as 25% of patients and develops in 31% to 94% of patients over the course of their illness. Manifestations of perianal disease include skin involvement (maceration, erosions, skin tags, ulceration, and abscesses), lesions of the anal canal (fissures, ulcers, and stenosis), and fistulae. Approximately two thirds of patients with Crohn's colitis have perianal fissures.

Unlike ordinary anal fissure, typical fissures associated with Crohn's disease are multiple, painless, and non-midline in location. Fistulae have been found to develop in 20% to 40% of patients with Crohn's disease and were difficult to be managed medically^[25-27]. More than half of patients with colonic involvement will have anal complications, whereas in less than 20% of patients with small-bowel disease, anal symptoms were likely to develop^[28,29]. Only 6% of our patients had perianal disease with fissures, sinuses and fistulae, all of them had involvement solely of the colon.

Patients with Crohn's disease who went into remission showed significant improvement in their hemoglobin and erythrocyte sedimentation rate (ESR) while other laboratory results remained statistically insignificant as that before remission.

Those who remained active showed no changes in all laboratory results.

The epidemiological characteristics of Crohn's disease among Saudi patients are comparable to those reported from other parts of the world. There is an increase in the incidence of Crohn's disease in our hospital over the last 10 years. However, the anatomic distribution of the disease is entirely different from other world institutions, with less isolated colonic disease and, all patients with perianal disease have colonic inflammation.

Abstract

AIM: To study the incidence, bacterial spectrum and drug sensitivity of catheter-related infection (CRI) in gastrointestinal fistula patients.

METHODS: A total of 216 patients with gastrointestinal fistulae during January 1998 to April 2001 were studied retrospectively. Two hundred and sixteen catheters of the 358 central venous catheters used in 216 gastrointestinal fistula patients were sent for microbiology analysis.

RESULTS: Ninety-five bacteria were cultivated in 88 catheters (24.6%). There were 54 Gram-negative bacteria (56.8%), 35 Gram-positive bacteria (36.8%), and 6 fungi (6.4%). During the treatment of CRI, 20 patients changed to use antibiotics or antifungal, and all patients were cured. The mean time of catheters used was 16.9 ± 13.0 d.

CONCLUSION: CRI is still the common complication during total parenteral nutrition (TPN) treatment in patients with gastrointestinal fistulae, and Gram-negative bacteria are the main pathogens, and bacterial translocation is considered the common reason for CRI.

INTRODUCTION

Total parenteral nutrition (TPN) support is one of the main treatments for gastrointestinal fistula patients, and central venous catheters (CVC) are widely used as the major route. Catheter-related infection (CRI) is a serious complication during TPN. This paper retrospectively reviewed patients with gastrointestinal fistulae complicated by CRI during TPN during January 1998 to April 2001, and studied the incidence, bacterial spectrum and drug sensitivity of CRI. There were special characteristics of CRI in gastrointestinal fistula patients.

MATERIALS AND METHODS

Patient data

Patient data were obtained from a retrospective review of 216 CVC of 358 CVC from 216 patients with gastrointestinal fistulae

in the surgical unit of Nanjing Jinling Hospital during January 1998 to April 2001.

Intervention

The catheters were removed and sent for microbiological culture and analysis, when the patients were clinically considered as CRI because of infection signs (e.g. tremble and fever) during TPN.

Diagnosis of CRI

Patients who had signs of infection and positive culture of CVC were diagnosed as CRI.

Statistical analysis

Patient data, culture of central venous catheters and drug sensitivity were collected and analyzed by the softwares of WHONET 5.0 and SPSS 10.0

RESULTS

Clinical data

In this study, 358 catheters were inserted in 216 gastrointestinal fistula patients. The number of male patients was 129, mean age was 42.5 ± 16.6 years, and that of female was 87, mean age was 43.9 ± 16.5 years. Two hundred and sixteen catheters were removed, and then the catheter tips and concurrent peripheral venous blood were sent for microbiological analysis when the patients had such infection signs as phricasmus, chill and fever. Of the catheters sent for microbiological analysis, 88 (24.6%) were confirmed to have infection by positive culture. Ninety-five bacteria were cultivated, and 8% were polymicrobes. Of the concurrent peripheral venous blood culture, 50 (14.0%) were confirmed to be positive. Fifty-two bacteria were cultivated, and 4% were polymicrobes. Twenty-four bacteria were cultivated from catheters and concurrent peripheral venous blood. The mean time of catheters used was 16.9 ± 13.0 d.

Treatment and outcome

All the 88 patients who were confirmed having CRI were cured. Five patients were self-cured without treatment of any antibiotics after CVC was removed. Among the other 83 patients who were treated by antibiotics, 63 were cured by antibiotics in 1-3 d, 16 changed to use antibiotics, and 4 were treated by antifungal drugs according to the drug sensitivity because of persistent infection.

Microbiological analysis

Ninety five bacteria were cultivated from 88 catheters. The bacterial spectrum is shown in Table 1. There were 54 Gram-negative bacteria (56.8%), 35 Gram-positive bacteria (36.8%), and 6 fungi (6.4%). Drug sensitivity test was performed in 77 of 95 bacteria. Drug sensitivity of 48 Gram-negative bacteria and 29 Gram-positive bacteria is shown in Table 2 and Table 3, respectively. The result of drug sensitivity test indicated severe drug resistance. The preferably sensitive antibiotics for Gram-negative bacteria were imipenem, amikacin, ciprofloxacin, ceftazidime and cefoperazone/sulbactam in turn, and those for Gram-positive bacteria were vancomycin, norfloxacin and ciprofloxacin.

Table 1 Organisms present in 88 catheters

Species of bacteria	No of bacteria	Percent (%)
Gram-negative bacteria		56.8
Enterobacteriaceae		
Enterobacter cloacae	6	6.3

Saccharomyces	1	1.1
Total	95	100.0

DISCUSSION

Characteristics of CRI in gastrointestinal fistula patients

As the serious complication during TPN support, the incidence of CRI was as high as 23% in simple malnutrition patients in the early years of TPN^[1]. Due to the development in nurse technology and catheter materials, the incidence of CRI has gradually decreased to 2-6%^[2-4]. However, the CRI incidence in surgical critical patients was still as high as 21.1-34%, and its mortality was increased^[5,6]. Based on this report, the CRI incidence in gastrointestinal fistula patients was similar to that in critical patients, and higher than that in simple malnutrition patients. The mean time of catheters used was 16.9±13.0 d, and it was 17 d in other reports^[2,5,6]. So it is important to supervise the symptoms of gastrointestinal fistula patients during TPN, especially 17 d after catheters were inserted.

In most literature reports, Gram-positive bacteria like *S. epidermidis* and *S. aureus* were most frequently cultivated from catheters^[5-8]. Bacterial skin colonization at the catheter-skin interface at the time of insertion or afterward distal spread of the bacteria along the external catheter surface is the basic pathogenesis. However, Gram-negative bacteria are the most common organisms causing CRI of gastrointestinal fistula patients, and the orderly are Gram-positive bacteria and Fungi. Three reasons were considered for this phenomenon. First, the importance of catheter nursing has been cognized and the means for decreasing bacterial skin colonization, such as disinfection and dressing replacement were performed 3 times per week. Second, gastrointestinal fistula patients always were complicated with inflammation of abdomen, microorganisms especial Gram-negative bacteria could broadcast from abdominal abscess to blood and adhere to catheter-hub and colonize. Third, patient were commonly fasting once gastrointestinal fistula occurred. If long-term lack of food stimulation and direct lumen nutrition, mucous atrophy, height of villus decrease and

barrier damage would arise, followed by bacterial translocation from gastrointestinal tract to the mesenteric lymph nodes even blood^[9-11]. Gram-negative bacterial translocation was considered to be the most common reason for the high incidence of CRI in gastrointestinal fistula patients. Several researches indicated that gut bacterial translocation might be the pathogenesis of catheter-related infection during TPN. Pierro *et al* found that in neonates and infants who were receiving long-term parenteral nutrition, enteric microorganisms including *Escherichia coli*, *Klebsiella*, *Candida species* and *enterococci* were the main microorganisms cultured from blood sample, and they figured out that CRI might be a gut-related phenomenon^[12]. Pappo *et al.* speculated that *Candida* sepsis during TPN might be the result of *Candida* translocation from the gut due to the combination of high-density *Candida* colonization and favorable local conditions in the gut induced by TPN and bowel rest^[13]. Another research indicated that patients with an extremely short remaining small bowel (shorter than 50 cm) receiving home TPN had a higher frequency of catheter-related sepsis, particularly by enteric microorganisms^[14]. Based on our research, Gram-negative bacterial translocation was considered to be the pathogenesis of CRI in gastrointestinal fistula patients. Absence of gastrointestinal integrality and extravasations of intestinal succus would induce abdominal or systemic infection once fistula occurs, and the best treatment to deal with fistulae and infection is more effective drainage. Without effective drainage, it is very difficult to control infection, even with antibiotics from low to high grade or narrow to broad spectrum. Abuse of antibiotic would result in arouse increase of drug resistance. Our study demonstrated that drug resistance of gastrointestinal fistula patients was high, and the preferably sensitive antibiotics for Gram-negative bacteria were imipenem, ceftazidime and cefoperazone/sulbactam, and those for Gram-positive bacteria were vancomycin, norfloxacin and ciprofloxacin.

Prevention and treatment of CRI

The methods for prevention of CRI included skin cleanout and antisepsis before catheter inserted, strictly disinfection system and operation during inserting, catheter nursing and dressing replacement after insertion, decreasing manipulation of catheter, and avoiding unnecessary device^[15-22]. Catheters must be removed once CRI occurred or clinically suspected to be, subsequently therapies of experiential antibiotics were supposed to utilize, though part of patients could self-cure without treatment of any antibiotics^[23-29]. Imipenem, ceftazidime and cefoperazone/sulbactam are the perfect choice for therapy of experiential antibiotics based on the result of drug sensitivity. If the infective symptom persisted after catheters were removed and antibiotics were utilized, drug resistance or *Candida* infection should be considered, and effective antibiotics or antifungal drugs should apply according to drug sensitivity. Intravenous glutamine or short-chain fatty acids could reduce central venous catheter related infection by reducing bacterial translocation from gut lumen^[30,31]. According to the advancement of gastrointestinal physiology, enteral nutrition has been confirmed to improve gut mucosa barrier and liver function and nutrition, reduce bacterial translocation and avoid infection complication of TPN^[32-34]. For avoiding CRI, enteral nutrition (EN) should be utilized, and the time of TPN should be reduced in gastrointestinal fistula patients. CRI is a severe complication in gastrointestinal fistula patients, and attention should be paid to its high incidence based on this retrospective study. Gram-negative bacteria with high drug resistance are the most common organisms causing CRI. Catheters must be removed and sent for microbiological analysis once CRI occurs, sensitive antibiotics for Gram-negative bacteria should be utilized. If the infective symptom persists, drug resistance or *Candida* infection should be considered, and effective antibiotics or antifungal

drugs should be applied according to drug sensitivity.

Abstract

AIM: To evaluate the effectiveness of wireless capsule endoscopy in patients with suspected Crohn's disease (CD) of the small bowel undetected by conventional modalities, and to determine the diagnostic yield of M2A Given Capsule.

METHODS: From May 2002 to April 2003, we prospectively examined 20 patients with suspected CD by capsule endoscopy. The patients had the following features: abdominal pain, weight loss, positive fecal occult blood test, iron deficiency anaemia, diarrhoea and fever. All the patients had normal results in small bowel series (SBS) and in upper and lower gastrointestinal endoscopy before they were examined. Mean duration of symptoms before diagnosis was 6.5 years.

RESULTS: Of the 20 patients, 13 (65%) were diagnosed as CD of the small bowel according to the findings of M2A Given Capsule. The findings detected by the capsule were mucosal erosions (2 patients), aphthas (5 patients), nodularity (1 patient), large ulcers (2 patients), and ulcerated stenosis (3 patients). The distribution of the lesions was mainly in the distal part of the small bowel, and the mild degree of lesions was 54%.

CONCLUSION: Wireless capsule endoscopy is effective in diagnosing patients with suspected CD undetected by conventional diagnostic methods. It can be used to detect early lesions in the small bowel of patients with CD.

INTRODUCTION

Crohn's disease (CD) is a systemic granulomatous disease that may involve any part of the alimentary tract. The small bowel is the affected site in 30-40% of cases^[1]. Recent studies have reported a worldwide rise in the incidence of CD. The "gold standard" for the diagnosis of CD includes the presence of following features: abdominal pain, weight loss, positive fecal occult blood test, iron deficiency anaemia, diarrhoea, fever, and typical evidence of pathological processes on conventional imaging techniques, such as, small bowel X ray, computerized tomography (CT) of the abdomen, enteroscopy, colonoscopy and ileoscopy. The small bowel is the most difficult part to be

examined by endoscopy because of its distance from the mouth and anus. Small bowel series (SBS) therefore remains the first line approach in the diagnosis of small bowel Crohn's disease. When the disease is mild, with inflammatory changes confined to the mucosa, CD lesions can be missed by SBS.

Wireless capsule endoscopy (CE)^[2-7] has now made painless imaging of the entire small bowel possible. In some trials, CE proved to have a higher diagnostic yield in patients with suspected small bowel diseases^[8-19]. It can be used to detect early lesions in the small bowel of patients with CD. The current study represented our initial experience with the M2A Capsule in diagnosing CD in patients undergone conventional investigations in which no characteristic abnormalities were detected.

MATERIALS AND METHODS

Patients

From May 2002 to April 2003, we prospectively examined 20 patients with suspected CD by capsule endoscopy. They were 5 women and 15 men, aged 16-78 years (mean 45.2). They had the following manifestations such as abdominal pain, weight loss, positive fecal occult blood test, iron deficiency anaemia, diarrhoea and fever. All patients had normal results in SBS and in upper and lower gastrointestinal endoscopy within 6 mo before they were examined. Exclusion criteria included a history of bowel obstruction, X ray evidence of small bowel stricture, evidence of any pathological abnormalities of the small bowel, any use of non-steroidal anti-inflammatory drugs during the past year.

The pertinent characteristics of the study population are shown in Table 1. The symptoms of the 20 patients enrolled in the study were consistent with suspected CD. Fourteen had abdominal pain, 13 had positive fecal occult blood test, 10 had iron deficiency anaemia (mean 81 g/L haemoglobin), 4 had diarrhoea, 3 had weight loss, and 2 had fever, some had more than one symptoms. Mean duration of the symptoms before diagnosis was 6.5 years (SD6.5).

Instrument^[2-7]

Wireless capsule endoscope (CE) (Given M2A, Given Imaging Ltd, Yoqneam, Israel) measures 11 mm×26 mm, has a battery life of approximately 6-8 h, and is propelled by peristalsis, not requiring air insufflation. CE is used in conjunction with an imaging system which includes a data recorder and interpretive workstation. CE is disposable and contains a complementary metal-oxide semiconductor (CMOS) chip camera, a transmitter, a light-emitting diode (LED) to provide illumination, and silver oxide batteries. Continuous video images were transmitted from the capsule to an antenna worn over the patient abdomen at a rate of two frames per second during passage of the CE through the gastrointestinal tract. The hemispheric lens yielded a 140-degree field of view. During the procedure, approximately 50 000 images were recorded by a solid-state recorder that was worn as a belt by the patient. The recorder was later connected to a computer workstation, in which the images were processed and then viewed on a monitor using a specifically designed reporting and processing of images and data (RAPID) software package.

Procedures

After an overnight fast for 8-12 h, the patients ingested CE with a small amount of water. They were then free to remain active as outpatients. After the study interval, the patients returned to the clinic and the recorded digital information was then downloaded into a computer. Images from the stomach and the length of small bowel were analyzed using the proprietary RAPID software. The images transmitted by the capsule were interpreted by two independent gastroenterologists. All patients were interviewed after completing the study to evaluate the tolerance or complications.

RESULTS

All the 20 patients described that the capsule was easy to swallow, painless, and preferable to conventional endoscopy. No complications were observed. The images displayed were considered to be good (Figure 1). Retention of the capsule was observed in three patients with small bowel stenosis caused by Crohn's disease (5, 7 and 22 d after capsule ingestion, respectively). One of them had a transient abdominal pain on the third and fourth day after capsule ingestion. None of the three patients with retention of the capsule showed any symptoms of acute or subacute obstruction during the follow-up. The capsule failed to reach the colon in 2 patients during the 8-h acquisition time.

Based on the results of the Given M2A Capsule, we diagnosed CD of the small bowel in 13/20 patients (65%) and normal small bowel mucosa in the remaining 6 of 7 (30%), a jejunal carcinoid confirmed by surgery in the other one. The findings detected by the capsule were mucosal erosions (2 patients), aphthas (5 patients), nodularity (1 patient), large ulcers (2 patients), and ulcerated stenosis (3 patients) (Figure 1). The distribution of the lesions was mainly in the distal part of small bowel (9 in ileum and 2 in the distal part of jejunum) which could not be reached with push endoscopy. The mild lesions or early stages of the disease accounted for 54% (2 mucosal erosions and 5 aphthas). Most of the patients underwent total colonoscopy (16/20), ileoscopy (the ileoscopy succeeded in only five patients) and gastroscopy (20/20). Fourteen out of 20 patients had abdominal CT and all had small bowel X ray series. Some of the patients underwent the procedures more than once. The mean number of procedures undergone previously was 5.4 (SD2.3).

Of the 13 patients who received medications, 11 showed a good clinical improvement after 5-ASA (mean 4 g/d) and a short term steroid treatment while the other two showed some

improvement in their clinical symptoms with the same treatment. Follow up ranged from one to eleven months (mean 4 mo).

Figure 1 Capsule endoscopic findings of Crohn's disease in small bowel. A: A large ulcer in the distal part of jejunum, B: Ulcerations in a narrow ring caused by Crohn's disease in jejunum, C: A large ulcer in ileum, D: Ileal ulcers, E: Aphthas in the distal part of ileum, F: Ileal mucosal erosions.

DISCUSSION

It is generally accepted that the current visualization and imaging methods available to gastroenterologists in identifying small bowel pathology, particularly inflammatory diseases, were unsatisfactory^[19,20].

The reliability of radiological studies is highly influenced by the skill and experience of the operator and how fine is the detail of the mucosa on the film. Neither enteroclysis nor small bowel follow-through (SBFT) X-ray series were able to detect flat mucosal lesions^[14,21-23]. CT of the abdomen could not detect mucosal inflammation, it could show transmural thickening and extramural complications but is incapable of discerning CD in early stages of the disease.

Push enteroscopy requires an experienced and skillful endoscopist, the procedure requires between 15 and 45 min and is often uncomfortable for patients. In addition, the instrument could only examine between 80 cm and 120 cm beyond the ligament of Treitz, and occasional complications might occur^[24-27].

Sonde endoscopy in theory, has the potential to examine the entire small bowel. The procedure time is often 8 h or longer and can be associated with significant patient discomforts. Among patients referred for Sonde examination, 10% had

complications, and up to 75% of the distal ileum was not reached. For these reasons, Sonde- enteroscopy was seldom performed and available in only a few diagnostic centers worldwide^[25-28].

Another approach to small bowel imaging is examination of the entire small bowel by intraoperative endoscopy. The limitations of this option were the drawbacks associated with exploratory laparotomy and general anaesthesia^[29].

The alternative solution should be relatively comfortable for patients, easy to use by gastroenterologists, and one that could provide a reasonable level of visual imaging for the detection of small bowel abnormalities. The Given diagnostic imaging system (M2A Capsule)^[2-7] is a new modality designed to accommodate these requirements.

Capsule endoscopy has now made imaging of the entire small bowel possible. Its indications^[30] are obscure gastrointestinal bleeding, abnormal imaging of small intestine, chronic abdominal pain with reasonable suspicion of organic cause in small intestine, chronic diarrhea, evaluation of extent of Crohn's disease and celiac disease and visualization of surgical anastomoses, surveillance of polyposis syndromes of small intestine.

The cost of the technology per test is about ¥8 500. In order to answer what is the cost of capsule endoscopy in comparison with the cost of traditional examinations, one must consider the diagnostic yield and *cost-effectiveness* of capsule endoscopy compared with traditional diagnostic tools. The diagnostic rate of wireless capsule endoscopy in patients with suspected small bowel diseases was about 70% in our experience^[8,9]. It was similar to some other reports and significantly superior to the traditional diagnostic tools^[10,19]. The potential for cost savings includes (1) improved diagnostic rate and reduction in recurrence, conclusive testing associated not only with the clarity of the images obtained by the Capsule, but also with the Capsule's ability to traverse the entire small bowel (whereas endoscopic examinations leave part of the small bowel unexamined); (2) improved diagnostic precision able to confirm the source of bleeding, and/or rule-out certain etiologies; (3) earlier diagnosis of potentially adverse conditions such as malignancies of the small bowel; (4) reduced complications associated with the diagnostic procedure such as intestinal tears resulting from placement of the enteroscope and/or infection; (5) reduced loss in productivity associated with undergoing testing and repetitive examinations, and reduced loss in quality of life associated with both testing and worry; (6) reduced pain and discomfort associated with the diagnostic procedures.

A significant advantage of wireless capsule endoscopy is its ability to detect small bowel abnormalities, including those areas not reached by traditional endoscopy. The current battery life of 8 h could allow a reliable examination of the upper GI tract and small bowel in most patients. This was our experience as well because the complete small bowel could be studied in 18 of the 20 (90%) patients (except for the three patients with small bowel stenosis caused by Crohn's disease). The lesions in the distal jejunum and ileum were identified in 11 of 13 patients (85%) with abnormal capsule endoscopy beyond the reach of push enteroscopy.

The only definite contraindication to the procedure is a patient who is a nonsurgical candidate or who refuses to entertain the idea of surgery. A retained capsule then would present the problem of retrieval with laparotomy. Severe motility disorders, including untreated achalasia and gastroparesis, should preclude CE, unless the capsule could be delivered endoscopically to the duodenum^[30].

In our study, retention of the capsule occurred in three patients with small bowel stenosis caused by Crohn's disease and delayed passage of the capsule was observed in two CD patients, possibly because of slow transit time due to the inflamed small bowel mucosa. Although the capsule failed to

reach the caecum, we could still identify typical lesions of CD from the recordings that emerged before the battery ran out. The information gained was helpful in further treatment planning for all these patients.

Possible complications existed with any procedure, CE was no exception. The major issue was capsule retention proximal to a stricture. The narrowed area might be anticipated or completely unexpected. Even enteroclysis could not preclude the possibility of a stricture. Our initial experience suggests the capsule does not itself cause intestinal obstruction, but proximal to a stricture it would tumble around and either eventually passes or rarely needs surgical retrieval. A retained capsule usually is asymptomatic and can be detected on the video when reviewed. Plain abdominal films could be obtained after several days to see whether the capsule passed spontaneously. The transient abdominal pain usually signals the passage of the capsule. Barkin *et al.*^[31] reported that surgical intervention to remove a non-passed capsule was only 0.75% (7/937). Therefore, capsule endoscopy should not be used in patients with a history of small bowel obstruction or evidence of significant bowel stenosis.

Our study demonstrated a high diagnostic rate in patients with clinical symptoms indicative of CD who had previously undergone several diagnostic procedures that showed normal results. The patients had long intervals from the onset of disease to diagnosis. The wireless capsule might have been able to provide a correct diagnosis during early stages of the disease as well as in cases of less severe forms. We propose the wireless capsule as an effective modality for diagnosing patients with suspected CD.

In conclusion, wireless capsule endoscopy is a valuable diagnostic tool in the evaluation of obscure GI bleeding and a variety of other small bowel disorders. It illustrates the power of innovative technology to advance our diagnostic capabilities that can be applied safely to patients in the outpatient setting. In our opinion, CE should become the initial diagnostic choice in patients with suspected small bowel diseases and negative upper and lower gastrointestinal endoscopic studies.

Abstract

AIM: To investigate the serum erythropoietin (Epo) levels in patients with chronic liver diseases and to compare to subjects with iron-deficiency anaemia and healthy controls.

METHODS: We examined 31 anaemic (ALC) and 22 non-anaemic (NALC) cirrhotic patients, 21 non-anaemic subjects with chronic active hepatitis (CAH), 24 patients with iron-deficiency anaemia (ID) and 15 healthy controls. Circulating Epo levels (ELISA; R&D Systems, Europe Ltd, Abingdon, UK) and haemoglobin (Hb) concentration were determined in all subjects.

RESULTS: Mean \pm SD of Epo values was 26.9 \pm 10.8 mU/mL in ALC patients, 12.5 \pm 8.0 mU/mL in NALC subjects, 11.6 \pm 6.3 mU/mL in CAH patients, 56.4 \pm 12.7 mU/mL in the cases of ID and 9.3 \pm 2.6 mU/mL in controls. No significant difference ($P>0.05$) was found in Epo levels between controls, CAH and NALC patients. ALC individuals had higher Epo levels ($P<0.01$) than these groups whereas ID subjects had even higher levels ($P<0.001$) than patients suffering from ALC.

CONCLUSION: Increased Epo values in cirrhotics, are only detectable when haemoglobin was lesser than 12 g/dL. Nevertheless, this rise in value is lower than that observed in anaemic patients with iron-deficiency and appears blunted and inadequate in comparison to the degree of anaemia.

INTRODUCTION

Chronic anaemia is often observed in patients with liver disease, especially in advanced stages, and an inverse relation has been reported between haemoglobin (Hb) concentration or hematocrit value and survivorship^[1]. Inapparent gastrointestinal bleeding, folate and vitamin B₁₂ deficiency, autoimmune haemolysis, altered oxide-reductive balance and hypersplenism are

underlying mechanisms responsible for the anaemic state^[2-4].

Moreover, a reduced proliferation of erythroid precursor cells has been described in the bone marrow of these patients^[4,5].

Erythropoietin (Epo) is an endogenous glycoprotein stimulating erythrocytosis which interacts with erythroid progenitor cells to promote their proliferation and maintain their viability as they differentiate^[6,7]. The regulation of erythropoiesis is a biological feedback loop whereby the degree of tissue oxygenation sets the amount of Epo production, the concentration of erythropoietin in turn drives the bone marrow to produce a level of red cells at which oxygen delivery is sufficient to lower Epo production^[8]. The gene codifying for this growth factor has been isolated and a regulatory region involved with oxygen sensing has been defined. Expression in response to hypoxia is mediated via a DNA-binding complex^[8].

Since literature data^[9,10] suggest an emerging role of this hormone in causing haematological changes in chronic diseases, suboptimal production of, or response to, Epo might contribute to the pathogenesis of chronic anaemia in cirrhotics. Some studies regarding the association between Epo levels and cirrhosis have appeared in literature^[11-16] but reported data are controversial.

The aim of this study was to investigate the circulating Epo levels in patients suffering from chronic liver disease of various degrees, with and without concomitant anaemia, compared to subjects with iron-deficiency uncomplicated anaemia as well as to healthy controls, in order to assess the relationship between serum Epo and Hb concentration.

MATERIALS AND METHODS

We examined 74 patients suffering from chronic liver diseases (21 chronic active hepatitis [CAH] and 53 cirrhosis), 24 patients with iron-deficiency (ID) uncomplicated anaemia and 15 healthy control subjects, comparable to sex and age. Haematology, albumin concentration, aspartate aminotransferase (AST) and alanine aminotransferase (ALT) levels, serum bilirubin and prothrombin time (as percentage of prothrombin activity), were measured in all patients and controls.

Diagnosis of patients with liver disease, was based on clinical (medical history, physical examination), instrumental (ultrasonography, endoscopy) and laboratory (liver function tests) data. In 47 out of these cases, hepatic damage was confirmed by liver biopsy (in the remaining subjects the procedure was not necessary, as diagnosis was clinically evident).

In 6 out of 21 CAH patients, the etiological agent was hepatitis B virus (HBV) while in the remaining 15, hepatitis C virus (HCV). Of the 53 cirrhotic subjects, 19 were infected with HBV, 31 with HCV while 3 had a history of alcohol abuse.

According to accepted criteria^[8], thirty-one cirrhotic patients had normocromic normocytic anaemia (ALC group, mean \pm SD Hb 10.2 \pm 0.9 gr/dL) and twenty-two were non anaemic (NALC group, mean \pm SD Hb 13.6 \pm 0.7 gr/dL).

None of anaemic cirrhotics had signs of iron-deficiency (serum iron ≥ 70 μ g/dL, serum ferritin ≥ 50 ng/mL and transferrin saturation $\geq 30\%$).

Table 1 Main characteristics of investigated subjects

	Controls <i>n</i> =15	CAH patients <i>n</i> =21	NALC patients <i>n</i> =22	ALC patients <i>n</i> =31	ID patients <i>n</i> =24
Age (yr, mean \pm SD)	52 \pm 6	54 \pm 8	59 \pm 3	60 \pm 5	54 \pm 5
Males	8	10	9	12	10
Females	7	11	13	19	14
Albumin (g/dL)	3.6 \pm 0.2	3.3 \pm 0.3	3.0 \pm 0.3	2.9 \pm 0.2	3.5 \pm 0.3
AST (U/L)	14.2 \pm 1.5	73.7 \pm 19.2	41.9 \pm 12.6	40.6 \pm 16.4	16.1 \pm 3.5
ALT (U/L)	15.6 \pm 2.7	69.7 \pm 8.4	39.8 \pm 10.1	37.9 \pm 12.5	14.2 \pm 3.1
Bilirubin (mg/dL)	0.6 \pm 0.1	0.8 \pm 0.1	1.1 \pm 0.2	1.3 \pm 0.2	0.7 \pm 0.1
Prothrombin time (%)	98.2 \pm 5.0	81.1 \pm 6.2	72.4 \pm 8.9	70.3 \pm 10.2	95.1 \pm 3.1

In agreement with Child-Pugh's classification^[17], 12 of NALC patients were in class B and 10 belonged to class C. In the ALC group, 13 patients were in class B whereas 18 in class C.

Cirrhotic subjects affected by gastrointestinal bleeding in the previous 3 mo (as confirmed by endoscopy and fecal occult blood testing) and those with suspected hepatocellular carcinoma (on the basis of ultrasonography, alpha-fetoprotein and carcinoembryonic antigen levels performed during the screening) were excluded from the study.

Diagnosis in patients with iron-deficiency anaemia, was based on clinical (medical history, physical examination), and laboratory (Hb concentration <12 g/dL, serum ferritin <40 ng/dL and transferrin saturation <16%) data. None of them had clinical or laboratory (C-reactive protein) evidence of inflammatory condition.

All subjects had normal renal function (serum creatinine <1.2 mg/dL, creatinine clearance \geq 70 mL/min). The main characteristics of our study groups are summarised in Table 1.

The study was conformed to Helsinki Declaration and informed consent was obtained from the whole study series.

A blood sample was obtained from all subjects and ethylenediaminetetraacetic acid (EDTA) was added. Samples were centrifuged and plasma was stored at -25 °C. Erythropoietin was determined by a commercial ELISA kit (R&D Systems Europe Ltd, Abingdon, UK). The sensitivity of assay was less than 0.6 mU/mL. Non specific binding was <1%. Intra and inter-assay variability averaged 3.1% and 3.5%, respectively. Epo concentrations were expressed as mU/mL.

Analysis of variance and Kruskal-Wallis test were used to compare mean \pm SD between various groups. Relationship between continuous variables was investigated by correlation test or multiple regression test when they were more than two. Covariance analysis was performed to assess the difference in Epo values for adjusted Hb, between ALC and ID patients. The regression lines between Hb concentration and Epo values in these two groups were compared by *t*-test, according to current statistical procedures^[18].

RESULTS

No significant difference ($P>0.05$) in Hb concentration was observed between controls (13.9 \pm 0.3 gr/dL), CAH (13.7 \pm 0.5 gr/dL) and NALC (13.6 \pm 0.7 gr/dL) patients. Subjects suffering from ALC (10.2 \pm 0.9 gr/dL) and ID (10.1 \pm 0.8 gr/dL) had values significantly lower than others ($P<0.05$), but Hb concentration was similar in these two groups ($P>0.05$). Among cirrhotic subjects, Hb concentration was similar ($P>0.05$) in Child-Pugh class B and class C patients both in ALC (10.4 \pm 0.7 gr/dL *versus* 10.1 \pm 0.9 gr/dL, respectively) and in NALC (13.8 \pm 0.4 gr/dL *versus* 13.5 \pm 0.9 gr/dL, respectively) groups.

Mean \pm SD of plasma Epo was 9.3 \pm 2.6 mU/mL in controls, 11.6 \pm 6.3 mU/mL in CAH patients, 12.5 \pm 8.0 mU/mL in NALC

subjects, 26.9 \pm 10.8 mU/mL in ALC patients and 56.4 \pm 12.7 mU/mL in ID individuals.

Regarding Child-Pugh related allocation, mean \pm SD of plasma Epo was 24.18 \pm 9.56 mU/mL for patients in class B *versus* 30.71 \pm 10.82 mU/mL for those in class C of the ALC group, 12.3 \pm 7.8 mU/mL in class B *versus* 12.9 \pm 8.1 mU/mL in class C patients of the NALC group, respectively.

Statistical analysis did not show any significant difference between controls, CAH patients and NALC patients ($P>0.05$). ALC subjects had significantly higher Epo levels than these three groups ($P<0.01$) and patients suffering from ID had significantly higher Epo levels than ALC patients ($P<0.001$). In both NALC and ALC groups, no significant difference ($P>0.05$) was observed between class B and class C patients.

Epo levels were not related ($P>0.05$) to albumin concentration, AST and ALT values, serum bilirubin and prothrombin time in any group of patients with liver disease.

An inverse significant relationship between Epo and Hb was found in ID patients ($r=-0.61$, $P=0.001$) but not in ALC patients ($r=-0.22$, $P>0.05$). Covariance analysis revealed a significant difference ($P<0.001$) in Epo values for adjusted Hb concentration between ALC and ID patients.

Finally, the regression lines between Epo and Hb in ALC and ID patients, were compared and a significant difference was found (ALC patients: slope -2.47, ES 2.02, y-intercept 52.39; ID patients: slope -9.79, ES 2.7, y-intercept 155.48; $t=2.23$, $df=53$, $P=0.03$).

DISCUSSION

Anaemia is a multifactorial complication of liver cirrhosis^[2-5]. Papers regarding abnormalities of circulating Epo in patients with liver diseases were few and results were contradictory^[11-18]. Some authors have reported higher Epo levels in cirrhotic patients when compared to healthy controls. An inverse relation between Epo values and the haematological indices has been described by some groups.

We assessed plasma Epo levels in anaemic and non-anaemic patients with chronic liver disease compared to healthy controls and iron-deficiency anaemic subjects.

Our results showed that non-anaemic patients with liver disease and controls had similar Epo values, in cirrhotic patients, circulating Epo was not related to Child-Pugh score. Moreover, multiple regression test documented that Epo levels were not related to concentration of albumin, bilirubin, ALT or AST values and prothrombin time in any of these three groups of patients with liver disease.

This was in part conflicting with the findings of other authors^[12,13,15] and suggested that liver damage itself, independent of the degree of dysfunction, was not able to alter circulating Epo levels.

On the other hand, we detected a significant increase in levels of this hormone both in ALC patients and in ID patients.

However, a significant inverse correlation between Epo and Hb was found in ID group ($r=-0.61$, $P<0.05$) but not in ALC group ($r=-0.22$, $P>0.05$).

Nevertheless, increased Epo level in anaemic patients *versus* healthy controls was not enough to assess Epo production.

In fact, the definition of defective Epo production has relied on a low Epo value in comparison to reference patients with similar Hb^[19]. Consequently, circulating Epo cannot be simply compared with normal values and levels found must be evaluated in relation to the degree of anaemia.

As it has been widely accepted that adequate Epo production occur in patients with iron-deficiency anaemia^[19], we chosen ID patients as reference group.

Mean \pm SD of Hb values was similar in the two groups of anaemic patients, but mean \pm SD of Epo concentrations in ALC group was much lower than that in ID patients.

Analysis of covariance showed a significant difference in Epo values between the two groups ($P<0.001$). Moreover, we also compared the regression lines between Epo and Hb in ALC and ID patients. The slope and y-intercept of two regression lines (Figure 1) were significantly different ($P<0.05$).

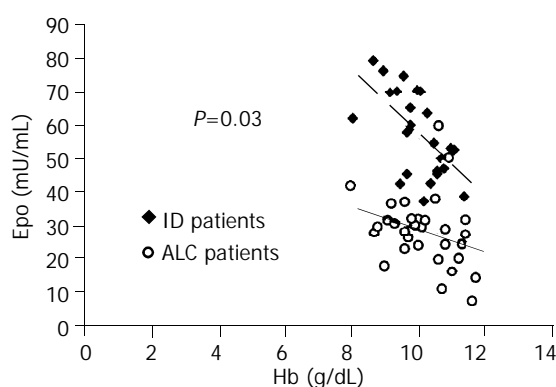

Figure 1 Comparison between regression lines of Epo and Hb in ALC and ID patients.

Therefore, although circulating Epo levels in ALC patients, were higher than that in non anaemic individuals with liver disease, they were significantly lower in healthy subjects, than in ID patients. The reason of this finding is unclear. It seems that an altered Epo clearance did not result in the difference because normal metabolism of this hormone was maintained in cirrhotics^[20].

Cazzola *et al.*^[21] described an inverse relationship between red blood precursor mass and serum Epo. As in cirrhosis, a reduction of erythroid cells has been reported^[4,5], the finding of lower Epo values in our ALC patients than in ID patients was not due to an increased utilization by precursor cells.

Therefore, lower Epo values in ALC subjects, are likely provoked by an impaired synthesis rather than by an increased metabolism.

Consequently, we think that Epo production occurred in different quantitative patterns in these two groups, and other factors besides Hb concentration, could affect its output in cirrhotic patients.

This can explain why no relationship was found between Hb and Epo in our ALC patients.

In adults, Epo has been found to be synthesised by the kidney and to a lesser extent by the liver^[22]. Thus, liver failure could endanger the hepatic residual share of Epo synthesis, even though in this study, the absence of relation between Epo values and investigated indices of liver dysfunction did not support this hypothesis. Alternatively, a reduced sensitivity of renal cells to hypoxic stimuli could be hypothesized. Furthermore, the inhibitory action of reactive oxygen species

and nitric oxide as well as malnutrition of cirrhotic patients might contribute to reduction in Epo synthesis^[23-26].

Finally, inflammatory cytokines, namely interleukin-1, tumor necrosis factor and transforming growth factor, are enhanced in liver diseases and have been found to inhibit hypoxia-induced erythropoietin production *in vitro* and *in vivo*^[27-29].

Whatever the cause of blunted and unsuitable rise in circulating Epo is the levels of this hormone in anaemic cirrhotics, appear defective and inadequate with regard to the degree of anaemia.

Even though Epo deficiency is not only the cause of anaemia in cirrhotics, its insufficient concentration could play a role in the persistence of anaemic status, worsening the outcome of cirrhotic patients.

In conclusion, non-anaemic patients with chronic liver disease have normal Epo levels. During cirrhosis, elevated Epo values are detectable in patients with Hb concentration lesser than 12 g/dL and are not related to the degree of both Hb concentration and severity of liver dysfunction. In addition, such an increase is lower than that observed in patients with iron-deficiency anaemia and appears blunted and inadequate in comparison to the degree of anaemia.

Abstract

AIM: To study the effect of cyclin G2 on proliferation of gastric adenocarcinoma cell line-SGC-7901 cell *in vitro*.

METHODS: By use of cation lipofectamine transfection reagent, the pIRES-G2 and pIRESneo plasmids were transferred into SGC-7901 cell line. Anticlonal were selected by G418. Positive clones were observed and counted using Giemsa staining. Cell proliferative ability was assayed by MTT.

RESULTS: (1) The clone number of pIRES-G2 group decreased, clone volume reduced. The number of cell clones in pIRESneo group was 87 ± 3 , that of pIRES-G2 group was 53 ± 4 , occupying 60.1% of pIRESneo group, there was significant difference obviously ($P < 0.01$, $t = 15.45$). (2) The average absorbance of clone cell obtained by stable transfection of pIRES-G2 at 570 nm was 1.6966 ± 0.2125 , the average absorbance of clone cell obtained by stable transfection of pIRESneo at 570 nm was 2.1182 ± 0.3675 , there was significant difference between them ($P < 0.01$, $t = 3.412$).

CONCLUSION: Cyclin G2 can inhibit SGC-7901 cell proliferative ability obviously, it may be a negative regulator in cell cycle regulation.

INTRODUCTION

Cell cycle regulation is the core part in cell proliferation, which has a close relationship with cell carcinogenesis. In recent years, the study of cell cycle regulation is the forefront and hotspot field in cell biology and genetics. At present, research on the formation, activation, inactivation of cyclin-CDK (cyclin-dependent kinase) holo-enzyme complex is the main molecular basis of cell cycle regulation^[1,2]. All the 12 type different cyclins found in mammalian cells contain a 100 amino-acid homologous region named cyclin box, which is the molecular structure marker of cyclins^[3]. Cyclin G is a new member of cyclin family, which

includes cyclin G1 and cyclin G2. Although the identity of amino acid sequence and nucleotide sequence of cDNA of cyclin G1 and cyclin G2 was 53% and 60% respectively, their biological function and distribution in tissue and organ differ greatly^[4,5]. Research shows that cyclin G1 is located mainly in nucleus, whose expression is induced by the damage of DNA and depends on the expression level of p53^[6,7]. Cyclin G2 is located mainly in cytoplasm, whose expression can be induced by the VHL protein and to some degree is independent of p53^[8]. We have known that cyclin G1 is a positive regulator in cell cycle regulation. But we still do not know if cyclin G2 is connected with CDKs and with which kind of CDKs. The expression of cyclin G2 induced by cancer-suppressing gene hints that it may act as a negative regulator in cell proliferation^[9]. Moreover, we purified oral squamous carcinoma cell by laser capture micro-dissection, and found that 4 cases showed low expression of cyclin G2 in 5 cases in the gene expression pedigree research with gene chip analysis^[10]. Thus, it is much more likely for cyclin G2 to have the negative regulating effect on the cell proliferation.

In this article, we transfected pIRES-G2 into SGC-7901 cell and studied the effect of cyclin G2 expression on the cell proliferation *in vitro*.

MATERIALS AND METHODS

Materials

The eukaryotic plasmid expression vector contains the whole length of cyclin G2 and selective marker gene, neo was constructed by the Medical Gene Group of China Medical University^[11]. pIRESneo vector was purchased from Clontech. *E. Coli* JM109 competent cell was the product of TaKaRa, plasmid extraction and purification kits were from Qiagen. Lipofectamine PlusTM and G418 were the products of Invitrogen. MTT was from Huamei. SABC kit and DAB kit were from Boster.

The human gastric adenocarcinoma cell line SGC-7901 (Cell Biology Laboratory of China Medical University) was grown in DMEM (Gibco) supplemented with 100 mL/L heat-inactivated fetal calf serum (Hyclone), 100 U/mL of penicillin sodium and 100 µg/mL streptomycin sulfate, cultured at 37 °C, with 50 mL/L CO₂.

Methods

Plasmid amplification reaction and evaluation *E. Coli* JM109 competent cells were transformed by pIRES-G2 plasmid, cultured in LB medium supplemented with Amp⁺ (100 µg/mL). The positive clones were selected and cultured. Abundant plasmids were produced and purified by alkaline lysis method, identified by 10 g/L agarose gel electrophoresis after restriction endogenous enzyme digestion. The concentration and purity were determined by ultraviolet scanning spectrophotometer.

Gene transfection Exponentially growing SGC-7901 cells were seeded using 2 mL non-antibiotics culture medium into 6-well plates. After 24 h when cells grew to 60-80% confluence transfection began. Cells were transiently transfected according to the protocol of Lipofectamine PlusTM. Briefly, the plasmid DNA was premixed with the Plus reagent by diluting 1 µg DNA into 100 µL transfection DMEM (serum-free, non-antibiotics) and adding 6 µL Plus reagents in polystyrene tubes. Solutions

were combined, gently mixed, and incubated for 15 min at room temperature to allow formation of DNA/Plus complexes. Meanwhile, 4 μ L Lipofectamine reagents were diluted in 100 μ L transfection DMEM. The DNA/Plus reagent was mixed with the diluted Lipofectamine reagent and incubated for 15 min again at room temperature. The growth medium was removed from the cells and replaced with 800 μ L transfection DMEM. The complexes were added to the cells and incubated for 3 h at 37 °C, with 50 mL/L CO₂. Then 1 mL of non-antibiotics DMEM containing 200 mL/L FCS was added to it. Transfection of the pIRESneo vector into SGC-7901 cell was the same.

Cell clone At 24 h after gene transfection, cells were trypsin digested and transferred into 100 mm culture dish, and cultured for another 2 wk in G418 (400 μ g/mL) selective culture medium. The clone formation and cell morphology were observed under an inverted microscope (Olympus IX70). Images were acquired using a cool charge-coupled device (Spot) and transferred into computer. Cells were fixed in methanol/ice acetic acid (3:1) and stained in 50-100 g/L Giemsa. Cell clones were observed and counted.

Immunocytochemistry staining for exogenous cyclin G2 expression Cell transfection and G418 selection were done as above. After fourteen days, cell clones could be seen in pIRES-G2 and pIRESneo group. After PBS washing, the cell clones were circled, separated with sterile tip and cultured in G418 (250 μ g/mL) selective culture medium for another 2 wk. The stably transfected cell lines were obtained after passage by 2-3 generations. Cells were seeded into 6-well culture plates containing coverslips allowed to grow until they were 60-80% confluence and coverslips were picked up, washed with PBS, then fixed in ice cold acetone for 30 min at room temperature, washed 3 times (5 min each) in PBS. Cytochemistry staining was preformed by the avidin-biotin peroxidase complex method using the SABC kit as follows: cells were treated to remove endogenous peroxidase activity, blocked with rabbit serum for 30 min at room temperature, and then incubated in primary goat anti-cyclin G2 polyclonal antibody (American Santa Cruz Company) for 1 h at 37 °C or overnight at 4 °C, washed 3 times with PBS, then incubated with a rabbit-anti-goat secondary antibody conjugated to horseradish peroxidase for 1 h. Following PBS washing, the coverslips were incubated with SABC elite reagent for 30 min at room temperature and washed 3 times in PBS. The bound horseradish peroxidase complexes were developed using DAB kit. The coverslips were counterstained with hematoxylin, for colored by 10 mL/L hydrochloric acid ethanol, dehydrated by graded ethanol, and enveloped by neutral resin, negative contrast was made by using PBS instead of primary antibody.

MTT assay The stably transfected cells were seeded into 24-well culture plates and cultured for 24 h at 37 °C, with 50 mL/L CO₂. Cells were seeded into 96-well culture plates at 4 000-6 000 cells/well. After 48 h culture, the culture solution was poured out and washed twice with PBS. 150 μ L (0.5 mg/mL) MTT was added at 37 °C for 4 h, the culture medium solution was poured out and 150 μ L/ each well DMSO was added again, shaken for 10 min in horizontal shaker. The absorbance at 570 nm was read by enzyme-labelling analysis equipment. The average absorbance reflected the cell proliferative ability. Data showed in mean \pm SD format and statistic significance was analyzed by *t* test.

RESULTS

Plasmid appraisal

The cyclin G2 fragment was inserted between the *Bam*HI and *Bst*XI restriction sites, the restriction enzyme digestion and gel electrophoresis results were the same as predicted.

Selection of the stable transfection cell line and exogenous cyclin G2 gene expression

After 14 d of selection by G418 in transfected cells, several cell clones could be seen in pIRES-G2 and pIRESneo group. After PBS washing, the cell clones were circled, and the larger single cell clones were separated with sterile tip, cultured in G418 (250 μ g/mL) selective culture medium for another 2 wk, the stable transfection cell lines were obtained after passage by 2-3 generations.

Immunocytochemistry staining result showed that a large number of gray positive granules appeared in SGC-7901 cell cytoplasm after pIRES-G2 transfection, while pIRESneo cell cytoplasm only appeared blue and no positive granule was seen in negative contrast cell.

The effect of cyclin G2 overexpression on the colony-formation of SGC-7901 cell

Observing the stably transfected SGC-7901 cell obtained by G418 selection under microscope, the clone number of pIRES-G2 group decreased, clone volume reduced and the cells in clone changed irregularly, many granules and bubbles appeared in cytoplasm. The 5 repeated experimental results were the same. The number of pIRESneo group was 87 \pm 3, that of pIRES-G2 group was 53 \pm 4, occupying 60.1% of pIRESneo group, there was significant difference obviously ($P < 0.01$, $t = 15.45$) (Figures 1, 2).

Figure 1 The positive clone number obtained with pIRES-G2 and pIRESneo plasmids after stable transfection in SGC-7901 cell line.

Figure 2 Effect of cyclin G2 overexpression on the colony-formation ability of SGC-7901.

Effects of cyclin G2 overexpression on SGC-7901 proliferative ability

By MTT assay analysis the proliferative ability change of stably transfected SGC-7901 cell obtained by G418 selection was as following: the average absorbance of clone cell obtained by stably transfected pIRES-G2 at 570 nm was 1.6966 ± 0.2125 , the average absorbance of clone cell obtained by stably transfected pIRESneo at 570 nm was 2.1182 ± 0.3675 , there was statistical difference between them ($P < 0.01$, $t = 3.412$) (Table 1).

Table 1 The proliferative ability compared between 2 clone-cell

Group	Well number	Average absorbance
pIRESneo	96	2.1182 ± 0.3675^b
pIRES-G2	96	1.6966 ± 0.2125

^b $P < 0.01$, $t = 3.412$ vs pIRES-G2.

DISCUSSION

There are many kind of cyclins and CDKs in mammalian cells, which combine with each other forming active cyclin-CDK complex as a triggering factor in the regulation of cell cycle. The expression level of cyclins shows phase specificity, which is obviously regulated by transcription and the rate of protein hydrolysis. Cyclin G, a recent addition to the cyclin family, has homology to fission yeast Cig1, B-type cyclins, and human cyclin A and I. The molecular structure of cyclin G differs from other cyclins. NH₂ terminus lacks a “destruction box” sequence controlling the ubiquitin-dependent degradation mitotic cyclins, while contains an epidermal growth factor receptor (EGF-R/ ErbB) like autophosphorylation motif in its carboxyl terminus^[12]. The structure suggested that a role for cyclin G in signal transduction. Cyclin G has not yet been matched with a CDK binding partner, and its biologic function is still elusive. Cyclin G is the only known cyclin that is transcriptionally activated by the p53 tumor suppressor gene. Cyclins G1 and G2 share the highest sequence identity and similarity to the fission yeast B-type cyclins Cig1 and Cig2 respectively, while cyclin G2 exhibits high sequence identity to the S-phase cyclin Clb-5 of budding yeast. Cloning and sequencing a partial cDNA sequence revealed the cyclin G1 transcript does not encode motifs which resemble known degradation signals. In contrast, the cyclin G2 protein contains a prototypic protein destabilizing (PEST) rich sequences which may be responsible for its potential regulated degradation in cell cycle. The cyclin G1 mRNA expression does not fluctuate with cell cycle phase, whereas the expression of cyclin G2 mRNA oscillated with cell cycle and reached peak in the mid-late S phase. In contrast to cyclin G1, cyclin G2 mRNA weakly expressed in skeletal muscles and heart. It showed high expression in cerebrum, thymus, spleen, prostate gland and kidney^[13]. Notably cyclin G2 transcripts are abundant in tissue rich in either terminally differentiated cells or cells reacting to growth inhibitory signals and apoptosis^[5]. Cyclin G1 is a positive regulator and prompts cell proliferation, so far, neither the physiological role nor the biochemical function of cyclin G2 has been defined. The mRNA expression of cyclin G1 and cyclin G2 can be induced by DNA-damage drug actinomycin-D, which has the p53 dependency for cyclin G1 but the p53 independency for cyclin G2^[14]. Cyclin G2 can be induced by negative growth regulators such as TGF- β 1 and dexamethasone. In the growth inhibition state of B cell, the transcription level of cyclin G2 is up-regulated. Re-conducting the VHL cancer-suppressing gene into renal cancer cells with VHL gene defect can induce cyclin G2 expression. The newest research also showed that lack of cyclin G2 plays an important role in the malignant transformation of papillary carcinoma of the thyroid. It may play an adjuvant role in the transformation of follicular

adenoma to carcinoma^[15]. So cyclin G2 most likely appears to be a negative regulator of the cell cycle.

The result showed that compared with the control group, the clones formed by transfected pIRES-G2 group were smaller and fewer, cells became wrinkled and irregular, which proved that the high expression of cyclin G2 inhibited the cell proliferation. In this research we had the gene transfection experiment through cloning cyclin G2 cDNA into bicistronic eukaryotic expression vector pIRESneo, the 2 open reading frame (ORF) of inserted gene cyclin G2 and selective label gene neo were separated by the inserted brain cardiomyoditis virus IRES^[16,17]. So the recombinant plasmid pIRES-G2 in host cells only produced a single transcriptional template, which made the 2 proteins to be translated simultaneously to ensure all positive cells after G418 selection express target genes, overcame the shortcoming that these 2 genes could not be transcribed and translated at the same time when using other eukaryotic expression vectors^[18,19]. The positive clones formed by G418 selection in the experimental group of pIRES-G2 should have the expression of cyclin G2. Thus, the difference of clones between the experimental and control groups was only caused by the high expression of cyclin G2. The MTT assay also testified that the average absorbance of pIRES-G2 group cell was lower than that of pIRESneo group, it showed that the proliferative ability decreased after pIRES-G2 transfection. Because by MTT assay, the cell numbers in pIRES-G2 group and pIRESneo group were the same and they also grew at the exponentially growing state, thus the average absorbance difference between them was merely caused by the difference of transfected genes. From this we could draw the conclusion that cyclin G2 overexpression makes the proliferative ability decrease.

Our experiment indicates that cyclin G2 could inhibit the SGC-7901 cell proliferation. Unlike other cyclins, it may be a negative regulating factor of cell cycle.

Abstract

AIM: NAG6 gene is a novel tumor related gene identified recently. This study was designed to examine the expression of this gene in gastric cancer and corresponding normal tissues, and to investigate its role in the occurrence and development of gastric cancer, also to study if the genetic structure of NAG6 was altered in gastric cancer.

METHODS: Reverse transcription-polymerase chain reaction (RT-PCR), Northern blot analysis and dot hybridization were used to compare the expression level of NAG6 gene in 42 cases of gastric cancer tissues with their corresponding normal tissues of the same patients respectively. In addition, restriction fragment length polymorphism (RFLP) analysis was adopted to study if the genetic structure of NAG6 was altered in gastric carcinomas.

RESULTS: The expression of NAG6 in 57.1% gastric cancer tissues (25/42) was absent by RT-PCR analysis. The down-regulation rate of NAG6 in gastric cancer tissues was significantly higher than that in corresponding normal tissues ($P < 0.01$). However no correlation between the down-regulation of NAG6 and lymph-node and/or distance metastasis was found in this study ($P > 0.05$). Dot hybridization confirmed the results of RT-PCR. Furthermore, the results of *EcoRI* RFLP analysis of NAG6 gene demonstrated that 3 of 7 cases of gastric cancer showed loss of 5 kb fragment in comparison with their corresponding normal tissues.

CONCLUSION: NAG6 gene is significantly down regulated in gastric cancer. The loss of genetic materials may be the cause of down-regulation of NAG6 expression. This seems to suggest that NAG6 may represent a candidate of putative tumor suppressor gene at 7q31-32 loci associated with gastric carcinoma. The down-regulation of this gene may play a role in occurrence and development of this disease, however it may not be associated with lymph node and/or distance metastasis.

INTRODUCTION

Gastric cancer (GC) is one of the leading causes of cancer death in the world, although its incidence has gradually declined in recent years^[1,2]. However, in the Far East, including China and Japan, gastric cancer remains a prevalent cancer with a high mortality^[3,4]. It is well known that carcinogenesis and progression of human gastric cancer are related to multiple genetic aberrations including activation of oncogenes and inactivation of tumor suppressor genes. The latter involves the loss of heterozygosities (LOH) of several chromosomal loci and mutations in tumor suppressor genes, such as *p53* and *DCC* genes. However, the mechanism of the process of multistage carcinogenesis is still not well understood^[5-12]. Recently, a number of cytogenetic and molecular genetic studies have revealed that LOH on the long arm of chromosome 7 occurs frequently in many types of primary cancers including nasopharyngeal, gastric, breast, ovarian, and oral carcinomas, and investigators have identified the most common site of LOH as 7q31-32, implying the existence of at least one multi-tissue tumor suppressor gene (TSG) at this locus^[13-22]. Based on these findings, in our previous studies, we have cloned a novel tumor related gene from this common deletion region in 7q31-32 by positional candidate cloning strategy, we named it NAG6, and its GenBank accession number was AF156971. It was found to be a potential tumor suppressor gene associated with NPC^[23-26]. To investigate whether the expression of NAG6 was also altered in GC and whether NAG6 gene also played a role in the pathogenesis of gastric carcinoma, we analyzed the expression level of NAG6 in 42 cases of human gastric carcinoma and their matched normal tissues by RT-PCR, Northern blot analysis and dot hybridization. Furthermore, to study if the genetic structure alteration of NAG6 was the reason of its abnormal expression in GC, RFLP analysis was adopted. These studies can lead to a better understanding of the molecular mechanism of gastric cancer.

MATERIALS AND METHODS

Tumor specimens

Fresh surgical specimens of forty-two gastric carcinoma (GC) and corresponding normal tissues were obtained from the Affiliated Xiangya Hospital of Central South University from January 2000 to July 2000. All tumor specimens were confirmed by pathological diagnosis. Each freshly resected specimen was frozen immediately and stored in liquid nitrogen until analyzed. Histologically, In the 42 cases of gastric carcinoma, 4 were well-differentiated adenocarcinomas, 30 poorly-differentiated adenocarcinomas, 6 signet ring cell carcinomas and 2 mucoid carcinomas. There were 22 males and 20 females, their age ranged from 30 to 68 years (mean

age, 51.7 years). Six cases had lymph node or distance metastases. No patient had received chemotherapy or radiation therapy before surgery.

RT-PCR

Total RNA was isolated using Trizol reagent (Gibco-BRL, Gaithersburg, MD, USA) according to the protocol provided by the manufacturer. After treated with DNase-I (Promega), 1–2 µg of total RNA was reversely transcribed into complementary DNA (cDNA) with oligo(dT) using cDNA synthesis kit (Promega). Then 1 µL product was used as the template to amplify specific fragments in a 25 µL reaction mixture. The subsequent PCR was performed using Taq polymerase and the buffer (Promega) supplied with 0.2 mmol/L dNTPs and 0.2 µmol/L primers. Primers corresponding to NAG6 sequences were designed with WWW Primer Picking (Primer 3) and synthesized by TaKaRa. Gene-specific forward and reverse primers for NAG6 were designed to produce a PCR product of 680 bp. RT-PCR reaction was carried out with an initial denaturation at 95 °C for 5 min, followed by 35 cycles at 94 °C for 50 s, annealing at 56 °C for 50 s, at 72 °C for 60 s, and a final extension at 72 °C for 10 min. At the same time, a housekeeping gene, GAPDH was amplified as internal control to normalize the relative levels of cDNA, which generated a PCR product of 475 bp. An aliquot (10 µL) of each reaction product was analyzed by 10 g/L agarose gel electrophoresis.

The sequences of primers were as follows: NAG6F1, 5'-GGCACTGGAGTACAAAGACA-3'; NAG6R1, 5'-TTACTTTTCCCATTGCTCA-3'; GAPDHF1, 5'-GTCATCCATGACAACCTTGGTATC-3'; GAPDHR1, 5'-CTGTAGCCAAATTCGTTGTCATAC-3'.

Northern blot analysis

Total RNA was isolated from human gastric carcinoma and corresponding normal tissues by Trizol reagent (Gibco-BRL), and hybridization was performed as described. A 30 µg RNA was separated by electrophoresis by denaturing agarose gels and blotted onto nylon membrane (Clontech). RNA was permanently attached to the membrane by UV illumination for 150 s (GS Gene Linker, Bio-Rad, USA), and the membrane was dried in a vacuum at 80 °C for 2 h and sealed in a plastic bag for use. The hybridization probes were obtained by RT-PCR amplification. NAG6 cDNA probe was random-prime labeled with [α -³²P]dCTP using primer-a-gene random labeling kit (Promega, USA) and following the protocol. Hybridization with the RNA blots was carried out at 68 °C overnight in Express Hyb TM hybridization solution (Clontech) in a rolling bottle. The membranes were washed twice at room temperature in 2×saline sodium citrate (SSC), 0.5 g/LSDS for 10 min, once at 42 °C in 1×SSC, 1 g/L SDS for 15 min and once at 50 °C in 0.1×SSC, 1 g/L SDS for 30 min. Then, they were exposed to film (Eastman Kodak, Rochester, NY, USA) for 4 d at -70 °C. After exposure, the blot was again hybridized with a GAPDH probe.

Dot blot analysis

GAPDH and NAG6 cDNA fragments containing open reading frames from cDNA of gastric carcinoma samples were obtained by RT-PCR. These cDNAs were reclaimed and purified by using a kit according to the instructions of its manufacturer (Shanghai Huashun Co.). After alkali dissolution, GAPDH and NAG6 cDNA were blotted onto nylon membranes. cDNA was permanently attached to the membrane by UV illumination for 150 s, and the membranes were dried in a vacuum at 80 °C for 2 h to fix the cDNA. Ten µg total RNA was isolated from 10 cases of human gastric carcinomas and 10 cases of each corresponding normal tissues, and reversely-transcribed into

cDNA probe with oligo (dT) and [α -³²P] dCTP using cDNA synthesis kit after treated with DNase I and RNasin at 37 °C for 1 h to remove contaminated DNA (1 µg total RNA of each case was used). Then the two cDNA probes were hybridized with GAPDH and NAG6 cDNA blots respectively as Northern hybridization described above.

Southern-based RFLP analysis

Genomic DNA was extracted from gastric cancer and corresponding normal tissues by using sodium dodecyl sulphate (SDS), EDTA, proteinase K, dispelled protein and phenol-chloroform methods, removing RNA with RNA enzyme, precipitating DNA with alcohol of two times in volume, mixed in proper TE buffer solution, and kept for use at 4 °C. Genomic DNA was digested with the stated restriction endonuclease *Eco*RI and electrophoresed on 7 g/L agarose (TAE) gel. After electrophoresis, DNAs were denatured, neutralized and transferred to nylon membranes. Then DNAs were permanently attached to the membrane by UV illumination and the membrane was dried in a vacuum at 80 °C for 2 h. The nylon membrane was hybridized with the radiolabelled NAG6 cDNA probe according to the method of Southern blot. After washed and autoradiographed at -70 °C for 3 to 5 d, hybridizing was carried out.

Statistical analysis

Chi-square test was used. A *P* value less than 0.05 was considered statistically significant.

RESULTS

Expression of NAG6 in gastric cancer and corresponding normal tissues

In 42 pairs of GC and corresponding normal tissues, NAG6 expression was undetectable in 24 tumors (57.1%), while it was detectable in all corresponding normal tissues. The expression of NAG6 in gastric carcinomas was significantly down-regulated than that in normal tissues ($\chi^2=33.6$, $P<0.005$). Representative cases of NAG6 expression detected by RT-PCR are shown in Figure 1. The down-regulation rate of NAG6 in patients with lymph node and/or distance metastases and those without lymph-node and/or distance metastases was 66.7%(4/6) and 47.2%(17/36) respectively. There was no apparent relevance between NAG6 down-expression and lymph node and/or distance metastasis of gastric carcinomas ($P>0.05$).

Figure 1 Expression of NAG6 in gastric carcinoma and corresponding normal tissues examined by RT-PCR. The RT products were examined by PCR with NAG6 primers, producing a 680 bp fragment and with GAPDH primers, producing a 466 bp fragment. Lane M: 2 000 bp marker, Lane N: normal epithelium tissues, Lane T: gastric carcinoma tissues.

In order to verify the results of RT-PCR, Northern hybridization was performed. Northern blot analysis did not detect NAG6 expression in both gastric carcinoma and

corresponding normal tissues, whereas GAPDH was strongly expressed in both of them. We speculated that the expression abundance of NAG6 gene in gastric cancer and corresponding normal tissues might be too low to be detected by Northern blot analysis. So, we used dot hybridization analysis to verify the reliability of RT-PCR on the other hand. The results of dot hybridization confirmed the results of RT-PCR that the expression of NAG6 was significantly down-regulated in gastric carcinoma tissues (Figure 2).

Figure 2 Dot hybridization analysis of NAG6 gene expression profiles in human gastric carcinoma and corresponding normal tissues. NAG6 cDNA obtained by RT-PCR was blotted onto nylon membranes. The membranes were hybridized with ^{32}P -labeled cDNA probes obtained from total RNA of human gastric carcinoma (1) and corresponding normal gastric epithelial (2) tissues. After stringent washes, membranes were exposed to X-ray film for 4 d at -70°C . NAG6 was down-regulated in gastric carcinoma tissues.

RFLP analysis

*Eco*RI RFLP analysis of NAG6 gene was performed in 7 cases of gastric cancer and corresponding normal tissues. The results showed that there were two kinds of common allelic fragments (11.5 Kb, 5.0 Kb) in all corresponding normal tissues and 4 cases of gastric cancer, but 3 cases of gastric cancer tissues showed loss of 5 Kb fragment in comparison with their matched normal tissues.

Figure 3 RFLP analysis using Southern hybridization. Gastric cancer and normal epithelium genome DNAs were digested with *Eco*RI and hybridized with NAG6 cDNA probe. Three cases of gastric cancer tissues showed loss of 5Kb fragment (N: normal epithelium tissues, Lane T: gastric carcinoma tissues).

DISCUSSION

NAG6 gene has been recently identified and cloned by our group at chromosome 7q31-32, the common deletion site in various human malignancies. Comparison with GenBank and EMBO database using the BLAST program the cDNA sequence of NAG6 gene was a unique gene with no homology to any previously reported human genes, and its GenBank accession number is AF156971. The predicted NAG6 protein contained four protein kinase C (PKC) phosphorylation sites, suggesting that the activity of NAG6 protein can be regulated by phosphorylation. Its mRNA expression level in NPC biopsies was significantly lower than that in normal nasopharyngeal epithelium, and the down-regulation of NAG6

in NPC was attributable to several factors including loss of genetic materials and hypermethylation. All these findings supported NAG6 as a candidate tumor suppressor gene at 7q31-32. The down-regulation of this gene might play a role in occurrence and development of NPC^[23-26].

Cytogenetic and molecular analyses demonstrated that frequent LOH on the long arm of chromosome 7 could also be observed in a high proportion of gastric cancer cases^[13-16]. Nishizuka *et al* reported LOH at any locus on 7q occurred in 34% (18 out of 53) of primary gastric carcinomas^[14]. Kuniyasu *et al* examined LOH on the long arm of chromosome 7 using 5 polymorphic marker probes in 98 gastric carcinomas^[15]. The results showed twenty-six of 82 (32%) informative cases showed LOH on 7q at least one locus of 5 loci. Xia *et al* studied a total of 28 primary gastric cancer specimens, and they found that deletion of 7q (21/26) was one of the characteristic structural changes of primary gastric cancer^[16]. Furthermore, investigators have identified the most common site of LOH as 7q32-qter, and concluded that in the 7q32-qter segments, at least one tumor suppressor gene probably existed and it might have a close relation to the development and progression of gastric cancer^[13-16]. NAG6 gene located at 7q31-32 locus. We were interested in whether expression of NAG6 was altered in GC and whether NAG6 was also a possible tumor suppressor in human gastric carcinoma. In this study, RT-PCR, Northern blot and dot hybridization were used to detect the expression abundance of the gene in gastric carcinoma and corresponding normal tissues. The results of RT-PCR showed that the down-regulation rate of NAG6 in gastric carcinoma tissues was significantly higher than that in corresponding normal tissues ($P < 0.005$). Dot hybridization confirmed the results of RT-PCR. However the expression of NAG6 was not relevant to lymph node and/or distance metastasis of gastric carcinomas. This seems to suggest that down-regulation of NAG6 might play a role in the occurrence and progression of GC.

In order to study the possible cause of down-regulation of NAG6 in gastric cancers, we studied on the restriction fragment length polymorphisms (RFLPs) of NAG6 gene in gastric cancer and corresponding normal tissues to detect if the genetic structure of NAG6 was changed in GC. We used restriction enzymes to cut DNA at specific recognition sites, fragments of restricted DNA separated by gel electrophoresis and detected by subsequent Southern blot hybridization to a radiolabeled DNA probe. In recent twenty years, the application value of restriction fragment length polymorphism (RFLP) analysis in the detection of genetic structure change and genetic polymorphisms of candidate gene has called attention of the scholars at home and abroad^[27-29]. Polymorphic sequences that result in RFLPs are used as markers on both physical maps and genetic linkage maps. In this study, *Eco*RI RFLP analysis of NAG6 gene was performed in 7 cases of gastric cancer and corresponding normal tissues. The results demonstrated that 3 of 7 cases of gastric cancer showed loss of 5 kb fragment in comparison with their corresponding normal tissues. In the previous study, RFLP analysis also found that 6 of 14 NPC cases lost the fragment of 3 kb in comparison with their matched peripheral blood lymphocytes. These results demonstrated that the genetic structure of NAG6 was changed in both NPC and GC. A preliminary conclusion was drawn that loss of genetic materials might be the cause of down-regulation of NAG6 expression.

To summarize, our data showed that NAG6 was down-regulated in gastric cancer, and loss of genetic materials of NAG6 was also found in GC. It is reasonable to predict that NAG6 may represent a candidate of putative tumor suppressor gene at 7q31-32 locus associated with GC and NPC, and this gene may play an important role in suppressing GC tumorigenesis, losses of its function may contribute to the occurrence and

development of GC. The mechanism of this gene is still unclear. Further studies on a large patient population are needed to verify these initial observations and to characterize the mechanism of down-regulation of NAG6 in tumors. It is important to examine the possible relationship between loss or preservation of NAG6 expression and clinical outcome in patients with tumor.

Abstract

AIM: To establish a high P-glycoprotein (P-gp) expressing cell line as a model for studying drug absorption and distribution, and to explore the preliminary application of this screening model.

METHODS: A full-length MDR1 cDNA fragment in plasmid pMDRA1 was first subcloned into plasmid pET28a(+), then MDR1 cDNA was cut from the recombinant plasmid with double-digestion and ligated into the mammalian expression vector pcDNA3.1(+). The recombinant plasmid pcDNA3.1(+)/MDR1 was transfected into breast cancer cell line Bcap37 using the Superfect transfection reagent. Several stably transfected clones were obtained after selection with G418. Real-time fluorescent quantitative RT-PCR and Western blot methods were used to detect the expression of P-gp, and the cellular location of the expressed protein was determined by immunohistochemical staining. Drug sensitivity assay was used to evaluate the biological function of expressed P-gp. Concentration of quercetin in cells was determined by high-performance liquid chromatography (HPLC).

RESULTS: The recombinant plasmid was confirmed to be inserted in the correct orientation by restrictive enzyme digestion and DNA sequencing. Real-time fluorescent quantitative RT-PCR showed a higher level of P-gp mRNA in transfected cells compared to that in the control cells, and the Western blot result also indicated that P-gp expression in transfected cells was higher than that in control cells. The immunohistochemical staining showed that the expressed P-gp was localized on cell membranes. Drug sensitivity assay showed that the IC₅₀ for adriamycin and colchicine of the transfected cells was higher than that of the control cells. The concentration of quercetin in model cells was lower than that in control cells by HPLC. After P-gp inhibitor verapamil was administered, the concentration of quercetin in model cells was increased.

CONCLUSION: A high P-gp expressing cell line can be established, which could provide a suitable *in vitro* model system for studying drug intestinal absorption mechanism, predicting the drug permeability characteristics and screening new multi-drug resistance reversing agents. With this model, quercetin can be found to be transported by P-gp, and it is a P-gp substrate.

INTRODUCTION

P-glycoprotein (P-gp), a product of the multidrug resistance (MDR) gene, is widely distributed in normal tissues of the body, including intestinal mucosa, proximal tubule of the kidneys, placenta, testes, and blood-brain barrier^[1]. It is an ATP-dependent efflux transporter that affects the absorption, distribution, and excretion of a number of clinically important drugs^[2]. For example, in intestinal mucosa, P-gp serves as a biochemical barrier to drug delivery. Drugs or drug candidates are bound to P-gp and transported back to the apical surface of the tissue, thereby restricting the overall permeability of drugs and drug candidates.

Due to *in vivo* disposition and pharmacokinetics of drug efflux transporters, identification of compounds as P-gp substrates can aid the optimization and screening of new drug candidates. A variety of *in vitro* assays have been used to classify compounds as P-gp substrates^[3]. These assays can be classified into three groups. One is transport across polarized cell monolayers expressing P-gp on the apical membrane, the other is drug uptake into cells over-expressing P-gp, the third is direct binding to P-gp using inside-outside membrane vesicles or reconstituted P-gp.

Quercetin, a flavonoid and phytoestrogen, is present in a wide variety of fruits and vegetables^[4]. Quercetin is also a potent antioxidant *in vivo* and *in vitro*, and thus quercetin and other flavonoids have been considered as therapeutic agents for a wide range of diseases, including cancer, viral infection, inflammation/allergy, hypertension and atherosclerosis^[5-7].

In this study we constructed a P-gp expressing plasmid, established a P-gp high-expression cell model, and identified quercetin as a P-gp substrate with this cell model.

MATERIALS AND METHODS

Cell lines and cell culture

Breast cancer cell line Bcap37 (maintained by the Cancer Institute of Zhejiang University) was cultured in RPMI 1640 medium (Hyclone, USA) containing 100 mL/L heat-inactivated newborn calf serum (GIBCO), 100 U/mL penicillin and 100 µg/mL streptomycin. The cells were incubated at 37 °C in a humidified atmosphere with 50 mL/L CO₂ in air.

Construction of expression vector

Plasmid pMDRA1 containing a full-length MDR1 cDNA was kindly provided by Professor Kazumitsu Ueda^[8]. The plasmid was digested with *Sac*I and *Xho*I, and the MDR1 cDNA fragment was ligated into pET28a(+) which was pre-cut with *Sac*I and *Xho*I. The recombinant plasmid was digested with *Bam*HI and *Xho*I, and the insert was purified by 0.8% agarose gel electrophoresis and ligated into the mammalian expression vector pcDNA3.1(+) pre-cut with *Bam*HI and *Xho*I. The resulting pcDNA3.1(+)/MDR1 was digested with *Eco*RI to

check the orientation of the insert and DNA sequencing was used to verify the inserted sequence.

Transfection of Bcap37 cells

Bcap37 cells were transfected with the recombinant expression vector pcDNA3.1(+)/MDR1 using Superfect transfection reagent according to the manufacturer's instructions (QIAGEN). After 48 h of transfection, stable transfectants were isolated by selection with 800 µg/mL G418 for 10 d. G418-resistant stable clones were picked for further characterization. The transfectants were maintained in RPMI 1640 containing 100 mL/L newborn calf serum and 400 µg/mL G418. Bcap37 cells were also transfected with pcDNA3.1(+) vector as the control.

Real-time fluorescent quantitative RT-PCR

Total RNAs in Bcap37/MDR1 cells and control cells were extracted using TRIzol™ reagent (GIBCO BRL, Life Technologies) according to the user's guide. Real-time fluorescent quantitative RT-PCR was done with the MDR1 mRNA quantification kit (designed by the Cancer Institute of Zhejiang University and manufactured by Shanghai Jiusheng Medical Instrument Company) according to the manufacturer's instructions^[9].

Western blot

Total proteins in Bcap37/MDR1 and control cells were extracted with 1 g/L Triton X-100 and protein concentration was determined with a Bio-Rad protein assay kit and standardized with bovine serum albumin. The samples were electrophoresed (SDS-PAGE, 80 g/L) and electroblotted onto PVDF membrane (BioRad). The membrane was blocked in buffer with 50 mL/L fat free dry milk, detected with anti P-gp antibody (monoclonal F4, Sigma).

Immunohistochemical staining

Bcap37/MDR1 cells and control cells were harvested by centrifugation at 2 000 r/min for 5 min, washed twice with PBS, and mounted onto the slides. Immunohistochemical staining was done with the UltraSensitive™-P mouse kit (Fuzhou Maxim Biotech, Inc). The protocol was accorded to the user guide. Primary antibody was monoclonal anti-human P-glycoprotein antibody purchased from Fuzhou Maxim Biotech (monoclonal number C494).

Drug sensitivity assay

Sensitivity of cells to anticancer drugs was examined by a colorimetric assay using MTT method. Cells (6×10^3 cells/well) were seeded on 96-well plates, and cultured in a humidified atmosphere with 50 mL/L CO₂ at 37 °C. Twenty-four hours later, drugs were added at various concentrations. Control wells were included for each drug that consisted of the respective solvents. Forty-eight hours later, 50 µL of 1 mg/mL MTT (in PBS) [3-[4,5-dimethylthiazol-2-yl]-2,5-diphenyltetrazolium bromide] was added to each well and incubated in a humidified atmosphere with for 4 h at 37 °C 50 mL/L CO₂. The supernatants were aspirated, and 200 µL /well of dimethyl sulfoxide was added to dissolve formazan crystals. Color intensity was measured at 570 nm using an ELISA reader. The 50% inhibitory concentration for a particular agent was defined as the drug concentration which resulted in a 50% reduction in cell number at 48 h relative to the control. Each experiment was performed in triplicate.

Accumulation of quercetin

Bcap37 and Bcap37/MDR1 cells were seeded at the density of 7.5×10^5 to a 35 mm i.d. tissue culture well. After twenty-four

hours, the culture medium was aspirated, and replaced by the medium containing 25 µmol/L quercetin. After 10 and 20 min, the medium was aspirated and the cells were washed 3 times with ice-cold PBS (pH7.4) to stop further uptake. A 1 mL of 1 g/L Triton X-100 was added to each well to lyse the cells. Drug concentration in lysis solution was determined by reverse-phase HPLC, and normalized with cellular protein content^[10].

Bcap37/MDR1 and control cells were seeded at the density of 7.5×10^5 to a 35 mm i.d. tissue culture well. After twenty-four hours, the culture medium was aspirated, and replaced by the medium containing 25 µmol/L quercetin with/without 6.6 µmol/L verapamil. After 30 min, the media were aspirated and the cells were washed 3 times with ice-cold PBS (pH7.4) to stop further uptake. A 1 mL of 1 g/L Triton X-100 was added to each well to lyse the cells. Drug concentration in lysis solution was determined by reverse-phase HPLC, and normalized with cellular protein content.

The HPLC system used was Agilent 1100 system (Agilent Technologies). Separation was done on a conLichrospher ODS-C18 (4.6 mm i.d. × 250 mm) column. The mobile phase consisted of pH2.0 phosphate buffer-tetrahydrofuran-methanol-isopropanol (65:15:10:20, v:v:v:v) at a flow rate of 0.5 mL/min, and the wavelength of UV detector was 380 nm. Morin was used as internal standard. Cell protein was quantitated by Bio-Rad DC protein assay kit.

RESULTS

Analysis of plasmid expression

After digestion with *Eco*RI, the recombinant plasmid pcDNA3.1(+)/MDR1 showed three DNA fragments about 1.2 kb, 3.4 kb and 5.4 kb as expected (Figure 1). DNA sequencing result further confirmed the correct construction of this P-gp expression vector.

Figure 1 Analysis of pcDNA3.1(+)/MDR1 digested by *Eco*RI. M: DNA ladder; A: pcDNA3.1(+)/MDR1 digested by *Eco*RI.

Figure 2 Map of real-time fluorescent quantitative RT-PCR. Blue curve: Bcap37; Other color curves: Bcap37 cell clones transfected with pcDNA3.1(+)/MDR1; Red curve stands for the clone expressing higher P-gp level than others.

Real-time fluorescent quantitative RT-PCR

The C_T of Bcap37/MDR1 and control cells was 19 and 40 cycles (Figure 2). It showed a significant increase of MDR1 mRNA levels in Bcap37/MDR1 than in control cells.

Western blot

The Bcap37/MDR1 cells showed significantly higher level of P-gp at 170 ku compared with control cells (Figure 3).

Figure 3 Western blot analysis of P-gp expression in Bcap37 and Bcap37/MDR1 cells. A: Bcap37; B, C, D, E: Bcap37 cell clones transfected with pcDNA3.1(+)/MDR1.

Immunohistochemical staining

The nuclei and plasma of control cells were stained blue (Figure 4A), demonstrating that the cells did not express P-gp. The Bcap37/MDR1 cells showed brown staining on cell membrane (Figure 4B). This indicated that P-gp was expressed on the transfected cell membrane.

Figure 4 P-gp immunohistochemical staining in Bcap37 (A) and Bcap37/MDR1 (B) cells.

The cells were stained using a human anti-Pgp primary antibody, biotinylated anti-rabbit IgG secondary antibody, followed by the avidin and horseradish containing Vector ABCD reagent. The sections were then stained with 3,3'-diaminobenzidine (DAB) and counterstained with hematoxylin. The brown color represented Pgp expression and the blue color was the non-specific counterstaining.

Drug sensitivity assay

Resistance to anticancer drugs was determined using MTT assay. Bcap/MDR1 exhibited multidrug resistant phenotypes characterized by cross-resistance to two unrelated antitumor agents (Table 1) including adriamycin and colchicine. The results confirmed the expressed Pgp in transfected cells played a role as an efflux pump.

Table 1 Relative resistance of multidrug resistant Bcap37 transfected cells

Cell line	IC ₅₀ (μg/mL)	
	Adriamycin	Colchicine
Bcap37	0.047	0.028
Bcap37/MDR1	2.203	0.391

Logarithmically growing cells were incubated for 48 h in the presence of the drug. IC₅₀ referred to the drug concentration that resulted in a 50% reduction in cell number.

Quercetin accumulation in cells

Quercetin was incubated with Bcap37/MDR1 and Bcap37 for 10 min and 20 min, and the drug accumulation in cells is listed in Table 2. After P-gp inhibitor verapamil was administered the concentration of quercetin in model cells was increased (Figure 5). All values were normalized with protein content. The results demonstrated that quercetin was accumulated in Bcap37 much more than in Bcap37/MDR1 ($P < 0.05$).

Table 2 Quercetin accumulation over different periods ($n=3$)

Cell line	10 min	20 min
Bcap37(μmol/L.mg)	2.44	3.33
Bcap37/MDR1(μmol/L.mg)	1.47 ^a	1.82 ^a

^a $P < 0.05$ vs Bcap37 cells.

The amount of quercetin accumulation in cells was determined by reverse phase HPLC through a standard curve, and the values were normalized with cellular protein content. There was a significantly higher concentration of quercetin accumulated in MDR1 transgenic cells ($P < 0.05$).

Figure 5 Amount of quercetin accumulation in cells with/without verapamil.

DISCUSSION

In recent years, it has become apparent that transport proteins play a major role in controlling the distribution, elimination and potentially the metabolism of some drugs, including organic cation transporters, organic anion transporters, MRP related transporters, and P-glycoprotein. P-gp has received considerable attention in recent years both as a barrier to drug absorption and distribution, and as a potential source for variability in drug pharmacokinetics and pharmacodynamics. In the intestine, P-gp could actively transport drugs counter-current to the absorptive transport of drugs, thus posing a barrier to absorption of exogenous compounds^[11]. This activity has been proposed to act in concert with intestinal cytochrome P-450 3A4 to increase pre-systemic metabolism of drugs, further minimizing systemic exposure to other drugs and xenobiotics^[12,13]. For

example, Pgp limited intestinal absorption of digoxin, talinolol, and cyclosporine after oral dosing, limited the central nervous system penetration of human immunodeficiency virus protease inhibitors, and helped excrete paclitaxel into intestine^[14-18].

A P-gp over-expressing cell line was established and characterized by Western blot, drug sensitivity assay and flow cytometry (data not shown). The results showed that the P-gp over-expressing cell line had biological functions.

In cellular drug accumulation assays, drug accumulation in P-gp expressing cells was compared with accumulation in cells from the parental cell line. Since the accumulation of P-gp substrates in P-gp over-expressing cells was restricted by P-gp mediated efflux of the compound back into the extracellular fluid, P-gp substrates showed less accumulation in P-gp expressing cells than in P-gp deficient cells. Similarly, drug accumulation was increased under conditions when P-gp was inhibited. In our experiment, quercetin showed less accumulation in Bcap37/MDR1 than in Bcap37. After P-gp inhibitor verapamil was administered, the concentration of this flavonoid in model cells increased. This implied the compound was a P-gp substrate. The result was similar to that of Walgren *et al*^[19].

A high P-gp expressing cell line can be established which provides a suitable *in vitro* model system for studying drug intestinal absorption mechanism, predicting the drug permeability characteristics and screening new multi-drug resistant reversing agents.

Abstract

AIM: To explore the value of avidin-biotin system enzyme-linked immunosorbent assay (ABC-ELISA) in diagnosis of intestinal acariasis.

METHODS: Mite-specific IgG levels in serum of 48 patients with intestinal acariasis were measured with ABC-ELISA. The sensitivity of this method was compared with that of staphylococcal protein A enzyme-linked immunosorbent assay (SPA-ELISA).

RESULTS: The positive rate of mite-specific IgG detected with ABC-ELISA and SPA-ELISA was 89.58% (43/48) and 56.25% (27/48), respectively. The positive rate with ABC-ELISA was statistically higher than that with SPA-ELISA ($\chi^2=13.50$, $P<0.01$).

CONCLUSION: ABC-ELISA is an effective method for the diagnosis of intestinal acariasis.

INTRODUCTION

Mites could live in intestinal tract and cause intestinal acariasis with most frequent symptoms of abdominal pain, diarrhea and pyohemofecia^[1-3]. Intestinal acariasis is traditionally diagnosed by identification of adult or larval mites, eggs or hypopus in either single or multiple fecal specimens under microscopy. The detection of the parasites is increased on examination of multiple fecal samples obtained on three different days. However, it is not easy to detect mites technically. Thus, the present study intended to develop and evaluate an enzyme-linked immunosorbent assay for mite-specific antibody detection in serum samples using *Dermatophagoides farinae* extract.

MATERIALS AND METHODS

Serum

A total of 78 serum specimens were collected from 48 patients with intestinal acariasis and 30 health blood donors. All of the

subjects investigated were asked to provide stools for detection of mites by saturated saline floatation method. The 48 patients with mites in stools were grouped as experimental group, while the health blood donors without mites as control group.

Reagents

Reagents for ABC-ELISA and SPA-ELISA were provided by Shanghai Institute of Biological Products (Batch No. 990004 and 990012). *Dermatophagoides farinae* extract was made according to NIBSC82/518 approved by World Health Organization (WHO) in 1984. The mites were cultured in the initial medium for several months. A 48-h maceration in a borate buffer (pH 8.5) was centrifuged. The supernatant was neutralized and precipitated with a series of acetone. The precipitated fraction at 800 mL/L acetone was isolated, washed and dried. This purified extract was lyophilized or stored as a solution in the presence of 500 mL/L glycerol and 50 mL/L phenol^[4-7].

Methods

ABC-ELISA procedure Initially 0.1 mL *Dermatophagoides farinae* extract with protein concentrations of 62.5 µg/mL was added in each well on a 40-well plate coated with enzyme, and the plate was placed at 4 °C overnight. Then the plate was washed with PBS (pH=7.4), sera of the patients with intestinal acariasis were diluted at 1:40 and added in duplicated wells, and incubated in water bath at 37 °C for 60 min. Following washing of the plate, bio-SAH IgG at the concentration of 1:40 was added and incubated at 37 °C for 60 min, avidin-HRP at the concentration of 1:20 was added for reaction at 37 °C for 30 min, and the substrate OPD-H₂O₂ was added and incubated at 37 °C for 30 min. Lastly, 2 mol/L H₂SO₄ was added to terminate the reaction. Sera of the control group were detected with the same procedure^[8,9].

SPA-ELISA procedure Concentrations of antigen and sera dilution in SPA-ELISA method were similar to those in ABC-ELISA. SPA-ELISA was performed as routine. Values of optic densities (OD) in each well were determined, the value of 2.1 times or more of the negative control was considered as positive.

RESULTS

General data

A total of 48 patients (male 32 and female 16) with intestinal acariasis were selected as mites were found in their stools. The 48 patients consisted of 13 workers in traditional Chinese medical storehouses, 22 workers in rice storehouse or mill, 8 miners, 2 workers in machine factory and 3 with other occupations. The mites in stool samples included *Acarus siro*, *Tyrophagus putrescentiae*, *Dermatophagoides farinae*, *D. pteronyssinus*, *Glycyphagus domesticus*, *G. ornatus*, *Carpoglyphus lactis* and *Tarsonemus granaries*.

ABC-ELISA data

In ABC-ELISA, the mean OD value of mite-specific IgG in sera of the 48 patients was 0.358±0.124 (0.176-0.615), while that in 30 controls was 0.112±0.065 (0.085-0.253). The Absorbent values in 43 of 48 patients were at least 2.1 times of 0.112, the positive

rate of the patients detected by ABC-ELISA was 89.58%. Interestingly, the A value of one case in normal control group was 0.253, and the false positive rate was 3.33%.

SPA-ELISA data

In SPA-ELISA, the mean OD value of mite-specific IgG in sera of the 48 patients was 0.225 ± 0.147 (0.133-0.574) and that in the control group was 0.078 ± 0.047 (0.043-0.172). The A values in 37 patients were at least 2.1 times of 0.078, the positive rate of the patients detected by SPA-ELISA was 56.25%. However, the A values of 2 cases in control group were 0.168 and 0.172, respectively, which were higher than 0.1638. The false positive rate in SPA-ELISA was 6.67%.

Comparison between ABC-ELISA data and SPA-ELISA data

The positive rate of the patients detected by ABC-ELISA and SPA-ELISA was 89.58% (43/48) and 56.25% (27/48) with a significant difference ($\chi^2=13.50$, $P<0.01$). Although only 25 cases were positive in both ABC-ELISA and SPA-ELISA, the positive number of patients was 45 (93.75%) by ABC-ELISA or SPA-ELISA (Table 1).

Table 1 Intestinal acariasis detected with ABC-ELISA and SPA-ELISA

Methods	ABC-ELISA method (+)	ABC-ELISA method (-)	Total
SPA-ELISA method (+)	25	2	27 ^b
SPA-ELISA method (-)	18	3	21
Total	43 ^b	5	48

^b: $\chi^2=13.50$, $P<0.01$.

DISCUSSION

ABC-ELISA and SPA-ELISA were used to detect mite-specific antibody IgG in serum samples from 48 patients with intestinal acariasis, and the positive rate in ABC-ELISA and SPA-ELISA was 89.58% and 56.25%, respectively. ABC-ELISA had high specificity in diagnosis of intestinal acariasis. Moreover, ABC-ELISA in detection of mite-specific antibody was easy to perform, inexpensive, and numerous samples could be performed simultaneously. The test could be carried out quickly for the diagnosis, particularly for individuals who suffered from recurrent diarrhea, chronic abdominal pain, malabsorption and stunting due to infection.

The occurrence of false positive in two methods in diagnosis of intestinal acariasis might be associated with mites' invasive locus, stool examination techniques and dilution of sera. In addition to gastrointestinal tract, acaroid mites could infest other organs of the human body such as respiratory tract and urinary tract, no matter where they were parasitized, mite-specific antibody would occur in peripheral blood^[10-18]. Although saturated saline floatation method is useful in examination of feces, some large and heavy mites may be missed because of difficult drift. Sera dilution at 1:40 in the present study was lower than that in routine ELISA with dilution at 1:100 to 1:200. It was suggested that much more times repeating stool examination should be carried out in the normal control group to avoid false positive detection^[19-24].

Our study showed 8 species of mites in human stools. We used *Dermatophagoides farinae* extract as coating antigen only, which might decrease the detectable rates of mite-specific antibody, because common antigen might exist in *Dermatophagoides farinae* and other seven species of mites^[25-28]. In addition, the number of mites in intestinal tract might affect the levels of mite-specific antibodies and detectable rates. In

conclusion, ABC-ELISA method is effective in diagnosis of intestinal acariasis.

Abstract

AIM: To assess the catheterization-associated complications during intraperitoneal chemotherapy (IPCT) for advanced gastric cancer.

METHODS: From 1998 to 2002, 80 patients with advanced gastric cancer received a total of 320 courses of IPCT using a large bore central venous catheter and associated complications were analyzed.

RESULTS: Catheterization-associated complications occurred in 11 of the 80 patients (13.8%), including abdominal pain caused by catheter in 2 cases (0.63%), insertion failure in 2 cases (0.63%), bowel perforation in 1 case (0.31%) and abdominal pain during chemotherapy in 6 cases (1.88%). No serious complications required surgical intervention.

CONCLUSION: IPCT using central venous catheters can be performed safely and simply without severe associated complications.

INTRODUCTION

Gastrointestinal tumor is quite common. In China, the morbidity of gastric cancer is the leading cause of malignant tumors. For non-advanced gastric cancer, surgical removal is the first choice, but for advanced gastric cancer, the outcome of surgical resection remains unsatisfactory. Fifty percent of gastric cancer patients have local recurrence or long distance metastasis after radical surgery within 5 years. The common sites of gastric cancer recurrence or metastasis are the resection site, liver and peritoneal surfaces^[1-4]. It was reported that intraperitoneal chemotherapy could result in markedly increased local drug concentration, and had favorable clinical results in preventing recurrence and metastasis of gastric cancer after surgical treatment, but some complications were reported by using Tenckhoff catheter in IPCT^[5-7]. From March 1998 to June 2002, 80 patients with advanced gastric cancer were treated by central venous catheterization during intraperitoneal chemotherapy (IPCT) after radical gastrectomy in SRRSH Cancer Center. The

main purpose of this study was to analyze the complications of central venous catheterization during IPCT.

MATERIALS AND METHODS

Patients

Between March 1998 and June 2002, 80 patients with advanced gastric cancer were treated in SRRSH Cancer Center. Forty-eight cases were males and 31 females aged 29 to 71 years (median 43.5 years). Patients in stage III_A were 18 cases, stage III_B 29 cases, stage IV 33 cases. The patients were treated with a total of 320 courses of IPCT. Each patient received at least 3 courses of IPCT (mean 4 courses for each patient).

Peritoneal catheters and methods

Single cavity central venous catheters were produced by Arrow Raulerson Syring Ltd, USA. Transparent protecting patches and heparin caps were produced by 3 mol/L Health Care Ltd, USA. As there are no large vessels in this site, puncture site is usually chosen at the cross-point of left midclavicular line and navel line, which is located at outer edge of rectus abdominis muscle. Two percent lidocaine was used for local anesthesia, then a conducting needle was put into the peritoneal cavity, after a steel string was put into peritoneal cavity though the conducting needle. The needle was taken out and the central venous catheter was put into the peritoneal cavity following the steel string after the abdominal wall was dilated. Then 100 mL normal saline was administrated though the catheter, if nothing abnormal was observed, and a heparin cap was put on the top of the catheter and the catheter was fixed to the abdominal wall.

The regimen of intraperitoneal chemotherapy was HCPT+5-FU+CF+VP-16, the dose of chemotherapeutic agents was 8 mg/m² for HCPT, 375 mg/m² for 5-FU, 100 mg for leucovorin (CF), 80 mg/m² for etoposide (VP-16) for three days. HCPT was administrated though peritoneal cavity, other agents were administrated though peripheral vein. Before chemotherapy started, 1 000 mL warm (42 °C) normal saline was administrated into the peritoneal cavity together with 10 mg DXM and 20 mL 20 g/L lidocaine. HCPT was dissolved in 500 mL of normal saline and instilled in the peritoneal cavity though the implanted catheter. Then 42 °C normal saline was instilled to the peritoneal cavity again, until the total volume reached 1 500 mL/m². Patients were asked to change their position every 15 min for 2 h after drug administration. Chemotherapy was given 2 wk after surgery, and repeated every 3 wk with the same regimen. The central venous catheter was taken out after each cycle of chemotherapy, a new catheter was put into peritoneal cavity just before the next cycle of IPCT started.

RESULTS

The complications associated with catheterization during IPCT in this series were common and mild. Moderate to severe pain induced by catheterization occurred in 2 cases (0.63%). Failure in catheterization because of intraabdominal adhesion occurred in 2 cases (0.63%), but the catheter was successfully put into peritoneal cavity through the other side of abdominal wall. Bowel perforation occurred in one case (0.31%) possibly due

to severe intraabdominal adhesion after surgery, and the catheter was put into bowel cavity. This patient received systemic chemotherapy instead of IPCT afterwards, and antibiotics were given to him. He had no signs of peritonitis during the procedure. Moderate pain during chemotherapy occurred in 6 cases (1.88%). There was no incidence of severe complications such as intestinal obstruction, peritonitis, intestinal hemorrhage, leakage of peritoneal fluid and anastomotic stoma fistula (Table 1).

Table 1 Catheterization-associated complications

Complications	Cases (n=320, %)
Pain by catheterization	2 (0.63)
Insertion failure	2 (0.63)
Bowel perforation	1 (0.31)
Pain during chemotherapy	6 (1.88)

DISCUSSION

Postoperative IPCT should be started early^[18-11]. Because surgery for gastrointestinal cancer is associated with an extremely high rate of dissemination within the peritoneal cavity and seeding on peritoneum, the resection site and abraded peritoneal surfaces are common sites of tumor cell seeding, early postoperative IPCT lets all intraabdominal surfaces expose to intraperitoneal chemotherapy agents. Because all adhesions are lysed at this time, the response rate of minor metastatic lesions on peritoneal surface to the chemotherapy agents can be 100%. Besides, tumor burden is light at this time according to tumor cell proliferative kinetics, chemotherapy agents can not only kill dissociative tumor cells in peritoneal cavity, but also kill inflammatory cells in peritoneal cavity, thus decreasing the releasing of cellular factors and preventing their effect on tumor cell proliferation. Regional chemotherapy could result in markedly increased local responses without compromising systemic effects^[12-14]. Studies of pharmacokinetics of IPCT also showed advantages. Sugarbaker^[15] summarized the pharmacokinetics of 4 kinds of chemotherapy agents often used in IPCT, the area under the curve (AUC) within peritoneal fluid compared with plasma of these agents was as follows, 5-FU 150/1, MMC 72/1, ADM 205/1, and DDP 20/1. There was an obvious difference between AUC within peritoneal fluid and AUC within plasma.

Several methods could be used in IPCT^[7,16]. The catheters commonly used are Tenckhoff catheter and single peritoneal cavity catheter. Tenckhoff catheter is popular in Western countries. After completing the surgical procedure and prior to closing the abdominal wall, Tenckhoff catheter is placed through the abdominal wall and then a Dacron cuff is fixed subcutaneously. A needle is inserted into the Dacron cuff during chemotherapy. The disadvantage of this method is that the catheter is left in the peritoneal cavity for a long period, and there are some complications. Esquivel *et al.*^[17] reported that in 44 patients who received IPCT during the first day to fifth day after surgery, 13% of the patients had pneumonia, 9% bleeding after surgery, 9% intestinal fistula, 7% a prolonged duration of intubation, 2% biliary fistula, 2% anastomotic stoma fistula, and 2% pancreatitis. The total complication morbidity was 37%, 17% of the complications were related to bowel function. Topuz *et al.*^[18] also reported that there were 39 patients in 205 cycles of intraperitoneal chemotherapy, severe abdominal pain was in 4 patients (10.3%), peritonitis and coloperitoneal fistula each in 1 patient (2.6%), catheter obstruction in 3 patients (7.7%) and colon puncture in 4 patients (10.3%). Sakuragi *et al.*^[19] did IPCT in 78 patients using Tenckhoff catheter, the total cycles were 365. Among them, 27 (34.6%) experienced IPCT related complications, 17 (21.8%) had extensive intraabdominal

adhesion, 13 (16.7%) had local infection around the reservoir, 3 (3.8%) had an abscess at the site of the implanted port of the catheter, 3 (3.8%) had catheter obstruction, one (1.3%) had ileus, one (1.3%) had perforation of small intestine, one (1.3%) underwent opening of the wound at the site of catheter implantation due to bleeding.

We used central venous catheter in IPCT, the procedure of catheterization was easy to master. Meanwhile it was not necessary to leave the catheter for a long time, the catheter could be taken out 2-3 d after chemotherapy, which could improve the life quality of patients. Moreover, central venous catheter was used only one time with few complications. In fact, our patients had no severe complications such as intestinal perforation, intestinal bleeding, peritonitis, anastomotic stoma fistula and implantation site infection. The morbidity of complications in our group was 13.75%, much lower than reported in other documents. Pain after catheterization was due to the length of catheter into the peritoneal cavity, and the pain could be relieved after pulling out the catheter. The pain during chemotherapy could be relieved by administering lidocaine and DXM into peritoneal cavity.

The reasons why our group has a low morbidity of complications are as follows. Chemotherapy was started two weeks after surgery instead of 5 d after surgery. Since surgical incision was healed 2 wk after surgery, many complications of IPCT were avoided by starting chemotherapy 2 wk after surgery. Besides, statistical analysis showed that there was no difference in response rate (data not shown). Tenckhoff catheter used by Sakuragi *et al.*^[19] had to put in the peritoneal cavity for a long period and there also must be a drainage system or an outflow tube. But we used central venous catheter only one time and did not need an outflow tube and the chemotherapy agents of IPCT were spontaneously absorbed by peritoneum. Clinical observation revealed that intraperitoneal fluid could be absorbed spontaneously 2 or 3 d after chemotherapy. Radical gastrectomy has a great surgical scope and can cause severe intraabdominal adhesion which can limit intraperitoneal fluid to flow freely. Sugarbaker *et al.*^[15] thought this would affect the distribution of chemotherapy agents in peritoneal cavity, and would affect chemotherapy agents to contact with peritoneum. If there was not enough fluid in the peritoneal cavity, the fluid could not flow freely in peritoneal cavity because of resistance. Though patients changed their position frequently, chemotherapy agents could not distribute to the whole peritoneal cavity, thus decreasing the response rate. Only a large volume of fluid causing abdominal distension could make chemotherapy agents distribute evenly in peritoneal cavity^[20]. Therefore, 1 500-2 000 mL fluid should be given to patients every time during chemotherapy, and the patients should change their position frequently in order to achieve chemotherapeutic effect. Besides, a large volume of fluid can decrease the incidence of complications such as abdominal pain, intestinal perforation, intestinal bleeding, ileus, peritonitis and anastomotic stoma fistula.

In conclusion, it is safe and convenient to use central venous catheters in intraperitoneal chemotherapy and it also has less side effects and fewer complications.

Abstract

AIM: To observe the protective effect of heat shock protein 72 (HSP 72) induced by pretreatment of doxorubicin (DXR) on long-term cold preservation injury of rat livers.

METHODS: Sprague-Dawley rats were administered intravenously DXR at a dose of 1 mg/kg body mass in DXR group and saline in control group. After 48 h, the rat liver was perfused with cold Linger's and University of Wisconsin (UW) solutions and then was preserved in UW solution at 4 °C for 24, 36 and 48 h. AST, ALT, LDH and hyaluronic acid in preservative solution were determined. Routine HE, immunohistochemical staining for HSP 72 and electron microscopic examination of hepatic tissues were performed.

RESULTS: After 24, 36 and 48 h, the levels of AST, ALT and hyaluronic acid in preservative solution were significantly higher in control group than in DXR group ($P < 0.05$), while LDH level was not significantly different between the 2 groups ($P > 0.05$). Hepatic tissues in DXR group were morphologically normal and significantly injured in control group. HSP 72 was expressed in hepatocytes and sinusoidal endothelial cells in DXR group but not in control group.

CONCLUSION: Pretreatment of DXR may extend the time of rat liver cold preservation and keep liver alive. The expression of HSP 72 in liver can prevent hepatocytes and sinusoidal endothelial cells from long-term cold preservation injury.

<http://www.wjgnet.com/1007-9327/10/1375.asp>

INTRODUCTION

The term of organ preservation has been extended enormously since Belzer invented University of Wisconsin (UW) solution in 1988^[1]. In liver transplantation, the use of UW solution doubles the time of liver cold preservation compared with the

use of Euro-Collins solution. But hepatic cold preservation reperfusion injury remains the important reason for the failure of liver transplantation^[2-5]. It was reported that cold preservation reperfusion injury in liver, kidney and lung could be prevented by the expression of heat shock protein, which was induced by heat shock reaction (HSR)^[6-8]. Kume *et al*^[9] reported that doxorubicin (DXR) could induce HSR, which attenuated hepatic warm ischemia reperfusion injury. DXR is a kind of cytotoxic agent and may induce HSR^[10]. Being administered intravenously, DXR was accumulated and metabolized in liver. As a result, semiquinone free radicals were produced, which could induce stress oxidative reaction and expression of HSP 72^[11]. Hela cells and cardiac cells could express HSP 72 by pretreatment of DXR *in vitro* in experiments^[12,13]. The aim of this study was to observe the protective effect of HSR induced by DXR on long-term hepatic cold preservation injury.

MATERIALS AND METHODS

Reagents

Doxorubicin was purchased from Shenzhen Main Luck Pharmaceuticals. Inc., China-Merian Corp., Japan. University of Wisconsin solution was purchased from Dupan Co., USA. HA RIA kit was purchased from Shanghai Ocean Research Biomedical Technology Center, China. Monoclonal antibody of HSP 72 was purchased from Oncogene Co. DAKO Envision™ kit was from Dako Co.

Animals

Male Sprague-Dawley rats weighing 200-300 g were purchased from Sino-British Sippr/BK Lab Animal Ltd. All rats were kept in animal quarters with controlled temperature (18-25 °C) and light (light on from 7 a.m. to 7 p.m.) and were fed with a standard laboratory chow and water in accordance with institutional animal care policies. Prior to the experimental procedure, the rats were fasted for 12 hours but allowed free access to water.

Experimental design

Thirty-six rats were randomly assigned into DXR group and control group. The rats in DXR group were injected intravenously DXR at a dose of 1 mg/kg body mass 48 h before the operation^[9], while those in control group were treated with 1 mL normal saline (NS). After being cold perfused orthotopically, the livers were preserved in UW solution for 24, 36 and 48 h.

Liver procurement and cold storage

Rat orthotopic liver cold perfusion was used according to the method described by Kamada and Calne^[14]. Under ether anesthesia, 2 mL of heparinized saline solution (250 units/mL) was injected intravenously. Laparotomy was performed via a midline incision. After the abdominal aorta was cannulated with a 14-gauge angiocatheter, the liver was flushed with 10 mL of Linger's solution at 4 °C. Simultaneously, the supra and infrahepatic vena cava were cut to enhance flushing of the liver. Then, 5 mL of Linger's solution, followed by 10 mL of

UW solution at 4 °C was progressively injected into portal vein. Finally the liver was excised and preserved in 40 mL of UW solution at 4 °C.

Hepatic enzyme assays of preservative solution

Alanine aminotransferase (ALT), aspartate aminotransferase (AST) and lactic dehydrogenase level (LDH) in the preservative solutions, collected at 24, 36 and 48 h after cold preservation, were determined by a standard biochemistry autoanalyzer (Backman DU 640).

