Phage display technique has been widely used in constructing antibody library or biopanning of random peptides according to their biological activities, and in many other fields or so^[13,14]. As a new technique, it makes use of the characteristics of the coat protein of the phage, that is, a peptide is expressed as a fusion with the phage coat protein pIII, resulting in the display of fused protein on the surface of virion. Phage display technique allows rapid identification and amplification of the peptide ligands for target molecules by the affinity of their specific-binding. Recently, random peptide libraries displayed on phage have been widely used in many fields, such as identification and analysis of a peptide mimic the epitope of HIV^[15] and HIV-1-infected cells^[16], identification of enzyme inhibitors^[17] and immunodepressants^[18], and many antigens etc.^[19-22]. Phage display technique is specially useful to mimic a variety of half-antigens and non-peptide target molecules' function, which is a very useful way to produce mimic peptide medication. Many reports have been available on the peptides mimicking epitope, which can neutralize *Neisseria meningitidis*^[23,24] and many other bacteria to produce bacterial vaccines.

There are still no cell models of HEV, or effective methods to produce HEV artificially. Different sections of HEV capsid protein were expressed, and the structures of the recombinant polyproteins were analysed, which can help us to speculate the crude structure of HEV capsid. We cloned a section of HEV ORF2 (named NE2) and expressed this recombinant protein in *E.coli*. It was found that NE2 formed polymer spontaneously, from dimer to hexamer concretely. This was very similar to the assemble process of HEV capsid protein^[4,25,26]. NE2 was used to immunize Rhesus monkey, and induce protective antibodies. The above findings indicate that polyprotein NE2 mimics the crude structure of HEV ORF2^[4]. Monoclonal antibodies were selected by immunizing BALB/c mice with NE2^[7,9], 3 of which named 8C11, 8H3 and 13D8 were identified to be mAbs which could recognize 2 different epitopes of HEV. These 3 mAbs were proved to be neutralizing mAb by *in vivo* neutralization test in rhesus. The 2 epitopes recognized by mAbs (1 bound to 8C11 and 13D8, and the other to 8H3) were tested to be conformational epitopes. We panned the random phage display heptapeptide library, which displayed the linear epitope constructed by heptapeptide, and the peptides could mimic the neutralizing epitope that could bind to the 2 mAbs (8C11 and 8H3). Furthermore, heptapeptides were recombined on HBcAg for expression in *E.coli*, and their activities were tested by Western blotting. The recombinant polyprotein expressed by plasmid pC149-mut-8C11A appeared to be the dimer of M_r 40 000 on SDS-PAGE, which could bind to mAb 8C11 similar to the monomer of NE2. While the production of plasmid pC149-mut-8H3A could form monomer (M_r 20 000) and dimer (M_r 40 000) on SDS-PAGE, and only the dimer could react with mAb on Western blotting. Maybe it is because that 7 amino acid peptide is too short, and to display it on the surface of recombinant HBcAg is in need of assistance of special conformation, HBcAg is a large protein while the monomer recombinant HBcAg can not display the exogenesis epitope of heptapeptide, so the activity of the monomer is not obvious.

The chemo-synthesized heptapeptide 8H3A could bind to mAb 8H3, but the binding was not stable. Comparing the dominant peptides' sequence with the primary structure of NE2, no same sequence was found, conforming that the epitopes recognized by mAbs 8C11 and 8H3 are not constructed by continuous amino acid of NE2, but the function of their spatial structure is similar to the mimic peptides.

The immunogenicity of HBcAg is the highest in all kinds of antigens of HBV. The design of vector pC149-mut was to insert foreign genes into amino acids 78 to 83^[10], the immunogenicity of that position was better. The inserted amino acid could replace the epitope that reacts with B cells easily, thus reducing their interference with the exogenous epitope in immune response. This feature made HBcAg to be a very useful vector for multi-epitope chimeric vaccine^[10,27], so did the pC149-mut vector, which was designed accordingly. In this study, heptapeptide was cloned into pC149-mut between the amino acids 78 to 83 of HBcAg, and the recombinant polyprotein could form VLP, which displayed the foreign heptapeptide on their surface and kept its immunogenicity. The known neutralizing epitopes of viruses are almost conformational epitopes, so the genetically engineered vaccine needs the recombinant protein to be in correct conformation, and be able to preserve the immunity. These 2 qualifications could result in a mass of genetically engineered screen. But if using the peptides which mimic the conformational neutralizing epitopes, using the plasmid pC149-mut as a vector to mimic peptide vaccine expression will get VLP antigens, which remain the activation of neutralizing epitopes, and ensure the immunity of the vaccine, at the same time result in protective immunity. On the one hand, this tactics makes it available to unite more than one kind of virus' s neutralizing epitopes on the VLP antigen. That is to say, it is a way to develop polyvalent vaccines, which shows new direction in the development of new vaccine^[28-31]. The preventer of polyvalent vaccine is that the neutralizing epitopes are almost conformational, if in term of the routine method the conformational epitope cannot be exactly formed. On the other hand, if the chemo-synthesized peptide is used, the immunity will be influenced because of the low molecular mass of peptide. In a word, using the recombinant vector to express the protein, which can form VLP, and using the linear functional mimic epitope, which is displayed on the surface of VLP antigen instead of the conformational neutralizing epitope, is a new feasible idea to settle the difficulties in polyvalent vaccines.

Abstract

AIM: To investigate the prevalence and risk factors of HCV/HIV coinfection in injection drug abusers (IDAs) in Lianshan Yi Autonomous Prefecture of Sichuan province, China.

METHODS: From November 8, 2002 to November 29, 2002, a community-based survey was conducted to investigate the demographic characteristics, patterns of shared injectors devices and sexual behaviors in IDAs. Blood samples were also collected to test HCV and HIV infection. A total of 379 subjects were recruited in the study through community outreach and peer recruiting methods.

RESULTS: Of the 379 IDAs, the HCV prevalence and HIV prevalence were 71.0% and 11.3%, respectively, and HCV/HIV coinfection was 11.3%. HCV infection was found in 100% and 67.3% of HIV-positive and HIV-negative IDAs, respectively. HIV prevalence was 16.0% in HCV positive IDAs while none of the HCV negative IDAs was positive for HIV. Ethnicity, shared needles or syringes and cotton in the past 3 mo and syphilis infection were associated with HCV/HIV coinfection shown by univariate analysis using chi-square test. Multivariate logistic regression analysis showed that shared needles or syringes in the past 3 mo (Odds ratio=3.121, 95% CI: 1.278-7.617, $P<0.05$) and syphilis infection (Odds ratio=2.914, 95% CI: 1.327-6.398, $P<0.01$) were significantly associated with HCV infection. No statistically significant association was found in univariate analysis between sexual behaviors and HCV/HIV coinfection.

CONCLUSION: Shared needles and syringes in the past 3 mo and syphilis infection were significantly associated with HCV infection. Further sero-epidemiological prospective cohort studies should be conducted to clarify the impact of syphilis and high risk sexual behaviors on HCV transmission through unprotected sexual intercourse.

INTRODUCTION

Since the first case in China of an injection drug abuser (IDA) with AIDS was reported in Yunnan Province along the border with Burma (Myanmar) in 1985^[1], China has experienced a rapid increase in the number of HIV/AIDS cases. The majority of HIV infections in China were currently found in rural residents in the western provinces. Furthermore, 71% of documented HIV cases were IDAs. The IDA population is at high risk for HIV infection and also has a high prevalence of HCV. The major mode of HCV and HIV transmission among IDAs is through shared drug injection devices^[2-9]. Because unprotected sexual intercourse is widespread among injection drug abusers, unsafe sexual intercourse is also a notable mode of HIV transmission in IDAs and general population. On the other hand, the association between HCV transmission and high-risk sexual behaviors needs to be clarified^[10-15]. Some studies have reported that HCV transmission through unsafe sexual intercourse can be enhanced in HIV positive patients due to HCV viremia and more active HCV infection with persistent viremia^[16,17]. Clinical progression is more rapid in patients with HCV/HIV coinfection than in patients with HIV only. The prognostic value of HCV infection for both clinical and immunological progression is significant at early stages of HIV infection^[18-24]. Furthermore, HIV coinfection in patients with HCV is associated with more rapid progression to liver failure and liver cancer. The HCV and HIV epidemics are a significant public health problem in China because of high HCV prevalence among HIV-positive IDAs. Studies have investigated HCV/HIV coinfection among IDAs recruited from detoxification centers or re-education centers in China. However, few community- or population-based studies have been performed on HCV/HIV coinfection among IDAs in China, especially in regard to the relationship between risk factors, such as shared injection devices and sexual behaviors, and HCV/HIV coinfection or HCV infection.

A community-based survey of HCV/HIV coinfection among IDAs was conducted in Xichang County, Sichuan Province, China, in November 2002. The aim of the cross-sectional study was to identify the specific risk factors for HCV/HIV coinfection among IDAs in Sichuan Province, China.

MATERIALS AND METHODS

Materials

Study participants were recruited through a community-based outreach method that involved the distribution of information materials regarding the study to the community. The outreach campaign was especially targeted to the known IDA groups. During the informed consent process, potential participants in our study were invited to be peer recruiters with the offer of financial incentives for recruiting other IDAs in the community.

After providing written informed consent, potential study participants underwent a screening interview designed to identify IDAs eligible for the study. All participants were at least 18 years of age, and injected drugs at least one time in the past 3 mo. Those who met the inclusion criteria then completed an HCV and HIV risk assessment interview, received HIV pre-test and risk reduction, underwent phlebotomy for HCV and HIV antibody testing, and received HIV post-testing counseling.

Sichuan Province is located in southwest China and the main drug transportation route from Yunnan and Guangxi to Xinjiang. Xichang County is located in Lianshan Yi Autonomous Prefecture of southwest Sichuan. The total population of Xichang County is 617 000. From November 8, 2002 to November 29, 2002, 379 IDAs based in the community of Xichang County were enrolled by the Xichang Center for STD and Leprosy Control to estimate the prevalence of HCV/HIV coinfection and to investigate the risk factors associated with HCV and HIV infection. The study protocol and informed consent were approved by the Institutional Review Board (IRB) of the Center for AIDS/STD Control and Prevention, Chinese Center for Disease Control and Prevention. Informed consent was obtained from all study participants before being interviewed.

Methods

Each study participant was assigned a unique and confidential identification number that was subsequently used to label questionnaire responses and serum specimens. An interviewer-administrated questionnaire was used to collect data on risk factors for HCV and HIV infection. Questions were concerned with demographic characteristics, drug use and drug injection behaviors, condom use and sexual behaviors. Demographic variables included age, gender, ethnicity, education, employment, marital status, and home ownership. Questions pertaining to drug use investigated the frequency of drug use and drug injection in the past 3 mo and the frequency of shared injection devices in the past 3 mo, including shared needles or syringes, cookers, cotton, rinse water, and use of front- or back-loading. Assessment of sexual behaviors included questions regarding sex behaviors with a steady partner or other partner(s) in the past 6 mo, condom use in the past month, exchange of money for sex partner in the past 6 mo, and the addition of any new sex partners in the past 6 mo. The interview, counseling and blood collection were performed at the site clinic of the Xichang Center for STD and Leprosy Control.

Each serum or plasma sample was collected from IDAs by venipuncture and tested for antibodies to HIV by enzyme-linked immunosorbent assay (ELISA; Beijing Wantai Biological Medicine Company, China). Positive results were confirmed by an HIV-1/HIV-2 Western immunoblot assay (HIV BLOT 2.2 WB; Genelabs, Singapore). Samples were considered as HIV-positive when both ELISA and Western immunoblot results were positive. Samples were tested for antibodies to HCV by ELISA (Beijing Jinhao Biological Production Company, China). The presence of antibodies to syphilis was tested by ELISA (Beijing Jinhao Biological Production Company, China), positivity was confirmed by passive particle agglutination test for detection of antibodies to *Treponema pallidum* (TPPA; Fujirebio, Inc., Japan).

EpiData software (EpiData 2.1 for Windows; The EpiData Association, Odense, Denmark) was used for data double entry and validation. Statistical analysis of chi-square test or Fisher's exact test was performed to screen behaviors and demographic characteristics associated with high risk for HCV and HIV infection. A multivariate logistic regression model was constructed to select independent risk factors of HCV infection and to control confoundings among various risk factors which provided both *P*-values and 95% confidence intervals for the Odds ratio (OR) point estimates. Data analyses were carried

out using the statistical analysis system (SAS 8.2 for Windows; SAS Institute Inc., North Carolina, USA).

RESULTS

Prevalence of HCV and HIV coinfection in IDAs

A total of 379 IDAs were investigated in this study. As shown in Table 1, HCV prevalence and HIV prevalence were 71.0% and 11.3%, respectively. HCV/HIV coinfection was 11.3%. HCV infection was found in 100% and 67.3% of HIV-positive and HIV-negative IDAs, respectively. HIV prevalence was 16.0% among HCV-positive IDAs and none of the HCV-negative IDAs was found to be HIV-positive.

Table 1 Prevalence of HCV/HIV coinfection in IDAs in Xichang County, Sichuan Province, China

HCV	HIV		Total
	Positive	Negative	
Positive	43	226	269
Negative	0	110	110
Total	43	336	379

Risk factors for HCV and HIV infection in IDAs

Table 2 presents the results of univariate analysis of demographics, risk variables of injection drug abusers in the past 3 mo, sexual behaviors in the past 6 mo, and syphilis infection. HCV/HIV coinfection showed a statistically significant association with ethnicity ($P<0.01$), frequency of shared needles or syringes ($P<0.05$) and cotton in the past 3 mo ($P<0.05$) and syphilis infection ($P<0.01$). The frequency of drug injection, shared rinse water and cooker in the past 3 mo all showed a strong but not statistically significant correlation with HCV/HIV coinfection, with *P* values near 0.05.

Stepwise multivariate logistic regression analyses were performed using risk factors of ethnicity; Frequency of drug injection, shared needles or syringes, rinse water, cooker and cotton in the past 3 mo and syphilis infection were included in the initial model to investigate the association with HCV infection. As shown in Table 3, shared needles or syringes in the past 3 mo ($P<0.05$) and syphilis infection ($P<0.01$) were independently associated with HCV infection.

DISCUSSION

Among male IDAs in preparatory cohorts for HIV vaccine trials in Thailand, the prevalence of HCV and HCV/HIV coinfection was 96.4% and 50.7%^[25]. In a study on IDAs from drug detoxification centers in Yunnan Province of China in 2000, the prevalence of HCV was 99.3% in HIV-positive IDAs^[26]. Lai *et al.*^[27] reported 15.4% HIV infection and 63.5% HCV infection in IDAs in Guangxi Zhuang Autonomous Region of China; HCV incidence was about 10 times more than HIV incidence. These studies showed that the prevalence of HCV and HIV was high in IDAs, and that HCV transmission was more rapid than HIV transmission.

In previous studies of HIV-positive populations in Xichang County in Sichuan Province, the prevalence of HCV was found to be approximately 60% in HIV-positive individuals^[28,29]. In this study, we found a relatively high prevalence (11.3%) of HCV/HIV coinfection in IDAs in Xichang County. Shared needles or syringes in the past 3 mo ($P<0.05$) was significantly associated with HCV infection after demographic characteristics and other risk factors were controlled. However, multivariate analysis showed that shared devices were indirectly related to drug injection, such as cotton, rinse water, cookers, and front- or back-loading, while not significantly associated with HCV/HIV coinfection or with HCV infection. Univariate analysis showed

Note:¹ χ^2 Fisher's exact test.**Table 3** Multivariate logistic regression analyses of risk factors associated with HCV prevalence in IDAs in Xichang County, Sichuan Province, China

Factor	β	SEM	<i>P</i> -value	Odds ratio	95% CI
Shared needle or syringe in the past 3 mo	1.1380	0.4553	0.0124	3.121	1.278-7.617
Syphilis infection	1.0695	0.4013	0.0077	2.914	1.327-6.398

that shared cotton in the past 3 mo was associated with HCV/HIV coinfection. Some studies reported that factors of indirectly shared injection devices, including cotton, rinse water, and cookers, posed significant risks for HIV infection in IDAs^[30-32].

The modes of HCV transmission have been a matter of important controversy in literature^[10-15]. Although a high prevalence of HCV was found in STD patients, female workers and homosexual partners might be suggestive of sexual transmission, drug injection might also play a significant role in HCV transmission^[14]. Furthermore, drug injection was the

main risk factor associated with HCV infection in homosexual and bisexual men, while the other risk factors after adjusting injection drug abuse included the number of sexual partners in the past year, anal sex and oral sex behaviors^[33]. Moreover, Alter *et al.*^[15] reported that unsafe heterosexual behavior, anal sex and oral sex behavior were associated with HCV infection, suggesting that both sex behavior and injection drug abuse may play significant roles in HCV transmission. Univariate and multivariate analysis showed that syphilis infection was associated with HCV/HIV coinfection and HCV infection.

However, univariate analysis showed that high risk sexual behaviors were not associated with HCV/HIV coinfection. Lai *et al.*^[27] reported that history of sexually transmitted diseases was independently associated with HIV infection in Guangxi Zhuang Autonomous Region. A study showed that the total number of past sexual partners was associated with HCV infection, but there was no relationship between HCV infection and the total number of sexual partners or sexual behaviors in the past several months^[34]. Two studies of STD individuals confirmed the important role that IDA played in HCV infection and sexual transmission played a minor role in HCV epidemiologies, such as homosexuality/bisexuality, syphilis seropositivity, and a history of syphilis^[35,36]. In our study, persistent use of condom (vaginal sex only) and non-use of condom in IDAs with steady sex partners, and non steady sex partners accounted for 7.6% (9/119) and 88.2% (105/119), 14.6% (13/89) and 68.5% (61/89) in the past month, respectively. This was the first evidence in our study that syphilis infection might contribute to HCV infection in IDAs in Sichuan Province, and syphilis infection is a significant indicator of past high risk sexual behaviors, which increase risk for HCV sexual transmission.

Further sero-epidemiological prospective cohort studies should be conducted to clarify the impact of syphilis and high risk sexual behaviors on HCV transmission through unprotected sexual intercourse.

Abstract

AIM: To investigate the role of Peyer's patch lymphocytes in the regulation of enteric epithelial barrier and ion transport function in homeostasis and host defense.

METHODS: Mouse Peyer's patch lymphocytes were co-cultured with human intestinal epithelial cell line Caco-2 either in the mixed or separated (isolated but permeable compartments) culture configuration. Barrier and transport functions of the Caco-2 epithelial monolayers were measured with short-circuit current (*I*_{sc}) technique. Release of cytokines was measured by enzyme-linked immunosorbent assay (ELISA) and cytokine mRNA expression was analyzed by semi-quantitative RT-PCR. Barrier and ion transport functions of both culture conditions following exposure to *Shigella* lipopolysaccharide (LPS) were also examined.

RESULTS: The transepithelial resistance (TER) of the epithelial monolayers co-cultured with Peyer's patch lymphocytes was maintained whereas that of the Caco-2 monolayers alone significantly decreased after eight days in culture. The forskolin-induced anion secretion, in either absence or presence of LPS, was significantly suppressed in the both co-cultures as compared with the Caco-2 cells alone. Furthermore, only the mixed co-culture condition induced the expression and release of *mIL-6* from Peyer's patch lymphocytes, which could be further enhanced by LPS. However, both co-culture conditions suppressed expression and release of epithelial *hIL-8* under the unstimulated conditions, while the treatment with LPS stimulated their *hIL-8* expression and release.

CONCLUSION: Peyer's patch lymphocytes may modulate intestinal epithelial barrier and ion transport function in homeostasis and host defense via cell-cell contact and cytokine signaling.

INTRODUCTION

The mucosal surface of the gastrointestinal tract is lined by a single layer of epithelial cells jointed together at their apical poles by tight junctions, forming a barrier that separates the luminal contents from the effector immune cells underneath. It has become increasingly clear that the intense immunological activities occurring at the enteric mucosal surface involve interactions between epithelial and immune cells^[1,2]. Accumulating evidence suggests that epithelial cells can produce cytokines and chemokines that attract and activate immune cells with potentially important effects on the immediate and long-term host defense functions. Effective immune surveillance of the mucosal surface requires transport of intact macromolecules and micro-organisms across the epithelial barrier to the cells of mucosal immune system. Groups of organized mucosal lymphoid follicles, named Peyer's patches, lined along the gastrointestinal tract in a specialized overlying epithelium, are the sites for transporting, processing and presenting foreign antigens. In Peyer's patches, each follicle is separated from the overlying epithelium by a subepithelial "dome" region that is rich in lymphocytes and dendritic cells. It is apparent that the immune cells in the dome region interact intimately with the overlying epithelium, giving rise to mucosal immune response without the needs of systemic involvement^[3]. Although a mucosal lympho-epithelial internet has been proposed to mediate the interactions between epithelial and immune cells, details of the interactions are far from understood. The close contact between Peyer's patch lymphocytes and intestinal epithelial cells suggests that these lymphocytes may play a role in the modulation of epithelial barrier/transport functions in homeostasis as well as host defense. However, no evidence has been provided so far concerning the role of Peyer's patch lymphocytes in intestinal epithelial physiology.

In addition to their major defensive role as a passive barrier, the intestinal epithelial cells also play an active role in physiology and pathophysiology of the gut. While the absorptive properties of the epithelium are known to be of vital importance for the nutrition of the body, as well as the maintenance electrolytes and fluid balance, the secretory activities of the epithelium are also important for protective purpose. Luminally directed transport of Cl^- and HCO_3^- is the driving force for fluid secretion that flushes away noxious substances from the intestinal mucosal surface. Secretory diarrhea is often the consequence for increased water and electrolyte secretion upon invasion by microorganisms. *Escherichia*, *Salmonella* and *Shigella* are the most important bacterial causes of diarrhea worldwide^[4]. The pathogenesis of bacteria-induced diarrhea with regard to the involvement of Peyer's patch lymphocytes remains largely unknown although the barrier function and ion secretory responses of the intestinal epithelium have been shown to be affected by both proinflammatory and anti-inflammatory cytokines^[5-7].

The co-culture of characterized epithelial cells with defined immune cell populations and subsequent analysis of epithelial physiology have contributed significantly to our appreciation of the immune regulation of epithelial function^[8,9]. Kerneis *et al.*^[10] have successfully induced functional M cells by co-culturing Caco-2 cells, a human intestinal surface epithelial cell line, with murine Peyer's patch lymphocytes. This phenomenon indicates the profound influence of Peyer's patch lymphocytes on intestinal epithelial phenotypes^[11]. Thus, to investigate the role of Peyer's patch lymphocytes in intestinal epithelial barrier/transport function during infection, we adopted this co-culture system to build an infection model with *Shigella* LPS, one of the major virulence factors of Gram-negative bacteria that is responsible for eliciting a wide array of immune responses^[11,12]. The present study includes different co-culture configurations: One consisting of upper and lower compartments with a permeable filter separating the epithelial layer and lymphocytes, and the other mixing both epithelial cells and lymphocytes in the same compartment. Using these co-culture configurations, epithelial-immune interactions through cell-cell contact as well as cytokine signaling could be examined independently.

MATERIALS AND METHODS

Isolation of peyer's patch lymphocytes

BALB/c mice (SPF, female, 6-8 wk old) were obtained from the Animal House of Chinese University of Hong Kong. The lymphoid follicles of the Peyer's patch were carefully excised from the intestinal serosal side and placed in 10 mL phosphate buffered saline (PBS, pH 7.4, GIBCO 10010-31) supplemented with 20 mL/L FBS and 2% penicillin-streptomycin. The collected patches were triturated by pipetting up and down a few times and smashing through a metallic grid (mesh: 100). Individual lymphocytes were released in the liquid below the metallic grid. The lymphocytes were washed with PBS, the distribution of Peyer's patch T and B cell populations was consistent with previous data when they were checked by flow cytometry^[10], then diluted to the expected concentration.

Enteric epithelial cell culture

Human colonic cell line Caco-2, which is a villus cell-like colonic cell line^[13], was purchased from American Type Culture Collection (Rockville, MD). The cells were grown in Dulbecco Modified Eagle's minimal essential medium (DMEM, high glucose, GIBC-BRL) with 100 mL/L fetal bovine serum (FBS, GIBCO 16000-044), 2 mmol/L L-glutamine (GIBCO-BRL), 100 µmol/L non-essential amino acid (GIBCO-BRL), 200 units/mL penicillin and 200 µg/mL streptomycin (GIBCO-BRL) at 37 °C in a 50 mL/L CO₂ atmosphere. Caco-2 cells were seeded at a density of 3×10⁵ cells on a floating permeable support, which was made of a membrane filter (Millipore, 0.45 µm pore size) with a silicone rubber ring attached on top of it for confining the cells (0.45 cm² growth area).

Co-culture configurations

Three types of culture configurations were established in this study: (1) Caco-2 culture alone: Caco-2 cells (3×10⁵ cells) were grown as a homogenous polarized monolayer according to the epithelial cell culture method mentioned above and served as the control. (2) Separated co-culture: Epithelial cells (3×10⁵ cells) were plated on a permeable support (growth area of 0.45 cm² as described), which floated above 2 mL culture medium containing Peyer's patch lymphocytes (5×10⁶ cells) in a Petri dish (3.5-cm diameter). (3) Mixed co-culture: Caco-2 cells (3×10⁵ cells) were directly mixed with Peyer's patch lymphocytes (1×10⁶ cells), and then were seeded on the same permeable support described above and grown at 37 °C in a 50 mL/L CO₂ atmosphere.

Shigella F2a-12 LPS pretreatment

When the Caco-2 cells grown as polarized monolayers on the membrane filter reached confluence on the 4th d, *Shigella F2a-12* LPS (5 µg/mL, obtained from the Immunology Department of Institute of Microbiology & Epidemiology, Academy of Military Medical Sciences) was added to the apical side of the epithelial monolayers and treated for 8, 24 and 48 h at 37 °C in a 50 mL/L CO₂ atmosphere.

Short-circuit current measurements (Isc)

The *Isc* measurement has been described previously^[14]. In short, the confluent monolayers were clamped vertically between the two halves of an Ussing chamber. Monolayers were short circuited (transepithelial potential difference clamped at zero) using a voltage-clamp amplifier (DVC-1000; World Precision Instruments Inc., New Haven, CT, USA). The resulting *Isc* was displayed on-line on a pen recorder (Kipp and Zonen, Delft, The Netherlands). Transepithelial electrical resistance (TER) was determined based on Ohm's law by clamping the tissue intermittently at a value of 0.2 mV. For most measurements, the monolayers were bathed in normal Krebs-Henseleit solutions (NaCl, 117 mmol/L; KCl, 4.7 mmol/L; MgCl₂, 1.2 mmol/L; NaHCO₃, 24.8 mmol/L; KH₂PO₄, 1.2 mmol/L; CaCl₂, 2.56 mmol/L; Glucose, 11.1 mmol/L) with 950 mL/L O₂ and 50 mL/L CO₂.

Semi-quantitative RT-PCR

Caco-2 monolayers grown on the filters (Millipore, 0.22 µm pore size, cell growth area of 7.065 cm²) were harvested for RT-PCR after 8-h and 24-h *Shigella F2a-12* LPS pre-treatment. The specific primers for hIL-8^[15] were 5' tct ctt ggc agc ctt cct 3' (sense) and 5' gaa gtt tca ctg gca tct tca c 3' (antisense), corresponding to the nucleotides 98-427 with the expected cDNA size of 390 bp (Tm 58 °C, 30 cycle); mIL-6^[16] were 5' ctg caa gag act tcc atc cag 3' (sense) and 5' tcc agt ttg gta gca tcc atc 3' (antisense), corresponding to the nucleotides 45-340 with the expected cDNA size of 296 bp (Tm 55 °C, 35 cycle). Their expression was compared to the house-keeping gene GAPDH (forward: 5' tcc cat cac cat ctt cca g 3' and reverse: 5' tcc acc act gac acg ttg 3'). RT-PCR was performed using the PTC-200 Peltier Thermal Cycler (MJ Research Company) and software for analysis data is GraphPad Prism 3.02.

Enzyme-linked immunosorbent assay (ELISA)

After confluent Caco-2 monolayers on the Millipore filter was challenged by *Shigella F2a-12* LPS pretreatment for 8 and 24 h, the culture medium was collected and kept at -20 °C until evaluation hIL-8 and mIL-6 bioassay using ELISA kits (BIOSOURCE Company) according to manufacturer's instructions.

Statistical analysis

All data were expressed as mean±SE. The number of experiments represents independent measurements on separate monolayers. Comparisons between groups of data were made by one-way ANOVA. A "P" value of less than 0.05 was considered statistically significant.

RESULTS

Co-culture with Peyer's patch lymphocytes results in better maintenance of epithelial barrier function but LPS decreases it

Polarized monolayers of Caco-2 were tested for transepithelial resistance (TER) at various times (the 4th, 6th and 8th d after co-culture) (Figure 1). A significant decrease in TER was observed in Caco-2 alone after eight days in culture, whereas high TER could still be maintained for either mixed or separated co-cultures for the same period of time (Figure 1). However, after treatment with *Shigella* LPS (5 µg/mL) for 48 h, TER measured on the

6th d of co-culture, decreased significantly in both co-culture groups but not in Caco-2 alone (Figure 2).

Figure 1 Comparison of time-dependent changes in transepithelial resistance (TER) of different culture groups. Data in all panels are mean±SE for 4 experiments, significant differences relative to its own 4-d of culture in Caco-2 alone (^b*P*<0.01), and to its own 6th day culture of Caco-2 alone (^d*P*<0.001) are indicated.

Figure 2 Effect of *Shigella* F2a-12 LPS on transepithelial resistance (TER) of different culture groups. Cultured monolayers were exposed to LPS 48-h prior to TER measurement on the 6 d of culture. Comparison of TER in the absence or presence of *Shigella* F2a-12 LPS among the three culture groups. The values indicate mean±SE; *n*=5; ^a*P*<0.05 (compared to its own control).

Figure 3 Effect of *Shigella* F2a-12 LPS on the Forskolin-induced *Isc*. Comparison of the Forskolin (4 μg/mL, basolateral addition)-induced *Isc* in the absence or presence of LPS for 8-h and 24-h under different culture conditions. The values indicate mean±SE; *n*=12; ^a*P*<0.05 (compared to its own control); ^c*P*<0.05 and ^b*P*<0.001 (compared to its own LPS treatment for 8-h).

Co-culture with Peyer's patch lymphocytes alters anion secretory responses

The *Isc* responses of the co-cultures and Caco-2 alone to the

challenge of an adenylate cyclase activator, forskolin, were characterized. As shown in Figure 3, significantly lower *Isc* response was observed in both co-cultures than that of the Caco-2 alone control in the absence of LPS. Increased responses in all groups were observed after 8-h LPS treatment. Significantly more upregulated *Isc* response was observed in Caco-2 alone group (Figure 3). After 24 h of LPS treatment, the *Isc* responses of the separated co-culture and Caco-2 alone groups decreased significantly as compared with that of 8-h LPS treatment but not the mixed co-culture (Figure 3). No significant differences in the basal *Isc* among the groups were observed, nor did it change significantly upon treatment with LPS (data not shown).

Figure 4 Induction of hIL-8 expression in Caco-2 cells by *Shigella* F2a-12 LPS in different culture groups. Comparison of hIL-8 expression in Caco-2 cells in the absence or presence of LPS for 8-h and 24-h between three culture groups by semi-quantitative RT-PCR with Peyer's patch lymphocytes as negative control. The values indicate mean±SE; ^a*P*<0.05, ^b*P*<0.01 (compared to its own control); ^c*P*<0.05 (compared to separated co-culture LPS pre-treatment for 8-h).

Separated co-culture results in enhanced expression and release of hIL-8 from Caco-2 cells

To examine the mRNA expression of hIL-8, primers specific for hIL-8 were used in RT-PCR experiments, and the RNA from mouse Peyer's patch lymphocytes was used as negative control to detect any potential. The results are shown in Figure 4. The highest level of hIL-8 expression was observed in the Caco-2 alone as compared to the other two co-cultures when they were cultured in the absence of LPS. However, after treatment with LPS for 8 h, lower hIL-8 expression was observed in the Caco-2 culture alone while increased hIL-8 expression was evident in both co-cultures. The increase in the hIL-8 expression was particularly more enhanced in the separated co-culture. After 24 h, the expression of hIL-8 in the co-cultures returned closer to their basal levels but the expression in the Caco-2 alone remained low as compared with its own control. The expression of hIL-8 was not detected in mouse Peyer's patch lymphocytes confirming that the above expression profile of hIL-8 was associated with human intestinal epithelial cells.

ELISA using a human kit was conducted to confirm the release of hIL-8 from different cultures with mouse Peyer's patch lymphocytes as a control for cross-reactivity. The results showed that the levels of hIL-8 released from the Caco-2 alone culture under the unstimulated condition and 8-h LPS treatment were significantly greater than that from both co-cultures (Figure 5). However, following the 24-h LPS treatment, levels of hIL-8 in both co-culture groups increased considerably while a decrease was observed in Caco-2 alone (Figure 5). A detectable amount of hIL-8 was also observed from mouse Peyer's patch lymphocytes (1×10^6 cells), indicating the presence of condition cross-reactivity of human IL-8 antibody to mouse IL-8 (Figure 5).

Figure 5 Comparison of *Shigella* F2a-12 LPS-induced hIL-8 release from different culture groups by ELISA. Culture groups and Peyer's patch lymphocytes alone (control, 1×10^6 cells) were treated with LPS for 8-h and 24-h. The presented values indicate mean \pm SE; $n=8$; ^a $P<0.001$ (compared to its own control); ^b $P<0.05$ and ^d $P<0.001$ (compared to its own LPS treatment for 8-h).

Figure 6 Induction of mIL-6 expression by *Shigella* F2a-12 LPS in different culture groups. Comparison of mIL-6 expression in the absence or presence of LPS for 8-h and 24-h among the culture groups by semi-quantitative RT-PCR with mouse Peyer's patch lymphocytes as positive control. The values indicate mean \pm SE ^a $P<0.01$ (compared to the mixed control).

The mixed co-culture condition triggers expression and release of mIL-6 from Peyer's patch lymphocytes

Using primers specific for mIL-6, the expected RT-PCR product of mIL-6 was detected in the mixed co-culture and mouse lymphocytes but not in the Caco-2 culture alone or separated co-culture, where only the epithelial cells in the upper compartment were subjected to RT-PCR, thus excluding detection of IL-6 from the Peyer's patch lymphocytes in the medium. The expression of mIL-6 in the mixed co-culture further increased after 8 and 24 h of treatment with LPS (Figure 6).

The release of mIL-6 from different cultures, as well as mouse Peyer's patch lymphocytes (1×10^6 cells), was measured using a mouse ELISA kit. The results showed that no groups except the mixed co-culture had detectable mIL-6 release either in the absence or presence of LPS treatment (Figure 7). The level of mIL-6 measured in the mixed co-culture group significantly increased after 24-h LPS treatment (Figure 7).

Figure 7 Comparison of *Shigella* F2a-12 LPS-induced mIL-6 release from different culture groups by ELISA. Culture groups and Peyer's patch lymphocytes (1×10^6 cells) were treated with LPS for 8-h and 24-h. The values indicate mean \pm SE; $n=5$; ^b $P<0.01$ (compared to mixed co-culture control) and ^d $P<0.01$ (compared to the mixed LPS treatment for 8-h).

DISCUSSION

The present study has demonstrated for the first time the role of Peyer's patch lymphocytes in intestinal epithelial physiology in homeostasis as well as host defense. Both epithelial barrier function and anion secretory activities, under normal or infected conditions, were affected by the presence of Peyer's patch lymphocytes to various extent depending on the co-culture configurations. TER has been used as an index of epithelial barrier integrity, which is sometimes compromised in certain infections, possibly as a direct result of modulation by immune cells^[17]. Previous studies in co-cultures of epithelial cells and immune cells, including lamina propria mononuclear cells (LPMC)^[18] and intraepithelial lymphocytes^[19], invariably resulted in disruption of epithelial barrier function as indicated by a decrease in TER. However, the present study did not observe significant reduction in the TER in the Caco-2 co-cultures with Peyer's patch lymphocytes, either in the separated or mixed configuration, as compared with the Caco-2 culture alone. On the contrary, the TER in both co-cultures could be maintained up to eight days whereas that in Caco-2 control decreased drastically. These results suggest that unlike other types of immune cells previously studied, Peyer's patch immune cells, which consist mostly of lymphocyte (99%)^[10], play a distinct homeostatic regulatory role in maintaining the barrier function of the epithelial monolayers. However, TER of both co-cultures decreased substantially after treatment with *Shigella* LPS for

48 h, indicating that *Shigella* LPS may have direct effect on epithelial barrier function without the modulation of Peyer's patch lymphocytes. This notion is also supported by the observed mRNA expression of tight junction-associated protein ZO-1 in both co-cultures with Peyer's patch lymphocytes (data not shown). It has been shown that LPS accounts for a large part of the transepithelial signaling caused by apical *Shigella* bacteria that induces adherence and transmigration of basal polymorphonuclear leukocytes (PMNs), which disrupt the monolayer permeability and facilitate bacterial invasion^[20].

Similar to the barrier function, the epithelial secretory activities, in both homeostasis and infection, were also affected by the presence of Peyer's patch lymphocytes, depending on the configuration of the co-cultures. In normal conditions (or in the absence of LPS), reduced forskolin-induced *Isc* was observed when Peyer's patch lymphocytes were co-cultured with Caco-2 and the *Isc* response in the Caco-2 alone group was significantly increased after LPS challenge up to eight hours. These results suggest that the forskolin-induced *Isc* response could be suppressed by Peyer's patch lymphocytes. However, down-regulation of forskolin-induced anion secretion could be seen in all groups 24 h after LPS challenge, suggesting that cytokine signaling also plays a role at later stages of infection, perhaps affecting the expression of ion channels. Interestingly, the *Isc* response of anion secretion in the mixed co-culture showed no significant change in the absence or presence of LPS, suggesting that cell-cell contact is important for modulation of epithelial anion secretion by Peyer's patch lymphocytes. In contrast to many previous results obtained from *in vitro* epithelial model cells showing anion secretion stimulated by bacteria^[21] or immune and inflammatory modulators produced by inflammatory cells^[22], the present results show no change in the forskolin-induced anion secretion in the mixed co-cultures in the absence or presence of LPS. Reduced secretory responsiveness has also been observed in the epithelial cell models that are co-cultured with a number of different immune cells^[7]. This is also consistent with the observation that colonic mucosa from patients with chronic inflammatory bowel disease respond poorly to secretagogues^[23]. Thus, it appears that the epithelial secretory response in homeostasis and infection is modulated by immune cells including Peyer's patch lymphocytes. The present results showed that Peyer's patch lymphocytes suppressed epithelial secretory activity, especially upon LPS challenge, suggesting that the secretory diarrhea caused by bacterial infection may not be solely due to enhanced water and electrolyte secretion. Recent studies have suggested that the inhibition of Na⁺-K⁺-ATPase by interferon γ that leads to the reduction of Na⁺ absorption may be a major cause of inflammation-associated diarrhea^[24]. The inhibition of Na⁺-K⁺-ATPase induced by interferon γ may also account for the presently observed Peyer's patch lymphocyte-suppressed anion secretion since secondary active anion secretion depends on the Na⁺ gradient generated by the Na⁺-K⁺-ATPase. Further studies examining the expression of various ion channels and transporters including Na⁺-K⁺-ATPase and CFTR in response to LPS challenge are currently undertaken in our laboratory.

The present results suggest that the modulation of epithelial physiology by Peyer's patch lymphocytes involves both cell-cell contact and cytokine signaling. The mouse-human hybrid co-cultures in different configurations, mixed and separated, not only allow the distinction of contact-dependent and independent signaling mechanisms but also the identification of the source of cytokines, although homology between human and mouse cytokine may result in cross-reactivity as seen in the ELISA results showing detectable hIL-8 measured from mouse Peyer's patch lymphocytes using a human kit. Further experiment with RT-PCR using species-specific primers could also be conducted to confirm the source of cytokines. In fact,

the ELISA results were closely correlated with the RT-PCR results with a time lag in the response to LPS. This observation is consistent with the fact that the transcriptional changes occur prior to the translational changes^[25].

The more prominent effects on forskolin-induced anion secretion observed in the mixed co-culture as compared to that in the separated co-culture indicate the importance of cell-cell contact in addition to cytokine communication. In fact, cell-cell contact appears to be absolutely required for the enhancement of the expression and release of mIL-6 from Peyer's patch lymphocytes under both normal condition and LPS challenge. This observation is of physiological significance considering the close contact between Peyer's patch lymphocytes and intestinal epithelial cells in the Peyer's patches. IL-6 is known to be produced by a number of cell types including antigen-presenting cells and B cells and it is involved in the acute phase response, B cell maturation and macrophage differentiation^[26]. IL-6 has also been reported to activate transcription of a variety of molecules including cytokines and receptors^[27]. Therefore, cell-cell contact-induced IL-6 release from Peyer's patch lymphocytes may affect the expression of epithelial ion channels and transporters and lead to modulation of epithelial function. On the other hand, more enhanced expression and release of hIL-8 from Caco-2 cells was observed in the separated co-culture than the mixed co-culture. This is consistent with the properties of IL-8 as a chemokine for attracting immune cells to the site of inflammation since the separation of Peyer's patch lymphocytes from Caco-2 cells in the separated co-culture presents a need for IL-8 to signal the recruitment of lymphocytes. However, there is no need for production of IL-8 if the lymphocytes are present next to the epithelial cells as in the mixed co-culture. Epithelial hIL-8 production has been implicated in the disruption of the epithelial barrier function by *Shigella*^[28] as well as other enteroinvasive bacteria^[29]. Bacterial invasion turns the infected epithelial cells to become strongly proinflammatory with subsequent IL-8 production that attracts polymorphonuclear leukocytes (PMNs), ultimately leading to the disruption of the epithelium. This study only investigated the mIL-6 and hIL-8 expression and release from lymphocytes and epithelial cell to illustrate possible interactions through soluble factors between epithelial and immune cells. Other cytokines may also play a role in the regulation of epithelial physiology by Peyer's patch lymphocytes. The observed expression and release of mIL-6 and hIL-8, constitutively and in response to the LPS challenge, suggest that they may be involved in mediating the modulatory effects of Peyer's patch lymphocytes on epithelial barrier and ion transport function in homeostasis and host defense. Further studies are required to identify their specific roles as well as the involvement of other immune mediators in the modulation of epithelial physiology.

In summary, being the sensory arm of the intestinal mucosa, Peyer's patches are not only involved in transporting, processing and presentation of antigens/pathogens that are essential to eliciting mucosal immune response, but also play an important role in modulating epithelial physiology. This function is distinct from other types of lymphocytes previously studied. Our results indicated that lymphocytes in Peyer's patches receive information from mucosal surface epithelial cells, via both cell-cell contact and cytokine signaling, and in return modulate epithelial barrier and ion transport function in both homeostasis and host defense. Since immune modulation determines the epithelial responsiveness to infection, the co-cultures of epithelial cells with Peyer's patch lymphocytes may provide useful models in studying the initiation process involved in the pathogenesis of inflammation-associated diarrhea.

Abstract

AIM: To characterize the gene expression profiles associated with activation of mouse hepatic stellate cell (HSC) and provide novel insights into the pathogenesis of hepatic fibrosis.

METHODS: Mice HSCs were isolated from BALB/c mice by *in situ* perfusion of collagenase and pronase and single-step density Nycodenz gradient. Total RNA and mRNA of quiescent HSC and culture-activated HSC were extracted, quantified and reversely transcribed into cDNA. cDNAs from activated HSC were labeled with Cy5 and cDNAs from the quiescent HSC were labeled with Cy3, which were mixed with equal quantity, then hybridized with cDNA chips containing 4 000 genes. Chips were washed, scanned and analyzed. Increased expression of 4 genes and decreased expression of one gene in activated HSC were confirmed by reverse transcription- polymerase chain reaction (RT-PCR).

RESULTS: A total of 835 differentially expressed genes were identified by cDNA chip between activated and quiescent HSC, and 465 genes were highly expressed in activated HSC. The differentially expressed genes included those involved in protein synthesis, cell-cycle regulation, apoptosis, and DNA damage response.

CONCLUSION: Many genes implicated in intrahepatic inflammation, fibrosis and proliferation were up-regulated in activated HSC. cDNA microarray is an effective technique in screening for differentially expressed genes between two different situations of the HSC. Further analysis of the obtained genes will help understand the molecular mechanism of activation of HSC and hepatic fibrosis.

INTRODUCTION

Liver fibrosis is a common consequence of chronic liver injury

and is characterized by the progressive accumulation of extracellular matrix (ECM) proteins, particularly type I and III collagens. Hepatic stellate cells (HSC) are the major source of ECM in hepatic fibrosis and HSC is one of the sinusoid-constituent cells that plays multiple roles in the liver pathophysiology. After hepatic injury, HSC undergoes an activation process, characterized by loss of vitamin A, trans-differentiation to a smooth muscle α -actin (α -SMA)-positive myofibroblast like cell type, increased proliferation and increased production of ECM proteins^[1,2]. Activation and transformation of HSC from the vitamin A-storing phenotype (also called "quiescent" phenotype) to the "myofibroblastic" one has been identified as a critical step in hepatic fibrogenesis and is regulated by several factors including cytokines and oxidative stress^[3-5]. However, the molecular mechanism for HSC activation is not well understood. The activation of HSC involves many genes from multiple pathogenic pathways.

cDNA microarray analysis is a powerful descriptive method of examining the expression profile of hundreds to thousands of genes in unison. It has become an increasingly popular tool to investigate the function of genes, especially those genes involved in tumor generation and growth^[6]. Recently, cDNA array has been used to identify differentially expressed genes in HCV-associated cirrhosis and achieve new insights into HCV liver injury^[7].

Further advances in our knowledge about HSC activation requires more genes to be identified. Microarray technology provides us with a genomic approach to explore the genetic markers and molecular mechanisms leading to hepatic fibrosis. To this end, we have used cDNA microarray analysis to detect genes whose mRNA expression changes in the cultured activated HSC. RT-PCR analysis confirmed up-regulation of 4 previously unreported transcripts and down-regulation of one gene transcript in the activated HSC. The identification of these genes provides new insight into the understanding of HSC activation and hepatic fibrogenesis. Culturing HSC on plastic surface converts them from a quiescent phenotype to an activated phenotype similar to *in vivo* activation and this cultured-induced activation has been extensively studied as a model of the activation secondary to liver fibrogenesis^[8,9]. Therefore, we used the *in vitro* model in which the activation of HSC was induced by growth on plastic dishes to study the differentially expressed genes associated with the activation of HSC.

MATERIALS AND METHODS

Materials

Male BALB/c mice were obtained from Experimental Animal Center of West China Medical School, Sichuan University (Chengdu, Sichuan). All animals were treated humanely according to the national guideline for the care of animals.

Pronase, DNase I and Collagenase B were from Roche Molecular Biochemicals (Mannheim, Germany). Nycodenz was from Sigma (St. Louis, USA). Dulbecco's modified medium (DMEM), trypsin-EDTA and new-born calf serum were from Invitrogen Corp (Grand Island, USA). Monoclonal antibodies against desmin, α -smooth muscle actin (α -SMA) were obtained from Dako (Glostrup, Denmark). Gene chips (MGEC-40s) were

purchased from BioStar Genechip Inc. (Shanghai, P.R.China), and each chip contains 4 000 mouse cDNAs, including 1 500 cDNAs of known sequence and function, and 2 500 novel cDNAs whose function has not been known in the public database.

Methods

HSC isolation and culture HSC was isolated from male Balb/c mice by *in situ* pronase, collagenase perfusion and single-step Nycodenz gradient according to our previous report. The purity of primary HSC after 3 d in culture was approximately 95% as estimated by vitamin A auto-fluorescence and immunocytochemistry with antibody against desmin. Therefore, HSC cultured in uncoated plastic dishes spontaneously acquired an activated phenotype, characterized by expression of α -SMA and by loss of vitamin A droplets. After reaching confluence (about 10–14 d after plating), activated HSC was detached by trypsin, and split in a 1:2 ratio. Experiments were performed on primary cells cultured for 3 d and activated HSC of the third passages using 3 independent cell lines, and the purity of activated HSC exceeded 98%.

Preparation of RNA and cDNA microarray Total RNA was isolated from primary mouse HSC and sub-confluent culture-activated mouse HSC (passage 3), using Trizol reagent (Invitrogen Life Technologies Inc, USA) according to the manufacturer's protocol. Poly (A) mRNA was isolated from total RNA using Oligotex mRNA Midi Kit (Qiagen, USA) according to the manufacturer's protocol.

All microarray procedures were performed by BioStar Genechip Inc. (Shanghai, P.R.China). Equal quantities of mRNA from each cell phenotype were used to prepare probes, hybridized to gene chips (MGEC-40 s, Biostar Genechip Inc.), and analyzed for the quantity of mRNA encoded by 4 000 mouse genes. The preparation of Cy5 and Cy3 probes from mRNA samples and the hybridization were conducted by the BioStar Genechip Inc.

RT-PCR assays To validate the expression pattern identified on the expression arrays, 4 genes (MIF, Annexin VI, N-Cadherin, DAD1) from the up-regulated genes and one gene (BHMT) from the down-regulated genes in activated HSC were picked and semi-quantitative RT-PCR was performed to confirm their changed expression with cDNA templates from activated and quiescent HSC. The total RNA was isolated from HSC using Trizol reagent, precipitated in ethanol and resuspended in sterile RNAase-free water and stored at -70 °C, as described previously. One-step reverse transcription-polymerase chain reaction (RT-PCR) was performed according to the method of the supplier (TaKaRa Biotechnology Co., Ltd, Dalian). Primers were designed using the Primer 3 program from Whitehead Institute for

Biomedical Research (Cambridge, MA, USA)^[10], synthesized and purified by PAGE in Genebase BRL Custom Primers (Genebase Biotechnology Co., Shanghai). Primer sequences are shown in Table 1. The PCR products was analyzed by 20 g/L agarose gel electrophoresis with TAE buffer at 80 V for 40 min, visualized with ethidium bromide and photographed under UV light by Gel Documentation system (Gel Doc 2000™, Bio-Rad, USA). The semi-quantitative analysis was performed using the volume analysis in the Quantity One Software (Bio-Rad, USA). Each detected gene/GAPDH quotient is the indication of the detected gene. Experiments were performed for at least five times with similar results.

Statistical analysis

RT-PCR results were expressed as mean \pm SD. Differences between means were analyzed with Student *t* test for paired samples. A value of *P*<0.05 was considered statistically significant.

RESULTS

Expression pattern of genes in activated HSC

Differences in gene expression patterns between mouse activated HSC and quiescent HSC were assessed using microarray analysis. This array allows a quantitative measurement of 4 000 known genes and expressed sequence tags. Genes that differed in intensity by at least 2-fold were considered to be differentially regulated. Figure 1 shows that the cDNA array images along with color charts indicating up-regulated genes with red, down-regulated ones with green and non-changed with yellow. Of the 4 000 genes analyzed by microarray, a total of 835 genes (20.8%) revealed differential expression in the activated HSC when compared with the quiescent HSC (Tables 2–4). Of the 835 genes with altered expression in the activated HSC, 462 genes (including 204 known function genes) revealed elevated expression whereas 373 genes (including 132 known function genes) revealed reduced expression. Array analysis identified many differentially expressed genes that are important in inflammation, fibrosis, proliferation, signaling, apoptosis and oxidative stress.

Validation of array data with RT-PCR

To further investigate the reliability of our array data, we picked 5 differential expressed genes and measured the expression of the genes in the activated and quiescent HSC. Figures 2 and 3 and Table 5 show that the different expression pattern of each of the five genes as determined by RT-PCR were similar to those observed with cDNA array, confirming the reliability of our array data.

Table 1 Primer sequences for RT-PCR

Gene name	Primer sequence	Expected product size
Betaine homocysteine methyltransferase (BHMT)	Left 5' -GCC TAT AGC GGC TAC CAT GT-3'	399 bp
	Right 5' -CTC TGC AAT GGC CCT GAT GT-3'

Figure 2 Electrophoresis analysis of RT-PCR products. Lane M: 100 bp DNA ladder; Lane 1: GAPDH; Lane 2, 3: MIF amplified from quiescent HSC and activated HSC mRNA respectively; Lane 3 shows increased expression of MIF in activated HSC compared with lane 2 in quiescent HSC. Lane 4, 5: Annexin VI amplified from quiescent HSC and activated HSC mRNA respectively; Lane 5 shows increased expression of Annexin VI in activated HSC compared with lane 4 in quiescent HSC.

Figure 3 Electrophoresis analysis of RT-PCR products. Lane M: 100 bp DNA ladder; Lane 1: GAPDH; Lane 2, 3: N-Cadherin amplified from quiescent HSC and activated HSC mRNA respectively; Lane 3 shows increased expression of N-Cadherin in activated HSC compared with lane 2 in quiescent HSC. Lane 4, 5: DAD1 amplified from quiescent HSC and activated HSC mRNA respectively; Lane 5 shows increased expression of Annexin VI in activated HSC compared with lane 4 in quiescent HSC. Lane 6, 7: BHMT amplified from quiescent HSC and activated HSC mRNA respectively; Lane 7 shows decreased expression of BHMT in activated HSC compared with lane 6 in quiescent HSC.

DISCUSSION

Genome-wide expression profiling by microarray of cDNA or oligonucleotide probes on a glass or nylon substrate is an exceptionally powerful tool for the study of gene regulation. This methodology has been used to investigate the phenomena particularly appropriate for the analysis of expressed liver genes^[7]. cDNA microarrays were used to profile changes in gene expression in activated HSC. Scatter plot analysis showed that approximately 20.8% of all mouse genes examined on the 4 000 gene microarrays exhibited altered expression, with 11.5% showing up-regulation and 9.3% showing down-regulation. These genes will be future studied.

Table 2 Part of the previously reported up-regulated genes in activation of HSC

GenBank accession number	Gene name	Ratio (Cy5/Cy3)	Potential gene function
M73741	Alpha-B2-crystallin, complete cds	155.619	Small heat shock protein gene, an early marker for HSC activation
X52046	Procollagen, type III, alpha 1	119.092	Extracellular matrix (ECM), over- expressed in hepatic fibrosis
M18194	Fibronectin mRNA	29.958	ECM, over expressed in hepatic fibrosis
J02870	Laminin receptor mRNA	6.62	ECM receptor (integrin), cell adhesion
L08115	CD9 antigen	6.094	Cell membrane glycoprotein, involved in cell activation and adhesion
U16163	Prolyl 4-hydroxylase alpha (II)-subunit mRNA, complete cds	4.555	An enzyme which is essential for the collagen synthesis in HSC
X62622	TIMP-2 mRNA for tissue inhibitor of metalloproteinase, type 2	3.732	Inhibition for ECM degradation
X04017	mRNA for cysteine-rich glycoprotein SPARC	3.435	Regulation of cell shape, adhesion, migration and proliferation
AF070470	SPARC-related protein (SRG) mRNA, complete cds	3.181	Regulation of cell shape, adhesion, migration and proliferation
M21495	Cytoskeletal gamma-actin mRNA,	3.092	Relate skeleton structure of cell
AF188297	TGF-beta receptor binding protein (Trip1) mRNA, complete cds	2.976	TGF-beta mediated signaling pathway
AJ245923	alpha-tubulin 8 (Tuba 8 gene) mRNA	2.901	Relate skeleton structure of cell
AF053454	Tetraspan TM4SF (Tspan-6) mRNA, complete cds	2.896	Cell development, differentiation, motility
AF013262	Lumican gene, complete cds	2.862	Small, leucine-rich proteoglycan which involves in the regulation of collagen fibril assembly
L02526	Protein kinase (MEK) mRNA	2.714	Signaling molecule in MAPK family
Y00769	mRNA for integrin beta subunit	2.521	Signaling molecular in cell adhesion, proliferation and migration

Table 3 A portion of up-regulated genes in activated HSC

GenBank accession number	Gene name	Ratio (Cy5/Cy3)	Potential gene function
AF061017	UDP-glucose dehydrogenase, mRNA complete cds	15.56	Glycosaminoglycan , hyaluronan and heparan sulfate biosynthesis
X65553	mRNA for poly (A) binding protein	7.405	A regulator of translation initiation
AF029844	Elongation factor 1-beta homology mRNA, complete cds	6.305	Translation factor and has multi-functions
NM_010798	Macrophage migration inhibitory factor (Mif), mRNA	5.847	Proinflammatory peptide and a mediator of growth factor dependent ERK MAP kinase activation and cell cycle progression
M31131	Neural cadherin (N-cadherin) mRNA	5.559	Cell adhesion molecule
AB029930	mRNA for caveolin-1 beta isoform	4.945	Inhibit the eNOS activity
D12618	mRNA for nucleosome assembly protein-1, complete cds	4.528	Histone H2A-H2B shutting protein that promotes histone deposition, and is important for maintaining chromatin structure
M22432	Protein synthesis elongation factor Tu (eEF-Yu, eEf-1-1alpha) mRNA, complete cds	4.344	Translation factor involved in the protein biosynthesis
D31717	mRNA for ribophorin	4.319	Glycoprotein synthesis
NM_012052	Ribosomal protein S3 (Rps3), mRNA	4.297	Protein biosynthesis
X72711	mRNA for replication factor C (140 Kda), long subunit	4.245	DNA synthesis and repair, and a regulator of NF-kappa B
X13460	Annexin VI, p68 (Mouse mRNA for p68 protein of the lipocortin family)	4.218	Calcium binding protein
NM_011290	Ribosomal protein L6 (Rp16), mRNA	4.089	Protein biosynthesis
U12273	Apurinic/apyrimidinic endonuclease (APEX) gene, complete cds	3.488	A DNA repair enzyme and an activator of several transcription factors
D42048	mRNA for squalene epoxidase	3.298	Rate-limiting enzyme of cholesterol biosynthesis
AJ250491	mRNA for receptor activity modifying protein 3 (Ramp3) gene	3.255	Complex with the calcitonin receptor-like receptor, establishing a functional receptor for adrenomedullin
L04280	Ribosomal protein (RPL12) mRNA	3.172	Protein biosynthesis
K02927	Ribonucleotide reductase subunit M1 mRNA, complete cds	3.156	Rate-limiting enzyme in DNA synthesis and repair
AF087568	Palmitoyl-protein thioesterase precursor mRNA, complete cds	3.059	Cell survival signaling
AF020039	NADP-dependent isocitrate dehydrogenase (Idh) mRNA, complete cds	3.038	A key enzyme of the tricarboxylic acid cycle
X57960	Ribosomal protein L7	2.962	Protein biosynthesis
U09816	GM2 activator protein (Gm2a) mRNA	2.888	Enzymatic hydrolysis of GM2
AB018575	Cdc 7 mRNA, complete cds	2.816	Essential for G1/S transition
AF041054	E1B19K/Bcl-2 binding protein homology (Nip3) mRNA, nuclear gene encoding mitochondria protein, complete cds	2.813	Nips is a pro-apoptotic mitochondria protein
L04128	Ribosomal protein L18 (rpL18) mRNA	2.751	Protein biosynthesis
Z31554	(129/SV) Cctd mRNA for CCT (chaperonin containing TCP-1) delta subunit	2.743	Stabilize the cytoskeletal protein actin and tubulin
D63784	mRNA for MIDA1, complete cds	2.703	Regulate cell growth
AF026481	eIF-1A (eIF-1A) mRNA, complete cds	2.682	Translation initiation factor
U35249	CDK-activating kinase assembly factor p36/MAT1, complete cds	2.645	An assembly factor and a targeting subunit of cyclin-dependent kinase-activating kinase that is involved in cell cycle control, transcription and DNA repair
M76131	Elongation factor (ef-2) mRNA, 3' end	2.614	Protein biosynthesis
X64713	mRNA for cyclin B1	2.576	Cell cycle regulatory protein
D26091	mRNA for mCDC47, complete cds	2.570	A member of the minichromosome maintenance (Mcm) family involve in the DNA replication licensing system
U78085	Ribosomal protein S5 mRNA	2.507	Protein synthesis
AF141322	Caveolin-2 mRNA, complete cds	2.458	Inhibit the eNOS activity
M33934	IMP dehydrogenase mRNA, complete cds	2.429	An enzyme involved in de novo synthesis of guanine nucleotides
U83628	Defender against cell death protein 1 (DAD1) mRNA, complete cds	2.372	Apoptotic suppressor gene

Table 4 Part of down-regulated genes in the activated HSC

GenBank accession number	Gene name	Ratio (Cy5/Cy3)	Potential gene function
D49949	mRNA for IGIF precursor poly-peptide in (Interleukin 18), complete cds	0.065	In the development of Th1 cells and tissue injury inflammatory reaction
U63146	Retinal binding protein (RBP) mRNA	0.125	Retinoid storage and metabolism
AF035644	Potentially prenylated protein tyrosine phosphatase mPRL-2 mRNA, complete cds	0.226	Cellular regulation
X58287	mR-PTPu gene for protein tyrosine phosphatase, receptor-type M	0.280	Cellular regulation
AF033381	Betaine homocysteine methyl transferase (BHMT) mRNA, complete cds	0.299	A key liver enzyme that is important for homocysteine homeostasis
M75720	Alpha-1 serine protease inhibitor 3 mRNA, complete cds	0.308	Anti-inflammatory effect
U20497	P19 protein mRNA, complete cds	0.324	CDK4&CDK6 inhibitor, cell cycle inhibitor
D85596	AMP deaminase H-type, complete cds	0.339	Involved in the biosynthesis, inter-conversion and degradation of purine compounds
Y10138	Gene encoding prostaglandin D synthase	0.361	A PGD producing enzyme and a retinoid transporter
NM_013498	CAMP response element modulator (CREM) mRNA	0.366	Down-regulator of CAMP-induced transcription
U67187	G protein signaling regulator RGS2 (rgs2) mRNA, complete cds	0.369	Negatively regulate G-coupled receptor function
AF023919	PK-120 precursor (itih-4) mRNA, complete cds	0.421	Inter-alpha-trypsin-inhibitor H4, is a potential regulator for ECM proteins
AF077950	Protein inhibitor of activated STAT protein PIAS 1 mRNA, complete cds	0.433	Inhibition of STAT-1-mediated gene activation
M75718	Alpha-1 protease inhibitor 4 mRNA, complete cds	0.437	Anti-inflammatory activity
D38046	mRNA for type II DNA topoisomerase beta isoform, complete cds	0.445	An essential enzyme that alters DNA topology which is important for cell survive and apoptosis
AF073996	myotubularin (Mtm1) mRNA complete cds	0.464	Subfamily of protein tyrosine phosphatases

Table 5 Semi-quantitative analysis of RT-PCR results

Groups	Mean±SD (quotient of the detected gene/GAPDH)	N	p value
MIF from quiescent HSC	0.269±0.016	5	
MIF from activated HSC	0.759±0.046	5	<0.05
N-Cadherin from quiescent HSC	0.177±0.063	5	
N-Cadherin from activated HSC	0.776±0.087	5	<0.05
Annexin VI from quiescent HSC	0.137±0.04	5	
Annexin VI from activated HSC	0.478±0.025	5	<0.05
DAD1 from quiescent HSC	0.174±0.016	5	
DAD1 from activated HSC	0.593±0.047	5	<0.05
BHMT from quiescent HSC	0.602±0.083	5	
BHMT from activated HSC	0.134±0.059	5	<0.05

In the up-regulated genes associated with the activation of HSC, some genes have already been reported (Table 2). Alpha B-crystallin was first reported by Lang *et al*^[11] recently as an early marker for HSC activation. In our experiment, the ratio of Cy5 to Cy3 for its mRNA was the highest in all the genes in the gene-chip, suggesting that mRNA expression of alpha B-crystallin in activated HSC up-regulated mostly comparing with the quiescent HSC. The mRNA expression for procollagen type III^[12], fibronectin^[13], laminin receptor, prolyl 4-hydroxylase^[14], TIMP-2, TGF-beta and its receptor binding protein^[15], MEK^[16] and integrin beta^[17] was increased in activated HSC. Tetraspanins (TM4SF) super family which includes CD9, CD53, CD81 and CD151 were highly expressed in the activated human HSC and have been implicated in HSC migration, a key event in liver

tissue wound healing and fibrogenesis^[18]. Secreted protein, acidic and rich in cysteine (SPARC), which functions in tissue remodeling, was expressed by activated HSC in chronic hepatitis, suggesting the involvement of SPARC in hepatic fibrogenesis after chronic injuries^[19]. Lumican is a small leucine-rich proteoglycan, which contributes to cell migration, proliferation, tissue hydration and collagen fibrillogenesis, and its expression is increased in HSC in diseased liver during the process of fibrogenesis^[20]. Although we employed different methods, animal models or different sources of HSC, our experimental data was consistent with the results observed by others, demonstrating that the technique of cDNA microarray has a higher reliability. In addition, the expression of those that were not previously linked to the activation of HSC was also

found to be changed. These include genes involved in the control of HSC morphology, growth, differentiation, migration and apoptosis.

Analysis of the genes showed elevated expression in the activated HSC clustered into distinct functional groups. Genes showing elevated expression included many genes involved in the formation and remodeling of the extracellular matrix (ECM) and in the regulation of cellular response (including cell adhesion, proliferation and migration) to the ECM, such as procollagen type III, fibronectin, TIMP-2, TGF beta, UDP-glucose dehydrogenase (AF061017), N-cadherin (M131131) and lumican (AF013262).

The enzyme UDP-glucose dehydrogenase (Udpghd) (EC 1.1.1.22) converts UDP-glucose to UDP-glucuronate, a critical component of the glycosaminoglycans, hyaluronan, chondroitin sulfate and heparan sulfate^[21]. It is known that heparan sulfate proteoglycans are essential cofactors in cell-matrix adhesion processes, in cell-cell recognition system, and in receptor-growth factor interactions. Cultured human HSC can synthesize all four cyndecans and the increased expression of glycosaminoglycans and hyaluronic acid may be important in the deposition of matrix components and activation of growth factors accompanying fibrogenesis. Our results suggested that the increased expression of heparan sulfate proteoglycans in activated HSC might be partially caused by the elevated expression of the enzyme UDP-glucose dehydrogenase.

Neural cadherin (N-cadherin) is an adhesion molecule of the cadherin family, whose expression was up regulated in response of smooth muscle cells to arterial injury^[22]. Annexin VI is a 68-Kda protein of the annexin family, a group of structural similar, calcium-dependent, phospholipid-binding proteins^[23]. Our cDNA microarray data along with the RT-PCR results showed increased expression of N-cadherin and annexin VI in activated HSC, suggesting their regulations might be important for the hepatic fibrogenesis.

In all cells, protein synthesis is coordinated by the ribosome, and the large ribonucleoprotein is composed of at least 50 distinct molecules and several large RNA molecules. Genes showing elevated expression included many genes that encode ribosomal proteins and proteins involved in the translation and protein synthesis, such as mRNA for poly A-binding protein (X65553), elongation factor 1-beta homology mRNA (AF029844), elongation factor Tu (M22432), ribosomal protein S3 (NM_012052), S5 (U78085), L6 (NM_011290), L12 (L04280), L18 (L04128) and eukaryotic initiation factor 1A (eIF1A) (AF026481). HSC proliferated during the process of activation, so it is not surprising that many genes involved in the protein synthesis up-regulated in the activated HSC.

Our work has identified some previously unreported genes involved in DNA synthesis and repair showing elevated expression in the activated HSC, such as replication factor C gene (X72711), apurinic/aprimidinic endonuclease (APEX) gene (U12273), ribonucleotide reductase subunit M1 (M1-RR) mRNA (K02917), and IMP dehydrogenase mRNA (M33934), an enzyme involved in *de novo* synthesis of guanine nucleotides.

Replication factor C (RFC) is a clamp loader, catalyzes assembly of circular proliferating cell nuclear antigen clamps around primed DNA, enabling processive synthesis by DNA polymerase during DNA replication and repair. The Rel A (p65) subunit of NF-kappa B is an important regulator of inflammation, proliferation and apoptosis, but the large subunit of RFC can function as a regulator of Rel A. In addition to its previously described function in DNA replication and repair, RFC plays an important role as a regulator of transcription factor NF-kappa B activity^[24].

APEX nuclease is a mammalian DNA repair enzyme having apurinic/aprimidinic endonuclease, 3' -5' -exonuclease, DNA 3' repair diesterase and DNA 3' -phosphatase activities. It is also a redox factor (Ref-1), stimulating DNA binding activity of

AP-1 binding proteins such as Fos and Jun^[25]. Ribonucleotide reductase (RR) is a cytoplasmatic enzyme catalyzing the reduction of all four ribonucleotides to their corresponding deoxyribonucleotides, so it is a rate-limiting enzyme in the DNA synthesis and repair. Its activity strongly correlates to the rate of DNA synthesis, and the expression of M1-RR antigen was found to correlate positively with the expression of Ki-67 and PCNA, the cell cycle markers of proliferating cells^[26]. We conclude that mechanisms for DNA synthesis and repair are activated during the process of HSC activation.

Elevated expression was also observed for a number of genes involved in the control of cell growth, survival, differentiation and apoptosis. Palmitoyl-protein thioesterase (PPT) is a newly described lysosomal enzyme that hydrolyzes long chain fatty acids from lipid-modified cysteine residues in proteins, and its precursor mRNA (AF087568) was up-regulated in activated HSC. It was reported that inhibition of PPT increased the susceptibility of neurons to apoptotic cell death^[27]. Id, a helix-loop-helix protein not only regulates cell differentiation negatively, but also promote growth and apoptosis, and an Id-associate protein, MIDA1 (Mouse Id associate1), regulated cell growth positively. MIDA1 is a novel sequence-specific DNA binding protein with some different properties from the usual transcription factors and may act as a mediator of Id-mediated growth-promoting function through its DNA binding activity^[28], and its gene expression was increased in the activated HSC.

The cyclin-dependent kinase (CDK)-activating kinase (CAK) is involved in cell cycle control, transcription, and DNA repair, and MAT1 gene (U35249), an assembly factor and a targeting subunit of CAK, was also up regulated in the activated HSC. It was reported that abrogation of MAT1 expression by retrovirus-mediated gene transfer of antisense MAT1 RNA in cultured rat aortic smooth muscle cells (SMC) retarded SMC proliferation and inhibits cell activation from a nonproliferation state, and this effect was due to G1 phase arrest and apoptotic cell death^[29].

Up-regulation of the DAD1 (U83628), a putative anti-apoptosis gene identified in several distantly related organisms^[28], was observed as well as the Nip3 (AF041054), a proapoptotic member of the Bcl-2 family of cell death factors^[29] in the activated HSC. CDC7, an evolutionarily conserved serine-threonine kinase, plays a pivotal role in linking cell cycle regulation to genome duplication, being essential for the firing of DNA replication origins^[30]. Our microarray experiments also identified elevated expression for CDC7 gene (AB018575) and cyclin B₁ (X64713) in the activated HSC. The strategy for terminating the proliferation of activated HSC by apoptosis might be an exciting therapy for patients with chronic liver injury and fibrosis^[10,31], therefore, our experimental data about the differentially expressed genes involved in apoptosis will give some new ideas on induce apoptosis in HSC.