Assessment of hyaluronic acid (HA) of preservative solution

HA in the preservative solutions collected at 24, 36 and 48 h after cold preservation was determined using a HA RIA kit according to the manufacturer's protocols.

Histology and immunohistochemical analysis for HSP 72

The liver specimens collected at 24, 36 and 48 h after cold preservation were fixed in buffered 10% formalin and embedded in paraffin. Tissue sections (4-μm thick) were stained with hematoxylin-eosin.

Immunohistochemical analysis was performed by using a mouse anti-HSP 72 monoclonal antibody at a dilution of 1:100, and rabbit anti-mouse IgG as a secondary antibody. Then the specimens were incubated with horseradish peroxidase-conjugated streptavidin complex. Diaminobenzidine was used as the substrate. The specimens were counterstained with hematoxylin. All specimens were examined under an optical microscope (Olympus BX51).

Transmission electron microscopical analysis

Liver fragments of approximately 1 mm×1 mm×2 mm were fixed in 20 g/L glutaraldehyde at 4 °C. After washed in phosphate buffer solution, fragments were postfixed with 10 g/L osmium tetroxide, dehydrated in graded alcohols, replaced in epoxy ethane and stained with uranyl acetate. All specimens were examined under an electron microscope (Hitachi 500).

Statistical analysis

Values are expressed as mean±SE. Intragroup analysis was performed by paired Student's *t* test. *P* value less than 0.05 was considered statistically significant.

RESULTS

ALT, AST and LDH level

ALT and AST levels were significantly higher in control group after preservation for 24, 36 and 48 h than in DXR group (*P*<0.05), but LDH level was not different between the 2 groups (*P*>0.05) (Table 1).

Table 1 Comparison of ALT, AST and LDH levels between two groups

Group	<i>n</i>	Term of storage	ALT (IU/L)	AST (IU/L)	LDH (IU/L)
Control	6	24 h	337.3±163.4 ^b	417.2±247.5 ^a	3 369.1±851.9 ^c

	6	48 h	90.2±13.5

^a*P*<0.05, ^b*P*<0.01 vs DXR.

Histology and immunohistochemistry for HSP 72

After cold storage for 24 to 48 h, hepatocytes in control group were swelling, ballooning, vacuolizing and partly autolyzing while the majority of sinusoidal endothelial cells (SECs) also became swollen, rounded and detached from basement membrane and hepatic sinusoids were narrowed. In DXR group, hepatocytes remained normal and few SECs appeared swollen, rounded or detached.

After cold storage for 24 to 48 h, some hepatocytes and SECs expressed HSP 72 in DXR group but not in control group.

Transmission electron microscopical analysis

After cold storage for 24 to 48 h, hepatocytes in control group showed swollen mitochondria, fatty dots, and while cellular swelling, rounding, detachment from the matrix and nuclear condensation were seen in part of SECs. In DXR group, hepatocytes remained normal and few SECs appeared swollen, rounded or detached.

DISCUSSION

The use of University of Wisconsin solution extended the time of organ cold preservation to 24 h in theory^[15]. UW solution was designed to attenuate cell swelling, inhibit reactive oxygen intermediates (ROIs), offer substrates for synthesizing adenosine triphosphates (ATP) and prevent cells from absorbing ions of sodium and calcium^[16,17]. But in the course of cold storage, cells remained to be injured in different degrees with the extension of preservation time. In the period of liver cold storage, hepatocytes and SECs were all injured, especially the latter^[18,19].

During warm ischemia hepatocytes were the most vulnerable cells whereas SECs were less sensitive^[20]. But hepatocytes were less damaged during cold preservation^[21]. However, along with the extension of the time of cold storage, hepatocytes were also injured in different degrees. The mechanisms underlying hepatocyte injury during hypothermia storage were intracellular acidosis due to anaerobic glycolysis and lactate accumulation, drawback of protein synthesis and exhaustion of heparin and ATP which lessen the ability to resist rewarm ischemia and reperfusion damage^[21]. In morphology, changes of hepatocytes included swelling, ballooning and vacuolization. Although little loss of cell viability occurred after 24 h of storage in UW solution, the cellular functions were already injured^[22]. In this study, histological results showed that hepatocytes were apparently damaged in control group after cold storage for 36 to 48 h. In contrast, the shapes of hepatocytes were normal in DXR group. In preservation solution, ALT and AST levels in DXR group were significantly lower than in control group (*P*<0.05). These data indicated that pretreatment with DXR could evidently protect hepatocytes.

During hepatic cold ischemia, SECs were most susceptible

to hypothermia injury. Injuries of SECs were due to angiogenic factors and proteases, resulting in digestion of fibronectin, a key molecule linking collagen to the sinusoidal lining cell membrane integrin^[23]. In morphology, SECs became rounded, detached, and sloughed into the sinusoidal lumen^[24-26]. These changes were more distinct along with the prolongation of cold storage^[27]. But little loss of viability of SECs occurred after 24 h of storage in UW solution^[28]. This study indicated that SECs in both groups were injured after 24 to 48 h of cold storage in UW solution, but the degree of injury was significantly attenuated in DXR group than in control group. The shape of SECs was normal after 24 h and a small quantity of SECs became rounded, and detached after 36 to 48 h in DXR group. But in control group, SECs were obviously rounded and detached after 24 h, and the morphological changes became more significant after 36 to 48 h. On the other hand, hyaluronic acid level was significantly higher in control group than in DXR group ($P < 0.05$). Hyaluronic acid is a high-molecular-weight polysaccharide that could be rapidly and specifically degraded by SEC^[29]. Hyaluronic acid level was a sensitive index of SECs' injury^[30]. These results showed that pretreatment with DXR could protect SECs.

Cold storage of livers for more than 12 to 18 h carried the risk for graft failure^[31-34] and post-transplantation infection^[35]. In recent years, preconditioning has been used to prolong hepatic cold ischemia^[6,36-38]. The liver graft was subjected to an acute sublethal stress and this preconditioning could offer resistance to subsequent lethal injury by inducing the expression of heat shock proteins (HSPs). One of the important functions of HSPs was to protect cells and organs from a wide variety of damages such as hypothermia, ischemia, and ROIs^[39-41]. Cheng^[42] reported that pretreated by Zinc and heat shock, the expression of HSP 72 was markedly elevated after rat livers were stored in UW solution for 24 h. It was also reported that rat kidneys were preserved well successively for 45 h in cold UW solution^[43]. In our study, the protective effect of pretreatment of DXR on hepatic long-term cold storage injury might be attributed to induction of HSR and expression of HSP 72 in rat livers. HSR induced by DXR extended the time of hepatic cold storage to 48 h while morphological shape and functions of both hepatocytes and SECs remained commendable. The expressions of HSP 72 in hepatocytes and SECs were confirmed by immunohistochemical staining. It was clear that induction of HSP 72 in advance could make rat livers enter into stress state ahead of schedule and endure long-term cold ischemia injury afterwards.

In conclusion, these results demonstrate that pretreatment with doxorubicin could induce the expression of HSP 72 in rat livers. Thus pharmacological induction of HSR may be a successful method to prevent liver from long-term hypothermia preservation injury.

Abstract

AIM: To study the role of hybrid bioartificial liver (HBL) in clearing proinflammatory cytokines and endotoxin in patients with acute and sub-acute liver failure and the effects of HBL on systemic inflammatory syndrome (SIRS) and multiple organ dysfunction syndrome (MODS).

METHODS: Five cases with severe liver failure (3 acute and 2 subacute) were treated with HBL. The clinical signs and symptoms, total bilirubin (TBIL), serum ammonia, endotoxin, TNF- α , IL-6 and prothrombin activity (PTA), cholinesterase (CHE) were recorded before, during and after treatment. The end-stage liver disease (MELD) was used for the study.

RESULTS: Two patients were bridged for spontaneous recovery and 1 patient was bridged for OLT successfully. Another 2 patients died on d 8 and d 21. The spontaneous recovery rate was 30.0%. PTA and CHE in all patients were significantly increased ($P < 0.01$), while the serum TBIL, endotoxin, TNF- α , IL-6 were decreased. MELD score (mean 43.6) predicted 100% deaths within 3 mo before treatment with HBL. After treatment with HBL, four out of 5 patients had decreased MELD scores (mean 36.6). The MELD score predicted 66% mortalities.

CONCLUSION: The proinflammatory cytokines (TNF α , IL-6 and endotoxin) can be significantly removed by hybrid bioartificial liver and HBL appears to be effective in blocking SIRS and MODS in patients with acute and sub-acute liver failure. MELD is a reliable measure for predicting short-term mortality risk in patients with end-stage liver disease. The prognostic result also corresponds to clinical outcome.

INTRODUCTION

About 80% ICU deaths may be attributable to progressive multiple organ dysfunction (MODS). MODS is also a major cause of death in patients suffering from severe hepatitis. The sequela of systemic inflammatory syndrome (SIRS) is MODS. Hybrid bioartificial liver (HBL) is a well-known liver support system that is close to native liver in function. In the present

study our primary goals were to investigate the role of HBL in removing serum proinflammatory cytokines such as TNF α , IL-6, endotoxin and in blocking SIRS to MODS.

In this report, we used the validity of end-stage liver disease model as a disease severity index for patients with end-stage liver disease treated with bioartificial liver support system. The model was considered to be able to provide a reliable estimate of short-term survival over a wide range of liver diseases.

MATERIALS AND METHODS

Subjects

The Beijing Youan Hospital Ethics Committee approved the study and informed consent was obtained from all patients or their relatives. Five patients with severe hepatitis treated with HBL in our center from March, 2000 to June 2001 were involved in the study. Three of 5 patients were acute severe hepatitis and 2 of them were sub-acute hepatitis. All the 5 patients suffered from SIRS, 4 of them were complicated with 2-organ failure and only one patient were with 3-organ failure (Table 1). The criteria for severe hepatitis, SIRS and MODS were based on the recommendations of references 1-3^[1-3].

HBL

HBL system consists of a bioreactor (Micrognlnc, Laguna Hills, CA with a pore size 0.2 μ m, total fiber internal surface area 6 000 cm², external surface area 7 000 cm², volume 200 mL loaded with fresh isolated hepatocytes ($2-4 \times 10^{10}$), a single-use plasma circuit, and a machine to control the fluid flow through these components. At first, plasma exchange was achieved by a membrane separation method (PLASAUTO-IQ, Asahi, Tokyo). The amount of plasma removal was set at 3 000 mL. In the following HBL treatment (SYBIOL, U.S.A), patients' plasma was separated using a plasma separation system (COBE-Spectra, Lakewood, CO) and was then perfused through an HBL system. The plasma was separated at a rate of 70-100 mL/min and perfused through the bioreactor at a rate of 28-30 mL/min; flow rate of porcine cell suspension was 60 mL/min. After exchange of patients' plasma with porcine cells across the hollow-fiber membranes, patients' blood was returned to the superficial femoral vein. Evaluation of the viability of hepatocytes in circuit of porcine liver cells was done by cell membrane exclusion of trypan blue dye.

Clinical assessments

All patients were managed in a specialized intensive care unit and received standard supportive care. The following parameters were monitored before, during and after treatment: vital signs (blood pressure, heart rate, breath rate and SaO₂), hemodynamics (mean artery pressure, central venous pressure) and urinary output. Liver biochemistry (bilirubin, transaminases, Creatinine, BUN, serum ammonia, prothrombin activity (PTA)), cytokines TNF α , IL-6 (ELISA, Bangding Co) and endotoxin were analysed. The mental state of hepatic encephalopathy was graded into five stages. When the patients regained consciousness or hepatic encephalopathy decreased by I stage, the treatments was considered as effective.

MELD score assessment system

According to Kamath *et al.*, the score was multiplied by 10 and then rounded to the nearest integer. The formula for the MELD scores $3.8 \times \log_e(\text{bilirubin}[\text{mg/dL}]) + 11.2 \times \log_e(\text{INR}) + 9.6 \times \log_e(\text{creatinine}[\text{mg/dL}])$. We used on-line available worksheet to compute MELD scores (www.mayo.edu/int-med/gi/model/mayomodl.htm).

Statistical analysis

Statistical comparisons were carried out using chi-square and Student *t*-tests. A *P* value <0.05 was considered statistically significant.

RESULTS

Patients' response to treatment

All treatments were completed as scheduled. Each treatment lasted for 8-10 h and all were well tolerated. All patients remained hemodynamically stable throughout the treatment period. No gastrointestinal coagulopathy, fever, allergy and other severe adverse reactions were observed.

HBL treatment outcome

Gastrointestinal symptoms such as anorexia, nausea and fatigue were significantly improved in 4 out of 5 patients. Three patients who suffered from hepatic encephalopathy (HE) experienced remarkable neurological improvement with reversal of the decerebrate state after HBL treatment. Two of

3 HE at grades III and II became respectively grades II and I, another one at grade IV regained consciousness. Four patients who were complicated with 2-organ failure recovered spontaneously, one died 8 and 21 d after HBL treatment. The patient who was complicated with 3-organ failure (liver, cardiovascular, and gastrointestinal coagulopathy) was successfully bridged until an organ became available for orthotopic liver transplantation 1 wk after HBL treatment. The spontaneous recovery rate was 40.0%.

The treatment with the PE lowered TBIL in all patients (from 23.08 ± 12.50 mg/dL to 12.34 ± 4.39 mg/dL). At the end of treatment TBIL was reduced about 50%. Post evaluation showed that TBIL had a significant difference before and after HBL treatment at 0, 24 and 72 h ($P < 0.05$). No statistically significant improvement in albumin and blood ammonia levels noted ($P < 0.05$). CHE and PTA were significantly increased in all patients at 0, 24, 72 h and at the end of HBL treatment ($P < 0.05-0.01$). The serum chemistry changes are shown in Table 2.

A significant decrease in serum endotoxin levels was observed by the end of PE ($P < 0.05$) and it was declined during the period of HBL treatment. By the end of HBL, endotoxin level was the lowest ($P < 0.001$). TNF- α and IL-6 were reduced rapidly, the clearance rate of TNF- α was approximately 45% and IL-6 was 55% ($P < 0.001$) (Figure 1).

Evaluation of effect of HBL with MELD

MELD was used for predicting the outcome of HBL before and after treatment (Table 3).

Table 1 General data of patients

No	Sex	Age(yr)	Diagnosis	Multi-organs failure	Outcome
1	Female	43	ALF, HBV	Liver, brain	Spontaneous recovery
2	Male	31	SALF, HBV	Liver, brain	Recovery spontaneous
3	Male	33	SALF, HBV and alcoholic liver disease	Liver, coagulopathy, cardiovascular	Orthotopic liver transplantation
4	Female	27	ALF, drug induced liver injury	Liver, brain	Death
5	Male	31	ALF, HBV	Liver, kidney	Death

ALF: acute liver failure, SALF: sub-acute liver failure, HBV: hepatitis B virus.

Table 2 Changes of partial biochemical indices pre- and post-treatment of HBL(mean \pm SD)

Item	TBIL (mg/dL)	NH ₃ (μ g/dL)	ALB (g/L)	CHE (U/L)	PTA%
Pre-treatment	23.08 ± 12.50	116.6 ± 23.1	29.79 ± 4.35	$3\ 801.5 \pm 1710.6$	17.25 ± 10.11
Post-treatment at 0 h	12.34 ± 4.39^b	98.3 ± 19.5	32.57 ± 4.76	$5\ 560.9 \pm 1067.6^a$	38.60 ± 10.25^b
Post-treatment at 24 h	14.10 ± 6.08^b	103.2 ± 23.5	33.13 ± 4.34	$5\ 438.5 \pm 1024.3^a$	34.31 ± 11.75^a
Post-treatment at 72 h	17.24 ± 8.34^a	110.8 ± 30.6	31.42 ± 4.07	$5\ 676.2 \pm 957.9^a$	35.20 ± 9.78^b

^a $P < 0.05$, ^b $P < 0.01$, vs pre-treatment, TBIL: total bilirubin, NH₃: serum ammonia, ALB: albumin, CHE: cholinesterase, PTA: prothrombin activity.

Table 3 Changes of MELD score before and after treatment of HBL

Patients	Before-treatment						After-treatment					
	1	2	3	4	5	(mean \pm SD)	1	2	3	4	5	(mean \pm SD)

DISCUSSION

In the present study we demonstrated that the patients with severe hepatitis and hepatic failure might benefit from HBL for temporary liver support. HBL could maintain patients with hepatic failure alive, neurologically intact and metabolic state improved until a donor organ was available^[4]. It could also allow the native liver to regenerate, thus avoiding liver transplantation. The study showed that TNF- α and IL-6 were reduced rapidly about 45% and 55% ($P < 0.001$) after HBL treatment. The alteration of serum endotoxin levels was similar to TNF α and IL-6. Four of 5 patients responded to HBL treatment and 3 of them survived. Since the case number was limited, there were not enough data in our study to show that HBL could improve the survival rate of patients with multiple organ dysfunction. However the beneficial effect of HBL on the systemic concentration of cytokines was definite and the efficacy was not reached by drug treatment in such a short period. Just as Stephen described^[5,6], a success liver support device was likely to depend on their ability to modify factors influencing liver cell death and regeneration and on the extent to which multi-organ failure could be prevented or reversed. Hybrid liver support devices replace the lost liver function through a combination of mechanical and biologic effects. Mechanical parts use activated charcoal or plasma exchange before the hepatocyte bioreactor, which may not only provide a “protective” effect on the porcine hepatocytes from possible toxic effect of hepatic failure plasma, but also strengthen the effect of plasma detoxification. HBL treatment could remarkably improve SIRS signs and symptoms. Also it slowed down the progression from SIRS to MODS and protected MODS from further deterioration.

The mechanism of HBL to block the progression from SIRS to MDOS was to support failed liver. In our study, It was observed that CHE and PTA were significantly increased in all patients at 0, 24 and 72 h after HBL treatment ($P < 0.05$ -0.01). Plasma cholinesterase, an enzyme with a short half-life, is not usually changed by the substitution of clotting factors or by freshly frozen plasma and therefore is a good parameter of synthesis. Increased cholinesterase level in plasma may reflect improvement of liver synthesis function. The metabolic ability of liver for various nervous toxicity implicates liver detoxification function. Similar to the previous report, 3 patients with hepatic encephalopathy were improved by HBL treatment in our study, but it was different from previous report, in that the blood ammonia

levels were not changed after HBL treatment. Impairment of central nervous system in hepatic encephalopathy is probably multifactorial in origin. Except ammonia, other neuroexcitatory factors like amino acid imbalance, mercaptans, phenols, fatty acids, GABA, and benzodiazepine, also play a role in hepatic encephalopathy. Therefore consciousness improvement may cause removal of other neuroexcitatory factors. There are two mechanisms blocking the progression from SIRS to MODS related to liver function improvement. First, liver is an amplifier of the systemic acute-phase reaction, proinflammatory cytokines enter the liver through the portal vein, eventually passing the smallest functional unit of the liver, the acinus. The special architecture of sinusoids ensures that cytokines in the liver primarily reach the nonparenchymal liver cells such as endothelial cells and kupffer cells. Because these cells express not only receptors of IL-1 β , TNF- α and IL6, but also modulators of cytokines^[7]. Also the most active cells have the potential for the systemic response to the intrahepatic release of inflammatory cytokines. They might function as intrahepatic amplifiers of the systemic acute-phase reaction by liberating a second wave of proinflammatory cytokines which could enhance the effect of injuring agents and accelerate or maintain development of liver fibrosis^[8]. Second, it has been found that LBP/CD14 is an endotoxin strengthening system. LBP is produced in liver. When under stress the production of LBP from liver would increase many times. Trace endotoxin binding to LBP and interacting with target cells would increase the sensitivity of target cells to endotoxin up to 10 000 times and stimulate the synthesis and secretion of a large number of proinflammatory cytokines, mainly IL1B and TNF α ^[8]. Therefore the improvement in liver function is the basis for decreasing proinflammatory cytokine levels.

MELD is a reliable measure and predictive of short-term mortality risk in patients with end-stage liver disease^[9].

Abstract

AIM: To investigate the expression and pathological factors of Angiopoietin-2 (Ang-2) in primary gastric cancers and adjacent normal tissues.

METHODS: The expression of Angiopoietin-2 and VEGF were studied in 72 primary gastric cancers and adjacent normal tissues from the same patients by semi-quantitative reverse transcriptase-polymerase chain reaction (RT-PCR) and immunohistochemistry.

RESULTS: Ang-2 was mainly expression in tumor cells. There were significantly difference between expression of Ang-2 in primary gastric cancer and in adjacent normal tissue samples ($P=0.003$). It was statistically correlation between Ang-2 and VEGF expression in tumors ($P=0.0055$). With regard to Ang-2 expression in tumors, there were significant difference between early stage and advanced stage ($P=0.017$), and significant difference between positive vascular involvement and negative vascular involvement ($P=0.032$). However, there was no significant difference between moderate-poor differential type and high differential type ($P=0.908$), between positive lymph node metastasis and negative lymph node metastasis ($P=0.752$), between positive serosal invasion and negative serosal invasion ($P=0.764$). The cases with expression of Ang-2 were increasing with advanced stage and vascular involvement.

CONCLUSION: The results manifested that Angiopoietin-2, coordinated with VEGF, play role in regulating tumor angiogenesis of gastric cancer.

INTRODUCTION

Angiogenesis is required for the growth and metastasis of malignant tumor, and is defined as the sprouting of blood vessels from pre-existing vessels that migrate into the tumor and form a new vascular network. Many factors attend the process of angiogenesis. Recently, several studies have shown

that, the expression of angiopoietin-2 (Ang-2) probably correlates to tumor angiogenesis^[1,2]. However, the role and mechanism of Ang-2 in tumor angiogenesis still remain to be determined. Here, we investigate the expression and significance of angiopoietin-2 in gastric cancer.

MATERIALS AND METHODS

Materials

Reagents Trizol liquid, AMV reverse transcriptase, Oligd(T)₁₄, RNAsin, dNTP, Taq DNA polymerase were purchased from shanghai sangon biological engineering technology and service co.Ltd, PCR primers were synthesized by shanghai sangon biological engineering technology and service co.Ltd. N-18 and P-20, the monoclonal antibodies of Ang-2 and VEGF respectively, were purchased from santa cruz company.

Clinical data Total of 72 patients with respectable primary gastric cancer were analysed. There were 46 males and 26 females with primary gastric cancer. Age varied from 38 to 72 years, with a mean age of 53.5 years. Routine pathological diagnosis showed that 53 cases were adenocarcinoma, 19 cases were signet carcinoma. Of these 72 patients, 48 individuals had lymph nodes metastasis, and 26 others had no lymph node metastasis.

Methods

Detection of expression of Ang-2 AND VEGF Expressions of Ang-2 and VEGF were assessed in every gastric cancer sample and its adjacent normal tissue by semi-quantitative RT-PCR.

RNA extraction Total RNA was extracted by Trizol one step procedure, and suspended in DEPC-treated reverse osmosis-H₂O, and conserved at -70 °C for reverse transcription. RNA yield and purity were determined by standard UV spectrophotometric assay. The ratio of A₂₆₀/A₂₈₀ is 1.80.

First strand cDNA synthesis A 5 µg of the total RNA was dissolved in 20 µL of a mixture containing 2 µL of 10× first-strand buffer, 20 µL of AMV reverse transcriptase, 2 µL of dNTP, 20 µL of RNAsin, 500 ng of Oligd(T)₁₄, and DEPC-treated reverse osmosis-H₂O. The reaction conditions were as following: at 42 °C for 60 min, at 95 °C for 5 min. The first strand cDNA was stored at -20 °C until use.

PCR amplification Primers of Ang-2, VEGF and β-actin were synthesized according to primer design principles, all primer sets used span an intron to control amplification of genomic DNA sequences. A 3 µL of the first strand cDNA were amplified in 20 µL volume. The primers of Ang-2 were yielded 921-bp product and as following: 5' -end primer: 5' -GGGGGAGGACTG GTGACAGCCACGG-3', 3' -end primer: 5' -GAAATCTGCTGGC CGGATCATCAT-3'. Following an initial denaturation at 94 °C for 5 min, the samples were amplified by 30 cycles of denaturation at 94 °C for 30 s, annealing at 58 °C for 30 s, extension at 72 °C for 30 s, and ended by extension at 72 °C for 10 min. The primers of VEGF were yielded 356-bp product and as following: 5' -end primer: 5' -ACCATGAACCTTCTGCTCTCTTGG-3', 3' -end primer: 5' -CCGCCTTGGCTTGTCACATCTGCA-3'. Following an initial denaturation at 94 °C for 5 min, the samples were amplified by 28 cycles of denaturation at 94 °C for 30 s, annealing at 58 °C for 1 min, extension at 72 °C for 1 min, and ended by extension at 72 °C for 10 min. The primers of β-actin, which was

amplified with Ang-2 and VEGF as internal control, were yielded 644 bp product and as following: 5' -end primer: 5' -ACGTTATG GATGATGATATCGC-3', 3' -end primer: 5' -CTTAATGTCACG CACGATTTCC-3'. PCR products were separated on 1.7% agarose gel, stained with ethidium bromide, and analysed with Quantity one 4.1.0 software. The ratios of Ang-2/ β -actin, AEGF/ β -actin were used to semiquantify the levels of Ang-2 and VEGF.

Immunohistochemical staining The immunohistochemical study of expression of Ang-2 and VEGF in gastric cancer and adjacent normal tissue was performed by the avidin-biotin-peroxidase technique using monoclonal antibody N-18 and P-20, as previously described^[3,4]. Briefly, after formaldehyde-fixed paraffin-embedded tissue sections were deparaffinized in xylene and rehydrated in alcohol, they were incubated in 3 mL/L H₂O₂ to block endogenous peroxidase activity. Each slide was incubated with normal horse serum for 20 min at room temperature, and then monoclonal antibody N-18 or P-20, the working dilution were 1:100 and 1:200 respectively, was incubated on the tissue section overnight at 4 °C. After incubated in biotinylated mouse anti-goat IgG (the working dilution were 1:200) for 30 min at room temperature, each slide was rinsed in phosphate-buffered saline and was incubated in the avidin-biotin peroxidase complex for 40 min at 37 °C. The peroxidase was visualized with 3-3'-diamino-benzidine-tetrahydrochloride solution and then counterstained with methyl green.

Expressions of Ang-2 and VEGF in primary gastric cancers and adjacent normal tissues were detected under microscopy.

Statistical analysis Results are calculated as mean \pm SD for each group. *t* test groups or *chisq* test was used to analyze the variables. Statistical analyses were performed with SPSS software, version 10.0.

RESULTS

Results of RT-PCR

Seventy-two primary gastric cancers and adjacent normal tissues from the same patients were examined for the expression of Ang-2 and VEGF by RT-PCR. In 72 cases of primary tumors, Ang-2 and VEGF were expressed in 46 (63.9%) and 48 cases (66.7%) respectively. However, in 72 adjacent normal samples, Ang-2 and VEGF were expressed in 10 (13.9%) and 16 (22.2%) respectively. The expression of Ang-2 in primary gastric cancer has significant differences from that in adjacent normal tissues ($P=0.003$), (Figure 1, Table 1).

Figure 1 Semi-quantitative RT-PCR amplified products of Ang-2 and VEGF in primary gastric cancer and adjacent normal tissue 644 bp: internal standards, 921 bp: Ang-2 expression, 365 bp: VEGF expression, Lane-M: puc mix marker 8 (1116, 883, 692, 501, 404, 331, 242, 190, 147, 110, 67, 34, 26, 19) bp, Lanes 1-5: Ang-2 expression, Lanes 6-10: VEGF expression.

Meanwhile, in 46 cases of gastric cancers with Ang-2

positive expression, VEGF was coexpressed in 36 cases (78.26%), but 26 cases of gastric cancers with Ang-2 negative expression showed VEGF expression in 12 cases (46.15%). The expressions of Ang-2 and VEGF in the primary tumors were significantly correlated ($P=0.0055$), (Table 2).

Table 1 Expression of Ang-2 in primary gastric cancers and adjacent normal tissues detected by semi-quantitative RT-PCR

	Cases	Ang-2 (mean \pm SD)
Primary gastric cancers	72	0.497 \pm 0.393 ^a
Adjacent normal tissues	72	0.088 \pm 0.224

a: $P=0.003$ vs adjacent normal tissues.

Table 2 Correlation between expression of Ang-2 and VEGF in 72 primary gastric cancer detected by semi-quantitative RT-PCR

Ang-2 expression (Cases)	VEGF expression (Cases)		<i>P</i>
	Positive	Negative	
Positive	36	10	0.0055
Negative	12	14	

Result of immunohistochemistry

Positive control included human placenta. Positive expression of Ang-2 and VEGF show brown staining in the cytoplasm of tumor or normal cells, Ang-2 was mainly expression in tumor cells (Figures 2,3).

Pathologic factors affecting expression of VEGF-C

Several pathological factors, including tumor stage, histological type, lymph node metastasis, serosal invasion and vascular involvement, were investigated to predicting expression of Ang-2 in gastric cancer. The results show that, in expression of Ang-2, there were significant difference between early stage and advanced stage ($P=0.017$), and significant difference between positive vascular involvement and negative vascular involvement ($P=0.032$). However, there was no significant difference between moderate-poor differential type and high differential type ($P=0.908$), no significant difference between positive lymph node metastasis and negative lymph node metastasis ($P=0.752$), and no significant difference between positive serosal invasion and negative serosal invasion ($P=0.764$), (Table 3).

Table 3 Correlation between pathological factors and Ang-2 expression in 72 primary gastric cancer

Pathological factors	No. of cases	Ang-2 mRNA (mean±SD)	<i>P</i> value
Tumor stage			
Early stage	26	0.222±0.310	0.017
Advanced stage	46	0.593±0.318	
Histological type			
Moderate-Poor differential type	45	0.425±0.350	0.908
High differential type	27	0.203±0.290	
Lymph node metastasis			
Positive	48	0.413±0.346	0.752
Negative	24	0.490±0.450	
Serosal invasion			
Positive	43	0.404±0.327	0.764
Negative	29	0.334±0.459	
Vascular involvement			
Positive	46	0.640±0.335	0.032
Negative	26	0.272±0.298	

Figure 2 Expression of Ang-2 and VEGF in gastric cancer, A: Ang-2 positive expression in gastric cancer ($\times 400$), B: VEGF positive expression in gastric cancer ($\times 400$).

Figure 3 Expression of Ang-2 and VEGF in adjacent normal tissue, A: Ang-2 negative expression in adjacent normal tissue ($\times 400$), B: VEGF negative expression in adjacent normal tissue ($\times 400$).

DISCUSSION

Solid tumors could recruit blood vessels from the neighboring tissue by angiogenesis, and adequate blood supply could promote solid tumor growth to a clinically relevant size^[5]. The ability of a tumor to induce angiogenesis could determine its rate of growth and its likelihood of metastasis^[6-8]. It has been found angiogenesis is dependent on a tightly regulated balance between angiogenic promoters and inhibitors^[9]. Numerous factors have been implicated in regulate angiogenesis, including

growth factors and their receptors, a variety of proteases, adhesion receptors and ECM component^[10,11].

Angiopoietins, novel endothelial factors, were found to be ligands for the endothelium-specific tyrosin kinase receptor Tie-2^[12]. Angiopoietins (Ang) included Ang-1, Ang-2, Ang-3 and Ang-4, the best characterized were Ang-1 and Ang-2. Ang-1 and Ang-2 were soluble 70-ku factors, which consist of an amino-terminal coiled-coil domain and a carboxy-terminal fibrinogen-like domain^[13,14].

Both of Ang-1 and Ang-2 could bind to the Tie-2 receptors. Ang-1 could bind to the Tie-2 receptor and activate it by inducing phosphorylation, and help to maintain and stabilize mature vessels by promoting interactions between endothelial cells and supporting cells^[15-17]. Ang-2 could also bind to the Tie-2, but not activate phosphorylation. Ang-2 could block the action of Ang-1^[18]. That is to say, Ang-2 was an antagonist of Ang-1 and induces the loosening of the interactions between endothelial and perivascular support cells and ECM, reducing vascular integrity and facilitating access to angiogenic induces^[19,20]. Recent studies have shown that the expression pattern of Ang-2 is strongly associated with that of VEGF in the process of tumor angiogenesis, VEGF and Ang-2 seemed to play complementary and coordinated roles in the development of new blood vessels^[21,22]. Angiopoietins were mainly produced by endothelial cells and pericytes, and their receptor Tie-2 was also expressed in endothelial cells and partly in hematopoietic cells^[23]. Ang-2 was selectively expressed in endothelial cells of tumors, ovaries, uterus and placenta, which are known to have extensive vascularization patterns^[24-26].

The role and mechanism of Ang-2 in tumor angiogenesis have not been clarified. Some studies suggested that the production of VEGF and Ang-2 must be coordinated in development of tumor angiogenesis^[27,28]. Ang-2 could produce destabilization and induce angiogenic response in the presence of VEGF, but lead to vessel regression in the absence of VEGF^[13,29]. While other studies manifested that VEGF upregulates expression of Ang-1, but not Ang-2^[30]. The expression of Ang-2 correlated with tumor size, but had no correlation with expression of VEGF^[31]. Kuroda's results showed that upregulation of Ang-1, Ang-2 and Tie-2 is closely associated with the development of microvascular proliferation in psoriasis, and the angiopoietin-Tie-2 system might act coordinately with VEGF to promote angiogenesis^[32]. Hatanaka's results suggested that tumor-produced IL-10 promotes stromal vascularization through expression of Ang-1, Ang-2 and Tie-2^[33]. Angiopoietin-Tie-2 system, particularly Ang-2, played critical role in the vascularization of prostate carcinoma, breast cancer, colon cancer, astrocytoma, gastric carcinoma, *etc*^[23,34-37]. Ang-2 expression was highest during the early stages of angiogenesis, perhaps reducing Tie-2 activity to allow the established vasculature to respond to angiogenic stimuli, consequently, Ang-2 expression was decreased and superseded by Ang-1 expression, perhaps activating Tie-2 and resulting in the stabilization and maturation of neovessel^[13].

We studied the expression of Ang-2 in 72 primary gastric cancer and adjacent normal tissues by semi-quantitative reverse transcriptase-polymerase chain reaction (RT-PCR) and immunohisto-chemistry. The results showed that Ang-2 was mainly expression in tumor cells, and there were significantly difference in Ang-2 expression between primary tumor and adjacent normal tissue samples. The present study also clearly manifested that it was statistically correlated between Ang-2 and VEGF expression in tumors. The expression of Ang-2 was related with tumor stage and vascular involvement. Ang-2 overexpression by newly formed tumor blood vessels may lead to vessel destabilization and relative hypoxia, which could drive the release of VEGF, leading to robust angiogenesis^[37].

Abstract

AIM: To investigate biogenesis and intracellular localizations of clusterin to elucidate the potential molecular mechanisms implicated in tumorigenesis of esophageal mucosa.

METHODS: Semi-quantitative RT-PCR for multi-region alteration analysis, Western blot for different transcriptional forms and immunohistochemical staining for intracellular localizations of clusterin were carried out in both tissues and cell lines of ESCC.

RESULTS: The N-terminal deletions of the clusterin gene and the appearance of a 50-53 ku nuclear clusterin, an uncleaved, nonglycosylated, and disulfide-linked isoform, were the major alterations in cancer cells of esophagus. Naturally the 40 ku clusterin was located in the connective tissue of the lamina propria of epithelial mucosa and right under the basal membrane of epithelia, but it was disappeared in stromal mucosa of esophagus and the pre-matured clusterin was found positive in cancerous epithelia.

CONCLUSION: The N-terminal deletion of clusterin may be essential for its alterations of biogenesis in ESCC.

INTRODUCTION

Clusterin, a 70-80 ku heterodimeric, disulfide-linked glycoprotein is expressed in a wide variety of tissues and secreted in all

human fluids^[1-3]. Human clusterin is encoded by a single copy gene located on chromosome 8p12 and 8p21 with nine exons and eight introns, spanning approximately 17 kb^[4,5]. Clusterin gene has a single functional promoter and a single transcript mRNA, 1.6 kb in length, containing an N-terminal hydrophobic leader sequence. There are two forms of clusterin: one set of proteins is directly for secreted into humour, and the other forms are expressed in the cytoplasm and nucleus. The secretory form of the clusterin protein is produced by translation on membrane-bound ribosomes from the first AUG codon of the full-length clusterin mRNA and is targeted to the endoplasmic reticulum (ER) by an initial leader peptide. Subsequently, this -60 ku pre-clusterin protein containing 427 amino acids has to be further glycosylated in the ER and proteolytically cleaved between R205 and S206 into a mature protein discrete α - and β -chains, held together by disulfide bonds in Golgi^[1,6]. External secretory clusterin is a 70-80 ku heterodimeric glycoprotein that appears as a -40 ku α - and β -subunits smear by sodium dodecyl sulfate-polyacrylamide gel (SDS-PAGE) electrophoresis under reducing conditions^[7-9]. Recent data suggest that secretory clusterin acts as a molecular chaperone to scavenge denatured proteins and cellular debris outside cells following specific stress-induced injury such as heat shock^[10-14].

Clusterin has been found highly conserved and implicated in a variety of biological processes including lipid transport, epithelial cell differentiation, transformation, and regulation of apoptosis in numerous models of epithelial cells during hormone ablation^[15-20]. It is induced during regression of most hormone-dependent secretory epithelial cells as one of the most potent proteins of the rat ventral prostate or mammary gland^[9,20-23]. Overexpression of secretory clusterin in human cancer cells caused drug resistance and protection against certain cytotoxic agents that induce apoptosis^[24-26]. In human prostate cancer cells, overexpression of clusterin provides protection against TNF α -induced cell death and oligonucleotide directed antisense inhibition enhances spontaneous cell death in untreated cultures^[24]. Clusterin may have a cytoprotective role in epithelial cell death. There are significant alterations in the biogenesis of clusterin during apoptosis, which lead to the appearance of a 50-53 ku uncleaved, nonglycosylated, disulfide-linked isoform that accumulates in the nucleus of MCF-7 cells^[20]. Nuclear clusterin synthesis is a product of alternative splicing, in which the exon II, containing the first AUG and encoding the ER-targeting peptide, was omitted. This "death" form of the clusterin protein was proposed to be synthesized from a second in-frame AUG codon in exon III as translation start site. The short mRNA produces the 49 ku precursor nuclear clusterin which overexpression acts as a pro-death signal, inhibiting cell growth and survival^[27-29].

Clusterin mRNA and protein was recently shown to be down-regulated in esophageal squamous cell carcinoma (ESCC), the major malignant tumor occurred in epithelium of esophagus^[7]. Thus, to the author's knowledge, it is unclear whether alternative splicing clusterin is also involved and the possible roles of clusterin in process of the ESCC. We additionally studied, by multi-regional RT-PCR, Western blot

and immunohistochemical staining, the levels of expression and cellular distribution of clusterin in both tissues and cell lines of human ESCC.

MATERIALS AND METHODS

Tissue sample

The esophageal specimens were obtained from patients diagnosed with ESCC by the pathologists that assisted in our previous work in Cancer Hospital of Chinese Academy of Medical Sciences and Beijing Yanjing Hospital^[7]. The study was approved by the Institutional Review Board. Briefly, immediately the specimens were dissected manually into several aliquots (about 0.3 cm³ in size), quickly frozen in the liquid nitrogen and, then stored at -80 °C until analysis. Carcinoma tissues were obtained from poorly, moderate, and well differentiated ESCC. The corresponding normal tissues were obtained from the distant edge of dissected esophagus. For immunohistochemical (IHC) staining, tissues were fixed in 700 mL/L ethanol or 40 mg/L neutral formalin and embedded in paraffin.

Cell lines

Human ESCC cell lines, EC0156 and EC0132, were generated in our laboratory from ESCC tissues.

RNA isolation and semi-quantative RT-PCR

Total RNAs were isolated from ESCC specimens and cell lines with RNeasy MinElute cleanup kit (QIAGEN, Valencia, CA) according to the manufacture's instruction. RNA quality was assessed on agarose gel electrophoresis and spectrophotometric analysis. Reverse transcription reactions were performed on 5 µg of total RNAs using SuperScript™ First-Strand synthesis for RT-PCR II kit (Invitrogen, Carlsbad, CA) at 42 °C for 80 min, and 0.5-1 µg aliquots of the cDNA were then subjected to RT-PCR. Based on probable splice sites, the following primers were used to investigate different regions whether alternative splice forms or deleted fragments of clusterin could be found (Table 1).

The PCR step was performed using Taq DNA polymerase (Invitrogen, Carlsbad, CA). As an internal control, *GAPDH* was amplified to ensure cDNA quality and quantity for each RT-PCR reactions. The amplified multiproducts were analyzed on 12-20 g/L agarose gels. Each PCR reaction was down triplicate.

Protein extraction and western blot

The tumor tissues and cell lines were lysed in the lysis buffer (50mmol/L Tris-HCl, pH 7.4, 150mmol/L NaCl, 10 g/L TritonX-100, 1 g/L SDS, 1 mmol/L AEBSF, 20 µg/mL Approtinin and 20 µg/mL Leupeptin) for soluble protein extraction or in the extraction/labeling buffer (BD Biosciences, San Jose, CA) for whole

proteins extraction, and then placed on ice for 20 min. Then they were sonicated and centrifuged at 12 000 g at 4 °C for 30 min. The supernatants were transferred and the protein concentration was measured by Bradford method^[30].

Equal amount of proteins were separated on 100 g/L of SDS-PAGE gels and transferred to polyvinylidene difluoride (PVDF) membranes. After being blocked with 10 g/L non-fat milk, the membranes were incubated with anti-clusterin monoclonal antibody B-5 (sc-5289, Santa Cruz Biotechnology, Santa Cruz, CA) (1:1 000 dilution) at 4 °C overnight. After washing for 3 times, the membranes were incubated with rabbit anti-mouse IgG at room temperature for 1 h. The signals were developed with the ECL kit (Amersham Pharmacia Biotechnology, Piscataway, NJ) and using anti-α-tubulin antibody (Santa Cruz Biotechnology, Santa Cruz, CA) as an internal loading control.

Rabbit anti-human clusterin polyclonal H-330 antibody (sc-8354, Santa Cruz Biotechnology, Santa Cruz, CA) was used to detect the truncated forms of clusterin in whole extracts from EC0156 and EC0132 cells and tissues. A 1:500 dilution of primary H-330 antibody was used, followed by a 1:3 000 dilution of horseradish peroxidase-conjugated anti-rabbit secondary antibody (Santa Cruz Biotechnology, Santa Cruz, CA).

Immunohistochemical analysis

The streptavidin-peroxidase method was used for the immunohistochemical staining of clusterin. Briefly, after deparaffinization in xylene and rehydration in grade ethanol, endogenous peroxidase activity was blocked by incubation with 30 mL/L hydrogen peroxide for 10 min. Tissue sections were then heated at 100 °C in citrate buffer (10 mmol/L, pH 6.0) to retrieve antigens for 10 min. After being incubated with anti-human clusterin monoclonal/polyclonal antibodies, clusterin was visualized by adding biotinylated secondary antibody and streptavidin-horseradish peroxidase (Zymed Laboratories, South San Francisco, CA). Counterstaining was performed with hematoxylin and 3,3'-diaminobenzidine used as a chromogen. Negative controls, made by PBS excluding mono- or polyclonal anti-human clusterin antibodies from the reaction, showed no specific staining and. Experiments performed using polyclonal and monoclonal anti-human clusterin antibodies from the same commercial source gave the same pattern of specific distributions. Cover slips were mounted with Eukitt (O. Kindler GmbH & Co., Freiburg, Germany).

RESULTS

N-terminal deletions of the clusterin transcription in ESCC

To detect the alterations of clusterin expression, a multi-region cDNA fragments of ESCC were analyzed by semi-quantitative

Table 1 Primers and PCR reactions for multi-region amplifications of clusterin

Amplified fragments (bp)	Sense primers	Antisense primers	PCR conditions

RT-PCR (Figure 1). The clusterin cDNA derived from the total RNA of both ESCC tissues and their matched dissected normal esophageal mucosa. The results of various fragments are shown in Figure 2. Comparing with the tumor matched normal epithelia of esophagus, the expressions of full-length and N-terminal fragment (1-320 bp) of clusterin were deleted obviously, however, there were no differences between the middle (437-1 056 bp) and C-terminal fragments (1 120-1 350 bp). By this approach, additionally using the primer containing the start codon of clusterin and the -3' end of the middle fragment obtained the same result with the one from full-length (1-1 056 bp), and also found the same expression level between the cancer tissue and normal epithelia from 437 to the end of clusterin (437-1 350 bp). The exceptional transcription area of clusterin was narrowed in the region of 1-437 bp, which contained the abnormal translation start site of the "death" form clusterin (nuclear clusterin) and omitted the region encoding the endoplasmic reticulum (ER)-targeting peptide of clusterin protein. These results indicated that clusterin was truncated at 5' end of gene.

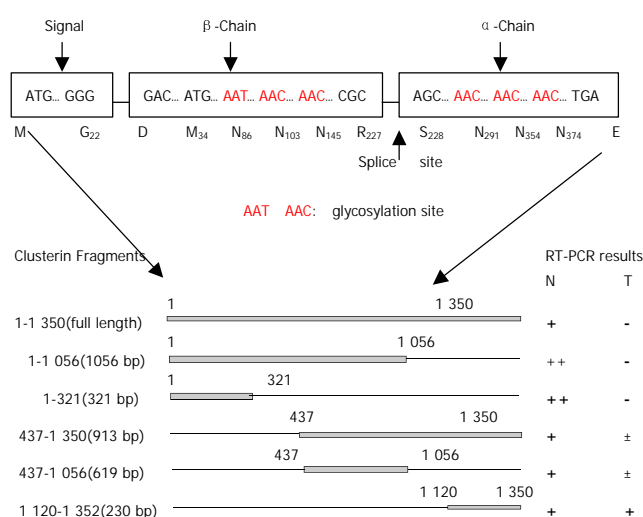

Figure 1 Schematic diagram of analyzed fragments of clusterin. A: structural map of the human clusterin protein. Letters and boxes signify the following: ER-targeting signal, endoplasmic reticulum-targeting hydrophobic leader peptide; splice site, α/β -cleavage site (amino acid 205 and 206) of cytoplasmic -60 ku pre-secreted clusterin which was glycosylated and cleaved into α and β chains to form an 80 ku matured secretory clusterin protein; rectangles, hydrophobic leader peptide (N-terminal 66 bp encode aa M1 to G22, 22 aa), β -chain (5' end) and α -chain (3' end); Red letters, the glycosylation sites. B: Schematic diagram of analyzed fragments of clusterin and their RT-PCR results.

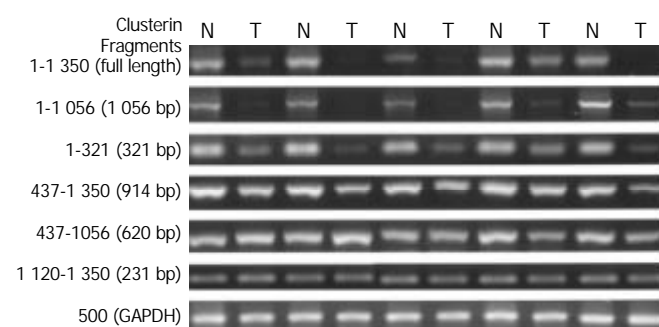

Figure 2 N-terminal truncated clusterin was analyzed by RT-PCR. GAPDH was used as internal control. N: tumor matched far edge normal esophageal mucosa. T: ESCC specimens. The expression of full-length and different of clusterin fragments

were analyzed comparing with the tumor matched normal esophageal mucosa. The truncated region was narrowed down at the 5' end of clusterin (1-437 bp).

Down-regulation of nuclear clusterin and secreted clusterin in ESCC

According to the results of RT-PCR, anti-clusterin antibodies were used to detect the expression of clusterin protein both in the tissues and cell lines of ESCC (Figure 3). The predominant form of clusterin in tumor tissues was the secreted heterodimeric glycoprotein with MW of 75-80 ku (37-40 ku smear in reducing SDS-PAGE), which was down-regulated in ESCC tissues compared with the normal epithelia of esophagus (100%, 21/21), but was absent in the ESCC cell lines (EC0516 and EC0132). The results confirmed our previous data that the clusterin gene is generally down-regulated in esophageal cancer^[7]. Meanwhile, an about 50 ku nuclear clusterin was appeared in both the ESCC tissues (100%, 21/21) and cell lines (100%, 2/2), and sometimes in normal epithelia. It was highly expressed in the tumor tissues and cells. Additionally, an about 35 ku band was detected by anti-clusterin antibody H-330 in the EC0132 cell line. Under these experimental conditions, it must be noticed that, as shown in Figure 3, the monoclonal antibody used (Clusterin- β , B-5 from Santa Cruz Biotechnology, Santa Cruz, CA) might react with the carboxy terminus of clusterin β chain of human origin and not react with uncleaved nuclear clusterin. However, the polyclonal antibody used (Clusterin- α/β , H-330 from Santa Cruz Biotechnology Inc., Santa Cruz, CA) recognized the major part of clusterin from 120 to 449 amino acids at the carboxy terminus of clusterin- α/β chains, including the 60 ku precursor (cytoplasmic clusterin), from which all clusterin isoforms are supposed to be derived, uncleaved nuclear clusterin (-50 ku) and the matured secreted clusterin (-37-40 ku, cleaved in $-\alpha$ and $-\beta$ chains).

Figure 3 Western blot analysis of expression of multiple forms of clusterin in ESCC. nCLU: the nonglycosylated uncleaved nuclear clusterin; α/β CLU: cleaved and glycosylated secreted clusterin protein; β CLU: cleaved and glycosylated clusterin β chain; B-5: monoclonal antibody (Santa Cruz Biotechnology, Santa Cruz, CA) reacted with the C-terminus of clusterin- β of human origin and did not react with the nuclear clusterin; H-330: polyclonal antibody (Santa Cruz Biotechnology, Santa Cruz, CA) recognized the major part of clusterin from 120 to 449 aa at the C-terminus of clusterin- α/β chains including uncleaved nuclear clusterin (-50 ku) and the matured secreted clusterin (-37-40 ku); Np: pooled normal esophageal mucosa from 10 cases; Cp: pooled ESCC tumor tissues from 10 cases; N109: normal esophageal mucosa from a single individual; C109: ESCC tumor tissue from a single individual. β -actin was used as loading control.

Intracellular localizations of clusterin in ESCC

Immunohistochemistry analysis was performed in the tissue sections of ESCC specimen and matched normal counterparts using the same antibody (B 5, Santa Cruz Biotechnology, Santa Cruz, CA) as previously used for Western blot analysis (Figure 4). In normal esophageal mucosa, clusterin protein localized prevalently to the stroma of esophageal mucosa, while the squamous epithelial cells and basal lamina were negative. Very

Figure 4 Detection of clusterin protein in tissue sections of human ESCC by immunohistochemistry. In normal esophageal mucosa, the expression of clusterin in squamous epithelial cells and basal lamina was negative, while clusterin immunostaining was visualized obviously in the stroma of epithelial mucosa (A, 100 \times); clusterin was positive in middle dysplasia, while the vast majority of stromal cells were negative in normal squamous epithelia of esophagus (B, 100 \times); clusterin was strong positive in the remnants of stromal extracellular matrix invaded by tumor cells in well-differentiated ESCC (C, 100 \times). D show that stromal and basal membrane are almost completely disrupted and invaded by tumor cells. (D, same section, different field of that of C, 400 \times). Counterstaining was performed with hematoxylin.

high levels of clusterin expression were found in the connective tissue of the lamina *propria* of epithelial mucosa, in which clusterin was confined to what appeared to be the remnants of the extra cellular matrix right under the basal membrane of epithelia, the cytoplasm of esophageal glandular cells, plasma membrane and cytoplasm of duct glandular epithelia, and plasma membrane and cytoplasm of lymphocytes in lymphatic follicle were detected positive by IHC (Figure 4A). During tumorigenesis the intracellular localizations of clusterin was translocated from stroma to the squamous epithelial cells at very early states. It was even found positive in middle dysplasia, a kind of very early lesion of esophagus versus negative in normal squamous epithelia (Figure 4B). However, clusterin and its pre-matured form were distributed in cancerous epithelia of ESCC (the antibody B 5 is able to detect the 60-ku secretory clusterin precursor by Western blot analysis, data not show here) and then, disappeared in stromal mucosa of esophagus (Figure 4C and D).

DISCUSSION

Based on our previous data, clusterin is markedly down-regulated in both serum and tissues of ESCC^[7]. To further clarify the mechanisms of clusterin alterations during tumorigenesis, we first analyzed the gene transcription using semi-quantitative RT-PCR by amplifying different regions from 5' end to 3' end of the gene. We found the same expression results from 437 to 1 350 bp of clusterin between cancer and their matched normal. However, comparing with the cDNA reverse-transcribed from the total mRNA of normal epithelial mucosa, using the cDNA of tumor tissues, no fragment was amplified completely by the N-terminus of 5' -primer which contains the start codon located in the first exon (see underline sequences of the primer 5' - CCGGATCCTTATGATGAAGACTCTGCTGCTG-3'). Those suggested that there was an N-terminal deletion or miss splicing located on 1-437 bp that induced a wrong transcription

forms of the clusterin in ESCC. A miss splicing site repeated in breast cancer cell line MCF 7 was right in this area^[29]. At protein expression level, this region is naturally corresponding to the β chain of clusterin protein. According this rationale, an N-terminal truncated form of clusterin protein would be also detectable. The different protein forms of clusterin in ESCC also describe the biogenesis of multi-transcription forms of clusterin.

The significance of alterations of clusterin gene expression during tumorigenesis remains a mystery. Our data indicated that human esophageal epithelial cells synthesized at least two forms of clusterin, secretory and nuclear clusterins, and their expression levels were changed during tumorigenesis. The secretory clusterin was down-regulated both in serum and tissues of ESCC; while, nuclear clusterin was induced in tumor cells. We also found a 60 ku secretory clusterin precursor protein in ESCC and normal epithelial cells (data not shown). Previous data indicated the existence of a mature about 55 ku nuclear clusterin protein, as a cell death protein and lack ER-signaling peptides, which did not appear to be either glycosylated or cleaved at its α/β site, a site cleaved during maturation of the 60 ku secretory clusterin precursor protein^[12,28,29]. Yang *et al*^[27], described nuclear clusterin was induced by relatively high levels of cytotoxic stress in direct proportion to lethality after growth stimulation of ionizing radiation (IR). Utilization of an in-framed secondary downstream AUG as a translation start site was proposed to result in the synthesis of an about 50 ku precursor nuclear clusterin protein that resided in cytoplasm of undamaged cells by confocal microscopy. Overexpression of this nuclear clusterin, even without IR treatment, caused cell death^[12]. In our immunoblotting results, an about 50 ku nuclear clusterin was detected in both ESCC tissues and cell lines, and occasionally in normal esophageal epithelia using H-330 anti-clusterin antibody. This form of nuclear clusterin could not be detected with B-5 anti-clusterin antibody. As Leskov *et al*^[29] used, H-330 anti-clusterin antibody recognizes the major part of clusterin from 120 to 449 amino acid at the

carboxy terminus of clusterin α/β chains, including the 60 ku precursor and a -49 ku nuclear clusterin precursor (pnCLU). These results were consistent with our findings by RT-PCR that deletion at 5' end or appearance of a splicing at different sites of clusterin gene resulted in N-terminal truncated forms of clusterin transcription. These abnormal forms of clusterin undergo alien post-translational modification compared to secretory clusterin.

Nuclear clusterin is associated with Ku70^[8], a DNA double-strand break repair protein. Its Ku70 binding activity was localized to the C-terminal coiled-coil domain of nuclear clusterin^[30]. The C-terminal coiled-coil domain of nuclear clusterin was the minimal region required for Ku binding and apoptosis. We also found that Ku70 altered in ESCC (data not shown). Although we do not yet know whether nuclear clusterin binding to Ku70 is essential for lethality, we could speculate that enhanced clusterin binding to Ku70 may hinder the formation of Ku70/Ku80 heterodimer, consequently interfere with non-homologous DNA repair, resulting in genomic instability or cell death.

Our studies suggested, on the other hand, the alterations of the localizations and intracellular localizations of clusterin. It was translocated from stroma to the epithelial cells by disrupting the basal membrane of epithelial mucosa during carcinogenesis.

In general, our results demonstrated that the alterations in the expression, proteolysis and intracellular localizations of clusterin and an N-terminus truncated form of clusterin were found in ESCC. Its possible roles in cell survival, cell death and neoplastic transformation remain an additional debate.

ACKNOWLEDGEMENTS

Abstract

AIM: To investigate the effect of *c9,t11*-conjugated linoleic acid (*c9,t11*-CLA) on the adhesion of human gastric carcinoma cell line (SGC-7901).

METHODS: SGC-7901 cells were at first treated with different concentrations (25, 50, 100, 200 $\mu\text{mol/L}$) of *c9,t11*-CLA and 1 mL/L ethanol (as a negative control) for 24 h. Using adhesion assay and Western blot, we investigated the ability of SGC-7901 cells to adhere to intracellular matrix and examined the expression of E-cadherin (ECD), α -catenin, intercellular adhesion molecule 1 (ICAM-1) and vascular cell adhesion molecule 1 (VCAM-1) in these cells.

RESULTS: The attachment rate to laminin of SGC-7901 cells treated with different concentrations of *c9,t11*-CLA (0, 25, 50, 100, and 200 $\mu\text{mol/L}$) was 100.0 ± 3.3 , 95.7 ± 4.0 , 89.2 ± 4.6 , 87.9 ± 6.1 , and 65.9 ± 5.8 , respectively. The attachment rate to fibronectin was 100.0 ± 4.7 , 96.8 ± 3.8 , 94.5 ± 4.1 , 76.5 ± 4.3 , and 61.8 ± 4.8 , respectively. The attachment rate to Matrigel was 99.9 ± 6.6 , 91.4 ± 6.8 , 85.5 ± 7.4 , 79.3 ± 5.6 , and 69.6 ± 5.1 , respectively. Besides, *c9,t11*-CLA could increase the level of ECD and α -catenin, and decrease the level of ICAM-1 and VCAM-1 in SGC-7901 cells.

CONCLUSION: *c9,t11*-CLA can reduce the adhesion of human gastric carcinoma cells to laminin, fibronectin and Matrigel. *c9,t11*-CLA can increase the level of ECD and α -catenin, and decrease the level of ICAM-1 and VCAM-1 in human gastric carcinoma cells.

INTRODUCTION

Although the incidence of gastric cancer is decreasing worldwide, it remains one of the most common tumors in China^[1-4] and is a major cause of cancer deaths in some countries^[5,6]. Most of gastric cancer patients die from metastasis. Although the mechanism of gastric cancer metastasis is not fully elucidated, the abnormal adhesion ability of cells has been reported to play a pivotal role. Cell-cell and cell-matrix adhesions are essential for establishing and maintaining normal cell morphology and function. Disturbance of cell adhesion may result in the malignant transformation of cells. Furthermore, cell adhesion molecules are important ingredients in maintaining cell-cell adhesion and cell-matrix interactions. The abnormality of cell adhesion molecules closely correlates with neoplastic transformation and metastasis^[7,8]. Cell adhesion molecules mediate tumor cell-cell, tumor cell-endothelial cell and tumor cell-matrix interactions. In tumor metastasis, cell-cell and cell-matrix interactions are determined by functional status of cell adhesion molecules. Glycoproteins are the cell adhesion molecules and can be classified into several classes according to their structure: cadherins, selectins, CD44, immunoglobulin family, and integrin family.

Conjugated linoleic acid (CLA) is a class of positional and stereoisomers of octadecadienoate (18:2) with conjugated double bonds. The predominant isomer in foods is the *c9,t11*-CLA isomer^[9-16]. In 1979, Pariza *et al.*^[17] detected mutagenic inhibitory activity in both cooked and uncooked ground beef. Then in 1985, they observed that the crude extracts could protect rats against tumors^[18]. In 1987, Ha *et al.*^[19] identified four isomers of CLA from cooked beef. In several animal models of chemical carcinogenesis, it has been reported that CLA was a potent cancer preventive agent. For example, CLA could inhibit skin papillomas^[18,20], forestomach neoplasia^[21-23], mammary tumors^[24-30], and colon aberrant crypt foci^[31]. Moreover, CLA was also effective in reducing the size and metastasis of transplanted human breast cancer cells and prostate cancer cells in SCID mice^[32,33]. Several studies^[34-43] suggested that CLA was cytostatic and cytotoxic to a variety of human cancer cells *in vitro*, including hepatoma, malignant melanoma, colorectal cancer, breast carcinoma, and gastric cancer.

One of our previous studies showed that *c9,t11*-CLA could inhibit the invasion of mouse melanoma cells (B16-MB) through reducing their adhesion ability to extracellular matrix^[44]. Two other studies of ours showed that *c9,t11*-CLA could decrease the invasive ability of human gastric carcinoma cells (SGC-7901)^[45,46]. However, it is unclear whether CLA influences the adhesive ability of SGC-7901 cells and the expression of their adhesion molecules. Therefore, in this study, we investigated the effect of *c9,t11*-CLA on the adhesive ability of SGC-7901 cells and detected the expression of E-cadherin (ECD), α -catenin, intercellular adhesion molecule 1 (ICAM-1) and vascular cell adhesion molecule 1 (VCAM-1) in SGC-7901 cells using adhesion and Western blot assays.

MATERIALS AND METHODS

Materials

c9,t11-CLA with 98% purity, was provided by Dr. Rui-Hai

Liu at Food Science and Toxicology, Department of Food Science, Cornell University, Ithaca, NY, USA. The *c9,t11*-CLA was dissolved in ethanol, then diluted to the following concentrations: 25, 50, 100, and 200 $\mu\text{mol/L}$.

To examine the expression of ECD, α -catenin, ICAM-1, and VCAM-1, we used four primary antibodies: rabbit polyclonal antibody for ECD, mouse monoclonal antibody for α -catenin, and goat polyclonal antibodies for ICAM-1 and VCAM-1, respectively. These antibodies were purchased from Zhongshan Co., China.

Methods

Cell culture Human gastric adenocarcinoma cells (SGC-7901), purchased from Cancer Research Institute of Beijing (China), were cultured in RPMI 1640 (Gibco) medium, supplemented with 100 mL/L fetal calf serum (FCS), 100×10^3 U/L penicillin, 100 mg/L streptomycin and 2 mmol/L L-glutamine under 50 mL/L CO_2 in a humidified incubator. The pH was maintained at 7.2–7.4 and the temperature at 37 °C. After sub-cultured with EDTA, the SGC-7901 cells were incubated with different concentrations (25, 50, 100, and 200 $\mu\text{mol/L}$) of *c9,t11*-CLA and 1 mL ethanol (as a negative control) for 24 h.

Cell adhesion assay A total of 96-well plates (Nunc. Co.) were incubated at 37 °C with laminin, fibronectin or Matrigel for 1 h and then blocked with phosphate-buffered saline (PBS) containing 100 g/L BSA at the same temperature for another 1 h. After exposed to different concentrations (25, 50, 100, and 200 $\mu\text{mol/L}$) of *c9,t11*-CLA for 24 h, the SGC-7901 cells were suspended in serum-free medium at a density of 8×10^5 cells/mL. Then, 0.1 mL of SGC-7901 cells suspension was added to each well and incubated at 37 °C for 1 h. The plates were washed three times with PBS to remove unattached cells. The remaining SGC-7901 cells in 96-well plates were reacted with MTT for 4 h at 37 °C, then solved with DMSO. The absorbance of each well was measured at 570 nm with an ELX800 microplate reader (Bio-TEK Co.). Results were expressed as the percentage of total cells assuming that the adhesion of cells in control was 100%.

Protein extract and western blot The SGC-7901 cells treated with different concentrations of *c9,t11*-CLA were harvested, washed twice times with PBS and lysed at 4 °C in lysis buffer containing 150 mmol/L NaCl, 1 mL/L NP-40, 5 mg/L sodium deoxycholate, 100 g/L SDS, 50 mmol Tris (pH 7.4), 1 mmol/L DTT, 0.5 mmol/L Na_3VO_4 , 10 mmol/L phenylmethylsulfonyl fluoride (PMSF), 10 mg/L aprotinin, and 5 mg/L leupeptin. Following the centrifugation of 10 000 *g* for 30 min at 4 °C, the amount of protein in the supernatant was determined using DUR 640 nucleic acid and protein analyzer. Equal amount of protein was separated on SDS-polyacrylamide gel electrophoresis and transferred to nitrocellulose membrane (Gibco BRL, USA) overnight. Blocked with 50 g/L defatted milk, the membrane was hybridized with rabbit anti-E-cadherin, mouse anti- α -catenin, goat anti-ICAM-1 and goat anti-VCAM-1 antibody, then incubated with horseradish peroxidase-conjugated IgG. Finally, the immunoreactive bands were detected using diaminobenzidine tetrahydrochloride (DAB) substrate and analyzed with a ChemiImager™ 4000 low light imaging system (Alpha Innotech Corporation). At the same time GAPDH was used as house-keeping protein.

RESULTS

Effect of *c9,t11*-CLA on adhesion of SGC-7901 cells

As shown in Table 1, *c9,t11*-CLA could reduce the cell attachment to FN, LN or Matrigel in a dose dependent manner after SGC-7901 cells were pre-incubated for 24 h with different concentrations of *c9,t11*-CLA.

Table 1 Effects of *c9,t11*-CLA on adhesion of SGC-7901 cells (*n*=3)

Doses ($\mu\text{mol/L}$)	Attachment rate to LN (%)	Attachment rate to FN (%)	Attachment rate to matrigel (%)
200	100.0 \pm 3.3	100.0 \pm 4.7	99.9 \pm 6.6
100	95.7 \pm 4.0	96.8 \pm 3.8	91.4 \pm 6.8
50	89.2 \pm 4.6 ^b	94.5 \pm 4.1	85.5 \pm 7.4 ^a
25	87.9 \pm 6.1 ^b	76.5 \pm 4.3 ^b	79.3 \pm 5.6 ^b
Negative control group	65.9 \pm 5.8 ^b	61.8 \pm 4.8 ^b	69.6 \pm 5.1 ^b

^a*P*<0.05 vs negative control, ^b*P*<0.01 vs negative control.

Effect of *c9,t11*-CLA on ECD and α -catenin in SGC-7901 cells

As shown in Figure 1, the level of ECD and α -catenin protein in SGC-7901 cells treated with different concentrations of *c9,t11*-CLA was increased in comparison with that in the negative control group. The level of ECD and α -catenin protein in SGC-7901 cells treated with 200 $\mu\text{mol/L}$ *c9,t11*-CLA increased 65.9% and 80.5% respectively, compared with those in the negative control group.

Figure 1 Effect of *c9,t11*-CLA on ECD and α -catenin in SGC-7901 cells detected by Western blot. A: Top: The expression of ECD in SGC-7901 cells treated with different concentrations of *c9,t11*-CLA. Middle: The expression of α -catenin protein in SGC-7901 cells treated with different concentrations of *c9,t11*-CLA. I - IV are 200, 100, 50, 25 $\mu\text{mol/L}$ *c9,t11*-CLA; V is the control group. B: the result of quantitation of ECD and α -catenin levels in SGC-7901 cells by ChemiImager™ 4000 digital system.

Effect of *c9,t11*-CLA on ICAM-1 and VCAM-1 in SGC-7901 cells

As shown in Figure 2, the expression of ICAM-1 and VCAM-1 protein in SGC-7901 cells treated with different concentrations of *c9,t11*-CLA was decreased in comparison with that in the negative control group. Analyzed by ChemiImager 4000 digital system, the level of ICAM-1 and VCAM-1 protein in SGC-7901 cells treated with 200 $\mu\text{mol/L}$ *c9,t11*-CLA increased 70.2% and 65.4% respectively, compared with that in the negative control group.

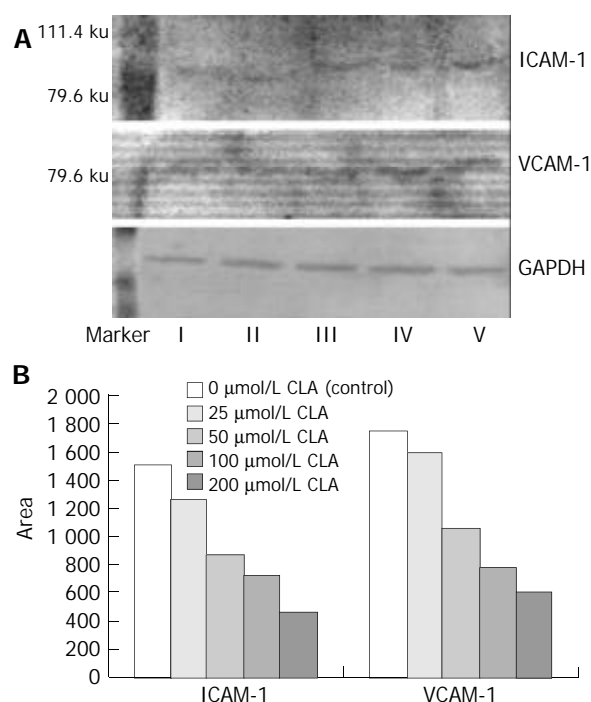

Figure 2 Effect of *c9,t11*-CLA on ICAM-1 and VCAM-1 in SGC-7901 cells detected by Western blot. A: Top: The expression of ICAM-1 in SGC-7901 cells treated with different concentrations of *c9,t11*-CLA. Middle: The expression of VCAM-1 in SGC-7901 cells treated with different concentrations of *c9,t11*-CLA. I-IV are 200, 100, 50, 25 $\mu\text{mol/L}$ *c9,t11*-CLA, respectively; V is the control group. B: the result of quantitation of ICAM-1 and VCAM-1 levels in SGC-7901 cells by ChemiImagerTM 4000 digital system.

DISCUSSION

Many researches have indicated the importance of cancer cell-extracellular matrix (ECM) interaction in tumor metastasis. Cell and matrix interactions could promote cell migration, proliferation, and ECM degradation^[47-51]. It also has been shown that prevention of tumor cell adhesion and migration is related to inhibition of tumor cell invasion into the basement membrane. Laminin (LN), fibronectin (FN) and type IV collagen are the principal components of ECM. The *in vitro* assays of FN, LN, or Matrigel that mainly contain FN, LN and type IV collagen can better simulate the *in vivo* adhesive process. It was shown that agents that inhibited cell attachment *in vitro* decreased the invasion and metastatic potential of tumor cells *in vivo*. Therefore, cell adhesion assay not only is employed in determining the adhesive interaction between tumor cells and matrix components, but also is suitable in screening agents that can inhibit adhesion and metastasis of tumor cell. We demonstrated in our current study that after incubation with 200, 100, and 50 $\mu\text{mol/L}$ of *c9,t11*-CLA for 1 h, the attachment to extracellular matrix components of SGC-7901 cells was significantly reduced. The result was consistent with the findings in our previous study^[44]. Therefore, we could conclude that *c9,t11*-CLA could inhibit the attachment to extracellular matrix components of tumor cells and this process might be a mechanism for the inhibition of tumor invasion.

Before they can invade or metastasize, tumor cells have to dissociate from primary neoplasms. A loss of cell-cell adhesive interaction is required for the detachment. Thus, adhesion molecules play an important role in metastatic process. Cadherins have been found to be a class of calcium dependent cell adhesion molecules involved in homotypic cell-cell adhesion^[7,8]. E-cadherin is a member of the cadherin family that is expressed in all epithelial cells and is essential to the

maintenance of cell morphology, cell movement and cell adhesive function. Because E-cadherin can maintain cell adhesion, its abnormalities may be associated with tumorigenesis. It was proved that abnormalities of E-cadherin mRNA and E-cadherin protein expression existed in various human primary cancers, such as gastric, colon, pancreas, esophagus, liver, prostate, bladder, breast, and head and neck tumors^[52]. Recent studies showed that gene mutations or loss of heterozygous E-cadherin occurred in gastric carcinomas, ovary cancer, and cervix cancer. It was found that E-cadherin had strong expression in well-differentiated noninvasive cancers with tight cell-cell adhesion, and had markedly reduced, heterogeneous, or even no expression in undifferentiated invasive cancers with lack of cell-cell adhesion. Several studies have offered the evidence that reduction or structural alternation of E-cadherin expression plays a causal role in metastasis of gastric and colon cancers. The role of E-cadherin in metastasis and invasion was further demonstrated by the fact that the invasion of epithelial tumor cell lines was inhibited *in vitro* by transfection and expression of E-cadherin cDNA, and induced again by exposure to anti-E-cadherin monoclonal antibodies^[53]. Through its cytoplasmic sequence, E-cadherin was associated with a group of proteins called catenins, which are necessary for E-cadherin function^[54]. Dysfunction of catenin can cause instability of homotypic cell-cell adhesion mediated by E-cadherin. Therefore, in tumors with normal E-cadherin expression, alteration of cell adhesion may result from abnormal expression of catenins. Catenins have been classified into α -catenin, β -catenin, and γ -catenin. α -catenin links E-cadherin with cytoskeleton. Expression of α -catenin is essential to the function of E-cadherin in normal cells. Thus, in cancers with normal E-cadherin expression, decreased expression of α -catenin leads to impaired cell adhesion. Downregulation of α -catenin and E-cadherin expression in several cancer tissues has been found to be associated with differentiation degree, invasion and metastasis of cancer cells^[55-57]. Our current study demonstrated that after incubation with different concentrations of *c9,t11*-CLA for 24 h, expression of E-cadherin and catenin in SGC-7901 cells increased. Through upregulation of expression of E-cadherin and catenin, *c9,t11*-CLA also increased homotypic adhesion of cancer cells.

ICAM-1 is a 70-110 ku glycoprotein belonging to the immunoglobulin superfamily and is also a ligand for leukocyte-function associated antigen-1 (LFA-1). It has been reported that ICAM-1 could express on the surface of tumor cells, endothelial cells, keratinocytes, and mediate heterotypic cell-cell interaction^[58]. Several studies indicated that high expression of ICAM-1 in melanoma cells was associated with tumor metastasis, and expression on the surface of metastasizing cancer cells in lymph node increased significantly^[59]. It is suggested that high expression of ICAM-1 on the surface of metastasizing cancer cells in lymph node plays a role in evading immune destruction, thus helping these cancer cells retain in lymphatic sinus to form metastasis. VCAM-1 is a 90 ku cell surface glycoprotein belonging to the immunoglobulin superfamily. Studies also showed that VCAM-1 in renal cell carcinoma, melanoma, and malignant sarcoma linked tumor cells to endothelial cells via binding to integrin $\alpha_4\beta_1$, and contributed to penetration into blood vessels^[60]. We demonstrated here that different concentrations of *c9,t11*-CLA could decrease expression of ICAM-1 and VCAM-1 in SGC-7901 cells after incubation for 24 h and also decrease heterotypic adhesion of cancer cells via downregulation of expression of ICAM-1 and VCAM-1.

In conclusion, *c9,t11*-CLA can inhibit cell-matrix component interactions, increase expression of E-cadherin and catenin and reduce expression of ICAM-1 and VCAM-1 in

SGC-7901 cells. Through these effects, *c9,t11*-CLA may inhibit the invasion of SGC-7901 cells.

Abstract

AIM: Hepatocellular carcinoma (HCC) with bile duct tumor thrombosis (BDT) is a rare event. The prognosis of this type of patients is very dismal. The aim of this study was to share the experience in the diagnosis and treatment of HCC with BDT, to further improve the prognosis of these patients.

METHODS: Thirty-four patients of HCC with BDT received surgical treatment in authors' institute from July 1987 to January 2003 were reviewed retrospectively. The experience in the diagnosis and treatment, and the outcome of this type of HCC patients were summarized.

RESULTS: Thirty of the 34 patients (88.2%) were positive for alpha-fetoprotein (AFP) ($>20 \mu\text{g/L}$), and 12 patients (35.3%) were found having obstructive jaundice before operation, 18 cases were suspected of "obstruction of bile duct" preoperatively. The primary tumors were frequently located at the left medial (13 cases) or right anterior lobe (14 cases). Thirty-one patients received liver resections and removal of BDT, while the other 3 patients received removal of BDT combined with hepatic artery ligation and cannulation (HAL+HAI), or only removal of BDT because their liver function reservation and general condition could not tolerate the primary tumor resection. The 1-year survival rate was 71.4%(20/28). The longest disease-free survival was over 15 years. The intrahepatic tumor recurrence within 1 year after operation was found in 14 patients (14/28, 50.0%).

CONCLUSION: Surgical removal of primary tumors and BDT is safe and beneficial to the HCC patients with BDT. Early detection, diagnosis, and surgical treatment are the key points to prolong the survival time of patients.

INTRODUCTION

Obstructive jaundice as the main presenting clinical feature is uncommon in patients with hepatocellular carcinoma (HCC). Only 1-12% of patients with HCC manifest obstructive jaundice as the initial complaint^[1-3]. Mallory *et al.* described

the first such case in 1947, in which HCC invaded the cystic duct and gave rise to obstructive jaundice caused by the tumor thrombosis^[4]. These kinds of patients were clinically classified as "icteric-type hepatoma"^[5] or "cholestatic type of HCC"^[6].

Tumor thrombus in bile duct (BDT) is one of the main reasons for obstructive jaundice. The incidence was 1.2-9% in previous reports^[2,3,5-8]. However, Huang *et al.* found the incidence was only 0.53%^[9]. It is usually difficult to make diagnosis before operation, because of the low incidence rate, ignorance of this disease, and the difficulty for the imaging diagnosis to find the BDT preoperatively. The prognosis of this type of HCC patients is very dismal, but is better than those with jaundice caused by hepatic insufficiency. Identification of this group of patients is clinically important, because surgical treatment may be beneficial. In this study, we summarized our experience in the diagnosis and treatment of 34 cases of this type of HCC during the past 15 years.

MATERIALS AND METHODS

Patients' information

From July 1987 to January 2003, totally 4 324 patients suffering from HCC received surgical treatment in Liver Cancer Institute and Zhongshan Hospital, Fudan University (former Shanghai Medical University), and 34 cases (0.79%) were found having tumor thrombosis in bile duct. Among of them, 28 cases were male, and 6 cases were female. The mean age of patients was 48.5 years (32-76 years). The history of hepatitis B virus (HBV) infection or HBsAg positive was found in all of the patients, and liver cirrhosis in 94.1%(32/34) of patients. Thirty of them (30/34, 88.2%) were positive for alpha-fetoprotein (AFP) ($>20 \mu\text{g/L}$), and the highest was over 2 000 $\mu\text{g/L}$. Preoperative obstructive jaundice was found in 12 patients (12/34, 35.3%), and 2 of them had the history of "transient cholangitis" with the manifestation of transient jaundice. The history of "hemorrhage of upper digestive system" was found in 2 patients. Four patients had the history of preoperative transcatheter arterial chemoembolization (TACE) (Table 1).

Imaging diagnostic features

Ultrasonography (US) and CT scan were performed in all of the patients. Magnetic resonance cholangiography (MRCP) was also done in 12 patients in recent 3 years. (Figures 1, 2) Eighteen cases were suspected of "obstruction of bile duct" because of the occurrence of preoperative jaundice (12 cases), and/or dilation of intrahepatic bile duct shown in imaging diagnosis (in 6 cases without obstructive jaundice). Only 9 cases of them were obviously shown tumor thrombosis in the bile duct by US, CT scan or MRI preoperatively. One case with neoplasm in the bile duct, while no obvious intrahepatic lesion, was misdiagnosed as cholangiocarcinoma, in spite of the positive AFP.

Characteristics of the primary tumors and BDT

The size of primary tumors was 6.4 ± 2.5 cm in diameter (2-15 cm). All of the primary tumors had no capsule, with unclear tumor margin, and invasive pattern of growth. The primary tumors

were located at the segment IV in 13 cases, right anterior section (segments V and VIII) in 14 cases, segment I (caudate lobe) in 1 case, segment II-III in 4 cases, and segment VI in 2 cases. The tumor thrombus located at left hepatic duct (LHD) in 5 cases, LHD to common hepatic duct (CHD)/common bile duct (CBD) in 9 cases, right hepatic bile duct (RHD) in 5 cases, RHD to CHD/CBD in 8 cases, and CBD in 7 cases. According to Ueda classification^[10], 2 cases belonged to type I, 8 cases type II, 16 cases type IIIa, 1 case type IIIb, and 7 cases type IV. In 2 cases, the BDT was as long as 6 cm, and 9 cm, respectively (Table 1, Figure 1).

Treatment strategies

All of the patients received surgical treatment. Thirty-one patients received liver resection and removal of the tumor thrombosis (or thrombectomy). Among them, 12 patients received left hemihepatectomy, 2 cases received left lateral sectionectomy, 11 cases received limited partial resection of the liver, 5 cases received right hemihepatectomy, and 1 case received resection of the left lobe and caudate lobe of liver, and CHD, and RHD-jejunum anastomosis. Two patients received removal of CBD thrombosis combined with hepatic artery ligation and cannulation (HAL+HAI), and 1 patient

Figure 1 The hepatocellular carcinoma (HCC) with tumor thrombosis in common bile duct. A-C: The three phases of CT scan. One small HCC with rich arterial blood flow is shown in the left medial lobe of liver (arrow), with the intrahepatic bile duct of both sides and common hepatic duct dilated obviously (arrow). D: The tumor thrombosis removed from the common bile duct of this HCC patient.

Figure 2 The imaging diagnosis of hepatocellular carcinoma with thrombosis in bile duct. A and B are pictures of CT scan, C and D are pictures of magnetic resonance cholangiography (MRCP). These pictures show the primary tumor in right anterior lobe of the liver, with tumor thrombosis in common hepatic duct (arrow).

received removal of BDT only because their liver function reservation and general condition could not tolerate the primary tumor resection.

The tumor thrombi were removed by the exploration of CBD in 14 cases, from the cut end of the bile duct after liver resection in 15 cases, and *en bloc* removal with the primary tumor in 5 patients. Intraoperative active bleeding from the CHD after removal of the thrombosis happened in 1 patient, and hemostasis was achieved finally by infusing noradrenalin in normal saline into the bile duct and oppressing locally.

The operations were well tolerated. After operation, the obstructive jaundice due to BDT was successfully relieved in all but 2 patients. One patient with severe liver cirrhosis and preoperative obstructive jaundice (the total serum bilirubin was 182 $\mu\text{mol/L}$) received partial resection of the right liver lobe, and died of liver failure at the 35th d after the operation. Another patient with severe preoperative obstructive jaundice (total serum bilirubin was 320 $\mu\text{mol/L}$, and the direct bilirubin was 210 $\mu\text{mol/L}$) received right hemihepatectomy and removal of thrombosis in CBD, the total serum bilirubin did not decrease although the general condition of the patient was good, the patient himself chose to give up the treatment and left the hospital at the 40th d after the operation. A third patient with obstructive jaundice (preoperative total serum bilirubin was 156 $\mu\text{mol/L}$) due to BDT in the CBD received left hemihepatectomy and removal of BDT. His total serum bilirubin rose to over 700 $\mu\text{mol/L}$ in 2 wk after operation, and finally returned to normal in 3 mo. By now, this patient has survived for 11 mo.

Table 1 The clinical information of the 34 HCC patients with tumor thrombosis in bile duct

Items	Cases (%)
Sex	
Male	28 (82.4%)
Female	6
HBV infection	
HBsAg+	34 (100%)
Liver cirrhosis	32 (94.1%)
AFP	
>20 $\mu\text{g/L}$	30 (88.2%)
≤20 $\mu\text{g/L}$	4
Obstructive jaundice	
+	12 (12, 35.3%)
-	
Ueda classification	
Type I	2
Type II	8
Type IIIa	16
Type IIIb	1
Type IV	7
Treatment	
Surgical resection	31 (91.2%)
Removal of BDT +HAL+HAI	2
Only removal of BDT	1
Survival	
>1 yr	20 (20/28, 71.4%)
>3 yr	3
>15 yr	1
HCC recurrence	
Within 1 yr	14 (14/28, 50.0%)
Within 3 mo	9 (9/31, 29.0%)

Survivals

The follow-up was up to February of 2003. Twenty-eight patients

were followed-up over 1 year. Twenty patients survived over 1 year. One-year survival rate was 71.4%(20/28). The longest disease-free survival time was over 15 years. It occurred in one female patient who received left hemihepatectomy and removal of the tumor thrombosis in CBD (Ueda type IV) in July of 1987. She was still alive without recurrence of cancer up to the last follow-up. Another female patient who received partial resection of right lobe and removal of BDT from the RHD (Ueda type II) in August of 1993 had survived over 9 years without recurrence. The third female patient received right hemihepatectomy and removal of CHD thrombosis (Ueda type IIIa) in May of 1995, and received the second operation due to HCC recurrence 3.5 years later. One male patient who received right hemihepatectomy in September of 1999 (Type II) had also survived over 2 years without recurrence. Fourteen patients (14/28, 50.0%) were found intrahepatic HCC recurrence within 1 year after operation. Nine of them (9/31, 29.0%) were found intrahepatic recurrence within 3 mo after operations. The survival times of the 3 patients received biliary decompression were only 2, 3, and 3.5 mo, respectively (Table 1).

DISCUSSION

Obstructive jaundice caused by BDT, especially as the initial presentation of HCC, is a rare event. And little is known about this type of HCC. However, there are more and more reports about this type of disease, and the incidence is increasing in patients with HCC^[11]. In this study, only 34 out of the 4 324 HCC patients who received surgical treatment in authors' institute were found BDT. The incidence was only 0.79%. And more, most of them (26/34, 76.5%) were treated in recent 5 years. This might be due to the increased understanding of this type of HCC, further improvement of diagnosis (particularly the imaging diagnosis), and more positive attitude towards the treatment to this kind of patients.

HCC invades into bile duct through the following different mechanisms: a distal tumor may grow continuously until it fills the entire extrahepatic biliary system; a fragment of necrotic tumor may separate from the proximal intraductal growth, migrate to the distal common bile duct and cause an obstruction; hemorrhage from the tumor may partially or completely fill the biliary tract with tumor-containing blood clots^[2,3,7-9,12,13]. These produce different types of BDT which will also affect the patients' prognosis^[10]. In this series, 4 patients without any obvious evidence of BDT at initial diagnosis were found BDT after TACE treatment, which suggested that TACE might increase the possibility of BDT^[11]. The exact mechanism is not clear yet.

Just as other types of HCC, no specific symptoms could be found in the early stage. Only when intraductal tumor growth occurs in the CHD and/or CBD does obstructive jaundice become a clinical concern. The common clinical features include high level of serum AFP, the history of cholangitis with dilation of intrahepatic bile duct, aggravating jaundice and rapidly developing into liver dysfunction. Unexplained hemobilia could be the initial complaint without any manifestation of primary tumor. And "hemorrhage of upper digestive system", which might be due to the hemorrhage of bile duct (hemobilia), could also be the first manifestation. The most important point is that we should think about the possibility of BDT when these manifestations are found in HCC patients.

There are still difficult and challenging problems in differential diagnosis of this type of HCC before operation. Despite remarkable recent improvements in the imaging techniques for diagnosis of HCC, such cases were still incorrectly diagnosed as cholangiocarcinoma or choledocholithiasis^[2,7-14]. In this series, only 9 out of the 18 cases suspected of "obstruction

of bile duct" were obviously shown BDT with US or CT scan preoperatively. The others were misdiagnosed as "bile duct stone" or cholangiocarcinoma, even though "neoplasm in CBD" was found. All of these suggest that deeper understanding of this type of disease is the key to further improving the diagnosis preoperatively. Further advanced imaging examination should be performed if the intrahepatic bile duct of one lobe or around the tumor is found dilated. The existence of tumor thrombosis in bile duct should be considered when an occupying lesion is found within bile duct. Fortunately, in recent years, more correct preoperative diagnosis could be made in this type of patients.

MR cholangiography (MRCP) is an absolutely noninvasive imaging modality, which has been shown to be superior to ERCP in detecting the presence of biliary obstruction. Both primary liver tumors and dilatation of biliary system could be demonstrated in MRCP^[15]. Presence of intraluminal soft tissue at the bile duct, and enhancement of the intraluminal soft tissue in the arterial phase are 2 typical features of HCC with BDT (Figure 2). However, these characteristic cholangiographic features should be differentially diagnosed with papillary type cholangiocarcinoma, intraductal polyps or mucin-hypersecreting intrahepatic biliary neoplasm, or intrahepatic cholangiocarcinoma with invasion of extrahepatic bile duct, and even the bile duct stones^[16]. It still relies on other information, such as the presence of liver cirrhosis, hepatitis markers, tumor markers (AFP, CEA), the fluctuation of jaundice, and hemobilia.

The prognosis of this type of HCC is generally dismal, particularly for those with obstructive jaundice^[2,3]. However, the prognosis of these patients is better than those HCC patients who have jaundice caused by hepatic insufficiency, which is closely related to the stage of disease, the location and extent of BDT. Different therapies also influence the prognosis of this type of patients. Surgical resection is the only way that possibly cures the patients. Jaundice is not necessarily a harbinger of advanced disease and a contraindication for surgery. The goals of operative intervention are biliary decompression with removal of tumor debris or tumor-containing blood clots, and, if possible, curative resection of the hepatic tumor. The usually used operative methods are lobectomy (including the primary tumor and the tumor thrombosis in bile duct), hepatectomy combined with thrombectomy, biliary decompression and drainage (choledochotomy with T-tube drainage alone, internal biliary stenting, or biliary diversion). The ideal treatment is hepatic resections^[17-19]. Patients who received curative liver resection had a much better survival rate than those without resection^[20-24]. In our series, the postoperative 1-year survival rate of patients was 71.4%, 1-year disease-free survival rate was 21.4%, and one patient has survived over 15 years. These are better than that of previous reports. It might be attributed to active attitude of the doctors and appropriate procedures of treatment taken. All of the 4 long-term survivors received major liver resection (hemihepatectomy) and removal of BDT, while the 3 patients who received biliary decompression only survived 2, 3, and 3.5 mo, respectively. So, to improve survival, if the patient's liver function and general condition could tolerate, it is suggested to perform major liver resection with removal of BDT. However, it should be very careful to perform major liver resection for those patients with both severe liver cirrhosis and severe obstructive jaundice, because their liver function reservation is very poor. In this series, one patient died of liver failure postoperatively even though his liver function test was good (except for obstructive jaundice). If hepatic resection cannot be accomplished with bile duct resection due to limited liver function, non-surgical modalities should be considered instead of surgery.

Surgical intervention is very effective to relieve the

obstruction of bile duct in this type of patients. It could take a long time (such as 3 mo in one case of this study) for the serum bilirubin of patients with obstructive jaundice to return to normal, or even transiently increase in short time after operation though the obstruction in bile duct has been dispelled completely. The altering pattern and the duration for the serum bilirubin to return to normal after operation, especially for those with severe preoperative obstructive jaundice, still need further studying.

The ideal way to remove BDT is *en bloc* resection with the primary tumor. It is also relatively easy to remove BDT either with the exploration of CBD or from the cut-end of bile duct after hepatectomy. However, active hemorrhage occurred during operation in some cases, possibly because of the continuity of the intraductal tumor debris with the main intrahepatic tumor. In this study, we met one patient with active bleeding during the operation after removing the thrombosis from the common hepatic duct. The hemostasis was achieved finally by infusing noradrenalin in normal saline into the bile duct and oppressing locally. Suturing, electrocauterization, compression, Pringle's maneuver, or hepatic arterial ligation are some alternative ways to achieve hemostasis.

BDT often grows faster than the primary cancer. We found in 2 cases, the BDT was as long as 6 cm, and 9 cm, respectively, while their primary HCC less than 6 cm. The primary tumor often has no capsule, with unclear tumor margin, and invasive growth. The infiltrative nature of this particular type of HCC may in part explain their invasion of the biliary tree early in their growth without regard to tumor size or type^[25,26], which might also be one of the reasons that the prognosis of this type of patients was very poor. In this series, the 1-year recurrence rate was 50.0%, and as high as 29.0% of the patients were found having tumor recurrence within 3 mo after operation. This might also indicate the poor malignant phenotype of this type of HCC. Combined chemotherapy or chemoembolization might be helpful to control the postoperative recurrence^[27].

In summary, HCC with tumor thrombosis in bile duct, particularly with obstructive jaundice as the main presenting clinical feature, is uncommon. The prognosis of this type of HCC is generally dismal, but is better than those HCC patients who have jaundice caused by hepatic insufficiency. Jaundice is not necessarily a harbinger of advanced disease and a contraindication for surgery. If appropriate procedures are selected and carried out safely, it can result in long-term relief of symptoms and occasional long-term survival. Deeper understanding, and active attitude to treatment of this type of disease are the keys to further improving survival of these patients.

Abstract

AIM: To gain tumor endothelium associated antigen genes from human liver cancer vascular endothelial cells (HLCVECs) cDNA expression library, so as to find some new possible targets for the diagnosis and therapy of liver tumor.

METHODS: HLCVECs were isolated and purified from a fresh hepatocellular carcinoma tissue sample, and were cultured and proliferated *in vitro*. A cDNA expression library was constructed with the mRNA extracted from HLCVECs. Anti-sera were prepared from immunized BALB/c mice through subcutaneous injection with high dose of fixed HLCVECs, and were then tested for their specificity against HLCVECs and angiogenic effects *in vitro*, such as inhibiting proliferation and inducing apoptosis of tumor endothelial cells, using immunocytochemistry, immunofluorescence, cell cycle analysis and MTT assays, etc. The identified xenogeneic sera from immunized mice were employed to screen the library of HLCVECs by modified serological analyses of recombinant cDNA expression libraries (SEREX). The positive clones were sequenced and analyzed by bio-informatics.

RESULTS: The primary cDNA library consisted of 2×10^6 recombinants. Thirty-six positive clones were obtained from 6×10^5 independent clones by immunoscreening. Bio-informatics analysis of cDNA sequences indicated that 36 positive clones represented 18 different genes. Among them, 3 were new genes previously unreported, 2 of which were hypothetical genes. The other 15 were already known ones. Series analysis of gene expression (SAGE) database showed that *ERP70*, *GRP58*, *GAPDH*, *SSB*, *S100A6*, *BMP-6*, *DVS27*, *HSP70* and *NAC alpha* in these genes were associated with endothelium and angiogenesis, but their effects on HLCVECs were still unclear. *GAPDH*, *S100A6*, *BMP-6* and *hsp70* were identified by SEREX in other tumor cDNA expression libraries.

CONCLUSION: By screening of HLCVECs cDNA expression library using sera from immunized mice with HLCVECs,

the functional genes associated with tumor endothelium or angiogenesis were identified. The modified SEREX, xenogeneic functional serum screening, was demonstrated to be effective for isolation and identification of antigen genes of tumor endothelium, and also for other tumor cell antigen genes. These antigen genes obtained in this study could be a valuable resource for basic and clinical studies of tumor angiogenesis, thus facilitating the development of anti- angiogenesis targeting therapy of tumors.

INTRODUCTION

Angiogenesis is a critical event in solid tumor growth, invasion, and metastasis. Recently, more attractive targets are thought to be vasculature of tumor compared with tumor cells themselves in the therapy of solid tumor^[1]. Tumor endothelium is a key mediator during the complex process of tumor angiogenesis. There will not form new blood vessels in tumor if tumor vascular endothelia are lacking of the functions of proliferation, activation, adhering, migration and vessel formation. To date, the morphology, phenotype, functional aspects and gene expression observed in tumor-derived endothelial cells (TEC) were proven to be different from normal-derived endothelial cells (NEC)^[2,3]. Virtually, the therapeutic strategy of solid tumors targeting for tumor vasculature makes use of these differences. Various methods have been developed to identify the differences between TEC and NEC, such as serial analysis of gene expression (SAGE)^[4], suppression subtractive hybridization (SSH)^[5], antibody target^[6], immunohistochemical analysis of known endothelial adhesion molecules^[7] phage display peptide library^[8], and cDNA microarray^[9], etc. Due to the difficulty of isolating highly purified TEC, most studies now selected activated endothelial cells as a substitute, however, the activated endothelial cells cannot completely represent TEC.

SEREX has recently emerged as a powerful method for serological identification of tumor associated antigens (TAAs) and/or tumor rejection antigens (TRAs). Up to date, more than 1 000 candidate tumor antigens in various cancers have been identified^[10,11]. Tumor antigens identified by SEREX could provide valuable targets for cancer diagnosis, therapy and the study of cancer vaccines. Similarly, the proliferation-associated antigens on tumor endothelial cells may be more useful candidates for antiangiogenic therapy/vascular targeting therapy of tumor. However, up to the present, no data are available that associated antigen genes have been isolated from TEC.

The goal of this study was to define tumor endothelium associated antigen genes by the method of modified SEREX.

Therefore, we constructed and screened the HLCVECs cDNA expression library with murine immunosera of anti-HLCVECs, and identified 18 HLCVECs associated antigen genes. These genes may not only provide a valuable tool for study on the roles of endothelial cells in tumor angiogenesis, but also some potent candidate targets for antiangiogenic therapy of cancer. Our results in this report also indicated that the approach of screening cDNA expression library with functional xenogeneic sera, a modified SEREX, could be an effective strategy for isolation and identification of tumor endothelium associated antigen genes.

MATERIALS AND METHODS

Tumor tissue samples and cells

Human tumor tissue was obtained from therapeutic surgical resection of one patient with hepatocellular carcinoma (HCC) at the Cancer Hospital of Peking Union Medical College. After surgical removal, the tissue sample was immediately transferred to the laboratory in cold culture medium (DMEM, GIBCO) with penicillin (400 U/mL) and EDTA (1 g/L) and was isolated for 2 h. Human umbilical vein endothelial cells (HUVECs) were isolated as described^[12]. HUVECs were stimulated to generate activated HUVECs with endothelium growth medium (Clontech) containing EC growth factors and tumor tissues homogenate prepared in our laboratory.

Isolation, purification and culturing of HLCVECs

Isolation, purification and culturing of HLCVECs were performed by previously described method^[13,14] with some modifications. Briefly, the liver cancer tissue from patient with HCC was finely minced with curved scissors into approximately 2 mm×2 mm×2 mm pieces, then was re-suspended in 20 mL of 1 g/L trypsin (type II, Sigma) in DMEM containing 1 g/L EDTA and incubated for 10 min at 37 °C. After digestion, the whole suspension was filtered through a 200 µm melt mesh sieve and the filtrate was washed twice in DMEM by centrifugation at 450 r/min for 5 min at room temperature. The pellet was re-suspended in 5 mL of DMEM + 100 g/L FCS (Hyclon) added to 25 mL of 200 g/L percoll (Pharmacia Biotech) in DMEM and centrifuged at 1500 g for 15 min at 4 °C. Again, the cell pellet was washed twice. The isolated cells were resuspended in complete culture medium (DMEM containing 200 mL/L FCS, 2 mmol/L L-glutamin (GIBCO), 100 µg/mL antibiotic (penicillin/streptomycin), 100 µg/mL endothelial cell growth supplement and 40 U/mL heparin). The cells were seeded into a 20 g/L gelatin-coated 6-well plate (FALCON), and cultured at 37 °C in 50 mL/L CO₂ incubator and the medium was changed every 3 d, the purification could be carried out by the way of sub-cell colonies after 1 wk. The cells were cultured and proliferated in gelatin-coated T75 plastic tissue culture flasks (Falcon), and passaged by 1 g/L trypsin (1 g/L EDTA). The purified endothelial cells were identified by immunocytochemistry for von Willebrand factor (vWF), CD31 and uptake of Ac-LDL. Fenestration was demonstrated by transmission electron microscopy.

Preparation of the anti-HLCVECs immunosera

Female BALB/c mice (6-8 wk) were purchased from Experimental Animal Center of Peking Union Medical College. Six mice were immunized with HLCVECs (immunized), and 4 mice were treated with PBS alone (non-immunized). All studies on mice were approved by the institute's Animal Care and Use Committee.

Sera were obtained as described^[15]. For the generation of immunosera, mice were immunized subcutaneously with 1-6×10⁶ HLCVECs fixed with 30 g/L paraformaldehyde in PBS or PBS alone once weekly for 8 continuous weeks. Serum was obtained from each mouse of immunized and non-immunized on d 21, 28, 35, 42, 49 and 56 after the first immunization. Serum from each

mouse of immunized and non-immunized groups was serially diluted, and the reactivity against HLCVECs was examined by immunocytochemistry.

Immunofluorescence

To determine the reactivity of sera from immunized and non-immunized mice reacting to different endothelium, HLCVECs, HUVECs and activated HUVECs were seeded onto glass coverslips in 6-cm plates, then fixed in cold acetone and incubated with serially diluted sera isolated from immunized or non-immunized mice at 37 °C for 1 h, fluorescein-conjugated goat-anti-mouse IgG (H+L) (Sigma) was subsequently applied to them and incubated for another 1h, then to be restained by 0.1 g/L Evens Blue and washed 3 times by PBS. The results were observed under fluorescence microscope (Nicon)^[16].

MTT assay

Approximately 8×10³ cells in 200 µL DMEM were seeded in triplicate into each well of the 96-well tissue culture plates, and immunized or non-immunized sera diluted at 1:30, 1:90, 1:270, 1:810, 1:2 430, 1:7 290 and 1: 21 870 were added to corresponding wells. After 72 h of incubation, 10 µL MTT (100 mg/mL) reagent was added to each well (5 g/L), and incubated for 4 h at 37 °C, 50 mL/L CO₂. Subsequently, 180 µL medium was pipetted out from each well and 50 µL DMSO was added to it. The absorbency A₅₇₀, which correlates to the number of cells, was measured with micro-plate reader (Model 450, Bio-Rad)^[17].

Cell cycle analysis by flow cytometry

HLCVECs were serum starved for 24 h and then treated with immunized and non-immunized sera diluted at 1:100 for 6 h. Cells were trypsinized, washed twice in PBS. Totally 1×10⁶ cells were resuspended in 500 µL PBS and stained with 500 µL propidium iodide (10 µg/mL, Sigma) for 30 min. Flow Cytometry (Becton) was performed to determine DNA content and apoptosis^[18].

Construction of cDNA expression library

The mRNA was directly extracted from HLCVECs with mRNA extraction kit (mRNA Poly(A) Tract System 1 000, Promega, Madison, WI), Oligo (dT)-primed double-stranded cDNA was synthesized from 6 µg purified mRNA and ligated into the ZAP phage expression vector DNA according to the user's manual (including THERMO Script™ RT-PCR System Kit, ZAP-cDNA synthesis kit, ZAP-cDNA Gigapack III Gold Mrna Cloning kit, Stratagene).

Screening the HLCVECs cDNA expression library with immunosera

Immunoscreening of the HLCVECs cDNA expression library was performed as described previously^[19] with the following modifications. Sera from immunized mice were diluted 1:10 and preabsorbed with lysate from *Escherichia coli* (*E.coli*) strain XL-1 coupled to Sepharose 4B to remove antibodies reacting with *E.coli* components. X-L1 infected with recombinant phage vectors containing HLCVECs cDNA were plated onto NZY-tetracycline-agar plates. After induction of protein synthesis in *E.coli*, we transferred the expressed polypeptides onto nitrocellulose membranes (Gelman) and incubated them with 1:500 diluted pre-absorbed sera overnight at 4 °C in the first screening. After being washed, the filters were incubated with a 1:10 000 dilution of alkaline phosphatase-conjugated goat-anti-mouse IgG (H+L) (Secondary Ab, Sigma) for 1-2 h at room temperature. Reactive clones were visualized with 5-bromo-4-chloro-3-indolyl-phosphate/nitro blue tetrazolium tablets (BCIP/NBT, Sigma). Only clones that appeared blue were considered serum positive. The positive clones were picked out and plated on NZY-tetracycline agar plates for secondary screening with

1:5 000 dilluted pre-absorbed immunosera. Subsequently, positive clones were subcloned 2 times to obtain monoclonality.

Sequence analyses of the reactive clones

Identified and subcloned positive clones were converted to pBluescript phagemide forms by *in vitro* excision, plasmid was purified and subjected to *Eco*R I and *Xho*I restriction enzyme digestion. Clones representing different cDNA inserts were sequenced with T3 primers by the dideoxy chain termination method using the Big Dye Terminator Cycle Sequencing Kit (PE Applied Biosystems, Foster city, CA) and an ABI PRISM automated DNA sequencer (Perkin-Elmer, Norwalk, CT). DNA and predicted amino acid sequences were compared with sequences in the GenBank and other public databases by using the BLAST program.

RESULTS

Identification of HLCVECs

The heterogeneity of human TEC is detectable at different levels and differentiates the behavior between different tumor tissues. HLCVECs here belong to micro-vascular ECs, and they grow in a monolayer and exhibit contact inhibition properties. Using electron microscopy, surface fenestrations and Weibel-Palade (W-P) bodies were observed in HLCVECs. Immunofluorescence staining showed that these cells expressed vWF, CD31 and took up large amounts of Ac-LDL (Figure 1). These results demonstrated that isolated and purified HLCVECs expressing specific markers of endothelial cells, especially fenestration, a tumor endothelium-specific structure, were also found in HLCVECs.

Detection of antibodies against endothelial cells in immunosera

The antibody titer in sera from immunized mice with HLCVECs are shown in Table 1. Titer of antibody reached 1:1 000 at 21 d after the first immunization, 1:9 000 at 42 d and 1:27 000 at 49 d as well as at 56 d. In contrast, the sera from non-immunized

mice were negative for anti-HLCVECs response. A similar antibody response, with a minimal variation in titer, was seen in all six immunized mice.

To determine whether differences existed in reactivity of sera from mice immunized with HLCVECs with human TEC versus NEC, immunofluorescence was applied to detect the reaction of anti-HLCVECs sera with HLCVECs, HUVECs and activated HUVECs. The results indicated that 1:500 dilution of the immunized serum showed the same degree fluorescence staining in HLCVECs and activated HUVECs, but the staining in HUVECs was distinctly weaker than that of the other 2 kinds of cells. The 1:5 000 dilutions of immunosera showed markedly stronger staining with HLCVECs than with activated HUVECs (Figures 2A and 2B), whereas the staining of HUVECs was completely negative in this dilution (Figure 2C). By comparison, the staining of all the 3 kinds of cells was negative when reacting with sera from non-immunized mice. Simultaneously, the fluorescence staining was observed in the membrane of positive endothelial cells. These data indicated that the murine anti-HLCVECs sera contained the specific antibodies with a high titer against TECs.

Table 1 Titer of anti-HLCVECs antibody in immunized animals

	D21	D28	D35	D42	D49	D56
HLCVEC	1:1 000	1:3 000	1:9 000-	1:9 000	1:27 000	1:27 000+

1 : 9 000- indicates that the titer is lower than 1:9 000, 1:27 000+ indicates that the titer is 1:27 000 or higher.

Identification of the effect of immunosera on ECs growth

To investigate whether the immunosera have any effects on the proliferation of HLCVECs, HLCVECs were treated with variously diluted sera isolated from mice immunized or non-immunized with HLCVECs. MTT assay demonstrated that the growth and proliferation of HLCVECs were apparently inhibited by the sera from immunized mice with HLCVECs, and there was

a dose dependent response from 1:30 to 1:2 430 dilution of the murine immunosera, while no inhibitory effects were observed in sera from non-immunized mice. Figure 3 shows the results of serum from one of six immunized mice and one of 4 non-immunized mice.

Using MTT assay, we observed that human TEC growth was inhibited when they were incubated with the immunosera, however, the underlying mechanism was unknown. We therefore studied further the effects of the sera on cell cycle of human TEC with Flow Cytometry. The results showed that the amount of apoptotic cells were increased in the group of immunosera compared with the group of non-immunosera at 6 h after treatment (Figure 4). Approximately 20.1% apoptotic cells were seen in the group of immunized serum and only 4.9% apoptotic cells were observed in the group of non-immunized serum. The results further indicated that, in terms of specificity and the effects on human TEC, the immunized sera were suitable to screen the HLCVECs cDNA expression library to obtain endothelium associated antigen genes.

Isolation of HLCVECs associated antigens genes by modified SEREX

HLCVEC cDNA expression library with 2×10^6 primary clones was established (Table 2). The 6×10^5 clones were immunoscreened with pooled sera from six immunized BALB/c mice collected on d 56 after inoculation of HLCVECs. Primary screening with 1:500 diluted pooled immunosera yielded 153 positive clones (named EC1 to EC153). After secondary screening with 1:5 000 immunosera and subcloning, a total of 36 positive clones were obtained (Figure 5). These 36 clones were then excised, to phagemide forms and purified *in vitro*. The size of inserts of these positive clones were determined by restriction enzyme digestion with *Eco*R I and *Xho*I, which yielded inserts sized from 900 bp to 3 600 bp, with an average of about 1 500 bp (Figure 6).

Figure 3 Inhibition of the HLCVECs proliferation by HLCVECs immunized murine serum from 1 of 6 immunized mice and 1 of 4 non-immunized mice. Points are the average of three wells.

Sequence analysis of the positive clones

Nucleotide sequences of cDNA inserts of 36 positive clones were sequenced. Sequence alignments were analyzed with DNASIS and BLAST software on EMBL and GeneBank. These 36 positive clones represented 18 different antigen genes (Table 3). EC36 was represented by 11 overlapping clones, EC42 by 6 overlapping clones, EC 62 by 4 overlapping clones and the others by a single clone. Of these 18 clones, 3 clones were new unknown genes, 2 of which may be functional genes encoding hypothetical proteins. The other 15 genes were known. However, all of them were first isolated and reported in the endothelial cells of human HCC here. By SAGE database analysis, the 15 genes can be grouped into different classes: (1) 9 of these genes are associated with endothelium and angiogenesis, such

as EC26, EC52, EC59, *etc.* (2) 4 of these genes have been reported previously as tumor antigen genes, such as NAPDH, S100A6, BMP-6 and hsp70, (3) The other genes are involved in genes transcription, protein translation and cell mitosis, such as inner membrane protein gene (IMMT).

DISCUSSION

Tumor angiogenesis is dependent on biochemical processes mediating the formation and development of the blood capillary network that supplies the tumor. In recent years, increasing evidence has indicated that targeting tumor vasculature is a very promising strategy for the therapy of solid tumor. Identifying molecular markers, target genes and antigen on endothelial cells of tumor vessels, in turn, is critical for the antiangiogenic therapeutic strategy of tumor. A number of researchers have gained some endothelia associated genes from activated HUVECs with cell growth factors and supernatant of cultured tumor cells. But it is difficult to determine tumor specific endothelial genes by these ways, because activated endothelium cannot completely represent tumor endothelium. In 2000, Croix^[4] first reported in *Science* that they successfully isolated tumor endothelium from human colorectal cancer and gained tumor endothelium associated genes by the method of SAGE. In the present study, to obtain specific endothelium genes of human liver cancer vascular endothelial cells, we isolated and purified endothelial cells from liver tumor tissue of the patients with HCC. These endothelial cells were confirmed to have characteristics of endothelial cells with expressing vWF, CD31, W-P bodies and taking up high level of Ac-LDL, *etc.*, and also have the structure of fenestrations found only in tumor endothelial cells. From cDNA expression library constructed with above purified HLCVECs, we isolated 18 endothelia associated genes. Some of them were related to human TEC. Up to date, there have been no reports about the successful isolation of human liver cancer vascular endothelial cells and their specific genes.

Over the past years, efforts have been made to isolate and identify the proliferating TEC genes, including the methods of phage display peptide libraries, SSH and SAGE analysis, *etc.* However, the genes identified using these methods, in terms of their specificity and functions were rarely known. Therefore, in this study, to isolate and identify functional TEC associated antigen genes, we modified traditional SEREX and used it to screen cDNA expression library of HLCVECs. SEREX has recently emerged as a powerful method for identification of human tumor-associated antigen. The identification of tumor antigens with SEREX was based on the existence of autoantibodies in sera of patients^[10]. It is not unexpected that the method is applicable to only a limited number of patients because autoantibodies against most antigens can only be detected in 10-30% patients who bear tumors expressing the corresponding antigens. Therefore, a number of modifications have been made since the introduction of SEREX methodology to expand the range of antigens identified. These modifications include using established cell lines instead of tumor specimen to construct the cDNA library, and using allogeneic sera or xenogeneic sera instead of autologous sera as the antibody source. Hideho *et al.*, introduced the "cytokine-assisted SEREX (CAS)", which resulted in an enhanced capacity to identify glioma tumor associated antigens (TAAs) with characteristics similar to TAAs identified by traditional SEREX^[19-21]. Despite extensive screening of various tumor cDNA libraries with sera from tumor patients, however, identification of human tumor endothelium associated antigens by SEREX have not been reported up to date. To develop a method to screen the endothelium associated functional genes, we first immunized BALB/c mice by injection subcutaneously with high dose purified HLCVECs. Sera from the immunized mice were identified with several fixed methods for their specificity against HLCVECs and the effects on endothelial cells. For example, detection by immunocytochemistry and immunofluorescence showed that the ability of immunosera to bind HLCVECs were higher compared with activated HUVECs when sera were diluted at 1:5 000, whereas the staining of unactivated HUVECs were completely negative. These data

indicated that the immunosera still contained specific antibodies directed against HLCVECs in this dilution. By MTT assay and cell cycles analysis, we have also demonstrated that the growth and proliferation of HLCVECs were significantly inhibited when treated with anti-HLCVECs immunosera in range of 1:30-1:2430 dilution, while this inhibitory effect of sera from non-immunized (only injected by PBS) mice was not observed. To identify the possible mechanism about anti-HLCVECs proliferation activity of immunosera, we employed Flow Cytometry to analyse cell cycle of HLCVECs treated with the immunosera. The results showed that there was a 4-fold increase in the amount of apoptotic cells compared with the group of non-immunosera. These findings suggested that the anti-sera obtained from mice immunized with high dose of fixed HLCVECs presented some functional immunoglobulin with potent antiangiogenic activity. Similar results were also observed by Scappaticci *et al.*^[18], who recently demonstrated that vaccination of rabbits with murine endothelial cells yielded immunized sera with antiangiogenic effects *in vitro* and that the mechanism of antiangiogenic effect was proven to be through induction of apoptosis of ECs by polyclonal immunoglobulin in this serum. Furthermore, Wei *et al.*^[15] reported also that vaccination of mice with human ECs could induce a specific antiangiogenic immune response with broad anti-tumor activity. In our study, using xenogeneic functional anti-sera from mice immunized with HLCVECs to screen cDNA expression library of HLCVECs, a modified xenogeneic SEREX, we first isolated endothelium associated antigen genes from human liver cancer vascular endothelium.

To isolate TEC associated functional antigens genes, we immunoscreened HLCVECs cDNA expression library by a modified xenogeneic SEREX. Thirty-six positive clones were identified after screening of 6×10^5 clones. Sequencing analysis for homology with the GeneBank and other public databases indicated that these clones represented 18 different genes which were first isolated and identified to be the endothelial genes from human HCC tissues. Three of them were previously not reported new genes, 2 of which may be functional gene encoding hypothetical proteins. There other 15 genes were known. SAGE analysis revealed that 9 of the 15 genes, have been reported as endothelium associated genes and some of them were involved in the proliferation, migration of endothelial cells and the process of angiogenesis. For example, EC26 has 99% homology with chemokine ligand 1(CXCL1), which was implicated having effects on endothelial cells in angiogenesis^[22]. EC35 has 99% homology with bone morphogenetic protein-6 (BMP-6), which stimulates angiogenesis and induces migration^[23,24]. EC52 may be one of the factors that up-regulate VEGF gene expression during hypoxia^[25-27]. The expression of EC59 gene was mostly highly up-regulated in cerebral arteries^[28]. Camby *et al.* found that the level of EC51 expression differed markedly in the blood vascular walls according to whether these vessels originated from low- or high-grade astrocyte tumors^[29,30]. EC53 had 99% homology with heat shock 70 ku protein (HSP70) and is expressed in human microvascular endothelial cells. The expression of HSP70 is known to increase endothelial cells survival and growth^[31-33]. These data indicated that the genes identified in this study using specific and functional antiserum from mice immunized with human TEC, may be functional genes for human endothelial cells and angiogenesis. Furthermore, this approach through screening cDNA expression library with xenogeneic serum containing specific antibodies may serve as an effective strategy for isolation and identification of human TEC genes, which will provide useful marker and targets for tumor anti-angiogenesis therapy.

In summary, the screening of HLCVECs cDNA expression library by using murine immunosera of anti-tumor endothelium yielded 18 functional antigen genes associated with tumor endothelium. These antigen genes may be related to the

proliferation, migration and vessel formation of tumor vascular endothelium. Further exploration of these genes and their relationship with tumor angiogenesis would provide a valuable resource for basic and clinical studies of anti- angiogenesis targeting therapy of tumor.

Abstract

AIM: To investigate the inhibitory effects of endostatin-vascular endothelial growth inhibitor (VEGI₁₅₁) recombinant adenoviruses on neovascularization.

METHODS: We used recombinant adenoviruses to treat human vascular endothelial cell line ECV304, human hepatocellular carcinoma cell line HepG2, and murine fibroblast cell line L929, in order to study the chimeric gene expression in these cell lines. Chick chorioallantoic membrane (CAM) model, rabbit inflammatory corneal neovascularization (CNV) model, and liver cancer-bearing nude mice model were employed to investigate the negative biological effect of fusion molecules on neovascularization *in vivo*.

RESULTS: Western blot showed that the molecular weight of fusion protein was about 41kD after infection of ECV304, HepG2 and L929 cells with supernatant of AdhENDO-VEGI₁₅₁. The fusion protein showed a specific inhibitory effect on the proliferation of ECV304 cells, but no inhibitory effect on the growth of HepG2 and L929 cells ($F=13112.13$, $P=0.0001$). In the chick chorioallantoic membrane (CAM) assay, the expressed fusion protein significantly inhibited neovascularization. Rabbit inflammatory corneal neovascularization (CNV) induced by intrastromal sutures resulted in a uniform neovascular response. In this model, direct subconjunctival injection of AdhENDO-VEGI₁₅₁ expressed the fusion protein *in vivo* and suppressed the development of CNV. Topical application of AdhENDO-VEGI₁₅₁ led to a significant suppression of CNV ($F=1413.11$, $P=0.0001$), as compared with the control group of AdLacZ. Immunohistochemical staining showed the fusion protein dominantly expressed in corneal epithelium. Compared with the control group of AdLacZ ($4075.9 \pm 1849.9 \text{ mm}^3$), the average tumor size of group AdhENDO-VEGI₁₅₁ reduced in size ($487.7 \pm 241.2 \text{ mm}^3$) ($F=14.80$, $P=0.0085$), with an inhibition rate of 88.03%. Immunohistochemical staining showed the adenoviruses carried the fusion gene expressed on liver cancer cell membrane. MVD decreased more significantly in treated mice ($30.75 \pm 3.31\%$) than in AdLacZ control ($50.25 \pm 8.65\%$) ($F=17.72$, $P=0.0056$) with an inhibition rate of 39%.

CONCLUSION: Fusion protein expressed by recombinant adenoviruses has a significant inhibitory effect on neovascularization.

INTRODUCTION

Neovascularization plays a critical role in solid tumor growth and corneal opacification. Researches indicated that angiogenesis inhibitors were highly potent in suppressing angiogenesis which could enable the tumor mass to remain in a dormant state^[1-4] and inhibit the development of corneal neovascularization^[5-7]. Endostatin could cause G(1) cell cycle arrest in endothelial cells, inhibit endothelial cell proliferation and migration, and promote apoptosis^[8]. Vascular endothelial cell growth inhibitor (VEGI) belongs to the tumor necrosis factor superfamily. VEGI is another endothelial cell-specific gene and a potent inhibitor of endothelial cell proliferation, angiogenesis^[9]. VEGI could mediate early G(1) arrest in G(0)/G(1) endothelial cells responding to growth stimuli, and programmed death in proliferating endothelial cells^[10]. In our laboratory two recombinant proteins have been used to treat tumor-bearing nude mice, but the inhibitory effect was not satisfactory. A few groups have demonstrated that antiangiogenic gene therapy with viral vectors is a potentially useful approach for inhibiting tumor growth in mouse models^[11-15]. In the current study, we acquired recombinant adenoviruses carrying endostatin-vascular endothelial growth inhibitor fusion gene to investigate its inhibitory effect *in vitro* on endothelial cells and antiangiogenic activity *in vivo* on chicken chorioallantoic membrane, inflammatory corneal neovascularization (CNV) in rabbit and liver cancer in nude mice.

MATERIALS AND METHODS

Materials

AdhENDO-VEGI₁₅₁ and AdLacZ were prepared in our laboratory. Endostatin polyclonal antibody was a gift from Dr. Stanker (Hanover, Germany). VEGI polyclonal antibody was prepared in our laboratory. Ad5-transformed human embryo renal cell line 293, human vascular endothelial cell line ECV304, human hepatocellular carcinoma cell line HepG2, and murine fibroblast cell line L929 were purchased from the Institute of Cell Biology, Chinese Academy of Sciences. Cell culture media were obtained from GIBCO. Nine-day-old fertilized white Leghorn eggs, New Zealand white rabbits, liver cancer-bearing nude mice SMMC-LTNM, and BALB/c nude mice were purchased from the Center of Experiment Animals, Second Military Medical University (Shanghai, China). All cell lines and animals were maintained under standard conditions.

Methods

Recombinant adenovirus infectivity examination AdhENDO-

VEGI₁₅₁ and AdLacZ were acquired as described previously^[16,17]. In a 24-well plate, 6×10^5 293 cells were infected with 50 μ L of identified recombinant adenoviruses AdhENDO-VEGI₁₅₁ or AdLacZ in 150 μ L of Dulbecco's modified Eagle's medium (DMEM) containing 100 mL/L fetal bovine serum (200 μ L in total) for 72 h. The cells showed evidence of cytopathic effect (CPE) and its supernatant was harvested. After three freeze/thaw cycles, the mixtures were passed through a 0.45 μ m millipore filter. The filtrate was frozen at -70 °C and stored. TCID₅₀ was used to determine the titer of recombinant adenoviruses^[18]. Ten thousand ECV304 cells were incubated in a 96-well plate for 5 h. Cells were infected with AdLacZ, covering a proper multiplicity of infection (MOI) range (0.1, 5, 10, 20, 50 and 100 MOI), and incubated for 48 h. X-gal staining was performed and blue stained cells were counted under a microscope.

Western blotting analysis Ad5-transformed human embryo renal cell line 293, human vascular endothelial cell line ECV304, human hepatocellular carcinoma cell line HepG2, and murine fibroblast cell line L929 were used in this assay. In a 6-well plate, 1×10^6 cells were infected with recombinant adenoviruses at an MOI of 20 for 4 h, then the medium containing recombinant adenoviruses was replaced with 1 mL of normal medium and cells were incubated for 24 h. Cell extracts were separated by 100 g/L sodium dodecyl sulfate-polyacrylamide gel electrophoresis under reducing conditions and electroblotted onto nitrocellulose membrane followed by treatment with blocking buffer containing 50 g/L nonfat dry milk in TBST (20 mmol/L Tris [pH8.0], 150 mmol/L NaCl, 1 g/L Tween-20) for 1 h. The electroblotted membranes were incubated with rabbit polyclonal antibodies against VEGI proteins, then subsequently incubated with peroxidase horseradish-conjugated anti-rabbit immunoglobulin for 1 h at 37 °C. The immune complexes were visualized with diaminobenzidine (DAB) staining.

In vitro bioactivity of fusion gene products One $\times 10^3$ cells were incubated in the 96-well plates, cells were infected with recombinant adenoviruses at an MOI of 20 for 4 h. The cell lines were ECV304, HepG2, and L929, respectively. The recombinant adenoviruses were AdhENDO-VEGI₁₅₁ and AdLacZ, respectively. The medium containing recombinant adenoviruses was replaced with 100 μ L of normal medium and cells were incubated at 37 °C for an appropriate period of time. The medium containing recombinant adenoviruses was removed, murine fibroblast cell line L929 was incubated with a normal medium containing 0.5 μ g/mL actinomycin D. Cell viability was determined by crystal violet vital staining^[19]. Cell viability (%) = (AdhENDO-VEGI₁₅₁ infected group $A_{570/630}$ / AdLacZ control group $A_{570/630}$) $\times 100$.

Inhibition of chick embryonic chorioallantoic membrane angiogenesis by recombinant adenoviruses A 1 cm \times 1 cm window in the shell was drilled over the air sac at the end of 9-day-old eggs. Chick embryonic chorioallantoic membrane was exposed by tearing up the egg membrane with a tip. A disk of methylcellulose was put on CAM, and 10 μ L recombinant adenoviruses was added at a titer of 1×10^{12} TCID₅₀/L. The windows were sealed with aseptic tapes and the eggs were incubated for 3 d. The membrane was cut around the air sac, which was turned upside down and observed by a stereomicroscope.

Suppression of rabbit inflammatory corneal neovascularization In this study, 4 female New Zealand white rabbits, weighing 4-5 kg, were used. Inflammatory CNV in rabbits induced by placement of intrastromal sutures resulted in a uniform neovascular response as described^[20]. On the first day after suturation, four rabbits were divided into AdlacZ control group and AdhENDO-VEGI₁₅₁ group. One hundred microliters of each recombinant adenovirus at a titer of 1×10^{12} TCID₅₀/L was injected into subconjunctiva. Then, gentamicin ointment was applied to the eyes once per day. Eyes were examined daily by

a slit-lamp biomicroscope and a surgical microscope was used to monitor angiogenic responses to recombinant adenoviruses. The area of corneal neovascularization was determined by measuring the vessel length (L) from the limbus and the number of clock hours (C) of limbus involved^[21-24]. Only the uniform contiguous band of neovascularization adjacent to the suture was measured. A formula was used to determine the area^[25]: $C/12 \times 3.1416 \times [r^2 - (r-L)^2]$, where $r=6$ mm (the measured radius of rabbit cornea). Rabbits were sacrificed on d 21. Rabbits' eyes were enucleated and inflammatory cornea was fixed in 40 g/L paraformaldehyde for 24 h.

Immunohistochemical staining of fusion protein in inflammatory cornea of rabbits Buffered formaldehyde fixed tissues were embedded in paraffin, 4- μ m thick sections were treated with 3 mL/L H₂O₂ in methanol for 20 min, and blocked with normal rabbit serum (1:20 dilution) for 20 min at room temperature. Then, the sections were incubated with rabbit polyclonal anti-endostatin (1:50 dilution) for 1 h at room temperature, followed by incubation with biotinylated goat anti-rabbit antibody IgG for 30 min and horseradish peroxidase-conjugated streptavidin at room temperature for 30 min. After completion of conjugation reaction, the slides were stained using 3,3'-diaminobenzidine (DAB)-H₂O₂. The sections were counterstained with hematoxylin, and viewed using a light microscope.

Treatment of liver cancer-bearing nude mice with recombinant adenoviruses Three SMMC-LTNM nude mice with liver cancer were sacrificed, and skin overlying the tumor was cleaned with ethanol. The tumors were resected under aseptic conditions. A suspension of tumor cells in Hank's was made by passage of viable tumor tissues small hypodermic needles. The final concentration was adjusted to 2×10^7 cells/mL. Female Balb/c nude mice, 3 wk of age, received injections sc into the dorsal midline in a 200 μ L volume. Tumors appeared approximately 10 d after implantation. The animals were randomized into 2 groups, and each group had four mice with comparable tumor size within and among the groups. Five hundred microliters of recombinant adenoviruses AdhENDO-VEGI₁₅₁ or AdLacZ at a titer of 1×10^{12} TCID₅₀/L was administered 10 times by sc every other day. The mice were sacrificed 24 h after the last injection, tumors from each mouse were removed and fixed in 40 g/L neutral buffered formaldehyde. Tumor size in all groups was measured, tumor volume was determined using the formula $\pi \times \text{width}^2 \times \text{length} / 6$. Tumor weight, inhibition rate and expression of target gene were evaluated, respectively.

Immunohistochemical staining of fusion protein in liver cancer of nude mice Tissues from liver cancer of nude mice were fixed in 40 g/L neutral buffered formaldehyde, embedded in paraffin, and sectioned into 4 μ m. The sections were treated with PBS, blocked with normal rabbit serum, incubated with rabbit polyclonal anti-endostatin (1:100 dilution) overnight at 4 °C, washed with PBS, incubated with HRP-conjugated goat anti-rabbit antibody (1:500 dilution) for 1 h at 37 °C, and stained using 3,3'-diaminobenzidine (DAB)-H₂O₂, counterstained with hematoxylin, and examined by a light microscope.

Determination of intratumor microvessel density Determination of microvessel density was carried out as described^[26-28]. Briefly, intratumor microvessels were immunostained with rat anti-human CD34 monoclonal antibody, and visualized with a biotinylated anti-rat IgG antibody by the Strept Avidin-Biotin Complex method. The sections were examined under low power to identify most vascular areas of the tumor. Within these areas, a maximum of 3 fields at $\times 200$ magnification was examined, and the mean values were calculated.

Statistical analysis Data were expressed as mean \pm SD. An analysis of variance was performed with Statview 4.0 statistical analysis software, and $P < 0.05$ was considered statistically significant.

RESULTS

Recombinant adenovirus infectivity

The titer of amplification of these two kinds of recombinant adenoviruses was 1×10^{12} TCID₅₀/L. When ECV304 cells were infected with AdLacZ at an MOI of 0.1, 20% cells showed LacZ-positive staining. If MOI was 20, 100% cells were stained blue (Figure 1). This result suggested recombinant adenoviruses had the highly efficient gene delivery.

Figure 1 Infection efficiency of AdLacZ with different MOI.

Fusion protein expression of AdhENDO-VEGI₁₅₁ *in vitro*

Four kinds of cell lines infected with AdhENDO-VEGI₁₅₁ were immunoblotting stained with polyclonal antibodies against VEGI and visualized with DAB system. The results demonstrated that the fusion gene carried by AdhENDO-VEGI₁₅₁ could be *in vitro* expressed in all the cell lines, and the specific bands were located at about 41 ku, which was the expected size of ENDO-VEGI₁₅₁ fusion protein (Figure 2).

Figure 2 Western blot analysis of expressed fusion protein by AdhENDO-VEGI₁₅₁ with polyclonal antibody against VEGI₁₅₁. Lane 1: protein marker; lane 2: 293 cell; lane 3: ECV304 cell; lane 4: HepG2 cell; lane 5: L929 cell.

Figure 3 Viability of cells infected with AdhENDO-VEGI₁₅₁.

In vitro bioactivity of fusion gene on different cell lines

Human vascular endothelial cells ECV304 were sensitive to AdhENDO-VEGI₁₅₁, and cell proliferation was significantly inhibited. In contrast, no inhibitory activities on HepG2 and L929 *in vitro* growth were observed following AdhENDO-

VEGI₁₅₁ infection (Figure 3). Further analysis of variance showed there was a significant difference in viability between ECV304 cells and non-endothelial cells (HepG2 cells and L929 cells) ($F=13112.13$, $P=0.0001$). At different time points, there was a significant difference between the two groups ($F=72.75$, $P=0.0001$). There was no significant difference in viability between HepG2 cells and L929 cells neither for the hypothesis of no time effect ($F=7.17$, $P=0.0554$) nor at different time point ($F=1.74$, $P=0.2424$).

Figure 4 Inhibition of chick embryonic chorioallantoic membrane angiogenesis ($\times 7$). A: AdLacZ control; B: AdhENDO-VEGI₁₅₁.

Figure 5 Suppression of rabbit corneal neovascularization ($\times 7$), CNV was examined on day 21. A: AdLacZ control; B: AdhENDO-VEGI₁₅₁.

Angiogenesis inhibition by AdhENDO-VEGI₁₅₁ in CAM

Nine-day old chick embryos were incubated with filter disks infected with AdhENDO-VEGI₁₅₁, or AdLacZ. The effect of AdhENDO-VEGI₁₅₁ on CAM angiogenesis was analyzed 3 d after incubation, by excising the membrane around the air sac and microscopy (Figure 4). At doses of 10-20 μ L/disc at a titer of 1×10^{12} TCID₅₀/L, there was a potent inhibition of angiogenesis of AdhENDO-VEGI₁₅₁ on the tested CAMs ($n=4$ /group). In contrast, AdLacZ failed to suppress angiogenesis in CAM. There was no evidence of toxicity in any chick embryos tested.

Vessel inhibition in inflammatory cornea of rabbits

After direct subconjunctival injection of recombinant adenoviruses, rabbit eyes were examined by a surgical microscope daily. A few small capillary buds that arose from engorged limbal arcades were observed. CNV increased gradually, peaked on d 12-14, and degenerated on day 15 after suture induction. So we chose d 7, 10, 13, or 16 as time points to determine the number and length of vessels, and the area of neovascularization. Analysis of the CNV area found that local application of AdhENDO-VEGI₁₅₁ resulted in a significant suppression of CNV (Figure 5, Figure 6). Repeated measurement of two factors and multilevel analysis of variance showed there were significant differences between AdhENDO-VEGI₁₅₁ group and AdLacZ group ($F=1413.11$, $P=0.0001$) for the hypothesis of no time effect. At different time points, there was a significant difference between the two groups ($F=15517.87$, $P=0.0001$).

Figure 6 Comparison of corneal neovascularization in 2 groups.

AdhENDO-VEGI₁₅₁ expression in inflammatory cornea of rabbits

The fusion gene expression in inflammatory cornea of rabbits was detected by immunohistochemistry. Corneal endothelium was stained brown in AdLacZ group, others were stained negative. Corneal endothelium and epithelium were stained brown in AdhENDO-VEGI₁₅₁ group (Figure 7), and lasted for 21 d.

AdhENDO-VEGI₁₅₁ inhibited growth of liver cancer

Twenty-one days after therapy, the mice were sacrificed. Compared with AdLacZ control group ($4\,075.9 \pm 1\,849.9$ mm³), the average tumor size of AdhENDO-VEGI₁₅₁ group had confirmed regression (487.7 ± 241.2 mm³) ($F=14.80$, $P=0.0085$) with an inhibition rate of 88.03%.

Immunohistochemical features in liver cancer of nude mice

When we examined the sections stained by rabbit polyclonal anti-endostatin by a light microscope, strongly positive staining of fusion molecules presented in all cases of animals treated with AdhENDO-VEGI₁₅₁. The recombinant adenoviruses carrying chimeric gene could be expressed in liver cancer. Brown staining was mainly located on the membrane of liver cancer cells (Figure 8). There was no positive staining in tumor tissues of the control animals.

Determination of intratumor microvessel density

The antiangiogenesis effect of fusion protein producing adenoviruses was evaluated in tumor model. Tumor microvessel density (MVD) was reduced by the production of hENDO-VEGI₁₅₁ fusion gene. The MVD was decreased ($30.75 \pm 3.31\%$) more significantly in treated mice than in control ($50.25 \pm 8.65\%$) ($F=17.72$, $P=0.0056$).

Figure 7 Immunohistochemical staining of rabbit cornea with polyclonal antibody against endostatin ($\times 200$). A: AdLacZ control; B: AdhENDO-VEGI₁₅₁.

Figure 8 Immunohistochemical staining of nude mice liver cancer with polyclonal antibody against endostatin ($\times 200$). A: AdLacZ control; B: AdhENDO-VEGI₁₅₁.

DISCUSSION

Endostatin and vascular endothelial growth inhibitor are

endogenous angiostatic molecules. Both of them are angiogenesis inhibitors that could suppress the growth of endothelial cells^[29,30]. To achieve effectiveness, antiangiogenic therapy with endostatin or VEGI in tumor-bearing mice required prolonged administration and high doses of recombinant proteins^[31,32]. Production of functional polypeptides has proven difficult, perhaps because of its physical properties or variations in the purification procedures in different laboratories^[33,34]. In our laboratory (Department of Microbiology, Second Military Medical University, Shanghai, China) these two recombinant proteins were used respectively to treat tumor-bearing nude mice, but their bioactivities were not satisfactory. So we performed antiangiogenic gene therapy with adenoviral vectors. The results suggested recombinant adenoviruses AdhENDO-VEGI₁₅₁ could express fusion protein about 41 ku in ECV304, HepG2, L929 and 293 cells, and showed a specific inhibition on the proliferation of ECV304 cells, the inhibition rate reached 49% in 24 h and 86% in 144 h, respectively. But the AdhENDO-VEGI₁₅₁ showed no suppression on growth of HepG2 cells. VEGI belongs to the tumor necrosis factor (TNF) superfamily^[35] and was constitutively expressed in endothelial cells. Since murine fibroblast cell line L929 was used to determine the bioactivity of TNF, we also used this cell line to test the bioactivity of AdhENDO-VEGI₁₅₁. The results showed it had no suppression on growth of L929 cells, suggesting that fusion protein expressed by AdhENDO-VEGI₁₅₁ infection had no cytotoxicity to non-endothelial cells. Chick choriocallant membrane assay showed that fusion protein expressed by AdhENDO-VEGI₁₅₁ infection could significantly inhibit angiogenesis, and form no vessel regions. Because CAM was formed during embryogenic period, it was difficult to distinguish new vessels from previously established vascular networks. On the other hand, inflammatory CNV assay could avoid any confusion between new vessels and previously existed vessels, and any vessels penetrating into the corneal stroma could be identified as newly formed, as the cornea was avascular. For CNV was the main reason for corneal opacification, and also the main risk factor of immunologic rejection in allogeneous corneal transplantation, we tried to use AdhENDO-VEGI₁₅₁ as a safe and effective agent to inhibit CNV. We used intrastromal sutures to induce inflammatory CNV in rabbits. Neovascularization began sprouting into the corneal stroma from the limbus to the site of sutures within a few days after direct subconjunctival injection. Since small capillary vessels subsided gradually 16 d after suture induction, we selected d 7, 10, 13, or 16 as time points to measure vessel length and clock hours of circumferential neovascularization. Analysis of CNV area found there were significant differences between AdhENDO-VEGI₁₅₁ group and AdLacZ group. Local application of AdhENDO-VEGI₁₅₁ led to significant suppression of CNV, the inhibition rate was 36%, 16%, 17%, or 13% in turn. Our results suggested that in order to sustain the angiogenesis inhibition, AdhENDO-VEGI₁₅₁ should be administrated every 7 d. Immunohistochemical staining showed that the positive reaction was predominant in corneal epithelium of AdhENDO-VEGI₁₅₁ group. These results suggested that the expression of recombinant adenoviruses was related with the site of injection. Positive staining in corneal endothelium was observed in two groups. This phenomenon might be caused by the endogenous endostatin expression of corneal endothelial cells. Compared with AdLacZ control group, the average tumor size of AdhENDO-VEGI₁₅₁ group was reduced with an inhibition rate of 88.03%. The gene of interest in adenoviruses could express in liver cancer. Since the fusion gene included IL-3 signal peptide coding sequence, the fusion protein might secrete out of the membrane of liver cancer cells. MVD was decreased more significantly in treated mice than that in control, the inhibition rate was 39%. These findings in combination with

the results of cell assay suggested that the antitumor activity of AdhENDO-VEGI₁₅₁ was not due to a direct effect on tumor cells, interference with the development of tumor microvessel density was responsible for tumor regression. However, up to now, we do not know whether the combination is more potent or not. Comparison of the effectiveness of fusion molecules with individual molecules has been under investigation.

Abstract

AIM: To observe the change of tumor microcirculation after transcatheter arterial chemoembolization (TACE) with *bletilla* microspheres by using first pass perfusion MR imaging (FP) and Chinese ink casting.

METHODS: VX2 carcinoma cells were surgically implanted into the left and right lobes of liver of 30 New Zealand white rabbits, which were divided into 3 groups at random. Emulsion of lipiodol mixed with mitomycin C, and 5-FU *bletilla* microspheres were injected into the hepatic artery respectively, and saline was used as control agent. MR imaging was performed with turbo-flash sequence 14 d after tumor implantation and 7 d after interventional therapy. The steepest slopes (SS) of the signal intensity versus time curves were created for quantitative analysis, 7.5% Chinese ink gelatin solution was injected through ascending artery (17 cases) or portal vein (2 cases) for lesion microvessel area (MVA) measurement after the last MRI examination. The correlation between perfusion imaging and MVA was studied blindly.

RESULTS: The SS values at the rim of tumor in lipiodol group (mean, 49% per second) and *bletilla* group (mean, 35% per second) were significantly decreased ($P < 0.05$) as compared with control group (mean, 124% per second), no difference was found between lipiodol and *bletilla* groups ($P > 0.05$). In lipiodol group, the MVAs ($24\ 974 \pm 11\ 836\ \mu\text{m}^2$) in the center of the tumor were significantly smaller than those of the control group ($35\ 510 \pm 15\ 675\ \mu\text{m}^2$) ($P < 0.05$), while the MVAs ($80\ 031 \pm 22\ 745\ \mu\text{m}^2$) around the tumor were significantly increased because small and dense plexuses appeared around the tumor which correlated to intense reaction of granulation tissue. None of the vessels was seen in the tumor in *bletilla* group, the peripheral MVAs of the tumor were significantly smaller than those of the control group ($P < 0.05$) and lipiodol group ($P < 0.05$). There was a good correlation between SS and MVAs in control group ($r_s, 0.985, P < 0.0001$) and *bletilla* group ($r_s, 0.743, P < 0.05$), the correlation was not significant in lipiodol group ($r_s, 0.527, P > 0.05$).

CONCLUSION: TACE with *bletilla* microspheres may

enhance its anti-tumor effect by inhibiting the angiogenesis, and FP-MRI provides useful information to assess the TACE effect by depicting tumor vascularization and perfusion.

INTRODUCTION

Transcatheter arterial chemoembolization (TACE) has been widely used and is considered to be an effective conservative treatment for hepatocellular carcinoma^[1,2]. Rapid development of small vessels after TACE resulting in incomplete necrosis, however, reduces therapeutic effectiveness^[1-9]. Therefore, inhibition of the development of arterial collaterals may be important in enhancing the therapeutic efficacy of this treatment. Recently, TACE with microspheres, microcapsules, cyanoacrylate and *bletilla* has been shown to improve the therapeutic results^[1,3,10-12]. *Bletilla* microspheres have also been shown to improve the therapeutic results because of its embolization of the hepatic artery and portal vein as well as controlled release systems, although changes at the level of hepatic microcirculation are not completely elucidated.

The purpose of this study was to observe the change of tumor microcirculation after TACE with *bletilla* microspheres by using first pass perfusion MR imaging (FP) and Chinese ink casting.

MATERIALS AND METHODS

Animals and tumor models

The VX2 tumor model used in this study was initially a virus-induced papilloma first seen in domestic rabbit in 1937. With sequential transplantations, the tumor line became increasingly anaplastic^[13]. VX2 carcinoma (Department of Radiology, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China) was retained for approximately 4 years by repeated passage of tumor every 14-21 d by way of intramuscular or subcutaneous implantation into the thighs of male New Zealand white rabbits.

Twenty-five male and five female New Zealand white rabbits (Laboratory Center, Tongji Medical College) weighing 1-1.5 kg were used. Prior to all procedures, including tumor implantation and imaging, rabbits received an intramuscular injection of 1.0 mL/kg of body weight of ketamine hydrochloride injection (Shanghai Sino-west Pharmaceutical Company), intravenous access was then acquired via a marginal ear vein. Anesthesia was maintained by using the same dose of intravenously administered ketamine hydrochloride.

The technique for tumor implantation was basically similar to that described by Li *et al*^[14]. Briefly, the liver was exposed

by performing midline laparotomy, VX2 tumor fragments of approximately 1 mm³ were injected intraparenchymally into the right and left lobes of the rabbit liver. Thirty New Zealand white rabbits with tumors were divided into three groups at random. They were group A (control group, 8 rabbits), group B (lipiodol group, 12 rabbits) and group C (*bletilla* group, 10 rabbits). All three groups received their interventional therapy 14-21 d after tumor inoculation when MRI confirmed the successful implantation.

Interventional therapy

A polyethylene catheter (inner diameter 0.3 mm, outer diameter 0.5 mm) was retrogradely inserted into the gastroduodenal artery, the following agents were manually injected into the gastroduodenal artery, namely, saline only into group A, 0.4-0.6 mL lipiodol (Aulnay Sous-Bios, France) emulsion (lipiodol mixed with MMC) into group B, 0.3 mL ultravist mixed with 10 mg *bletilla* microspheres (Department of Radiology, Union Hospital, Wuhan, China, 40-200 μm in diameter, combined with 5-FU) into group C.

MR imaging and data analysis

Fourteen days after tumor implantation and 7 d after interventional therapy, MR imaging was undertaken by using a 1.5 T system (Magnetom Vision, Siemens Medical Systems) with a head coil. Transverse spin-echo T1-weighted images (repetition time was 525 ms, the echo time was 14 ms) and HASTE T2-weighted images (repetition time was 4.4 ms, the echo time was 90 ms) were obtained by using a 3 mm thick section, 0.5 mm intersection space, and four signals were acquired.

For the FP, a strongly T1-weighted, turbo-FLASH sequence was used with a high temporal resolution of 1.196 s per section, a single image was acquired sequentially with 65 repetitions, which resulted in an acquisition time of 2 min. The repetition time was 3.3 ms, the echo time was 1.4 ms, and time interval was 300 ms. At the end of the fourth acquisition, a dose of 0.1 mmol/kg body weight of gadopentetate dimeglumine (Bellona, Beijing, China) was administered via a marginal ear vein.

To quantitatively analyze FP, four circular ROIs were hand drawn, covering the center and rim of the lesion, signal intensity time curve was obtained over ROIs, and the steepest slope of the curve (SS) was calculated according to the previously described method^[15].

Evaluation of anti-tumor effect

Tumor size was measured with calipers. The size of each tumor on the liver surface was measured immediately before treatment and seven days after treatment on MR imaging. We evaluated the anti-tumor effect based on the tumor volume, which was calculated as follows: tumor volume (mm³)=0.5×*a*×*b*², where *a* is the length of major axis and *b* is the length of minor axis measured with calipers.

Chinese ink casting and histological evaluation

The tumor microvessels were demonstrated by perfusion of 75 g/L Chinese ink (Beijing Chinese Ink Company) gelatin solution into the ascending artery (17 cases) or portal vein (2 cases) after the last MR imaging examination. Before perfused with 75 g/L Chinese ink gelatin solution, 500 units of heparin was administered intravenously. After the rabbits were killed, the livers were removed and stored at -20 °C for 24 h. The specimens were immersed in 250-995 mL/L ethyl alcohol at increasing concentrations, and finally in a solution of methyl salicylate. When the oil penetrated the tissue, the specimens became transparent. The sections (50 μm) were observed first under a low power microscope (×40), then the sections with most dense area of microvessels were selected and observed under a high

power (×200). Micro-vessels filled with Chinese ink gelatin were evaluated under a microscope, micro-vessel areas (MVAs) in the center and rim of the lesion were calculated by an imaging analysis system (Beijing Aeronautic University). A 5 μm sections of the same specimens were stained with hematoxylin and eosin for light microscopy.

Statistical analysis

All data were expressed as mean±SD, the statistical differences between different groups were analyzed by ANOVA, and the correlation between SS and MVA was assessed by Spearman correlation analysis. Significance was accepted when *P*<0.05.

RESULTS

MR imaging

MR imaging depicted all tumors on pretreatment images. All untreated tumors had a low signal intensity on T1-weighted images and an intermediate signal intensity on T2-weighted images. Central areas of high signal intensity on T2-weighted images and low signal intensity on T1-weighted images were compatible with the central necrosis when tumors were larger than 1 cm. T1-weighted images after injection of gadolinium showed a slight enhancement in the center of lesion and a rim enhancement around the center of lesion in all tumors (Figure 1). No significant difference in tumor volume was observed among the three groups before therapy.

Tumor volumes in the lipiodol group and *bletilla* group after TACE were significantly decreased compared with the control group on d 7 after treatment, no significant difference in tumor volumes was observed between lipiodol group and *bletilla* group (Figure 2, Table 1). The central slight enhancement area was larger, and the peripheral arterial phase rim enhancement in the two groups was thinner. The SS values at the rim of tumor in lipiodol group (mean, 49% per second) and *bletilla* group (mean, 35% per second) were significantly decreased (*P*<0.05), as compared with the control group (mean, 124% per second), no difference was found between lipiodol group and *bletilla* one (*P*>0.05) (Table 2).

Table 1 Tumor volumes pre- and post-treatment (cm³)

Group	Pre-treatment	Post treatment
Control	0.430±0.067	1.620±0.327
Lipiodol	0.465±0.120	0.971±0.285 ^a
Bletilla	0.402±0.171	0.736±0.145 ^a

^a*P*<0.05 vs control.

Table 2 SS values at the rim of tumor in different groups

Group	SS (%·s ⁻¹)	<i>F</i>	<i>P</i>
Control	124±62		
Lipiodol	49±15	11.08	0.004 ^a
Bletilla	35±9	6.88	0.019 ^a

^a*P*<0.05 vs control.

Table 3 Correlation between SS values and MVA in different groups

Group	SS (%·s ⁻¹)	MVA (μm ²)	<i>r</i> _s	<i>P</i>
Control	124±62	35 510±15 675	0.985	<0.05
Lipiodol	49±15	80 031±22 745	0.527	>0.05
Bletilla	35±9	15 530±7 973	0.743	<0.05

Figure 1 Images obtained before treatment in control group. A: T1WI shows hypointense lesions in left lobe of the liver. B: T2WI shows homogeneous hyperintense lesions in left lobe of the liver. C: FP T1-weighted image with gadolinium shows rim enhancement and no enhancement in the center of lesion. D: Signal intensity time curve derived from FP, SS of the curve in the border of the lesion is steeper than that of the normal liver.

Figure 2 Images obtained after treatment in lipiodol group. Inhomogeneous hyperintense lesions with intermediate intense rim (arrow head) can be seen on T1WI (A) and T2WI (B), indicating the necrosis of the lesion and intratumor retention of lipiodol. (C) FP T1-weighted image with gadolinium shows thinner rim enhancement and no enhancement in the center of the lesion compared with control group although the lesion volume is increased. (D) SS of the curve in center of the lesion is decreased compared with those of the border.

Chinese ink casting

Investigation under microscope ($\times 40$) of the livers filled with Chinese ink in control group revealed networks of vessels or plexuses of dilated and tortuous course around and within the tumor originated from the arterioles, some sinusoid vessels were observed in the tumors, all these vessels were clearly distinct from the lobular architecture. In lipiodol group after TACE, the MVAs within the tumor ($24\,974 \pm 11\,836\ \mu\text{m}^2$) were significantly smaller than those of the control group ($35\,510 \pm 15\,675\ \mu\text{m}^2$) ($P < 0.05$), while the MVAs around the tumor ($80\,031 \pm 22\,745\ \mu\text{m}^2$) were significantly increased, as

compared with the control group ($35\,510 \pm 15\,675\ \mu\text{m}^2$) ($P < 0.05$). Small and dense plexuses appeared around the tumor, with unknown origin. None of the vessels was seen in the tumor in *bletilla* group after TACE (Figure 3). The peripheral MVAs of the tumor ($15\,530 \pm 7\,973\ \mu\text{m}^2$) in *bletilla* group were significantly smaller than those of the control group ($35\,510 \pm 15\,675\ \mu\text{m}^2$) ($P < 0.05$) and lipiodol group ($80\,031 \pm 22\,745\ \mu\text{m}^2$) ($P < 0.05$). There was a good correlation between SS and MVA at the rim of tumor in control group (r_s , 0.985, $P < 0.0001$) and *bletilla* group (r_s , 0.743, $P < 0.05$), the correlation was not significant in lipiodol group (r_s , 0.527, $P > 0.05$) (Table 3).

Figure 3 Micro-vessel casting with Chinese ink through ascending artery. A: The specimens show a lobular architecture of normal liver, magnification $\times 100$. B: In control group, hepatic artery perfusion shows networks of micro-vessels or plexuses of dilated and tortuous course around and within the tumor originated from the arterioles, some sinusoid vessels can be observed in this tumor, magnification $\times 100$. C: The original micro-vessels of the tumor are remarkably diminished, small and dense new plexuses appear around the tumor in lipiodol group, which are correlated to intense reaction of granulation tissue, magnification $\times 100$. D: micro-vessels are decreased in *betilla* group, no new micro-vessels can be seen at all, magnification $\times 100$.

Figure 4 Histological examinations of hepatic lesion before and after treatment. A: HE stain shows nidal arrangement of VX2 cells as well as micro-vessels filled with Chinese ink before treatment, magnification $\times 200$. B: In lipiodol group, histological examination shows coagulation necrosis at the center of lesion, very few micro-vessels can be seen within this zone, residual tumor cells are seen at the periphery of the lesion, moreover, an intense reaction of granulation tissue is seen within this area, small dense vessels are scattered at border of the lesion, and congested sinusoids are seen in the periphery of the tumor, magnification $\times 200$. C: Coagulation necrosis as well as large infarcts involving multiple adjacent lobules is seen in *betilla* group, few vessels are seen at the border of the lesion, magnification $\times 200$.

Pathologic correlation

The specimens did not show necrosis or infarct when the lesion was less than 1 cm in control group. In lipiodol group none lesions underwent complete necrosis, coagulation necrosis was demonstrated at the center of all lesions. Viable or residual cancerous tissues as well as an intense reaction of granulation tissue were seen at the periphery of all lesions in lipiodol groups after TACE, small and dense vessels were scattered at the border of the lesions, correlating with the irregular thick rim enhancement on MR image. In *betilla* group after TACE, all lesions demonstrated complete coagulation necrosis, large infarcts involving multiple adjacent lobules were seen as well, few vessels were seen at the border of the lesion, no granulation tissue was seen (Figure 4).

DISCUSSION

Bletilla inhibition of tumor micro-vessels

A previous study reported an intense reaction of granulation tissue at the periphery of all lesions in lipiodol group^[16], the dense angiogenic plexus in the granulation tissue is, to our knowledge, a new finding. Granulation tissue which resulted in capillary proliferation and permeability increase was correlated to arterial phase rim enhancement on MR image. Angiogenesis was central to tumor stroma formation and offered nutrition to the remaining viable tumor cells, which limited lipiodol embolization and anti-tumor effect. As a result, local tumor recurrence would occur sooner or later^[7-9,16].

TNP-470, cyanoacrylate and Plcg-mitomycin-microsphere have been used to inhibit capillary networks or to prolong

first-pass effect and to enhance the anti-tumor effect of TACE^[11,17-20]. Our experimental study indicated that *bletilla* could enhance the anti-tumor effect of TACE as well. *Bletilla*, as an anti-tumor and anti-inflammation agent, is a Chinese medicine^[10,12]. Its microspheres (mixed with 5-FU, 40-200 μm in diameter) can result in dual embolization (embolization of hepatic arterial and portal venous blood supply) and inhibit the microvessels around and in the tumor completely. The reason why no microvessels developed after TACE was partly due to its anti-tumor and anti-inflammation effect, partly through inhibition of the binding of vascular endothelial growth factor to its receptor^[10]. As a result, treatment with *bletilla* could necrose the tumor thoroughly. This was why *bletilla* could enhance the anti-tumor effect of TACE even the lesion was very large^[12].

VX2 microcirculation morphology

Many materials, including Chinese ink and microfil, have been used to demonstrate the vascular morphology of tumors^[17,21]. Among them, microfil is commonly used because of its different colors, which could identify the origin of vessels. But microfil was too viscous to get into the sinusoid, no vessel was visible inside the tumors less than 0.25 mm in diameter^[17]. So we selected less viscous materials to reveal microvessel morphology of VX2. Three percent of Chinese ink gelatin solution was used to explore the vascular architecture of cheek pouch carcinoma^[21]. To avoid overfilling the microvessels, we added gelatin to increase the viscosity of the solution to obtain 7.5% solution. As a result, all the microvessels of normal liver including arterioles and sinusoid were filled with black Chinese ink, so did those of tumor. Moreover, the pathologic change of the other part of the same specimens stained with HE could be observed. So microvessel casting correlating with pathologic change could assess the changes of tumor microcirculation at the same time. We believe that Chinese ink gelatin solution casting may be used as the golden standard to evaluate the microvessels in perfusion study with CT and MR imaging.

Value of FP-MRI

Although power Doppler US has been used to assess vascularity of tumors^[23-25], before contrast enhanced harmonic power Doppler US has widely been used, the major problems in the use of power Doppler are as follows. The detected velocities were too slow in the tumor, there were too many blooming artifacts associated with micro-bubble injection, the duration of enhancement was short and there were artifacts resulted from respiration^[23]. So the vascularity of tumors could not be evaluated in detail by power Doppler US. FP-MRI, with a high time resolution, can monitor the contrast agent first passing the target tissue by using signal intensity time curve, the steepest slope of which (SS, i.e. the maximum upward slope of the curve) correlates linearly with flow velocity and angiogenesis, and has been successfully used to quantify the myocardial perfusion reserve and to depict the tumor vascularization^[15,22], but no study has assessed the tumor microcirculation after TACE by FP^[26,27]. Our experimental result revealed that areas with the fastest contrast medium uptake (SS) colocalized significantly with focal hot spots of MVA in control group and *bletilla* group, but no significant correlation was observed between SS and MVA in lipiodol group, suggesting that factors beyond the MVA are involved in the gadopentetate dimeglumine-related signals enhanced in microvessels. We believed that the discrepancy could reflect the difference between small dense vessels newly developed at the border of the lesion after lipiodol treatment and tumor microvessels before treatment. The new vessels were hyperpermeable^[28], part of the small molecular contrast media (gadopentetate dimeglumine) might leak out of microvessels even at first pass

course. On the other hand, the new vessels might be too small to have the same flow velocity like those before treatment. So we believed that when the same categoric vessels were assessed by FP, the flow velocity might be constant, the SS was correlated linearly with MVA. When different categoric vessels were evaluated by FP, the flow velocity and permeability were different, and not dependent only on MVA.

In this study, *bletilla* microspheres were administered for 7 d only, and further studies of extended duration are needed. We conclude that tumor microvessels can be markedly inhibited by using *bletilla* microspheres in combination with 5-FU, which can explain and confirm its effectiveness in clinic. The SS derived from FP has a good correlation with MVA and may be used as a noninvasive method to quantitatively evaluate tumor angiogenesis after TACE.

Abstract

AIM: To transfect murine angiostatin cDNA into human hepatocellular carcinoma cell line SMMC-7721 and to investigate its effects on implanted carcinoma in nude mice.

METHODS: A eukaryotic expression vector of pcDNA3.1-mAST containing murine angiostatin was constructed. Then pcDNA3.1-mAST plasmid was transfected into cell line SMMC-7721 by Lipofectamine. The resistant clone was screened by G418 filtration and identified by RT-PCR and Western blotting. Nude mice were divided into three groups of 10 each. Mice in blank control group were only injected with SMMC-7721 cells. Mice in vector control group were injected with SMMC-7721 cells transfected with pcDNA3.1 (+) vector, whereas mice in angiostatin group were injected with SMMC-7721 cells transfected with pcDNA3.1-mAST plasmid. Volume, mass and microvessel density (MVD) of the tumors in different groups were measured and compared.

RESULTS: Murine angiostatin cDNA was successfully cloned into the eukaryotic expression vector pcDNA3.1 (+). pcDNA3.1-mAST was successfully transfected into SMMC-7721 cell line and showed stable expression in this cell line. No significant difference was observed in the growth speed of SMMC-7721 cells between groups transfected with and without angiostatin cDNA. Tumor volume, mass and MVD in the angiostatin group were significantly lower than those in the blank control group and vector control group ($P < 0.01$). The inhibitory rate of tumor reached 78.6%. Mass and MVD of the tumors only accounted for 34.6% and 48.9% respectively of those in the blank control group.

CONCLUSION: Angiostatin cDNA could be stably expressed in human hepatocellular carcinoma cell line SMMC-7721 without obvious inhibitory effects on the growth of SMMC-7721 cells. When implanted into nude mice, SMMC-7721 cells transfected with angiostatin cDNA show a decreased tumorigenic capability. It suggests that angiostatin can inhibit tumor growth through its inhibition on angiogenesis in tumors.

INTRODUCTION

The growth and metastasis of a tumor depend on the growth of blood vessels^[1-5], so anti-angiogenesis becoming a new way in treatment of tumors^[6-9]. Recently, angiostatin has been found to be one of the most effective inhibitory genes of angiogenesis. It can inhibit specifically the proliferation and migration of endothelial cells of blood vessels, and has been regarded as a very useful target gene in anti-angiogenesis-based cancer treatment^[10]. Liver cancer is one kind of cancers rich in blood vessels, so therapeutic angiogenesis represents a potential option in the therapy of primary liver cancer. We investigated the construction of an expression vector containing angiostatin cDNA and evaluated its effect on implanted tumor in nude mice.

MATERIALS AND METHODS

Transfection of pcDNA3.1-mAST into SMMC-7721

Eukaryotic expression vector of pcDNA3.1 (+) (Invitrogen, USA) and plasmid pRC-mAST containing full-length of angiostatin gene (a gift from Dr. Zhang DX in Folkman Laboratory, Yale University, USA) were digested by restriction enzymes *Xba* I and *Hind* III. The digested vector and angiostatin cDNA fragment were ligated. Recombinant clones were identified by *Xba* I and *Hind* III double digestion. Positive clones named pcDNA3.1-mAST were further confirmed by sequencing.

Cultured SMMC-7721 cells were divided into three groups: transfected with recombinant pcDNA3.1-mAST (group A), transfected with pcDNA3.1 (+) vector (group B), not transfected with pcDNA3.1 (+) vector (group C). Transfection was performed according to the instructions of Lipofectamine TM2000 reagent kit (Gibco). Cells were cultured in RPMI 1640 medium containing 200 mL/L fetal calf serum and 350 mg/L G418. Resistant clones could be detected two weeks later. Cell growth curve was also made.

RT-PCR and Western blotting

Total RNA was extracted following reversal transcriptase PCR. Primers used in PCR were designed according to the reported angiostatin cDNA sequence^[7]. The primer sequences were as follows: 5' end: 5'-ATGGACCATAAGGAAGTAA-3'; 3' end: 5'-GGTGGGCAATTCCACAAACA-3'. The products of PCR were identified on 10 g/L agarose gel electrophoresis.

Cultured cells in the three groups were treated by adding 500 L solution containing 500 g/L lysine-Sepharose and 50 mmol/L Tris-HCl (pH 8.0) into the culture medium. Western blotting was then performed according to the reported methods^[11]. The primary antibody was anti-rabbit HA-tagged antibody (a gift from Dr. Zhang DX in Yale University).

Animal experiment

Thirty Balb/c nu/nu male mice aged 4-6 wk (body mass 18-20 g) were bred under SPF conditions. They were randomly divided into three groups of 10 each. The mice in blank control group were injected only with SMMC-7721 cells, the mice in vector-treated control group were injected with SMMC-7721 cells transfected with pcDNA3.1 (+) vector, the mice in angiostatin group received an injection of SMMC-7721 cells transfected with recombinant pcDNA3.1-mAST. After cancer cells were cultured into the stage of logarithmic growth phase, they were digested with trypsin to make cancer cell suspension of $5 \times 10^{10}/L$. Then, 0.2 mL of each suspension was subcutaneously injected into the right back of nude mice.

Tumor volume measurement

The survival of nude mice was observed every day. Tumor volume and inhibitory rate were measured on days 7, 14, 21, 28 and 35 after injection.

Tumor volume = $\pi/6 \times (\text{long radius} \times \text{short radius}^2)^{1/2}$.

Inhibition rate = (tumor volume of blank control group - tumor volume of angiostatin group) / tumor volume of blank control group $\times 100\%$.

Microvessel density counting

Thirty-five days after cancer cell injection, the nude mice were killed and their tumors were removed. The surrounding fatty tissues were dissected and the tumors were weighed. CD34 immunohistochemical staining was carried out according to the previously reported methods^[11] to label endothelial cells of blood vessels. Five areas with the highest microvessel density (MVD) in each section were selected under $40 \times$ subjective lens. The number of blood vessels in each area was counted under a magnification of 200 fields ($0.708 \text{ mm}^2/\text{field}$). The data from 5 areas were averaged and the value was regarded as the tumor MVD of each nude mouse. The average MVD from 10 mice in each group was regarded as the MVD of implanted tumor of that group^[13].

Statistical analysis

All data were expressed as mean \pm SD and analyzed by Student's *t* test. A *P* value less than 0.05 was considered statistically significant.

RESULTS

Identification of recombinant plasmid pcDNA3.1-mAST

After digestion by *Xba* I and *Hind* III, bands at 1.4 kb could be detected for positive clones (Figure 1), which suggested that mAST fragment was inserted into the pcDNA3.1 (+) vector, named recombinant plasmid pcDNA3.1-mAST.

Figure 1 Restriction enzyme digestion of recombinant plasmid pcDNA3.1-mAST by *Xba* I and *Hind* III. Lane 1: DNA/*Eco*R I + *Hind* III Marker; Lanes 2, 3, 5, 6: positive clones; Lanes 4, 7: negative clones.

pcDNA3.1-mAST plasmid DNA was prepared and performed for sequencing. The sequence obtained was the same as the reported sequence of angiostatin cDNA, indicating that

the murine angiostatin gene was successfully cloned into the eukaryotic expression vector pcDNA3.1 (+).

Screening of angiostatin gene-transfected cells

No significant differences between the morphological characteristics of transfected cells and normal SMCC-7721 cells (Figure 2) were observed. No differences were detected in their growth rates (Figure 3).

Figure 2 Morphology of HCC cells. A: SMMC-7721 cells; B: SMCC-7721 cells transfected with pcDNA3.1(+); C: SMCC-7721 cells transfected with pcDNA3.1-mAST.

Figure 3 Growth curve of SMCC-7721 cells.

RT-PCR and Western blotting of angiostatin expression in transfected cells

SMMC-7721 cells transfected with pcDNA3.1-mAST were prepared and used as the template. By using angiostatin primers, a band was detected at 1.4 kb with PCR, indicating the presence of angiostatin cDNA in SMMC-7721 liver cancer cells (Figure 4).

Figure 4 RT-PCR of transfected cells. Lane 1: DNA/*EcoR* I + *Hind* III Markers; Lane 2: positive clones.

Supernatants of cultured cells in three groups were collected and analyzed by Western blotting. A band in a molecular mass of 58 000 was detected with rabbit anti-HA-tagged antibody from the cells transfected with pcDNA3.1-mAST, but no bands were detected from blank control group or vector control group (Figure 5).

Figure 5 Western blotting of angiostatin expression. Lane 1: Marker protein; Lanes 2, 3: SMMC-7721/pcDNA3.1-mAST; Lane 4: SMMC-7721/pcDNA3.1 (+); Lane 5: SMMC-7721.

Tumor growth in nude mice

Tumors were observed in the nude mice just 5 d after they were implanted with cells in blank control group or vector control group. There was no significant difference in tumor volume between blank control group and vector control group ($t=1.53$, $P>0.05$). Mice had a visible tumor 10 d after cell injection in pcDNA3.1-mAST transfection group, and the tumor grew slowly. Tumor volumes among three groups were quite different, and a significant difference was observed when compared angiostatin group with blank control group or vector control group ($t=13.07$ and $t=12.91$, respectively, $P<0.01$, Table 1).

Table 1 Volume of implanted tumors in nude mice of three groups (mm³)

Group	Time after implantation (d)				
	7	14	21	28	35
Blank control	20±5	91±25	624±139	1 631±363	3 538±643
Vector control	19±6	85±24	653±149	1 542±358	3 128±547
Angiostatin	0	23±6	112±20	237±46	755±198 ^b

^b $P<0.01$ vs blank control and vector control group.

On the 35th day, the tumor growth inhibition rate in angiostatin group reached 78.6% vs the control group. In addition, the speed of tumor growth in angiostatin group was significantly slower than that in blank control or vector control group (Figure 6).

On the other hand, the tumor mass in three groups was measured on day 35. It was found that the tumor mass in angiostatin group (2.1 ± 0.5 g) was significantly smaller than

that in blank control (6.0 ± 0.7 g) or vector control (5.9 ± 0.5 g) group ($t=14.98$ and 16.14 , respectively, $P<0.01$), whereas there was no significant difference in tumor mass between the blank control and vector control groups ($t=0.59$, $P>0.05$).

Figure 6 Growth curve of tumors.

MVD

Blood vessels were visualized by CD34 immunohistochemistry and endothelial cells were stained in brown color (Figure 7). There were no significant differences of MVD between the vector control group (49 ± 7 , mm²) and the blank control group (52 ± 6 , mm²) ($t=0.92$, $P>0.05$). But the tumor MVD in the angiostatin group (26 ± 4 , mm²) was significantly lower than that in other two control groups ($t=9.33$, 10.94 , respectively, $P<0.01$), and was about 48.9% of that in the blank control group.

Figure 7 Immunohistochemical analysis of MVD in tumor tissue (×200). A: blank control group; B: angiostatin group

DISCUSSION

The growth and metastasis of a tumor depend upon the growth of blood vessels. Therefore, inhibition of blood vessel growth is a potential therapy for primary tumors, and it has become an important way to treat tumors by increasing the expression of inhibitory factors of angiogenesis in the tumor area. Angiostatin is one of the endogenous angiogenesis inhibitory factors^[10] and has been proved *in vitro* to inhibit the proliferation of endothelial cells. *In vivo* studies also confirmed

that angiostatin could inhibit the angiogenesis in solid tumors that could result in the inhibition of tumor growth^[14-20].

In the present study, we constructed a target fragment that contained a sequence encoding a secretory signal (SS) and a preactivation peptide (PA), the N-terminal kringle1-4 sequence of plasminogen and 11 amino acids in the C-terminal HA-tagged gene. The target gene fragment of 1.4 kb in length was cloned into *Xba* I and *Hind* III restriction sites of eukaryotic expression vector pcDNA3.1(+). Restriction digestion and sequencing analysis for positive clones indicated that a recombinant eukaryotic expression vector containing the angiostatin gene was successfully constructed. This recombinant vector was then transfected into human liver cancer cell line SMMC-7721 and screened by G418. The result of RT-PCR showed that the recombinant plasmid was stably integrated into the cells. By Western blotting, a protein ($M_r=38\ 000$) was detected, indicating that angiostatin protein was expressed in transfected SMMC-7721 cells. Furthermore, the growth curve showed that there was no significant difference in growth rate between transfected and non-transfected SMMC-7721 cells. This indicated that angiostatin had no inhibitory effect on the growth of SMMC-7721 cells.

CD34 is specifically located in endothelial cells. It was reported that CD34 could be regarded as a good marker of endothelial cells in liver cancer because of its high sensibility and specificity. Therefore, the expression of CD34 can reflect the angiogenesis of primary liver cancer and implanted liver tumors. So in this experiment we used CD34 antibody to label endothelial cells.

In this experiment, SMMC-7721 cells that stably expressed angiostatin cDNA (angiostatin group), SMMC-7721 cells alone (blank control group) and SMMC-7721 cells transfected with pcDNA3.1 (+) vector (vector control group) were subcutaneously implanted into nude mice respectively. We found that the implanted tumors appeared later in the angiostatin group, and the mass and volume of the tumor were significantly lower and smaller than those of the other two groups. The inhibitory rate reached 78.6%, and the mass was only 34.6% of that of the blank control group. These results suggested that angiostatin could significantly inhibit the growth of primary tumors. The MVD of the tumor in the angiostatin group was much less than that in the other two groups ($P<0.01$). These data indicated that angiostatin could upregulate the expression of angiogenic inhibitory factors and/or downregulate the expression of angiogenic stimulus factors after its cDNA was transfected into SMMC-7721 cells. This would change the balance between angiogenesis stimulus factors and angiogenic inhibitory factors, thus inhibiting of the angiogenesis and growth of tumors.

Gene therapy, concerning the special angiogenic inhibitory factor of endothelial cells of tumor tissue, is a new way of cancer treatment. We believe that this treatment in combination with chemotherapy and radiotherapy would definitely improve the effect of cancer treatment. Because liver cancer is more prevalent in the world^[21-23], especially in China^[24], our results have the significance in further research.

Abstract

AIM: To investigate p27 expression in hepatocellular carcinoma (HCC), adjacent nontumoral and normal liver tissues, and to verify whether the subcellular localization of p27 was altered in HCC.

METHODS: The level of p27 in tumoral, nontumoral, and normal liver tissues were assessed by immunohistochemical (IHC) analysis. Parallel immunostaining was done for proliferating cell nuclear antigen (PCNA) to evaluate cell proliferation.

RESULTS: The labeling index (LI) of p27 in tumoral lesions was significantly lower than that in adjacent nontumoral lesions ($t=2.444$, $P=0.017$) and normal controls ($t=2.268$, $P=0.029$). The LI of p27 significantly decreased in patients with massive type ($t=2.227$, $P=0.037$) and infiltration ($t=2.197$, $P=0.036$). The prognosis of patients with higher p27 LI was longer than that of patients with lower p27 LI ($P=0.0247$, log-rank test). The LI of PCNA was significantly higher in HCC than that in adjacent nontumoral lesions ($t=2.092$, $P=0.041$) and normal controls ($t=3.533$, $P=0.002$). There was no significant correlation between p27 expression and cell proliferation in tumor samples. The level of p27 in the cytoplasmic fraction was higher in tumoral and nontumoral liver tissues, and was associated with clinical stage ($t=2.520$, $P=0.029$) and the degree of invasion ($t=2.640$, $P=0.019$). Survival analysis showed that p27 was an independent prognosis marker for HCC patients.

CONCLUSION: These results suggest that p27 underexpressing in patients with HCC is closely associated with infiltration, metastasis, and prognosis. Alterations in the subcellular localization of p27 protein may occur early during hepatocarcinogenesis.

INTRODUCTION

Abnormalities in various regulators of cell cycle frequently

occur in human cancers^[1-4]. Cell cycle is tightly controlled by the regulators, including cyclins, cyclin-dependent kinases (CDKs), and their inhibitors. Cyclin-dependent kinase inhibitors (CKIs) are potent negative regulators of cell cycle, and have two families on the basis of sequence homology. The inhibitors of CDK4 (INK4) family, including p16^{Ink4a}, p15^{Ink4b}, p18^{Ink4c}, and p19^{Ink4}, specifically binds to CDK4 and CDK6, and inhibits cyclin D binding. The Cip/Kip family, including p21^{Cip1}, p27^{Kip1}, and p57^{Kip2}, binds to and inhibits cyclin-bound CDKs^[5]. Among CKIs, p27 is thought to have crucial^[6] and important roles in a variety of fundamental cellular processes^[7-10]. The underexpression of p27 assessed by IHC analysis has been associated with more severe tumor grade and a negative prognostic marker in different carcinomas^[11-16].

Furthermore, studies showed that reduced p27 expression was correlated with advanced tumor stages and poorer disease-free survival in patients with HCC at a variety of evolutionary stages^[17-20]. However, most precious investigations are based on immunostaining of tumoral liver samples without comparing with surrounding nontumoral liver, which should be the best control tissue to be used for comparison.

In addition, p27 functions at the nuclear level by binding to and inhibiting cyclin/CDK complexes. It was recently reported that cytoplasmic displacement was an alternative way to inhibit p27 activity and might also play a role in tumor development^[21]. Indeed, positive immunostaining of cytoplasmic p27 has been previously reported in various human cancers^[22-25]. To address this hypothesis, the expression of p27 in tumoral, adjacent nontumoral, and normal liver tissues was evaluated by IHC analysis in patients with HCC, and the subcellular distribution of p27 was also investigated in this study.

MATERIALS AND METHODS

Patients and tumor samples

From January 2000 to December 2001, 32 liver samples were collected from patients who had HCC and underwent surgery in our institution. All liver tumors were histologically diagnosed. Tumor gross type and stage were diagnosed using Eggel's classification and Union International Contre Cancer (UICC) criteria. Tumor cellular differentiation was identified by Edmondson's classification. No patient received pre-operative chemotherapy or chemoembolization. The clinicopathologic characteristics of 32 patients with HCC are listed in Table 1. Normal livers were prepared from 10 patients who were died from the accident as the controls.

After curative surgery, all patients were followed up every 3 mo till death. They were followed from 2 to 32 mo (mean 15.2 mo). Actuarial survival was measured from the day of surgical operation to that of death or last follow-up.

Immunohistochemical study

Liver samples were routinely fixed in 40 g/L formaldehyde solution and embedded in paraffin. After slicing into 4 μ m-thick sections, IHC analysis was performed using Dako ElivisionTM plus two-step System. In brief, the sections were dewaxed in xylene, and rinsed in alcohol and graded alcohol/water mixtures. Then, 30 mL/L hydrogen peroxide was applied to block

endogenous peroxidase activity. The sections were subsequently treated in a microwave oven twice for 5 min in citrate buffer (pH 6.0) at high power. After blocking with goat serum, the mouse monoclonal antibodies against p27 (ZM-0340) and PCNA (ZM-0213) (Zymed Biotechnology, Zymed, CA) were applied on the slides at the dilution of 1:120 and 1:50, respectively. After rising, staining was performed by the Elivision™ plus two-step System (kit-9902, Dako, Carpinteria, CA). The color was developed by reacting with 3,3-diaminobenzidine. Slides were then counterstained with hematoxylin, dehydrated, cleared, and mounted. Negative controls were performed by replacing the primary antibody with nonimmune mouse serum or PBS (Figure 1). A human breast cancer specimen and the reactive tonsil were used as positive controls for p27 (Figure 2) and PCNA, respectively.

Immunostaining evaluation

Slides were mounted independently by 2 investigators without notifying any clinical or pathological information. The positive cells for p27 and PCNA were measured by counting at least 1 000 HCC cells from at least 5 randomly selected fields under the microscope. Then, LI was calculated as a percentage for each protein.

Statistical analysis

Values were expressed as mean±SD. The Student's *t* test was performed to analyze the relationship between the expression of the proteins and various clinicopathologic parameters. The

cumulative survival rate was computed and actuarial survival curves were constructed by the Kaplan-Meier method. The cumulative survival rate was compared between groups using the log-rank test. Relevant prognostic factors were identified by univariate and multivariate Cox proportional hazard regression analyses. Tests were considered significant when the *P* values were <0.05.

Figure 1 Negative control of p27 (×400).

Figure 2 Positive control of p27 (×400).

RESULTS

Reduced expression of p27 in HCC

The mean LI of p27 in HCC was 27.7±19.9%, which was lower than that in adjacent nontumoral lesions (42.3±21.4%, *t*=2.444, *P*=0.017) and that in normal controls (39.1±17.5%, *t*=2.268, *P*=0.029). Furthermore, the LI of p27 in adjacent nontumoral lesions was not significantly different from that in normal controls (Figure 3). Table 2 shows the relationship between p27 expression and clinicopathologic characteristics. The LI of p27 significantly decreased in patients with massive type (*t*=2.227, *P*=0.037) and infiltration (*t*=2.197, *P*=0.036).

Proliferating activity in HCC

The mean LI of PCNA was 49.5±14.2% in HCC, which was higher than that in adjacent nontumoral lesions (42.8±11.2%, *t*=2.092, *P*=0.041) and normal controls (36.2±8.9%, *t*=3.533, *P*=0.002). The LI of PCNA in adjacent nontumoral lesions was not significantly different from that in normal controls (Figure 4). The LI of PCNA significantly increased in cases with poor differentiation (*t*=2.259, *P*=0.031, Table 2). The patients were divided into low p27 and high p27 groups with the cut-off value of the median LI. The LI of PCNA was 51.2±15.6% and 48.1±13.0% in low p27 and high p27 groups, respectively. There was no significant difference between these two groups (*t*=0.578, *P*=0.568).

Altered subcellular localization of p27 in HCC

The cytoplasmic expression of p27 was found in the HCC,

adjacent nontumoral, and normal liver tissues. Therefore, the cytoplasmic displacement of p27 might not be a specific phenomenon of tumor cells. However, the cytoplasmic sequestration of p27 was more frequent in HCC and adjacent nontumoral lesions (Figure 3).

The mean LI of cytoplasmic p27 was $31.0 \pm 12.6\%$ in adjacent nontumoral lesions, which was higher than that in HCC ($21.6 \pm 18.2\%$, $t=2.378$, $P=0.021$) and normal controls ($13.9 \pm 5.6\%$, $t=5.994$, $P<0.001$). The LI of cytoplasmic p27 in HCC was higher than that in normal controls ($t=2.106$, $P=0.042$).

Whereas, the nuclear LI in normal controls ($31.3 \pm 12.6\%$) was higher than that in HCC ($12.5 \pm 9.7\%$, $t=4.968$, $P<0.001$) and nontumoral lesions ($16.5 \pm 10.4\%$, $t=3.731$, $P=0.001$). Altered subcellular localization of p27 was correlated with clinical stage ($t=2.520$, $P=0.029$) and the degree of invasion ($t=2.640$, $P=0.019$) (Table 2).

Expression of p27 and PCNA and survival

The survival rate of 6, 12, and 24 mo was 71.9%, 47.8%, and 25.1%, respectively. The patients were divided into 2 groups according

to the median LI of p27, cytoplasmic p27, and PCNA. The survival analysis was performed on 32 patients and took into account for the following variables: age, gender, gross type, tumor size, UICC tumor stage, Edmondson's grade, portal invasion, lymph node metastasis, depth of invasion, infiltration, p27 LI, cytoplasmic p27 LI, and PCNA LI. In univariate analysis, a significant correlation with short survival was found only for present portal invasion ($P=0.021$) and low p27 expression ($P=0.033$). The prognosis of patients with higher p27 LI was longer than that of patients with lower p27 LI ($P=0.0247$, log-rank test, Figure 5). Multivariate analysis was performed by Cox proportional hazard regression model, age ≥ 45 years ($P=0.016$) and low p27 expression ($P=0.009$) were significantly associated with shorter survival. In addition, there was a trend of present lymphocyte metastasis ($P=0.05$) and advanced stage ($P=0.08$) correlated with poor prognosis (Table 3). For gross type, tumor size, Edmondson grade, depth of invasion, infiltration, cytoplasmic p27 LI, and PCNA LI, no significant correlations with overall survival were found.

DISCUSSION

Hepatocellular carcinoma is one of the most common malignant tumors in China, and the incidence of HCC has increased in recent years^[26]. Cell proliferating activity is one of the prominent parameters for evaluating the biological aggressiveness of tumors. The study in cell proliferating status of HCC is very important for evaluating the biological aggressiveness^[27,28], because distant and lymph node metastasis are not very common.

The protein p27 is an important member of CKI family. It regulates G1 progression by binding to and inhibiting cyclin/CDKs^[29,30]. Loss or reduced expression of p27 has been found in a variety of human cancers and associated with more aggressive tumor behavior. The present study showed that p27 expression significantly decreased in HCC. The finding of p27 underexpression in HCC was similar to the previous reports^[31]. This study showed that the expression of p27 in

HCC was associated with gross type and direct liver invasion. Univariate analysis showed that portal invasion and p27 LI were related to survival in this study. In multivariate analysis, p27 expression was the strongest predictor of survival for HCC patients, which was independent of the other variables. Similar findings have also been observed in other cancers^[32-34]. It is therefore suggested that p27 should work as a negative regulator during hepatocarcinogenesis and may exert a useful prognostic marker. Interestingly, as reported by Milde-Langosch^[35], there was no correlation between p27 expression and proliferating level, indicating that reduced expression of p27 did not merely reflect high proliferating activity during tumor progression.

To our knowledge, this was the first study to report the altered subcellular localization of p27 in HCC. The protein p27 can bind to and inhibit the active cyclin/CDK complexes in the nucleus, so the cytoplasmic displacement may play an important role in inactivating this protein in tumor cells and in contributing to tumor development. Indeed, cytoplasmic localization of p27 immunostaining has been reported in various types of human cancers. In our study, we found that the cytoplasmic localization of p27 was more frequent in HCC and surrounding nontumoral livers. Furthermore, the cytoplasmic staining for p27 was more frequently accompanied with nuclear staining in normal controls. However, the increase in the cytoplasmic staining for p27 was often observed in the absence of a concomitant increase in the nuclear staining and was sometimes associated with a decrease in the nuclear staining. Some tumors expressed an increased level of p27 mainly because of an increase in the cytoplasmic level of this protein. The increase in the amount of cytoplasmic p27 was more frequent in early stage (I and II) tumors. Altered subcellular localization of p27 was also reported in Barrett's associated adenocarcinoma and colon cancer^[22,23]. In agreement with our results, cytoplasmic localization of p27 was an early event during carcinogenesis.

Although the mechanism responsible for the abnormal subcellular localization was not known, it may be due to loss of the tuberous sclerosis complex gene-2 (TSC2), the HER/Grb2/MAPK pathway which leads to nuclear export of p27^[36], overexpression of cyclin D3 which contributes to retaining p27 in the cytoplasm^[37], or PKB/Akt which phosphorylates p27 to impair its nuclear import^[38-40].

In conclusion, our results suggest that underexpression of p27 can contribute to the development of HCC. Cytoplasmic displacement is an alternative mechanism of inactivating p27 that acts early during hepatocarcinogenesis. Furthermore, studies on a large number of cases will reveal the significance of p27 subcellular localization in hepatocarcinogenesis and its relationship with clinicopathologic and prognostic parameters.

Abstract

AIM: Loss of heterozygosity (LOH) on tumor suppressor genes is believed to play a key role in carcinogenesis of colorectal cancer. When it occurs at a tumor suppressor gene locus with abnormal allele, neoplastic transformation happens. In this study, we analyzed the LOH at 21 loci on chromosome 1 in sporadic colorectal cancer to identify additional loci involved in colorectal tumorigenesis.

METHODS: Twenty-one polymorphic micro-satellite DNA markers were analyzed with PCR both in 83 cases of colorectal cancer and in normal tissues. PCR products were electrophoresed on an ABI 377 DNA sequencer. Genescan 3.1 and Genotype 2.1 software were used for LOH scanning and analysis. χ^2 test was used to compare LOH frequency with clinicopathological data. $P < 0.05$ was considered as statistically significant.

RESULTS: The average LOH frequency of chromosome 1, short arm and long arm was 19.83%, 18.00% and 21.66%, respectively. The 2 highest LOH loci with a frequency of 36.54% and 32.50% were identified on D1S468 (1p36.33-p36.31) and D1S413 (1q31.3), respectively. On D1S2726 locus, LOH frequency of rectal cancer was 28.57% (6/21), which was higher than that of colon cancer (0.00%, 0/33) ($P = 0.002$), suggesting that the mechanism of carcinogenesis was different in both groups.

CONCLUSION: Putative tumor suppressor genes on chromosome 1 may relate to sporadic colorectal carcinomas. Tumor-suppressor-genes might locate on 1p36.33-36.31 and/or 1q31.3.

INTRODUCTION

Colorectal cancer is one of the three leading causes of cancer mortality worldwide. The progression of the cancer is due to an accumulation of genetic alteration in controlling growth

and proliferation at numerous loci. As a model for both multistep and multipathway carcinogenesis, colorectal neoplastic progression provides paradigms of both oncogenes and tumor suppressor genes^[1,2]. The loss of heterozygosity (LOH) on tumor suppressor genes is believed as one of the key steps to carcinogenesis of colorectal cancer^[3]. The loss of one allele at a specific locus is caused by a deletion mutation or loss of a chromosome from a chromosome pair^[4]. When this occurs at a tumor suppressor gene with an abnormal allele, neoplastic transformation occurs. In colorectal cancers, frequent allelic loss has been identified in chromosome 5q (30%), 8p (40%), 17p (75-80%), 18q (80%), and 22q (20-30%)^[5,6]. Tumor suppressor genes APC, p53, and DCC were found to be located on chromosome 5q, 17p, and 18q, respectively. LOH analysis became an effective way to find informative loci candidate tumor suppressor genes afterwards^[7,8]. In this study we analyzed the LOH at 21 loci on chromosome 1 in sporadic colorectal cancers to identify additional loci involved in colorectal tumorigenesis.

MATERIALS AND METHODS

Materials

From 1998 to 1999, 83 consecutively collected tumors were treated surgically at Surgical Department of First People's Hospital in Shanghai Jiaotong University. There were 40 males and 43 females with a median age of 66 years (range 31-84). The diagnosis was verified pathologically. The number of Dukes stages A, B, C, D was 8, 21, 40 and 14, respectively. The number of proximal colon cancer, distal colon cancer, and rectal cancer was 33, 21 and 29, respectively. Well-differentiated adenocarcinomas, moderately differentiated adenocarcinomas and poorly differentiated adenocarcinomas were 23, 39 and 6, respectively, and mucinous adenocarcinomas were 15. HNPCC patients were ruled out by Amsterdam criteria^[9,10]. Informed consent to use surgical specimens in this study was obtained from patients.

Methods

DNA extraction Thirty min after surgery, fresh cancerous and adjacent normal tissues were cut into approximately 2 mm³ and immediately frozen in liquid nitrogen. DNA was extracted using standard method with proteinase K digestion and phenol/chloroform purification.

Microsatellite markers and PCR Twenty-one fluorescence-labeled primers for polymorphic microsatellite markers (Perkin-Elmer, USA), at a density of approximately one marker every 10 cm (Figure 1), were used to amplify DNAs from normal and tumor tissues for LOH analysis. PCR for DNAs from normal and tumor tissue was done to analyze the polymorphic microsatellite markers. PCR conditions were as follows: 5 μ L total volume with approximately 1.4 ng of DNA as a template with 10 \times standard buffer, 0.3 μ L Mg²⁺, 0.8 μ L deoxynucleotide triphosphates, 0.3 unit of Hot-start taq polymerase and 0.06 μ L of each oligonucleotide primer, with the forward primer fluorescence labeled with HEX, FAM or NED. Cycling conditions consisted of 3 stages: an initial

denaturation at 96 °C for 12 min in stage I; 14 cycles each at 94 °C for 20 s, at 63-56 °C for 1 min (0.5 °C decreased per cycle), at 72 °C for 1 min in stage II; 35 cycles each at 94 °C for 20 s, at 56 °C for 1 min, at 72 °C for 1 min in stage III^[11-13].

Figure 1 Twenty-one microsatellite markers on chromosome 1.

LOH analysis PCR product (0.5 µL) was mixed with 0.1 µL of Genescan 500 size standard (PE Applied Biosystems, USA) and 0.9 µL of formamide loading buffer. After denaturation

at 96 °C for 5 min, products were electrophoresed on 50 g/L polyacrylamide gels on an ABI 377 DNA sequencer (PE Applied Biosystems, USA) for 3 h. Genotype 2.1 software displayed individual gel lanes as electropherograms with a given size, height, and area for each detected fluorescent peak. Stringent criteria were used to score the samples. Alleles were defined as the two highest peaks within the expected size range. A ratio of T1:T2/N1:N2 less than 0.67 or greater than 1.50 was scored as a loss of heterozygosity (Figure 2). Most amplifications of normal DNA producing two PCR products indicated preserve of heterozygosity. A single fragment amplified from normal DNA (homozygote) and fragments not clearly amplified from PCR reactions were scored as not informative. The LOH frequency of a locus was equal to the ratio of the number between allelic loss and informative cases. The average LOH frequency of chromosome 1 was the mean of the LOH frequency in all loci^[14-17].

Statistics χ^2 test was used to compare LOH with clinicopathological data. $P < 0.05$ was considered statistically significant.

RESULTS

LOH of 21 microsatellite markers on chromosome 1

The average LOH frequency at chromosome 1, short arm and long arm was 19.83%, 18.00% and 21.66%, respectively. The two highest LOH loci with a frequency of 36.54% and 32.50% were identified on D1S468 (1p36.33-36.31) and D1S413 (1q31.3). Other loci also exhibited higher LOH frequencies, including D1S255 (1p34.1-32.3), D1S2868 (1p22.1), D1S218 (1q24.1-24.3), D1S249 (1q32.2), D1S2800 (1q42.12-42.2) and D1S2836 (1q43-44) (Table 1).

Relationship of clinicopathological features and LOH on chromosome 1

On D1S2726 locus, LOH frequency of rectal cancer was 28.57% (6/21), which was higher than that of colon cancer (0%, 0/33) ($P = 0.002$). No association between LOH of each marker on chromosome 1 and other clinicopathological data (patient sex, age, tumor size, growth pattern or Dukes stage) was observed. It indicated that LOH on chromosome 1 was a common phenomenon in all kinds of sporadic colorectal cancers (Tables 2A, 2B).

Figure 2 Typical peak and normal peak of LOH3. A: Typical peak of LOH: Allele ratio=(T1/T2)/(N1/N2)=(190/62)/(341/270)=2.43>1.5, B: The normal peak (no LOH): Allele ratio=(T1/T2)/(N1/N2)=(1172/764)/(350/264)=1.15, T: Tumor, N: Normal.

DISCUSSION

During tumorigenesis, loss of wild-type alleles (inherited from the non-mutation-carrying parents) is frequently observed. Loss of heterozygosity (LOH) on tumor suppressor genes played a key role in colorectal cancer transformation, and LOH analysis of sporadic colorectal cancers could help discover unknown tumor suppressor genes^[7,8]. In this study, LOH scanning was analyzed by Genotyper software in 83 sporadic colorectal cancer samples with 21 highly polymorphic markers, the ratio of the fluorescence intensity of alleles was studied to identify additional loci involved in colorectal tumorigenesis.

In this study, the average LOH frequency at chromosome 1 (19.83%), short arm (18.00%) and long arm (21.66%) was consistent with the previous study^[5]. The two highest LOH loci with a frequency of 36.54% and 32.50% was identified on D1S468 (1p36.33-36.31) and D1S413 (1q31.3). There were few reports about the relationship between the long arm of chromosome 1 and colorectal cancer. But some previous studies showed that the 1q31-32 region frequently presented allelic loss in breast cancers and medulloblastomas. Pietsch *et al.*^[18] found that 36% of medulloblastomas showed loss of heterozygosity (LOH) on chromosome 1q. The study of Benitez J showed more than 60% of breast tumors exhibited allelic loss in the 1q31-32 region^[19]. These results suggested that putative tumor suppressor genes might locate on the 1q31-32 region. Our study also found that D1S413(1q31.3) exhibited a higher LOH frequency and that the LOH frequency of long arm of chromosome 1 was higher than that of short arm^[5]. If D1S413 could be excluded, the LOH frequency of long arm was nearly equal to that of short arm. Thus, we hypothesized that the higher LOH frequency of D1S413 might be the reason why the LOH frequency of long arm of chromosome 1 was higher than that of short arm, suggesting the presence of a tumor suppressor gene in this region. This gene might be involved in the neoplastic process of colorectal cancer, breast cancer and medulloblastoma.

Previous studies showed that the 1p36 region frequently presented allelic loss in various cancers, such as colon cancer^[20], neuroblastoma^[21], hepatocellular carcinomas^[22], lung cancer^[23], and breast cancer^[24]. But only NB gene was confirmed to be the tumor suppressor gene of neuroblastomas. In 1993, Tanaka *et al.* believed that a normal chromosome 1p36 might contain a tumor suppressor gene of colon carcinogenesis^[25]. By database referring, we found TP73 gene (1p36) might be the known candidate tumor-suppressor genes related to colon cancer in this region. TP73, a novel family member of p53, was predicted to encode a protein with significant amino acid sequence similarity to p53^[29]. TP73 could inhibit cell growth in a p53-like manner by inducing apoptosis^[27]. Kaghad *et al.*^[26] regarded TP73 as a tumor suppressor gene. But Sunahara found that allelic loss of p73 occurred only in 17% of colorectal carcinomas, and suggested that p73 might not play a role as a tumor suppressor in colorectal carcinoma at least not in a classic Knudson manner^[28]. In our study, the highest LOH frequency was exhibited in 1p36.33-36.31, and colorectal cancer related tumor suppressor gene (s) might locate in the region. TP73 gene is a member of p53 family, its effect on colorectal carcinogenesis is not certain and requires further study. Due to many genes located in the region of 1p36.33-36.31, further LOH scanning with high-density microsatellite markers in the region is necessary in order to find new candidate genes.

No association between LOH markers on chromosome 1 and the clinicopathological data was found, indicating that LOH was a common phenomenon in all sporadic colorectal cancers. However, we found that on D1S2726 locus, LOH frequency of rectal cancer was high, no LOH was found in colon cancer. In 2001, Kapiteijn *et al.*^[29] proposed that rectal cancer had more significant expression of p53 and more nuclear beta-catenin than colon cancer, and considered that the mechanism of carcinogenesis in distal colon was different from that in proximal colon. Our results could show that the mechanism of carcinogenesis in distal colon and rectum was not completely the same as in proximal colon.

In conclusion, colorectal cancer associated candidate genes are likely to locate on D1S468 and D1S413. Further LOH scanning with high-density microsatellite markers in the region may provide much more genetic information and discover novel tumor suppressor genes.

Abstract

AIM: To explore the effect of Hejie decoction (HJD) (mediation decoction) on T cellular immune state of chronic hepatitis B patients.

METHODS: Sixty-five patients with chronic hepatitis B were randomly divided into 2 groups. Forty patients in the treatment group were treated by HJD, and 25 patients in the control group were treated by routine Western medicine. The TCRV β_7 gene expression, T lymphocyte subsets (CD $_3^+$, CD $_4^+$, CD $_8^+$, CD $_4$ /CD $_8^+$) levels were observed before and after treatment.

RESULTS: The level of CD $_4^+$ cells was lower whereas the level of CD $_8^+$ cells was higher in patients than in the normal group. There was no significant difference between the levels of CD $_3^+$ cells in patients and normal persons. After 6 months of treatment, ALT, AST, TB levels of the 2 groups were obviously decreased, and the level of CD $_4^+$ cells was increased whereas the level of CD $_8^+$ cells was decreased in the treatment group. However, the level of CD $_4^+$ cells and CD $_8^+$ cells had no significant difference in the control group. TCRV β_7 expressions were detected in 6 patients of the treatment group, whose HBV-DNA and HBeAg turned negative and ALT became normal. HBeAg in another 3 patients turned negative while HBV-DNA did not, and TCRV β_7 expressions were not detectable. TCRV β_7 expression could not be detected in the control group, HBV-DNA of the control group did not turn negative. HBeAg in 1 patient turned negative while HBV-DNA did not, and TCRV β_7 expressions were not detectable. The total effective rate was not significantly different between the 2 groups and the markedly effective rate was significantly different ($P < 0.01$).

CONCLUSION: HJD is effective for treating chronic hepatitis B, and its effect seems to relate with the improvement of the TCRV β_7 expression of chronic hepatitis B patients, thus activating T cells and eliminating HBV. T cellular immune function plays an important role in HBV infection and virus elimination.

INTRODUCTION

T cells take charge of recognizing the cells infected with bacilli and virus, as well as cancer cells^[1]. Recent studies have demonstrated that the stimulating signal would be transferred to the inside of cells by CD $_3$ molecules when antigens are recognized by T cell receptor (TCR), sequentially activating T lymphocyte cells. TCR plays a crucial role in exerting T cellular immune function. Therefore it is very important to investigate the relation of T cellular function and clinical effect by studying the function of T cell receptor^[2-4]. We treated chronic hepatitis B patients with HJD from June 1999 to March 2003, and observed the relation between clinical effects and T lymphocyte subsets, TCRV β_7 gene expression. The results are reported as follows.

MATERIALS AND METHODS

Materials

All the 65 patients with chronic hepatitis B enrolled were outpatients from the special clinics of liver diseases, and were divided into 2 groups according to random number table. The 40 patients in the treatment group were 22 males and 18 females, aged 18-60 years, averaged 38.6 \pm 9.8 years, with an average course of illness of 0.8-12.5, 3.5 \pm 1.2 years. The 25 patients in the control group were 14 males and 11 females, aged 18-60 years, averaged 39.0 \pm 8.9 years, with an average course of illness of 0.6-11.1, 3.2 \pm 1.1 years. The difference of clinical data between the 2 groups was insignificant, so the 2 groups were comparable. Ten age-matched healthy donors from the Blood Center of our hospital were assigned as normal group.

Diagnostic criteria

The patient had a history of hepatitis B or HBsAg carrier for at least 6 mo and still had the symptoms and signs of hepatitis and abnormal liver function at the time when they were included in the trial. Their HBsAg, HBeAg and HBVDNA were positive.

Criteria of enrollment

The patients were aged 18-60 years, their serum levels of alanine aminotransferase (ALT) were between 80 U/L and 240 U/L, their serum HBeAg and HBV-DNA (quantitative PCR) were positive. The diagnostic criteria of hepatitis B were in accordance with the standards for chronic viral hepatitis issued in the Fifth National Conference on Infectious Diseases and Parasitosis in China (Beijing, China, 1995)^[5].

Criteria of exclusion

The patients who were over 60, or less than 18 years old, and those who were pregnant or in breast-feeding period, those who were complicated with hepatitis C or other hepatic viral infection, suspicious of autoimmune hepatitis, and drug hepatitis or alcoholic hepatitis, as well as those who had severe

complications of cardiovascular, renal or hematopoietic systems and mental diseases were excluded from the trial.

Methods

The treatment group was treated with Hejie decoction, consisting of Radix Bupleuri 10 g, Radix Scutellariae 12 g, Rhizoma Pinelliae 9 g, Radix Codonopsis Pilosulae 30 g, Radix Glycyrrhizae Praeparata 6 g, Fructus Ziziphi Jujubae 9 g, Rhizoma Polygoni Cuspidati 30 g, Radix Morindae Officinalis 8 g, Herba Hedyotis Diffusae 30 g. One dose was taken per day for 6 mo. The control group was treated with compound vitamin B₂, 2 tablets, vitamin C 100 mg, vitamin E 50 mg, Wuzhi capsules, 2 tablets, 3 times a day for 6 mo. Patients who had normal serum ALT, HBeAg and HBV DNA (quantitative PCR) after treatment were defined as responders, while those with negative results were taken as non-responders.

Patients' symptoms and signs were recorded in detail using "Clinical Observation Table" once a month before and during the treatment. HBV-M and anti-HAV, anti-HCV, anti-HDV and anti-EBV marks: Enzyme linked immunosorbent assay (ELISA) kit was obtained from Shanghai Kehua Corporation. HBV-DNA: Quantitative polymerized chain reaction (PCR) kit was from Diagnostic Center of Sun Yat-Sen University.

The patients had liver function examination (American Experiment Instrument Corporation) every month during the treatment, including contents of serum proteins, total bilirubin (TB), and activities of ALT and AST (aspartate aminotransferase). The kit was a product of American Experiment Instrument Corporation.

T-lymphocyte subsets were detected using single clone antibody APAAP method, the kits were purchased from Wuhan Boster Biological Technology Co. Ltd.

Peripheral blood mononuclear cells (PBMC) were prepared from 8 mL of freshly, heparinized blood by centrifugation at 400 r/min through a Ficoll-hypaque density gradient, washed 3 times with 10 g/L BSA in PBS and resuspended in 5 g/L BSA in PBS, stored on ice or at -70 °C for extraction of RNA.

Total cellular RNA was extracted from fresh PBMC with acid guanidinium thiocyanate-phenol-chloroform extraction according to the manufacturer's instructions, RNAs were purchased from Promega Corporation.

The primers were synthesized on an applied biosystems DNA synthesizer (Shanghai Shengong Company, China), and the sequences^[6] were (5' -3'): CCTGAATGCCCAACAGCTCTC,

expanding length: 235. β -actin was prepared as an internal standard to quantify the products. Three micrograms of total RNA was used to synthesize first-strand cDNA. RT-PCR was carried out according to the manufacturer's instructions (Promega, USA). The amplified products were then electrophoresed on 20 g/L agarose gel. The electrophoresis images were scanned by Fluor-S MultiImager (Bio-Rad, USA) and analyzed according to the V β / β -actin ratios by computing densitometer and Image Quant software.

Statistical analysis

All statistics were performed by using statistical procedure of social science (SPSS), including chi-square test and Wilcoxon rank sum test. The probability values less than 0.05 were considered significant.

RESULTS

Standard for efficacy evaluation

The clinical efficacy of treatment was evaluated according to the following standards formulated by authors: (1) Markedly effective: Chief symptoms including right upper abdomen pain, poor appetite and abdominal distention disappeared, HBeAg and HBV-DNA turned negative, serum levels of ALT, AST, TBIL restored to normal. (2) Effective: Chief symptoms were alleviated or improved, the level of HBV-DNA decreased, HBeAg did not turn negative, serum levels of ALT, AST, TBIL decreased by >1/2 of the original levels. (3) Ineffective: Neither the chief symptoms nor the serum levels of ALT, AST and TBIL or HBeAg, HBV-DNA showed any improvement.

Clinical efficacy of treatment

In the treated group, the treatment was markedly effective in 6 cases, effective in 33 and ineffective in 1, the total effective rate was 97.5%. In the control group, the treatment was markedly effective in 0 cases, effective in 22 and ineffective in 3, the total effective rate was 88.0%. The difference of total effective rate was insignificant between the 2 groups ($P>0.05$) and that of markedly effective rate was significant ($P<0.01$).

ALT, AST, TB and HBVDNA levels before and after treatment, as well as TCRV β gene expression

After 6 mo of treatment, the ALT, AST, TB levels of the 2 groups

Table 1 ALT, AST, TB and HBVDNA levels before and after treatment (mean \pm SD)

were obviously decreased ($P<0.01$), HBVDNA levels of the treatment group were obviously decreased ($P<0.05$, Table 1). TCRV β_7 expressions were detected in 6 patients of the treated group, and their HBV-DNA and HBeAg turned negative, and HBeAg in another 3 patients turned negative, but HBV-DNA did not turn negative, and TCRV β_7 expressions were not detectable. The TCRV β_7 expression could not be detected in the control group, HBV-DNA of the control group did not turn negative. HBeAg in 1 patient turned negative in the control group, but HBV-DNA did not turn negative, and TCRV β_7 expressions were not detectable. In patients without HBeAg negative conversion, or patients with HBeAg negative conversion and positive HBV-DNA and normal liver function, TCRV β_7 expression could not be detected.

T lymphocyte subsets before and after treatment

The level of CD $_4^+$ cells was lower whereas the level of CD $_8^+$ cells was higher in the patients than in the normal group ($P<0.01$), there was no significant difference between the levels of CD $_3^+$ cells of the patients and normal persons. After 6 mo of treatment, the level of CD $_4^+$ cells increased whereas the level of CD $_8^+$ cells decreased ($P<0.05$) in the treated group. However, the level of CD $_4^+$ cells and CD $_8^+$ cells had no significant difference in the control group ($P>0.05$, Table 2).

Table 3 T lymphocyte subsets of responders and non-responders in treatment group before and after treatment (mean \pm SD)

	Post-T	34	66.09 \pm 9.35	35.72 \pm 8.70	33.85 \pm 5.52
Normal		10	67.80 \pm 8.65	39.07 \pm 8.50	30.55 \pm 5.52

n: number; responders: patients who had normal ALT and HBeAg and HBV DNA after treatment; non-responders: patients who had abnormal ALT, HBeAg and HBV DNA after treatment; normal: normal group; Pre-T: before treatment; Post-T: after treatment; ^a $P<0.05$, vs before treatment in the same group, ^b $P<0.01$, vs normal group.

T lymphocyte subsets of responders and non-responders in treatment group before and after treatment

The level of CD $_3^+$, CD $_4^+$, CD $_8^+$ cells in the 2 groups had no significant difference before treatment ($P>0.05$). The level of CD $_4^+$ cells increased whereas the level of CD $_8^+$ cells decreased in the responders' group ($P<0.01$). The level of CD $_4^+$ and CD $_8^+$ cells in the non-responders' group had no significant difference after treatment ($P>0.05$, Table 3).

DISCUSSION

Although the pathogenesis of chronic hepatitis B has not been fully studied, the importance of cellular immune in the occurrence of chronic HBV infection and elimination of HBV has received more and more attention^[7]. CD $_3^+$, CD $_4^+$ and CD $_8^+$ are the major function subsets of T cells, many studies have discovered that CD $_3^+$, CD $_4^+$ of chronic hepatitis B with serum HBV positive are lower than those of chronic hepatitis B with serum HBV negative, and the higher the quantity of HBVDNA is, the lower the T cellular immune function is. Antiviral cellular immune response of CD $_4^+$ and CD $_8^+$ is the important mechanism of hepatocyte injury induced by HBV, the specific response of CD $_4^+$ and CD $_8^+$ to the virus antigen is closely related with the elimination of the virus. It is suggested that T cells could play a critical role in response to HBV infection, and their level and mutual relationship could be used to identify the cellular immune

level and could serve as one of the valuable immunologic targets to forecast the change of patients' condition^[8-12]. Some studies on chronic hepatitis B showed that T cell receptor function was the important cause of the obstacle to T cells, sequentially bringing about HBV escaping immune response, and finally resulting in standing HBV infection^[2,3,13-16]. Therefore, it is very important to study the antiviral effect of T cells starting with immune identification.

TCR has been found to be the receptor of T lymphocyte surface recognising extra antigen and the major histocompatibility complex I (MHC I), as well as the specific sign of T cells^[17-19]. The genes of the α and β chains which promote TCR α β reset formation of large amount of specific TCR to recognise the extra antigen when they meet antigen. TCR and CD $_3$ would inosculate on the surface cells and form TCRCD3 compounds, the stimulating signals would be transferred to the inside of cells by CD3 molecules when antigens were recognised by TCR, activating T lymphocyte cells^[20-26]. Some studies have indicated that the priority expression and employment of TCRV β_7 were related with the specific immune reaction of chronic hepatitis B^[27-29]. Therefore, It is a meaningful pathway to eliminate HBV and decrease the occurrence of liver cancer by screening experimental recipes to activate T cells by improving T cell recognising function under the present circumstances of low cure ratio and high recurrence. We discovered that in the outbreak period of chronic hepatitis B, TCRV β_7 gene expression was low. The level of CD $_4^+$ cells was lower whereas the level of CD $_8^+$ cells was higher in patients than in the normal group ($P<0.01$). The serum TCRV β_7 gene expressions of non-responders were low, the level of CD $_4^+$ cells of non-responders was lower in patients than in normal persons whereas the level of CD $_8^+$ cells of non-responders was higher in patients than in the normal persons. After treatment, the TCRV β_7 gene expression was high in patients with the conversion of HBV-DNA and HBeAg, and the liver function, the level of CD $_4^+$ and CD $_8^+$ cells resumed to normal. The levels of CD $_4^+$ and CD $_8^+$ cells in the treatment group were significantly different from those before treatment ($P<0.01$). The results showed that TCRV β_7 participated in the elimination of HBV and cytotoxic function, and the occurrence of chronic hepatitis B was related to the low expression of TCRV β_7 . The CTL could not be effectively activated to kill or injure HBV due to the obstacle of T cell receptor function, sequentially bringing about stable reproduction of HBV and resulting in chronic inflammation of hepatocytes. At the same time, we also discovered that TCRV β_7 expression of some patients in the palliating period was still low, indicating that recurrence might increase.

When HBeAg in chronic hepatitis B patients transforms to Anti-HBe, hepatocyte injury aggravates, which is considered to be mediated by CTL antiviral cellular immune response. The dynamic observation of 6 cases whose TCRV β_7 gene expressions were positive showed that the TCRV β_7 gene expression related with the HBeAg serum conversion, the decreased quantity of HBVDNA, and ALT levels experienced a period of acute exacerbation in the course of descending, suggesting that TCRV β_7 participated in the elimination of HBV and cytotoxic function. ALT fluctuation in patients with TCRV β_7 negative was small, and there was no obvious decrease in HBVDNA, or obvious HBeAg serum conversion, suggesting the cellular immune response of the patients was feeble. Thus TCRV β_7 might be an index to evaluate the cellular immune state of hepatitis B patients.

HBeAg is a good index that reflects the HBV replication. When HBeAg transforms to Anti-HBe, the reproduction of HBV will obviously weaken or cease, along with the relief of the state of illness. Among the 10 patients with HBeAg serum conversion, the quantity of HBVDNA in some patients did not alleviate or vanish after HBeAg serum conversion, and the

state of illness fluctuated, which should be treated continually. HJD is a proved recipe for treating hepatitis, in which cold and warm drugs are used to eliminate evils and restore healthy energy. Previous researches indicated that HJD had the effect to protect the liver, as well as the function of antiviral and immune regulation^[30-33]. We discovered that HJD could meliorate liver function, regulate TCRV β 7 gene expression, improve T cellular immune function of chronic hepatitis B in this study. The results suggest that the clinical effects of HJD on chronic hepatitis B, especially on the elimination of HBV, might relate with the improvement of TCR identifying function, and effectively activate CTL. However, HJD could not interrupt immune endurance of some patients, resulting in the failure of treatment, which needs further study to explore the cause and resolving methods.

ASBT and t-ASBT in cholangiocytes is regulated by a negative feedback loop while the expression of these transporters in terminal ileum is modified via positive feedback. Thus, while transcriptional regulatory mechanisms in response to alterations in bile acid pool size are operative in both cholangiocytes and ileocytes, each cell type responds differently to bile acid supplementation and depletion.

Abstract

AIM: We have previously demonstrated that cholangiocytes, the epithelial cells lining intrahepatic bile ducts, encode two functional bile acid transporters via alternative splicing of a single gene to facilitate bile acid vectorial transport. Cholangiocytes possess ASBT, an apical sodium-dependent bile acid transporter to take up bile acids, and t-ASBT, a basolateral alternatively spliced and truncated form of ASBT to efflux bile acids. Though hepatocyte and ileal bile acid transporters are in part regulated by the flux of bile acids, the effect of alterations in bile acid flux on the expression of t-ASBT in terminal ileocytes remains unclear. Thus, we tested the hypothesis that expression of ASBT and t-ASBT in cholangiocytes and ileocytes was regulated by bile acid flux.

METHODS: Expression of ASBT and t-ASBT message and protein in cholangiocytes and ileocytes isolated from paired rats given control (C) and 1% taurocholate (TCA) or 5% cholestyramine (CY) enriched diets, were assessed by both quantitative RNase protection assays and quantitative immunoblotting. The data obtained from each of the control groups were pooled to reflect the changes observed following TCA and CY treatments with respect to the control diets. Cholangiocyte taurocholate uptake was determined using a novel microperfusion technique on intrahepatic bile duct units (IBDUs) derived from C, TCA and CY fed rats.

RESULTS: In cholangiocytes, both ASBT and t-ASBT message RNA and protein were significantly decreased in response to TCA feeding compared to C diet. In contrast, message and protein of both bile acid transporters significantly increased following CY feeding compared to C diet. In the ileum, TCA feeding significantly up-regulated both ASBT and t-ASBT message and protein compared to C diet, while CY feeding significantly down-regulated message and protein of both bile acid transporters compared to C diet. As anticipated from alterations in cholangiocyte ASBT expression, the uptake of taurocholate in microperfused IBDUs derived from rats on TCA diet decreased 2.7-fold, whereas it increased 1.7-fold in those on CY diet compared to C diet fed groups.