Macrophage migration inhibitory factor (MIF) (NM_010798), a pro-inflammatory peptide and a mediator of growth factor-dependent ERK MAP kinase activation and cell cycle progression^[32], was up-regulated by the process of HSC activation. MIF has been shown to contribute significantly to the development of immuno-pathology in several models of inflammatory, such as glomerulonephritis^[33]. Our RT-PCR results confirmed the increased expression of MIF mRNA in the activated HSC. This is the first study to demonstrate that activated HSC can produce MIF *in vitro*, and its up-regulation in activated HSC might suggest a role for MIF in the hepatic fibrogenesis *in vivo*. It is necessary to carry further more research to understand how MIF regulates proliferation in activated HSC.

Down-regulation was observed for genes encoding interleukin 18 (D49949) and retinal binding protein (RBP) (U63146) in the activated HSC. IL-18 has an anti-fibrotic effect and it was reported that intrasplenic transplantation of IL-18

gene modified hepatocytes could be a candidate for therapeutic intervention in hepatic fibrosis through induction of a dominant Th1 response^[34]. HSCs are the body's major cellular storage sites for retinoid, but the immortalized rat HSC cell line HSC-T6 failed to express RBP^[35]. Our cDNA microarray results were consistent with the previous reports.

In the activated HSC, reduced expression was observed for genes involved in general cellular regulation including a family of protein-tyrosine phosphatase (PTPases) and some negative regulators of cell growth signaling, such as P19 protein (U20497), CAMP response element modulator (Crem)(NM_013498), G protein signaling regulator RGS2 (U67187), and protein inhibitor of activated STAT protein - PIAS1 (AF077950). The PTPases included the potentially prenylated protein tyrosine phosphatase mPRL-2 (AF035644)^[36], myotubularin (Mtm1)(AF071996)^[37] and mR-PTPu gene for protein tyrosine phosphatase, receptor type M. Protein tyrosine kinase and phosphatase play diverse roles in involving energy metabolism, cell proliferation and stimulation of MHC class I molecule pathway. Down-regulation was also observed for the alpha-1 serine protease inhibitor 3 (M75720), alpha-1 protease inhibitor 4 (M75718) and PK-120 precursor (itih-4)(AF023919), a serine protease inhibitor.

P19 is a tumor suppressing protein and belongs to a family of cyclin D-dependent kinase inhibitors of CDK4 and CDK6, which play a key role in human cell cycle control^[38]. Addition of p19 protein can lead to inhibition of the CDK's activity and may cause the cells to arrest at G1 phase. Transcriptional factors binding to camp-response elements (CREs) in the promoters of various genes belong to the basic domain-leucine zipper super family and are composed of three genes in mammals, CREB, CREM, and ATF-1. Activation is classically brought about by signaling-dependent phosphorylation of a key acceptor site (Ser133 in CREB) by a number of possible kinases, including PKA, CamKIV and RSK-2. Repression may involve dynamic dephosphorylation of the activators and decreased association with CREB-binding protein (CBP). Another pathway of transcriptional repression on CRE sites implicates the inducible repressor ICER (inducible camp early repressor), a product of the CREM gene. Being an inducible repressor, ICER is involved in auto-regulatory feedback loops of transcription that govern the down-regulation of early response genes, such as the proto-oncogene c-fos^[39]. It is known that CREB is one of the transcription factors whose expression is increased in the activated HSC during the liver injury^[40], but the important role of CREM in the pathophysiology of liver fibrogenesis has not been studied. Similarly, Jak-Stat signaling is one of the signaling pathways in the HSC proliferation and activation^[41], but the role of a negative regulator in this cytokine signaling, protein inhibitor of activated STAT-1 (PIAS-1), has not been understood. Thus, our microarray data might provide novel potential approaches to the treatment of hepatic fibrogenesis in patients with chronic liver diseases.

Reduced mRNA expression was also found for betaine-homocysteine methyl transferase (BHMT). BHMT is a key liver enzyme for homocysteine (Hcy) homeostasis. It catalyzes the synthesis of methionine from betaine and homocysteine, utilizing a zinc ion to activate Hcy. Elevated plasma levels of Hcy have been shown to interfere with normal cell function in a variety of tissues and organs, such as the vascular wall and the liver. It is known that Hcy is able to induce the expression and synthesis of the TIMP-1 in variety of cell types ranging from vascular smooth muscle cells to hepatocytes, HepG2 cells and HSCs. In HSCs, Hcy also stimulates alpha₁(I) procollagen mRNA expression, promotes activating protein-1 (AP-1) binding activity^[42]. Hcy is a key metabolite in methionine metabolism, which takes place mainly in the liver. Hyperhomocysteinemia may develop as a consequence of defects in Hcy-metabolizing genes (such as BHMT); nutritional conditions leading to vitamin

B (6), B (12), or folate deficiencies; or chronic alcohol consumption. We postulated that hyperhomocysteinemia in the hepatic fibrosis was partly due to the reduced expression of BHMT gene in the activated HSC.

We used cDNA array analysis to detect genes whose mRNA expression changes in the activated mouse HSC after culture on the plastic dishes. RT-PCR analysis confirmed the up-regulation of four previously unreported transcripts and down-regulation of one gene in activated HSC. The identity of these genes provides new insights into the understanding of activation of HSC during the liver injury and hepatic fibrogenesis.

Abstract

AIM: To investigate the importance of direct contact between Kupffer cells (KCs) and hepatocytes (HCs) during hepatic inflammatory responses, and the effect of leflunomide's active metabolite, A₇₇₁₇₂₆, on cytokines in KCs, HCs and KC cocultures (DC cocultures).

METHODS: KCs and HCs in liver were isolated by digestion with pronase and collagenase. Lipopolysaccharide (LPS)-induced inflammatory response in monocultures of rat HCs and KCs was compared with that in DC cocultures. Tumor necrosis factor- α (TNF- α) and interleukin-1 (IL-1) concentrations in different culture supernatants were measured with ELISA. TNF- α mRNA in KCs of inflammatory liver injury was analyzed with reverse transcriptase polymerase chain reaction (RT-PCR).

RESULTS: DC cocultures strongly exhibited the production of TNF- α and IL-1 compared with other cultures, and these cytokines were mainly produced by KCs, especially by activated KCs. Time course studies revealed an increased production of TNF- α preceding the IL-1 production, suggesting that increased TNF- α levels could be involved in the increase of IL-1 production. Leflunomide's active metabolite, A₇₇₁₇₂₆, had significantly inhibitory effect on TNF- α and IL-1 at protein and transcription levels, and the reduced production of IL-1 by A₇₇₁₇₂₆ was associated with the inhibitory action of A₇₇₁₇₂₆ on TNF- α .

CONCLUSION: Leflunomide can inhibit hepatocyte damage by inhibiting proinflammatory cytokine release from KCs.

INTRODUCTION

Tissue inflammation plays a critical role in liver pathology via induction of cellular injury. In fact, infiltration of mononuclear phagocytes into the liver correlates with the severity of liver

injury. Moreover, proinflammatory cytokines such as tumor necrosis factor- α (TNF- α) and interleukin-1 (IL-1) have been linked to the promotion of liver injury^[1-3], and the anti-inflammatory cytokine interleukin-10 (IL-10) was believed to inhibit liver injury^[4,5]. Kupffer cells (KCs) are among the first cells that respond to endotoxins, including lipopolysaccharides (LPS), and are considered to be the primary macrophages involved in the clearance of gut-derived bacteria or bacterial toxins. High portal level of LPS could lead to a pronounced secretion of proinflammatory mediators by KCs and ultimately to endotoxin-induced liver injury^[6,7]. KCs are located in hepatic sinusoids and lie in between or on top of endothelial cells. However, they do have direct cell contacts with parenchymatous hepatocytes (HCs) through their cytoplasmic extensions. Cellular communication between KCs and HCs has been thought to occur mainly by production of cytokines and excretion of inflammatory mediators such as eicosanoids, nitric oxide (NO), and/or reactive oxygen species (ROS)^[8,9]. Proinflammatory cytokines, TNF- α and IL-1 in particular, have been shown to be early and important mediators of HC injury^[8,10].

Leflunomide, an isoxazole derivative and a unique immunomodulatory agent, is capable of treating rheumatoid arthritis, allograft and xenograft rejection, systemic lupus erythematosus, Crohn's disease, and prostate cancer^[11-16]. Leflunomide is a prodrug that could be rapidly converted in the cell to an active metabolite, A₇₇₁₇₂₆^[17-19]. Our investigations demonstrated that leflunomide had therapeutic actions on acute and chronic liver diseases^[20-22]. In order to study the mechanisms of leflunomide on liver injury, the interaction between KCs and HCs *in vitro*, and the effect of leflunomide's active metabolite, A₇₇₁₇₂₆, on TNF- α and IL-1 were investigated.

MATERIALS AND METHODS

Animals and reagents

Male Sprague-Dawley rats weighing 200-250 g were purchased from Animal Center of Anhui Medical University. Rats were allowed to take food and tap water *ad libitum*. *Bacillus Calmette-Guérin* (BCG) was purchased from Institute of Shanghai Biological company. Collagenase, Nycodenz, LPS from *Escherichia coli* O111:B4, 3-(4,5-dimethylthiazol-2-yl)-2, 5-diphenyltetrazolium bromide (MTT), and ELISA kits of TNF- α and IL-1 were obtained from Sigma Chemical (St. Louis, Mo). Powdered 1640 medium was obtained from GIBCO Co., USA. Leflunomide and its active metabolite, A₇₇₁₇₂₆, were kindly donated by Cinkate Co., USA.

Preparation of inflammatory liver injury

Each rat was injected with 15 mg BCG in 0.2 mL saline via tail vein, and 14 d later with 10 μ g LPS in 0.2 mL saline^[23]. At 16 h post-injection of LPS, rats were anesthetized and KCs were isolated.

Preparation of HCs

The procedure for isolation of rat HCs was based on Seglen's method^[24], with some modifications. The obtained cell suspension was diluted in modified Hanks' buffered salt solution

(pH 7.65, 4 °C, 9.2 mmol/L HEPES, 9.91 g/L Hanks' buffered salt solution without Ca^{2+} and Mg^{2+}) and centrifuged at 200 g for 5 min. The supernatant was discarded, and cells were resuspended with PBS (pH 7.4) to a final volume of 100 mL and centrifuged for 2 min at 50 g. The supernatant, containing mainly nonparenchymal cells, was collected for isolation of KCs (see Preparation of KCs). Pellets containing mainly HCs were resuspended in RPMI 1640 medium and washed 4 times for 2 min at 50 g. After the final wash step, cells were counted and diluted with RPMI 1640 medium supplemented with 50 mL/L FBS, glutamine (2 mmol/L), and gentamicin (50 µg/mL) to a final concentration of 1×10^6 cells/mL. Viability of cultures was $\geq 95\%$ as assessed by trypan blue dye exclusion. Light microscopic observations revealed a purity of 90–95% HCs for HC cultures.

Preparation of KCs

The procedure for KCs isolation was based on the method of Smedsrod *et al.*^[25], with slight modifications. Supernatants (see Preparation of HC cultures) containing mainly nonparenchymal cells were transferred to four 50 mL Falcon tubes followed by centrifugation at 50 g in a swing-out rotor at 4 °C for 2 min. This procedure was repeated twice to discard the remaining HCs. After the final step, supernatants were centrifuged at 200 g in a swing-out rotor at 4 °C for 10 min, and discarded. The resulting pellets were resuspended in PBS to a final volume of 40 mL. The nonparenchymal cell suspension was prepared by centrifugation on a double-layered (17.2%/11.5%) Nycodenz solution. After centrifugation at 1400 g for 20 min (4 °C), KCs and endothelial cells were present at the boundary between the upper and lower layers. The cell suspension containing both KCs and endothelial cells, was collected and centrifuged at 200 g for 10 min, and the resulting pellets were diluted with RPMI 1640 medium (without serum) and washed again. Hereafter, the pellets consisting of 50% KCs and 50% endothelial cells were diluted in RPMI 1640 medium (without serum) to a final concentration of 2×10^6 cells/mL. To separate KCs from endothelial cells, cells were plated on tissue culture plates at 37 °C and 50 mL/L CO_2 for 30 min followed by a single wash step discarding the nonadherent endothelial cells. Viability of KCs was $\geq 95\%$ as determined by trypan blue dye exclusion assay. Immunohistochemistry and fluoroscopy revealed a purity of $\geq 85\%$ KCs for KC cultures.

Cell cultures

HCs were cultured at a density of 0.5×10^6 cells/well in 24-well culture dishes using RPMI 1640 medium, supplemented with 50 mL/L FBS, glutamine (2 mmol/L), and gentamicin (50 µg/mL). KCs were cultured in RPMI 1640 medium containing 100 mL/L FBS, 2 mmol/L glutamine, and 50 µg/mL gentamicin at a density of 0.5×10^6 cells/well in 24-well culture dishes. DC cocultures consisted of 0.5×10^6 attached KCs in 24-well tissue culture plates with the addition of 0.5×10^6 HCs in direct contact. RPMI 1640 medium supplemented with 50 mL/L FBS, glutamine (2 mmol/L), and gentamicin (50 µg/mL) was used. After an attachment period of 4 h, the medium was replaced by a fresh medium in all culture types.

Experimental design

After a recovery period of 24 h at 37 °C and 50 mL/L CO_2 , the medium was replaced by a medium containing 0, 1, 5, or 10 µg/mL LPS. Because HCs are known to produce various important serum compounds such as LPS-binding protein, medium of KC cultures still contained 50 mL/L FBS. After 2, 4, 8, and 24 h of incubation, tissue culture supernatants were collected for analysis of cytokines. To study the effect of A_{771726} on excretion of TNF- α and IL-1 in DC coculture supernatants, A_{771726} was dissolved with RPMI 1640 medium and added to DC cocultures

from 0 h to 4 h (0–4 h), to 24 h (0–24 h) and from 4 h to 24 h (4–24 h) after incubation with LPS, respectively.

Measurement of TNF- α and IL-1

TNF- α and IL-1 concentrations in cell culture supernatants were measured using commercial ELISA kits with recombinant rat TNF- α and IL-1 as standard. Measurements were performed in duplicate.

Semiquantitative RT-PCR assay for TNF- α mRNA in KCs of inflammatory liver tissue

After incubation with or without A_{771726} (0.001–10 µmol/L), KCs of inflammatory liver tissue were harvested and kept at -70 °C until RNA extraction. Total cellular RNA was extracted using RNA easy kits (Invitrogen, USA). To test the efficacy of reverse transcriptase, RT-PCR was performed for GPDH mRNA. Briefly, the first strain of cDNA was synthesized by reverse transcriptase and pooled. The resulting cDNA samples were adjusted to PCR buffer conditions and run for PCR simultaneously. The primers for TNF- α were 5' -CGAGTGACAAGCCCGTAGCC and 5' -GGATGAACACGCCAGTCGCC. The primers for GPDH were 5' -CCACCCATGGCAAATTCATGGCA and 5' -TCTAGACGGCAGGTCAGGTCCACC^[26]. The amplification of TNF- α and GPDH genes was expected to generate 753 bp and 600 bp fragments, respectively. Amplification was performed for 35 cycles, each consisting of denaturation at 94 °C for 1 min, annealing at 51 °C for 1 min, and extension at 72 °C for 2 min. Ten µL of reaction mixture was loaded to 10 g/L agarose gel containing 0.5 µg/mL ethidium bromide for electrophoresis, the gel was then placed under ultraviolet ray for semi-quantitation detection.

Statistics

Unless stated otherwise, data were expressed as mean \pm SD and evaluated using two-way ANOVA followed by Student's *t* test for comparison between 2 groups. $P < 0.05$ was considered statistically significant.

RESULTS

Proinflammatory cytokine production after stimulation with LPS

The production of TNF- α and IL-1 was measured after incubation of HC and KC cultures, and DC cocultures in medium with or without LPS. A time course study showed that maximal cytokine levels in KC cultures and DC cocultures were observed after 4 h incubation for TNF- α and 24 h incubation for IL-1 respectively (Figure 1). Moreover, TNF- α and IL-1 levels in culture supernatants were positive correlated with the concentration of LPS (Figure 2). TNF- α and IL-1 levels at 2, 4, 8, 24 h in DC cocultures were significantly higher than those in KC or HC cultures (Figure 1). However, two cytokines levels in HC cultures showed no statistically significant changes throughout the experiments (Figures 1–2).

Effect of A_{771726} on TNF- α and IL-1 production in DC cocultures after stimulation with LPS

Based on the results as above, we selected DC cocultures stimulated with 10 µg/mL LPS as targets, and A_{771726} was added to DC cocultures with different time course. After 4 h incubation (0–4 h), TNF- α and IL-1 production in DC cocultures stimulated with LPS (10 µg/mL) was significantly inhibited in A_{771726} (0.1, 10 µmol/L) and dexamethasone (2×10^{-5} µmol/L) group (Figure 3A). Likewise, TNF- α and IL-1 production in DC cocultures was also significantly inhibited after 24 h incubation (0–24 h) in A_{771726} (10 µmol/L) group (Figure 3B). Because the concentration of TNF- α reached its maximal level after 4 h incubation, we designed a protocol that A_{771726} was added to DC cocultures from 4 h to 24 h after incubation (4–24 h). The results showed

that the concentration of TNF- α and IL-1 in DC cocultures supernatants was not inhibited in A_{771726} (10 $\mu\text{mol/L}$, 4-24 h) group (Figure 3B). Furthermore, TNF- α and IL-1 levels in A_{771726} (10 $\mu\text{mol/L}$, 0-24 h) group were significantly lower than those in A_{771726} (10 $\mu\text{mol/L}$, 4-24 h) group.

Figure 2 Changes of TNF- α and IL-1 levels in culture supernatants of HC, DC, KC after 4 h and 24 h incubation with various concentrations of LPS ($n=3$, mean \pm SD). ^b $P<0.01$ for TNF- α and IL-1 levels in DC, KC vs control; ^d $P<0.01$ for DC coculture vs other cultures after 0, 1, 5, and 10 $\mu\text{g/mL}$ LPS. A: Changes of TNF- α levels in culture supernatants of HC, DC, KC after 4 h incubation with various concentrations of LPS. B: Changes of IL-1 levels in culture supernatants of HC, DC, KC after 24 h incubation with various concentrations of LPS.

Effect of A_{771726} on TNF- α mRNA in KCs of inflammatory liver tissue
 A_{771726} had significantly inhibitory actions on the production of TNF- α in supernatants of DC cocultures. To gain insights into the potentially inhibitory action of A_{771726} on TNF- α via transcriptional level, TNF- α mRNA was analyzed by RT-PCR in KCs during liver inflammation induced by injection with BCG and LPS. Gel electrophoresis and semiquantitation analysis showed that A_{771726} significantly reduced the expression of TNF- α mRNA in KCs of inflammatory liver tissue induced by BCG and LPS (Figure 4, Table 1).

DISCUSSION

In the intact liver, HCs are in direct contact with KCs. The present experiments were designed to assess whether direct contact between HCs and KCs was of influence on the LPS-induced inflammatory response. When compared the production of TNF- α and IL-1 in the different culture types, direct cell-to-cell contact between KCs and HCs seemed to be essential, because an 4- or 7-fold increase of TNF- α and IL-1, could be observed in DC cocultures. Although the cytokine levels in KC cultures were markedly lower than those observed in DC cocultures, incubation of KC cultures with LPS still resulted in an abundant cytokine response. LPS-induced cytokine expression in DC cocultures or KC cultures has been extensively studied, but in this study we showed that direct contact between KCs and HCs significantly increased TNF- α and IL-1 production by rat KCs. However, the levels of two cytokines in HC cultures showed no statistically significant changes throughout the experiments. The results indicated proinflammatory mediators such as TNF- α and IL-1 in culture supernatants were mainly produced by KCs, especially activated KCs. Time course studies performed with these cultures revealed an increased production of TNF- α preceding the IL-1 production, suggesting that increased TNF- α levels could be involved in IL-1 production. The results were consistent with Shito's report^[1] that TNF- α could be a cause of liver injury and might help regulate the expression of IL-1.

Leflunomide was mainly used to inhibit the activity of dihydroorotate dehydrogenase (DHODH) involved in *de novo* pyrimidine biosynthesis. But at a high concentration, it mainly inhibited protein tyrosine kinases initiating signaling, and therefore reduced the cell response to mitogens and cytokines. Recent evidences suggested the anti-inflammatory and immunoregulatory effects of leflunomide were related with its ability to suppress TNF- α and IL-1 selectively over their inhibitors in T lymphocyte/monocyte activation, and the activation of nuclear factor kappa B, a potent mediator of inflammation when stimulated by inflammatory stimuli. We found that TNF- α and IL-1 levels in supernatants of DC cocultures were apparently inhibited by A₇₇₁₇₂₆ (0.1, 10 μ mol/L, 0-4 h) and A₇₇₁₇₂₆ (10 μ mol/L, 0-24 h). However, TNF- α and IL-1 levels in supernatants of DC cocultures were not affected in A₇₇₁₇₂₆ (10 μ mol/L, 4-24 h) group, and the levels of the two cytokines in A₇₇₁₇₂₆ (10 μ mol/L, 0-24 h) group were significantly lower than those in A₇₇₁₇₂₆ (10 μ mol/L, 4-24 h) group. The results indicated that the inhibitory action of A₇₇₁₇₂₆ on TNF- α and IL-1 levels was generated mainly from 0-4 h incubation, and reduced production of IL-1 by A₇₇₁₇₂₆ was associated with the inhibitory action of A₇₇₁₇₂₆ on TNF- α . Furthermore, RT-PCR analysis showed that A₇₇₁₇₂₆ significantly reduced the expression of TNF- α mRNA in KCs of inflammatory liver tissue induced by BCG+LPS. The results showed A₇₇₁₇₂₆ had significantly inhibitory effects on production of TNF- α in KCs at transcriptional level.

Although further work is required to demonstrate whether A₇₇₁₇₂₆ has other targets in inflammatory liver injury, A₇₇₁₇₂₆ can inhibit hepatocyte damage by inhibiting proinflammatory cytokine release from KCs.

Abstract

AIM: To investigate the modification of baculovirus vector and the feasibility of delivering exogenous genes into mammalian cells with the culture supernatant of *Spodoptera frugiperda* (Sf9) cells infected by recombinant baculoviruses.

METHODS: Two recombinant baculoviruses (BacV-CMV-EGFP, BacV-CMV-EGFPB) containing CMV-EGFP expression cassette were constructed. HepG2 cells were directly incubated with the culture supernatant of Sf9 cells infected by recombinant baculoviruses, and reporter gene transfer and expression efficiencies were analyzed by flow cytometry (FCM). The optimal transduction conditions were investigated by FCM assay in HepG2 cells. Gene-transfer and expression efficiencies in HepG2 or CV1 cells by baculovirus vectors were compared with lipofectAMINE, recombinant retrovirus and vaccinia virus expression systems. Twenty different mammalian cell lines were used to investigate the feasibility of delivering exogenous genes into different mammalian cells with the culture supernatant of infected Sf9 cells.

RESULTS: CMV promoter could directly express reporter genes in Sf9 cells with a relatively low efficiency. Target cells incubated with the 1:1 diluted culture supernatant (moi=50) for 12 h at 37 °C could achieve the highest transduction and expression efficiencies with least impairment to cell viability. Under similar conditions the baculovirus vector could achieve the highest gene-transfer and expression efficiency than lipofectAMINE, recombinant retrovirus and vaccinia virus expression systems. Most mammalian cell lines could be transduced with recombinant baculovirus. In primate adherent culture cells the recombinant baculovirus could arrive the highest infection and expression efficiencies, but it was not very satisfactory in the cell lines from mice and suspended culture cells.

CONCLUSION: Mammalian cells incubated with the culture supernatant of infected Sf9 cells could serve as a very convenient way for rapid and efficient expression of foreign genes in mammalian cells, but it might be more suitable for primate adherent culture cells.

INTRODUCTION

The baculovirus (*Autographa californica* multiple nuclear polyhedrosis virus, AcMNPV) insect cell expression system has been extensively developed and widely used for the production of numerous recombinant proteins in insect cells^[1-5]. As the previous reports described, baculovirus had a strict host range, which was only limited to lepidopteran insects. However, researchers have reported that baculoviruses can be taken up by some mammalian cells^[6,7], but are incapable of replicating in these mammalian cells^[8,9]. A modified AcMNPV containing promoters that are active in mammalian cells, such as Rous sarcoma virus (RSV) promoter and cytomegalovirus immediate early (CMV-IE) promoter, can express exogenous genes in mammalian cells^[10-14]. So a new way could be chosen by researchers for experiments of delivering target genes into mammalian cells, besides the conventional lipid transfection and mammalian viral vector expression systems, such as retrovirus expression system, adenovirus expression system. Previous reports have described that recombinant baculoviruses used in gene-transfer experiments were often concentrated by ultracentrifugation. Although this way can markedly increase the virus titer, but it needs to culture a large number of cells to obtain sufficient viruses, and the manipulation is complex and burdensome. So it is inconvenient in some daily common experiments.

Bac-to-Bac system is the most often used baculovirus-based expression system for the production of recombinant proteins in insect cells. In our research, based on the Bac-to-Bac system recombinant baculoviruses were constructed, which contain the enhanced green fluorescent protein (eGFP) gene driven by CMV promoter, to investigate the modification of baculovirus vector and the feasibility of delivering exogenous genes into mammalian cells with the culture supernatant of Sf9 cells infected by recombinant baculoviruses. Compared with lipid transfection, retrovirus and vaccinia virus expression system, efficiencies of gene transfer and expression in mammalian cells by the culture supernatant of infected Sf9 cells were superior to the traditional ways. Since direct application of the culture supernatant could simplify the procedures of delivering foreign genes into mammalian cells by baculovirus vectors, it could serve as a valuable tool for some daily common experiments.

MATERIALS AND METHODS

Cell lines

Spodoptera frugiperda (Sf9) cell line was purchased from Invitrogen (California, USA). CV1, 293, 143B, HepG2, PLC/PRF/5, BNL 1ME A.7R.1, WI-38, DMS-114, JC, L-929, P815, PT67 cell lines were obtained from the American Type Culture Collection. HeLa, CHO, NIH3T3, Raji, CNE, MCF-7, BGC-223 cell lines were stored in our laboratory. LCL-cm and pT67-EGFP cell lines were constructed in our laboratory.

Bacteria and plasmids

E.coli DH5 α was stored in our laboratory. *E.coli* DH10Bac was purchased from Invitrogen (California, USA). pcDNA3.1

(+) was purchased from Invitrogen (California, USA). pEGFP was purchased from Clontech (California, USA). pMD18-EF1A, pCDNA3.1-EGFP was constructed in our laboratory.

Construction of shuttle vectors

Plasmid pEGFP was digested with *Bam*HI and *Eco*RI, a 760 bp fragment containing EGFP gene was retrieved and inserted into the pFastBacI backbone that was digested with *Bam*HI and *Eco*RI to form pFB-EGFP. EGFP gene was moved from pEGFP to pCDNA3.1(+) as an *Eco*RI-*Bam*HI fragment to construct pN31-EGFP. An 1.6 kb *Bgl*III-*Eco*RI fragment from pN31-EGFP, containing CMV-IE promoter/enhancer and EGFP gene, was inserted into the pFastBacI backbone which was digested with *Bam*HI and *Eco*RI to obtain pFB-CMV-EGFP. A *Bgl*III-*Bam*HI fragment containing the polyadenylation signal was inserted into the *Bam*HI site of pFastBacI to construct pFB-EF1A. An 1.6 kb *Sal*I-*Eco*RI fragment from pN31-EGFP was inserted into pFB-EF1A which was digested with *Xho*I and *Eco*RI to construct pFB-CMV-EGFPB (Figure 1).

Construction of recombinant baculoviruses^[15]

Shuttle vectors pFB-EGFP, pFB-CMV-EGFP, pFB-CMV-EGFPB were transformed into *E. coli* DH10Bac cells, which were incubated on LB agar plates containing 100 µg/mL Blu-gal, 40 µg/mL IPTG, 7 µg/mL gentamicin, 50 µg/mL kanamycin, 10 µg/mL tetracycline for 24-48 h at 37 °C. White colonies were inoculated into LB medium containing the same antibiotics and bacmid DNA was isolated according to the standard manual (Invitrogen).

pUC/M13 amplification primers were directed at sequences on either side of the miniattTn7 site within the *lacZ*α-complementation region of bacmid. If transposition occurred, the PCR product produced by these primers (at 94 °C for 50 s, at 55 °C for 50 s, at 72 °C for 5 min, 30 cycles, at 72 °C for 10 min) was 2 300 bp plus the size of the insert. The PCR product of bacmid alone was about 300 bp, bacmid transposed with pFB-EGFP was 3 060 bp, bacmid transposed with pFB-CMV-EGFP was 3 978 bp, and bacmid transposed with pFB-CMV-EGFPB was 4 633 bp.

Sf9 cells were cultured in Grace's supplemented insect medium containing 100 mL/L fetal bovine serum (HyClone). Recombinant baculoviruses were generated by Bac-to-Bac system according to the standard manual (Invitrogen). Viruses were amplified to a high titer by propagation in Sf9 cells. Virus titers were measured by plaque assay on Sf9 cells.

Transduction of mammalian cells by recombinant baculoviruses

Mammalian cells were seeded in 24-well culture dishes about 50 000 cells per well and incubated in a 37 °C CO₂ incubator for 12 h. Culture medium was removed, replaced with the collected culture supernatant (500 µL), and incubated for 1-24 h at 37 °C. After removal of viruses, fresh medium was added

and cultures were incubated at 37 °C. Cells that grew in suspension were pelleted by centrifugation before addition of virus inoculums. Forty-eight h post transduction, cultures were examined for eGFP expression using fluorescence microscopy and FCM.

Fluorescence microscopy

The cells transduced with recombinant baculoviruses were observed by Nikon ECLIPSE TE200 inverted microscope, and fluorescence photos were collected by the digital camera Nikon coolpix990.

Flow cytometry

After 48 h, transduction cultures were harvested with trypsin and washed with Dulbecco's PBS. Dispersive cells were pelleted by centrifugation (1 500 r/min, 5 min) and resuspended in Dulbecco's PBS with 50 mL/L fetal bovine serum and filtered by a nylon filter. Data collection was performed on a flow cytometer (FCM, Beckman Coulter EPICS XL), the exciting spectrum was 488 nm, and the detection spectrum was 525 nm. About 20 000 signals were collected per specimen. The negative control was the cells without treatment with the viruses, the eGFP positive domain (B domain) was set and the percentage of cell numbers in B domain of the negative control sample did not exceed 2%. The transfer efficiency of reporter genes was obtained by subtracting the percentage of cell numbers in B domain of the negative control from the percentage of cell numbers in B domain of the target sample. The reporter gene expression efficiency was reflected by mean fluorescence intensity of positive cells in the B domain.

Mammalian cells transfected by LipofectAMINE

Cells were seeded in 24-well culture dishes about 50 000 cells per well and incubated in a 37 °C CO₂ incubator for 12 h. One µg of target DNA was diluted into 50 µL free-serum culture medium (solution A), 2 µL LipofectAMINE reagent was diluted into 50 µL free-serum culture medium (solution B), the two solutions were mixed gently and incubated for 45 min at room temperature. The cells were washed twice with 1 mL free-serum culture medium. Five hundred µL free-serum culture medium and transfection mixture was added, cells were incubated for 6 h in a 37 °C incubator. The transfection mixture was removed and 500 µL supplemented culture media containing 100 mL/L fetal bovine serum was added. After 48 h transfection cultures were examined for GFP expression by FCM.

Mammalian cells infected by retrovirus

pT67-EGFP cell line constructed in our laboratory could produce recombinant retroviruses containing the EGFP expression cassette. Mammalian cells were seeded in 24-well culture dishes about 50 000 cells per well and incubated in a 37 °C CO₂ incubator for 12 h. The culture medium was removed

Figure 1 Plasmids pFB-EGFP, pFB-CMV-EGFP and pFB-CMV-EGFPB.

and replaced with the collected culture supernatant of pT67-EGFP (500 μ L), and incubated at 37 °C for 12 h. After removal of the viruses, fresh medium was added and cultures were incubated at 37 °C. After 48 h, infection cultures were examined for GFP expression by FCM.

Mammalian cells infected by vaccinia virus

The recombinant vaccinia viruses containing the EGFP expression cassette were constructed in our laboratory. Mammalian cells were seeded in 24-well culture dishes about 50 000 cells per well and incubated in a 37 °C CO₂ incubator for 12 h. The culture medium was removed and replaced with the collected vaccinia viruses diluted by PBS (500 μ L), and incubated at 37 °C for 1 h. After removal of the viruses, fresh medium was added and cultures were incubated at 37 °C. After 24 h, infection cultures were examined for GFP expression by FCM.

RESULTS

EGFP expression in Sf9 cells driven by different promoters

The recombinant baculoviruses (BacV-EGFP, BacV-CMV-EGFPA, BacV-CMV-EGFPB) were constructed with the reporter gene coding for eGFP under the control of either the PH promoter of baculovirus or the immediate early promoter of CMV. Sf9 cells were infected by the recombinant baculoviruses at a moi of 10. After 72 h, cells were observed by inverted

fluorescence microscope (Figure 2). High level of eGFP expression was observed in Sf9 cells infected by BacV-EGFP, whereas low levels of eGFP expression were found in Sf9 cells infected by BacV-CMV-EGFPA or BacV-CMV-EGFPB, showing that CMV promoter was utilized weakly in insect cells, resulting in low expression of eGFP in these cultures.

EGFP expression in HepG2 cells transduced with different recombinant baculoviruses

The culture supernatants of Sf9 cells infected by recombinant baculoviruses (BacV-EGFP, BacV-CMV-EGFPA, and BacV-CMV-EGFPB) for 4 d were collected and virus titers were determined by plaque assay. All the collected culture supernatants were diluted with fresh Grace's culture medium to make the virus titers 1.0×10^7 pfu/mL. HepG2 cells were incubated with the collected supernatants (moi=100) for 8 h at 37 °C. Twenty-four h post transduction, gene transfer and expression efficiencies were analyzed by inverted microscopy and FCM (Figure 3). High levels of eGFP expression could be detected in HepG2 cells transduced with BacV-CMV-EGFPA or BacV-CMV-EGFPB, and the gene transfer and expression efficiencies were similar. In contrast, no eGFP expression was found in HepG2 cells transduced with BacV-EGFP, showing that the PH promoter of baculoviruses was inactive in HepG2 cells. During the experiment, the morphological characteristics and growth of HepG2 cells were normal.

Figure 3 Fluorescence photos (up) and FCM analysis (down) of HepG2 cells transduced with recombinant baculoviruses. A: BacV-EGFP; B: BacV-CMV-EGFPA; C: BacV-CMV-EGFPB.

Effects of different dilution ratio and incubation time on efficiencies of gene transfer and expression

To optimize the way of delivering exogenous genes into mammalian cells with the culture supernatant of Sf9 cells infected by recombinant baculoviruses, HepG2 cells were incubated with the collected culture supernatant serially diluted by DMEM culture medium containing 100 mL/L fetal bovine serum and the transduction time ranged from 1 h to 24 h. After 24 h, the reporter gene transfer and expression efficiencies were analyzed by FCM (Figure 4). With increase of incubation time and moi, the efficiencies of gene transfer and expression in target cells increased.

Continuous expression of eGFP in HepG2 cells by baculovirus vector

HepG2 cells seeded in 24-well culture dishes were incubated with the culture supernatant of Sf9 cells infected by BacV-CMV-EGFPA (moi=50). Culture medium was changed every two days. The cells were harvested at various times and quantitatively assayed for eGFP expression by FCM. As shown in Figure 5, the expression of EGFP could be detected during a long time post transduction and peaked 24-48 h after transduction, which implied that the target gene could be continuously expressed in mammalian cells by recombinant baculovirus vectors.

Comparison of different gene delivery methods

pcDNA3.1(+)-EGFP was transfected into HepG2 and CV1 cells by LipofectAMINE. After 48 h, the reporter gene transfer and expression efficiencies were analyzed by FCM. pT67-EGFP cell line was constructed in our laboratory, which could produce the recombinant retroviruses containing the EGFP expression cassette. HepG2 and CV1 cells were incubated with the collected culture supernatant of pT67-EGFP for 12 h at 37 °C. After 48 h, the reporter gene transfer and expression efficiencies were analyzed by FCM. HepG2 and CV1 cells

were incubated with the culture supernatant of Sf9 cells infected by BacV-CMV-EGFPA for 12 h at 37 °C (moi=50). After 48 h, the reporter gene transfer and expression efficiencies were analyzed by FCM. The recombinant vaccinia viruses containing the EGFP expression cassette were constructed in our laboratory. HepG2 and CV1 cells were incubated with the collected vaccinia viruses diluted by PBS at 37 °C for 1 h. After 24 h, infection cultures were examined for GFP expression by FCM.

As shown in Table 1, under the similar conditions recombinant baculoviruses and vaccinia viruses could achieve higher gene-transfer and expression efficiencies than lipofectAMINE and recombinant retrovirus system. But obvious cytopathic effects could be observed at 24-32 h on HepG2 or CV1 cells infected by vaccinia viruses, while in mammalian cells transduced with recombinant baculoviruses, no cytopathic effect could be observed during the experiment.

Table 1 Comparison of gene-transfer and expression efficiency in HepG2 and CV1 cells among different gene-transfer systems

	Gene-transfer rate (%)		Mean fluorescence intensity	
	HepG2	CV1	HepG2	CV1
LipofectAMINE	29.6	34.2	138.1	103.4
Retro-EGFP	13.5	18.2	95.8	76.6

BacV-CMV-EGFPA	92.5	95.6	294.5	232.1

¹Cytopathic effects could be observed within 24 h post infection and most cells were lysed within 48 h.

Baculovirus-mediated gene delivery to various mammalian cell lines

To investigate the feasibility of delivering the reporter gene into various mammalian cells with the culture supernatant of

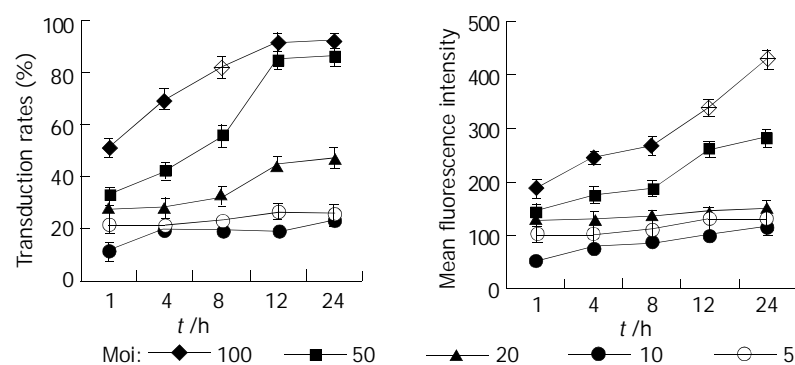

Figure 4 Effect of different moi and incubation time on gene transfer and expression efficiencies in HepG2 cells transduced with BacV-CMV-EGFPA.

Figure 5 Reporter gene transfer and expression efficiencies at different times in HepG2 cells transduced with BacV-CMV-EGFPA.

infected Sf9 cells, twenty different mammalian cell lines were used, including twelve human cell lines (WI-38, HeLa, HepG2, 293, PLC/PRF/5, 143B, MCF-7, BGC-223, DMS 114, CNE, Raji, LCL-cm), seven mice cell lines (BNL 1ME A.7R.1, CHO-K1, L-929, JC, PT67, NIH3T3, P815), and one monkey cell line (CV1). These cells were incubated with the infected Sf9 cell culture supernatant diluted with complete culture medium for the corresponding mammalian cells at ratio 1:1(vol:vol) for 12 h (BacV-CMV-EGFP, moi=50). After 48 h, the reporter gene transfer and expression efficiencies were analyzed by FCM (Table 2). Results showed that most mammalian cell lines could be transduced with recombinant baculoviruses by this way.

Activity of CMV promoter in different mammalian cell lines

In our research the susceptibility of mammalian cells lines to recombinant baculoviruses was determined by the expression of reporter gene in different cells. So the results might be affected by different expression efficiencies of reporter gene

in different cell lines. The reporter gene used in these experiments was the EGFP gene, which was one of the most widely used reporter genes and had many advantages such as no cytotoxicity to host cells, easy detectable, more sensitive^[16,17]. The CMV promoter was usually used in experiments, which had the ability to give strong expression of target genes in a variety of mammalian cell types^[18].

We investigated the activity of CMV promoter in different mammalian cell lines used in our experiments by FCM. Plasmid pcDNA3.1-EGFP containing an expression cassette of EGFP reporter gene under control of CMV promoter, was transfected by LipofectAMINE into some mammalian cells especially those difficult for baculoviruses to enter. After 48 h, reporter gene transfer and expression efficiencies were analyzed by FCM (Table 3). Results showed that CMV promoter could effectively direct the expression of reporter gene in these mammalian cells. Although the expression efficiencies differed in various cell lines, all the expressions could be detected by FCM. So the gene transfer efficiencies to mammalian cells by

recombinant baculoviruses containing CMV-EGFP expression cassette could basically show the ability of baculoviruses to enter different mammalian cell lines.

Efficiencies of gene transfer into suspended or adherent culture cells by recombinant baculoviruses

The cells used in our experiments were derived from primate or mice. We compared the transfer efficiencies of reporter gene in adherent or suspended culture cells of these two cell types (Table 4). The result showed that in primate cell lines the efficiencies of gene transfer into adherent culture cells were markedly higher than those of gene transfer into the suspended culture cells ($t=20.6484$, $P<0.05$). In mice cell lines, only one suspended culture cell line was used in our experiment, its gene transfer efficiency by baculovirus vector was also markedly lower than the adherent culture cell line from the same organism. Furthermore we also noticed that, the efficiencies of gene transfer into the primate adherent culture cells were markedly higher than those of gene transfer into the adherent culture cells from mice ($t=7.9674$, $P<0.05$), and the efficiencies of reporter gene transfer to the suspended culture cells from primate and mice were both low, the difference between them was not distinct. In primate adherent culture cells recombinant baculoviruses could arrive the highest infection and expression efficiencies, but they were not very satisfactory in the cell lines from mice and suspended culture cells.

	Mean transduction efficiency(%)	77.25±11.37	1.12±0.53
Mice	Total	6	1
	Mean transduction efficiency(%)	21.84±15.85	0.61

DISCUSSION

It has been proved that recombinant baculoviruses could serve as a powerful tool for delivering foreign genes into mammalian cells^[19]. Previous reports have described that recombinant baculoviruses used in gene-transfer experiments were often concentrated by ultracentrifugation. This could yield a large number of recombinant viruses with high purity, but it needed to culture a large number of cells to obtain sufficient viruses, and the manipulation was complex and burdensome. We investigated the feasibility of delivering exogenous genes into mammalian cells directly with the culture supernatant of Sf9 cells infected by recombinant baculoviruses. The results showed that when the incubation time was identical, with the increase of dilution ratio and the decrease of moi, the reporter gene transfer and expression efficiencies were decreased; when the dilution ratio and moi were identical, with the prolongation of incubation time, the gene transfer and expression efficiencies were increased too, suggesting that virus titers and incubation time were the most important factors that affected the efficiencies of the gene transfer and expression, and the virus titer was the crucial factor. In direct morphological observation in the transduced cells, we found that the growth of target cells was affected when undiluted culture supernatant was used or the incubation time was long. The morphological characteristics of some cells were abnormal, and the number of dead cells increased. So according to the observed results of the morphology and growth of transduced cells, we thought that incubating

target mammalian cells with the culture supernatant of infected Sf9 cells ($\geq 1.0 \times 10^7$ pfu/mL) 1:1(vol:vol) diluted by the mammalian cell complete culture medium for 12 h in a 37 °C CO₂ incubator (moi=50) could achieve the highest efficiency of gene transfer and expression, together with the least impairment to cell viability.

In our research twenty mammalian cell lines were used to investigate the feasibility of delivering reporter genes into various mammalian cells with the culture supernatant of infected Sf9 cells. The results showed that the reporter gene could be effectively transferred into the majority of mammalian cell lines by recombinant baculovirus vectors. The gene transfer efficiencies in adherent culture cells from human or monkey by baculovirus vectors were markedly higher than those from mice, indicating that the susceptibility of mammalian adherent culture cell lines to baculoviruses might be different between different species. Furthermore, baculoviruses could be hardly taken up by suspended culture cells. A total of four suspended culture cell lines were used in our experiment, three from human, and one from mice. Their efficiencies of gene transfer by baculovirus vectors were not more than 2%, markedly lower than those of the adherent culture cell lines from the same species respectively. Similar results were also observed by Condreay *et al*^[20].

Numerous methods have been developed for introducing target genes into mammalian cells including chemical-based procedures, electroporation, and mammalian viral vector-based systems. Lipid transfection, retrovirus expression system and vaccinia virus expression system were most often used in experiments among these methods. The advantages of lipid transfection were short time-used, wide host range, but in common cases the transfection efficiencies were low, and was not suitable for some experiments that needed high transfection efficiencies^[21]. Retroviruses could infect many mammalian cell lines, and were able to integrate with host cell genomes stably. But retroviruses could only be taken up by the cells in mitosis phase, and the infection efficiencies in the non dividing cells were very low^[22,23]. The successful application of the retrovirus expression system needs high virus titers. If the culture supernatants of retrovirus package cell line were directly used in the gene transfer experiment, the virus titers were usually difficult to meet our need. So increasing the virus titer of recombinant retroviruses has become an important research content in the application of retrovirus expression system, and this was also an important factor that restricted the wide application of the retrovirus expression system^[24,25]. A package cell line that can stably generate high titer recombinant viruses would also take a long time for cloning. The vaccinia virus expression systems have been widely used for *in vitro* production and functional characterization of proteins and live vaccines in vaccine research^[26,27]. The life cycle of poxviruses occurs exclusively within the cytoplasm of infected cells and can lead to the lysis of infected cells within 12-24 h^[28]. So the vaccinia virus expression system is unsuitable for continuous expression of foreign genes in target cells. Similar problems also occur in application of other mammalian viral vector-based systems. The cost and time-used in application of these expression systems were too expensive and burdensome for some daily common experiments.

As described in our report, the culture supernatant of Sf9 cells infected by recombinant baculoviruses could be directly used for delivery of foreign genes into mammalian cells. Their virus titer was sufficient for efficient gene transfer experiments. So under common circumstances without special requirements, there is no need for concentration and purification of the virus, which can markedly decrease our workloads, and improve our work. In comparison to lipid transfection system, retrovirus expression system and vaccinia virus expression system, we

could find that under similar conditions recombinant baculoviruses could achieve the highest gene-transfer and expression efficiencies in mammalian cells. Baculoviruses are inherently unable to replicate in mammalian cells, have few or no microscopically observable cytopathic effects on target cells. These modified recombinant baculoviruses containing mammalian cell-active expression cassettes could be used more widely in a variety of gene transfer. We also noticed that the gene transfer and expression efficiencies in mice cells and suspended culture cells by recombinant baculoviruses containing CMV promoter were not satisfactory, suggesting that although recombinant baculoviruses could serve as a very convenient tool for gene transfer in mammalian cells, but they also have limitations and might not be suitable for all cell lines.

Abstract

AIM: Studies have demonstrated that gut-derived bacterial translocation (BT) might play a role in the occurrence of sepsis and multiple organ dysfunction syndrome (MODS). Yet, no convincing overall analysis of risk factors for BT has been reported. The purpose of this study was to evaluate the related factors for the development of BT in burned rats.

METHODS: Wistar rats were subjected to 30% third-degree burns. Then samples were taken on postburn d 1, 3, and 5. Incidence of BT and counts of mucosal bifidobacteria, fungi and *E. coli*, mucus sIgA, degree of injury to ileal mucosa, and plasma interleukin-6 were observed. Univariate analysis and multivariate logistic regression analysis were performed.

RESULTS: The overall BT rate was 53.9% (69 in 128). The result of univariate analysis showed that the levels of plasma endotoxin and interleukin-6, the counts of mucosal fungi and *E. coli*, and the scores of ileum lesion were markedly increased in animals with BT compared with those without ($P=0.000-0.005$), while the levels of mucus sIgA and the counts of mucosal bifidobacteria were significantly reduced in animals with translocation compared with those without ($P=0.000$). There was a significant positive correlation between mucus sIgA and the counts of mucosal bifidobacteria ($r=0.74$, $P=0.001$). Moreover, there were strong negative correlations between scores of ileum-lesion and counts of bifidobacteria ($r=-0.67$, $P=0.001$). Multivariate logistic regression revealed that ileum lesion score (odds ratio [OR] 45.52, 95% confidence interval [CI] 5.25-394.80), and counts of mucosal bifidobacteria (OR 0.039, 95% CI 0.0032-0.48) were independent predictors of BT secondary to severe burns.

CONCLUSION: Ileal lesion score and counts of mucosal bifidobacteria can be chosen as independent prognosis factors of the development of BT. Specific interventions targeting these high-risk factors might be implemented to attenuate BT, including strategies for repair of damaged intestinal mucosae and restoration of the balance of gastrointestinal flora.

INTRODUCTION

Sepsis and multiple organ dysfunction syndrome (MODS) remain the leading causes of death 72 h after a severe burn and other traumas. Early MODS after a severe injury is usually due to an excessive and overwhelming malignant systemic inflammatory response and massive hemorrhagic shock as a result of the initial insults. On account of the finding that as many as 30% patients died of early sepsis and MODS with no identifiable septic foci^[1], some investigators postulated that systemic infections might be originated from the gut.

At present, many animal and a few clinical studies have demonstrated that gut-derived bacterial translocation does play a role in the occurrence of early sepsis and MODS^[2-5]. Because most of the pathogens come from the gut, the gastrointestinal tract is even termed as an "undrained abscess" under certain circumstances such as trauma, endotoxemia, hemorrhage, and thermal injury. A generally accepted theory is that translocation of luminal bacteria and toxins is mechanically linked to the following factors, namely disruption of the normal balance in indigenous microflora with subsequent overgrowth of potentially pathogenic bacteria, impaired intestinal immunologic barrier of the host, and disruption of the mucosal physical barrier of the gut^[1]. However, to our knowledge, what role these three factors play in the incidence of bacterial translocation under some conditions has not been fully elucidated.

In the past decade, literature on the mechanisms and methods of treatment and prevention of bacterial translocation has been substantial. However, to date no convincing overall analysis of risk factors for bacterial translocation has been reported.

The purpose of our study was to clarify the individual role of intestinal mucosa, mucosal flora, and gut sIgA in producing bacterial translocation in scalded rats, in an attempt to propose a formula for predicting the probability of incidence of bacterial translocation by using univariate analysis and multivariate logistic regression.

MATERIALS AND METHODS

Animals

Wistar rats, weighing 180 to 220 g, male and female in equal number, were purchased from the Experiment Animal Center of Third Military Medical University in Chongqing, China. Animals were housed in separate steel cages in a temperature-controlled room with a 12-h light-dark cycle, and acclimatized for at least seven days prior to use. Animals had free access to an irradiated commercial rodent diet and autoclaved water *ad lib*. All experimental manipulations were undertaken in accordance with the NIH Guide for the Care and Use of Laboratory Animals, with the approval of the Scientific Investigation Board of the Institute of Burn Research, Southwestern Hospital, Third Military Medical University, Chongqing, China.

Burn injury

After an overnight fast, rats were weighed, numbered, and anesthetized with sodium pentobarbital (40 mg/kg body mass, i.p.), with the dorsal hair shaved, and then subjected to 30% total body surface area skin full-thickness thermal injury, which was produced by exposure to 94 °C water bath for 18 s using a wood template with an aluminium wand for fixing rat abdomen. Rats were quickly dried and resuscitated with Ringer's lactate (40 mL/kg, i.p.) immediately after injury. Animals were then allowed to fully recover from anesthesia before being returned to their cages, and had free access to radiated commercial rodent chow and autoclaved water *ad lib*. Sulphadiazine silver suspension (20 g in 100 mL water) was applied to the wounds once a day to prevent infection. Samples were taken on post-burn d 1, 3, and 5. Fifty animals were included at each time point except for sham burned group with ten.

Microbiologic analysis

Techniques for culturing and bacterial translocation studies were performed with a modification of the methodology described by Tadros *et al*^[6]. After the animals were anesthetized (50 mg/kg body mass, i.p.), their abdomens were shaved, sterilized with tincture of iodine and 750 mL/L alcohol, and opened through a midline incision with sterile scissors. Under aseptic conditions, blood was obtained from portal vein and vena cava under direct visualization, and a swab culture was taken from the exposed belly cavity. Then mesenteric lymph nodes (MLN), spleen, liver, and kidney were obtained and weighed. Each organ was homogenized in brain heart infusion broth. Two hundred μ L homogenates from tissues, as well as 200 μ L blood, were inoculated on both Gram-negative bacteria-specific MacConkey's agar and blood agar. A duplicate culture was made for each specimen. All specimens were incubated at 37 °C for 24 h. Positive specimens were sub-cultured, and the bacteria were identified by standard bacteriologic techniques. Cultures were considered positive when more than 100 colonies per gram of tissue were found. No culture for obligate anaerobics was made, because they had a low tendency to translocate to extra-intestinal sites.

Following removal of the aforementioned organs, the terminal ileal loop was excised, opened longitudinally, then its content was wiped off lightly with sterile cotton swabs, rinsed three times with 10 mL sterile 0.01 mol/L phosphate-buffered saline (PBS). The residual liquid was dried with sterile filter paper. The specimen was then put into a CO₂ filled bottle immediately. The samples were weighed, homogenized with a sterile blender, and diluted by 10-fold with brain heart infusion broth. One hundred μ L desired diluted specimen was poured separately onto the *E. coli*-specific MacConkey's agar, bifidobacteria-specific BLB agar, and fungi-specific medium (modified by including Imipenium 30 μ g/mL). The cultures were all duplicated. Plates were incubated for 24 h for aerobic bacterial culture, and 72 h for anaerobic and fungus cultures, at 37 °C, respectively. Then colonies of bacteria or fungi were counted, and the suspiciousness was identified using standard microbiologic technique. All plates and brain-heart infusion were purchased from Shanghai Med&Chem Institute, Shanghai, China.

Quantitative culture results were expressed as the number of log₁₀ colony-forming units (CFU) per gram tissue. The terminal ileal loop was used because bacterial translocation correlated with colonization of the ileum rather than that of the colon^[6]. The limit detection of the assay was 10 bacteria.

Plasma endotoxin measurement

Portal blood was collected and put into pyrogen-free polypropylene tubes containing 2 μ L of sterile heparin. Platelet-

rich plasma was obtained by centrifugation at 4 °C, 260 r/min for 10 min, and then aliquots of which were prepared and transferred to sterile pyrogen-free tubes under laminar air flow, and stored at -35 °C until use. Plasma endotoxin concentration was measured by the chromogenic limulus amebocyte lysate (LAL) method. The procedure followed was based on the protocol provided with the kit (Shanghai Med&Chem Institute, Shanghai, China). Briefly, in order to avoid activation and inhibitory effects of plasma on LAL test, 0.1 mL serum specimen was diluted (1:10) in apyrogenic sterile water 0.2 mL and Tris-HCl buffer 0.2 mL, boiled for 10 min, and then supernatant obtained by centrifugation at 4 °C, 5 000 r/min for 10 min was used for detection. The supernatants were coincubated for 25 min at 37 °C with LAL, and 3 min after chromogenic substrate was added, reaction was stopped with an aqueous solution of 0.5 g/L naphthyl ethylenediamine. Absorbance was read in a spectrophotometer at 545 nm. The absorbance of a control was subtracted from these absorbances in order to adjust the samples' intrinsic color development. The endotoxin concentration was corrected for dilution and calculated from a standard curve derived from assay of standard (*Escherichia coli* 0111:B4, 1EU [endotoxin units]=100 pg) supplied by the company. This method was sensitive to 0.03 EU/mL of endotoxin. Depyrogen of detection material was approved by ⁶⁰Co exposure.

Measurement of intestinal mucus sIgA

Duodenum, jejunum and ileum were excised, cut into 3 segments, opened longitudinally. Intestinal contents were wiped off with bamboo sticks. Intestinal mucus was collected by scraping with glass slides, and dissolved in 1 mL 0.01 mol/L PBS [including 1 mmol/L dithiothreitol (DTT), 100 μ g/mL phenylmethyl sulfonylfluoride (PMSF), 10 μ g/mL Leupeptin, 10 μ g/mL soybean trypsin inhibitor, and 2 μ g/mL aprotinin]. The solution was centrifuged at 30 000 g at 4 °C for 10 min. The supernatant was aspirated and frozen until use.

The supernatants were diluted to 1:400 with 0.01 mol/L PBS for measurement of sIgA concentrations by radioimmunoassay (RIA), based on the protocol supplied with the kit (Biotinge-Tech. Co., Beijing, China). In short, samples were added into glass tubes, incubated with polystyrene-balls which were coated with mouse anti-rat sIgA mAb (Sigma chemical co., St Louis, MO), at 37 °C for 2 h, washed 4 times with deionized water, then ¹²⁵I conjugated goat anti-rat IgA antibody was added. They were kept at room temperature over night. After washed four times, the balls were transferred into another tube for detection. Additionally, a rat myeloma IgA (Zymed, San Francisco, CA) diluted into 15.6 ng/mL, 31.3 ng/mL, 62.5 ng/mL, 125 ng/mL, 250 ng/mL, 500 ng/mL, 1 000 ng/mL, and 2 000 ng/mL, was serially measured for a standard curve. Radionuclide counts were determined in term of disintegrations per minute (dpm) using a gamma counter and calibrated by subtracting the background count. Interassay and intraassay coefficients of variation were < 10%. The assay had a sensitivity of 20 pg/mL. Total protein in supernatants was estimated using the Lowry method, simultaneously. Therefore, the concentrations of sIgA from gut mucus were expressed as μ g per mg of protein (sIgA μ g/mg protein).

Microscopic evaluation

Ileum specimens were dehydrated in progressive concentrations of ethanol, cleared in xylene, and embedded in paraffin. Deparaffinized 4- μ m thick sections were stained with hematoxylin-eosin. Glass slides were coded to allow two experienced histopathologists to examine the tissue sections blindly. The degree of intestinal tissue injuries was evaluated using a grading scale from 0 to 8^[7]. Grade 0 was defined as

normal mucosa. Pathognomonic for grades 1 to 3 was an increasing subepithelial space of the villi. In grade 4, the villi were denuded, and grade 5 was characterized by loss of the villi. In grade 6, the intestinal crypt layer was also injured, and in grade 7, the entire intestinal mucosa was necrotic. Grade 8 represented transmural infarction.

ELISA for IL-6

Caval blood was collected, centrifuged at 260 r/min for 10 min. Samples were serially diluted with 0.01 mol/L PBS, and IL-6 was determined by sandwich ELISA. The following procedure was based on the protocol supplied with the kit (Bioting-Tech. Co., Beijing, China). Briefly, 96-well plates (Corning Costar, Cambridge, MA) were coated with 100 μ L anti-IL-6 mAb diluted in 0.1 mL bicarbonate buffer (pH 8.2) and incubated at 4 °C for 48 h. The wells were blocked with PBS containing 10 g/L BSA at room temperature for 1 h. Serial 2-fold dilutions of plasma were added to duplicate wells over night at 4 °C. Then the wells were incubated with biotinylated anti-IL-6 Ab, at 37 °C for 1 h, and then with peroxidase-labeled anti-biotin Ab for 1 h, and developed with ABTS reagent (Sigma). Similarly, a standard curve ranging from 0 to 2 000 pg/mL was plotted using recombinant human IL-6. Absorbance was then read at 410 nm, and the amount of IL-6 in each sample was computed from the standard curve. Interassay and intraassay coefficients of variation were <10%. The assay had a sensitivity of 100 pg/mL.

Statistical analysis

The software package Stata for Windows (Version 6.0) was used for analysis. Results were expressed as mean \pm SD, except for data of the grading of mucosal injury, which were expressed as median and range. Continuous variables were compared by

Student's *t* test or Wilcoxon-Mann-Whitney rank sum test, whereas the Chi-square test (χ^2 test) was used for comparing proportions. Correlation analysis, univariate and stepwise multivariate logistic regression analysis, with bacterial translocation as the dependent variable, were used to identify factors associated with bacterial translocation to develop a model to predict the probability of incidence. A *P* value of 0.05 or less was considered to statistically significance.

RESULTS

Incidence of bacterial translocation

The overall mortality was 14.7% (22 in 150) during the experiment. The incidence of bacterial translocation was 53.9% (69 in 128) after burn. There were 17 positively cultured strains from abdominal cavity swabs, which were coincident with those strains cultured in organs. The rate of bacterial translocation was 84%, 59%, and 28% on post-burn d 1, 3, and 5, respectively (84% vs 59%, *P*=0.02; 84% vs 28%, *P*=0.000; 59% vs 28%, *P*=0.04), while it was 10% in shame-burn animals.

Univariate analysis

Univariate analysis showed that the levels of plasma endotoxin and interleukin-6, the counts of mucosal fungi and *E. coli*, and the scores of ileum lesion were markedly increased in animals with bacterial translocation compared with those without (*P*=0.000-0.005), while mucus sIgA and the counts of mucosal bifidobacteria were significantly reduced in animals with bacterial translocation compared with those without (*P*=0.000). Moreover, the ratio of bifidobacteria to *E. coli* was decreased significantly from 2 000:1 in animals without bacterial translocation to 10:1 in animals with translocation (Table 1).

Correlations among experimental findings

As shown at Table 2, there was a significant positive correlation between levels of endotoxin and counts of mucosal fungi and *E. coli*, scores of ileum lesion, and levels of interleukin-6 ($r=0.72, 0.46, 0.48, 0.48$, respectively, $P<0.001$), and between mucus sIgA and counts of mucosal bifidobacteria ($r=0.74$, $P<0.001$). Moreover, there were strong negative correlations between scores of ileum lesion and counts of bifidobacteria and concentrations of sIgA ($r=-0.67, -0.73$, respectively, $P<0.001$), as well as significant negative correlations between counts of mucosal bifidobacteria and levels of endotoxin, and counts of fungi and *E. coli* ($r=-0.51, -0.40, -0.55$, respectively, $P<0.01$). Figures 1 and 2 respectively showed the correlation between levels of mucus sIgA and counts of mucosal bifidobacteria, and between counts of mucosal bifidobacteria and scores of ileum lesion.

Figure 1 Correlation between counts of mucosal bifidobacteria and intestinal mucous sIgA ($r=0.74$, $P=0.000$).

Figure 2 Correlation between counts of mucosal bifidobacteria and scores of ileum injury ($r=-0.67$, $P=0.000$).

Multivariate analysis

In multivariate analysis, as shown in Table 3, only two variables in seven parameters remained independent prognosis factors of the development of bacterial translocation associated with postburn injuries. Ileal lesion score was considered as the auxo-action factor, and the counts of mucosal bifidobacteria as the prevention factor. This model was described by the following formula: $P(\text{bacterial translocation}) = e^{\text{logit}} / (1 + e^{\text{logit}})$ { $\text{logit} = 9.9220 - 3.2424 [\log_{10}(\text{count of bifidobacteria/g tissue})] + 3.8182 (\text{ileal-lesion score})$ }, with likelihood ratio $\chi^2=141.28$, and the accuracy of the formula for burn rats was $(50+67)/128=91\%$ when ileal-lesion score was no less than 4, and the counts of bifidobacteria was no more than 10^6 CFU/g tissue.

DISCUSSION

Intestinal mucosa is a key barrier to prevent the invasion and spread of microorganisms that normally reside within the gut lumen. Under certain conditions, however, bacteria and their

products such as endotoxin, can cross this barrier and get access to visceral organs via lymph or blood stream, a process that has been referred to as bacterial translocation. Factors that could promote bacterial translocation included overgrowth of Gram-negative enteric bacilli, impaired host immune defenses, and injury to the intestinal mucosa resulting in increased intestinal permeability^[1]. These mechanisms could act in concert to promote synergistically the systemic spread of indigenous translocating bacteria to cause lethal sepsis. Many pathological conditions could evoke bacterial translocation, such as ionization radiation, endotoxemia, dystrophia, peritonitis, renal failure, intestinal obstruction, lesion of mucosa, hemorrhagic shock, long-term fasting, deficiency in secretory IgA, total parenteral nutrition, severe trauma, massive operation, and extensive burn. Recently, some measures were taken to prevent and treat bacterial translocation secondary to trauma with bactericidal/permeability increasing protein, glucagons-like peptide, growth hormone, insulin-like growth factor I, inhibitor of angiotensin II, C1 inhibitor, bombesin, inhibitors of NO synthase, glutamine, lactulose, interleukin-1alpha, probiotics and selective digestive tract decontamination^[6,8-17], and their effects on the incidence of bacterial translocation were found to be resulted from ameliorating indigenous flora, strengthening the mucosal barrier, and promoting host systemic or intestinal immunity. However, what role does each of the above mentioned factors play in inciting bacterial translocation is yet to be clarified.

At the early stage of severe burns, there was a considerable change in gut mucosal flora, while only mild alternations occurred in intestinal luminal flora. It is noteworthy that bacterial translocation correlated with the state of colonization in ileum rather than in colon^[16]. With these facts in mind, in the present study, we paid more attention to the changes in mucosal microorganisms of the terminal ileal loop. Bifidobacterium, which was the most common species in feces of human^[18,19], *E. coli*, which was known to be the most commonly translocated microorganism^[4,20,21], as well as fungi, which commonly constituted the pathogens of nosocomial infection in an intensive care unit (ICU), were chosen as representatives of intestinal microflora. Concomitantly, the main pathological changes were located in mucosa of the terminal ileum^[22], the scores of lesion in ileum, reflecting the status of mucosa barrier^[7], and the levels of mucus sIgA, showing the function of intestinal immunity^[23], were determined. The levels of plasma endotoxin and IL-6 were used to evaluate the systemic inflammatory reactions^[24,25]. Furthermore, univariate analysis was used to identify the relationship between different variables with occurrence of bacterial translocation, correlation analysis was used for the compliance with the examined variables, and then logistic regression analysis was used to determine the independent predicting factors associated with bacterial translocation.

Bacterial translocation might result from a breach of the intestinal mucosa, as a result of ischemia, atrophy, mechanical injury, etc. Repair of injured mucosa depended on the improvement of local microcirculation^[26]. During burn shock, with re-distribution of blood circulation, the gastrointestinal suffered a prolonged ischemia, even when systemic hemodynamic parameters were normalized. This condition is known as compensatory covert shock. Our data showed that this hypoxic condition produced injuries to the mucosa of terminal ileum, followed by a significantly increased incidence of bacterial translocation at the early postburn stage. Moreover, the scores of ileal lesion had a significantly positive correlation with serum endotoxin levels. It has been documented that translocated endotoxin could trigger systemic inflammatory response through LBP/CD14 sensibility-increasing system^[27], and resulted in an over-release of inflammatory factors such as TNF- α , IL-6, which might further damage intestinal

mucosae^[25,27].

There was a marked negative correlation between scores of ileal lesion and mucosal bifidobacteria counts or mucus sIgA. The injury to intestinal mucosa predisposed bacteria to escape from the intestinal wall, while mucosal bifidobacteria and mucus sIgA might be protective against it^[15,23,28].

Katouli and colleagues demonstrated that the composition and diversity of gut flora were associated with bacterial translocation, and the proportion and quantity of *E. coli* might influence the incidence of bacterial translocation secondary to hemorrhagic shock^[20]. Our results showed that the counts of bifidobacteria decreased by 16-fold, and the counts of *E. coli* and fungi increased respectively by 8- and 4-fold in animals in which bacterial translocation was found. Moreover, the ratio of bifidobacteria to *E. coli* was decreased from 2 000:1 in animals without translocation to 16:1 in animals with translocation. This result might imply that the number of bifidobacteria, especially the ratio of bifidobacteria to *E. coli*, might be of more significance as a marker of bacterial translocation than the quantity and proportion of *E. coli*. Multivariate analysis showed that only the count of mucosal bifidobacteria was the independent predictor for the incidence of bacterial translocation, indicating that bifidobacteria, the predominant anaerobes in the gut, might play a key role in maintaining the biological barrier. The work of others showed that bifidobacteria as a mucosal flora could prevent other intestinal bacteria from adhering to intestinal epithelia through a competitive mechanism, and by producing lactic acid and acetate to create a harmful environment of lowered pH for the growth of *E. coli*, *Salmonella*, and methicillin-resistant *Staphylococcus aureus*^[28-35]. Our data supported these assertions that administration of bifidobacteria could restore the disrupted gut micro-ecology, which was favorable to the host. As a result, endotoxin release was lessened, and the incidence of bacterial translocation was lowered.

Local immunological defense of the gut was mainly provided by the gut-associated lymphoid tissue (GALT), principally in the form of secretory IgA. sIgA, the predominant immunoglobulin present in mucosal secretions, was the first line of defense on the intestinal mucosal surface^[23]. The importance of the mucosal immune system has been extensively recognized, for it relates to the potential pathogenic role of gut flora. Failure of the barrier function of the gut challenged by stress of severe trauma could lead to the translocation of viable enteric bacteria and endotoxin^[1]. Our results showed that mucous sIgA was reduced by 56% in animals with bacterial translocation as compared to animals without translocation. However, the concentration of intestinal mucous sIgA was excluded as an independent predictor when examined by multivariate statistical analysis. This might be partially due to the significant positive correlation between the level of sIgA and the count of bifidobacteria. Moreover, the synthesis and excretion of sIgA depended mainly on healthy and stable commensal bacteria^[23,30,34]. Overgrowth of Gram-negative bacteria after hemorrhagic shock might also suppress intestinal immunological function and sIgA secretion, augmenting bacterial translocation^[36,37]. On the contrary, selective decontamination of the digestive tract (SDD) or supplement of exogenous bifidobacteria could attenuate the incidence of bacterial translocation accompanied by improved intestinal and systemic immunity^[15,17,23].

In summary, the development of bacterial translocation was closely associated with overgrowth of pathogens such as fungi and *E. coli*, lowering of intestinal immunologic barrier function, breaching of gut mucosal barrier, and systemic inflammatory reaction subsequent to severe burns. The independent factors related to bacterial translocation were ileal injury score and the counts of gut bifidobacteria. Among them, the score of ileal injury was considered as the augmentative

factor, and the counts of mucosal bifidobacteria as the protective factor. Thus specific interventions targeting the high-risk factors, including repair of damaged intestinal mucosa by improving gut microcirculation and improvement of gastrointestinal micro-ecology by increasing the quantity and proportion of bifidobacteria, might be beneficial to the attenuation of bacterial translocation. Moreover, determination of the quantity of bifidobacteria and the ratio of bifidobacteria to *E. coli* in feces might be used to predict the occurrence of bacterial translocation.

Abstract

AIM: To compare the gene expression between $\text{La}(\text{NO}_3)_3$ -exposed and control rats *in vivo*.

METHODS: Rats were fed $\text{La}(\text{NO}_3)_3$ once daily at a dose of 20 mg/kg for one month by gavage. Gene expression of hepatocytes was detected using mRNA differential display (DD) technique and cDNA microarray and compared between treated and control groups.