CONCLUSION: These data demonstrate that expression of

INTRODUCTION

Bile acids are synthesized in hepatocytes from cholesterol, conjugated to either taurine or glycine, secreted into bile and reach the small intestine via the bile ducts to facilitate lipid absorption^[1]. Subsequently, bile acids are reclaimed at the terminal ileum, returned to the liver via the portal circulation, and resecreted into bile accomplishing their enterohepatic circulation^[1]. At the cellular level, this recycling of bile acids, important for conservation of the bile acid pool, is achieved by the coordinated activities of a series of apical and basolateral membrane bile acid transporters expressed on the epithelial cells of the terminal ileum and liver^[2].

The active recovery of conjugated bile acids in the terminal ileum is mediated by a Na⁺ driven bile acid transporter, ASBT, located at the luminal domain of the ileocyte^[2]. Following uptake into the ileocytes, bile acids bind to the intestinal bile acid binding protein (I-BABP) in the cytoplasm to be directed across the cell to the basolateral membrane where they enter into the portal venous circulation by a Na⁺-independent mechanism^[2]. Subsequently, the majority of conjugated bile acids are efficiently reabsorbed from portal vein blood into hepatocytes, mainly via the Na⁺-taurocholate cotransporter (ntcp)^[3] and then are secreted into the biliary system primarily via ATP-dependent export pumps located on the apical (*i.e.*, canalicular) domain of hepatocytes^[3].

As bile percolates through the intrahepatic bile ducts, it undergoes numerous modifications due to both secretory and absorptive activities of cholangiocytes. We and others, have previously shown that biliary epithelia can take up conjugated bile acids via ASBT^[4,5] expressed on the cholangiocyte apical membrane, a protein identical to that cloned from rat ileum and kidney^[6,7]. We have also recently identified an alternatively spliced and truncated transcript of ASBT, designated t-ASBT that allows cholangiocytes and possibly other bile-acid transporting epithelia (*i.e.*, ileum and kidney) to extrude bile acids at the basolateral domain^[8].

Despite these advances in our understanding of the physiology of bile acid transport, little is known about the regulation of ASBT and t-ASBT in bile acid transporting epithelia, especially in cholangiocytes. While recent studies have assessed the effects of ursodeoxycholic acid supplementation^[9], bile acid depletion and repletion in bile duct ligated rats^[10,11]

and bile acid feeding on different physiologic responses by cholangiocytes, including in some instances ASBT expression^[12]. No studies have addressed the regulation of t- ASBT or systematically compared the responses of the liver and ileum to bile acid expansion or depletion. We, therefore, designed the present study to further investigate the role of bile acids in the regulation of ASBT and t- ASBT in both the biliary tree and terminal ileum. For this purpose, we performed studies in non-surgically manipulated rats to determine the message and protein levels of ASBT and t- ASBT in both cholangiocytes and ileocytes following well-accepted experimental perturbations to either expand (*i.e.*, taurocholate feeding) or deplete (*i.e.*, cholestyramine feeding) the bile acid pool. To ensure that our molecular observations were physiologically relevant, we also employed functional studies using microperfusion of rat intrahepatic bile duct units (IBDUs), a technique recently developed in our laboratory.

MATERIALS AND METHODS

Materials

[α -³²P] UTP (specific activity 800 Ci/mmol) of >95% purity was purchased from Amersham (Arlington Heights, IL), taurocholate (TCA) of 98% purity was obtained from Calbiochem-Novabiochem Corp (La Jolla, CA). MAXIscript SP6/T7 high specific activity transcription kit and RPA III kit were purchased from Ambion Inc (Austin, TX). All sodium dodecyl sulfate-polyacrylamide gel reagents were purchased from Biorad (Hercules, CA). The ASBT antibody used in immunoblotting was a generous gift of Paul Dawson^[2]. The t-ASBT antibody was produced as described previously^[8]. The secondary antibody (goat anti-rabbit), a horseradish peroxidase (HRP) conjugate, was obtained from Biosource International. Enhanced chemiluminescence (ECL) Western blotting detection reagents were bought from Amersham (Arlington Heights, IL). X-ray films were purchased from Eastman Kodak Co (Rochester, NY). For measurement of biliary phospholipids and cholesterol, commercial kits were purchased from Wako Chemicals (Richmond, VA) and Boehringer Mannheim (Indianapolis, IN). All other commercially available reagents, including cholestyramine, were obtained from Sigma Chemical Co (St. Louis, MO).

Animals

All procedures involving rats were in compliance with guidelines of the Mayo Foundation Animal Care Committee, which approved the experimental protocols. Male Fischer 344 rats (225–275 g) purchased from Harlan Sprague Dawley Inc (Indianapolis, IN) were maintained in a temperature-controlled environment (22 °C) with alternating 12-h light-dark cycles. Rats had free access to water but were pair-fed for 10 d, either control diet (C), or diets enriched with 1% taurocholate (TCA) (wt/wt) or 5% cholestyramine (CY) (wt/wt) prepared by Dyets Inc (Bethlehem, PA). The feeding studies were conducted in two paired groups (*i.e.*, control and test) and four sets of rats (TCA *vs* C and CY *vs* C). However for data analysis, results from each of the control groups with respect to the message and protein data were pooled. To ensure equal chow consumption between the pair-fed groups, each rat was kept in an individual cage and its food intake and weight were monitored daily. According to the pair-feeding protocol, the amount of chow consumed by each one of the TCA or CY designated rats one day was provided the following day to the corresponding pair-fed C animal as control chow. At the end of each feeding study, rats were anesthetized with sodium pentobarbital (50 mg/kg) intraperitoneally, the common bile duct was cannulated and bile was collected continuously in timed aliquots to determine bile flow rate. Bile samples were extracted with 4 volumes of isopropanol and immediately frozen in liquid nitrogen for later

measurements of biliary bile acids, phospholipids and cholesterol. Subsequently, rats were euthanized consistently between 8 and 9 am to control possible circadian variation in ASBT and t- ASBT expression.

Isolation of cholangiocytes

Freshly isolated, highly purified cholangiocytes (>95%) were prepared from the livers of C, TCA, and CY fed rats using collagenase perfusion, enzymatic digestion, mechanical disruption and immunopurification as described^[13]. Cholangiocytes derived from animals of the same feeding group were pooled and kept at -70 °C until used for mRNA or protein extraction.

Isolation of ileocytes

The small intestine was prepped and 15 cm of terminal ileum was excised, flushed with cold 9 g/L NaCl solution and the luminal surface was scraped to harvest the epithelial cells. Ileocytes collected from animals of the same feeding group were pooled, centrifuged at 2 000 rpm for 5 min, and the pellet was kept at -70 °C until used for mRNA isolation and protein extraction.

Quantitative ribonuclease protection assay (Q-RPA)

Following extraction of total cellular RNA from freshly isolated cholangiocytes and ileocytes^[14], ASBT and t- ASBT mRNA were determined by Q-RPA using the RPA III kit, as previously described^[8]. Yeast and kidney RNA were used as a negative and positive control, respectively. Following RPA, the ASBT or t- ASBT mRNA content of the samples was measured both by scanning the X-ray film of the protected bands corresponding to either ASBT or t- ASBT and by comparing their arbitrary densitometric units to those obtained from their respective standard curves as described^[8]. The comparability of the total RNA used in this assay was determined both spectrophotometrically and by ultraviolet detection of the intensity of 28S and 18S ribosomal bands on ethidium bromide stained gels.

Quantitative immunoblotting (Q-IB)

Following cholangiocyte immunoisolation, the cells were sonicated twice for 7 s, using a Sonifier cell disrupter (Heat Systems-Ultrasonic, Inc. Plainview, NY) in a buffer containing 50 mmol/L Tris-HCl (pH 7.4), 50 mmol/L EDTA, 100 μ mol/L leupeptin, 1 μ mol/L pepstatin and 0.2 mmol/L PMSF. Cell fragments attached to immunomagnetic beads were removed by applying the samples to a magnet. The remaining cell lysate was centrifuged at 4 °C for 10 min at 2 500 rpm. Subsequently, the cholangiocyte post nuclear supernatant (PNS) was collected, protein concentration was determined and stored at -70 °C until used. To obtain PNS from ileocytes of the terminal ileum, the scraped ileocytes were sonicated in the same buffer and centrifuged as indicated above. In the PNS fraction of ileocytes, protein concentration was calculated and then it was stored at -70 °C until used.

Cholangiocyte and ileal PNS were run on a 120 g/L SDS-polyacrylamide gel. Electrophoresis was done at 100 volts (V) in the presence of a prestained low molecular range protein as a size marker (Biorad) and 40 μ g of kidney PNS as a positive control. Proteins were transferred overnight at 4 °C at 25 V onto nitrocellulose membranes (Micron Separations Inc., Westboro, MA) as described^[4]. Immunoblotting of ASBT and t- ASBT was performed using the well-characterized, specific, rabbit anti rat, polyclonal anti- ASBT^[6] and anti-t- ASBT^[8] antibodies. In brief, membranes were blocked in 50 mL/L milk and incubated at room temperature for 2 h with ASBT antibody (1:4 000) or t- ASBT antibody (1:1 000). Subsequently, membranes were washed 3 times and exposed to horseradish peroxidase conjugated secondary (goat anti-rabbit) antibody (1:7 000) for

1 h at room temperature. Following three additional washings of the membrane, the immunoreactive ASBT (48 kDa) and t-ASBT (19 kDa) bands were detected by enhanced chemiluminescence detection system (ECL).

Immunoblotting for β -actin (41 kDa), a housekeeping protein, was employed to demonstrate equal protein loading. Quantitative comparisons among experimental groups were made by determining the immunoreactive areas by densitometry using an imaging densitometer (Model GS-700) and the Molecular Analyst software program (Bio-Rad Laboratories, Hercules, CA) to calculate the ratios of ASBT or t-ASBT to that of β -actin. The immunoblotting data were also evaluated using another technique to exclude possible risk of β -actin being altered by any of the experimental perturbations. For this purpose, arbitrary densitometric units of each immunoreactive band were divided by the μ g of protein loaded and this value was further divided by the exposure time of the autoradiograph. The specificity of ASBT and t-ASBT antibodies and the bands observed in the immunoblots were evaluated by stripping the membranes and reprobing them with ASBT and t-ASBT antibodies (3 mg/mL) previously blocked with their respective peptides (2 mg/mL) for 1 h at 37°C^[4,8].

Isolation and microperfusion of rat intrahepatic bile duct units (IBDUs)

Isolation and microperfusion of IBDUs were performed, as previously described^[15]. Microperfusion of an IBDU was carried out using Ringer-HCO₃ (KRB solution) containing 40 mmol/L taurocholate at a perfusion rate of 436 nl/min and bile acid (*i.e.*, taurocholate) uptake by individual microperfused IBDU was calculated as published previously^[15].

Protein concentration

Concentrations of proteins were measured by the fluorescamine method using bovine serum albumin (BSA) as standard^[16]. Data were confirmed using the colorimetric Bradford method where vendor's (Sigma) instructions were applied. No differences were observed in protein recovery in TCA or CY groups when compared to controls for a specific cell type.

Measurements of biological samples

Biliary phospholipids and cholesterol were analyzed spectrophotometrically using commercial kits from Wako Chemicals and Boehringer Mannheim, respectively. Biliary bile acid concentration was determined spectrophotometrically according to the vendor's instructions (Sigma). Bile acid concentration of samples was derived from a calibration curve prepared using bile acid of known concentrations: 5, 10, 50, 100 and 200 μ mol/L.

Statistical analysis

All data were expressed as mean \pm SE. Statistical differences were analyzed by Student's *t*-test, and results were considered to be statistically different at $P < 0.05$.

RESULTS

Effect of TCA and CY feeding on body mass, bile flow, and biliary bile acids, phospholipids and cholesterol

The effects of TCA and CY feeding on rat body mass, bile flow and biliary lipid composition compared to C diet are provided in Table 1. Though an approximate 6% weight loss was observed following TCA and CY feedings, the differences in total body masses in experimental groups vs C diet were not significant. Bile flow was significantly higher (2.2-fold) in the TCA group, but similar in the CY group compared to the C group. As expected, the biliary bile acids in the TCA fed rats

were 3.2-fold higher, but 2-fold lower in the CY fed rats compared to the C fed rats. Biliary phospholipids of the TCA fed rats were significantly greater. In the CY group, biliary phospholipids were significantly lower than in the C group. Finally, biliary cholesterol levels of both the TCA and CY groups were similar compared to the C rats. These data indicated that the diets employed significantly altered bile flow and the biliary lipid parameters as anticipated.

Table 1 Alterations of weight and biliary constituents after TCA and CY feeding

	Control	TCA	CY
Body mass (g)	261(\pm 7)	247(\pm 3)	246(\pm 9)
Bile flow (μ L/min)	9.2(\pm 0.4)	19.8(\pm 0.3) ^a	9.7(\pm 0.8)
Biliary bile acids (mmol/L)	20(\pm 2)	65(\pm 3) ^a	10(\pm 1) ^a
Biliary phospholipids (mg/dL)	248(\pm 60)	470(\pm 87) ^a	127(\pm 76) ^a
Biliary cholesterol (g/L)	0.16(\pm 0.03)	0.16(\pm 0.01)	0.15(\pm 0.03)

^a $P < 0.05$.

Effect of TCA and CY feeding on ASBT and t-ASBT messages in cholangiocytes

Using Q-RPA, ASBT mRNA levels were significantly lower (2.3-fold) in cholangiocytes of the TCA fed rats than in cholangiocytes of the C fed rats (0.0035 \pm 0.002 ng mRNA/ μ g total RNA and 0.0081 \pm 0.002 ng mRNA/ μ g total RNA, respectively, $P = 0.009$) (Figure 1). Parallel to the down-regulation of ASBT in the TCA fed rats, t-ASBT mRNA of the same group was also 4.3-fold lower compared to the C fed rats (0.003 \pm 0.001 ng mRNA/ μ g total RNA and 0.013 \pm 0.003 ng mRNA/ μ g total RNA, respectively, $P = 0.01$) (Figure 1). ASBT mRNA levels were 1.5-fold higher in cholangiocytes of the CY fed rats than in those of the C fed rats (0.012 \pm 0.002 ng mRNA/ μ g total RNA and 0.0081 \pm 0.002 ng, RNA/ μ g total RNA, respectively, $P = 0.04$) (Figure 1). Corresponding to the upregulation of ASBT in the CY fed rats, t-ASBT mRNA of the same group was also 1.3-fold greater compared to the C fed rats. However, this was not statistically significant (0.015 \pm 0.004 ng mRNA/ μ g total RNA and 0.013 \pm 0.003 ng mRNA/ μ g total RNA, respectively, $P = 0.4$) (Figure 1). The insignificant increase in the t-ASBT message and the significant increase in the protein levels of t-ASBT (Figure 2) following CY treatment might indicate post-transcriptional modifications.

Figure 1 Q-RPA data demonstrating down-regulation of ASBT and t-ASBT message following TCA feeding and up-regulation of their expression following CY feeding in cholangiocytes. Bar graphs demonstrating ASBT and t-ASBT mRNA expression, in which 40 μ g total cellular RNA isolated from cholangiocytes obtained from rats fed regular chow (C), 1% TCA or 5% CY incorporated diets were used. Densitometric values shown here are expressed as mean \pm SE and represent 3 feeding studies in which 30 rats in total were analyzed per group (^a $P < 0.05$).

Effect of TCA and CY feeding on ASBT and t-ASBT proteins in cholangiocytes

ASBT protein in the TCA group decreased 2.2-fold compared to the C fed rats and that was statistically significant ($P=0.006$) (Figure 2). Protein levels of t-ASBT were also repressed 2.4-fold following TCA feeding compared to C fed rats that was also statistically significant ($P=0.004$) (Figure 2). The protein quantitative data were also analyzed using an additional approach to verify the above findings. In this case, to exclude the possibility of β -actin being affected by the bile acid feeding, quantitative analysis was made by determining the arbitrary densitometric units of each immunoreactive band and further dividing it by the amount of protein loaded and exposure time of the autoradiograph. Using this alternative approach, cholangiocyte ASBT protein from the TCA group was shown to be downregulated 2.2-fold compared to C fed rats. This finding reassured us about the accuracy of the data we obtained by the first quantitative method and provided evidence that actin was not affected by TCA feeding. In addition, following CY feeding, the ASBT protein was 2.3-fold higher and statistically significant compared to C fed rats ($P=0.003$) (Figure 2). Moreover, after CY feeding, the t-ASBT protein was also increased 2.4-fold compared to C fed rats ($P=0.04$) (Figure 2).

Figure 2 Effect of TCA and CY feeding on the expression of ASBT and t-ASBT protein in cholangiocytes. Bar graphs showing densitometric ratios of ASBT and t-ASBT standardized to β -actin in PNS fractions of freshly isolated cholangiocytes from rats fed control (C), 1% TCA or 5% CY incorporated diet. A 80 μ g for ASBT and 120 μ g for t-ASBT PNS protein were subjected to SDS-PAGE, immunoblotted for ASBT (48 kDa), t-ASBT (19 kDa) and β -Actin (41 kDa) and the bands were then visualized using enhanced chemiluminescence techniques. Densitometric values shown here are expressed as mean \pm SE ($^aP<0.05$) and represent 3 feeding studies for ASBT protein analyses of the TCA and CY groups. Similarly, 3 feeding studies were performed to reflect the data obtained on t-ASBT protein following CY feeding, but only 2 feeding studies were done for t-ASBT protein analysis of the TCA group. Ten rats per group were analyzed in each of these feeding studies, thus a total of 30 rats per feeding study were used in all of the above groups, whereas 20 rats were incorporated into the analysis of t-ASBT in the TCA group.

Effect of TCA and CY feeding on ASBT and t-ASBT messages in ileum

Using Q-RPA, ASBT mRNA levels in ileum of the TCA fed rats were 2.1-fold higher than those in ileum of the C fed rats (0.073 ± 0.01 ng mRNA/ μ g total RNA and 0.036 ± 0.01 ng mRNA/ μ g total RNA, respectively, $P=0.01$) (Figure 3). Parallel to upregulation of ASBT message, t-ASBT mRNA of the TCA group was also 1.9 fold higher compared to the C fed rats (0.076 ± 0.015 ng mRNA/ μ g total RNA and 0.040 ± 0.004 ng mRNA/ μ g total RNA, respectively, $P=0.01$) (Figure 3). In addition, the ileal ASBT mRNA levels of the CY fed rats were 1.4-fold less and statistically

significant than those of the C fed rats (0.026 ± 0.003 ng mRNA/ μ g total RNA and 0.036 ± 0.007 ng mRNA/ μ g total RNA, respectively, $P=0.07$) (Figure 3). Corresponding to these findings, t-ASBT mRNA levels of the CY fed rats were 1.3-fold lower and statistically significant compared to the C fed rats (0.031 ± 0.002 ng mRNA/ μ g total RNA and 0.040 ± 0.004 ng mRNA/ μ g total RNA, $P=0.01$) (Figure 3).

Figure 3 Q-RPA data demonstrating upregulation of ASBT and t-ASBT message following TCA feeding and downregulation of their message following CY feeding in ileum. Bar graphs demonstrating ASBT and t-ASBT mRNAs, in which 40 μ g total cellular RNA isolated from cholangiocytes obtained from rats fed regular chow (C), 1% TCA or 5% CY incorporated diets were used. Densitometric values demonstrated here are expressed as mean \pm SE and represent $n=3$ feeding studies in which 30 rats in total were analyzed for each group ($^aP<0.05$).

Effect of TCA and CY feeding on ASBT and t-ASBT proteins in ileum

Parallel to increased ASBT transcript observed following bile acid feeding, ASBT protein expression was also 2.3-fold higher and statistically significant in the TCA fed rats compared to the C fed rats ($P=0.001$) (Figure 4). Moreover, the t-ASBT protein expression was also supportive of the mRNA data, t-ASBT protein was 2.7-fold higher and statistically significant in the TCA fed rats compared to the C fed rats ($P=0.02$) (Figure 4). Furthermore, following CY feeding, and parallel to decreased ASBT transcript, ileal ASBT protein was also 2.1-fold significantly down-regulated ($P=0.008$) compared to the C fed rats (Figure 4). Finally, the ileal t-ASBT protein was also in support of the message results for this transporter. Indeed, t-ASBT protein was 2.3-fold significantly decreased in the CY fed rats compared to the C fed rats ($P=0.01$) (Figure 4).

Figure 4 Effect of TCA and CY feeding on the amount of ASBT and t-ASBT protein in ileum. Bar graphs showing ratios of ASBT/ β -actin and t-ASBT/ β -Actin in PNS of ileal scrapings obtained from rats fed C, TCA and CY diets. Forty and 80 μ g of protein were subjected to SDS-PAGE and immunoblotted to visualize ASBT and t-ASBT, respectively. Data shown here are representative of $n=3$ feeding studies were analyzed per group

and expressed as mean \pm SE ($^aP<0.05$). For the analysis of ASBT and t-ASBT in the TCA treated groups, 7 and 3 rats in total were used, respectively. Whereas, the number of animals analyzed in the CY groups totaled 10 and 3 for ASBT and t-ASBT, respectively. Hence, the number of control rats was 17 for ASBT and 6 for t-ASBT in total.

Effect of TCA and CY feeding on bile acid uptake by IBDUs

To further verify and extend our observations at the functional level, taurocholate uptake was measured in IBDUs isolated from rats fed either TCA or CY diets and compared to those obtained from C fed animals using a novel microperfusion technique. Specifically, taurocholate uptake by IBDUs derived from the C diet group was 1.1 ± 0.2 nmol/min/mm². Taurocholate uptake was significantly lower in the TCA group (0.4 ± 0.1 nmol/min/mm², $P=0.002$, $n=4$ IBDU, 2 feeding studies) and significantly higher in CY group (1.95 ± 0.3 nmol/min/mm², $P=0.007$) (Figure 5).

Figure 5 Effect of TCA and CY feeding on taurocholate uptake by ASBT in rat IBDUs. Bar graphs showing 2.7-fold decrease and 1.7-fold increase in taurocholate uptake in TCA and CY fed rats, respectively, compared to controls. Data shown here, and expressed as mean \pm SE, were obtained from $n=3$ feeding studies in which 11 control, 4 TCA and 5 CY IBDUs were analyzed ($^aP<0.05$).

DISCUSSION

The major findings described here are TCA feeding downregulates but CY feeding upregulates both ASBT and t-ASBT in cholangiocytes and TCA feeding upregulates whereas CY feeding downregulates both ASBT and t-ASBT in terminal ileum. Our findings suggested that both ASBT and t-ASBT in a specific cell type underwent parallel modes of regulation. On the other hand, reciprocal changes were observed between cholangiocytes and ileocytes in terms of ASBT and t-ASBT expression, suggesting organ-specific differences in regulation of these bile acid transporters.

Regulation of transporter expression to accommodate altered substrate loads is a well-recognized physiologic phenomenon. For example, adaptive up- or down-regulation of hepatic and ileal bile acid transporters occurred in response to changes in bile acid pool size^[3]. Moreover, a limited number of very recent studies addressed the problem of whether the same adaptive events could operate in cholangiocytes with respect to ASBT^[9-12]. However, no data exist regarding the regulation of t-ASBT in the liver or terminal ileum after bile acid supplementation or depletion. Regarding ASBT expression in terminal ileum, prior investigations have shown evidence of transcriptional regulation by bile acids^[17-19]. Nevertheless, results of these studies appeared to be species-specific given reported differences in ASBT regulation. For example, Lillienau *et al.* reported a negative feedback regulation of the ileal bile acid transporter in the guinea pig based on whole organ, ileal perfusion studies^[17]. Following cloning of ASBT in rats, Stravitz *et al.* described a positive

feedback regulatory mechanism of the ileal ASBT. These authors demonstrated induction of both mRNA and protein levels of ASBT after cholic acid feeding including supportive functional studies using ileal brush border membrane vesicles^[18]. More recently, Arrese *et al.* reported no change in ASBT expression and function following bile duct ligation and intestinal sequestration of bile acids^[19].

In the present study, we demonstrated that in cholangiocytes compared to C fed rats, TCA feeding downregulated both ASBT transcript and protein abundance as well as t-ASBT transcript and protein expression. On the other hand, CY feeding upregulated both ASBT transcript and protein abundance as well as t-ASBT transcript and protein expression compared to C fed rats. To support these molecular findings, microperfusion studies in rat IBDUs compared to C fed animals revealed 2.7-fold decrease and 1.7-fold increase in taurocholate uptake by IBDUs derived from TCA or CY fed rats, respectively. In terminal ileum, TCA feeding upregulated both ASBT transcript and protein abundance as well as t-ASBT transcript and protein expression. In contrast, CY feeding downregulated both ileal ASBT transcript and protein abundance as well as t-ASBT transcript and protein expression compared to C fed rats.

The pathophysiological significance of ASBT and t-ASBT adaptive changes in biliary epithelia and terminal ileum in response to bile acid pool perturbations described in this paper are intriguing. It appears that bile acid transporting epithelia of different organs (*i.e.*, bile ducts and ileum) respond differently to bile acid supplementation or depletion. ASBT and t-ASBT transcriptional down-regulation in cholangiocytes upon TCA feeding could diminish the cholehepatic shunt of conjugated bile acids. This pathway is believed to play a role in reclamation of bile acids from bile back to liver. Thus, during bile acid feeding, decreased expression of bile acid transporters in cholangiocytes and the ensuing reduction of bile acid shunting may provide protection to cholangiocytes and subsequently hepatocytes from the deleterious effects of excessive intracellular accumulation of bile acids. In fact, this protective mechanism became even more relevant given the fact that bile acid feeding increased the expression of bile acid transporters in terminal ileum as shown in the present and other studies^[18] and thus enhancing the uptake capacity of ileum for bile acids for delivery to the liver, perhaps to compensate the decreased cholehepatic shunt, and thus keeping the bile acid synthesis at a balance.

We have also observed that in CY fed rats, cholangiocyte ASBT and t-ASBT were up-regulated. These data should be reviewed in parallel with the reciprocal findings in the terminal ileum where CY feeding caused upregulation of both ASBT and t-ASBT. The potential pathophysiologic relevance of ASBT and t-ASBT induction in cholangiocytes after CY feeding may relate to increasing the biliary bile acid return to the liver via an enhanced cholehepatic shunt. This condition would potentially assist maintaining cholesterol homeostasis, given the concurrent observation of diminished expression of bile acid transporters in distal intestine and thus reducing absorption of bile acids from the terminal ileum. The experimental effect of CY on the expression of cholangiocyte bile acid transporters is analogous to the bile duct ligated (BDL) model, in which the enterohepatic circulation of bile acids is interrupted due to mechanical obstruction of the common bile duct. To this end, our observations in cholangiocytes were comparable to those reported by Lee *et al.*^[11]. These authors reported adaptive up-regulation and down-regulation of ASBT in biliary epithelia and kidney, respectively, in BDL rats, postulating that these changes might accommodate alternative pathways for secretion of excessive bile acids in cholestasis^[11]. However, others have shown in both BDL^[9,10] and bile acid fed rats^[12] that bile acid depletion and repletion could decrease and increase the expression of ASBT, respectively, in cholangiocytes. Differences

in results may very well reflect differences in study design (e.g., feeding rats in a paired vs non-paired manner, feeding them until the surgical procedure vs fasting them overnight, feeding for 10 d vs 7 d, the age of the animals 225–275 g vs 125–150 g starting masses).

In our ileal studies, a significant increase in ASBT and t-ASBT occurred after TCA feeding, whereas a decrease in message and protein levels of both transporters was seen in bile acid depleted rats. These data suggest that changes in bile acid pool size could result in marked alterations in these bile acid carrier molecules. Our data agree with the work of Stravitz *et al.*^[18] who also reported a positive feedback mechanism on the regulation of ASBT in ileum. Arrese *et al.* reported that neither the pharmacological sequestration of bile acids nor common bile duct ligation affected the expression and function of ileal ASBT^[19]. Whether the different pharmacological agents used for bile acid depletion by Arrese (*i.e.*, the novel sequestrant GT31-104)^[19], and in our work, the well-established cholestyramine, accounted for these differences is unclear^[18].

Recently, the promoter region of the ASBT gene has been extensively analyzed^[20]. It appears that two AP-1 consensus sites have been identified in the proximal promoter of ASBT. At least four nuclear binding proteins, designated ABP 1-4, interacting with AP-1 sites, have been described. Of interest, formation of the ABP2 nuclear binding protein complex appeared to be correlated with regional and developmental stage-specific expression of ASBT in the rat intestine^[20]. In a study clarifying the transcriptional mechanisms involved in cytokine-mediated repression of rat ASBT, the authors observed reductions in ileal ASBT message and protein following proinflammatory cytokine and IL-1 beta treatment of IEC-6 and Caco-2 cells, along with significant increases in c-fos expression^[22]. The proinflammatory cytokines and interleukin-1 beta have thus been shown to repress the activity of the ASBT promoter via serine phosphorylation, and nuclear translocation of c-fos. Inflammation, associated with up-regulation, phosphorylation, and nuclear translocation of c-fos, which then represses ASBT promoter activity via binding to the 3' AP-1 element by a c-fos/c-jun heterodimer, may be operative following bile acid treatment, a stimulus known to increase inflammation in cholangiocytes. The inflammatory influence of bile acids might occur following directly activating eosinophils and inducing their effector functions^[23], or triggering interferon-gamma and tumor necrosis factor alpha production, which might in turn stimulate superoxide and interleukin release that resulted in disruption of the tight junctions in cholangiocytes^[24]. Bile acids, with the potential of altering the profile of cytokines, chemokines, and proinflammatory stimuli, which in turn were likely to activate fibrogenesis, stimulate apoptotic and proliferative responses, seemed to be important players in the pathophysiology of chronic cholestatic disorders^[25]. It is therefore imperative to begin to investigate the role of AP-1, ABP 1-4 and c-fos expression in bile acid transporting epithelia hoping to shed light on the adaptive and reciprocal expression of ASBT and t-ASBT. In a recent study, decreased expression of ileal ASBT protein and mRNA in mice following bile acid treatment was related to the presence of a potential liver receptor homologue-1 (LRH-1) cis acting element in the bile acid responsive region of the mouse but not the rat promoter. The mouse but not the rat promoter was activated by LRH-1 and this correlated with nuclear protein binding to the mouse but not rat LRH-1 element. Thus, species-specific negative feedback regulation of ASBT by bile acids was mediated by FXR via SHP-dependent repression of LRH-1 activation of the ASBT promoter^[21]. It is possible, therefore that, the reciprocal regulation pattern we have observed between cholangiocytes and ileocytes may reflect the role of FXR and LRH-1 in cholangiocytes.

In conclusion, we present data demonstrate that a bile acid enriched diet can down-regulate ASBT and t-ASBT in cholangiocytes but upregulate both transporters in terminal ileum. Conversely, bile acid depletion by sequestration can upregulate ASBT and t-ASBT in cholangiocytes, but down-regulate both transporters in terminal ileum. To have a better understanding of the mechanism (s) affecting the expression of bile acid transporters in relevant epithelia, a systematic comparative evaluation of their regulatory elements in different tissues known to be involved in bile acid homeostasis is required. Unraveling the presumed cell-specific regulatory mechanisms that affect bile acid transporter expression and function will help to develop novel rational options to treat cholestasis and chronic cholestatic liver diseases.

Abstract

AIM: To clarify the fractional activity of promoters from human $\alpha 1(I)$ procollagen gene, the interaction between cis-elements and consensus DNA-binding proteins responsible for high promoter activity, and the potential application of promoter competitors as well as cytokines for antifibrogenesis.

METHODS: Sequence between 2 483 bp upstream of the start of transcription and 42 bp downstream of this site was investigated with serial 5' -deletion. The 5' -deleted promoters recombined with chloramphenicol acetyltransferase (CAT) as reporter gene were transiently transfected to human dermal fibroblasts. Electrophoretic mobility shift assay was performed to show the DNA-protein binding capacity of the promoter sequence. Cytokines including tumor necrosis factor α (TNF α) and interferons (IFNs) were added to the culture medium of transiently transfected fibroblasts. Competitor DNA for the binding sites of Sp-1, Ap-1 and NF-1 was individually cotransfected transiently in order to block the promoter-driven CAT expression.

RESULTS: Sequences of -2 483 to +42 bp and -268 to +42 bp of human $\alpha 1(I)$ procollagen gene had high activity as promoters. Binding sites for Ap-1 and Sp-1 were among the cis-regulatory elements recognizing consensus transcription factors responsible for basal promoter activity of sequence -268 to +42 bp. TNF α , IFN α , IFN β showed inhibitory effects on sequence -2 483 to +42 bp as promoter with activities 43%, 62% and 60% of control respectively. Transfection of the promoter competitors could reverse the promoter activity of -268 to +42 bp 40-60%.

CONCLUSION: Sequences of -2 483 to +42 bp recombined with reporter gene provide an ideal construction for transcriptional study of $\alpha 1(I)$ procollagen gene. The anti-collagen capacity of TNF α and IFNs is associated with their transcriptional regulation. Ap-1 and Sp-1 mediate the basal transcriptional activation of human $\alpha 1(I)$ procollagen gene in dermal fibroblasts. Competitors for highly active promoters might be a novel potential candidate in fibrotic blockade.

INTRODUCTION

Excessive accumulation of extracellular matrix (ECM) following chronic impairment of tissue gives rise to the development of fibrosis which might occur in skin and other organs, such as liver, kidney and lung^[1]. Scarring or cirrhosis with the progression of fibrosis can cause functional failure of the organ due to the distortion of the structure. Type I collagen, composed of two chains of $\alpha 1(I)$ and one chain of $\alpha 2(I)$, is the most abundant component of ECM in most fibrotic tissues^[1]. The expression of genes coding for the $\alpha 1(I)$ and $\alpha 2(I)$ chains of type I collagen is regulated coordinatively^[2]. Researches on the expression of type I collagen in the past decades have been ascribed to fluctuations under various pathophysiological conditions at transcriptional and translational levels^[3]. Most of the recent available evidence suggest that the principal mechanisms operate at the level of transcription, although control and changes in mRNA processing and stability may also play a role^[4-7]. The mechanisms of transcriptional activation of collagen genes are poorly understood till now. Several putative regulatory elements that may determine the transcriptional efficiency of type I collagen gene have been identified in their corresponding promoters^[8-11]. Fine mapping of the cis-acting elements as well as the identification of their consensus DNA-binding proteins involved in the modulation of collagen gene expression is crucial for understanding the pathological regulation of collagen accumulation. In our previous work, we analyzed the promoter activity from mouse $\alpha 2(I)$ procollagen gene as well as its modulation by cytokines^[12,13]. In this study, we investigated the fractional activity of promoter from human $\alpha 1(I)$ procollagen gene and the interaction between cis-elements and consensus DNA-binding proteins responsible for high promoter activity. Sequence between 2 500 bp upstream of the start of transcription and 42 bp downstream of this site was studied with serial 5' -deletion. We report that regions from -2 483 to +42 bp, -268 to +42 bp of human $\alpha 1(I)$ procollagen gene have higher promoter activities. Binding sites for Ap-1, Sp-1 may be among the cis-regulatory elements recognizing consensus transcription factors responsible for basal promoter activity of sequence -268 to +42 bp. The anti-fibrotic capacities of TNF α and IFNs are associated with their transcriptional regulation of type I collagen. Transfection of the promoter competitors can partially reverse the promoter activity, suggesting that promoter competitors for highly active promoters may be a novel antifibrotic tool.

MATERIALS AND METHODS

Cell culture

Human dermal fibroblast culture was established by explanting tissue specimens obtained from the abdominal skin of a 3-year old male patient because of burn of his left arm and requiring skin transplantation. The cells were maintained under standard conditions in Dulbecco's modified Eagle's medium (DMEM, Gibco, USA) supplemented with 100 mL/L fetal calf serum (FCS, Gibco, USA). The cells in passages 3-8 were used for study.

Construction of plasmids

Plasmid pCAT3-enhancer (Promega, USA), a promoterless vector which contains SV40 enhancer and chloramphenicol

acetyltransferase (CAT) as reporter gene, was used as the recombinant plasmid backbone. The putative promoters in 6 constructions named pCOLH_{0.1}, pCOLH_{0.27}, COLH_{0.5}, pCOLH_{0.9}, pCOLH_{1.5} and pCOLH_{2.5} corresponded to sequences -105 to +42 bp, -268 to +42 bp, -496 to +42 bp, -829 to +42 bp, -1 448 to +42 bp, -2 483 to +42 bp, respectively in human $\alpha 1$ (I) procollagen gene with the same 3' ends. They were obtained by PCR with p5.3K $\alpha 1$ containing 5' flanking region -5 300 to +42 bp of human $\alpha 1$ (I) procollagen gene (gift from Dr. Sergio A. Jimenez) as template^[14]. Sense primers for PCR were as follows: pCOLH_{0.1}: 5' -ATGTCTACGCGTCTGATTGGCTGGGGCACGG-3', pCOLH_{0.27}: 5' -ATGTCTACGCGTCTGAGGACCCAGCTGCAC-3', pCOLH_{0.5}: 5' -ATGTCTACGCGTGGAGAGGTCCTCAGC ATGC-3', pCOLH_{0.9}: 5' -ATGTCTACGCGTGGCTGCTCCATCACCAAC-3', pCOLH_{1.5}: 5' -ATGTCTACGCGTCTCAGGACGAGGTA GATTG-3', pCOLH_{2.5}: 5' -ATGTCTACGCGTACATCTT CAGCCTGGGCAC-3'. Antisense primers for the 6 putative promoters were the same: 5' -ATAGTACTCGAGCGTGC CTCCTGCTCCGAC-3'. The sense and antisense primers contained *Mlu*I and *Xho*I adaptors (underlined part) which were 6 bases away from the 5' end of the primers. PCR was performed as routine with high-fidelity PCR kit (Roche) and PE-9600 PCR amplifier. The PCR products were digested with *Mlu*I and *Xho*I and then ligated to *Mlu*I-*Xho*I linearized pCAT3 vector with T4 DNA ligase (Promega). The ligation mixtures were transformed to competent *E. coli* (JM109), and the ampicillin resistant positive clones were further identified by small-scale restriction enzyme digestion and DNA sequencing (ABI 377). The correct clones were amplified and recombinant plasmids were extracted and purified with plasmid isolation kit (Qiagen). The purity and yield rate were determined in UV spectrophotometer (Du 600, Beckman).

Synthesis of oligonucleotide for binding sites of Ap-1, Sp-1 and NF-1

Consensus binding sites for Ap-1, Sp-1, and NF-1 were first synthesized as single stranded DNA (Sangon, Shanghai) and sequences were: Ap-1, 5' CGCTTGATGACTCAGCCGGAA 3'; Sp-1, 5' ATCGATCGGGGCGGGGCGCGC3'; NF-1, 5' TTTTGGATTGAAGCCAATATGATA3'. The synthesized sense and antisense single stranded DNAs were matched and mixed at a molar ratio of 1:1. After incubation of the mixtures at 95 °C for 10 min and then cooling slowly down to room temperature, the double stranded DNAs were stored at -20 °C.

DNA transfection

DNA transfection was performed with Dospo liposomal transfecting reagent (Roche, Germany) according to manufacturer's instruction. Briefly, the day before transfection, dermal fibroblasts were seeded at 5×10^5 /well in a 6-well plate (Nunc, USA) in 2 mL DMEM. The cells were incubated until 60-80% confluence. Then the medium was replaced with fresh culture medium without FCS shortly before adding transfection reagent. Two micrograms of construct plasmid together with 1 μ g of pSV β -gal (Promega, USA) as internal standard were cotransfected. CAT expression plasmid pCAT6.2 (Invitrogen, USA) was also transfected as CAT expression positive control. One milliliter medium containing 20 mL/L FCS was added to each well 6 h later. The medium was then replaced with fresh normal culture medium 24 h later. Two days after transfection, the cells were ready for reporter gene (CAT) expression measurement. For the cells transfected with pCOLH_{0.27}, 10 μ g of DNA for binding sites of Ap-1, Sp-1 or NF-1 was transfected to the cells 24 h after pCOLH_{0.27} transfection. Mock DNA transfection was included. The transfection was terminated 24 h later and ready for reporter gene detection.

To study the regulatory effect of cytokines, cells were starved for 4 h after being transfected with pCOLH_{2.5} for 24 h, then culture medium was replaced by fresh medium containing TNF α 10 μ g/L (R&D, USA), IFN α 1×10^5 U/L (PBL, England), IFN γ 1×10^5 U/L (Roche, USA) respectively. Another 24 h later, the transfection was terminated and ready for reporter gene detection.

Determination of CAT and β -galactosidase

Forty-eight hours after initial transfection, cells were washed with precooled phosphate buffered solution (PBS, 0.1 mol/L, pH7.4) and lysed with lysis buffer (Roche, USA). Aliquots of cell extracts were made for protein determination as described previously^[15]. CAT was measured by ELISA (Roche, USA) and β -galactosidase with enzyme activity analysis method (Promega, USA).

Electrophoretic mobility shift assay (EMSA)

EMSA was performed as described previously^[16]. Briefly, a fragment spanning -268 to +42 bp of the human $\alpha 1$ (I) procollagen gene was obtained by PCR with p5.3K $\alpha 1$ as template. The fragment obtained from PCR was purified, digested with *Eco*RII and 3' end-labeled with digoxigenin (Roche). Crude nuclear extracts from early passage confluent human fibroblasts were prepared according to the method described by Erdos *et al*^[17]. The protein concentration in nuclear extract was determined by Bradford method^[15]. DNA-protein binding reactions (20 μ L) were performed in a buffer containing 1 μ g of poly[d(A-T)], 1 μ g of poly L-lysine, 15 μ g of crude nuclear extract, 50 fmol of dig-labeled probes. Unlabeled probes and synthetic binding sites of Ap-1, Sp-1 and NF-1 were applied with 100-fold molar excess for competition tests. Following 20-min incubation at room temperature, DNA-protein complexes were resolved from free DNA probes by electrophoresis on 60 g/L non-denatured polyacrylamide gels. Transfer of DNA was finished by electroblotting. Signals were captured by chemiluminescent detection with alkaline phosphatase labeled anti-dig antibody and CSPD (Roche) as substrate.

RESULTS

Construction and transfection of 5'-deleted recombinant plasmids

Constructions of the 6 recombinant plasmids were verified by small-scale restriction enzyme digestion and DNA sequencing. Figure 1 shows the correct digestion of the constructs. The putative promoters in the constructions were 0.1 kb, 0.27 kb, 0.5 kb, 0.9 kb, 1.5 kb, and 2.5 kb, corresponding to -105 to +42 bp, -268 to +42 bp, -496 to +42 bp, -829 to +42 bp, -1 448 to +42 bp, -2 483 to +42 bp of human $\alpha 1$ (I) procollagen gene. DNA sequencing indicated that the inserted sequences of the putative promoters were the same as that published in GeneBank (accession No X98705). The 6 constructs containing serial 5'-deleted promoters were transiently transfected to early passage confluent human fibroblasts. Forty-eight hours after transfection, the expression of reporter gene CAT was determined by ELISA with the detection of β -galactosidase activity and protein for normalization. The expression of normalized CAT in the cells transfected with pCOLH_{2.5} was set as 1, the relative expression level of normalized CAT in cells transfected with other constructs is shown in Table 1 (mean \pm SD of three independent experiments), indicating that the highest CAT expressions were driven by -2 483 to +42 bp and -268 to +42 bp as promoters while the lowest by -105 to +42 bp.

Transfection of promoter competitors

For the cells transfected with pCOLH_{0.27}, 10 μ g of consensus recognition DNA for Ap-1, Sp-1 or NF-1 was transfected to

cells 24 h after pCOLH₁0.27 transfection. Reporter gene (CAT) was determined another 24 h later. Relative CAT expression values in different transfection groups were calculated relative to that of mock DNA transfection. The result shown in Figure 2 indicated that transfection of Ap-1 or Sp-1 DNA inhibited CAT expression approximately by 25% and 20% respectively compared to mock DNA transfection ($P < 0.05$). Transfection of NF-1 DNA did not show definite effect on reporter gene expression.

Figure 1 Electrophoresis of six constructs digested with *MluI* and *XhoI*. M1: 100 bp DNA ladder marker, M2: 1 kb DNA ladder marker, Lane1: pCOLH₁0.1, lane2: pCOLH₁0.27, lane3: pCOLH₁0.5, Lane4: pCOLH₁0.9, Lane5: pCOLH₁1.5, Lane6: pCOLH₁2.5. Six recombinant plasmids containing serial 5' -deleted flanking sequences of human $\alpha 1(I)$ procollagen gene as putative promoter were digested with *MluI* and *XhoI* at 37 °C for 1 h. The digested DNAs were fractionated on 15 g/L agarose gel showing vector DNA (4.3 kb) and insertion promoters with different sizes.

Table 1 Summary of CAT expression driven by various lengths of the 5' flanking sequence from human $\alpha 1(I)$ procollagen gene

Name of transfected constructions	Putative promoters' length (bp)	Relative activities of reporter gene (CAT, mean \pm SD) ¹
pCOLH ₁ 0.1	-105 to 42	0.10 \pm 0.02
pCOLH ₁ 0.27	-268 to 42	0.97 \pm 0.04
pCOLH ₁ 0.5	-496 to 42	0.20 \pm 0.05
pCOLH ₁ 0.9	-829 to 42	0.36 \pm 0.09
pCOLH ₁ 1.5	-1 448 to 42	0.73 \pm 0.11
pCOLH ₁ 2.5	-2 483 to 42	1.0

¹The expression of normalized CAT in the cells transfected with pCOLH₁2.5 was set as 1, the relative expression level of normalized CAT in the cells transfected with other constructs is shown in Table 1 (mean \pm SD of three independent experiments).

Figure 2 Effects of consensus DNA on CAT expression in pCOLH₁0.27 transfected cells. Control: mock DNA transfection, Ap-1: transfection of Ap-1 consensus DNA (10 μ g), Sp-1: transfection of Sp-1 consensus DNA (10 μ g), NF-1: transfection of NF-1 consensus DNA (10 μ g). For the cells transfected with pCOLH₁0.27, transfection of consensus recognition DNA for Ap-1, Sp-1 or NF-1 was performed 24 h after initial transfection. Reporter gene CAT was determined with ELISA after another 24 h. Relative CAT values in different transfection groups were calculated relative to that in mock DNA transfection. The

result represented three independent experiments. ^a $P < 0.05$ compared to control.

EMSA

The fragment spanning -268 to +42 bp in human $\alpha 1(I)$ procollagen gene was digested into three smaller ones (42 bp, 113 bp, 155 bp) with *EcoRII* (Figure 3). EMSA with these three labeled oligonucleotides mixture as probes showed that DNA-protein complexes were generated and detected in form of retardation bands. Competition with molar excesses of the same unlabeled probe prevented the formation of DNA-protein complexes, suggesting the specificity of the binding between DNA and protein. Excess consensus DNA for Sp-1, Ap-1 or NF-1 partially inhibited the occurrence of retardation differently, indicating the potential binding sites for Sp-1, Ap-1 and NF-1 in -268 to +42 bp of human $\alpha 1(I)$ procollagen gene (Figure 4).

Figure 3 Electrophoresis (20 g/L agarose gel) of the fragment -268 to +42 bp digested with *EcoRII*. Lane1: *EcoRII*-digested fragment, Lane2: 100 bp DNA ladder, Lane3: 310 bp length of fragment spanning from -268 to +42bp. The 310 bp fragment spanning -268 to +42 bp of the human $\alpha 1(I)$ procollagen gene was obtained by PCR with p5.3K α 1 as template. The fragment was digested with *EcoRII*. Electrophoresis (20 g/L agarose gel) of the digested mixture showed 3 bands with different sizes (42 bp, 113 bp, 155 bp) which were labeled and used as probes in EMSA.

Figure 4 Result of EMSA with *EcoRII*-digested -268 to +42 bp as probe. Lane1: Labeled DNA, Lane2: Labeled DNA+ nuclear protein +NF-1 consensus DNA, Lane3: Labeled DNA + nuclear protein + Sp-1 consensus DNA, Lane4: Labeled DNA + nuclear protein + Ap-1 consensus DNA, Lane 5: Labeled DNA + nuclear protein, Lane 6: Labeled DNA + excess unlabeled DNA + nuclear protein. The existence of several retarded bands in EMSA indicated that there were several nuclear protein binding sites in sequence -268 to +42 bp (lane 5). No retardation occurred when excess unlabeled DNA probe was added to the DNA-protein reaction, confirming the specificity of the retardation (lane 6). Consensus DNAs for Sp1, Ap-1 and NF-1 were among the possible regulatory elements since the molar excess of the consensus unlabeled probe (Sp1, Ap-1, NF-1) inhibited partially the formation of retardation bands differently (lanes 2,3 and 4).

Effect of cytokines on reporter gene activity

TNF α , IFN α and IFN γ inhibited the reporter gene activity by 40-60% in the cells transfected with pCOLH₁2.5 ($P < 0.05$) compared to the control. The strongest inhibitory effect appeared in TNF α group (Table 2).

Table 2 Effect of cytokines on reporter gene activity in cells transfected with pCOLH_{2.5}

Cytokines	Relative value of reporter gene activity ¹	P Value (compared to control)
Control	1.00±0.15	
TNFα 10 μg/L	0.43±0.17	<0.05
IFNα 1×10 ⁵ U/L	0.62±0.15	<0.05
IFNγ 1×10 ⁵ U/L	0.60±0.16	<0.05

¹The reporter gene activity of the cells transfected with pCOLH_{2.5} was set as 1, the relative expression level of normalized CAT in transfected cells treated with cytokines was expressed as mean±SD of three independent experiments.

DISCUSSION

The mechanisms involved in the regulation of collagen production under fibrotic conditions are not yet completely understood. The synthesis of collagen might be modulated transcriptionally and post-transcriptionally, similar to the regulation of most of the other proteins in eukaryotic cells. Evidence suggests that the stability of newly synthesized mRNA as well as some enzymes devoted to collagen synthesis and degradation may play important roles in excessive accumulation of collagen in tissues^[18]. Recently, studies focused on transcriptional regulation revealed that there existed several important cis-acting elements in the upstream region of human or rodent type I procollagen genes^[8-11,19]. Activation of type I collagen gene was regarded to be related to the MAP kinase cascade pathway^[6,20]. Newly identified tissue specific transcription factors for transcription of collagen genes have been increasing^[21-26]. Some responsive elements of cytokines, including TGFβ₁, TNFα and IFNγ have been reported to be located in procollagen genes^[7,27-29]. In previous work, we analyzed the promoter activity from mouse α2(I) procollagen gene as well as its modulation by cytokines and retinoic acid^[12,13,30]. Sequence spanning from -348 bp to +54 bp in mouse α2(I) procollagen was found to be of the highest promoter activity and partial cell specificity. The activity was influenced by TGFβ, TNFα and IFNs. In order to elucidate the transcriptional regulation of type I collagen in humans, especially the cis-acting elements and consensus transcription factors involved, six recombinant plasmids containing serial 5'-deleted flanking sequences of α1(I) procollagen gene as putative promoter were constructed here. Transient transfection of these constructions into human dermal fibroblasts showed that the sequences spanning from -2 483 bp to +42 bp and from -268 to +42 bp could drive the reporter gene with higher activity, while -105 to +42 bp had lower activity, indicating that there might be some positive and negative elements in the 2.5 kb flanking region. Our result was in agreement partially with that of Jimenez *et al.* though the fine mapping was different because of different constructs and host cells used^[14]. Further deduction from the ranked driving activity of the putative promoter suggests that positive elements may be localized at -2 483 to 1 448 bp, -1 448 to 829 bp, -829 to -498 bp, -268 to -105 bp and negative ones at -498 to 268 bp, -105 to +42 bp. Computer-based prediction (DNAssist 1.0) of this 2.5 kb flanking sequence revealed that there might be 5 binding sites for *Sp-1* (-123 bp, -1 615 bp, -1 628 bp, -2 170 bp, -2 176 bp), 1 for *NFκB* (-1 571 bp), 2 for *c-myc* (-1 118 bp, -2 406 bp), 2 for *Ap-1* (-103 bp, -1 985 bp), 1 for *NF-1* (-101 bp). Obviously, one site for *NF-1* (-101 bp), *Ap-1* (-103 bp) and *Sp-1* (-123 bp) might be located in -268+42 bp.

To further characterize the existence of Ap-1, Sp-1, and NF-1 as potential transcription factors transactivating α1(I) procollagen gene, we studied the DNA-binding capacity of sequence -268+42 bp, which showed a higher promoter activity

in transfection experiment with modified EMSA. Restriction enzyme *EcoR* II cut the target sequence into 3 smaller fragments with different sizes, *i.e.* -268 to -227 bp (42 bp), -226 to 114 bp (113 bp), and -113 to +42 bp (155 bp). The digested fragments were end-labeled with digoxigenin and used as probes in DNA-protein binding reaction (see details in MATERIALS AND METHODS). DNA-protein complexes were shown in form of DNA bands with low mobility. The existence of several retarded bands in EMSA indicates there are several nuclear protein binding sites in sequence -268 to +42 bp. No retardation could be found if excess unlabeled DNA probe was added to the DNA-protein reaction, confirming the specificity of the retardation. Consensus DNAs for Sp1, Ap-1 and NF-1 were among the possible regulatory elements since the molar excess of the consensus unlabeled probe (*Sp1*, *Ap-1*, *NF-1*) partially inhibited the formation of retardation bands differently (Figure 4).

In order to confirm the potential binding sites and their transcriptional regulatory effects on -268 to +42 bp flanking sequence, a set of competitors in forms of double stranded DNA consensus to Ap-1, Sp-1 and NF-1 were transfected to cells 24 h after pCOLH_{2.5} transfection. The competitive inhibitory effects were found in *Ap-1* (25%) and *Sp-1* (20%), indicating the positive effects of the sequences on *Ap-1* and *Sp-1* in -268 to +42 bp. The transfected sequence for *Ap-1* or *Sp-1* thus decreased -268 to +42 bp activity as promoter due to competition for binding of nuclear protein. The results were similar to those reported by Sugiura and Inagaki *et al.* who showed that some cytokines or calcium channel blockers could modulate the expression of collagen via Ap-1 and Sp-1^[9,31]. The anticipated inhibitory effect of *NF-1* competitor has not been found due to unknown reasons. No effect of *NF-1* on basal transcription or the weak effect of *NF-1* beyond detection limit might be the explanation.

The Sp1 is a ubiquitously expressed zinc-finger transcription factor recognizing GC rich sequence that is widely distributed in the promoters of various genes and is thought to be a target of intracellular signaling^[32]. It is regarded that Sp1 plays an important role in both basal and inducible regulation of type I collagen expression, and may be implicated in the increased production of collagen during the development of pathological fibrosis^[9]. Ap-1 consists of either Jun homodimers or Fos/Jun heterodimeric complexes which bind the palindromic TRE sequence TGA(C/G)TGA. Ap-1 is subjected to regulation by both phosphorylation and chemical oxidation of specific cysteine residues mapping within the DNA binding domains^[33]. In this study transfection of Ap-1 and Sp-1 oligonucleotides to pCOLH_{2.5} 0.27 transfected cells inhibited the promoter activity of -268 to +42 bp, suggesting that Ap-1 and Sp-1 sites are important for the basal promoter activity of the α1(I) procollagen gene besides mediating the response of cytokines and chemicals^[31-34]. Increased promoter activity of procollagen α2(I) induced by TGFβ₁ or acetaldehyde is mediated through NF-1. The existence of NF-1 in -268 to +42 bp of human α1(I) gene has been shown by our competitive EMSA. Transfection of consensus DNA for NF-1 failed to inhibit the promoter activity of -268 bp to +42 bp in our experiment. The possible reason might be due to no or weak effect of NF-1 and thus its weak competition for the basal promoter activity.

The antifibrotic capacity of TNFα and IFNs has been reconfirmed in our study and their transcriptional regulation on collagen promoter definitely play a role in their anti-collagen production effect.

In conclusion, we find that sequences spanning from -2 483 bp to +42 bp and -268 to +42 bp in 5'-flanking region from α1(I) procollagen gene are highly active as promoters. The inhibitory cytokines including TNFα and IFNs downregulate collagen production via at least partially transcriptional regulation. The promoter activity of -268 bp to +42 bp shows

that binding sites for Sp-1, Ap-1 and NF-1 are existing candidate cis-element for transcriptional regulation in sequence -268 to +42 bp. Binding sites for Sp-1, Ap-1 are positive for basal transcription since transfections of their competitor oligo DNAs decrease the promoter activity of sequence -268 to +42 bp. Thus, transfection of competitor DNAs is applied for the first time to confirm that the sites for Sp-1 and Ap-1 are important for basal highly promoter activity. Competitors for the high active binding sites for transcription factors may be novel and promising tools for fibrotic blockade.

ACKNOWLEDGMENTS

We are especially grateful for the critical reading of the manuscript by Professor A.M. Gressner and Dr. Weiskirchen. We thank Dr. Sergio A. Jimenez for generously providing plasmid p5.3K $\alpha 1$.

Abstract

AIM: To isolate, culture and identify the human fetal pancreatic ductal stem cells *in vitro*, and to observe the potency of these multipotential cells differentiation into insulin-producing cells.

METHODS: The human fetal pancreas was digested by 1 g/L collagenase type IV and then 2.5 g/L trypsin was used to isolate the pancreatic ductal stem cells, followed by culture in serum-free, glucose-free DMEM media with some additional chemical substrates *in vitro* (according to the different stage). The cells were induced by glucose-free (control), 5 mmol/L, 17.8 mmol/L and 25 mmol/L glucose, respectively. The cell types of differentiated cells were identified using immunocytochemical staining.

RESULTS: The shape of human fetal pancreatic ductal stem cells cultured *in vitro* was firstly fusiform in the first 2 wk, and became monolayer and cobblestone pattern after another 3 to 4 wk. After induced and differentiated by the glucose of different concentrations for another 1 to 2 wk, the cells formed the pancreatic islet-like structures. The identification and potency of these cells were then identified by using the pancreatic ductal stem cell marker, cytokeratin-19 (CK-19), pancreatic β cell marker, insulin and pancreatic α cell marker, glucagons with immunocytochemical staining. At the end of the second week, 95.2% of the cells were positive for CK-19 immunoreactivity. Up to 22.7% of the cells induced by glucose were positive for insulin immunoreactivity, and less than 3.8% of the cells were positive for glucagon immunoreactivity in pancreatic islet-like structures. The positive ratio of immunoreactive staining was dependent on the concentration of glucose, and it was observed that the 17.8 mmol/L glucose stimulated effectively to produce insulin- and glucagons-producing cells.

CONCLUSION: The human fetal pancreatic ductal stem cells are capable of proliferation *in vitro*. These cells have multidifferentiation potential and can be induced by glucose and differentiated into insulin-producing cells *in vitro*.

INTRODUCTION

Even 20 years ago, the accepted concept was that one was born with all the pancreatic β cells one ever had^[1]. However, now the concept that the pancreatic ductal stem cells exist and can differentiate into pancreatic endocrine cells are generally accepted^[2-7]. When the inability of the β cells to match the increased demand for insulin can be seen, diabetes occurs. One of the main obstacles to successful islet transplantation for diabetes is the limitation of available insulin-producing tissue^[8]. The lack of pancreatic insulin-producing tissue has given a high priority to efforts to stimulate the growth of pancreatic insulin-producing cells^[9-10].

It has been reported that the embryonic stem (ES) cells induce to generate cells expressing insulin and other pancreatic endocrine hormones^[11-15]. The cells self-assembled to form three-dimensional clusters similar in topology to normal pancreatic islets where pancreatic cell types were in close association with neurons. Glucose triggered insulin release from these cell clusters by mechanisms similar to those employed *in vivo*. When injected into diabetic mice, the insulin-producing cells underwent rapid vascularization and maintained a clustered, islet-like organization. Their use might lead to many clinical benefits but it was difficult that the differentiated cells derived from the ES cells were used to assemble functional organs^[10,16-21]. It was also shown that the duct tissue from adult human pancreas could be expanded in culture and then was directed to differentiate into glucose responsive islet-like tissue *in vitro*, but the quantities were limited, the amount would be expected to have little clinical impact^[22].

Herein we show it is easier to cultivate human fetal pancreatic ductal stem cells than adult human pancreatic ductal stem cells *in vitro* and the ductal stem cells can be induced by glucose and differentiate to insulin-producing cells.

MATERIALS AND METHODS

Specimens

The specimens ($n=5$) were collected from the Southwest Hospital of the Third Military Medical University. The samples were taken from the spontaneous abortion fetus of the embryonic age 8 stage (about 16-20 wk) of fetus according to the methods of Jirasek^[23].

Cell culture

Human fetal pancreas was digested in 1 g/L type IV collagenase for 40 min at 37 °C, naturally deposited for 10 min, the supernatant was removed. The cells were then digested in 2.5 g/L trypsin for 30 min at 37 °C, followed by centrifugation for 10 min at 1 000 r/min. The deposited cells were put into glucose-free DMEM culture medium containing 2 \times non-essential amino acid (NEAA), 1 \times B27, 100 U/mL penicillin, and 100 μ g/mL streptomycin. The cell suspensions were put into non-treated T-75 flasks having non-sticky glass coverslips inside and incubated at 37 °C in a humidified atmosphere containing 50 mL/L CO₂ in air. After 24 h the nonadherent tissue (both viable and dead) was removed, followed by the media change with additional keratinocyte growth factor (KGF, 10 ng/mL, F. Hoffmann-La

Roche Ltd, Basel, Switzerland), insulin-transferrin-selenium (ITS, 1 g/L, Sigma-Aldrich China Inc. Shanghai, China), and 2 g/mL BSA, 10 mmol/L nicotinamide (F. Hoffmann-La Roche Ltd, Basel, Switzerland). The adherent or residual cells were continuously cultured and expanded for 5-7 wk by changing the medium every 3 d. The cells were used for identification by immunostaining and further differentiation.

Cell induction and differentiation

For inducing the cells differentiation, the media with or without glucose were subdivided into 4 groups: glucose-free (control), 5 mmol/L, 17.8 mmol/L and 25 mmol/L glucose. Other elements of the media were the same as mentioned above.

Tissue fixation and immunocytochemical staining

Monolayer cells were fixed for 30 min in 40 g/L polyformaldehyde (PFA, in 0.1 mol/L phosphate buffer, pH 7.2), and then rinsed in 0.01 mol/L phosphate buffer saline (PBS, pH 7.2). The specimens were incubated with 30 mL/L H_2O_2 in pure methanol for 30 min at room temperature, followed by retrieval 3 times (1 min each time) on a microwave (750 W) in 0.1 mol/L pH 6.0 citrate buffer, and incubation with 10 g/L BSA plus 4 g/L Triton X-100 at 37 °C for 30 min. Then immunocytochemical staining was carried out by using primary antibodies of different species: monoclonal mouse anti-human cytokeratin 19 IgG1 antibody (1:100, Santa Cruz Biotechnology, Inc. California, United States of American), polyclonal rabbit anti-human insulin antibody (H-86, 1:200, Santa Cruz Biotechnology, Inc. California, United States of American), polyclonal goat anti-human glucagons IgG antibody (C-18, 1:100, Santa Cruz Biotechnology, Inc. California, United States of American). Horseradish peroxidase-labeled secondary antibody (Sigma-Aldrich China Inc. Shanghai, China) was detected by reaction with 30 mL/L H_2O_2 and 1 g/L 3, 3'-diaminobenzidine (DAB, Sigma) in solution at room temperature for 5 min, then the specimens were washed and dehydrated in a graded series by ethanol. Finally, the coverslips were mounted cell-side down on glass slides with a drop of DPX and then examined using an Olympus light microscope. Photographs were taken on Lekai-135 film. Positive cells were randomly counted on the montage of photographs generated.

RESULTS

Isolation, cultures and identification of human fetus pancreatic ductal stem cells

To promote the attachment of duct cells rather than islet cells, nonsticky culture flasks were used; these flasks had been used to maintain islets in suspension. The clumps of nonislet tissue could adhere to this nonsticky surface starting about 24 h after culture (Figure 1). Although there was considerable loss of floating tissue of pancreatic acinar tissue in culture, the quantity of cell clumps adhered increased with time. The nonadherent clumps were removed by changing the culture media. In the beginning, the adherent cells were seldom and fusiform. After the nonadherent clumps were removed, the media was changed by serum-free media with additional keratinocyte growth factor to stimulate the growth of only pancreatic ductal stem cells but not the growth of fibroblasts. The cells grew very slowly in the first 2 wk (Figure 2) and 95.2% (975/1024) of the cells were positive for CK-19 immunoreactivity (Figure 3). With additional time of 3 to 4 wk, the cells grew from the adherent clumps and formed monolayer with clear epithelial morphology. The cells were large, cobblestone patterns (Figures 4 and 5). There was a significant increase of the cultured tissue during the 5-6 wk of culture.

Differentiation of pancreatic ductal stem cells into insulin-producing cells

Once the clumps were attached and formed monolayers, the

media were changed by adding glucose in different concentration of 0, 5, 17.8 and 25 mmol/L, respectively. Over next 1-2 wk the plaques of epithelial cells became crowded, and formed a few pancreatic islet-like structures (Figure 6). Some of the cells in pancreatic islet-like structures were positive for insulin immunoreactivity (Figure 7), and a few cells were positive for glucagon immunoreactivity (Figure 8).

Figure 1 After being cultured for 24 h, a few cells were adhered on the bottom of non-sticky flasks, some of the cells processed protrusions ($\times 100$).

Figure 2 After being cultured for 2 wk in the media added the keratinocyte growth factor, the number of cells increased, the cells became fusiform with a few processes ($\times 100$).

Figure 3 Most cells of culture were positive for CK-19 immunoreactivity after being cultured for 2 wk ($\times 100$).

The stainings in immunopositive cells were located in the cytoplasm, but the immunonegative cells also revealed light stainings in the perinuclear region similar to those in control group. The intensity of the immunostaining varied from one cell to another. The shape of the positive cells also varied; most of the cells were polygonal in shape, but spherical or fusiform cells were also observed. The nucleus was unstained, and some cells seemed to have 2 nuclei. Analysis of the cells from randomly generated micrographs of 25 cultured coverslips revealed different percentages of the cells immunoreactivity

for CK-19, insulin and glucagons after the cells were induced by different concentration of glucose for 1-2 wk.

After induction for 2 wk with different concentrations of glucose, the numbers of positive cells for insulin and glucagon were different. The cells were CK-19 immunonegative, while the insulin immunopositive cells were obviously increased. When the concentration of glucose was 17.8 mmol/L, the ratio of insulin positive cells reached a very high level. In the media without glucose, 108 cells of total counting 1 325 (8.2%) were positive for insulin immunostaining, and 15 cells of total counting 1 187 (1.3%) were positive for glucagons immunostaining. When the concentration of glucose reached 5 mmol/L, the number of insulin-positive cells was 153 of total counting 1 142 (13.4%), while the number of glucagons-positive cells was 19 of total counting 1 092 (1.7%). In the medium containing 17.8 mmol/L glucose, 230 insulin-positive cells of total counting 1 079 (21.3%) and 40 glucagon-positive cells of total counting 1 046 (3.8%) were observed. When the concentration of glucose was 25 mmol/L, the insulin-positive cells were 255 of total counting 1 125 (22.7%) and the glucagons-positive cells were 39 of total counting 1 127 (3.5%) (Figure 9).

Figure 4 The cells were cobblestone pattern after being cultured for 4 wk ($\times 150$).

Figure 5 The cells were cobblestone pattern and formed monolayer after being cultured for 6 wk ($\times 100$).

Figure 6 The cells were induced to form pancreatic islet-like structures after being cultured in the media containing 17.8 mmol/L glucose for 1 wk ($\times 100$).

Figure 7 After being cultured in the medium containing 17.8 mmol/L glucose for 1 wk, many cells in islet-like structures were positive for insulin immunoreactivity ($\times 150$).

Figure 8 After being cultured in the medium containing 17 mmol/L glucose for 1 wk, a few cells in islet-like structures were positive for glucagon immunoreactivity ($\times 150$).

Figure 9 Percentage of immunopositive cells induced by glucose.

DISCUSSION

In pancreas, insulin is produced and secreted by specialized structures, islets of Langerhans. Diabetes, which affects thousands of million people in the world, results from abnormal function of pancreatic islets. The main obstacle to successful islet transplantation for diabetes is the limitation of available insulin-producing tissue^[24]. Herein, we introduced to generate cells expressing insulin from human fetal pancreas duct tissue. This approach may provide a potential new source of pancreatic islet cells for transplantation.

Most studies have shown there is limited *in vitro* growth of adult islet cells of any species^[25]. From the studies on rat pancreatic regeneration, it inferred that the capacity of adult pancreatic duct cells were strongly to both expand and differentiate^[26]. Bonner-Weir *et al.* showed the expansion of adult human pancreatic ductal tissue *in vitro* and its subsequent differentiation to islet cells after being overlaid with Matrigel, and over 3-4 wk culture there was a significant increase in

insulin as well as formation of islet-like structures called cultivated human islet buds^[27]. These data further provided proofs for the hypothesis that pancreatic ductal cells have the potential to lose their specific ductal epithelial cell phenotype with rapid proliferation *in vitro*, reverting to multipotent stem cells that then can differentiate into islet cells with the appropriate external stimuli^[28]. But the report showed the amount limitation and associated with loss of insulin production^[27]. In order to avoid these problems, we made use of human fetal pancreas from the spontaneous abortion human fetus, combined 2-enzyme digestion with mechanical dissection of the pancreas. The duct tissue could be dissected effectively and the single cells were rich in stem cells. The cell proliferation could be extended for at least 6 wk. The glucose can stimulate the pancreatic ductal stem cells to differentiate into insulin-producing cells.

Now, human islet isolations can yield maximum 400 000-600 000 islets per donor, which means that more than one donor may be requested for a successful transplant. In our study reported here that the pancreatic ductal stem cells, after *in vitro* expansion and glucose-induced differentiation, became organized into islet-like structures consisting of insulin- and glucagons-producing cells. Their use may lead to many clinical benefits. Because the pancreatic islets rarely adhered directly to the nonsticky flasks, and the culture medium was changed at time, the culture conditions did not favor the islets inclusion. These data provide evidence of the potential to expand and differentiate human pancreatic ductal stem cells to islet cells *in vitro*, but further optimization of conditions is needed to generate yields of islet tissue that will make an impact on islet transplantation. We have been able to expand human pancreatic ductal stem cells and then to direct its differentiation into insulin- and glucagons-producing cells, respectively. The ability to cultivate human islets from digested pancreatic ductal stem cells opens a new approach for β cell replacement therapy.

The culture condition's optimization could include further expansion of the ductal tissue or higher efficiency in differentiating cells. Of the cells adhered in the beginning, the most cells were ductal stem cells, some were fibroblasts. But the culture medium without serum and with keratinocyte growth factor favored the growth of ductal stem cells. The data from rodents suggested that *in vitro* culture of exocrine tissue (the ducts and acini) would result in ductal epithelial cells. Moreover, mouse pancreatic exocrine (acinar and ductular) tissue gave rise to epithelial cultures that were indistinguishable from cultures of isolated duct, raising the possibility that acinar cells could dedifferentiate to form duct cells^[29,30]. It is entirely possible that the cells from the smaller ducts/acini have a little capacity to differentiate into endocrine cells^[27]. Other studies suggested that between 50-95% of the rodent exocrine cells died in the initial culture condition with mainly the ductal stem cells left to replenish the cultures^[31].

In our study, the adherent cells during the early culture period seemed to be pancreatic ductal stem cells. The culture conditions were serum-free, glucose-free but including keratinocyte growth factor, and these media stimulated the proliferation of ductal stem cells but not fibroblasts. The CK-19 positive cells that formed in fusiform and cobblestone pattern were characteristic of pancreatic ductal stem cells. In contrast, the insulin-producing cells were CK-19 immunonegative and insulin immunopositive. The glucose could induce the ductal stem cells differentiation into insulin-producing cells, and the ratio of positive cells is dependent on the concentration of glucose.

Our study differs from previous work in several ways. In most other study, the human islets were isolated and expanded on an extracellular matrix substrate, in which islets were easily mixed with the ductal stem cells^[27,32,33]. With expansion as monolayers and culture in three-dimensional collagen gels,

human islets gradually lost endocrine phenotype^[27]. In the study of Bonner-Weir, mainly ductal tissue remaining after islet isolation was expanded and then coated with extracellular matrix to induce differentiation into islet cells^[27]. The potential of extracellular matrix to induce differentiation has been shown for other epithelial cell types. In the present study, we selected different concentration of glucose as the inducing element, which effectively induced the fetal ductal stem cells differentiation.

The expansion of duct tissue is effective and extensive, probably because of the removal of normal intercellular restraints found. Because the default pathway of differentiation of embryonic pancreas is thought to be that of islet formation, such restraint might be protective and necessary to prevent excessive islet formation that could produce too much insulin and even hypoglycemia^[29,30]. In the present experiment, we are able to generate new islet cells from duct stem cells, but the quantities are limited. Despite the limitations at this early stage, these findings raise the tantalizing possibility that this approach, once optimized, may generate meaningful amounts of new human insulin-producing cells from duct stem cells. This possibility has important implications for making β cell replacement therapy available to a larger number of patients with type 1 and 2 diabetes mellitus.

Abstract

AIM: To observe the effect of tail vein injection with donor hepatocytes and/or splenocytes on the islet xenotransplantation rejection.

METHODS: New-born male pigs and BALB/C mice were selected as donors and recipients respectively. Islet xenotransplantation was performed in recipients just after the third time of tail vein injection with donor hepatocytes and/or splenocytes. Macrophage phagocytosis, NK(natural killing cell) killing activity, T lymphocyte transforming function of spleen cells, antibody forming function of B lymphocytes, and T lymphocyte subsets were taken to monitor transplantation rejection. The effects of this kind of transplantation were indicated as variation of blood glucose and survival days of recipients.

RESULTS: The results showed that streptozotocin (STZ) could induce diabetes mellitus models of mice. The pre-injection of donor hepatocytes, splenocytes or their mixture by tail vein injection was effective in preventing donor islet transplantation from rejection, which was demonstrated by the above-mentioned immunological marks. Each group of transplantation could decrease blood glucose in recipients and increase survival days. Pre-injection of mixture of donor hepatocytes and splenocytes was more effective in preventing rejection as compared with that of donor hepatocyte or splenocyte pre-injection respectively.

CONCLUSION: Pre-injection of donor hepatocytes, splenocytes or their mixture before donor islet transplantation is a good way in preventing rejection.

INTRODUCTION

Insulin dependent diabetes mellitus (IDDM) so far is treated with a constant low dose insulin injection and immunosuppressive agents. But a large quantity of clinical data indicated that long-term insulin injection could induce insulin resistance and was

not favorable to prevent some serious complications^[1]. Long-term application of immunosuppressive drugs, for example, high-dose cyclosporine and tacrolimus, could bring about toxic effects on islets and normal liver and kidney^[2,3]. So in some cases, it is limited to use immunosuppressive drugs for a long period at high dose. However, islet transplantation has the potential to cure diabetes mellitus^[4], especially insulin-dependent diabetes mellitus^[5]. Islet transplantation could make insulin maintain normal level of blood glucose and prevent serious complications. In general, islet allotransplantation is safe and efficient to reduce hyperglycemia, and leads to insulin independence in patients with insulin dependent diabetes^[6,7]. But this kind of islets source is limited, which becomes the chief obstacle for treating patients. So it is necessary to find alternative islet sources, such as xenotransplantation of islets of new-born pigs. However, the rejection for xenotransplantation should be monitored efficiently. Usually, the way of preventing rejection lies in using high dose of immunosuppressive drugs, which gives rise to serious side effects. On the other hand, pre-injection of a suitable number of the same donor lymphocytes or blood cells could induce immune tolerance in different kinds of organ transplantations^[8-14]. Some other laboratories also reported that immunologic isolation, or transplantation of microencapsulated islets, could reduce rejection of islet xenotransplantation^[15,16]. In the present study, pig islet xenotransplantation in mice was performed after injection of donor hepatocytes, splenocytes or their mixture.

MATERIALS AND METHODS

Animals and induction of diabetes mellitus model

Eighty-four BALB/C female mice (22-24 g) and 6 new born male pigs were used as recipients and donors respectively. Each BALB/C mouse was injected 0.18-0.2 mL streptozotocin (STZ) (220 mg/kg) via tail vein. When blood glucose was increased to 11.1 mmol/L, the diabetes mellitus model of mice was used in the present experiments.

Isolation of islets, hepatocytes and splenocytes

Under sterile condition, Pig pancreases were washed three times with Hanks' solution. Trypsin digestion method was used to isolate single β cells or islets, referring to the method reported by Heiser^[17]. Activity of β cells was evaluated by dithiozon (DTZ) staining and the activity should be equal or over 90%. Under bacteria-free condition, pig livers or spleens were washed three times with serum-free RPMI1640, then ground on a 200 μ stainless steel net to make single cell suspension, washing two times (2 000 rpm/min, 5 min) with normal saline (N.S). The number of cells was adjusted to 2×10^7 /mL. The cell viability was detected by Hoechst/propidium iodine (Ho/PI), both hepatocytes and splenocytes were used as donor cells with viability of more than 95%.

Islet transplantation

For hepatocyte injection group, 0.2 mL liver single cell suspension was injected into diabetic mice via tail vein every 24 h for 3 times. After the last injection of donor hepatocytes, 0.5 mL pig islets (the number of islets was 980) was transplanted into peritoneal of mouse recipient.

For splenocyte injection group, 0.2 mL spleen single cell suspension was injected into diabetes mellitus mice via tail vein every 24 h for 3 times. After the last time of injection, 0.5 mL pig islets (the number of islets was 980) was transplanted into peritoneal mouse recipient.

For mixture injection group, 0.1 mL single hepatocyte cell suspension and 0.1 mL splenocyte single cell suspension were injected into model mice via tail vein every 24 h for 3 times. After the last time of injection, 0.5 mL pig islets (the number of islets was 980) was transplanted into their peritoneal.

For islets group, 0.2 mL serum-free RPMI1640 was injected into model mice via tail vein every 24 h for 3 times. After the last time of injection, 0.5 mL pig islets (the number of islets was 980) was transplanted into recipient peritoneal. Three mice in parallel were measured for each mark and the result was indicated as an average. Twelve mice in each group were observed in terms of their living days and survival rate.

Blood glucose measurement

The level of blood glucose in mice was measured every three days by a Glucose monitoring system before and after islet transplantation. The level of blood glucose in model mice before transplantation should be over 11.1 mmol/L. The survival of transplanted-islets was indicated as at least decreasing 2-fold as compared with that before transplantation, which was indicated as functional surviving. Rejection was monitored by the level of blood glucose in mice after islet transplantation with more than 16.5 mmol/L for a continuation of 2 times.

Macrophage phagocytosis assay

Candida albicans were used as targets, constant method in our laboratory was taken to detect phagocytosis of macrophages in abdominal cavity of mice.

Phagocytosis percent=(phagocytosis of macrophages/total macrophages)×100%,

Phagocytosis index=(number of phagocytotic *Candida albicans* in 100 macrophages /total macrophages)×100%.

Lymphocyte transformation assay

Pig spleens were washed three times with serum-free RPMI1640. The spleens were ground on a 200[#] stainless steel net. The number of cells was adjusted to 1×10⁶/mL with RPMI1640. Each well of the culture plate was added 100 μL cell suspension, 6 wells in parallel, 3 wells were added conA solution 50 μL, the other 3 wells were added RPMI1640 50 μL as control. The cells were incubated in 50 mL/L CO₂, at 37 °C for 56 h, then ³H-TdR 1 μCi/well was added and cultured cells for 72 h. Cpm value was detected with a β-liquid scintillation counter. Transformation function was evaluated as average Cpm value.

Assay of NK killing activity

For effector cells, mice spleens were made into single cell suspension as the same as above-mentioned method, and the cell density was adjusted to 1×10⁷/mL in 100 mL/L fetal calf serum(FCS) RPMI1640 medium. For target cells, exponentially growing YAC-1 cells were adjusted to 2×10⁵/mL cell suspension with 100 mL/L FCS RPMI1640. A 100 μL effector cell suspension and 100 μL target cell suspension were added into each well respectively in a 40-well plate as experimental group, 3 wells in parallel. On the other hand, 100 μL/well effector cells and 100 μL/well RPMI1640 were used as effector group, 100 μL 100 mL/L FCS RPMI1640 and 100 uL target cells as target group. They were cultured them in 50 mL/L CO₂, at 37 °C for 24 h. Then 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl tetrazolium bromide(MTT) 20 μL/well, continually cultured

for another 4 h, centrifuged at 2 000 rpm/min 10 min, the supernatant was discarded, add 1 000 g/L dimethyl sulfoxide (MDS) 100 μL was added into each well, cells were lysed with vibration. After 10 min, A value was measured at 570 nm with an ELISA reader. NK killing activity=[1-(Experimental A-Effector A)/Target A]×100%.

T lymphocytes and subpopulations

The total number of lymphocytes was calculated directly under microscopy. T lymphocytes and its subpopulations were measured by constant strept avidin-biotin complex (SABC) staining. SABC kit was supplied by Wuhan Boshide Company.

Antibody-forming assay in vitro

Quantitative hemolytic spectrometry (QHS) was used to run antibody-forming assay. Mice spleens were washed three times with normal saline. A 200[#] stainless steel net was used to grind spleen tissues into single cell suspension. The cells were re-suspended and adjusted to a final concentration of 2×10⁷/mL Hanks buffer (pH 7.2). A 1 mL cell suspension and 1 mL 2 mL/L sheep red blood cell (SRBC) (1.5×10⁸/mL cells), then 1:10 complement 1 mL was added at 37 °C for 1 h, centrifuged at 3 000 rpm/min for 5 min, the A value of supernatant at 413 nm detected by 721 spectrophotometer. A value was indicated as the ability of antibody formation of B lymphocytes *in vitro*.

Pathological examination

Pathologic changes including inflammatory infiltration of local site of islet transplantation in different experimental groups were examined.

Statistical analysis

The experiments were repeated 3 times and the data were expressed as mean±SE, and significant difference was assessed by Student's *t* test.

RESULTS

The Variations of blood glucose level after islet transplantation is shown in Figure 1.

Figure 1 Variations of blood glucose after islet transplantation.

The survival time of hepatocyte injection group, splenocyte injection group, mixture group and islet group was 26.42±5.87 d, 29.56±4.52 d, 43.00±4.55 d and 16.92±2.47 d respectively (survival time of diabetic model mice was 3.86±0.85 d). The survival time of islet transplantation group was shorter than any other experimental group (*P*<0.05). So pre-injection of hepatocytes, splenocytes or their mixture from the same donor was effective in preventing rejection and delaying the time of death.

Macrophage phagocytosis in diabetic mice after pig islet xenotransplantation

Phagocytosis of macrophages in diabetic mice after pig islet xenotransplantation is summarized in Table 1.

Table 1 shows that phagocytosis percentage of islet group was increased, and the phagocytosis index of islet or hepatocyte group was obviously increased ($P<0.05$). There was no significant variation of phagocytosis percentage or index in other transplantation groups that received pre-injection of hepatocytes or mixture of hepatocytes and splenocytes 7 d after islet transplantation ($P<0.05$). After 14 d, phagocytosis percentage in hepatocyte, splenocyte and islet groups was significantly increased ($P<0.05$), phagocytosis index of islet or hepatocyte group was significantly increased ($P<0.05$).

Effect of pig islet xenotransplantation on splenic lymphocyte transforming function in mice

Seven days after transplantation, the cpm value of spleen lymphocytes in recipients of hepatocyte group, splenocyte group, mixture group or islet group was higher after pig islet

xenotransplantation than before transplantation ($P<0.05$). After 14 d, the value of hepatocyte group or islet group was still higher than that before transplantation ($P<0.05$). But there was no significant difference between splenocyte group and mixture group ($P>0.05$) (Table 2).

Effect of pig islet transplantation on NK activity of diabetic mice

NK activity of each experimental group, as compared with that before transplantation, was increased 7 d after islet transplantation ($P<0.05$), and their NK activity was continually higher than that before transplantation even 14 d after transplantation ($P<0.05$). As to the mixture group, there was no significant increase of NK activity 7 or 14 d after islet transplantation as compared with that before islet transplantation ($P>0.05$) (Table 3).

Islet group	0.34±0.06	0.74±0.11	0.81±0.13

were up-regulated 7 days after islet transplantation. CD₈ counts in splenocyte or islet group was higher than that before islet transplantation ($P<0.05$). Fourteen days after transplantation, CD₃ and CD₄ in hepatocyte and islet groups increased ($P<0.05$), and CD₈ in splenocyte and islet groups became higher than that before transplantation ($P<0.05$).

Antibody forming assay of B lymphocytes in mice after transplantation (Table 5)

Table 5 shows that antibody forming function of all four kinds of islet transplantation group was significantly increased as compared with that before islets transplantation 7 or 14 d after transplantation ($P<0.05$).

Pathological examination

In islet transplantation group, there were a lot of lymphocyte infiltration, disruption of islets structure, or denaturation and necrosis of islet cells. Hepatocyte group with moderate lymphocyte infiltration. The mixture group had light lymphocytes infiltration.

DISCUSSION

Insulin dependent diabetes mellitus was considered as an autoimmune disease against beta cells^[18], which is usually treated with a low dose insulin injection and immunosuppressive agents. But a large quantity of clinical data indicated that long-term insulin injection could induce insulin resistance and could not prevent some serious complications^[1]. Recent studies focused on islet transplantation as a primary therapy for insulin dependent mellitus diabetes, accompanied by induction of immune tolerance to immunosuppressive agents^[19,20]. Islet allotransplantation could correct glucose imbalance and related complications, because successful islet transplantation could not only supplies the natural insulins but also other necessary biological factors. But most patients with insulin dependent diabetes mellitus could not be treated by this kind of islet transplantation because the source of allo-islets was limited. However, xenotransplantation, for example pig islet, could resolve the above-mentioned problems. Although xenotransplantation could renew the balance of glucose, rejection usually occurs, thus reducing the effect of transplantation. Islet transplantation combined with other organs or cells from the same donor could reduce rejection. Some laboratories have tried pancreas allotransplantation in combination with the same donor spleen transplantation. The results showed that the survival time of pancreas was significantly prolonged, which was attributed to the induced immunotolerance. It has been reported that bone marrow transplantation could induce the formation of hematopoiesis chimera, which could prevent acute or chronic rejection^[13-15,21,22]. So it is possible to use hematopoiesis chimera to treat insulin dependent diabetes mellitus.

T lymphocyte vaccine (TCV) could induce immunotolerance for transplantation^[23]. For example, TCV with recipient spleen cells pre-sensitized by donor antigen was used in rat heart transplantation, to observe the survival time of rat heart graft. The results showed that TCV could prolong the survival time of rat heart graft^[24]. As to the immune response, T lymphocyte proliferation reaction increased, B lymphocyte proliferation reaction was not affected, but mixed lymphocyte reaction (MLR) declined. The analysis of phenotype showed that CD₈ subpopulation increased, however there was no obvious change of antibody-dependent cell-mediated cytotoxicity (ADCC) reaction. Many other studies demonstrated that liver cells (or hepatocytes) and/or spleen cells (or splenocytes) could induce specific immune tolerance in different organ transplantations, such as kidney, marrow, heart, skin^[25-28]. In the aspect of islet transplantation, some scholars administrated pre-injection of

donor hepatocytes and/or splenocytes to induce the immune tolerance and got the positive result^[29-31].

In the present study, islet xenotransplantation was performed after pre-injection of donor hepatocytes, splenocytes, or their mixture. The results showed that the survival time of hepatocyte group, splenocyte group, mixture group was longer than islet group ($P<0.05$). Pre-injection of hepatocytes, splenocytes or their mixture from the same donor was effective in preventing rejection and prolonging survival time. In the aspect of macrophage function, macrophage phagocytosis percent in islet transplantation group was increased, and the phagocytosis index in islet or hepatocyte group was increased ($P<0.05$). There was no significant variation of phagocytosis percent or index in other transplantation groups 7 d after transplantation. After 14 d, phagocytosis in hepatocyte, splenocyte and islet group was significantly increased, phagocytosis index in islet or hepatocyte group was increased. The antibody-forming function of spleen B lymphocytes of recipients in hepatocyte group, splenocyte group, mixture group or islet group was increased 7 d after pig islet xenotransplantation. After 14 d, the B lymphocyte function in hepatocyte group or islet group was still higher than that before transplantation ($P<0.05$). As to NK cells, NK killing activity of each experimental group, as compared with before transplantation, was increased 7 d after islet transplantation, and their NK activity maintained higher than that before transplantation 14 d after transplantation. As to the mixture group, there was no significant increase in NK activity 7 or 14 d after islet transplantation as compared with that before islet transplantation ($P>0.05$). T lymphocyte subpopulation was also analyzed, the results showed that CD₃ and CD₄ percent of hepatocyte, splenocyte or islet group increased 7 d after islet transplantation. CD₈ percent of splenocyte or islet group was higher than that before islet transplantation. Fourteen days after transplantation, CD₃ and CD₄ percent of hepatocyte and islet group was still higher, and CD₈ percent of splenocyte and islet groups was higher than that before transplantation. To further examine immune tolerance in different experimental groups, pathological examination was performed. In islet transplantation group, lymphocyte infiltration was extensive, disruption of islet structure and necrosis of islet cells were also obvious. Hepatocyte group had moderate lymphocyte infiltration. The mixture group has slight lymphocyte infiltration. The results indicate that pre-injection of hepatocytes, splenocytes or mixture of them could reduce rejection by inducing immunotolerance. Although the concrete mechanism is not completely clear, pre-injection of hepatocytes and splenocytes from the same donor could induce immunotolerance of islet xenotransplantation, and prolong the survival time of islets.

Abstract

AIM: To establish a novel human hepatocellular carcinoma (HCC) cell line FHCC-98 from HCC tissue and to provide a suitable model for studying HCC occurrence, progress and metastasis.

METHODS: Serially passaged cells were cultured and their morphologies were observed under light and electron microscope. Cytogenetic study was conducted by using flow cytometry and chromosome analysis. Expressions of tumor markers such as α -fetoprotein (AFP), cytokeratin (CK) and hepatoma metastasis-associated factor HAb18G/CD147 on the FHCC-98 cells were detected by immunocytochemistry or Western blotting. Lactic dehydrogenase (LDH) isoenzymes were detected by polyacrylamide gel electrophoresis (PAGE). Xenograft was performed by inoculating FHCC-98 cells into the flanks of nude mice.

RESULTS: Morphology of FHCC-98 cells was the same as that of other malignant cells. The expressions of the cells were positive for HAb18G/CD147 and CK, and negative for AFP. Its population doubling time was 21.4 h. The cell DNA was tetraploid and the major chromosomes were triploid by cytogenetics analysis. The tumorigenicity in nude mice was 100%. PAGE showed four bands representing LDH₂, LDH₃, LDH₄ and LDH₅.

CONCLUSION: FHCC-98 is a novel HCC cell line and an ideal cell model for further exploring the mechanism of hepatocellular carcinoma invasion and metastasis.

INTRODUCTION

Hepatocellular carcinoma (HCC) is one of the most common malignant tumors. It ranks fifth in frequency worldwide among

all malignancies and causes 1 million deaths annually^[1], yet its incidence is increasing steadily in various countries^[2-4]. Epidemiology studies showed that primary liver cancer is the second mortality in China^[5] and it accounts for 53% of all liver cancer death worldwide^[6]. Though with great development in diagnosis and therapy, the prognosis of patients with HCC remains dismal for its high rate of metastasis and recurrence. For patients in advanced stages, the median survival is less than 6 mo, no matter what kinds of therapy were managed^[7-11]. So it is urgent to further explore the mechanism of HCC occurrence, progress and metastasis. HCC cell lines are powerful tools. Until now, ten of human HCC cell lines^[12-27] have been established, and every cell line has its own characteristics and offers convenience for various experiments. Stability, homogeneity and easy to culture are important parameters for good cell lines. Here we report a new HCC cell line, which has been maintained for five years through 500 passages.

MATERIALS AND METHODS

Patient

Tumor tissue obtained from a 39-year-old male HCC patient who lived in northwest China was used to establish a cell line. His family history of oncology was unknown, but there was no history of hepatitis or blood transfusions. There was no operation history. Investigations showed AST of 86 U/L, α -fetoprotein 8 ng/mL, carcinoembryonic antigen (CEA) 2.8 ng/mL and HBsAg(-). In 1998, the patient complained of upper right abdominal tender pain. A computerized-tomography demonstrated a 10 cm×11 cm space-occupying lesion in the right lobe of liver. A partial liver resection was performed. Pathologic diagnosis confirmed HCC with middle differentiation. The patient died of lung metastasis after 3 mo.

Primary culture

A slice portion of sample was obtained under sterile conditions and washed by RPMI 1640 (Life Technology) 3 times and minced with surgical blades into pieces smaller than 1 mm³, then these pieces were put into tissue-culture flasks and incubated at 37 °C and 50 mL/L CO₂ (Heraeus, Germany) with RPMI 1640 medium supplemented with 100 U/mL penicillin, 100 μ g/mL streptomycin and 200 mL/L FBS. One week later, cells migration was observed and some colonies were formed. Those colonies were detached with 2.5 g/L trypsin and pulled into 25 cm² flasks in RPMI 1640 medium with 200 mL/L FBS. The medium was renewed two or three times a week. After stable growth, the same medium with 100 mL/L FBS was used as maintenance medium. When cells were confluent, they were detached with 2.5 g/L trypsin and passaged at the ratio of 1:2 or 1:3. At the 80th passage (about 30 mo after the sample was got), a stable cell line was considered to be established.

Morphological observations

Cells were observed daily under an invert microscope (Olympus). Cells coated on tissue-culture slides were washed with PBS (pH 7.4) 3 times, then fixed with cool pure acetone for 10 min and stained with hematoxylin and eosin (HE

staining). For electron microscope observation, 4×10^6 cells were centrifuged at 1 000 r/min for 10 min, then fixed in 30 g/L glutaraldehyde for 30 min and embedded in paraffin and ultra-thin sectioned. The section was observed with a JEM 2000 transmission electron microscope (JEOL)^[22].

Growth properties

Growth curve was analyzed by modified MTT assay^[24]. Cells in exponential growth phase at 16th passage were collected. Single-cell suspension (5×10^4 /mL) was added to (200 μ L/well) a 24-well plate, incubated at 37 °C with 50 mL/L CO₂, then MTT (5 mg/mL) was added to the wells (20 μ L/well) every 24 h for 7 consecutive days. The plate was incubated in cell incubator for 4 h, and then the supernatants were removed and 150 μ L DMSO was added into each well. After incubation for 30 min, the dye-stained liquid was removed to a 96-well plate. Absorbency at 490 nm ($A_{490\text{nm}}$) was determined by M450 (Bio-Rad) enzyme-linked reader. The growth curve was plotted by half-height method.

FHCC-98 cells were incubated in another 24-well plate (1.2×10^4 /mL). Attachment efficiency was measured by counting the cell number every 2 h.

Attachment efficiency = (number of cells/120 000) \times 100%.

To determine the cloning rate, 1.5×10^2 cells in suspension in a culture medium containing 8 g/L agar were applied to a base layer of a culture medium containing 1.7% agar. The Petri dish was incubated for 12 d at 37 °C in a humidified atmosphere containing 50 mL/L CO₂, and colonies containing more than 5 cells were counted.

$$\text{Cloning rate} = \frac{\text{Number of clones}}{150} \times 100\%$$

Flow cytometry

Single-cell suspensions containing 2×10^6 cells were treated following the standardized protocol and cell cycle analysis was performed by flow-cytometry (ELITE ESP Coulter)^[22].

Chromosome analysis

Cells were cultured for 2 h in the culture medium containing 0.05 μ g/mL of colcemid and trypsinized, swollen with 0.075 mol/L KCl solution for 15 min and fixed with methanol: acetic acid (3:1) 3 times. Following air-drying, metaphase smears were stained with Giemsa. Samples were observed with oil immersion objective and photographed^[18].

Immunocytochemistry

Cells cultured on slides for 24 h were washed 3 times with PBS and then fixed in acetone for 10 min at room temperature. AFP and cytokeratin were detected by immunocytochemistry using SP method. The slides were viewed under light microscope and the degree of staining was assessed.

Western blotting

Tumor metastasis-associated factor HAb18G/CD147^[28,29] was detected by western blotting. Single-cell suspension (1.0×10^5 /mL) was collected, and centrifuged at 800 r/min. The cell pellets were collected and resuspended in lysis buffer of 50 mmol/L Tris-HCl (pH 8.0), 150 mmol/L NaCl, 0.2 g/L azido sodium, 1 g/L SDS, 100 μ g/mL PMSF, 10 g/L Triton X-100, 5 g/L deoxycholic acid and protease inhibitor for 10 min on the ice. The lysis solution was centrifuged at 16 000 g for 10 min at 4 °C and the supernatants were collected, and the protein concentration was detected with Lowery's method. SDS-PAGE was carried out. Western blotting was performed with secondary antibodies coupled to horseradish peroxidases and detected using ECL reagents (Amersham, Freiburg, German).

ConA coagulation test

Single-cell suspension (5.0×10^5 /mL) was mixed with the same volume of ConA and the mixture were diluted and incubated at 37 °C in 50 mL/L CO₂ for 20 min. Human embryonic lung cell was used as contrast. Assembling reaction was observed.

Isoenzyme analysis

LDH isoenzymes were detected by PAGE. FHCC-98 cells were trypsinized and 8.0×10^6 cells were re-suspended in sterile saline. The cell suspension was centrifuged at 1 000 r/min for 10 min twice and then re-suspended in 0.5 mL Tris-HCl (150 mmol/L, pH 7.6). The sample was repeatedly frozen and thawed at -40 °C and 37 °C for 6 times, then centrifuged at 3 000 r/min 4 °C for 20 min. The supernatant was stored under -20 °C for using. The SDS-PAGE sample buffer was 100 mmol/L Tris-HCl (pH 6.8) supplemented with 200 mL/L glycerite and 2 g/L bromphenol blue. The sample was mixed with an equal volume of buffer and used for PAGE. The stacking gel was 50 g/L while separation gel 60 g/L. The staining solution was composed of oxidized NAD⁺ (5 mg/mL), NBT (2 mg/mL), PMS (1 mg/mL) and sodium lactate (60 g/L). The minigels were run at a constant voltage (100 V) for 2 h and then stained for 1 h. The gel was fixed in 70 mL/L acetic acid over 16 h and photographed.

Xenograft

Ten 4-6-week-old nude mice (supplied by the animal center of Fourth Military Medical University) of both sexes bred under specific pathogen-free (SPF) conditions were used in the heterotransplantation experiments. Cells (2.0×10^6) suspended in medium (0.2 mL) were injected subcutaneously into flanks of each mouse.

Mycoplasma detection

Mycoplasma was detected by transmission electron microscopy.

RESULTS

Morphology

Polygonal epithelial-like cells in culture were identified to have large nuclei and the ratio of nuclear/cytoplasmic increased. Cells grew well at a high density ($>1 \times 10^6$ /mL). Electron microscopy revealed that abundant microvilli distributed on the cell surface (Figure 1). Desmosomes and gap junction could be seen between cells (Figure 2). Glycogen granules were rich in cytoplasm and mitochondria were in a round shape. Ribosome and rough endoplasmic reticulum were moderate. Atypical nuclei were conspicuous and euchromatin was rich. Karyokinesis and pathologic mitosis were frequently uncoupled.

Figure 1 Ultrastructure of FHCC-98 illustrating the clear and abundant microvilli (Original magnification: $\times 4\,000$).

Figure 2 Desmosomes (A) and gap junction (B) between cells (Original magnification: $\times 30\,000$).

Growth kinetics

The growth curve at the sixteenth passage (Figure 3) showed a stationary-phase at the beginning and at the end of the experiment, the exponential growth lasted about 3 d. The population doubling time of FHCC-98 was 21.4 h. At the time points of 2, 4, 6 and 8 h, the attachment efficiencies were 54.2%, 83.3%, 89.2% and 93.7%, respectively. The percentage of colony-forming cells in soft agar was an average of 32.6%.

Figure 3 Growth curve of FHCC-98 cells in RPMI 1640+100 mL/LFBS at the 16th passage.

Cytogenetics studies

Chromosome analysis revealed the number of chromosomes per cell varied from 58 to 80 with a number in the triploid of 91%. FHCC-98 cell DNA became tetraploid. 75.0% cells were in G₁ phase, while 7.0% cells were in G₂ phase and 18.0% in S phase. The DNA index was 1.857.

Immunological characteristics

The FHCC-98 cell line was positive for CK and negative for AFP.

Western blotting

Western blotting showed that FHCC-98 was positive for HAb18G/CD147 and the band showed a single one with M_r 61 000 (Figure 4).

Figure 4 Western blotting of HAb18G/CD147 on FHCC-98 cell line. Lane 1: HAb18 mAb; Lane 2: HAb18G.

ConA test

The FHCC-98 cells were coagulated in 3.91 $\mu\text{g/mL}$ of ConA while human embryonic lung cells had no response to 250 $\mu\text{g/mL}$ of ConA.

Isoenzyme analysis

PAGE analysis revealed that FHCC-98 had tumor typical isoenzymes of LDH without LDH₁ (Figure 5). LDH₂, LDH₃, LDH₄ and LDH₅ isoenzymes were separated to relative activities (percentage of total LDH) of 3%, 19%, 49% and 29%, respectively.

Figure 5 LDH isoenzyme analysis of FHCC-98.

Xenograft

Ten days after heterotransplantation of FHCC-98 cells into nude mice, subcutaneous tumors appeared at the sites of inoculation and grew rapidly in size during the next 20 d. Average tumor volumes on d 10, 14 and 30 were 42.4 ± 17.8 , 76.6 ± 43.4 , and $471.4 \pm 187.5 \text{ mm}^3$, respectively.

Mycoplasma detection

No mycoplasma contamination was detected in FHCC-98 cells from passages 16 and 28.

DISCUSSION

It is well known that heterogeneous tumors have diverse biologic behaviors, outcomes, and responses to therapy whether *in vivo* or *in vitro*. Malignant tumors show their genetic heterogeneities, differentiation and metastasis, which have been demonstrated in various kinds of tumors^[30-34], and even in permanent cell lines with different biological characteristics^[22,23,34]. Since the establishment of the first human HCC cell line in 1963 (Chen *et al.* *Chin Med J*, 1963; 82: 228), more than ten human HCC cell lines have been established, most of which are positive for either HBV, HCV or AFP, yet they differed in biological properties. HBV is the main viral cause of HCC in China. Unfortunately, there are about 30% HCC patients are AFP or HBV negative, partially due to the extensive necrosis of tumor mass. As a tumor marker, AFP's sensitivity and specificity for HCC detection depend on the diagnostic level and the cutoff level^[35]. Different detection approaches may have different results. In this study, immunocytochemical method was applied to detect AFP and the result was consistent with that by RIA. Up to now, human HCC cell lines with both AFP negative and HBV negative have been rarely reported. Fortunately, we established a HCC cell line, which was negative for both AFP and HBV.

FHCC-98 demonstrated the same epithelial-type morphology as other HCC cell lines. FHCC-98 showed no contact inhibition when the cell density was high. As important metabolic parameters of HCC, LDH₄ and LDH₅ had high activities, and LDH₁ had no, suggesting the existence of anaerobic respiration in HCC. Hypoxia and overgrowth of

cancerous tissue specifically repressed the activity of AFP, and the target was c-Myc, suggesting that c-Myc regulated AFP gene expression^[36]. Such changes in LDH₅ might be a factor hindering the synthesis of AFP and resulting in AFP-negative patients. FHCC-98 may be used as a model for anti-oxidant therapy of tumors. FHCC-98 has its own characteristics. The first prominent characteristic of the cell line is its biological properties of high concordance and little variation among different passages including its morphology, growth kinetics, chromosome, AFP and LDH isoenzyme; The second one is that its population doubling time was relatively shorter and it grew more rapidly compared with other human HCC cell lines^[12,14,18,20,23,25]. High coagulation of the cells showed that it could proliferate rapidly without contact inhibition. The third one is its high tumorigenicity in nude mice. And the last one of the cell line is that it can grow in various medium cultures, such as RPMI 1640 and DMEM with different concentrations of FBS.

In conclusion, we believe that FHCC-98 is a novel HCC cell line and a valuable cell model for studying HCC *in vitro* and *in vivo*, especially for AFP- and HBV-negative HCC.

Abstract

AIM: To investigate the expression of annexin I in pancreatic cancer and its relationship with the clinicopathologic factors, and to evaluate its potential clinical significance.

METHODS: Annexin I expression was analyzed by Western blot and immunohistochemical staining in pancreatic adenocarcinoma and multi-tissue microarrays (MTAs).

RESULTS: Western blot analysis showed that annexin I was overexpressed in 84.6% (11/13) pancreatic ductal adenocarcinomas. Immunohistochemistry analysis of pancreatic cancer in MTAs showed that annexin I protein was 71.4%(30/42) positive which was markedly increased compared with that in the tumor matched normal pancreas tissues 18.4%(7/38) ($P<0.01$). In the meantime, the high expression of annexin 1 was correlated with the poor differentiation of pancreatic adenocarcinoma.

CONCLUSION: Annexin 1 overexpression is a frequent biological marker and correlates with the differentiation of pancreatic cancer during tumorigenesis.

INTRODUCTION

Pancreatic cancer is one of the most lethal malignancies with less than 3-5% of the overall five-year survival rate, and the patients normally die within six months after diagnosis^[1]. There

are some indications that the incidence of pancreatic cancer following an upward increase, in recent years it has reached a plateau and in some countries there is even a slight decrease. But in China the incidence and mortality rates of this disease have taken an upward trend countrywide. Based on the data of demography and death collected through Chinese Disease Surveillance Point System (DSPS) over the period of 1991-2000, the age-standardized mortality rate due to pancreatic cancer increased from 2.18 in 1991 to 3.26 in 2000 per 1000 000 populations and the peak mortality of pancreatic cancer might arrive in China in the next few decades^[2]. In the United States, more than >30 000 people were diagnosed and died of pancreatic cancer in 2003, representing the fourth leading cause of cancer death^[1]. The significant factor for the poor prognosis of pancreatic cancer may be attributed to its biological aggressiveness, the difficulty of early diagnosis, and poor response to conventional therapeutics, those reflect a fact that pancreatic cancer is a poorly understood disease and the etiologic factors and the molecular basis for these characteristics are unknown. Comparisons of global gene and protein expression profiles between pancreatic cancer and normal pancreas using high-throughput methods could provide important information about the molecular characteristics and reveal some new specific or associated biomarkers of pancreatic cancer with promise for development into novel diagnostic or therapeutic targets^[3-7].

Annexin 1, a member of annexin family, was found with expression alterations in different kinds of malignant tumors. The molecular mechanisms and the clinical significance of annexin I altered expression still remain a debate. In this study, we investigated annexin I expression and distributions in a large number of pancreatic cancer specimens via Western blot and immunohistochemistry analysis based on multi-tissue microarrays (MTAs).