RESULTS: Six differentially expressed sequence tags were cloned by DD, of which five were up regulated and one was down regulated in treated rats. Two sequences were determined. One band was novel. The other shared 100% sequence homology with AU080263 Sugano mouse brain mncb Mus musculus cDNA clone MNCb-5435 5'. With DNA microarray, 136 differentially expressed genes were identified including 131 over-expressed genes and 5 under-expressed genes. Most of these differentially expressed genes were cell signal and transmission genes, genes associated with metabolism, protein translation and synthesis.

CONCLUSION: $\text{La}(\text{NO}_3)_3$ could change the expression levels of some kinds of genes. Further analysis of the differentially expressed genes would be helpful for understanding the wide biological effect spectrum of rare earth elements.

INTRODUCTION

Rare earth (RE) includes 17 elements. According to the physical and chemical nature, 16 elements except for scandium (Sc) are categorized into two groups. One is called light RE, which is represented by cerium, including lanthanum (La), cerium (Ce), praseodymium (Pr), neodymium (Nd), promethium (Pm), samarium (Sm) and europium (Eu). The other is called heavy RE, which is represented by yttrium, including gadolinium (Gd), terbium (Tb), dysprosium (Dy), holmium (Ho), erbium (Er), thulium (Tm), ytterbium (Yb), lutetium (Lu) and yttrium (Y).

Recently, RE has become one of the common xenobiotics in our surroundings as it is widely used in industry, stockbreeding and medicine, especially as trace fertilizers in agriculture, and they can be concentrated by food chain. Therefore, understanding the effects of RE on health has become more and more important.

Studies on RE toxicology have lasted for a long time. However, deeper exploration of its mechanism is highly needed. It is well known the biological effect spectrum of RE is wide and the dose-response relationship is complicated. For example, RE elements could induce chromosome damage of blood lymphocytes^[1] and liver damage^[2-4], depress learning and memory^[5], increase or suppress cell-mediated immunity of the spleen^[6], inhibit gap junctional intercellular communication^[7], etc. However, safety evaluation of RE is not easy, and the research of biomarkers by molecular biology is in its infancy. It is necessary to find more sensitive biomarkers by new techniques and methods, and to acquire a deeper understanding of the mechanism.

In this paper, the molecular mechanism of RE toxicity was explored by DD and cDNA microarray. $\text{La}(\text{NO}_3)_3$, which is the major component in RE trace fertilizers, was selected as the study material.

MATERIALS AND METHODS

$\text{La}(\text{NO}_3)_3$ treatment of rats

In the study of DD, 86-week-old Wistar rats were chosen. One half of them were male, and the others were female. To guarantee the treated rats and control had similar heredity backgrounds, the rule of same-breeding and same-sex control was applied. A $\text{La}(\text{NO}_3)_3$ -treated rat and its control were called a pair of test animals. There were two pairs of male rats and female rats, respectively. Treated rats were fed $\text{La}(\text{NO}_3)_3$ once daily at a dose of 20 mg/kg for one month by gavage. Control rats were fed distilled water. One pair of female rats was chosen in the study of cDNA microarray. Parts of isolated rat livers were used to observe morphology of hepatocytes by light microscopy and electron microscopy. Others were snap frozen in liquid nitrogen and then stored at -80°C until RNA extraction.

Preparation of total RNA

Total RNA was prepared with single-step method by acid guanidinium isothiocyanate-phenol-chloroform according to Chomczynski and Sacchi^[8]. In brief, 0.5 g liver was homogenized with 2.5 mL solution D, then 0.25 mL 0.2 mol/L NaAc/0.1 mmol/L ATA, 2.75 mL phenol, 0.55 mL chloroform/isoamyl alcohol (24:1) were added and shaken in order. It was cooled on ice for 15 min and centrifuged at 10 000 g at 4°C for 20 min. The supernatant was removed put into new tubes and 2.75 mL isopropanol was added to precipitate at -20°C . It was then centrifuged at 10 000 g at 4°C for 20 min. The supernatant was discarded and the pellet was dissolved in RNA denature buffer, then 15 μL 3 mol/L NaAc and 330 μL 1 000 mL/L ethanol were added to precipitate at -20°C for 1 h. Contaminated chromosomal DNA was digested with DNase I (Promega).

Differential Display (DD)

For reverse transcription, RNA (in 1.0 μL DEPC treated water) was mixed with 2.0 μL API (Beckman) and incubated at 70°C

for 5 min, then cooled on ice immediately. The solution was mixed with 8.8 μ L DEPC treated water, 4.0 μ L 5 \times reverse transcript buffer, 2.0 μ L dNTP (250 μ mol/L), 2.0 μ L DTT (100 mmol/L) and 0.2 μ L MMLV reverse transcriptase (200 U/ μ L, GIBCO). Reverse transcription was performed at 42 $^{\circ}$ C for 5 min, then at 50 $^{\circ}$ C for 50 min, and finally at 70 $^{\circ}$ C for 15 min.

For amplification of cDNA, AP1 was chosen as anchor 3' primer and ARP1-ARP4 were selected as arbitrary 5' primers. A 2 μ L cDNA was mixed with 8.2 μ L DEPC treated water, 2.0 μ L 10 \times PCR buffer (Promega), 2.0 μ L MgCl₂ (25 mmol/L, Promega), 1.6 μ L dNTP (2.5 mmol/L), 2.0 μ L ARP (2 μ mol/L), 2.0 μ L AP (2 μ mol/L) and 0.2 μ L TaqE (2.0 U/ μ L, Promega). The PCR amplification program was at 95 $^{\circ}$ C for 2 min, then 4 cycles at 92 $^{\circ}$ C for 15 s, at 50 $^{\circ}$ C for 30 s, and at 72 $^{\circ}$ C for 2 min, followed by 30 cycles at 92 $^{\circ}$ C for 15 s, at 60 $^{\circ}$ C for 30 s, at 72 $^{\circ}$ C for 2 min, and finally at 72 $^{\circ}$ C for 7 min.

A 7 μ L PCR mixture was redissolved in 4 μ L loading dye, heated at 95 $^{\circ}$ C for 2 min, then run on 80 g/L polyacrylamide-urea gels at 9 mA. DNA fragments on gels were displayed by silver stain method. Bands representing cDNA, which appeared to be differentially expressed, were excised and reamplified under the same conditions as above except the primers. In this procedure, T7 promoter and M13 reverse (-48) were used.

DNA sequence analysis

DNA sequence analysis was carried out with dye-terminator method in ABI DNA sequencer. DNA sequences were identified by comparison to those in GenBank BLASTn on Internet.

cDNA microarray

cDNA probes were prepared through reverse transcription and then purified. The probes from normal rats were labeled with Cy3-dUTP, and the probes from La(NO₃)₃-treated rats were labeled with Cy5-dUTP. The chips were scanned using ScanArray3000 laser scanner (General Scanning, Inc) at two wavelengths to detect emissions from both Cy3 and Cy5. The acquired images were analysed using ImaGene3.0 software (BioDiscovery, Inc.). The intensity of each spot at the two wavelengths represented the quantity of Cy3-dUTP and Cy5-dUTP, respectively. Each ratio of Cy3 and Cy5 was computed. Overall intensities were normalized by a coefficient according to the ratios of the located 40 housekeeping genes. To minimize artifacts arising from low expression values, only the genes with raw intensity values larger than 800 counts for one or both of Cy3 and Cy5 were chosen for differential analysis.

RESULTS

Effects of La(NO₃)₃ on morphology of rat hepatocytes

La(NO₃)₃ had no significant effects on histopathology by light microscopy. Swollen or cavitated mitochondria were observed in hepatocytes by electron microscopy (Figure 1).

Differential expression of La(NO₃)₃-induced genes of rat hepatocytes

Six differentially expressed bands in two pairs of rats, were obtained (Figure 2). Among them, five were up regulated and one was down regulated in treated rats. Two bands were sequenced. The results were as follows. LaFT1-4-1: The expression level of EST in treated rats was higher than that in control. Its length was about 160 bp (Figure 3A). EST was compared with known ESTs in GeneBank BLASTn. The homology was low ($\leq 15\%$). LaFT1-4-1 was novel. Its sequence was as follow: 5'-AGCGGATAACAATTTCACACAGGAGTAGCAGACCCCTGCCCCAGGAAATAACACACTAACTCTCAAAAAAAGCCCTATAGTGAGTCGTATTACACCCTATAGTGAGTCGTATTAGCGGATAACAATTTCACACAGGACGCCCTATAGTGAGTA-3'.

LaMT1-4-1: The expression level of EST in treated rats was higher than that in control. Its length was about 144 bp (Figure 3B). The EST was compared with known ESTs in GenBank BLASTn and it shared 100% sequence homology with AU080263 Sugano mouse brain mncb Mus musculus cDNA clone MNCb-5435 5'. Its sequence was as follow: 5'-ACTCAAAGGCGGTAATACGGTTATCCACAGAATCAGGGGATAACGCAGGAAAGAACATGTGAGCAAAAAGGCCAGCAAAAAGGCCAGGAACCGTAAAAAGGCCGCGTTGCTGGCGTTTTTCCATAGGCTCCGCCCCCTGACGAGC-3'.

Figure 1 Electron microscopic images of hepatocytes. A: Normal mitochondria in control hepatocytes (TEM $\times 6700$), B: Swollen or cavitated mitochondria in treated hepatocytes (TEM $\times 8800$).

Figure 2 Polyacrylamide-urea gel of DNA fragments. Six differentially expressed bands in two pairs of rats were obtained. "T" above the bands and in name represents treated group, while "C" represents control group, "M" represents male, and "F" represents female. Among the bands, the expression levels of LaFT1-1-2, LaFT1-3-1, LaFT1-3-2, LaFT1-4-1 and LaMT1-4-1 were increased in treated rats. However, the level of LaFC1-4-1 was decreased.

Profile of gene expression in La(NO₃)₃-treated rat liver

HGEC-40D expression profile microarray, which consisted of 4 096 human cDNAs containing 60 control genes and 4 036 target genes, was provided by United Gene Holdings, Ltd. For every gene, there were two parallels in microarray. Target genes were divided into 15 types: oncogenes and tumor suppressor genes, ionic passage and transportation protein genes, cell cycle protein genes, stress reaction protein genes, cell skeleton

and movement protein genes, genes related to cell apoptosis, DNA synthesis, repair and recombination genes, DNA binding, transcription and transcription factor genes, cell receptor genes, immunity related genes, cell signal and transmission genes, metabolism related genes, protein translation and synthesis genes, growth related genes, and others.

Figure 3 Sequences of cDNA. A: Sequence of LaFT1-4-1. Its length was about 160 bp. The primers used were AP1 and ARP4. B: Sequence of LaMT1-4-1. Its length was about 144 bp. The primers used were AP1 and ARP4.

In order to monitor the preparation and hybridization of DNA microarray, positive and negative controls were arranged. Forty housekeeping genes were used as positive controls. 821 gene (8 spots) and 1×spot solution (8 spots) were used as negative control spots. Positive control spots showed high intensity of signals and negative control spots showed low intensity, which proved the reliability of the data.

Cy3 fluorescent signal (labeled control) and Cy5 fluorescent signal (labeled treated group) were represented with red and green respectively. For overlying two signals of one spot, the spot showed green if the intensity of Cy3 signal was stronger (indicating down-regulation tendency), the spot showed red if the intensity of Cy5 signal was stronger (indicating up-regulation tendency), the spot showed yellow if the intensities of Cy3 and Cy5 signals were similar. In this study, the result of microarray is shown in Figure 4.

Figure 4 Two overlying fluorescent signals.

We screened out 136 differentially expressed genes according to the following rules. The ratio of Cy3 and Cy5 signal was larger than 2 or smaller than 0.5, the raw intensity value of one or both of Cy3 and Cy5 was larger than 800, the trend of up-regulation or down-regulation in parallels was the same. Of the

136 genes with altered expression, 131 genes had an elevated expression and 5 genes had a reduced expression. Most of the differentially expressed genes were cell signal and transmission genes, genes related to metabolism, protein translation and synthesis genes. Five down-regulated and 19 up-regulated genes with their differential expression levels more than 4-fold and having similar trends, are described in Table 1.

DISCUSSION

Studies on toxicities of RE elements by different intake pathways showed that the liver was the target organ of RE element toxicity^[9-15], and 20 mg/kg was believed to be the effective dose in oral administration^[15]. So, rats treated with $\text{La}(\text{NO}_3)_3$ at a dose of 20 mg/kg by gavage were chosen in our study.

mRNA differential display could provide a unique and powerful experimental system to study differential gene expression. In this study, six differentially expressed tags were obtained. Of the 2 bands sequenced, one (LaFT1-4-1) was novel.

The technique of DNA microarray could allow expression monitoring of thousands of genes in parallel^[16]. This technique promotes the identification of differentially expressed genes and investigation of the function of genes. In this study, human cDNA microarray was used. The genomes of human and rodent were very similar^[17,18], the homology of human genes and rat genes was over 70%. So it is of significance to analyse rat samples by a HGEC-40D expression profile microarray. One hundred and thirty-six differentially expressed genes were found by DNA microarray, which included mainly cell signal and transmission genes, genes related to metabolism, protein translation and synthesis genes. These genes accounted for 15%, 14% and 13%, respectively. Analysis on capital genes was described as follows.

Some genes encoding mitochondrial proteins were up regulated. The levels of homo sapiens NADH-ubiquinone oxidoreductase B22 subunit mRNA, ND2 gene, NDUFA5 gene and NDUF8 gene were elevated 2.543, 3.540, 3.645 and 3.767 fold respectively, which were possibly associated with the damage of mitochondria.

Twelve differentially expressed KIAA genes were found in the study. Eleven were up regulated and one was down regulated. The expression level of KIAA0931 was elevated 23.4-fold. A family of KIAA includes new genes published by Kazusa DNA Research Institute in Japan. The functions of KIAA genes were supposed to be related to cell signal transmission, cell structure and cell movement based on the sequence studies^[19-21].

Phosphatidylcholine-specific phospholipase D1a (hPLD), is an important member of cell signal transducers. Active hPLD could produce biological effects by the following mechanisms. Phosphatidic acid (PA), diacyl-glycerol (DG) and lysophosphatidic acid (LPA), which are the direct and indirect products of hPLD, are important second messengers. Hydrolysis of phosphatidyl choline (PC) by hPLD could change local components of the membranes, consequently the characteristics of the membranes^[22]. It has been revealed that the process of hydrolysis of PC is related to many physiological activities including metabolism, cell cleavage, secretion, immunity, inflammatory reaction^[23]. In this study the expression level of hPLD gene was elevated by 10.1-fold, suggesting that activated hPLD which affects cell signal transmission is an important pathway of $\text{La}(\text{NO}_3)_3$ toxicity.

Signal transducer and activator of transcription (STAT) proteins play an important role in cell proliferation and differentiation induced by cytokines. STAT1 protein is believed to be the transcription factor of IFN reactivity. In addition, the mice with Stat1 gene picked out were found to be lacking of congenital immunity to viruses and bacteria^[24]. Protein inhibitor of activated STAT1 (PIAS1) could depress the activity of STAT1

by blocking STAT1 binding to specific DNA^[25]. PIAS1 gene was up regulated 5.3-fold in the study. It was suggested that $\text{La}(\text{NO}_3)_3$ might affect congenital immunity and the reactivity to IFN.

There were 7 differentially expressed genes related to immunity, of which 6 genes were up regulated and 1 was down regulated. In the up-regulated genes, H12.3 protein gene could regulate lymphocyte proliferation^[26]. CD9 antigen gene^[27], β -globulin gene, immuno-globulin light chain gene, CD24 signal transducer gene were related to humoral immunity. Calnexin protein gene played a role in cellular immunity and humoral immunity^[28]. The results suggested that $\text{La}(\text{NO}_3)_3$ had effects on both cellular immunity and humoral immunity. This was in good agreement with the results obtained by other researchers^[29-31].

In conclusion, the expression profiles of certain genes of $\text{La}(\text{NO}_3)_3$ treated rats differed markedly from those of control rats. This is consistent with the wide biological effect spectrum of RE elements. Multiple genes may join together to play a same role. Further analysis of the differentially expressed genes would be helpful for understanding the wide biological effect spectrum of RE elements. It would be interesting to explore further if the differentially expressed genes could be used as more sensitive biomarkers.

Abstract

AIM: To observe competitive inhibition of adherence of enterotoxigenic *Escherichia coli* (ETEC), enteropathogenic *Escherichia coli* (EPEC) and *Clostridium difficile* (*C. difficile*) to intestinal epithelial cell line Lovo by purified adhesin of *Bifidobacterium adolescentis* 1027 (*B. ado* 1027).

METHODS: The binding of bacteria to intestinal epithelial cell line Lovo was counted by adhesion assay. The inhibition of adherence of ETEC, EPEC and *C. difficile* to intestinal epithelial cell line Lovo by purified adhesin of *B. ado* 1027 was evaluated quantitatively by flow cytometry.

RESULTS: The purified adhesin at the concentration of 10 µg/mL, 20 µg/mL and 30 µg/mL except at 1 µg/mL and 5 µg/mL could inhibit significantly the adhesion of ETEC, EPEC and *C. difficile* to intestinal epithelial cell line Lovo. Moreover, we observed that a reduction in bacterial adhesion was occurred with increase in the concentration of adhesin, and MFI (Mean fluorescent intensity) was decreased with increase in the concentration of adhesin.

CONCLUSION: The purified adhesin of *B. ado* 1027 can inhibit the adhesion of ETEC, EPEC and *C. difficile* to intestinal epithelial cell line Lovo in a dose-dependent manner.

INTRODUCTION

It is well known that enterotoxigenic *Escherichia coli* (ETEC) and enteropathogenic *Escherichia coli* (EPEC) are major cause of diarrhoea in neonates and travelers. The gastrointestinal tract appears to be a reservoir for *E. coli* which are able to translocate across the intestinal mucosa. *Clostridium difficile* (*C. difficile*),

a gram-positive spore-forming anaerobic bacillus, is the most common cause of infectious diarrhoea in hospitalized patients^[1]. Adherence of bacteria to intestinal epithelium is known to be a prerequisite for colonization and infection of the gastrointestinal tract by many gastrointestinal pathogens^[2-4]. The intestinal epithelium is the primary site of contact for pathogens with host cells and plays an important role in the cross-talk between epithelial cells, luminal micro-organisms and immune cells. Therefore, inhibition of bacterial adhesion to the intestinal surface may prevent enteropathogens from translocating across the intestinal mucosa.

Bifidobacterium is known to be a predominant constituent of the human intestinal microflora^[5]. The presence of bifidobacteria in the human intestine has been reported to contribute to human health and well being^[6,7]. Adherence of bifidobacteria to intestinal mucus is regarded as one of the prerequisites for successful colonization^[8], antagonistic activity against enteropathogens^[9,10], modulation of the immune system^[11]. In addition, mucosal adhesion has been proposed as one of the main selection criteria for probiotic strains^[12-14]. Recently, studies have focused on its anti-infectious effects, particularly the inhibition activity against enteropathogens for protecting human^[15-17]. As the production and preservation of live bifidobacterium are difficult, so its application is restricted. Bernet *et al.*^[18] observed that the occurrence of bifidobacteria adhering to the human intestinal cells by a mechanism of adhesion which involved a proteinaceous component. Fujiwara *et al.*^[19,20] clarified that bifidobacterium longum SBT2928 produced a proteinaceous factor which prevented the binding of ETEC to the binding receptor ganglioside GM1. Zheng *et al.*^[21] extracted and purified a protein with a molecular weight of 16 ku from spent culture supernatant of *Bifidobacterium adolescentis* 1027 (*B. ado* 1027). In the present study, competitive inhibition of adherence of ETEC, EPEC and *Clostridium difficile* to intestinal epithelial cells by purified adhesin of *B. ado* 1027 was observed by adhesion assay and flow cytometry assay.

MATERIALS AND METHODS

Bacterial strains

B. ado 1027 was isolated from healthy infants feces and identified by API-20A and TAB system (British). *B. ado* 1027 was cultured in sulfglycolic acid salt broth at 37 °C for 48 h under anaerobic conditions. ETEC and EPEC were obtained from Department of Epidemiology, First Military Medical University. ETEC and EPEC were cultured in agitation, nutrient broth at 37 °C for 48 h. A toxin-producing *C. difficile* strain (VPI10463) was obtained from Lanzhou Institute of Biological Products (China). *C. difficile* strain was grown in brain-heart infusion broth at 37 °C for 48 h under anaerobic conditions. All bacteria were harvested from the broth culture by centrifugation at 2 500 r/min for 10 min, followed by resuspension of the pellet in phosphate buffered saline (PBS, pH 7.4) to a concentration of 1×10⁸ colony forming units (cfu)/mL.

Cell line

Human intestinal epithelial cell line Lovo was obtained from American type culture collection (ATCC) and was maintained in RPMI-1 640 (Gibco) supplemented with 2 mmol/L *L*-glutamine and 100 mL/L FCS at 37 °C in a humidified atmosphere containing 50 mL/L CO₂. For the adhesion assay, monolayer of Lovo cell was prepared on glass coverslips which were placed in six-well tissue culture plates (Corning Glass Works, Corning, N.Y.).

Extraction and purification of adhesin

The adhesin of bifidobacterium was extracted and purified as reported earlier by Zheng *et al.*^[21]. In short, the adhesin of bifidobacterium was isolated and purified by Superdex 75 gel filtration and Q-Sepharose FF ion exchange chromatography, and the adhesin was analyzed by SDS-PAGE. It was a protein with a molecular weight of 16 Ku, stored at -20 °C.

In vitro adhesion assay

The adherence of bacteria strains to Lovo cells was examined as described previously^[22-24]. Briefly, the Lovo monolayer prepared on glass coverslips which were placed in six-well tissue culture plates, was washed twice with PBS. The adhesin (1 µg/mL, 5 µg/mL, 10 µg/mL, 20 µg/mL, and 30 µg/mL) of bifidobacterium was added to each well of the tissue culture plate, and the plate was incubated at 37 °C in a humidified atmosphere containing 50 mL/L CO₂. After 30 min of incubation, the monolayer was washed one time with PBS. The suspensions of bacteria (1 mL) were added to each well, respectively. After 3 h of incubation at 37 °C atmosphere, the monolayer was washed twice with

sterile PBS, fixed with methanol, stained with Gram stain, and examined microscopically. For each monolayer on a glass coverslip, the number of adherent bacteria was evaluated in 30 random microscopic areas. Adherence was evaluated by two different technicians to eliminate bias. Bifidobacterium+bacteria and alone bacteria group were used as controls of adhesion.

Mean fluorescent intensity (MFI) of human intestinal epithelial cell with adherent bacteria were detected by flow cytometer

The fluorochrome FITC (Fluorescein isothiocyanate) was used in this study. All bacteria were washed 2 times in bicarbonate buffer (0.1 mol/L, pH 9.2), and labelled with fluorochrome FITC (1.5 mg/mL) by incubating 1×10⁸ bacteria/mL at 4 °C for 1 h. Excess fluorochrome was removed by washing 5 times with PBS at 1 500 g. All bacteria were resuspended in PBS which contained *B. ado* 1027 (1×10⁸/mL), adhesin of different concentrations and non-adhesin. Fluorescently labelled bacteria (1×10⁸) were incubated with 1×10⁵ epithelial cells for 2 h at 37 °C. After incubation, cells were washed three times with PBS to remove non-adherent bacteria. MFI (wave-length of excitation: 488 nm, wave-length of emission: 575 nm) of human intestinal epithelial cells with adherent bacteria was measured in a FACS-420 flow cytometer (Coulter, U.S). A total of 10 000 cells was acquired and the data were analysed with the Cell Quest software program from Coulter.

Statistical analysis

Values were expressed as mean±SD. Statistical comparisons between the means were made with students *t* test by SPSS 10.0 version. A *P* value of <0.05 was assumed for statistical significance.

Figure 1 Gram staining of ETEC, EPEC and *Clostridium difficile* (×1000). Competitive inhibition of adherence of ETEC, EPEC and *Clostridium difficile* to intestinal epithelial cells by purified adhesin of *B. ado* 1027 was observed by adhesion assay. A: adherence of ETEC to intestinal epithelial cells without adhesin; B: adherence of ETEC to intestinal epithelial cells with adhesin; C: adherence of EPEC to intestinal epithelial cells without adhesin; D: adherence of EPEC to intestinal epithelial cells with adhesin; E: adherence of *C. difficile* to intestinal epithelial cells without adhesin; and F: adherence of *C. difficile* to intestinal epithelial cells with adhesin.

RESULTS

Effect of purified adhesin of *B. ado 1027* on adherence of ETEC, EPEC and *C. difficile* to intestinal epithelial cells

The adhesion assay was performed after Lovo cell and different concentrations adhesin were incubated at 37 °C for 30 min. As shown in Table 1, the purified adhesin at the concentration of 10 µg/mL, 20 µg/mL and 30 µg/mL except at 1 µg/mL and 5 µg/mL could significantly inhibit the adhesion of ETEC, EPEC and clostridium difficile to intestinal epithelial cell line Lovo. Adhesion of ETEC, EPEC or *Clostridium difficile* to intestinal epithelial cell was significantly decreased when the concentration of purified adhesin was 10 µg/mL, 20 µg/mL or 30 µg/mL ($P<0.05$, $P<0.01$). Moreover, we observed that the ability of inhibition was enhanced with increase in the concentration of adhesin. These results indicated that purified adhesin of *B. ado 1027* was involved in the adhesion of bacteria. The adhesion of ETEC and EPEC to intestinal epithelial cell was linear (Figures 1A, B, C and D). The adhesion of *C. difficile* to intestinal epithelial cell was like cluster (Figures 1E and F). The number of adherence of ETEC, EPEC and clostridium difficile to intestinal epithelial cells with adhesin was less than that of without adhesin. Inhibition of adherence of ETEC, EPEC and *Clostridium difficile* to intestinal epithelial cell by purified adhesin of *B. ado 1027* was not significantly different between adhesin (30 µg/mL) and bacteria+ *B. ado 1027* group (1×10^8 /mL).

Flow cytometric analysis of bacteria adherence to intestinal epithelial cell

ETEC, EPEC and a toxin-producing *C. difficile* strain (VPI10463) were assessed for their ability to adhere to human intestinal epithelial cell line Lovo (Table.2). There was no significant difference in MFI of ETEC, EPEC or *C. difficile* when the concentrations of adhesin were 1 µg/mL and 5 µg/mL. However, MFI was significantly decreased when the concentrations of adhesin were 10 µg/mL, 20 µg/mL and 30 µg/mL ($P<0.05$, $P<0.01$).

MFI was decreased with increase in the concentration of adhesin. There was no significant difference in MFI between adhesin (30 µg/mL) and bacteria+ *B. ado 1027* group (1×10^8 /mL).

DISCUSSION

Adherence of pathogenic to the intestinal mucus is regarded a prerequisite for prolonged transient colonization and infection of the gastrointestinal tract, and plays an important role in invasion and in yielding and secretion of virulence factor^[25]. Bifidobacteria, the predominant bacteria in the human intestinal microflora, are considered to be microorganisms with a great influence on human health^[26]. There have been many studies demonstrating that strains of bifidobacteria have anti-infectious properties against enteropathogenic bacteria^[18,27-29]. However, there existed a few flaws when live bifidobacteria agents was used in gut barrier dysfunction: live bifidobacteria was difficult to produce and preserve, and also difficult to breed sufficiently due to lack of local gas and growth substrate. Bernet *et al.*^[18] and Zheng *et al.*^[30] reported the occurrence of bifidobacteria adhering to the human intestinal cells by a mechanism of adhesion which involves a proteinaceous component. Fujiwara *et al.*^[31] reported that SBT2928 produced a proteinaceous factor, binding inhibitory factor (BIF), which prevented the binding of the ETEC to GA1 *in vitro*, and the binding of ETEC to the human intestinal epithelial cell line HCT-8 was reduced by BIF treatment in a dose-dependent manner. These results showed there was adhesin component in bifidobacteria.

Adherence assay which can Gram stain and microscopically examine bacteria to human intestinal epithelial has been accepted widely for quantitative and direct visual. However, light microscopic methods, while useful, are tedious and time-consuming and may be prone to observer error. Flow cytometry allows analysis of cell populations by virtue of their physical characteristics and has been used previously to assess the adherence of *Helicobacter pylori*^[32]. With this approach, it is possible to distinguish differences in cell populations based on changes in fluorescent intensities for test and control populations. When compared with conventional microscopy, it is also possible to examine much larger numbers of cells in a shorter time period^[33]. The present study used Gram stain and flow cytometry to demonstrate competitive inhibition of adherence of ETEC, EPEC and *C. difficile* to intestinal epithelial cell line Lovo by purified adhesin of *B. ado 1027*. Our study showed that the purified adhesin at the concentration of 10 µg/mL, 20 µg/mL and 30 µg/mL except at 1 µg/mL and 5 µg/mL could significantly inhibit the adhesion of ETEC, EPEC and *C. difficile* to intestinal epithelial cell line Lovo. Moreover, we observed that the ETEC, EPEC and *C. difficile* adhesion were reduced by adhesin treatment in a dose-dependent manner. Inhibition of the binding of ETEC, EPEC and *C. difficile* to intestinal epithelial cell was not significantly different between adhesin (30 µg/mL) and bacteria+ *B. ado 1027* group. The results of flow cytometry analysis of bacteria adherence to intestinal epithelial cell also confirmed it. MFI was decreased with increase in the concentration of adhesin. These results indicated that purified adhesin of *B. ado 1027* was involved in the adhesion of bacteria. Two basic factors, receptor and adhesin, are required for classical adhesion. One of the mechanisms by which probiotic bacteria can protect epithelial is receptor competition^[34]. Our results suggest that adhesin functions by blocking the binding site of ETEC, EPEC and *C. difficile* to intestinal epithelial cell. Adhesin produced by bifidobacterial may play an important role in protecting the host. Future studies need to carry out a survey of the resistance of adhesin against the activities of digestive enzymes in the gastrointestinal tract of human. In addition, it is important to determine whether all strains or all species of bifidobacteria produce adhesin or a similar protein(s).

which prevents the binding of pathogens to receptor in intestinal epithelial surfaces.

We also observed that the adhesive behaviors of bacteria to intestinal epithelial cell line Lovo were different. The adhesion of ETEC and EPEC to intestinal epithelial cell was linear, whereas the adhesion of *C. difficile* to intestinal epithelial cell was like cluster. This suggests that different bacteria may have different distribution of receptor on cell surface.

In conclusion, the purified adhesin of *B. ado* 1027 can effectively inhibit adherence of ETEC, EPEC and *C. difficile* to intestinal epithelial cell *in vitro*. However, whether adhesin could prevent diseases related with ETEC, EPEC and *C. difficile*, still needs to be proved *in vivo* by human clinical studies.

Abstract

AIM: To test the hypothesis that introduction of antisense T β R I and T β R II eukaryotic expressing plasmids into a rat model of immunologically induced liver fibrosis might block the action of TGF- β_1 and halt the progression of liver fibrosis.

METHODS: RT-Nest-PCR and gene recombination techniques were used to construct rat antisense T β R I and T β R II recombinant plasmids which could be expressed in eukaryotic cells. The recombinant plasmids and empty vector (pcDNA3) were encapsulated by glycosyl-poly-L-lysine and then transduced into rats of pig serum-induced liver fibrosis model. Expression of exogenously transfected gene was assessed by Northern blot, and hepatic expressions of T β R I and T β R II were evaluated by RT-PCR and Western blot. We also performed ELISA for serum TGF- β_1 , hydroxyproline of hepatic tissues, immunohistochemistry for collagen types I and III, and VG staining for pathological study of the liver tissues.

RESULTS: The exogenous antisense T β R I and T β R II plasmids could be well expressed *in vivo*, and block mRNA and protein expression of T β R I and T β R II in the fibrotic liver at the level of mRNA respectively. These exogenous plasmid expressions reduced the level of TGF- β_1 (antisense T β R I group 23.998 \pm 3.045 ng/mL, antisense T β R II group 23.156 \pm 3.131 ng/mL, disease control group 32.960 \pm 3.789 ng/mL; $F=38.19$, 36.73, $P<0.01$). Compared with disease control group, the contents of hepatic hydroxyproline (antisense T β R I group 0.169 \pm 0.015 mg/g liver, antisense T β R II group 0.167 \pm 0.009 mg/g liver, disease control group 0.296 \pm 0.026 mg/g liver; $F=14.39$, 15.48, $P<0.01$) and the deposition of collagen types I and III decreased in the two antisense treatment groups (antisense T β R I group, collagen type I 669.90 \pm 50.67, collagen type III 657.29 \pm 49.48; antisense T β R II group, collagen type I 650.26 \pm 51.51, collagen type III 661.58 \pm 55.28; disease control group, collagen type I 1209.44 \pm 116.60, collagen type III 1175.14 \pm 121.44; $F=15.48$ to 74.89, $P<0.01$). Their expression also improved the pathologic classification of liver fibrosis models (compared with disease control group, $\chi^2=17.14$, 17.24, $P<0.01$). No difference was found in the level of TGF- β_1 , the contents of hepatic hydroxyproline and collagen types I and III and pathologic grade between pcDNA3 control group and disease control group or between the two antisense treatment groups ($F=0.11$ to 1.06, $\chi^2=0.13$ to 0.16, $P>0.05$).

INTRODUCTION

Liver fibrosis is a common sequel to diverse liver injuries. In the formation of liver fibrosis and cirrhosis, synthesis of collagen increases and its degradation decreases. It has been thought that liver fibrosis can be reversed and liver cirrhosis is irreversible^[1-5]. Profound studies have been conducted on the treatment of liver fibrosis. However, this disease is still lack of efficient therapy^[6-11]. Searching for a new therapy seems very important.

In the formation of liver fibrosis and cirrhosis, many cytokines produce marked effects through autocrine and paracrine^[1,2,5]. Molecular mechanisms involved in fibrogenesis reveal that transforming growth factor β (TGF- β), especially TGF- β_1 , plays a pivotal role^[12-16]. Signaling by TGF- β occurs through a family of transmembranes and ser/thr kinase receptors. Both components of the receptor complex, known as receptor I (T β R I) and receptor II (T β R II) are essential for signal transduction^[17,18]. So in theory, blockage of TGF- β signal transduction by inhibiting the expression of T β R I and/or T β R II may have therapeutic effects on liver fibrosis.

At present, gene therapy for liver fibrosis targeting TGF- β mainly includes inhibiting the expression of TGF- β_1 (for instance, antisense TGF- β_1 RNA) and using deficient T β R II^[19-21]. But therapeutic researches which target T β R I or use antisense T β R II as a therapeutic tool have not been reported. In the present experiments, we constructed antisense T β R I and T β R II eukaryotic expressing plasmids and performed *in vivo* transfection. We aimed to test the hypothesis that introduction of these two exogenous plasmids into a rat model of immunologically induced liver fibrosis might block the action of TGF- β_1 and halt the progression of liver fibrosis.

MATERIALS AND METHODS

Construction of recombinant plasmid

Nested primers were designed and synthesized according to rat T β R I and T β R II cDNA sequences (GenBank)^[22,23]. The length of amplified PCR products was anticipated to be 470 bp, 606 bp (Table 1). Total RNA was extracted from normal rat liver with Trizol reagent (GIBCO, USA) according to the manufacturer's directions. RT-Nest-PCR was used to construct T β R I and T β R II cDNA fragments. Samples were heated at 94 °C for 7 min and subjected to 32 PCR cycles of denaturation at 94 °C for 1 min, annealing at 55 °C for 1 min, extension at 72 °C for 1 min, followed by a final extension at 72 °C for 5 min. After separation, reclaim and purification, the PCR products of T β R I and T β R II were

connected with T vector (Promega, USA) and then transferred into JM-109 strain. PT/T β R I and PT/T β R II were successfully constructed after IPTG/X-gal screening. The target fragments were cut and inserted reversely into eukaryotic expressing plasmid pcDNA3 (Invitrogen, CA), and then transferred into JM-109 strain again. By using enzyme-cutting identification (T β R I: *Eco*RI and *Xho*I; T β R II: *Eco*RI and *Bam*HI) and DNA autosequencing (PE377 Auto sequencer, USA), the successful constructions of antisense T β R I and T β R II eukaryotic expressing plasmids were proved (Figure 1).

Experimental protocols

Forty-six male Sprague-Dawley rats (weighing 100 to 120 g) provided by Experimental Animal Center, Zhongshan Hospital, Fudan University, were randomly divided into the following 5 groups: 10 in experimental liver fibrosis model induced by pig-serum as disease control group (M), 10 in antisense T β R I plasmid transfection as treatment group (A), 10 in antisense T β R II plasmid transfection as treatment group (B), 10 in pcDNA3 transfection as pcDNA3 control group (C) and 6 in normal control group (N). Animals in the normal control group received 0.5 mL of NS twice weekly by intraperitoneal injection for 8 wk. Rats in the other 4 groups received 0.5 mL of pig-serum twice weekly by intraperitoneal injection for 8 wk^[24]. Among groups A, B and C, the recombinant antisense T β R I and T β R II plasmids and empty vector (pcDNA3) of 100 μ g each time were encapsulated by glycosyl-poly-L-lysine (G-PLL) and then transduced into rats of liver fibrosis model via caudal vein every 2 wk respectively. The molecular ratio of galactose and poly-L-lysine was 15:28 and the average molecular weight of G-PLL was 8.5 ku. All experimental rats were sacrificed at the end of the 8th wk. The middle lobes of the livers were removed and specimens were fixed in Carnoy's fixative (glacial acetic acid, chloroform, and ethanol at a volume ratio of 1:3:6) and

then embedded in paraffin for histological analysis. The remaining tissue was quickly partitioned and immediately stored in liquid nitrogen and then frozen below -70 °C. After that the rats were humanely killed.

RNA isolation and Northern blot analysis for exogenous gene and hepatic T β R I and T β R II expression

For Northern blot analysis, 30 μ g of total tissue RNAs was separated by electrophoresis on a 1% denaturing agarose gel, transferred to a Hybond-N membrane (Amersham, UK) and fixed by baking for 2 h at 80 °C. The probe for pcDNA3 according to its special T7 promoter sequence (the oligonucleotide fragment: 5'-CAGAGGGATATCACTCAGCATAAT-3'), which was to detect exogenous gene expression, was labeled with [α -³²P]dATP using DNA tailing kit (Roche, Germany). T β R I and T β R II cDNA probes were labeled with [α -³²P]dCTP using a high prime DNA labeling kit (Roche, Germany) to detect rat T β R I and T β R II expression. Blots were pre-hybridized for at least 3 h at 42 °C, and then hybridized for 20 h at 42 °C. Auto radiographs were exposed for indicated times to Kodak films at -70 °C for 7 d. As an internal standard (loading control) the blots were re-hybridized with [α -³²P] β -actin.

RT-PCR analysis for T β R I and T β R II mRNA expression

Total RNA of 1 μ g from each sample was reversely transcribed and amplified using an RT-PCR kit (ShengNeng-BoCai Biotechnology Co. Shanghai, China). The RT-PCR reaction contained 12.5 pmol each primer (T β R I: sense sequence 5' - TCACTAGATCGCCCTTTCAT-3'; antisense sequence 5' - GATAATCCGACACCAACCAC-3', a product of 355 bp; T β R II: sense sequence 5' - CCACGACCCCAAGTTCACCT-3', antisense sequence 5' - TGGGCAGCAGTTCGATTG-3', a product of 428 bp) for detecting the T β R I and T β R II mRNA expression in rat liver tissues. Additionally primer pairs (sense sequence 5' - TGGGACGATATGGAGAAGAT-3'; antisense sequence 5' - ATTGCCGATAGTGATGACCT-3') were used for amplifying the expression of β -actin (a product of 521 bp) as internal control. Samples were placed in a thermocycler with the incubation program at 37 °C for 60 min, at 90 °C for 5 min, then 30 cycles at 94 °C for 45 s, at 54 °C for 45 s, and at 72 °C for 1 min, and a final extension at 72 °C for 5 min. Products of RT-PCR were electrophoresed on a 20 g/L agarose gel to show the amplified bands. The areas under curve of the bands were calculated by Photo-Treater (Tanon GIS-1000, China). The ratio of the objective band and β -actin (control) represented the relative value of expression of the objective band.

Western blot for hepatic T β R I and T β R II expression

Lysates from 50 mg rat liver tissues were prepared with RIPA buffer [1 \times PBS, 10 g/L NP40, 5 g/L sodium deoxycholate, 1 g/L SDS, 10 mmol/L PMSF (in isopropanol), 36 μ g/mL aprotinin and 1 mmol/L sodium orthovanadate]. Tissue lysates were centrifuged at 3000 r/min for 10 min at 4 °C, and protein concentrations were determined by BCA protein assay (Pierce, IL). Protein samples (100 μ g) were heated for 5 min at 100 °C and separated on 120 g/L SDS-PAGE and then transferred to PVDF membranes (Schleicher&Schuell, Germany) in Tris-glycine buffer (pH 8.5) plus 200 mL/L methanol. The membranes were blocked overnight in 50 mL/L non-fat dried milk in Tris-buffer containing 1 g/L Tween-20 and then washed with Tris-buffer. The blots were incubated overnight at 4 °C with rabbit T β R I, T β R II and β -actin polyclonal IgG (Santa Cruz, USA) diluted 1:200 in Tris-buffer. The blots were washed and then incubated with AP-conjugated secondary antibodies (Santa Cruz, USA) at 1:500 dilution for 2 h at room temperature. The protein bands were visualized with BCIP/NBT (DAKO, USA) system.

ELISA assay of serum TGF- β_1

Assay of serum TGF- β_1 content was performed with double antibody ABC-ELISA method according to the previous reports of Ueno *et al.*^[21] and Roth *et al.*^[25].

Hepatic hydroxyproline (OH-Pro) content

Hydroxyproline content was determined by the previous method with some modification^[26]. A total of 500 mg of liver tissues was hydrolyzed in 6 mol/L HCl solution at 120 °C for 24 h. The hydroxyproline content of the liver was expressed as micrograms per gram of wet weight.

Immunohistochemistry of hepatic collagen types I and II

After dewaxed with xylene and rehydrated through a graded alcohol series, sections were digested with 4 g/L trypsin. The sections were incubated with rabbit polyclonal antibodies against types I or II collagen (diluted 1:100) at 37 °C for 60 min and then overnight at 4 °C. Then the sections were incubated with Envision™ secondary antibodies of biotinylated sheep anti-rabbit IgG (DAKO, USA) at 37 °C for 30 min and then with the substrate solution (3,3'-diaminobenzidine tetrahydrochloride in H₂O₂ in Tris buffer pH 7.4) for 10 min, followed by counterstaining with hematoxylin. The sections were washed 3 times with 0.01 mol/L PBS (pH 7.4) after each step. For control staining, PBS was used instead of the primary antibody. The slides were then analyzed with an image analyzing system (LeiCA-Q500IW System, Germany) to obtain the integral light density and the average area of positive staining. The multiplication of both parameters represented the relative contents of hepatic collagen types I and II.

Histology

Sections from paraffin-embedded blocks were dewaxed and stained with Van Gieson method. Fibrosis was scored according to the classification which graded liver fibrosis into seven degrees (0-VI).

Statistical analysis

All values were expressed as mean±SD. Differences between groups were analyzed by one-way ANOVA (SPSS10.0 software) and the pathological grading of fibrosis of each group was analyzed by trend analysis and chi-square test (EPI5.0 software). $P < 0.05$ was considered statistically significant.

RESULTS

General situation of animals

No animal died during the experimental period. No significant difference was found in the levels of ALT (51±9 U/L vs 53±8 U/L) and Cr (91±13 μmol/L vs 92±14 μmol/L) between pcDNA3 control group and disease control group ($P > 0.05$). No significant difference was found in the height or weight of rats among antisense TβR I, antisense TβR II and pcDNA3 control groups ($P > 0.05$).

Expression of exogenous gene and TβR I, TβR II gene in liver tissues by Northern blot

The exogenous gene expression could be detected in transfection groups (antisense TβR I, antisense TβR II and pcDNA3 control groups) by Northern blot, but not in disease control group (Figure 1). The expression of TβR I mRNA was much higher in pcDNA3 control group and disease control group than in antisense TβR I group. The expression of TβR II was also much higher in pcDNA3 control group and disease control group than in antisense TβR II group at mRNA level (Figure 2).

Hepatic TβR I and TβR II mRNA expression by RT-PCR

The expression of antisense TβR I RNA induced a decreased mRNA level of TβR I in antisense TβR I group (1.039±0.110)

compared with pcDNA3 control group (1.453±0.112) and disease control group (1.472±0.099) ($P < 0.01$). The expression of antisense TβR II RNA also induced a decreased mRNA level of TβR II in antisense TβR II group (0.805±0.105) compared with pcDNA3 control group (1.743±0.151) and disease control group (1.798±0.139) ($P < 0.01$). No difference was found in the level of TβR I and TβR II mRNA between pcDNA3 control and disease control groups ($P > 0.05$).

Figure 2 Expression of exogenous transfected gene assessed by Northern blot, A: Hybridization using ³²P labeled oligonucleotide probe which targets T7 promoter; B: Hybridization by using ³²P labeled TβR II cDNA probe; C: Hybridization by using ³²P labeled TβR I cDNA probe; D: β-actin probe used as control. Lane 1: Antisense TβR II group; Lane 2: pcDNA3 control group; Lane 3: Disease control group; Lane 4: Antisense TβR I group.

Figure 3 Hepatic protein expression of TβR I, TβR II assessed by Western blot, A: Hepatic protein expression of TβR II; B: Hepatic protein expression of TβR I; Lanes 1,8: Disease control group; Lanes 2,7: pcDNA3 control group; Lane 3: Antisense TβR II group; Lanes 4,6: Normal control group; Lane 5: Antisense TβR I group.

Hepatic TβR I and TβR II protein expression by Western blot

The expression of TβR I protein was decreased in antisense TβR I group and the expression of TβR II protein was also decreased in antisense TβR II group when compared with pcDNA3 control group and disease control group, but they were still slightly higher than those in normal control group. The expressions of TβR I and TβR II protein in pcDNA3 control group were similar to those in disease control group (Figure 3).

Table 2 Effects of transfected plasmid on the content of hepatic hydroxyproline and deposition of collagen types I and III (mean \pm SD)

Group	Number	Hydroxyproline (mg/g liver)	Collagen I	Collagen III
Disease control group	10	0.296 \pm 0.026 ^d	1 209.44 \pm 116.60 ^d	1 175.14 \pm 121.44 ^d
Antisense T β R II group	10	0.167 \pm 0.009 ^{bd}	650.26 \pm 51.51 ^{bd}	661.58 \pm 55.28 ^{bd}

ELISA assay of serum TGF- β_1

The level of serum TGF- β_1 was reduced in antisense T β R I group (23.998 \pm 3.045 ng/mL) and antisense T β R II group (23.156 \pm 3.131 ng/mL) compared with pcDNA3 control group (32.275 \pm 1.884 ng/mL) and disease control group (32.960 \pm 3.789 ng/mL), but was still higher than that in normal control group (14.338 \pm 2.421 ng/mL) ($P<0.01$). No significant difference was found between antisense T β R I and antisense T β R II groups ($P>0.05$).

Effects of antisense T β R I and T β R II plasmid transfection on hepatic hydroxyproline and collagen types I and II content

The hepatic hydroxyproline content and the accumulation of hepatic collagen types I and III in antisense T β R I and antisense T β R II groups were significantly decreased compared with disease control and pcDNA3 control groups ($P<0.01$). No statistical difference was found between pcDNA3 control and disease control groups or between antisense T β R I and antisense T β R II groups ($P>0.05$). Hepatic hydroxyproline content and accumulation of collagen in these four groups were significantly higher than those in normal control group ($P<0.01$) (Table 2).

Effects of transfected plasmid on patho-histology

The fibrosis grade of antisense T β R I and antisense T β R II groups alleviated significantly compared with disease control and pcDNA3 control groups ($P<0.01$). All these four groups had significantly higher fibrosis grades when compared to normal control group ($P<0.01$). No significant difference was found between disease control and pcDNA3 control groups or between antisense T β R I and antisense T β R II groups ($P>0.05$) (Table 3).

DISCUSSION

Pig serum-induced rat hepatic fibrosis is a model that shows an intense immune response to the administration of heterologous serum. Histologically, the changes were characterized by mononuclear cell infiltration and fibrotic response in the periportal area, followed by the septum formation connecting portal tract with central veins without hepatocyte injury^[24].

In the formation of liver fibrosis and cirrhosis, a number of cytokines could produce marked effects through autocrine and

paracrine^[25,26]. Molecular mechanisms involved in fibrogenesis revealed that transforming growth factor β (TGF- β), especially TGF- β_1 , played a pivotal role in the regulation of the production, degradation and accumulation of extracellular matrix (ECM)^[1,21,27]. Secreted as a latent precursor, TGF- β is activated at sites of injury. Active TGF- β binds to specific, high-affinity receptors present on most cells, initiating a signaling cascade that results in biological effects. Signaling by TGF- β occurs through a family of transmembranes and ser/thr kinase receptors. Both components of the receptor complex, known as receptor I (T β R I) and receptor II (T β R II) are essential for signal transduction. Signaling is initiated by binding of TGF- β to the T β R II. Once bound, the TGF- β /T β R II complex then recruits T β R I into a heteromeric complex. Within the heteromeric complex, the kinase domain of type II receptor could transphosphorylate and activate type I receptor kinase, which then functioned to propagate the signal to downstream targets^[21-23]. At present, gene therapy for liver fibrosis targeting TGF- β receptor mainly used adenoviral vectors expressing a dominant-negative type II TGF- β receptor or an adenovirus expressing an entire ectodomain of human TGF- β type II receptor fused to Fc portion of human IgG to block the TGF- β signal transduction^[19,21].

Antisense technique has been used to inhibit the target genes and proteins expressed in experimental rat hepatic fibrosis^[7]. We used RT-Nest-PCR and gene recombination techniques to construct rat antisense T β R I and T β R II recombinant plasmids successfully which could be expressed in eucaryotic cells. We transduced the exogenous plasmid into the fibrotic liver based on our previous research on gene target therapy. The exogenous antisense T β R I and T β R II recombinant plasmids were well expressed *in vivo*, and could block the mRNA and protein expression of T β R I and T β R II in the fibrotic liver induced by pig serum.

In our study, serum TGF- β_1 analysis showed the expression of TGF- β_1 was decreased after the expression of T β R I and T β R II was blocked. Our results were similar to the previous report that used deficient T β R II in treating experimental liver fibrosis. It was indicated that the production of active TGF- β_1 was inhibited after the expression of TGF- β receptors was blocked and the signal transduction of TGF- β was also inhibited.

Collagen types I and III constitute the main components of increased ECM in liver fibrosis. It has been proposed that degradation of collagen types I and III is very important in the

reversion of liver fibrosis^[5,28,29]. In our study, the recombinant plasmid could be delivered to liver by G-PLL and expressed in the tissue of liver. In addition, there was a significant decrease of collagen deposition after the recombinant antisense T β R I and T β R II plasmids was transduced into fibrotic liver through measuring the hepatic hydroxyproline content and immunohistochemistry of collagen types I and III. This suggested that the recombinant plasmids could increase the degrading capacity of collagen types I and III, decrease the deposition of ECM, and probably reverse hepatic fibrosis. In the data analysis, there was a significant difference in fibrosis grades between the disease control group and the recombinant plasmid transfected group. It showed that the antisense T β R I and T β R II plasmids had significant ameliorative effects on liver fibrosis.

No difference was found in the level of TGF- β ₁, the contents of hepatic hydroxyproline and collagen types I and III and the pathologic grade between empty plasmid control and disease control groups or between the two antisense treatment groups. It indicated that the signal transduction of TGF- β could be inhibited by blocking the expression of either T β R I or T β R II and the effects of antisense T β R I and antisense T β R II plasmids on experimental liver fibrosis were similar. Both T β R I and T β R II were essential for signal transduction.

In summary, our results demonstrate that TGF- β ₁ plays an important role in liver fibrosis development especially in degradation of collagens. Antisense T β R I and antisense T β R II recombinant plasmids have certain reverse effects on liver fibrosis and could be used as possible candidates for gene therapy. As a new therapeutic means, gene therapy has a long way to go, especially in transductive efficiency, gene targeting, stability and adverse effects.

Abstract

AIM: To assess CT, MR manifestations and their diagnostic value in hepatic tuberculosis.

METHODS: CT findings in 12 cases and MR findings in 4 cases of hepatic tuberculosis proved by surgery or biopsy were retrospectively analyzed.

RESULTS: (1) CT findings: One case of serohepatic type of hepatic tuberculosis had multiple-nodular lesions in the subcapsule of liver. Parenchymal type was found in 10 cases, including multiple, miliary, micronodular and low-density lesions with miliary calcifications in 2 cases; singular, low-density mass with multiple flecked calcifications in 3 cases; multiple cystic lesions in 1 case; multiple micronodular and low-density lesions fusing into multiloculated cystic mass or "cluser" sign in 3 cases; and singular, macronodular and low-density lesion with multiple miliary calcifications in 1 case. One case of tuberculous cholangitis showed marked dilated intrahepatic ducts with multiple flecked calcifications in the porta hepatis. (2) MR findings in 4 cases were hypointense on both T1-weighted imagings and T2-weighted imagings in one case, hypointense on T1-weighted imagings and hyperintense on T2-weighted imagings in 3 cases. Enhanced MR in 3 cases was slightly shown peripheral enhancement or with multilocular enhancement.

CONCLUSION: Various types of hepatic tuberculosis have different imaging findings, and typical CT and MR findings can suggest the diagnosis.

INTRODUCTION

During the second half of the twentieth century, as a result of improved nutrition, reduced crowding, public health measures, and effective chemotherapy, a dramatic decrease in the incidence of tuberculosis was seen in the world^[1]. But in recent years, increased incidence of tuberculosis has been attributed to several causes, including AIDS epidemic, iv drug abuse and

increase in the number of immunocompromised patients^[2,3]. Hepatic tuberculosis is the most common manifestation of upper abdominal parenchymatous organ tuberculosis and its incidence has also been increasing.

Imaging features of hepatic tuberculosis have been described by several researchers at computed tomography (CT) and magnetic resonance imaging (MRI), the imaging appearance of these lesions is considered as nonspecific and, a histopathological or bacteriological confirmation is often required^[4-7].

The CT and MRI features of 12 patients with pathologically proven hepatic tuberculosis examined between 1984 and 1999 were analyzed retrospectively to improve the imaging diagnostic accuracy and differentiation of hepatic tuberculosis.

MATERIALS AND METHODS

Subjects

Of the 12 hepatic tuberculosis patients, 7 were male and 5 female, aged from 18 to 69 years (mean, 38.2 years). The diagnosis was proved by surgery (8 cases), liver biopsy (3 cases) and abdominoscopy (1 case). The duration of symptoms ranged from 1 to 18 mo. The most frequent clinical symptoms and signs were right upper abdominal pain ($n=10$), upper abdominal tenderness ($n=8$), low-grade fever ($n=8$), night sweat ($n=6$), weight-loss and fatigue ($n=5$), abdominal mass ($n=1$), hepatomegaly ($n=4$) and jaundice ($n=2$). Among the 12 cases, 4 were accompanied by extra-hepatic tuberculosis. Laboratory test showed anemia ($n=10$), raised erythrocyte sedimentation rate ($n=9$) and abnormal liver function ($n=7$). Tuberculin test was positive in 4 out of 5 patients tested. Eight patients were examined with ultrasound, but only 2 were correctly diagnosed. All the 12 patients had chest x-ray, and evidences of pulmonary tuberculosis were found in 2.

CT scanning

CT was performed with Siemens Somatom DR3 and HiQ units for the patients in routine fasting state. Some patients were given 500 mL of diluted iodinated contrast medium (10 g/L meglumine diatrizoate) orally 30 min before scanning. Scan scope ranged from the dome of diaphragm to the last plane of liver. All patients were examined with plain scanning at first and then using 600 g/L meglumine diatrizoate 60-80 mL for enhanced scanning with section thickness of 8-10 mm and interval of 10 mm.

MR scanning

MR was performed with a superconducting unit (Impact; Siemens, Germany) operating at a field strength of 1.0 T by using a body coil. The matrix size for data acquisition was 256×128, and a 6-10-mm section thickness with a section gap of 0-4-mm. Conventional fast spin-echo (TSE) included T1-weighted images (700/12 ms, TR/TE) and T2-weighted images (2 600-5 000/128-165 ms, TR/TE). If necessary, FLASH T1-weighted images with transverse angle of 70-75° were added. Post-contrast MRI was obtained on FLASH T1-weighted images and TSE T1-weighted images after 0.2 mmol/kg GD-DTPA. Some patients were examined by using T1-weighted imaging fat suppression.

RESULTS

CT findings of hepatic tuberculosis based on its pathologic classification

Serohepatic type One case of serohepatic type of hepatic tuberculosis had multiple-nodular hypodense lesions with slightly peripheral enhancement in the subcapsule of liver and thickened subcapsule of quadratus lobe on CT (Figure 1).

Figure 1 Serohepatic type: multiple-nodular hypodense lesions in the subcapsule of liver and thickened subcapsule of quadratus lobe on CT.

Parenchymal type Ten cases of parenchymal type of hepatic tuberculosis were divided into 3 subtypes: (1) Miliary tuberculosis ($n=2$): CT showed multiple, miliary, micronodular and low-density lesions with size ranging from 0.6 cm to 1.8 cm and no marked enhancement (Figure 2). Multiple miliary calcifications were found in 1 case. (2) Nodular tuberculosis ($n=7$): Nodule was more than 2.0 cm in diameter. Singular, slightly low-density (ranging from 34-42 Hu) lesions in liver were seen in 3 cases with multiple flecked calcifications in 2 cases (Figure 3), and with slightly peripheral enhancement in 2 cases, no marked enhancement in 1 case. Multi-nodular lesions were in 4 cases. One case of scattered multi-nodular lesions was two isolated cystic masses, with 23 Hu and 29 Hu respectively, and had no marked enhancement (Figure 4). Gathered multiple masses were found in the other 3 cases. CT revealed multiple micronodular and low-density lesions fusing into multiloculated cystic mass or "cluser" sign with multiloculated enhancement. (3) Mixed tuberculosis ($n=1$): CT demonstrated singular, macronodular and low-density lesion with slightly enhanced rim and multiple miliary calcifications (Figure 5).

Figure 2 Miliary tuberculosis: scattered distribution of multiple, miliary, micronodular and low-density lesions in liver.

Figure 3 Nodular tuberculosis: singular low-density mass with multiple flecked calcifications in the right lobe of liver and tuberculous lymphadenopathy encroaching on head of pancreas.

Figure 4 Nodular tuberculosis: cystic mass with 23 Hu in the right lobe of liver.

Figure 5 Mixed tuberculosis: singular, round-like and low-density lesion and multiple miliary calcifications in the right lobe of liver.

Tuberculous cholangitis One case of tuberculous cholangitis showed slightly diffuse hepatomegaly, marked- dilated intrahepatic ducts, multiple calcificated lymph nodes in the porta hepatis and other regional distribution of lymph nodes in abdomen, and a large amount of hyperdense ascites. It was proved by surgery and pathology that tuberculosis of common hepatic duct involved left and right intrahepatic ducts and secondary marked dilated distant ducts. Lymph node tuberculosis and tuberculous peritonitis were also diagnosed pathologically.

MR findings

MR was performed in 4 patients. One case of serohepatic type of hepatic tuberculosis diagnosed on CT was reexamined with MR after therapy, showing multiple-nodular lesions with hypointense on T1-weighted images and hyperintense on T2-weighted images in the subcapsule of liver. The lesions had slightly peripheral enhancement after contrast administration. The other 3 cases were classified as parenchymal type of hepatic tuberculosis on CT, including miliary tuberculosis, mixed tuberculosis and nodular tuberculosis. Miliary tuberculosis showed multiple, miliary, micronodular lesions with hypointense on T1-weighted images and hyperintense on T2-weighted images. Mixed tuberculosis showed singular, macronodular lesion presented as a hypointense mass on both T1-weighted images and T2-weighted images (Figure 6) with peripheral enhancement. In this case, the lesion presented round-like on axial plane but irregular strip with multilocular enhancement on coronary and sagittal planes (Figure 7). Nodular tuberculosis revealed multiple micronodular lesions fusing into multiloculated cystic mass, which was hypointense on T1-weighted images and marked hyperintense on T2-weighted images, with multiloculated enhancement (Figure 8).

Abdominal extra-hepatic tuberculosis

Among the 12 cases, 4 had lymph node tuberculosis, showing enlarged lymph nodes, with ringed peripheral enhancement or calcifications in 2 cases respectively (Figure 3). Pancreatic tuberculosis, adrenal tuberculosis and tuberculous peritonitis were found in 1 case.

Figure 6 MR T2-weighted images showing singular, round-like hypointense lesion.

Figure 7 MRI showing irregular strip lesion with multilocular enhancement on coronary plane.

Figure 8 Enhanced MRI showing multiple micronodular lesions fusing into multiloculated cystic mass near the second porta hepatis.

DISCUSSION

Hepatic tuberculosis is considered to be a rare clinical entity. Unless there was a high index of suspicion, the diagnosis was often overlooked^[1,4]. Hepatic tuberculosis can be manifested by relatively nonspecific clinical presentation. The most frequent clinical symptoms and signs were right upper abdominal pain, upper abdominal tenderness, low-grade fever, night sweat, weight-loss and fatigue, abdominal mass, hepatomegaly and jaundice^[4,8,9]. Anemia, raised ESR, abnormal hepatic function and positive tuberculin test could be found in laboratory examinations.

Classification

Classification of hepatic tuberculosis has remained in dispute by now^[8-10]. The authors of this article considered it comprehensive and reasonable to classify hepatic tuberculosis into serohepatic type, parenchyma type and tuberculous cholangitis. In a sense, we do not agree that tuberculous cholangitis belonged to parenchymal type of hepatic tuberculosis^[8]. The parenchymal type is the most common one among the 3 types, which can be further divided into 3 subtypes, *i.e.* miliary tuberculosis, nodular tuberculosis and mixed tuberculosis.

CT findings of various types of hepatic tuberculosis

Parenchyma type Miliary tuberculosis: This subtype is the most common form of hepatic tuberculosis and was found in 80-100% of autopsied patients with disseminated pulmonary tuberculosis^[11]. It is depicted as multiple or diffuse miliary micronodular lesions (≤ 2.0 cm in diameter on CT), often as a

part of tuberculosis in the whole body. So clinically it was not difficult to diagnose correctly^[9,12]. Radiographic examination could detect hepatomegaly and micronodular lesions, but it was extremely difficult to find noncalcificated lesions with less than 0.5 cm in diameter with CT^[12-17]. In this series, CT revealed multiple, miliary, micronodular, hypodense lesions (>0.5 cm in diameter) scattered in liver in 2 cases with miliary calcifications in one case.

Nodular tuberculosis: The lesion, with a diameter >2 cm, is less common and has been found to be fused by miliary lesions or micronodular lesions^[4]. Because nodular lesion is apt to be found by CT and MRI, most reported hepatic tuberculosis belongs to nodular tuberculosis^[10,12-15,17-28]. Pathological features of this subtype are more complex than those of other subtypes. If tuberculous granuloma had no evident caseating necrosis or had a large amount of fibrous tissue existed, CT revealed a hypodense mass with slightly peripheral enhancement and no features on imaging findings could be found, it was difficult to diagnose it correctly^[13]. In tuberculous granuloma, when calcium deposited calcificans punctata or even “powdery” calcificans, it might appear in the hypodense lesion that could be detected on CT and is therefore helpful to the diagnosis^[6,13,24-26]. Two cases in this study were found to have calcificans punctata in the lesion center. When marked caseation or liquefaction necrosis emerged in the center of tuberculous granuloma, it means tuberculous abscess was formed and CT manifestation would be a cystic lesion with slightly or no enhanced rim^[12,17,18]. In this study there were two isolated cystic masses with no marked enhancement. Compared with liver cyst, the CT findings of the isolated cystic masses were higher than those of liver cyst and the wall of isolated cystic was more blurring. When multiple micronodular lesions fused into macronodular mass, CT present as a “clunter” sign or a multilobulated cystic mass with multilobulated enhancement^[13,19], which could be considered as a special CT feature but small pyogenic hepatic abscesses needed to be ruled out firstly^[29]. Such manifestation was characterized by a less marked enhancement and a shorter duration, being different from bacterial hepatic abscess. Three cases in this study were found.

Mixed tuberculosis (or miliary macronodular tuberculosis): One case showed multiple miliary calcifications with singular hypodense lesion. We considered that one of the typical CT features of hepatic tuberculosis might be multiple, various-dense lesions, indicating that there are lesions developed in different pathologic stage coexisting in hepatic tuberculosis, including tuberculous granuloma, liquefaction necrosis, fibrosis or calcification.

Tuberculous cholangitis Tuberculous cholangitis is rare and occurs mainly in children. Obstructive jaundice is the most common in clinic. Pathology revealed regional or diffuse duct dilation with duct wall thickening and stiffening^[8]. Imaging findings showed irregular dilated intrahepatic ducts or diffuse miliary calcifications along the course of the bile ducts. The latter was considered as a typical feature of tuberculous cholangitis^[13,30]. In our case, CT demonstrated mild diffuse hepatomegaly, marked dilated intrahepatic ducts and multiple flecked calcifications in the porta hepatis, complicated with tuberculous peritonitis.

Serohepatic type Serohepatic type of hepatic tuberculosis is the most uncommon one in the 3 types and was depicted as miliary tuberculous lesions in the subcapsule of liver or “frosted liver”, formed by thickened subcapsule^[8]. To our knowledge, the imaging findings of this type have not been reported. In our case, CT revealed multi-nodular hypodense lesions in the subcapsule of liver and thickened subcapsule of quadratus lobe. On MRI, multi-nodular lesions appeared as hypointense areas on T1-weighted imagings and as hyperintense areas on T2-weighted imagings, with slightly peripheral enhancement

after contrast administration. The features of CT and MRI were consistent with pathological features.

MR findings

MRI of hepatic tuberculosis showed a hypointense nodule with a hypointense rim on T1-weighted imagings, and hypointense, isointense or hyperintense with a less intense rim on T2-weighted imagings, and peripheral enhancement or internal septal enhancement on post-contrasted MRI^[20,21,24,31]. MR findings were related to different pathological stages of tuberculosis^[20,24,31]. At the early and medium stages of granuloma with or without caseation or liquefaction necrosis, the lesion showed a low signal intensity on T1-weighted imagings and a high signal intensity on T2-weighted imagings. Similar lesions with hypointense on T1-weighted imaging and hypo- and isointense on T2-weighted imagings were corresponding to fibrous stage of tuberculosis and may have slightly or no peripheral enhancement. Tuberculous granuloma at early or medium stage and fibro-proliferous lesions all depicted as a low-density area on CT but as various signal intensities on T2-weighted imaging, which is the main advantage of MRI in the diagnosis of hepatic tuberculosis. In addition, 3D-MR imaging is helpful to distinguish the pattern of lesions and diagnose the disease. But MRI is limited to detect calcification. MR findings in 4 cases of this study were hypointense on T1-weighted imaging, hypointense in one case and hyperintense on T2-weighted imaging in 3 cases. Calcificated lesions on CT showed no signal intensity on MRI. In 2 cases in our study, lesions with hyperintense on T2-weighted imaging were pathologically proved by surgery to be a caseation necrosis in tuberculous granuloma and hypointense, and were proved to be a complete fibrosis. In short, CT and MRI have some characteristic manifestations valuable for the qualitative diagnosis of hepatic tuberculosis.

Abstract

AIM: Tumor formation is generally linked to an expansion of glycolytic phosphometabolite pools and aerobic glycolytic flux rates. To achieve this, tumor cells generally overexpress a special glycolytic isoenzyme, termed pyruvate kinase type M₂. The present study was designed to evaluate the use of a new tumor marker, tumor M₂-PK, in discriminating gastrointestinal cancer patients from healthy controls, and to compare with the reference tumor markers CEA and CA72-4.

METHODS: The concentration of tumor M₂-PK in body fluids could be quantitatively determined by a commercially available enzyme-linked immunosorbent assay (ELISA)-kit (ScheBo® Tech, Giessen, Germany). By using this kit, the tumor M₂-PK concentration was measured in EDTA-plasma of 108 patients. For the healthy blood donors a cut-off value of 15 U/mL was evaluated, which corresponded to 90% specificity. Overall 108 patients were included in this study, 54 patients had a histological confirmed gastric cancer, 54 patients colorectal cancer, and 20 healthy volunteers served as controls.

RESULTS: The cut-off value to discriminate patients from controls was established at 15 U/mL for tumor M₂-PK. The mean tumor M₂-PK concentration of gastric cancer was 26.937 U/mL. According to the TNM stage system, the mean tumor M₂-PK concentration of stage I was 16.324 U/mL, of stage II 15.290 U/mL, of stage III 30.289 U/mL, of stage IV 127.31 U/mL, of non-metastasis 12.854 U/mL and of metastasis 35.711 U/mL. The mean Tumor M₂-PK concentration of colorectal cancer was 30.588 U/mL. According to the Dukes stage system, the mean tumor M₂-PK concentration of Dukes A was 16.638 U/mL, of Dukes B 22.070 U/mL, and of Dukes C 48.024 U/mL, of non-metastasis 19.501 U/mL, of metastasis 49.437 U/mL. The mean tumor M₂-PK concentration allowed a significant discrimination of colorectal cancers (30.588 U/mL) from controls (10.965 U/mL) ($P < 0.01$), and gastric cancer (26.937 U/mL) from controls (10.965 U/mL) ($P < 0.05$). The overall sensitivity of tumor M₂-PK for colorectal cancer was 68.52%, while that of CEA was 43.12%. In gastric cancer, tumor M₂-PK showed a high sensitivity of 50.47%, while CA72-4 showed a sensitivity of 35.37%.

CONCLUSION: Tumor M₂-PK has a higher sensitivity than markers CEA and CA72-4, and is a valuable tumor marker for the detection of gastrointestinal cancer.

INTRODUCTION

Pyruvate kinase plays a key role in the glycolytic pathway. One of its functions is to control nucleotide triphosphate generation^[1-3]. Different isoforms of this enzyme exist (pyruvate kinases L, R, M₁, M₂, Tumor M₂), which are tissue-specifically expressed in various organisms. All isoforms are known to be homotetramers in their active state. In tumor cells, however, tetrameric pyruvate kinase M₂ isoenzyme is disrupted and predominant in a dimeric form. It has been suggested that at least a part of the mechanisms is to disrupt the tetrameric form of pyruvate kinase M₂ phosphorylated by receptor tyrosine kinases. The concentration of dimeric pyruvate kinase M₂ isoenzyme is dramatically increased in a metabolic state characteristic for tumor cells. It is thus called tumor M₂-PK^[4,5]. Tumor M₂-PK is also present in body fluids, most likely released from tumor cells by tumor necrosis and cell turnover. It can be detected by a sandwich-ELISA based on two monoclonal antibodies. Furthermore, it has been demonstrated that tumor M₂-PK determination should be carried out in EDTA-plasma for its stability^[6-9].