MATERIALS AND METHODS

Patients and specimens

Fresh tissue samples of 13 pancreatic cancers and their corresponding normal counterparts were obtained at the time of resection with informed consent from Cancer Institute and Hospital (CIH), Chinese Academy of Medical Sciences (CAMS) and Peking Union Medical College (PUMC) during November 2001 and November 2003. The samples were cut into two parts, one was snap-frozen in liquid nitrogen before storage at -80 °C, and the other was fixed with 10% formalin for histopathological diagnosis. Histological diagnosis of these samples was all pancreatic ductal adenocarcinomas. This group consisted of 8 males and 5 females with a median age of 64 years (range, 39-75 years). None of them received preoperative radiotherapy or chemotherapy.

Formalin-fixed paraffin-embedded tissue blocks of pancreatic cancer and normal pancreatic tissue were collected from the archives of the Department of Surgery at CIH, CAMS and Mudanjiang Tumor Hospital between January 1991 and August 2002 and subjected to tissue microarray construction. There were 32 pancreatic ductal adenocarcinomas, 6 mucinous

adenocarcinomas, 4 acinar cell carcinomas, 7 islet cell carcinomas, 8 ampulla of Vater carcinomas. The median age of these patients (37 males and 20 females) at the diagnosis was 60 years (range, 19-71 years).

Human pancreatic cancer cell lines BxPC-3 and PANC-1 were purchased from American Type Culture Collection (Manassas, VA). BxPC-3 and PANC-1 cells were cultured in RPMI 1640 and Dulbecco's modified Eagle's medium, respectively, and supplemented with 100 g/L heat-inactivated fetal bovine serum, 100 U/mL penicillin, and 100 µg/mL streptomycin.

Western blot analysis

Total tissue and cell lysate were prepared in extraction buffer containing 50 mmol/L Tris-HCl (pH 7.4), 150 mmol/L NaCl, 10 g/L Triton-100, 1 g/L SDS, 1 mmol/L EDTA, 1 mmol/L AEBSF, 20 µg/mL aprotinin, and 20 µg/mL leupeptin. After centrifugation at 12 000 g for 15 min at 4 °C, the supernatant was collected, and protein concentration was determined by Bradford method^[8]. Equal amounts of total protein (10 µg) from each sample were loaded and separated by 120 g/L SDS-polyacrylamide gel electrophoresis, and then transferred to Hybond-P polyvinylidene difluoride (PVDF) membrane (Amersham Pharmacia Biotech, Piscataway, NJ). After blocked with 50 g/L nonfat dry milk in PBS (pH 7.4) with 1 g/L Tween-20, membranes were probed with a mouse anti-annexin I monoclonal antibody (1:1 000 dilution, BD Biosciences Pharmingen, Chicago, IL), followed by subsequent incubation with horseradish peroxidase-conjugated goat anti-mouse secondary antibody (1:3 000 dilution, Santa Cruz Biotechnology, Santa Cruz, CA). Visualization of the protein bands was performed by the enhanced chemiluminescence kit (Santa Cruz Biotechnology). Parallel Western blot was probed with an anti- α -tubulin monoclonal antibody (Santa Cruz Biotechnology) as a loading control.

MTAs construction and immunohistochemistry analysis

Formalin-fixed paraffin-embedded tissue blocks containing pancreatic adenocarcinoma and normal pancreatic tissues were identified on the hematoxylin and eosin stained slide and marked. The marked areas in the corresponding paraffin block (donor block) were used for tissue microarray construction. From these defined areas of each specimen, triplicate tissue cores with a diameter of 0.6 mm were taken from donor block and arrayed into a recipient paraffin block using a tissue puncher/arrayer (Beecher Instruments, Silver Spring, MD) as previously described^[9]. Five micrometer sections of the tissue array block were cut and placed on Fisherbrand Colorfrost/Plus microscope slides (Fisher scientific, Pittsburgh, PA) for immunohistochemical staining.

The streptavidin-peroxidase method was used for the immunostaining of annexin I. Briefly, after deparaffinization in xylene and rehydration in grade ethanol, endogenous peroxidase activity was blocked by incubation with 3% hydrogen peroxide for 10 min. Tissue sections were then heated at 100 °C in 10 mmol/L citrate buffer (pH 6.0) for 10 min to retrieve antigens and pre-incubated with normal horse serum for 20 min at room temperature. Mouse anti-annexin I monoclonal antibody (BD Biosciences Pharmingen) diluted 1:100 was used as the primary antibody, and the specimens were incubated with it overnight at 4 °C, followed by addition of biotinylated anti-mouse secondary antibody and streptavidin-horseradish peroxidase (Zymed Laboratories, South San Francisco, CA). 3,3'-diaminobenzidine was used as a chromogen, and hematoxylin was used for counterstaining. For negative control purposes, the same procedure was followed except that the primary antibody was replaced by PBS. Known immunostaining-positive slides were used as positive controls.

The level of annexin I expression was calculated by combining an estimate of the percentage of immunoreactive cells (quantity score) with an estimate of the staining intensity (staining intensity score) as follows. No staining was scored as 0, 1-10% of cells with positive staining were scored as 1, 10-50% as 2, 50-70% as 3, and 70-100% as 4. Staining intensity was rated on a scale of 0 to 3 as follows: 0=negative (no color); 1=weak (weak yellow), 2=moderate (yellow), and 3=strong (brown). The raw data were converted to the immunohistochemical score (IHS) by multiplying the quantity and staining intensity scores. Therefore, the score could range from 0 to 12. The IHS score >3 was considered as positive expression^[10].

Statistical analysis

Statistical analysis was performed using the SPSS 10.0 software package (SPSS, Chicago, IL). The annexin I expression in different groups was analyzed using Mann-Whitney *U* test. The correlation between annexin I and each clinicopathologic factor was assessed with the Spearman rank correlation test. *P* value of less than 0.05 was considered statistically significant.

RESULTS

Western blot analysis of annexin I expression

Ten micrograms of protein extracts of pancreatic ductal adenocarcinoma tissues and their corresponding normal pancreas tissues from 13 different patients was prepared for Western blot analysis using monoclonal anti-annexin I antibody. This antibody could detect specific bands migrating at 37 ku (Figure 1). Western blot revealed that the expression of annexin I was low or undetectable in normal pancreas tissues. The level of annexin I expression was markedly increased in pancreatic ductal adenocarcinoma. Annexin I overexpression was found in 84.6% (11/13) pancreatic ductal adenocarcinoma tissues. There was also a strong expression of annexin I in pancreatic cancer cell lines.

Figure 1 Western blot analysis of annexin I in pancreatic ductal adenocarcinoma. Ten micrograms of total protein extracts from pancreatic tissues and cell lines were run on 120 g/L SDS-PAGE, and annexin I protein expression was probed with mouse anti-annexin I monoclonal antibody and visualized by chemiluminescence (*top panel*). C: pancreatic ductal adenocarcinoma tissues; N: normal pancreas tissues; BxPC-3: human pancreatic adenocarcinoma cell line. α -Tubulin was used as an internal control (*bottom panel*).

Immunohistochemistry analysis of annexin I using pancreatic cancer MTAs

We carried out immunohistochemical studies for annexin I on the paraffin-embedded pancreatic cancer tissue microarray (Figure 2. A, B). This tissue microarray contained a total of 256 tissue spots consisting of 32 pancreatic ductal adenocarcinomas, 6 mucinous adenocarcinomas, 4 acinar cell carcinomas, 7 islet cell carcinomas, 8 ampulla of Vater carcinomas, and 38 normal pancreas tissues. In the normal pancreas, the positive rate of annexin I expression was 18.4% (7/38). It was found that most of normal pancreatic acinar and ductal cells did not express annexin I. There were only a small number of acinar cells that were observed. Annexin I cytoplasmic positive and the scattered positive cells were mainly located on the outside of acinar lumen (Figure 2. C, D). In contrast, positive expression of annexin I in

Figure 2 Immunohistochemical analysis of annexin I expression on pancreatic cancer MTAs. A and B: Overview of the H & E staining and immunohistochemical staining of annexin I on pancreatic cancer MTAs; C ($\times 200$) and D ($\times 400$): normal pancreas; E ($\times 200$) and F ($\times 400$): well differentiated ductal adenocarcinoma; G ($\times 200$) and H ($\times 400$): poorly differentiated ductal adenocarcinoma.

pancreatic cancer (71.4%, 30/42) was up-regulated significantly ($P < 0.01$). The different subtypes of the tumor were observed partially positive (Table 1). The possible relationships between annexin I expression with some clinicopathologic factors were additionally analyzed. It was found that the positive expression rate of annexin I in poorly differentiated pancreatic ductal adenocarcinomas (81.8%, 9/11) increased markedly compared with the well and moderately differentiated types (71.4%, 15/21) ($P < 0.05$). According to the progress of tumorigenesis, the distributions of annexin I were found altered from the outside of normal acinar lumen to the inside cancerous acinar lumen in the well differentiated ductal adenocarcinomas, and then to the most of poorly differentiated ductal adenocarcinomas separately (Figure 2. C, D, E, F, G, H). There were no statistically significant correlations between annexin I expression and lymph node metastasis and TNM stages (Table 2).

Table 1 Annexin I expression in normal pancreas and cancer tissues

Group	<i>n</i>	Positive rate of annexin I expression (%)	<i>P</i> value
Normal pancreas	38	18.4(7/38)	<0.0001
Pancreatic cancer	42	71.4(30/42)	
Ductal adenocarcinoma	32	75(24/32)	
Mucinous adenocarcinoma	6	83.3(5/6)	
Acinar cell carcinoma	4	25(1/4)	
Islet cell carcinoma	7	57.1(4/7)	
Ampulla of Vater carcinoma	7	57.1(4/7)	

Table 2 Correlation of annexin I expression with clinicopathologic factors of pancreatic adenocarcinoma on tissue microarray

Clinicopathologic factors	<i>n</i>	Positive expression rate of annexin I (%)	<i>P</i> value
Histological differentiation			0.012
High and moderate	21	71.4(15/21)	
Poor	11	81.8(9/11)	
Lymph node metastasis			0.810
Yes	8	75(6/8)	
No	34	73.5(25/3)	
TNM stage			0.551
I	15	66.7(10/15)	
II	21	81(17/21)	
III	5	60(3/5)	

DISCUSSION

Annexin I belongs to the family of the calcium and phospholipid-binding proteins, called annexins. Annexins are cytosolic or associated with the membrane or the cytoskeleton in a calcium-dependent manner. Annexin I is one of the more extensively studied annexins, which was initially cloned as phospholipase A2 (PLA2) inhibitor^[11]. Annexin I is a steroid-regulated protein and thus implicated in some actions of glucocorticoids, including inhibition of cell proliferation, anti-inflammatory effects, the regulation of cell migration, differentiation, death and the hypothalamic-pituitary axis^[12-16]. To date, there are some contradictory descriptions on annexin I expression in human

cancers. It has been reported that annexin I is up-regulated in human breast cancer^[17], hepatocellular carcinoma^[18], and pituitary adenoma^[19] and down-regulated in human esophageal squamous cell carcinoma^[20], prostate cancer^[21], and endometrial carcinoma^[22]. In this study, we found that annexin I was significantly overexpressed in pancreatic cancer by Western blot and immunohistochemistry, which was consistent with the results of gene expression profile analysis.

Annexin I is expressed in a tissue-specific manner in rodents. The highest annexin 1 expression level was found in lung and placenta; moderate in spleen, thymus, prostate, and submaxillary gland; and low (or absent) in muscle, brain, and liver^[23]. However, it was found that annexin I expression and phosphorylation were not only up-regulated during liver regeneration and transformation in antithrombin III SV40 T large antigen transgenic mice, but also overexpressed at both the transcriptional and translational levels in tumorous and nontumorous regions of hepatocellular carcinoma (HCC)^[18,24]. Annexin I up-regulation has been found to be correlated with increased synthesis of epidermal growth factor (EGF) and consequently with increased phosphorylation of EGF receptor (EGFR). Annexin I is a substrate for tyrosine kinases such as EGFR^[23,25] and for serine/threonine kinases such as protein kinase C^[26]. Annexin I can specifically modulate the extracellular signal-regulated kinase (ERK) signal cascade at an upstream site probably by associating with key signal components including the adaptor protein Grb2. Increased expression of annexin I could lead to constitutive activation of ERK1/2 kinase in macrophages^[27]. These findings implicated that annexin I might involve in mitogenic signal transduction and regulate cell growth. It was found that the level of annexin I expression increased three to four fold when quiescent human diploid foreskin fibroblasts (HFF) cells were stimulated to proliferate^[28]. This observation suggested that annexin I might be directly or indirectly involved in cellular proliferation. Pancreatic cancer demonstrated abnormally high expression of a number of important tyrosine kinase growth factors and receptors, particularly of the EGF family, which may contribute to the neoplasm's growth by autocrine and paracrine effects^[29]. Because annexin I is a substrate protein of EGFR, we can postulate that activated EGFR pathway promotes the annexin I up-regulation and then might associate with pancreas malignant transformation. We evaluated the relationship between annexin I and the clinicopathological factors of pancreatic cancer, and found that higher annexin I expression was correlated with the poorly differentiated type of pancreatic cancer, which was similar to the finding in HCC^[18]. These results suggest that annexin I is also involved in histological differentiation. It is interesting that the location of annexin I expression in different histologically differentiated types was changed, the reason for this change is not clear, which might be due to the role of annexin I in different places^[30].

On the other hand, enhanced expression of annexin I could reduce *in vitro* peripheral blood lymphocyte response to mitogens and might involve in the immunosuppressive mechanism of tumor-bearing hosts^[31]. Annexin I-derived peptides could inhibit antigen-driven human T cell proliferation and cytokine production^[32]. High constitutive levels of annexin I in leukaemic cells might protect them against immune-mediated killing^[33]. These evidences suggested that elevated annexin I might influence the immune defence system of body and might serve as a poor prognostic marker.

In conclusion, the present results show that overexpression of annexin I is a frequent event in pancreatic cancer, which may be one of the factors that link with the malignant transformation, lower differentiation and poor prognosis of pancreatic cancer. Detection of annexin I expression may be assistant to clinical diagnosis and can assess the prognosis of

pancreatic cancer. However, more efforts need to address the molecular mechanisms.

Abstract

AIM: To investigate the remodeling of mesenteric artery and the expression of TGF- β_1 , c-Jun in mesenteric artery and effects of imidapril and irbesartan on the remodeling in spontaneously hypertensive rats (SHR).

METHODS: Thirty SHR (male/female, 21/9), aged 13 wk, were randomly divided into 3 groups (7 male rats and 3 female rats each group): SHR group, imidapril group (imidapril 3 mg/kg·d was given in drinking water for 14 wk), and irbesartan group (irbesartan 50 mg/kg·d was given in drinking water for 14 wk). Ten homogenous Wistar Kyoto rats, 5 males and 5 females, weighing 206±49 g, were selected as normal control group (WKY group). Systolic pressure was measured on d 1, 2, 4, 6, 8, 10, 12 and 14 during the experiment and the rats were killed at the end of the experiment. Angiotensin II (Ang II) level in plasma and mesenteric arteries was measured by radioimmunoassay. The morphology of the secondary branches of mesenteric artery were examined by light microscopy and electron microscopy. Reverse transcription polymerase chain reaction (RT-PCR) was used to detect the expression of transforming growth factor TGF- β_1 and c-Jun mRNA.

RESULTS: Compared with imidapril group and irbesartan group, the blood pressure was remarkably increased in SHR group. Ang II level in plasma and mesenteric arteries in SHR group was the same or lower than that in WKY group, and was higher in irbesartan group and lower in imidapril group. The remodeling of mesenteric arteries in SHR group was mostly obvious among the 4 groups. The ratio of TGF- β_1 absorbed light value to GAPDH absorbed light value in the SHR group was 0.887±0.019, which was significantly higher than that in WKY group, imidapril group, and irbesartan group with the ratios of 0.780±0.018, 0.803±0.005, and 0.847±0.017, respectively ($P<0.01$). Ang II level in plasma and mesenteric arteries in imidapril group was significantly lower than that in irbesartan group ($P<0.05$). The c-Jun absorbed light value/GAPDH absorbed light value of mesenteric arteries in the SHR group was 0.850±0.015, which was significantly higher than that in the WKY, imidapril, and irbesartan groups (0.582±0.013,

0.743±0.012, and 0.789±0.013, respectively, $P<0.01$), and was significantly lower in imidapril group than in irbesartan group ($P<0.05$).

CONCLUSION: Imidapril and irbesartan can not only control blood pressure but also inhibit mesenteric arteries remodeling and mRNA expression of TGF- β_1 , c-Jun in SHR. Imidapril is more effective than irbesartan.

INTRODUCTION

It has been reported^[1-3] that angiotensin-converting enzyme inhibitor (ACEI) and angiotensin II type 1 (AT1) receptor antagonist can inhibit resistance blood vessel remodeling, but their action mechanism is still unknown. We selected irbesartan and imidapril to interfere mesenteric artery remodeling in spontaneously hypertensive rats (SHR) to investigate the expression of c-Jun and TGF- β_1 mRNA in resistance blood vessel of each group rats with reverse transcription polymerase chain reaction (RT-PCR) and to illustrate the mechanism of resistance blood vessel remodeling in hypertension and possible mechanism of these two drugs inhibiting mesenteric artery remodeling and possible effect on the inhibition of mesenteric artery remodeling.

MATERIALS AND METHODS

Materials

Thirty 13-wk old SHR (male/female, 21/9, provided by Fuwai Hospital in Beijing) with an average body mass of 228±39 g were randomly divided into 3 groups: SHR positive control group, imidapril treatment group (3 mg/kg·d), irbesartan treatment group (50 mg/kg·d). Ten homogenous Wistar-Kyoto rats [provided by Fuwai Hospital in Beijing, in which female rats were 5, male rats were 5, their average body mass was 206±49 g.] were selected as normal control group. During the 14-wk trial, all rats were in the breeding conditions: temperature 18-25 °C, humidity 40-60%, protein feed concentration 22-25%.

Methods

Irbesartan (presented by Hengrui Pharmacy Factory of Jiangsu Province) 50 mg/kg·d^[4] and imidapril (presented by Tianbian Pharmacy Factory of Tianjin) 3 mg/kg·d^[5] were dissolved in drinking water for 14 successive wk, respectively. Index observed included tail artery systolic blood pressure, angiotensin II (Ang II), histology of mesenteric artery. Fourteen weeks after irbesartan and imidapril interfering, all rats were killed and the second grade embranchment of mesenteric artery (about 2 mm) was taken and put into 25/L of glutaral for fixing, then transmission electron microscope (H-600, Hitachi in Japan) was used. About 1 mm of the artery was put into 100 g/L of neutral

formaldehyde and stained with HE, then observed by light microscope. Morphology of mesenteric artery was by a computer-assisted image analysis system. RT-PCR analysis was performed for TGF- β_1 ^[6] and c-Jun^[7] mRNA level in mesenteric artery.

SPSS 10.0 statistically analyzed the data and results were expressed as mean \pm SD.

RESULTS

Blood pressure from 4 groups was recorded in Table 1

Concentration of Ang II in plasma is shown in Table 2

Morphology of mesenteric artery (Figure 1)

Intima, vessel media, vessel wall were not increased in WKY group. Vessel lumen was relatively wider (A). Intima, vessel media and vessel wall were increased. Vessel lumen was relatively narrow in SHR (B), imidapril (C) and irbesartan (D) groups. The ratios of intima-media thickness / lumen radius, media / lumen area, lumen / vessel radius in 4 groups are shown in Table 3.

Microstructure of mesenteric arteries (transmission electron microscope, Figure 2)

As shown in A for WKY group, endothelial cells of intima were

abundant and normal, media had more smooth muscle cells. As shown in B for SHR group, endothelial cells of intima had vacuoles and fibrous tissues with adventitial hyperplasia, the thickness of adventitia was increased, media was severely fibrous and the fibrous tissue extended to smooth muscle layer and invaded internal elastic lamina, internal elastic lamina was tortuous and atrophic, some of smooth muscle cells were replaced by fibrous tissue. As shown in C for irbesartan group, endothelial cells of intima had vacuoles and marrow type corpses, internal elastic lamina was tortuous and atrophic and infiltrated by collagen fibers, but fibrosis in whole blood vessel wall relieved as compared with SHR group. The number of smooth muscle cells in media was slightly more than that in SHR group. As shown in D for imidapril group, endothelial cells of intima had marrow type corpses but no vacuole, the number of smooth muscle cells in media was more than that in irbesartan group, internal elastic lamina had a close-to-normal distribution, local internal elastic lamina was narrowed, fibrosis did not occur on blood vessel walls.

RT-PCR analysis of TGF- β_1 and c-Jun mRNA level in mesenteric artery (Figure 3)

mRNA expression levels of TGF- β_1 and c-Jun were analyzed by RT-PCR. Agarose gel electrophoresis of the PCR products was carried out to measure the relative intensity of the expression (A and B, Table 4).

Figure 1 Morphology of mesenteric artery, A: Intima, media of vessel wall are not increased in WKY group and vessel lumen is relatively wider (HE, $\times 100$). B: Intima, media of vessel wall are increased in SHR group and vessel lumen is relatively narrow (HE, $\times 400$). C: Intima, media of vessel wall are increased in imidapril group and lumen of vessel is relatively narrow (HE, $\times 400$). D: Intima, media of vessel wall are increased in irbesartan group and lumen of vessel is relatively narrow (HE, $\times 400$).

Figure 2 Microstructure of mesenteric arteries (transmission electron microscope). A: WKY group, endothelial cells of intima were abundant and normal, Media has more smooth muscle cells, internal elastic lamina is normal ($\times 2\,000$). B: SHR group, endothelial cells of intima had vacuole and fibrous tissue with adventitial hyperplasia; thickness of the adventitia was increased; media was severely fibrous and the fibrous tissue extended to smooth muscle layer and invaded internal elastic lamina; internal elastic lamina was tortuous and atrophic; some of smooth muscle cells were replaced by fibrous tissue ($\times 2\,500$). C: Irbesartan group, endothelial cells of intima have vacuole and marrow type corpses, internal elastic lamina was tortuous and atrophic and infiltrated by collagen fibers ($\times 2\,500$). D: Imidapril group, endothelial cells of intima have marrow type corpses but no vacuole, numbers of smooth muscle cells in media were more than those in irbesartan group; internal elastic lamina got a close-to-normal distribution; local internal elastic lamina got narrow, fibrosis did not occur on blood vessel wall ($\times 2\,000$).

DISCUSSION

It is known that elevated blood pressure in essential hypertension patients and spontaneously hypertensive rats (SHR) related to the renin-angiotensin system (RAS)^[8-10]. The main effector peptide of RAS was Ang II^[11], which played an essential role in the pathogenesis of hypertension through the regulation of cell growth, inflammation, and fibrosis^[12]. The main biological effects of Ang II has been found to be the enhancement of smooth muscle contraction, aldosterone release^[13], arginine vasopressin release, cell proliferation, adjustment of body fluid balance. It had a close relation to blood vessel remodeling^[14]. There were 2 main angiotensin II receptors, AT1 and AT2^[15,16]. The AT1 receptor was responsible for most of the pathophysiologic actions of angiotensin II^[17], including cell proliferation, production of growth factors and cytokines, and fibrosis. AT2 could cause antiproliferation and counteract the cell growth induced by AT1 activation^[18]. In addition, pressure-lowering agent also had actions on blood vessel remodeling^[19]. Both

ACEI and AT1 acceptor antagonists have been shown to act selectively on different cycles and they not only had satisfactory decompression effect, but also might inhibit blood vessel remodeling^[20,21].

These results suggest that imidapril and irbesartan have ideal decompression effects and inhibiting action upon angiotensin-converting enzymes and AT1 acceptors. Blood pressure gradually rose and arrived to 200 mmHg in 26 wk-old SHR, but blood pressure in imidapril and irbesartan groups fluctuated within normal ranges and no obvious difference was observed between the 2 groups. Ang II level in plasma gradually increased in SHR group and slowly decreased in imidapril group compared with that in WKY group performed with radioimmunoassay, but there was no statistical significance between them. Ang II level in plasma increased in irbesartan group and it had a significant difference when compared with that in WKY group. Ang II level decreased in mesenteric artery in SHR group and it was obvious in imidapril group. Ang II level increased in mesenteric artery in irbesartan group and it had a significant difference. Campbell *et al.*^[22] made clear with experiment that Ang II levels in SHR plasma, lung, kidney, heart, adrenal, aorta, brown adipose tissue were lower than the levels in Donryu rats. In this experiment, Ang II levels in plasma of SHR group and WKY group and mesenteric artery were consistent with Duncan's experiment. Moreover, imidapril decreased Ang II levels and irbesartan increased Ang II levels^[23] in SHR plasma and mesenteric artery in this experiment.

Light microscopy and electron microscopy displayed that imidapril and irbesartan might inhibit structure alterations especially interstitial fibrosis. Furthermore, the effect of imidapril was better than that of irbesartan. It should be pointed out that electron microscopy of mesenteric artery displayed that the pathology of mesenteric artery remodeling in SHR possibly involved in fibrous tissue hyperplasia in adventitia, fibrosis in media, structure and function damage in endothelial cells. Castro *et al.*^[24] believed that extracellular matrix (ECM) accumulation in blood vessel walls could be attributable to constriction of artery lumen in hypertension. The pathological changes of resistance vessels could relate to the synthesis and excretion reduction of proteoglycan in blood vessel smooth muscle cells.

Several experiments have shown that Ang II could induce vascular smooth muscle cell proliferation *in vivo*. Griffin suggested that Ang II infusion in rats increased mesenteric vascular media width, media cross-sectional area and media/lumen ratio, and these changes were not inhibited by hydralazine despite normalization of blood pressure. Kim *et al.*^[25] also revealed that aortic ERK and JNK activities were significantly increased with the development of hypertension, and in particular, these activities were gradually and chronically enhanced in the development of hypertension and associated with an increase in aortic weight. *In vitro* experiments have also shown that Ang II stimulated protein synthesis and induced cellular hypertrophy in cultured vascular smooth muscle cells via AT1 receptors. More and more evidences have shown that AT1 receptors couple to a heterotrimeric G protein Gq. The activation of AT1 receptors could not only lead to the activation of PLC- β and increases of diacylglycerol and Ca²⁺ in cells but also activate intracellular signal transduction in cultured vascular smooth muscle cells. Schmitz *et al.*^[26] reported that Ang II could also activate JNK of vascular smooth muscle cells. JNK is well known to increase c-Jun transactivation by phosphorylating c-Jun on 2 critical N-terminal serine residues and inducing *c-fos* gene expression. Therefore, it has been well known that JNK is involved in the activation of transcription factor, AP-1^[27]. AP-1 is bound to TPA response component (TRE) of nucleus DNA to accelerate transcription and to increase proliferation and protein synthesis of vascular smooth

muscle cells. In vascular smooth muscle cells, activation of ERK and AP-1 could increase expression of TGF- β_1 mRNA^[28]. Both vascular endothelial cells and vascular smooth muscle cells could synthesis TGF- β_1 ^[29]. TGF- β_1 has been found to be one kind of multi-function proteins^[30] and to adjust hypertrophy and polyploidy of many kinds of cells and to stimulate and inhibit hyperplasia. In a word, it relates to vessel remodeling. TGF- β_1 is bound to specific receptors in cell surface to initiate the intracellular p53-dependent signaling cascade, resulting in down regulation or inhibition of cyclin-dependent kinases 2 and 4, and inducing cell cycle arrest in G₁. Ang II can mediate intracellular signal transduction of vascular smooth muscle cells. Remodeling of mesenteric artery in SHR would be inhibited if the expression of c-Jun and/or TGF- β_1 could be inhibited. Therefore, this experiment used AT1 receptor antagonist irbesartan and ACE inhibitor imidapril to interfere mesenteric artery remodeling in SHR in order to investigate the expression difference of c-Jun and TGF- β_1 mRNA in mesenteric artery with RT-PCR and to illustrate the intervention action and effect difference of these two kinds of drugs on inhibiting mesenteric artery remodeling.

Compared with WKY group, the mRNA level of TGF- β_1 and c-Jun in mesenteric arteries of SHR group was obviously increased. Imidapril and irbesartan might inhibit the expression of c-Jun and TGF- β_1 mRNA in mesenteric artery of SHR. Imidapril was better than irbesartan in preventing mesenteric arteries from structure modulation especially fibrosis and expression of TGF- β_1 , -Jun mRNA. Ohta *et al* proved that aortic TGF- β_1 , fibronectin, and collagen type IV WmRNA levels were higher in SHR than in WKY, and all of these elevated mRNAs in the aorta of SHR were significantly reduced by an ACE inhibitor, alacepril (50 mg/kg·d), or an AT1 receptor antagonist, SC-52458 (50 mg/kg·d). Kim *et al.*^[31] also showed that treatment with AT1 receptor antagonist (E4177, 20 mg/kg·d) significantly inhibited the activation of JNK and ERK in injured arteries. These experiments illuminate that the results in our investigation are acceptable. Further study should be done for the combined action of imidapril and irbesartan.

Abstract

AIM: To investigate the effects induced by emodin on single smooth muscle cells from rat colon *in vitro*, and to determine the signal pathways involved.

METHODS: Cells were isolated from the muscle layers of Wistar rat colon by enzymatic digestion. Cell length was measured by computerized image micrometry. Intracellular Ca^{2+} ($[\text{Ca}^{2+}]_i$) signals were studied using the fluorescent Ca^{2+} indicator fluo-3 and confocal microscopy. PKC α distribution at rest state or after stimulation was measured with immunofluorescence confocal microscopy.

RESULTS: (1) Emodin dose-dependently caused colonic smooth muscle cells contraction; (2) emodin induced an increase in intracellular Ca^{2+} concentration; (3) the contractile responses induced by emodin were respectively inhibited by preincubation of the cells with ML-7 (an inhibitor of MLCK) and calphostin C (an inhibitor of PKC); (4) Incubation of cells with emodin caused translocation of PKC α from cytosolic area to the membrane.

CONCLUSION: Emodin has a direct contractile effect on colonic smooth muscle cell. This signal cascade induced by emodin is initiated by increased $[\text{Ca}^{2+}]_i$ and PKC α translocation, which in turn lead to the activation of MLCK and the suppression of MLCP. Both of them contribute to the emodin-induced contraction.

INTRODUCTION

Gastrointestinal dysmotility underlies frequent clinical entities such as diabetes mellitus, chronic constipation, irritable bowel syndrome, postoperative ileus *etc.* Currently few drugs have been proven to be efficient at improving motility. Emodin is a naturally occurring anthraquinone present in the roots and bark of numerous plants of the genus *Rhamnus*^[1]. Extracts from the roots, bark, and/or dried leaves of buckthorn, senna, cascara,

aloe, frangula, and rhubarb have been used as laxatives since ancient times and currently are widely used in the preparation of herbal laxative preparations in China^[2-5]. Anthraquinone glycosides are poorly absorbed from the gastrointestinal tract but are cleaved by gut bacteria to produce aglycones, including emodin which are more readily absorbed and thought to be responsible for the purgative properties of these preparations^[1]. The reported biological effects of emodin include antitumor, antibacterial and anti-inflammatory actions^[6-9]. Emodin also possesses prokinetic effect on gastrointestinal tract. Stimulatory actions of emodin on gastrointestinal smooth muscle have been described in several studies^[10-12]. However, its mechanism in accelerating gastrointestinal motion is not yet clarified.

It is now understood that the contraction of smooth muscle cells involves two processes^[13-16]: (a) The concentration of intracellular Ca^{2+} increases; this Ca^{2+} increase results in phosphorylation of myosin and consequently an increased contractility. (b) The sensitivity of the myofilaments to Ca^{2+} increases. Pharmacological agents can stimulate smooth muscle cell contractions by mobilizing intracellular Ca^{2+} and/or enhancing Ca^{2+} sensitivity.

Because of the potential therapeutic implications of emodin in gastrointestinal hypomotility disorders, this study was then designed to further characterize the effects of emodin on smooth muscle cells from rat colon *in vitro* and to investigate the signal transduction cascade leading to cell contraction induced by emodin.

MATERIALS AND METHODS

Materials

Fluo-3 AM and Pluronic F-127 were from Molecular Probes (USA). Rabbit anti-PKC α IgG and goat anti-rabbit IgG FITC were from Santa Cruz Biotechnology (USA). Collagenase type II, emodin, trypsin inhibitor and HEPES were all purchased from Sigma Co (USA). DMEM was purchased from GIBCO Co., USA. FBS was from Hyclone (USA). All other reagents were from LianXing Co., Ltd (China). Emodin was dissolved in dimethyl sulfoxide and ethanol mixture (2:8) to make stock solution and the final concentration of the vehicle in the solution did not exceed 0.1%.

Methods

Isolation of smooth muscle cells Smooth muscle cells from rat distal colon were isolated as described previously^[13]. Briefly, a segment of 5-cm long distal colon was dissected and digested to yield isolated smooth muscle cells. The tissue was incubated for 2 successive 30-min periods at 31 °C in 10 mL of HEPES (pH7.4) containing 1 g/L collagenase type II and 0.1 g/L soybean trypsin inhibitor. After the second enzymatic incubation, the medium was filtered through 500 μm Nitex mesh. The partially digested tissue left on the filter was washed with collagenase-free buffer solution, and muscle cells were allowed to disperse spontaneously for 30 min. The cells were harvested by centrifugation at 350 r/min for 10 min. After a hemocytometric cell count, the harvested cells were resuspended in collagenase-free buffer solution and diluted as needed.

Measurement of smooth muscle cell contraction Individual cell length was measured by scanning micrometry as described previously^[13]. Aliquots consisting of 1×10^4 cells in 0.25 mL of medium were added to 50 μ L of a solution containing emodin with or without prior incubation with ML-7 (10^{-5} mol/L) or Calphostin C (10^{-6} mol/L). The reaction was allowed to proceed for 1 min and terminated by the addition of acrolein at a final concentration of 10 mL/L. The lengths of 30 consecutive intact healthy cells were measured through a phase-contrast microscope fitted with a video camera and connected to a Legend computer. The CIMAS program was used to measure the length. The contractile response was defined as the decrease in the average length of the 30 cells and was expressed as the percent change relative to control length.

Single cell intracellular Ca^{2+} measurements Changes in $[\text{Ca}^{2+}]_i$ were estimated as described elsewhere by using laser scanning confocal microscopy (Radiance 2000; Bio-rad, Hertfordshire, UK)^[17] linked to an inverted epifluorescence microscope (Olympus, Japan). The scanning box was set at a resolution of 256×256 . Only one fixed combination of laser intensity (20% maximum) and photomultiplier gain (1 800 of a maximum of 4 096) was used during scanning.

To load the cells with fluorescent Ca^{2+} indicator fluo-3, smooth muscle cells on the coverslips were incubated with 5 μ mol/L of the membrane permeant acetoxymethyl ester of the dye (fluo-3 AM; Molecular Probes, USA) and Pluronic F-127 (0.4 g/L; Molecular Probes, USA) dissolved in HEPES-ringer buffer [containing (mmol/L): NaCl 135, KCl 5.9, CaCl_2 1.5, MgCl_2 1.2, HEPES 11.6 and glucose 11.5, at pH 7.3] for 30 min at 37 °C. Cells were subsequently washed twice with HEPES-ringer buffer and further incubated for 20 min to allow de-esterification of the dye.

Coverglass chambers were then mounted on the microscope stage and continuously superfused with HEPES-ringer buffer. The cells loaded with fluo-3 were illuminated at 488 nm, and fluorescent emissions of 525/30 nm were recorded at an intensity of fluo-3. Digital Ca^{2+} images were collected at 10 s intervals. Because fluo-3 is a single wavelength indicator, it is not possible to apply the ratiometric method to quantitative determination of $[\text{Ca}^{2+}]_i$. Therefore, the intensity of fluo-3 fluorescence was normalized in the temporal analysis. The relative values of fluorescence intensity of the dye (Ft) were used to represent the $[\text{Ca}^{2+}]_i$.

Cell culture and confocal imaging of PKC α cell culture After enzymatic incubation, the dispersed cells were collected in DMEM with 100 mL/L FBS-medium, then transferred to coverslips coated with poly-L-lysine, and allowed to settle overnight in a humidified 50 mL/L CO_2 environment.

Cell fixation and permeabilization Cells were either untreated or treated with emodin (50 μ mol/L), and the reaction was stopped by removing the medium and adding 40 g/L formaldehyde to PBS. Cells were fixed in PBS for 10 min. Then the fixative was removed, and the cells were washed with PBS. Thereafter the cells were permeabilized by adding the permeabilization solution [(0.1 mL TritonX-100, 90 mL distilled water, and 10 mL PBS (10 \times)] for 10 min. After permeabilization, the cells were rinsed 3 times with PBS.

Labeling with PKC α antibody and confocal microscopy Cells were incubated for 1 h with normal goat serum, followed by 3 washes in PBS with gentle agitation. Subsequently, the cells were incubated for 1 h with the primary antibody, a rabbit anti-PKC α IgG followed by 3 washes with PBS with gentle agitation. This step was followed by incubation of the cells for 1 h with secondary antibody (goat anti-rabbit IgG FITC). Then the cells were washed 3 times with PBS with gentle agitation. Finally, the cells on the coverslip were mounted onto a slide. Control slides were made by incubating cells with the secondary antibody only. The excitation parameter for fluorescent probes

was as follows: FITC excitation at 488 nm and emission at 520 nm. Immunostained cells were visualized with an Olympus $\times 40$ objective by confocal laser scanning microscopy (Bio-Rad radiance 2000). Image restoration and analysis were performed in Lasersnap2000 and Laserpix.

Statistical analysis

The data are presented as mean \pm SD, and n represents the number of experiments. Statistical analysis was made by Student's unpaired *t* test when applicable. *P* values less than 0.05 were considered to be significant.

RESULTS

Effect of emodin on colonic smooth muscle cell length

Freshly isolated colonic smooth muscle cells appeared in spindle shape with diverse length (range from 44–121 μ m). Some of them were relaxed while others were at different phases of contraction (Figure 1). In resting state, the average cell length was 84.26 μ m. The application of emodin to freshly isolated smooth muscle cells induced a reduction in cell length. This reduction in cell length reflected contraction of the smooth muscle cells. Emodin at concentrations of 5 to 100 μ mol/L induced a concentration-dependent contraction (Figure 2). Maximal contraction of $19.17 \pm 2.59\%$ was observed with 50 μ mol/L of emodin.

Figure 1 Freshly isolated colonic smooth muscle cells appeared in spindle shape with diverse length. Some of them were relaxed while others were at different phases of contraction.

Figure 2 Dose-response curve representing the effects of emodin on the length of isolated colonic smooth muscle cell. Values are mean \pm SD of 3 experiments.

Effect of emodin on $[\text{Ca}^{2+}]_i$

Basal $[\text{Ca}^{2+}]_i$ levels were not significantly different between cells and the relative fluorescence intensity ranged from 38.46 to 52.59 (46.56 ± 3.79). At each concentration of emodin, the $[\text{Ca}^{2+}]_i$ response of 20 cells was determined. The application of emodin at concentrations from 5 to 100 μ mol/L could trigger

an increase in $[Ca^{2+}]_i$. The $[Ca^{2+}]_i$ responses to varying emodin concentrations are shown in Figure 3.

Figure 3 $[Ca^{2+}]_i$ response of colonic smooth muscle cells to emodin.

Effect of ML-7 and Calphostin C on emodin-induced contraction of colonic smooth muscle cells

Freshly isolated smooth muscle cells were treated with emodin (50 μmol/L) for 1 min with or without prior incubation with ML-7 (an inhibitor of MLCK, 10^{-5} mol/L) or Calphostin C (an inhibitor of PKC, 10^{-6} mol/L). The application of 50 μmol/L emodin to freshly isolated colonic smooth muscle cells induced a reduction in cell length ($19.17 \pm 2.59\%$). And $42.93 \pm 6.16\%$ of the contractile response induced by emodin was inhibited by preincubation of the cells with ML-7 ($P < 0.05$). Similarly, $51.12 \pm 3.87\%$ of the contractile response induced by emodin was inhibited by Calphostin C ($P < 0.05$). (Figure 4).

Figure 4 Effect of ML-7 and calphostin C on emodin-induced contraction of colonic smooth muscle cells. Emodin-induced cell shortening was $19.17 \pm 2.59\%$. Preincubation of the cells with ML-7 and calphostin C resulted in a decrease in cell contraction. ^a $P < 0.05$ vs Emodin group.

Figure 5 Membrane translocation of PKCα in response to emodin stimulation in smooth muscle cells of rat colon. Confocal microscopy showed PKCα distributed throughout the cell at rest state (left). When cells were stimulated with emodin (50 μmol/L), PKCα translocated to the membrane (right).

Emodin-induced translocation of PKCα in colonic smooth muscle cell

PKCα is thought to be inactive in the cytoplasm and therefore must translocate to the plasma membrane to be activated. Recent studies have demonstrated that PKCα can translocate from the cytoplasm to membrane on stimulation by contractile agonists during smooth muscle cell contraction^[18-21]. To determine whether activation of PKCα is involved in contraction of smooth muscle cells induced by emodin, we performed immunofluorescent labeling of PKCα in isolated smooth muscle cells, followed by confocal microscopy. Our data indicate that, at resting state, PKCα is mainly distributed throughout the cytoplasm. This is in contrast to the distribution of PKCα following emodin stimulation, as shown in Figure 5, PKCα translocated from the cytosolic part and aligned itself along the membranes of contracted cells.

DISCUSSION

Previous studies have indicated that emodin possesses prokinetic effect on gastrointestinal tract^[10-12]. Using confocal microscopy and cell isolation technique, the present study focused on emodin's cellular effect on smooth muscle cells from rat colon *in vitro* and investigated the signal mechanisms underlying its effect.

Our study showed that some of the action of emodin on gastrointestinal tract is exerted on the smooth muscle cells, as application of emodin to colonic smooth muscle cells resulted in a decrease in cell length. To our knowledge, this is the first study to show a direct contractile effect of emodin on gastrointestinal smooth muscle cells.

It is well established that Ca^{2+} /calmodulin-mediated phosphorylation of the light chain of smooth muscle myosin is a major regulatory mechanism for smooth muscle contraction^[22-26]. Stimulation of smooth muscle cells by specific agonists induces Ca^{2+} mobilization and activation of myosin light chain (MLC) kinase, which subsequently phosphorylates MLC and activates the myosin ATPase. The cascade of events described above leads to contraction of smooth muscle. Yang *et al.* have demonstrated that emodin could evoke increases in $[Ca^{2+}]_i$ in guinea-pigs taenia coli cells^[12]. In the present study, we observed the changes in $[Ca^{2+}]_i$ induced by emodin in single smooth muscle cell by using confocal microscopy and fluo-3 loading technique. Our data showed that, when applied to isolated smooth muscle cells, emodin induced a significant increase in $[Ca^{2+}]_i$. The effect of emodin on $[Ca^{2+}]_i$ indicated that emodin-mediated contractions were Ca^{2+} -dependent and MLCK pathways might be involved in emodin-induced contractions. We then carried out contraction studies in which we tested the effect of ML-7, a MLCK inhibitor, on emodin-induced contraction. As shown in Figure 4, the emodin-mediated contraction was significantly attenuated by ML-7. Taken together, these observations suggested that incubation of smooth muscle cells with emodin seemed to trigger a cascade of events including increase in $[Ca^{2+}]_i$, activation of MLCK and then cell contraction.

However, only $(42.93 \pm 6.16)\%$ of the contractile effect elicited by emodin was inhibited by ML-7. Therefore, it is possible that the rest of the emodin-induced contraction is mediated through an alternative pathway different from myosin light chain phosphorylation. Indeed, the rising of $[Ca^{2+}]_i$ has been found to be insufficient to explain excitation-contraction of smooth muscle cell, because the cytosolic concentration of Ca^{2+} is not always proportional to the extent of MLC phosphorylation and the force of contraction in smooth muscle cells. Other regulatory mechanisms have been proposed^[22,2-30]. Evidence accumulated that PKCα activation may contribute to the contraction of smooth muscle cells through a kinase cascade involving suppressing the activity of myosin light

chain phosphatase (MLCP) and increasing the sensitivity of contractile apparatus to Ca^{2+} . Therefore, we attempted to study the role of PKC α in emodin-induced contraction. The results of our contractile experiments showed that calphostin C, a PKC inhibitor, significantly suppressed the contraction induced by emodin, which suggested that PKC α might play a role in emodin-induced cell contraction. Lee has demonstrated that PKC α plays a critical role in emodin-induced apoptosis in CH27 and H460 cells^[7]. In order to verify the role of PKC α in emodin-induced contraction, we next examined the effect of emodin on the activity of PKC α . Previous studies have demonstrated that PKC α is activated by agonist and translocated from the cytoplasm to the plasma membrane through a complex mechanism during smooth muscle cell contraction. Although the exact nature of the translocation is still unclear, it has been suggested that the recruitment of cytosolic PKC α to the membrane is a pivotal component of signal mechanism which mediates the contraction of smooth muscle cell^[31-33]. In our study, it was shown that PKC α distribution at rest appeared homogeneous throughout the cell, which is in agreement with previous studies. After stimulation of colonic smooth muscle cells with emodin, PKC α underwent a distinct translocation to the membrane. These data above strongly suggest that emodin may exert its contractile effects on smooth muscle cells via PKC α activation.

On the basis of our findings, we propose the existence of an intracellular signaling cascade leading to cell contraction in colonic smooth muscle induced by emodin. This cascade is initiated by increased $[\text{Ca}^{2+}]_i$ and PKC α translocation, which in turn lead to the activation of MLCK and the suppression of MLCP, both of which contribute to the emodin-induced contraction. And these results provide evidence for an excitatory role of emodin in colonic smooth muscle cells contraction and indicate that emodin may be a promising prokinetic agent in ameliorating colonic hypomotility.

Abstract

AIM: To detect the markers of oval cells in adult rat liver and to enrich them for further analysis of characterization *in vitro*.

METHODS: Rat model for hepatic oval cell proliferation was established with 2-acetylaminofluorene and two third partial hepatectomy (2-AAF/PH). Paraffin embedded rat liver sections from model (11 d after hepatectomy) and control groups were stained with HE and OV6, cytokeratin19 (CK19), albumin, alpha fetoprotein (AFP), connexin43, and c-kit antibodies by immunohistochemistry. Oval cell proliferation was measured with BrdU incorporation test. C-kit positive oval cells were enriched by using magnetic activated cell sorting (MACS). The sorted oval cells were cultured in a low density to observe colony formation and to examine their characterization *in vitro* by immunocytochemistry and RT-PCR.

RESULTS: A 2-AAF/PH model was successfully established to activate the oval cell compartment in rat liver. BrdU incorporation test of oval cell was positive. The hepatic oval cells coexpressed oval cell specific marker OV6, hepatocyte-marker albumin and cholangiocyte-marker CK19. They also expressed AFP and connexin 43. C-kit, one hematopoietic stem cell receptor, was expressed in hepatic oval cells at high levels. By using c-kit antibody in conjunction with MACS, we developed a rapid oval cell isolation protocol. The sorted cells formed colony when cultured *in vitro*. Cells in the colony expressed albumin or CK19 or coexpressed both and BrdU incorporation test was positive. RT-PCR on colony showed expression of albumin and CK19 gene.

CONCLUSION: Hepatic oval cells in the 2-AAF/PH model had the properties of hepatic stem/progenitor cells. Using MACS, we established a method to isolate oval cells. The sorted hepatic oval cells can form colony *in vitro* which expresses different combinations of phenotypic markers and genes from both hepatocytes and cholangiocyte lineage.

INTRODUCTION

It has ever been disputed whether there are stem/progenitor

cells in liver, because the liver is a quiescent organ and the adult liver can regenerate by hepatocytes reentering into cell cycle after surgical resection or injury^[1-3]. But it is now generally accepted that the liver contains hepatic stem cells/progenitor cells. When the ability of hepatocytes to divide and replace damaged tissues is compromised under the condition of severe and chronic liver injury caused by drugs, viruses and toxins, a subpopulation of liver cells termed oval cells, is induced to proliferate. Extensive studies in rodent models of hepatocarcinogenesis and other non-carcinogenic injury models suggest that oval cells may represent a facultative hepatic progenitor/stem cell compartment. These cells not only can be activated to proliferate but also differentiate both into mature hepatocytes and biliary epithelial cells under certain conditions^[4-7]. So these hepatic stem/progenitor cells (HSCs/HPCs) are ideal sources for cell therapy such as cell transplantation or tissue engineered bioartificial organs and identification of HSCs/HPCs has become increasingly important.

Hematopoiesis and hepatic development share common stages. During fetal development, hematopoietic stem cells move out of the yolk sac and into the developing liver. Simultaneous with the appearance of hematopoiesis, hematopoietic stem cells can be detected in the fetal liver (data not shown). It is increasingly apparent that HSCs/HPCs share common characteristics with stem cells of the hematopoietic system^[8,9]. C-kit is a hematopoietic stem cell receptor, and it is also expressed in hepatic oval cells^[10,11]. 2-Acetylaminofluorene and partial hepatectomy (2-AAF/PH) are a traditional model to activate oval cells in rat liver^[12]. We were also successful in establishment of an oval cell proliferation model treated with 2-AAF/PH. The current studies were performed to detect the markers expressed in rat oval cells and used c-kit antibody as well as magnetic activated cell sorting (MACS) to highly enrich the population of hepatic oval cells for further analysis of colony formation and characterization *in vitro*.

MATERIALS AND METHODS

Oval cell compartment proliferation/activation

Male SD rats (about 150 g) were supplied by Laboratory Animal Center of Chinese Academy of Sciences. They were fed 5, 10, 15 and 20 mg/kg body mass 2-AAF (dissolved in polyethylene glycol, Sigma) daily by oral gavage for 6 d and up to 7 d after operation and the control rats were fed saline. On the 7th d, rats were partially hepatectomized under general ether anesthesia and were not fed 2-AAF on the same day. The time points of this study were counted when partial hepatectomy was performed. One hour before the animals were killed, they received an intraperitoneal injection of BrdU (100 mg/kg body weight) (Sigma) to detect proliferation of oval cells (BrdU incorporation test). Liver tissue obtained was processed in the same manner described in immunohistochemistry methods.

Immunohistochemistry

Liver tissue was divided and fixed in 40 g/L buffered formaldehyde. All staining procedures for light microscopy

Table 1 First and second antibodies for immunohistochemistry

First antibody	Dilution	Second antibody	Dilution	Chromogen
OV6 (mouse IgG) ¹	1:100	Goat anti-mouse IgG (HRP or FITC)	1:150 1:200	DAB(brown) green fluorescence
CK19(mouse IgG) ²	1:150	Goat anti-mouse IgG (HRP)	1:150	DAB (brown)
Albumin (rabbit IgG)	1:400	Goat anti-rabbit IgG (AP)	1:50	Fuchsin (red) or NBT/BCIP(blue)
AFP (mouse IgG)	1:400	Goat anti-mouse IgG (HRP)	1:200	DAB(brown)
Connexin 43(mouse IgM) ²	1:400	Goat anti-mouse IgM (HRP)	1:200	DAB (brown)
C-kit (rabbit IgG) ³	1:50	Goat anti-rabbit IgG (AP)	1:50	Fuchsin(red) or NBT/BCIP(blue)
BrdU (mouse IgG)	1:50	Goat anti-mouse IgG (HRP)	1:150	DAB(brown)

Note:1=a gift from professor Sell S, 2=from Sigma, 3=from Santa Cruz, others were from DAKO Company.

were performed on paraffin-embedded 4 μ m sections. The sections were deparaffinized in xylene and rehydrated through graded alcohol. Routine histological examinations were made for liver sections stained with hematoxylin-eosin. Antigen retrieval was made by microwave - citrate buffer method, and then they were digested with trypsin (1 g/L trypsin, 1 g/L calcium chloride) at 37 °C for 30 min. For BrdU staining, the sections were immersed in 4N HCl for 15 min for DNA degeneration and neutralized with TBS. Single cells from suspensions were collected on glass slides by cytocentrifugation and air dried. All cells were fixed in methanol at 4 °C for 20 min. Endogenous peroxidase was inactivated by DAKO peroxidase blocking reagent for 10 min. The sections were incubated with 100 mL/L normal goat serum in TBS at room temperature for 20 min to block non-specific binding. For immunostaining, the primary antibody and second antibody are shown in Table 1. Double immunostaining for studies of antigen colocalization was performed with selected antibodies (OV6 vs albumin, CK19 vs albumin) using different chromogens (DAB and Fuchsin or NTB/BCIP). All antibodies were diluted with DAKO antibody diluent. Specimens were incubated with first antibody at 4 °C overnight, and then incubated with second antibody at room temperature for 1 h. For each antibody negative controls were performed by either blocking with appropriate nonimmune serum or by omitting the primary antibody from the protocol.

Cell sorting and culture

Rat liver cells were isolated by a two-step collagenase IV digestion method according to the protocol established by Seglen^[13]. The nonparenchymal cell fraction was determined to contain the hepatic oval cell population as described by Yaswen *et al*^[14]. Hepatocytes were separated from the nonparenchymal cell portion by low-speed centrifugation (50 r/min \times 1 min). About one third of the total liver cells were nonparenchymal cells.

Immunohistochemistry was performed on the parenchymal and nonparenchymal fractions to ensure that the cells of interest were in the nonparenchymal cell fraction. The portion of nonparenchymal cells was further purified using magnetic activated cell sorting (MACS). Cells were incubated with CD45 antibody (1:50) and rat erythroid cell antibody (1:200) (BD Pharmingen) at 4 °C for 10 min and incubated with magnetic goat anti-mouse IgG (1:5) at 4 °C for 15 min. MACS was performed according to the manufacturer's recommendations (Miltenyi Biotec). The depleted fraction was incubated with c-kit antibody (1:50) and then incubated with magnetic goat anti-rabbit IgG (1:50). The c-kit+ fraction was collected for immunohistochemistry and culture *in vitro*.

The sorted c-kit+ cells were resuspended in DMEM/F-12

medium supplemented with 100 g/L fetal bovine serum, insulin-transferrin-sodium selenite, dexamethasone (1×10^{-7} mol/L), nicotinamide (10 mmol/L), L-glutamine (2 mmol/L), β -mercaptoethanol (0.1 mmol/L), HEPES (10 mmol/L) and penicillin/streptomycin. They were placed in 96-well plates, the same volume of supernatant from cultured ED13 fetal liver cells was added and incubated at 37 °C with 50 mL/L CO₂. Human recombinant hepatocyte growth factor (HGF, 50 ng/mL), epidermal growth factor (EGF, 20 ng/mL) and α -transforming growth factor (TGF- α , 20 ng/mL) were added 24-48 h after initiation of culture.

Phenotypic characterization of cultured cells

After 7 days, BrdU with a final concentration of 10 μ M/L was added to the medium and incubated for 3 h. The cells were fixed with methanol at 4 °C for 20 min, and washed with PBS containing 0.5 g/L polyoxyethylene sorbitan monolaurate (Tween 20). Cytochemical staining was performed with BrdU, c-kit, albumin, and CK19 antibodies. The staining method was the same as immunohistochemistry.

Reverse-transcription polymerase chain reaction analysis

Characteristics of cultured cells were evaluated by reverse-transcription polymerase chain reaction (RT-PCR). mRNA was extracted from the cell colonies using a QuickPrep micro mRNA purification kit (Qiagen) according to the supplier's recommended protocol. cDNA was synthesized using oligo-d (T)15 and Omniscript RT kit. A 20 μ L of reaction mixture containing 1 \times Buffer RT, 0.5 mmol/L dNTP, 10 unit RNasin, 4 unit Omniscript reverse transcriptase and 1-2 μ g RNA template was incubated at 37 °C for 1 h. PCR was done using HotStarTaq DNA polymerase in 25 μ L of the reaction mixture (1 \times PCR buffer, 0.5 unit HotStar Taq DNA polymerase, 200 μ mol/L dNTP) with hepatocyte-specific primers for albumin (5' -GAG AAG TGC TGT GCT GAA GG-3' and 5' -TCA GAG TGG AAG GTG AAG GT-3'), α -fetoprotein (5' -AAC ACA TCC AGG AGA GCC AG-3' and 5' -TTC TCC AAG AGG CCA GAG AA-3'), cholangiocyte-specific primers for CK19 (5' -CTG TCT TGG TCC GGT CAC TG-3' and 5' -GGC ATC TTG GTC TGT GTC AT-3'). PCR cycles were as follows: initial denaturation at 95 °C for 15 min, followed by 35 cycles at 94 °C for 45 s, at 55 °C for 1 min, at 72 °C for 45 s, and final extension at 72 °C for 10 min. PCR products were separated in 20 g/L agarose gel.

RESULTS

Activation of oval cell proliferation

Oval cells could be seen in 2-AAF treated rat liver at the dosage from 10 mg/kg to 20 mg/kg weight mass 7 to 13 d after partial

hepatectomy. The peak of oval cell proliferation occurred 11 d after hepatectomy. The histologic changes in liver sections from rats exposed to 2-AAF at the dosage of 10 mg/kg body mass for 6 d, followed by partial hepatectomy and sacrifice 11 d posthepatic injury are shown in Figure 1. The proliferated oval cells were small in size (approximately 10 μ m) with a large nuclei to cytoplasm ratio, radiating from the periportal region forming primitive ductular structures with poorly defined lumen. The control rat liver showed complete lobular structure without oval cell proliferation (Figures 1C and D). DNA synthesis in the oval cells was examined by BrdU incorporation test, and many of the oval cells were in S-phase with their nuclei stained positive by nuclear immunohistochemical staining for BrdU. DNA synthesis in epithelial cells of the portal bile ductules was also examined by BrdU incorporation (Figure 2).

Figure 1 Rat liver sections obtained from 2-AAF/PH (11 d after operation) and control. Sections were stained with hematoxylin-eosin. (A and B) show liver sections obtained from

2-AAF/PH-treated rats at low ($\times 100$) and high ($\times 400$) magnification. Small oval cells (arrows) can be seen close proximity to proliferating bile ducts and in areas of ductular proliferation or in acinar arrangements around hepatocytes. The oval cells radiate from the periportal region, forming primitive ductular structures with poorly defined lumen. (C and D) show liver tissue from control rats at low and high magnification. Hepatocyte proliferation can be seen in the typical liver architecture. Central vein (CV) and portal triad region can be seen.

Figure 2 Immunohistochemistry of liver sections obtained from 11 2-AAF/PH rats. BrdU staining of oval cells in proliferative state. Arrows indicate oval cells.

Immunohistochemistry for marker on activated hepatic oval cells

The sections were stained with antibodies for oval specific marker, biliary lineage marker and hepatocyte lineage markers (OV6, CK19, albumin and AFP). The oval cells generated from 2-AAF/PH treated rat liver were positive for OV6 (Figure 3A), CK19 (Figure 3C), albumin (Figures 3B and D) and AFP (Figure 3E). Double immunohistochemistry showed that oval cells coexpressed OV6 and albumin or CK19 and albumin (Figures 3B and D). The oval cells were stained positive for connexin 43, but the sections from control rats were negative for connexin 43 (Figure 3F). In Figure 3G, oval cells expressed c-kit antigen, the ductular cells appeared to be positive with little to no staining for c-kit. No liver sections from control rat were stained positive for c-kit (Figure 3H).

Figure 3 Immunohistochemical staining of liver sections from rat liver exposed to 2-AAF/PH (d 11) at high magnification. A: Staining for OV6, Arrows point to OV6-positive oval cells. B: Double immunohistochemical staining for OV6 (brown) and albumin (red). C: Staining for cytokeratin19(CK19). Ductular lumen face and oval cells were positive. Arrows point to CK19-positive cells. D: Double immunohistochemical staining for CK19 (brown) and albumin (red). Arrows point to oval cells with two markers. E: Staining for AFP. F: Staining for connexin43, Arrows point to connexin43 positive oval cells. G: Staining for C-kit, Oval cells were stained with red. H: Negative control.

Purification and proliferation of *c-kit*⁺ oval cells

In order to define the phenotype, growth, and differentiation potential of individual *c-kit*⁺ cells, we used an immunoselection and cell culture strategy. After parenchymal cells were separated from nonparenchymal cells, antibody against *c-kit* was used to purify *c-kit*⁺ cells from nonparenchymal fraction by MACS. Immunohistochemical staining for OV6 showed that more than 90% sorted cells were positive (Figure 4).

After incubated for 24 h, most sorted *c-kit*⁺ cells adhered to collagen IV coated plate. By day 3 single cells proliferated to form colonies which expanded up to several hundred cells at 2 wk (Figures 5A, B). Figure 6 shows BrdU incorporation of a cultured *c-kit*⁺ oval cell colony, most cells were positive with their nuclei stained brown.

Characterization of *c-kit*⁺ oval cells

To determine the characterization of the colonies, we studied constituent cells by immunohistochemistry using albumin and CK19 as lineage markers as well as *c-kit*. After 1 wk, some progeny of *c-kit*⁺ oval cells in the colony lost the *c-kit* marker of parental generation (Figure 6). Most colonies at 2 wk contained 3 types of cells, namely albumin positive cells, CK19 positive cells, both albumin and CK19 positive cells (Figure 7). RT-PCR was performed to identify the expression

of genes encoding markers in both hepatocyte and cholangiocyte lineages (hepatocytes: albumin, α -fetoprotein; cholangiocytes: CK19). Almost all colonies contained mRNA of both hepatocyte-specific and cholangiocyte-specific genes at 2 wk (Figure 8). These results of RT-PCR and immunocytochemistry showed the bipotent differentiation ability of the sorted *c-kit*⁺ oval cells.

Figure 4 Immunocytochemistry for OV6 on cytocentrifuged preparations of *C-kit*⁺ MACS sorted cells from 2-AAF/PH treated rats. The sorted *C-kit*⁺ cells were stained with oval cell-specific antibody OV6 (green).

DISCUSSION

Since liver transplantation is the only available current therapy for end-stage liver failure and there is an ever-increasing shortage of donor livers, cell therapy from alternative cell source might offer a new therapeutic approach against liver disease^[15]. In recent years, such studies have been conducted successfully using primary hepatocytes in rodent models, and current research is being conducted to isolate progenitor or stem cells that should have the highest potential for effective liver repopulation. Therefore, identification of hepatic/progenitor cells has become increasingly important. Stem cells are defined as the cells with the self-renewing activity and capability of generating multiple types of lineage committed cells. As for the hepatocytic lineage, stem cells had to possess the ability to generate both parenchymal hepatocytes and bile duct epithelial cells^[16]. After debated for many years, it has been generally accepted that the liver contains cells with stem-like properties and that these cells can be activated to proliferate and differentiate into mature hepatocytes and cholangiocytes under certain pathophysiologic circumstances^[17,18]. These cells might be related to the so-called “oval cells”, originally identified by Farber as immature epithelial cells with oval shaped nuclei and scant cytoplasm^[19].

Activation of the oval cell proliferation could be induced by many rodent models^[20-22], we chose modified Solt-Farber model to activate oval cells^[12]. The model could be successfully established by 2-AAF at the dosage from 10 mg to 20 mg and the peak of oval cell proliferation was on d11 after partial hepatectomy. Immunohistochemical staining showed that the oval cells expressed oval cell-specific marker OV6, cholangiocyte lineage marker CK19 and hepatocyte lineage marker albumin and AFP. OV6 and albumin or CK19. Albumin was coexpressed in the same oval cells by double immunohistochemistry. These data suggest that the oval cells may represent a facultative hepatic progenitor/stem cell compartment. The oval cells also expressed connexin 43, but the liver cells in the control rat liver expressed connexin 32 instead of connexin 43 (data not shown). Gap junctional intercellular communication (GJIC) was considered to play a key role in the maintenance of tissue independence and homeostasis in multicellular organisms by controlling the growth of GJIC-connected cells. Gap junction channels are composed of connexin molecules, connexin 43 is expressed on immature liver cells or cholangiocytes, connexin 26 and connexin 32 are expressed on hepatocytes. As hepatocytes differentiate, the proportions of connexin 43 then 26 mRNAs decrease while that of connexin 32 mRNA increases. Connexin 43 was also expressed in fetal liver cells and the expression of connexin 43 declined after birth^[23]. Neveu reported that proliferating oval cells expressed diffuse connexin 43 immunoreactivity. Differentiation of oval cells into basophilic hepatocytes resulted in their alterations in Cx32 and

Cx26 expression^[24]. Since the oval cells were generated by the proliferation of terminal bile ducts, they formed structures representing an extension of the canals of Hering^[25], and there are many common features between immature embryonic hepatic cells and oval cells such as expression of AFP and connexin 43. It is reasonable to assume that oval cells may be a direct progeny of resident undifferentiated liver stem cells. Suzuki *et al.* have identified a population of hepatic stem cells that exist in developing mouse liver, and these cells may represent the resident hepatic stem cells which possess multilineage differentiation potential and self-renewing capability^[26,27]. Chen also^[28] reported that transfused oval cells through caudal vein can migrate into the parenchyma of the liver and are settled there.

Hepatic progenitor cells share common characteristics with stem cells of the hematopoietic system. Classical hematopoietic markers, including Thy-1, CD34, c-kit were expressed on the surface of oval cells^[8-11]. After bone marrow transplantation, a proportion of the regenerated hepatic cells was shown to be donor-derived^[29]. Intravenous injection of adult bone marrow cells (c-kit^{high}Thy^{low}Lin^{low}Sca-1⁺) in the FAH^{-/-} mouse, an animal model of tyrosinemia type I, rescued the mouse and restored the biochemical function of its liver^[30]. Crosby *et al.*^[11] reported that there were c-kit⁺ cells in the periportal tract surrounding bile ducts, which coexpressed CK19. After cultured in biliary cell growth media, the isolated c-kit positive cells could form colony with the properties of cholangiocytes^[11]. We also found that oval cells in the periportal area in 2-AAF/PH expressed c-kit, but hepatocytes and liver in control animal were stained negative. The evidence of a cell lineage relationship between the hematopoietic system and the liver supports the extrahepatic origin of hepatic progenitors.

Suzuki *et al.* recently reported that CD49f^{low}c-Kit⁺ CD45^{TER119} cell subpopulation in ED13.5 mouse fetal liver could form large colonies designated as 'hepatic colony-forming-unit in culture' (H-CFU-C), and expression of *c-kit*, *CD34* and *thy-1* became detectable in some of these colonies on d 21^[26]. These data may suggest that not only exogenous hepatic stem/progenitor cells derived from circulating bone marrow express hematopoietic stem cell markers, but endogenous tissue-determined stem/progenitor cells express such markers.

C-kit stem cell receptor tyrosine kinase (KIT) and its ligand, stem cell factor (SCF) system play a crucial role in the development of oval cells. If the c-kit kinase activity was severely impaired, the number of oval cells on d 7, 9, and 13 after PH was significantly reduced to 15%, 18%, and 27% of those in control normal rats in the AAF/PH model, respectively^[10]. So we chose c-kit as a surface marker to purify oval cells. After depletion of CD45⁺ cells and rat erythroid cells from nonparenchymal fractions, oval cells were further enriched by MACS using c-kit antibody. The result showed that more than 90% sorted cells were OV6 positive. After cultured in our special medium the sorted oval cells could form large colonies. BrdU incorporation test was positive in most progenies of oval cells on d 7, indicating that the sorted oval cells have high growth potential. At wk 2, some of the progenies lost the c-kit marker of the sorted cells. Immunohistochemical staining showed that there were 3 types of cells in the colony after cultured for 2 wk *in vitro*, that marked albumine, only CK19, and both albumin and CK19. RT-PCR on the colony showed that expression of albumin, AFP and CK19 genes was detectable. All these data suggest that the sorted oval cells are facultative hepatic stem/progenitor cells with self-renewing capacity and can differentiate along hepatocyte and cholangiocyte lineages *in vitro*, and the progeny lost stem cell marker during differentiation. Crosby *et al.* purified c-kit positive cells from

cirrhotic tissue by MACS and the sorted cells could form colonies with 2 types of cells in morphology cultured *in vitro* on d 7. But the sorted c-kit⁺ or CD34⁺ cells by Crosby *et al.* could only differentiate along cholangiocyte lineage^[11]. The difference might be due to the fact that they used just biliary cell growth medium.

In conclusion, we successfully isolated and purified viable c-kit positive oval cells which had high growth potential and multilineage differentiation activity from the 2-AAF/PH rat liver. The properties of proliferation and differentiation *in vivo* are still to be studied by cell transplantation.

Abstract

AIM: To observe the effect of compound *Biejiaaruangan* decoction (CJRG) (composite prescription of Carapax trionycis for softening the liver) on proliferation, activation, excretion of collagen and cytokine of hepatic stellate cells (HSCs) and to find the mechanism of prevention and treatment of hepatic fibrosis by CJRG.

METHODS: Using MTT, immunohistochemistry and image analysis technology, the related indexes for proliferation, activation, excretion of collagen and cytokine of hepatic stellate cells were detected in 24 h, 48 h, and 72 h after administration of different dosages of CJRG.

RESULTS: Statistical analysis showed that serum collected from rat perfused with CJRG could restrain the proliferation of HSC in 48 h and 72 h especially in high and medium dosage groups, markedly decrease the expression of desmin, synapsin and platelet derived growth factor (PDGF) in HSC in 24 h, 48 h and 72 h, as well as the expression of α -SMA, collagen III, TIMP and TGF β 1 in 48 h and 72 h, decrease the excretion of collagen I in 72 h. CJRG serum had no significant effect on collagens I, III and TIMP in 24 h.

CONCLUSION: CJRG serum has a good curative effect on hepatic fibrosis. Its main mechanism may be related to the following factors. The drug serum can restrain the proliferation and activation of HSC, decrease the number of activated HSC and the total number of HSC, the excretion of collagens I, III, enhance the degradation of collagen and restore the balance of synthesis and degradation of collagen, inhibit the expression of transforming growth factor β 1 (TGF β 1) and platelet derived growth factor (PDGF) in HSC, block and delay the process of hepatic fibrosis. Synapsin is a new marker of activation of HSC, which provides a theoretical and testing basis for neural regulation in the developing process of hepatic fibrosis.

INTRODUCTION

Hepatic fibrosis is an inevitable pathological process of chronic liver disease to hepatic cirrhosis. Hepatic fibrosis is caused by excessive deposition of extracellular matrix (ECM), which is the result of more synthesis and less degradation of ECM. A clinical and experimental study has found that liver cells, hepatic stellate cells (HSC), kupffer cells and sinus endothelial cells all take part in the formation of hepatic fibrosis, in which HSC plays a very important role^[1]. Activation of HSC is commonly regarded as the major link of hepatic fibrosis and the main resource of synthesis of ECM^[2]. The main characteristic of activation of HSC is excessive proliferation of HSC^[3]. In addition, desmin is regarded as a marking protein of HSC and α -SMA is regarded as a marker of activation of HSC^[4]. A foreign study has reported that in process of activation of HSC, the expression of synapsin can increase^[5]. Activation of HSC can lead to excessive synthesis of collagen. MMP and TIMP also jointly take part in the synthesis and degradation of collagen^[6]. Multiple cytokines including TGF β 1 and PDGF play a very important role in proliferation, activation of HSC and synthesis of ECM^[7]. Therefore, it may be a good strategy to restrain the amount of activated HSC, decrease the synthesis and excretion of collagens I, III and TIMPs, and promote the synthesis and excretion of MMPs. Aiming at HSC, it has become a control issue in anti-hepatic fibrosis to restrain its proliferation, decrease the synthesis of ECM and accelerate the degradation of ECM, and even inverse activated HSC to silent HSC. Traditional Chinese medicine has shown its own advantage in treating some difficult diseases. Approved by the government, compound *Biejiaaruangan* decoction (CJRG) has been used as the first traditional Chinese medicine for treating hepatic fibrosis (approval document number: 1999 2-102). Clinical observations in Beijing, Shanghai and Hubei Province proved that its effective rate was 78.9% in 121 patients by the first hepatic puncture and in 52 patients by the second hepatic puncture. However, further study of its detailed anti-hepatic fibrosis mechanism is still needed. On the basis of the above-mentioned theory and research developments, our study with the cell culture as technical platform, was to observe the influence of serum collected from rats perfused with CJRG on activation and proliferation of HSC *in vitro*, and using immunohistochemistry and image analysis technology to observe its influence on the expressions of desmin, α -SMA, synapsin, collagens I, III, TIMP, TGF β 1 and PDGF of HSC *in vitro*.

MATERIALS AND METHODS

Main reagents

RPMI1640 was produced by Gibco, fetal bovine serum was produced by Hyclone, and 96-well plates by Costa. Dimethyl sulfoxide (DMSO), ethylenediaminetetra-acetic acid (EDTA), 3-

(4,5-dimethyl-1-thiazol-2-yl), 2,5-diphenyl tetrazolium bromide (MTT), N-2-Hydroxyethylpiperazine-N'-2-ethane sulfonine acid (HEPES), and trypsin were all products of Sigma. Rat desmin monoclonal antibody and rat α -SMA monoclonal antibody were bought from DAKO, rat synapsin monoclonal antibody was bought from Santa Cruz. Rat collagen I and III monoclonal antibodies, rat TIMP and PDGF as well as TGF- β 1 monoclonal antibodies, ABC and DAB test kits were all bought from Beijing Zhongshan Biotechnology Inc.

SD rat HSC line

The HSC line was established in our laboratory and prepared after long-term generation.

Preparation of SD rat serum^[8]

Normal SD rat serum A normal rat weighting 350 g fasted for 12 h was injected with diethylether for anesthesia. Under the sterile condition, 10 mL blood was obtained from abdominal aorta, then held for 2 h at room temperature. Blood serum was made by centrifugation at 427 g for 10 min, inactivated at 56 °C for 60 min, and frozen at -60 °C.

Hepatic fibrosis model SD rat serum Adapted Hernandez-Munoz method was used to establish animal model of hepatic fibrosis^[9], 0.2 mL CCl₄ (Olive oil, 1:6 dilution) was injected into abdominal cavity, three times each week for 7 wk. Serum preparation and preservation were the same as those of the normal SD rat serum.

Drug serum With 3.5, 7 and 14 times of human body dosage as low, medium and high dosage groups respectively, CBJRGC was perfused into rat stomach 3 times at 12 h intervals. Rats were fasted for 12 h before the third perfusion and blood sampling was conducted from abdominal aorta 2 h after the third perfusion. Serum preparation and preservation were the same as those of the normal SD rat serum.

Cell culture and grouping

Rat HSCs were inoculated in RPMI1640 with 100 g/L fetal bovine serum, and cultivated at 37 °C in an incubator containing 50 mL/L CO₂ to logarithm growth time. After treatment with digestive fluid, HSCs were suspended by adding D-Hank's fluid, deposited by centrifugation at 190 g with 5 min, and then counted. Using RPMI1640 containing 100 g/L fetal bovine serum, HSCs were adjusted to a density of 5×10^4 /mL and added to a 24-well plate containing flying sheet, 0.2 mL each well. According to intervening factors, HSCs were divided into 5 groups, i.e. control group, model group, high dosage serum group, medium dosage serum group and low dosage serum group. Each group had 4 wells. Upper culture medium was removed after cultivated for 12 h. Control group serum, model group serum, high dosage group serum, medium dosage group serum and low dosage group serum were accordingly added. Flying sheets were taken out respectively at 24 h, 48 h and 72 h, fixed with cold acetone for 10 min, dried and preserved at -60 °C.

Using MTT method to detect effect of drug serum on proliferation of HSC

HSCs with a density of 5×10^4 /mL were added to a 96-well plate, 0.2 mL each well. Each group contained 8 wells. Upper medium was removed after cultivated for 12 h. Control group serum, model group serum, high dosage group, medium dosage group serum and low dosage group serum were accordingly added. 50 μ L cultivating fluid was taken out respectively at 24 h, 48 h and 72 h. A 50 μ L of MTT (50 μ g MTT) was then added and the culture continued for 4 h at 37 °C. After upper fluid was removed, 150 μ L DMSO was added to each well. After concussed and dissolved, Absorbency value with wave-length of 450 nm was detected by enzyme labeled instrument (BioRad 2250, Japan).

The test was repeated 5 times.

Immunohistochemical staining

α -SMA staining Preserved cell flying sheets were immersed with PBC for 5 min, blocked with 10 mL/L H₂O₂ for 10 min, washed 3 times with PBC, 5 min each time, and then incubated with 10% goat serum for 30 min. Rat α -SMA, desmin, synapsin collagens I and II, TIMP, TGF β 1 and PDGF antibodies were diluted at a concentration of 1:100 and added as the first antibodies, staying overnight at 4 °C. After washed 3 times with PBC, 5 min each time, biotin goat anti-rat IgM was added, staying overnight at 4 °C, washed with PBC 3 times, 5 min each time. Streptavidin was added for 30 min, stained with DAB. The first antibody was replaced with fetal bovine serum as negative control, α -SMA male staining Absorbency value and relative area occupied by α -SMA male cells in the reference system were detected with TN-8502 image analysis system (Tractor Northern Co, USA). Data were treated with SPSS for ANOVA test. Results were presented mean \pm SD. $P < 0.05$ was considered statistically significant.

RESULTS

Influence of each group serum on proliferation of HSC at different time points

HSC just after digesting phase showed a global form under contrast microscope. After cultivated for 12 h, HSCs were pasted to the wall, changing into the oblate form. There were obvious lipid droplets in cytoplasm. Few cells started to show the extension of cytoplasm. After cultivated for 24 h, most cells showed the extension of cytoplasm, and some cells showed multi-angle pseudopodium and typical star-like form. The influence on proliferation of HSC detected by MTT method is presented in Table 1.

Influence of each group serum on α -SMA, desmin, synapsin of HSC at different time points

Tables 2, 3, 4 and Figures 1, 2 show the influence of each group serum on α -SMA, desmin, synapsin of HSC at different time points, which were detected with TN-8502 image analysis system.

Figure 1 Immunohistochemical staining of α -SMA of SD rat HSC line in model group and medium dosage group ($\times 66$). A: Immunohistochemical staining of α -SMA of SD rat HSC line in model group. B: Immunohistochemical staining of α -SMA of SD rat HSC line in medium dosage group.

Influence of each group serum on collagen I, III and TIMP of HSC at different time points

The influence of each group serum detected with TN-8502 image analysis system on collagens I, III and TIMP of HSC at different time points is shown in Tables 5, 6, 7 and Figures 3, 4.

DISCUSSION

In past studies about traditional Chinese medicine, the method of adding directly coarse extract of the medicine to environment of cells was adopted in most experiments *in vitro*. Because of the complicated components of traditional Chinese medicine, it could not effectively reflect its pharmacological role. Therefore, we adopted the blood serum pharmacological method in our experiment^[8]. After giving the drug to the animal orally, we took the drug serum as the drug source to add to the response system *in vitro*. This method could not only present the biotransformation *in vivo*, but also overcome confusion of other substances, aiding to make a pharmacokinetic study by finding the effective locus and the activity of components of traditional Chinese medicine. To avoid influence of different species animal sera on cells, animals were adopted in our experiment which were the same species with cultivated HSCs. Considering that the tested object of the drug was cells and the drug with biological reactivity in organism, we gave the drug to the animal orally with an equivalent dosage, to assure the maximum homeostasis concentration of the drug after bioconversion *in vivo*. The results of our experiment indicated that our experiment method was effective, stable and reliable.

A recent investigation has shown that proliferation and activation of HSCs are not only the central link of hepatic fibrosis, but also the cytological background of hepatic fibrosis^[10,11]. Therefore, inhibiting the proliferation and activation of HSC has important significance in prevention and treatment of chronic liver disease and anti-hepatic fibrosis. Cultivated in a non-coating plastic Petri dish, HSC could be automatically activated, thus possessing the biological characteristics of activation *in vivo*, and becoming an ideal anti-hepatic fibrosis cell model^[12]. Just as shown by the results of our experiment, with elongation of cultivating time, HSC showed multi-angle pseudopodium and typical star form. Cell proliferation and collagen synthesis were two important behaviors in activation of HSC. MTT chromatometry methods could be employed to detect cell ability of proliferation, which was based on the principle that succinic dehydrogenase in mitochondria of living cells could make ectogenous MTT recover to non-dissolvable blue and purple crystals and deposit in cells. DMSO could dissolve blue and purple crystals in cells. Adopting enzyme labeled instruments to detect the Absorbency value at some wave-length, the quantity of cells could be reflected indirectly.

The results of our experiment showed that there was no significant difference ($P > 0.05$) between all the groups 24 h after serum was added. It means that adding serum to cultivate for 24 h did not exert any effective influence and HSCs still proliferated at its original rate, suggesting that intervention in proliferation of HSCs needs a time process, which from accepting excitation of cell signal to changing proliferation quantity of HSC, is undoubtedly longer than 24 h. Thus, how to restrain the activation of HSC at earlier time to hold back quick proliferation of HSC, has undoubtedly important significance in prevention and cure of hepatic fibrosis. Our results showed that proliferation of HSC in model group in 48 h and 72 h had a significant difference compared with other groups, indicating that the model group might contain substances which could promote quick proliferation of HSC. The reason may be that after cultivated for 48 h and 72 h, the PDGF of HSC in the model group increased to the effective content, leading to excessive proliferation of HSC. But a 24 h cultivation was not enough for PDGF to increase to the effective content. This could explain our results that there was no significant proliferation of HSC in the model group after 24 h serum culture. The results of our experiment also showed that after cultivated for 48 h and 72 h, there were significant differences among the high, medium and low dosage drug serum groups and the model group ($P < 0.05$),

and between the high and medium dosage drug serum groups and the control group ($P < 0.05$), indicating that different dosage drug sera could inhibit the proliferation of HSC, and had an especially significant effect on the high and medium dosage groups. CBJRGC serum could significantly decrease and inhibit the proliferation of HSC. Its mechanism may be related to the inhibition of self-excretion or para-excretion of PDGF and TGF- β_1 ^[13], thus inhibiting the proliferation of HSC by decreasing the conversion from HSC to α -SMA.

Changes in form and function after HSC is activated could lead to production increase and degradation decrease of ECM, eventually resulting in deposition of hepatic collagens and hepatic fibrosis. Desmin could be regarded as a marker of HSC^[14], and α -SMA as the marker of activation of HSC^[15]. α -SMA is a kind of filament protein which is about 7 nm in diameter and mainly exists in smooth muscle cells as a portion of cytoplasm framework and a functional unit of cell contraction. Under normal conditions, this protein mainly exists in smooth muscle cells and myofibroblasts. There is a very small amount of this protein in HSCs of rats. In the animal model of liver diseases, HSC lost desmin expression and was changed to the expression of α -SMA in its activation process. So, α -SMA could be regarded as the marker of activation of HSC^[16]. In the process of inducing rat hepatic fibrosis by CCl₄^[17], the dynamic change of desmin male cells was a mono-cusp curve, increasing in number in the earlier period, reaching the peak in 12 wk and then gradually decreasing. A foreign study has found that increase of expression of synapsin could be regarded as another marker of activation of HSC^[18]. Our results showed that the dynamic changes in A value of male staining of α -SMA, desmin and synapsin and in the area occupied by α -SMA and synapsin male cells were almost synchronous. The area occupied by desmin male cells showed a tendency to decrease with elongation of cultivating time. This result was consistent with that reported by Li *et al.* that HSC lost the expression of desmin in its activation process^[19], suggesting that in the process of hepatic fibrosis, α -SMA, desmin and synapsin all can be regarded as the markers of activation of HSC, but each has its own characteristics. The expression of desmin in the earlier period of activation was significant, but weakened with elongation of activating time, while the expression of α -SMA and synapsin developed with elongation of activating time. It is estimated that activation and proliferation of HSC can synchronically occur. Our results also showed that after cultivated for 24 h, the expression of α -SMA had no significant difference among all groups, and after cultivated for 48 h, α -SMA male cell area was smaller than that of desmin, indicating that in the period of cultivation for 24 h and 48 h, proliferation was the main form of HSC growth, but with elongation of cultivating time, HSC began to be partly activated and changed to expression of α -SMA. Seventy-two h after cultivation, α -SMA male cell area was bigger than desmin male cell area, the amount of activated HSCs was more than that of silent HSCs and lots of HSCs altered in phenotype, further indicating that the activation of HSC could be synchronically expressed as proliferation and transformation of HSC. The results of our experiment showed that CBJRGC serum could inhibit the expressions of α -SMA, desmin and synapsin in HSC and inhibit the activation of HSC, whose drug effect was closely related to the concentration of drug serum.

Synapsin can be regarded as a new marker of activation of HSC. Its significance is to provide an important theoretic and testing basis for neuroregulation in the process of hepatic fibrosis. So far, no such study has been found in China. Our experiment firstly showed that after cultivated for 24 h, synapsin could express in HSC, and after cultivated for 48 h and 72 h, synapsin could continue to express. Expression of synapsin occurred before it was cultivated for 24 h and continued to

maintain a high level. CBJRGC serum could significantly inhibit expression of synapsin in HSC. Nevertheless, further studies such as the precise time of synapsin expression, the essential significance of the increase in its lasting expression, whether the nervous system involves regulation of stress condition of liver, and whether CBJRGC serum takes part in nervous regulation in hepatic fibrosis, are still needed.

Under normal conditions, liver contains collagen of types I, III, IV, V, and VI. Collagens I and III take the most proportion of collagen, accounting for about 60% of total collagen in liver. When hepatic fibrosis occurred, the proportion of collagens I and III might reach 95% of total collagen in liver^[20]. Thus, in hepatic fibrosis, deposited ECM mainly consists of collagens I and III.

Synthesis of collagen could reflect alternative ability of individual fiber hyperplasia of cells^[21]. Our experiment showed that after cultivated for 24 h, there was no significant difference of collagens I and III among all groups, indicating that within 24 h after acceptance of activating signal, HSC did not yet achieve enough time to excrete collagen. The outcome of our experiment showed that activated time should be longer than 24 h, so that activated HSC and transcription of collagen and cytokine could be altered. In further investigations we should observe and analyze changes in collagen-mRNA in this time process to test whether CBJRGC serum can influence collagen-mRNA. The results also suggested that to inhibit collagen in its transcriptional stage might have important significance in clinical treatment. In our experiment, collagen III began to markedly express after cultivated for 48 h, but collagen I started to markedly express after cultivated for 72 h, showing that expression of collagen III was earlier than that of collagen I, and that in the early time of hepatic fibrosis, collagen III expression took the most part of expression of collagen. Therefore collagen III can be the testing index of earlier hepatic fibrosis. The outcome of our experiment also showed that high and medium dosage groups could significantly inhibit the expression of collagen III in 48 h and 72 h and the expression of collagen I in 72 h. It means CBJRGC serum could play a role in anti-hepatic fibrosis at the earlier time when collagen was significantly expressed. It further suggested that CBJRGC serum could help quickly recover equilibration of synthesis and degradation of ECM in hepatic fibrosis, thus helping to cure hepatic fibrosis. Besides, low dosage group could only significantly inhibit the expression of collagen III in 48 h, but there was no significant difference compared with control group in 72 h. It is estimated that the effect of CBJRGC serum in inhibiting collagen III expression is related to the serum concentration of the drug.

MMP and TIMP mainly take part in regulation of equilibration in synthesis and degradation of collagen^[22]. Among numerous MMPs, MMP1 is the chief MMP, decomposing collagens I and III in liver^[23]. TIMP1 is an inhibiting factor of MMP, which plays its role by irreversibly binding to activated MMP1. Therefore, the imbalance of ratio of MMP/TIMP 1 plays a very important role in hepatic fibrosis. MMP can be inhibited by many specific or non-specific inhibitors, which at present, mainly include TIMP and α_2 -macroglobulin. TIMP 1 is the most important inhibitor of MMP and is negatively correlated to the activity of MMP.

TIMP is a kind of coding protein of multigene family^[24]. It could irreversibly bind to activated MMP and inhibit the degradation of ECM^[25]. So far, there are four kinds of TIMP isolated from tissues and cloned^[26]. TIMP-1 is a kind of 28.5 ku glycoprotein, mainly inhibiting the activity of MMPs-1 and MMP-9. As the specific inhibitor of MMP, TIMP plays a very important role in hepatic fibrosis. TIMP could inhibit MMP, which is the important reason for specific descent of degradation of ECM^[27]. HSC is the main source cell of TIMP and MMP.

The results of our experiment showed that after cultivated for 24 h, there was no significant expression of TIMP in all groups, indicating that HSC did not have enough time to excrete excessive TIMP. The activated time should be longer than 24 h, and within this time, transcription of TIMP of activated HSC might be altered. In further studies, we should observe and analyze the change of TIMP-mRNA within this time, so as to find whether CBJRGC serum can influence TIMP-mRNA. It is also suggested that to inhibit TIMP in transcriptional stage might have important significance in clinical treatment. In this experiment, TIMP of the model group maintained high expression in 48 h and 72 h, indicating that there was some substance to promote high expression of TIMP in the model group. Further study on the precise characteristics of the substance is suggested.

Researches have found that HSC is the key cell in hepatic fibrosis. Under the stimulation of chronic injury and inflammation, HSC can be activated from normal silent behavior to MFB, and meanwhile can secrete and synthesize excessive ECM, forming the foundation of hepatic fibrosis. Previous studies have indicated that activation and phenotype conversion of HSC are closely related to TGF- β 1. TGF- β is a kind of polypeptide molecule of hormone activity, which is produced from kupffer cells by self-excretion and para-excretion and could take part in many pathological and physiological processes^[28]. TGF- β has at least 5 sub-types, but there are only TGF- β 1, TGF- β 2 and TGF- β 3 in human tissue cells. After binding to the recipient on the membrane, TGF- β could phosphorylate and activate its signal transduction molecule (SMAD protein) of intracytoplasmic downstream, which could subsequently enter the nucleus, regulating the transcription of related target gene^[29]. TGF- β 1 exhibits the significant biological activity of TGF- β and is the main cytokine inducing the production of collagen. Through the mechanism of para-excretion and self-excretion, TGF- β 1 could start and maintain the activation of HSC, regulating cell proliferation, accelerating transcription of collagen and proliferation of ECM^[30].

The results of our experiment showed that after cultivated for 24 h, there was no significant expression of TGF- β 1 among all groups. It showed that it was not enough for HSC to secrete TGF- β 1 24 h after it received the activated signal. It is suggested that in further studies we should observe and analyze the change in TGF- β 1-mRNA within this time, so as to find whether CBJRGC serum can influence TGF- β 1-mRNA. Our results also showed that after cultivated for 48 h and 72 h, TGF- β 1 in the model group maintained high expression, suggesting that it could continuously stimulate activated HSC to produce collagen and accelerate hepatic fibrosis. There might be some substance in the model group which could promote high expression of TGF- β 1. Study on the precise characteristics of this substance is still needed. The results also showed that the high and medium dosage groups could markedly inhibit the expression of TGF- β 1 in 48 h and 72 h, but the low dosage group did not obviously inhibit the expression of TGF- β 1 in 48 h and 72 h, suggesting that CBJRGC serum can inhibit the expression of TGF- β 1 and its effectiveness is related to the concentration of the drug serum.

PDGF is a kind of splitting agent and can promote activation and proliferation of HSC. It has been found PI3-K is the important pathway of intramembrane signal transduction^[31]. The outcome of our experiment showed that after cultivated for 24 h, the A value and male cell area of PDGF were not completely consistent. In 24 h, the A value of PDGF in the model group was significantly higher than that in the other groups, but the male cell area did not show any significant difference compared with the other groups. Although PDGF in the model group achieved significant expression, the PDGF might not entirely come from the excretion of HSC and might

include original PDGF existing in the model group. While PDGF bound to PDGF recipient of HSC and accelerated the proliferation of HSC, the absolute proportion of HSC in the situation of excretion of PDGF did not significantly increase. The outcome of our experiment showed that the high, medium and low dosage groups all could obviously inhibit the excretion of PDGF by HSC.

In summary, we suggest that further studies on the mechanism of anti-hepatic fibrosis of CBJRGC serum should focus on mRNA expression of TIMP1, collagens I, III and TGF- β 1 and signal transduction within the cell.

Abstract

AIM: To investigate the designation, synthesis and biological activity of against vascular endothelial growth factor₁₆₅ (VEGF₁₆₅) ribozyme.

METHODS: The ribozyme against VEGF₁₆₅ was designed with computer. The transcriptional vector was constructed which included the anti-VEGF₁₆₅ ribozyme and 5', 3' self-splicing ribozymes. The hammerhead ribozyme and substrate VEGF₁₆₅ mRNA were synthesized through transcription *in vitro*. The cleavage activity of the ribozyme on target RNA was observed in a cell-free system.

RESULTS: The anti-VEGF₁₆₅ ribozyme was released properly from the transcription of pGEMRz212 cleaved by 5' and 3' self-splicing ribozymes which retained its catalytic activity, and the cleavage efficiency of ribozyme reached 90.7%.

CONCLUSION: The anti-VEGF₁₆₅ ribozyme designed with computer can cleave VEGF₁₆₅ mRNA effectively.

INTRODUCTION

Ribozyme (Rz) is one kind of RNA with site-specific ligation and cleavage activities. Being sequence-specific binding and cleaving specific RNA of ribozyme, the target gene expression can be destructed by an artificially designed and synthesized ribozyme^[1-5]. A great attention has been attracted into the field of gene therapy for cancers with the hammerhead ribozyme, by the virtue of its simple structure, small molecule, easy designation, site-specific mRNA cleavage activity, and catalytic potential^[6-13]. Many studies have showed that the growth, metastasis and prognosis of solid tumors critically related to the angiogenesis. Tumor angiogenesis is a complex process. Among all of the known factors of tumor angiogenesis, vascular endothelial growth factor (VEGF) is a vascular endothelial cell-specific mitogen and the most important and direct one that can stimulate

tumor angiogenesis. VEGF₁₆₅ is the most effective angiogenic factor in the VEGF family^[14-22]. Conversely, inhibition of VEGF expression and tumor angiogenesis to inhibit tumor growth and metastasis become a new hot spot of tumor treatment^[23-34]. In this study, the ribozyme against VEGF₁₆₅ site 212 was designed with computer, the transcriptional vector including the anti-VEGF₁₆₅ ribozyme and self-splicing ribozymes were synthesized and constructed, and the cleavage effect of the ribozyme on target mRNA in cell-free system was observed.

MATERIALS AND METHODS

Vectors

The vector pGEM-3zf(+)VEGF (carrying full length amino acids cDNA of VEGF₁₆₅) was kindly provided by Dr. Abraham (Columbia University, USA). Vector pGEMRzHBV and bacterium JM 109 were gift from Dr. Li (Department of Infectious Disease, Tangdu Hospital, Fourth Military Medical University, China).

Ribozyme design

The cleavage sites of ribozyme anti-VEGF₁₆₅ were designed by computer analysis of the secondary structure of VEGF₁₆₅ mRNA with a computer program (Chen Nong-an, Shanghai Institute of Biochemistry, Academia Sinica). According to Symon's hammerhead ribozyme structural model, the sequences of the cleavage active core of ribozyme and the flanking sequences around the cleavage sites were designed.

Ribozyme synthesis

The hammerhead ribozyme was synthesized by 35 amplification cycles of PCR (TakaRa Biotechnology Co. Ltd. Dalian, China) with the following primer: 5' TGAAGATGCTGATGAGTCCGT GAGGACGAAACTCGAT 3' and purified by electrophoresis on a 100 g/L denaturing polyacrylamide gel.

Plasmid construction

In the down stream of T7 promoter, plasmid pGEMRzHBV included 5' cis-self-splicing ribozyme, RzHBV and 3' cis-self-splicing ribozyme in order. The pGEMRzHBV was digested with *Xba* I and *Aat* II, then the linear vector was purified by 10 g/L agarose gel electrophoresis by using plasmid purification kit (Gibco, USA) according to the manufacturer's instruction. The two complementary strands of designed ribozyme gene cDNA ends were prepared by adding linkers to create sticky ends (*Xba* I and *Aat* II). The double-stranded DNA was then subcloned into the multicloning site (at *Xba* I and *Aat* II) of pGEM by using T4 DNA ligase (Promega, USA) to create the self-splicing transcriptional plasmid pGEMRz212 (Figure 1). After being transformed competent JM109 cells with pGEMRz212 and blue-white screening, the plasmids were extracted from the positive colonies. The sequences of the VEGF₁₆₅ ribozyme and self-splicing ribozymes were confirmed by restriction enzyme and DNA sequencing.

Ribozyme transcription and cleavage activity *in vitro*

The pGEM-3zf(+)VEGF was cut by *Eco*R I, and pGEMRz212 by *Xba* I and *Aat* II. The ribozyme and substrate RNAs were

prepared from the cDNA templates with T7 RNA polymerase (Gibco-BRL, USA) with [α - 32 P]UTP (Yahui Co., Beijing) by *in vitro* transcription. Both the ribozyme and substrate mRNA were synthesized by using T7 *in vitro* transcriptional kit (Gibco-BRL, USA). Equal amounts of ribozyme and substrate were mixed in 10 μ L of reaction buffer (10 mmol/L MgCl₂ and pH 7.6, 75 mmol/L Tris-HCl) at 95 °C for one minute and cooled in ice immediately. The mixture was then reacted at 37 °C for 2 h. The reaction was quenched with EDTA. The cleavage products were detected by autoradiography after 60 g/L denaturing polyacrylamide gel electrophoresis.

Figure 1 Diagram of construction of the vector pGEMRz212.

RESULTS

Ribozyme designation with computer

The topography of the substrate RNA could be simulated by analyzing the cleavage site and the region surrounding the cleavage site by using a RAN secondary structure folding program. In this way, it might be possible to determine whether or not the target site is buried within an obvious thermodynamically stable region of secondary structure. Among the VEGF₁₆₅ mRNA, there were four hammerhead ribozyme cleavage sites. The site 212 was selected as the optimal cleavage site due to its in single chain region of substrate RNA secondary structure and its both binding arms forming a loop structure to expose for ribozyme cleavage interaction as well as site 212 creating the ribozyme essential core (Figure 2). We called the ribozyme RZ212.

Figure 2 Sequencing of the RZ212 and the target mRNA of VEGF₁₆₅.

Synthesis and transcription RZ212

The synthesized ribozyme was confirmed by restriction enzyme and sequencing analysis. The ribozyme molecule was transcribed *in vitro*. Autoradiography showed three fragments after electrophoresis. The fragments were 5' *cis* ribozyme (64 nt), 3' *cis* ribozyme (54 nt) and RZ212 (47 nt), respectively (Figure 3). The results indicated synthesized ribozyme presenting self-cleavage and releasing the desired ribozyme.

Cleavage activity of RZ212

The cleavage reaction was carried out *in vitro* in a cell-free system. RZ212 cleaved the substrate VEGF₁₆₅ mRNA into 2 fragments (259 nt and 380 nt) (Figure 4) consistent with anticipation. After being cleaved by ribozyme, the density was analyzed by using laser density scanner and the substrate residue was just about 9.3%, indicating that the substrate was nearly cleaved completely by ribozyme.

Figure 3 Transcription of pGEMRz212.

Figure 4 Cleavage activity of VEGF₁₆₅ mRNA with RZ212.

DISCUSSION

The cleavage site and both binding arms must be considered attentively while designing ribozyme. First of all, the cleavage site should be in the important functional region of the target gene assuring the corresponding protein function lost after being cleaved. In addition, the flanking sequences around the cleavage site should be as conserved as possible so that the ribozyme cleavage spectrum become broader. The ribozyme arms sequence context can also influence cleavage rate significantly. In a simple term, the longer the binding arms, the lower the turnover in cleavage of short substrate^[35]. Results from various studies have indicated that ribozyme activity is closely related to the arms length and this depends somewhat on the sequence context^[36,37]. The ribozyme design program we used was approved and improved continuously by experiments. It can resolve the cleavage site design and the sequence surrounding the cleavage site as well as the predicting of ribozyme secondary structure. In this study, we designed successfully the ribozyme target VEGF₁₆₅ mRNA site 212 using the program, synthesized RZ212 and constructed self-cleavage plasmid pGEMRz212. *In vitro* transcription and cleavage

experiment showed that the designed ribozyme was released and cut the target mRNA into two fragments.

Practically, ribozyme gene was constructed in the transcriptional and eukaryotic vector. The ribozyme molecule was transcribed in cells. But there are some long additional sequence in the both arms of ribozyme. The long additional sequence has a strong secondary structure and influenced ribozyme catalytic core, resulted in forming the incorrect secondary structure, even blocking ribozyme binding site. The long additional sequence also influenced ribozyme dissociation from the cleaved target mRNA and reduced cleavage rate^[38,39]. In order to cleave the long additional sequence, we designed and constructed the trimming plasmid pGEMRz212, which included 5' *cis*-self-splicing ribozyme, Rz212 and 3' *cis*-self-splicing ribozyme in order. The long additional sequence was cleaved while pGEMRz212 transcription *in vitro* and VEGF₁₆₅ mRNA specific ribozyme released without long additional sequence. The result showed 5' and 3' *cis* ribozyme neither cleaved the substrate and nor influenced Rz212 cleavage efficacy.

Compared with antisense RNA, ribozyme can not only block target mRNA but also cleave the target mRNA in a sequence-specific manner. Ribozyme has received much attention for their potential use due to their inherent simplicity, relatively small size, repetition use and the ability to be incorporated into a variety of flanking sequence motifs without changing site-specific cleavage capacities^[40-42]. In this experiment, the cleavage efficacy of ribozyme we designed and synthesized reached up to 90.7%. It can suppress effectively the expression of substrate. This research may facilitate the development of ribozyme anti-angiogenesis gene therapy for the treatment in the tumors. Further studies are required for therapeutic application of anti-angiogenesis in human cancer.

Abstract

AIM: The aim of this study was to describe an auxiliary combined liver-small bowel transplantation model with the preservation of duodenum, head of pancreas and hepatic biliary system in pigs. The technique, feasibility, security and immunosuppression were commented.

METHODS: Forty outbred long-white pigs were randomized into two groups, and the auxiliary composite liver/small bowel allotransplantations were undertaken in 10 long-white pigs in each group with the recipient liver preserved. Group A was not treated with immunosuppressive drugs while group B was treated with cyclosporine A and methylprednisolone after operation. The hemodynamic changes and amylase of body fluid (including blood, urine and abdominal drain) were analyzed.

RESULTS: The average survival time of the animals was 10 ± 1.929 d (6 to 25 d) in group A while more than 30 d in group B. The pigs could tolerate the hemodynamic fluctuation during operation and the hemodynamic parameters recovered to normal 2 h after blood reperfusion. The transient high amylase level was decreased to normal one week after operation and autopsy showed no pancreatitis.

CONCLUSION: Auxiliary *en-bloc* liver-small bowel transplantation with partial pancreas preservation is a feasible and safe model with simplified surgical techniques for composite liver/small bowel transplantation. This model may be used as a preclinical training model for clinical transplantation method, clinical liver-small bowel transplantation related complication research, basic research including immunosuppressive treatment, organ preservation, acute rejection, chronic rejection, immuno-tolerance and xenotransplantation.

INTRODUCTION

Combined liver and small bowel transplantation (LSBT) is a

life-saving procedure in patients especially in children with intestinal failure and parenteral nutrition-related end-stage liver diseases^[1]. Recently, due to success in clinical technology and improvement of the operative modality, the American Health Care Financing Administration (HCFA) has granted combined liver-intestinal transplantation as the standard therapeutic modality for patients with irreversible intestinal failure^[2]. Patients undergoing composite liver-small bowel transplantation are mostly children. As conventional LSBT requires a loop of defunctionalized (Roux) allograft small bowel for biliary drainage^[3], its posttransplant biliary complications including anastomotic leaks and obstruction in 12% of cases, were significantly related with morbidity and mortality^[4]. In addition, the conventional composite transplantation needs more vascular anastomoses which would lead not only to more complications including vascular thrombosis but also more difficulties of the surgical techniques. In the present study, we described an auxiliary transplantation technique for LSBT by preserving duodenum, partial head of pancreas and hepatobiliary system in pigs. Experience with this technique and the immunosuppressive treatment for LSBT in pig has not been reported in the literature.

MATERIALS AND METHODS

Forty outbred long-white pigs weighing 20 - 40 kg were divided into 2 groups with random sex, and 10 LSBTs were undertaken in each group. The weight of the donor was generally lower than that of the corresponding recipient. Group A was not treated with immunosuppressive drugs while group B was treated by immunosuppressive therapy consisting of cyclosporine A and methylprednisolone after operation.

The animals were not allowed to eat for 24 h and to drink for 4 h before operation respectively. Gut decontamination was attempted in all donors with an oral antibiotic preparation 3 d before surgery.

After anesthesia with 25 mg/kg of intravenous pentobarbital sodium, the animals were intubated and mechanically ventilated with a mixture of oxygen, nitrous oxide and isoflurane. In addition, standard intravenous antibiotic prophylaxis was instituted with cefotaxime at the time of surgery.

Initial exposure and isolation of abdominal organs

The procurement varied in details but followed the standard techniques for human multiorgan retrieval and our previous report^[5-8].

Briefly, the proximal 3 to 4 m of jejunum (the total length of porcine small bowel is about 15 m) together with the liver was procured as the graft. After the redundant small bowel and the dissociative colon were removed from the operative field, the duodenum, proximal jejunum and aorta could be well exposed. An extensive Kocher maneuver allowed visualization of the inferior vena cava and its branch. The subhepatic vena cava was dissected and encircled. The left and right renal veins were ligated respectively. The superior mesenteric and celiac arteries were identified after extending dissection of the aorta. The right and left renal arteries were then isolated and ligated. The subrenal aorta was isolated and encircled distally for the

eventual insertion of an infusion cannula. The abdominal aorta was also encircled above the celiac axis for later crossclamping when cold fluid was infused through the distal aortic cannula^[9]. The splenic vein was then freed and prepared for portal perfusion cannulation after division of the splenic artery. The splenic vein should be well protected when dividing the splenic artery^[10].

In situ cooling and removal of organs

After completion of the preliminary dissection and collection of the donor's blood, the liver and small bowel connected by the portal vein and aortic segment were lavaged *in situ* with UW solution (Figure 1). The donor was fully heparinized and the previously encircled proximal aorta was crossclamped, and the distal donor aorta was cannulated with infusion of cold UW solution. For simultaneous portal venous infusion, a venous cannula was placed into the splenic vein and infused with the UW solution. The intrapericardial inferior vena cava and subhepatic vena cava were transected to decompress the infused solution as in other reports^[11,12]. The amount of infusion was variable (50-100 mL/kg). After infusion, the graft containing liver, hepatic hilus, pancreatic-duodeno complex, spleen together with splenic vein, and small bowel was achieved with preservation of a segment of aorta containing the superior mesenteric artery and celiac trunk in continuity. The intestine was entrapped by stapling its two ends and carried with the specimen throughout the preservation. Thus the graft was *en bloc* removed and stored in UW solution at 0 to 4 °C.

Back table procedure was performed in the cold UW solution. It included suturing the orifice of suprahepatic vena cava and the proximal end of the aorta. The spleen was removed. The body and tail of the pancreas along the portal vein were isolated and transected, leaving partial pancreatic head attached to the allograft duodenum. This preserved the superior and inferior pancreaticoduodenal arcades. The stump of the pancreas was stapled and then oversewn with a running suture using 4-0 polypropylene.

Figure 1 Infusion of grafts, (UWS=UW solution, SV=splenic vein, S=spleen, P=pancreas, SB=small bowel, AO=abdominal aorta, TAO=thoracic aorta, L=liver, HA=hepatic artery, SMA=supermesenteric artery, VC=vena cava).

Recipient operation

After anesthesia, a monitor was placed on the recipient. Two venous catheters (with one Swan-Ganz catheter) were inserted

for transfusion and hemodynamic parameters including central venous pressure (CVP), right ventricle pressure (VP), cardiac output (CO), pulmonary artery wedge pressure (PAWP) at the time of preoperation, the time just before blood reperfusion, 5 min, 30 min, 1 h and 2 h after blood reperfusion. The arterial blood pressure was monitored through a femoral artery catheter. The amylase levels of the blood, urine and abdominal drainage postoperative d 1, 3, 5, 7 were collected (determined by Somogyi method).

When the recipient's abdomen was opened, the dissociative colon and its mesentery were dissected and removed to ensure enough celiac space for the composite graft. Then, the end of the ascending colon and the end of the ileum were anastomosed directly to maintain the gastroenterologic continuity of the recipient.

The subrenal aorta was exposed and encircled 2 cm under the renal artery. Small arterial and lymphatic vessels along the aorta were ligated to avoid later bleeding or lymphorrhea. Subhepatic vena cava was also dissected and encircled. The subrenal vena cava was used for the donor out-flow anastomosis.

Figure 2 Auxiliary en-bloc liver-small bowel transplantation, (D=donor, R=recipient, AO=aorta, L=liver, HA=hepatic artery, SV= splenic vein, SB=small bowel, SMA=supermesenteric artery, VC= vena cava, PV=portal vein, CBD=common bile duct, P=pancreas, JO=jejunum ostomy, AS1=aorta-aorta anastomosis, AS2=vena cava- vena cava anastomosis).

Graft implantation and revascularization

The transplantation methods varied in details but followed the principles as described previously^[6,8] (Figure 2).

The arterial inflow was created via an end-to-side anastomosis of the graft aorta to the subrenal native aorta with a running polypropylene suture. Donor and recipient vena cava were anastomosed end to side. The venous outflow was the anastomosis of the end of the graft subhepatic vena cava to the side of the native subhepatic vena cava.

Before reperfusion, unclamping and perfusion of the allograft liver were achieved after a lavage of 300 to 500 mL donor blood or Ringer's solution through the splenic vein. The end of the spleen vein was ligated after the lavage.

The proximal duodenum was closed. A jejunostomy was

made at the end of donor distal intestine for early decompression and surveillance endoscopy as described in some clinical reports^[13,14].

After operation, the animals were returned to the monitor room, where hemodynamic monitoring and mechanical ventilation were performed as needed 24 h after operation. Due to the high rate of inflammatory complications, broad-spectrum antibacterial prophylaxis was administered for 5 d. Lactated Ringer's solution and parenteral nutrition were given daily for 2 d after operation.

Immunosuppressive drugs were used in the pigs of group B. Cyclosporine A was started at 15 mg/kg·d by venous injection in the first week, then reduced to 5 mg/kg·d from the second week as maintenance treatment. Methylprednisolone, used for induction and maintenance, was started with 500 mg at the first 24 h postoperation, reduced by 50% to about 2 mg/kg·d for the first week, then reduced by 50% on d 8 and again on day 15.

The survived animals were sacrificed for autopsy 30 d after operation.

RESULTS

After reperfusion, the liver was soft and pink with bile production, evidenced by jejunostomy drainage. If the liver was harder than normal, the outflow of the liver might be obstructed and the vena cava anastomosis needed to be checked. The small bowel should be perfused well, with good mesenteric arterial inflow and venous outflow. The peristalsis and intraluminal mucus production were evident within 15 min after reperfusion.

Table 2 Hemodynamics changes

Time	N	preRP	RP5	RP30	RP60	RP120
CVP (cmH ₂ O)	14.80±0.42	13.00±0.49	10.20±1.07	9.50±0.27	9.90±0.37	14.00±0.36
VP (cmH ₂ O)	33.70±2.09	31.70±2.64	27.70±1.93	24.60±1.65	27.30±1.71	32.60±1.92
PAWP (cmH ₂ O)	16.70±0.59	13.40±0.40	16.30±0.52	14.10±0.41	15.90±0.46	17.20±0.44
CO (L/min)	4.48±0.15	3.36±0.22	4.27±0.15	3.98±0.15	4.23±0.15	4.59±0.16

CVP=central venous pressure, VP=ventricle pressure, PAWP=pulmonary artery wedge pressure, CO=cardiac output, N=normal, preRP=pre-reperfusion, RP5=5 min after reperfusion, RP30=30 min after reperfusion, RP60=60 min after reperfusion, RP120=120 min after reperfusion.

During the first three days, the intestinal graft stoma appeared healthy, and the mucosa was pink, moist, and well vascularized. No intestinal edema was found in most cases with output of bile-stained stool.

Histopathologic studies of the grafts showed no significant preservation injury. None of the biopsies obtained in the first postoperative week had histological evidence of submucosal bacterial invasion. The frequent cause of death of the pigs in group A was postoperative rejection evidenced by graft pathological examinations when the animal was dead.

Animals died 24 h after reperfusion were ruled out from the statistic series. One pig died because of operative techniques in group A, and all other animals in groups A and B lived for more than 24 h. The average survival time was 10.33±1.929 d (6 to 25 d) in group A while more than 30 d in group B. The difference was significant by Student's *t* test ($P<0.01$).

The hemodynamic changes are shown in Table 1. The results suggested that all hemodynamic parameters including CVP, CO, VP and PAWP were decreased during operation, but recovered very quickly after blood reperfusion, and returned to normal 2 h after blood reperfusion as shown in Figure 3.

Neither the duodenal allografts had signs of ischemia or stump leakage, nor any biliary complication. Blood, urine and abdominal drains were monitored serially for amylase level. Chemical pancreatitis was observed during the early postoperative period with amylase-rich fluid drainage.

Figure 4 Hemodynamic changes.

The amylases in the body fluid are shown in Table 2. Amylases in blood, urine and abdominal drainage increased promptly after operation and reached their peak in the first three postoperative days. The levels then decreased with time.

and returned to preoperative level after one week as shown in Figure 4. Postoperative biopsy showed no sign of pancreatitis and also autopsy did not show any evidence of severe pancreatitis or calcification. Autopsy of the pigs in group B showed no evidence of graft rejection.

DISCUSSION

Total parenteral nutrition (TPN) for short bowel syndrome would induce end-stage liver diseases. In considering intestinal transplantation for treatment, 60% to 70% them required simultaneous liver allografts^[4,7]. Although many clinical liver/small bowel transplantations (LSBT) were reported from different medical centers^[15-17], it remains an experimental procedure^[18]. Although large animals that share physiological and anatomical similarities with humans, comparing to the widely used rat LSBT model^[19,20], large animal models such as LSBT in pigs and its related research were rarely reported.

Feasibility and benefits of auxiliary composite liver-small bowel transplantation model

As compared to the five anastomoses in conventional composite liver-small bowel transplantation including suprahepatic vena cava anastomosis, subhepatic vena cava anastomosis, hepatic artery anastomosis, portal vein anastomosis and bile duct anastomosis, only two anastomoses including aorta-aorta anastomosis and subhepatic vena cava anastomosis were needed in the auxiliary composite liver-small bowel transplantation model. This model could not only decrease possible complications related to the anastomoses such as bleeding, vascular obstruction, postoperative thromboses and bile leakage, but also simplify the surgical techniques. In this model, the vena cava anastomosis was modified by replacing the major hepatic vein (or suprahepatic vena cava) anastomosis in classical Piggy-back transplantation by the subhepatic vena cava anastomosis. This modification has at least two advantages in porcine LSBT. One is that subhepatic vena cava anastomosis can be easily performed, the other is that subhepatic vena cava anastomosis can adjust a flexible anastomotic interval to ensure the aorta-aorta anastomosis easier.

In clinical practice, Abu-Elmagd suggested that LSBT with preservation of pancreatic head and duodenum had some advantages including avoidance of biliary complications and simplification of the operative procedure^[20]. These possible advantages were also shown in animal LSBT.

The LSBT transplant procedure is a much more arduous surgical endeavor. The technique of retaining duodenum and the head of pancreas would simplify the back table preparation and avoid risks associated with dissection of the donor hepatic hilus.

Retrieval for composite grafts using the standard technique involved an obligatory reconstruction of the biliary system with a defunctionalized loop of proximal allograft jejunum^[3]. In this porcine LSBT model, no biliary reconstruction was required, so that the source of complications such as bile leakage, biliary tract stricture or even death of recipient could be avoided. Liver transplantation related biliary complication rate was about 12%, which would result in about 19% of mortality^[21,22]. LSBT with preservation of partial pancreas and duodenum would remarkably decrease such complications.

The potential benefits of any intestinal segment which was kept in direct continuity with alimentary tract freeing the pig for TPN would be enhanced without donor or recipient bowel for Roux-en-Y biliary reconstruction. The advantage of the composite technique was to maintain the hepatic hilus. The use of liver artery and superior mesenteric artery with a large arterial conduit would minimize the risk of hepatic artery thrombosis compared to isolated graft^[13,23].

Safety of porcine auxiliary LSBT with pancreatic head and duodenum

The porcine retrohepatic vena cava is passing through the liver parenchyma with numerous small hepatic veins in this segment besides the major hepatic veins. It is dangerous to remove the liver parenchyma by dissecting the retrohepatic vena cava with high risk of fetal blood loss. This is the reason why the classic piggyback liver transplantation is not suitable in pig. Typical orthotopic liver transplantation in combined LSBT needs not only blood shunt during operation but also a segment of additional artery to prolong the aorta to ensure the arterial anastomosis in pigs. Auxiliary LSBT could avoid the disadvantages of these transplantations.

In conventional composite liver-small bowel transplantation, blood shunt was always needed in the process of vascular exclusion. In pigs, this was much more important because the blood passing through portal vein was accounted for more than 60% of the total porcine blood. The vascular exclusion would lead to sudden cardiac failure and death of the pigs. Auxiliary composite liver-small bowel transplantation model with partial vascular exclusion during the vascular anastomosis did not lead to irreversible hemodynamic changes that would occur without blood shunt. This method would also avoid other possible hemodynamic damages such as kidney injuries, postoperative thrombosis and ischemia of the lower limb.

Inclusion of duodenum and pancreatic head to maintain continuity of the biliary system was associated with early postoperative allograft pancreatitis, but no significant mortality was reported^[24]. This complication was also found in our study. It could be detected by measuring amylase and lipase in peritoneal fluid from abdominal drains, blood and urine^[25]. In our study, chemical pancreatitis as shown in the experiment was always transient. The elevated amylase level would return to normal within one week and autopsy showed no signs of severe pancreatitis. At present, the following measures could be considered to protect the allografted pancreas from postoperative pancreatitis, namely to limit the amount and pressure of the cold solution used in perfusion^[3], to procure the pancreas *en-bloc* with the graft and avoid over-dissection of the tissue and vessels around duodenum and pancreas^[26], to ligate the pancreatic duct and suture the pancreatic interface efficiently and definitely.

Immunosuppressive treatment of auxiliary LSBT pigs

The optimal immunosuppressive treatment was not determined in big organ transplantations. Triple drugs (cyclosporine or FK506, azathioprine and prednisolone) and quadruple drugs (ATG, cyclosporine or FK506, azathioprine and prednisolone) treatment in pig transplantation were reported in the literature^[27-29]. But the optimal dose of immunosuppressive drugs was ascertained in previous reports. The suggested dose of cyclosporine was from 3 mg/kg·d to 25 mg/kg·d by IV or SB injection^[27,28,30,31]. Some reports indicated that pigs required a higher dose of cyclosporine than humans to prevent allograft rejection in thymus transplantation^[32]. Other authors suggested that immunosuppressive protocols that were successful in preventing allograft rejection in humans had no long-term effect on allografted pigs and the dose of most immunosuppressive agents administered to control rejection in pigs should be higher than that used in humans^[33]. This might be due to differences of absorption, binding, metabolism and excretion of the drugs in pigs. So we used the maintenance dose of CsA 5 mg/kg·d after a loading dose of 15 mg/kg·d, and the composite transplanted liver small bowel graft with preservation of pancreas head could be protected by CsA and methylprednisolone against acute rejection.

Some reports suggested that LSBT with preservation of duodenum and pancreatic head would neither increase the possibility of rejection nor require more immunosuppressive

treatment than standard LSBT without preservation of pancreas and duodenum^[13,23]. The presence of allograft pancreas in multivisceral allografts was not an important risk factor for mortality, and the incidence of rejection of pancreatic was only 12% in some report^[13]. So the technique with preservation of the pancreas should be considered safe in composite LSBT.

In summary, auxiliary en-bloc liver-small bowel transplantation with partial pancreas preservation is a feasible and safe model with simplified surgical techniques for composite liver/small bowel transplantation in pigs. This model might be used as a preclinical training model for clinical transplantation method, clinical liver-small bowel transplantation related complication research, basic research including immunosuppressive treatment, organ preservation, acute rejection, chronic rejection, immuno-tolerance and xenotransplantation research.

Abstract

AIM: Differentiation of benign biliary strictures (BBS) from malignant biliary strictures (MBS) remains difficult despite improvement in imaging and endoscopic techniques. The aim of this study was to identify the clinical, biochemical and or radiological predictors of malignant biliary strictures.

METHODS: We retrospectively reviewed all charts of patients who had biliary strictures (BS) on endoscopic retrograde cholangiopancreatography (ERCP) or percutaneous cholangiography (PTC) in case of unsuccessful ERCP from March 1998 to August 2002. Patient characteristics, clinical features, biochemical, radiological and biopsy results were all recorded. Stricture etiology was determined based on cytology, biopsy or clinical follow-up. A receiver operator characteristic (ROC) curve was constructed to determine the optimal laboratory diagnostic criterion threshold in predicting MBS.

RESULTS: One hundred twenty six patients with biliary strictures were enrolled, of which 72 were malignant. The mean age for BBS was 53 years compared to 62.4 years for MBS ($P=0.0006$). Distal bile duct stricture was mainly due to a malignant process 48.6% vs 9% ($P=0.001$). Alkaline phosphates and AST levels were more significantly elevated in MBS ($P=0.0002$). ROC curve showed that a bilirubin level of 84 $\mu\text{mol/L}$ or more was the most predictive of MBS with a sensitivity of 98.6%, specificity of 59.3% and a positive likelihood ratio of 2.42 (95% CI=0.649-0.810). Proximal biliary dilatation was more frequently encountered in MBS compared to BBS, 73.8% vs 39.5% ($P=0.0001$). Majority of BBS (87%) and MBS (78%) were managed endoscopically.

CONCLUSION: A serum bilirubin level of 84 $\mu\text{mol/L}$ or greater is the best predictor of MBS. Older age, proximal biliary dilatation, higher levels of bilirubin, alkaline phosphatase, ALT and AST are all associated with MBS. ERCP is necessary to diagnose and treat benign and malignant biliary strictures.

INTRODUCTION

Biliary stricture (BS) may result from an intra or extra-luminal benign or malignant process. Although history, laboratory investigations and imaging techniques may help to differentiate benign from malignant biliary strictures, it remains a clinical challenge. Endoscopic retrograde cholangiopancreatography (ERCP) has been considered the method of choice for the diagnosis of BS as a result of its accuracy in establishing the site and cholangiographic features of stricture^[1]. Cytology specimens can be obtained, which has a sensitivity rate of only 35% but a specificity rate approaching 100% for the diagnosis of malignancy^[2].

Recently, new imaging techniques with increased diagnostic yield have emerged. For instance, magnetic resonance cholangiopancreatography (MRCP) as a non-invasive method has similar or even better diagnostic yield with the advantage of avoiding complications of ERCP^[1,3,4]. Also, with the advent of multislice CT (MS-CT), it has been possible to detect minute biliary and pancreatic tumours as well as small lymph nodes and vessels^[5]. MS-CT cholangiography has become valuable in pre-operative evaluation and determining unresectability^[6]. Therefore, CT has maintained as the method of choice for pancreatic and biliary tumours imaging^[7,8]. Furthermore, intraductal ultrasonography (IDUS) has been valuable in the differentiation of MBS from BBS. It has increased the accuracy of ERC-tissue sampling, but it has not been suitable for staging lymphadenopathy-associated MBS^[8].

The aim of this study was to identify the clinical, biochemical and or radiological predictors of malignant biliary strictures.

MATERIALS AND METHODS

All patients with biliary strictures from March 1998 to August 2002 who had ERCP or PTC in case of unsuccessful ERCP were included. Demographic characteristics, presenting features, laboratory data, imaging technique findings and management modalities were analyzed.

Definition of biliary strictures was suggested by cholangiographic features and it was supported by brush cytology, fine needle aspiration (FNA), the presence of mass or metastases by imaging and or clinical follow-up.

ERCP was performed by three experienced gastroenterologists using 4.2 mm channel duodenoscopes (Pentax or Olympus). All patients received diazepam and demerol as premedication. In addition, patients with biliary dilatation received cefuroxime prophylaxis. Endoscopic and cholangiographic findings were recorded.

Biopsy and brushing materials were obtained when feasible, strictures dilated with balloon or Soehendra dilator and large 10-12 F stent inserted.

Data collected were entered into the computer using Microsoft Excel. After all data were checked for completeness, statistical analysis was performed using Stat Pac gold analysis software and Microsoft Excel programs. Two-tailed P values of less than 0.05 were considered statistically significant. A receiver operator characteristic (ROC) curve was constructed

to determine the optimal laboratory diagnostic criterion threshold (*i.e.* total bilirubin, ALT, AST and alkaline phosphatase) in predicting a malignant biliary stricture. A ROC curve displayed the false positive rate on the x axis (specificity), and the true positive rate on the y axis (sensitivity) for varying test thresholds, thus plotting the performance of a diagnostic test^[10]. The ideal cut-off criteria for the laboratory results were chosen by determining the point lying geometrically closest to an ideal test with 100% specificity and sensitivity^[11].

RESULTS

One hundred twenty six patients were included, 54 of those had a BBS while 72 had a MBS. The main causes of BBS were related to stone disease (choledocholithiasis, Mirizzi syndrome or postcholecystectomy). In 22 patients the cause could not be identified. Cholangiocarcinoma and pancreatic head carcinoma were the most common causes of MBS. Other causes of BS are shown in Table 1.

The mean age of patients with MBS (62.4±11.7 years) was significantly higher than that of patients with BBS (53±18 years) ($P=0.0006$). Fifty percent of BBS were proximal ($P=0.01$) and approximately 50% of MBS were distal ($P<0.001$). There were no significant gender differences (Table 2). Jaundice was found in more than 80% of patients with BBS and MBS, and right upper quadrant (RUQ) pain in 50% of patients. Anorexia, weight loss and fever were less common and no significant differences were observed when both groups were compared (Table 3).

Table 1 Causes of biliary strictures ($n=126$)

Benign	n	%	Malignant	n	%
Choledocholithiasis	12	22	Cholangiocarcinoma	31	43
Mirizzi syndrome	7	13	Pancreatic head CA	23	32
Postcholecystectomy	6	11	Ampullary CA	5	7
Sclerosing cholangitis	3	5.5	Gallbladder CA	5	7
Choledochal cyst	2	3.7	Metastatic CA	4	5.5
Chronic pancreatitis	1	1.9	Hepatocellular CA	2	2.7
Juxtapapillary diverticulum	1	1.9	Lymphoma	2	2.7
Non-specified	22	40.7			
TOTAL	54		TOTAL	72	

Table 2 Demographic data of patients with biliary strictures ($n=126$)

	Benign	Malignant	P value
Number of patients	54 (%)	72 (%)	
Mean age	53±18	62.4±11.7	0.0006
Males	25 (46)	41 (56.9)	0.2255
Females	29 (54)	31 (43.1)	0.2255
Sites of biliary stricture			
Proximal	27 (50)	20 (27.7)	0.0107
Middle	22 (41)	17 (23.6)	0.0394
Distal	5 (9)	35 (48.6)	<0.001

Table 3 Presenting symptoms of patients with biliary strictures ($n=126$)

	Benign $n=54$ (%)	Malignant $n=72$ (%)	P value
Jaundice	44 (81)	61 (84.7)	0.5884
RUQ pain	27 (50)	38 (52.8)	0.7561
Weight loss	4 (7)	11 (15.3)	0.1326
Fever	3 (5)	7 (9.7)	0.3066
Anorexia	4 (7)	7 (9.7)	0.5843

Mean serum values of bilirubin, alkaline phosphatase, ALT and AST were significantly higher in patients with MBS. However GGT levels were not significantly different in both groups (Table 4).

As shown in Table 5 and Figure 1, ROC analysis identified total bilirubin of 84 $\mu\text{mol/L}$ as the best cut-off value for predicting a malignant biliary stricture with a sensitivity of 98.6%, a specificity of 59.3% and a positive likelihood ratio of 2.42 (area under the curve=0.735, SE=0.044, 95% CI=0.649-0.810). On the other hand, ROC analysis showed that other laboratory tests including ALT, AST and alkaline phosphates to have a poor sensitivity and specificity.

Proximal biliary dilatation was more frequently encountered in MBS compared to BBS, 73.8% vs 39.5% ($P=0.0001$). Majority of patients, 87% of BBS and 78% of MBS were treated endoscopically.

Table 4 Laboratory data of patients with biliary strictures ($n=126$)

	Benign $n=54$	Malignant $n=72$	P value
Total bilirubin ($\mu\text{mol/L}$)	142.6±98.4	184.61±120.8	0.0389
Direct bilirubin ($\mu\text{mol/L}$)	102.4±95.3	138.10±98.5	0.0433
Alkaline phosphatase (IU/L)	108.5±48.5	145.50±57.5	0.0002
GGT (IU/L)	397.0±496.5	436.50±325.1	0.591
ALT (IU/L)	52.7±38.3	66.94±35.6	0.0339
AST (IU/L)	76.5±43.2	107.80±45.7	0.0002

Table 5 Receiver operator characteristic (ROC) test results in predicting malignant biliary strictures

Parameter	Cut-off value	Sensitivity (%)	Specificity (%)	+LR	-LR
Total bilirubin ($\mu\text{mol/L}$)	84	98.6	59.3	2.42	0.02
Direct bilirubin ($\mu\text{mol/L}$)	63	91.7	61.1	2.36	0.14
Alkaline phosphatase (IU/L)	136	59.7	83.3	3.58	0.48
GGT (IU/L)	246	80.6	53.7	1.74	0.36

DISCUSSION

The differentiation between benign and malignant biliary strictures can be difficult but is of obvious importance in regard to prognosis and planning optimal therapy.

In our study, majority of patients with BS presented with obstructive jaundice and half had right upper quadrant pain. Other less frequent symptoms included anorexia, weight loss and fever. In contrast to Tandon *et al*^[12], who have encountered more anorexia and weight loss in MBS, we found no significant difference between MBS and BBS. This could be due to the early stage at presentation in our patients.

In our study, although statistically significant differences were found in most biochemical parameters, bilirubin was the best predictor of malignant biliary stricture. A serum bilirubin level of 84 $\mu\text{mol/L}$ or greater was highly predictive of malignant biliary stricture with a sensitivity of 98.6%, a specificity of 59.3% and a positive likelihood ratio of 2.42. Furthermore, proximal biliary dilatation was more frequently encountered in MBS compared to BBS, 73.8% vs 39.5% ($P=0.0001$). Similarly, in a prospective study of 29 patients, Bain *et al.* have shown that a bilirubin of level of 75 $\mu\text{mol/L}$ or greater or a stricture length of greater than 14 mm was highly predictive of malignant biliary stricture. In the same study, intrahepatic duct dilatation was present in 93% of malignant strictures versus 36% of BBS ($P=0.002$)^[13].

In our study, we found that distal bile duct strictures were mainly due to a malignant process, 48.6% vs 9% in BBS ($P<0.001$), which is contrary to other studies. This is probably because we have rarely encountered BBS secondary to chronic pancreatitis which is commonly present with distal benign BS (we had only one patient).

ERCP remains to be an important imaging technique in the diagnosis and treatment of obstructive jaundice^[14]. The yield of ERCP in differentiating MBS from BBS can be further improved with tissue sampling. Sensitivity of biliary fluid and brushing cytology is unsatisfactorily low. It can be improved by combining fine needle aspiration biopsy with intraductal forceps biopsy. This method has been known as triple tissue sampling^[15,16]. Despite the triple tissue sampling, the sensitivity and negative predictive value have not exceeded 62% and 39%, respectively^[16]. Furthermore, brushing cytology yield could be improved by stricture brushing after a 10 F dilatation of malignant stricture^[17]. Similar observation on improvement of bile cytology has been reported earlier by Mohandas *et al*^[18]. Evaluation of cytology specimens for aneuploidy and tumour markers, CA 19-9 and CEA might also increase the diagnostic yield^[19].

Recently, intraductal ultrasonography (IDUS) has been evaluated in the differential diagnosis of MBS from BBS with conflicting results. While Gress *et al.* have not found reliable differentiation criteria^[20], Inui *et al.* and Tamada *et al.*, who used special biliary and pancreatic probes, have provided encouraging results^[21,22]. However, its accuracy is still not exceeding 80%. IDUS has been reported to be superior to conventional endoscopic ultrasonography in terms of diagnostic accuracy, and prediction of tumour respectability^[23].

Treatment of BS depends on the etiology, benign or malignant, magnitude of damage in post-surgical injuries and prediction of respectability of MBS. Endoscopic management of BBS has been considered the primary method before the decision of surgical intervention^[24]. Major bile duct injuries require surgical construction. After initial evaluation of anatomy by direct cholangiogram and inserting a biliary drain, surgical reconstruction with Roux-en-Y hepaticojejunostomy has been associated with an overall success rate exceeding 90%^[25]. It has been considered as the best treatment modality of BBS^[26]. On the other hand Born *et al.* have considered endoscopic or percutaneous management as an adequate short and long-term alternative to surgery^[27].

The decision of therapeutic modality for biliary or pancreatic tumours depends on the evaluation of respectability. It is important to determine preoperatively the spread of MBS. These events may help decide the appropriate treatment for

each condition. Surgery has to be considered for the management of resectable tumours. However, at the time when the diagnosis of MBS has been established, it is often late for curable resection^[28]. Therefore, endoscopic approach remains the method of choice for palliation. Majority of our patients (78%) had endoscopic palliation.

In a large series with 505 patients, Costamagna *et al.* strongly suggested ERCP in the diagnosis and palliation of all patients with suspected MBS^[29]. ERCP has been considered as the optimal technique for diagnosis and palliation of MBS^[30].

In conclusion, a serum bilirubin level of 84 $\mu\text{mol/L}$ or greater is the best predictor of MBS. Older age, proximal biliary dilatation, higher levels of bilirubin, alkaline phosphates, ALT and AST are all associated with MBS. ERCP is the best imaging technique in demonstrating stricture and biliary dilatation, and remains the method of choice in managing BBS and MBS.

Abstract

AIM: To investigate the relationship between gallbladder stone disease (GSD) and single nucleotide polymorphisms of cholesterol 7 α -hydroxylase (*CYP7A*) gene promoter, apolipoprotein (*APO*) B gene exon 26, *APOE* gene exon 4 or microsatellite polymorphism of low density lipoprotein receptor (*LDLR*) gene exon 18.

METHODS: Genotypes of *CYP7A*, *APOB*, *APOE* and *LDLR* genes were determined in 105 patients with GSD diagnosed by B-mode ultrasonography and 274 control subjects. Serum lipids were analyzed with HITACHI 7060 automatic biochemical analyzer.

RESULTS: Body mass index (BMI) was significantly higher in patients with GSD (24.47 \pm 3.09) than in controls (23.50 \pm 2.16). Plasma total cholesterol was lower in patients with GSD (4.66 \pm 0.92 mmol/L) than in controls (4.91 \pm 0.96 mmol/L), $P < 0.01$ after adjusted for age, sex and BMI. The significantly higher frequency of A allele of *CYP7A* gene polymorphism and X+ allele of *APOB* gene polymorphism was seen in GSD patients. Percentages of A allele in patients and controls were 62.86% and 54.38% ($P < 0.05$) and those of X+ allele 8.57% and 4.01% ($P < 0.01$). Subjects with A allele had significantly lower plasma total cholesterol and LDL cholesterol than subjects with CC homozygote. In a multiple variable logistic regression model, the BMI (OR=1.13, 95% CI: 1.05-1.22), A allele (OR=1.48, 95% CI: 1.05-2.09) and X+ allele (OR=2.28, 95% CI: 1.14-4.59) were positively associated with GSD ($P < 0.05$). Plasma total cholesterol (OR=0.69, 95% CI: 0.64-0.74) was negatively related to GSD ($P < 0.05$).

CONCLUSION: With an association analysis, it was determined that A allele of *CYP7A* gene and X+ allele of *APOB* gene might be considered as risk genes for GSD. These alleles are related with differences of serum lipids among subjects. Multiple-variable logistic regression model analysis showed that besides BMI, GSD was affected by polygenetic factors. But the mechanism for these two alleles responsible for GSD requires further investigations.

INTRODUCTION

Gallbladder stone disease (GSD) is prevalent in China with a gradually increasing incidence. Studies on the pathogenesis of GSD have demonstrated that supersaturation of biliary cholesterol caused by excessive biliary cholesterol and/or decreased bile acid is the requisite for the formation of gallstones^[1]. Both the cholesterol secreted into bile and the bile acids converted from cholesterol in the liver are involved in regulating cholesterol homeostasis. It was shown in studies^[2-4] that genetic variations might affect gallstone formation. In 1995, Khajuana *et al.* reported a murine lithogenic gene, *Lith 1*, as a possible regulator of hepatic cholesterol synthesis^[4]. The primary *Lith* phenotype was considered to induce secondary events characterized by multiple enzyme alterations which increase available cholesterol and supply the sterol to hepatocytes for hypersecretion into bile^[5]. Additional quantitative traits linkage analysis^[6] maps other *Lith* genes on murine chromosomes 6, 7, 8, 10, 19 and X to confirm the polygenic mode of inheritance. A few studies^[7-10] have focused on the relationship between human GSD and certain genetic factors contributing to cholesterol metabolism.

Cholesterol 7 α -hydroxylase (*CYP7A*, EC 1.14.13.17), a cytochrome P-450 enzyme, is the rate limiting enzyme of hepatic bile acid synthesis, with its activity regulated by bile acids, cholesterol and hormones^[11]. Although the amino acid sequence of *CYP7A* between species is highly homologous (80-90% sequence identity), species respond differently to diet cholesterol^[12]. As compared with control subjects, the activity of *CYP7A* varied in patients with gallstones^[13-15], and diminished or elevated patterns were observed. The heterogeneity of activities of *CYP7A* in patients with GSD may be related to *CYP7A* polymorphisms. A linkage of A-204C single nucleotide polymorphism of the *CYP7A* gene promoter with plasma low density lipoprotein (*LDL*) cholesterol was found in recent studies of nuclear families^[16] and within the general population^[17]. However, the polymorphism for patients with GSD has never been studied. Apolipoprotein (*APO*) E^[18] is an extremely efficient ligand for the *LDLR* and is the determinant for receptor-mediated catabolism of all *APOE* containing lipoproteins. The polymorphism of *APOE* is controlled by three alleles in exon 4, namely $\epsilon 2$, $\epsilon 3$ and $\epsilon 4$. The physiological importance of *APOE* exhibits in disorders of lipoprotein metabolism such as atherosclerosis^[19] as well as in Alzheimer's disease which is not obviously related to lipoprotein metabolism^[20]. The role of *APOE* has also been examined in relation to GSD^[7,9]. The *APOE4* allele is associated with high cholesterol content in gallstones^[7,9], faster crystallization^[7] and frequent stone recurrence after lithotripsy^[21].

The *LDLR* on the surface of hepatocytes plays an important role in cholesterol homeostasis in humans^[22]. The receptor can recognize *APOB* or *APOE* containing lipoproteins such as LDL and high-density lipoprotein (HDL) with different affinities mediating the absorption of plasma lipoproteins. There are many polymorphic sites on this gene and some of those are related to plasma cholesterol metabolism^[23].

In the present study, we analyzed the polymorphism of A-204C of *CYP7A* gene promoter, *APOE* exon 4 and microsatellite polymorphism of *LDLR* gene exon 18. Their relationships with asymptomatic GSD on the Chinese Han population were examined. The association of Xba I polymorphism on *APOB* gene exon 26 with GSD, shown in our previous study^[10], was also evaluated using multiple regression analysis.

MATERIALS AND METHODS

Patients

A total of 379 subjects were recruited for this study from February to May 1998. Patients in this study consisted of 78 males and 27 females with stones and/or cholesterol crystals in their gallbladder. None of the patients had previous onset of cholecystitis defined as colic, fever with chills or jaundice. Two hundred and seventy-four healthy subjects (184 males and 90 females) with normal liver, kidney and endocrine function were included as controls. The mean ages of patients and controls were 47.53 and 47.94 years, respectively. After a 12-h fast, the participants received B-mode ultrasonography with Aloka 500/SSD equipped with a transducer of 3.5 MHz. A total of 10 mL venous blood was extracted and half of it was immediately mixed with ACD anti-coagulants containing citric acid, sodium citric acid and glucose for DNA extraction. The other half of this sample was prepared for biochemical analysis. Body mass index (BMI) was calculated by weight/height² (kg/m²). All subjects gave informed consent to participate in this study which was approved by the Ethical Committee of Ruijin Hospital, Shanghai Second Medical University.

Analysis of plasma lipids and lipoproteins

Plasma total cholesterol, triglyceride, HDL cholesterol, LDL cholesterol, APO AI and APO B were assayed by commercially available kits (Boehringer Mannheim GmbH, Mannheim, Germany) on an automatic analyzer (HITACHI 7060, Hitachi Koki Co. Ltd., Hitachinaka City, Japan).

Genotyping

Genomic DNA was extracted from leukocytes using a method provided by GIBCO-BRL DNA extraction kit (Cat: #28350-015, GIBCO-BRL, Gaithersburg, MD, USA). The fragments containing target polymorphic sequences of *CYP7A*, *APOB*, *APOE* and *LDLR* genes were amplified using polymerase chain reaction (PCR) on PTC-200 Peltier Thermal Cycler (MJ Research Inc, MA, USA). Primers and the conditions of PCR are listed in Table 1. For the single nucleotide polymorphisms of *CYP7A*,

APOB and *APOE*, the products of PCR were each digested by restriction enzymes (New England Biolabs Inc., Beverly, MA, USA). The enzymes are indicated in Table 1. The digested PCR products were electrophoresed in agarose gel; then stained with ethidium bromide and visualized under ultraviolet light. A 968-bp fragment containing A-204C polymorphism of *CYP7A* gene was digested with restrictive enzyme *Bsa I* (New England Biolabs Inc., Beverly, MA, USA) and electrophoresed on 10 g/L agarose gel and stained with ethidium bromide. The band with a cutting site was designated as C allele and that without as A allele. A 244-bp fragment containing *APOE* exon 4 gene was digested with *Hha I* followed by electrophoresis on 100 g/L polyacrylamide gel and then stained with silver. The genotypes were determined from the pattern of restrictive fragments on the gel as described in detail by Hixson and Vernier^[24]. The bands representing the genotype of microsatellite polymorphism of *LDLR* gene exon 18 were obtained from direct electrophoresis on 100 g/L PAGE (100 v, 2.5 h) and stained with silver. The genotype of *LDLR* gene was determined for the bands with 106-bp as A allele (7 repeats of TA), 108-bp as B allele (8 repeats of TA) or 112-bp as C allele (10 repeats of TA)^[25]. Genotyping of *APOB* gene was performed as previously described by Han *et al.*^[10].

Statistics

The results were expressed as means±SD. The differences in concentrations of lipids between patients and controls and those among genotypes were calculated using Student's *t* test. Statistical analysis was performed using the statistical software package SAS 6.12 for Windows (SAS Institute Inc., Cary, NC, USA). SAS GLM procedure was used to compare the concentrations of lipids between patients and controls after adjustment for sex, age and BMI. Frequencies of alleles between patients and controls were evaluated for statistical significance using Chi-square test. A multivariate model was used to predict the relative odds of GSD with all the variables by multiple logistic regressions. Logistic regression coefficients and standard errors were calculated to determine the estimates of odds ratio (OR) and 95% confidence intervals (CI) for significant factors.

RESULTS

Demographic and biochemical characteristics

Gallbladder stones and/or cholesterol crystals were detected in 105 cases by B-mode ultrasonography. The demographic characteristics and biochemistry are shown in Table 2. BMI was significantly higher in the patients than in the controls (24.47±3.09 vs 23.50±2.16, *P*<0.01). Concentrations of plasma total cholesterol and APO AI were significantly lower in patients than in controls. Although the concentrations of HDL cholesterol and LDL cholesterol were slightly lower in patients than in controls, the differences were not significant. Plasma lipid levels varied with sex, age and BMI. We compared the plasma lipids between patients and controls using the analysis of covariance. After

adjustment for sex, age and BMI, the plasma total cholesterol and LDL cholesterol as well as APO B were found significantly lower in patients than in controls as shown in Table 2.

Table 2 Demographic characteristics and biochemistry for patients and controls

	Patients	Controls	P value	P value ¹
No. (male/female)	105 (78/27)	274 (184/90)		
Age (yr)	47.53±10.98	47.94±12.21		
BMI (kg/m ²)	24.47±3.09	23.50±2.16	<0.01	
Triglycerine (mmol/L)	1.32±1.15	1.19±0.82		
Cholesterol (mmol/L)	4.66±0.92	4.91±0.96	<0.05	<0.01
HDL (mmol/L)	1.33±0.36	1.40±0.34		
LDL (mmol/L)	2.56±0.67	2.69±0.73		<0.05
apo A I (g/L)	1.34±0.21	1.39±0.18	<0.05	
apo B (g/L)	1.00±0.22	1.03±0.24		<0.05

¹After adjustment for sex, age and BMI.

Distribution of genotypes and association of polymorphisms with GSD

Figure 1 indicates the genotypes of *CYP7A*, *APOB*, *APOE* and *LDLR* gene polymorphisms. The distributions of genotypes for patients and controls are listed in Table 3. Using Chi-square test, there was a significantly higher frequency of A allele of *CYP7A* gene and X+ allele of *APOB* gene observed in patients compared with controls (A allele: 62.86% vs 54.38%, $P<0.05$; X+ allele: 8.57% vs 4.01%, $P<0.01$, Table 4). There were no significant differences between patients and controls in the polymorphisms of *APOE* gene and *LDLR* gene.

Association between gene polymorphism and plasma lipid concentrations

Table 5 indicates that plasma total cholesterol, LDL cholesterol and APOB were lower in subjects with A allele (AA homozygote or AC heterozygote) than in those without A allele (CC homozygote). The difference was significant only within the control group or within the group combining patients and controls, but not in the patients only group. Within each genotype, the difference of lipid concentration was incongruent between

patients and controls. In subjects with A allele, the LDL cholesterol was significantly higher in patients than in controls, while in subjects without A allele, patients had significantly lower concentrations of HDL cholesterol and APOAI.

Table 3 Distribution of genotypes for patients and controls

Genes	Genotypes	Patients (%)	Controls (%)
CYP7A	AA	44 (41.90)	79 (28.83)

Logistic regression analysis

A multiple variable logistic regression analysis was performed to compare the effects of both genetic factors and other quantitative variables. In Table 6, only *CYP7A* (OR=1.48, *P*<0.05) and *APOB* (OR=2.28, *P*<0.05) gene polymorphism, plasma cholesterol (OR=0.69, *P*<0.01) and BMI (OR=1.13, *P*<0.05) were correlated with GSD (Table 6).

Table 6 Stepwise logistic regression of multiple variables

Variables	OR	95% CI
A allele ^a	1.48	1.05-2.09
X+ allele ^a	2.28	1.14-4.59
Cholesterol ^b	0.69	0.64-0.74
BMI ^a	1.13	1.05-1.22

^a*P*<0.05; ^b*P*<0.01.

DISCUSSION

Epidemiological studies have stressed the relationship between plasma lipid concentration and GSD. The present study indicated that patients with GSD had lower plasma cholesterol, even after adjustment for sex, age and BMI. Our results were consistent with those of Juvonen^[7], Scragg^[26] and Attili^[27], although there were unchanged results^[28] or only lowered plasma cholesterol levels in women^[29] reported by other authors. The plasma lipid concentrations varied in populations due to diet habits, genetic factors, ethnicity, etc. This explains why previous studies remain controversial. Whether changes in plasma lipid concentration are major factors inducing GSD or represent the end stage of gallstone formation is still questionable. The mechanism for the change in plasma lipid concentrations that increases the risk for GSD is also unclear. However, epidemiological studies indicate that genetic predisposition has been confirmed to have a close relation with GSD. Our present study on the Chinese Han population verified that GSD was genetically controlled by polygenic factors. A-204C polymorphism at *CYP7A* gene promoter and Xba I polymorphism at *APOB* gene may be susceptible genes linked to GSD.

Our previous study on the *APOB* gene Xba I polymorphism revealed that X+ allele was associated with a higher incidence of GSD^[10]. The relationship between GSD and the other three polymorphic sites, A-204C polymorphism of *CYP7A*, Hha I polymorphism of *APOE* and a dinucleotide repeat microsatellite polymorphism of *LDLR*, was also studied by our group. Only did *CYP7A* gene polymorphism seem to be related to GSD. We found a significantly higher frequency of A allele in patients than in controls (0.62 vs 0.54, *P*<0.05). The A-204C polymorphism located 204 bp upstream of the transcription start site of *CYP7A*^[17]. This single nucleotide polymorphism^[16],

at which site C replaced A, created a cutting site for the Bsa I restrictive enzyme. The frequency of A allele of *CYP7A* gene was 0.58^[16] in the Caucasian population and 0.60 in Framingham families^[17] which was slightly higher than that in the Chinese Han population. Analysis of plasma lipid levels revealed that plasma LDL cholesterol concentrations were associated with A-204C polymorphism, similar to the results of Wang *et al.* and Couture^[16,17]. Individuals with A allele tended to have lower LDL cholesterol concentrations. This difference was significant in controls, but not in patients in this study. No studies have assayed the activity of hepatic *CYP7A* among different genotypes up to this time. The mechanism and rationale for A allele to induce low LDL cholesterol are still unknown.

Contrary to our expectation, there was no association between *APOE* gene and GSD or between *LDLR* gene and GSD. Since *APOE* isoforms had different affinities to receptors^[22] affecting lipid metabolism, there was a demonstrated relationship between *APOE* gene polymorphism and various plasma lipids. Its polymorphism was well documented in atherosclerosis^[19] and Alzheimer's disease^[20] as well as cholesterol gallstone disease^[7,9]. Juvonen^[7] studied for the first time the relationship between *APOE* polymorphism and gallstones. Patients with ε4 allele had higher cholesterol content in stones, rapid cholesterol crystallization and shorter median nucleation time in the Finnish population^[7] while Bertomeu^[9] found significantly higher ε4 allele frequency in Spanish patients with gallstones. But other studies^[9,30,31] had contradictory results. There were reports that median nucleation time^[9] was similar in patients between the genotypes and that the cholesterol saturation index^[30] was lower in patients with ε4 allele. Our study concluded that there was no significant difference in the frequency of ε4 allele between patients and controls. A similar result on Chinese patients with GSD was reported previously in a study from Sichuan, China^[32].

LDLR was important for the absorption of APOB and APOE containing lipoproteins^[22]. Herein, we studied a dinucleotide repeat polymorphism. The frequency of these alleles did not differ between the patient and control groups. But we could not exclude the possibility of existence of other polymorphic sites to account for the differences in hepatic LDLR activities that, in turn, would lead to high absorption of plasma cholesterol for biliary secretion.

We analyzed all our variables using a logistic regression model to evaluate the role of genetic factors and quantitative variables. Higher cholesterol concentration in serum may provide a protective factor for GSD since it is negatively related with GSD (OR<1). The cause of gallstone formation might be due to hepatic overabsorption of cholesterol via receptors such as SRB1^[33] or LDLR^[22] leading to hypersaturation of biliary cholesterol. Besides BMI and cholesterol, GSD may be controlled by multiple genetic factors such as the *APOB* gene or *CYP7A* gene. The OR of the *APOB* gene polymorphism

was 2.28, and *CYP7A* was 1.48 with $P < 0.05$. This implies that subjects with A allele of *CYP7A* gene or X+ allele of *APOB* gene can easily form gallstones.

The present study determined the relationship between *CYP7A* or *APOB* gene polymorphism and GSD. However, the relationship should be investigated further in family pedigrees with GSD. Since gene polymorphisms are heterogeneous among ethnic groups, GSD may be caused by different risk genes among different population. The main cause for GSD is hypersaturation of biliary cholesterol. So all genes (known or yet to be determined) involved in hepatic cholesterol metabolism remain the focus for future studies to discover the primary risk genes for GSD. Once a human genomic map for GSD, similar to murine^[34], is completed, it can be useful for early predictive and preventive measures for subjects susceptible to GSD. The genomic map will provide the necessary link in the discovery of effective pharmaceutical agents for treatment.

Abstract

AIM: To study the different therapy for different types of ulcerative colitis (UC) in China.

METHODS: Among 102 UC patients, 42 chronic relapse type UC patients were randomly divided into olsalazine sodium treatment group ($n=21$) and SASP group ($n=21$). Clinical effects and safety were observed in the 2 groups. Forty-two first episode type UC patients were randomly divided into Heartleaf houttuynia herb treatment group ($n=21$) and SASP group ($n=21$). Clinical effects were observed in the 2 groups while ultrastructure of colonic mucosa, ICAM-1 and the pressure of distant colon were studied in Heartleaf houttuynia herb group. Eighteen patients (8 males, 10 females) with refractory UC and unresponsive to high-dose prednisolone and sulfasalazine therapy more than one month were treated with Kangshuanling (7 200 U/d). Prednisolone was gradually stopped and sulfasalazine was maintained. Stool frequency, rectal bleeding, colonoscopy, general well-being, histology were observed and CD62p, CD63, CD54, Pgp-170 (flow cytometry), TXA2 (RIA), blood platelet aggregation rate and thrombosis length *in vitro* were assessed.

RESULTS: In the 42 chronic relapse type UC patients, the overall clinical effects of olsalazine sodium group (complete remission in 16, improvement in 4, inefficiency in 1) were better than those of SASP group (complete remission in 10, improvement in 4, inefficiency in 7, $P<0.05$). Symptomatic remission of olsalazine sodium group (complete remission in 15, partial remission in 5, inefficiency in 1) was better than that of SASP group (complete remission in 10, partial remission in 5, inefficiency in 6, $P<0.05$). The colonoscopic remission of olsalazine sodium group (complete remission in 11, partial remission in 9, inefficiency in 1) was better than that of SASP group (complete remission in 7, partial remission in 8, inefficiency in 6, $P<0.05$). The histologic remission of olsalazine sodium group (complete remission in 13, partial remission in 7, inefficiency in 1) was better than that of SASP group (complete remission in 6, partial remission in 10, inefficiency in 5, $P<0.05$). The side effects of gastrointestinal tract in olsalazine sodium group were less than those of SASP group except for frequency of watery diarrhea. No other side effects were observed in

olsalazine sodium group while ALT increase, WBC decrease and skin eruption were observed in SASP group. Two patients relapsed in olsalazine sodium group while 8 cases relapsed in SASP group during the flow-up period (from six months to one year). In the 42 first episode type UC patients, the clinical effect of Heartleaf houttuynia herb group (complete remission in 20, 95.2%; improvement in 1, 4.8%) was better than that of SASP group (complete remission in 15, 72.4%, improvement in 5, 23.8%; inefficiency in 1, 3.8%, $P<0.01$). The time of stool frequency recovering to normal (5.6 ± 3.3 d), and blood stool disappearance (6.7 ± 3.8 d) and abdominal pain disappearance (6.1 ± 3.5 d) in Heartleaf houttuynia herb group was all shorter than that in SASP group (9.5 ± 4.9 d, 11.7 ± 6.1 d, 10.6 ± 5.3 d, $P<0.01$). Heartleaf houttuynia herb could inhibit the epithelial cell apoptosis of colonic mucous membrane and the expression of ICAM-1 ($45.8\pm 5.7\%$ vs $30.7\pm 4.1\%$, $P<0.05$). Compared with normal persons, the mean promotive speed of contraction wave stepped up (4.6 ± 1.6 cm/min vs 3.2 ± 1.8 cm/min, $P<0.05$) and the mean amplitude of the wave decreased (14.2 ± 9.3 kPa vs 18.4 ± 8.0 kPa, $P<0.05$) in active UC patients. After treatment with Heartleaf houttuynia herb, these 2 indexes improved significantly (17.3 ± 8.3 kPa, 3.7 ± 1.7 cm/min, $P<0.05$). In normal persons, the postprandial pressure of sigmoid (2.9 ± 0.9 kPa) was higher than that of descending colon (2.0 ± 0.7 kPa) and splenic flexure (1.7 ± 0.6 kPa), while the colonic pressure (1.5 ± 0.5 kPa, 1.4 ± 0.6 kPa, 1.3 ± 0.6 kPa) decreased significantly ($P<0.05$) in active UC patients. After treatment with Heartleaf houttuynia herb, the colonic pressure (2.6 ± 0.8 kPa, 1.8 ± 0.6 kPa, 1.6 ± 0.5 kPa) recovered to normal. The pain threshold of distant colon (67.3 ± 18.9 mL) in active UC patients decreased significantly compared with that of normal persons (216.2 ± 40.8 mL, $P<0.05$) and recovered to normal after treatment with Heartleaf houttuynia herb (187.4 ± 27.2 mL, $P<0.05$). In the 18 refractory UC patients with platelet activation, after more than 4 wk of combined Kangshuanling and sulfasalazine therapy, 16 patients achieved clinical remission, with a highly significant statistical difference ($P<0.01$) between pre-and post-treatment mean scores for all disease parameters: stool frequency (8.2/d vs 1.6/d), rectal bleeding (score 2.7 vs 0.3), colonoscopy (score 2.6 vs 1.1), histology (score 12.0 vs 5.0), general well being (score 4.0 vs 0.6) and CD62p ($8.0\pm 3.1\%$ vs $4.1\pm 1.8\%$), CD63 ($6.3\pm 2.1\%$ vs $3.2\pm 1.6\%$), TXA2 (548 ± 85 ng/L vs 390 ± 67 ng/L), platelet aggregation rate ($43.2\pm 10.7\%$ vs $34.8\pm 8.1\%$), thrombosis length *in vitro* (2.3 ± 0.6 cm vs 1.8 ± 0.3 cm), CD54 in blood ($26.9\pm 6.9\%$ vs $14.4\pm 5.1\%$), CD54 in tissues ($51.1\pm 6.2\%$ vs $23.1\pm 4.1\%$), Pgp-170 in blood ($18.9\pm 3.9\%$ vs $10.4\pm 2.7\%$), Pgp-170 in tissues ($16.5\pm 3.2\%$ vs $10.2\pm 2.3\%$, $P<0.01$ or 0.05).

CONCLUSION: Based on the characteristics of UC cases in China, different therapy should be given to different types of UC with expected satisfactory results.

INTRODUCTION

Ulcerative colitis (UC) is a common digestive disease in Western countries. It was believed that the occurrence of UC was rare in China. But recent reports reveal that UC cases have increased remarkably^[1,2]. According to our study, UC cases from 1991 to 2000 have increased 2.7 times compared with those from 1981 to 1990^[3-5]. Due to the fact that the etiology and mechanism of UC are still not quite clear, and there is no specific treatment available, the disease usually becomes chronic with repeated relapses, thus seriously endangering patient's health^[6-25]. SASP and corticosteroid, despite their widespread use in the treatment of UC, do not offer an ideal cure because of its long course of treatment, various adverse reactions as well as tendency to relapse when medication stops. The emphasis laid on the study of UC, therefore, is to find an effective drug with fewer adverse reactions in accord with the characteristics of UC cases in China. The diagnosis and treatment of UC still remain a challenge to clinicians^[26-34]. Respecting treatment and improvement of curative effect in refractory cases, lower of relapse rate and reduction of side effects of aminosalicylic acid and corticosteroids are questions to be encountered. Based upon the characteristics of UC cases in China, we adopted the method of giving different therapy to different types of UC, hoping to get better therapeutic results.

MATERIALS AND METHODS

Total cases

A total of 102 UC patients (42 chronic relapse type, 42 first episode type, 18 refractory type) were studied, their diagnoses conformed to the criteria of Lennard-Jones^[28].

Chronic relapse type

Among the 42 chronic relapse type cases, 19 were males and 23 females with an average age of 32.6 years. They had a UC history of 6 mo to 5 years and bloody diarrhea, abdominal pain of varying degrees. Pathological changes above the sigmoid were found in 12 and 30 patients by colonoscopic examinations, respectively. Lesions were characterized by ulcerations, crypt abscesses, non-specific inflammation and atypical hyperplasia, etc. They were randomly divided into treatment group which received olsalazine sodium capsules (Tianjin Lisheng Pharmaceutical Co., Ltd. 250 mg) were used twice a day (1.0 g/d) for 8 wk, and comparison group received sulfasalazine (1.0) 4 times a day for 8 wk. There was no significant difference in the severity of symptoms between olsalazine group (11 mild, 8 moderate, 2 severe) and SASP group (13 mild, 7 moderate, 1 severe, Ridit analysis, $P>0.05$). For patients who could not tolerate diarrhea of 2-3 times a day, 1-2 bills of imodium were given daily, but not more than 10 d. Patients were seen before and after 1, 2, 4, 6, 8 wk of treatment. Symptoms and physical signs were recorded. Colonoscopy was done 3 d before treatment and within 3 d after completion of treatment. A total of 7 items were observed and recorded. Purulent secretion and pseudopolyp were classified into 2 grades. Ulcer, erosion, mucous bleeding, hyperemic edema and vascular blurring were classified into grades 0, 1, 2, 3, 4 based upon the severity (0=nil, 1=mild, 2=moderate, 3=relative severe, 4=severe). Routine blood and stool tests were performed before and after 1, 2, 4, 6 and 8 wk of treatment. Coagulation time and erythrocyte sedimentation rate were examined before and after 4 and 8 wk of treatment. Blood serum potassium, sodium, chloride, anhydride, urea nitrogen, ALT and total bilirubin were examined before and after 8 wk of treatment. Histological examination with grading of its changes was performed on colonoscopic biopsy specimens before and after treatment (grade 0: no polymorphonuclear cell, grade 1: some polymorphonuclear cells in lamina

propria, grade 2: obvious polymorphonuclear cells infiltration in lamina propria involving more than 50% of recesses, grade 3: massive polymorphonuclear cells with recess abscess, grade 4: obvious acute inflammation with ulcer). Criteria of therapeutic efficacy were adopted that proposed by Chinese Society of Gastroenterology^[35] (complete remission: subsidence of clinical symptoms with relative normal mucous membrane in colonoscopy, effective: basically without symptoms and mild mucous inflammatory reaction or pseudopolyp formation upon colonoscopy, ineffective: no improvement in clinical symptoms, colonoscopic and pathologic examinations). Complete clinical remission: after 8 wk treatment, defecation 0-2 times a day, with no gross blood or microscopic red cells in stool; partial remission: after 8 wk of treatment, defecation 3-4 times a day, with no gross blood in stool but less than 10 RBC per high power microscopic field; no improvement: defecation 5 times or more per day with gross bloody stool. Colonoscopic remission: complete remission (among the 7 items, 5 or more lowered by a grade after treatment), partial remission (3-4 items lowered by a grade after treatment), no remission (0-2 items lowered by a grade after treatment). Histological remission: complete remission (pathological grade lowered after treatment, being grades 0-1), partial remission (pathological grade lowered after treatment, but still >1), no remission (no change before and after treatment). Adverse reactions record: nausea, diarrhea, insomnia, abdominal pain, dizziness, rash, lumbar soreness, edema, etc. Their time of occurrence, severity, duration and measures taken for treatment were recorded.

First episode type

Among the 42 cases of first episode type, 16 were males and 26 females with average age of 31.4 years. They had a UC history of 1 mo to a year, and all had bloody diarrhea, abdominal pain of different degrees. Lesions above the sigmoid were found in 2 patients by colonoscopic examination, while pathological changes were found below the sigmoid in 40 patients. Lesions were characterized by ulceration, crypt abscesses, non-specific inflammation and atypical hyperplasia, etc. They were randomly divided into treatment group that received treatment of heartleaf houttuynia (2 kg/L, pH 4.0-6.0, Nanfang pharmaceutical Co., Ltd.) enema (20 mL diluted with NS 100 mL, once every evening before sleep for 1-2 mo), and SASP group that administered 1 g of SASP four times a day for 1-2 mo. Clinical observations included frequency of defecation, bloody stool, and general condition. Therapeutic effects^[28]: complete remission (complete disappearance of symptoms with mucous membrane returned to normal in colonoscopy), partial remission (abatement of symptoms with conditions of mucous membrane improved, only a small amount of red blood cells and leucocytes found in routine stool test), no remission (no obvious changes both in symptoms and in colonoscopy). Ultrastructure^[7] Microvilli, mitochondria and apoptosis were observed under electronic microscopy. Content of CD54 (ICAM-1, Immunotech) in colonic mucous membrane was examined according to our methods^[15].

PC Polygraph HR (CTD-SYNECTICS, Sweden) was used to examine colonic motility. Distances between the 8 tracts (outer diameter 8 mm and side hole diameter 1 mm) of manometric tube were 5 cm, medication that would affect gastrointestinal motility was suspended at least for 3 d before the examination. Intestinal tract was cleaned in the afternoon prior to the examination and food intake was suspended during the day of examination. Manometric tube was inserted to colonic splenic flexure as guided by colonoscopy. Colonic motility of each patient was recorded one hour before meal and two hours after meal, the result was then analyzed by Polygram and Windows Polygram. Contractions above 6.67 kPa and spreading

to side holes 10 cm away were regarded as propulsive contractions, while contractions below 1.33 kPa were not considered so as to minimize the effect of respiration. Baseline was automatically set up by computer, which calculated the mean oscillation amplitude every 30 min before and after meals. Hand injectors were used to fill air of 20 mL each time to the self-made rubber air pocket with the maximum capacity of 120 mL at 30 s intervals. Patients' feeling of expansion of air pocket was recorded (cognitive, defecation and pain threshold values).

Refractory UC patients with platelet activation

Among the 18 refractory UC patients, there were 8 males and 10 females aged 20 to 52 years (mean 32.4 years), including 10 cases of severe UC, and 8 moderately severe UC. Duration of diseases ranged from 7 mo to 10 years (mean 4.3 years). Rectal bleeding, diarrhea, mucus stool, abdominal pain were the main symptoms. Three patients were associated with thromboembolic diseases. All patients were treated with high-dose corticosteroid and sulfasalazine for more than 4 wk without effect, sulfasalazine was maintained in combination with Kangshuanling sublingual tablet (low molecular heparin, produced by Shandong Songling Pharmaceutical Factory, 2 tablets, 3 times daily (7 200U/d) for 15 d, then 1 tablet, 3 times daily (3 600 U/d) for more than 4 wk). Prednisolone was tapered and stopped.

Pre- and post-treatment scores were calculated for the following disease parameters^[36]: (1) Stool frequency (average number per day for the past week); (2) Rectal bleeding (0: absent, 1: streak of blood on stools occasionally, 2: obvious blood on stool frequently, 3: complete bloody stools); (3) Colonoscopic appearance 0: normal vascular pattern, 1: mild lesion (loss of vascular pattern, mucosal edema, no bleeding), 2: moderate lesion (granularity and friability of the mucosa), 3: severe lesion (discrete ulceration and spontaneous bleeding); (4) Histological grading: serial biopsies from rectum and colon were taken. Five histological changes seen in UC (cellular infiltrate in lamina propria, cryptitis, crypt abscess formation, goblet cell depletion, and regenerative hyperplasia of epithelium). Each was scored from 0 (absent) to 3 (severe). A total UC score of 5 or less indicated mild disease; 5-10, moderate; and 10-15, severe disease. (5) General health status (0: excellent, 1: good, 2: poor, 3: poorer, 4: very poor, 5: poorest).

To assess platelet activation and aggregability^[22,37], we used a sensitive flow cytometric technic designed to render minimize sample handling and render fixation unnecessary to quantify platelet activation. Blood samples were incubated 10 min before venesection with fluorescein isothiocyanate (FITC) conjugated antibodies to the platelet surface antigens, P-selectin (CD62P) and CD63 (Immunotech, Marseilles, France). Analysis was made 15 min before venesection using a BD (Becton Dickinson Immunocytometry Systems) FAC scan. TXA-2 (Suzhou Medical College) was measured using RIA method, samples were taken without tourniquet into chilled tubes containing 1:9 anticoagulant/ antiaggregant solution (trisodium citrate 3.8%), centrifuged for 15-30 min, later at 4 °C for 30 min to minimize *in vitro* activation, supernatant was decanted off and stored at -20 °C for assay within 3 mo. Platelet aggregation rates (PAR) and thrombosis length (TL) *in vitro* were assessed by XSN-RII instrument according to the manufacturer's instructions. CD54 and Pgp-170 in blood and tissues were measured using flow cytometric technique according to our previous report^[15] and literature^[38,39].

Statistical analysis

T test and Ridit analysis were adopted. Student's *t* test and Friedman test were used to assess the significance of differences between mean pre- and post-treatment parameters.

RESULTS

Chronic relapse type UC

In the 42 chronic relapse type UC patients, the total clinical effect of olsalazine sodium group (complete remission in 16 cases, improvement in 4 patients, inefficiency in one case) was better than that of SASP group (complete remission in 10 cases, improvement in 4, inefficiency in 7, $P < 0.05$). The clinical symptomatic remission of olsalazine sodium group (complete remission in 15 cases, partial in 5, inefficiency in one) was better than that of SASP group (complete remission in 10 cases, partial in 5, inefficiency in 6, $P < 0.05$). The colonoscopic remission of olsalazine sodium group (complete remission in 11 cases, partial in 9, inefficiency in 1) was better than that of SASP group (complete remission in 7 cases, partial in 8, inefficiency in 6, $P < 0.05$). The colonoscopic images of pre and post treatment with olsalazine are shown in Figure 1. The histologic remission of olsalazine sodium group (complete remission in 13 cases, partial in 7, inefficiency in 1) was better than that of SASP group (complete remission in 6 cases, partial in 10, inefficiency in 5, $P < 0.05$). The side effects of gastrointestinal tract in olsalazine sodium group were less than those of SASP group (abdominal discomfort: 3 vs 15, heartburn 1 vs 7, nausea 2 vs 5) except for frequency of watery diarrhea (5 vs 1). No other side effects were observed in olsalazine sodium group while increased ALT (1 case), decreased WBC (1 case) and skin eruption (2 cases) were observed in SASP group. Two patients relapsed in olsalazine sodium group while 8 cases relapsed in SASP group during the flow-up period (from 6 mo to 1 year).

Figure 1 Colonoscopic image before and after treatment of olsalazine. A: Colonoscopic image before treatment of olsalazine; B: Colonoscopic image after treatment of olsalazine for 4 wk.

First episode type UC

In the 42 first episode type UC patients, the clinical effect of Heartleaf houttuynia herb group (complete remission in 20 cases, 95.2%; improvement in 1 case, 4.8%) was better than that of SASP group (complete remission in 15 cases, 72.4%; improvement in 5 cases, 23.8%; inefficiency in 1 case, 3.8%, $P < 0.01$). The time of stool frequency recovering to normal (5.6 ± 3.3 d), blood stool disappearance time (6.7 ± 3.8 d) and abdominal pain disappearance time (6.1 ± 3.5 d) in Heartleaf houttuynia herb group were all shorter than those in SASP group (9.5 ± 4.9 d, 11.7 ± 6.1 d, 10.6 ± 5.3 d, $P < 0.01$). Pathological changes of ultrastructure, such as swollen mitochondria with depleted ridge, shortened microvilli, maldevelopment of goblet cells and increased epithelial cell apoptosis (Figure 2) could be found on the surface of mucous membrane and recess prior to Heartleaf houttuynia herb injection treatment, which recovered to normal gradually after treatment (Figure 3).

Heartleaf houttuynia herb could inhibit the expression of CD54 (ICAM-1) of colonic mucous membrane (45.8 ± 5.7 vs $30.7 \pm 4.1\%$, $P < 0.05$, Figure 4).

Figure 2 Epithelial cell apoptosis and swollen mitochondria with depleted ridge in UC patients.

Figure 3 Gradual recovery of epithelial cells to normal after treatment with Heartleaf houttuynia herb injection.

Figure 4 Expression of CD54 (ICAM-1) in colonic mucous membrane of UC patients before and after treatment of Heartleaf houttuynia herb. A: Increased expression of CD54 in colonic mucous membrane of UC patients before treatment of Heartleaf houttuynia herb; B: Decreased expression of CD54 in colonic mucous membrane of UC patients after treatment of Heartleaf houttuynia herb.

Compared with normal persons, the mean promotive speed of contraction wave stepped up (4.6 ± 1.6 cm/min vs 3.2 ± 1.8 cm/min, $P < 0.05$) and the mean amplitude of wave decreased (14.2 ± 9.3 kPa vs 18.4 ± 8.0 kPa, $P < 0.05$) in active UC patients. After treatment of Heartleaf houttuynia herb, these 2 indexes improved significantly (17.3 ± 8.3 kPa, 3.7 ± 1.7 cm/min, $P < 0.05$). In normal persons, the

post-meal pressure of sigmoid (2.9 ± 0.9 kPa) was higher than that of descending colon (2.0 ± 0.7 kPa) and splenic flexure (1.7 ± 0.6 kPa), while the respective colonic pressures (1.5 ± 0.5 kPa, 1.4 ± 0.6 kPa, 1.3 ± 0.6 kPa) were significantly decreased ($P < 0.05$) in active UC patients. After treatment of Heartleaf houttuynia herb, the colonic pressures (2.6 ± 0.8 kPa, 1.8 ± 0.6 kPa, 1.6 ± 0.5 kPa) recovered to normal.

The pain threshold of distant colon (67.3 ± 18.9 mL) in active UC patients decreased significantly compared with that in normal persons (216.2 ± 40.8 mL, $P < 0.05$) and recovered to normal after treatment of Heartleaf houttuynia herb (187.4 ± 27.2 mL, $P < 0.05$). There were no adverse reactions in Heartleaf houttuynia herb therapy, while SASP therapy had adverse reactions such as heartburn (5 cases), increased ALT (1 case), decreased WBC (1 case) and rash (2 cases).

Refractory UC patients with platelet activation

Sixteen patients achieved clinical remission (normal stool frequency and no rectal bleeding) after combined treatment of Kangshuanling sublingual tablets with sulfasalazine. Two patients had reduced rectal bleeding only. The average time of marked improvement and remission was 3 wk (1-5 wk), and 6 wk (1-12 wk), respectively. Rectal bleeding ceased in 16 patients (4 patients within 7-14 d, the others within 2-6 wk). Sixteen patients improved in general health condition earlier than bowel symptoms. There was highly significant improvement in mean scores for all disease parameters (Table 1).

Blood contents of CD62p, CD63, TXA2, platelet aggregation rate (PAR) and thrombosis length (TL) in vitro

All the indexes in refractory UC patients increased significantly as compared with the normal controls ($P < 0.01$). After treatment with Kangshuanling sublingual tablets, all the parameters of UC patients decreased ($P < 0.05$, but CD62P and CD63 remained higher than normal ($P < 0.05$, Table 2, Figure 5).

Figure 5 CD62p in blood of normal persons and active UC patients. A: CD62p in blood of normal persons; B: Significant increase of CD62p in blood of active UC patients.

CD54 and products of MDR expression (Pgp-170) in blood and tissues

Compared with normal persons (Figure 6A), CD54 elevated in both blood and tissues in refractory UC patients ($P < 0.01$), CD54 in tissues was higher than in blood (Figure 6B). After treatment

Complications

No complications were found during the treatment with Kangshuanling sublingual tablets.

DISCUSSION

SASP is still widely used in the treatment of chronic relapse type ulcerative colitis, with advantages such as quick effect and high clinical remission rate. However, its effect is not satisfactory in some chronic cases and has various adverse reactions. In addition, UC usually relapses when medication is stopped. Therefore, we should place emphasis in the study of UC on more effective drugs with less adverse reactions^[2,27-31]. At present, the cause and pathogenesis of UC are unclear^[1-15], nonspecific anti-inflammatory drugs, in a relatively long period, will still remain as the main drugs for treating UC. While the curative effect of traditional aminosalicic acid has been affirmed, its side reactions are too many. Main approaches today centered on enhancing the curative effect and reducing side reactions by developing new preparations and changing routes of administration^[1]. SASP, when taken orally, is cleaved by bacteria in the colon into 5-ASA and Sulfapyridine. The

former is the effective component of SASP, and the latter is the carrier of 5-ASA, which may cause such side reactions as sulfanilamide allergy, gastrointestinal upset, hepatorenal impairment, thus affecting its clinical application. In the present study, the above mentioned side reactions in various degrees were also seen in the SASP group. Therefore, to achieve a satisfactory curative effect but without toxicity, the best therapy for UC is to administer 5-ASA that does not contain sulfapyridine and to make it working on diseased areas directly. 5-ASA, however, is usually absorbed rapidly, hence unable to reach inflamed mucous membrane. So, the question posed for the development of new drugs for UC, is how to make 5-ASA reaching and working on the diseased area. Olsalazine sodium gives an answer to this problem, for it is the prodrug of 5-ASA, formed by 2-molecules of 5-ASA jointed by diazo bond. When it is taken orally, only a very small amount is absorbed before reaching colon (absorbing rate <5%). It does not decompose and its biological utilization rate in the body is extremely low. When it reaches the colon, bacterial enzymes in the colon split the diazo bond, liberating the two-molecules of 5-ASA. It has no side effects of SASP, while maintaining the same curative effects. Olsalazine sodium has been on market for more than 10 years and its curative effect on UC and safety have been widely accepted. Domestic olsalazine sodium is a fourth grade new drug jointly developed by Tianjin Lisheng Pharmaceutical Co., Ltd. and Tianjing Medical Research Institute. The fourth grade new drug with the trade name "Changmei", in capsule form was put into market in 2000. This study centered on the clinical effects and safety of olsalazine sodium in patients with chronic UC. Our results indicated that olsalazine sodium was superior to SASP in overall clinical response rate, amelioration of clinical symptoms, colonoscopic examination and histology test. In addition, it has fewer side effects on digestive tract and is unharmed to liver function, WBC and skin. The cause of the increased watery stool frequencies may be related with sodium salt, which inhibits intestinal absorption of water. It mainly occurs at the beginning of medication or during increase of dosage. This side effect, however, does not affect the continuing medication. Patients' worries may be eliminated when the cause is explained. To increase medication frequencies or to take medicine after meal may ameliorate or eliminate this symptom. Imodium may also be given temporarily to some patients to maintain curative effect. In China, the chronic relapse type accounted for 52.6% of all UC cases^[3], maintenance treatment may lower relapse rate. In summary, this study shows that the curative effect and safety of domestic olsalazine sodium is superior to SASP in the treatment of chronic UC. It boosts remission rate, lowers relapse rate and causes fewer side effect, especially applicable to patients who are irresponsive or allergic to SASP therapy.

According to our statistics, the first episode type accounted for 34.8% of all ulcerative colitis cases in China^[3]. The disease mostly starts in rectum and sigmoid colon. When Heartleaf houttuynia enema is used, it can work on diseased areas directly. In this way, it not only can avoid the effects of pH and enzyme on the medicine, but also can make the herb absorbed completely and prolong the time of drug action. Then, colonic mucous membrane will recover gradually to normal with healing of the ulcers. Volatile oil extract of fresh Heartleaf houttuynia is used to produce Heartleaf houttuynia injection. Its utility components (Houttuynin, lauraldehyde, quercitrin, isoquercitrin, etc.) are higher than that of Heartleaf houttuynia herb with widespread pharmacological actions. For instance, relaxation of intestinal smooth muscle could relieve enterospasm, prolong the retention time of intestinal contents, alleviate and eliminate the symptoms of diarrhea and abdominal pain^[8,24,25]. Quercitrin and isoquercitrin can ameliorate capillary fragility for haemostasis, which lead to the stoppage of bloody stool. Pathological changes, such

as swollen mitochondria with depleted ridge, shortened microvilli, maldevelopment of goblet cells and increased epithelial cell apoptosis could be found on the surface of mucous membrane and recess prior to Heartleaf houttuynia herb injection treatment. All these results in malabsorption of water with symptoms of diarrhea, while the increase of epithelial cell apoptosis can lead to the formation of ulcer due to damage of the colonic mucous membrane barrier. The expression of CD54 can further promote the inflammatory reaction. After treatment with Heartleaf houttuynia herb injection, epithelial cell apoptosis^[11], swollen mitochondria, shortened microvilli and the expression of CD54 could recover to normal gradually, which led to plerosis of colonic mucous membrane and healing of ulcer, the effect was superior to that of SASP. Heartleaf houttuynia herb is not only a medicine, but also a safe edible plant. The pH and osmotic pressure of the injection are close to those of intrinsic human environment, so there are no adverse reactions in Heartleaf houttuynia herb therapy, while SASP therapy may have side effects such as the heartburn, increased ALT, decrease WBC and rash.

UC patients often have symptoms of diarrhea, abdominal pain and tenesmus. Are these symptoms related to colonic motility disturbance? In this study, compared with the normal persons, the mean promotive speed of contraction wave stepped up and the mean amplitude of wave decreased in active UC patients, which led to diarrhea. The gastrocolic hyperreflex resulted in awareness of defecation and abdominal pain after eating that could be relieved after defecation. These two indexes improved significantly after treatment with Heartleaf houttuynia herb ($P < 0.05$). In normal persons, the postprandial pressure of sigmoid was higher than that of descending colon and splenic flexure, the pressure gradient and segmental construction made the colonic contents mixed and milled to expose to the colonic mucous membrane fully. Reabsorption of water and electrolytes were thus promoted. In active UC patients, the colonic pressure was significantly decreased ($P < 0.05$), and there was no pressure gradient in different colonic loci which could lead to disturbance of reabsorption of water and electrolytes. Diarrhea occurred due to the decrease of segmental construction and also inflammation of colonic mucosa occurred. The pain threshold of distant colon in active UC patients decreased significantly compared with that of normal persons, indicating that the distant colonic sensibility was increased. So, a small amount of intestinal contents could stimulate defecation reflex, leading to symptoms of diarrhea^[23], abdominal pain and tenesmus. After treatment with Heartleaf houttuynia herb, the colonic pressure and pain threshold recovered to normal due to the following reasons. Heartleaf houttuynia caused relaxation of intestinal smooth muscle which could relieve the enterospasm, prolong the retention time of intestinal contents, alleviate and eliminate the symptoms of diarrhea and abdominal pain. Our prophase study proved that Heartleaf houttuynia herb could improve the colonic motility disturbance of UC rats. In this study, the remission of diarrhea and abdominal pain might be partly related to this. Heartleaf houttuynia herb also has anti-inflammatory actions as we have proven in our previous animal study, which led to the remission of symptoms.

The main component of Kangshuangling sublingual tablets is low molecular mass (molecular mass ranged from 5-15 ku, peak ranged from 5-8 ku) heparin substance. Each tablet contains 1 200IU LMWH, which can be absorbed by the sublingual mucosa, so it not only has no first-pass effects by the liver compared with oral LMWH used in our previous study^[29], but also has no inconvenience of injection. Heparin, a group of sulphated glycosaminoglycans, in addition to its physiological effects and anticoagulant, antithromboembolic, antiallergic, antiviral, antiendotoxic and immunoregulative biological activities, has been found with a wide range of potentially anti-

inflammatory effects, including inhibition of neutrophil elastase and inactivation of chemokines^[40]. Compared with heparin, LMWH has higher antithromboembolic effects, longer half life period, less bleeding tendency, higher bioavailability, easier absorption by sublingual administration, as well as anti-inflammatory effects^[29,41]. Previous reports^[29] on improvement of UC patients treated with heparin prompted us to perform a pilot study of Kangshuangling sublingual tablets to find a more convenient and effective drug for patients with refractory UC. The observed response to Kangshuangling sublingual tablets was paradoxical. Sixteen of 18 patients with refractory UC unresponsive to high-dose prednisolone and sulfasalazine therapy for more than 4 wk achieved clinical remission and became asymptomatic after treatment of Kangshuangling sublingual tablets in combination with sulfasalazine. Contrary to the traditional idea that heparin could enhance bleeding, rectal bleeding was the first symptom to be improved by Kangshuangling sublingual tablets. The results were similar to other reports of heparin treatment^[42,43].

If Kangshuangling sublingual tablets have a therapeutic effect on UC, their mechanism of action should shed some lights on the elusive pathogenesis of this disease. Several thrombophilic features of UC that suggest the effect of Kangshuangling sublingual tablets on colitic symptoms may be attributable to their anticoagulant and antithrombotic properties. Evidences of a thrombotic process in UC included: reports of a hypercoagulable state^[20,22], an increased incidence of thromboembolic event^[44], and ischemic complications such as toxic megacolon and pyoderma gangrenosum. In this study, the membrane marks of platelet activity CD62p and CD63 were increased significantly, and the derivative of active platelet TXA2 was also elevated, suggesting that blood platelet TXA2 was in an active state, which not only led to a hypercoagulable state and an increased incidence of thromboembolic events, but also enhanced inflammatory reaction^[20,22]. Activated hyperaggregable platelets in the mesenteric circulation could amplify the inflammatory cascade by promoting neutrophil recruitment and chemotaxis. P-selectin has an established action as the adhesion molecule for neutrophils, and circulating platelet aggregates may contribute to ischemic damage and infarction by occluding the intestinal microvasculature. Platelets derived thromboxane A₂ may also contribute to ischemia by inducing local vasoconstriction. After treatment with Kangshuangling sublingual tablets, all these parameters dropped markedly, suggesting that the therapeutic effect of LMWH was partly related to inhibition of platelet activity, and improvement of hypercoagulable state, leading to the remission of clinical symptoms. But the membrane marks of platelet CD62p and CD63 were still higher than those of the normal controls. Whether it has predictive value for recurrence or prognosis should be further studied.

CD54 antigen could react with 85-110 ku integral membrane glycoprotein, and it is also known as an intercellular adhesion molecule-1 (ICAM-1) expressed on endothelial cells and both resting (weak) and activated (moderate) lymphocytes and monocytes^[15]. CD54 is ligand for the leukocyte function antigen-1 (CD11a). Its expression was up-regulated upon stimulation by inflammatory mediators such as cytokines and LPS, and it was involved in B cell-T cell co-stimulatory interactions. In this study, CD54 elevated significantly in blood and tissues of UC patients, being higher in tissues than in blood. Therefore, it could reflect the inflammation of intestinal mucosa. After treatment with Kangshuangling sublingual tablets, CD54 dropped significantly in both blood and tissues, indicating that Kangshuangling sublingual tablets could relieve the inflammatory activity in refractory UC patients who received high-dose prednisolone and sulfasalazine therapy for a long period (more than 4 wk) without significant improvement and

were regarded as corticosteroid-resistant refractory cases of UC. It was reported that heparin could also inhibit c-reactive protein (CRP), tumor necrosis factor (TNF) and L-selectin of UC patients. The detailed mechanisms by which anti-inflammatory properties of oral L MWH are mediated in UC remain to be elucidated further.

The multidrug resistance (MDR) gene coding for a drug efflux pump P-glycoprotein 170(Pgp-170) expressed on the surface of lymphocytes and intestinal epithelial cells^[38,39]. In this study, Pgp-170 was elevated significantly in blood and tissues of refractory UC patients. Poor response to medical therapy of certain UC patients might be related to MDR expression because glucocorticoids are known Pgp-170 substrates. There was no difference of Pgp-170 in tissues and blood, indicating that peripheral blood lymphocyte (PBL) MDR remained stable over time and was not influenced by disease activity or glucocorticoid therapy, both PBL and mucosal MDR expression appeared independent of disease activity, and there was a significant correlation between PBL and MDR expression and intestinal epithelial lymphocyte and epithelial cell expression^[38,39]. After treatment with Kangshuangling sublingual tablets, Pgp-170 dropped significantly in both blood and tissues, indicating that Kangshuangling sublingual tablet could inhibit the expression of MDR, but Pgp-170 was still higher than that of the normal controls, indicating that PBL and mucosal MDR may play an important role in determining the response of refractory UC patients to glucocorticoid therapy. From these results, we conclude that Kangshuanling sublingual tablets may play a role in treating refractory UC with activated platelets, the mechanism is partly related to the inhibition of platelet activity, hypercoagulable state, MDR expression, and its anti-inflammatory effects. No complications are found to be associated with the use of Kangshuanling sublingual tablets. It is still the focus of study in treating refractory UC with the Chinese features^[3].

Abstract

AIM: To investigate the effects of probiotic on intestinal mucosae of patients with ulcerative colitis (UC), and to evaluate the role of probiotic in preventing the relapse of UC.

METHODS: Thirty patients received treatment with sulphasalazine (SASP) and glucocorticoid and then were randomly administered bifid triple viable capsule (BIFICO) (1.26 g/d), or an identical placebo (starch) for 8 wk. Fecal samples were collected for stool culture 2 wk before and after the randomized treatments. The patients were evaluated clinically, endoscopically and histologically after 2 mo of treatment or in case of relapse of UC. p65 and I κ B expressions were determined by Western blot analysis. DNA-binding activity of NF- κ B in colonic nuclear extracts was detected by electrophoretic mobility shift assay (EMSA). mRNA expressions of cytokines were identified by semi-quantitative assay, reverse transcriptase-polymerase chain reaction (RT-PCR).

RESULTS: Three patients (20%) in the BIFICO group had relapses during 2-mo follow-up period, compared with 14 (93.3%) in placebo group ($P < 0.01$). The concentration of fecal lactobacilli, bifidobacteria was significantly increased in BIFICO-treated group only ($P < 0.01$). The expressions of NF- κ B p65 and DNA binding activity of NF- κ B were significantly attenuated in the treatment group than that in control ($P < 0.05$). The mRNA expression of anti-inflammatory cytokines was elevated in comparison with the control group.

CONCLUSION: The probiotic could impede the activation of NF- κ B, decrease the expressions of TNF- α and IL-1 β and elevate the expression of IL-10. These results suggest that oral administration of this new probiotic preparation is effective in preventing flare-ups of chronic UC. It may become a prophylactic drug to decrease the relapse of UC.

INTRODUCTION

Ulcerative colitis (UC) is a chronic disease and easy to relapse, its etiology and pathogenesis have not been definitively elaborated^[1]. Primary therapy for UC is usually a combination of sulfasalazine and glucocorticoids. Sulfasalazine can be given alone or in combination with other drugs. However, a large number of patients are resistant or intolerant to sulfasalazine. Glucocorticoids suppress active inflammation very effectively, but its long-term use is associated with high rates of relapse and unacceptable toxicities. Recently, probiotic has been recommended to ameliorate the milieu of intestine and prolong the time of relapse^[2-14]. This study intended to evaluate the role of bifidobacteria in remission of UC.

MATERIALS AND METHODS

Sample collection and processing

Thirty active UC patients were recruited for this study from 2001 to 2002 at Nanfang Hospital. Severity of the disease in colon and rectum was assessed by one gastroenterologist with an endoscope. These patients on sulphasalazine (SASP) and glucocorticoid had clinical and endoscopic remission and were randomized to receive either bifid triple viable capsule (BIFICO) (1.26 g/d), or an identical placebo (starch) for 8 wk. Biopsy specimens were obtained with standard biopsy forceps to include the most macroscopically inflamed site with UC and immediately frozen in liquid nitrogen and stored at -80 °C for RNA and protein extraction. Meanwhile, fecal samples were collected for stool culture before and after 2 wk of treatments. Patients were assessed clinically, endoscopically and histologically after a 2-mo period of treatment or in case of relapse of UC.

Fecal analysis

Fecal samples were collected for microbiological examinations. We prepared the selective medium to incubate ten strains of luminal resident bacteria in large intestine. *Enterobacteria* (EMB), *Enterococcus* (EC), *Staphylococcus* (SP) and *Saccharomyces* (yeast) (SB) are aerobes. *Bacteroides* (BD), *Bifidobacterium* (BL), *Lactobacillus* (LC), *Peptococcus* (PS), *Eubacterium* (ES) and *Clostridium* (CD) are anaerobes. 0.5 g feces in a small bottle containing 4.5 mL diluted solution and 4-5 beads were concussed 1 min on a vortex agitator, 1.8 mL diluted solution was added to each of other 7 bottles. The solution was diluted in series as 10⁻², 10⁻³, ...10⁻⁸, respectively. Aerobes and anaerobes were observed 24 h and 72 h after incubation at 37 °C.

Preparation of cytoplasmic and nuclear extracts

Nuclear extracts from biopsy tissues were prepared by the method of Deryckere and Gannon^[15]. Frozen tissue was ground with a mortar in liquid nitrogen and transferred to a tissue homogenizer. Protease inhibitor cocktail (Sigma) was added and centrifuged at 2 000 r/min for 30 s. Supernatant was incubated on ice for 5 min and then centrifuged at 5 000 r/min for 5 min. The final supernatant containing cytoplasmic extracts was collected and stored at -80 °C. Pelleted nuclei were then resuspended in 50-100 μ L of buffer G and incubated on ice for 20 min.

The lysed nuclei were then transferred to a microcentrifuge tube, centrifuged at 12 000 r/min for 10 min, and the supernatant containing the nuclear extracts was collected and stored at -80°C . Protein concentration was determined with BCA-protein estimation kit.

Western blot analysis

For each sample, an equal amount (50 μg) of protein lysates was analyzed on 100 g/L or 120 g/L sodium dodecyl sulfate-polyacrylamide gel. Proteins were electroblotted onto Immobilon PVDF membranes (Millipore, Bedford, MA), blocked in 50 g/L dry skim milk for 1 h, and then incubated with the indicated antibodies. The antibodies used were 1:700 rabbit polyclonal anti-NF- κB and I κB antibodies, the secondary antibodies used were provided in an enhanced chemiluminescence detection kit (Santa Cruz, CA). Exposure time (5-60 s) varied with the antibodies used.

Electrophoretic mobility shift assays

DNA-binding activity of NF- κB in colon nuclear extracts was determined by electrophoretic mobility shift assay (EMSA). The sequence of NF- κB probe was 5' -AGT TGA GGG GAC TTT CCC AGG C-3' [16], 10 μg of nuclear protein was incubated at room temperature for 20 min with radiolabeled [$\gamma\text{-}^{32}\text{P}$] ATP using T4 polynucleotide kinase. A 20 μL reaction buffer contained 2 μg poly dI-dC (Sigma), 10 mmol/L tris-HCl (pH7.5), 100 mmol/L NaCl, 10 mmol/L EDTA, 20 mmol/L MgCl₂, 10 mmol/L DTT, 3 μL of 250 mL/L glycerol and 1 μL of labeled probe. For competition assays, 100-fold molar excess of unlabeled oligonucleotide was added to the binding reaction. Nucleoprotein- oligonucleotide complexes were resolved by electrophoresis on a 50 g/L non-denaturing polyacrylamide gel (PAGE; acrylamide/bisacrylamide at 30:1) in 0.1 \times TBE buffer at 150 V for 2 h at 4°C . The gel was dried and autoradiographed with intensifying screen at -80°C for 72 h. The radioactivity of appropriate bands was counted using a BAS2000 phosphorimage analyzer (Fuji Film, Minamiasigara, Japan).

Proinflammatory and inhibitive factor mRNA detected by RT-PCR

Total RNA was isolated from biopsies using TRIzol reagent (Life Technologies). cDNA was generated from 1 μg of total RNA in a reaction volume of 20 μL , using M-MLV reverse transcriptase (MBI). PCR was performed in the linear range of amplification (determined for each primer pair-cDNA combination). Standard PCR reactions were performed with 1 μL of the cDNA solution, 50 $\mu\text{mol/L}$ of each primer solution, 10 mmol/L of each Dntp, 25 mmol/L MgCl₂, 10 \times Goldstar DNA polymerase reaction buffer, and 0.5 units of Goldstar DNA polymerase (Eurogentec, Seraing, Belgium). Each PCR cycle was performed at 94°C for 1 min, at 56°C for 1 min, and at 72°C for 1 min, respectively. Following sense / antisense primers were designed to amplify cDNA fragments [17,18]: glyceraldehyde-3-phosphate dehydrogenase (G3PDH): sense primer: 5' -ACCACAGTCCATGCCATCAC-3', antisense: 5' -TCCACCACCTGTGCTGTGTA-3' (452 bp); TNF- α : sense primer: 5' -CTGTA GCCATGTTGTAGC-3', antisense: 5' -CAATGATCCCAAAGTAGACCT-3' (467 bp); IL-1 β : sense primer: 5' -CAGCCATGGCAGAAGTACCT-3', antisense: 5' -GGCCACAACAACTGACGC-3' (223 bp); IL-10: sense primer: 5' -CTGAGGCGCTGTCATCGATT-3', antisense: 5' -AGGTCCTGGAGTCCAGCAGA-3' (328 bp). The PCR products were then visualized on a 10 g/L agarose gel by ethidium bromide (5 $\mu\text{g/mL}$) staining.

Statistical analysis

All results were expressed as mean \pm SD. Statistical differences between means were determined using independent-sample *t* test and paired-sample *t* test by SPSS 10.0 statistical software.

A *P* value ≤ 0.05 was considered statistically significant.

RESULTS

Fecal analysis

The number of fecal bacteria before treatment in these 2 groups had no significant difference. After treatment, the fecal specimens of the patients on BIFICO were obviously different from the patients on placebo. The number of Gram-positive Bacilli and Enterococci was significantly higher than that in control group. The number of *Enterococci*, *Bacteroides* and *Bifidobacteria* was obviously less than that in control group ($P < 0.05$). In control group, the number of *Bifidobacteria* (6.44 ± 0.25 , $P < 0.01$) and Lactobacilli (6.67 ± 0.43 , $P < 0.05$) was less than that in treatment group (Table 1).

Figure 1 Expressions of NF- κB p65 and I κB in nuclei and cytoplasm. A: Expression of NF- κB p65 in nuclei, B: Expression of I κB in cytoplasm, Lanes 1-2: expression before treatment, Lanes 3: expression after probiotics treatment, Lanes 4: expression in control.

Figure 2 Inhibition of NF- κB binding DNA by BIFICO. 1, Cool probe; 2, Activation NF- κB before treatment; 3: Probiotic significantly inhibited activation of NF- κB .

Figure 3 Activation of NF- κB in. Placebo group 1, Cool probe; 2, Activation of NF- κB before treatment; 3, Placebo did not obviously inhibit the activation of NF- κB .

NF- κB and I κB examination

The degradation of I κB in cytoplasm was obviously inhibited by BIFICO and NF- κB in nuclei was less expressed after treatment ($P < 0.05$) (Figures 1, Table 2).

Figure 4 Expressions of IL-1 mRNA, TNF- α mRNA and IL-10 mRNA. A: Expression of IL-1 mRNA, Lanes 1,2: IL-1 mRNA expression before treatment; lane 3: BIFICO inhibited IL-1 mRNA expression; lane 4: IL-1 mRNA expression in placebo group. B: Expression of TNF- α mRNA, Lanes 1,2,3,4 G3PDH; lanes 5,6: TNF- α mRNA expression before treatment; Lane 7: BIFICO inhibited significantly mRNA expression of TNF- α ; lane 8: TNF- α mRNA expression in placebo group. C: Expression of IL-10 mRNA, Lanes 1,2: IL-10 mRNA before treatment; lane 3: BIFICO enhanced IL-10 mRNA expression; lane 4: IL-10 mRNA in placebo group.

Activation of NF- κ B in nuclei

The results of EMSA showed that activation of NF- κ B was

elevated in patients who did not take BIFICO in comparison with pretreatment, more NF- κ B was combined with special recognition sites of DNA (P <0.05, Figures 2,3).

Table 2 Expression of NF- κ B (nucleus) and I κ B (cytoplasm) before and after therapy (mean \pm SD)

Index	BIFICO group		Placebo group	
	Pretreatment	Post-treatment	Pretreatment	Post-treatment
I κ B (cytoplasm)	0.99 \pm 0.11	0.97 \pm 0.07	0.89 \pm 0.08	0.43 \pm 0.15 ^{bd}
NF- κ B (nucleus)	0.82 \pm 0.05	0.31 \pm 0.05 ^b	0.79 \pm 0.14	0.97 \pm 0.09 ^d

^a P <0.05, ^b P <0.01 vs post-treatment; ^c P <0.05, ^d P <0.01 vs control.

Expression of IL-1- β , TNF- α , IL-10 mRNA

IL-1- β , TNF- α , IL-10 mRNAs in both groups were determined with RT-PCR. In control group, the level of IL-1- β , TNF- α mRNA at intestinal epithelial mucosa did not significantly decrease. (P <0.05, Figures 4, Table 3).

Table 3 mRNA expression of cytokines before and after therapy (OD value, mean \pm SD)

Index	BIFICO group		Placebo group	
	Pretreatment	Post-treatment	Pretreatment	Post-treatment
IL-1	0.41 \pm 0.09	0.53 \pm 0.11	0.38 \pm 0.12	1.20 \pm 0.08 ^d

^a P <0.05, ^b P <0.01 vs post-treatment; ^c P <0.05, ^d P <0.01 vs control.

DISCUSSION

The pathogenesis of UC remains unknown. Genetic and environmental factors are obviously contributory. Luminal bacteria could play a major role in the initiation and perpetuation of chronic UC^[14,19-21]. Thousand of endogenous bacteria live in the large intestine and may be an essential factor in certain pathological disorders. Animal models of UC showed that colitis did not occur in a germ-free environment. In human UC, inflammation is present in parts of the gut housing the highest concentration of bacteria. Moreover, terminal ileum, caecum and rectum are relatively static, providing prolonged mucosal contact with luminal contents. Enhanced mucosal permeability may play a pivotal role in maintaining a chronic inflammatory state due to a genetic predisposition or direct contact with bacteria or their products. So far, no specific micro-organism has been directly associated with the pathogenesis of UC. Analysis of the luminal enteric flora, however, has revealed differences in the composition of this flora to healthy controls. In UC, concentrations of *Bacteroides*, *Eubacteria*, *Peptostreptococci* and facultative anaerobic bacteria are increased, whereas the number of *Bifidobacteria* is significantly reduced. Over the past few years, use of probiotics in IBD and other intestinal disorders has gained attention. Manipulation of the colonic bacteria with antibiotics and probiotics proved to be more effective and tolerable than immunosuppressants^[11,22]. Probiotics and prebiotics have a role in prevention or treatment of some diseases. The mechanisms through which dysregulation may play a central role in initiation and perpetuation of inflammatory bowel disease were discussed^[23]. BIFICO probiotic capsule was used for *Enterococci*, *Bifidobacteria*, *Lactobacilli* triple viable bacteria, probiotics such as VSL#3 could also be used to maintain clinical remission and prevent relapse in patients with

relapsing or chronic pouchitis. Therapy with anti-inflammatory agents and immunomodulators were often required for patients with chronic pouchitis resistant to antibiotics^[24,25]. Probiotic *Lactobacillus rhamnosus* GG (LGG) has proved to be beneficial to the treatment of viral- and antibiotic-associated diarrhea. Nitric oxide (NO) is involved in the protective mechanisms in the gastrointestinal tract and may contribute to some of the beneficial effects of probiotics. LGG induces NO production in J774 macrophages and in human T84 colon epithelial cells through induction of iNOS by a mechanism involving activation of transcription factor NF- κ B. Induction of iNOS and low-level synthesis of NO might be involved in the protective actions of LGG in the gastrointestinal tract^[26]. Recent results supported the concept that intestinal bacteria could induce endogenous signals that play a pathogenic role in hepatic insulin resistance and NAFLD and suggest novel therapies for these common conditions^[27,28]. We discovered that the high concentration of Gram-positive bacteria in luminal flora could effectively prolong the time of relapse of ulcerative colitis.

It is well known that transcriptional factor NF- κ B plays a pivotal role in expression of LPS-induced inflammatory factors. Because NF- κ B activation could lead to enhanced expression of proinflammatory cytokines, chemokines, inflammatory enzymes such as inducible NO synthase (iNOS) and cyclooxygenase (COX-2), adhesion molecules and inflammatory receptors^[29], modulation of NF- κ B activation might provide a direct way to inhibit inflammatory mediators^[30]. Activation of NF- κ B is triggered by phosphorylation of an inhibitory subunit, I κ B. In unstimulated cells, NF- κ B is sequestered in the cytoplasm through interaction with I κ B α and I κ B α inhibitory proteins. In response to proinflammatory stimuli, I κ B is first phosphorylated in its N-terminal domain by a large multi-kinase complex, then polyubiquitinated, and finally degraded by the proteasome. The released NF- κ B complex could translocate into the nuclei where it initiates gene transcription upon binding to its cognate DNA motifs in regulatory segments of TNF- α gene and other target genes involved in inflammatory and immune process^[31]. At the same time, we also detected the effect of probiotics on the initiation and perpetuation of inflammation. The expressions of I κ B in cytoplasm and NF- κ B in nuclei were detected by Western blot. The result manifested that probiotics efficaciously inhibited the degradation of I κ B protein. Less NF- κ B translocation into nuclei could be detected by Western blot in treatment group. Activation of NF- κ B was analyzed by EMSA, the result likewise manifested that much more NF- κ B proteins were significantly activated in control group than in probiotics group.

Recent data have demonstrated that mucosal immune response is involved in patients with IBD. The nuclear transcription factor NF- κ B is a key regulator of inducible expressions of many genes involved in immune and inflammatory responses in the gut. Stimuli like oxidative stress, cytokines (IL-1, IL-6, TNF- α), bacteria and viruses can release NF- κ B from their inactive cytoplasmatic form to the nuclei. Inhibitory cytokines can prevent the activation of NF- κ B. More potent and selective treatment strategies with anti-sense p65, proteasome inhibitors and viral I kappa B α expression vectors have been aimed to prevent NF- κ B activation in mucosal macrophages and T lymphocytes. However, NF- κ B regulated genes are also involved in survival responses of epithelial cells. Selective inhibition of NF- κ B activation in inflammatory cells could be an option in management of IBD^[32-35]. In our study, the expression of proinflammatory cytokines such as TNF- α , IL-1 β influenced by the activation of NF- κ B obviously were inhibited by probiotics and mRNA expression of anti-inflammatory cytokine IL-10 was elevated by the effect of probiotics.

In conclusion, supplementation with probiotics is helpful in maintaining remission and preventing the relapse of UC.

Abstract

AIM: To develop a double cuff method for rat liver transplantation without preservation of “phrenic ring” to shorten the portal vein clamping time.

METHODS: “Phrenic ring” was completely excluded from the donor liver, and end to end anastomosis of suprahepatic inferior vena cava was performed.

RESULTS: The portal vein clamping time was shortened to 10.6 min, the successful rate was 83.1%.

CONCLUSION: This method can simplify the operation and shorten the portal vein clamping time.

<http://www.wjgnet.com/1007-9327/10/1526.asp>

INTRODUCTION

The orthotopic rat liver transplantation (ORLT) model was first described by Lee *et al.* in 1973^[1], and subsequently modified by Kamada and Calne in 1979^[2]. This model has been widely accepted and used in current scientific researches^[3-13]. In order to study the ischemia/reperfusion injury after liver transplantation, we modified the ORLT model established by Jiang *et al.*^[14]. We constructed a double cuff ORLT model without preservation of “phrenic ring”. This model can simplify the operation and shorten the portal vein clamping time.

MATERIALS AND METHODS

Animals

Male Sprague Dawley rats weighing 200-250 g were used as donors and recipients respectively. The body mass of donors was generally lower than that of corresponding recipients. The rats were housed in pathogen-free conditions with a 12 h light-dark cycle and had free access to water and were fasted for 14 h before operation. All experiments were performed in compliance with the standards for animal use and care set by Institutional Animal Care Committee.

Surgical procedures

All surgical procedures were performed under the naked eye. On the basis of the procedures described by Kamada *et al.*^[2], we made the following modifications. (1) The harvested liver from the donor was placed in a 4 °C saline bath measuring 6 cm in diameter and 3 cm in depth. The whole “phrenic ring” was removed from the suprahepatic inferior vena cava (IVC), leaving the vessel wall of suprahepatic IVC. After the double-cuff preparation was finished, the liver was perfused with cold lactated Ringer's solution through the portal vein and infrahepatic IVC. The liver was preserved in 4 °C University of Wisconsin (UW) solution for 24 h (in order to study cold preservation/reperfusion injury). (2) Instead of anastomosis of the donor “phrenic ring” with the receptor's suprahepatic IVC, the donor suprahepatic IVC was anastomosed end-to-end with the receptor suprahepatic IVC using a 7/0 continuous nylon suture.

RESULTS

Seventy-two ORLTs were performed without preservation of “phrenic ring” in rats. Of which, 59 were successful (success rate 83.1%). The rats survived over 24 h. One rat had survived more than 2 mo. One-week survival rate was not obtained because specimens were taken for study. Our criteria for operative success were as follows. After ORLT, the receptor rat could turn over, and run about actively. The rats were agile to the surrounding and could drink water. The portal vein clamping time (PVCT) was shortened (10.6 ± 1.36 min), and the shortest PVCT reached 8 min. The cause of death included a number of contributing factors: anesthesia too deep and respiratory failure (4/13); thrombosis of the portal vein (1/13); wound bleeding of the right adrenal gland area (1/13); failure of the portal vein anastomosis (2/13); stenosis or obstruction of suprahepatic IVC (4/13); and failure of the infrahepatic IVC anastomosis (1/13). Failure to control ether anesthesia and narrowing or obstruction of the outflow tract was the main cause of operative failure. In the latter case, most of them occurred at the initial stage.

DISCUSSION

Original intention of establishing the model

The author has been engaged in the research of ischemia/reperfusion injury of liver transplantation. In this process, PVCT needs to be shortened in order to reduce the interference with a too long period of splanchnic congestion. PVCT should be shortened to less than 14 min, otherwise a lethal endotoxin like syndrome induced by splanchnic congestion might play the central role which might bring about a noted systemic error in research^[15]. In the beginning by following Kamada's method, we found that the repair of “phrenic ring” and eversion anastomosis were the “bottleneck” of PVCT. Thus we established the double cuff method for ORLT without preservation of “phrenic ring”. In the early stage, suprahepatic IVC was sometimes lacerated. But on the basis of improved microsurgery and vascular anastomosis technique, this method can not only avoid laceration of the suprahepatic IVC, but also shorten PVCT. A more scientific model is thus provided for

the research of ischemia-reperfusion and rejection-tolerance in liver transplantation.

Good exposure is the key point of a successful operation

As other surgical operations, good exposure is also the key point of liver transplantation. As “phrenic ring” is not preserved, anastomosis of suprahepatic IVC becomes more important. Good exposure was achieved in the following ways. Full-length median incision on the abdomen was dragged to both sides and fixed, xiphoid process was dragged cephalad with our designed apparatus, a small pillow underlied the rat chest to raise the suprahepatic IVC stoma. By this method, no suprahepatic IVC was lacerated, PVCT was shortened to nearly 10 min. Not only the disturbance of respiratory and circulation was reduced, but also splanchnic congestion induced endotoxin like syndrome was reduced, which was hard to be attained by “triple-cuff” or conventional “double-cuff” liver transplantation.

Other relevant experiences concerning anaesthesia of donor and receptor rats

Donor livers were anaesthetized by ketamine. Kamada *et al.* recommended a dosage of 100 mg/5 Kg body mass^[2], but actually 40 to 50 mg ketamine was administrated to rats weighing 180-230 g. Receptor rats were maintained by ether inhalation anaesthesia. Steadiness of this anaesthesia is also crucial to a successful ORLT. The shallow anaesthesia would result in difficulty of operation and even bleeding, but too deep anaesthesia would lead to depression of breath and difficulty in postoperative recovery or even death. Out of control of the depth of ether anaesthesia was the main reason of postoperative respiratory failure, and also one of the main causes of death of the receptor rats (30.8%, 4/13). Our experience is “deep induction, shallow maintenance”. In the induction period, a bigger dosage of ether was given, but a low density of ether in mask was maintained during operation.

Turning over of the donor liver during its harvest

We adopted the methods recommended by Wang *et al.*^[16]. After a midline abdominal incision was made, the liver was freed from surrounding ligaments, the left infraphrenic vein and para-oesophagus vein were ligated and divided. Then the right renal vein and right adrenal vein were ligated. The suprahepatic vein was freed. Hepatoportal structure was dissected and freed. The common duct was cannulated. The donor liver was thus harvested. It was turned over only once. So this method can not only protect the donor liver, but also shorten the heat ischemic time.

Abstract

AIM: To study the immune response of host to *Helicobacter pylori* VacA.

METHODS: The monocyte/macrophage-like U937 cells were infected with *Helicobacter pylori* vacA-positive strain NCTC 11638 or isogenic vacA-negative mutant. Differentially expressed genes were identified at 2, 6, 10, and 24 h post-infection by cDNA microarray. Differential expressions of some genes were confirmed by Northern blot.

RESULTS: More than 100 genes altered their mRNA expression at different time points respectively, many of which were identified to be related to immune evasion.

CONCLUSION: VacA is a crucial element for *H pylori* to escape from host immune defense by means of differentially regulating the expression of some related genes. These genes, previously known or unknown to be involved in the mechanism of immune evasion, deserve further investigation to unearth much more information complicated in the immune response.

INTRODUCTION

Helicobacter pylori infects about half of the world's population. Despite the induction of an immunological reaction, the infection of *H pylori* is commonly life-long, suggesting that this pathogen has evolved mechanisms to evade protective immune responses to achieve the state of host-microbial equilibrium^[1]. Some products of *H pylori* have been determined to have immunosuppressive effects for prolonging the infection. A 100 ku *H pylori* protein inhibits proliferation of T-cell and macrophage^[2], and VacA, a cytotoxin that has been found to cause massive vacuolation in several mammalian cell lines and in the gastric epithelia of patients with active chronic

gastritis associated with *H pylori* infection^[3], may perform targeted action to disable T cells. VacA interferes with proteolytic processing of tetanus toxin and toxoid and specifically inhibits the Ii-dependent pathway of antigen presentation mediated by newly synthesized major histocompatibility complex (MHC) class II, suggesting that VacA may contribute to the persistence of *H pylori* by interfering with protective immunity^[4]. However, to the author's knowledge, the exact mechanism of such an immunosuppression effect has not been fully studied. Hence, in this study, we performed a large scale measurement of gene expression alteration in host cells using gene microarray technology, which provided the crucial information for interpreting the mechanisms of immunosuppression.

MATERIALS AND METHODS

Bacterial strains and growth conditions

H pylori NCTC 11638 strain positive for vacA was given as a gift by Dr. Shi (Shanghai Institute of Gastroenterology). Isogenic vacA-negative mutant 11638-Δ vacA was constructed by substitution of a kanamycin resistant gene for a short fragment of vacA through homologous recombination, as described previously^[5]. *H pylori* strains were cultured routinely on brain heart infusion (BHI) agar plates with 5% sheep blood in mixed air containing 100 ml/L CO₂, 50 ml/L O₂, and 850 ml/L N₂ at 37 °C.