Circulating tumor markers are an established index of monitoring systemic therapies in a number of solid tumors. In the diagnosis of gastrointestinal cancer, CA19-9, CA72-4 and CEA are the major tumor markers. Since the diagnosis of gastrointestinal cancer was dependent on endoscopies and cytology more than these tumor markers, the present study was designed to evaluate the use of a new tumor marker tumor M₂-PK in discriminating gastrointestinal cancer patients from healthy donors in order to increase the sensitivity of the diagnosis for gastrointestinal cancer^[10-13].

It was previously shown for renal and pancreatic carcinoma that tumor M₂-PK determination in circulation could provide a good discrimination of benign disease from malignant one and might correlate with stage of disease^[14-18]. Only limited data are available on tumor M₂-PK in gastrointestinal cancer. Thus, we investigated this new marker in patients with gastrointestinal cancer focusing on whether tumor M₂-PK plasma levels increased in gastrointestinal cancer patients in comparison to healthy controls, whether tumor M₂-PK was correlated with the classical tumor marker CEA, whether tumor M₂-PK gave any predictive information on response to therapy.

MATERIALS AND METHODS

Patients

A total of 108 consecutive patients with histological confirmed primary gastrointestinal cancer were included in the study. The

mean age was 47.9 years (ranging from 32 to 66 years). There were 76 men and 32 women. Among them, 54 were gastric cancer patients (25 non metastasized, 29 metastasized), 54 were colorectal cancer patients (20 non-metastasized, 34 metastasized). According to TNM stage system, 5 gastric cancer patients were classified as stage I, 24 as stage II, 23 as stage III, 2 as stage IV. According to Dukes stage system, 14 colorectal cancer patients were classified as Dukes A, 19 as Dukes B, 21 as Dukes C. Twenty healthy donors served as a control group.

Methods

The test kit (ScheBo· Tu M₂-PK, ScheBo@Tech GmbH, Giessen, Germany) required 10 µL EDTA-plasma per sample and was performed according to the manufacturer's instructions. Samples were collected as EDTA-blood, followed by centrifugation (2 000 r/min, 10 min) and removal of the supernatant plasma. Tumor M₂-PK concentration in EDTA-plasma was determined immunologically using a sandwich enzyme-linked immunosorbent assay (ELISA) based on two monoclonal antibodies (clones I and II) specific for tumor M₂-PK. The antibodies did not cross-react with other isoforms of pyruvate kinase.

The ELISA plate was coated with a monoclonal antibody that only recognized tumor M₂-PK. Tumor M₂-PK from EDTA plasma samples and standards bound to the antibody and thus were immobilized on the plate. EDTA plasma samples were diluted (1:100) with sample/washing buffer, 50 µL of diluted sample and ready-to-use standard were transferred into wells, incubated for 60 min at room temperature. Then the wells were emptied of the sample and each well was washed 3 times with sample/washing buffer (250 µL/well). The plate was inverted and tapped on a clean paper towel to remove any remaining liquid. Fifty µL/well of the 1:100 biotin-conjugated second monoclonal antibody was added and incubated for 30 min at room temperature. After washing, 50 µL/well of ready-to-use POD-streptavidin was added and incubated for 30 min in dark at room temperature. After washing, 100 µL of ready-to-use substrate solution was added to each well, and incubated for 30 min in dark at room temperature. The substrate reaction was stopped by adding 100 µL of stop solution per well. The contents were mixed well by agitating the plate. The optical density was read at 405 nm wavelengths with a micro titer plate reader between 5 and 30 min after addition of the stop solution. The contents were mixed well before measuring. The 492 nm was used as a reference wavelength.

For determination of CEA and CA72-4, serum samples (25 µL, undiluted) were measured using the fully automatic, competitive chemiluminescent immunoassay with a diagnosis kit.

Statistical analysis

Data were statistically analyzed with origin 6.1 for windows. All *P* values were resulted from a two-sided test. *P* value less than 0.05 was considered statistically significant.

RESULTS

The mean tumor M₂-PK concentration of gastric cancer was 26.937 U/mL. According to the TNM stage system, the mean tumor M₂-PK concentration of stage I was 16.324 U/mL, of stage II 15.290 U/mL, of stage III 30.289 U/mL, of stage IV 127.31 U/mL, of non-metastasis 12.854 U/mL and of metastasis 35.711 U/mL (Table 1).

The mean tumor M₂-PK concentration of colorectal cancer was 30.588 U/mL. According to the Dukes stage system, the mean tumor M₂-PK concentration of Dukes A was 16.638 U/mL, of Dukes B 22.070 U/mL, of Dukes C 48.024 U/mL, of non-metastasis 19.501 U/mL, and of metastasis 49.437 U/mL (Table 2).

The mean tumor M₂-PK concentration allowed a significant discrimination of colorectal cancers (30.588 U/mL) from controls (10.965 U/mL) ($t=3.173$, $P=0.0022$, $P<0.01$), gastric cancer (26.937 U/mL) from controls (10.965 U/mL) ($t=2.314$, $P=0.024$, $P<0.05$) (Table 3 and Figure 1).

The sensitivity of tumor M₂-PK for a cutoff point of 15 U/mL was compared to the established tumor markers CEA (cutoff point of 3.0 µg/µL) and CA72-4 (cut-off point of 4 KU/L). The overall sensitivity of tumor M₂-PK to colorectal cancer was 68.52%, while that of CEA was 43.12%. In gastric cancer, tumor M₂-PK showed a higher sensitivity of 50.47%, while CA72-4

showed a sensitivity of 35.37% (Figure 2).

DISCUSSION

The metabolic state of tumor cells is different from that of normally proliferating cells. Tumor cells exhibit an increased glycolysis to lactate initiated by multiple steps, including a switch of isoenzyme pattern and activity. Pyruvate kinase is a key enzyme of glycolysis. Different isoforms of this enzyme exist (pyruvate kinases L, R, M₁, M₂, tumor M₂) and are tissue-specifically expressed in various organisms. The L-type is found in the liver and proximal tubules of normal kidneys, erythrocytes express the R-type, the M₁-type predominates in skeletal muscle, heart and brain, and the M₂-type is expressed in the lung, distal tubules of normal kidney, fetal and undifferentiated or proliferating tissues. All isoforms are known to be homotetramers in their active state.

In tumor cells, pyruvate kinase isoenzyme M₂ is strongly overexpressed and shifted into the dimeric state. The tetrameric form has a high affinity to phosphoenolpyruvate (PEP), whereas the dimeric form has a considerably lower PEP affinity, which consequently leads to an increase of phosphometabolite pool. The concentration of the dimeric pyruvate kinase M₂ isoenzyme is dramatically increased in a metabolic state characteristic of tumor cells. It is thus called tumor type M₂ pyruvate kinase (tumor M₂-PK) by means of specific monoclonal antibodies against tumor M₂-PK, which does not cross-react with the pyruvate kinase M₂ tetramer and other pyruvate kinase isoforms. A sensitive immunoassay (ELISA) was employed to measure tumor M₂-PK in body fluids.

It was previously shown that tumor M₂-PK determination in the circulation provided a good discrimination of benign disease from a malignant one and might correlate with stage of disease^[19-22]. Only limited data are available on tumor M₂-PK in gastrointestinal cancer. In the present study, tumor M₂-PK in the diagnosis of gastrointestinal cancer was evaluated.

Since proliferating cells had an altered metabolism with an over-expression of the dimeric form of the tumor-specific pyruvate kinase isoenzyme tumor M₂-PK, the present study was initiated to evaluate tumor M₂-PK in diagnosis of gastrointestinal cancer, in comparison with the established tumor markers CEA and CA72-4. Significant discrimination of tumor patients from healthy controls was observed^[23-28]. In the diagnosis of colorectal cancer, the sensitivity of tumor M₂-PK was higher than that of CEA. But the sensitivity of tumor M₂-PK in the diagnosis of gastric cancer was lower than that in the diagnosis of colorectal cancer, whereas it was higher than that of CA72-4.

From the presented data, it is concluded that tumor M₂-PK can be used as a valuable diagnostic marker for gastrointestinal cancer. Further studies should focus on disease monitoring, therapy evaluation and the combination of tumor M₂-PK with other tumor markers^[29-32].

Abstract

AIM: Gastroesophageal reflux disease (GERD) is a common disorder in the Western population, but detailed population-based data in China are limited. The aim of this study was to understand the epidemiology of symptomatic gastroesophageal reflux (SGER) in adults of Xi'an, a northwestern city of China, and to explore the potential risk factors of GERD.

METHODS: Symptoms suggestive of GERD, functional dyspepsia (FD), irritable bowel syndrome (IBS), upper respiratory diseases and some potential risk factors were investigated in a face-to-face manner in a region-stratified random samples of 2 789 residents aged 18-70 years in Xi'an by using a standardized questionnaire.

RESULTS: With a response rate of 91.8%, the prevalence of SGER was 16.98% (95% CI, 14.2-18.92) in Xi'an adults, and no gender-related difference was observed ($P>0.05$). SGER was more common among subjects aged 30-70 years than in those aged 18-29 years ($P<0.05$). The prevalence of SGER in rural, urban and suburban subjects was 21.07%, 17.44% and 12.12%, respectively, and there was a significant difference between rural, urban and suburban regions ($P<0.05$). Compared with subjects without SGER, the prevalence of symptoms suggestive of FD and IBS, pneumonia, asthma, bronchitis, laryngitis, pharyngitis, chronic cough, wheeze, globus sensation, oral ulcer and snore was significantly increased in subjects with SGER ($P<0.01$). Heavy smoking (OR=4.94; CI, 3.70-6.61), heavy alcohol use (OR=2.85; CI, 1.67-4.49), peptic ulcer (OR=5.76; CI, 3.99-8.32), cerebral palsy (OR=3.97; CI, 1.97-8.00), abdominal operation (OR=2.69; CI, 1.75-4.13), obesity (OR=2.16; CI, 1.47-3.16), excessive food intake (OR=1.43; CI, 1.17-1.75), sweet food (OR=1.23; CI, 0.89-1.54), and consumption of coffee (OR=1.23; CI, 0.76-2.00) were independently associated with SGER. The episodes of GERD were commonly precipitated by dietary factors (66.05%), followed by body posture (26.54%), ill temper (23.72%), fatigue (22.32%) and stress (10.93%).

CONCLUSION: GERD is common in Xi'an's adult population with a mild or moderate degree. The etiology and pathogenesis of GERD are probably associated with FD, IBS, and some respiratory, laryngopharyngeal and odontostological diseases or symptoms. Some lifestyles, diseases and dietary factors are the risk factors of GERD.

INTRODUCTION

Gastroesophageal reflux disease (GERD) is a common disorder, and approximately 17-38% of adults in the Western population experienced heartburn and/or acid regurgitation, the main symptoms of GERD, at least once per week; with 4-9% having daily symptoms^[1-3]. Some patients with GERD would develop Barrett's esophagus, intestinal metaplasia of esophageal mucosa that predisposes to adenocarcinoma of the esophagus^[4-8], which has increased rapidly since 1970s^[9,10]. Patients with esophageal carcinoma have been proved to have a low 5-year survival rate^[11,12]. In addition to the risk of cancer, GERD is well recognized to be associated with some upper respiratory diseases, having an adverse impact on the quality of life, and the cost of long-term medical therapy is substantial. Therefore, it is of much importance to understand the prevalence of GERD and to identify the potential risk factors to prevent GERD and GERD-related diseases. As detailed population-based data on GERD in China are currently limited, we aimed in this study to estimate the prevalence of SGER in Xi'an adults, to determine the relationship between GERD and FD, IBS, and upper respiratory diseases, and to explore the risk factors of GERD.

MATERIALS AND METHODS

Subjects

Xi'an is a northwestern city of China, consisting of 7 administrative districts and 3 counties. Of the administrative districts 4 are in the urban region and 3 in the suburban region, and the counties are all in the rural region. Each district includes numerous neighboring communities including multiple residential areas, and each of the county covers several townships governing a number of villages. Based on the 1997 census data obtained from the local government and the proportion of population within the regions, we randomly selected one or more residential areas or villages in the urban, suburban and rural regions, respectively. Finally, a total of 2 789 subjects entered this survey, including 911 subjects from the urban region, 853 from the suburban region, and 1 025 from the rural region. The proportion of subjects in different regions was similar to that of Xi'an population ($P>0.05$), and the selected samples were matched for age and gender with Xi'an population ($P>0.05$).

Questionnaire

The questionnaire was designed on the basis of previous works from two university hospitals^[13], but modified to suit the local conditions. The modified version contained 8 fractions covering a total of 130 relative questions (items), of which 15 were specifically concerned with the frequency and severity of symptoms suggestive of GERD in the past years. Other questions included those concerning general condition of the subject (self-reported

height and weight), the symptoms suggestive of functional dyspepsia (FD) and irritable bowel syndrome (IBS) in the past year, symptoms or history of respiratory, laryngopharyngeal, and odontostological diseases in the past year; history of illness and operation, personal habits (smoking, alcohol), and dietary habits.

Definitions

The following definitions for symptom categories and diseases were used. Only symptoms occurring in the past year before the interview were considered. (1) Heartburn: a burning pain or burning sensation behind the sternum in the chest. (2) Acid regurgitation: a bitter or sour-tasting fluid reflux into the throat or mouth. (3) Food regurgitation: eaten food reflux into the mouth. Heartburn, acid regurgitation, and food regurgitation were considered to be the main symptoms of GERD. Each of the typical symptoms was estimated according to its severity and frequency, which measured on a 4-score scale. The severity was assessed as follows: 0, none; 1, mild (could be ignored); 2, moderate (could not be ignored but did not affect lifestyle); 3, severe (affected lifestyle). The score of symptom frequency was estimated as follows: 0, none or less than one occasion per month on average; 1, several occasions (1 to 3) a month; 2, several occasions (1 to 6) a week; 3, one or more than one occasions daily. Based on the scores of the severity and frequency of the main GERD symptoms, a total score (range, 0 to 18) of each subject was calculated. (4) SGER: subjects with a total score (St) no less than 3. (5) Chest pain: any pain or discomfort felt inside the chest more than once per month on average but not including any pain caused by diagnosed heart disease. (6) Dysphagia: a feeling that food stuck in the throat or chest more than one per month. (7) Symptoms suggestive of FD and IBS and symptoms of respiratory, laryngopharyngeal, and odontostological diseases: any of these symptoms presented more than once a week on average in the past year. (8) History of diseases or operations: any disease or operation diagnosed or performed in a hospital before the interview. (9) Alcohol use: taking 300 g of alcohol per month. (10) Heavy alcohol use: taking 210 g or more of alcohol per week. (11) Smoking status: defined as current smoking, current non-smoking, and heavy smoking (more than one pack a day). (12) Obesity: a body mass index ≥ 30 kg/m². (13) Coffee and special beverages: drinking more than one cup per day on average. (14) Dietary habits: taking special food more than one servings per day on average.

Training of interviewers

The team of interviewers was constituted mainly by medical students studying preventive medicine in our university, who were trained by the same two professors, one was a physician of gastroenterology and understood well the relative definitions, and the other was a specialist in preventive medicine and had rich experience in survey.

Assessment of feasibility

Before the actual study, a pilot study was conducted among 100 unselected outpatients attending our gastroenterological clinic, to test the appropriateness of the questionnaire and to familiarize the interviewers with the survey procedure and the definitions. The problems that the interviewers encountered during the pilot study were discussed and their solutions were provided accordingly.

Survey design and response rate

According to the list of selected subjects and guiding by the members of residents or village's committee, all subjects were interviewed face to face at their home by the interviewers. The completed questionnaires were checked and kept by same physician. The absent subjects were registered and two reminder

interviews were conducted at weekly intervals. Finally, the survey was closed after 16 wk. Among the 2 789 selected subjects, 74 had moved away, 58 could not be interviewed due to their absence during the survey period, 6 died, and 91 explicitly refused to participate in the study. A total of 2 560 subjects were successfully interviewed within a period of 4 mo, resulting in a response rate of 91.8%. There was no difference between the responders and non-responders with respect to their age and gender ($P>0.05$), and the constitution of the non-responder in different regions was reasonably similar ($P>0.05$). Twenty-eight individuals were subsequently excluded from the analysis because of inadequately questionnaires. Data from 2 532 questionnaires were entered in a computer.

Statistical analysis

The questionnaires were coded for analysis, and the data were entered in a computer and analyzed by using DBASE δ software. The prevalence was derived with 95% confidence intervals (95%CI). Comparison of the data was performed using EP15.0 χ^2 test. The odds ratios (OR) and 95% CI for each significant variable in the final model were calculated from the coefficients estimated in the logistic regression model. All P values were two-tailed, with the level of statistical significance specified at 0.05.

RESULTS

Main symptoms of GERD

The prevalence of heartburn for at least once monthly, weekly and daily episodes was 10.98% (278/2 532), 4.07% (103/2 532) and 1.66% (42/2 532), respectively. That for acid regurgitation monthly was 21.01% (532/2 532), weekly 7.78% (197/2 532), and daily 3.53% (89/2 532). For food regurgitation, the prevalence was 8.57% (217/2 532), 3.28% (83/2 532), and 1.42% (36/2 532) for at least one occasion monthly, weekly, and daily, respectively.

Symptomatic gastroesophageal reflux

The distribution of the total score of main GERD symptoms in the responders is shown in Table 1. The prevalence of SGER was 16.98% (95%CI, 14.20-18.92), of which, 13.11%, 2.92%, and 0.95% were considered as mild, moderate, and severe, respectively. Responders with SGER were more likely to be a mild or moderate degree.

Table 1 The distribution of total score of main GERD symptoms of responders ($n=2$ 532)

Total score (St)	Responders (n)	Rate (%)
≥ 3	2 102	83.02
≥ 3 (SGER)	430	16.98
3-7 (mild)	332	13.11
8-12 (moderate)	74	2.92
13-18 (severe)	24	0.95

Relationship between SGER and gender, age, and region

There was no statistically significant difference between men and women in the prevalence of GERD (61.71% vs 17.25%, $P>0.05$), and the ratio of male/female was 1:1.03. The prevalence of SGER was relatively constant across each of 10-year age interval (Table 2, χ^2 for trend; $P=0.075$), but by cutting χ^2 apart, we found that the prevalence of GERD was significantly higher in the responders aged 30-70 years than in those aged 18-29 years ($\chi^2=4.40$, $P<0.05$), and the group aged 50-59 years had the highest prevalence of SGER (21.39%). The responders in the urban and rural regions were more likely than the responders in suburban regions to have SGER (21.07% and 17.44% vs 12.12%, $P<0.05$). However, SGER was similarly prevalent in the urban and rural regions ($P>0.05$).

Table 2 The prevalence of SGED in each age group

Age group (yr)	Responders (n)	Responders with SGED (n)	Prevalence of SGED (%)
<20	64	9	14.06
20-29	517	73	14.12
30-39	621	106	17.07
40-49	584	100	17.12
50-59	360	77	21.39
60-69	354	60	16.95
70	32	5	15.63
18-70	2 532	430	16.98

Association between SGED and respiratory, laryngopharyngeal, and odontostological diseases

Table 3 summarized the prevalence of some respiratory, laryngopharyngeal, and odontostological diseases or symptoms in responders with and without SGED. The responders with SGED reported a higher prevalence of pneumonia, asthma, bronchitis, pharyngitis, laryngitis, chronic cough, wheeze, globus sensation, oral ulcer, and snore than the responders without SGED.

Table 3 The prevalence of respiratory, laryngopharyngeal, and odontostological diseases or symptoms in responders with and without SGED

Disease or symptom	Responders with SGED (n=430)		Responders without SGED (n=2 102)		P value
	n	Rate (%)	n	Rate (%)	
Pneumonia	12	2.79	15	0.73	<0.01
Asthma	28	6.51	46	2.19	<0.01
Bronchitis	66	15.35	187	8.90	<0.01
Pharyngitis	35	8.14	82	3.90	<0.01
Laryngitis	102	23.73	248	11.80	<0.01
Chronic cough	92	21.40	232	11.04	<0.01
Wheeze	33	7.67	80	3.80	<0.01
Globus sensation	102	23.72	104	4.95	<0.01
Oral ulcer	77	17.91	162	7.71	<0.01
Snore	121	28.14	362	12.27	<0.01

Relationship between SGED and other common gastrointestinal symptoms

The prevalence rate of pain behind the sternum, dysphagia,

retching, nausea, vomiting, epigastric discomfort, epigastric fullness, epigastric pain, diarrhoea, and constipation in responders with SGED was significantly higher than that in the responders without SGED ($P<0.01$, Table 4).

Table 4 Other common gastrointestinal symptoms in responders with and without GERD

Symptom	Responders with SGED (n=430)		Responders without SGED (n=2 102)		P value
	n	Rate (%)	n	Rate (%)	
Pain behind breastbone	100	23.25	84	4.14	<0.01
Dysphagia	24	5.58	20	0.95	<0.01
Retching	164	38.14	228	10.85	<0.01
Nausea	137	31.86	148	7.04	<0.01
Vomiting	78	18.14	71	3.38	<0.01
Epigastric discomfort	161	37.44	216	10.28	<0.01
Epigastric fullness	201	46.74	303	14.41	<0.01
Epigastric pain	122	28.37	147	6.99	<0.01
Diarrhoea	59	13.72	102	5.07	<0.01
Constipation	93	21.63	199	9.47	<0.01

The potential risk factors

The data obtained from Table 5 showed that heavy smoking (OR=4.94; CI, 3.70-6.61), heavy alcohol use (OR=2.85; CI, 1.67-4.49), peptic ulcer (OR=5.76; CI, 3.99-8.32), abdominal operation (OR=2.69; CI, 1.75-4.13) were strongly associated with SGED; obesity (OR=2.16; CI, 1.47-3.16) was moderately associated. The association between SGED and current smoking (OR=1.27; CI, 1.17-1.38), excessive food intake (OR=1.43; CI, 1.17-1.75), sweet food (OR=1.23; CI, 0.98-1.54), and coffee (OR=1.23; CI, 0.76-2.00) still existed, but it was mild. The prevalence of SGED was not influenced by tea (OR=1.13; CI, 0.91-1.44), pepper food (OR=1.07; CI, 0.86-1.32), and fat intake (OR=1.00; CI, 0.81-1.23).

Precipitating factors for SGED

Of 430 responders with SGED, 79.07% (340/432) reported the episodes of SGED with specially precipitating factors. Some dietary factors (sweet foods, peppery foods, fat or oil foods, and sour beverage) were the most common precipitating factors (66.05%), followed by body posture (26.54%), ill temper (23.72%), fatigue (22.32%), and stress (10.93%).

Table 5 The Association Between SGED and Selected Risk Factors

Selected risk factors	Factor exposure			Non-factor exposure			P value	OR ¹ (95%CI)
	Responders n	Responders with SGED n	Rate (%)	Responders n	Responders with SGED n	Rate (%)		
Current smoking	992	189	19.05	1 540	241	15.65	<0.05	1.27(1.17-1.38)
Heavy smoking	219	99	45.21	2 313	320	13.84	<0.01	4.94(3.70-6.61)

¹OR ~RR 2.6: a strong association; OR=1.7-2.5: a moderate association; OR=1.2-1.6: a mild association; OR=0.9-1.1: no association.

DISCUSSION

Population-based research well suits the purpose of investigating the epidemiology of gastroesophageal reflux disease, which is a common disorder in the community. The diagnosis could be made on the basis of its specific symptoms of heartburn and acid regurgitation without further diagnostic test^[14]. Thus, the methodology utilizing a self-reported questionnaire has become popular in population-based study of GERD^[1-3]. However, this kind of research can be limited by the varied ability of the interviewees to comprehend the definitions used and also by the relatively low response rates. Our research was conducted face to face in subjects' home with the guidance by the members of local community, therefore a high response rate (91.8%) was insured, significant responder bias was avoided, and the definitions were understood accurately assisted by the explanation provided by the trained interviewers, making possible a semi-quantitative diagnosis of SGER which was made by quantifying not only the frequency, but also the severity of main GERD symptoms so as to exclude those subjects with trivial symptoms. The prevalence of heartburn for at least weekly episodes in our study was 4.07%, similar to the prevalence rates reported in other two studies in Asia^[15,16], but was lower than those of Western population, such as the rate of 17.8% in Americans^[2], 14.7% in Australians^[17], 15% in Finlanders^[18] and 11.76% in Belgians^[19].

In the past few years, there has been an increase in the frequency of GERD in Asia, but the related information remains scarce^[20]. The prevalence of GERD in Western adult population varied between 17% and 38%, depending on the definitions and methodology used^[1,2,3]. A community-based study showed that the ethnic-adjusted prevalence of GERD was 1.6% in Singapore, in which GERD was defined as the presence of heartburn and/or acid regurgitation at least once a month^[15]. The prevalence of SGER was 16.98% in the present study. Although these studies are not comparable because of differences in methodologies and definitions used, the different prevalence of GERD may suggest that the prevalence of GERD actually varies between these populations. These differences were probably caused by genetic factors, environmental factors, dietary habits, and health habits. In our study, the variation of the prevalence of SGER in different regions was more likely to be explained by these factors. We found that the prevalence rate of SGER did not differ between men and women, which agreed with many studies^[1,2,15]. Our data also suggested that elder subjects were more likely to have SGER. The reasons are mainly that old people had a poor esophageal acid clearance and decreased defense mechanisms against reflux of acid gastric contents on the esophageal mucosa^[21,22].

The association between GERD and atypical reflux symptoms^[2], FD^[1,15,17], and IBS^[23-26] was assessed in some studies, but no related studies were conducted in China. The high prevalence of atypical reflux symptoms (pain behind the sternum and dysphagia) and symptoms suggestive of FD (retching, nausea, vomiting, epigastric discomfort, epigastric fullness, *etc.*), and IBS (epigastric pain, diarrhoea, and constipation.) in the responders with SGER in this population-based study confirmed the association among these symptoms. Subjects with aggravated dysphagia and pain behind the sternum caused by heart or coronary diseases were excluded in the analysis, so to some extent, the high prevalence of non-obstructive dysphagia and non-cardiac chest pain in subjects with SGER suggested that these two symptoms might be a late sequela of GERD. The considerable overlap among symptoms suggestive of GERD, FD and IBS may imply the same etiology and pathogenesis in these diseases. This conclusion, however, needs to be tested by further clinical and experimental studies.

Clinical studies have shown a cause-effect relationship between GERD and some respiratory, laryngopharyngeal, and odontostological diseases or symptoms^[27-32]. This association was further confirmed by our population-based research. Therefore, when a general medical therapy failed to improve the patients' conditions, a 24-h pH monitoring was necessary to detect pathological reflux, and a medical antireflux treatment would be more effective to relieve these conditions with pathological reflux^[28].

Laboratory studies demonstrated a correlation between both weight and body mass index with gastroesophageal reflux^[33,34]. This correlation was still held in our population-based study. Cigarette smoking could reduce lower esophageal sphincter pressure and predispose strain-induced reflux^[35,36]. Our research confirmed the association between smoking and SGER, and the association was weaker when cigarette consumption was decreased. We also observed a more than twofold increase in the prevalence of SGER in heavy alcohol users (42.9%) as compared with non-drinkers (15.7%). Although weight loss, smoking and drinking cessation have been recommended for patients with GERD, some patients reported improvement in their symptoms by doing so^[37], a multicentre-randomized clinical trial is still needed to certify the efficacy of these therapies for GERD.

We also found that GERD was strongly associated with peptic ulcer, post abdominal operation conditions (cholecystectomy and gastrectomy), and cerebral palsy (intellectually disabled and sequela of apoplexy) which were not reported by the other population-based studies. High gastric acid output and abnormal gastric empty are responsible for the increased prevalence of GERD in patients with peptic ulcer. Abdominal operations change the normal anatomic structure of upper gastrointestinal tract and commonly cause alkaline reflux. The main reasons for the high prevalence of SGER in individuals with cerebral palsy were the abnormal motility of esophagus or gastric tract of these patients and a number of common medications used (calcium channel blockers and tricyclic antidepressants) which promote GER by relaxing the lower esophageal sphincter^[38,39].

Consumption of special foods such as fat, chocolate, mints, coffee, onion, citrus fruit and tomato products and eating habits have been shown to be associated with temporary GER or relaxed LES in laboratory settings^[40-42]. However, our population-based study demonstrated that excessive food intake, sweat foods, and coffee were only weakly associated with SGER and no positive association was observed between SGER and fat intake, tea, and peppery foods. Our results were partly similar to the observation by Paul and his colleagues, whose nationwide population-based case-control study showed that GER symptoms and the risk of adenocarcinoma of esophagus or gastric cardia were not associated with dietary factors^[43]. The main explanation is that the quantity of these special foods was difficult to be accurately assessed in population-based study other than in a laboratory experiment. Another conceivable explanation is that the consumption of these foods might not be enough in quantity and/or frequency to cause GERD symptoms. The finding that episodes of SGER were commonly precipitated by dietary factors in our study also supports the above explanations.

In summary, GERD is common in Xi'an adult population, and a significant health problem in the community. The etiology and pathogenesis of GERD are probably associated with FD, IBS, and some respiratory, laryngopharyngeal and odontostological diseases or symptoms. Some life habits, diseases and dietary factors are the risk factors for GERD, and avoidance of these risk factors should be recommended as a primary prevention therapy of GERD.

Abstract

AIM: To evaluate the hepatic function in patients with severe acute respiratory syndrome (SARS) and possible causes of hepatic disorder in these patients.

METHODS: One hundred and eighty-two patients with SARS were employed in a retrospective study that investigated hepatic dysfunction. Liver alanine aminotransferase (ALT), aspartate aminotransferase (AST) and lactic dehydrogenase (LDH) were analyzed in these patients. Patients with different hospital treatments were further investigated.

RESULTS: Of the 182 patients, 128(70.3%) had abnormal ALT activity, 57(31.3%) had abnormal AST activity and 87 (47.8%) had abnormal LDH activity. The peak of elevated hepatic enzyme activities occurred between the sixth day and the tenth day after the first day of reported fever. Of the 182 patients, 160(87.9%) had been treated with antibiotics, 137(75.2%) with Ribavirin, and 115(63.2%) with methylprednisolone. There was no statistically significant correlation between the duration of Ribavirin treatment and hepatic dysfunction.

CONCLUSION: Abnormal liver functions were common in patients with SARS and could be associated with virus replication in the liver.

INTRODUCTION

Severe acute respiratory syndrome (SARS) or so-called atypical pneumonia with unknown etiology started to appear in Guangdong Province, China in November 2002 and quickly spread to other parts of China and around the world^[1,2-4]. A novel coronavirus has been identified as the etiological agent of the syndrome^[5-8]. Most coronaviruses may cause either a respiratory or an enteric change. During the outbreak of SARS,

abnormal hepatic enzyme activity was reported in patients of Toronto area, Canada^[9]. The present study summarized the hepatic enzyme activities in patients with SARS who were treated at the China-Japan Friendship Hospital, Beijing, which started to receive patients with SARS in mid-March 2003, and was designated as one of the three hospitals in Beijing to treat patients with SARS in April 2003.

MATERIALS AND METHODS

Patients

Our study included all patients who received a diagnosis of SARS with no pre-existing live diseases and were treated at the China-Japan Friendship Hospital between March 10 and May 31, 2003, and excluded such patients with a history of liver disorders. According to the criteria for SARS that have been established by the Ministry of Health, China-Clinical Diagnostic Criteria for Severe Acute Respiratory Syndrome^[10], our case definition was a fever (temperature $>38^{\circ}\text{C}$), a chest radiograph of the thorax showing evidence of consolidation with or without respiratory symptoms and a history of close contact with a person to whom SARS had been diagnosed. The diagnosis was confirmed by an indirect immunofluorescence assay with fetal rhesus kidney cells that were infected with coronavirus and fixed in acetone to detect a serological response to the virus^[3] or by a positive viral culture. Patients in the study included 103 male and 79 female with age ranging from 11 to 86. The age distribution is shown in Table 1.

Table 1 Age distribution of the patient

Age range (yr)	Case number (n)	%
Under 20	18	9.89
21-30	45	24.73
31-40	35	19.23
41-50	29	15.93
51-60	18	9.89
Above 60	37	20.33

Laboratory examination

Hepatic functions included alanine aminopeptidase (ALT), aspartate aminotransferase (AST) and lactic dehydrogenase (LDH). We studied these variables from the first day of admission to May 31, 2003. The normal values of these enzymes were 0-40 U/L for ALT, 0-42 U/L for AST and 100-250 U/L for LDH.

Data collection

We retrospectively analyzed data from 3 aspects. First, total incidence rate of abnormal liver enzyme activities were analyzed from 182 patients with SARS. Second, the time course of abnormal liver enzyme activities was dissected in 57 patients because these patients were admitted to China-Japan Friendship Hospital from beginning of the illness. The other large proportion of patients with SARS was transferred to China-Japan Friendship Hospital after the hospital was designated

specifically to treat patients with SARS on April 28, 2003. Third, analysis of ribavirin treatment for patients with SARS was performed in 84 cases, as well as their abnormal liver enzyme activities after ribavirin treatment.

Statistical analysis

We used univariate analysis to compare patients with normal and abnormal serum hepatic enzyme activities, and an unpaired Student's *t* test, χ^2 test, or Fisher's exact test, as appropriate. We then performed multiple logistic regression analysis with stepwise analysis to identify independent predictors of the abnormality^[3]. A *P* value of less than 0.05 was considered to indicate statistical significance. All probabilities are two tailed. Statistical analysis software StatView 5.0 for Macintosh OS was employed and data were reported as mean \pm SD unless otherwise indicated.

RESULTS

Between March 10, and May 31, 2003, more than 100 of patients with SARS were admitted to the China-Japan Friendship Hospital; especially on May 8 a large number of patients with SARS were transferred to our hospital at severe stage and some patients were at convalescent stage. Serum samples were collected immediately after the patients were admitted to the hospital. The study included 103 male and 79 female patients from all ethnic background. The mean age was 40.42 years (range 15-78 years).

Incidence rate of abnormal liver enzyme activities in 182 patients

Transiently elevated ALT was observed in 128 (70.3%) patients with SARS. Of the 182 patients with SARS, 57 (31.3%) had elevated AST while 87 (47.8%) had abnormal LDH as indicated in Table 2.

Table 2 Incidence rate of abnormal-liver-function outcomes

	ALT	AST	LDH
Total cases (<i>n</i>)	182	182	139
Abnormal cases (<i>n</i>)	128	57	87
Ratio (%)	70.3	31.3	62.6

Time course of abnormal liver enzyme activities

The time course of abnormal liver enzyme activities was obtained from 57 patients with SARS who were admitted to our hospital at the beginning of illness. The earliest day of abnormal liver enzyme activities was the first day of illness. The peak of abnormal liver enzyme activities was between the sixth and the tenth d of illness. Liver function started to recover 15 d after onset. However, for some patients, abnormal liver enzyme activities could last for almost a month (Figure 1).

Figure 1 Abnormal-liver-function outcomes at different days.

Comparison of liver enzyme activities before and after hospital treatment

To explore whether hospital treatment could lead to abnormal liver enzyme activities in patients with SARS, we analyzed data of all patients who had normal or abnormal liver enzyme activities before and after hospital treatment. The deadline for entering analysis was June 15, 2003. Patients with hospital treatment less than 15 d were excluded from the study. As shown in Table 3, statistically significant difference was observed in AST and LDH ($P < 0.01$) while no significant difference was obtained in ALT.

Table 3 Abnormal-liver-function outcomes before treatment vs after treatment

Cases (<i>n</i>)	ALT		AST		LDH	
	Before	After	Before	After	Before	After
Total	182	166	182	164	122	105
Normal	93	85	133	145	46	81
Abnormal	89	81	49	19	76	24

Hospital treatment in 182 patients with SARS

Most patients with SARS in our hospital received empirical treatment with antibiotics or ribavirin 400-500 mg, twice daily, or intravenous methylprednisolone at high dosage. As listed in Table 4, of the 182 patients with SARS, 160 (87.9%) received antibiotics, 137 (75.2%) received ribavirin and 115 (63.2%) received methylprednisolone. Since Ribavirin is a drug that inhibits viral replication, it has been widely used in patients with SARS after it was confirmed that coronavirus is etiological factor of SARS. We further analyzed the duration of Ribavirin treatment and its relation to abnormal liver enzyme activities in patients with SARS.

Table 4 Therapeutic drugs in 182 SARS patients

	Antibiotics	Ribavirin	Methylprednisolone
Cases (<i>n</i>)	160	137	115
Rate of usage (%)	87.9	75.2	63.2

Figure 2 The distribution of of ribavirin treatment in 84 SARS patients.

Distribution of ribavirin treatment in 84 patients with SARS

Although 137 patients with SARS were recorded of ribavirin treatment, only 84 patients were employed for analysis of ribavirin treatment. The reason for choosing these patients was that these patients had detailed record of receiving ribavirin in our hospital and the other 53 patients had already received ribavirin treatment before admitting to our hospital. As shown in Figure 2, 32 (38.1%) patients with SARS received ribavirin treatment at d 1 to 3 after diagnosis of SARS, 23 (27.4%) patients received ribavirin treatment at d 4 to 5, 17 (20.2%)

patients received ribavirin treatment at days 6 to 10. A total of 55(65.5%) patients with SARS received ribavirin treatment within 5 d of the illness while a total of 72(85.7%) patients received ribavirin treatment within 10 d of the illness.

Correlation of ribavirin treatment and abnormal liver enzyme activities

Correlation of ribavirin treatment and abnormal liver enzyme activities was analyzed in 84 patients with SARS. The duration of ribavirin treatment was different among these patients. Twenty-six (29.8%) patients with SARS received ribavirin treatment for 1 to 7 d, 32(35.7%) patients for 8 to 14 d, 20(22.6%) patients for 15 to 21 d and 10(11.9%) patients for more than 22 d. However, as shown in Table 5, there was small increase in liver enzyme activities in patients with longer Ribavirin treatment, but it did not reach statistically significant.

Table 5 The distribution of ribavirin treatment in 84 SARS patients

Treatment	Days 1-3	Days 4-5	Days 6-10	Days 11-20	Days 21-30	Days 30
Cases number	32	23	17	8	3	1
%	38.1%	27.4%	20.2%	9.5%	3.6%	1.2%

DISCUSSION

Abnormal serum liver enzyme activities have been reported by different hospitals with inconsistent incident rates. It was reported that there were 44.7% patients with SARS having abnormal liver enzyme activities in Guangzhou Southern Hospital^[11]. And 53.3% was reported in the First Hospital of Beijing University^[12]. Moreover, 40% patients with SARS having abnormal liver enzyme activities were reported in hospitals around great Toronto area^[9]. In our study, we have found that 70% patients with SARS suffered from abnormal liver enzyme activities. The higher percentage of liver damage in our patients might be related to the fact that large number of patients with severe illness were transferred to our hospital.

The difference between these reports may also be associated with different treatment strategies between these areas, especially in the use of ribavirin. Ribavirin (1-b-D- ribofuranosyl- 1,2,4-triazole), a broad spectrum antiviral nucleoside, is one of the first antiviral drugs ever discovered. It was first approved in the United States in an aerosol form for the treatment of a severe lung infection in infants^[13]. Recently, it has been employed as an anti-HIV treatment^[14-17] and in combination with interferon for the treatment of hepatitis A, B, and C^[18-21]. Compared with hospitals around great Toronto area (88%), the usage of ribavirin in our hospital (75%) was less. However there were a larger proportion of patients (70%) with abnormal liver enzyme activities in our hospital than that (40%) in hospital around Toronto area. This indicated that ribavirin could not be a contributing factor for abnormal liver enzyme activities observed in patients with SARS. Although there was an increased trend of elevated liver enzyme activities with duration of ribavirin treatment, there was no statistic significant correlation between abnormal liver enzyme activities and duration of ribavirin treatment.

Abnormal liver enzyme activities could also be caused by coronavirus induced liver damage. Although liver biopsy was not feasible in these patients, pathological evaluation of the fatal cases revealed that hepatocytes underwent fatty degeneration, cloudy swelling, focal hemorrhage, apoptosis and dot necrosis, Kupffer cell proliferation, portal infiltration of lymphocytes and dispersive eosinophilic body in the liver^[22, 23]. There was an enlargement of the liver in 23 patients with SARS in our study observed by B-ultrasonic examination

(data reported in another study). Because of difficulty in clinical practice, it was not documented whether pathological impairments of liver function and structure were present in the early stage of the disease. However, we have used herbal medicines and liver protective drugs in these patients. These treatments did not alter the outcome of abnormal liver enzyme activities. Therefore, it is unlikely that hospital treatment contributes to the outcome of abnormal liver enzyme activities in patients with SARS.

Our conclusions are that abnormal liver enzyme activities are common in patients with SARS and coronaviruses that cause severe acute respiratory syndrome might affect the liver and induce liver damage in the course of infection.

Abstract

AIM: The Maastricht II criteria suggest the use of amoxicillin and clarithromycin in addition to a proton pump inhibitor over 7-10 d as a first line therapy in the eradication of *Helicobacter pylori* (*H. pylori*). For each proton pump inhibitor, various rates of eradication have been reported. The present study was to compare the efficacy of different proton pump inhibitors like omeprazole, lansoprazole and pantoprazole in combination with amoxicillin and clarithromycin in the first line eradication of *H. pylori* and to investigate the success of *H. pylori* eradication in our district.

METHODS: A total of 139 patients were included having a *Helicobacter pylori* (+) gastroduodenal disorders diagnosed by means of histology and urease test. Besides amoxicillin (1 000 mg twice a day) and clarithromycin (500 mg twice a day), they were randomized to take omeprazole (20 mg twice a day), or lansoprazole (30 mg twice a day), or pantoprazole (40 mg twice a day) for 14 d. Four weeks after the therapy, the eradication was assessed by means of histology and urease test. It was evaluated as eradicated if the *H. pylori* was found negative in both. The complaints (pain in epigastrium, nocturnal pain, pyrosis and bloating) were graded in accordance with the Licert scale. The compliance of the patients was recorded.

RESULTS: The eradication was found to be 40.8% in the omeprazole group, 43.5% in the lansoprazole group and 47.4% in the pantoprazole group. Sixty-three out of 139 patients (45%) had eradication. No statistically significant difference was observed between the groups. Significant improvements were seen in terms of the impact on the symptom scores in each group.

CONCLUSION: There was no difference between omeprazole, lansoprazole and pantoprazole in *H. pylori* eradication, and the rate of eradication was as low as 45%. Symptoms were improved independent of the eradication in each treatment group. The low eradication rates suggest that the antibiotic resistance or the genetic differences of the microorganism might be in effect. Further studies are required to verify these suggestions.

INTRODUCTION

So far, no ideal treatment exists although there have been plenty of treatment schemes in the eradication of *Helicobacter pylori* (*Hp*). Therefore, research on this subject has substantially increased. In order to achieve the optimal treatment regimen various combinations including antibiotics and antisecretory agents have been tested^[1]. In 2000, use of amoxicillin and clarithromycin for a period of at least 1 wk in combination with a proton pump inhibitor (PPI) was suggested^[2]. Diverse eradication rates have been reported with this specific treatment scheme^[3-6]. Up to date, five diverse PPIs have been launched in our country. The outcomes obtained from studies related with those inhibitors have resulted in confusing eradication rates.

The present study aimed to investigate the efficacy of three different PPIs given in combination with antibiotics, which have been accepted to be standard in the eradication of *Hp* and the success of *Hp* eradication by this standard treatment.

MATERIALS AND METHODS

Between September 2001 and July 2002, 139 patients with gastritis, gastric ulcer and duodenal ulcer were enrolled in this study. All patients were positive in urease test and histopathological examination for *Hp*. Patients with a concomitant serious illness and a history of gastric surgery, pregnancy, patients taking antibiotics, H-2 receptor blockers or on PPI treatment within the last two months, being allergic to macrolides and having a previous eradication treatment were excluded. Their written informed consent was received. They were randomized to take omeprazole 2×20 mg/d (OAC), lansoprazole 2×30 mg/d (LAC) or pantoprazole 2×40 mg/d (PAC) plus amoxicillin 2×1 000 mg/d and clarithromycin 2×500 mg/d for 14 d. All of the eligible patients had standard laboratory tests, and their history, physical examination and concomitant treatment regimens were recorded. Their complaints (epigastric pain, bloating, nocturnal pain and pyrosis) were graded in accordance to the Licert scale (0=none, 1=mild, 2=moderate, 3=severe, 4=very severe). Two biopsies were taken from the antrum and corpus for pathology, and a biopsy from the antrum for urease test. The pathological assessment was based on the Sidney classification for gastritis. 4 wk after the therapy the side effects and alterations were re-evaluated, and a blinded gastroenterologist repeated the endoscopical examination. Negative *Hp* in both urease test and biopsy was accepted as eradication.

To understand the compliance, the patients were asked to report how many prescribed drugs they used (100%-forgotten for 0 d, 80-99%-forgotten only for 1 d, 60-79%-forgotten for 2 d and below 59%-forgotten more than 2 d). The side effects were recorded.

Statistical analysis

The definitive statistics were calculated (mean \pm SD, numbers and % values). For age comparison in three groups, simple analysis of variance was used while gender, smoking, NSAID use, alcohol consumption, eradication status and relationship between the three groups were determined by Pearson chi-square test, which was also used to determine the relation between the eradication status and antral gastritis and pangastritis plus smoking and histological activity in the antrum prior to eradication. The differences in the symptom score between the eradicated and non-eradicated were investigated by Wilcoxon test before and after the eradication. Furthermore, t-test was applied to compare the improvement rates in the separate symptom score between the eradicated and non-eradicated in relation to the difference between the rates in 3 groups.

RESULTS

Table 1 gives the demographical characteristics of the patients in the three groups. Of the patients, 73(58.3%) were women, and 66(41.7%) were men, and the average age was 47.9 \pm 11.8 years. The patient compliance was 95%. Two patients from each group discontinued the therapy for 8 d due to side effects (nausea, vomiting, and diarrhea). The endoscopical lesions are shown in Table 2. The eradication was found in 22 out of 49 patients (40.8%) in the omeprazole group, 20 out of 46 patients (43.5%) in the lansoprazole group, and 21 out of 44 patients (47.4%) in the pantoprazole group. There was no any differences between three groups ($P>0.05$). The overall eradication rate was 45%. Twenty-two out of 62 patients (37%) with antral gastritis had eradication while 19 out of 34 patients (55%) with pangastritis had eradication ($P<0.05$). No correlation was found between eradication and smoking and histological activity in the antrum prior to eradication ($P>0.05$). Significant improvements were observed in the symptom score between the eradicated and non-eradicated compared to pre-eradication status ($P<0.05$), but no significant differences were found between the groups.

Table 1 Demographic features of study population

	OAC	LAC	PAC	P
Patient number	49	46	44	NS
Female/Male	26/23	23/23	24/20	NS
Year				
Mean	47.5 \pm 13.4	45.7 \pm 12.5	44.5 \pm 13.5	NS
Range	20-75	21-73	20-70	NS
Smoking	7 (14.2%)	6 (13%)	6 (13.6%)	NS
NSAID	9 (18.3%)	8 (17.3%)	8 (17.1%)	NS
Alcohol	(22.4%)	9 (19.5%)	10 (22.7%)	NS

Table 2 Endoscopic findings

Finding	Patient n, (%)
Antral gastritis	62 (44.5)
Pangastritis	34 (24.5)
Bulbitis	14 (10)
Bile reflux gastritis	12 (8.6)
Duodenal ulcer	7 (5.3)
Atrophic gastritis	6 (4.3)
Gastric ulcer	4 (2.8)

DISCUSSION

Recently, triple therapies including a PPI and two antibiotics have been found to be the most effective eradication regimens

in the treatment of *Hp* eradication^[7,8]. The most common antibiotics used in the triple therapies were amoxicillin, clarithromycin and metronidazole^[7,8]. Treatment regimens including PPIs are now used at all stages of the *Hp* eradication. The highest eradication rates for *Hp* (80-95%) have been achieved by using antibiotics at least for one week^[9]. However, even the highest doses of omeprazole or an increased treatment duration for 2 wk did not provide 100% eradication^[10-13]. In the European consensus meeting, it suggested that PPI treatment for one week including amoxicillin and clarithromycin was the first line therapy^[10].

Our study showed that triple therapy for 2 wk was safe and well tolerated. The patient compliance was 95%. However, the eradication rate was 45%. Similarly in a study from Adana (Southern Anatolia), a two-week usage of lansoprazole, amoxicillin and clarithromycin resulted in 59% eradication^[14]. In Istanbul (North Western Anatolia) and Nigde (Central Anatolia) the eradication rates were found below 50% in two different studies^[15,16].

Similarly, in Iran, the eradication rates with omeprazole, amoxicillin and clarithromycin were found to be below 70%^[17]. Also, some European studies reported similar rates of eradication^[12,13,18-20,22,23]. Rinaldi^[21] studied 278 patients by using a treatment regimen similar to ours (omeprazole, lansoprazole and pantoprazole in combination with amoxicillin and clarithromycin for one week). The eradication rates were found to be 86%, 74% and 76% respectively, which were higher than our results, yet far beyond the acceptance levels^[21].

Different eradication results obtained by similar treatment regimens suggest that resistance to antibiotics, virulent factors of *Hp* or type of gastroduodenal disorders of patients might have played a role in the outcomes. In some of the studies resulted in lower eradication rates, the resistance to clarithromycin was as high as 10%^[24]. In a study carried out in Ankara (Central Anatolia), the resistance to clarithromycin was 11.4%^[25]. An Italian study found the primary resistance to clarithromycin was 3.2%^[26]. The primary resistance to macrolides was between 3-12% in Europe and 2-10% in the United States^[27,28]. We did not investigate the resistance to antibiotics in the present study. However, we believe that the resistance to antibiotics might have played an important role in our results. Also the majority of the events were from the non-ulcer dyspepsia group, therefore this might have an effect on the result because a lower rate of eradication was reported in patients with non-ulcer dyspepsia compared to those with peptic ulcer^[24,29]. Our results showed that patients with pangastritis had a better eradication than those with antral gastritis ($P<0.05$). This was in compliance with the correlation between the severity of gastritis and the rate of eradication^[30,31].

In conclusion, our findings from Mersin (Southern Anatolia) with lower eradication rates obtained by similar treatment regimens compared to other districts in Turkey and in the World demonstrate that it is necessary to find out a treatment scheme specific to the district. The findings prove that standard treatment regimens might not be suitable and therefore establishment of a new treatment protocol in accordance with the results obtained locally is inevitable. We believe that the lower rates of eradication might have resulted from the resistance to antibiotics.

Abstract

AIM: To evaluate the feasibility and safety of the intraarterial chemotherapy of the liver cancer by an interventional method, catheter-port system.

METHODS: Thirty-two catheter-port systems were implanted percutaneously via the femoral artery or subclavian artery. Chemotherapies were performed 0-5 d after the implantation of the catheter-port systems. The mean interval between two sequent chemotherapies was 4 wk. The occurrence of side effects of the implantation was examined clinically.

RESULTS: Implantation of the catheter-port was successful in all patients. Mean patency period was 210 d. One occlusion (3.1%) of the catheter was observed. Displacement of the catheter was observed in one case (3.1%). One patient rated a hematoma in the chest wall as important. Mild hematoma was reported in 8 cases (25%). In 3 of 32 cases (9.4%), mild pain was reported initially, and dysesthesia was reported in seven (21.9%). No patient rated overall discomfort as mild, severe, or important.

CONCLUSION: Percutaneous placement is feasible and safe for liver regional continuous chemotherapy. Compared with surgical placement, the overall complication rate is comparable or less.

<http://www.wjgnet.com/1007-9327/10/1659.asp>

INTRODUCTION

Systemic chemotherapy in cases of liver cancer and liver metastases of colorectal cancer has nearly been abandoned due to the high non-response rates. Regional continuously intraarterial chemotherapy has demonstrated better response rates than systemic chemotherapy^[1-4]. Percutaneously

implantable catheter-port systems have been developed for long-term use to facilitate the long-term administration of chemotherapeutic agents. These systems allow easy and repetitive puncture in infusion therapy without doing much harm to the vessels, and their use is comfortable for the patient. So far, the implantation of permanent intraarterial catheter systems in the gastroduodenal artery^[1,5-9] or via the subclavian, axillary, or brachial arteries into the common hepatic artery^[10-12] has been performed surgically with considerable complication rates. Moreover, the repair and replacement of malfunctioning port systems previously required surgery^[9,13,15,16]. Thus far, percutaneous implantation of catheter-port systems for intraarterial use in various target organs, particularly in regional chemotherapy of the liver, has been successfully performed by radiologists^[14,17-20].

MATERIALS AND METHODS

Patients

From December 1999 to July 2003, 32 percutaneously implantable catheter-port systems (B|BRAUN, Germany) were placed in 32 patients (23 men and 9 women; age range, 26-65 years; mean age, 56 years) with primary malignancies of the liver (26 cases) and metastasizes (6 cases). Three patients had Cholangioma within the 25 primary malignancies. In all patients, the catheter-port system implanted percutaneously with radiologic guidance was the first method used to administer intraarterial chemotherapy. One patient had been performed intervention for 2 times because the catheter-port systems failed to be implanted through the femoral arteries in the first performance of intervention. The catheter-ports were implanted percutaneously through subclavian arteries in the second time. We obtained informed consent from each patient prior to the procedure.

Catheter-port system

The standard catheter-port device consisted of a polysulphone port reservoir with a silicone septum at the puncture site and a lateral stem to slip the silicone catheter over. The connection between the silicone catheter and the polyurethane catheter was reinforced with a small plastic cannula. The port reservoir, polyurethane catheter, cannula, and suture material were commercially available as part of the standard catheter-port system.

Technical procedure

The angiographic catheter was advanced into the respective target vessel such as the common or proper hepatic artery with fluoroscopic guidance after the common femoral or subclavian artery was punctured with use of the Seldinger technique, and visceral arteriography was performed to assess variant arterial supply. The final position of the catheter tip, and thereby the region of perfusion, was chosen according to the anatomy of each patient and the location of the lesion at digital subtraction angiography. The catheter tip was placed into the right hepatic artery ($n=9$), the proper hepatic artery ($n=21$), and the common hepatic artery ($n=1$). The latter position was used in one patient

with variant common hepatic artery without the proper hepatic artery (Figure 1). In this patient, the gastroduodenal artery was occluded because of the variant arterial supplies (Figure 2). The correct position of the catheter was verified with digital subtraction angiography.

Figure 1 The gastroduodenal artery is the end of the branch of the common hepatic artery. The proper hepatic artery was absent. Gastroduodenal artery (white arrow), right hepatic artery (black arrow).

Figure 2 The gastroduodenal artery has been occluded by a fibred platinum coil (arrow).

The catheter-port systems were implanted percutaneously in inpatients. The antibiotic agent was given 20 min before operation and no conscious sedation treatment was administered.

To insert the catheter-port system, an incision approximately 3 cm long was made in the skin distally to the right groin at the anterior surface of the thigh or at the anterior surface of the left or right chest wall, starting from 3 cm distally to the cutaneous puncture site and leading downward along the femoral triangle or leading parallel to the dermatoglyph. A subcutaneous pocket was then formed wherein the port reservoir was to be placed. The end of the catheter was cut off distally to the puncture site, and then was connected tightly to the port reservoir.

Tunneling was made from the puncture site to the incision and the port reservoir was not fixed to the subcutaneous tissue with an extra suture (Figure 3). Final port angiography helped verify the integrity of the system and correct position of the catheter. When necessary, malposition or dysfunction was corrected before the subcutaneous pocket was closed. A compression bandage was applied in each patient for 24 h.

The patients were mobilized 24 h after the intervention. There were no restrictions on patient activity 24 h after the device was in place. Bed rest was not necessary. By choice, most patients stayed in hospital until the onset of chemotherapy, which was 0-5 d after implantation (mean, 2 d) because of the healing of the incisions or the amelioration of liver function. We regularly flushed the catheter system with 10 mL of heparin sodium (25 eIU/mL heparin) at the end of each chemotherapeutic cycle, and before final withdrawal of the port needle, but not

between two chemotherapeutic cycles. Patients did not receive any anticoagulation therapy systemically or via the catheter system. At the end of the study, no patients were lost to follow-up. Correct functioning of each catheter-port system was verified with digital subtraction angiography prior to each chemotherapeutic treatment cycle. At each angiographic study, patients were examined clinically for the occurrence of negative side effects, such as peripheral embolization, occlusion. They were also asked to complete a questionnaire regarding their satisfaction with the percutaneously implanted catheter-port system and the presence of local complications, such as hematoma, infection, pain, restriction of motion, dysesthesia, and long-term discomfort. The patients rated these complications as absent, mild, or important. Mild hematoma was defined as discoloration of the skin without subcutaneous swelling or induration for a maximum of 1 wk. Important hematoma was defined as subcutaneous induration with palpable liquid collection around the device of more than 2 cm in diameter.

Figure 3 Fluoroscopic image depicts a catheter-port system in the right side of the groin in a 36-year-old male patient with hepatic carcinoma catheter (arrowheads), stem (large open arrow), and port reservoir (thin black arrow).

RESULTS

Implantation of the catheter-port was successful in all patients. Only 2 patients were performed for 2 times because of the failures of implantation through femoral arteries in the first operation. We changed to the subclavian artery and the implantation was successful in the second time. All implantation procedures were performed in the interventional radiology suite with a mean procedure time of 51 min (range, 30-145 min). No peri-interventional complications were noticed. The mean follow-up of the systems was 210 d (range, 36-680 d).

Complications occurred in 2 (6.25%) of 32 cases. One occlusion (1 of 32 cases, 3%) of the catheter was observed on d 36. The occlusion was a result of misuse of heparin solution after the chemotherapy with a subsequent reflux of blood into the catheter. Because lytic therapy with 10 000 IU of urokinase in 2 mL of water solution was not successful in this patient, the catheter-port system was disused.

Displacement of the catheter was observed in one case (1 of 32 cases, 3%) at the third angiographic follow-up study. The catheter tip was dislocated into the abdominal artery and could be repositioned into the common hepatic artery by using an interventional maneuver. Since the patient did not want to continue chemotherapy, the port system was entirely disused, but was not removed by operation.

The overall disused rate was 6% (2 of 32 cases). All disused catheter-ports were not removed.

After implantation of a catheter-port system, one patient rated a hematoma in the chest wall as important, but this could not be verified at any clinical follow-up examination, and it did

not require surgical intervention. Immediately after implantation, mild hematoma was reported in 8 of 32 cases (25%), but no hemorrhage at the implantation or puncture site was found at the first follow-up examination in any of these cases. In 3 of 32 cases (9%), mild pain was reported initially, and dysesthesia was reported in 7 (22%). No patient rated overall discomfort as mild, severe, or important.

Till July 2003, 145 port angiographic studies were performed as follow-up examinations at a mean interval of 4 wk between each study. The patients were examined clinically for the occurrence of side effects at the time of each angiographic examination. No patients showed signs of peripheral arterial embolization, occlusion, or embolic effects. At all follow-up examinations, we did not find infection, leakage, kinking, or disconnection of any catheter-port system. According to the patient questionnaires, all patients were entirely satisfied with the system. No patient reported restriction of motion or discomfort owing to the port reservoir in the groin or chest wall.

DISCUSSION

Continuous chemotherapeutic infusion has proved to be prior to the systemic chemotherapy in liver cancer. Permanent percutaneously implanted catheter-port systems are widely used method for it with the advantage for repeated external arterial or central venous access for regional or systemic chemotherapy and prolonged parenteral nutrition^[2,6,16]. The majority of catheter-port devices developed for intraarterial regional chemotherapy have necessitated surgical implantation before the interventional method was applied clinically^[7,11,21-23]. The common sites of surgical implantation are gastroduodenal, common or proper hepatic arteries for regional intraarterial chemotherapy of the liver.

It has been reported the implantation of an intraarterial catheter-port with fluoroscopic guidance in the interventional radiology suite without laparotomy^[8]. The femoral arteries were used for minimally invasive catheter placement. Radiologic implantation is also associated with various complications, such as catheter dislocation, occlusion, and infection. Dislocation and occlusion of catheter are the severest complications, which lead to the termination of chemotherapy or another traumatic implantation procedure^[10,12,16,23].

Thrombotic complications such as catheter occlusion and occlusion of the hepatic artery are also commonly associated with both surgically and radiologically implanted catheter-port systems^[11,7,9,10,12,23]. Catheter placement via the brachial artery can also be accompanied by thrombosis or occlusion of the brachial artery^[12,13]. In our patient group, one case of catheter occlusion was caused by blood reflux into the 4-F catheter. Catheters with small diameters have higher occlusion rates. Niederhuber *et al.*^[20] also found that small-bore catheters had an inferior patency rate and drug infusion might be difficult owing to the higher resistance of small catheters. Some infusion pumps might stop at pressure levels that are too high. Therefore, on the basis of results in our study and the literature, we do not recommend the use of catheter below 4-F for permanent implantation in this context.

With regard to prevent catheter thrombosis, different authors have various ideas. Two methods have been recommended: administration of warfarin sodium and continuous catheter perfusion with heparin^[18]. We believe that keeping blood from the lumen of catheter and perfusion with the end of each chemotherapy are the efficient methods. We do not consider systemic or other type of anticoagulation therapy necessary. Lytic therapy with tissue plasminogen activator, urokinase, or streptokinase has been reported to be useful in cases of catheter occlusion, but this method is successful only in a few cases^[9,16]. In our study, lytic therapy was not effective.

But the permanent existence of the disused catheter-port system has no harm to the patient if there is no septic episode.

The frequency of dislocation appeared to be particularly high when the axillary or brachial artery was used^[10,12]. It could be due to the too soft and flexible catheter material and the mobility of the upper limb. In our study, displacement occurred in one of our cases (3.1%), in which the port reservoir was implanted in the chest wall through right subclavian artery, into the abdominal artery. Retrospectively, we believe this displacement into the abdominal artery was probably due to too much tension on the indwelling catheter and the mobility of upper limb. Therefore, optimal catheter configuration and the approach are crucial. We recommend that the right femoral artery should be the best approach.

Infection is another complication in permanently implanted catheter systems that often makes removal of the device necessary^[18,19,24,29,30]. Infection rates ranged from 0%^[25-28] to 7.6%^[11,17,23,24]. Infection and sepsis during chemotherapy can be caused by the use of inappropriate hygienic measures and can be treated successfully with antibiotic therapy. It has been noticed that after an infected catheter-port system was removed and replaced with a new one, however, infection recurred in some patients^[14]. In our study patients, antibiotic agents were administered 20 min before operation for the aim of prophylaxis of infection, and infection was not observed. Infection rates after radiologic implantation are lower than those after surgical implantation. Therefore, interventional radiology suites and the antibiotic agent seem to provide sufficient hygienic conditions for this type of intervention.

The relatively low complication rate and pain increase patient acceptance of this procedure. Placement of the catheter-port system on the anterior surface of the thigh below the groin or chest wall seems to be well accepted, even in very active patients. Its superficial placement allows easy palpation and puncture, and provides little risk for dislocation or disconnection of the port needle from the reservoir during chemotherapy. But careful palpations are required in obese patients.

Radiologic implantation of catheter-port systems is a quick and simple procedure that does not require general anesthesia compared with surgical implantation. Patency rates are equal to or higher than those for surgically implanted systems. Radiologic placement is also possible in patients with anatomic vascular variations. In contrast to the surgical method, catheter-port systems placed radiologically cause less morbidity in the case of dysfunction, because the systems can be removed or repositioned more easily. Complicated surgical revisions or corrections requiring laparotomy can be avoided as proposed by Doughty *et al.*^[31]. Radiologic placement does not allow performance of preventive cholecystectomy to avoid cholecystitis, but this does not seem to be a crucial problem.

Our results indicate that percutaneous implantation of a catheter-port system via the femoral artery or subclavian artery is easy to perform, simplifies intraarterial chemotherapy of the liver with equal patency rates, and has fewer complications as compared with surgical placement, and is well accepted by patients.

Abstract

AIM: To elucidate the mechanism by which somatostatin and its analogue exert the influence on liver fibrosis, and to investigate the mRNA expression of somatostatin receptors subtypes (SSTRs) and the distribution of somatostatin analogue octreotide in rat hepatic stellate cells (HSCs).

METHODS: HSCs were isolated from Sprague Dawley (SD) rats by *in situ* perfusion and density gradient centrifugation. After several passages, the mRNA expression of 5 subtypes of SSTRs were assessed by reverse transcription-polymerase chain reaction (RT-PCR). HSCs were planted on coverslip and co-cultured with octreotide tagged by FITC. Then the distribution of FITC fluorescence was observed under laser scanning confocal microscope (LSCM) in 12-24 h.

RESULTS: There were mRNA expression of SSTR2, SSTR3 and SSTR5 but not SSTR1 and SSTR4 in SD rat HSCs. The mRNA expression level of SSTR2 was significantly higher than that of other subtypes ($P < 0.01$). FITC fluorescence of octreotide was clearly observed on the surface and in the cytoplasm, but not in the nuclei of HSCs under LSCM.

CONCLUSION: The effect exerted by somatostatin and its analogues on HSCs may mainly depend on the expression of SSTR2, SSTR3 and SSTR5. Octreotide can perfectly combine with HSCs, and thereby exerts its biological activity on regulating the characters of active HSCs. This provides a potential prevention and management against liver fibrosis.

INTRODUCTION

In recent years, it has become clear that HSCs play an important role during occurrence and progress of hepatic fibrosis and portal hypertension^[1,2]. HSCs are located in a perisinusoidal orientation within the sinusoid and encircle vascular endothelial cells. They can also contract or relax in response to various vasoactive mediators. All of these suggest that these cells may

have the capacity to modulate intrahepatic vascular resistance and blood flow at the sinusoidal level^[3]. When HSCs are activated and proliferated abundantly, they can excrete many kinds of cytokine related to fibrosis to promote synthesis and deposition of extracellular matrix (ECM)^[4,5]. Therefore, how to reduce and inhibit activation and proliferation of HSCs has become a hot spot in the area of liver fibrosis research^[6].

Somatostatin and its analogues have comprehensive inhibitory actions on proliferation of many kinds of cells and the capacity to induce apoptosis, so they have been applied in cancer biotherapy at the present time^[7,8]. The biological base by which somatostatin exerts its actions is the existence of somatostatin receptors (SSTRs). SSTRs belong to G-protein-coupled receptors family and are located on cell membrane. Only after somatostatin combines with SSTRs, could it exert the actions of anti-proliferation. Up to date, five different SSTR subtypes, termed SSTR1 to SSTR5, have been cloned and characterized^[9].

In this research, we studied the mRNA expression and distribution of somatostatin receptors in hepatic stellate cells (HSCs) of rats to elucidate the mechanism by which somatostatin and its analogue exert the influence on liver fibrosis.

MATERIALS AND METHODS

Materials

Male Sprague Dawley rats, weighing (450±50) g, were purchased from Experimental Animal Center of the Chinese Academy of Medical Science, Beijing, China. Nycodenz, fluorescein isothiocyanate (FITC) and collagenase IV were purchased from Sigma Co., U.S.A. Fetal bovine serum (FBS), Dulbecco MEM (DMEM) culture medium, Trizol and superscript II reverse transcriptase were produced by Gibco Co., U.S.A. Taq DNA polymerase, dNTPs, Oligo (dT) and RNasin were products of Promega Co. Octreotide (0.1 g/mL) was provided by Novartis Co. Mouse anti-human desmin antibody and rabbit anti-cow glial fibrillary acidic protein (GFAP) antibody were purchased from Genetech Co. Primers were synthesized by Shanghai Sangon Co.

Isolation and culture of hepatic stellate cells (HSC)

Adult male Sprague Dawley rats (450±50 g) were treated in accordance with the institution's guidelines for the care and use of laboratory animals in research. All procedures were performed with animals under ether anesthesia. According to the method of Geerts and Weng *et al*^[10,11], HSCs were isolated by *in situ* perfusion and density gradient centrifugation with nycodenz. Firstly, the trocar was inserted into the rat's portal vein and the liver was perfused with pre-perfusion liquid. Then the liver was removed from the body and continuously perfused with perfusion liquid containing collagenase IV to digest the extracellular matrix. After centrifugation with 150 g/L nycodenz, the cells located in the interface were extracted and cultured in DMEM containing 200 mL/L FBS. HSC were fully stick to the wall within 48 h. Then the culture medium was exchanged in every 2-3 d. The identification of HSC was performed by observation of ultraviolet-excited fluorescence of vitamin A

lipid droplet in HSC and immunocytochemical stain for desmin and GFAP.

Isolation of total RNA and semiquantitative RT-PCR

Total RNA was isolated from HSC with Trizol by phenol-chloroform extraction and isopropanol precipitation following manufacturer's instructions. Reverse transcription of total RNA was carried out according to the instructions of the RT kit. Design of specific primers against rat SSTRs sequences was referred to the references^[12] and verified in NCBI Blast. They are shown in Table 1. The PCR system (total 25 μ L) contained 40 pmol/L primers of SSTRs or β -actin, 0.5 μ L of 10 mmol/L dNTPs, 1.5 μ L of 50 mmol/L $MgCl_2$, 2 μ L of cDNA, 2.5 μ L of 10 \times PCR buffer, 2.5 μ L of Taq DNA polymerase. The PCR conditions included an initial denaturation for 5 min at 94 $^{\circ}C$; 40 amplification cycles consisting of denaturation at 94 $^{\circ}C$ for 1 min, primer annealing at 60 $^{\circ}C$ for 1 min and elongation at 72 $^{\circ}C$ for 1 min; and a final extension at 72 $^{\circ}C$ for 7 min. The PCR products or DNA marker mixed with 2 μ L of loading buffer were electrophoresed on a 15 g/L agarose gel and visualized under ultraviolet light excitation. Then the images were taken and analyzed by Kodak digital camera and science software (Kodak, EDAS290, U.S.A). The expression of SSTRs was calculated by determining the ratio of SSTRs relative to β -actin.

Table 1 Primer sequence and expected PCR product length

Primer designation	Sequence	Product length

The observation of combination of octreotide with HSC and distribution in HSC

After 3-4 passages, HSCs were planted on coverslip and culture medium was exchanged after sticking to the walls. Then octreotide tagged by FITC was added into the culture medium (10 μ g/mL). After 24 h, the culture medium was removed and the coverslips were rinsed three times with PBS, whereafter the distribution of FITC fluorescence in live HSCs was observed by laser scanning confocal microscope (LSCM).

Statistical methods

The results of electrophoresis of PCR products were expressed as mean \pm SD and analyzed by *t*-test and analysis of variance.

RESULTS

Expression of mRNA of somatostatin receptor subtypes

The mRNA expression of SSTR2, SSTR3 and SSTR5 were observed, whereas those of SSTR1 and SSTR4 were not observed in rat HSCs. Moreover the mRNA expression level of SSTR2 was significantly higher than those of other subtypes (4 and 5.64 times higher than that of SSTR3 and SSTR5, respectively, $P<0.01$). There was no significant difference between the mRNA expression of SSTR3 and SSTR5 (Figures 1, 2, and 3, Table 2).