H pylori infection of monocyte/macrophage-like cell line U937

The U937 cells were maintained in RPMI 1640 medium (Gibco BRL, USA) with 2 mmol/L L-glutamine, 1.5 g/L sodium bicarbonate, 4.5 g/L glucose, 10 mmol/L HEPES, 1.0 mmol/L sodium pyruvate and 100 ml/L fetal bovine serum. The day before *H pylori* infection, fresh medium with 20 ml/L fetal calf serum was substituted. Eighteen hours later, the cells grown to 90% confluency were cocultured with *H pylori* isogenic strains at a multiplicity of infection of 10 in culture medium for 2, 6, 10, and 24 h.

Total RNA Isolation

U937 cells cocultured with NCTC 11638 and 11638-Δ vacA were collected at 2, 6, 10, and 24 h after the infection for mRNA extraction. Total RNA was isolated using TRIZOL reagent (Invitrogen, USA) according to the manufacturer's instruction.

cDNA microarrays

The cDNA microarrays were designed by Shanghai BioStar Genechip Inc. In this study, microarrays with 8 464 human cDNAs were used, including full-length and partial complementary DNAs representing novel, known, and control genes.

Preparation and hybridization of fluorescent-labeled cDNA

Aliquots of 30 μg of total RNA were fluorescently labeled with Cy5- or Cy3-dCTP (Amersham Pharmacia, Sweden) by reverse transcription in the presence of 5 μg of oligo(dT) and 1 μL of SuperScriptII (Gibco-BRL, USA). The labeled cDNAs were purified using MicroSpin S-200 columns (Amersham

Pharmacia, Sweden) and lyophilized. The probes were resuspended in 20 µL hybridization solution containing 8 µg of poly(dA), 2 µg of yeast tRNA, 10 µg of human *Cot* I DNA (Gibco-BRL, USA). After heated to 95 °C for 2 min and then cooled to room temperature, the mixture was applied to the slides and covered by a coverslip. The slides were incubated in a humid cabinet of an incubator for 16–18 h at 42 °C. Then the slides were washed at 60 °C for 10 min in solutions of 2×SSC with 2 g/L SDS, 0.1×SSC with 2 g/L SDS, and 0.1×SSC sequentially, and then dried at room temperature.

Array scanning and data processing

Each slide was scanned at 10 µm resolution on a GenePix 4000B scanner (Axon Instruments, Inc., Foster City, CA) at variable PMT voltage to obtain maximal signal intensities with no more than 1% probe saturation. The images were processed with GenePix Pro 3.0. Ratios were normalized by a linear regression between ln(Cy5) and ln(Cy3) of all the genes' background-corrected signal intensities on the microarray. Genes exhibited a 2-fold or greater change in expression level and exceeded 200 in signal intensity were considered true outliers.

Preparation of ³²P-labeled probes

The plasmids containing cDNA clone used for preparing probes were provided by Shanghai BioStar Genechip Inc. A total amount of 200 ng plasmids were used as templates for PCR amplification. PCR products were purified using QIAquick Gel Extraction Kit (Qiagen, Germany). The probes were labeled using random primed Strip-EZ DNA Kit (Ambion, Austin, TX). A total amount of 25 ng purified DNA diluted in 9 µL TE (10 mmol/L Tris-HCl, pH8, 1 mmol/L EDTA) was denatured at 95 °C for 5 min and then immediately frozen in liquid nitrogen, thawed, microfuged, and placed on ice. Afterwards, the following reaction was assembled as follows and mixed gently: A 9.0 µL of denatured DNA, 2.5 µL of 10×Decamer solution, 5.0 µL of 5×buffer-dATP/-dCTP, 2.5 µL of 10×dCTP, 5.0 µL of [α-³²P]dATP (3 000 Ci/mmol,

10 mCi/mL), 1.0 µL of exonuclease-free Klenow, and nuclease-free water to 25 µL. After 20 min incubation at 37 °C, 1 µL of 0.5 mol/L EDTA was added to stop the reaction.

Northern blot analysis

A 10 µg sample of total RNA per lane was subjected to electrophoresis on 12 g/L agarose gels containing 2.2 mol/L formaldehyde. RNAs were transferred onto Zeta-probe blotting membranes (Bio-Rad Laboratories, Hercules, CA) using Vacuum Blotter (model 785, Bio-Rad Laboratories) and baked under vacuum at 80 °C for 2 h. Membranes were hybridized for 16 h at 60 °C with ULTRArray hybridization solution (Ambion, Austin, TX) containing cDNA probes labeled with [α-³²P] dCTP by random priming (Strip-EZ DNA labeling system, Ambion). The hybridized membranes were serially washed at 55 °C using 2×SSC with 1 g/L SDS solution, then exposed to a phosphorimager. Blots were scanned and quantified by a phosphorimager in combination with Optiquant software v. 2.50 (Cyclone Storage Phosphor System, Packard Instruments).

RESULTS

The mRNA expression in U937 cells was compared at 2, 6, 10, and 24 h after the infection with NCTC 11638 or 11638-Δ vacA. More than 100 genes altered their mRNA expression at different time points respectively, among which, the genes related to immune evasion were selected (Table 1). To confirm the differential expression profiling of the cDNA microarrays, two genes: *PSMD13* and *ILK* were chosen for northern blot analysis. As shown in Figure 1, the expression levels of these 2 genes were lower in the cells treated with *H pylori* NCTC11638 than those treated with 11638-Δ vacA. In addition, in both cases, the fold ratio changes detected by the microarray were confirmed by Northern blot (Table 2). The level of β-actin transcript was present at approximately the same level in both samples, providing an assessment of RNA content in each sample used for Northern blot analysis.

**Figure 1** Northern blot analysis result. RNA from U937 cells cocultured with *H pylori* NCTC11638 (wild type, w) or 11638- Δ vacA (mutant type, m) or RNA from normal cells (c) were separated by agarose electrophoresis, transferred onto nylon membranes, and probed with the human cDNAs as follows: NM_002817 (PSMD13), and NM_004517 (ILK). Control blots with human β -actin were provided.

DISCUSSION

Helicobacter pylori has found its own way to thrive within host cells, despite the presence of a well-functioning immune system. In the present study, differential expression of macrophage upon stimulation of VacA gives clear evidence that this vacuolating cytotoxin has evolved with various tricks to escape from the innate and adaptive immunity of the host.

Recognition of pathogen-infected host cells by effector T lymphocytes requires intracellular processing of microbial antigens and their presentation on the surface of the antigen-presenting cells (APCs) in association with MHC molecules. To avoid immune recognition, many kinds of microorganisms have evolved mechanisms which interfere with antigen presentation pathways. These mechanisms may be pivotal, especially for those pathogens causing persistent infections. The present differential expressions provide clear evidence that VacA downregulates the expression of MHC class I and class II molecules in macrophage. Thus, specific T lymphocytes may not be activated, resulting in the evasion of *H pylori* from the host's immune response and colonization of the bacteria in gastric mucosa persistently, remaining "invisible" to both CD8⁺ and CD4⁺ T cells. Interference with the class II antigen presentation pathway by *Listeria monocytogenes* has been shown to result in a reduced proliferation of CD4⁺ T lymphocytes in response to heterologous antigens^[6]. Interactions between MHC class I and human immunodeficiency virus (HIV) resulted in down-regulation of MHC-I surface expression, contributing to pathogenesis by suppressing the host's immune response^[7]. The role of MHC class I and class II-restricted functions in *H pylori* infection and immunity upon oral immunization has also been examined *in vivo*. It was found that experimental challenge with *H pylori* resulted in significantly greater colonization in MHC class I and class II mutant mice than in wild-type mice^[8]. MHC class II-deficient mice were unable to respond to oral antigenic stimulation and

remained persistently infected with *H pylori*^[8].

Nitric oxide (NO) is an important mediator of biological processes including inflammatory response. It is synthesized from L-arginine by a family of nitric oxide synthases (NOS), in which, endothelial NOS (eNOS) is a constitutively expressed isoform present in vascular endothelial cells, cardiac myocytes, and blood platelets^[9]. eNOS interacting protein (NOSIP) is a 34 ku protein specifically binds to the carboxylterminal region of the human eNOS oxygenase domain, overexpression of which in eNOS-expressing cells has been demonstrated to inhibit NO synthase activity^[10]. Thus, down-regulation of this protein upon stimulation of VacA may relieve such inhibition, leading to more NO production. The original concept that the small quantities of NO generated in a pulsatile fashion by constitutive eNOS mainly fulfil regulatory functions required for normal homeostatic function of the vasculature, while the high amount of NO produced by inducible NOS (iNOS) exerts antimicrobial and cytotoxic effects in the immune system, has recently been modified^[11]. The expression of eNOS is not restricted to endothelial cells, as it has been found to be present in monocytes/macrophages and in B and T lymphocytes^[12]. eNOS can also assume typical immunological functions previously assigned to iNOS, such as the induction of apoptotic cell death and the control of viruses^[11]. NO endows macrophages with cytostatic or cytotoxic activity against microbes and tumor cells^[13]. Nevertheless, more and more evidences have demonstrated a role for NO in the induction of immunosuppression by inhibiting T-cell proliferation during G1/S transition^[14-16]. In mouse models of T-cell-mediated autoimmunity, such as myelin antigen-induced EAE, the disease was exacerbated by genetic deletion of iNOS, indicating that NO suppressed T-cell-mediated immunity *in vivo*^[17]. In addition, NO induces apoptosis, which, the ubiquitin/proteasome and NF- κ B pathway have been determined to be involved in^[18].

In eukaryotic cells, degradation of many proteins involves their initial modification by conjugation of ubiquitin (Ub). Ubiquitinated proteins are rapidly degraded by the 26S proteasome^[19]. NO can inhibit the activities of the 20S and 26S proteasomes, providing a likely mechanism for the accumulation of NO-induced pro-apoptotic proteins p53 and Bax, the substrates of the ubiquitin/proteasome system^[18]. Apart from the indirect effect via NO functioning, the mRNA expression of proteasomes shows a significant downregulation as the result of being directly stimulated by VacA. Ub/proteasome pathway can catalyze the proteolytic processing of inactive 105 ku NF- κ B precursor into 50 ku subunit. p50 is then maintained in the cytosol conjugated with the p65 subunit in an inactive complex bound to I κ B. In addition, Ub/proteasome is involved in proteolytic digestion of I κ B, which is required for NF- κ B activation^[19]. Therefore, decreased proteasome activity should inhibit the proteolysis of NF- κ B precursor and inhibit I κ B degradation, thus blocking NF- κ B activation. Another involved protein, integrin-linked kinase (ILK), which has been determined to upregulate NF- κ B activity^[20], also shows decreased expression in this study. It might be the result of VacA induction, and moreover, ILK mRNA expression was found to be downregulated by NO^[21], corresponding to the above speculation that more NO may be produced due to downregulation of NOSIP. NF- κ B is known to be important

to cell survival. Fibroblasts and macrophages from Rel A (p65 subunit of NF- κ B) (-/-) mice were sensitive to TNF- α -induced cell death, and reintroduction of Rel A enhanced cell survival^[22]. Activation of NF- κ B is required for inflammatory cytokine release by macrophages during infection^[23]. Consequently, inhibition of NF- κ B activation may be responsible for decreased cytokine release from macrophages and the resulting immunosuppression. Additionally, because ILK is an apoptosis suppressor^[24], decreased production of this protein in macrophage may accelerate apoptosis of the cell that plays important roles in innate host defense and antigen presentation, leading to the evasion from host immunity against *H pylori*.

The capability of degrading proteins by the proteasome accounts for another important function to generate peptides presented on MHC-class I molecules to circulating lymphocytes. The presentation of these peptides enables the immune system to screen for and destroy cells expressing unusual polypeptides^[19]. Selective proteasome inhibitors were determined to prevent MHC-class I presentation of the antigenic peptide^[25]. Moreover, LMP2 and LMP7, two subunits of the proteasome, were found to be encoded in the major histocompatibility complex (MHC)^[26-28]. The experiment using specific antibodies against LMP2 and LMP7 showed that they were co-expressed with MHC-class I molecules^[29]. The levels of MHC-class I expression were shown to coincide perfectly with the LMP levels in different tissues, corresponding to the result in the present study, which shows simultaneous downregulation of MHC-class I and LMP7.

MSP, also known as HGF-like protein, is a serum protein belonging to the plasminogen-related growth factor family. It was originally discovered by Leonard and Skeel as a serum protein that stimulates shape change, movement, chemotaxis and phagocytosis of mouse peritoneal resident macrophages^[30,31]. The other important effect of MSP on macrophages was to inhibit endotoxin- or cytokine-stimulated NO production^[32]. Thereby, the decreased expression of MSP may contribute to deactivating macrophage and producing more NO, which, as described above, functions as an immunosuppressor.

The early growth response 1 (EGR1), a zinc-finger transcription factor that was shown to be significantly upregulated by 2 h postinfection in the present study, has been determined to induce downregulation of copper-zinc superoxide dismutase and manganese superoxide dismutase and stimulate the generation of reactive oxygen species (ROS) via the NADH/NADPH-oxidase system^[33]. In addition to NO, ROS produced by NADPH oxidase also have the ability to inhibit the proliferation of lymphocytes by a mechanism that suppressor macrophages impair the proliferative response of T lymphocytes to antigens or mitogens^[11]. Otsuji *et al.*^[34] demonstrated that the oxidative stress from tumor-derived macrophages mediated the decrease of CD3 ζ chain within T cells, which suppressed the antigen-specific T-cell responses. Pre-treatment of CTL or NK cells with nontoxic concentrations of H₂O₂ severely reduced their cytotoxic activity, leading to the speculation that macrophage-derived reactive oxygen metabolites contribute directly to alterations in signal transducing molecules of T cells and NK cells and to the mechanism of immunosuppression^[35]. Furthermore, the defective expression of CD3 ζ on lymphocytes has been related to some kind of carcinoma, including gastric adenocarcinoma^[36,37].

From Table 1, we may find up-regulation of MRC OX-2 (the antigen identified by monoclonal antibody, MOX2), a broadly expressed membrane glycoprotein, which has been shown to be important for regulation of the macrophage lineage. In the OX-2-deficient spleens, the number of macrophages was nearly twice the number of those in normal spleens^[38], implying a role of OX-2 in suppressing the activation of macrophage. The immunosuppression effects of OX-2 could be further

determined by many other studies. For example, several studies reported that increased expression of OX-2 in mice receiving renal allografts was associated with immunosuppression leading to increased graft survival, along with the polarization of cytokine production to type 2 cytokines in lymphocytes harvested from the transplanted animals^[39-41]. Furthermore, infusion of a mAb to OX-2 blocks both the increased graft survival and the altered cytokine production^[42]. All these data make clear that upregulation of OX-2 does favor to the immune evasion of *H pylori*.

Table 1 also demonstrates significant downregulation of many cytoskeleton-related gene expression. For example, RhoG is a member of the Rho family of GTPases, which signals to actin assembly during phagocytosis^[43]. Vav1 serves as a guanine nucleotide exchange factor (GEF) for Rho proteins, and establishes an essential and direct link between receptors with intrinsic or associated tyrosine kinase activity and the mitogenic and cytoskeletal pathways regulated by Rho proteins^[44]. Cytoskeleton has been known to be an important structural basis for phagocytosis since cytochalasin B, a toxin that blocks actin polymerization, was shown to inhibit uptake of IgG-coated erythrocytes by mouse macrophages^[45]. Phagocytosis is a process by which macrophages and leukocytes could ingest microbial pathogens to accomplish two essential immune functions, *i.e.*, to initiate the microbial death pathway, and to direct antigens to both MHC I and MHC II compartments. That is to say, phagocytosis serves not only as an innate immune effector but as a bridge between the innate and acquired immune responses^[1]. Thus, to destruct cytoskeleton may be another trick of VacA to evade host immune response.

In conclusion, we have shown that *H pylori* VacA induces the alteration of a series of genes related to immune evasion in macrophage, which ultimately establishes a state of host-microbial equilibrium. Some of these genes are for the first time made an association with VacA stimulation. Further investigations of the previously uncharacterized genes should be made to help us see through the underlying mechanisms utilized by *H pylori* to escape host immunity.

Abstract

AIM: To explore the effect of c-myc, Ki-67, MMP-2 and VEGF expression on prognosis of hepatocellular carcinoma (HCC) patients undergoing tumor resection.

METHODS: Primary HCC patients underwent tumor resection were retrospectively analysed. The maximum size of the tumor was less than 5 cm, there was only one nodule in each patient. No chemoembolization was performed before resection. They were followed up after resection, and the time of recurrence was recorded. They were divided into 2 groups: group A (15 cases): tumor recurrence within 1 year after tumor resection, and group B (15 cases): with or without tumor recurrence 2 years after tumor resection. Pathological slices were made with tumor wax-sample. Immunohistochemistry staining was performed with c-myc, Ki-67, MMP-2 and VEGF monoclonal antibodies. Staining intensity was quantitatively analysed with a pathological diagram-writing analyzing system. The expressing intensity differences of stained molecules in cancer tissue and para-cancer were analysed.

RESULTS: c-myc, Ki-67, MMP-2 and VEGF expressing intensities in cancer tissue in group A were higher than those in group B (*P* values were 0.010, 0.030, 0.022 and 0.004, respectively), but they were not significantly different in para-cancer tissue in groups A and B (*P* values were 0.334, 0.343, 0.334 and 0.334, respectively).

CONCLUSION: The expression of c-myc, Ki-67, MMP-2 and VEGF in cancer tissue is related to the recurrence of HCC after tumor resection.

INTRODUCTION

Recurrence is the main factor influencing prognosis of hepatocellular carcinoma (HCC) after tumor resection. The therapeutic measures for patients before and after operation are similar, but their prognosis after operation differs largely.

Some patients had tumor recurrence within 1 year after operation, while others had or did not have tumor recurrence 2 years after operation. The reason why there is such a difference is not clear. Researches on molecular biology have demonstrated that the prognosis of HCC is related to the activation of proto-oncogene, inactivation of tumor suppressor gene, abnormal expression of growth factors and/or their receptors^[1]. Four kinds of molecules related to biologic characteristics of HCC were studied in this experiment to clarify their relationship with recurrence of HCC after resection.

MATERIALS AND METHODS

Patients

Thirty primary HCC patients undergoing resection at Department of Hepatobiliary Surgery in General Hospital of PLA (301 Hospital) were retrospectively analysed. All resected samples were proved as HCC with pathologic examination. The selecting standards were as follows: solitary nodule with its maximum size less than 5 cm, no transarterial chemoembolization (TACE) or local thermal therapy (such as microwave coagulation or radiofrequency) before resection, no other specific treatment after resection. There were 28 males and 2 females. Their mean age was 51.5 (range, 27-75) years. The mean size of tumors was 3.0 cm. The patients were divided into two groups according to follow-up results: group A, which had tumor recurrence within 1 year after resection, group B, had or did not have tumor recurrence 2 years after resection. 15 cases were in group A (14 males and 1 female) and 15 cases in group B (14 males and 1 female). The differences of clinical data (sex, age, tumor size, liver function, serum AFP, transaminase, HBV infection) were not significant (Table 1).

Table 1 Clinical data of patients in groups A and B

Item	Group A (n=15)	Group B (n=15)
Sex	14 males, 1 female	14 males, 1 female
Age (yr)	54.7±14.3	48.2±8.4
Mean diameter (cm)	3.2±1.0	2.9±1.1
Tumor volume (cm ³)	22.0±21.4	18.2±17.6
Liver function	grade A	grade A
Serum AFP ^a (grade)	0.9±1.0	0.6±1.0
ALT (U/L)	58.0±54.1	64.9±56.6
AST (U/L)	49.9±46.8	42.0±37.7
HBV infection rate	87% (13/15)	100 (15/15)

^aserum AFP was graded as follows: 0: 0-200 µg/L, 1: 201-400 µg/L, 2: >400 µg/L.

Instrument and reagent

HPIAS-1000 high acuity color pathologic diagram-writing analyzing system (produced by Wuhan Champion Image Technology Corporation Limited). SP and DAB kit, monoclonal antibodies of c-myc, Ki-67, MMP-2 and VEGF were all purchased from Beijing Zhongshan Biological Technology Corporation Limited. The characteristics of antibodies are listed in Table 2.

Table 2 Characteristics of antibodies used in this study

Name of antibody	Specificity	Dilution	Secondary antibody
c-myc	Monoclonal	1:50	Goat anti mouse
	Mouse anti human		
Ki-67	Monoclonal	1:50	Goat anti mouse
	Mouse anti human		
MMP-2	Monoclonal	1:50	Goat anti mouse
	Mouse anti human		
VEGF	Monoclonal	1:50	Goat anti mouse
	Mouse anti human		

Immunohistochemistry staining

Serial 4 μ m thick sections were made with wax sample of resected tumors. Immunohistochemistry staining was performed with SP three-step method using the monoclonal antibodies listed in Table 2.

Quantitative analysis of positive cells

Quantitative analysis of the examined molecules was performed with HPIAS-1000 high acuity color pathologic diagram-writing analyzing system. Molecules in cancer and para-cancer tissues were analysed. Three fields of view (FOV) were randomly selected in cancer and para-cancer tissues to quantitatively analyse the expressing intensity. One hundred cells were observed in each FOV, positively stained cells were calculated, finally the average positively stained cells in 100 observed cells were determined. The cells were determined as positive-staining only if they were stained without considering their staining intensity. The medium optical density (MOD) of plasma or nuclei in positively stained cells was calculated with a pathologic diagram-writing analyzing system. The product of multiplication of average positively stained cells and MOD was calculated, which was considered as the expressing intensity of positively stained molecules.

Comparison of staining

The difference of expressing intensity of examined molecules in cancer and para-cancer tissues was compared in the same group (group A or B), the difference of expressing intensity in groups A and B was compared in the same tissue (cancer tissue or para-cancer tissue).

Statistical analysis

Data were presented as mean \pm SD. Paired-sample *t* test was used to compare the difference, the statistic software SPSS 10.0 was used. *P*<0.05 was considered statistically significant.

RESULTS

Expressing rate and intensity of examined molecules in cancer and para-cancer tissues in group A (Table 3)

Table 3 Expressing rate(%) and intensity of examined molecules in cancer and para-cancer tissues in group A

Micrographs of *c-myc*, Ki-67, MMP-2 and VEGF

The micrographs of *c-myc*, Ki-67, MMP-2 and VEGF positive and negative expression were listed in figures 1-4.

DISCUSSION

Relationship of *c-myc* expression with prognosis of HCC

Activation of *c-myc* oncogene plays important role in cancer occurrence, gene location on chromosome of 8q24. *c-myc* oncogene can be activated through two ways. One is that it is confluent by light chain sequence of immunoglobulin through chromosomal translocation, the other is through DNA amplification. The protein coded by *c-myc* oncogene contains 439 amino acids, and can be combined specifically with intranuclear DNA to play transcription regulating function. *c-myc* oncogene is not expressed in the resting phase of cells, while it is rapidly expressed under the induction of mitoses, then it promotes cell proliferation and infiltration. It was reported in literature^[2] that HBV interpolation could promote amplification and over-expression of *c-myc* oncogene, then normal cellular genetic regulation was disturbed. Genetic mutation related with cancer occurrence could be induced through this mechanism, it was related with occurrence of HCC. *c-myc* oncogene codes phosphoric acid protein whose molecular weight is 62 KD. The protein is located in the nuclei of normal hepatocytes and HCC cells, as well as in plasm of some cells. It was demonstrated *in vitro* that the blockage of *c-myc* expression could suppress the growth of HCC cells^[3-5]. Some researchers demonstrated that the expression of *c-myc* in HCC tissue was related with the prognosis of HCC patients^[6]. Wang *et al.*^[7] reported that amplification of *c-myc* oncogene was correlated with a poor prognosis of HCC. Niu *et al.*^[8] reported that the positive expressing rate of *c-myc* in HCC was correlated with the histological differentiation, and was significantly higher in the poorly differentiated samples than in well differentiated samples. Zhang *et al.*^[9] reported that *c-myc* gene amplification was closely related to the development and progression of HCC. This study showed that *c-myc* expressing rate and intensity in cancer tissue in patients of group A were higher than those in para-cancer tissue, while the *c-myc* expressing rate and intensity in cancer tissue in patients of group B were not significantly

different from those in para-cancer tissue. *c-myc* expressing intensity in cancer tissue in patients of group A was higher than that in patients of group B. It demonstrated that the expression of *c-myc* in cancer tissue could reflect the malignancy of HCC. HCC with high *c-myc* expression in cancer tissue had a high recurrence rate. *c-myc* expressing rates in cancer tissue in the two groups of patients were significantly different, suggesting that *c-myc* over-expression occurs in HCC, its expressing intensity is related to the prognosis of HCC.

Relationship of Ki-67 expression with prognosis of HCC

Tumor cells consist of proliferating cells (S, G2, M, G1 stage), temporarily non-proliferating cells (G0) and non-proliferating cells. Ki-67 can label proliferating cells in any stage except those in stage G0, while it is not expressed in cells in silent stage. Ki-67 is rapidly degraded or its antigenic determinant is disappeared after mitosis. So Ki-67 is considered as a kind of objective marker reflecting proliferating activity of cells. Ki-67 is located in cell nuclei, and always in particle shape in immunohistochemistry staining. Ki-67 labelling index has been considered as a marker of cellular proliferative activity, the higher the Ki-67 labelling index, the lower the cellular differentiation and the poorer the prognosis of HCC^[10-16]. It was demonstrated in this study that Ki-67 expressing rate in cancer tissue in group A was higher than that in para-cancer tissue, while the expressing intensity was not significantly different. Ki-67 expressing rate and intensity in cancer tissue in group B were not significantly different from those in para-cancer tissue. Ki-67 expressing intensity in cancer tissue in group A was much higher than that in group B, suggesting that Ki-67 expression could reflex malignancy of HCC. HCC with a high Ki-67 expression had a high recurrence rate. Ki-67 expressing rate in cancer tissue of the two groups was not significantly different, suggesting that Ki-67 is abnormally expressed in HCC, its expressing intensity is related to the prognosis of HCC.

Relationship of MMP-2 expression with prognosis of HCC

A main step of invasion and metastasis of malignant tumor is to degrade extracellular matrix (ECM) and basement membrane. There are much collagen IV in ECM and basement membrane, collagen IV is very important for maintaining the integrity of ECM and basement membrane. Collagenase IV could degrade collagen IV and destroy the integrity of basement membrane. Matrix metalloproteinase II (MMP-2) is a kind of collagenase IV, its expression is related to tumor recurrence and metastasis. Positive particles of MMP-2 are located in cell plasm. Some researchers reported that MMP-2 expression in cancer tissue was related with prognosis of HCC, HCC with high MMP-2 expression had high malignancy, easy recurrence and metastasis^[17-23]. This study showed that MMP-2 expressing rate and intensity in cancer tissue in group A were higher than those in para-cancer tissue, MMP-2 expressing rate and intensity in cancer tissue in group B were not significantly different from those in para-cancer tissue. MMP-2 expressing intensity in cancer tissue in group A was much higher than that in group B, suggesting that MMP-2 expression could reflex malignancy of HCC. HCC with a high MMP-2 expression had a high recurrence rate. MMP-2 expressing rate in cancer tissue of the two groups was not significantly different, suggesting that MMP-2 is abnormally expressed in HCC, its expressing intensity is related to the prognosis of HCC.

Relationship of VEGF expression with prognosis of HCC

Vascularization is an important link in tumor growth, invasion and metastasis. Tumor blood vessels not only provide nutrition needed for tumor growth, but also provide pathways for spreading tumor cells. Vascular endothelial growth factor (VEGF) could promote cell proliferation and vascularization, and is

closely related to growth, invasion and metastasis of HCC. Expression of VEGF in HCC tissue is positively correlated with growth and metastasis of HCC, it could be a marker for determining the prognosis of HCC. Positive particles of VEGF are located in plasm of tumor cells. Some researchers reported that HCC patients with high VEGF expression had poor prognosis^[24-28]. This study showed that VEGF expressing rate and intensity in cancer tissue in group A were higher than those in para-cancer tissue, VEGF expressing rate and intensity in cancer tissue in group B were not significantly different from those in para-cancer tissue. VEGF expressing intensity in cancer tissue in group A was much higher than that in group B, suggesting that VEGF expression could reflex malignancy of HCC. HCC with a high VEGF expression had a high recurrence rate. VEGF expressing rate in cancer tissue of the two groups was not significantly different, suggesting that VEGF is abnormally expressed in HCC, its expressing intensity is related to the prognosis of HCC.

Clinical value of this study

Ultrasound guided biopsy becomes a kind of mature diagnostic technique for HCC. It was shown in this study that characters of HCC with recurrence within 1 year after tumor resection were *c-myc*, Ki-67, MMP-2 and VEGF high expression in cancer tissue. If prognosis of HCC patients could be determined through quantitative analysis of biopsied tissue stained with immunohistochemistry before treatment, then theoretical fundamentals for HCC patients to select therapy method could be provided.

Abstract

AIM: To investigate the effects of bile reflux and intragastric microflora changes on lesions of remnant gastric mucosa after gastric operation.

METHODS: Concentration of bile acid and total bacterial counts (TBC) in gastric juice were measured in 49 patients with peptic ulcer before and after gastrectomy. One year after the operation, sample of gastric mucosa taken from all the patients were used for histological examination.

RESULTS: The concentration of gastric bile acid was significantly increased in group B-I, or B-II and SV+A than that in group HSV ($P < 0.05-0.01$). The abnormal histological changes in the remnant gastric mucosa were more common in the first 2 groups than in the last group.

CONCLUSION: The type of gastrectomy can affect bile reflux. The abnormal histological changes in the remnant gastric mucosa are closely related to the elevation of bile acid concentration and increase of TBC in gastric juice. HSV can effectively prevent bile reflux and keep the gastric physiological functions stable.

INTRODUCTION

Bile reflux was usually found after routine operation in the treatment of peptic ulcer, and for some patients, it could be found very serious complications, such as epigastric causalgia, obstinate bilious vomiting, body mass descent and so on, its incidence is 5-35%^[1-4]. Forty-nine patients with gastric resection in treating peptic ulcer were observed in order to investigate the effects of bile reflux and intragastric microflora changes on lesions of remnant gastric mucosa after gastrectomy gastric resection.

MATERIALS AND METHODS

A total of 49 patients with peptic ulcer (32 male, 17 female, average age 44.3 years) including 14 patients with gastric ulcer, 28 patients with duodenal ulcer and 7 patients with compound

ulcer were investigated in a retrospective manner. These patients were divided into 4 groups according to the operation kind: 10 patients with Billroth I (B-I), 14 patients with Billroth II (B-II), 12 patients with selected vagotomy plus antrectomy (SV+A), 13 patients with High selected vagotomy (HSV).

Gastric juice on an empty stomach was been extracted at 3-5 d pre-operation, 7 d post-operation, 3 wk and 1 year post-operation, the bile acid concentration was measured by radio-immunity analysis (RIA), obtained from Wuzhou Institute of Isotope.

A 0.5 mL gastric juice plus 5 mL broth was put into sterilization test tube and cultured at 37 °C for 24-48 h, it was defined sterile growth if it had no bacteria growth through observation of 48 h, if bacteria were found, it were separated and evaluated by means of platinum loop.

For pro-operation annual patients, 2 samples of gastric mucosa were fixed by formaldehyde solution, then were observed through light microscope. Diagnosis of gastric ulcer was based on the detection standard of gastric mucosal disease formulated by gastric cancer co-operation group in 1981. The result was indicated by count scores as follow: the normal gastric mucosa was equal to 0; slight-degree, medium-degree, and sever-degree superficial gastritis were 1, 2, and 3; slight -degree, medium-degree, and sever-degree atrophic gastritis were 4, 5, and 6; if gastritis plused slight-degree, medium-degree and severe-degree intestinal metaplasia, the scores would be plus 1, 2, 3.

RESULTS

Bile acid concentration at post-operation 3 wk and 1 year was significantly increased than that at pre-operation in group B-II ($P < 0.05$), and is the same in group B-I ($P < 0.05$) and in group SV+V ($P < 0.05$); Bile acid concentration at post-operation was slight increased ($P > 0.05$). From post-operation 3 wk, bile acid concentration in B-II, B-I and group SV+V were significantly increased than that in group HSV, especially in group B-II (Table 1).

After operation, total bacterial count of gastric juice in group B-II, B-I and group SV+V were significantly increased than that in group HSV ($P < 0.05-0.01$). In this study, 204 samples of gastric juice were cultivated, 88 samples were found bacteria growing in 92 samples that pH was > 4.0 and the count of bacteria will be more along the higher of pH ($r = 0.784$, $P < 0.01$). Gram-Negative bacillus were always found after operation, and associated with the level of bile reflux. The rate of finding Gram-Negative bacillus was 64.1% in group B-II, 25.81% in group B-I, 29.62% in SV+A, and 10.25% in group HSV and significantly lower than that in 3 groups ($P < 0.01$, $P < 0.05$, $P < 0.05$). *Escherichia coli* and *Bacillus proteus* were common in group B-II, B-I and group SV+V, but, *Streptococcus* and *Lactobacillus* were common in group HSV.

During 1 year after operation, the incidence of atrophic gastritis was 35.7% in group B-II, 30% in group B-I, 33.3% in SV+A, 15.4% in group HSV. The incidence of Intestinal metaplasia was 28.6% in group B-II, 20% in group B-I, 25% in SV+A, 7.8% in group HSV. It was found by statistics analysis that the degree of change of gastric remnant

Table 1 Changes of bile acid concentration of gastric juice in different group($C_B/\text{nmol} \cdot \text{mL}^{-1}$, mean \pm SD)

Group	n	Pre-operation	Post-operation

Table 2 Changes of total bacterial count of gastric juice in different groups (log10/mL, mean \pm SD)

Group	n	Pre-operation	Post-operation		
			1 wk	3 wk	1 yr
B-II	14	1.27 \pm 2.14	3.83 \pm 2.09 ^a	4.86 \pm 0.38 ^b	3.97 \pm 1.97 ^b
B-I	10	1.77 \pm 2.35	4.30 \pm 1.64 ^a	4.33 \pm 1.55 ^a	3.82 \pm 1.99 ^b
SV+A	12	1.84 \pm 2.27	3.90 \pm 1.79 ^a	4.13 \pm 1.68 ^a	3.85 \pm 2.04 ^b
HSV	13	1.26 \pm 2.07	2.41 \pm 2.35	2.59 \pm 2.78	1.56 \pm 2.13

^a $P < 0.05$, ^b $P < 0.01$ vs HSV.

Table 3 Results of histological examination of remnant gastric mucosa 1 year after operation

Group	n	Normal	Superficial gastric	Atrophic gastritis			Intestinal metaplasia		
				Slight	Medium	Severe	Slight	Medium	Severe
B-II	14	0	9	2	2	1	1	1	2
B-I	10	0	7	2	1	0	1	0	1
SV+A	12	0	8	1	1	1	1	1	1
HSV	13	0	10	1	1	0	1	0	0

histological abnormality alteration in group B-II, B-I and group SV+V was significantly higher than that in group HSV (t values separately were 2.047, 2.025, 2.029, $P < 0.05$), and the change of gastric remnant histological abnormality alteration associated with increasing of concentration of gastric juice cholic acid.

DISCUSSION

Bile reflux was common in gastric post-operation and the mod of operation could affect the degree of bile reflux, generally speaking, it was slight after high selected vagotomy, it was severe after gastrectomy, and it was very common in Billroth II^[1]. In our study, the concentration of gastric juice cholic acid was significantly increased in group B-II, it was higher in group B-I and group SV+V than that in group HSV. There was no significant difference between pre-operation and post-operation in group HSV although it was slight higher after operation, so it suggested that HSV could reduce bile reflux. Traditional gastrectomy and SV+A destructed the normal gastric dissection and deleted the function of Pyloric and innervation, these factors resulted in gastric emptying disorder and dodecadactylon increased reversed peristalsis, so bile reflux was increased and it could lead to the lesion of gastric mucosa. HSV remained the Pyloric dissection and innervation, it maintained the usual diet passage, and the function of Pyloric is normal, so it could prevent intestines and stomach reflux^[2].

Alkaline reflux gastritis was a complex complication after gastric operation, and its mechanism is not yet fully understood. We think when mod of operation was selected, we should excerpt the mod in coincidence to normal physiology function and based on the patient's specific situation in order to reduce the complication.

The effect of bile reflux on total bacterial count and the

changes of remnant gastric mucosa histological Current concepts suggest that gastric acid possesses strongly germicidal effect, the count of bacteria of gastric acid was only $10^5/\text{mL}$, and the denomination of bacteria was similar to that in buccal cavity. Oxyntic cell was deleted or its innervation was broken after gastric operation, so the ability of stomach excreting acid was decreased, the data of pH were creasing, if the small intestinal juice including bile reflux to stomach, the data of pH would be more increased. These factors are advantageous to bacteria growth and breeding, resulted in intragastric bacterial over-growth (IBO), the flora in Lower digestive tract (especially Gram-Negative bacillus and Anaerobe) could reflux to stomach and reproduced here^[5-10]. Because of these bacteria, the conjugate cholic acid changed to freeing cholic acid which has a strongly toxic effect, and the following could damaged the integrity of gastric mucosa, certain cationic permeability could increased, such as H^+ could contra-direction diffuse, and these changes can resulted in Mast cell releasing histamine and 5-serotonin, so it could be found capillary telangiectasia, mucosa hyperemia, edema, bleeding, and superficial Ulceration^[11,12].

In our study, the concentration of cholic acid in gastric juice was higher, the bacterial count of gastric juice was more, and the denomination of flora in intestinal tract was more. Pathological examination found that flaming cell infiltration, atrophic gastritis, and intestinal metaplasia, all these could indicate that the abnormal histological changes of gastric mucosa associated with the increasing concentration of cholic acid in gastric juice and increasing total bacterial count of gastric juice.

The role of dodecadactylon regurgitation resulting in gastric mucosa precancerous lesion and gastric cancer was though highly, Houghton *et al.* found that follicle cell and DNA count was increased if rat was raised by carcinogens (MNNG) and

at the same time reinforced regurgitation from dodecadactylon to stomach, so the ratio of gastric carcinoma was significantly increased. Freeing cholalic acid was confirmed as carcinogen, it could result in stomach carcinoma if it was higher in a long term^[13-17]. For patients with higher concentration of cholalic acid in gastric juice, intragastric bacterial over-growth (IBO), and pathological examination finding abnormal changes, should be thought highly of the occurrence of stomach carcinoma.

INTRODUCTION

Awareness of the digestive system began with the dawn of civilization, when man observing the feeding habits of animals in the surrounding environment, experimented with foods, edible and inedible. Identity came with discoveries of the digestive organs during the 16th and 17th centuries. Function was revealed by physiologic studies of digestion, absorption and secretion, metabolism, and motility during the 18th and 19th centuries. Diagnostic access improved with the technological advances of the 20th century. Understanding of gastrointestinal (GI) disease followed growth of the basic sciences and gastroenterology's increased involvement in scientific research during the 20th century.

The scientification of medicine and gastroenterology began during the latter part of the 19th century when the discovery of bacterial causes of disease revealed the potential of research in the discovery of new knowledge, and when the dogma of the past began to yield to clinical and basic investigation. Additional impetus came from A. Flexner's 1910 report on medical education, documenting the importance of a scientific foundation in medicine. Funds for gastroenterologic investigation were small, but research was in progress in the physiology laboratories of academic medical centers. Early in the 20th century, gastroenterology was yet an incompletely defined activity; but during the 1920s, outstanding clinicians established gastroenterology programs at university academic centers and major clinics. The entry of scientifically trained young physicians into gastroenterology during the 1930s and 1940s increased research interest.

Specialization in medicine was underway and, in the United States in 1940, gastroenterology was certified as an academic specialty, important to the attraction of students and support for education and research. Similar recognition occurred elsewhere, but further progress was interrupted by World War II (1939-1945).

Post-World War II was a highly productive period for the basic and biomedical sciences. Wartime discoveries had documented the remarkable success of research and had motivated public and governmental support of basic investigation.

This trend accelerated in the United States, when the office of Scientific Research and Development (U.S. War Department) transferred 44 research contracts with universities and with industry to the then fledgling National Institutes of Health (NIH) at the end of World War II. The General Medicine Study Section of the National Institute of Arthritis and Metabolic Diseases (NIH) became a major support of GI research and training. During the 1960s, 1970s and 1980s, academic medical center faculties enlarged and research training programs increased, creating new technologies and new disciplines. Important advances occasionally developed from insightful clinical observations. A classic example concerns the "epidemic" of pellagra, considered an infection early in the 20th century and accounting annually for 250 000 cases and 7 000 deaths in 15 Southern cotton-growing U.S. states. In 1914, at age 40, Dr. Joseph G. Goldberger of the Public Health Service, through shrewd clinical observations of patients, hospital staff, and patient diets, implicated a dietary deficiency (confirmed later as a nicotinic acid deficiency) as the cause of pellagra. However, scientific activity was associated with much prestige, and gastroenterology sought to become more "scientific".

Gastroenterology essentially incorporates basic concepts and technology, from multiple scientific disciplines, into its own investigation. The early 1900s' view of swallowing, as the forceful "bolting" of food from the throat directly into the stomach, was replaced by the recognition of pharyngeal and esophageal neuromuscular function, facilitating the physiological management of swallowing disorders. Histologic and microbiologic examination of endoscopically obtained gastric biopsies replaced the subjective diagnosis of "chronic gastritis". Not until the 1980s, however, was the role of *Helicobacter pylori* in gastritis and peptic ulcer identified. Multidisciplinary research clarified the process of gastric secretion and led to the development of H₂ blockers and proton pump inhibitors. Metabolic studies identified the specific L-glutamine requirement for the intestinal epithelium and the short-chain fatty acid, n-butyrate, for the colonic epithelium. Research into the nature of inflammation led to more effective strategies for the treatment of inflammatory bowel disease. Cellular biology identified the intracellular heat shock proteins, trefoil peptides, and stem cell growth factors, with therapeutic potential. The important role of genetic influence, in the development of colorectal cancer, celiac disease, and inflammatory bowel disease, was extended to other GI diseases.

Gastroenterology's 20th-century technological progress was equally impressive. The study of esophageal motility progressed from balloon kymography to intraluminal catheter manometry, transducers, and neuropharmacologic methodology. Fiberoptic endoscopy expanded diagnostic access to virtually all areas of the gastrointestinal tract. Safer polyethylene tubing eased transintestinal intubation and perfusion studies, and with small bowel biopsy and radioimmuno-assays, clarified intestinal absorption mechanisms. Microbiological and chromatographic technologies, including hydrogen and carbon-14 breath tests, increased knowledge of the enteric flora, enabling the diagnosis of bacterial overgrowth responsive to antibacterial therapy. Needle biopsy of the liver established the morphological basis of hepatic disease and provided guidelines for the treatment of hepatitis and the monitoring of

liver transplantation. Discovery of the Australia antigen stimulated research, identifying seven types of hepatitis viruses (A, B, C, D, E, F, G), a major impetus in the growth of knowledge of liver disease. Biochemical and chromatographic technology determined the composition of bile and the process of formation, as well as the chemical dissolution of cholesterol gallstones. Enzyme and protein chemistry established the synthesis and trafficking of intracellular proteins and intracellular enzyme activation as the cause of acute pancreatitis. Transmission, electron microscopy and laser-scanning confocal microscopy facilitated the study of intestinal epithelial cells, intracellular protein processing, and epithelial barrier function. Molecular biological techniques made possible the cloning of genes for cystic fibrosis, sodium, calcium, glucose, and amino acid transport. Advances in radiologic image intensification, ultrasonography, computed x-ray tomography of the abdomen, and magnetic resonance imaging among other achievements, increased access to the gastrointestinal tract.

Neuro-humoral and neuro-immune interactions of the GI tract, mediating colonic motility and visceral sensitivity, replaced psychogenic hypotheses of the irritable bowel. Studies of gastrointestinal immunology, including the gut mucosal immune system and the molecular mechanisms of inflammation, generated new pathogenic concepts and therapeutic resources in inflammatory bowel disease (IBD). Measurements of gastrointestinal blood flow, including laser Doppler velocimetry, facilitated recognition of abdominal vascular impairment. Neurogastroenterology introduced methods of electrophysiology and cellular neurophysiology, identified the enteric nervous system as a "minibrain with intelligent circuits", and provided new understanding of "physiologic" GI disorders. Transgenic methodology created innovative animal models, enabling multidisciplinary studies of intestinal inflammation.

Expanded access to the gastrointestinal tract, including fiberoptic endoscopy, biopsies of the esophagus, stomach, small intestine, and colon, X-ray (CT scan)-guided biopsy of the liver and the pancreas, tests of hepatic and pancreatic functions, breath tests, quality X-rays, ultrasonography, computerized abdominal tomography, magnetic resonance imaging, and assessment of gastrointestinal motility improved the diagnosis of digestive disorders. Gastrointestinal therapy advanced with the discovery of sulfonamides, antibiotics, adrenocortical steroids, immune modifiers, H₂ receptor blockers, proton pump inhibitors, anti-inflammatory compounds, nutritional supports, vaccines, cancer chemotherapy, organ transplantation, and increasingly skilled abdominal surgery.

Many favorable circumstances converged to bring gastroenterology into the mainstream of advancing scientific thought, including an enlarging body of scientific knowledge, technological innovations permitting safer, more precise human studies, increased support of research and training, controlled clinical studies, establishment of research and scientific training programs, by the NIH and private philanthropy, and the enlarging global scientific communication network (journals, databases, electronic and computer systems).

The major accomplishment of gastroenterology during the 20th century has been the successful application of new scientific knowledge and technology to the investigation of gastrointestinal disorders. Digestive diseases involving multiple disciplines and innovative technology today are recognized as exciting and challenging problems. Now that gastroenterologic research frontiers are at the cutting edge of modern science, including such "new" sciences as biotechnology, structural biology, and pharmacogenetics, together with the ongoing molecular disciplines (microbiology, immunology, genetics). They will establish the 21st century as the gastroenterologic century.

Abstract

AIM: The survival rate of patients with stomach cancer is used to evaluate the effects of treatments. The short- and mid-term survival of patients on the present level of treatments can be described by calculating 1- to 5-year survival rates. The aims of this study were to document patterns of survival after treatments for stomach cancer in Changle city and analyze whether the stage of cancer and the way of treatment impacted on survival of patients or not.

METHODS: A total number of 745 patients with stomach cancer reported in the Changle Cancer Registry from 1993 to 1998 were investigated with respect to the disease condition, the way of treatment and survival time. 1- to 5-year survival rates were estimated by using life-table method.

RESULTS: The 1- to 5-year survival rates in the patients with stomach cancer in Changle city were 54.23%, 41.77%, 37.95%, 33.98% and 30.47%, respectively. The 1- to 5-year survival rates in stagel or II group were 3, 6.1, 7.4, 8.9 and 9.8 times as high as those in stage III or IV group, respectively. The 1- to 5-year survival rates in operation group were 3.5, 8.7, 11.2, 11.7 and 19 times as high as those in no operation group, respectively. For the patients with stage III or IV stomach cancer the 1-year survival rate in operation group was 3 times as high as that in no operation group and 2-year survival rate in operation group was 11.9 times as high as that in no operation group. For the patients with stage III or IV stomach cancer, the differences of the survival rates average survival times between total gastrectomy and partial gastrectomy were not significant and the median survival times in these 2 groups were 8 mo and 9 mo, respectively.

CONCLUSION: Mid-term survival rates of patients with stomach cancer in Changle city are low. Stage of cancer is an important factor influencing survival of patients with stomach cancer. Surgery is an effective treatment for the patients with stage IV cancer and can raise short- and mid-term survival rates. Total gastrectomy should not be encouraged for the patients with late stage of cancer.

INTRODUCTION

The survival time is used to evaluate the effects of treatments for stomach cancer. The survival rates are calculated in the analysis for the survival time^[1]. Many studies have been conducted on the survival analysis of stomach cancer in recent several decades^[2-8]. The survival of patients with stomach cancer was influenced by the stage of cancer and the way of treatment^[8,9]. Since stomach cancer often was not detected until an advanced state, survival rate was rather low. Only a few patients diagnosed with stomach cancer survive five years or more after diagnosis. There is a higher incidence rate of stomach cancer in Changle city of Fujian Province. To study the survival rates of the patients with stomach cancer and the prognostic factors in Changle city, we investigated the survival time of the patients with stomach cancer diagnosed from 1993 to 1998 and registered in the Changle Cancer Registry. The contents of our research were: (1) to estimate the survival rates of the patients with different stages of cancer and to compare these survival rates; (2) to estimate the survival rates of the patients with different ways of treatments and to compare these survival rates; (3) to analyze the survival benefit of the operation on the patients with stage IV stomach cancer; and (4) To make a comparison of survival between the patients with total gastrectomy and partial gastrectomy of stage IV stomach cancer.

MATERIALS AND METHODS

Materials

There were 747 patients with stomach cancer reported in Changle Cancer Registry from 1993 to 1998. Since two patients had no information of survival, the study sample consisted of 745 patients aged from 28 to 85 at registration. There were 593 male with age (60.1±10.1) years and 152 female with age (62.1±11.4) years in our sample. There were 473 dead patients and 272 patients were still alive during the term of investigation with the age (58.4±9.9).

Methods

The survival times of the 745 patients were obtained by visiting their home. After informed consent was obtained from each patient's family, the stage of cancer at diagnosis and way of treatment for the patient were obtained from the patient's medical record. The cause of death for each dead patient with stomach cancer was identified in the Hospital of Changle. The survival times of the patients who were not died of gastric cancer were not included in the data.

The proportion of stomach cancer patients surviving for one, two, three and five years can be a measure of the effect of treatments. The total survival rates by the stage of cancer and surgery were calculated and analyzed by Chi-square (χ^2 test) statistics. Survival analyses were performed by the life-table method^[1]. The data were analyzed using the SAS 8.2 software.

RESULTS

The 1-, 2-, 3-, 4- and 5-year survival rates and their 95% confidence intervals (CI) were estimated using life-table method (Table 1). Table 1 shows that the 1-year survival rate is 54.2% and the 5-year survival rate is 30.5%.

Table 1 Survival rates using life-table method

Time(yr)	Survival rate	95% confidence interval
1	0.542	0.506-0.578
2	0.418	0.382-0.454
3	0.379	0.343-0.416
4	0.340	0.302-0.377
5	0.305	0.265-0.345

The survival rates by the stage of cancer

The stages of cancer and survival status of 745 patients are shown in Table 2. The patients with stage III or IV cancer had 66.67% total survival rate. There were significance differences between these four total survival rates ($\chi^2=353.76$, $P<0.0001$).

A total number of 745 patients were grouped according to their stages of cancer. One group consisted of the patients with stage I or stage II stomach cancer and the other group consisted of the patients with stage III or stage IV stomach cancer. The survival rates using life-table method in two groups are shown in Table 3. The 1-, 2-, 3-, 4- and 5-year survival rates in stage I or stage II group were 3, 6.1, 7.4, 8.9 and 9.8 times higher than those in stage III or IV group, respectively. The difference of the distributions of survival times between the two groups was significant since the two 95% confidence intervals at each year did not overlap.

Table 2 Total survival rates by stage of cancer

Stage of cancer	Number of patients	Patients alive (n)	Death patients (n)	Total survival rate(%)
I	120	115	5	95.83
II	120	80	40	66.67
III	121	42	79	34.71
IV	384	35	349	9.11

Table 3 Survival rates using life-table method by stage of cancer

Time (yr)	Stage I or II		Stage III or IV	
	Survival rate	95% confidence interval	Survival rate	95% confidence interval

5	0.739	0.665-0.813	0.075	0.034-0.117

Table 4 Survival rates of surgical and non-surgical patients using life-table method by surgery

Time (yr)	Operation		No operation	
	Survival rate	95% confidence interval	Survival rate	95% confidence interval
1	0.753	0.713-0.793	0.217	0.170-0.265
2	0.639	0.594-0.684	0.074	0.043-0.105
3	0.589	0.541-0.636	0.053	0.024-0.081
4	0.528	0.477-0.580	0.045	0.017-0.073
5	0.478	0.420-0.535	0.025	0.013-0.051

The survival rates of patients with and without surgery

A total number of 745 patients were divided into 2 groups according to the way of treatments. One group consisted of 453 patients who underwent operation with total survival rate 55.63% (252/453) and the other group consisted of 292 patients who had no operation with total survival rate 6.85% (20/292). The

difference of the total survival rates between the two groups was significant ($\chi^2=182.26$, $P<0.0001$). The survival rates using life-table method in 2 groups are shown in Table 4. The 1-, 2-, 3-, 4- and 5-year survival rates in operation group were 3.5, 8.7, 11.2, 11.7 and 19 times as high as those in no operation group, respectively. The difference of the distributions of survival times between these two groups was significant.

The survival of the patients with late stage of cancer with and without surgery

A total number of 505 patients with stage III or IV stomach cancer were divided into two groups according to the way of treatments. One group consisted of 230 patients who underwent the gastrectomy operations and the other group consisted of 275 patients who had no operation. The survival rates using life-table method in the two groups are shown in Table 5. The 1-year and 2-year survival rates in operation group were 3 times and 11.9 times as high as those in no operation group, respectively. It was obvious that the survival times of the patients undergone the operation were longer than those of the patients not operated.

A total number of 145 (37.76%) patients with stage IV stomach cancer had gastric resection and 239 (62.24%) were not subjected to surgery. The 1-year survival rates in the 2 groups of patients with stage IV stomach cancer were 0.244 (95% CI 0.173-0.315) and 0.063 (95% CI 0.032-0.094), respectively. The averages of survival times in the two groups of the patients were 13.3 mo (95% CI 11.03-15.57) and 6.1 mo (95% CI 5.64-6.56), respectively. Median survival times in these 2 groups of the patients were 8 mo and 6 mo, respectively. The 1- and 2-year survival rates were significantly higher in operated patients than no operated patients. However, the average of survival time in operated patients prolonged only for 7.2 mo.

Table 5 Survival rates of surgical and non-surgical patients with stage III or IV stomach cancer using life-table method by surgery for patients

Time(yr)	Operation		No Operation	
	Survival rate	95% confidence interval	Survival rate	95% confidence interval
1	0.511	0.446-0.576	0.168	0.124-0.213
2	0.314	0.251-0.376	0.026	0.007-0.046
3	0.252	0.189-0.315	0.000	-
4	0.202	0.130-0.274	0.000	-
5	0.165	0.078-0.253	0.000	-

The survival of the patients with late stage of cancer by way of operation

Of 230 operated patients with late stage of cancer, 85 (36.96%) patients were with stage III cancer. There were 106 (46.09%) patients had total gastrectomy, 89 (38.70%) had partial gastrectomy and 20 (8.70%) had nonresectional surgery. The survival rates using life-table method in both total gastrectomy and partial gastrectomy are shown in Table 6. The averages of survival times and their 95% confidence intervals are shown in Table 7.

Table 6 Survival rates using life-table method by the way of operation for patients with stage III or IV stomach cancer

Time(yr)	Total gastrectomy		Partial gastrectomy	
	Survival rate	95% CI	Survival rate	95% CI
1	0.536	0.451-0.627	0.571	0.466-0.677
2	0.289	0.207-0.370	0.416	0.306-0.526

The 95% confidence interval for both the 1-year survival rate and 2-year survival rate in total gastrectomy group and those in partial gastrectomy group overlapped. These indicated that all the differences of the survival rates (both 1- and 2-year survival rates) between total gastrectomy group and partial gastrectomy group were not significant. Also, the 95% confidence interval for average of survival time in total gastrectomy group and that in partial gastrectomy group overlapped. This indicated that the difference of survival times between total gastrectomy group and partial gastrectomy group was not significant.

Table 7 Average of survival time by the way of operation in the patients with stage III or IV stomach cancer

Way of operation	Number of patients	Average of survival time (mo)	95% confidence interval
Total Gastrectomy	106	19.56	16.408-22.712
Partial Gastrectomy	89	16.42	14.300-18.540
Nonresectional Surgery	20	5.22	3.84-6.60

Of 145 operated patients with stage IV stomach cancer, 89(61.38%) were subjected to total gastrectomy and 41(28.28%) had partial gastrectomy. The 1-year survival rates in total gastrectomy and in partial gastrectomy were 0.1846(95% *CI* 0.0903-0.2789) and 0.2911(95% *CI* 0.1478-0.4344), respectively. The averages of survival times in total gastrectomy and in partial gastrectomy were 12.36 mo (95% *CI* 9.37-15.350) and 9.28 mo (95% *CI* 8.10-10.46), respectively. Median survival times in total gastrectomy and in partial gastrectomy were 8 mo and 9 mo, respectively. The result showed that prognosis of the patients with total gastrectomy was not better than that with partial gastrectomy.

DISCUSSION

Compared to other tumors, stomach cancer has a dismal prognosis and a low 5-year survival rate. In our research, 5-year survival rate of patients with stomach cancer in Changle city is 30.47%, which close to the results of some previous researches^[7,8,14].

The stage of cancer is the most important independent prognostic factor^[5,8-11]. The results using COX model in some researches showed that the death hazard of the patients with stage III cancer was 2.82 time as high as that of the patients with stage II cancer, and that with stage IV was 3.29 times as high as that with stage II cancer^[5]. The 1- and 2-year survival rates in stage IV stomach cancer were 1.65 and 10 times as high as those in stage III cancer respectively^[12]. The 5-year survival rate in stage I-stage IV were 81.2%, 50.4%, 24.4% and 5.2%, respectively^[7]. Our research also showed that stage of cancer might make a notable impact on survival rate of stomach cancer and 1- to 5- year survival rates in stage I or II of cancer were higher than those in stage III or IV. Among the patients in our study, 94% of the patients visited the doctors after they had had the symptoms of stomach cancer, so 51.54% of the patients had late stage of cancer (stage IV). Only 1.6% of the patients were discovered tumor by the general check up, and they had long survival times since they were diagnosed at early stage. So, researching on how to discover stomach cancer at early stage must play an important role in preventing and curing of tumors.

Surgery provides the only possibility of cure in stomach cancer patients. The 1- and 2-year survival rates of operated patients were much higher than those of not operated patients^[12-16]. Our results also confirmed this. However, whether resection should be performed in patients with the stage IV stomach cancer is still a question^[12,17,18]. Some researchers suggested that surgery could raise 3-year survival rate of patients

with stage IV cancer only if tumors were not diffusely infiltrative type, while short-term survival rates could not be raised even though resections were conducted for the patients with diffusely infiltrative type of cancer^[19]. However, surgery did not prolong survival time in patients with peritoneal dissemination, hepatic metastasis, lymph node involvement and invasion to adjacent organs or with 3 of these 4 factors^[12,20]. Some other researchers suggested that short-term improvement in survival for resected patients with distant metastases could be obtained and resectional surgery should be undertaken whenever possible in patients with stage IV stomach cancer as both short-term and long-term survival advantages had been demonstrated^[12,21-23]. We suggest that surgery not only can raise 1-year survival rate for the patients with stage IV cancer, but also can make them have the possibility of survival for more than 2 years, however, the average of survival time in operated patients with stage IV cancer does not prolong much.

Some researchers suggested that total gastrectomy had a lower relapsing rate than partial gastrectomy, so it could raise long-term survival^[12,14,24]. To improve long-term therapeutic effects, total gastrectomy should be recommended for stage III patients with cancer of the cardia and stomach fundus when tumor size is bigger than 3.0 cm or lymph node metastasis occur^[22]. Some researches also showed that subtotal and total gastrectomies had a similar postoperative complication rate and surgical outcome, and total gastrectomies had benefits of survival prolongation and symptomatic palliation^[23,25,26]. However, other researchers suggested that total gastrectomy could not get a higher survival rate than partial gastrectomy, but carried a higher postoperative complications rate and poorer quality of life than partial resections^[8,27-33]. We suggest that although surgery can raise 1-year survival rate of patients with stage IV cancer, total gastrectomy does not get a better survival than partial gastrectomy for the patients with stage IV stomach cancer. Besides, result obtained from earlier stage research also showed that the quality of life in the patients with total gastrectomy was worse than those with partial gastrectomy.

In summary, our data obtained by epidemiological survey have shown that mid-term survival rates of patients with stomach cancer in Changle city are low. Stage of cancer is an important factor influencing survival of patients with stomach cancer. Surgery is an effective treatment for the patients with stage IV cancer and can raise short- and mid-term survival rates. Total gastrectomy should not be encouraged for the patients with late stage of cancer.

Abstract

AIM: To determine the influence of gender on the clinicopathologic characteristics and survival of patients with hepatocellular carcinoma (HCC).

METHODS: A retrospective analysis of medical records was performed in 299 patients with HCC and their clinicopathologic features and survival were compared in relation to gender.

RESULTS: There were 260 male (87%) and 39 female patients (13%), with a male-to-female ratio of 6.7:1. Female patients had lower mean serum bilirubin levels ($P=0.03$), lower proportion of alcohol abuse ($P=0.002$), smaller mean tumor size ($P=0.02$), more frequent nodular type but less frequent massive and diffuse types of HCC ($P=0.01$), were less advanced in Okuda's staging ($P=0.04$), and less frequently associated with venous invasion ($P=0.03$). The median survivals in females (14 mo) were significantly longer than that of male patients (4 mo) ($P=0.004$, log-rank test). Multivariate analysis demonstrated that high serum alpha-fetoprotein levels, venous invasion, extrahepatic metastasis and lack of therapy were independent factors related to unfavorable prognosis. However, gender did not constitute a predictive variable associated with patient survival.

CONCLUSION: Female patients tend to have higher survival rates than males. These differences were probably due to more favorable pathologic features of HCC at initial diagnosis and greater likelihood to undergo curative therapy in female patients.

INTRODUCTION

Hepatocellular carcinoma (HCC) is one of the most common cancers worldwide with a particularly high incidence in areas where chronic hepatitis B virus (HBV) and hepatitis C virus

(HCV) are common^[1,2]. These regions include sub-Saharan Africa, Far East and Southeast Asia where the annual rate is more than 30 cases per 100 000 persons. In contrast, in low-incidence areas such as Europe and North America, the annual rate is less than 5 cases per 100 000 persons^[3]. In Thailand, where chronic HBV is endemic, it is estimated that more than 10 000 new cases of HCC are diagnosed each year. Indeed, HCC represents the most common malignancy in Thai males and the third most common malignancy in females^[4].

Previously, we demonstrated that HCC in Thailand had an indisputable male predominance, with a male-to-female ratio of approximately 6:1^[5]. In fact, HCC is notably more prevalent in males worldwide, with reported male-to-female ratios ranging from 2:1 to 8:1 in most series. Until now, however, only a few studies have specifically compared the clinicopathologic characteristics of patients with HCC in relation to gender. In addition, the contribution of sex difference to patient survival and prognosis is controversial^[6-13]. The aim of the present study was, therefore, to determine the influence of gender on clinicopathologic features and patient survival. In this respect, we analyzed the medical records on individuals in whom HCC was diagnosed during a four-year period at King Chulalongkorn Memorial Hospital (Bangkok, Thailand).

MATERIALS AND METHODS

A total of 299 patients with HCC who were admitted to King Chulalongkorn Memorial Hospital between January 1996 and September 1999 were retrospectively analyzed and included in this study. All patients were diagnosed based on liver tumor characteristics detected by ultrasound/CT scan and confirmed by histology or serum alpha-fetoprotein (AFP) levels above 400 IU/mL. Of those, there were 260 male (87%) and 39 female patients (13%), making a male-to-female ratio of 6.7:1. We compared the difference and the clinicopathologic features, including age, biochemical liver function test, presence or absence of associated cirrhosis, etiologic factors predisposing towards HCC (alcohol abuse, hepatitis B or C), degree of tumor differentiation, gross pathology of tumor, tumor size, presence of vascular invasion, stage of HCC according to Okuda's criteria, evidence of distant metastasis and modalities of therapy of HCC. In addition, the patients' survival time for each group was also calculated, starting with the time of cancer diagnosis (including any incidence of perioperative mortality).

Gross pathology, tumor size, and localization of HCC as well as presence of portal or hepatic venous involvement, were obtained by abdominal ultrasound or computerized tomography (CT). In this study, the gross pathologic types of HCC were categorized according to Trevisani *et al.*^[14] as follows: nodular, multinodular, infiltrative, diffuse (the mass was not clearly defined and the boundary was indistinct) or massive type (a huge mass >10 cm with the boundary not well defined).

Biochemical liver function tests were determined by automated chemical analyzer (Hitachi 911) at the central laboratory of Chulalongkorn Hospital. The normal levels obtained with healthy adults are within the range of 0-38 IU/L for serum aspartate aminotransferase (AST) and alanine aminotransferase (ALT) and 98-279 IU/L for serum alkaline

phosphatase (AP). Enzyme-linked immunosorbent assays (ELISA) were used for the detection of HBsAg (Auszyme II, Abbott Laboratories, North Chicago, IL), anti-HCV (ELISA II; Ortho Diagnostic Systems, Chiron Corp., Emeryville, CA) and AFP (Cobus®Core, Roche Diagnostics, Basel, Switzerland).

Statistical analysis

Data were presented as percentage, mean and standard deviation. The Chi-square test and unpaired *t* test were used to assess the statistical significance of the difference between groups as appropriate. Survival curves were established using the Kaplan-Meier method and differences between curves were demonstrated using the log-rank test. The Cox regression analysis was performed to identify which independent factors have a significant influence on the overall survival. *P* values below 0.05 were considered statistically significant.

RESULTS

As shown in Table 1, the mean age of female patients (56.4±15.2 years) was slightly higher, but not significantly different from that of male patients (52.6±13.2 years). There was a significantly lower proportion of heavy alcohol consumption among females than males (*P*=0.002). However, there were no significant differences in positive rates of serum HBsAg and anti-HCV, nor in the frequency of associated liver cirrhosis between the two groups. Similarly, no significant differences between groups were observed regarding mean serum AFP levels and biochemical abnormalities, with the exception that female patients had significantly lower serum bilirubin levels than male patients (*P*=0.03).

Table 1 Demographic and clinical data of female and male patients with HCC at initial diagnosis

Characteristics	Female (n=39)	Male (n=260)	<i>P</i>
Age (yr)	56.4±15.2	52.6±13.2	NS
Underlying cirrhosis (+/-)	36:3	251:9	NS
Viral hepatitis marker			
HBsAg (+/-)	18:21	147:113	NS
Anti-HCV (+/-)	5:34	23:237	NS
Heavy alcohol consumption (+/-)	3:36	83:177	0.002
Mean AFP (IU/mL)	48 435.4±105 231.6	40 221.9±89 147.9	NS
Biochemical liver function tests			
Total bilirubin (mg/dL)	1.5±1.2	3.1±2.3	0.03
Alkaline phosphatase (IU/L)	451.6±277.3	529.3±375.0	NS
AST (IU/L)	128.4±133.2	154.3±135.2	NS
ALT (IU/L)	62.7±52.6	87.6±97.5	NS
Albumin (g/dL)	3.6±0.7	3.4±0.7	NS
Prothrombin time (sec)	14.5±2.8	15.1±9.3	NS

Quantitative variables were expressed as mean±SD; (+/-) indicates positive:negative. NS=not significant.

Table 2 demonstrates the clinicopathologic data of the patients at the time of the diagnosis of HCC. Female patients in this study tended to have less aggressive tumor characteristics than male patients. For instance, the mean tumor size in females (8.6 cm) was significantly smaller than that of male patients (11.6 cm) (*P*=0.02). In addition, the nodular type of HCC appeared to be more frequently found among female patients, whereas the massive and diffuse types were more common among males (*P*=0.01). Furthermore, the tumors in the female group tended to be of a less advanced stage according to Okuda's criteria (*P*=0.04) and less frequently associated with portal or hepatic vein invasion (*P*=0.03). Nonetheless, no significant differences between groups were observed as to the degree of tumor differentiation, the prevalence of extrahepatic metastasis or ruptured HCC.

Table 2 Clinicopathologic data of female and male patients with HCC at initial diagnosis

Characteristics	Female (n=39)	Male (n=260)	<i>P</i>
Mean tumor size (cm)	8.1±3.9	11.6±4.5	0.02
Tumor size			
≤5 cm:>5cm	9:30	30:230	0.04
Gross appearance of HCC			
Nodular:Multinodular:	12:10:14:3	30:52:115:63	0.01
Massive:Diffuse			
Tumor cell differentiation			
Well:Moderately:Poorly	3:5:4	11:66:32	NS
Okuda's staging (I:II:III)	13:23:3	43:180:37	0.04
Portal or hepatic vein invasion (+/-)	6:33	84:176	0.03
Extrahepatic metastasis (+/-)	5:34	37:223	NS
Ruptured HCC (+/-)	1:38	29:231	NS
Therapy for HCC (+/-)	22:17	105:155	NS
Modality of therapy			
Surgical resection (+/-)	9:30	27:233	0.02
Chemoembolization (+/-)	13:26	43:217	0.01
Systemic chemotherapy (+/-)	0:39	31:229	0.02

Quantitative variables were expressed as mean±SD; (+/-) indicates positive:negative.

Likewise, there was no statistically significant difference between groups in terms of the number of patients treated with specific therapeutic modalities. However, female patients were more likely than male patients to undergo surgical resection, which included segmental and lobar resection, or treated with transcatheter arterial chemoembolization (TACE) (*P*=0.02 and 0.01, respectively). In contrast, a significantly higher proportion of male patients were treated with systemic chemotherapy than females (*P*=0.02).

The median survival time of all patients in this study, regardless of their gender, was 5 mo. The Kaplan-Meier survival curves demonstrated that the overall median survival for female and male patients were 14 and 4 mo, respectively (*P*=0.004, using log-rank test) (Figure 1). For patients who were treated with any specific therapeutic modality, the median survival for the female and male group were 17 and 7 mo, respectively (*P*=0.025). In the untreated cases, the median survival of the female group was longer than that of the male group (9 and 3 mo, respectively), however, this difference did not achieve statistical significance (*P*=0.24).

Figure 1 Overall survival of male and female patients with HCC.

Univariate analysis of the main variables was performed to determine significant risk factors associated with the overall survival. In addition to male sex, serum AFP levels >400 IU/mL, Okuda's stage II and III HCC, massive or diffuse types of tumors, tumor mass size over 5 cm in diameter, venous invasion and

extrahepatic metastasis, and an unfavorable prognosis were observed in patients who did not receive any specific therapy for HCC. Stepwise Cox regression multivariate analysis revealed that high serum AFP levels, venous invasion, extrahepatic metastasis and absence of specific therapy were significantly and independently predictive for unfavorable prognosis (Table 3). Nonetheless, gender was not selected in the final analysis as an independent predictor of survival.

Table 3 Independent predictors influencing survival in HCC

Variables	Regression coefficient (95% CI)	P value ¹
AFP (>400 IU/mL)	1.67 (1.03-2.71)	0.037
Portal or hepatic vein invasion	1.73 (1.04-2.89)	0.035
Extrahepatic metastasis	2.37 (1.30-4.37)	0.005
No therapy	2.87 (1.63-5.04)	0.0002

95% CI: 95% confidence interval; ¹P value based on multivariate Cox regression analysis

DISCUSSION

Various types of cancer occur more frequently in male than in female patients. Such is also the case with HCC. In fact, marked male predominance in HCC incidence is observed in both high- and low-risk areas, regardless of ethnic and geographic diversity^[15]. Despite this, the exact reasons for sex difference in the incidence of HCC are unclear. It has been reported that DNA synthetic activities are higher in male than in female cirrhotics and this might be one of the possible explanations for the gender discrepancy in HCC^[16]. However, in patients who had already developed HCC, a significant difference in tumor cellular proliferation between male and female patients was not detected^[11]. It has also been suggested that the effect of sex hormones may contribute, at least in part, to the greater incidence of HCC observed in male patients. Although the mechanism remains to be elucidated, studies from animal models has implicated that the hormonal effect may be related to testosterone's ability in enhancing transforming growth factor (TGF) alpha related hepatocarcinogenesis and hepatocyte proliferation^[17].

Beside this, other possible factors contributing to the male predominance in HCC include the association with HBV infection, the higher proportion of male cirrhotics and differences in life-style habits, such as heavy alcohol consumption and smoking^[6,10]. However, in this study, no significant difference was found between groups in the prevalence of associated cirrhosis. Likewise, although HBsAg carriers were slightly more common in males, this discrepancy did not reach statistical significance. Notably, this was also the case with the prevalence of chronic HCV infection in our study. In contrast, the prevalence of heavy alcohol consumption was significantly different, being higher in male than in female patients. Indeed, alcoholic cirrhosis has long been recognized as a risk factor for developing HCC, although its role in direct hepatocarcinogenesis is uncertain^[18]. Nonetheless, it is reasonable to speculate that chronic alcohol abuse might accelerate cancer development in some cases with HBV- or HCV-associated cirrhosis and this may be partially responsible for the male preponderance of HCC in our series.

In addition, to confirm the marked male predominance, our study has demonstrated that male patients with HCC had a less favorable prognosis than females after initial diagnosis. Specifically, better survival in females was observed in those who had undergone surgical resection or treated with TACE. For untreated cases, the influence of gender on prognosis seemed to be limited since significant difference in survival between groups was not achieved, although there was a trend for females to survive longer. These results were consistent

with previous reports in which a better prognosis was observed in females following hepatic resection^[9-13]. For instance, according to the study in Japan by Nagasue *et al.*, significantly better survival rates were found in females after 4 years of hepatic surgery^[9]. A previous report on Chinese patients by Cong *et al.* also demonstrated that the survival rates after surgery were approximately 50% and 25% in females and males, respectively^[10]. Likewise, a study in Hong Kong by Ng *et al.*, indicated that females had a lower incidence of tumor recurrence following the surgical operations, with a median disease free survival of 19.5 mo compared with 4.5 mo for males^[11]. Recently, Lee *et al.* reported that female cirrhotics with HCC had 5-year disease survival rates after hepatic resection, which was higher than males (approximately 65% and 30%, respectively)^[12]. Conversely, such favorable prognosis in females was not consistently observed among patients with inoperable tumors^[6-8].

Thus, it could be speculated that the prognosis of HCC is not directly influenced by the sex of the patients. This is confirmed in our study that gender was not selected as an independent predictor of survival from the multivariate analysis. In fact, a better prognosis in females was probably attributed to a less advanced stage of HCC at initial diagnosis and, as a result, a higher proportion of cases was likely to undergo surgical resection or treated with TACE. In this study, for example, approximately 25% and 35% of female patients were treated with hepatic resection or TACE, respectively, while only approximately 10% and 15% of males were treated with such modalities. It has been generally recognized that hepatic resection is one of the most effective therapeutic modalities offering a hope of cure for patients with HCC^[19,20]. Moreover, a non-surgical approach such as TACE appears to be beneficial in prolonging survival for some patients with unresectable tumors^[21-22].

In addition to therapeutic factors, some pathobiologic features indicative of tumor invasiveness, such as venous involvement, appear to be significant factors influencing the survival of HCC^[23]. It has also been demonstrated that the presence of venous invasion is associated with a higher intrahepatic recurrence rate after the resection of the tumor^[24]. Although HCC is characterized by its propensity for vascular invasion, it is interesting that female patients with HCC had a much lower prevalence of venous involvement than males. It seems, therefore, that this is probably one of the main factors contributing to different survival rates between the two sexes in our study. Similarly, yet to be addressed, are the effects of other tumor pathologic features, such as tumor encapsulation during the disease-free period after surgical resection of HCC^[25]. Previous data have demonstrated that females have a significantly higher prevalence of tumor encapsulation than males (80% and 45%, respectively). Furthermore, the tumors in females were frequently less invasive in terms of lower prevalence of tumor microsatellites and positive histological margin^[11].

In conclusion, our data indicated that female patients with HCC had certain clinicopathologic features different from those in male patients. Moreover, females with HCC appeared to have better survival rates than males. This better prognosis in females was related to more favorable tumor characteristics such as a lower prevalence of hepatic or portal venous invasion and less advanced stages at initial diagnosis. As a result, female patients were more likely than male patients to undergo hepatic resection or to be treated with TACE.

ACKNOWLEDGEMENT

We would like to express our gratitude to the Thailand Research Fund, Senior Research Scholar and the Molecular Biology Project, Chulalongkorn University for supporting the study.

We also would like to thank Ms. Pisanee Saiklin for editing the manuscript.

Abstract

AIM: To study the effects of phosphorus-32 glass microspheres (^{32}P -GMS) on human hepatocellular carcinoma in nude mice.

METHODS: Human liver cancer cell line was implanted into the dorsal subcutaneous tissue of 40 BALB/c nude mice. Then the 40 tumor-bearing BALB/c nude mice were allocated into treatment group ($n=32$) and control group ($n=8$). In the former group different doses of ^{32}P -GMS were injected into the tumor mass, while in the latter nonradioactive ^{31}P -GMS was injected into the tumor mass. The experimental animals were sacrificed on the 14th day. The ultrastructural changes of tumor in both treatment group and control group were studied with transmission electron microscopy (TEM) and stereology.

RESULTS: In treatment group, a lot of tumor cells were killed and the death rate of tumor cells was much higher (35-70%). Ultrastructurally, severe nuclear damage was observed in the death cells. The characteristics of apoptosis such as margination of heterochromatin was also found in some tumor cells. Besides, well differentiated tumor cells, degenerative tumor cells and some lymphocytes were seen. The skin and muscle adjacent to the tumor were normal. In control group, the tumor consisted of poorly differentiated tumor cells, in which there were only a few of dead cells (5%). Stereological analysis of ultrastructural morphology showed that Vv of nuclei (53.31 ± 3.46) and Vv of nucleoli (20.40 ± 1.84) in the control group were larger than those (30.21 ± 3.52 and 10.96 ± 2.52) in the treatment group respectively ($P<0.01$), and Vv of RER (3.21 ± 0.54) and Vv of mitochondria (4.53 ± 0.89) in the control group were smaller than those (8.67 ± 1.25 and 7.12 ± 0.95) in the treatment group respectively ($P<0.01$, 0.05). Sv of the membrane of microvilli and canaliculi ($27.12\text{ }\mu\text{m}^2/100\text{ }\mu\text{m}^3\pm11.84\text{ }\mu\text{m}^2/100\text{ }\mu\text{m}^3$) in the control group was smaller than that ($78.81\text{ }\mu\text{m}^2/100\text{ }\mu\text{m}^3\pm19.69\text{ }\mu\text{m}^2/100\text{ }\mu\text{m}^3$) in the treatment group ($P<0.01$). But Vv of lipid particles (3.71 ± 1.97) and Vv of vacuoles (5.72 ± 1.58) were much larger than those (0.30 ± 0.16 and 0.35 ± 0.15) in the treatment group respectively ($P<0.05$, $P<0.01$).

CONCLUSION: The experimental results indicate that local administration of ^{32}P -GMS can produce obvious effect on

liver cancer cells and the anticancer effect of ^{32}P -GMS is directly proportional to the dose administrated. Ultrastructural stereology can also show the effect of ^{32}P -GMS on the normalization of tumor cells, which is beneficial to the prognosis and treatment of patients. Moreover, local administration of ^{32}P -GMS is also safe.

INTRODUCTION

In recent years, nuclide labeled nontoxic and undegradable micro-carriers such as phosphorus-32 glass microsphere (^{32}P -GMS)^[1,2] and yttrium-90 glass microsphere^[3-5] have been successfully developed and gained much attention as a new radioactive medicine for treating malignant liver neoplasms. Experimental researches using micro-carriers such as microsphere, microcapsule, nano-microsphere (nano-sphere), liposome and nano-liposome in treating malignant tumors have been carried out for more than a decade and gained much interesting development. Microspheres conjugated with anticancer drugs including traditional Chinese medicine could release drugs slowly into the cancer tissues, thus keeping their anti-cancer effect for a long time^[6-9]. However, there are only a few reports about the researches of cytotoxic effect of local internal irradiation of ^{32}P -GMS on tumor cells. The ultrastructural stereology study of human liver cancer cell treated by ^{32}P -GMS has not been reported^[10,11]. So the authors used a human liver tumor-bearing nude mouse model to explore the anticancer effect of ^{32}P -GMS and the ultrastructural stereology changes in the tumor with TEM.

MATERIALS AND METHODS

Materials

^{32}P -GMS By activating of standardized glass microspheres through nuclear-chemical reaction, nonradioactive ^{31}P (^{31}P -GMS, cold sphere) was transformed into radioactive ^{32}P glass microsphere (provided by Nuclear Power Research Institute of China). It had the following properties. The diameter of glass sphere was 46-76 μm , ^{32}P physical half-life was 14.28 d, average β ray energy per disintegration was 0.695 MeV, and soft tissue penetration distance was max. 8.0 mm, averaging 3.2 mm. ^{32}P -GMS suspension was prepared by mixing ^{32}P -GMS with super-liquidized iodized oil or 500 g/L glucose solution to the concentrations of 370 MBq.mL/L and 37 MBq.mL/L on an oscillator.

Animal experiment Human liver cancer cell line subset (H-CS) with higher oncogenicity and liability of metastasis was implanted into the dorsal subcutaneous tissue of 40 BALB/c nu/nu nude mice (male, mean body mass 19.2 g, aged 4 wk, derived from Shanghai Experimental Animal Center, Chinese Academy of Sciences) at the dosage of 0.1-0.2 mL (1×10^7 tumor cells for each animal).

Forty tumor-bearing nude mice with the tumor mass diameter of 0.7-1.0 cm, different doses (7 320 Gy, 3 660 Gy, 1 830 Gy, 366 Gy and 183 Gy) of ^{32}P -GMS were injected to the mass center of 32 nude mice (subgroup A: $n=6$, B: $n=6$, C: $n=8$, D: $n=6$, E: $n=6$) in the treatment group and non-radioactive ^{31}P -GMS to the mass center of 8 nude mice as the control group. The experimental animals were sacrificed on the 14th day.

Preparation of electron microscopical sections Biopsy specimens from all the tumors and their adjacent tissues were immediately placed in 40 g/L glutaraldehyde and allowed to stand for 2 h at room temperature. Then the tissue was washed 3 times and postfixed for 1 h in 10 g/L osmium tetroxide. After rinsed in distilled water and dehydrated in acetone, the tissue specimens were embedded in Epon 812, polymerized for 48 h, ultrathin sectioned and stained. The electron microscopical sections were viewed in a H600 transmission electron microscope. At the same time, all specimens from tumors and their adjacent tissues were subjected to gross inspection, light microscopy to observe the morphological changes, and compared with the ultrastructural changes, and then the death rate of tumor cells was calculated. Death rate = the number of death cells/the number of total cells.

Method of stereological study Test grid method was used^[12]. The areas of test web was 120 mm×90 mm, and the length of each small grid was 5 mm. There were 432 tested dots in test web. The TEM pictures were magnified to 30 000-fold, and 30 pictures were taken in each group. When the picture was tested, the test web was put on the picture to test the constructure observed. Stereological parameters (volume density V_v ; surface density S_v) were used to test the cell organallae such as nucleus, nucleolus, RER and mitochondrion, lysosome, lipid, vesicles and membrane of microvilli and canaliculi. The point counting method was used. The standard deviation and standard error of stereological parameters in each group were calculated. The statistical method used was t test.

The formula of volume density V_v is

$$V_v = \frac{\sum_{i=1}^n P_{xi}}{\sum_{i=1}^n P_{ri}}$$

(n : the number of pictures, i : the ordinal number of pictures, P_{xi} : the number of test points within the scope of some constructures in i picture, P_{ri} : the number of test points within the section scope of the frames of reference in the same picture as above).

The formula of surface density S_v is

$$S_v = \frac{2 \sum_{i=1}^n I_{xi}}{z \sum_{i=1}^n P_{ri}}$$

(n : the number of pictures, i : the ordinal number of pictures, I_{xi} : the number of the points of transversal intersection of some membranes and test line in i picture, P_{ri} : the number of test points within the section scope of the frames of reference in the same picture as above, $2/z$ is coefficient).

RESULTS

Ultrastructure observation

In the treatment group, the tumor cells of subgroup A revealed necrotic injury and a lot of tumor cells were killed (Figure 1A). In the severely injured cells the nuclei lysed, cell membrane disrupted and numerous debris were found. The injured tumor cells showed condensation of nuclear chromatin, peripheral aggregation of heterochromatin in pieces, damaged organellae in cytoplasm, disappearance of mitochondrial cristae and ribosomes, appearance of a few of vacuoles and lipid particles. The death rate of tumor cells in the subgroup A was much higher (70%). In subgroup B, many tumor cells presented histological structures similar to those in subgroup A (the death rate: 65%), but with many lysosomes. Some were differentiated

tumor cells with the characteristics of round nuclei with small nucleoli, evenly distributed chromatin, mainly euchromatin, lots of mitochondria and rough endoplasmic reticula in the cytoplasm, formation of plenty of microvilli at the interface of tumor cells (Figure 1B). The capillaries between the moderately differentiated tumor cells had thickened or loosened basal membranes with local defects. Abundant fibroblasts and collagen fibers could be found in the matrix. There was a tendency to form bile canaliculi somewhere between tumor cells (Figure 1C). Under light microscope, the tumor tissues both in subgroups A and B showed scattered focal necrosis. The tumor cells in subgroup C (the death rate: 50%) showed different morphologic appearances, some damaged mildly and others severely, but some were moderately differentiated with plenty of cytoplasmic free polyribosomes. Plasma cells were scattered among the tumor cells, and some lymphocytes protruded the pseudopodia when they were contacted with the tumor cells. There were residual tumor cells showing active proliferation. In subgroups D and E (the death rate: 35%), the histological structure was manifested in various complicated forms, and active multiplication of tumor cells was readily seen. Under light microscope, the histological characteristics in subgroups C, D and E were the arrangement of tumor cells transformed from dense to loose with scattered spot necrosis. No abnormality was found in the muscle and dermal cells of adjacent skin nearby the tumor.

In the control group, most tumor cells were poorly differentiated and rapidly multiplied (Figure 1D), with characteristics of irregular large nuclei with deep indentations and plenty of chromatin, several peripherally aggregated large and prominent nucleoli. In cytoplasm, a lot of free polyribosomes, vacuoles and lipid particles were presented, while mitochondria, glycogen and rough endoplasmic reticulum were scant. Only a few of dead cells (5%) were found in this group. In the nearby interstitial tissue infiltrated tumor cells, degenerative lymphocytes, damaged fibroblasts, loose collagen fibers were found.

Figure 1 Ultrastructural characteristics of effect of ^{32}P -GMS on human hepatocellular carcinoma. A: Necrosed tumor cells (×12 000). B: Microvilli on the surface of tumor cells and mitochondria in cytoplasm (×18 000). C: Formation of bile duct-like structure in tumor cells (arrow, ×18 000). D: Heteromorphic tumor cells with cleavage of nuclei and scanty microvilli on surface (×12 000).

Stereological study

The results of stereological analysis of ultrastructural morphology are summarized in Tables 1, 2 and 3.

Table 1 Comparison of liver cancer cell Vv in control group and treatment group

Constructure	Liver cancer cell Vv(mean±SD)×100%	
	Control group	Treatment group
Nuclei	53.31±3.46 ^b	30.21±3.52 ^b
Cytoplasm	46.79±3.46	69.79±3.52
Mitochondria	4.53±0.89 ^a	7.12±0.95 ^a
Lysosomes	2.07±0.22	1.94±1.12
RER	3.21±0.54 ^d	8.67±1.25 ^d
Lipid particles	3.71±1.97 ^c	0.30±0.16 ^c
Vacuoles	5.72±1.58 ^f	0.35±0.15 ^f

Nuclei Vv in control group was larger than that in treatment group, ^a $P<0.05$. Vv of RER in control group was smaller than that in treatment group, ^b $P<0.01$. Vv of mitochondria in control group was smaller than that in treatment group, ^d $P<0.01$. Vv of lipid particles was larger in control group than that in treatment group, ^c $P<0.05$. Vv of vacuoles was larger in control group than that in treatment group, ^f $P<0.01$.

Table 2 Comparison of nucleoli Vv of liver cancer cells in control group and treatment group

Constructure	Nucleoli Vv liver cancer cell Vv(mean±SD)×100%	
	Control group	Treatment group
Nucleoli	20.40±1.84 ^b	10.96±2.52 ^b
Nuclei	79.60±1.84	89.04±2.52

Nucleoli Vv in control group was larger than that in treatment group, ^b $P<0.01$.

Table 3 Comparison of Sv in membranes of microvilli and canaliculi of liver cancer cells in control group and treatment group

Constructure	Sv of liver cancer cell (mean±SD)×100%	
	Control group	Treatment group
Membrane of microvilli and canaliculi	27.12 $\mu\text{m}^2/100 \mu\text{m}^3$ ±11.84 $\mu\text{m}^2/100 \mu\text{m}^3$ ^b	78.81 $\mu\text{m}^2/100 \mu\text{m}^3$ ±19.69 $\mu\text{m}^2/100 \mu\text{m}^3$ ^b

Sv of the membranes of microvilli and canaliculi of liver cancer cells in control group was smaller than that in treatment group, ^b $P<0.01$.

DISCUSSION

Anticancer effect and mechanism of ³²P-GMS

On the 14th day of local injection of ³²P-GMS to the tumor, the tumor cell death rate was 35-70% in different treatment groups, and was 5% in control group. The results showed that local internal irradiation of ³²P-GMS had cytotoxic effects on tumor cells and the anticancer effect of ³²P-GMS was directly proportional to the dose administrated.

Anticancer mechanism of ³²P-GMS mainly includes two parts. The first is that β -ray energy of ³²P-GMS could directly destroy or injury DNA of tumor cells to induce cell death because of the breakage, disaggregation and synthetic obstruction of DNA. The second is that β -ray irradiation conducted ionization and irradiation of the water molecules in intracellular environment to produce several kinds of free radicals and superoxides which indirectly killed the tumor cells by injuring the biological macromolecules^[13,14]. Besides, researches also

showed that β -ray could induce cell-death related gene expressions to accelerate the apoptosis of tumor cells^[15]. Because ³²P-GMS internal irradiation is one kind of continued low linear energy transfer(LET) irradiation, its indirect effect on tumor cells might be much more important^[16].

Ultrastructure characteristics and significance of effect of ³²P-GMS on tumor

In specimens of different treatment groups, the tumor cells might exhibit as survived, degenerative or necrosed (in early or typical changes). It seems that this reflected the whole course of tumor cell progression from degeneration to death after irradiation. The ultrastructural changes demonstrated that under the effect of high-dose irradiation, the tumor tissues received a lethal radiation energy in a short period, resulting in nonexistence of tumor cells which had a high ability to synthesize endogenous proteins. Under the appropriate dose of irradiation, besides the necrosis of most tumor cells, the tendency to derive to nearly normal histological pictures appeared, such as microvilli on the cell surface, formation of bile canaliculi-like structure. These demonstrated that ³²P-GMS had the ability to kill actively proliferative tumor cells and to promote their normalization. On the other hand, proliferation of connective tissue after irradiation could lead to disorganization, which could destroy the survived tumor cells. This was consistent with what was reported^[13]. At the lower dose of irradiation, plasma cells and some lymphocytes were scattered among tumor cells, but this was rarely seen in the high-dose subgroup. Whether the immune function during treatment can be enhanced to some extent is still unknown. The irradiation injured some interstitial tissues such as thickened or loosened basal membrane of capillaries with local defects and damaged collagen fibers. But acute irradiative inflammation was not found and the tissue adjacent the tumor was normal, indicating that local administration of ³²P-GMS is safe.

Stereological ultrastructure analysis of effect of ³²P-GMS on tumor

Stereological analysis is a kind of image analysis technology widely used in pathomorphological researches. Researches discovered that image analysis was of importance to explore the criteria for pathological diagnosis, grading and morphogenesis of human hepatocellular carcinoma^[17-19]. Compared with qualitative analysis, stereological analysis was much more objective.

Differentiated malignant tumor cells have some characteristics under electron microscope. The general characteristics of poorly differentiated and rapidly multiplied tumor cells included irregular large nuclei, peripherally aggregated large and prominent nucleoli, lots of free polyribosomes in cytoplasm, scanty mitochondria and rough endoplasmic reticulum^[20,21]. The characteristics of differentiated tumor cells are different, including round nuclei with small nucleoli, mitochondria and rough endoplasmic reticula in the cytoplasm, formation of microvilli at the interface of tumor cells. There was a tendency to form bile canaliculi somewhere between liver tumor cells. Stereological results showed that Vv of nuclei (53.31±3.46) and Vv of nucleoli (20.40±1.84) in the control group were larger than those (30.21±3.52 and 10.96±2.52) in the treatment group respectively ($P<0.01$) and Vv of RER (3.21±0.54) and Vv of mitochondria (4.53±0.89) in the control group were smaller than those (8.67±1.25 and 7.12±0.95) in the treatment group respectively ($P<0.01$, 0.05). Sv of the membrane of microvilli and canaliculi (27.12 $\mu\text{m}^2/100 \mu\text{m}^3$ ±11.84 $\mu\text{m}^2/100 \mu\text{m}^3$) in the control group was smaller than that (78.81 $\mu\text{m}^2/100 \mu\text{m}^3$ ±19.69 $\mu\text{m}^2/100 \mu\text{m}^3$) in the treatment group ($P<0.01$). The results indicated that local administration of ³²P-GMS could produce obvious anticancer effects, besides, it played a role in

making poorly differentiated tumor cells become well differentiated ones, which was obviously beneficial to the prognosis and treatment of patient. Stereological study also showed that Vv of lipid particles (3.71 ± 1.97) and Vv of vacuoles (5.72 ± 1.58) in control group were much larger than those (0.30 ± 0.16 , and 0.35 ± 0.15) in treatment group ($P < 0.05$, $P < 0.01$). There is a possibility that the cells with lipid particles and vacuoles were degenerative cells which were much easier to be killed by β -ray energy of ^{32}P -GMS, so the Vv of lipid particles and vacuoles in treatment group was smaller than that in control group.

In conclusion, local administration of ^{32}P -GMS has obvious anticancer effects on liver cancer cells, which is directly proportional to the dose administrated. Ultrastructural stereology can also show the role of ^{32}P -GMS in promoting the normalization of tumor cells. Moreover, local administration of ^{32}P -GMS is safe.

Abstract

AIM: To analyze the structure and expressions of the protein encoded by an HCC-associated novel gene, lysosome-associated protein transmembrane 4 β (*LAPTM4B*).

METHODS: Primary structure and fundamental characteristics of *LAPTM4B* protein were analysed with bioinformatics. Expressions of *LAPTM4B* in HCC tissues and various cell lines were detected using polyclonal antibodies and Western blot.

RESULTS: *LAPTM4B* encoded two isoforms of proteins with molecular masses 35-ku and 24-ku, respectively. The expression level of *LAPTM4B*-35 protein in HCC tissues was dramatically upregulated and related to the differentiation status of HCC tissues, and it was also high in some cancer cell lines. Computer analysis showed *LAPTM4B* was an integral membrane protein with four transmembrane domains. *LAPTM4B* showed relatively high homology to *LAPTM4A* and *LAPTM5* in various species.

CONCLUSION: *LAPTM4B* gene encoded two isoforms of tetratransmembrane proteins, *LAPTM4B*-35 and *LAPTM4B*-24. The expression of *LAPTM4B*-35 protein is upregulated and associated with poor differentiation in human HCC tissues, and also at high levels in some cancer cell lines. *LAPTM4B* is an original and conserved protein.

INTRODUCTION

We have previously reported the cloning and identification of a novel gene, which was designated by the International

Nomenclature Committee as lysosomal associated protein transmembrane 4 β (*LAPTM4B*)^[1-4]. *LAPTM4B* was overexpressed in 87.3% human hepatocellular carcinomas (HCC) at mRNA level performed by Northern blot^[2]. BLAST program analysis showed that the *LAPTM4B* gene was mapped to chromosome 8 q22.1, spanning approximately at least 50 kb. It is composed of seven exons separated by six introns. The cloned full-length cDNA sequence (GenBank accession number: AY057051) of *LAPTM4B* is 2.2 kb and contains two ATGs at the 5' end with an interval of 273 bp and two polyadenylation signals: aataaa and aattaaa^[2].

In this study, primary structures of proteins encoded by *LAPTM4B* gene were analyzed using bioinformatics. Specific polyclonal antibodies directing against two epitopes of the 10-peptides localized at the N-terminus (28-37aa) and in between the 3rd and 4th transmembrane domains (232-241aa) of *LAPTM4B*, respectively, were prepared. The expressions of *LAPTM4B* proteins in HCC, paired noncancerous liver (PNL), normal liver (NL) tissues and various cancer cell lines were detected by Western blot. The functions of *LAPTM4B* protein was discussed.

MATERIALS AND METHODS

Specimens

Fresh HCC and paired noncancerous liver specimens were obtained during operations on patients with HCC, normal liver tissues were obtained during operations on patients with hepatohemangioma.

Cell lines and culture

Human hepatoma cell lines BEL-7402, QGY-7701, SMMC-7721, HLE and human hepatic cell line L-02, human cervical cancer cell line HeLa, human prostate carcinoma cell lines PC3M and PC3, human pulmonary giant cell carcinoma cell lines BE1 and LH7, and human melanoma cell lines WM451 and WM983A were maintained in RPMI 1640 (GIBCO BRL) medium supplemented with 100 mL/L fetal bovine serum.

Protein extraction^[5-7]

The tissues stored at -80 °C or living cells were homogenized and extracted with lysis buffer (pH7.6) containing 10 mmol/L Tris, 150 mmol/L NaCl, 1 mmol/L EDTA, 5 g/L NP40, 1 mmol/L PMSF, 1 μ g/mL aprotinin, 1 μ g/mL pepstatin A. After centrifugation at 12 000 g for 10 min at 4 °C, the supernatants were collected and the proteins were quantitated by Bradford microassay.

Peptide synthesis and antibody preparation^[8-10]

Two KLH-conjugated 10 peptides (KLH-Ala-Lys-Gly-Thr-Asp-Pro-Ala-Glu-Ala-Arg and KLH-Pro-Tyr-Arg-Asp-Asp-Val-Met-Ser-Val-Asn) were synthesized by Invitrogen Company. Rabbits were immunized subcutaneously with 1 mg of KLH-peptide conjugates emulsified in Freund's complete adjuvant (GIBCO BRL). The immunization was repeated with the antigens in Freund's incomplete adjuvant (GIBCO BRL) 4 wk after the first

injection and 2 wk after the second injection. The anti-sera were designated as LAPTM4B-N28-37-pAb and LAPTM4B-EC2-pAb, respectively. The titers of these two sera were both above 1×10^5 detected by ELISA with peptide-coated plates. The pre-immune sera did not show any reactivity to the peptides.

Western blotting

Proteins in cell lysates were fractionated by 100 g/L SDS-PAGE and then electrotransferred onto a nitrocellulose filter (Bio-Rad). The filters were blocked at 4 °C overnight with blocking buffer (pH7.6) containing 50 g/L fat free dry milk. Then the filters were incubated with indicated antibody for 2 h at room temperature. After washed with TBST (pH6.0), the filters were incubated at room temperature for 1 h with horseradish peroxidase conjugated goat anti-rabbit IgG at 1:2 000 dilution in TBS-5 g/L fat free dry milk. Immunoreactive bands were visualized using ECL detection reagents (Santa Cruz).

Bioinformatics analysis tool

The Bioinformatics analysis tool included BLAST and FASTA for basic local alignment of sequences, PCGENE software for predicting primary structure and fundamental characteristics of the protein, Kyte&Doolittle hydrophobicity index for calculating

hydrophobicity value, ClustalW software for multiple sequence alignment and DNAMAN software for displaying phylogenetic tree.

RESULTS

Bioinformatics analysis of primary structure of LAPTM4B protein

The primary structure of LAPTM4B is shown in Figure 1. The *LAPTM4B* cDNA may encode two putative proteins with 35 ku (317 aa) and 24 ku (226 aa). Computer analysis (PCGENE) showed that LAPTM4B was an integral membrane protein with four highly conserved hydrophobic transmembrane domains, forming two extracellular loops (EC1 and EC2), a cytoplasmic loop and intracellular amino- and carboxyl tails. The transmembrane regions were located at 117-133, 163-179, 200-216, and 243-259 aa, respectively. The full amino acid sequence contained one N-glycosylation site, eight phosphorylation sites, and four N-myristoylation sites. A tyrosine phosphorylation site was predicted at 285 aa at C-terminal region, which depending on phosphorylation might form a binding site for specific SH2 domain in some signaling proteins. It was also predicted that LAPTM4B containing proline-rich motif (PXXP) at N-terminal region would be a SH3 domain binding protein. Moreover, LAPTM4B contained typical lysosomal targeting signals (3 YXX Φ motifs)^[11] at C-terminal region. Human LAPTM4B

Figure 1 Putative amino-acid sequence of LAPTM4B. The four transmembrane domains are shadowed with gray color. Two translation initiation sites are thick black. Putative SH3 ligand is indicated by thick underlining. The sequence containing 10 amino acid residues (28aa-37aa or 232aa-241aa) and used as immunogen is wavy underlined. PKC-P, cAMP-P, cGMP-P, CK2-P, Tyr-P: various phosphorylation sites; G: N-glycosylation site; M: myristylation site.

Figure 2 Phylogenetic tree of LAPTM4B.

shared 92% homology with mouse LAPTM4B (GenBank accession number: AAH1912)^[12] at amino acid level, suggesting that LAPTM4B was highly conserved within vertebrate species. The region from 140 aa to 317 aa of LAPTM4B was highly conserved compared with mouse LAPTM4B. But the N-terminal region from 1 aa to 91 aa (between the first ATG and the second ATG) of LAPTM4B-35 was highly specific and no homological sequence was found using BLAST in nr database. LAPTM4B also showed 46% homology to a lysosomal tetra-transmembrane protein, LAPTM4A, at amino acid level. The ortholog of LAPTM4A in murine was a nucleoside transporter in intracellular membrane-bound compartments, and mediated a multidrug resistance phenotype in drug-sensitive strains of *S. cerevisiae*^[12-14].

The phylogenetic tree (Figure 2) was constructed according to multiple sequence alignment results. It showed that LAPTM4B, LAPTM4A and LAPTM5 proteins were distributed in clusters. Human LAPTM4B showed the most close homology to *Mus musculus* and also had certain homology to *Danio rerio* and *Fugu rubripes*, as well as *Drosophila melanogaster*, but was far-away from Yeast. In addition, LAPTM4B showed relatively high homology to LAPTM4A and LAPTM5 in various species to a certain extent, and LAPTM4B was closer to LAPTM4A than LAPTM5. These results indicated that LAPTM4B was an original and conserved protein.

Expression of LAPTM4B protein in HCC tissues

As shown in Figure 3, 2 proteins with molecular masses 35-ku and 24-ku both reacted with LAPTM4B-EC2-pAb were identified by Western blot in HCC, PNL and NL tissues, and designated as LAPTM4B-35 and LAPTM4B-24, respectively. Nevertheless, only one band at the 35 ku position appeared when LAPTM4B-N28-37-pAb was used for Western blot in HCC tissues, indicating that LAPTM4B-35 was translated from the whole ORF and initiated from the first ATG, whereas LAPTM4B-24 was translated from the second ATG. Furthermore, LAPTM4B proteins were significantly overexpressed in HCC tissues than in PNL and NL tissues. Notably, the expression levels of LAPTM4B-35 were significantly related to the differentiation status of HCC tissues, they were higher in poorly differentiated HCCs than in moderately and well differentiated HCCs (Figure 4)^[4]. In addition, the ratio of LAPTM4B-35 to LAPTM4B-24 was remarkably higher in HCC than in PNL and NL (Table 1). However, the ratio of LAPTM4B-35 to LAPTM4B-24 in PNL was kept at the same level as in NL, even though LAPTM4B-35 and LAPTM4B-24 were both slightly increased. Thus the development of HCC might be associated with the raised ratio of LAPTM4B-35 to LAPTM4B-24.

Expression of LAPTM4B proteins in various cell lines

LAPTM4B proteins in 12 cell lines were detected by Western blot with LAPTM4B-EC2-pAb (Figure 5). With exception of HLE cells, LAPTM4B proteins were remarkably expressed in

all of HCC-derived cell lines including BEL-7402, QGY-7701 and SMMC-7721, and human hepatic cell line L-02 cells. The ratio of LAPTM4B-35 to LAPTM4B-24 was higher in HCC cell lines than in immortal hepatic cell line L-02 (Table 2), suggesting that disturbance of LAPTM4B-35 to LAPTM4B-24 equilibrium in expressions might cause the malignant transformation in hepatocarcinogenesis. Moreover, the expressions of LAPTM4B-35 were also higher in highly metastatic cell lines^[15-17], including prostate carcinoma PC-3M and pulmonary giant cell carcinoma BE1 cell lines than in the syngenic low metastatic cell lines, including PC-3 and LH7 cell lines. Therefore, the overexpression of LAPTM4B-35 was likely related to cancer cell invasion and metastasis. However, LAPTM4B was not detected in human cervical carcinoma cell line HeLa and human melanoma cell lines WM451 and WM983A^[15], indicating that overexpression of LAPTM4B-35 was somehow specific for some carcinomas.

DISCUSSION

HCC is one of the most common cancers world-wide, and is the major cause of malignant deaths in Asia and Africa^[18-20]. The pathogenesis of HCC is particularly complex. The current model for HCC carcinogenesis postulated a multistage progression involving an accumulation of genetic alterations^[21,22], including activation of oncogenes N-ras, H-ras, K-ras, c-erbA, c-met, and c-myc etc.^[23,24], repression or mutation of tumor suppressor genes^[25], besides the transcriptional activation of c-jun and nuclear factor NF- κ B by HBV and HCV^[26,27]. But the roles of these genes in cell proliferation, differentiation, and premalignant status in liver malignancy are far from elucidated.

We previously reported^[2] that *LAPTM4B* was a novel gene associated with HCC, and significantly overexpressed in HCC as shown via Northern blot and *in situ* hybridization. *LAPTM4B* is also widely expressed in human tissues with a relatively high level in the testis, heart and skeletal muscles, and moderately in the ovary, kidney and pancreas, and poorly in the liver, spleen, and thymus, and lowest in the lung and peripheral leukocytes. It was remarkably overexpressed in 87.3% (48/55 cases) HCC tissues when compared with PNL and NL tissues. Furthermore, the *LAPTM4B* mRNA expression levels were significantly related to the differentiation status of HCC tissues. They were highest in poorly differentiated HCCs, higher in moderately differentiated HCCs, and relatively low in well differentiated HCCs.