Table 2 Expression of SSTRs mRNA in quantity (mean \pm SD)

Subtypes	<i>n</i>	Expression of mRNA
SSTR2	3	0.8213 \pm 0.1210
SSTR3	3	0.2041 \pm 0.1662 ^b
SSTR5	3	0.1457 \pm 0.1981 ^d

^b $P<0.01$ vs SSTR2, ^d $P<0.01$ vs SSTR2.

Figure 1 Expression of SSTR2 mRNA. M: 100 bp Marker; Lanes 1-3: three groups of samples.

Figure 2 Expression of SSTR3 mRNA. M: 100 bp Marker; Lanes 1-3: three groups of samples.

Figure 3 Expression of SSTR5 mRNA. M: 100 bp Marker; Lanes 1-3: three groups of samples.

Distribution of octreotide in HSCs

The green fluorescence of FITC had an extensive distribution on the surface of HSCs and also in cytoplasm, but not in nucleus (Figure 4).

Figure 4 Distribution of the green fluorescence of octreotide tagged by FITC in live HSCs. FITC fluorescence of octreotide was clearly observed on the surface and in the cytoplasm, but not in the nuclei of HSCs under LSCM.

DISCUSSION

Several studies have demonstrated that somatostatin could restrain and decrease the process of hepatic fibrosis of rat liver cirrhosis models^[14-16]. In addition, researchers studied the anti-fibrosis mechanisms of somatostatin. Reynaert *et al.*^[13] proved that somatostatin could suppress rat hepatic stellate cell contraction induced by endothelin-1. Chatterjee *et al.*^[17] found that in rat liver cirrhosis models of schistosomiasis, somatostatin might have the direct anti-fibrosis effects through modulating the synthesis and expression of collagen I, III and smooth muscle actin (SMA) of rat HSCs. All of these findings suggest that there are SSTRs on the surface of HSCs, thereby somatostatin could exert its actions on HSCs.

Whether SSTRs exist and what kind of SSTRs subtypes are expressed in rat HSCs? We observed mRNA expression of SSTR2, SSTR3 and SSTR5, but not of SSTR1 and SSTR4 in Sprague Dawley rat HSCs. Our results slightly differed from Reynaert *et al.*^[13] that SSTR1, SSTR2 and SSTR3 were expressed, but not SSTR4 and SSTR5 in Wistar rat HSCs. Besides, we found that the mRNA level of SSTR2 was significantly higher than those of other subtypes in quantity. These results suggest that theoretically, somatostatin may be available to exert its inhibitive and pre-apoptosis actions on active HSCs by means of SSTRs (especially SSTR2) and consequently has the ability of anti-fibrotic action. Therefore, if the proper somatostatin analogues that have strong affinity to SSTR2, 3 and 5 are chosen, they will be able to exert better effect on active HSCs.

Taking advantage of the strong appetency by which somatostatin could combine with SSTRs, some researchers have applied the somatostatin analogues tagged by radioactive isotope to study the expression and distribution of SSTRs in cancer tissues and consequently the locational diagnosis of cancers. This kind of method has been proved to be satisfactory. Since our results showed that SSTR2, 3 and 5 were expressed and other studies reported that octreotide had the special affinity to SSTR2 and SSTR5^[7,9], we treated HSCs with octreotide tagged by FITC. By means of the characteristics that hormones can specially bind to its receptors, we observed the green fluorescence on the surface of live HSCs, which reflected the distribution of SSTRs. This proves that octreotide has strong affinity with HSCs and thus the existence of SSTRs is supported. Meanwhile, we also observed the distribution of octreotide in the cytoplasm, but not in the nuclei of HSCs. In general, octreotide contains 8 peptides, so it can't pass through the cell membrane without other pathways were introduced. Thereby, we presume that the endocytosis conducted by the receptors may works. But whether octreotide in cytoplasm is able to exert its biological actions by a certain mechanism independent of SSTRs remains to be confirmed in the future.

In conclusion, we demonstrates that SSTR2, 3 and 5 are obviously expressed in SD rat HSCs. In addition, octreotide, a somatostatin analogue, is able to combine perfectly with HSCs

and thereby exerts its biological actions on liver fibrosis in clinical practice.

Abstract

AIM: To establish a method for optical sections of HepG2 human hepatoblastoma cells with confocal laser scanning microscope (CLSM) and to study the spatial structure of filamentous actin (F-actin) in HepG2 cells.

METHODS: HepG2 cells were stained with FITC-phalloidin that specifically binds F-actin, with propidium iodide (PI) to the nucleus, and scanned with a CLSM to generate optically sectioned images. A series of optical sections taken successively at different focal levels in steps of 0.7 μm were reconstructed with the CLSM reconstruction program.

RESULTS: CLSM images showed that the FITC-stained F-actin was abundant microfilament bundles parallel or netted through the whole cell and its processes. Most F-actin microfilaments extended through the cell from one part toward the other or run through the process. Some microfilaments were attached to the plasma membrane, or formed a structural bridge connecting to the neighboring cells.

CONCLUSION: A method for double labeling HepG2 human hepatoblastoma cells and CLSM imaging F-actin microfilaments and nuclei by image thin optical sections and spatial structure was developed. It provides a very useful way to study the spatial structure of F-actin.

INTRODUCTION

Cytoskeleton, consisting of proteins, is the structural network in cells. It closely relates to the functions of cells, such as cell movement, cell morphology and transmembrane signal conduction, etc. Observation and analysis of cell F-actin with CLSM are a precise, rapid, and simple method. This paper aimed at using CLSM in combination with double label for the observation and analysing of the three-dimensional structure of cytoskeleton system in HepG2 hepatocarcinoma cells.

MATERIALS AND METHODS

Cell culture

HepG2 cells were inoculated in improved Petri dish (normal

Petri dishes with a center hole bottomed by quartz glass), with 100 mL/L BAS/RPMI-1640 as culture medium for 24-48 h in an incubator at 37 °C with a 950 mL/L air/50 mL/L CO₂ atmosphere. After the dish glass was covered fully with cells, the culture medium was poured out. The cells were rinsed with PBS twice, and then fixed in 40 g/L paraformaldehyde for 30 min at 4 °C.

Specimen preparation

The above-mentioned specimens were rinsed with PBS twice, then permeabilized for 10 min in 2 g/L Triton X-100 at room temperature, and nonspecific background was blocked using 5 g/L BSA for a while. Specimens were then stained with 5 mg/L FITC-phalloidin (Sigma) at room temperature for 30 min. After that, the specimens were rinsed with PBS twice and stained with 5 mg/L PI (Sigma), and finally rinsed twice with PBS and a little PBS in dishes was reserved for observation. All procedures must be performed from light.

CLSM observation and examination

Specimens were examined with an ACAS Ultima 312 CLSM (Meridian Instruments, USA) equipped with an argon ion laser providing simultaneous excitation at 514.5 nm, 488 nm and 351-364 nm, an output power of 50 mW for the UV and 200 mW for the combined visible wavelengths, a high-precision mechanical scanning stage (0.1 μm in the X-Y plane and 0.1 μm in the Z axis), and an inverted microscope (Olympus), three photomultiplier tubes (PMT). The availability of a variety of excitation wavelengths on a single microscope setup offers the power and convenience of using combinations of fluorescent probes in a single specimen. In this experiment, the parameters were as follows: Objective: 100 \times 1.30 oil, Pinhole: 255 μm , X points: 270, Y point: 290, Z step: 0.7 μm , Data model: Z image, Scan Type: Mirror, Step Size: 0.20 μm , Speed: 20 mm/s, Samples/pt: 15, Laser Power: 612 mw, Scan stress: 100%, PMT 1: 40%, PMT 2: 40%, Z point: 15. According to the above parameters, a series of images were collected sequentially from single optical sections at 0.7 μm intervals (15 planes per series) using the 488, 530 nm laser lines to excite FITC and PI, respectively. Randomly selected regions of specimens were scanned to image using Z-series program of CLSM. With the program the specimens could be scanned cross-sectionally along the X, Y, and Z axes, and serial optical sections of different layers could be obtained without injury. Firstly, the cell top was confirmed by prescanning, and then the specimen from top to bottom was scanned according to Z-step to obtain optical sections layer by layer, and each image was recorded. The images were electronically colored. The optical sections were reconstructed to stereoscopic images with CLSM reconstruction program.

RESULTS

The HepG2 cells stained with FITC-phalloidin and PI were successfully labeled. There were six serial optical sections of HepG2 cells as shown in Figure 1. The interval between two sections was fixed at 0.7 μm . The images shown on Figure 2-Figure 4 were all three-dimensional images obtained from sequential optical sections, which were reconstructed with the reconstruction program of CLSM. The HepG2 cells, having many primary and secondary processes, were irregular in shape. The FITC-stained F-actin filaments appeared in bundles,

which ran in parallel to the main cell axis or through cell processes. Some microfilaments were attached to the plasma membrane, or formed a structural bridge connecting to the neighboring cells. When detector 1 of CLSM for 488 nm line was on, only F-actin marked with FITC-phalloidin could be shown (Figure 1). When both of the two detectors of CLSM were turned on, F-actin marked with FITC-phalloidin and the nuclei marked with PI could be shown simultaneously (Figure 2). F-actin appeared green, the distinct nuclei appeared red, and the region around the nuclei was overlapped by green F-actin and red nuclei appeared yellow.

Figure 1 CLSM images of HepG2 cells stained with FITC-phalloidin. (A: Serial optical sections (1-6) B: Three-dimensional images of Figure 1 serial optical sections. C: Three-dimensional images of HepG2 cells).

DISCUSSION

Cytoskeleton, composed largely of actin filaments, is the internal framework of a cell. It includes micro-tubes, microfilaments and middling fibers, and is the base structure for cell movement, cell morphology and transmembrane signal conduction. Microfilament mainly consists of actin participating in keeping cell pattern and tight junction between cells. It is also related to the adhesion of the ground substance outside the cells. Microfilament exists in the form of G-actin when it is dissociated or exists in the form of F-actin when it is polymerized. The change and balance of microfilament dissociation and polymerization in normal cells are the important regulatory factors for the movement, adhesion and fission cycle of cells^[1,2]. Cell mutation involves cytoskeletal rearrangement and morphological alterations. As a sensitive norm in examining the development of tumor cells at the early stage, F-actin has been used in human mammary gland cancer and T-lymphocyte cancer^[3-5]. Our result showed that F-actin microfilaments of HepG2 cells existed in the form of bunches of fibers that were thick, long and dense. F-actin filaments formed bundles running through the main cell axis or cellular processes. The relationship between the change of microfilament morphology and cancer occurrence in cells is still unknown. But when microfilament's component and distribution change, cells cannot receive normal regulation. And it leads to the loss of control of cell growth and propagation and to cancer occurrence. According to some researches, the change of microfilaments might reduce the gap junction in number and function, and the communication function of cells, which is the main reason why propagation ability of carcinoma cells rose up and the ability of adherence lowered, and easily fell off^[6-9]. The mechanism underlying the morphological changes of microfilaments in the process of cancer cells is unclear.

In this experiment, F-actin was marked with FITC-phalloidin and the nuclei with PI, so the cytoskeleton and nuclei could be observed. This provides a very useful way to study the relationship between cytoskeleton and nucleus. Compared with other methods, such as immunohistochemistry, light microscopy or electrical microscopy^[10-12], CLSM has several advantages^[13-17]: Firstly, resolution obtained with a CLSM is better than that of conventional microscopy because of the combination of laser illuminator and detection pinhole. With conventional light microscopy, the fluorescence of the entire specimen interferes with the resolution, while CLSM allows examining the organization of fluorescent labeled cells and tissues by eliminating the "out-of-focus" flare of the specimen, thus providing sharp, high-contrast images of cells and subcellular structures within thick samples. Since images are obtained by scanning, excessive illumination of the specimen and quick decrease of the fluorescent signal are avoided. And light bleaching is minimized because exposure to light is restricted

to the area of the preparation being examined. Secondly, this method of embedding and sectioning specimens, which are a time-consuming and a destructive procedure, can now be avoided. So it is quick and simple to make samples using CLSM. Under conventional microscopy, structures present in the tissues can be observed only after sectioning (microtome sections). With the CLSM it is possible to obtain a number of serial optical sections of quite thick specimens without physical sectioning. Furthermore, serial optical sections can be collected and displayed as digitalized images, and by using a computer, the digitalized images obtained may be reconstructed as a 3-dimensional structure. In addition, the procedure is not destructive for a living cell or tissue. In this experiment using CLSM, the images of the cytoskeleton marked by the double label technique and the stereoscopy of three-dimensional images were very clear. As the sectioning with CLSM is not done physically but optically, the procedure is not destructive for an intact cell, and the process of sectioning turns simpler and quicker and more reliable, and it can notably keep the normal morphology and function of the cell.

In summary, our results showed that in HepG2 cells F-actin microfilaments existed in the form of bunches of fibers that were thick, long and dense, and ran through the main cell axis or cellular processes. It is suggested that F-actin may play an important role in HepG2 cells.

Abstract

AIM: To determine the survival of advanced pancreatic cancer patients treated with intraoperative radiotherapy (IORT) combined with external beam radiation therapy (EBRT) following internal drainage (cholecystojejunostomy or choledochojejunostomy).

METHODS: Eighty-one patients with advanced pancreatic cancer who received IORT combined with EBRT following internal drainage (ID) between 1996 and 2001 were retrospectively analyzed. Among the 81 patients, 18 underwent ID+IORT, 25 ID+IORT+EBRT (meanwhile, given 5-Fu 300 mg/m² iv drip, 2f/w), 16 EBRT, 22 had undergone simple internal drainage. The IORT dose was 15-25Gy in a single fraction. The usual EBRT dose was 30-40Gy with a daily fraction of 1.8-2.0 Gy.

RESULTS: The complete remission rate, partial remission rate of patients with backache and abdominal pain treated with ID+IORT were 55.5%, 33.3% respectively. Alleviation of pain was observed 2 or 3 wk after IORT. The median survival time (MST) of ID+IORT group was 10.7 mo. The pain remission rate of patients treated with ID+IORT+EBRT was 92%, and their MST was 12.2 mo. The MST of patients treated with EBRT and simple internal drainage was 5.1 mo and 7.0 mo, respectively. The survival curve of ID+IORT group and ID+IORT+EBRT group was significantly better than that of EBRT group ($P<0.05$). The difference between the ID+IORT+EBRT group and ID group was significant ($P<0.05$).

CONCLUSION: IORT combined with EBRT following internal drainage can alleviate pain, improve quality of life and prolong survival time of patients with advanced pancreatic cancer.

<http://www.wjgnet.com/1007-9327/10/1669.asp>

INTRODUCTION

During the past two decades, the incidence rate of pancreatic cancer has been increasing. Pancreatic cancer is extremely difficult to diagnose at early stage, and the prognosis is very poor. In spite of the developments in surgical and anesthetic techniques, the median survival time (MST) remains in the range of 7-11 mo, and only 3% of the patients were alive 5 years after diagnosis^[1-6].

The local recurrence rate is extremely high even after curative resection. Evans *et al.*^[7] reported that more than 50% of patients with post-operative relapse were due to local recurrence. Local recurrence is the most uncomfortable event for patients, and often produces various complications, and decreases the patients' quality of life. Thus, local control is an important issue for pancreatic cancer. IORT is one of the most potent local interventions. Saeki *et al.*^[8] reported that IORT could reduce pain and improve quality of life in patients with unresectable pancreatic cancer. In the present study, we investigated the survival time of advanced pancreatic cancer patients treated with intraoperative radiotherapy (IORT) combined with external beam radiation therapy (EBRT) following internal drainage.

MATERIALS AND METHODS

Patient selection

From 1996 to 2001, 81 patients with advanced pancreatic cancer were treated at our hospital. The patients aged from 43 to 72 years with a median of 57 years. Fifty-nine patients were male and 22 were female. All the tumors had no interspace between the superior mesenteric vein and portal vein, and the blood vessel was wrapped by the tumor. All patients had jaundice, the blood total bilirubin ranged from 156 μ mol/L to 402 μ mol/L with a median of 304 μ mol/L. Sixty-one (75.3%) 81 of the patients were given AP-237 or pethidine to relieve pain, and other 20 (24.7%) patients took oral acesodyne intermittently. No ascitic fluid and liver metastasis were noted. Among the 81 patients, 18 received ID+IORT, 25 received ID+IORT+EBRT (meanwhile, given 5-Fu 300 mg/m² iv drip, 2 f/w), 16 received simple EBRT and 22 received simple internal drainage.

Surgery

Under continuous epidural anesthesia, all patients underwent laparotomy and their tumors were found unresectable. Cholecystojejunostomy and choledochojejunostomy were performed for patients whose cystic ducts were obstructed and unobstructed after IORT.

IORT

IORT was administered using high-energy electron beams from a Varian Clinac linear accelerator for patients without distant metastases and severe cardiac and lung diseases. A cylinder of 5 cm×5 cm to 8 cm×8 cm, 5 to 8 cm in diameter, or an ellipse with an inclination angle of 10-30° degree was introduced into the patients to encompass the tumor bed and paraaortic lymph

node area. The IORT dose was 15-25 Gy with a median dose of 20 Gy in a single fraction.

EBRT

EBRT was administered mainly postoperatively by 6- or 15-MV photons from a linear accelerator, mostly using two portal veins from the anterior, left, right and/or posterior in directions. In the irradiated field, the paraaortic lymph node area and tumor or tumor bed were completely included with a margin of 3 cm. The usual median EBRT dose was 42 Gy (range, 30-45 Gy) with a daily fraction of 1.8-2.0 Gy, 5F/w. The patients, meanwhile, were given 5-Fu 300 mg/m², iv drip, 2f/w.

Statistic analysis

The cause-specific survival rate was calculated and plotted from the day of operation using the Kaplan-Meier method with significance compared by log-rank test.

RESULTS

Relief of pain and survival condition

The causes of death were local relapse and extensive metastasis. The MST of patients treated with ID+IORT, ID+IORT+EBRT, EBRT, ID, was 10.7, 12.2, 5.1 and 7 mo, respectively, which was significantly longer than the patients treated with EBRT ($\chi^2=10.5835$, $P<0.05$; $\chi^2=17.8972$, $P<0.05$). The difference of MST between ID+IORT+EBRT and ID was significant ($\chi^2=8.1361$, $P<0.05$), and it was not significant while between ID+IORT and ID+IORT+EBRT, ($P>0.05$) (Figure 1). No significant differences in remission of pain and tumor were detected among ID+IORT, ID+IORT+EBRT, and EBRT ($P>0.05$) groups (Table 1).

Figure 1 Survival curves for pancreatic cancer according to radiation modalities.

Complications

Three patients had the delayed gastric emptying after ID+IORT, and they recovered after given parenteral nutritional support for 4-5 wk. One patient died of liver and renal failure in the ID+IORT group. Intestinal perforation and digestive tract bleeding

were unrelated to ID+IORT. Nausea, decreased appetite and frequent defecation were found early after ID+IORT+EBRT. One patient died of liver and renal failure after simple internal drainage, and 2 patients had delayed gastric emptying and 1 wound infection. No significant difference in the occurrence rate of complications was observed among different treatment methods ($P>0.05$).

DISCUSSION

The goal of IORT is used to enhance regional tumor control, and have been IORT is used in most modern protocol studies as a radiation boost component of multidisciplinary treatment approaches. More recently, clinical experiences have shown that IORT could improve local control and disease-free survival time, especially when it was used in adjuvant setting, combined with external beam irradiation in some neoplasms such as cancer of the stomach, pancreas, colorectum, and soft tissue sarcoma^[9].

The use of IORT for unresectable pancreatic cancer has been reported by several groups. Many reports failed to prove its survival benefit^[9,10]. Miyamatsu demonstrated that the MST to IORT group was 7.6 mo, compared to 3 mo for palliative therapy group, with no statistical significance^[10]. Ouchi proposed that IORT was not beneficial to either survival or quality of life^[11]. Shibamoto reported that among non-stage IV patients, the median survival of the EBRT+IORT group (8.5 mo) and the EBRT group (8 mo) was similar, while in stage IV patients, the prognosis was not influenced by the type of radiotherapy^[12]. In contrast to these results, survival advantage with IORT was reported by several groups. Literature data suggested the use of schedules with IORT had a better local control and perhaps a better survival than surgery alone or the palliative treatment^[13]. Tanada demonstrated a significant difference in the survival rate between IORT cases and no treatment cases (median survival of 212 d and 109 d, respectively)^[14]. Dobelbower reported that the median survival time of patients treated with radical surgery alone was 6.5 mo. The median survival time for the surgery plus IORT group was 9 mo, and 33.3% (2 of 6) of these patients survived longer than 5 years. This survival pattern was significantly better than that for the surgery alone group. The surgery plus EBRT and the surgery plus IORT and EBRT groups had a median survival time of 14.5 and 17.5 mo, respectively. These were significantly better than that of the surgery alone group. The addition of radiation therapy did not increase the treatment complication rate^[15].

Patients with advanced pancreatic cancer usually have symptoms such as obstructive jaundice, poor appetite, fatigue and weight loss. Therefore, relief of symptoms, especially relief of obstructive jaundice and improvement of liver function, is clinically beneficial to these patients. In the colligation treatment, internal drainage has been used for the extinction of obstructive jaundice, enhancement of appetite and improvement of liver

Table 1 Patient characteristics after treated with ID+IORT, ID+IORT+EBRT, ID, and EBRT

	IORT+ID		IORT+EBRT+ID		ID		EBRT	
	<i>n</i>	%	<i>n</i>	%	<i>n</i>	%	<i>n</i>	%
Pain								
Complete remission	10	55.5	15	60.0	/		5	31.3
Partial remission	6	33.3	8	32.0	/		7	43.7
Tumor								
Light diminution	4	22.2	8	32.0	/		2	12.5
Unchanged	14	77.7	17	68.0	22	100.0	14	87.5
Jaundice	extinction		extinction		extinction		extinction	

function, which was also beneficial to IORT and EBRT^[16,17]. IORT has also been used in an attempt to increase the radiotherapy dose on the target without damaging surrounding normal tissues. A higher radiation dose could be given to the target tumor by combining IORT with EBRT^[11,18]. Our studies showed that colligation treatment (ID+IORT+EBRT) could relieve jaundice, pain, improve quality of life, diminish tumor and prolong survival time in patients with unresectable pancreatic cancer.

Among the groups of ID+IORT, surgery, ID+IORT+EBRT, jaundice was improved quickly. However, it was not obviously improved in EBRT group. Pain was not relieved in surgery group, but obviously relieved in 75-92% of the patients in the other groups. So radiotherapy had a good and a long-term pain relieving effect. IORT relieved pain quickly and could kill the remnant tumor, better than drugs. The tumor was not reduced in size in surgery group, while in the other groups, the tumor size was decreased in varying degrees, with no statistical significance ($P>0.05$).

In the present study, the MST was 5.1 mo for EBRT group, 7 mo for ID group, 10.7 mo for ID+IORT group and 12.2 mo for ID+IORT+EBRT group. The survival curves of the ID+IORT group and ID+IORT+EBRT group were significantly better than that of the EBRT group ($P<0.05$). The difference between the ID+IORT+EBRT and the ID groups was significant ($P<0.05$). Thus, ID+IORT+EBRT could relieve the pain and jaundice, improve survival and quality of life.

Complications resulting from surgery and radiotherapy occurred in 9.3% of patients (4/43) in both ID+IORT and ID+IORT+EBRT groups. No major side effects were noted during the course of treatment. Schwarz reported IORT was not related to a significantly increased risk of complications, hospital stay, or survival hazard^[19]. Though a very small amount of normal tissues was exposed in IORT, complications often occurred if radiotherapy dose was too big. The safety level of a radiation dose for IORT alone is limited to 30 Gy^[20]. The dose in IORT ranging from 20 Gy to 25 Gy combined with the dose in EBRT ranging from 40 Gy to 50 Gy was considered to contribute to the improvement of prognosis without causing serious side effects^[21].

In conclusion, multimodal therapy can relieve jaundice, pain, improve quality of life, reduce tumor mass and prolong survival time of patients with advanced pancreatic cancer.

Abstract

AIM: To study the effects of *mu* and *kappa* opioid receptor agonists and antagonists on the isolated colon strips of rats with cathartic colon.

METHODS: Cathartic colon model was established by feeding rats with contact laxatives, and effects of *mu* and *kappa* opioid receptor agonists and antagonists on electricity-stimulated contraction of isolated colon strips of rats with cathartic colon were observed.

RESULTS: Compared with control group, exogenous *mu* and *kappa* agonists inhibited significantly electricity-stimulated contraction of strips of cathartic colon (8.50 ± 0.89 mm, 6.24 ± 0.91 mm, 3.35 ± 0.6 mm vs 11.40 ± 0.21 mm $P < 0.01$; 8.98 ± 0.69 mm, 6.89 ± 0.71 mm, 4.43 ± 0.99 mm vs 11.40 ± 0.21 mm, $P < 0.01$). In contrast, the exogenous *mu* antagonist significantly enhanced electricity-stimulated contraction of isolated colon strips (13.18 ± 0.93 mm, 15.87 ± 0.98 mm, 19.46 ± 1.79 mm vs 11.40 ± 0.21 mm, $P < 0.01$), but *kappa* antagonist had no effect on the isolated colon strips of rats with cathartic colon.

CONCLUSION: *Mu* and *kappa* opioid receptors are involved in the regulation of colon motility of rats with cathartic colon.

INTRODUCTION

The cause and pathogenesis of slow-transit constipation (STC) still remain unknown now^[1]. To study the mechanism of STC, more and more attention has been recently paid on the function of numerous neurotransmitters involved in the onset of STC^[2-8]. With a rat model of cathartic colon^[9,10], we investigated the effects of opioids, inhibitory neurotransmitters, on the electricity-stimulated contraction of isolated cathartic colon strips.

MATERIALS AND METHODS

Materials

Rhubarb and phenolphthalein powders were provided by

Chongqing Traditional Chinese Medicine Pharmaceutical Factory and Chongqing Dongfeng Reagent Factory, respectively. *Mu* and *kappa* opioid receptor antagonists (Naloxone, Norbni) and agonists (Damgo, U50488H) were purchased from Sigma Co USA.

Fifty Wistar rats of either sex, weighing 230 ± 70 g, were divided randomly into control group ($n=10$) and cathartic colon group treated with rhubarb ($n=20$) and phenolphthalein ($n=20$). Because both rhubarb and phenolphthalein belong to the same kind of contact cathartics, the two groups were considered as one cathartic colon group.

Rats were housed in cage, one per cage under standard laboratory conditions (room temperature, 18-28 °C, relative humidity, 40-80%). Control rats were given soft chows, while the rats in rhubarb group were given chows premixed with rhubarb powder. The initial rhubarb dosage was 200 mg/kg.d, and another 200 mg/kg was added every day until it reached 1000 mg/kg.d for several days until loose stool disappeared. Then, rhubarb was added 200 mg/kg.d again until 2 400 mg/kg.d for 3 mo. The rats in phenolphthalein group were fed chows premixed with an initial dosage of phenolphthalein 200 mg/kg. Its 50% for dosage diarrhea was 1 400 mg/kg.d and its final dosage was 3 200 mg/kg.d.

Method

Rats were killed by head-strike, the abdominal cavity was opened through a median incision, and a 5 cm colon in length far from the ileocecum was then quickly dissected and transferred to Krebs solution and rinsed. The Krebs solution contained NaCl, 112.8 mmol; KCl, 5.90 mmol; CaCl₂, 1.97; MgCl₂, 1.18 mmol; NaHPO₄, 1.22 mmol; NaHCO₃, 25.0 mmol; Glu, 11.49 mmol (pH 7.2-7.4). Rinsed colon was scratched off serous membrane and cut into 2 cm×2 cm strips. One end of the strip was fixed on a supporting rod, and the another was fixed to the tension transducer. Each muscle strip was vertically placed in an organ bath filled with 10 mL Krebs solution maintained at 37 °C and gased with (950 mL/LO₂)/(50 mL/LCO₂). Muscle contraction was activated by electrical field stimulation with a pair of external platinum ring electrodes connected to a square wave stimulator. The electrodes were parallelly placed on each end of the strip, on which continuous electrical stimulations (4 ms in duration, 10 Hz and 70 V in electric pressure) were conducted. The strips were given 1 g initial tensions and equilibrated for 60 min. Isometric contraction was measured with a tension transducer connected to a physiological recorder, and the contraction amplitude was printed on standard chart paper. The direct effects of opioid receptor agonists and antagonists on the contractility of isolated muscle strips were studied by addition of opioid receptor agonists and antagonists to organ bath to make a required solution. The recorded data were depicted into concentration-response curves. To evaluate the response of muscle strips to electrical stimulation, the contraction amplitude was calculated and the average of amplitude was accounted.

Statistical Analysis

Results were expressed as mean±SE. Differences were

analyzed by Student *t* test. $P < 0.05$ was considered statistically significant.

RESULTS

Electricity-stimulated contractile response of isolated colon strips

The contractile response of most colon strips (about 70%) showed a typical sinusoid curve, while about 30% strips demonstrated wild and irregular waves. In the cathartic colon group, the decrease of contraction amplitude was about 27.43% of that in control group.

Effect of mu opioid receptor agonists on electricity-stimulated contractile response of cathartic colon strips

The mu opioid receptor, agonist Damgo, caused a concentration-dependent inhibition of electricity-stimulated contraction of cathartic colon strips. Damgo solutions (0.05 $\mu\text{mol/L}$, 0.10 $\mu\text{mol/L}$, 1.00 $\mu\text{mol/L}$) could induce a significant inhibition of the contractile response, which showed that the amplitude of muscle strip contraction was significantly reduced ($P < 0.01$) in the presence of Damgo (Table 1).

Table 1 Effect of Damgo on electricity-stimulated contractile response of cathartic colon strips (mean \pm SD)

Concentration ($\mu\text{mol/L}$)	Basic contraction amplitude without Damgo (mm)	Contraction amplitude with Damgo (mm)
0.05	11.40 \pm 0.21	8.50 \pm 0.89 ^b
0.10	11.40 \pm 0.21	6.24 \pm 0.91 ^{ab}
1.00	11.40 \pm 0.21	3.35 \pm 0.64 ^{bd}

^a $P < 0.05$ vs 0.05 $\mu\text{mol/L}$, ^b $P < 0.01$ vs without Damgo, ^d $P < 0.01$ vs 0.05 $\mu\text{mol/L}$.

Effect of mu opioid receptor antagonists on electricity-stimulated contractile response of cathartic colon strips

The mu opioid receptor antagonist, naloxone, could induce a concentration-dependent elevation of electricity-stimulated contraction amplitude of cathartic colon strips. Each naloxone concentration (0.05 $\mu\text{mol/L}$, 0.10 $\mu\text{mol/L}$, 1.00 $\mu\text{mol/L}$) induced a significant elevation of the contractile response, which showed the contraction amplitude was significantly elevated ($P < 0.01$) in the presence of naloxone (Table 2).

Table 2 Effect of naloxone on electricity-stimulated contractile response of cathartic colon strips (mean \pm SD)

Concentration ($\mu\text{mol/L}$)	Basic contraction amplitude without naloxone (mm)	Contraction amplitude with naloxone (mm)
0.05	11.40 \pm 0.21	13.18 \pm 0.93 ^b
0.10	11.40 \pm 0.21	15.87 \pm 0.98 ^{ab}
1.00	11.40 \pm 0.21	19.46 \pm 1.79 ^{bd}

^a $P < 0.05$ vs 0.05 $\mu\text{mol/L}$, ^b $P < 0.01$ vs without Naloxone, ^d $P < 0.01$ vs 0.05 $\mu\text{mol/L}$.

Table 3 Effects of U50488H on electricity-stimulated contractile response of cathartic colon strips (mean \pm SD)

Concentration ($\mu\text{mol/L}$)	Basic contraction amplitude before administration (mm)	Contraction amplitude after administration (mm)
0.05	11.40 \pm 0.21	8.98 \pm 0.69 ^b
0.10	11.40 \pm 0.21	6.89 \pm 0.71 ^{ab}
1.00	11.40 \pm 0.21	4.43 \pm 0.99 ^{bd}

^a $P < 0.05$ vs 0.05 $\mu\text{mol/L}$, ^b $P < 0.01$ vs before administration, ^d $P < 0.01$ vs 0.05 $\mu\text{mol/L}$.

Effect of kappa opioid receptor agonists on electricity-stimulated contractile response of cathartic colon strips

U50488H, a highly-selective kappa opioid receptor agonist, could cause an evident suppression of the electricity stimulated contraction of colon strips of rats with cathartic colon. Each U50488H concentration (0.05 $\mu\text{mol/L}$, 0.10 $\mu\text{mol/L}$, 1.00 $\mu\text{mol/L}$) induced a significant inhibition of the contractile response ($P < 0.01$) (Table 3).

Effect of kappa opioid receptor antagonists on electricity-stimulated contractile response of cathartic colon strips

Norbin is a highly-selective kappa opioid receptor antagonist, which did not show any evident effect on the electricity stimulated contraction of colon strips of rats with cathartic colon. No concentration of Norbin in our experiment could induce any effect on the contraction amplitude of muscle strips, even at the maximal concentration of Norbin (data not shown).

DISCUSSION

Opioids have extensive distributions and potent effects on the gastrointestinal tract^[11,12]. Contractility studies also indicated that opioids, in combination with mu, kappa and delta opioid receptor agonists, could inhibit motor activity of the gastrointestinal tract by suppression of excitatory neurotransmitter release^[13-15]. Our study manifested that exogenously added opioid receptor agonists (*mu*, *kappa*) inhibited the contractility of colon strips of rats with cathartic colon, which showed a significant reduction of contraction amplitude as compared to the basic contraction with no agonists. The inhibitory effects were negatively correlated with concentrations. In contrast, mu receptor antagonists elevated electricity stimulated contraction of cathartic colon in rats. However, kappa receptor antagonists had no effect. The results suggested that mu and kappa opioid receptor might play an important role in the regulation of gastrointestinal motility in rats. It also further approved that opioids could slow down the propulsive peristalsis performed by nerves and muscles in colon and played a very important role in the onset and pathologic process of STC.

Kreek hypothesized that the changes of opioids activity were the important etiological factor, and STC patients could be successfully treated with naloxone, a mu opioid receptor antagonists. The present study was designed to investigate the effects of opioid agonists and antagonists on isolated cathartic colon muscle strips, it provided a new fundamental theory on the STC treatment with opioid receptor antagonists. It also indicated that the studies on the subtype and binding site of opioid receptors, as well as the overall research in clinic, would provide new methods for STC therapies, and also benefit the clarification of the pathogenesis of STC. In conclusion, mu and kappa opioid receptors are involved in the regulation of colon motility of rats with cathartic colon.

Abstract

AIM: To establish a method to detect the expression of the tumor specific growth factor TSGF, CA242 and CA19-9 in serum and evaluate their value in diagnosis of pancreatic cancer.

METHODS: ELISA and Biochemical colorimetric assay were used to detect the serum content of TSGF, CA242 and CA19-9 in 200 normal cases, 52 pancreatitis patients and 96 pancreatic cancer patients.

RESULTS: The positive likelihood ratios of TSGF, CA242 and CA19-9 were 5.4, 12.6 and 6.3, respectively, and their negative likelihood ratios were 0.10, 0.19 and 0.17, respectively. With single tumor marker diagnosed pancreatic cancer, the highest sensitivity and specificity of TSGF were 91.6% and 93.5%. In combined test with 3 markers, when all of them were positive, the sensitivity changed to 77.0% and the specificity and the positive predictive value were 100%. The levels of TSGF and CA242 were significantly higher in the patients with pancreatic cancer of head than those in the patients with pancreatic cancer of body, tail and whole pancreas, but the expression of CA19-9 had no correlation with the positions of the pancreatic cancer. The sensitivity of TSGF, CA242 and CA19-9 was increased with the progress in stages of pancreatic cancer. In stage I, the sensitivity of TSGF was markedly higher than CA242 and CA19-9.

CONCLUSION: The combined use of TSGF, CA242 and CA19-9 expressions can elevate the specificity for pancreatic cancer diagnosis. And it shows that it plays an important role to differentiate positions and tissue typing. It is a forepart diagnosis for the pancreatic cancer by combination checking. There is very important correlation between the three markers and the pancreatic cancer.

<http://www.wjgnet.com/1007-9327/10/1675.asp>

INTRODUCTION

Early period of pancreatic cancer lacked the typical clinic performances^[1,2], was high malignant and had a low survival time in five years^[3-6]. And it was difficult to be diagnosed and made the patients lose the chances of radical cures. So it was very important to diagnose pancreatic cancer early^[7-9]. But the sensitivity and specificity were not ideal in examining pancreatic

cancer with a single method. We assayed the content of TSGF, CA242 and CA19-9 in serum of pancreatic cancer suffers and analyzed their expression in different positions and tissue typing in order to improve the level of early period of the pancreatic cancer diagnosis.

MATERIALS AND METHODS

Materials

To collect 200 normal people who had medical check-up in the hospital as normal group, including 112 males and 88 females with a mean age of 55.0 ± 11.2 (range, 22-68 years). To collect 52 pancreatitis suffers as pancreatitis group, including 29 males and 23 females with an average age of 66.0 ± 8.0 (range, 60-74 years). To collect 96 pancreatic cancer suffers as pancreatic cancer group, including 61 males and 35 females with an average age of 67.6 ± 6.7 (range, 60-88 years). There were 64 heads of pancreatic cancer, 18 body of pancreatic cancer and 10 tail of pancreatic cancer, which were all proved by pathology.

Methods

TSGF was assayed by colorimetric of biochemistry from Fujian New Continent Biochemical Technology Limited Company. CA242 and CA19-9 were assayed by ELISA from Sweden CanAg Company. All operations were followed by manuals. All data were showed as mean \pm SD and calculated by *t* test, and positive ratios were calculated by χ^2 test.

RESULTS

TSGF, CA242 and CA19-9 assay of three groups

Statistical significance of the contents of the three markers was found when pancreatic cancer group was compared with normal group and pancreatitis group ($P < 0.01$). No statistical significance was found between normal group and pancreatitis group ($P > 0.05$, Table 1).

Table 1 Laboratory parameters of the 3 tumor markers in pancreatic cancer group, pancreatitis group and normal group (mean \pm SD, $\times 10^3$ U/L)

Evaluate the value of diagnosis in pancreatic cancer by a single tumor marker

When diagnosing pancreatic cancer by a single tumor marker, TSGF had the highest sensitivity of 91.6%, CA242 had the highest specificity of 93.5%; TSGF and CA19-9 had the exactly validity. The positive likelihood ratio of TSGF, CA242 and CA19-9 were 5.4, 12.6 and 6.3, and the negative likelihood ratio were 0.10, 0.19 and 0.17 (Table 2).

Table 2 Evaluation of the value of diagnosis in pancreatic cancer by a single tumor marker of 96 cases

Value of diagnosis	Sensitivity (%)	Specificity (%)	Positive likelihood ratio	Negative likelihood ratio
TSGF	91.6 (88) ^a	83.0	5.4	0.10
CA242	82.3 (79)	93.5 ^b	12.6	0.19
CA19-9	85.4 (82)	86.5	6.3	0.17

(), No. of cases; ^a $P < 0.05$, ^b $P < 0.01$ vs the other two indexes. sensitivity=true positive/patients $\times 100\%$ =TP/(TP+FN) $\times 100\%$, specificity=true negative/normal $\times 100\%$ =TN/(TN+FP) $\times 100\%$ positive likelihood ratio=true positive/false positive=sensitivity/(1-specificity) negative likelihood ratio=(1-true positive)/(1-false positive)=(1-sensitivity)/specificity.

The different combinations of the 3 markers to the diagnosis in pancreatic cancer

When diagnosing pancreatic cancer by any of the 3 markers was over the critical value, the sensitivity, specificity and positive predictive value were 93.8%, 79.0% and 68.2%. When two of the 3 markers were over the critical value, the sensitivity, specificity and positive predictive value were 89.5%, 95.5% and 90.5%. When the 3 markers were all over the critical value, the sensitivity was 77.0% and the specificity and positive predictive value were both 100%. Therefore, the combination diagnosis in pancreatic cancer could increase the specificity of the diagnosis (Table 3).

Table 3 Analyses of The different combinations of the 3 markers to the diagnosis in pancreatic cancer (No. of cases)

Group	No. of cases	1 Item (+)	2 Item (+)	3 Item (+)
Pancreatic cancer	96	90 (93.8)	86 (89.5)	74 (77.0)
Normal	200	42 (21.0)	9 (4.5)	0 (100)
Positive likelihood rate (%)		68.2	90.5	100

(), sensitivity (%).

The correlation between the different positions of pancreatic cancer and the levels of the 3 markers

International Union Against Cancer (UICC) divided pancreatic cancer into head, body, tail and whole of pancreatic cancer. Statistical significance was found that the levels of TSGF and CA242 in head of pancreatic cancer were extra better than those in the other three kinds of pancreatic cancer ($P < 0.01$). But no statistical significance was found in the levels of the 3 markers in the other three kinds of pancreatic cancer ($P > 0.05$). The levels of CA19-9 had no correlation with the positions of the pancreatic cancer ($P > 0.05$). (Table 4).

Table 4 The content of the 3 markers in the different positions of pancreatic cancer (mean \pm SD, $\times 10^3$ U/L)

Position of pancreatic cancer	No. of cases	TSGF	CA242	CA19-9
Head	64	88.5 \pm 9.0 ^b	106.4 \pm 12.6 ^b	653.7 \pm 217.8
Body	18	78.2 \pm 6.7	82.5 \pm 10.4	633.9 \pm 192.4
Tail	10	77.1 \pm 5.7	81.6 \pm 8.2	659.4 \pm 211.0
Whole	4	74.5 \pm 3.1	83.0 \pm 9.5	615.3 \pm 187.1

^b $P < 0.001$ vs body, tail and whole of pancreatic cancer.

To compare the sensitivity of the 3 tumor markers in different stages of pancreatic cancer

We analyzed the sensitivity of the 3 tumor markers in serum in different stages of pancreatic cancer (Table 5). The results showed that the sensitivity gradually strengthened by the progress of clinical stages. Statistical significance was found

between stage II, III, IV, and stage I ($P < 0.01$). The sensitivity of CA19-9 was higher than that of CA242, but there was no statistical significance ($P > 0.05$). The sensitivity of TSGF in stage I was significant better than that of CA242 and CA19-9 ($P < 0.01$). So TSGF could be regarded as a tumor marker to filtrate pancreatic cancer in early stage.

Table 5 Analyses of the sensitivity of the 3 tumor markers in different stages of pancreatic cancer (No. of cases)

Clinical stages	No. of cases	TSGF	CA242	CA19-9
I	10	6 (60.0) ^{bd}	3 (30.0) ^d	4 (40.0) ^d
II	12	9 (75.0)	6 (50.0)	7 (58.3)
III	25	22 (88.0)	20 (80.0)	21 (84.0)
IV	49	46 (93.8)	40 (81.6)	42 (85.7)

Note: (), sensitivity (%); ^a $P < 0.01$ vs the sensitivity of stage II, III, IV; ^b $P < 0.01$ vs the sensitivity of CA242, CA19-9.

DISCUSSION

The incidence of pancreatic cancer is rising^[10,11]. We want to diagnose pancreatic cancer in early stage by tumor markers^[12]. First, we should find one tumor marker of good specificity^[13,14]. TSGF was a gene that could promote the growth of tumor blood vessels. It could greatly hyperplasia in the tumor tissues and capillary vessels around. No correlation was found in the hyperplasia of non-tumor blood vessels. TSGF had good sensitivity to malignant tumors. CA19-9 belonged to the ramification of lactotetraose and was a kind of the ganglioside lipoprotein protein^[15-17]. It was mucoprotein when in serum and its epipositions was pentaglucose determinant. Despite advances in preoperative radiologic imaging, a significant fraction of potentially resectable pancreatic cancers are found to be unresectable at laparotomy^[18]. CA242 was a kind of sialic acid mucoprotein tumor associated antigen linked Mucin pyrenoid by -O-. It existed in the same molecule with CA19-9. But it belonged to the different antigen determinant with CA19-9. Therefore, there was no correlation between CA19-9 and CA242^[19]. But they were complementary. They had good sensitivity in pancreatic cancer diagnosis. This result was exactly similar with the report of Ichihara *et al*^[20]. This research also showed that 3 tumor markers in pancreatic cancer group were remarkably higher than that of normal group. And the levels of the 3 tumor markers in pancreatitis group were not high.

The research showed that the positive likelihood ratio of TSGF, CA242 and CA19-9 were 5.4, 12.6 and 6.3, and the negative likelihood ratio were 0.1, 0.19 and 0.17. So the three indexes were very important in clinical pancreatic cancer diagnosis. TSGF had good sensitivity in pancreatic cancer diagnosis as 91.6%. CA19-9 was very important to evaluate the curative effect of chemotherapy and to judge the survival time^[21-26]. CA242 had good specificity as 93.5%. When diagnosing with the combination assay of the 3 indexes, the sensitivity was 77.0% and the specificity and positive predictive value were both 100%. Therefore, combination diagnosis should be used in pancreatic cancer diagnosis in order to improve the specificity^[27-29].

The research of Metsuyama *et al*. proved that there was significant correlation in malignant tumors between the creation of blood vessels and blood transfer^[30]. TSGF and CA242 had high levels. It was related to the rich blood supply of the head of pancreas. Pancreas had the priority and step artery pancreaticoduodenalis superior and the forward and back branches down pancereaticoduodenales inferiors. The arteries were connected by anastomosis at the head of pancreas to be arcuate arterial. The arcuate arterial gave out branches to supply the forward and back parts of the head of pancreas and duodenum. It accelerated the head of pancreas circulation. So

it made the carbohydrate antigen excreted by tumors to be a high level in serum. But there was no correlation between the expression of CA19-9 and the position of tumor. This needs further researches. TSGF was a new tumor marker related to the blood vessel hyperplasia of malignant tumors. It was also a result of the hyperplasia of the malignant tumors and the capillary vessels around. It was released to blood with the acceleration of blood circulation. In the different stage of pancreatic cancer, the sensitivity of the tumor markers TSGF, CA242 and CA19-9 increased with the progress in different stages. Statistical significance was found in the sensitivity of stage II, III, IV and stage I. This result disagreed that Frebourg *et al* reported that there was no correlation between the level of CA19-9 in serum and the stage of pancreatic cancer^[31]. The sensitivity of CA19-9 was a little higher than that of CA242, but there was no statistical significance. In the stage I of pancreatic cancer, the sensitivity of TSGF was remarkably higher than that of CA242 and CA19-9. Therefore, TSGF can be regarded as a tumor marker to filtrate pancreatic cancer in early stage.

The research shows that there is very important correlation between the levels of TSGF, CA242 and CA19-9 and pancreatic cancer. The combined assay of the 3 indexes does help to diagnose pancreatic cancer in early stage. At the same time they are very important in analyzing the position of pancreatic cancer and the pathology typings. Therefore, the 3 indexes can be regarded as the tumor markers of pancreatic cancer diagnosis in early stage.

Abstract

AIM: To analyze the role of liver biopsies in differential diagnosis after liver transplantation.

METHODS: A total of 50 biopsies from 27 patients with liver dysfunction out of 52 liver transplantation cases were included. Biopsies were obtained 0-330 d after operation, in which, 44 were fine needle biopsies, another 6 were wedge biopsies during surgery. All tissues were stained with haematoxylin-eosin. Histochemical or immunohistochemical stain was done.

RESULTS: The rate of acute rejection in detected cases and total transplantation cases was 48.2% and 25.0%, chronic rejection rate in detected cases and total transplantation cases was 14.8% and 7.7%, preservation-reperfusion injury in detected cases and total transplantation cases was 25.9% and 13.5%, hepatic artery thrombosis rate in detected cases and total transplantation cases was 11.1% and 5.8%, intrahepatic biliary injury rate in detected cases and total transplantation cases was 7.4 % and 3.8%, CMV infection rate in detected cases and total transplantation cases was 3.7% and 1.9%, hepatitis B recurrence rate in detected cases and total transplantation cases was 3.7% and 1.9%, the ratio of suspicious drug-induced hepatic injury in detected cases and total transplantation cases was 11.1% and 5.8%.

CONCLUSION: Acute rejection and preservation-reperfusion injury are the major factors in early liver dysfunction after liver transplantation. Hepatic artery thrombosis and prolonged cold preservation may result in intrahepatic biliary injury. Acute rejection and viral infection may involve in the pathogenesis of chronic rejection. Since there are no specific lesions in drug-induced hepatic injury, the diagnosis must closely combine clinical history and rule out other possible complications.

INTRODUCTION

Liver transplantation has been accepted as an effective therapeutic option for patients with acute or chronic end-stage

liver diseases. However, the postoperative course of liver transplant recipients will face to rejection for alloantigens and a number of complications. Among which, hepatic artery thrombosis, intrahepatic biliary injury, preservation-reperfusion injury, opportunistic infection as well as immunosuppressive drug-induced hepatic injury are critically for allograft liver poor function. Clinically, the complications are short of specific symptoms and signs, although the supervision for blood biochemistry, Doppler-ultrasound and radiologic image has some value to the evaluation of graft liver dysfunction, the final diagnosis still relies on liver biopsy evaluation. Here is a pathological study on fifty allograft liver biopsies which have been collected in our transplantation center since June 2002. These biopsies covered a number of complications following liver transplantation.

MATERIALS AND METHODS

Collection of allograft liver biopsies

From June 2002 to September 2003, a total of 52 orthotopic liver transplantations (OLTs) were performed in Transplantation Center, Ruijin Hospital of Shanghai. Fifty liver biopsies were obtained from 27 patients with liver dysfunction 0-330 d after operation. In which, 44 were fine needle biopsies, another 6 were wedge biopsies during surgery. All tissues were fixed in 40 g/L buffered formaldehyde and embedded in paraffin.

Histopathologic evaluation of liver biopsies

Serial 3 µm thick sections were cut on all biopsies. One section was stained with hemotoxylin-eosin. Others were stained by histochemical or immunohistochemical methods whenever it was needed. For example, if cytomegalovirus (CMV) infection was suspicious, CMV antigen immunohistochemistry would be done. If chronic rejection was suspicious, CK19 or CA19-9 immunohistochemistry for bile duct detection would be done. Criteria for evaluating acute rejection were based on Banff Schema published in 1997^[1,2]. Criteria for evaluating chronic rejection were based on Banff Schema published in 2000^[3]. Acute rejection was characterized by predominant portal-based lesions, including a classical triad of mixed inflammatory cell infiltrates, venous endothelial inflammation and inflammatory infiltration of bile ducts. Chronic rejection was characterized by ductopenia and obliterative arteriopathy.

Evaluation of preservation-reperfusion injury was based on the criteria proposed by Starzl Transplantation Institute of Pittsburgh University as well as University of Birmingham^[4]. The histological features included: sinusoidal neutrophilic infiltration without portal mixed inflammatory cell infiltration, hepatocyte ballooning, cholestasis, hepatocyte apoptosis and regenerative change. Macrovesicular steatosis was graded as follows: mild, fat present in less than 30% of hepatocyte; moderate, fat infiltration of 30-60%; and severe, fat infiltration greater than 60% of hepatocytes.

This clinical study was performed on archival pathological files, which were obtained as part of routine clinical practice.

RESULTS

In this group, the earliest biopsy was got at 5 h following the

re-vascularization during transplantation procedure, the latest biopsy was got 330 d after transplantation. Twenty-seven cases out of 52 liver transplantation patients with poor allograft function accepted 1 to 6 liver biopsy detections according to clinical requirement. The lesions revealed in biopsy tissues are summarized in Table 1.

Table 1 Classification of lesions in 50 allograft liver biopsies

Lesions	<i>n</i>	Rate in detected cases (%) (<i>n</i> =27)	Ratio in total transplantation cases(%) (<i>n</i> =52)
Acute rejection	13	48.2	25.0
Chronic rejection	4	14.8	7.7
CMV infection	1	3.7	1.9
Hepatic artery thrombosis	3	11.1	5.8
Intrahepatic biliary injury	2	7.4	3.8
Drug-induced hepatic injury	3	11.1	5.8
Preservation-reperfusion injury	7	25.9	13.5
Recurrent hepatitis	1	3.7	1.9

The occurring time of different complications was different. Preservation-reperfusion injury and hepatic artery thrombosis mainly occurred within 2 wk following operation. Acute rejection could happen at any time from 1 wk to 310 d, but often took place at the end of 1 wk to 30 d following operation. The poor graft liver function that occurred 60-90 d postoperation was closely related to intrahepatic biliary injury. Early chronic rejection could happen as early as 45 d after transplantation but mainly occurred from 90 to 330 d post-transplantation. Only one recurrent hepatitis B happened in this group, 300 d after transplantation. The occurring time features of different complications are shown in Figure 1.

Figure 1 Time features of different complications in allograft liver biopsy.

Figure 2 Hepatocytes necrosis and bleeding surrounding central vein caused by HAT 12 d after transplantation, HE $\times 200$.

Figure 3 Bile duct damage with inflammation 80 d after transplantation. HE $\times 200$.

Figure 4 CMV infection in peripheral blood and micro-abscess without inclusion bodies in liver cells 1 mo after transplantation. HE $\times 200$.

Figure 5 Bile duct loss in portal tract compatible with early chronic rejection 3 mo after transplantation. HE $\times 200$.

Figure 6 Fibrosis in portal area with lymphocyte infiltration and interface hepatitis in patient with recurrent hepatitis B 300 d post-transplantation, HE $\times 100$.

Figure 7 Acute rejection and mixed inflammatory cells in portal area with bile duct infiltration and venous endothelial inflammation 7 d post-transplantation. HE $\times 100$.

The pathological examination on different biopsies from the same patient showed that one patient with hepatic artery thrombosis (HAT) 12 d postoperation (Figure 2) developed to intrahepatic biliary injury (IBI) 80 d following transplantation (Figure 3). Two cases in our group occurred IBI 2-3 mo after operation. One of which was secondary to HAT (the donor liver with warm ischemia for 5 min, cold storage time was 9 h), there was warm ischemia after 7 min, and cold storage time was 8 h for donor liver in another case with IBI. One case was diagnosed as chronic rejection (Figure 4) at 3 mo postoperation and disclosed persistent cytomegalovirus (CMV) infection at early stage following transplantation (Figure 5). Chronic rejection was occurred in another case due to recurrence of hepatitis B (Figure 6). Chronic rejection occurred in one case due to acute rejection (Figure 7), early chronic rejection occurred in one case at onset. If poor allograft liver function was persistent, liver biopsy showed hepatocyte ballooning, macrovesicular steatosis, cholestasis, and above-mentioned complications could not be confirmed, drug-induced hepatic injury was suspected.

DISCUSSION

In liver transplantation, liver biopsy is currently used to confirm the clinical diagnosis, to assess the degree of necroinflammatory injury or fibrosis, to evaluate a space-occupying lesion, and to evaluate the changes following therapeutic intervention. Since liver biopsy plays an important role in the diagnosis and management, a representative tissue sampling is needed. Ideally, a good biopsy sample should include at least 4 portal tracts. The subcapsular hepatic parenchyma is avoided in interpretation, as it often contains fibrous extensions from the capsule and has some injuries during peri-operative period^[5].

The experience for evaluation of allograft liver biopsy in our transplantation center revealed that although acute rejection was still the major factor of liver dysfunction at the first few weeks following operation, there was referable international consensus evaluating criteria for acute rejection. All the cases with acute rejection were promptly diagnosed and cured by the close cooperation between the clinician and pathologist^[2]. Chronic rejection is also called ductopenic allograft rejection and characterized by the presence of ductopenia and foamy cell arteriopathy. The overall occurrence rate of chronic rejection was 2-20%. The pathogenesis of chronic rejection was more complex than that in acute rejection. It involved in several factors such as cellular immunology, humoral immunology, ischemia and infection^[6]. In our group, the chronic rejection rate in detected cases and total transplantation cases was 14.8% and 7.7% respectively, similar to those reported by other transplantation center. Chronic rejection occurred due to CMV infection and hepatitis B recurrence in two cases, due to acute rejection in one case, early chronic rejection occurred in one case 45 d post-transplantation. Therefore, the mechanisms of chronic rejection are multiple and complex. The above data confirmed that viral infection was the inducing factor of chronic rejection.

Preservation-reperfusion injury (PRI) refers to any injury during donor liver harvesting, cold storage as well as liver implantation. It is a major contributing factor to primary allograft failure after orthotopic liver transplantation. Clinically, it is characterized by high serum aspartate transaminase (AST) levels in the early postoperative period without technique problem, hepatic artery thrombosis and hyperacute rejection. To date, the pathogenesis of PRI is not very clear and there are no consistent histological evaluation criteria for PRI. A number of histological features have been observed in our group. For example, the predominant features of reperfusion especially at the first several hours after re-vascularization were sinusoidal endothelial cell impairment with neutrophilic cells infiltration;

hepatocyte injuries such as ballooning change, centrilobular cholestasis and apoptosis become predominance at late course of reperfusion. It is suggested that sinusoidal endothelial cells are more susceptible to PRI than hepatocytes themselves. Busquets *et al.*^[7] found that there were 17% PRI out of 162 postreperfusion liver biopsy specimens in their retrospective analysis. They also disclosed that if cold storage time longer than 12 h, intrahepatic biliary complications resulted from PRI were increased. Another report revealed that storage time exceed 10 to 12 h, late posttransplantation biliary strictures occurred in more than 25% of liver transplant recipients, 30% of patients with graft dysfunction needed retransplantation within the first 3 mo after transplantation^[8].

Hepatic artery thrombosis (HAT) occurred in 2-9% of adult transplantation recipients. It is the most frequent arterial complication in liver transplantation. Surgical technique, hemodynamic, immunologic factors, PRI and hypercoagulation have been suggested as the causes for HAT^[9]. In Humboldt University Transplantation Center, among 1 192 liver transplantation cases, 30 HAT were observed, resulting in an incidence of 2.5%. Re-transplantation was necessary in 46.7% of patients with HAT in that group^[10]. The histological features in HAT showed severe midzonal hepatocyte necrosis and bleeding, especially in centrilobular of allograft.

Intrahepatic biliary injury (IBI) is characterized by non anastomotic biliary strictures and is a relatively late complication, usually diagnosed between 1 and 4 mo after liver transplantation. The incidence of IBI was 2-10% of transplantation recipients. Clinically, there were repeated episodes of cholangitis and the necessity for re-transplantation was about 30-50%. Accumulating evidence has shown that IBI is associated with ischemia, secondary to HAT, ABO incompatible blood group donors, and chronic ductopenic rejection as well as prolonged warm ischemic time or cold ischemic time prior to implantation^[11-14]. IBI occurred in 2 cases of our group 2-3 mo after operation. One of which was secondary to HAT (the donor liver with warm ischemia was 5 min, cold storage time was 9 h), another case of IBI showed warm ischemia for 7 min, cold storage time was 8 h for donor liver. It is suggested that improved hepatic artery supplying and the lowest total ischemia time may reduce the incidence of IBI.

Drug-induced hepatic injury (DIHI) is the "hot" but also troublesome problem in hepatic diseases. Therapeutic drugs such as corticosteroids, azathioprine and cyclosporine A in transplantation recipients could cause liver damage^[15]. However, the report about DIHI after liver transplantation is rare. Recently, an introductory review about drug-induced hepatotoxicity progress was published in The New England Journal of Medicine^[16]. The most frequent hepatotoxic drug reactions could lead to moderate to severe injuries to hepatocytes with a clinical symptom that resembles viral hepatitis, characterized by a rapid onset of jaundice in association with elevated aminotransferase levels. Acute liver failure may develop after weeks of onset, particularly if the patient has continued the drug. The histological characteristics of DIHI include ballooning degeneration or steatosis of hepatocytes with cholestasis, centrilobular or midzonal hepatocyte dropout or necrosis, portal tracts with severe bile duct damage surrounded by lymphocytes, plasma cells and eosinophils with or without granulomas, and lobular disarray with acidophilic bodies and sinusoidal chronic inflammation. Since many pathological changes in DIHI overlapped with the features observed at acute or chronic rejection, PRI or viral hepatitis recurrence, the diagnosis of DIHI in transplantation population is more difficult than in non-transplant population.

Abstract

AIM: To study the expression of CDw75 in patients with gastric carcinoma and to correlate CDw75 expression with progression of the tumor.

METHODS: Immunohistochemical method was used to examine the expression of CDw75 in 72 cases of the gastric carcinoma and adjacent normal gastric mucosa, and the percentage of the cells positively stained with CDw75 was calculated using a computer-aided microscopic image analysis system.

RESULTS: CDw75 was not expressed in normal gastric mucosa but detected in 37 of the 72 neoplastic gastric lesions. The expression of CDw75 was associated with the tumor progression as indicated by its close correlation with the depth of the tumor infiltration ($\chi^2=18.415$, $P<0.01$), TNM stage ($\chi^2=10.419$, $P<0.05$) and lymph node metastasis ($\chi^2=6.675$, $P<0.01$). The overall survival rate of the patients with positive CDw75 expression (32.4%) was significantly lower than that of the patients without CDw75 expression (71.4%) ($P<0.01$). There was no significant correlation between the expression of CDw75 and the sex and age and histological type of patients ($P>0.05$).

CONCLUSION: These findings suggest that the expression of CDw75 is a significant histopathological marker for more advanced stage of gastric carcinoma and indicates a poor prognosis for the patients.

INTRODUCTION

Invasiveness and metastasis are the most important characteristics of malignant tumor and mortality factors. Clinicopathological parameters are usually used for diagnosis and prognosis. Recent studies have shown that the expression of sialylated glycoconjugates is closely associated with the aggressiveness and metastatic potential of malignant cells. CDw75 epitope is a sialylated carbohydrate determinant generated by the β -galactosyl α -2,6-sialyltransferase, and it has been reported to be associated with the progression of gastric cancer^[1]. Gastric cancer is one of the most common tumors of alimentary tract in China, and its mortality is high. In this study, we examined the

expression of CDw75 in 72 cases of gastric carcinoma and adjacent normal gastric mucosa using immunohistochemical method to determine whether CDw75 is correlated with the invasiveness and metastasis of gastric carcinoma.

MATERIALS AND METHODS

Materials

Seventy-two patients with gastric cancer, who were diagnosed and treated at the Departments of Pathology and General Surgery, Renmin Hospital of Wuhan University, from 1995 to 1999, were randomly selected for this study. The patients had undergone subtotal or total gastrectomy combined with lymph node resection. Sections from the surgical specimens were fixed in 40 g/L formaldehyde and embedded in paraffin. The mean age of the patients was 59 years with a range from 35 to 74 years and a male-to-female ratio of 1.48. The patients were followed to determine clinical outcome and the median follow-up time at the end of the study was 45 mo (range, 3-64 mo). The other clinicopathological characteristics are listed in Table 1. The histological type of the tumor was defined by World Health Organization classification (tubular, papillary, mucinous, or signet ring^[2]), the degree of differentiation (well, moderate, or poor) was recorded on haematoxylin and eosin (H & E) stained tissues, and tumor stage was graded according to new PTNM criterion which was published by International Union Against Cancer (IUCN)^[2].

Immunohistochemistry

Streptavidin-peroxidase (S-P) method was used to detect the expression of CDw75. The mouse monoclonal antibody against human CDw75 (LN1) was purchased from NeoMarkers Company, Wuhan, China, immunostaining S-P kit and DAB reagent were purchased from Fuzhou Maxim Biotechnical Company, Fuzhou, China. Sections from each primary tumor and adjacent mucosa were deparaffinized and heated in a microwave oven for 15 min to retrieve antigens. Endogenous peroxidase was blocked with 3 mL/L hydrogen peroxide methanol for 10 min at room temperature. After washing with phosphate-buffered saline (0.01 g/L, pH 7.4) for 3×5 min, the tumor sections were incubated with normal non-immune serum from bull for 15 min at room temperature to eliminate nonspecific staining. The sections were then incubated with the primary antibody against CDw75 (dilution 1/100) for 60 min at room temperature, washed with PBS for 3×5 min, and incubated with the secondary biotinylated antibody for 15 min followed by avidin-biotin-peroxidase for 15 min at room temperature. Finally, the slides were washed for 3×15 min with PBS, visualized with DAB reagent and counterstained with haematoxylin. Negative and positive controls were used simultaneously to ensure specificity and reliability of the staining process. The negative controls were performed by substituting the primary antibody with PBS, and a positive section supplied by manufacturer of the staining kit was taken as positive control.

Positive staining with CDw75 was defined as brown staining of cell membrane or cytoplasm. The degree of the CDw75 staining was calculated semiquantitatively with computer-aided analysis of four non-overlapping high power microscopic fields and classified as follows: -, negative staining; +, less than 25% tumor cells were CDw75 positive; ++, between 25% and 50% of

tumor cells were CDw75 positive; +++, between 51% and 75% of tumor cells were CDw75 positive; and +++, more than 75% of tumor cells were CDw75 positive.

Statistical analysis

CDw75 expression in all patients with gastric carcinoma was analyzed against clinicopathological parameters. The correlation between CDw75 expression and selected clinicopathological parameters was analyzed with the Wilcoxon rank sum test and χ^2 test. Kaplan-meier curve was constructed to assess the survival. *P* value of less than 0.05 was considered to be statistically significant.

RESULTS

Immunohistochemical staining of CDw75

Normal gastric mucosa was consistently negative for CDw75 staining (Figure 1), while positive staining was observed in 37 of 72 (51.4%) gastric cancers. The staining intensity was as follows: -, 35 cases (48.6%); +, 9 cases (12.5%); ++, 13 cases (18.1%); +++, 9 cases (12.5%); +++, 6 cases (8.3%). The positive staining of CDw75 was localized predominantly in gastric cancer cells, and all the positive cases showed diffuse membrane staining, or cytoplasmic staining in some cases (Figure 2). The immunoreactive cells were either distributed unevenly throughout the tumor tissue or aggregated in focal clusters. In addition, positive staining was occasionally detected in lymphocytes or other inflammatory cells infiltrating the cancer nests (Figure 3).

Figure 2 Weak staining of CDw75 in gastric cancer cells. There were a few gastric cancer cells brown-stained on membrane or in cytoplasm (SP×200).

Figure 3 Strong staining of CDw75 in gastric cancer cells. There were many gastric cancer cells brown-stained on membrane or in cytoplasm (SP×200).

Correlation between CDw75 and the invasiveness or the metastasis of gastric carcinoma

The CDw75 expression in tumor tissues was related significantly to clinicopathologic factors, such as the depth of tumor invasion, TNM stage and lymph node metastasis (Table 1). The percentage of CDw75 expression in tumors which invaded serosal or deeper layers (T3 or T4) was significantly higher than that in tumors which were restricted within mucosa or muscular layers (T1 or T2) (*P*<0.01). When tumors were accompanied by lymph node metastasis, CDw75 expression was elevated significantly

compared with those without metastasis ($P < 0.05$). The cases were also categorized by TNM staging. To compensate the error due to shortage of cases, stage I and stage II cases were combined into one group. CDw75 expression was found in 10 of 32 (31.3%) stage I+II cases, 12 of 20 (60.0%) stage III cases and 15 of 20 (75.0%) stage IV cases. The percentage of positive CDw75 staining in stage III and IV cases was significantly higher than that in stage I+II ($P < 0.05$ and $P < 0.01$, respectively), while there was no significant difference in those between stage III and stage IV ($P > 0.05$).

No significant correlation was found between the expression of CDw75 antigen and the distant metastasis or the histological type of gastric cancer. Similarly, no significant difference was found between the cases with positive and negative CDw75 expression regarding the sex and age of patients.

Correlation between CDw75 expression and the survival of the patients with gastric carcinoma

At the end of the follow-up period, 37 of 72 patients (51.4%) were alive. The survival of patients with positive CDw75 expression was significantly shorter than those with negative CDw75 expression (Table 2). As shown by the Kaplan-Meier curve, the overall survival rate of patients with CDw75 expression (32.4%) was significantly lower than that of patients without CDw75 expression (71.4%) ($P < 0.01$, Figure 4).

Figure 4 A Kaplan-Meier plot shows the survival rates after curative resection for gastric carcinoma patients with or without CDw75 expression.

DISCUSSION

The infiltration and metastasis of gastric carcinoma is a multi-stage, complicated process, which could be influenced by many factors, such as the formation of neoplastic vessels, degradation of tissue membrane and matrix, mobility of tumor cells and quantity and activity of infiltrating leucocyte inside the tumor tissues. Recently, many tumor makers have been identified which are used not only for diagnosis but also for assessment of aggressiveness and prognosis of tumors^[3-8]. Tumor markers are antigens or other biological products generated by tumor cells, which are present few or none in normal and non-neoplastic tissues. They usually indicate the change of genes associated with development of tumor and can be detected in tumor tissues or body humour or excretions of the patients^[9,10]. CDw75 antigen is one plausible tumor marker that has been shown recently to be associated with the progression and metastasis of gastric carcinoma^[1]. Consistent with previous finding^[1], the present work demonstrated that CDw75 expression was constantly negative in normal gastric mucosa but positive in 37 of 72 (51.4%) gastric cancers.

CDw75 antigen is a cluster of differentiation antigen of human leucocyte designated at the fourth World Leucocyte-Type Conference in 1989^[1]. It is a sialylated carbohydrate determinant generated by Sia-T1^[11] and has many different

isomers, which are specifically expressed in different tissues and can be recognized by corresponding monoclonal antibodies. There have been 4 monoclonal antibodies raised to react with CDw75 antigen, including EBU-141, OKB4, HH2 and LN1, etc.^[1]. These CDw75 monoclonal antibodies are likely to identify spatially related structures since binding inhibition studies have shown that binding of each CDw75 monoclonal antibody blocks the binding of the other CDw75 monoclonal antibody. The epitopes recognized by HH2, LN1 and EBU-141 are completely destroyed when cells are treated with neuraminidase, suggesting that sialic acid is a part of these CDw75 determinants^[1,12]. In contrast, when the epitope reacts with neuraminidase, the binding of OKB4 with CDw75 epitope is increased, indicating that the OKB4 epitope may be masked by sialic acid and can appear after treatment with the neuraminidase^[1,12]. These results suggest that sialic acid may have determinant impact on the character of CDw75 antigen.

Furthermore, studies have shown that cell-surface glycoconjugates play an important role in cell proliferation, adhesion, metastasis and immunogenicity. Only the subclone of primary tumor cells that express specific glycoconjugates has metastatic ability^[1,12]. The composition and structure of cell surface glycoproteins change frequently during the neoplastic transformation, and most of these changes are the extensive sialylation of cell surface glycoproteins. Moreover, tumor-associated expression of sialylated glycoconjugates has been found to be closely associated with aggressive activity and increased metastatic potential of malignant cells^[3]. There are several plausible mechanisms underlining such a correlation: sialic acid reduces the attachment of tumor cells to collagen type IV and fibronectin, masks antigen determinants, inhibits the action of natural killer cells, and induces immunologic tolerance through an increase of the serum half-life of glycoconjugates, etc^[1,12]. In gastric carcinoma, various sialylated glycoconjugates, such as Lewis X (Le^x), Lewis A (CA-19-9) and sialosyl-Tn, etc, have become clinically important in the detection of aggressive behavior of tumor cells and prediction of disease prognosis^[13-16].

CDw75, a Sia-T1-dependent sialylated glycoconjugate, is associated with the biological behaviors of tumors^[12,17]. In patients with gastric carcinoma, David and Elpek *et al.*^[1] found that there was no CDw75 expression in normal gastric mucosa (except a few isolated parietal cells in the body of the stomach), foveolar hyperplasia, intestinal metaplasia and the adjacent tissues to carcinoma. In contrast, the expression of CDw75 in primary tumor and the metastatic focus of gastric carcinoma was significantly increased. The CDw75 antigen could, therefore, be used as a marker of malignant transformation of gastric epithelium. Our study agreed with their findings. In addition, we found that the expression of CDw75 antigen is closely associated with the depth of the tumor invasion. Patients with serosal or deeper layer invasion of the tumor (T3 or T4) showed significantly higher expression of CDw75 than those with the tumor restricted within mucosa or muscular layers (T1 or T2), indicating that the gastric cancer cells with CDw75 high expression might have increased potential to invade into adjacent tissues. The most important feature of gastric carcinoma is its infiltrative growth and the earliest metastasis path is lymph node metastasis. We found that the positive expression rate of CDw75 (65%) in gastric cancer tissues with lymph node metastasis was significantly higher than that without lymph node metastasis (34%). With regard to TNM stage, CDw75 expression in stage I or stage II tumor tissues was not much higher than normal mucosa, but significantly higher in stage III and stage IV tumor tissues. These findings suggested that CDw75 plays an important role in the progression of gastric cancer from localized lesion to metastasized neoplasia. As a result, overall survival rate of patients with CDw75

expression (32.4%) was lower than that of patients without CDw75 expression (71.4%), and the survival curve of patients with CDw75 expression was significantly poorer than that of patients without CDw75 expression by Kaplan Meier analysis.. In conclusion, CDw75 was not detected in normal gastric mucosa but expressed in gastric cancer tissues and the higher expression rate was seen in patients with deeper tumor invasion, higher TNM stage and in patients with lymph node metastasis. The survival time of patients with CDw75 expression was less than that of patients without CDw75 expression. Therefore, CDw75 appears to be a useful marker indicating more advanced stage of the malignancy and poor prognosis in patients with gastric carcinoma.

Abstract

We report a case of fatal liver failure due to reactivation of lamivudine-resistant HBV. A 53-year-old man was followed since 1998 for HBV-related chronic hepatitis. Serum HBV-DNA was 150 MEq/mL (branched DNA signal amplification assay) and ALT levels fluctuated between 50-200 IU/L with no clinical signs of liver cirrhosis. Lamivudine (100 mg/d) was started in May 2001 and serum HBV-DNA subsequently decreased below undetectable levels. In May 2002, serum HBV-DNA had increased to 410 MEq/mL, along with ALT flare (226 IU/L). The YMDD motif in the DNA polymerase gene had been replaced by YIDD. Lamivudine was continued and ALT spontaneously decreased to the former levels. On Oct 3 the patient presenting with general fatigue, nausea and jaundice was admitted to our hospital. The laboratory data revealed HBV reactivation and liver failure (ALT: 1828 IU/L, total bilirubin: 10 mg/dL, and prothrombin INR: 3.24). For religious reasons, the patient and his family refused blood transfusion, plasma exchange and liver transplantation. The patient died 10 d after admission. The autopsy revealed remarkable liver atrophy.

INTRODUCTION

The emergence of lamivudine-resistant hepatitis B virus (HBV) mutant is relatively frequent after long-term lamivudine treatment. Liaw *et al.* reported acute exacerbation in 41% of lamivudine-treated patients who developed YMDD mutation, recovering mostly with HBeAg seroconversion^[1]. Conversely, evolution toward acute liver failure is rare but possibly fatal as published in 2001 by Kim *et al.*^[2]. We report here a new case of fatal liver failure consecutive to the emergence of a lamivudine-resistant mutant HBV.

CASE REPORT

This 53-year-old man had been followed since 1998 for HBV-related chronic hepatitis. He was positive for HBs and HBe antigens. Serum HBV-DNA was 150 MEq/mL (branched DNA signal amplification assay)^[3]. Alanine aminotransferase (ALT) fluctuated between 50-200 IU/L with no clinical signs of liver cirrhosis. Serum albumin and prothrombin time were normal. Lamivudine (100 mg/d) was started in May 2001 (Figure 1). Subsequently, serum HBV-DNA decreased below undetectable level (October 2001). In May 2002, serum HBV-DNA had increased to 410 MEq/mL, along with ALT flare (226 IU/L). Mini-sequencing^[4] showed that the YMDD motif in the DNA polymerase gene had been replaced by YIDD, supporting reactivation was due to the emergence of a lamivudine-resistant HBV mutant. Lamivudine was continued and ALT spontaneously decreased to the former levels. To improve a pre-existing non-insulin dependent diabetes mellitus (serum HbA1c: 6.5-7.6%) acarbose (300 mg/d) was initiated on Aug 20, 2002, but

Figure 1 Serum ALT, total bilirubin and HBV-DNA levels.

discontinued after only 3 d due to flatulence. At the next outpatient clinic visit (Sept 17), the patient presented no clinical sign of liver disorder, so acarbose was restarted. In fact, laboratory investigations performed prior to restarting acarbose revealed that HBV-DNA had dramatically increased to 3 800 MEq/mL while ALT was 9 times that of the upper limit of normal (357 IU/L). On Oct 3, the patient presenting with general fatigue, nausea and jaundice was admitted to the hospital. ALT was 1 828 IU/L, total and direct bilirubin, 10 and 5.8 mg/dL, respectively, and prothrombin INR 3.24. Antinuclear and antismooth muscle antibodies as well as HIV tests were negative. Despite discontinuation of acarbose, liver failure developed and hepatic encephalopathy appeared. For religious reasons, the patient and his family refused blood transfusion, plasma exchange and liver transplantation. The patient died 10 d after admission. The autopsy revealed liver atrophy (620 g) and panlobular necrosis surrounded by extensive fibrosis consisting of immature collagen (Figure 2). Lymphoid cell infiltration was observed in the fibrosis.

Figure 2 Histological findings of liver autopsy specimens. Irregularly shaped parenchymal islands are surrounded by extensive fibrosis consisting of immature collagen. 75 x EVG staining.

DISCUSSION

The reactivation of HBV prior to any clinical sign and administration of acarbose supports that the liver failure reported here is consecutive to the rapid proliferation of lamivudine-resistant HBV (YIDD). Although rare, acute liver failure associated with lamivudine-resistant HBV is reported in the literature, including one successfully treated with liver transplant^[5], one co-infected with HIV^[6], two with advanced cirrhosis^[7] and one immunocompetent patient^[2]. The last case was a Korean male, who developed fatal liver failure after 20 mo of lamivudine therapy. The background is similar to our patient, indicating that Asian males might be susceptible to this type of mutants. Lamivudine-resistant HBV is sensitive to adefovir dipivoxil^[8], a nucleotide analogue, shown to be effective for chronic HBV infection^[9]. Adefovir dipivoxil, unavailable in Japan, could not be used in our case.

Acarbose is a pseudotetrasaccharide acting by competitive inhibition of intestinal alpha-glucosidases, indicated for the

treatment of type II diabetes mellitus. The incidence of acarbose-related liver injury is low although a few severe cases were reported^[10,11]. It is unclear whether acarbose might have aggravated the liver injury consecutive to the mutation-related relapse of viral activity. In any case, as stressed in the Summary of Product Characteristics for acarbose “*Glucobay is contraindicated in patients with hepatic impairment*”. The above medical history supports closely monitoring patients with lamivudine-resistant HBV even in immunocompetent patients and, once reactivation occurs, adefovir dipivoxil should be administered.

ACKNOWLEDGEMENTS

We thank Dr. Jean C. Delumeau for his help with preparation of manuscript.

INTRODUCTION

Hepatocellular carcinoma (HCC) is one of the most frequent malignancies in the world. It is more common in far eastern countries and relatively rare in the United States and western European countries where at autopsy it accounts for only 1-2% of malignant tumors. The disease is usually manifested in the 6th and 7th decade of life. HCC is one of the highly malignant neoplasms. Extrahepatic metastases are seen in 64% of patients with HCC. The lungs, regional lymph nodes, kidney, bone marrow and adrenals are common sites of HCC metastasis^[1-3]. But, metastasis to brain and skull is extremely rare. Table 1 shows some of the reported cases of HCC with brain metastasis. These case reports reaffirms the complex and multidisciplinary care of these patients^[4-15].

The interval between diagnosis of primary cancer and detection of brain metastasis ranged from 2 to 54 mo. The mean survival period was only 3 mo after diagnosis of brain metastasis. The patients with HCC metastasized to brain died of neurologic causes rather than hepatic failure. Although no treatment is clearly defined to increase survival in patients with unresectable tumors, early diagnosis could improve the chance of curative surgical resection^[9-12].

We describe a case of HCC presenting with the initial manifestations of an intracranial mass lesion without any symptoms or signs suggestive of the primary hepatic site of the tumor. The diagnosis could not be made until he was admitted to hospital with unilateral weakness and numbness.

CASE REPORT

The patient was a 55-year-old man admitted to our hospital due to numbness and weakness on his right side. The patient's medical history was significant for chronic HBV-related hepatitis and insulin dependent-diabetes mellitus. The patient was oriented and did not have pathologic reflexes. His initial laboratory examination revealed Hb: 12.6 g/dL, Hct: 36.8, white blood cell count 3 560/μL, plt: 54 000/μL, prothrombin time (INR): 1.9, erythrocyte sedimentation rate: 28 mm/h, blood glucose: 196 mg/dL, urea: 39 mg/dL, creatinine: 0.8 mg/dL, AST: 160 U/L, ALT: 88 U/L, GGT: 55 U/L, alkalene phosphatase: 288 mg/dL, albumin: 2.59, globulin: 3.7, total bilirubin: 1.6 mg/dL. Serum electrolyte levels, urinalysis were within normal range.

Computed tomography (CT) of the patient's head revealed multiple intracranial masses and homogenous enhancement by post-contrast CT (Figure 1).

Figure 1 CT image of the lesion in the liver.

Abdominal sonography revealed findings consistent with chronic hepatitis. Thorax-abdomen-pelvic CT scan showed a hypodense mass lesion with irregular margins and 2.8 cm in diameter in the left lobe of the liver (Figure 2). Serum alpha-feto-protein level was higher than 400 U/L. Fine needle biopsy from the mass in the liver was performed. Pathological examination was consistent with the HCC.

He was given glucocorticoid therapy and referred to radiation oncology division for cranial radiotherapy.

Table 1 Some of the previous case presentations with HCC and brain metastasis in the literature

Author	Distinctive presentation
Moriya <i>et al.</i>	Brain metastasis seen in 1 year interval after hepatectomy for HCC
Endo <i>et al.</i>	Subgaleal and epidural metastasis presenting as epidural hemorrhage and died from hepatic failure
Peres <i>et al.</i>	Cerebral metastasis presenting as initial finding of HCC
Tanabe <i>et al.</i>	15-year-old boy and the other case presenting as headache
Loo <i>et al.</i>	Two cases with cerebral metastasis presenting as initial finding of HCC
Salvati <i>et al.</i>	Cerebral metastasis with stroke-like presentation
Asahara <i>et al.</i>	Brain metastasis seen after hepatectomy for HCC in 5 cases
Kim <i>et al.</i>	Seven patients with brain metastasis
Yen <i>et al.</i>	Eighteen cases with brain metastasis
Shuangshoti <i>et al.</i>	Nine cases with brain metastasis
Friedman <i>et al.</i>	A rare case with no identifiable risk factor for primary liver cancer

Figure 2 CT image of the metastatic lesions in brain.

DISCUSSION

Although brain metastasis may arise from primary sites in various organs and tissues, they are frequently seen with bronchogenic, breast, and prostate cancers. HCC commonly metastasizes to the lung, regional lymph nodes, peritoneum, and adrenal glands, but rarely to brain. Shuangshoti *et al.* reported that the secondary intracranial hepatic carcinomas were 1.3-2.9% among intracranial metastatic tumors^[14].

Most extrahepatic HCC occurs in patients at advanced intrahepatic tumor stage. Incidental extrahepatic lesions found at CT in patients having HCC of intrahepatic stage I or II are unlikely to represent metastatic HCC^[2]. Our case had single nodule 2.8 cm in diameter. His bilirubin level was near normal. He did not have ascites. He had neither ascites nor history of hepatic encephalopathy. He had liver cirrhosis in Child A stage. If he had not had brain metastasis, he could have been candidate for curative hepatectomy. We believe that brain metastasis from HCC is relatively early in the disease progression.

Yen *et al.* reported a well documented group of 33 patients. Eighteen had brain parenchymal metastasis without skull involvement, the other 15 cases disclosed skull metastasis with brain invasion. The underlying HCC are mainly of expanding 39.4% and multifocal 39.4% types, and 54.5% had mental changes not related to hypoglycemia or hepatic encephalopathy. Nevertheless, our case had unifocal HCC^[16].

Yen *et al.* reported that 90% of 15 cases had hyperdense mass lesion by non-contrast computed tomography scan and 17 cases showed homogenous enhancement (77.3%) by post-contrast CT images. In the non-skull involved group, 41.7% disclosed ring-shape enhancement and 87.5% had perifocal edema, and 24.2% presented as intracerebral hemorrhage. Our patient had perifocal edema in the brain but without hemorrhage^[16].

Because no effective treatment for brain metastasis from HCC is available, further study is needed. Yen *et al.* reported 36.4% death of brain herniation^[16].

Most of non-skull involved cases had simultaneous lung metastasis without bony metastasis, while the skull involved group (66.7%) disclosed extracranial bony metastasis without lung metastasis^[15,16]. However, no other simultaneous metastasis site was found of our patient. HCC with intracranial metastasis is symptomatic and life threatening. Half the cases may come from pulmonary metastasis and the other half may be from bony metastasis even though our patient had neither of them. Surgery of the brain or skull metastasis is of no particular technical problem as long as they are located in accessible areas. Brain irradiation or surgery can prolong the survival. Radiotherapy seems to improve the quality and quantity of residual life, although the number of patients describes in the literature is not large enough

to draw any definite conclusion.

Loo *et al.* reported that light microscopic examination of the metastatic tumor from HCC revealed a trabecular HCC with focal hemorrhage and necrosis. Their immunohistochemical profile was identical to that described in primary HCC^[12].

Salvati *et al.* suggested that the stroke-like presentation of the cerebral localization of the disease can be explained by both the important vascularization of the tumor and the frequent hemocoagulative alterations caused by the cirrhosis^[9].

In conclusion, the rarity of this type of case gives the clinician the suspicion of such associations when confronted with a patient with liver dysfunction and neurologic findings.

Tovey FI, Hobsley M. Milling of wheat, maize and rice: Effects on fibre and lipid content and health. *World J Gastroenterol* 2004; 10(12): 1695-1696

<http://www.wjgnet.com/1007-9327/10/1695.asp>

During the last thirty years the main interest in the medical consequences of milling of staple carbohydrate foods, particularly wheat and maize, has been in its effect on the fibre content as a result of the milling. The late nineteenth and early twentieth centuries in the West saw great changes in milling processes, from stone milling using water or wind power, to increasingly sophisticated roller milling, with an increasing loss of fibre in the process. In the 1970s and onwards there was an enhanced interest in possible diseases which could be related to the loss of fibre in the diet. At one time the list included diverticulitis, appendicitis, varicose veins, deep vein thrombosis, carcinoma of the colon, Crohn's disease, ulcerative colitis, irritable bowel syndrome, peptic ulcer, gall stones, hiatus hernia and gastro-oesophageal reflux, disorders of lipid metabolism and coronary heart disease! Over the course of time medical evidence has narrowed this list down to a much smaller number, of which the most important are diverticular disease and carcinoma of the colon.

The effect of fibre on peptic ulcer disease was attributed to its buffering effect on acid secretion. There seemed to be a relationship between the fibre content of staple diet and the geographical prevalence of duodenal ulceration. The prevalence was lower in populations using unrefined wheat, millets or maize with a high fibre content and higher in populations using refined wheat or maize flour or milled rice with low fibre contents^[1-4]. There were, however, abnormalities which did not fit in with this pattern, such as the high prevalence of duodenal ulcer in the Highlands of Ethiopia, where the staple food was unrefined teff (*Eragrostis abyssinica*) with a high fibre content^[4]. A possible explanation of this abnormality may lie in the lipid content of teff (see next paragraph). However, in addition, acid secretion studies showed that, whilst fibre had an initial buffering effect on gastric acidity, the resulting antral stimulation led to a higher acid output^[5].

A further effect of milling was on the lipid content of staple carbohydrate foods. Experiments on animal peptic ulcer models showed that the lipids present in the unrefined staple foods in areas with low prevalence of duodenal ulcer had a gastroprotective effect against ulceration and also promoted ulcer healing. These were not present in the refined staple foods of the areas with high duodenal ulcer prevalence^[6-9].

Lipids are found in both the bran and the germ of staple carbohydrate foods. In wheat and rice more lipids are found in the bran, but in maize the bulk lies in the predominantly large germ. Lipases are also present principally in the germ.

Milling has different effects on the bran and germ. In the case of wheat the two come apart separately. They can be separated by sieving and are stable for a period of time without further treatment. In the case of maize and rice the bran and germ come away together and the resultant bruising releases the lipases which interact with the oil content leading, if left untreated, to early rancidity of the combined germ and bran. Thus wholemeal wheat flour has a stable shelf life for a variable period of time, but the only satisfactory way to eat whole maize is either on the cob or home-pounded and cooked on the same day. Rice can only be eaten in the unrefined state as brown or unmilled rice. Milled rice undergoes changes during storage. During the milling of rice some of the lipase present in the bran enters the endosperm and as the rice is stored it reacts with a small amount of oil present in the rice grain. Some say that this results in an improvement in taste. The resulting lipolysis results in the formation of free fatty acids followed by a process of peroxidation that produces ketoaldehydes. Experiments on animal peptic ulcer models have shown that the latter are ulcerogenic. Similar experiments have shown that freshly milled rice bran is protective, but that it rapidly becomes ulcerogenic^[10,11]. Thus milled rice is not only deprived of gastroprotective lipids but also, on storage, becomes ulcerogenic, which is a possible factor in the high prevalence of duodenal ulceration in milled rice-eating countries.

With the discovery of *Helicobacter pylori* there has been much emphasis on its being the prime cause of duodenal ulceration. However, evidence is increasing to suggest that it may be a secondary infection affecting chronicity^[12,13]. Moreover, it should be remembered that many other factors have been shown to be associated with duodenal ulceration. These include familial tendency, acute anxiety as in the Second World War, cigarette smoking and the introduction of roller milling. Of these factors, the latter two greatly increased at the beginning of the twentieth century, which is the time when the epidemic of duodenal ulceration began. A suggestive feature about smoking is that it results in an increase in the parietal cell mass and therefore in an increase in the maximal ability of the stomach to secrete acid^[14], which itself is so strongly associated with duodenal ulceration^[15]. Which of these factors are truly aetiological and which are confounding factors that happened to be increasing at the same time remain unknown. It is important to keep an open mind.

The results of experiments on animal peptic ulcer models, however, strongly support the possibility that the loss of certain protective lipids, resulting from the milling of staple carbohydrate foods, may be an important factor. More needs to be known about the nature and action of these lipids.

<http://www.wjgnet.com/1007-9327/10/1697.asp>

Acute pancreatitis is a common condition in which 70% of patients will recover with simple medical management. For patients who develop extensive or infected pancreatic necrosis the outcome is significantly different with a high morbidity and mortality^[1]. Surgery is the mainstay of treatment for these patients but several unresolved issues remain including *who requires surgery, when is the optimal time to intervene and what technique should be used*.

Infected necrosis is generally accepted as a strong indication for surgery^[2]. This has developed not from randomised data but observational studies over time that seemed to show a reduction in the previously reported mortality^[3-5]. A small number of recent reports^[6-8] have attempted to cast doubt on whether all patients with infected pancreatic necrosis should undergo surgery. So should a randomised controlled trial be undertaken? On the available evidence most surgeons and gastroenterologists would lack the “equipoise” required to perform such a trial. The number of patients successfully responding to conservative treatment remains small compared to the overall population with infected pancreatic necrosis. Further identification of factors associated with spontaneous resolution of infected necrosis needs to be identified before conservative treatment can be recommended as an acceptable alternative.

With the main indication for surgery being infected necrosis, the absence of infection is not an absolute contraindication. Over 90% of patients with sterile necrosis can be successfully treated without surgical intervention^[9,10], but a small subset with extensive necrosis warrants surgery. Indications in this setting include deteriorating organ failure despite maximal support^[10,11] or persisting symptoms which preclude hospital discharge despite several weeks of optimum conservative treatment^[9,12].

The timing of surgery is an important determinant of outcome with early surgery (within the first week) associated with a high mortality^[13,14]. The development of infected necrosis is time dependant, increasing to a peak in weeks 2-4^[15]. Some studies have suggested that antibiotics may reduce the incidence of infected necrosis^[16-22] but other recent large randomized controlled trials now reject this notion^[23,24]. Moreover whether prophylactic antibiotics can delay the onset of infected necrosis or the need for intervention is unknown. Another unknown factor is whether those patients who develop infected necrosis within the first 14 d of their illness should continue to be managed conservatively to allow the necrotic tissue to demarcate the reduction of complications associated with early debridement. Infected necrosis is almost universally associated with the progressive escalation of organ failure^[17].

Increasing pre-operative organ dysfunction scores have been associated with an increase in mortality^[25,26] and thus any delay in surgery following the diagnosis of infected necrosis is likely to be detrimental.

The aim of intervention in those with pancreatic necrosis is to remove the necrotic tissue and to provide adequate drainage for the remaining debris while preserving viable pancreatic tissue with minimal morbidity and mortality. It is generally accepted that debridement is preferable to resection^[2] and the approaches to the pancreatic necrosis include trans-peritoneal, retro-peritoneal, minimally invasive and percutaneous techniques^[4,12,14,25-32]. Post operative management includes laparostomy, packing, closed retroperitoneal lavage and repeat debridement^[4,12,14,25-32]. There is no standardised optimal technique as there are no randomised trials that compared surgical techniques. In the largest reported series^[17] the mortality was 39% but it has been reported as low as 6-8%^[12,28], which was the same as that for the overall mortality associated with pancreatitis in the United Kingdom^[33]. The reason for this wide inter-study variation is likely to be due to a number of factors. Firstly, there was an inter-study heterogeneity in both the reporting and the frequency of adverse patient prognostic factors. Secondly, intervention rates varied 10-fold^[34,35], suggesting that the indications for intervention provided by guidelines are not uniformly interpreted. Thirdly, many studies were relatively small, retrospective or based over long time periods during which there was often a change in management.

The Regional Pancreas Centre at the Royal Liverpool University Hospital has adopted a minimally invasive approach in preference to an open approach because it was associated with a very high mortality despite expert surgery and intensive care^[26,27]. Minimally, invasive retroperitoneal pancreatic necrosectomy has the dual advantages of removal of the solid necrotic material under direct vision through a wide bore tract^[27,31,32] and the use of high volume post-operative lavage through the wide tract^[27]. Moreover minimally invasive retroperitoneal pancreatic necrosectomy can be performed under local anaesthesia and reduces the need for post-operative intensive care, by avoiding an escalation in organ dysfunction which is usually seen after open surgery^[26,31]. The disadvantages of minimally invasive retroperitoneal pancreatic necrosectomy include an increase in the number of procedures and possible increase in hospital stay^[26,27]. Minimally invasive retroperitoneal pancreatic necrosectomy has not yet been shown to significantly reduce mortality although the trend is strong in this direction. Further experience with this technique and possible multi-centre randomised trials are needed.

Future studies on the outcome from intervention for pancreatic necrosis should incorporate standardised reporting of the precise profile of patients to allow for more valid comparisons between the different surgical techniques. In particular, there should be a clear description of the indications for intervention, the overall sample size from which the patients are selected, key prognostic indicators including age, organ dysfunction scores, extent of necrosis and the incidence of primary infection of the necrosis. It is notable that most studies failed to provide these critical factors and did not distinguish primary from secondary infection. Improving the reporting of studies will lead to the identification of the optimal patient at the optimal time undergoing the optimal procedure.

Abstract

Deficiencies in vitamins or other factors (B6, B12, folic acid, betaine) and genetic disorders for the metabolism of the non-protein amino acid-homocysteine (Hcy) lead to hyperhomocysteinemia (HHcy). HHcy is an integral component of several disorders including cardiovascular disease, neurodegeneration, diabetes and alcoholic liver disease. HHcy unleashes mediators of inflammation such as NF κ B, IL-1 β , IL-6, and IL-8, increases production of intracellular superoxide anion causing oxidative stress and reducing intracellular level of nitric oxide (NO), and induces endoplasmic reticulum (ER) stress which can explain many processes of Hcy-promoted cell injury such as apoptosis, fat accumulation, and inflammation. Animal models have played an important role in determining the biological effects of HHcy. ER stress may also be involved in other liver diseases such as α_1 -antitrypsin (α_1 -AT) deficiency and hepatitis C and/or B virus infection. Future research should evaluate the possible potentiative effects of alcohol and hepatic virus infection on ER stress-induced liver injury, study potentially beneficial effects of lowering Hcy and preventing ER stress in alcoholic humans, and examine polymorphism of Hcy metabolizing enzymes as potential risk-factors for the development of HHcy and liver disease.

INTRODUCTION

Homocysteine (Hcy) is a toxic non-protein sulfur containing amino acids in humans. It is formed exclusively upon demethylation of the essential amino acid- methionine. Hcy is metabolized either through remethylation or transsulfuration pathways and is nutritionally regulated. Normal concentrations of total homocysteine in plasma are in the range of 5 to 16 μ mol/L and the desired upper limit for Hcy concentration should be 10 μ mol/L. An elevated plasma Hcy level is denoted hyperhomocysteinemia (HHcy). Three ranges of HHcy are defined: moderate (16 to 30 μ mol/L), intermediate (31 to 100 μ mol/L), and severe (>100 μ mol/L). Individuals who

consume a large amount of food rich in animal protein may ingest two to three grams of methionine, resulting in postprandial Hcy concentrations greater than 20 μ mol/L. Clinical HHcy was first described more than 40 years ago in children with learning difficulties^[1-3], and it has since been estimated that moderate HHcy occurs in 5-7% of the general population. Evidence now indicates that moderate HHcy is an important and independent risk factor for several disorders, including atherosclerosis, diabetes, fatty liver, immune activation, and neurodegenerations such as Alzheimer's and Parkinson's diseases^[3-9].

Readers are referred to recent reviews on HHcy and functions of Hcy^[10,11]. The main goal of this article is to provide information on major causes of HHcy, potential mechanisms of Hcy toxicity, with emphasis on endoplasmic reticulum (ER) stress mechanism, and animal models for the study of biological effects of HHcy. We would also summarize our ongoing work on ethanol-induced HHcy and liver injury in an intragastric ethanol fed murine model.

Hcy METABOLISM AND HHcy

Figure 1 Homocysteine metabolism. Homocysteine has three main metabolic fates: to be remethylated to methionine, to enter the cysteine biosynthetic pathway, and to be released into the extracellular medium. CBS, cystathionine synthase; MS, methionine synthase; THF, tetrahydrofolate; MTHFR, 5, 10-methylenetetrahydrofolate reductase; BHMT, betaine-homocysteine methyltransferase; DMG, dimethylglycine; MAT, methionine adenosyltransferase; SAM, S-adenosylmethionine; SAH, S-adenosylhomocysteine.

Hcy was formed from methionine after removal of the methyl group on S-adenosylmethionine (SAM) (Figure 1). Hcy metabolism involves reversible formation of S-adenosylhomocysteine (SAH), remethylation to methionine by betaine-homocysteine methyltransferase (BHMT) (liver and kidney restricted), which is vitamin-independent, and by the ubiquitous methionine synthase (MS), which is dependent on vitamin B12 and

methylenetetrahydrofolate (MTHF) production *via* 5, 10-methylenetetrahydrofolate reductase (MTHFR). Hcy can also be converted through transsulfuration to cystathionine for the formation of cysteine and glutathione (GSH). The transsulfuration is catalyzed by cystathionine- β -synthase (CBS) and is dependent on vitamin B6. In addition, Hcy can be converted to Hcy-tRNA. Although it was not incorporated into protein due to editing mechanisms, nitroso-Hcy-tRNA is stable and might play a role in Hcy-induced protein misfolding along with the formation of Hcy-protein-SH mixed disulfides and Hcy thiolactone covalent binding to lysine amino groups^[11]. Hcy-tRNA is edited through the action of methionyl-tRNA synthetase (ATP consuming) by formation of a thioester thiolactone which could covalently bind to protein amino groups. Thus, homocysteinylation of proteins depends on the formation of thiolactone^[12,13].

Tight regulation of Hcy metabolism depends on different affinities of MS, BHMT, and CBS for Hcy. MS and BHMT show low K_m values for Hcy (<0.1 mmol/L), and CBS has high K_m values for Hcy (>1 mmol/L). At low Hcy concentrations, methionine conservation was favored; and at high Hcy concentrations, immediate and long-term drainage of Hcy via the transsulfuration pathway was ensured^[14]. SAM could play a key regulatory role by allosterically inhibiting MTHFR and BHMT and activating CBS^[15-18]. Thus, SAM may be a regulatory switch in Hcy metabolism: low SAM favors remethylation and conservation of Hcy for methionine synthesis, whereas high levels favor transsulfuration. High Hcy levels can decrease the SAM/SAH ratio, since most methyltransferases bind to SAH with higher affinity than SAM, elevated SAH inhibits methylation. *In vitro*, under "physiological" conditions of concentrated 27 000 g postmitochondrial supernatant with 8 mmol/L GSH, 0.3 mmol/L serine, 2 mmol/L betaine, 60 μ mol/L methionine, 50 μ mol/L methyl THF, 60 μ mol/L SAM and 10 μ mol/L SAH, transsulfuration accounted for 46% of Hcy metabolism and the remainder was equally contributed to by MS and BHMT. The need to conserve methionine (*e.g.* low protein diet) resulted in decreased cystathionine production and increased Hcy remethylation. Conversely, in the presence of excess methionine, SAM activated the cystathionine pathway.

HHcy results from increased levels of intracellular Hcy that is readily released into the extracellular medium: plasma or body fluid. Kidney might be a major site for the removal and metabolism of Hcy primarily through the transsulfuration pathway^[19]. Renal impairment often causes HHcy, reflecting a role of kidney in Hcy clearance from plasma. This fact might contribute to the high incidence of vascular complications in patients with chronic renal failure^[20]. Genetic abnormalities, age, sex and various nutritional and hormonal determinants contribute to HHcy. However, genetic and nutritional disorders are the major factors. Genetic disorders involve polymorphism in the genes coding for MTHFR and CBS. The most common genetic defect associated with mild HHcy is a point mutation, namely, a C to T substitution at nucleotide 677 (C677 \rightarrow T) in the open reading frame of the gene for MTHFR. This point mutation could cause a substitution of valine for alanine in the functional enzyme^[21], resulting in a thermolabile variant of the enzyme with decreased total activity. This is an autosomal recessive mutation, and the frequency of the C677 \rightarrow T polymorphism varied among racial and ethnic groups, with 13% of T/T homozygous and 50% C/T heterozygous among Caucasian and Asian populations, and very low incidence among African-Americans^[21-27]. Premature atherosclerosis and thrombotic disease were observed in MTHFR deficiency^[23-28]. The most common genetic cause associated with severe HHcy is homozygous CBS deficiency, which resulted in plasma Hcy concentrations of up to 400 μ mol/L, compared to normal

plasma levels of 10 μ mol/L^[28-30]. Homozygous CBS deficiency, T833 \rightarrow C and G919 \rightarrow A mutations, were inherited as an autosomal recessive disorder with pleiotropic clinical manifestations, including mental retardation, ectopia lentis, osteoporosis, skeletal abnormalities and hepatic steatosis^[28-30]. Patients were usually at higher risk for premature atherosclerosis and thrombotic disease, which is the major cause of death^[31-33]. CBS deficiency has a worldwide incidence of 1:344 000 live births, ranging from 1:58 000 to 1:1 000 000 in countries that perform newborn screening^[31]. While homozygous CBS deficiency is rare, heterozygous CBS deficiency occurs in approximately 1% of the general population and is associated with premature atherosclerosis and thrombotic disease in phenotypically normal individuals^[31-33].

Nutritional disorders that potentially lead to HHcy include deficiencies in vitamin B12, folate and vitamin B6, as the *de novo* synthesis of methionine methyl groups requires both vitamin B12 and folate cofactors whereas the synthesis of cystathionine requires pyridoxal 5-phosphate (vitamin B6). Although it has been shown that deficiencies of vitamin B12 and folate are related to increased plasma Hcy concentrations^[32-35], the relationship of Hcy levels to vitamin B6 status is less clear^[36,37]. In addition, excess dietary methionine in normal mice has been shown to induce HHcy^[38]. Under normal conditions, several methylation reactions in the liver contribute to the bulk (90%) of SAM utilization and Hcy production via SAH. For example, phosphatidylethanolamine to phosphatidylcholine is mediated by phosphatidylethanolamine N-methyltransferase (PEMT). PEMT $^{-/-}$ mice had 50% decreased plasma Hcy despite being choline and betaine deficient^[39]. PEMT null mice exhibited fatty liver and apoptosis but this was not prevented by betaine administration, impaired lipoprotein secretion rather than methyl donor deficiency appeared to be the dominant effect of choline deficiency^[40]. The other major source of Hcy is the activity of hepatic guanidinoacetate (GAA) N-methyltransferase (NMT). GAA is produced in the kidney by L-arginine:glycine amidinotransferase. GAA is then converted to creatine in the liver by GAA-NMT, utilizing SAM and generating SAH. Creatine is exported to muscle and also represses the kidney enzyme which produces GAA. GAA supplementation could induce HHcy and creatine feeding lowers Hcy^[41].

HCY TOXICITY

Possible cellular mechanisms by which elevated Hcy promotes liver disease are oxidative stress, endoplasmic reticulum (ER) stress and the activation of pro-inflammatory factors (Figure 2). Hcy enhances the production of several pro-inflammatory cytokines. Expression of monocyte chemoattractant protein 1 (MCP-1) was increased in cultured human vascular endothelial cells, smooth muscle cells and monocytes treated with Hcy^[42-44]. Hcy has also been shown to increase expression of IL-8^[42], a T-lymphocyte and neutrophil chemoattractant, in cultured endothelial cells. Hcy-induced expression of MCP-1 and IL-8 in monocytes and endothelial cells has been shown to occur through activation of NF- κ B, a transcription factor involved in mediating downstream inflammatory processes^[44,45]. Active NF- κ B could stimulate production of cytokines, chemokines, interferons, leukocyte adhesion molecules, hemopoietic growth factors and major histocompatibility (MHC) class I molecules—all of which are thought to influence inflammation^[45,46].

Hcy can generate a procoagulant state, which may be related to its proclivity to auto-oxidize, generating H₂O₂. Various *in vitro* studies using vascular tissues have implicated Hcy in causing abnormal vascular relaxation responses by enhancing the intracellular production of superoxide anion (O₂⁻)^[47-54]. O₂⁻ is believed to react with and decrease the availability of endothelial nitric oxide (NO) and yield peroxynitrite, thereby

limiting normal vasodilation responses^[55,56]. Decreased GSH peroxidase transcription (reduction of peroxides protects NO) may play a role in this process^[49,57], since overexpression of GSH peroxidase could restore the NO response^[57]. O₂⁻ and peroxynitrite are also known to contribute to the oxidative modification of tissues, resulting in the formation of lipid peroxides and nitrosated end products such as 3-nitrotyrosine. The observations that Hcy decreased the expression of a wide range of antioxidant enzymes^[57-59] and impaired endothelial NO bioavailability by inhibiting glutathione peroxidase activity raise the possibility that Hcy sensitizes cells to the cytotoxic effects of agents or conditions known to generate ROS. Decreased NO bioavailability has also been shown *in vitro* to increase the expression of MCP-1, which may enhance intravascular monocyte recruitment and lead to accelerated lesion formation^[60].

Figure 2 Cellular mechanisms by which homocysteine promotes cell injury. Homocysteine causes activation of necrosis factor- κ B (NF- κ B) and enhances production of cytokines (IL-1 β , IL-6, and IL-8) resulting in inflammatory reactions, increases intracellular levels of superoxide anion causing oxidative stress, and induces endoplasmic reticulum (ER) stress by causing misfolding of proteins traversing the ER. Homocysteinyl-tRNA increases production of highly reactive derivative homocysteine thiolactone which damages enzymes and DNA. IRE1, type 1 ER transmembrane protein kinase; ATF6, the activating transcription factor 6; PERK, the PKR like ER kinase; SREBP, sterol regulatory element binding protein, PON, paraoxonase.

Intracellular Hcy can be converted by methionyl tRNA synthase into an Hcy-AMP complex, which is subsequently catabolised to Hcy thiolactone, thereby preventing the incorporation of Hcy into nascent polypeptide chains. Hcy thiolactone has unique reactive properties that can lead to the homocysteinylation of lysine residues and free amine groups on numerous cellular proteins, thereby resulting in decreased biological activity and premature degradation^[61]. In addition, Hcy thiolactone secreted into the circulation may induce widespread modifications of plasma proteins that could potentially contribute to the development of liver and cardiovascular diseases. Recent studies have demonstrated that Hcy thiolactone decreases paraoxonase activity associated with HDL, thereby rendering HDL less protective against oxidative damage or against toxicity of Hcy thiolactone^[62].

HCY-INDUCED ER STRESS

ER is a principal site for protein synthesis and folding, calcium storage and calcium signaling. It also serves as a site of biosynthesis for steroids, cholesterol and other lipids. The physiological roles of the ER include regulation of protein synthesis, folding and targeting and maintenance of cellular calcium homeostasis. The ER has a high concentration of numerous resident chaperone proteins such as glucose

regulated protein-78 (GRP78) and GRP94, a high level of calcium and an oxidative environment to carry out these functions efficiently. Proteins that were translocated into the ER lumen underwent post-translational modifications and the folding required for optimal function. Properly folded proteins were allowed to reach their destiny via the secretory pathway, whereas unfolded and misfolded proteins were exported or dislocated from the ER and degraded by cytoplasmic proteasomes^[63-68]. ER stress is a condition under which unfolded and misfolded proteins accumulate (Figure 3). ER stress triggers unfolded protein response (UPR), which is an intracellular signaling pathway and is mediated via three ER-resident sensors in mammalian cells: a type-I ER transmembrane protein kinase (IRE-1), the activating transcription factor 6 (ATF-6) and the PKR like ER kinase (PERK). Activation of these three pathways is mediated by GRP78, which is associated with each sensor in the absence of ER stress. As unfolded proteins accumulated in the ER, GRP78 dissociated from and thereby activating IRE-1, ATF-6 and PERK^[68-70]. Activation of both IRE-1 and ATF-6 increases the expression of ER-resident chaperones. IRE-1 is a stress-activated transmembrane protein kinase having endoribonuclease activity. Following ER stress, IRE-1 dimerized and was autophosphorylated, thereby allowing IRE-1 to act as an endoribonuclease in the alternative splicing of XBP-1 mRNA. The removal of a 26 base pair intron resulted in a translation frameshift that permits XBP-1 to act as a transcriptional activator of genes containing upstream ER stress response elements (ERSE). Upon ER stress, ATF-6 was transported to the Golgi where the cytosolic transactivation domain of ATF-6 is cleaved from the membrane by specific proteases (S1P and S2P) that also recognize, cleave and activate sterol regulatory element-binding proteins (SREBPs) leading to increased lipids needed for ER membrane synthesis. Following release, the transactivation domain of ATF-6 localized to the nucleus where it interacts with ERSE, thereby activating transcription of numerous UPR-responsive genes, including GRP78, GADD153 (CHOP), XBP-1, ERp72, and Hcy-induced ER protein (Herp). ER stress could also lead to a rapid attenuation in protein synthesis, a cellular process mediated by the transmembrane protein kinase, PERK. Activation of PERK could cause phosphorylation of eukaryotic initiation factor-2 α (eIF-2 α), which blocks mRNA translation initiation to help relieve the unfolded protein burden on the ER. Recent studies have also demonstrated that PERK-dependent eIF-2 α phosphorylation is required for transcriptional activation of a wide range of UPR-responsive genes^[71,72]. The early UPR co-coordinately enhances cell survival by ensuring that the adverse effects of ER stress are dealt with in a timely and efficient manner. However, prolonged UPR following ER stress has severe consequences. It can lead to activation of the tumor necrosis factor receptor associated factor 2 (TRAF2), which activates caspases (e.g. caspase-12 in mice) and JNK resulting in programmed cell death. Overexpression of CHOP, a basic region leucine zipper transcription factor, could also promote cell death^[71]. Overproduction of lipids by SREBP can lead to fat accumulation. In addition, ER stress is associated with release of ER Ca²⁺ stores which can trigger oxidative stress *via* effects on mitochondria and NF- κ B activation leading to inflammatory reactions^[73]. NF- κ B activation could be blocked by calcium chelators and antioxidants^[19]. Increased cytosol calcium also activates calpains which proteolytically cleave Bcl-X_L (inactivation) and caspase 12 (activation). ER stress could contribute to the pathogenesis of a number of human diseases, including diabetes, Alzheimer's disease, Parkinson's disease and cancer^[72].

Hcy induced ER stress response has recently received much attention^[6,74-79]. Hcy causes ER stress by disrupting disulphide bond formation and causing misfolding of proteins traversing

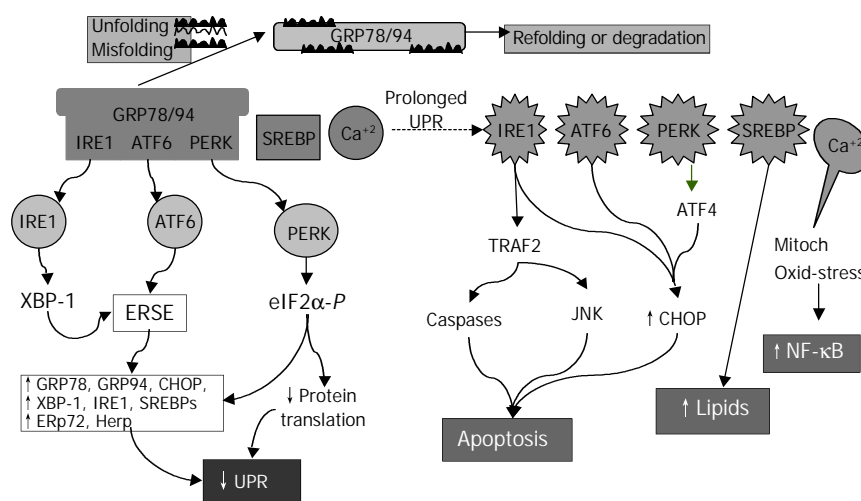

Figure 3 Consequences of endoplasmic reticulum (ER) stress response. In the early phase, unfolded proteins cause dissociation of chaperones such as Bip/GRP78 from ER resident kinases-IRE1 and PERK and transcription factor-ATF6. Activated PERK phosphorylates eIF2 resulting in translational attenuation. Activated IRE1 and ATF6 up-regulate genes encoding ER chaperone proteins such as GRP78/94 leading to increased protein-folding capacity. Overall, the unfolded protein response (UPR) goes down. In the late phase, IRE1 interacts with TRAF2 (tumor necrosis factor receptor associated factor 2) which activates caspases and JNK (cJUN NH2-terminal kinase) leads to apoptosis. ATF6 and PERK upregulate CHOP (C/EBP homologous protein) promoting cell death. SREBP upregulates lipid synthesis. Prolonged UPR leads to Ca^{2+} release from ER causing production of reactive oxygen intermediates which may lead to activation of NF- κ B.

the ER. Elevated levels of intracellular Hcy could increase the expression of several ER stress response genes, including GRP78, GRP94, Herp and RTP^[6,58,74,77,78,80-82]. Hcy could induce expression of GADD153^[58,78,79] involved in ER stress-induced cell death^[83]. Hcy-induced ER stress could cause dysregulation of lipid biosynthesis by activating the SREBPs^[6,76-79], ER resident transcription factors are responsible for the induction of genes in the cholesterol/triglyceride biosynthesis and uptake pathways^[6]. Hcy-induced cell death was mimicked by other ER stress agents and was dependent on IRE-1 signaling. Activation of IRE-1 by Hcy could lead to a rapid and sustained activation of JNK protein kinases^[84,85], a result consistent with the finding that activation of JNK by ER stress involved binding of IRE-1 to TRAF2^[86]. Because persistent activation of JNK correlated with cell death^[87], these studies could provide further support for a mechanism involving Hcy-induced programmed cell death.

APPROACHES FOR STUDY OF HHcy

Cell and animal models with altered plasma Hcy are among the most useful approaches in determining the biological effects of HHcy. However, cell and transgenic animal models expressing Hcy metabolism-related genes/enzymes are not available. Nevertheless, diet- and, especially, genetic-induced animal models of HHcy have been developed. The gene knockout animals have significantly enhanced the status of Hcy as an independent risk factor for several disorders.

Homozygous and heterozygous CBS-deficient mice were generated in 1995^[88]. Homozygous mutants completely lacking CBS were born at the expected frequency from mating of heterozygotes, but they suffered from severe growth retardation and a majority of them died within 5 wk after birth. Histological examination showed that the hepatocytes of homozygotes were enlarged, multinucleated, and filled with microvesicular lipid droplets. Plasma Hcy levels of the homozygotes ($203.6 \pm 65.3 \mu\text{mol/L}$) were 33 times higher than normal ($6.1 \pm 0.8 \mu\text{mol/L}$). The homozygous CBS deficient mice represented a model for severe HHcy. Heterozygous CBS deficient mice had 50% reduction in CBS mRNA and enzyme activity in the liver and had twice normal plasma Hcy levels ($13.5 \pm 3.2 \mu\text{mol/L}$). The CBS knockouts significantly help elucidate the *in vivo* role of

elevated levels of Hcy in the etiology of several HHcy-related disorders and in the cellular mechanisms by which Hcy promote cell injury. The CBS-deficient mice were predisposed to HHcy during dietary folate deficiency, and moderate HHcy was associated with marked impairment of endothelial function in mice^[89]. Results from a subsequent study indicated that endothelial dysfunction occurred in HHcy mice even in the absence of folate deficiency^[90]. Endothelial dysfunction in CBS (+/-) mice was associated with increased tissue levels of SAH, which suggests that altered SAM-dependent methylation may contribute to vascular dysfunction in HHcy^[91]. Further studies with the CBS deficient mice revealed the importance of intracellular redox balance for nitric oxide bioactivity and endothelial function, and the importance of ER stress in abnormal hepatic accumulation of lipid^[92,93]. Expression of several genes analyzed by DNA microarray was found to be reproducibly abnormal in the livers of heterozygous and homozygous CBS-deficient mice^[94]. These genes encode ribosomal protein S3a and methylthioadenosine phosphorylase, suggesting cellular growth and proliferation perturbations may occur in homozygous CBS-deficient mice liver.

MTHFR-deficient mice have been recently developed to examine the effects of HHcy resulting from genetic deficiencies in the remethylation pathway^[95]. MTHFR-deficient mice shared basic phenotypic similarities with CBS-deficient mice. However, they were unique in that they developed mild HHcy and atherosclerosis. Recent study has demonstrated the importance of choline metabolism in HHcy in this model^[96]. Comparison study by administering the alternate choline-derived methyl donor, betaine, to wild-type mice and MTHFR deficient mice revealed that plasma Hcy and liver choline metabolite levels were strongly dependent on the MTHFR genotype. Betaine supplementation decreased Hcy in all three genotypes, restored liver betaine and phosphocholine pools, and prevented severe steatosis in MTHFR-deficient mice. Since there was a significant negative correlation between plasma betaine and Hcy concentrations in humans with cardiovascular disease, the results emphasize the strong interrelationship between Hcy, folate, and choline metabolism. MTHFR-compromised mice with HHcy appeared to be much more sensitive to changes of choline/betaine intake than wild-type

animals. HHcy, in the range of that associated with folate deficiency or with homozygosity for the 677T MTHFR variant, may be associated with disturbed choline metabolism.

MS could directly catalyze the remethylation pathway and inactivation of this gene has been attempted recently^[97]. Heterozygous MS knockout mice from an outbred background had slightly elevated plasma Hcy (6.1 mol/L) and methionine compared to wild-type mice (4.1 μ mol/L) but seemed to be otherwise indistinguishable. Homozygous knockout embryos survived through implantation but died soon thereafter. Nutritional supplementation during pregnancy was unable to rescue embryos that were completely deficient in MS. This study indicated that MS activity was essential for early embryonic development of mice. Although the MS knockout mouse has not provided an immediately obvious animal model of human disease, heterozygotes with 50% reduction of MS activity may be useful. It is likely that MS heterozygote knockouts are more susceptible to dietary deficiencies than wild type mice and thus having merits as a model in which interactions between genetic status and nutritional status can be studied.

The animal models are valuable *in vivo* tools to further examine potential therapeutic approaches in lowering plasma Hcy while decreasing the prevalence of HHcy-induced disorders. However, the animal models neither have tissue or organ specificity nor exclude potential compensatory pathways of Hcy metabolism. Conditional disruption of Hcy metabolism-related genes and crossing between animal models that are deficient in different genes should be the future directions in the effort of creating animal models for study of HHcy.

ETHANOL-INDUCED HHCY AND LIVER INJURY

The pathogenesis of the pathologic features of alcoholic liver injury, namely steatosis, apoptosis, necrosis, inflammation and fibrosis, is an area of intense interest. Although much progress has been made over the past decade, we still do not have a complete understanding of this process^[98]. We recently found that in a murine model of intragastric ethanol there was an upregulation of genes associated with endoplasmic reticulum (ER) stress response, including GRP78 and 94, CHOP and SREBP. The expression of these genes was associated with protein misfolding as well as apoptosis and lipid synthesis^[78,79]. Since alcoholism and alcohol-related diseases constitute a severe health problem in the world and ER stress has been linked to Hcy in the pathogenesis of several disorders such as atherosclerosis, Alzheimer's disease, and liver steatosis, we would direct the readers' attention to ethanol-induced alterations in Hcy metabolism.

Alcoholic patients have been shown to have elevated plasma Hcy (average two-fold) which ranged from 10–120 mol/L (normal 5–15 mol/L)^[99–101]. Total folate, B₁₂ and B₆ levels were normal. However, Hcy levels correlated with folate levels and blood alcohol levels. Well nourished alcoholics exhibited markedly lower levels of serum pyridoxal-phosphate (PLP) and mildly lower red cell folate^[102]. Even "social" drinking (30 g/d \times 6 wk) caused 20% increased Hcy and decreased folate^[99,103]. Heavy alcohol consumption is a risk factor for stroke and brain atrophy^[103–105]. Rats fed ethanol exhibited a doubling of plasma Hcy despite normal levels of folate, PLP and B₁₂^[106]. We have observed a 7 fold increase of plasma Hcy levels (22.3 \pm 2.8 μ mol/L *vs* pair-fed control 3.0 \pm 0.9 μ mol/L) in mice fed ethanol intragastrically for 4 wk^[78].

With alcohol feeding of rats intragastrically for 9 wk liver specific MAT1A protein expression did not change, whereas MAT2A increased in conjunction with -40% decreased hepatic levels of methionine and SAM^[107]. However, shorter exposure of rats and minipigs to ethanol was not associated with a decrease in methionine or SAM in most studies. Depending

on route, ethanol dose and duration, variable changes in SAM and SAH have been described^[107–110].

Ethanol feeding has been known to lower MS^[111], leading to increased accumulation of 5-methyl THF and to increased BHMT leading to utilization-induced decreased betaine levels^[111]. These effects depended on increased blood ethanol. Golden Syrian hamsters with high ADH fed a 360 mL/L ethanol diet did not develop increased blood ethanol levels or changes in Hcy metabolism unless ADH was inhibited^[112]. Of note, the SAM levels were maintained by the utilization of betaine. However prolonged ethanol feeding eventually could lead to depletion of SAM. Chronic alcohol could increase choline uptake^[113] and mitochondrial oxidation to betaine^[114] suggesting compensation for increased demand for betaine. Feeding betaine (0.5%) raised SAM levels which was accentuated in alcohol fed animals (minimal to begin with) and prevented fatty liver^[78,108,111]. Raised SAM was initially assumed to contribute to betaine's ameliorative effect on fatty liver. It may be equally important that the protective role of betaine was due to lowering Hcy directly through BHMT and indirectly by raised SAM leading to activation of CBS.

The mechanism of the ethanol induced decrease in MS is not well understood. Kenyon *et al.*^[110] showed that the enzyme was inhibited by high concentrations of acetaldehyde, whereas we have found decreased mRNA. Increase in BHMT activity appeared to be a compensatory phenomenon to maintain methionine and was seen after 2 wk in ethanol fed rats and after 4 wk in ethanol fed mice.

In the chronic (12 mo) ethanol fed micropigs with adequate folate, MS activity decreased by 20% which was associated with slightly decreased serum methionine, 20% increased serum Hcy, and increased hepatic SAH but no change in SAM. These small changes due to ethanol were not associated with increased ALT or fatty liver but were associated with increased scattered apoptosis^[115]. Interestingly addition of folate deficient diet to ethanol feeding of the castrated minipig accentuated plasma Hcy and liver injury^[116] although ER stress was not considered in this study.

Betaine lowered Hcy and prevented ER stress and alcoholic liver injury in alcohol fed mice^[78]. However, we need to be cognizant of other actions of betaine. Feeding rats betaine in drinking water (1.5 g/kg) blunted the TNF response to LPS and decreased concomitant liver injury^[117]. Importantly, however, taurine was equally effective. Earlier work has suggested an indirect protective role of choline supplementation, suggesting choline oxidation to betaine could protect against Kupffer cell activation^[118–120]. It has been suggested that betaine and taurine serve as organic osmolytes which are critical in regulating Kupffer cell function^[121]. Hyperosmotic conditions induce Na⁺ betaine transporter mRNA while hypoosmotic conditions do the opposite, this occurred in Kupffer cells but not hepatocytes. Betaine or taurine protects the liver against warm ischemia-reperfusion. Recently, betaine pretreatment was shown to protect the hepatocyte from bile acid induced apoptosis. The mechanism is not certain and high concentrations of betaine (mmol/L) were required^[122,123]. We observed that increased gene expression of TNF and CD 14 was indicative of the alcohol-induced Kupffer cell activation^[78]. However, betaine treatment did not significantly attenuate these changes, suggesting that betaine either acts downstream of alcohol-induced Kupffer cell activation or acts via an independent pathway.

The effect of SAM feeding is of interest since it was reported to decrease fatty liver and mitochondrial abnormalities^[115]. SAM might be expected to inhibit re-methylation and promote transsulfuration of Hcy. It is unclear as to what the overall effect on Hcy would be. Severe SAM deficiency in MAT1A knockout did not alter Hcy but was associated with increased expression of BHMT and CBS^[124]. SAM could transcriptionally

activate MAT1A and suppress MAT2A^[125].

Overall chronic ethanol exposure seemed to cause a modest decrease in SAM and increase in SAH along with early-decreased MS and late-increased BHMT. All these changes were accompanied with increased Hcy which occurs despite adequate dietary folate, B₁₂, B₆ and choline. Thus there are possible contributions of decreased MS, unknown effects on CBS, and decreased SAM (decreased activation of CBS) leading to HHcy. The decrease in SAM levels was accompanied with increased SAH levels. Since both SAM and SAH activated CBS, it is doubtful that changes in levels of these metabolites exerted a significant regulatory role on transsulfuration^[11,16]. The increase in BHMT appeared insufficient to lower Hcy due to limitation on the availability of betaine and already-impaired cell function. Although high dietary choline might generate sufficient betaine in rodents, the choline oxidase pathway is normally low in primates. Thus, providing excess dietary betaine rather than choline would seem to be an approach more applicable to the human situation. Since betaine corrects hyperhomocysteinemia, fatty liver injury and ER stress, and homocysteine is known to cause all these changes, it is reasonable to state that an important mechanism by which betaine protects against alcoholic liver disease is the correction of hyperhomocysteinemia and proof of this hypothesis requires further work.

POSSIBLE ROLE OF ER STRESS IN OTHER LIVER DISEASES

ER stress may also be involved in liver injury caused by α_1 -antitrypsin (α_1 -AT) deficiency and hepatitis C virus (HCV) or hepatitis B virus (HBV) infection. α_1 -antitrypsin (α_1 -AT) deficiency was caused by a point mutation encoding a substitution of lysine for glutamate-342^[126]. Aggregated mutant α_1 -AT was retained in ER rather than secreted in the blood and body fluids where its function is to inhibit neutrophil proteases. Individuals with this deficiency had a markedly increased risk of developing emphysema by a loss of function mechanism by which reduced levels of α_1 -AT in the lung inhibit connective tissue breakdown by neutrophil elastase, cathepsin G, and proteinase 3. Some individuals with α_1 -AT deficiency developed liver injury and hepatocellular carcinoma by a gain of function mechanism, i.e., accumulation of aggregated mutant α_1 -AT within the ER which is toxic to liver cells. However, the exact mechanism by which ER retention of this aggregated mutant protein leads to cellular injury is still unknown. Recent studies have demonstrated that ER retention of mutant α_1 -AT induces a marked autophagic response in cell culture and transgenic mouse models of α_1 -AT deficiency as well as in the liver of patients with α_1 -AT deficiency^[127]. The autophagic response is a general mechanism whereby cytosol and intracellular organelles, such as ER, are first sequestered from the rest of the cytoplasm within unique vacuoles and then degraded by fusion with lysosomes to clear the cells of senescent constituents. Under a fasting condition, a marked increase in fat accumulation was observed in α_1 -AT-containing globules in the liver of α_1 -AT deficient mice^[128], suggesting a malfunction of ER caused by accumulation of mutant α_1 -AT. Investigations of ER stress markers such as GRP78, CHOP, SREBP, XBP1, and ATF6 are needed to assess the direct involvement of ER stress in α_1 -AT deficiency-induced liver injury.

Evidence of ER stress in HBV or HCV infection is emerging. HBV codes for three forms of surface protein. The minor and large forms are translated from transcripts specified by the preS1 promoter, while the middle and small forms are translated from transcripts specified by the downstream S promoter. Overexpression of the large surface protein of HBV could lead to a 10-fold activation of the S promoter but not of an unrelated promoter^[129]. The large surface protein could also activate the cellular grp78 and grp94 promoters. Neither the

middle nor the small surface protein, nor a secretable form of the large surface protein, could activate the S promoter, but agents that induced endoplasmic reticulum (ER) stress had an effect similar to that of the large surface protein, suggesting that HBV may evolve a feedback mechanism, such that ER stress induced by accumulation of the large surface protein increases the synthesis of the middle and small surface proteins, which in combination with the large surface protein can form mixed, secretable particles. HCV-induced ER stress was more evident. HCV replicates from a ribonucleoprotein (RNP) complex that is associated with ER membrane. The replication activities of the HCV subgenomic replicon have been shown to induce ER stress^[130]. HCV replicons induce the UPR which is paralleled by the proteolytic cleavage of ATF6. The HCV non-structural protein 5A (NS5A) can bind to and inactivate the cellular double-stranded RNA-activated protein kinase, PKR. NS5A has recently been demonstrated to engage ER-nucleus signal transduction pathway^[131]. Expression of NS5A in the ER could induce an ER stress leading to the activation of STAT-3 and NF- κ B, which is sensitive to inhibitors of Ca²⁺ uptake. The NS5A-induced ER stress signaling has also been shown in the context of an HCV subgenomic replicon^[131]. Another HCV component, the HCV envelope protein E2, is an ER-bound protein that contains a region of sequence homology with the PKR and its substrate, the eIF2 α . E2 could modulate global translation by inhibition of the interferon-induced PKR through its PKR-eIF2 α phosphorylation site homology domain (PePHD)^[132]. E2 could also bind to and inhibit PERK^[132]. At low expression levels, E2 induced ER stress, but at high expression levels, E2 inhibited PERK kinase activity *in vitro*. Mammalian cells that stably expressed E2 were refractory to the translation-inhibitory effects of ER stress inducers, and E2 relieved general translation inhibition induced by PERK. The PePHD of E2 was required for the rescue of translation that was inhibited by activated PERK. These findings may explain why the virus promotes persistent infection by overcoming the cellular ER stress response. In addition, HCV-induced ER stress resulted in a decline in protein glycosylation. Decreasing protein glycosylation could disrupt the proper protein folding of MHC class I molecules, preventing the assembly of MHC class I molecules. Cells expressing HCV subgenomic replicons had a lower MHC class I cell surface expression^[133]. HCV-infected cells may thus be undetectable in the immune system by suppressing MHC class I antigen presentation to cytotoxic T lymphocytes. Therefore, the persistence and pathogenesis of HCV may depend upon the ER stress-mediated interference of MHC class I assembly and cell surface expression. Finally, HCV infection may suppress the degradation of misfolded proteins while stimulating the synthesis of its viral proteins in the ER. In the ER, IRE1-XBP1 pathway directs both protein refolding and degradation in response to ER stress. It was demonstrated that XBP1 expression was elevated in cells carrying HCV subgenomic replicons, but XBP1 transactivating activity was repressed^[134]. This prevents the IRE1-XBP1 transcriptional induction of EDEM (ER degradation-enhancing -mannosidase-like protein), which is required for the degradation of misfolded proteins. Consequently, misfolded proteins are stable in cells expressing HCV replicons. Study with a cell line with a defective IRE1-XBP1 pathway showed elevated levels of HCV internal ribosome entry site-mediated translation^[134]. This study indicated that the HCV suppression of misfolded protein degradation in the ER not only promoted HCV expression but also contributed to the persistence of the virus in infected hepatocytes.

HCV infection is common in alcoholic patients presenting with liver disease. Heavy alcohol intake would worsen the outcome of HCV infection^[135-137], which has directed much attention to the interaction between alcohol and HCV infection.

Alcohol plays an important role in HCV infection resulting in increased viral replication, enhanced HCV quasispecies complexity, increased liver-cell death, suppression of immune responses, and iron overload^[138]. However, the pathogenic mechanisms underlying the alcohol-HCV interactions are not fully understood. Based on the above evidence that both HCV and homocysteine could induce endoplasmic reticulum (ER) stress response^[6,78,130] and that there was a link between alcohol-induced significant elevation of homocysteine level, ER stress, and the pathogenesis of liver injury^[78], it is reasonable to hypothesize that a locus of the potentiative interaction between alcohol and HCV in accelerating the progression of liver disease is at the level of ER stress. In the case of both HBV and HCV infection, it is widely recognized that severely immunosuppressed patients may develop a paradoxically severe and rapidly progressive liver disease. This has been seen in the post-OLT setting and in patient with AIDS. Therefore, the loss of immune detection of viral-infected hepatocytes may lead to an unopposed massive overload of hepatocytes with viral proteins triggering ER stress. Future studies should examine the contribution of ER stress to these pathologic conditions.

CONCLUSION

HHcy is an integral component of several disorders including cardiovascular and cerebrovascular diseases, neurodegeneration, liver steatosis, diabetes, and cancer. HHcy can result from deficiencies of vitamin cofactors (B6, B12, folic acid) required for Hcy metabolism and/or from genetic disorders of its metabolism. Hcy unleashes inflammation mediators such as NF κ B, IL-1 β , IL-6, and IL-8. Hcy increases production of intracellular superoxide anion causing oxidative stress. Hcy-induced misfolding or malfunctioning of numerous intracellular proteins are increasingly important and attract much attention because the Hcy-induced ER stress mechanism can explain many processes of cell injury. Animal model creation and integral investigation of available animal models will certainly play important role in determining precisely the biological effects of HHcy. Our observations with the murine intragastric ethanol fed model have suggested a link between Hcy metabolism, ER stress, and the pathogenesis of alcohol induced liver injury. Figure 4 demonstrates our hypothesis in which ethanol feeding causes HHcy which then induces the ER stress response in parenchymal and nonparenchymal cells in the liver leading to fatty liver, apoptosis and possibly inflammation. The potential beneficial effects of lowering Hcy and preventing ER stress in alcoholic humans needs to be studied. In addition, since a minority of alcoholics develop liver disease and a wide range of Hcy levels are seen in alcoholics, it will be important to examine polymorphism of Hcy metabolizing enzymes as potential risk-factors for the development of HHcy and liver disease.

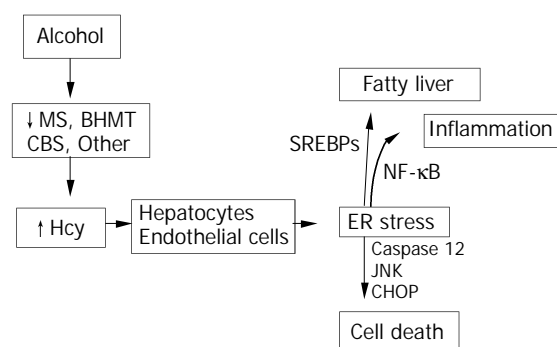

Figure 4 Hypothesis for the role of ethanol-induced HHcy in the pathogenesis of alcoholic liver disease.

Abstract

The development of T helper 1 versus T helper 2 cells is a major branch point in the immune response and is an important determinant of the body's response to an infectious pathogen, leading to protection of the host or dissemination of the disease. Recent studies have shown that there exist macrophage activation states in parallel to the T helper cell type 1/2 paradigm, and the T helper 1 development process is governed to a great degree by cytokine IL-12 provided mainly by antigen presenting cells such as macrophages and dendritic cells. A model in patients with hepatitis is proposed that links the pathogen, macrophage activation and T helper cell polarization.

INTRODUCTION

The immune response that occurs during infectious disease is characterized by plasticity in both its nature and its magnitude. This feature provides an important advantage that permits the immune system to tailor its defense strategy to particular groups of infectious pathogens. Interactions between CD4+T helper (Th) lymphocytes and antigen-presenting-macrophage cells in liver shape and amplify the subsequent immune response. The Th precursors differentiate into 2 subsets of effector Th cells with different functions^[1,2]. Th1 cells produce IFN- γ , IL-2 and Th2 cells produce IL-4, IL-10 and IL-13. The ensuing Th1- and Th2-type immune responses include both potent humoral and cell-mediated components. Th1-derived IFN- γ suppresses Th2 response and Th2-derived IL-10 inhibits the development of Th1 populations^[3]. In addition, the effector cells and antibody isotypes involved are quite distinct^[4]. Th1 cells are responsible for activation of macrophages to a microbicidal state, induction of IgG2a Abs that mediate phagocytosis, and support of CD8+ antiviral effector T cells. By contrast, Th2 cells stimulate the growth and differentiation of mast cells and eosinophils, as well as the production of Ab isotypes, including IgE and IgG4, which can mediate the activation of these cells. IL-12, a cytokine elaborated mainly by macrophages/monocytes, induces the maturation of Th1 cells. An imbalance of Th1 and Th2 appears to be important in the pathogenesis of chronic viral and nonviral infections in humans, such as infection with human immunodeficiency virus, leprosy, leishmaniasis^[5-7], and viral hepatitis^[8].

Recent studies have shown macrophage activation states in parallel to the Th cell type 1/2 paradigm. IFN- γ has long been known as the classical macrophage activating factor inducing cytokine secretion by macrophages to support Th1-driven immune responses. IL-4 which was historically regarded as macrophage deactivators is now thought to induce alternative immunological activation of macrophages^[9], in that it enhances of the capacity of macrophages for endocytosis and antigen presentation by the induction of mannose receptor expression^[10]. In normal immunological process, classical and alternative macrophage activation maintains the balance of macrophage.

IMBALANCE OF Th1/Th2

Th1 and Th2 type cytokines in patients with hepatitis

Chronic hepatitis is characterized by incomplete clearance of virus and damage hepatocytes. Since hepatitis B virus (HBV) is known to have no cytopathic effect on the infected hepatocytes, cell-mediated immunity is thought to play an important role in the pathogenesis of hepatocellular damage and HBV clearance^[11]. Although immune evading mechanisms used by HBV are largely unknown, defects in T cell response have been suspected as a major factor involved in the pathogenesis of chronic hepatitis^[11-15]. Different from acute self-limited hepatitis in which protective immunity develops after elimination of HBV, immune response fails to remove HBV-infected hepatocytes in chronic hepatitis B. Th1 type pattern of secreted immunity can be considered as an appropriate response of the immune system to inhibit viral replication and HBV eradication. Mechanisms by which IFN- γ favors the elimination of HBV may include enhancement of cytotoxic T lymphocyte (CTL) activation, direct anti-viral activity, increased expression of major histocompatibility complex class I molecules on infected cells, and activation of macrophages^[16-18]. It has been shown in a transgenic mouse model that adoptive transfer of CTLs producing IFN- γ could inhibit HBV replication without cytotoxicity^[19].

Studies have shown^[18] that predominant Th1 (IFN- γ) cytokine profile of hepatitis B core Ag (HbcAg)-specific and hepatitis B surface Ag (HbsAg)-reactive T cells is associated with acute self-limited hepatitis B. In most patients with acute hepatitis, CTL responses to epitopes of HbsAg, while there are no such responses in patients with chronic hepatitis^[20]. Thus, Th1 might be insufficient for complete removal of HBV in chronic hepatitis and positively correlated with hepatic inflammatory activity.

Meanwhile, Barnaba *et al.* cloned CD4+ HBV envelope antigen (HbeAg)-reactive T cells and showed signs of cytotoxicity only when they produced IFN- γ ^[21]. This is in agreement with findings that production of IFN- γ ^[22] by peripheral blood mononuclear cells (PBMCs) upon HbsAg stimulation was associated with higher level of hepatocyte damage. The dissociation between the mechanisms responsible for the immune-mediated hepatocytolysis, and for viral clearance in HBV infection was proposed^[23]. It has been demonstrated that the interaction between Ag-specific CTL and target hepatocytes results in spotty necrosis which is limited to a very few hepatocytes^[24]. Instead, the antiviral effect is mediated by IFN- γ , IL-2, and TNF- α released by HBV-specific CTLs or by antigen nonspecific macrophages, and these

cytokines profoundly suppress HBV gene expression in infected hepatocytes by noncytolytic mechanisms^[25] through eliminating HBV nucleocapsid particles and destabilizing the viral RNA^[26]. Thus, after recognition of HBV antigens on the surface of infected hepatocytes, CTLs perform two distinct functions; they kill a small fraction of infected hepatocytes and secrete IFN- γ and TNF- α , which exert antiviral effects without destruction of hepatocytes. Effective clearance of duck HBV and woodchuck hepatitis virus has also been shown to occur without massive hepatocellular necrosis^[27].

In addition, a cytokine balance favoring Th2 type cytokine production such as IL-4 and IL-10 has been associated with progressive virus infections. Co-activation of Th3 cells with Th2 cells can negatively regulate immune responses and may be associated with the immune tolerant state of chronic HBV infection^[28]. The shift from Th1 to Th2 or Th0 profiles was observed in acquired immune deficiency syndrome^[29]. Result also indicates the existence of a Th2 type response to HBsAg in chronic hepatitis B patients with more severe liver damage^[30]. Th2 cells may be associated with the persistence of HBV infection^[31]. Probably the virus can mutate effectively and evade T-cell immune defense mechanisms. Persistent infection upsets the balance between immunostimulatory and inhibitory cytokines which can prolong inflammation and lead to necrosis, fibrosis, and chronic liver disease^[32].