Here we report the expressions of LAPTM4B proteins in HCC, PNL, NL and a number of cell lines via Western blot analysis using two antibodies, LAPTM4B-N28-37-pAb or LAPTM4B-EC2-pAb, which were prepared by immunization with two KLH-conjugated 10-peptides whose sequences are localized at either the second extracellular loop (EC2) between the third and fourth transmembrane regions or the N-terminal region in the cytoplasm. These two 10-peptides used as immunogens were highly specific, i.e. having very low homology compared to known proteins of *Homo sapiens*. By using PCGENE software, the 10-peptides should have characteristics of high hydrophilicity and no residues of putative glycosylation and phosphorylation. KLH was conjugated with the N-termini of 10-peptides in order to increase immunogenicity. Two isoforms of LAPTM4B, LAPTM4B-35 and LAPTM4B-24, whose mass was coincident with the predicted products translated from the first and second ATG in ORF, were identified. Expressions of LAPTM4B-35 proteins were highly upregulated in HCC with poor differentiation. This result was coincident with expression of *LAPTM4B* mRNA in HCC tissues. LAPTM4B expressions were also high in human HCC cell lines and some other cancer cell lines. Transient transfection of murine BHK cells was performed with two plasmids, *pcDNA3/LAPTM4B-AE*

containing a full-length cDNA of *LAPTM4B* ORF and *pcDNA3/LAPTM4B-BE* containing the same ORF sequence but with 273 nucleotides deleted at 5' end, respectively. The transfectants in AE-series expressed mainly LAPTM4B-35 and slightly LAPTM4B-24, and proliferated very rapidly and formed colonies powerfully. However, the transfectants in BE-series expressed only LAPTM4B-24, and lost potentials of long term survival and growth. Therefore, it is suggested that LAPTM4B-24 may play an antagonistic role in cell survival and proliferation, and the equilibrium of LAPTM4B-35 and LAPTM4B-24 in expression is involved in controlling cell survival/proliferation and differentiation. The disequilibrium in expressions of LAPTM4B-35 and LAPTM4B-24 may be involved in malignant transformation of hepatocytes and carcinogenesis.

Abstract

AIM: To study the deletion of mitochondrial DNA in hepatocellular carcinoma and hepatocellular nodular hyperplasia and its significance in the development of cancer.

METHODS: Deleted mtDNA (CD-mtDNA) and wild type mtDNA (WT-mtDNA) were quantitatively analyzed by using real-time PCR in 27 hepatocellular carcinomas (HCC) and corresponding noncancerous liver tissues and 27 hepatocellular nodular hyperplasias (HNH).

RESULTS: A novel CD (4 981 bp) was detected in 85% (23/27) and 83% (22/27) of HCC and HNH tumor tissues, respectively, which were significantly higher than that in paired noncancerous liver tissues (57%, 15/27) ($P < 0.05$). The CD/WT-mtDNA ratio in HCC tumors was 0.00092 (median, interquartile range, 0.0001202-0.00105), which was significantly higher than that in paired noncancerous liver tissues (median, 0.000, quartile range, 0-0) ($P = 0.002$, Mann-Whitney Test), and was 25 of times of that in HNH tissues (median, 0.0000374, quartile range, 0-0.0004225) ($P = 0.002$, Mann-Whitney test).

CONCLUSION: CD-mtDNA mutation plays an important role in the development and progression of HCC.

INTRODUCTION

Hepatocellular carcinoma (HCC) is one of the common malignancies worldwide, and has been ranked the 2nd cancer killer in China. Hepatitis B and C viruses (HBV and HCV) and dietary aflatoxin intake remain the major causative factors of HCC^[1]. Previous

studies also revealed that frequent genetic aberrations were involved in hepatocarcinogenesis^[2,3]. However, the molecular mechanisms of hepatocarcinogenesis remain unclear. Recently, morphological features of the tumor, both gross and histological, have been found to be significantly associated with tumor recurrence and patient survival.

Nuclear gene alterations are correlated to invasion, metastasis, recurrence of HCC, which are regarded as biomarkers for the malignant phenotype of HCC, and related to the prognosis and therapeutic outcomes. These biomarkers include p53 gene mutation^[4], VEGF overexpression^[5,6], apoptosis related genes, cell adhesion and extracellular matrix related genes such as E-cadherin, β -catenins, CD44s, MMPs and their inhibitor TIMPs^[7-13].

Human mitochondrial DNA (mtDNA) is located in cytoplasm, is becoming the study hotspot for its alteration in correlation with its tumorigenesis. Mitochondria are involved in apoptosis^[14], and probably also tumorigenesis^[15], which has led researchers to examination the potential roles of mtDNA alterations in the development and maintenance of cancers.

The most abundant change in mtDNA is called common deletion (4 977 bp, CD). CD-containing mitochondrial DNA (CD-mtDNA) was first observed in patients with mitochondrial myopathies, and was also found to accumulate in patients with heteroplasmic mtDNA mutations and in normal individuals during aging, particularly in postmitotic tissues such as muscle and brain^[16]. The CD-mtDNA mutation has been detected in several types of human tumors including thyroid Hürthle cell tumor^[17], gastric cancer^[18], and hepatocellular carcinoma^[19]. However, knowledge about the common deletion of mtDNA in HCC in China is poor. This is the first report of a high incidence (70%) of a novel CD-mtDNA (4 981 bp) in tumor tissues of HCC and hepatocellular nodular hyperplasia (HNH) from southern China, and the first analysis correlating CD-mtDNA level to clinicopathological parameters and age.

MATERIALS AND METHODS

Clinical data and histopathologic analysis of tumor samples

Patients with histologically proved HCC and HNH at the Cancer Center, Sun Yat-Sen University (Guangzhou, China) were recruited with informed consent from January 1999 to January 2003. Samples consisted of 27 surgically resected HCC and 27 HNH specimens. In HCC specimens, the tumor tissue and paired adjacent noncancerous liver tissue were obtained independently for mtDNA analysis. In serum, hepatitis B viral surface antigen and HCV antibody titer were detected by enzyme-linked immunosorbent assay and radio-immunoassay. Grading of differentiation was performed according to the method of Edmondson and Steiner. Tumors were classified into well differentiated group (grades 1 and 2) and poorly differentiated group (grades 3 and 4). The tumor size was classified into small (tumor mass < 3 cm in greatest diameter) and large (tumor mass size > 3 cm in greatest diameter). There were 24 males and 3 females aged from 40 to 79 years, with an average age of 58 years.

DNA extraction

Total (nuclear and mitochondria) DNA was extracted from

Table 1 TaqMan primers and probes for detection of WT-mtDNA and CD-mtDNA

Target	Amplicon	Oligonucleotide sequence (5' -3')
Wild Type mtDNA	101 bp	WT1 forward primer (7 878-7 897): 5'-AATCAATTGGCGACCAATGG-3' WT2 reverse primer (7 979-7 958): 5'-CGCCTGGTTCTAGGAATAATGG-3' WT probe (7 899-7 917): 5' FAM-ACTGAACCTACGAGTACAC-MGB-3'

paraffin-embedded tissues of HNH, HCC and adjacent noncancerous liver tissues using the QIAamp DNeasy Tissue Kit (Qiagen, Hilden, Germany). Prior to DNA extraction, a microdissection technique was used in certain cases when tumor tissues and non-tumor tissues were mixed in one sample to enrich tumor cells^[20]. Five 10- μ m thick sections were cut and placed into a 1.5 mL Eppendorff tube. The sections were deparaffinized twice with xylene and alcohol.

Conventional PCR detection of CD-mtDNA

In this investigation, we developed a real-time PCR protocol that reliably quantified mtDNA through amplification of different regions of the mitochondrial genomes: one just outside the CD region in cytochrome c oxidase II (MTCO2) coding region (IS), and one overlapping the CD itself (Figure 1). PCR primers for detection of CD-mtDNA were designed according to MITOMAP Human mtDNA Cambridge Sequence data (www.mitomap.org). Real-time PCR primers and fluorogenic probes for regions of WT-mtDNA (forward primer, L7878-7897; reverse primer, H7979-7958; probe, L7899-7917) and CD-mtDNA (forward primer, L8448-8472; reverse primer, H13560-13539; probe, L13456-13471) were designed with the Primer Express software (Table 1).

Conventional PCR was performed in 20 μ L volume consisting of 2 μ L 10 \times PCR buffer, 25 μ mol/L of each dNTP, 2.5 U Taq polymerase, 15 pmol/L of each primer and 50 ng of DNA template. The reaction was performed in a PE2700 thermocycler (Applied Biosystem Inc., USA). PCR reaction included at 95 $^{\circ}$ C for 10 min, 40 cycles at 94 $^{\circ}$ C for 30 s, at 60 $^{\circ}$ C for 30 s and at 72 $^{\circ}$ C for 30 s. The PCR products were separated on 20 g/L agarose gels at 80 V for 60 min, visualized by ethidium bromide staining and UV light, and photographed. The results of amplification of CD-mtDNA by conventional PCR in HCC and HNH tissues are shown in Figure 2A.

Figure 1 Human mitochondrial DNA showing the 4 997-bp deletion. The genes disrupted by the 4 997 bp deletion between nucleotide positions 8 469 and 13 447 encode four polypeptides for complex I (ND3, ND4, ND4L and ND5), one for complex IV (CO III) and two for complex V (ATP8 and ATP6), and five tRNA genes for the amino acids G, R, H, S and L. CD represent the PCR primers position that flank the common deletion region.

Figure 2 Detection results of CD-mtDNA in HCC. A: Conventional PCR results: Lane M, marker, Lane 1, negative control, Lane 2, positive control, Lane 3-4, nasopharyngitis samples, and Lane 5-8, NPC samples; B: Real-time PCR result shows the amplification plot of fluorescence intensity against the PCR cycle. Each plot corresponds to a HCC sample. The X axis denotes the cycle number of a quantitative PCR reaction. The Y axis denotes the Rn, which is the fluorescence intensity over the background. The correlation coefficient is 0.994.

TaqMan-PCR

The principles of real-time PCR and methods for absolutely quantification of target DNA were described^[18]. The quantitative TaqMan-PCR method could provide real-time measurement of target input.

Triplicate amplification reactions were performed in a 96-well microplate. Total WT-mtDNA and CD-mtDNA reactions (25 μ L) each containing 100 ng DNA, 1 \times TaqMan Universal PCR Master Mix, 300 mmol/L of each dNTP and 300 mmol/L of each IS or CD primer were performed. The reactions were completed by adding 100 nmol/L of the specific WT or CD probe. PCR and fluorescence analysis were performed using the ABI GeneAmp 7900HT sequence detection system (Applied Biosystems Inc., USA). Amplification conditions included at 50 $^{\circ}$ C for 2 min (for optimal AmpErase UNG activity), at 95 $^{\circ}$ C for 10 min (for deactivation of AmpErase UNG and activation of AmpliTaq Gold), then 40 cycles at 95 $^{\circ}$ C 15 s and at 60 $^{\circ}$ C for 1 min (for probe/primer hybridization and DNA synthesis).

Analysis of the reactions was carried out in an ABI PRISM 7900HT sequence detector equipped with the sequence detection software version 2.0 (PE Applied Biosystems, Foster City, USA). Absolute DNA quantification was performed using the standard curve method. Reactions were carried out with different concentrations (10^{10} , 10^9 , 10^8 , 10^7 , 10^6 , 10^5 , 10^4 copies/mL) of two standard plasmids in parallel with test reactions. The standard plasmids, one carrying sequences flanking the common deletion and one carrying a unique mtDNA sequence independent of the CD, allowed the generation of two standard curves showing the number of copies of total WT-mtDNA or CD-mtDNA versus the measured CT. The CT values of samples were then converted to the number of DNA copies by comparing the sample CT to that of a known concentration of plasmid DNA.

The amount of mutation corresponded to the concentration ratio of CD-mtDNA to WT-mtDNA within each sample. If DNA was not detected within 40 cycles (CT=40), it was considered absent from a particular sample. The amplification plot CD-mtDNA detected by TaqMan PCR in HCC tissues is presented in Figure 2B.

The CD-mtDNA PCR products were sequenced using the ABI PRISM BigDye termination cycle sequencing ready reaction kit on an ABI PRISM377 sequencer (Applied Biosystem Inc., USA). Blast sequencing analysis confirmed that PCR products of the CD-mtDNA were homologous to the Cambridge version of the mtDNA sequence.

Statistical analysis

The levels of CD/MT-mtDNA ratio in different groups were compared using the Mann-Whitney rank-sum test. The chi-square test and Fisher's exact test were used to assess the difference in different groups. A *P* value less than 0.05 was considered statistically significant.

RESULTS

The 132 bp PCR fragment amplified from CD-mtDNA was cloned and sequenced to confirm the deletion junction created by the CD, which was characterized by the presence of one of the two 13 bp repeats that normally flanked wild-type mtDNA. Sequence comparison (Human mtDNA Cambridge Sequence data, www.mitomap.org) revealed that the common deletion region in our HCC samples was a 4 981 bp fragment extending from position 8 470 bp to 13 450 bp (Figure 3). This was a novel mtDNA deletion belonging to the 4 977 bp deletion subtype that was first reported in liver diseases.

Incidence of CD-mtDNA by conventional PCR detection

CD-mtDNA was detected by conventional PCR in 70% (19/27), 63% (17/27) and 44% (12/27) in HCC tumors, HNH tissues and HCC adjacent liver tissues, respectively. The detected rate of CD-mtDNA in HCC and HNH tumors by conventional PCR was significantly higher than that in adjacent liver tissues ($P < 0.05$, chi-square test). There was no significant difference in CD-mtDNA detected rate between HCC and HNH ($P > 0.05$, chi-square test).

By quantitative TaqMan-PCR, the detection rate of CD-mtDNA in HCC tumors, HNH tissues and adjacent liver tissues was 70% (19/27), 63% (17/27) and 44% (12/27), respectively. When these results were combined with those of conventional PCR, CD-mtDNA was detected in 85% (23/27) of HCC, 83% (22/27) of HNH, and 57% (15/27) of HCC paired adjacent liver tissues. The detected CD-mtDNA rate in HCC and HNH tumors was significantly higher than that in paired noncancerous liver tissues ($P < 0.05$, chi-square test). (Figure 4).

Figure 4 Correlations of CD-mtDNA with HCC and HNH. The CD-mtDNA rate in HCC and HNH lesions was significantly higher than that in paired noncancerous tissues; the CD/WT-mtDNA ratio in HCC was significant higher than that in paired noncancerous liver tissues ($P = 0.02$), and was about 25 times that in HNH lesions ($P = 0.02$).

CD/WT-mtDNA ratio in HCC and HNH lesions

We evaluated the relative level of CD-mtDNA by calculating the ratio of CD-mtDNA to WT-mtDNA in each sample. In this study, the CD/WT-mtDNA ratio was 0.00092 (median, interquartile range, 0.0001202-0.00105) in HCC tumor, 0.000 (median, quartile range, 0-0) in paired noncancerous liver tissues, and 0.0000374 (median, quartile range, 0-0.0004225) in HNH tissues. The CD/WT-mtDNA ratio in HCC tumor was significantly higher than that in paired noncancerous liver tissues ($P = 0.002$, Mann-Whitney test), and was 25 times of that in HNH tissues ($P = 0.002$, Mann-Whitney test, Figure 4). No correlation of the detected rate and the ratio of CD-mtDNA with ageing, staging, tumor size, HBV infection and differentiation of patients with HCC were found.

DISCUSSION

It has been found that human mitochondrial DNA (mtDNA) has a double-stranded circular molecule of 16 569 bp that encodes 37 genes: 2 rRNAs, 22 tRNAs and 13 polypeptides^[21]. The mtDNA was present in high copy levels (10^3 - 10^4 copies per cell) in virtually all cells, and the vast majority of an individual's copies were identical at birth^[22]. It has been generally accepted that high mutation rates of mtDNA are caused by a lack of protective histones, inefficient DNA repair systems, and continuous exposure to mutagenic effects of oxygen radicals generated by oxidative phosphorylation^[23,24]. The deletion was thought to be the product of an intragenomic recombination event between two 13 bp direct repeats (positions 8 470-8 482 and 13 447-13 459) after a single-strand break caused by ultraviolet A (UVA) or ROS^[25].

Recently, somatic mutations in mitochondrial DNA (mtDNA)

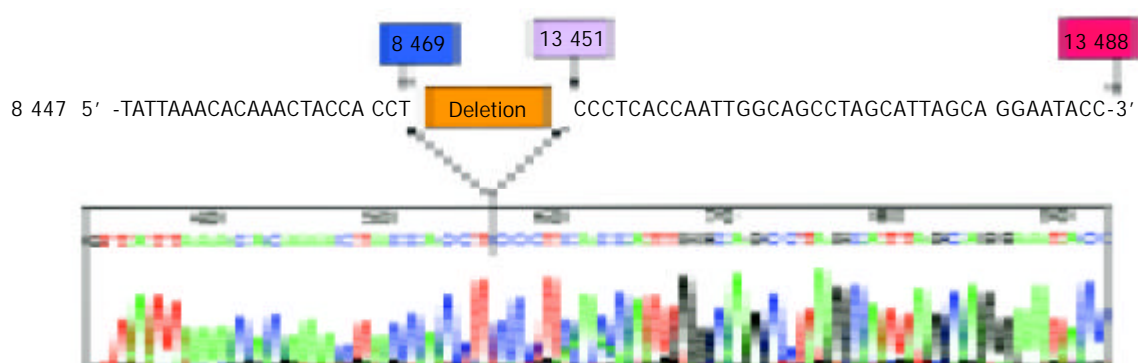

Figure 3 Sequencing result of the amplified CD-mtDNA from HCC. Comparison with the MITOMAP Human mtDNA Cambridge Sequence data (www.mitomap.org), the deletion region (red bar region) is a 4981 bp deletion from position 8 470 to 13 450 of the mtDNA.

have been detected in various cancers including HCC. Mutations in the D-loop were frequent events and could be used as a molecular tool to determine clonality of HCC^[26]. There are controversial reports of CD-mtDNA mutation in HCC. CD-mtDNA was reported to be detected in HCC tumors and noncancerous liver tissues, whereas lower level even no CD-mtDNA was detected in HCC tumors^[27,28]. In this investigation, we detected a novel CD-mtDNA mutation (4 981 bp) in 85% HCC, which was higher than that in gastric cancer (50%)^[18], but less than that in thyroid Hürthle cell tumors (100%)^[17]. Moreover, we found that both the detected CD-mtDNA rate and CD/WT-mtDNA ratio in HCC were higher than those in paired noncancerous liver tissues of individuals with HCC. This result was different from previous studies. The different risk factors and different genetic background in HCC tumorigenesis between Chinese and Japanese might explain the disparity of the results. Further studies are required to determine if CD-mtDNA mutation is correlated with malignant transformation.

However, the biological impact of mtDNA deletion on HCC tumors is not entirely clear. Defects in mitochondrial function have long been suspected to contribute to the development and progression of cancer. These mutations could contribute to neoplastic transformation by changing cellular energy capacities, increasing mitochondrial oxidative stress, and/or modulating apoptosis^[25]. Diaz *et al.*^[29] reported that mtDNA with large deletions, but not with pathogenic point mutations, repopulated organelles significantly faster than wild-type genomes in the same cell. Under proliferating conditions, cells harboring relatively high levels of deleted mtDNAs showed a slight reduction in the mutated fraction. This was consistent with the observation that patients with mitochondrial diseases had relatively low percentages of mutated mtDNA in proliferating peripheral blood cells and fibroblasts^[30]. This situation paralleled the accumulation of large-scale mtDNA deletions in postmitotic tissues, where selection based on cellular growth or survival did not take place, and abnormal organelle proliferation would lead to an increase in mtDNA replication rates^[31,32]. Amuthan^[33] showed that damage to mtDNA and the mitochondrial membrane might change nuclear gene expression, leading to overexpression of genes including cathepsin L, transforming growth factor (TGF β), and mouse melanoma antigen (MMA), which are well known markers for tumor progression. Singh^[34] showed that mtDNA played an important role in cellular sensitivity to cancer therapeutic agents. Since each cell contains many mitochondria with multiple copies of mtDNAs, it is possible that wild-type and mutant mtDNA can co-exist in a state called heteroplasmy. Thus, the biological impact of a given mutation may vary, depending on the proportion of mutant mtDNAs carried by individuals.

It has been shown that mtDNA deletions accumulate with age in many tissues. However, in tumors, the CD has been associated with external factors such as radiation and cigarette smoking^[35-37]. In this investigation, we found that although there was no significant difference in detected CD-mtDNA rate between HCC and paired adjacent liver tissues as well as HNH, the CD-mtDNA ratio in HCC was significantly higher than that in HNH (25-fold) and paired noncancerous liver tissues. These results suggest that CD-mtDNA mutation may be accumulated during the hepatocyte transformation. No correlation of CD-mtDNA with ageing, staging and HBV infection of the individuals with HCC and HNH was found. In this investigation, the high detected rate and high ratio of CD-mtDNA in HCC and HNH suggested that this rapid and quantitative assay of CD-mtDNA and WT-mtDNA copy number was potentially useful in a variety of molecular and evolutionary fields of HCC.

In conclusion, this is the first quantitative study of frequent occurrence of CD-mtDNA mutations in patients with HCC. This study provides further evidence that CD-mtDNA mutation

might play an important role in the development and progression of HCC. Studies evaluating the CD-mtDNA mutations as a biomarker may be potentially useful for early diagnosis of HCC.

Abstract

AIM: To investigate *cytochrome P4502E1* (*CYP2E1*) gene expression in occurrence and progression of hepatocellular carcinoma (HCC).

METHODS: The human liver arrayed library was spotted onto the nylon membranes to make cDNA array. Hybridization of cDNA array was performed with labeled probes synthesized from RNA isolated from HCC and adjacent liver tissues. Sprague-Dawley rats were administrated diethylnitrosamine (DEN) to induce HCC. *CYP2E1* expression was detected by the method of RT-PCR and Northern blot analysis.

RESULTS: *CYP2E1* was found by cDNA array hybridization to express differently between HCC and liver tissues. *CYP2E1* only expressed in liver, but did not express in HCC tissues and expressed lowly in cirrhotic tissues. In the progression of cirrhosis and HCC, the expression level of *CYP2E1* was gradually decreased and hardly detected until the late stage of HCC.

CONCLUSION: Using arrayed library to make cDNA arrays is an effective method to find differential expression genes. *CYP2E1* is a unique gene expressing in liver but did not express in HCC. *CYP2E1* expression descended along with the initiation and progression of HCC, which is noteworthy further investigations in its significance in the development of HCC.

INTRODUCTION

Hepatocellular carcinoma (HCC) is one of the most common cancers in China and the world^[1,2]. Although the wide use of diagnostic technology and the improvement in curative treatment may evolve to a better scenario, it still represents more than 5% of all cancers^[3]. To investigate HCC associated

genes is very helpful to elucidating the molecular mechanism of proliferation, differentiation and transformation of hepatocytes in the occurrence and development of HCC^[4,5]. cDNA microarray analysis is a powerful technique in the investigation of cancer associated gene identification and function^[6]. The gene expression can be simultaneously monitored in a large scale with cDNA microarray^[7]. The potential analysis of the expression of thousands of genes in one experiment provided new insights into the molecular study of the occurrence and development of HCC^[8-10].

In the present study, a method of making cDNA array from the arrayed library was developed to identify the differentially expressed genes. *CYP2E1*, the gene encoding cytochrome P450 2E1 (*CYP2E1*), a member of cytochrome P450s present in prokaryotes and through the eukaryotes^[11], was identified to express in normal liver or cirrhotic tissues adjacent to tumors but not express in HCC tissues. *CYP2E1* is one of the important members of cytochrome P450 superfamily, with functions ranging from catalysis of the conversion of ethanol to acetaldehyde and from acetate to metabolism of many exotic drugs and procarcinogens^[12]. A rat HCC model was then induced to study *CYP2E1* expression in the procession of HCC. The results showed that *CYP2E1* expression descended along with the initiation, promotion and progression of HCC. It is suggested that *CYP2E1* is correlated to HCC and noteworthy further investigations for its significance in the development of HCC.

MATERIALS AND METHODS

Arrayed library preparation

The human liver cDNA library (Invitrogen, USA) was cultured on the agar plate and were picked into 96-well microplates with 200 µL culture medium. After an overnight culture, 1 µL of the bacterial medium in each well was diluted into 20 µL from which 1 µL was transferred to the corresponding 96-well PCR microplates and the remaining was added to 50 µL glycerol and stored at -80 °C.

PCR amplification of plasmids

PCR reaction was carried out with oligonucleotide T7 (5' gga aga agg gaa ctg att cag 3') and oligonucleotide BGHR (5' cac atc cag atc ata tgc cag 3') as forward primer and reverse primer. The procedure of PCR was made with denaturing at 94 °C for 4 min followed by 35 cycles of reaction including denaturing at 94 °C for 50 s, annealing at 58 °C for 50 s and elongation at 72 °C for 90 s, and a final bonus extension elongation at 72 °C for 7 min. The amplified products were randomly selected for electrophoresis to validate PCR efficiency.

DNA arrays preparation

The PCR products in the microplates were spotted with TAS (BioRobotics, UK) onto the 8 cm×12 cm nylon membrane to form 2×2×96 array in each membrane. The 0.7 mm diameter 96-pin spotting setting was used. Each product from a well was spotted onto the same position 3 times. The membranes were denatured immediately in the denature buffer (1.5 mol/L

NaCl, 0.5 mol/L NaOH) for 5 min and then equalized in the equalizing buffer (0.9 mol/L NaCl, 0.5 mol/L Tris, pH7.5) for 5 min followed by baking at 80 °C.

DENA-induced HCC in rats

DENA (Sigma, USA) was diluted into 1×10^{-4} concentration in drinkable water. Male Sprague-Dawley rats were obtained from the Experimental Animal Center of Chinese Academy of Sciences, Shanghai. The rats in HCC group were administrated DENA via drinking DENA-diluted water while the rats in control group drank clean water. Three HCC-induced rats and one control rat were sacrificed by decollation under pentobarbital anesthesia every week. The liver tissue was immediately stored in liquid nitrogen for RNA isolation and fixed for histological analysis.

Total RNA and mRNA isolation

Total RNA was isolated from 0.1 g frozen tissues in 1 mL Trizol™ reagent (Invitrogen, USA) according to the manufacturer's instructions. Isolation of mRNA was carried out with the Oligotex™ mRNA Mini kit (Qiagen, Germany) from 250 µg total RNA.

Labeling of cDNA from mRNA of HCC tissues

Probes for the array hybridization were labeled with Atlas™ SpotLight™ labeling kit (Clontech, USA) according to the user's manual. A 2 µg mRNA respectively from paired HCC tumor and adjacent normal or cirrhotic tissues was added with 2.5 µL CDS Primer Mix and incubated at 70 °C for 10 min. Reaction buffer (5×) 5 µL, Labeling Mix (10×) 2.5 µL, DTT (100 mmol/L) 1.25 µL were added and incubated at 48 °C for 5 min. PowerScript reverse transcriptase (1.25 µL) per reaction and 10 mL of Master Mix were added and incubated at 48 °C for an additional 45 min. The reaction was stopped by adding 0.5 mL of 0.5 mol/L EDTA (pH8.0) and then purified routinely.

Hybridization of DNA array

DNA array hybridization and detection were preceded with SpotLight™ chemiluminescent hybridization & detection kit (Clontech, USA). The array membranes were wetted and pre-hybridized while a biotinylated array probe was denatured. Cot-1 and the biotinylated probe were added to pre-hybridization solution to incubate overnight. The membranes were washed and blocked, and added with enough stabilized Streptavidin-HRP conjugate. After equilibrated, the membranes were covered with the luminol/peroxide working solution and incubated at room temperature for 5 min and exposed the membrane to film for an appropriate time to obtain desired signals.

RT-PCR of CYP2E1 in rats

First strand cDNA was reversibly transcribed from total RNA with SuperScript™ reverse transcriptase (Invitrogen, USA). The procedure of RT-PCR of *CYP2E1* was carried out in normal rat tissues with the oligonucleotide (5' act tct acc tgc tga gca c 3') and oligonucleotide (5' ttc agg tct cat gaa cgg g 3') as forward and reverse primer respectively and with denaturing at 94 °C for 4 min followed by 33 cycles of reaction including denaturing at 94 °C for 50 s, annealing at 55 °C for 50 s and extension at 72 °C for 1 min, and a final bonus extension for 7 min. An 874-bp sequence product was amplified.

Cloning of rat CYP2E1

The PCR product was purified using the QIAquick PCR purification kit (Qiagen, Germany) and cloned into the T-vector (Promega, USA) directly and transfected into DH5- α bacteria. The plasmid was purified to be sequenced and confirmed according to the GenBank sequence.

Northern blot analysis

The plasmid was digested and electrophoresed. The template fragment was purified from agarose gel using the gel extracting kit (Qiagen, Germany). The probe was labeled from 25 ng template DNA by the random primer method using DNA polymerase I large (Klenow) fragment (Promega, USA) with α -³²P-dCTP followed by purification using the QIAquick purification kit (Qiagen, Germany). Total RNA (40 µg) justified by 28 s and 18 s intensity of each sample, was loaded. Electrophoresis was carried out under denaturing conditions and RNA was transferred onto nitrocellulose membrane and cross-linked by baking at 80 °C for 2 h. The filters were then prehybridized, hybridized, and washed under high stringency conditions. All blots were screened by Fuji BAS2000 and analyzed by LABwork software and then exposed at -80 °C to Kodak X-ray film for 2 wk.

RESULTS

Identification of CYP2E1 as an HCC-silent gene with cDNA array gene expression profile analysis

The arrayed library clones were spotted onto each nylon membrane to $2 \times 2 \times 96$ array from 4 microplates. There were 96 subarrays in one membrane. The arrayed membranes were denatured, fixed and preserved under dry condition. The mRNA from HCC tissues and corresponding adjacent liver tissues was labeled to hybridize to the above arrayed membranes. A spot then identified low signals in HCC tissues but high signals in corresponding adjacent liver tissues (Figure 1). It was suggested that the gene was a liver-expressing gene that was downregulated in HCC tissues. According to the position of the spot in membrane, the clones in microplates of arrayed library was recruited and sequenced as *CYP2E1*.

Figure 1 Differential expression profile of cDNA array hybridization result. Part of the membrane is displayed. The clones the arrows point represent *CYP2E1*. K: HCC tissue, L: adjacent liver tissue.

HCC model of DENA-induced rats

The liver tissue from DENA-induced rats that were killed after 3 wk appeared almost normal as the control rats. The pathological examination indicated the liver lesion in these rats. The livers of rats after the 4th wk were smaller than those of control rats and the color of the liver surface was much dingy. Cirrhotic nodi could be seen on the liver surface of rats killed in the 7th wk and cirrhosis could be detected as early as in the 5th wk by pathological examination. There were few liver cancer nodi in 1 rat detected in the 9th wk. So the 9th wk might be the boundary between cirrhosis and HCC in the present study. In the 10th wk, HCC could be detected in all rats and HCC nodi could be seen by naked eyes after the 10th wk. After the 16th wk, HCC nodi were spread almost all over the rat liver.

CYP2E1 expression in normal tissues

Twelve types of human normal tissues except liver were used

for Northern blot analysis of *CYP2E1* expression. *CYP2E1* did not express at all in the 12 normal human tissues. To represent the expression level of *CYP2E1* in these organs, the RNA sample of heart, brain, lung, intestine and liver were selected with 2 cases of HCC tissues and 1 case of kidney cancer tissue to be transferred onto one membrane for Northern blot analysis. The hybridization result showed that *CYP2E1* indeed only expressed in non-tumor liver tissues (Figure 2). The expression pattern of *CYP2E1* in rats was the same as in human. By RT-PCR analysis, it was indicated that *CYP2E1* was only amplified from normal liver tissues and did not express in other tissues (Figure 3).

Figure 2 *CYP2E1* expression in normal human organs and HCC tissues detected by Northern blot analysis. 1: heart, 2: brain, 3: muscle, 4: intestine, 5: stomach, 6: lung, 7: liver tissues adjacent to HCC, 8: HCC, 9: liver tissues adjacent to HCC, 10: HCC, 11: renal tissues adjacent to carcinoma, 12: renal carcinoma.

Figure 4 *CYP2E1* expression in human HCC tissues detected by Northern blot analysis. N: normal liver, K: HCC, L: liver tissue adjacent to HCC.

Figure 5 *CYP2E1* expression in occurrence and development of rat HCC detected by Northern blot analysis. There were 12

lanes in one membrane including specimen of 3 wk. Ribosomal RNA of 28 s and 18 s as control was in the bottom. N: normal control group, D: DENA-induced group.

CYP2E1 expression in HCC

Northern blot analysis showed that *CYP2E1* expressed in normal liver tissues and adjacent tissues with cirrhosis. There was no hybridization signal in HCC tissues from all 14 cases. *CYP2E1* was significantly downregulated in HCC (Figure 4). The rat HCC model simulated the progression of HCC. The change of expression was analyzed also by Northern blot (Figure 5). In the early liver lesion stage of the DENA-induced rats after 1-3 wk, *CYP2E1* expression was slightly upregulated compared with normal livers. But after 4 wk, the gene was down-regulated and when cirrhosis occurred after 5 wk, the expression level was almost the same in the liver between the 2 groups. It was obvious that the cirrhotic tissues of the rats expressed at lower level than the normal livers after 7 wk. When the DENA-induced rats progressed to the stage of tumor from the 10th wk, *CYP2E1* expressed at much lower level than normal livers and liver of cirrhotic stages. Until the very later stage of HCC, the expression level was very low and the hybridization signal was hardly detected.

DISCUSSION

An ideal support allowed effective immobilization of probe onto its surface, and robust hybridization of target with the probe^[13]. Nylon membrane, as a standard support used for making microarrays^[14,15] could hold more DNA. The hybridization and detection of membranes arrays cost much less. Here we used the nylon membranes as the matrix of cDNA arrays. The DNA on the membranes was denatured before cross-linking to the matrix by baking the array at 80 °C. In many cases, the cDNA targets were chosen directly from cDNAs library of interest for DNA microarray manufacturing^[16]. The collection should include an aggregation of gene clones as many as possible. On the other hand, for certain purpose of an investigation, most genes on a large content array might not be necessary. The method to make cDNA microarray in this study arose from the concept of arrayed library. The cDNA plasmid library was transferred to the microplates to be the arrayed library, which was copied to the nylon membranes to make the DNA arrays after PCR amplification. Because most genes on the arrays did not differently express between samples, the tumor and normal tissues, for example, the sequencing expense of these genes could be saved. It was after the array hybridization, the genes that were detected to express differently would be selected from the arrayed library and were sequenced for further studies. In this study, most genes showed no differential expression between HCC and adjacent liver tissues. Only the differently expressed genes were sequenced for further investigations. *CYP2E1* was identified as a liver profound but HCC silent gene.

P450 enzymes were found in almost all eukaryotes and prokaryotes^[17]. *CYP2E1* enzyme had a molecular weight of 57 KD and the encoding gene was located on chromosome 10 spanning 11 413 base pairs^[18,19]. *CYP2E1* was found to play an important role in its polymorphism during tumor occurrence. The significance of this polymorphism currently unclear^[20,21]. To date, the results in possible associations between *CYP2E1* genetic polymorphisms and alcoholic liver disease susceptibility have been varied and often contradictory^[22]. Because hepatic *CYP2E1* has been shown to activate various carcinogens, there has been interest in whether certain *CYP2E1* polymorphisms might predispose to liver cancer^[23,24]. It was demonstrated that possession of the less common *Rsa* I/*Pst* I allele was associated with increased susceptibility to HCC^[25].

Although CYP2E1 was said to be located in most tissues with the largest concentration in the liver, it was constitutively expressed in the liver and only induced to express in other tissues by treatment with acetone, ethanol, isoniazid and other compounds, many of which are substrates for the enzyme^[26-28]. This study showed that *CYP2E1* expressed only in the liver but did not express in the other normal organs in human and rats. So it could be concluded that *CYP2E1* is the liver-specific functional gene. Furthermore, *CYP2E1* was found to loose expression in HCC. Northern blot analysis was performed to validate the result of chip experiment. *CYP2E1* expressed at a high level in normal or cirrhotic tissues but was silent in HCC tissues from 14 cases of HCC. So *CYP2E1* did not express in HCC. To further understand the expression of *CYP2E1* in the initiation, promotion and progression of HCC, the DENA-induced rat HCC model was made to study the role of *CYP2E1* in the process of HCC. The development of rat HCC underwent the progression of liver lesion and cirrhosis until the tumor occurrence. The results showed that at the early stage of the rat model the expression level of *CYP2E1* in the liver lesion tissues was slightly higher than that in normal rat liver in the first to third week. Because CYP2E1 was involved in the metabolism of nitrosamines, DENA might induce *CYP2E1* expression. But along with the aggravation of liver lesion and development of cirrhosis, the expression level of *CYP2E1* was gradually descended. After the progressing stage of HCC, *CYP2E1* did not express as in human HCC. There were very low signals because at the late stages of HCC the tumor were grown sporadically and the samples were intermixed with cirrhotic tissues where *CYP2E1* still expressed. The expression pattern of *CYP2E1* in the HCC was worth of further studies. It is suggested that these differential expression might help further understand the molecular genetic and gene regulation mechanism of HCC progression. Because *CYP2E1* does not express in HCC cells, there might be a guided biological treatment for HCC with its potential substrate.

Abstract

AIM: Signal transducers and activators of transcription (STATs) are a family of transcription factors activated in response to cytokines and growth factors. Constitutive activation of Stat3 has been observed in a growing number of tumor-derived cell lines, as well as tumor specimens from human cancers. The purpose of this study was to investigate the expression of p-Stat3, activated form of Stat3, and its downstream mediators including cyclin D1 and Bcl-x_L in colorectal carcinoma (CRC), and to explore the possible mechanism of Stat3 signaling pathway in the tumorigenesis of colorectal carcinoma.

METHODS: Tissue samples from 45 patients of primary colorectal carcinoma were selected for studying Stat3 signaling pathway protein expression. Western blot analysis was used to measure the expression of p-Stat3, cyclin D1, and Bcl-x_L proteins in colorectal carcinomas. Furthermore, the expression patterns of these proteins were analyzed for their distribution at the cellular level by immunohistochemical staining of the tissues.

RESULTS: Protein levels of p-Stat3, cyclin D1, and Bcl-x_L were increased in colorectal carcinomas compared with adjacent normal mucosae ($P < 0.05$). Elevated levels of p-Stat3 were correlated with the nodal metastasis and the stage ($P < 0.05$). Overexpression of cyclin D1 was associated with the nodal metastasis ($P < 0.05$). There was also a significant correlation between the expressions of p-Stat3 and cyclin D1 ($r = 0.382$, $P < 0.05$).

CONCLUSION: Constitutive activation of Stat3 may play an important role in the tumorigenesis of colorectal carcinoma, and the detailed mechanism of Stat3 signaling pathway in CRC deserves further investigation.

INTRODUCTION

Colorectal carcinoma (CRC) is a very common malignancy in developed countries and the incidence of CRC has been increasing rapidly in the latter part of the twentieth century in urban China^[1,2]. Although there have been advances in surgical and cytotoxic treatments of colorectal carcinoma, the overall survival percentage has not changed in recent years. While significant progresses have been achieved in identifying oncogenes and tumor suppressor genes involved in the tumorigenesis of colorectal carcinoma, the molecular mechanisms in colorectal carcinoma are still poorly understood. Recently, with the delineation of important signal transduction cascades, it has become clear that the signal transducers and activators of transcription (STATs) signaling pathway may play an important role in the malignant transformation of a number of human malignancies^[3].

STATs are transcription factors activated in response to cytokines and growth factors. At present, seven STATs have been identified in mammals: Stat1, Stat2, Stat3, Stat4, Stat5a, Stat5 b, and Stat6. Stat5 a and Stat5 b are encoded by distinct genes whereas Stat1 and Stat3 exhibit two isoforms, each resulting from alternative splicing^[4]. These proteins have a conserved structural organization and range in size from 750 to 900 amino acids. Activated STATs rapidly translocate into nuclei, bind to recognition sequences in the promoter region of target genes, and regulate their transcription. Recent studies have demonstrated the essential roles of STATs proteins in modulating the process of cell proliferation, differentiation, and apoptosis^[5-7].

Constitutively activated STAT proteins have been observed in a wide variety of human tumor cell lines and primary tumors including leukemia, multiple myeloma, breast cancer, prostate cancer, and other cancers^[8-13]. Further investigation demonstrated that activation of Stat3 was associated with the transformation by v-Src and other viral oncoproteins^[13-15]. Stat3 has been classified as an oncogene because constitutively activated Stat3 was found to mediate oncogenic transformation in cultured cells and tumor formation in nude mice^[16,17]. Stat3 activation may not only provide a growth advantage, but also confer resistance to conventional therapies that rely on the mechanism of apoptosis to eliminate tumor cells^[18]. The events downstream from constitutive activation of Stat3 that promote tumorigenesis are unclear but could include deregulation of cell cycle progression and/or providing protection against apoptosis. Recent studies showed that constitutive activation of Stat3 correlated with cyclin D1 expression and might provide a prognostic marker in head and neck cancer^[19], and activated Stat3 contributed to the process of apoptosis in ovarian cancer cells by regulating the expression of Bcl-x_L^[20]. These findings suggest that constitutive activation of Stat3 participates in the development of different human malignancies. However, the expression and activation of Stat3 protein in human colorectal carcinomas have not been studied. It is important to know whether or not constitutive activation of Stat3 signaling pathway plays a central role in human colorectal carcinomas.

In the present study, we examined the expression of p-Stat3, the activated form of Stat3, cyclin D1, and Bcl-x_L in 45 primary

tumor samples obtained from patients with CRC. Our results demonstrate that constitutive activation of Stat3 signaling pathway may play an important role in the tumorigenesis of colorectal carcinoma. Furthermore, activation of Stat3 is correlated with the overexpression of cyclin D1 in colorectal carcinoma.

MATERIALS AND METHODS

Materials

PVDF membranes for Western blot analysis were purchased from Millipore (Bedford, MA), and x-ray film was from Eastman Kodak (Rochester, NY). All antibodies were from Santa Cruz Biotechnology (Santa Cruz, CA). Prestained molecular mass markers were from GIBCO/BRL (Grand Island, NY). The enhanced chemiluminescence (ECL) system for Western blot analysis was from Amersham (Arlington Heights, IL). Concentrated protein assay dye reagents were from Bio-Rad Laboratories (Hercules, CA). All other reagents were of molecular biology grade and were purchased from either Sigma (St. Louis, MO) or Amresco (Solon, OH).

Patients and tissue samples

Primary colorectal adenocarcinomas and adjacent normal mucosae distant from the tumor (5-10 cm away) were obtained from 45 patients undergoing colorectal cancer resection at the Department of Surgery, Peking University People's Hospital from February, 1999 to February, 2000. No patient had received chemotherapy or radiation therapy before surgery. The samples were collected after informed consent was obtained from the patients at the time of surgery. Malignant tissues and adjacent normal mucosae were immediately snap-frozen in liquid nitrogen within 15-20 min after surgical removal to ensure preservation of Stat3 activities. Detailed clinicopathological parameters including gender, age, site of primary tumor, stage, and degree of differentiation are shown in Table 1. Staging of the tumors was conducted according to the American Joint Committee on Cancer (AJCC)/International Union Against Cancer (UICC) TNM Classification after brief histological studies.

Table 1 Clinicopathological parameters of 45 patients with colorectal carcinoma

Clinicopathological parameters		Numbers (%)
Gender	Male	24 (53.3)
	Female	21 (46.7)
Age (yr)	Range	35-81
	Mean	61.7
	Median	66.0
Primary site	Colon	25 (55.6)
	Rectum	20 (44.4)
	I	1 (0.22)
	II	24 (53.3)
	III	14 (31.1)
Depth of invasion and Lymph node involvement	IV	6 (13.3)
	T1-T2 N0	7 (15.6)
	T3-T4 N0	18 (40.0)
	T1-T2 N1-2N2	12 (26.7)
Distant Metastasis	T3-T4 N1-N2	8 (17.8)
	M0	39 (86.7)
	M1	6 (13.3)
Histological grade	G1	12 (26.7)
	G2	22 (48.9)
	G3	11 (24.4)
Tumor size	>5 cm	22 (48.9)
	≤5 cm	23 (51.1)

T1: tumor invades the submucosa; T2: tumor invades the mus-

cularis propria; T3: tumor invades through the muscularis propria into the subserosa or perirectal tissues; T4: tumor directly invades other organs or structures and/or perforates visceral peritoneum; N0: no regional lymph node metastasis; N1: metastasis in one to three regional lymph nodes; N2: metastasis in four or more regional lymph nodes; M0: no distant metastasis; M1: distant metastasis; G1: well differentiated tumor; G2: moderately differentiated tumor; G3: poorly differentiated tumor.

Western blot analysis

Tissues were lysed with lysis buffer (150 mmol/L NaCl, 10 g/L sodium deoxycholate, 10 g/L Triton X-100, 1 g/L SDS, 10 mmol/L Tris, pH 7.2, 1 mmol/L Na_3VO_4 , 1 mmol/L phenylmethylsulfonyl fluoride, 1 mmol/L NaF, 0.1 mmol/L aprotinin, and 1 mmol/L leupeptin). After centrifugation at 13 000 g for 30 min at 4 °C, the protein concentrations in the cell lysates were determined by the Bradford assay. For Western blot analysis, whole cell extracts were mixed with 2×sodium dodecyl sulfate (SDS) sample buffer (125 mmol/L Tris·HCl, pH 6.8, 40 g/L SDS, 200 mL/L glycerol, 100 mL/L 2-mercaptoethanol) at 1:1 ratio and were heated for 5 min at 100 °C. Proteins (50 µg/lane) were separated by electrophoresis on 7.5-10% gradient SDS-polyacrylamide gel and transferred onto a PVDF membrane. Prestained molecular weight markers were included in each gel. Membranes were blocked for 30 min in Tris-buffered saline (TBS: 10 mmol/L Tris·HCl, pH 7.5 and 150 mmol/L NaCl) with 5 g/L Tween-20 (TBST) and 50 g/L BSA. After blocking, membranes were incubated at 4 °C overnight with Stat3 (C-20) phospho-independent, phospho-specific (Tyr-705) p-Stat3 (B-7); cyclin D1 (M-20), and Bcl-x_L (H-62) antibody in TBST and 10 g/L BSA respectively. Additionally, anti-glyceraldehydes-3-phosphate dehydrogenase (GAPDH) antibody was used to determine the amount of endogenous GAPDH protein to serve as an internal control. After the membranes were washed three times with TBST (5 min each), they were incubated with horseradish peroxidase-conjugated secondary antibody in TBST and 10 g/L BSA for 30 min. Subsequently, membranes were washed three times with TBST and developed by using the enhanced chemiluminescence (ECL) detection system. The optical density (OD) was measured by densitometry using a Storm PhosphorImager (Molecular Dynamics, Sunnyvale, CA) and the result was shown as relative expression for tumor (T) versus normal mucosae (N).

Immunohistochemical staining

Tissue samples were fixed in 40 g/L buffered formaldehyde, and embedded in paraffin. Five-micrometer sections of normal mucosa and colorectal carcinoma were cut and mounted onto poly-L-lysine-coated glass slides, air-dried, and heated for 2 h at 60 °C in an oven. The sections were dewaxed in xylene, rehydrated in descending alcohols, and endogenous peroxidase activity was blocked using 3 mL/L H_2O_2 -methanol solution. These sections were then subjected to an antigen retrieval procedure; slides were heated in citrate buffer 10 mmol/L (pH 6.0) for 10 min. The sections were then cooled and washed in phosphate-buffered saline (pH 7.4) and nonspecific binding sites were blocked by incubating with 50 mL/L goat serum for 30 min in a humidified chamber at room temperature. The slides were incubated at 4 °C overnight with appropriate primary antibody [Stat3 (C-20), dilution 1:75; p-Stat3 (B-7), dilution 1:150; cyclin D1 (M-20), dilution 1:100; Bcl-x_L (H-62), dilution 1:100]. Immunologic reaction was developed using 3-3'-diaminobenzidine in TBS containing 0.2 mL/L hydrogen peroxide. The slides were counterstained with hematoxylin. Negative controls were performed by substituting the primary antibody with Tris-buffered saline.

Statistical analysis

Statistical analysis was performed with SPSS software version 10.0 (SPSS Inc., Chicago, IL). Data were presented as mean±SD.

The relationship between levels of p-Stat3, cyclin D1 or Bcl-x_L and various clinicopathological parameters was determined by Student's *t* test or one-way ANOVA. The association between p-Stat3, cyclin D1 and Bcl-x_L expression was analyzed by Pearson's correlation coefficient. $P < 0.05$ was considered statistically significant.

RESULTS

Activated Stat3 was constitutively expressed in colorectal carcinoma

One objective was to determine whether Stat3 was constitutively activated in human colorectal carcinoma and whether activation of Stat3 correlated with various clinicopathological parameters in patients with CRC. To determine whether Stat3 was activated in CRC, we performed Western blot analysis using antibody to p-Stat3, activated form of Stat3. Representative cases are shown in Figure 1. Of the 45 CRC samples examined, 57.8% (26 of 45) of the samples showed strong p-Stat3 expression. Quantitative evaluation of the relative expression (tumor versus normal mucosae) of these experiments demonstrated an average 2.6-fold increase in the level of p-Stat3 protein in cancers compared with adjacent normal mucosae ($P = 0.002$, Table 2). Both cytoplasmic and nuclear localizations of the Stat3 (p-Stat3) were detected in CRC primary tumors (Figure 2). When we examined possible correlations with various clinicopathological parameters, we found that increased levels of p-Stat3 were significantly correlated with the existence of nodal metastasis ($P = 0.018$). We also found that the levels of p-Stat3 were increased in stages III and IV, whereas its levels were decreased in stages I and II ($P = 0.026$). No statistically significant correlation was observed between p-Stat3 expression and gender, age, primary site, size, and grade of tumors (Table 3).

Expression of downstream mediators of Stat3 in colorectal carcinoma

We next investigated the expression of cyclin D1 and Bcl-x_L, which could be potential downstream mediators of Stat3 in

CRC. We found that cyclin D1 and Bcl-x_L were overexpressed in CRC tissues ($P < 0.05$, Table 2). When we examined possible correlations with various clinicopathological parameters, we found that increased expression of cyclin D1 correlated with the nodal metastasis ($P = 0.041$), whereas increased expression of Bcl-x_L did not significantly correlate with any of these parameters (Figure 1, Table 3). The expression pattern of cyclin D1 and Bcl-x_L was also checked with immunohistochemistry. Representative examples of immunohistochemical staining are shown in Figure 2. Furthermore, we studied the possible correlations between expression of p-Stat3 and downstream mediators. When these data were analyzed by Pearson's correlation coefficient, we found a significant association between expressions of p-Stat3 and cyclin D1 ($r = 0.382$, $P < 0.05$). No statistically significant correlation was observed between p-Stat3 and Bcl-x_L expressions ($r = 0.162$, $P > 0.05$).

Figure 1 Expressions of Stat3, p-Stat3, cyclin D1, and Bcl-x_L in colorectal carcinoma. Lysates were made as described under Materials and Methods. GAPDH represents the internal protein control. Elevated levels of Stat3, p-Stat3 (Tyr-705), cyclin D1, and Bcl-x_L in tumor (T) tissues were compared to adjacent normal mucosae (N).

Figure 2 Expressions of Stat3, p-Stat3, cyclin D1, and Bcl-x_L in colorectal carcinoma. A: Cytoplasmic staining of Stat3 in CRC (original magnification $\times 200$); B: Nuclear staining of p-Stat3 in CRC (original magnification $\times 200$); C: Nuclear staining of cyclin D1 in CRC (original magnification $\times 200$); D: Cytoplasmic staining of Bcl-x_L (original magnification $\times 200$).

Table 2 Expressions of p-Stat3, cyclin D1, and Bcl-x_L in colorectal carcinoma (mean±SD)

Items	n	Percentage (%)	A Value		t	P

G1: well differentiated tumor, G2: moderately differentiated tumor, G3: poorly differentiated tumor, M0: no distant metastasis, M1: distant metastasis.

DISCUSSION

Though significant progresses have been achieved in delineating the molecular mechanisms of colorectal carcinoma tumorigenesis, specific signal transduction pathways involved in CRC have not been fully characterized^[21]. Increasing reports suggested that Stat3 signaling pathway played a critical role in malignant transformation and tumor progression^[3]. Constitutive activation of Stat3 has been detected in a wide variety of human primary tumors and tumor cell lines including blood malignancies, breast cancer, and other cancers^[8-13]. In the current study, we provided evidences that constitutive activation of Stat3 signaling might play an important role in human colorectal carcinoma.

Western blot analysis with p-Stat3 antibody showed that the activated form of Stat3 was elevated in the majority (57.8%) of CRC samples. Both cytoplasmic and nuclear localizations of Stat3 (p-Stat3) were also detected in CRC primary tumors. Nagpal *et al.*^[22] reported in their work on head and neck carcinomas that 58.9% (53/90) of HNSCC tumors showed very high Stat3 protein accumulation, and none of the normal epithelium samples showed Stat3 absence. Campbell *et al.*^[23] found that in 51 human primary tissues from normal prostate, benign prostatic hyperplasia, and prostate cancer, p-Stat3 was observed more

prominently in the nuclei of cells residing in malignant glands compared to those in nonmalignant samples. As previously discussed, there were a growing number of evidences associating constitutive or aberrant activation of Stat3 with human cancers. The presence of p-Stat3 and its up-regulation in colorectal carcinoma could have important implications in colorectal cancer biology.

Because the above results provided evidence that Stat3 was constitutively activated in colorectal carcinomas, it was of interest to determine whether activation of stat3 correlated with various clinicopathological parameters in patients with CRC. When we examined possible correlations with various parameters, we found that increased levels of p-Stat3 significantly correlated with the existence of nodal metastasis and its stage but not with other parameters. Masuda *et al.*^[19] indicated in their work on HNSCC, that elevated levels of the activated form of Stat3 had a significant association with the clinical stage of HNSCC. Ni *et al.*^[24,25] demonstrated that Stat3 DNA binding activity was correlated with malignant potential in both human prostate cancer cell lines and a large series of rat Dunning prostate cancer cell lines. The most aggressive cell lines were found to have the highest Stat3 DNA binding activities. Blockade of activated Stat3 by dominant-negative Stat3 constructs significantly suppressed their growth *in vitro* and tumorigenicity *in vivo*. This specific activation of Stat3 in the tumorigenesis of colorectal carcinoma could qualify it as a potential diagnostic marker.

Tumor progression could be facilitated by activation of genes that regulate proliferation and/or apoptosis. However, the downstream events from constitutively activated Stat3 are not fully understood. Cyclin D1, an important cell cycle regulator, was overexpressed and associated with the poor prognosis in colorectal carcinoma^[26]. We investigated the expression of cyclin D1 in CRC tissues. When we examined possible correlations with various parameters, we found that increased levels of cyclin D1 correlated with the nodal metastasis, and there was a significant correlation between overexpressions of p-Stat3 and cyclin D1. However, the precise mechanism underlying the overexpression of cyclin D1 in CRC is unclear. In the majority of the cases of CRC, cyclin D1 gene was not amplified, suggesting that the increased expression of cyclin D1 was due to defects at the level of gene transcription^[27]. The similar discrepancy between cyclin D1 overexpression and gene amplification was also reported in breast and HNSCC cancers^[28,29]. Constitutive activation of Stat3 constructs has been shown to activate the cyclin D1 promoter in rodent fibroblast cell lines^[16], and overexpression of cyclin D1 was associated with increased activation of Stat3 in ovarian carcinoma and HNSCC^[20,30]. Therefore, frequent overexpression of cyclin D1 in CRC might be attributable, at least in part, to increased levels of p-Stat3.

Another important downstream mediator is Bcl-x_L. Bcl-x_L is a member of Bcl-2 family that could play a critical role in apoptosis^[31]. Previous studies showed that Bcl-x_L was overexpressed in colorectal carcinomas, and Bcl-x_L might be a useful prognostic marker in CRC^[32,33]. We also found that Bcl-x_L was overexpressed in CRC tissues, but the increased protein level did not significantly correlate with the clinicopathological parameters in CRC. No statistically significant correlation was observed between p-Stat3 and Bcl-x_L expressions. Bromberg *et al.*^[16] observed that Stat3 could transcriptionally up-regulate the expression of Bcl-x_L in Stat3 transformed cell lines. Evidence suggested that blocking of the activated Stat3 in multiple myeloma cells and ovarian cancer cells could down-regulate the expression of Bcl-x_L and enhance the apoptosis, and the cells regained the sensitivity to chemotherapy^[9,20]. The precise mechanism by which activation of Stat3 enhances the transcription of Bcl-x_L in CRC remains to be determined.

Our results demonstrated that in comparison with normal

mucosae, p-Stat3 protein was overexpressed in human colorectal carcinomas. Expression of p-Stat3 was associated with the presence of nodal metastasis and its stage. Our clinical data also provides evidence that there is a strong association of p-Stat3 and cyclin D1 overexpression in CRC. These results suggest that constitutive activation of Stat3 signaling pathway may play an important role in the tumorigenesis of colorectal carcinoma, and the detailed mechanism of Stat3 signaling pathway in CRC deserves further investigation.

Abstract

AIM: To evaluate the value of postprocessing techniques of CT colonography, including multiplanar reformation (MPR), virtual colonoscopy (VC), shaded surface display (SSD) and Raysum, in detection of colorectal carcinomas.

METHODS: Sixty-four patients with colorectal carcinoma underwent volume scanning with spiral CT. MPR, VC, SSD and Raysum images were obtained by using four kinds of postprocessing techniques in workstation. The results were comparatively analyzed according to circumferential extent, lesion length and pathology pattern of colorectal carcinomas. All diagnoses were proved pathologically and surgically.

RESULTS: The accuracy of circumferential extent of colorectal carcinoma determined by MPR, VC, SSD and Raysum was 100.0%, 82.8%, 79.7% and 79.7%, respectively. There was a significant statistical difference between MPR and VC. The consistent rate of lesion length was 89.1%, 76.6%, 95.3% and 100.0%, respectively. There was a statistical difference between VC and SSD. The accuracy of discriminating pathology pattern was 81.3%, 92.2%, 71.9% and 71.9%, respectively. There was a statistical difference between VC and SSD. MPR could determine accurately the circumference of colorectal carcinoma, Raysum could determine the length of lesion more precisely than SSD, VC was helpful in discriminating pathology patterns.

CONCLUSION: MPR, VC, SSD and Raysum have advantage and disadvantage in detection of colorectal carcinoma, use of these methods in combination can disclose the lesion more accurately.

INTRODUCTION

Multiplanar reformation (MPR), virtual colonoscopy (VC), shaded surface display (SSD) and Raysum images could be obtained after source data of CT colonography are processed

in workstation. Numerous literatures on CT colonography are based on examination of colon polyp^[1-17]. No research report on the diagnosis of colorectal carcinoma with postprocessing techniques of MPR, VC, SSD and Raysum is available. The aim of this study was to investigate the clinical value of four postprocessing techniques in detection of colorectal carcinomas by comparing the results of 64 colorectal carcinomas.

MATERIALS AND METHODS

Clinical data

Sixty-four patients (39 men, 25 women, aged 20-78 years, mean age 55.6 years) with colorectal carcinomas were studied. All cases were diagnosed surgically and pathologically.

Examination protocol

The whole procedure of CT colonography included patient preparation, volume scanning and image postprocessing^[18-20].

Patient preparation

A liquid diet for 48 h was used and 500 mL of 200 g/L mannite mixed with 1 000 mL of 50 g/L glycol saline solution was administered orally in the evening prior to examination.

Anisodamine hydrochloride injection (654-2) (10 mg) was administered intramuscularly 10 min before CT scanning to alleviate colon spasm, minimize peristalsis and allow optimal colonic distention. The patient lay on right lateral decubitus position on CT table after dwelling a rectal enema tube. Then, the patient lay on supine, and room air was gently insufflated into the colorectum to distend the colon as long as the patient was tolerable.

Volume scanning

A HighSpeed advantage helical CT scanner (General Electric Medical System) was used to acquire a standard scout view image of the abdomen and pelvis to assess the degree of colorectal distension, room air was further insufflated if required. Images were acquired by using 3.0 mm collimation with a pitch of 2.0, 100-120 mA, 120 kV, and a 512×512 matrix. The range of scanning encompassed the entire colon from the rectum to cecum.

Image postprocessing

Image reconstruction data were transferred to a workstation (Sun Sparc 20 workstation, GE Advantage Windows 2.0 image analysis software) via picture archive and communication system, after retro-reconstructing the initial image data of scanning with 1.5 mm thickness, 0.5 mm interval. MPR, VC, SSD and Raysum images were obtained with postprocessing techniques in workstation.

MPR image: axial, coronal, sagittal and oblique images were acquired with the center on colorectal carcinoma segment by using CT software to display wall, lumen and adjacent structure of the lesion.

VC image: intraluminal image was obtained by applying Navigator software with about - 700 HU threshold from the rectum to cecum. Lesions were observed with Fly-through program along the longitudinal lumen^[21].

SSD image: image reconstruction of colorectal area was performed with SSD software, then the interested colorectal segment were obtained by trimming off unnecessary part with Scalpel program, magnification and rotation were done to demonstrate colorectal carcinoma.

Raysum image: transparent image of interested colorectum was acquired by using Raysum software on the basis of SSD image to display the situation of endolumen and wall.

Statistical analysis

The following 3 aspects were comparatively analyzed according to surgery and pathology results. According to the invasive extent of colorectal carcinoma along the wall, tumors were divided into <1/2, 1/2-3/4 and >3/4 circumference. According to the longitudinal length of the lesion, it was classified into categories of 2.0-3.0 cm, 3.1-5.0 cm and 5.1-11.0 cm, respectively. The pathology pattern was classified into massive, ulcerous, infiltrative, ulcerous and infiltrative types.

Results of 4 kinds of postprocessing techniques were compared with surgical observation and pathology results. Accuracy of diagnosis with 4 kinds of postprocessing techniques was compared by using *U* test.

RESULTS

Examination results of circumferential extents, lesion lengths and pathology patterns in 64 colorectal carcinomas with 4 kinds of postprocessing techniques (Table 1)

Diagnostic accordance of 64 colorectal carcinomas with 4 kinds of postprocessing techniques (Table 2)

DISCUSSION

MPR, VC, SSD and Raysum images obtained by postprocessing technique displayed colorectal carcinoma in different manners with different clinical values.

Circumferential extent

The accuracy of circumferential extent of colorectal carcinoma determined with MPR, VC, SSD and Raysum was 100.0%, 82.8%,

79.7% and 79.7%, respectively (Tables 1, 2). Significant statistical difference between MPR and VC, MPR and SSD, MPR and Raysum were obtained, respectively.

Table 2 Diagnosis accordance of 64 colorectal carcinomas with postprocessing techniques

Postprocessing technique	Circumferential extent		Lesion length		Pathological pattern	
	Case (n)	%	Case (n)	%	Case (n)	%
MPR	64	100.0	57	89.1	52	81.2
VC	53	82.8	49	76.6	59	92.2
SSD	51	79.7	61	95.3	46	71.9
Raysum	51	79.7	64	100.0	46	71.9
χ^2 value		14.748 ^b		22.430 ^b		10.909 ^a

^a*P*<0.05 vs pathological pattern, ^b*P*<0.01 vs circumferential extent and lesion length.

MPR had two dimensional axial, coronal, sagittal and oblique reconstruction images in series, on the center of colorectal carcinoma segments. MPR might reflect different density tissues by using different attenuation scales with high density resolution and it has no obvious artifact. It could clearly display intraluminal lesion and range invaded by carcinoma along its wall and adjacent structure, and accurately determine the circumferential extent of colorectal carcinoma^[22].

VC, SSD and Raysum images could be obtained by using appropriate CT threshold values with transparency of the part beyond them, could make use of only certain information without favorable disclosure of lesions in detail. Sometimes, they had difficulty in showing directly the condition of colorectal wall when thickening was not obvious. Therefore, the determination of circumferential extent of colorectal carcinoma was not so accurate as MPR (Figure 1A-C).

Length of tumors

The correction rate of lesion lengths determined with MPR, VC, SSD and Raysum was 89.1%, 76.6%, 95.3% and 100.0%, respectively (Tables 1, 2).

Table 1 Circumferential extents, lesion lengths and pathology patterns in 64 colorectal carcinomas determined with postprocessing techniques

Item	S&p c	Diagnostic accordance (n)				Accurate diagnosis (%)			
		MPR	VC	SSD	Raysum	MPR	VC	SSD	Raysum
Circumf extent	64	64	53	51	51	100.0	82.8	79.7	79.7

S & p c=Surgery and pathology case, Circumf=Circumferential, circum=circumference, Ulc and inf=Ulcerous and infiltrative. For circumferential extent, comparison between MPR and VC, *U*=3.472, *P*<0.001; comparison between VC and SSD, *U*=0.449, *P*>0.05; comparison between SSD and Raysum, *U*=0.000, *P*>0.05. For Lesion length, comparison between MPR and VC, *U*=1.875, *P*>0.05; comparison between VC and SSD, *U*=3.034, *P*<0.05; comparison between SSD and Raysum *U*=1.759, *P*>0.05. For pathologic pattern, comparison between MPR and VC, *U*=1.817, *P*>0.05; comparison between VC and SSD, *U*=2.991, *P*<0.05; comparison between SSD and Raysum, *U*=0.000, *P*>0.05.

Figure 1 Massive rectal carcinoma in a 74 years old man. VC, SSD displayed an irregular mass, but unable to determine circumferential extent (A, B). MPR showed the mass with 1/4 circumference around rectal wall (C).

Figure 2 Infiltrative rectal carcinoma in a 46 years old man. SSD disclosed the two ends of carcinoma and measured its length (A). Raysum manifested the two ends of carcinoma more clearly and measured its length more accurately than SSD (B).

Figure 3 Infiltrative rectal carcinoma in a 48 years old man. VC demonstrated the carcinoma around rectal wall (A). Combination of coronal and sagittal images of MPR revealed an infiltrative carcinoma, but was not so obvious as VC (B, C).

SSD image displayed the surface of colorectal lumen from outside to inside, being similar to the image of filling phase in double contrast barium enema. It could be locally magnified and rotated polygonally to demonstrate colorectal carcinoma as clear as possible and show lesion lengths and morphology of two ends. But it utilized only certain information and did not reveal the lesion in detail due to the appropriate CT threshold value and transparency of the part beyond it. Moreover, because of partial covering of lesions by the colorectum, sometimes its manifestation was not quite precise^[23]. Its correction rate of lesion lengths was 95.3 % in our series.

Raysum was obtained on the basis of SSD image similar to the image of mucosa phase in double contrast barium enema. It could display the situation of endolumen and wall by transparency and avoid the disadvantages of partial overlapping of lesions by colorectum with SSD, hence clearly revealing lesion lengths and morphology at two ends and accurately manifesting the lesion lengths^[24] (Figure 2A, B).

MPR was a two dimensional image formed by reconstruction. But the colorectum was tortuous in structure, moreover, it was

complicated by the presence of colorectal carcinoma. Therefore, measurement of the lesion length with MPR was not accurate^[25]. In our study its accuracy was 89.1%.

VC could obtain virtual cubic images from colorectal endolumen. Its image was similar to that of fiberoptic colonoscopy. It could directly show the surface morphology of colorectal carcinoma, and its distal and proximal situations. But its manifestation of lesion lengths had a comparatively great error^[3,4,14,18,26-28]. The correct rate was only 76.6% in our series.

Pathological patterns

The accuracy of pathology patterns determined by MPR, VC, SSD and Raysum was 81.3%, 92.2%, 71.9% and 71.9%, respectively (Tables 1, 2). Significant statistical differences between VC and SSD were noticed.

VC image could disclose the surface morphology of colorectal carcinoma and its distal and proximal situations directly with observations from endolumen, favoring the discrimination of pathology patterns. However, there was certain difficulty in revealing the detail of carcinoma. It had errors in discriminating

pathology patterns^[29-30]. The correction rate was 92.2% in our study.

MPR was a two-dimensional image formed by reconstruction, and was combined with axial, coronal, sagittal and oblique images. But it had no direct three dimensional manifestation with a relative great error in discriminating pathology patterns (Figure 3A-C).

SSD, Raysum images could display the surface of colorectal lumen from outside to inside, similar to the images of filling and mucosa phase in double contrast barium enema. But they could use certain information and could not show carcinoma details, and were fairly inaccurate in discriminating pathology patterns. Its correction rate was only 71.9% in our series.

In conclusion, MPR, VC, SSD and Raysum have both advantage and disadvantage in detection of colorectal carcinoma. MPR can accurately determine the circumferential extent, Raysum can fairly determine the length of lesions, and is more trustworthy than SSD, VC is helpful in discriminating pathology patterns. Their combination can disclose colorectal carcinomas more accurately.

Abstract

AIM: To determine whether dendritic cells (DCs) from chronic hepatitis B patients could induce HBV antigen-specific T cell responses or not.

METHODS: DCs were generated from peripheral blood mononuclear cells of patients with chronic hepatitis B (CHB) infection and healthy donors. We compared the phenotypes of these DCs and their ability to secrete cytokines and to participate in mixed lymphocyte reactions. In addition, autologous lymphocytes were cultured with DCs loaded with HBV core region peptide HBcAg8-27, an epitope recognized by cytotoxic T lymphocytes (CTL), and bearing human leucocyte antigen (HLA)-A2 for 10 d. Cytokine secretion and lytic activity against peptide-pulsed target cells were assessed.

RESULTS: DCs with typical morphology were generated successfully by culturing peripheral blood mononuclear cells (PBMCs) from CHB patients with AIM-V containing GM-CSF and IL-4. Compared with DCs from normal donors, the level of CD80 expressed in DCs from CHB patients was lower, and DCs from patients had lower capacity of stimulate T cell proliferation. When PBMCs isolated from patients with chronic or acute hepatitis B infection and from normal donors were cocultured with HBcAg18-27 peptide, the antigen-specific memory response of PBMCs from acute hepatitis B patients was stronger than that of PBMCs from chronic hepatitis B patients or normal donors. PBMCs cocultured with DCs treated with HBcAg18-27 CTL epitope peptide induced an antigen-specific T cell reaction, in which the level of secreted cytokines and lytic activity were higher than those produced by memory T cells.

CONCLUSION: DCs from patients with CHB can induce HBV antigen-specific T cell reactions, including secretion of cytokines essential for HBV clearance and for killing cells infected with HBV.

INTRODUCTION

In patients infected by hepatitis B virus (HBV), the virus may easily escape from immune surveillance, thus inducing tolerance and becoming a persistent infection. Persistently infected patients produce a weak or undetectable HBV-specific CTL response^[1]. Therefore, when treating chronically infected patients with HBV, the population of T cells recognizing HBV should be increased, thus producing an effective immune response.

Dendritic cells (DCs) are the most potent antigen presenting cells throughout the body. These cells express high levels of MHC class I and II antigens, as well as costimulatory molecules, and play essential roles in triggering primary immune responses^[2,3]. The use of DCs, as a type of natural adjuvant, has been applied to the immunotherapy of melanomas and prostate gland carcinomas^[4]. In addition, administration of DCs activated by cytokines to transgenic mice has been shown to break CTL immune tolerance and induce specific CTL reactions against HBV^[5]. The aim of this study was to compare the anti-HBV activity of DCs derived from patients infected with HBV with those from healthy donors. DCs derived from different individuals were cultured, reacted with a peptide specific to the HBV antigen, HBcAg18-27, and cocultured with autogeneic PBMCs to determine if this procedure could induce antigen-specific CTL, which could then be utilized to kill target cells loaded with HBV antigens or to secrete specific cytokines.

MATERIALS AND METHODS

Patients

Of the HBV patients, four were studied during an episode of acute hepatitis B, and 12 (8 males, 4 females; average age, 38.3 years) were chronically infected with HBV. In addition, 20 patients were HLA-A2 positive, and 4 patients were HLA-A2 negative. We also included eight uninfected healthy volunteers (4 males, 4 females; average age, 35.2 years) as normal controls, of them six were HLA-A2 positive and two were HLA-A2 negative.

The diagnosis of acute and chronic hepatitis B was based on standard diagnostic criteria, as formulated by the 5th China Infection Disease and Parasitology Conference in 2000. HBV-infected patients had no complications of other organs. Normal controls had no clinical history of HBV infection and were serologically negative for HBV markers. All patients and normal controls were serologically negative for antibodies to HIV and HCV.

Cytokines and reagents

Recombinant human GM-CSF was purchased from Leucomax Corp (Germany), and recombinant human IL-4 and TNF- α were purchased from Peprotech Corp (England). Ficoll-Hypaque fluid was from Dingguo Corporation, Beijing. Mouse anti-human HLA-A*02 monoclonal antibody (BB7.2 cell line) was a gift from Professor. Wei-Feng Chen, and T₂ cell line was a gift from Professor. Yan-Fang Sui. FITC-conjugated mouse monoclonal antibodies to human CD86, CD14, and CD3, and PE-labeled mouse monoclonal antibodies to human CD80, HLA-DR, CD54, CD11c, and CD19, were obtained from B-D Corp (USA). Mouse monoclonal antibodies to human CD83 and CD1a, FITC- and

PE-labeled goat anti-mouse Ig (H+L) antibodies, PE-labeled mouse anti-human IFN- γ , TNF- α , and IL-2 were all purchased from Pharmingen Corp (USA). CytoTox 96 non-radioactive cytotoxicity assay kits were from Promega Corp (USA). AIMV and RPMI 1 640 were from GIBCO Corp (USA), and IL-12 ELISA kit was from Endogen Corp (USA).

Synthetic peptide

HLA-A2 restricted HBcAg18-27 CTL epitope peptide, FLPSDFFPVS, was synthesized by Saibaisheng Biological Corporation (Beijing) and purified to >90% homogeneity by HPLC. The lyophilized peptide was dissolved in DMSO at a concentration of 2 mg/mL, and stored at -20 °C.

Isolation of PBMCs

Following informed consent obtained from each subject, 100 mL anticoagulated venous blood was obtained from each, and peripheral blood mononuclear cells (PBMCs) were isolated by Ficoll-Hypaque density gradient centrifugation (density, 1.077). Cells at the interface were transferred to RPMI 1 640 incomplete medium containing 100 U/mL penicillin and 100 U/mL streptomycin, and washed twice.

Generation of DCs from PBMCs

DCs were cultured as described previously^[6,7] with slight modifications. PBMCs were suspended in DC culture medium (AIMV), plated at a density of 2×10^7 cells/well in 6-well polystyrene culture plates, and cultured overnight at 37 °C in 950 mL air/50 mL CO₂. Nonadherent cells were removed by gently swirling the plate, and the adherent cells were cultured in AIMV containing 1 000 U/mL recombinant human GM-CSF and 500 U/mL recombinant human IL-4 at 37 °C in 950 mL air/50 mL CO₂ and refed daily with half volumes of fresh medium. Cells and culture supernatants were harvested on d 3, 5, 7, 9, 11, 13, and 15. Where indicated, TNF- α (20 ng/mL) was added on d 7, and the cells and supernatant were harvested on d 9.

Flow cytometric analysis

The phenotype of harvested DCs was analyzed by flow cytometry (Becton Dickinson, FACScalibur). Cells (5×10^5) were suspended in PBS, centrifuged at 313 r/min for 5 min at 4 °C, incubated for 30 min at 4 °C with fluorescent monoclonal antibody, and fixed in 4 g/L paraformaldehyde.

IL-12 detection

IL-12 concentration in cell supernatants was assayed by ELISA, using standard curves according to the manufacturer's instructions.

Allogeneic mixed lymphocyte reaction

To test T cell stimulatory function of DCs, DCs were irradiated with ⁶⁰Co (3 000 rad), suspended in AIMV and placed in 96-well flat bottom culture plates at densities of 0.5, 1.0, and 2.5×10^4 cells/well. Responder T cells were added to each well, at a density of 5×10^5 cells/well, and cultured for 120 h. The ratio of DC:T was 1:20, 1:50, and 1:100, and each assay was performed in triplicate. T cells plated without DCs were utilized as negative controls. During the last 16 h of incubation, 1 Ci/well of [³H] thymidine was added. On d 5, the cells were harvested, and the amounts of [³H] thymidine incorporated into responder cells were counted with a beta counter.

Isolation of CD8⁺ T cells

Purified populations of T cells were isolated from PBMCs using magnetic beads. Briefly, PBMCs were incubated with anti-CD8 MACS (Miltenyi Biotech, Germany) according to the manufacturer's protocol. Cells retained by MACS beads were regarded as CD8 positive cells, with purity greater than 90%.

Stimulation of PBMCs with synthetic peptide

PBMCs from patients and normal donors were plated in 24-well plates at densities of 2×10^6 cells/well, in 2 mL RPMI 1 640 containing IL-2 (50 mg/L). Synthetic peptides were added to the cell cultures at a final concentration of 20 mg/L. As a negative control, DMSO alone was added to the wells. After 1 h, 0.7 μ L Golgistop was added per mL culture medium, cells were collected 4 h later, and intracellular cytokine stain (ICCS) was applied.

Intracellular cytokine stain assay

Harvested cells were washed twice with PBS, 10 μ L FITC-labelled mouse anti-human CD8 Ab was added to each tube, and the tubes were incubated in the dark on ice for 30 min. To each tube 250 μ L FACS permeabilization solution was added, and the tubes were incubated for 20 min on ice in the dark. Cells were washed twice with 1 mL/tube FACS perm-wash and incubated with PE-conjugated mouse monoclonal antibody to human IFN- γ , IL-2, or TNF- α for 30 min on ice in the dark. The cells were washed with FACS perm-wash solution, PBS + 1 g/L BSA was added, and the cells were loaded onto a FACS calibur flow cytometer within 24 h, with data analysis performed using Cell Quest software (Becton Dickinson). A total of 400 000 events were measured in each analysis. PE-conjugated mouse Ab was used as isotype controls. A lymphocyte gate was set to exclude monocytes, debris and dead cells.

CTL generation

CD8⁺ responders for peptide-specific CTL were generated from nonadherent PBMCs. CD8⁺ T cells were stimulated with DCs loaded with peptide at a stimulator-to-responder (S:R) ratio of 1:30. These cells were cultured in RPMI containing 100 g/L fetal calf serum (FCS) and IL-2 (50 mg/L). Responders were restimulated every 5 d with DCs pulsed with peptide. As controls, CD8⁺ T cells were stimulated with unpulsed DC. Six h before harvesting, 0.7 μ L Golgistop was added to per mL culture medium. On d 10, CD8⁺ T cells were harvested, ICCS was applied, and CTL cytotoxicity assays were performed.

CTL cytotoxicity assay

HLA-A2 restricted antigen recognition by CTL was assessed by a standard cytotox 96 non-radioactive cytotoxicity assay. Recognition of HBcAg18-27 peptide by CTL was assessed using T2 cells preincubated for 4 h with 20 μ g/mL peptide. Target cells were resuspended at a density of 1×10^5 cells/mL, thus making the ratios of effectors to target cells 30:1, 10:1, and 3:1, with a triplicate set of wells prepared for each ratio and for the controls. The percent of lyses was calculated as:

$$\text{Percent of lysis (\%)} = \frac{100 \times A (\text{experimental-effector} - \text{spontaneous-target spontaneous})}{A (\text{target maximum-target spontaneous})}$$

Statistical analysis

Result were expressed as mean \pm SD and analyzed using the Student's *t* test. *P* < 0.05 was regarded as statistically significant.

RESULTS

Detection of DC surface markers

PBMCs were isolated from patients and healthy donors and cultured overnight. After removal of the nonadherent cells, the remaining adherent monocytes were cultured in AIMV containing GM-CSF and IL-4. Cell cultures were observed after 24 h, becoming larger after 48 h and exhibiting DC morphology with veiled processes and dendrites (Figure 1). The yields of DCs from hepatitis B patients and normal donors did not differ significantly.

Figure 1 Morphology of dendritic cells after 7 and 9 d. A: Cluster of DCs after 9 d (light microscope, $\times 100$); B: A DC on day 7 (scanning electron microscope, $\times 5\,000$); C: A DC on day 7 (transmitting electron microscope, $\times 5\,000$).

DCs were identified by their typical morphology and by CD86/HLA-DR double positive expression. These cells were harvested and counted, and surface markers were measured over time. The number of DCs peaked on d 9, decreasing gradually thereafter. The expression of DC-related cell markers was first detected on d 3. After cultured for 7 d with GM-CSF and IL-4, these DCs expressed costimulatory and MHC molecules, showing that cells derived from both patients and controls were morphologically compatible with DCs. Among the MHC and costimulatory molecules examined, we found that CD80 expression in patients with hepatitis B was weaker than that in normal donors (Table 1).

Table 1 Phenotype of DCs from HB patients and normal donors ($n=10$, %, mean \pm SD)

DC Antigen	Positive DCs of HB patients	Positive DCs of normal donors	<i>P</i>
CD86	89.89 \pm 1.14	91.17 \pm 3.41	0.633
CD80	36.86 \pm 2.30	59.87 \pm 6.31	0.021
CD1a	23.25 \pm 7.04	32.92 \pm 4.58	0.405
HLA-DR	97.29 \pm 1.09	97.11 \pm 1.14	0.852
CD83	23.25 \pm 7.34	33.18 \pm 11.12	0.265

Responses to TNF- α in DCs from HBV patients and healthy donors

Following addition of 20 μ g/mL TNF- α to the culture medium on the 5th d of culture, the cells and culture supernatants were harvested 48 h later. When cell phenotypes were assayed by flow cytometry, we found that the expression of CD83 was weaker in cells cultured in the absence of TNF- α than in its presence. However, culture in the presence of TNF- α did not alter the expression of CD86, CD80 or HLA-DR. While production of IL-12 by cultured DCs from hepatitis B patients and healthy donors did not differ, the secretion of IL-12 was significantly increased in cells cultured with TNF- α (Figure 2).

Figure 2 Effect of TNF- α on DC secretion of IL-12.

DCs from HB patients and healthy donors were cultured for 5 d, at which time TNF- α was added to some of the cultures

(TNF-D7) but not to others (NTNF-D7), and incubation was continued for an additional 2 d. IL-12 secretion was measured on d 5 and 7. Each bar represents mean \pm SD of DCs from 6 different individuals.

Immune stimulatory activity of DCs

When we tested T cell-stimulatory activity of DCs in allogeneic MLR, we found that patients with chronic hepatitis B tended to have decreased T cell-stimulatory activity compared with normal donors, but the difference did not attain statistical significance (Figure 3).

Figure 3 MLR of DCs against allogeneic T cells.

Each MLR was set up in triplicate in flat-bottom 96-well plates. The responder T cells were obtained from a healthy donor, while irradiated DCs were used as stimulators at different ratios to T cells. Each point represents the mean \pm SD. of measurements from 6 different individuals.

T cell memory response to HBcAg18-27 CTL epitope

PBMCs isolated from patients with chronic hepatitis B (CHB) and acute hepatitis B (AHB) and from normal donors were incubated with HBcAg 18-27 peptide for 6 h, and ICCS was used to determine the frequency of HBcAg 18-27 peptide reactive T cells secreting cytokines. We found that stimulated PBMCs from the AHB group produced significantly stronger T cell memory reactions than PBMCs from either of the other groups ($P<0.05$) (Table 2).

DCs from CHB patients induced specific immune responses of CD8⁺ T cells

DCs primed with HBcAg18-27 peptide were cultured with lymphocytes for 10 d to determine whether peptide-reactive T cells were able to secrete various cytokines, including IFN- γ , IL-2 and TNF- α . Using the ICCS assay, we found that DCs from CHB patients induced peptide-reactive T cells to secrete cytokines (Figure 4), to a significantly greater degree than that secreted by peptide-stimulated PBMCs ($P<0.05$). We also

observed significant differences between DCs and PBMCs of CHB patients (Table 3).

Table 2 Memory immune responses of PBMCs from patients with chronic hepatitis B (CHB), acute hepatitis B (AHB) and normal donors (mean±SD)

Group	n	Percent CD8 ⁺ T cells secreting cytokines		
		IFN- γ /CD8	IL-2/CD8	TNF- α /CD8
CHB	7	0.18±0.14	0.13±0.05	0.37±0.18
AHB	4	4.26±2.49	4.80±2.23	4.57±2.29
Donor	6	0.28±0.13	0.59±0.27	0.68±0.33
P value ^a		0.019	0.024	0.010
P value ^c		0.013	0.031	0.010

^aP<0.05 AHB vs CHB. ^cP<0.05 AHB vs Donor.

Table 3 CD8⁺T cell immune responses induced by peptide-pulsed DCs (mean±SD)

Group	n	Percent of CD8 ⁺ T cells secreting cytokines (%)		
		IFN- γ /CD8	IL-2/CD8	TNF- α /CD8
CHB ¹	7	0.28±0.15	0.46±0.13	0.68±0.15

P value ^a		0.043	0.049	0.028

1: T cells induced by unpulsed DCs; 2: T cells induced by peptide-pulsed DCs; a: comparison of CHB¹ and CHB².

Figure 4 Cytokine secretion of peptide-reactive T cells induced by DCs from one CHB patient. T cells from one CHB patient was incubated with autologous DCs pulsed with the HBV-specific peptide HBcAg 18-27 (Peptide) or without peptide (No peptide), and T cell response was detected by flow cytometry by measuring cytokine secretion by the activated T cells. The dot-plots show levels of intracellular staining for IFN- γ , IL-2 and TNF- α (y-axis) and surface CD8 molecule (x-axis). The number in the upper-right quadrant indicates the percentage of CD8-positive T cells that secrete cytokines.

CTL cytotoxicity induced by DCs loaded with peptide

Target cells were divided into 2 groups, with one group incubated with peptide and the other group without. CTL cytotoxicity of the DCs from CHB patients against T cells incubated with peptide was (57.28±20.00)%, (47.54±20.70)%, and (21.38±12.86)% at effector to target cell ratios of 30:1, 10:1, and 3:1, respectively, while CTL cytotoxicity of these same DCs against T cells incubated without peptide was (30.38±10.00)%, (26.99±12.72)%, and (13.74±3.22)%, respectively (Figure 5).

Figure 5 T cell cytotoxicity induced by DCs in CHB patients. DC+pep+T, T cells induced by DCs loaded with specific peptide; DC+T, T cells induced by DCs without peptide; T₂+pep, peptide-loaded target cells; T₂, target cells.

DISCUSSION

DCs are the most potent antigen presenting cells crucial for activating CD8⁺ killer T cells and CD4⁺ helper T cells. DCs release bioactive cytokine IL-12, which can stimulate NK cells, induce Th1 type cytokine production and foster the development of cytotoxic T lymphocytes. DCs may thus be a powerful natural adjuvant for the treatment of tumors and viral infections. It is now known that the function of DCs is not fixed, depending on alterations in the cellular environment. Alterations in DC function may result from the effects of anti-inflammatory cytokines, including IL-10 and TGF- β , and on the characteristics of pathogens.

It was observed that, the functional activity of DCs was decreased, as measured by the stimulation of allogeneic T cell proliferation. In patients with chronic hepatitis B, however, it was unclear if DCs could act as natural adjuvants. In HBV transgenic (Tg) mice, DC function was normal, and there were CTLs specific for HBsAg, which were functionally quiescent. When cytokine-activated DCs were administered to these Tg mice, tolerance was broken, and antiviral reactions were induced^[2]. In contrast, the expression of MHC II (I a) and CD86 and the ability of DCs to induce cell proliferation were lower in Tg than in normal mice^[8].

In this study, we isolated PBMCs from the peripheral blood of patients with chronic hepatitis B infection and from healthy donors and compared the functional activity of their DCs. We found that, while CD80 expression was lower on DCs from patients than on those from healthy donors, other surface markers including HLA and costimulatory molecules were expressed to an equal extent. Functionally, DCs from CHB patients were able to stimulate the proliferation of allogeneic T cells, but to a lower extent than observed with DCs from non-CHB donors.

T cell activation requires costimulatory molecules (*e.g.*, CD28-B7), which provide a second signal. The B7 family is comprised primarily of B7-1 (CD80) and B7-2 (CD86). Although their function is not fully known, several studies have shown that CD80 signals preferentially promote development of Th1 cells, whereas CD86 signals promote Th2 development. While

CD80 gene knockout mice have a normal immunoglobulin superfamily repertoire, a complete deficiency of CD86 would destroy humoral immunity. B7 receptors have two ligands. CD28 provides a costimulatory signal essential to T cell activation, whereas CTLA-4 blocks T cell proliferation. CTLA-4 bound with greater affinity to CD80 than to CD86, suggesting that the binding of CD80 tends to inhibit T cell proliferation^[9-11]. Our finding, that CD80 expression by DCs from patients with chronic hepatitis B was weaker than that from healthy donors, might be related to the inhibition of T cell activation seen in these patients and to the decreased function of DCs from these patients observed in our MLR assay. In addition, our results confirmed Akbar's study^[7], in that the decreased functional activity of patient DCs results in the inability of these cells to present antigens to T cells, thus leading to reduced induction of a specific cytotoxic reaction. This, in turn, resulted in a lower rate of killing of infected cells and a reduction in the suppression of viral replication, finally leading to a state of persistent infection.

When pathogens invade a host, a potent immune response is produced to eliminate the pathogens. At the end stage of this immune response, the majority of effector T and B cells gradually undergo apoptosis, while a smaller number differentiate into long-lived memory T or B cells. Memory T cells produce vigorous secondary responses to antigen and rapidly eliminate pathogens. For example, the infected cells were cytolysed by CTLs. On the other hand, the primary difference between memory and naïve T cells is that, when they are activated, the former had higher reactivity to antigens and secreted more cytokines^[12-14]. Thus, when an individual is infected with HBV, certain soluble products of the immune response, especially IFN- γ , IL-2, and TNF- α , can suppress HBV gene expression, as well as replication *in vivo*.

Hepatocellular HBV gene expression has been shown to be profoundly suppressed by non-cytolytic regulatory signals delivered by HBsAg-specific CTL through their secretion of IFN- γ and induction of TNF- α following antigen recognition. These effects were mediated by a posttranscriptional mechanism that selectively accelerates the degradation of cytoplasmic HBV mRNA^[15]. We therefore assayed the cytokines secreted by CD8⁺T cells to illuminate the immune response of individuals to viral infection. We found that PBMCs from patients with CHB and AHB and from normal donors could be stimulated by HBcAg18-27 peptide. However, stimulated PBMCs from patients with AHB produced stronger memory reactions than those from patients with CHB or healthy donors, suggesting that AHB PBMCs have potent memory immune reactions to this specific antigen, whereas CHB PBMCs are at least partially tolerant to this antigen. The mechanism of tolerance includes factors from the host and from the virus. New-born babies contaminated by HBV transmitted from their mothers were in a state of immune tolerance to HBV and about 90% carry HBV as a persistent infection.

T cells play an important role in the immune system. Not only do they have effector functions, but also they are the major regulators of immune function. T cell activation requires two signals, one from the T cell receptor that recognizes the complex of MHC and antigen on the surfaces of antigen presenting cells (APCs), and the other from costimulatory molecules such as CD28-B7. To determine whether the immune tolerance of DCs from CHB patients could be broken, we primed DCs with HBcAg18-27 and incubated them with lymphocytes, and we assayed CTL generation. Our finding, that an antigen-specific T cell reaction was induced when these peptide-primed DCs

were co-cultured with CD8⁺ T cells, and that the cytotoxic activity of CTLs against target cells cultured with peptide was higher than that against target cells cultured without peptide, suggested that DCs from patients with CHB could break immune tolerance and induce an HBV antigen-specific T cell reactions.

DCs have great potential in anti-viral therapy as antigen presenting cells. Our findings showed that, although the function of patient DCs was lower than that of control DCs, the former still expressed signals necessary for T cell activation, released of IL-12 and stimulation of allogeneic T cell proliferation. Moreover DCs from these patients could break immune tolerance to induce HBV antigen-specific T cell responses. IL-12 is a critical cytokine secreted by DCs, which can induce the production of specific T cells, suggesting that TNF- α is an important factor in immunotherapy. Thus, our findings suggest that DCs originating from cytokine activated PBMCs of CHB patients can be utilized in immunotherapy, which will be a potential treatment for hepatitis B.

Abstract

AIM: To select the peptide mimicking the neutralization epitope of hepatitis E virus which bound to non-type-specific and conformational monoclonal antibodies (mAbs) 8C11 and 8H3 fromed 7-peptide phage display library, and expressed the peptide recombinant with HBcAg in *E.coli*, and to observe whether the recombinant HBcAg could still form virus like particle (VLP) and to test the activation of the recombinant polyprotein and chemo-synthesized peptide that was selected by mAb 8H3.

METHODS: 8C11 and 8H3 were used to screen for binding peptides through a 7-peptide phage display library. After 4 rounds of panning, monoclonal phages were selected and sequenced. The obtained dominant peptide coding sequences was then synthesized and inserted into amino acid 78 to 83 of hepatitis B core antigen (HBcAg), and then expressed in *E.coli*. Activity of the recombinant proteins was detected by Western blotting, VLPs of the recombinant polyproteins were tested by transmission electron microscopy and binding activity of the chemo-synthesized peptide was confirmed by BIAcore biosensor.

RESULTS: Twenty-one positive monoclonal phages (10 for 8C11, and 11 for 8H3) were selected and the inserted fragments were sequenced. The DNA sequence coding for the obtained dominant peptides 8C11 (N'-His-Pro-Thr-Leu-Leu-Arg-Ile-C', named 8C11A) and 8H3 (N'-Ser-Ile-Leu-Pro-Tyr-Pro-Tyr-C', named 8H3A) were then synthesized and cloned to the HBcAg vector, then expressed in *E.coli*. The recombinant proteins aggregated into homodimer or polymer on SDS-PAGE, and could bind to mAb 8C11 and 8H3 in Western blotting. At the same time, the recombinant polyprotein could form virus like particles (VLPs), which could be visualized on electron micrograph. The dominant peptide 8H3A selected by mAb 8H3 was further chemo-synthesized, and its binding to mAb 8H3 could be detected by BIAcore biosensor.

CONCLUSION: These results implicate that conformational neutralizing epitope can be partially modeled by a short peptide, which provides a feasible route for subunit vaccine development.

INTRODUCTION

Hepatitis E is an acute hepatitis caused by hepatitis E virus (HEV) in developing countries, where it occurs sporadically and in an epidemic form. The causative agent, HEV, is transmitted primarily by the fecal-oral route, and it accounts for about 15-20% sporadic cases of acute hepatitis in China^[1,2]. HEV is an icosahedron non-enveloped virus, and its genome is a single-stranded positive-sense, 3'-polyadenylated RNA about 7.5 kb in length. It contains 3 open reading frames (ORFs). ORF1 codes for a polyprotein of 1 693 amino acids and contains domains homologous to a viral methyltransferase, a papainlike cysteine protease, an RNA helicase, and an RNA-dependent RNA polymerase, and the most hypervariable region of HEV genome. ORF2 codes for the viral capsid protein of 660 amino acids, while ORF3 codes for a 123-amino-acid-long polypeptide with unknown function.

It has been proved that the major viral capsid protein encoded by ORF2 contains the protective epitope^[3]. We recombined a fragment of HEV ORF2 and expressed the polypeptide named NE2 in *E.coli* recently^[4], and proved it to be a protective antigen^[5], which naturally forms homodimer by virtue of its interface domain^[6]. Three anti-NE2 neutralization mAbs, 8C11, 8H3 and 13D8 were selected, which could recognize 2 separated neutralization conformational surface epitopes of HEV, 8C11 and 13D8 against one and 8H3 against the other. The 3 mAbs can neutralize HEV *in vitro* and *in vivo* test of Rhesus monkey^[7-9].

8C11 and 8H3 were used to screen binding peptides from a heptapeptide phage display library, which could mimic the 2 neutralizing epitopes of HEV binding to 8C11 and 8H3 respectively. The obtained dominant peptides' DNA sequences were then synthesized and cloned into amino acid 78 to 83 of hepatitis B core antigen (HBcAg), then expressed in *E.coli*. While it has been proven that HBcAg could be expressed in eukaryocytes or prokaryocytes, and assembled into VLP automatically. The inserted sequence between amino acids 73 and 94 could be expressed on the HBcAg VLP surface^[10]. Because HBcAg is an immunodominant immunogen^[11], which results in the immunodominance of the insertion, we expressed the linear epitopes, which could conformationally mimic epitope on the surface of HBcAg, resulting in a VLP antigen, and prove its activity. This assay would not only mimic the neutralizing epitope of HEV but also provide insights into a novel route for subunit vaccine development.

MATERIALS AND METHODS

Monoclonal antibodies

8C11 and 8H3 mAbs, which could conformationally bind to neutralizing epitopes of HEV were prepared in our

laboratory^[7,9]. Affinity purified antibody phosphatase labeled goat anti-mouse IgG (H+L) was from Kirkegaard & Perry Laboratory (2 Cessua Court, Gaithersburg Maryland 20879, USA).

Affinity selection and amplification of peptide library

Heptapeptide phage display library and host strain *E.coli* ER2738 were purchased from New England BioLabs Company. Anti-HEV mAbs binding phages were isolated from the phage display library by successive cycles of selection and amplification. The biopanning procedure was essentially used as described in the phage display library user manual. Briefly, mAbs 8C11 and 8H3 (100 µg/mL) were coated on 96-well microtiter plates. After blocked with 20 g/L BSA, 100 µL diluted phage (10 uL of the original library) was piped onto the coated plate and shaken gently for 1 h at room temperature, the plates were washed for 10 times with PBST (10 g/L Tween 20). The bound phages were eluted with 100 µL 10 mmol/L Glycyl (pH 2.2), 1 mg/mL BSA, rocked gently for 10 min. The eluate was piped into a microcentrifuge tube and neutralized with 10 µL 1 mol/L Tris-HCl (pH 9.1). The eluate was added to 20 mL ER2738 culture and incubated at 37 °C with vigorous shaking for 4.5 h. The culture was transferred to a centrifuge tube and spun for 10 min at 10 000 g at 4 °C. The supernatant was collected and 1/6 volume of PEG/NaCl (200 g/L PEG8000, 2.5 mol/L NaCl) was added. The phage was allowed to precipitate at 4 °C overnight. PEG precipitation was spun for 15 min at 10 000 g at 4 °C. The pellet was re-suspended in 1 mL PBS, and re-precipitated with PEG/NaCl. Finally the pellet was suspended in 200 µL PBS, and stored at 4 °C. The amplified eluate was titered as general methods. The concentration of target mAbs was lowered to 50 µg/mL, at the same time the concentration of Tween-20 was risen to 50 g/L in the washing step, then was panned 3 more times by repeating the above steps. After 4 rounds panning, individual monoclones were sequenced. The single-stranded DNA of M13 phages was purified by using the M13 mini kit purchased from Shanghai Huashun Biotech Ltd, and then sequenced by Shanghai Boya Ltd.

Construction of recombinant expression vector for peptide

The recombinant expression vector named pC149-mut was composed in our laboratory. The peptide of amino acids 1 to 149 of HBcAg expressed in *E.coli* formed viral like particles (VLPs). The amino acid residues 78 to 83 were exposed at the VLP's surface. According to this we cloned the HBcAg's genome of amino acid residues 1 to 149 into the expression vector pTO-T7^[12] of *E.coli*, and designed a linker to replace the immunodominant epitope located at 79 to 80aa of HBc and composed the mutant vector pC149-mut. After exogenous gene was inserted into the amino acid residues 78 to 83, recombinant C antigen was still able to form VLP and expose the exogenous epitope.

We designed the primer (Table 1) according to the dominant sequence of selected monoclonal phages, and the linker sequence of pC149-mut vector. Therefore, we could insert heptapeptide exogenome into the vector and co-express it with HBcAg using 8C11AFP or 8H3AFP as a former primer and

149 mutRP as a lower primer, and using the pC149-mut vector as a template. PCR was carried out after pre-denaturation at 94 °C for 5 min, 25 cycles of denaturation at 94 °C for 50 s, annealing at 56 °C for 50 s, and extension at 72 °C for 25 s, then extension at 72 °C for 10 min. The PCR fragment was cloned into pMD 18-T vector and formed positive clones containing the genome of peptide 8C11A (CATCCTACTC TTTTGCGTATT), which could bind to mAb 8C11 or the genome of peptide 8H3A (TCTATTCTGCCGTATCCTTAT), which could bind to mAb 8H3. Then they were digested with *Bam*H I and *Eco*R I, and the product fragment was linked into the pC149-mut vector to compose the expression vector named pC149-mut-8C11A or pC149-mut-8H3A (Figure 1).

Expression and purification of recombinant polyprotein

Host stain ER2566 was cultured and transformed with the recombinant vector pC149-mut-8C11A or pC149-mut-8H3A in LB culture medium at 37 °C in a shaker, till the A_{600} reached 0.8-1.0, then the culture was incubated with 0.2 mmol/L IPTG for 6 h at 37 °C. The cells were spun to be collected and were disintegrated by an ultrasonic disintegrator (Uilbra-Cell VGX500 of SONICS & MATERIALS Co.). The insoluble protein was spun and collected, then suspended and deposited 2 times into 10 g/L Triton X-200. The pellet was finally suspended into buffer A (4 mol/L Urea, 20 mmol/L Tris-HCl pH 8.5, 5 mmol/L EDTA, 100 mmol/L NaCl), dialysed in PBS overnight. The lysate was spun and collected.

Western blotting

Boiled supernatant of ultrasonic lysate and boiled deposition of ultrasonic lysate and control samples (the expression of pC149-mut could not react with mAbs, and the recombinant polyprotein NE2 was used to select mAbs including 8C11 and 8H3^[7,9]) were dissolved in 120 g/L SDS-PAGE, transferred to a nitrocellulose membrane. Each contained one lane of the protein molecular mass mark between 18.3 and 215 ku. The membrane containing proteins with 5 g/L non-fat dry milk as blocking solution was incubated for 90 min and reacted with the test mAb 8H3 or 8C11 diluted in 5 g/L non-fat dry milk. The immunocomplexes were detected by using Ap-labeled goat-anti-mouse IgG, BCIP and NBT as substrates.

Transmission electron microscopy of chimeric VLPs

After renatured by the methods described above, the particles were adsorbed to carbon-coated grids, stained with 2 g/L uranyl acetate, and examined by JEM-100CXII electron microscope at about ×100 000 magnification.

Active analysis of recombinant proteins by BIAcore biosensor

Heptapeptide named 8H3A (N'-Ser-Ile-Leu-Pro-Tyr-Pro-Tyr-C') was synthesized and purified by Xi'an Meilian Ltd (Xi'an, China). Then the biosensor chip was coupled with anti-mouse Fc, which was carried out according to the user manual. Briefly, the sensor chip CM5 with CM Dextran on its reaction-surface was activated with EDC and NHS, and then the flow cells were treated with a standard amine-coupling reagent (injecting 10 mm/L NaOAc, pH4.8, instead of protein) or with amine-coupling reagents and anti-mouse Fc polyclonal antibody. The

Table 1 Primers for expression vector of mimic peptide

Primer ID	Primer sequence

coupling density of the antibody was 900 RU. Experiments were run at 25 °C. After mAb 8H3 was bound to anti-mouse Fc antibody, peptide 8H3A was injected. The data of association and dissociation indicating the reaction between mAb 8H3 and peptide 8H3A were collected. Biacore X biosensor, CM5 sensor chip and reagent of EDC & NHS were from Amersham Biosciences Company (Uppsala, Sweden).

RESULTS

Sequence characteristics of peptide binding to neutralizing mAb 8C11 or 8H3

After 4 rounds of biopanning, 21 monoclonal phages were

selected for sequencing (in which 10 phage could bind to mAb 8C11, and the other 11 could bind to mAb 8H3). According to the DNA sequence, the peptide sequence of the phage displayed was made out (Figure 2). Heptapeptide with amino acid sequence HPTLLRI was dominant (50%) in the 10 monoclones bound to mAb 8C11. While in the 11 monoclones bound to mAb 8H3, the preponderant amino acid sequence was SILPYPY (27.3%). Furthermore, in the heptapeptide binding to mAb 8H3, the amino acid sequence of S*LP, S*P, S*L or LP was also more frequent, indicating that S, L and P would be more important to form the domain binding to mAb 8H3. Likewise, amino acids P, T and L were found to be more important in the interaction between peptide and mAb 8C11.

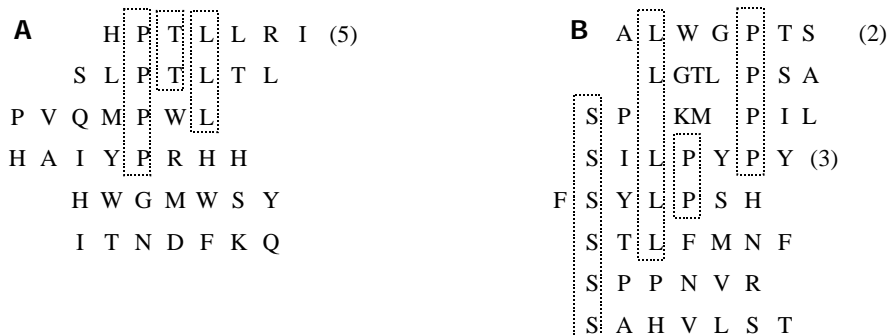

Figure 2 Sequences of peptides selected by monoclonal antibodies. A: Selected by mAb 8C11, B: Selected by mAb 8H3.

Expression and western blotting of peptide mimic neutralization epitope

Dominant peptides 8C11A (N'-His-Pro-Thr-Leu-Leu-Arg-Ile-C') and 8H3A (N'-Ser-Ile-Leu-Pro-Tyr-Pro-Tyr-C') were cloned into the vector pC149-mut named C8C11A and C8H3A respectively, and expressed. The result of expression was shown in Figure 3. Recombinant polyprotein C8C11A was found in the insoluble cell pellet, and formed dimer (about M_r 40 000 in mass) on the SDS-PAGE mainly while the monomer (about M_r 20 000) was hard to be seen. As to the Western blotting result, it was the dimer that could interact with mAb 8C11 in the same level as the monomer of NE2 protein (about M_r 29 000). C8H3A fusions were also found in the insoluble cell pellet. Beside the dimer, a monomer was in the majority, but only the $-M_r$ 40 000 dimer was able to bind to mAb 8H3 when tested by Western blotting.

A, C: SDS-PAGE, B, D: Western blotting of mAbs 8C11 and 8H3 respectively, A, B: pC149-mut-8C11A, C, D: pC149-mut-8H3A. 1, Protein molecular weight marker; 2, Supernatant of ultrasonic lysate; 3, Deposition of ultrasonic lysate; 4, C149-mut control; 5, Purified NE2 antigen

Electron micrograph of VLP

The renatured recombinant polyprotein particles were adsorbed to carbon-coated grids, stained with 20 g/L uranyl acetate, and examined with TEM. The recombinant HBcAg with 8C11A or 8H3A on its surface and HBcAg could form VLPs and VLPs' diameter was about 20 nm (Figure 4).

Figure 4 Virus like particles assembled by recombinant protein C8C11A, C8H3A or C149 mut (Negative staining electron microscopy, $\times 100\ 000$).

Figure 5 Binding curve of chemo-synthesized seven peptide 8H3A against monoclonal antibody 8H3 in BIAcore biosensor.

Interaction between chemo-synthesized heptapeptide 8H3A and mAb 8H3

The mAb 8H3 was bound to the anti-mouse Fc polyclonal antibody coupled on the cells of CM5 chip. After mAb 8H3 was bound to the anti-mouse Fc antibody, peptide 8H3A (1 mg/mL) was injected and the data of association and dissociation were collected. Chemo-synthesized heptapeptide 8H3A could bind to mAb 8H3, but not stably (Figure 5).

DISCUSSION