In chronic hepatitis C virus (HCV) infection, Fan *et al.* observed that the elevated levels of Th2 cytokines were greater than Th1 cytokines measured by ELISA^[33]. This result is in agreement with Kobayashi *et al.* who showed a significant increase in number of IL-4-producing Th2 cells and a significant decrease in number of IFN- γ -producing Th1 cells (PBMC stimulated by anti-CD3 antibody)^[34]. They^[34] suggested that, theoretically, stimulation with anti-CD3 antibody results in the expansion of T lymphocytes, whereas stimulation with HCV core protein results in the expansion of T lymphocytes responsive to HCV core antigen. The stimulation of PBMC with anti-CD3 antibody could reflect the patient's real situation better than that with HCV core protein. In addition, they measured the IFN- γ after the depletion of CD8+ T cells—one of the major sources of IFN- γ production. This could explain that the increased production of IFN- γ (Th1) shown in others studies were due to IFN- γ secretion by CD8+ T lymphocytes.

However, Iwata *et al.* found that in patients with chronic hepatitis C there was the increasing production of IFN- γ (Th1) by PBMC after stimulation with HCV core protein^[35]. Bergamini *et al.* obtained the similar result that the percentage of Th1 cells was significantly increased in CD4+, CD8+, 'naive' - CD45RA+ and 'memory' - CD45RO+ T-cell subsets (PBMC by mitogen-stimulation) from patients versus controls^[36], and Sobue *et al.*^[37] also found that a shift to Th1 cytokine profile correlated with the progress of liver damage, which could be related to the higher proportion of CD4+ T cells. Although in chronic hepatitis C infection, the levels of mononuclear cells derived from peripheral blood reflected the level of mononuclear cells derived from liver, the profile of Th1/Th2 in liver tissue and in peripheral blood was different^[37]. In liver tissue, a predominance of Th1-type cytokines was seen in CD4+ T cells^[38], while a predominance of Th1 type cytokines was observed in CD8+ cells in peripheral blood. Thus, the elevated cytokine production may also have been caused by a higher proportion of CD4+ T cells in the liver tissue of patients with chronic HCV infection compared with that in healthy controls, and intrahepatic CD4+ T cells may be more important than CD8+ T cells in the pathogenesis of liver damage in chronic hepatitis C infection. In addition, the percentage of CD4+ T cells in liver correlated with the histological activity of hepatitis^[38,39]. These results may indicate a preferential compartmentalization of Th1 cytokine-producing CD4+ T cells in the liver^[40], suggesting that

some liver-derived CD4+ T cells had a direct cytotoxic effect^[41,42]. Meanwhile cytokines produced may inhibit viral replication, such as IFN- γ and TNF- α ^[26].

The probable mechanism of Th1 predominance in HCV infection is that in order to eliminate HCV and inhibit viral replication, the compartmentalized CD4+ T cells may shift to a Th1 profile and induce nonspecific immune responses to activate nonspecific immune cells and effector molecules, resulting in liver cell damage. Nevertheless, further studies are needed to investigate the significance of CD4+ T cells in liver tissue.

But the different result was observed regarding Th1 or Th2 predominance in patients with chronic hepatitis C, which was probably due to the administration of PBMC and the measurement for Th1 cytokines from CD4+ T, or both CD4+ and CD8+ T cells. It is also possible that the HCV-related antigen influences T helper cells to produce a different cytokine profile from that in healthy subjects. For example, in transgenic mice with HBeAg, the T cell response against peptide 120-31 of HBeAg was predominantly Th1, whereas the response against peptide 129-40 was predominantly Th2-like^[42]. Moreover, escaping variants of HCV epitope attenuate or fail to stimulate T-cell proliferation, which is accompanied by a shift in cytokine secretion patterns from one characteristic of a Th1 antiviral responses to a Th2 form^[43]. Recent evidence suggests that the polymorphic nature of the MHC binding sites and differences in the T-cell repertoire among persons lead to highly variable binding affinity for the immunodominant HBV peptides, which in turn determines the outcome after acute HBV infection^[44,45].

The role of IL-12 in hepatitis disease

IL-12, a heterodimer composed of 2 subunits of p40 and p35 and secreted mainly by antigen-presenting cells (APC) such as activated macrophages and dendritic cells (DCs), is a crucial mediator between innate and adaptive immune responses. The transcriptional factor T-bet, which can induce transcription of an IFN- γ reporter gene and is specifically expressed in Th1 cells generated in the presence of IL-12^[46], suppresses the expression of genes encoding IL-4, IL-5 and induces the synthesis of IFN- γ . These studies suggest that Th1 development process is governed by cytokine IL-12 to a great degree.

IL-12 is a key cytokine not only promoting Th1-synergizing with IL-2, IL-12 induces rapid and efficient production of IFN- γ ^[47] by stimulation of the TCR-CD3 complex and activation of the CD28 receptor, but also maintaining Th1 responses^[48] (Figure 1), in that Th-cell differentiation is determined most probably early after infection by the balance between IL-12 and IL-10, IL-4, which favour Th1- and Th2-cell development, respectively. In addition, IL-12 correlates with virus clearance. In HBV-infected patients, a significant increase in IL-12 production was observed only in patients who cleared the virus. The peak of serum IL-12 associated with Th1 cytokines (IFN- γ) occurred after the ALT flare and preceded or coincided with the time of HBe seroconversion^[8]. Thus, the findings in patients with chronic HBV infection support a proposed combination strategy for therapy with IL-12 plus vaccination^[49,50]. After the ALT flare, the occurrence of IL-12 peak would be the reason that hepatocellular necrosis induced by CTL leads to the recruitment of macrophages and noncommitted T helper cells in the liver. Then the native particles of HBeAg are released from damaged hepatocytes and provide potent antigenic stimulation for these cells. In patients who are able to respond with an increase in IL-12 production, this will promote Th1 cell development and stimulate the production of IFN- γ and TNF- α , which will exert their noncytolytic antiviral effects.

IL-12 may be instrumental in the defense mechanism against HBV infection, and the elevation of its level can be indicative of hepatitis recovery^[51]. The enhancing effect of IL-12 on IFN- γ production of PBMC in patients with chronic hepatitis B virus

infection is increased during IFN- α treatment. Therefore, IFN- α and IL-12 may enhance the efficacy for the treatment of chronic HBV infection^[52], and HCV-related cellular immune defect in patients with hepatitis C can be restored in most patients by IL-12^[53]. However, Quiroga *et al.*^[54] found that HCV-infected patients with greater necro-inflammatory activity of liver showed greater IL-12 production by PBMC than those with minimal or mild activity and normal donors. Massive induction of the proinflammatory cytokines IL-12 and IFN- γ in liver specimens is apparently not counterbalanced by the anti-inflammatory cytokine IL-10, which may play an important role in promoting inflammatory reactions leading to massive liver damage in murine models of fulminant hepatitis B^[55].

Figure 1 Development of Th1/Th2 From Marc and Weeber.

BLANCE OF MACROPHAGE IN PATIENTS WITH HEPATITIS

Macrophage and macrophage activation

Macrophages can be segregated into two broad groups: resident tissue macrophages and inflammatory macrophages. Tissue macrophages are heterogeneous, and those isolated from different anatomical sites differ in function presumably because of adaptive responses to the local micro-environment^[56]. Inflammatory macrophages are derived largely from circulating monocytes, which infiltrate damaged tissue, but some arise by local cell division^[57]. There is now increasing evidence for the heterogeneity of macrophages that have infiltrated inflamed or otherwise damaged tissue, depending on the type and severity of injury, the stage of its evolution and the localization of the macrophages within the tissue^[58].

One major function of macrophages is to provide a defense line against microbial invasion and to recognize and kill tumor cells. Macrophages can accomplish this in a direct manner, involving the release of products such as oxygen radicals and tumor necrosis factor that are harmful to microorganisms or cancer cells. On the other hand, they play an indirect role in these anti-microbial or anti-tumor activities by secretion of cytokines or by antigen processing and presentation, thereby regulating the immune system^[59].

The macrophage presents HBV-derived proteins which activates CD4+T cells. The effects of stimulation on macrophages include increased cytokine production (TNF- α , IFN- γ , IL-1), expression of inducible nitric oxide synthase, nitric oxide secretion, and up-regulation of adhesion molecules. All these processes can lead, directly or indirectly, to increased cytotoxicity of the macrophages. We also found the higher expression level of granulate and activation-linked surface antigen CD69 by CD14 macrophage from peripheral blood in patients with chronic hepatitis than in controls^[60]. This activity was associated with high level transcription of IL-1, IL-6 and TNF- α (unpublished data). Probably, plasma HBV antigens activate macrophages from peripheral blood. Subsequently, such cytokines are produced. In addition, the increasing number of macrophage functions and heterogeneity *in vitro* and *in vivo* has led to the definition of macrophage activation states

in parallel to the Th 1/2 paradigm. IFN- γ has long been known as the classical macrophage activating factor inducing cytokine secretion by macrophages supporting Th1-driven immune responses. IL-4 which was historically regarded as macrophage deactivators is now thought to induce alternative immunological activation of macrophages^[9], in that it enhances the capacity of macrophages for endocytosis and antigen presentation by the induction of mannose receptor expression^[10]. In normal immunological process, classical and alternative macrophage activation maintains the balance of macrophage.

Balanced macrophage activation hypothesis

Figure 2 shows a macrophage activation cycle wherein multiple steps occur during various forms of activation and recycling of macrophage function so as to achieve balanced macrophage activation (Steps 1-5)^[61]. When hepatitis virus invades the body, tissue-resident macrophages undergo local activation and engulf the virus or antigen and enhanced recruitment of monocytes and precursors from bone-marrow pools results in the accumulation of tissue macrophages that have enhanced turnover and an altered phenotype^[62]. After the antigen presentation, Th cells are activated through MHC class II. Th1 (stand for active Th) cell produces IL-2 and IFN- γ and Th2 (stand for inhibitor T) cell secretes IL-4 and IL-10, which is involved in B cell activation as well as providing signals for balanced macrophage activation. Production of IL-4 is known to activate the alternative macrophage activation pathway^[10] (step 5). Although IL-4 induces mannose receptor expression and enhance the capacity of macrophages for endocytosis and antigen presentation^[62], alternative pathway activated macrophages *in vitro* actively inhibit mitogen-induced proliferation of peripheral blood lymphocytes^[63] and CD4+T cells^[64-66]. These findings convincingly confirm that alternative activation generates immunosuppressive macrophage populations. In fact, co-induction of IL-10 with IL-4 secreted by Th2 cells, mainly contributes to the inhibition effect. The net result of excess IL-10 production shuts off the Th1 activation pathway^[61]. Therefore, the balance of macrophage and these cytokines are closely related to viral infectious diseases such as AIDS and viral hepatitis.

Figure 2 Blanced macrophage activation cycles From Michael^[61].

Macrophages may contribute either directly or indirectly to the hepatonecrosis with fulminant virus infection^[67] through classical macrophage pathway. Macrophages in the liver called Kupffer cells activate Th1 (IFN- γ), IFN- γ will activate Kupffer cells^[68,69]. This results in Kupffer overactivation, which in turn promotes cytokines production (TNF- α , IFN- γ), expression of inducible NOS (iNOS), nitric oxide (NO) secretion. All these processes can lead, directly or indirectly, to increased cytotoxicity of the macrophages-this is the classical macrophage activation pathway.

IL-12 is a cytokine secreted by APCs such as activated macrophages and DCs^[70]. It has an important role against intracellular pathogens by promoting Th1 cell development, cell mediated cytotoxicity and IFN- γ production^[71,72]. For

example, a significant increase in IL-12 production was observed only in patients with chronic hepatitis C who cleared the virus^[73]. On the one hand, IFN- γ , activating macrophage and TNF- α secreted by macrophage, exert their noncytolytic antiviral effects. On the other hand, macrophage kills small fraction of infected hepatocytes. As mentioned above, the increase of serum IL-12 and Th1 cytokines always followed the ALT flare^[73], confirming the function of IL-12 in promoting Th1 cell development, and binary function of macrophage. This also explains that HCV-infected patients with greater necro-inflammatory activity of liver showed greater IL-12 production by PBMC than those with minimal or mild activity in normal donors, and why Th1 predominance in HCV infection was correlated with the direct cytotoxic effect^[41,21] and the inhibition of viral replication.

The greater production of IL-12 associated with greater necro-inflammatory activity of liver in HCV-infected patients^[54] and response of IFN- γ to HCV core protein with chronic liver disease suggest a cellular immune response to the onset of the necroinflammatory process of hepatitis^[35]. In murine model of fulminant hepatitis B, massive liver damage was associated with the massive induction of IL-12 and IFN- γ in liver specimens. Probably, the proinflammatory cytokines are apparently not counterbalanced by the anti-inflammatory cytokine IL-10. Thus IL-12 may play an important role in promoting inflammatory reactions^[55]. These cases suggest that the macrophages are in the hyperactive situation, probably due to the imbalance of Th1/Th2 and failing to establish the alternative macrophage activation, which results in the imbalance of macrophage. Thus massive hepatocytes are killed by macrophages or overactivated CTLs.

The steps 2 and 3 in Figure 2 are continually stimulated when foreign virus can not be cleared by successful immune response for Lack of optimal T-cell reactivity that would reestablish balanced macrophage activation. The immunologic overstimulation would predictably lead to pathologic sequelae such as cirrhosis and hepatoma in chronic hepatitis B and C infections^[74].

After long periods of time during which steps 2 and 3 are overemphasized, there would be a predicted shortage of cells to accomplish steps 5 and 1. There would also be an initial overdrive of Th1 cell population. Patients with HIV also have been observed to have a dramatic Th1 to Th2 shift as described in step 4 and patients with chronic hepatitis B appeared to be Th2 predominant^[30]. The balanced macrophage activation theory predicts that this shift is compensatory in nature with the T cells attempting to regulate balanced macrophage activation through production of IL-4 which induces step 5. Th2 predominance would be suffered by patients with chronic viral disease, which would cause secondary immunopathogenic changes, such as HCV-related liver cirrhosis (HCC)^[75], while patients with histology of inflammation showed a significantly higher CD4+Th1 response to the HCV core antigen as compared to patients with histology of fibrosis/cirrhosis^[76]. These findings suggest that Th1/Th2 imbalance in HCV-related cirrhosis would decrease the antitumor immunity and its improvement might present the protective effect from HCC^[75]. At the same time, there exists the exhaustion of cells in steps 5 and 1. This would decrease the rate of phagocytosis.

Alternative macrophage pathway (step 4) has the following features: (1) the production of angiogenic factors, (2) inhibition of T cell responses, (3) associated downregulation of inflammatory-mediator production characteristic of classical activated macrophages, and (4) with the alternative macrophage activation chemokine-1 (AMAC-1)^[77], also known as macrophage inflammatory protein-4 (MIP-4). But few studies were performed in aspect of macrophage, and little is known about the mechanism of the balanced macrophage theory in chronic virus liver infection.

CONCLUSION

Recent data have made a major shift in the role of macrophages in HIV^[78] and inflammatory kidney disease. They can no longer be regarded solely as causing injury but rather as cells that can also promote resolution^[79,80]. This means that strategies to prevent macrophage influx may be beneficial to patients with hepatitis. Future experiments will need to define methods for determining the functional attributes of macrophages in clinical liver biopsies, and effective ways to manipulate the function of inflammatory macrophages *in vivo*.

Given the diverse range of functions macrophages can assume, it becomes possible to modulate disease by altering macrophage activity. The classic view would be that the overall inflammatory environment is a balance between pro- and anti-inflammatory cytokines, determining infiltrating and resident cell function. An increase of pro-inflammatory cytokines from macrophages such as TNF- α or IL-1 β thus worsens inflammation, whereas antagonists of these molecules such as IL-1 receptor antagonist (IL-1ra), IL-1 type II decoy receptor (IL-1RII) and soluble TNF receptor result in reduced injury^[81]. A number of cytokines are described as anti-inflammatory, including the Th2 cytokines IL-4, IL-10 and IL-13, IL-6 and TGF- β . rIL-10 treatment of patients with advanced fibrosis who had failed antiviral therapy appeared to decrease disease activity^[82]. TGF- β 2 significantly suppressed IFN- γ production at the single-cell level, indicating that the enhanced down-regulation of Th1 by TGF- β 2 in patients with HCV-related liver cirrhosis might be effective against hepatoma^[83]. But not all anti-inflammatory cytokines are equal in their ability to modulate macrophage function *in vivo*. In contrast to the results with the Th2 cytokines, IL-4 and IL-10, infusions of TGF- β do not modulate inflammatory macrophage function in glomerulonephritis. For example, Infusion of TGF- β 3 in rats with NTN (nephrotoxic nephritis RANTES) before the onset of disease did not alter the degree of proteinuria, although the number of infiltrating macrophages was reduced^[84]. The study about TGF- β treatment of animal models and patients with hepatitis is still unknown.

Advanced clinical studies of WF10 (completely blocked antigen activation of T cells responsiveness -in step 2) are currently underway in the USA for treatment of patients with HIV disease. The patients who received two cycles of WF10 showed chronic immunological changes by downregulating inflammatory macrophages and reestablished alternative macrophage activation, which was consistent with induction of balanced macrophage activation^[85]. Similarly, it is possible to modify inflammatory virus liver disease using a range of cytokines (Th1/Th2 types) with well-defined effects on macrophage activation. For example, defects in T cell response have been suspected as a major factor involved in the pathogenesis of chronic hepatitis B^[11-15], and favoring Th2 type cytokine may lead to chronic infections with HBV. Recent study has shown that activation of Th1 immunity accompanied by enhancement of CTL activity during therapy is a common immune mechanism for the successful treatment of hepatitis B and C^[86]. Using HBV core gene transduced DCs as APCs, HBcAg specific CTLs and Th1 type immune responses could be generated in the mice, which would be a new way to deal with the viral hepatitis^[87]. Thus, treatment with IL-12 to drive T cell reactivity^[88], and usage of IL-4 receptor antagonist are probably the practicable way to clear virus and remove HBV-infected hepatocytes. Although IL-12 as monotherapy in patients with HCV did not alter the production of regulatory cytokines produced by Th1/2 cells^[89] and had low efficacy^[90,91], IL-12 combining with IFN- α may enhance the efficacy for the treatment of chronic hepatitis B virus infection^[92] and may be a predisposition for elimination of HBeAg and successful treatment of hepatitis B^[93].

Many other cDNAs remained to further studies.

CONCLUSION: The mal gene which is switched-off in all ESCC samples can be considered as a tumor suppressor gene that more studies in its regulation may lead to valuable explanations in ESCC development. Akr1c2 which is up-regulated in ESCC probably plays an important role in tumor development of esophagus and may be proposed as a potential molecular target in ESCC treatments. Differential display technique in spite of many disadvantages is still a valuable technique in gene function exploration studies to find new candidates for improved ones like gene chips.

Abstract

AIM: To identify the altered gene expression patterns in squamous cell carcinoma of esophagus (ESCC) in relation to adjacent normal esophageal epithelium.

METHODS: Total RNA was extracted using SV total RNA isolation kit from snap frozen tissues of ESCC samples and normal esophageal epithelium far from the tumor. Radio-labeled cDNA were synthesized from equal quantities of total RNAs of tumor and normal tissues using combinations of 24 arbitrary 13-mer primers and three different anchoring oligo-dT primers and separated on sequencing gels. cDNA with considerable different amounts of signals in tumor and normal tissue were reamplified and cloned. Using southern blot, the clones of each band were controlled for false positive results caused by probable heterogeneity of cDNA population with the same size. Clones that confirmed differential expression by slot blot selected for sequencing and northern analysis. Corresponding full-length gene sequences was predicted using human genome project data, related transcripts were translated and used for various protein/motif searches to speculate their probable functions.

RESULTS: The 97 genes showed different levels of cDNA in tumor and normal tissues of esophagus. The expression of mal gene was remarkably down regulated in all 10 surveyed tumor tissues. Akr1c2, a member of the aldo-keto reductase 1C family, which is involved in metabolism of sex hormones and xenobiotics, was up-regulated in 8 out of 10 inspected ESCC samples. Rab11a, RPL7, and RPL28 showed moderate levels of differential expression.

INTRODUCTION

Esophageal squamous cell carcinoma (ESCC) is a predominant kind of cancer in the developing world as well as the north and northeast of Iran, which show age-standardized incidence rate of about 150 per 100 000 person-years for both sexes^[1]. The exposure of esophageal cells to both exogenous agents such as food, alcohol, smoke and endogenous causes such as genetic and inflammation of esophagus tissue as well as the race and cultural habits have been accounted for high incidence in certain geographical regions^[2]. Many genes including several oncogenes and tumor suppressor genes are deregulated in esophageal carcinoma^[3, 4]. Some new publications reported gene expression profiles of normal and ESCC tissues recently^[5-8].

Two-dimensional gel electrophoresis has been already studied in Institute of Biochemistry and Biophysics, University of Tehran, Tehran, Iran to compare the protein populations of normal esophagus and ESCC tissues^[9]. A predominant transition of C to T at CpG dinucleotides has been reported for p53 gene as well as over expression of cox-2 gene and accumulation of nitrotyrosine was detected in ESCC tumors of Iranian patients^[10] confirming the concept of chronic inflammatory stress and sensitivity of esophageal cells to exogenous risk factors are involved in ESCC development in Iranian patients.

In order to find new molecular markers suitable for diagnosis and to identify probable potent molecular targets for drug design we started to screen genes with different levels of expression in normal and ESCC tissues of patients that were operated in 2 000 in Madaen Hospital. Using differential display methodology on fresh normal and cancer tissues in this propose we scanned expression of almost 6 000 genes. Using this

technique we tried to screen out all real mRNA population of transcribed genes in tumor and normal tissues in order to include the probable unknown genes too. Among them 97 cDNAs were found with lower or higher expression levels in comparing normal and tumor tissues. 47 cDNAs with remarkable different levels of expression between normal and tumor states were cloned. Six genes that confirmed to have different expression in normal and ESCC tumor tissues are reported here.

MATERIALS AND METHODS

Tissue collection and sample preparation

Tumor tissues of ESCC patients and normal adjacent parts were surgically removed and snap frozen in liquid nitrogen and stored at -80 °C until use. By histopathological examinations tumors were classified into three major groups of well, moderately, and poorly differentiated squamous cell carcinoma according to WHO classification by a pathologist. A brief pathological and clinical data of the patients were shown in Table 1^[12]. Histological normal adjacent epithelium from the same patient was used as the normal pair. A pair of tumor and normal tissues both from the same patient (RP; as reference patient) was chosen randomly for differential display. According to the clinical date this patient is a 47-year-old woman carried moderately differentiated tumor with reactive lymph nodes, which is an indicative of non-metastatic tumor. For a survey of gene expression in other ECSS patients, northern blotting was conducted for RP and nine other ESCC patients at different stages of tumor development. Patients were middle- to old-age all living in north of Iran.

Table 1 Sex, age and histopathological status of the inspected ESCC patients

No	Sex	Age	Differentiation degree of ESCC tumor	Metastatic lymphnodes
1	F	47	Moderately differentiated	None
2	M	53	Well differentiated	3 out of 8
3	F	47	Well differentiated	2 out of 10
4	F	50	Moderately differentiated	1 out of 1
5	M	69	Moderately differentiated	3 out of 9
6	F	60	Moderately differentiated	1 out of 6
7	M	66	Moderately differentiated	All five
8	M	76	Moderately differentiated	None
9	F	55	Poorly differentiated	No evidence
10	F	70	Well differentiated	All three

RNA purification

Using SV Total RNA extraction Kit (Promega), total RNA was purified from ESCC tumor and normal tissue pairs of the same patient in parallel. After DNase-I treatment, DNA-free RNA was recovered in a solution of 0.01 mol/L dithionitrotol (DTT), 10 U/L RNasin (Promega) in diethyl pyrocarbonate-treated water. The quality of RNAs and quantifications were done by spectrophotometry of Absorbency at 260 nm and gel electrophoresis.

Differential display reverse transcriptase-PCR

After 5 min of incubation of 0.2 g of RNA samples at 65 °C, reverse transcriptions were done in 20 L reactions RT buffer containing 50 mmol/L Tris-HCl (pH 8.3), 125 mmol/L KCl, 5 mmol/L MgCl₂, 0.01 mol/L DDT, 0.2 mol/L of a anchored oligo-dT 11M (where M is A, C or G), 20 mol/L dNTPs and 200 U SuperScript™ RNase-H⁻ Reverse Transcriptase (Gibco BRL), for 60 min at 37 °C. For amplification 2.0 µL of each reverse transcribed RNA was added into a 20 l reaction containing 1.25 mmol/L MgCl₂, 2.0 µmol/L dNTPs, 0.2 µmol/L of the respective oligo-dT 11 mol/L, 0.2 mol/L of one 13-mer arbitrary primer, 1 µL [³⁵S]dATP [4.44×10⁴ GBq/mmol

(1 200 Ci/mmol), Amersham] and 1.0 U of Ampli-Taq (Perkin Elmer). PCR cycles/parameters were: a denaturation step at 94 °C for 5 min followed by 3 cycles at 94 °C for 30 s, 42 °C for 2 min, 72 °C for 30 s, and 37 cycles at 94 °C for 30 s, 45 °C for 2 min, 72 °C 30 s and a final extension at 72 °C for 5 min.

Identification and cloning of differentially expressed cDNA bands

The amplified products of DDRT-PCR were fractionated on standard 60 g/L poly-acrylamide/urea gel, and then transferred to 3 mm filter paper (Amersham) without methanol/acetic acid fixing, dried and exposed to X-ray film overnight. The putative differentially displayed bands that showed the same pattern of expression in repeated DDRT gels were eluted and re-amplified by the same primers used in related first amplification sets. Molecular mass and quality of re-amplified cDNA fragments were checked by gel electrophoresis before cloning into the cloning vector pCR2.1 (Invitrogen Co, CA). Escherichia coli TOP10 harboring recombinant plasmids of pCR2.1 were selected on agar plates containing ampicillin and X-gal. Since probable heterogeneity in cDNA populations of the same size existing in each band can leads to false positive results, for each cloned band six single well grown colonies were subjected to Southern blot. Radio-labeled probe was prepared from the inserted fragment of one of these six colonies.

Slot and northern blots analysis

For slot blots preparation, 2.0 g of RNA samples were vacuum-dried and resuspended in 50 L of DEPC-dd H₂O. Fifty microliters of formaldehyde/20SSC solution (1:1 vol/vol) was added and incubated for 15 min at 60 °C before loading on nylon filters (Hybond, Amersham, UK). For northern blots, 30 g of N and T total RNAs were run on denaturing 1.2 g/L agarose gel and blotted onto Hybond membrane dried at 37 °C and fixed using UV cross-linking. As probes, gel purified cDNA fragments of interest were radio-labeled using High Prim™ DNA labeling system (Boehringer) and 4 of [³²P]-dCTP [1.11×10⁵ GBq/mmol (3 000 Ci/mmol), Amersham]. Blots were hybridized with respective probes in hybridization solution containing 0.5 mol/L phosphate buffer pH 7.2, 10 mmol/L EDTA and 50 g/L SDS at 60 °C overnight. Filters were washed twice at 55 °C in 0.1 hybridization solution for 15 min and scanned with a phosphor imager SF (Molecular Dynamics) following 4 h exposure at room temperature. Differentially expressed cDNA clones were sequenced using Sequenase kit Version 2.0 (USB) and fractionated on standard sequencing gels^[13].

Analysis of the sequences

Data entry, sequence management, sequence alignment and protein sequence analysis were performed by Lasergene software package^[12]. Sequence similarity search and several structural features were predicted by the use of online databases and related software including BLAST N, X and P (www.ncbi.nlm.nih.gov/BLAST/)^[13,14], Pfam (www.sanger.ac.uk/Software/Pfam/search.shtml)^[15], PRINTS (www.bioinf.man.ac.uk/dbbrowser/PRINTS/)^[16,17], Blocks (condor.urbb.jussieu.fr/logiciels/Protein_Blocks/Structural_Words/motif_PB_m.html)^[18], SMART (www.bork.embl-heidelberg.de/NAIL/RSmart)^[19,20], PROSITE (www.expasy.org/prosite/)^[21] and PSORT (psort.nibb.ac.jp/form.html)^[22].

RESULTS

Isolation of differentially expressed genes

The expression pattern of about 6 000 genes was scanned using combinations of 24 arbitrary 13-mer primers and three different anchoring oligo-dT primers in differential display reverse transcription-PCR reactions. We identified 97 genes with

different levels of cDNA in tumor and normal tissues of esophagus. 47 bands with considerable differential level of cDNA signals in tumor and normal tissues (Figure 1 panel A; Table 2) were reamplified and cloned. The clones that confirmed differential expression by slot blot (Figure 1 panel B) were selected for sequencing and northern analysis on other tumor samples. To annotate the isolated cDNA fragments, corresponding full-length gene sequences was predicted by the use of human genome project data (Table 2). The generated transcripts were translated and used for various protein motif searches.

Down regulation of mal gene

A 360-bp cDNA fragment, ESC1 clone, was found down regulated in ESCC tumor cells (Figure 1). ESC1 sequence was localized to 2cen-q13 locus of chromosome 2 that encompass

mal gene, a T-cell differentiation antigen. The amino acid sequence encoded by ESC1 aligned with the last 34 amino acids at the C-terminal of human MAL protein family members (Table 2). The available data shows that mal gene encodes four transcript variants as a result of alternative splicing. The detected band with estimated mRNA size of almost 1.1 kb by northern blot, strongly suggests that Mal-a variant is the only form expressed in normal esophagus. The expression of this gene was found to be down regulated in all 10 surveyed patients carrying tumors at different stages of ESCC (Figure 2).

Induced expression of a member of ras oncogene family

Another under-represented gene was found as a 273-bp cDNA fragment named ESC2 (Figure 1). The expression level of the related gene to ESC2, with approximate length of 1.0 kb mRNA,

Figure 1 Parts of DDRT gels including cDNA fragments that show transcriptional alteration in comparing normal esophageal and ESCC tissues (have been pointed with arrows (panel A)), and the results of slot blots containing two microgram RNAs of normal (N) and tumor (T) tissues of esophagus in hybridization with radio-labeled related cDNAs (panel B). All of the slots have been prepared simultaneously and from the same RNA stocks of T and N. One piece of the slots has been hybridized with radio-labeled GADPH probe as shown in the right most side in panel B.

Figure 2 Northern results of patient 1 (RP) and other patients in hybridization with radio-labeled probes of ESC1, ESC2 and ESC3. Each northern membrane contains about 30 micrograms RNA of normal (N) and tumor (T) tissues of esophagus. The differentiation status of each tumor has been shown as W: Well differentiated tumor; M: Moderately differentiated tumor; P: poorly differentiated tumor. The estimated sizes of each bands has been shown on the right side and the ethidium bromide stained gel on top shows the relative amounts of RNAs loaded in each lane.

Table 2 The cDNAs, primers have been used in RT reactions and their related genes with different expression level in normal esophageal and ESCC tissues

cDNA name	cDNA' s length (bp)	3' end primer (5'→3')	5' end primer (5'→3')	GeneBank accession number

ESC2	273	AAG CTT TTT TTT TTT A	AAG CTT CTC AGA C	BC013348
ESC3	300	AAG CTT TTT TTT TTT C	AAG CTT CTC AGA C	BC007024
ESC4	325	AAG CTT TTT TTT TTT C	AAG CTT AAC GAGG	BC006095
ESC5	442	AAG CTT TTT TTT TTT G	AAG CTT GAT TCG C	BC000072
ESC6	271	AAG CTT TTT TTT TTT C	AAG CTT GCG ATG T	AF_061732
ESC7	273	AAG CTT TTT TTT TTT C	AAG CTT TGG TCA G	NM001759

in RP and patient no. 6 was consistent with that observation. However it showed increased level of expression in five tumors (no. 2, 5, 7, 9, 10) out of eight other patients (Figure 2). The sequence of ESC2 was identical to a sequence localized at chromosome 15q21 of human genome corresponding to the 3' region of human *rab11a* gene. The expression of this gene was down regulated in RP and patient no.6 while over-expressed in 5 other surveyed patients and unchanged in three others. No clear correlation was detected between the *rab11a* expression and pathological parameters and/or patients prognosis.

Up-regulation of an aldo-keto reductase encoding gene

A 300 bp of cDNA fragment, ESC3 clone, was clearly up regulated in ESCC tumor (Figure 1). ESC3 sequence identified a locus on chromosome 10 p15 encoding AKR1C1, 2 and 3 three members of aldo-keto reductase protein family 1C. The nucleotide sequence of ESC3 is identical to 3' end of AKR1C2. The corresponding protein sequence encompasses all six conserved blocks of the family. This gene is highly expressed in 8 out of 10 tumors of different stages of ESCC (Figure 2). Low abundance of its transcripts was detected in the other two patients. Again, no clear correlation was found between the expression level and histopathological classification of tumor samples (Figure 2) (Table 2).

Other differentially expressed genes

The expression of two cDNA fragments ESC4 and 5 with the length of 325 bp and 442 bp, respectively, were found to be induced in tumor tissues (Figure 1). They are localized on locus 5q32, the location of ribosomal protein L7 (RplL7), which is a member of RPL30 gene family, and on chromosome 19q13.4 that juxtaexpose the location of ribosomal protein 28 (RplL28) encoding gene respectively. Both of these ribosomal proteins are the components of 60S subunit of ribosome. Northern blots showed increase expression of RplL7 (ESC4) in three tumor samples of ESCC (pair no.1; 4 and 5 if RNA shown in the first panel is normalized), while there is no substantial alterations for its expression in other pairs (Figure 3). The over-expression of RplL28 (ESC5) was confirmed on at least 4 out of 6 ESCC tumor samples by northern (Figure 3, pair samples No: 1, 3, 5 and 8). ESC6 clone carries a 271 bp cDNA fragment that contains a sequence identical to 100-amino acid hypothetical protein, which is moderately over expressed in tumor tissues of RP. A longer transcript of this sequence is also seen in related counting constructed from ESTs in TIGR and GeneBank (Table 2). This contig for ESC6 locates on 19p13.2 as shown by BLAST searches in Map Viewer. This aligned with a fetus brain protein called My029. The motif searches in BLOCKS, Pfam, CD, TIGR

fam failed to identify any conserved motif, while there are two bipartite nuclear targeting sequence (RRqpslrglksrrkprc), three protein kinase C phosphorylation sites as showed by PSORT seraches. Northern analysis shows a moderate over expression of this gene in at least 4 out of 6 samples of well and moderately differentiated ESCC tumors (Figure 3).

The sequence of a 273 bp cDNA fragment, ESC7, localized in 12p13 that code for cyclin D2. Northern analysis on normal and tumor RNA of RP indicates the over expression of this gene in ESCC (Figure 1). No further work was done on this clone.

DISCUSSION

The expression level of two genes encoding MAL, and AKR1C2 have been enormously altered, so that they may be mentioned as switched off and on genes respectively, while the other genes as ribosomal proteins L7 and L28 and a hypothetical protein showed moderate differences of expression between normal and tumor tissues. Except for *mal* gene^[23], differential expression of the other genes in ESCC is reported for the first time in this study.

ESC1 and 2 are the related clones for genes encode for two membrane proteins MAL and Rab11a respectively. A clear suppression of *mal* gene is seen in all ten ESCC samples (Figure 2). *Mal* gene has been already shown to express in four alternatively spliced forms of transcripts during intermediate and late stages of T-cell differentiation^[24], also in differentiating epithelial cells^[25]. The possible roles for MAL-Cglycosphingolipid complexes in cell signaling, differentiation and apical sorting have been suggested^[25]. Here, we report down-regulation of this gene in all surveyed Iranian ESCC patients with different stages of tumor development, which is in good agreement by similar observations from China^[23] and Japan^[26]. As *mal* gene is up-regulated during the late stages of T-cell^[24] and urothelial cells^[25] differentiation, the switching-off of this gene in ESCC may suggest its involvement in a determining event in developing esophageal cancer. Although further studies are needed to clarify the role of MAL in normal esophageal cells and regulation of its expression, in a recent study the ectopic expression of MAL in carcinoma TE3 cells led to repressed formation of tumor induced by TE3 cells in nude mice, inhibition of cell motility and production of apoptosis by Fas pathway^[26]. These observations suggest MAL protein as a potential candidate for ESCC diagnosis/treatment and we expect it to be a tumor suppressor protein as it has been reported just recently^[26].

Rab11a, a non-oncogene member of small GTPase Ras oncogene family, involves in secretory pathways, vesicle trafficking and apical recycling system in epithelial cells^[27]. The most important role of Rab11a might be to facilitate cell migration

Figure 3 Northern results of patient 1 (RP) and other patients in hybridization with radio-labeled probes of ESC4, ESC5 and ESC6. Each northern membrane contains about 20 µg RNA of normal (N) and tumor (T) tissues of esophagus. The differentiation status of each tumor has been shown as W: Well differentiated tumor; M: Moderately differentiated tumor. The estimated sizes of each bands has been shown on the right side and the ethidium bromide stained gel on top shows the relative amounts of RNAs loaded in each lane.

by internalizing integrins at the rear of cell and transporting them forward at the leading edge to form new contacts with the extra cellular matrix^[28]. To our knowledge, this is the first report of alterations of Rab11a expression in ESCC cancer. Similarly, massive synthesis of mRNA and protein of Rab11 was observed in cell line of esophagus adenocarcinoma and in low-grade dysplastic cells during esophageal adenocarcinoma development^[29]. Roles rab11a can play in ESCC is to be studied.

One of the most important results of this study was demonstration of the up regulation of gene encoding AKR1C2 that catalyzes the interconversion of aldehydes and ketones to their corresponding alcohol compounds in sex hormones and similar substrates. Such reactions lead to the production of reactive oxygen species (ROS) and consequent DNA damage as carcinogenesis progresses^[30]. Akr1c2 is also over expressed in lung carcinoma cell line^[31], in non-small cell lung cancer^[32], and in ovarian carcinoma cells^[33]. The pertinent enzyme activity, dehydration dehydrogenase type 2 (DDH2), (EC 1.1.1.213) plays a critical role in metabolism of steroid hormone^[34], drugs^[35] and polycyclic aromatic hydrocarbons (PAH)^[36]. As the esophagus tissue is not directly involved in steroid hormone metabolism the most probable substrate for this enzyme can be polycyclic aromatic hydrocarbons (PAH), some drugs and so on^[35]. During metabolic pathway of these xenobiotic compounds, the resulting o-quinones lead to stable depurination of DNA adducts^[36] that in turn can establish futile redox cycles and amplify ROS. These by-products are potent causative agents for establishing G to T transversion commonly found in ras and p53 genes^[37,38] as shown to occur in ESCC tumors too^[10]. Indeed oxidative stress has been considered as a major pathogenic factor in esophageal carcinoma^[39].

Furthermore oxidative stress leads to 4-hydroxy-2-nonenal (HNE) formation during lipid peroxidation, which diffuses through the cell membranes and with a longer half-life, it is even more destructive than ROS^[40]. On the other hand HNE specifically induces the expression of AKR1C1 isoform^[40]. Since AKR1C2 and AKR1C1 differ for only seven amino acids, it is indistinguishable if AKR1C1 is also being over-expressed in ESCC. As these two enzymes differ just slightly in their untranslated 3' end regions, at least some portions of the signal in northern can belong to akr1c1 transcripts so that both enzymes may be up-regulated in ESCC.

A clear up-regulation of akr1c2 in 8 out of 10 tumor samples of Iranian ESCC patients with different degrees of tumor development was shown in Figure 2. This enzyme is suggested to be involved in esophageal carcinogenesis at least indirectly, and this speculation is in a good agreement with the hypothesis of PAH exposure association with carcinogenesis of this tissue^[41]. However AKR1C2 is of special interest in cancer biology and drug design for prostate cancer^[42] and may be considered also as a potent molecular target in ESCC treatments.

The expression of RpL7 is higher in tumor tissues of all three samples of ESCC, wherein the amount of normal and tumor RNA can be normalized, considering the signals showed in Figure 2 for ESC4. The up-regulation of RpL7 has been reported recently in prostate cancer too^[43]. Several ribosomal proteins are suggested to be involved in cell proliferation, apoptosis, DNA repair, regulation of development and malignancies as their second function^[44], however the possible role of this protein in cancer cells remains to be clear. ESC5 cDNA fragment, that identified as RpL28 shows a higher expression in tumor tissues of ESCC. RpL28 seems to have a regulatory role as it is strongly ubiquitinated during S phase in *Saccharomyces cerevisiae*, while the levels of RpL28 ubiquitination is reduced in G1. As the human ortholog of RpL28 is also ubiquitinated, this modification is highly conserved in evolution, and a probable regulatory role for multiubiquitin of RpL28 has been speculated not necessarily as a target for degradation^[45].

We have seen also the over expression of cyclin D2 using Northern blot on RNA samples of RP, but no more experiments have done on other patients because of low amounts of available RNA. Although the over expression of Cyclin D2 in different kinds of squamous carcinoma cell lines has been shown to modulate proliferation after induced quiescence and enhance *in vivo* aggressive growth behavior^[46], however the RP sample has no metastasis in pathology report of tumor.

It is obviously anticipated that many genes are involved in carcinogenesis of esophagus, although differential expression of these genes could be the consequence rather than a cause. Many complicated events like cell to cell/matrix interactions, cell communications and transportations, normal regulation of protein synthesis, translation and cell cycle regulation as well as metabolic enzymes are affected by cancer development of esophagus.

ACKNOWLEDGEMENTS

We would like to thank Alfredo Franco Romano for his technical assists. This work has been done in collaboration between Molecular Biology Lab, Institute of Biochemistry and Biophysics, University of Tehran and Cell Stress Lab, International Institute of Biophysics and Genetics, Naples as a part of Ph.D. thesis of Sakineh Kazemi-Noureini.

Abstract

AIM: To explore the reversal effect of mifepristone on multidrug resistance (MDR) in drug-resistant human gastric cancer cell line SGC7901/VCR and its mechanisms.

METHODS: Expression of multidrug resistance-associated protein(MRP) was detected using reverse transcription-polymerase chain reaction(RT-PCR). Flow cytometry was used to assay the expression of P-glycoprotein(P-gp), Bcl-2, Bax, and the mean fluorescent intensity of intracellular rhodamine 123 in the cells. Meanwhile, the protein levels of Bcl-2 and Bax were also detected by Western blotting analysis. The sensitivity of cells to the anticancer agent, vincristine(VCR), and the intracellular [³H]VCR accumulation were determined by tetrazolium blue (MTT) assay and a liquid scintillation counter, respectively.

RESULTS: Expression of MRP and P-gp in SGC7901/VCR cells was 6.04- and 8.37-fold higher as compared with its parental SGC7901 cells, respectively. After treatment with 1, 5, 10, and 20 μ mol/L mifepristone, SGC7901/VCR cells showed a 1.34-, 2.29-, 3.11-, and 3.71-fold increase in the accumulation of intracellular VCR, a known substrate of MRP, and a 1.03-, 2.04-, 3.08-, and 3.68-fold increase in the retention of rhodamine 123, an indicator of P-gp function, respectively. MTT assay revealed that the resistance of SGC7901/VCR cells to VCR was 11.96-fold higher than that of its parental cells. The chemosensitivity of SGC7901/VCR cells to VCR was enhanced by 1.02-, 7.19-, 12.84-, and 21.17-fold after treatment with mifepristone at above-mentioned dose. After 96 h of incubation with mifepristone 10 μ mol/L, a concentration close to plasma concentrations achievable in human, the expression of Bcl-2 protein was decreased to (9.21 \pm 0.65)% from (25.32 \pm 1.44)%, whereas the expression of Bax protein was increased to (19.69 \pm 1.13)% from (1.24 \pm 0.78)% (P <0.01). Additionally, the effects of mifepristone on the expression of Bcl-2 and Bax proteins in SGC7901/VCR cells were further demonstrated by Western blotting analysis.

CONCLUSION: Mifepristone has potent reversal effect on MDR in SGC7901/VCR via inhibiting the function of MRP and P-gp, modulating the expression of Bcl-2 and Bax proteins, and enhancing the sensitivity to anticancer agent VCR.

INTRODUCTION

Gastric cancer is still the second most common cancer and the second most cause of cancer-related mortality^[1-2]. Surgery is effective for the majority of cases but chemotherapy plays an important role in the management of the patients with advanced gastric cancer^[3-4]. However, intrinsic or acquired resistance of gastric cancer cells to a broad spectrum of structurally and functionally unrelated anticancer agents, termed multidrug resistance(MDR), is a major obstacle to effective chemotherapy^[5-7]. Thus, there is an urgent need to identify effective reversal agents against the tumor.

The accumulating evidence^[8-12] showed that the mechanisms responsible for the MDR of gastric cancer involve, at least in part, overexpression of two ATP-dependent drug transporter proteins, P-glycoprotein(P-gp) and multidrug resistance-associated protein(MRP), as well as maladjustment of apoptosis-related genes Bcl-2 and Bax. Recent studies^[13-15] proved that mifepristone, as a potent antiprogesterone agent, effectively reversed P-gp- and MRP-mediated MDR in mouse S7CD-5 thymoma cells and human GLC4/sb30 lung cancer cells, and induced apoptosis in human LNCaP prostate cancer cells by regulating the expression of Bcl-2 and Bax. However, the effects of mifepristone on MDR in human gastric cancer cells remain unknown. The present study was therefore undertaken to explore the reversal effect of mifepristone on the MDR in drug-resistant human gastric cancer cell line SGC7901/VCR and its mechanisms.

MATERIALS AND METHODS

Cell culture and treatment

Human gastric cancer cell line SGC7901, and its drug-resistant counterpart SGC7901/VCR selected by stepwise exposure of parental SGC7901 cells to increasing concentrations of vincristine (VCR), were purchased from Wuhan University Type Culture Collection (Wuhan, China). Both cell lines were maintained in RPMI1640 medium (Gibco BRL, Grand Island, NY) supplemented with 100 mL/L heat-inactivated fetal bovine serum(Hyclone, Logan, UT), 10⁵ U/L penicillin and 100 mg/L streptomycin in a incubator containing 50 mL/L CO₂ at 37 °C. When cells were grown to approximately 50% confluence, the medium was then replaced with serum- free RPMI1640. After 24 h, fresh media containing 1, 5, 10, and 20 μ mol/L mifepristone (Sigma Chemical Co., St Louis, MO) was added, respectively. Control cells were treated with the same volume of vehicle (ethanol). Unless otherwise indicated, the cells were harvested after 96 h of incubation.

RT-PCR for MRP

Total RNA was extracted from the cultured cells using Trizol reagent (Gibco BRL) according to the manufacturer's instructions. Two milligrams of total RNA was used for reverse transcription in a total volume of 20 μ L with the SuperScript

preamplification system (Gibco BRL). Aliquots of 2 μ L cDNA were then amplified using a PCR kit (Promega, USA) following conditions recommended by the manufacturer. The sense and antisense primers for MRP, designed according to the sequences published previously^[16], were 5'-AGGAGAGAT-CATCATCGATGG-3' and 5'-GCCTCCTGCACATTCATGG-3', respectively. The sense and anti-sense primers for β -actin were 5'-ATCTG-GCACCACACCTTCTACAATGAGCTGC-G-3' and 5'-CGTCATACTCCTGCTTGCTGATCCACATCTGC-3', respectively. The cycling conditions were 95 °C for 1 min, followed by 30 cycles of 94 °C for 60 s, 58 °C for 45 s, and 72 °C for 1 min and a final extension of 72 °C for 8 min. PCR products were separated on a 20 g/L agarose gel and visualized by ethidium bromide staining. The density of each band was measured on a densitometer, and the relative level of MRP mRNA expression in cells was calculated according to the ratio of MRP gene to β -actin.

Detection of P-gp, Bcl-2, Bax by flow cytometry

The harvested cells were fixed with 40 g/L paraformaldehyde for 10 min, followed by treatment with 2 g/L Triton X-100 for 10 min. After incubation with normal rabbit serum for 10 min to block non-specific binding, the cells were incubated for 1 h at 4 °C with mouse anti-human monoclonal antibodies against P-gp, Bcl-2, Bax (Santa Cruz Biotechnology, Inc., USA) respectively, followed by treatment with FITC-conjugated goat anti-mouse IgG for 30 min at 4 °C. The percentage of positive cells were determined using the FACS Calibur flow cytometry (Becton & Dickinson) with an excitation wavelength of 488 nm.

Western blotting analysis of Bcl-2 and Bax

Western blotting analysis was made to detect Bcl-2 and Bax protein levels according to the published method with some modifications^[17]. Briefly, proteins were extracted from the harvested cells using a lysis buffer containing 50 mmol/L HEPES, pH7.2, 100 mmol/L NaCl, 200 mL/L glycerol, 0.1 mmol/L EDTA, pH8.0, 2 g/L Triton X-100, 2 mmol/L phenylmethylsulfonyl fluoride (PMSF) and 1 mmol/L dithiothreitol (DTT), and then quantitated using the Bio-Rad Detergent Compatible Protein Assay kit (Bio-Rad, Hercules, CA). Equal amounts of protein (10-20 μ g) were resolved on a 100 g/L minigel by SDS-polyacrylamide gel electrophoresis. Proteins were transferred to a PVDF membrane (Millipore, Bedford, MA) using the Multiphor Novoblot electrophoresis transfer system, followed by immunoblotting using a monoclonal mouse anti-human antibody against Bcl-2 and Bax (Santa Cruz Biotechnology, Inc., USA), respectively. A horseradish peroxidase-conjugated secondary antibody (goat anti-mouse HRP, Amersham, Arlington Heights, IL) was used at a dilution of 1:3 000. The membranes were subsequently developed using Enhanced Chemiluminescence (ECL, Amersham) and exposed to film.

Intracellular [³H]VCR accumulation

Cells were incubated with 20 nmol/L [³H]VCR (specific activity

5.8 Ci/mmol, Amersham Pharmacia Biotech Co.) at 37 °C for 90 min in the absence or presence of various concentrations of mifepristone. Cells were then washed three times with ice-cold PBS and lysed in distilled water by ultrasonication. Radioactivity of [³H]VCR in the cell extract was then determined with a liquid scintillation counter (Beckman LS1801, USA) and normalized to cellular protein content.

Rhodamine 123 retention assay

Retention of rhodamine 123 (Sigma) was determined by flow cytometry as a functional index of P-gp activity. Cells (2×10^5) were treated with various concentrations of mifepristone for 24 h prior to the addition of 10 g/L rhodamine 123. After incubation at 37 °C for 1 h, cells were harvested and centrifuged at 300 g for 10 min. Cell pellets were resuspended with 500 μ L of PBS and immediately used for flow cytometric analysis of rhodamine 123 retention.

Drug-sensitivity assay

The sensitivity of cells to VCR was determined using the MTT assay as described previously^[18]. The drug concentration producing 50% inhibition of growth (IC_{50}) was determined graphically for VCR using the relative survival curves. The reversal effects of mifepristone were determined as the IC_{50} value in the absence of mifepristone to that in the presence of mifepristone. Assays were performed in quadruplicate for at least three times.

Statistical analysis

Data were expressed as mean \pm SD. Statistical analysis of the data was performed using the Student's *t* test and the Chi-square test. $P < 0.05$ was considered statistically significant.

RESULTS

Expression of MRP mRNA and P-gp protein

To examine the relationship between the levels of MRP and P-gp expression in SGC7901/VCR and SGC7901 cells and the changes in drug resistance, RT-PCR and flow cytometry were used to detect the expression of MRP mRNA and P-gp protein. As indicated in Figure.1, a 6.04-fold overexpression of MRP mRNA was found in SGC7901/VCR cells as compared with the parental line. The relative level of MRP mRNA expression in drug-resistant cells and drug-sensitive cells was 1.45 ± 0.23 and 0.24 ± 0.17 , respectively. Similarly, the expression of P-gp was significantly increased in the SGC7901/VCR cells in comparison with the parental cells ($57.64 \pm 8.56\%$ vs $6.89 \pm 1.25\%$, 8.37-fold, $P < 0.005$).

Intracellular [³H]VCR accumulation and rhodamine 123 retention

Intracellular accumulation of [³H]VCR, a known substrate of MRP, was measured in the presence or the absence of various concentrations of mifepristone in both cell lines. After treatment with 1, 5, 10, and 20 μ mol/L mifepristone for 90 min, the

accumulation of intracellular VCR in SGC7901/VCR cells was enhanced by 1.34-, 2.29-, 3.11-, and 3.71-fold as compared with medium control, respectively (Table 1). It had been documented that the efflux of rhodamine 123 correlated with well P-gp expression. By this rational, we used rhodamine 123 to evaluate the function of P-gp. As shown in Table 1, after treatment with various concentrations of mifepristone for 24 h, the retention of rhodamine 123 in SGC7901/VCR cells was increased by 1.03-, 2.04-, 3.08-, and 3.68-fold as compared with the medium control. In contrast, no significant increase in the intracellular rhodamine 123 retention and VCR accumulation was observed in mifepristone-treated SGC7901 cells.

Figure 1 RT-PCR analysis of MRP mRNA expression in human gastric cancer cell line SGC7901 and its drug-resistant counterpart SGC7901/VCR. Lane 1-3: marker(bp), SGC7901/VCR, SGC7901, respectively.

Expression of Bcl-2 and Bax

Flow cytometric assay revealed that the expression of Bcl-2 protein was significantly increased, whereas the expression of Bax was decreased in SGC-7901/VCR cells as compared with drug-sensitive SGC7901 cells (Table 2). Mifepristone when used at 10 $\mu\text{mol/L}$, a concentration close to plasma concentrations achievable in human, markedly up-regulated the expression of Bax and simultaneously down-regulated the expression of Bcl-2 in SGC7901/VCR cells (Table 3). Additionally, the results were further demonstrated by Western blotting analysis (Figure 2). Western blotting revealed that mifepristone dose-dependently modulated the expression of Bcl-2 and Bax proteins, which was especially remarkable at the 20 $\mu\text{mol/L}$ concentration.

^a $P < 0.05$ vs control group.

Drug sensitivity assay

The sensitivity of SGC7901/VCR cells and its parental cells to VCR is shown in Table 4. Our results showed that the resistance of the SGC7901/VCR cells to VCR was 11.96-fold higher than that of its parental counterparts in terms of IC_{50} value. After incubation with 1, 5, 10, and 20 $\mu\text{mol/L}$ mifepristone for 96 h, the sensitivity of SGC7901/VCR cells to VCR was enhanced by 1.02, 7.19, 12.84, and 21.17 times, respectively. In contrast, mifepristone did not obviously alter the sensitivity to VCR in parental SGC-7901 cells.

DISCUSSION

Mifepristone is a potent antiprogesterone agent that has been widely used as the first-line drug for the termination of early pregnancy^[19,20]. Interestingly, recent studies^[21-25] have proved that mifepristone exerts markedly anticancer effects and reversal effects on MDR in some cancer cells with no serious side-effects. Thus, there is an increasing interest in exploring the reversal effect of mifepristone on MDR in human gastric cancer cells. In the present study, we reported for the first time that mifepristone effectively reversed MDR in SGC7901/VCR via multiple mechanisms.

Previous studies^[26-28] have proved that MDR in gastric cancer cells is closely related to overexpression of two ATP-dependent transporter proteins, P-gp encoded by MDR1 gene and MRP identified by Cole *et al.*^[16] from adriamycin-selected MDR lung cancer cell line H69/ADR. Both proteins belong to the ATP-binding cassette(ABC) protein superfamily, and efflux anticancer agents out of cells and therefore decrease their intracellular accumulation. Thus, we firstly determined the relationship between the levels of P-gp and MRP expression in SGC7901/VCR and its parental cells and the changes of drug resistance. Results showed that the expression of P-gp and MRP in SGC7901/VCR cells was 8.37- and 6.04-fold higher as compared with its parental counterparts. The data indicate that the overexpression P-gp and MRP confers, at least in part, the MDR phenotype of VCR-selected SGC7901/VCR cells.

To determine the effects of mifepristone on the function of P-gp and MRP, we further investigated the accumulation of intracellular VCR, a substrate of MRP, and the retention of rhodamine 123, an indicator of P-gp function, in both cell lines. Results revealed that mifepristone dose-dependently enhanced the intracellular VCR accumulation and rhodamine 123 retention in SGC7901/VCR cells. In contrast, mifepristone had no significant effects on the drug-sensitive SGC7901 cells. The results were further proved by the drug sensitivity assay. We found that, after incubation with 1, 5, 10, and 20 $\mu\text{mol/L}$ mifepristone for 96 h, the sensitivity of SGC7901/VCR cells to VCR was enhanced by 1.02, 7.19, 12.84, and 21.17 times, whereas

no significant changes in the sensitivity to VCR were observed in mifepristone-treated SGC901 cells. The findings are in agreement with those of previous studies on other cancer cell lines *in vitro*^[13,14]. Taken together, it seems reasonable to conclude that mifepristone can inhibit the function of P-gp and MRP and therefore enhance the sensitivity of cells to anticancer agent VCR.

Although overexpression of the P-gp and MRP plays an important role in the MDR of gastric cancer, this does not explain all of the MDR^[29]. Recent studies have shown that overexpression of anti-apoptotic proteins, such as Bcl-2, Bcl-X_L and Mcl-1, induces cancer cells resistance to chemotherapeutic agents in cancer cells that act by apoptosis, whereas high levels of pro-apoptotic proteins, Bcl-Xs and Bax, contribute to sensitize MCF-7 breast cancer cells to etoposide (VP16), taxol and epirubicin. These data were also proved by the work of Zhao *et al.*^[10], who reported that the Bax gene-transfected SGC7901/VCR cells were more sensitive to adriamycin and VCR than mock vector transfected cells. In a word, Bcl-2/Bax pathway may be an alternative mechanism of drug resistance in gastric cancer. In this study, we proved that mifepristone when used at 10 µmol/L, a concentration close to plasma concentrations achievable in human, significantly up-regulated the expression of Bcl-2 and simultaneously down-regulated the expression of Bax in SGC7901/VCR cells. In addition, the modulating effects of mifepristone on the expression of Bcl-2 and Bax proteins in SGC7901/VCR cells were further demonstrated by Western blotting analysis. These results may partly explain the reversal effects of mifepristone on SGC7901/VCR.

In conclusion, mifepristone exerts potent reversal effect on MDR in SGC7901/VCR via inhibiting MRP- and P-gp-mediated drug transporter, modulating the expression of apoptosis-related genes Bcl-2 and Bax, and enhancing the sensitivity of cells to anticancer agents such as VCR. These results indicate that mifepristone may be a promising chemosensitizer likely allowing to reverse the MDR of human gastric cancer cells although further studies are clearly needed to prove the possibility.

Abstract

AIM: To investigate the effects of mifepristone on the invasive and metastatic potential of human gastric adenocarcinoma cell line MKN-45 and its mechanisms.

METHODS: After incubation with various concentrations of mifepristone (5, 10, 20 $\mu\text{mol/L}$), the adhesion to artificial basement membrane, Matrigel, and the migration of MKN-45 cells were assayed using MTT assay and Transwell cell culture chambers, respectively. Enzyme-linked immunoabsorbent assay (ELISA) and flow cytometry were used to determine the expression of vascular endothelial growth factor (VEGF) and integrin $\beta 3$ in the cells. After subcutaneous transplantation of MKN-45 cells in nude mice, mifepristone (50 mg/kg·d) was administrated subcutaneously for 8 wk to assess its effects on tumor metastasis. Immunohistochemical analysis was used to detect the expression of VEGF and microvascular density (MVD) in xenografted tumors.

RESULTS: Mifepristone dose-dependently inhibited the heterotypic adhesion to Matrigel of MKN-45 cells. The inhibition was accompanied by a significant down-regulation of integrin $\beta 3$ expression in the cells. After incubation with 5, 10, 20 $\mu\text{mol/L}$ mifepristone, the number of migrated MKN-45 cells was 72 ± 8 , 50 ± 6 , 41 ± 5 in experiment group, and 94 ± 16 in control group ($P < 0.01$). Meanwhile, secreted VEGF protein of MKN-45 cells in mifepristone-treated group (14.2 ± 2.9 , 8.9 ± 3.1 , 5.4 ± 2.1 ng/g per liter) was significantly lower than that in control group (22.7 ± 4.3 ng/g per liter, $P < 0.01$). *In vivo*, mifepristone decreased the number of metastatic foci in lungs of nude mice and down-regulated the expression of VEGF and MVD in the xenografted tumors.

CONCLUSION: Mifepristone can effectively inhibit the invasive and metastatic potential of human gastric adenocarcinoma cell line MKN-45 *in vitro* and *in vivo* through inhibition of heterotypic adhesion to basement membrane, cell migration and angiogenesis.

INTRODUCTION

Mifepristone is a progesterone receptor (PR) antagonist that has been widely used as the first-line drug for the termination of early pregnancy^[1]. Recently, considerable studies^[2,3] have proved that mifepristone exerts markedly anti-tumor effects on PR-positive tumor cells, such as breast cancer and ovarian cancer, without obvious side-effects and drug resistance. Its similar effect on PR-positive human gastric adenocarcinoma cell line MKN-45 was also demonstrated in our laboratory.

More interestingly, accumulating evidences show that embryo implantation and tumor metastasis share striking similarities in biological behaviors, such as cell adhesion^[4], immune escape^[5], angiogenesis^[6], invasion^[7] and tumor metastasis-related gene expression^[8]. By this rational, there is an increasing interest in addressing the role of mifepristone, an agent against embryo implantation, in anti-tumor invasion and metastasis. Therefore, the present study was undertaken to further investigate the effects of mifepristone on the invasive and metastatic potential of MKN-45 cells *in vitro* and *in vivo* and its possible mechanisms.

MATERIALS AND METHODS

Cell culture and treatment

Human gastric adenocarcinoma cell line MKN-45 was obtained from Wuhan University Type Culture Collection (Wuhan, China), and maintained in phenol red-free RPMI1640 (Gibco BRL, Grand Island, NY) supplemented with 100 mL/L¹ fetal bovine serum (Hyclone, Logan, UT), 10^5 U/L penicillin and 100 mg/L streptomycin at 37 °C in a humidified atmosphere containing 50 mL/L CO₂ in air. When cells were grown to approximately 50% confluence, the medium was then replaced with serum-free RPMI1640. After 24 h, fresh media containing 5, 10, 20 $\mu\text{mol/L}$ mifepristone (Sigma Chemical Co., St Louis, MO) were added, respectively. Control cells were treated with the same volumes of vehicle (ethanol). Unless otherwise stated, the cells were harvested after 96 h of incubation.

Adhesion assay

Each well in 96-well tissue culture plates was coated with 2 μg of Matrigel (Collaborative Research Inc., Bedford, MA) and allowed to dry in a laminar flow cabinet overnight at room temperature. After washed three times with PBS to remove excess and unbound Matrigel, the wells were blocked with 20 μL of a 20 mg/L bovine serum albumin (BSA, Sigma) solution in RPMI1640 medium for 1 h at 37 °C. Aliquots of 8×10^4 cells, in 100 μL of serum-free RPMI1640 medium containing various concentrations of mifepristone, were added to each well and the cells were allowed to adhere for 1 h at 37 °C. When the incubation was completed, the wells were washed three times with PBS to remove unbound cells. Then, the remaining cells were continuously incubated with MTT solutions (40 μg /well) for 4 h at 37 °C, followed by treatment with 200 μL of dimethyl sulfoxide (DMSO) for 10 min. Finally, $A_{570\text{nm}}$ of each well was measured using an ELISA plate reader (Bio-Rad, USA). Results were expressed as the adhesive rate(%) that was calculated according to the

following formula: (A_{570nm} of the adhered cells/ A_{570nm} of total cells) $\times 100\%$.

Detection of integrin $\beta 3$ by flow cytometry

The harvested cells were fixed with 40 mg/L paraformaldehyde for 10 min, followed by treatment with 2 mg/L Triton X-100 for 10 min. After treatment with normal rabbit serum for 10 min to block non-specific binding, the cells were incubated for 1 h at 4 °C with mouse anti-human monoclonal antibody against $\beta 3$ (Santa Cruz, USA), followed by treatment with FITC-conjugated goat anti-mouse IgG (Vector, Burlingame, CA) for 30 min at 4 °C. The percentage of positive cells was determined using the FACS Calibur flow cytometry (Becton & Dickinson) with an excitation wavelength of 488 nm.

Migration assay

Migration of MKN-45 cells was assayed in Transwell cell culture chambers with 6.5-mm-diameter polycarbonate membrane filters containing 8- μ m-pore size (Becton Dickinson Labware, Bedford, MA). Fibroblast-conditioned medium, obtained from confluent NIH 3T3 cell cultures in serum-free RPMI 1640, was used as the chemoattractant and added to the lower wells of the chambers. Aliquots of 2×10^4 cells in 300 μ L fresh medium containing various concentrations of mifepristone were seeded into the upper wells of the cell inserts. After 24 h of incubation at 37 °C, the non-migrating cells were removed from the upper surface of the membrane with a cotton swab. The cells on the lower surface of the membrane were fixed with ice-cold methanol and then stained with haematoxylin and eosin. The number of migrated cells was counted under a light microscope. Five random microscopic fields ($\times 400$) were counted per well and the mean was determined.

Measurement of VEGF by ELISA

The media were collected after 48 h for VEGF ELISA determinations as described below. The cells were taken through three freeze-thaw cycles, centrifuged and supernatant was collected for determination of protein concentration as described previously. VEGF levels in the cell culture media were measured using a Quantikine kit from R & D Diagnostics (Minneapolis, MN) using the procedure provided by the supplier. Human recombinant VEGF included in the kit was used to construct a standard curve and obtain absolute values of VEGF protein content. The values were then normalized to the total protein concentration in each dish.

Xenografts of MKN-45 cells in nude mice

Two $\times 10^7$ MKN-45 cells were subcutaneously xenografted in the right flank of 8-wk-old male BALB/c-*nu/nu* mice (Shanghai Experimental Animal Center, Chinese Academy of Sciences, China). When tumors reached a mean volume of 100 mm³, mice were randomly divided into two groups (8 mice in per group) and treated as the following. Mice in experiment group were administrated subcutaneously with mifepristone at the dose of 50 mg/kg·d, whereas mice in control were subcutaneously injected with saline every day. After 8 wk of treatment, lungs were harvested, and the weights of lungs were determined. The number of metastatic foci in lungs fixed with Bouin's solution for 24 h was counted under a stereomicroscope. Meanwhile, the tumors were resected, fixed with 40 g/L formaldehyde in PBS, embedded in paraffin and sliced into 4- μ m-thick sections for immunohistochemical analysis.

Immunohistochemical staining for VEGF and MVD

The expression of VEGF and MVD in harvested tumors was determined immunohistochemically using an avidin-biotin-peroxidase complex (ABC) kit (Vector Laboratories, USA).

Unless otherwise stated, all steps were performed at room temperature. Briefly, after removal of wax, tissue sections were treated with 30 mL/L hydrogen peroxidase for 30 min to block endogenous peroxidase activity, and microwaved in 10 mmol/L citrate buffer for 10 min to retrieve antigens. After blocked with normal goat serum, rabbit anti-human polyclonal antibody against VEGF and factor VIII-related antigen (Santa Cruz Biotechnology, USA) at a 100-fold dilution were separately applied to sections and incubated overnight at 4 °C. This was followed by treatment with biotin-labeled goat anti-rabbit IgG for 60 min. The ABC complex was added and allowed to stand for 30 min. Sites of immunoreaction were visualized with 3, 3'-diaminobenzidine (DAB), followed by counterstaining with Mayer's haematoxylin, if necessary. Between each step, the sections were washed three times with 100 mmol/L Tris-HCl buffer containing 0.1 mg/L Triton X-100. For a positive control, breast cancer tissue was used and the primary antibody was replaced by normal rabbit serum as a negative control.

Statistical analysis

Data were expressed as mean \pm SD. Statistical analysis was performed using the Student's *t* test and chi-square test. $P < 0.05$ was considered statistically significant.

RESULTS

Adhesion assay and expression of integrin $\beta 3$

MTT assay revealed that mifepristone dose-dependently inhibited the cell adhesion to artificial basement membrane, Matrigel. The adhesive rate of MKN-45 cells was $78.2 \pm 5.0\%$, $65.4 \pm 4.7\%$, $49.8 \pm 4.2\%$ in mifepristone-treated group, and $85.6 \pm 6.3\%$ in control group ($P < 0.05$). To further explore whether the change of cell adhesion molecule expression in MKN-45 cells contributed to the inhibition, flow cytometry was used to detect the expression of integrin $\beta 3$ in the cells. Results showed that the expression of integrin $\beta 3$ in MKN-45 cells treated with 5, 10, 20 μ mol/L mifepristone was significantly lower than that in control group ($25.4 \pm 3.6\%$, $19.6 \pm 2.9\%$, $15.8 \pm 2.2\%$ vs $31.8 \pm 4.1\%$, $P < 0.05$).

Migration assay

The effect of mifepristone on the migration of MKN-45 cells was evaluated in the Transwell cell culture chambers. As shown in Figure 1, there was a significant decrease in the number of migrated MKN-45 cells in mifepristone-treated group (72 ± 8 , 50 ± 6 , 41 ± 5) as compared with that in control group (94 ± 16 , $P < 0.01$).

Expression of VEGF protein

After treatment with 5, 10, 20 μ mol/L mifepristone for 48 h, secreted VEGF protein in the cell culture media measured by ELISA assay, was 14.2 ± 2.9 , 8.9 ± 3.1 and 5.4 ± 2.1 ng/g per liter, respectively. There was a significant difference in VEGF expression as compared with that in the control cells (22.7 ± 4.3 ng/g per liter, $P < 0.01$).

Xenografts of MKN-45 cells in nude mice

During necropsy, lung metastasis of gastric cancer was found in 6 mice of the control group, and in 4 mice of mifepristone group (Figure 2). As far as the number of metastatic foci in lungs was concerned, there was a significant difference in mifepristone-treated group as compared with control group (8 ± 2 vs 18 ± 7 , $P < 0.05$). In addition, the weights of xenografted tumors in nude mice treated with mifepristone (201 ± 36 mg) were significantly lower than those in control group (298 ± 54 mg, $P < 0.05$). To evaluate the effects of mifepristone on MVD and VEGF expression in xenografted tumors, immunohistochemical

staining was performed using ABC method. Results revealed that VEGF was highly expressed in xenografted gastric cancer in nude mice (Figure 3A). After treatment with mifepristone for 8 wk, the expression of VEGF was markedly down-regulated in the tumors (Figure 3B). In addition, MVD of xenografted tumors was $(11.2 \pm 2.5)/400 \times \text{visual field}$ in mifepristone-treated group, and $(29.8 \pm 7.6)/400 \times$ in the control group ($P < 0.01$).

Figure 1 Effect of mifepristone on migration of MKN-45 cells incubated in Transwell cell culture chambers for 24 h in the absence (A) or presence of 10 $\mu\text{mol/L}$ (B) and 20 $\mu\text{mol/L}$ (C) mifepristone (H.E, $\times 200$).

Figure 2 Metastatic foci in lungs of nude mice (arrow). After 24 h of fixation with Bouin's solution, lung tissues exhibited yellow, whereas the tumors exhibited white.

Figure 3 Immunohistochemical detection of VEGF expression in xenografted gastric cancer tissues of nude mice treated for 8 wk without (A) or with (B) 50 mg/kg·d mifepristone (ABC, $\times 100$).

DISCUSSION

Although considerable evidence^[9,10], both clinical and experimental, has demonstrated that mifepristone exerts markedly anti-proliferative effects on PR-positive malignant tumor cells, the role of mifepristone in anti-tumor invasion and metastasis, especially on gastric cancer, is poorly understood. In the present study, we demonstrated that mifepristone effectively inhibited the invasive and metastatic potential of human gastric adenocarcinoma cell line MKN-45 *in vitro* and *in vivo* through multiple mechanisms.

For tumor cells, increase of heterotypic adhesion to basement membrane and decrease of homotypic adhesion to the same cells have been defined as the critical event of tumor invasion that signals the initiation of metastatic cascade^[11,12]. In the present study, heterotypic adhesion of MKN-45 cells to artificial basement membrane, Matrigel, was examined with MTT dye assay to stain the adhered cells. Results showed that mifepristone dose-dependently decreased the adhesive rate of MKN-45 cells. Moreover, the findings were further proved by the down-regulation of integrin $\beta 3$ expression in the cells treated with mifepristone.

Integrin $\beta 3$, one member of integrins superfamily, plays a fundamental role in tumor cell heterotypic adhesion to extracellular matrix and basement membrane, which has been found to be mediated through a specific arginine-glycine-aspartic acid (RGD) amino acid sequence^[13]. Brakebusch *et al.*^[14] reported that high expression of integrin $\beta 3$ directly correlated with tumorigenicity and tumor progression. To further explore whether the change of integrin $\beta 3$ expression in MKN-45 cells contributed to the inhibitory effect of mifepristone on cell adhesion, flow cytometry was performed. We found that mifepristone down-regulated the expression of integrin $\beta 3$ in MKN-45 cells in a dose-dependent manner. The results were also demonstrated by the work of Li *et al.*^[15], who reported that mifepristone significantly down-regulated the expression of integrin $\beta 3$ in decidua and chorionic villi of early pregnancy, and the effect might be related with the anti-pregnancy mechanism of mifepristone. Taken together, the inhibitory

effect of mifepristone on heterotypic adhesion of MKN-45 cells may be associated with the down-regulation of integrin $\beta 3$. Moreover, integrin $\beta 3$ has been found to function not only as a cell adhesion molecule, but also as a signaling molecule for regulation of angiogenesis^[16]. Therefore, down-regulation of integrin $\beta 3$ expression in MKN-45 cells may be partially responsible for the inhibition of angiogenesis in the cells by mifepristone.

Continuous growth, invasion and metastasis of malignant tumors including human gastric cancer are dependent on angiogenesis factors regulated by peptide growth factors, of which VEGF is one of the most selective and potent^[17]. Hyder *et al.*^[18] reported that progestins could induce the expression of VEGF mRNA and protein in human breast cancer cell line T47D, and this effect was blocked by the antiprogestin agent mifepristone. The finding suggests that mifepristone may be useful to inhibit proliferation and metastasis in some tumors by blocking VEGF production. Thus, there is a great interest in exploring the effect of mifepristone on the expression of VEGF in MKN-45 cells. After exposure of MKN-45 cells to various concentrations of mifepristone for 48 h, a dose-dependent decrease in the media levels of VEGF was observed. Furthermore, the results were further supported by animal experiments. Immunohistochemical analysis showed that mifepristone significantly down-regulated the expression of VEGF and MVD in xenografted gastric cancer in nude mice. Summarily, it seems reasonable to conclude that the inhibitory effect of mifepristone on the invasive and metastatic potential of MKN-45 cells is mediated partially via blocking VEGF production.

On the other hand, tumor cell migration was necessary at the initiation of metastatic cascade, when the tumor cells left the primary site and gained access to the circulation and also at the end of invasion, when they were entering the secondary site^[19]. Theoretically, the decrease of tumor cell migration would contribute to the inhibition of tumor invasion and metastasis. In the study, the effect of mifepristone on the migration of MKN-45 cells was estimated in Transwell cell culture chambers. Results showed that a significant decrease in the number of migrated MKN-45 cells was observed in mifepristone-treated group as compared with control group.

In summary, mifepristone effectively inhibited the invasive and metastatic potential of human MKN-45 gastric adenocarcinoma cells through inhibition of the heterotypic adhesion to basement membrane, cell migration and angiogenesis. These findings, linked to its anti-proliferative effects, indicate that mifepristone may be a beneficial agent for additional and complementary use in the management of gastric cancer.

Abstract

AIM: To study the difference of microvessel density (MVD) between malignant and benign hepatic lesions and study the relationship between MVD and dynamic enhanced magnetic resonance imaging (MRI) for evaluation of microvessels within malignant and benign hepatic lesions.

METHODS: A total of 265 specimens of hepatocellular carcinoma (HCC), 122 cirrhosis tissues and 22 hepatic benign lesions were enrolled for MVD by immunohistochemistry on tissue microarray, of which 49 underwent MRI examination before surgery, then contrast-to-noise ratios (CNR) and enhancement index (EI) in all the phases were calculated. Pearson correlation was performed for correlation analysis between CNR, EI and MVD.

RESULTS: MVD of HCC was 22.7 ± 15.8 (mean \pm SD), which was obviously higher than that of cirrhosis tissue (8.3 ± 7.6 , $P < 0.01$), but was not statistically different from that of benign lesions (31.3 ± 22.7 , $P > 0.05$). Among HCC, MVD of grades I-II was 29.9 ± 18.6 , which was much higher than those of grade III (22.2 ± 18.2 , $P < 0.01$) and grade IV (22.9 ± 19.0 , $P < 0.01$). MVD of HCC ($P = 0.018$) and of benign lesions ($P = 0.014$) were both correlative with CNR in arterial phase.

CONCLUSION: Neoangiogenesis is an important feature for malignant tumor, and MVD may act as a biological marker in differentiating malignant from benign hepatic lesions. Dynamic enhanced MRI, especially image in arterial phase, may act as an MVD evaluation criterion for malignant and benign hepatic lesions.

INTRODUCTION

It is well known that hepatocellular carcinoma (HCC) is a type of hypervascular lesion^[1], but there were seldom reports on

difference of microvessel density (MVD) between HCC and benign hepatic lesions. The tissue microarray, which has been developed recently as a high-throughput technique for rapid scanning hundreds or thousands of samples at the same time, can be applied in analyzing expression of some DNA, RNA or protein^[2]. In this research, differences of MVD of a large number of hepatic malignant and benign lesions were studied with tissue microarray, which further demonstrated some biological features of HCC.

Recent advances in magnetic resonance imaging (MRI) have led to the establishment of fast scan techniques, which, combined with bolus injection of contrast material, allows the acquisition of dynamic enhanced MRI for higher confident detection of HCC^[3-5]. There have been reports on correlation among digital subtraction angiography (DSA), ultrasound angiography (USAG), computed tomography during arterial portography (CTAP) and immunohistochemical findings^[6], but the relationship between MVD and dynamic MRI has been seldom reported. In this research, correlation between MVD and dynamic enhanced MRI of hepatic malignant and benign lesions was studied in order to establish a theoretical foundation for microvessels evaluation within these lesions with MRI images, which will give more references to clinical diagnosis or HCC therapy.

MATERIALS AND METHODS

Tissue specimens

Tissue specimens were obtained at surgery from Eastern Hepatobiliary Surgery Institute, including 265 of HCC, 122 of cirrhosis tissue adjacent to carcinoma, 5 of hepatocellular adenoma and 17 of focal nodular hyperplasia (FNH). The 265 specimens of HCC included 45 of small HCC (tumor diameter ≤ 3 cm). All the case of HCC were graded by Edmondson-Steiner's pathological criteria into 3 groups: grades I-II (37 cases), grade III (218 cases) and grade IV (10 cases). All the specimens were fixed in 10% formalin and embedded in paraffin. All the pathologic diagnoses were confirmed by two the pathologists.

Constructing tissue microarray

For tissue microarray construction, a hematoxylin and eosin (H&E)-stained section was made from each block to define representative regions. With a tissue-microarray-constructor (Beecher Instruments, Silver Spring, MD), a hole (diameter = 6 mm) was punched into a recipient paraffin block, and then a cylindrical core sample (diameter = 6 mm), which had been punched from the donor tissue block, was deposited into the hole. This process was repeated till all the samples were deposited into the recipient block. After finishing the recipient block, multiple sections were cut from the block with a microtome.

Immunohistochemical staining and evaluation criteria

Avidin-biotin-peroxidase complex (ABC) method was used for immunohistochemical staining with monoclonal antibody CD-34 (Antibody Dignostic Inc., U.S.A.). After staining, the tubular, sinusoidal, cystiform or vacuolar structures shaped by endothelial cells or immature endothelial cells, which were stained yellow

or brown by CD34, were considered as positive microvessels. In high power microscopic views, all the positive microvessels were counted for MVD.

MRI technique

Forty-eight patients with 49 of the lesions underwent MRI examination before surgery, including 33 HCC (only one belonged to grade IV, and the others belonged to grade III and all diameters were ≤ 3 cm) and 16 benign lesions. MRI was performed with a 1.5 T system (Symphony, Siemens) and a phased array coil was used. All the patients underwent axial T1 weighted (fast low angle shot, FLASH, TR=123 ms, TE=4.8 ms), T2 weighted (half-fourier acquisition single-shot turbo spin echo, HASTE, TR=1 200 ms, TE=57 ms) and multiphase dynamic gadolinium-DTPA enhanced (the same sequence as T1 weighted) imaging. The section thickness was 8 mm, with an intersection gap of 0.5–2 mm. The contrast material dose was 0.2 mmol/kg b.w. and was administered as a rapid bolus. Arterial phase images were obtained in 15–20 s after the start of bolus administration. Portal venous and equilibrium phase images were obtained in the 45 s and 90 s, respectively.

Image analyses

In all the images, signal intensities of lesions (SI_l), liver parenchyma (SI_p) and background noise (SI_n) were evaluated, respectively. Signal-to-noise ratios (SNR) of lesions and parenchyma were both calculated as $SNR = SI_l / SI_n$. Contrast-to-noise ratios (CNR) in all the phases were calculated as $CNR = SNR_l - SNR_p$. Enhancement indexes (EI) of lesions in all the phases were calculated as $EI = (SNR_{\text{contrasted}} - SNR_{\text{uncontrasted}}) / SNR_{\text{uncontrasted}}$.

Statistical analyses

All data were analyzed by SPSS 9.0. Analysis of variance was used to determine significant differences of MVD among HCC, cirrhosis and benign lesion, of MVD of HCC among different pathological grades and tumor diameters, and of CNR between HCC and benign lesion among nonenhanced, arterial, portal venous and equilibrium phases. Pearson correlation was performed for correlation analysis among CNRs, EIs and MVD in arterial, portal venous and equilibrium phases of HCC or

benign lesion, respectively.

RESULTS

Outcome of tissue microarray constructing, immunohistochemical staining and MRI

Overview of a piece of tissue microarray is shown in Figure 1. Microvessel density stained by immunohistochemistry and dynamic MR images of HCC, hepatocellular adenoma and FNH are shown in Figures 2, 3 and 4, respectively.

Figure 1 Overview of a piece of tissue microarray including 234 samples (HE staining).

Table 1 MVD of malignant and benign liver lesions

	Number	MVD (mean \pm SD)
HCC	265	22.7 \pm 15.8 ^b
Cirrhosis	122	8.3 \pm 7.6
Benign lesion	22	31.3 \pm 22.7

^b $P < 0.01$ vs cirrhosis.

MVD of hepatic benign and malignant lesions

MVD of HCC was significantly higher than that of cirrhosis, but there was no significant difference between those of HCC and of benign lesions (Table 1).

Figure 2 HCC in right lobar of liver. A: Microvessel density, stained by CD34 (Original magnification: $\times 200$); B: MR image, T1 weighted, nonenhanced, CNR=-1.50; C: MR image, arterial phase, CNR=11.00; D: MR image, portal venous phase, CNR=10.50; E: MR image, equilibrium phase, CNR=-6.00.

Figure 3 Hepatocellular adenoma in right lobar of liver. A: Microvessel density, stained by CD34 (Original magnification: $\times 200$); B: MR image, T1 weighted, nonenhanced, CNR=-0.10; C: MR image, arterial phase, CNR=16.93; D: MR image, portal venous phase, CNR=9.42; E: MR image, equilibrium phase, CNR=6.42.

Figure 4 FNH in left inner lobar of liver. A: Microvessel density, stained by CD34 (Original magnification: $\times 200$); B: MR image, T1 weighted, nonenhanced, CNR=-3.48; C: MR image, arterial phase, CNR=15.43; D: MR image, portal venous phase, CNR=5.81; E: MR image, equilibrium phase, CNR=2.97.

MVD of HCC among different pathological grades and tumor sizes

MVD of grades I-II was 29.9 ± 18.6 (mean \pm SD), which was much higher than those of grade III (22.2 ± 18.2 , $P < 0.01$) and grade IV (22.9 ± 19.0 , $P < 0.01$). There was no significant difference in MVD between small HCC (26.1 ± 15.3) and those HCC whose diameters were more than 3 cm (22.1 ± 15.8).

CNR of HCC and benign lesion in all the phases

CNRs of HCC and benign lesion in T1 weighted nonenhanced, arterial, portal venous and equilibrium phases are shown in

Table 2. There was significant difference among all the phases ($F = 9.761$, $P < 0.001$), but no significant difference among nonenhanced, portal venous and equilibrium phases ($P = 0.279$) or between HCC and benign lesion ($F = 0.380$, $P = 0.539$).

Correlation between MVD and CNRs

Forty-eight patients with 49 of the lesions underwent MRI examination before surgery, including 33 HCC (only one belonged to grade IV, and the others belonged to grade III and all the diameters were ≤ 3 cm) and 16 benign lesions. Pearson

Correlation coefficients among MVD and CNRs of HCC in arterial, portal venous and equilibrium phases were 0.409 ($P=0.018$), 0.264 ($P=0.138$) and 0.212 ($P=0.236$), respectively, while Pearson Correlation coefficients between MVD and CNRs of benign lesions in arterial, portal venous and equilibrium phases were 0.599 ($P=0.014$), 0.581 ($P=0.018$) and 0.540 ($P=0.031$), respectively.

Table 2 CNR of HCC and benign lesion (mean \pm SD)

	Nonenhanced	Arterial phase	Portal venous phase	Equilibrium phases
HCC				
(n=33)	-2.86 \pm 2.94	3.88 \pm 5.63	-1.43 \pm 8.39	-1.08 \pm 2.80
Benign lesion				
(n=16)	-2.91 \pm 2.79	2.12 \pm 9.08	-2.05 \pm 8.56	-0.92 \pm 6.59

Correlation between MVD and EIs

Pearson Correlation coefficients between MVD and EIs of the 33 specimens of HCC in arterial, portal venous and equilibrium phases were 0.155 ($P=0.389$), 0.072 ($P=0.692$) and -0.122 ($P=0.497$), respectively, while Pearson Correlation coefficients between MVD and EIs of the 16 specimens of benign lesions in arterial, portal venous and equilibrium phases were 0.077 ($P=0.776$), 0.180 ($P=0.506$) and -0.062 ($P=0.821$), respectively.

DISCUSSION

Utilization of tissue microarray technique in detecting nucleic acid and protein has recently made great progress in basic research of tumor. A large number of samples in one section of tissue microarray can be stained under the same pre-treatment condition, the same antibody titer and the same detection systems. And reproducibility of the staining reaction, as well as the speed and reliability of the interpretation, is improved, since all the samples are on the same slide^[7,8]. Then, quickly and efficiently scanning a great number of specimens with tissue microarray can reduce mistakes not only from sample selecting and statistical analysis but also from tumor heterogeneity. In MVD counting, utilization of tissue microarray can standardize sample areas and overcome manual deviation. In this research, tissue microarray technique, combined with immunohistochemistry, was used to study difference of MVD between malignant and benign hepatic lesions in order to further demonstrate some biological features of these lesions.

CD34, which is expressed in blood stem cells and neovessel endothelial cells, is the most distinctive marker for demonstrating vessel endothelial cells^[9,10], especially for demonstrating sinusoid-like vessels in tumor tissues^[11,12]. Angiogenesis is very common within normal and pathologic tissues and is regulated by many factors, such as hypoxia-inducible factor 1 α (HIF-1 α), vascular endothelial growth factor (VEGF), human macrophage metalloelastase (HME), basic fibroblast growth factor (bFGF) and so on^[13-16]. Vessels, as an important part of tumorous interstitial tissue, interact with tumor cells to construct microenvironment of tumor. Researches showed that angiogenesis plays an important role in tumor invasion^[17], MVD is a novel prognostic marker in patients after resection of small HCC^[11,18-20], and high expression of CD34-positive sinusoidal endothelial cells is a risk factor for HCC in patients with chronic liver diseases^[21]. Sun *et al.*^[18] reported that MVD level was not related to tumor size, capsule status, Edmondson-Steiner's grade, alpha-fetoprotein (AFP) level, associated cirrhosis, gamma-glutamyltransferase and serum HBsAg status. Yamamoto *et al.*^[22] demonstrated that sinusoidal capillarization occurring in well-differentiated HCC is related to dedifferentiation of parenchymal tumor cells, but not to tumor size. But some reports showed that tumor size, poor differentiation and portal invasion are significantly related to MVD^[11,23]. In this research,

MVD of HCC was significantly higher than that of cirrhosis, but there was no significant difference between those of HCC and of benign lesion, which probably means that microvessels play an important role not only in occurrence and development of HCC, but also in some other benign lesions, thus may be helpful to identify malignant lesions or precancerous lesions (for example, high-grade dysplastic nodule) from regenerative nodules or low-grade dysplastic nodules^[24,25]. MVD in grades I-II was higher than those in grade III and grade IV, suggesting that angiogenesis is more active during the beginning of hepatocarcinogenesis.

DSA and CTAP have been used for assessing angiogenesis of HCC^[6], but these examinations are all invasive and expensive with dangerousnesses of ionized radiation and allergy induced by iodine contrast material. Shimizu *et al.*^[26] used xenon-enhanced CT to quantitatively measure tissue blood flow in HCC, but xenon is a kind of scarce gas. Compared with DSA, CTAP and xenon-enhanced CT, MRI is uninvase, safe, rapid, and cheap. Gadolinium has a strong hydrogen-proton spin-lattice relaxation effect, which will increase the signal intensity of adjacent tissue on T1 weighted images. The MRI contrast agent, gadolinium-DTPA, does not penetrate cell membrane and only diffuses into vascular space and interstitial space, which may reveal that the signal intensity of tissue on enhanced T1 weighted image is correlated with the vascularity. There have been reports on correlation of dynamic contrast enhancement MRI with MVD in prostate cancer and in breast cancer^[27,28]. With development of fast scan technique, rapid MRI is available to image the whole liver during the arterial phase^[29]. In this research, CNR in arterial phase, regardless of malignant or benign lesions, was correlative with MVD. Since MVD of HCC is much higher than that of cirrhosis, arterial phase images of MRI could be a useful method to distinguish HCC from regenerative nodules. Some reports have confirmed this view^[30,31]. In this research, CNR of HCC in portal venous or equilibrium phase was not correlated with MVD. This phenomenon probably demonstrates that CNR is regulated by many factors besides MVD. Reports have shown that with small HCC increasing in size and becoming increasingly dedifferentiated, the number of portal tracts apparently decreases and intratumoral arteriole develops^[22,23]. Because of portal tracts' decreasing and intratumoral arterioles' developing, there was no unified blood supply in HCC nodules, which would not demonstrate unified relationship between MVD and CNR in portal venous or equilibrium phase. There was no change of blood supply in benign nodules, so unified relationship between MVD and CNR in portal venous or equilibrium phase was demonstrated. CNR in arterial phase is mostly regulated by MVD, while in portal venous or equilibrium phase, blood supply plays a more important role. This hypothesis should be tested by advanced research.

In conclusion, angiogenesis is secondary to occurrence and development of benign and malignant tumors. Since dynamic MRI could evaluate microvessel of lesions, it is a very useful method to demonstrate HCC.

Abstract

AIM: To clone, identify and study new *NS5ATP2* gene and its spliced variant transactivated by hepatitis C virus non-structural protein 5A.

METHODS: On the basis of subtractive cDNA library of genes transactivated by NS5A protein of hepatitis C virus, the coding sequence of new gene and its spliced variant were obtained by bioinformatics method. Polymerase chain reaction (PCR) was conducted to amplify *NS5ATP2* gene.

RESULTS: The coding sequence of a new gene and its spliced variant were cloned and identified successfully.

CONCLUSION: A new gene has been recognized as the new target transactivated by HCV NS5A protein. These results brought some new clues for studying the biological functions of new genes and pathogenesis of the viral proteins.

INTRODUCTION

Hepatitis C virus (HCV) is the major causative agent of non-A, non-B hepatitis worldwide, which often leads to cirrhosis and an increased risk of hepatocellular carcinoma. The single-stranded RNA genome of HCV is a 9.6 kb-long positive-sense molecule, belonging to the *Flaviviridae* family. The viral genome encodes a single polyprotein precursor of approximately 3 010 amino acids, which is cleaved by both host and viral proteases to generate putative structural proteins (core, E1, and E2/p7) and the nonstructural proteins (NS2, NS3, NS4A, NS4B, NS5A, and NS5B)^[1-3]. The nonstructural protein 5A (NS5A) is a phosphoprotein consisting of 447 amino acid residues. NS5A exists in two

forms of polypeptide p56 and p58, which are phosphorylated mainly at serine residues both *in vitro* and *in vivo*^[4,5].

It was previously shown that NS5A could function as a transcriptional trans-activator. Although these reports implicate a functional role of NS5A in transcription, the exact nature of its role or the mechanism(s) involved in regulating the cellular transcription has not been investigated. NS5A is localized to the endocytosolic reticulum (ER), whereas transcriptional trans-activation traditionally requires the protein to be in the nucleus. The NS5A protein must participate in signal transduction pathways that are initiated in the cytoplasm where it resides^[6,7]. However, some studies show NS5A protein possesses a nuclear localization-like signal sequence and is present in the nuclear periplasmic membrane fraction related to transcription or translation^[8]. The present study shows NS5A protein has transactivating effect on SV40 early promoter.

MATERIALS AND METHODS

Plasmid construction

The HCV-NS5A sequences were generated by PCR amplification of HCV plasmid (HCV strain 1b). The plasmid contains coding sequences for all of the nonstructural proteins. The PCR conditions were as follows: 94 °C for 40 s. 10 ng of PCR product was cloned with pEGM-T vector (Promega). The primary structure of insert was confirmed by direct sequencing. To create pcDNA3.1 (-)-NS5A, the fragments of encoding NS5A were released from the pEGM-T-NS5A by digestion with *Eco*R I and *Kpn* I, and ligated to pcDNA3.1 (-)^[9].

Cell culture and transfection

The hepatoblastoma cell line HepG2 was propagated in DMEM supplemented with 10% FBS, 200 µmol/L L-glutamine, penicillin, and streptomycin. The HepG2 cells were plated at a density of 1×10^6 /well in 35-mm dishes. About 60-70% confluent HepG2 cells were cotransfected with plasmids pcDNA3.1 (-)-NS5A and pCAT3-promoter, transfected with pcDNA3.1 (-)-NS5A, pcDNA3.1 (-) with FuGENE 6(Roche).

Confirmation of protein expression of HCV-NS5A

Expression plasmid pcDNA3.1 (-)-NS5A was transfected using FuGENE 6 into HepG2 cells. The proteins expressed in these cells were analyzed on an immunoblot using the NS5A-specific antibody. The proteins were resolved by electrophoresis on a sodium dodecyl sulfate 125 g/L polyacrylamide gel. The lysate of cells transfected with expression vector pcDNA3.1 (-) served as negative control^[10].

CAT assay

Cells were then harvested after 48 h for CAT assay. Lysates of transfected cells were analyzed for CAT density using a commercial enzyme-linked immunosorbent assay (Roche Molecular Biochemicals). The absorbance of the samples was measured at 405 nm^[11].

RNA extraction and SSH

mRNAs from HepG2 cells transfected with plasmids pcDNA3.1

(-)-NS5A and pcDNA3.1(-) were extracted by using QuickPrep micro mRNA Purification Kit (Amersham Pharmacia). The amount of mRNA from two samples was 3-4 μ g.

SSH was performed with the cDNA Subtraction Kit (Clontech) according to the manufacturer's protocol. cDNA was synthesized from 2 μ g of poly A+RNA from two samples being compared. The cDNA from pcDNA3.1 (-)-NS5A acted as the tester, the cDNA from pcDNA3.1 (-) as the driver. The tester and driver cDNAs were digested with *Rsa* I, which yielded blunt ends. Two different PCR adaptors that could join only 5' ends DNA were ligated to different aliquots of tester DNA. These ligated DNAs were denatured, mixed with an excess of driver DNA (that had no adaptors), and allowed to anneal. The two DNA pools were then mixed together, and more denatured driver DNAs were added to further bind tester that was also present in the driver. Remaining complementary single strands of tester DNA were allowed to anneal, and the adaptor sequences were copied into their 3' ends. PCR was then performed to obtain exponential amplification of tester DNAs with different adaptors at each end. PCR amplifications products were directly purified by using Wizard PCR Preps DNA Purification System (Promega), and subcloned into pEGM-T easy vectors (Promega) to set up the subtractive library^[12,13].

New gene cloned

On the basis of subtractive cDNA library of genes transactivated by NS5A protein of hepatitis C virus, the coding sequence of a new gene, named NS5ATP2, was obtained by bioinformatics methods. The standard PCR cloning technique was used to amplify NS5ATP2 gene. Cytoplasmic RNA was isolated from HepG2 cells. RNA was used for RT-PCR as described previously, primers were: sense 5' -GGA TTC ATG GCT TCG GTC TCC TCT GC-3', antisense 5' -GGT ACC TCA GGA GTG TGG CTC ACT GG -3' (HepG2 cDNA). The PCR condition was as follows: at 94 °C for 60 s, at 60 °C for 60 s, at 72 °C for 60 s, for 30 cycles. The PCR product was cloned with pGEM-T vector (Promega). The primary structure of insert was confirmed by direct sequencing.

RESULTS

NS5A protein expressed in HepG2 cells

NS5A protein expressed in cells was analyzed by Western blot. The lysates of cells transfected with plasmid pcDNA3.1 (-)-NS5A were specifically detected by NS5A specific antibody (Figure 1).

Figure 1 Western blotting of NS5A protein expression in HepG2 cells. Lane 1: Expression plasmid pcDNA3.1 (-)-NS5A; Lane 2: Plasmid pcDNA3.1 (-)-vector.

Transactivating effect of NS5A on SV40 early promoter

To determine whether NS5A protein has transactivating effect, we constructed plasmid pcDNA3.1 (-)-NS5A, and HCV NS5A protein expressed in Hep G2 cells was detected by reverse transcription PCR (RT-PCR) and Western blotting. HepG2 cells were transiently cotransfected with pcDNA3.1 (-)-NS5A/pCAT3-promoter, pcDNA3.1(-)/pCAT3-promoter. Chloramphenicol acetyltransferase (CAT) activity in cells

that were cotransfected with pcDNA3.1 (-)-NS5A/pCAT3-promoter is shown in Figure 2.

Figure 2 Transactivation on SV40 promoter by NS5A. 1: Plasmid pcDNA3.1 (-)-NS5A was cotransfected with pCAT3-promoter in HepG2 cells. 2: Plasmid pcDNA3.1 (-) was cotransfected with pCAT3-promoter in HepG2 cells.

Construction of subtractive cDNA library

Our studies showed NS5A protein had transactivation effect on SV40 promoter. In order to investigate influence of NS5A protein on cells gene expression, Suppression subtraction hybridization (SSH) was introduced to establish subtractive cDNA library of HepG2 transfected with plasmid pcDNA3.1 (-)-NS5A. We performed the PCR experiment to analyse the ligation efficiency. The result showed that at least 25% of the cDNA had adaptors at both ends. The efficiency of subtraction was estimated by PCR experiment. The test was done by comparison of the abundance of G3PDH before and after subtraction. G3PDH primers were provided by the kit (Figure 3).

Figure 3 Reduction of G3PDH amount by PCR-selective subtraction. PCR was performed on unsubtracted (Lanes 1-4) and subtracted (Lanes 5-8) secondary PCR products with the G3PDH 5' and 3' primers. Lanes 1, 5: 18 cycles; Lanes 2,6: 23 cycles; Lanes 3,7: 28 cycles.

Figure 4 Map of colony PCR on 9 g/L agarose/EtBr gel.

After tester cDNA was hybridized with driver cDNA twice and underwent nested PCR twice, they were then subcloned into pGEM-T easy vectors to set up the subtractive library. Amplification of the library was carried out with *E. coli* strain JM109. The amplified library contained 121 positive clones.

Colony PCR showed that 115 clones contained 200-1 000 bp inserts (Figure 4). The nucleotide sequences of 90 clones from this cDNA library was analyzed, the full length sequences were obtained with Vector NTI 6 and BLAST database homology search (<http://www.ncbi.nlm.nih.gov/>). Altogether 44 kinds of coding sequences were obtained, consisting of 29 known and 15 unknown ones. Some genes code for proteins involved in cell cycle regulation, cell apoptosis, signal transduction pathway and tumour (Table 1).

Table 1 Sequence analysis of 46 clones isolated from subtractive cDNA library

Known genes	Number of clones	Homology (%)
Ribosomal protein	15	99
Eukaryotic translation initiation factor	4	99
HCV NS5A protein	4	98
Sentrin	4	99
Pro-oncosis receptor inducing membrane injury (Porimin)	3	100
Importin	3	98
Serine/threonine kinase	3	100
Cadherin-associated protein	2	100
Mitogen-activated protein kinase phosphatase	2	99
Adenylyl cyclase-associated protein	2	100
Serum response element	2	100
Rho GTPase activating protein	2	100
Fibronectin	3	99
Laminin	3	99
Lysophospholipase A2	2	100
Lysophospholipase B	2	100
Dual specificity phosphatase 6	1	99
Putative homeodomain transcription factor	2	92
Transcription factor B2	2	100
NF-E2-like basic leucine zipper	2	98
Transcriptional activator	2	98
Transcriptional elongation factor (TFIIS)	2	100
MHC-I binding protein	1	100
C response protein binding protein (CRPBP)	1	99
Integrin	2	99
Iron-regulated transporter (IREG)	1	99
Tumor associated protein L6	2	100
WW domain-containing protein 1 (WWP1)	1	100
Nascent polypeptide-associate complex α (NACA)	1	99
Thioredoxin reductase	1	99

Confirmation of new gene expression by RT-PCR

We found the spliced variant of NS5A-TP2 (Figures 5, 6). After EST database homology search (<http://www.ncbi.nlm.nih.gov/>), the locations of NS5A-TP2 and its spliced variant were detected on chromosome 6q22. 1-23. 3. The exons and introns of two new genes were compared (Figure 7). The direct sequencing showed we acquired the ORF of NS5A-TP2 (Figure 8).

DISCUSSION

Hepatitis C virus often causes persistent infection with a significant risk of end-stage cirrhosis and hepatocellular carcinoma. HCV may benefit by regulation of cellular genes leading to the disruption of normal cell growth. Viral genes can override cellular control mechanisms, which in untransformed cells regulate cell cycle progression in response to various antiproliferative signals. In HCV persistently infected cells, the continued presence of viral gene products is likely to be detrimental for host cells. Many studies demonstrated NS5A protein of HCV transcriptionally modulates cellular genes and promotes murine fibroblast cell growth into a tumorigenic phenotype. It may be possible that the NS5A protein plays a role in hepatocarcinogenesis, since many other viral proteins that play a role in carcinogenesis often function as transcriptional activators^[14-17]. However, the precise mechanism is still unknown.

In the present study, we investigated the possible mechanism by which NS5A protein transactivated gene expression and its role in hepatocarcinogenesis. NS5A protein in Hep G2 cells was detected by RT-PCR and Western blotting. HepG2 cells were transiently cotransfected with pcDNA3.1 (-)-NS5A/pCAT3-promoter. CAT activity was evidently higher in the cotransfected cells than in control. It is suggested that NS5A protein has transactivating effect on SV40 early promoter. We predicted that NS5A protein transcriptionally regulated gene expression through regulating promoter activity, either directly or through signal transduction pathways.

On the basis of this study, we constructed subtractive cDNA library by SSH. After sequencing analysis, we obtained coding sequences of 46 genes, which consisted of 26 kinds of known and 15 kinds of unknown ones. Some genes code for proteins involved in cell cycle regulation, cell apoptosis, and tumor angiogenesis. Sentrin is a 101-amino acid ubiquitin-like protein that interacts with the death domains of Fas and TNFR1, with PML, a tumor suppressor implicated in the pathogenesis of promyelocytic leukemia, with Rad51 and Rad52, proteins that are involved in repairing double-stranded DNA breaks, and with RanGAP1, a GTPase-activating protein that is critically involved in nuclear protein transport^[18-20]. Overexpression of sentrin in mammalian cells protects them against anti-Fas or tumor necrosis factor-induced cell death^[21]. Porimin is a highly glycosylated protein that can be classified as a member of the cell membrane-associated mucin family^[22]. Porimin is a membrane mucin that mediates cell death. Although mucins mainly affect cell adhesion and ligand binding, several membrane mucins have also been documented to trigger cell death or inhibit cell proliferation, such as CD43 (leukosialin, sialophorin), CD162 (PSGL-1), and CD164 (MGC-24v)^[23]. Likewise, serine/threonine kinase, cadherin-associated protein, adenylyl cyclase-associated protein, mitogen-activated protein kinase phosphatase involving in cell cycle regulation, and cell growth may be correlated with hepatocarcinogenesis of NS5A protein^[24-28].

Alternative pre-mRNA splicing is a fundamental mechanism for differential gene expression that has been reported to regulate the tissue distribution, the intracellular localization, and the activity of different protein kinases. In the process of our study on new genes, we accidentally acquired the spliced variant of NS5A-TP2 and confirmed the ORF of NS5A-TP2 (516) and its location on chromosome. Both of NS5A-TP2 (615) and its spliced variant- NS5A-TP2 (516) locate on 6q22.1-23.3, but they have different exons and introns^[29-31].

The result of this study shows that the NS5A protein is a potent transcriptional activator and transactivates some genes involved in cell cycle regulation, cell apoptosis, and tumor angiogenesis. The study on new genes NS5A-TP2 (516), and

NS5A-TP2 (615) brings some new clues to the biological functions of novel genes and pathogenesis of the viral proteins.

Abstract

AIM: To study interactions between hepatitis B virus (HBV) and interferon- α in liver- derived cells.

METHODS: mRNAs were separately isolated from an HBV-transfected cell line (HepG₂2.2.15) and its parental cell line (HepG₂) pre- and post-interferon- α (IFN- α) treatment at 6, 24 and 48 h, followed by hybridization with a cDNA microarray filter dotted with 14 000 human genes. After hybridization and scanning of the arrays, the data were analyzed using ArrayGauge software. The microarray data were further verified by Northern blot analysis.

RESULTS: Compared to HepG₂ cells, 14 genes with known functions were down-regulated 3 to 12- magnitudes, while 7 genes were up-regulated 3-13 magnitudes in HepG₂2.2.15 cells prior to IFN- α treatment. After interferon- α treatment, the expression of four genes (vascular endothelial growth factor, tyrosine phosphate 1E, serine protein with IGF-binding motif and one gene of clathrin light chain) in HepG₂2.2.15 were up-regulated, while one gene encoding a GTP-binding protein, two genes of interferon-induced kinases and two proto-oncogenes were further down- regulated. Interestingly, under IFN- α treatment, a number of differentially regulated genes were new ESTs or genes with unknown functions.

CONCLUSION: The up-regulated genes in HepG₂2.2.15 cell line suggested that under IFN- α treatment, these repressed cellular genes in HBV infected hepatocytes could be partially restored, while the down- regulated genes were most likely the cellular genes which could not be restored under interferon treatment. These down-regulated genes identified by microarray analysis could serve as new targets for anti-HBV drug development or for novel therapies.

INTRODUCTION

Viral hepatitis B continues to be a significant global problem. It is estimated that there are approximately 350 million chronic hepatitis B virus (HBV) carriers world-wide. Furthermore, chronic hepatitis B patients are at high risk of developing liver cirrhosis and hepatocellular carcinoma with high mortality rates.

In the past two decades, interferon- α (IFN- α) has proven effective in the treatment of chronic hepatitis B patients. However, sustained responses were observed in only one-third of chronic hepatitis B patients^[1-3]. In the normal physiological state, interferon- α is expressed at a low level and is induced to high levels by viral or bacterial infections and the exposure to double-stranded RNA^[4]. In contrast to other types of viral infections, IFN- α was either non-detectable or present in extremely low levels in HBV chronically infected patients^[5,6]. Additionally, decreased synthesis of 2' -5' A synthetase, belonging to a family of enzymes induced by IFNs, has been reported in chronic hepatitis B patients^[7,8]. To date, mechanisms underlying defective production of IFN or defective responses to IFN in chronic hepatitis B patients have not been fully elucidated.

Development of microarray technology has provided a powerful tool for study of the complicated biological process in cells which results in altered global gene expression. cDNA microarray has been used to analyze virus-host cell interactions in Human Immunodeficiency Virus (HIV), Human Cytomegalovirus (HCMV), Herpes Simplex Virus (HSV) and Influenza Virus infected cell cultures^[9-13]. By comparing virus infected cell cultures with non-infected cell cultures, a number of differentially expressed genes were identified. For HBV, although several studies have been undertaken to clarify the effects of HBV infection on hepatocytes^[14-16], the global effects of all HBV proteins or HBV replication on host cells, especially the interaction between HBV and interferon remain unclear. Therefore, in this study, cDNA microarray filters dotted with 14 000 human genes were used to analyze transcriptional changes between an HBV DNA-transfected cell line (HepG₂2.2.15)^[17,18] and its parental cell line (HepG₂) pre- and post- IFN treatment. Based on analysis of altered mRNA expression, several IFN-differentially regulated genes including new ESTs or genes with unknown functions were further investigated for their potential antiviral activity.

MATERIALS AND METHODS

Cell culture

The HBV DNA transfected hepatoblastoma cell line HepG₂2.2.15, that has been confirmed to produce infectious virus^[18,19], and its parental cell line HepG₂ were maintained in Dulbecco's modified Eagle's medium supplemented with 10 mL/L fetal calf serum and antibiotics. The cells were incubated at 37 °C in 50 mL/LCO₂. Cell viability was estimated by the trypan blue dye exclusion method.

Preparation of cell samples for cDNA microarray

The cells were separately seeded into T-75 flasks at 40%

confluence (4×10^4 cells/cm²) one day prior to the experiment. After overnight culture, two flasks of cells for each cell line were harvested before treatment with IFN- α for RNA preparation and were regarded as 0 h cells for IFN- α treatment. The other cells were exposed to 5×10^3 IU/mL of IFN- α (Calbiochem, San Diego, CA, USA) and harvested 6, 24 and 48 h after IFN- α treatment. The culture media were removed and stored at -70 °C. For each flask of cells, 5 mL of TRIzol Reagent (Gibco BRL) was added directly into the flask.

RNA extraction

Total RNA was extracted using standard TRIzol RNA isolation protocol (Gibco BRL). The isolated total RNA was divided into two aliquots, one for RNA slot analysis and the other for mRNA preparation.

Generation of microarray

Generation of microarrays and microarray analysis were carried out by the Institute of Biochemistry and Cell Biology, CAS as described previously^[20]. Human cDNA clones were derived from liver, hepatocarcinoma cell lines and hypothalamus-pituitary-adrenal libraries^[21] or purchased from Research Genetics (Huntsville, AL, USA). A cDNA array was assembled with 14 000 cDNA clones representing the same number of independent cDNA clusters, of which 7 565 clusters were homologous to that in the UniGene Database. All cDNA fragments were amplified and verified by gel electrophoresis and sequencing. The average length of the cDNA fragments was -1 kb. PCR products were precipitated in isopropanol, redissolved in 10 μ L of denaturing buffer (1.5 mol/L NaCl, 0.5 mol/L NaOH) and spotted onto 8 \times 12 cm Hybond-N nylon membranes (Amersham Pharmacia, Buckinghamshire, UK) using an arrayer (BioRobotics, Cambridge, UK). Each spot carried -100 nL in volume and was 0.4 mm in diameter; each cDNA fragment was spotted as two different spots (double-offset). Lambda phage and pUC18 vector DNA were spotted as negative controls.

Eight housekeeping genes encoding ribosomal protein S9 (RPS9), β -actin (ACTB), glyceraldehydes-3-phosphate dehydrogenase, hypoxanthine phosphoribosyltransferase 1, M_r 23 000 highly basic protein (RPL13A), ubiquitin C, phospholipase A2, and ubiquitin thiolesterase (UCHL1) were each evenly distributed in 12 spots on each 8 \times 12 cm array as an intramembrane control. Hybridization data were considered invalid if the intensity of the darkest spot exceeded 1.5 times that of the weakest spot among the 12 spots representing the same gene.

mRNA isolation and probe preparation

The poly (A)⁺ mRNA was isolated from the total RNA using a poly (dT) resin (Qiagen, Hilden, Germany). Approximately 1 - 2 μ g of mRNA were labeled in a reverse transcription reaction in the presence of 200 μ Ci [α^{32} P] deoxyadenosine 5' -triphosphate (DuPont NEN, Boston, MA, USA) using Moloney murine leukemia virus reverse transcriptase as recommended by the manufacturer (Promega Corp., Madison, WI, USA).

Hybridization and Image Procession

Prehybridization was carried out in 20 mL of prehybridization

solution (6 \times SSC, 5 g/L SDS, 5 \times Denhardt's and 100 μ g/mL denatured salmon sperm DNA) at 68 °C for 3 h. Overnight hybridization with the 32 P-labeled cDNA in 6 mL of hybridization solution (6 \times SSC, 5 g/L SDS, and 100 μ g/mL denatured salmon sperm DNA) was followed by stringent washing (0.1 \times SSC, 5 g/L SDS, at 65 °C for 1 h). Membranes were exposed to Phosphor Screen overnight and scanned with an FLA-3 000A Plate/Fluorescent Image Analyzer (Fuji Photo Film, Tokyo, Japan). Radioactive intensity of each spot was linearly digitalized to 65 536 gray-grade in a pixel size of 50 μ m in the Image Reader and recorded using the Array Gauge software (Fuji Photo Film, Tokyo, Japan). After subtraction of background (3 ± 3) chosen from an area where no cDNA was spotted, genes with intensities >10 were considered as positive signals to ensure that they were distinguished from background with statistical significance >99.9%. Normalization among arrays was based on the sum of background-subtracted signals from all genes on the membrane^[22].

RNA slot analysis

Total cellular RNA, 10 μ g/sample was mixed with 7 μ L formaldehyde, 20 μ L formamide and 2 μ L 20 \times SSC (1 \times SSC=0.15 mol/L NaCl plus 0.015 mol/L sodium citrate). After being denatured at 65 °C for 15 min and immediately cooled in an ice bath, the RNA sample was applied to the nylon membrane (Boehringer Mannheim, Germany) with Minifold I (Schleicher & Schuell). After fixation at 120 °C for 30 min, the membrane was pre-hybridized in 20 mL of prehybridization solution (6 \times SSC, 5 g/L SDS, 5 \times Denhardt's and 100 μ g/mL denatured salmon sperm DNA) at 42 °C for 6 h, and followed by hybridization with 20 mL hybridization solution (6 \times SSC, 5 g/L SDS, 5 \times Denhardt's and 100 μ g/mL denatured salmon sperm DNA) including [α^{32} P]dCTP labeled cDNA probes (Random labeling kit, Boehringer Mannheim, Germany) at 42 °C for 16 h. The cDNA probes represented the unique sequence of IFN related P27, KIAA0919, beta3gal-T5 and FLJ12673. After stringent membrane washing process (0.1 \times SSC, 5 g/L SDS at 68 °C for 30 min, thrice), autoradiographs were exposed to X-ray film (Fijifilm, Japan) overnight at -70 °C. Quantitative analysis was undertaken by scanning the intensity of the membranes. In order to normalize the total RNA quantity in each blot, an [α^{32} -P]dCTP labeled β -actin probe was hybridized to the membrane again after the first probe was removed. The change of regulated gene expression between different cell samples could be detected by comparing the intensity ratio of specific gene and β -actin.

RESULTS

Validation of microarray results

Similar to previous study, results from the reproducible analysis confirmed that the replicated experiments were in concordance with an R^2 (square of Pearson correlation coefficient, measuring similarity in gene expression pattern) of 0.97-0.98 on scatterplot^[20].

To confirm the altered expression level, 4 genes (interferon related genes P27, KIAA0919, β -3-gal-T5 gene and FLJ12673 human cDNA clone) were selected and tested by RNA slot

analysis (Figure 1). The ratios of the signal intensity of specific genes and β -actin and their comparison with microarray result are listed in Table 1. It is observed that the results of RNA slot analysis are aligned with those from the microarray analyses (Figure 1 and Table 1).

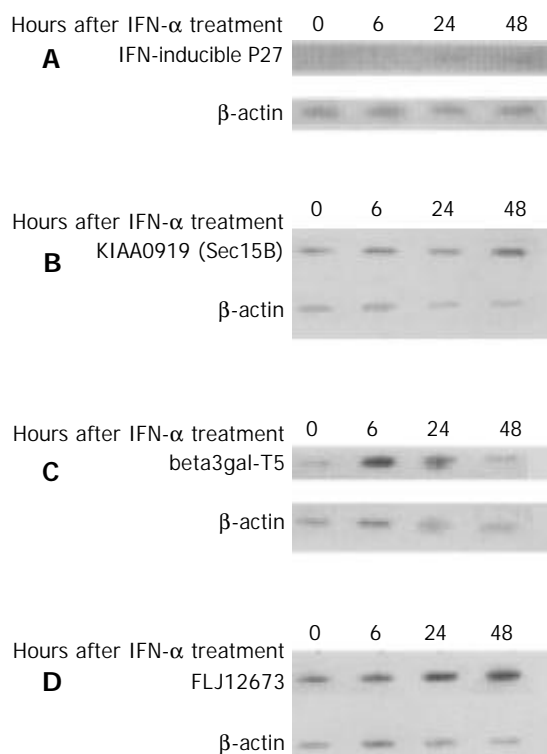

Figure 1 RNA slot analyses of IFN-inducible P27, KIAA0919 (Sec15B), beta3gal-T5 and FLJ12673 genes in HepG₂.2.2.15 before and after IFN treatment. Four genes (interferon related genes P27, KIAA0919, β -3-gal-T5 gene and FLJ12673 human cDNA clone) were selected and tested by RNA slot analysis to confirm the altered expression level indicated by the results of the microarrays. 10 μ g/sample total cellular RNA was blotted to the nylon membrane. The membrane was then hybridized with [α -³²P]dCTP labeled cDNA probes. Autoradiographs were exposed to X-ray film overnight at -70 °C. The β -actin gene was used as the control to normalize the total RNA quantity.

Differentially expressed genes in HepG₂.2.2.15 cell line and HepG₂ cell line prior to IFN- α treatment

To study the basic differentially expressed genes between HepG₂.2.2.15 cell line and its parental cell line HepG₂, systematic comparison of gene expression profiles from both cell lines before treatment with IFN- α was done at 0 h. Totally 89 genes were either up- or down-regulated three-fold (Table 2). In these 89 genes, 22 genes have defined functional activities (Table 3) while 67 genes were new ESTs with unknown functions. Fifteen of the 22 known genes were down-regulated by three- to twelve-fold, while 7 genes were up-regulated by three- to thirteen-fold. 4 genes could be catalogued in four classes, such as cell cycle (Y13467), ligands and receptors (AF022375), phosphatase (U12128), and transcription factors (D87258).

Table 2 Gene expression profiling in the microarray analysis

5	10	18	12	37	37	23	27	12	8	11

Differentially regulated genes in HepG₂.2.2.15 cell line and HepG₂ after IFN- α treatment

Six hours after treatment with interferon- α , significant changes in mRNA expression were observed in both HepG₂ and HepG₂.2.2.15 cells, with 83 and 34 genes up- or down-regulated by at least three-fold (Table 2). A moderate increase in changes of cellular gene expression was detected at 24 h, at which time, 103 and 48 genes were up- or down-regulated respectively by at least three-fold (Table 2). Approximately half of these genes could be classified in functional categories, including interferon responsive proteins, signal transducing genes such as kinase, phosphatase and ligand as well as receptors (Table 4). It is interesting to note that the number of differentially expressed cellular genes in HepG₂ and HepG₂.2.2.15 cell lines could be decreased by interferon- α treatment from 89 to 40, 33 and 36 genes at 6, 24, 48 h post treatment (Table 2). The differentially regulated gene expressed profile in HepG₂.2.2.15 and HepG₂ cell lines after IFN- α treatment are available at <http://www.mvlab-fudan.cn/microarray> databases.

Kinetics of IFN-treated gene expression profile in 23 genes from HepG₂ and HepG₂.2.2.15 cell lines

Twenty three selected genes, belonging catalogues of interferon induced proteins kinase/phosphatase, ligands and receptors, phosphatase, protein degradation, viral and clathrin receptors, protooncogenes and transcription factors respectively, were further compared between HepG₂.2.2.15 and its parental cell line HepG₂ to study the effect of interferon- α treatment on HBV and cellular gene expressions (Table 5). From this table, it is noted that most of these selected genes with known functions have two- three-fold expression regulated in both HepG₂ cell line and HepG₂.2.2.15 cell post interferon treatment. However, five genes (U02680, U07358, U52969, U50529 and U70321), were up-regulated only in HepG₂ cell line, while down-regulated in HepG₂.2.2.15 cells.

DISCUSSION

DNA microarray is an important and powerful tool for surveying changes in cellular gene expression on a large scale. Several groups have used this approach to analyze virus-host cell interactions in HBV infection. Rho *et al.* constructed a HepG₂ cell line stably expressing HBx (HepG₂-HBx), and performed cDNA microarray analysis on 588 cellular cDNAs to study the effect of HBx on the transcriptional regulation in the human liver cell^[15]. To gain more information on how HBV proteins regulate host cellular gene expression, Otsuka *et al.* examined the differences in the gene expression profiles of HepG₂.2.2.15 and HepG₂ cells, using an in-house cDNA microarray dotted with 2 304 cellular genes^[16]. To identify hepatocellular genes whose transcriptional regulation is tightly linked with IFN- γ and IFN- α / β -mediated inhibition of HBV replication, Chisari *et al.* used DNA microarrays and a high-throughput cDNA differential display method (total gene expression analysis (TOGA)) to examine the gene expression profiles of HBV transgenic mouse livers before and after the intrahepatic induction of IFN- α / β and IFN- γ ^[23]. To further understand molecular mechanisms underlying HBV pathogenesis and identify novel cellular genes as new targets for anti-HBV drug development or for novel

therapies, we used cDNA microarray filters dotted with 14 000 human genes to analyze transcriptional changes between an HBV DNA-transfected cell line (HepG₂ 2.2.15) and its parental cell line (HepG₂) pre- and post-IFN treatment. The HepG₂ 2.2.15 cell line, that has four copies of HBV genome integrated in the cellular chromosome and can persistently secrete HBV virions, was used for HBV infected liver-derived cells^[17,18]. The parental hepatoblastoma cell line, HepG₂, from which HepG₂ 2.2.15 cell line was generated, was used as the uninfected cell control. In this study, the differentially expressed cellular genes detected between these two cell lines could be due to the integration of

HBV DNA, the replication of HBV or the expression of HBV proteins. In chronic HBV infections, the virus usually persists in hepatocytes similar to the status of HBV in HepG₂ 2.2.15 cell line; the differentially expressed cellular genes in HepG₂ 2.2.15 cell line could reveal similar changes in the hepatocytes of HBV chronically infected patients.

Prior to interferon- α treatment, compared to HepG₂ cells, 15 known genes were more than three-fold down-regulated, while 7 genes were more than 3-fold up-regulated (Table 3) in HepG₂ 2.2.15 cells. To concentrate on the down-regulated genes, 4 genes belonging to the categories of cell cycle, ligands and receptors,

phosphatase and transcription factors were down-regulated more than three-fold in HepG₂.2.2.15 cells (Table 3). In a microarray study on HCMV-host cell interactions compared to non-infected human fibroblasts, down-regulated genes belonging to these categories were also reported in HCMV infected cells^[10]. Though identical down-regulated genes from these categories were not found in the HCMV infected and HBV transfected cells, changes in the expression of cellular genes in these categories could reflect the common adverse effects of virus infections on host cells. In future studies, when more microarray analyses on virus-host interactions will be performed, it may be possible to identify significant changes of cellular gene expression due to HBV-hepatocyte interactions.

The effects of IFN- α on the global gene expression of HepG₂ and HepG₂.2.2.15 cells revealed interesting differences (data available at <http://www.mvlab-fudan.cn/microarray/databases>). In HepG₂ cells, compared with the expression of cellular genes at 0 h, no known gene was three-fold down-regulated 48 hr after IFN- α treatment. In contrast, 21 genes were up-regulated three-fold or more, and among these, five were IFN-induced genes, one belonging to the GTP-binding protein and signal transduction category, and one belonging to the phosphatase and phosphodiesterase category associated with the IFN-induced cascade. In HepG₂.2.2.15 cells, after being treated with IFN- α for 48 h, eight genes remained down-regulated three-fold or more. In comparison to the known functional genes, one gene was predicted as encoding the regulatory G protein

beta subunit, one was predicted as encoding an antigen of B cell differentiation, one encoding the thymosin beta 4Y isoform, one encoding a LDL-receptor related protein, which was also reported as encoding a human IFN- γ receptor, and one was an exon encoding a protein of the phosphatase and phosphodiesterase category, and the other 3 genes belonged to coagulation, mitochondrial and miscellaneous categories, respectively. These genes remained down-regulated and thus seemed refractory to the treatment of IFN- α . Since 2 of these genes are associated with thymosin and IFN- γ , microarray studies of HepG₂.2.2.15 cells treated with IFN- γ and/or cytokines may be able to elucidate whether these defects in cellular functions could be reversed. In HepG₂.2.2.15 cells, a number of IFN induced genes were up-regulated post IFN- α treatment; among these, genes p27 and 2' -5' A synthetase E were the top two up-regulated genes, being 6.1 and 9.1 respectively. Compared to the increases in these two genes up-regulated in HepG₂ (being 7.1 and 8.4 respectively), IFN- α was as effective in inducing these two genes in HBV infected cells as that in the uninfected hepatocytes.

To analyze whether there were HBV specific down-regulated cellular genes, which could be restored by IFN- α treatment, 23 matched genes from HepG₂ and HepG₂.2.2.15 cell lines were compared post IFN- α treatment. As shown in Table 5, the three genes which were found down-regulated in HepG₂.2.2.15 prior to IFN- α treatment (Table 3), namely described as encoding vascular endothelial growth factor, tyrosine phosphatase 1E,

serine protease with IGF-binding motif were all up-regulated by IFN- α treatment. In addition, a gene described as coding for clathrin light chain, which belongs to the viral and clathrin receptor category was also up-regulated 5.2 times. However, even after IFN- α treatment, the down-regulated protein kinase zpk and protein tyrosine kinase genes could not be restored (Table 5), which suggested a possible defective link in the IFN- α induced cascade. Measures for restoring the functions of the kinases could help to improve the therapeutic efficacy of IFN- α . The clinical implications of non-restorable down-regulated protooncogenes in HepG₂ 2.2.15 cell lines merit further study.

Analysis of gene expression profiles in HBV-hepatocyte interaction by microarray is an interesting field. The information gathered in this study, though preliminary in scope, provides an important basis for further study. The differentially expressed genes detected in this study should be further evaluated by cell transfection or by *in vivo* studies and should provide new insight into the molecular mechanisms of HBV infection. In addition, there were approximately 200 unknown genes or ESTs being up- or down-regulated in HepG₂ 2.2.15 cells. Preliminary transiently co-transfected functional assay has already shown that some of cellular genes significantly regulated by HBV infection and IFN are associated with the inhibition of HBV gene replication and expression (data not shown). It is predicted that other IFN-inducible proteins could be discovered and new mechanisms of this cytokine may be revealed.

Abstract

AIM: To investigate the transactivating effect of hepatitis C virus (HCV) core protein and to screen genes transactivated by HCV core protein.

METHODS: pcDNA3.1(-)-core containing full-length HCV core gene was constructed by insertion of HCV core gene into *EcoRI/BamHI* site. HepG2 cells were cotransfected with pcDNA3.1(-)-core and pSV-lacZ. After 48 h, cells were collected and detected for the expression of β -gal by an enzyme-linked immunosorbent assay (ELISA) kit. HepG2 cells were transiently transfected with pcDNA3.1(-)-core using Lipofectamine reagent. Cells were collected and total mRNA was isolated. A subtracted cDNA library was generated and constructed into a pGEM-Teasy vector. The library was amplified with *E. coli* strain JM109. The cDNAs were sequenced and analyzed in GenBank with BLAST search after polymerase chain reaction (PCR).

RESULTS: The core mRNA and protein could be detected in HepG2 cell lysate which was transfected by the pcDNA3.1(-)-core. The activity of β -galactosidase in HepG2 cells transfected by the pcDNA3.1(-)-core was 5.4 times higher than that of HepG2 cells transfected by control plasmid. The subtractive library of genes transactivated by HCV core protein was constructed successfully. The amplified library contained 233 positive clones. Colony PCR showed that 213 clones contained 100-1 000 bp inserts. Sequence analysis was performed in 63 clones. Six of the sequences were unknown genes. The full length sequences were obtained with bioinformatics method, accepted by GenBank. It was suggested that six novel cDNA sequences might be target genes transactivated by HCV core protein.

CONCLUSION: The core protein of HCV has transactivating effects on SV40 early promoter/enhancer. A total of 63 clones from cDNA library were randomly chosen and sequenced. Using the BLAST program at the National Center for Biotechnology Information, six of the sequences were unknown genes. The other 57 sequences were highly similar to known genes.

INTRODUCTION

Hepatitis C virus (HCV) is a major causative agent of chronic liver diseases including chronic hepatitis, liver cirrhosis, and hepatocellular carcinoma worldwide^[1-4]. The majority of individuals infected with HCV cannot resolve their infection and suffer from persistent chronic hepatitis. The molecular mechanism of HCV persistence and pathogenesis is not well understood. HCV contains a single-stranded positive-sense RNA genome which encodes a precursor polypeptide of approximately 3 000 amino acids. After translation, a capsid protein (core), envelope glycoproteins (E1 and E2), and nonstructural proteins (NS2, NS3a, NS3b, NS4A, NS4B, NS5A, and NS5B) are processed from the polyprotein by cellular and viral proteases^[5-10].

HCV core gene contains the most conserved sequences in the coding region of most HCV genotypes, which implies an important biological function. Since suitable viral culture systems are not generally available^[10-13], analysis of HCV genome organization and viral-product function is important to understand the viral life cycle and the pathogenesis of HCV infection. In order to understand the pathogenesis of HCV infection, we investigated the transactivating effect of HCV core protein.

MATERIALS AND METHODS

Construction and identification of expression vectors

pcDNA3.1(-)-core containing full-length HCV core gene was constructed by insertion of HCV core gene into *EcoRI/BamHI* site, which could directly express core protein. pcDNA3.1(-) was obtained from Invitrogen. The gene was identified by PCR and digested by *EcoR* I, *BamH* I, and *Hind* III (Takara). PCR primers were: up primer, 5' -GAA TTC AAT GAG CAC GAA TCC TAA-3'; down primer, 5' -GGA TCC AGG CTG AAG CGG GCA CA-3' (Shanghai BioAsia Biotechnology Co., Ltd).

Cotransfection with reporter vectors pSV-lacZ

HepG2 cells were transfected by various concentrations of pSV-lacZ (0.1-1.8 μ g) (Promega). Expression of β -gal was detected by using β -gal assay kit (Promega). The best concentration of pSV-lacZ was selected, HepG2 cells with pcDNA3.1(-)-core and pSV-lacZ were cotransfected. At the same time, HepG2 cells were cotransfected with empty pcDNA3.1(-) and pSV-lacZ as control. After 48 h, cells were collected and the expression of β -gal was detected.

Expression of pcDNA3.1(-)-core in HepG2 cells

HepG2 cells were transiently transfected with pcDNA3.1(-)-core using Lipofectamine. At the same time, empty vectors were also transfected into cells as control. HepG2 cells were

plated at a density of 1×10^6 on a 35 mm plate in RPMI1640 containing 100 U/mL of penicillin, 100 μ g/mL of streptomycin, and 100 mL/L heat-inactivated FBS. After 24 h of growth to 40-50% confluence, the cells were transfected with plasmids by using Lipofectamine according to the manufacturer's protocol (Gibco Co.).

mRNA and cDNA isolation

Total cellular RNA was isolated using TRIzol (Invitrogen) according to the manufacturer's instructions. cDNAs were reversely-transcribed from total RNA. The result was identified by PCR. Cells were collected and mRNA was isolated by using a micro mRNA purification kit (Amersham Biosciences).

Generation of a subtracted cDNA library

Genome comparisons were performed by suppression subtraction hybridization according to the manufacturer's instructions of PCR-selectTM cDNA subtraction kit (Clontech). In brief, 2 μ g aliquots each of poly(A)⁺ mRNA from the tester and the pooled driver were subjected to cDNA synthesis. Tester and driver cDNAs were digested with *Rsa*I. The tester cDNA was subdivided into two portions, and each was ligated with a different cDNA adapter. In the first hybridization reaction, an excess of driver was added to each sample of tester. The samples were heat denatured and allowed to be annealed. Because of the second-order kinetics of hybridization, the concentration of high- and low-abundance sequences was equalized among the single-stranded tester molecules. At the same time single-stranded tester molecules were significantly enriched for differentially expressed sequences. During the second hybridization, the two primary hybridization samples were mixed without denaturation. Only the remaining equalized and subtracted single-stranded tester cDNAs could reassociate, forming double-stranded tester molecules with different ends. After the ends were filled with DNA polymerase, the entire population of molecules was subjected to nested PCR with two adapter-specific primer pairs.

Cloning subtracted library into pGEM-Teasy vector

Products of these amplified A overhangs containing a subtracted cDNA library (3 μ L) were ligated into a pGEM-Teasy plasmid (Promega). Subsequently, the plasmid was introduced into *Escherichia coli* strain JM109. Bacteria were transferred into 800 μ L of SOC medium and allowed to be incubated for 45 min at 37 °C and centrifuged at 225 rpm. Then they were plated onto agar plates containing ampicillin (50 μ g/mL), 5-bromo-4-chloro-3-indolyl- β -D-galactoside (X-Gal; 20 μ g/cm²), and isopropyl- β -D-thiogalactoside (IPTG; 12.1 μ g/cm²) and incubated overnight at 37 °C. White colonies were picked and identified by PCR. Primers were T7/SP6 primer of pGEM-Teasy plasmid. After the positive colonies (Shanghai BioAsia Biotechnology Co., Ltd) were sequenced, nucleic acid homology searches were performed using the BLAST (basic local alignment search tool) server at the National Center for Biotechnology Information.

RESULTS

Identification of expression vector

Figure 1 shows pcDNA3.1(-)-core of the PCR assay for plasmid and digestion of restriction enzyme analysis. Restriction enzyme analysis of pcDNA3.1(-)-core plasmid with *Eco*RI/*Bam*HI yielded two bands: 4 900 bp empty pcDNA3.1 (-) and 573 bp HCV core. Cleavage with *Hind*III produced only one 5 500 bp band (4 900 bp+573 bp). The products of plasmid were amplified by PCR. Analysis of the PCR reaction

products by agarose gel electrophoresis showed a clear band with the expected size (573 bp). Sequence of the PCR product was correct.

Figure 1 Products of pcDNA3.1(-)-core PCR and restriction enzyme cleavage were electrophoresed in 1% agarose gel. Lane 1: *Eco*RI/*Bam*HI cleaved; lane 2: *Hind*III cleaved; lane 3: products of plasmid PCR; M: DNA marker, (15 000 bp+ 2 000 bp).

Identification of HCV core transient expression

The total mRNA was reversely-transcribed by three different Oligo dT, identification of cDNA by PCR yielded a common 573 bp band (Figure 2). Table 1 shows co-transfected pcDNA3.1 (-)-core and pSV-lacZ into HepG2 cells, transient expression of HCV core was positive. On the contrary, empty pcDNA3.1 (-) co-transfected HepG2 cells were negative.

Figure 2 RT-PCR products were electrophoresed in 1% agarose gel. Lane 1: negative control; lanes 2-4: total RNA was isolated from pcDNA3.1(-)-core and RT-PCR was performed by three different Oligo dT; lane 5: blank control; lane 6: positive control; M: DNA marker (2 000 bp).

Table 1 Transient expression of pcDNA3.1(-)-core in HepG2 cells

Group	Coat Ag	P	P/N (n=0.05)	Results (+/-)
pcDNA3.1(-)-core	pcDNA3.1(-)-core lysate	0.219	4.38	+
Blank plasmid	pcDNA3.1(-) lysate	0.034	0.68	-
Positive control	HCV core Ag	1.299	24.60	+
Negative control	PBS	0.012	0.24	-

Result of pcDNA3.1(-)-core and pSV-lacZ cotransfection

Selection of 0.3 μ g pSV-lacZ served as the best concentration by analysis. After cotransfection of pcDNA3.1(-)-core and pSV-lacZ, the A value of expression of β -gal was 0.219. In contrast, the A value of expression of β -gal by cotransfected empty pcDNA3.1(-) and pSV-lacZ was 0.034. Expression of β -gal was 5.4-fold higher in cotransfected pcDNA3.1(-)-core and pSV-lacZ than in cotransfected empty pcDNA3.1(-) and pSV-lacZ (Figure 3). The significant increase of expression of β -gal was attributed to the transactivating effect of HCV core on early promoter of SV40, leading to the increased expression of downstream gene lacZ.

Figure 3 Comparison of A values among transfection groups. 1. Negative control (PBS); 2. pcDNA3.1(-)-core; 3. Blank plasmid; 4. Positive control.

Analysis of subtraction library

Using suppression subtractive hybridization technique (SSH), we obtained a total of 233 positive clones. These clones were prescreened by using PCR amplification to make sure that only clones with different inserts were subjected to sequencing (Figure 4). Two hundred and thirteen clones contained 100-1 000 bp inserts. A total of 63 clones from cDNA library were randomly chosen and sequenced. Using the BLAST program at the National Center for Biotechnology Information, six of the sequences were unknown genes. The full length sequences accepted by GenBank were obtained with bioinformatics method. The other 57 sequences had a high similarity to known genes. Twenty-one of the sequences were 100% identical in nucleotide sequence to previously described sequences. Summary of the data is presented in Table 2.

Figure 4 Agarose gel electrophoresis of PCR products of some clones (30-45). M: DNA marker (2 000 bp).

Table 2 Comparison between positive clones and similar sequences in GenBank

High similarity to known genes	Number of similar clones
Ribosomal protein	21
Eukaryotic translation elongation factor	6
Eukaryotic translation initiation factor	5
Heat shock factor binding protein (HSBP)	5
Apolipoprotein	5
NADH dehydrogenase	3
Heterogeneous nuclear ribonucleoprotein	3
D-like (HNRPDL), transcript variant	
Alpha-2-macroglobulin (A2M)	2
Bile acid-binding protein (BABP)	2
Cathepsin C (CTSC)	1
Fibronectin (FN precursor)	1
Magnesium-dependent protein phosphatase	1
Thioredoxin-related transmembrane protein	1
WEE1 gene for protein kinase	1

DISCUSSION

The diverse functional activities of HCV putative core protein have already been noted by a number of investigators. These include nucleocytoplasmic localization^[14], regulation of cellular and unrelated viral promoters in *in vitro* studies^[15-18], inhibition of apoptosis under certain conditions^[19], physical association with apolipoprotein II^[20] and cytoplasmic tail of the lymphotoxin β -receptor^[21,22], promotion of normal cells to a transformed phenotype^[23], and transactivation of suppression of cell growth^[12,24].

We cotransfected HepG2 cells with pcDNA3.1(-)-core and pSV-lacZ and demonstrated that the HCV core was successfully expressed in transfected HepG2 cells. Expression of β -gal was 5.4-fold higher in cotransfected pcDNA3.1(-)-core and pSV-lacZ than in cotransfected empty pcDNA3.1(-) and pSV-lacZ. HCV core had significant transactivating effects on the early promoter of SV40, through increasing the expression of downstream gene lacZ. This result indicates that the HCV core protein expressed in HepG2 cells retains its biological activity in terms of transcriptional activation, which was inconsistent with the previous report^[23].

The nucleocapsid core protein of HCV has been shown to trans-act on several viral or cellular promoters^[15,16,25,26]. To get insight into the trans-action mechanism of HCV core protein, an SSH was used for identification of relatively transactivated target genes of HCV core protein. HCV core protein relatively transactivated gene subtractive library was set up successfully. Sequence analysis was performed in 63 clones. Five of the sequences matched strongly (>97% nucleotide identity) with the apolipoprotein (Apo) sequence. Two of those sequences matched strongly (>97% nucleotide identity) with the bile acid-binding protein (BABP).

Several lines of evidence suggest that HCV core protein may modulate cellular transduction signals and alter lipid metabolism. A characteristic of HCV infection is the presence of liver steatosis. It is plausible that this steatosis could arise, at least in part, from direct effects of HCV proteins on lipid metabolism. The levels of apoAI and high density lipoprotein are independent predictive factors response to treatment^[27]. Apo, a protein that bind to lipids and renders them water soluble in the form of lipoproteins, could be a good candidate for an interaction with the core protein. HCV has been described as a lipid-containing virus and in plasma of patients shows a heterogeneous density distribution partially due to its binding to low density lipoprotein, very low density lipoprotein, IgG, and to a minor degree of IgM and high density lipoprotein^[28]. Barba *et al.*^[20] by double immunofluorescence and confocal analysis of the core and apo revealed colocalization of apoAII and the HCV core protein in the globular structures. Sabile *et al.*^[29] investigated the binding of HCV core protein to cellular proteins expressed in HepG2 cells by combining 2 yeast hybrid, confocal and surface plasmon resonance assays. The results showed the direct binding of the viral protein to apolipoprotein AII (apoAII) and mapped the interaction domain to the C-terminal of HCV core protein. Taking advantage of the well-established increase in apoAII expression caused by fibers in HepG2 cells, they identified that apoAII was one of the cellular targets for HCV core protein and the intervention of fenofibric acid in cellular lipid metabolism directly affected the expression pattern of HCV core protein.

It has been discovered that bile acids are the natural ligand for a nuclear receptor termed farnesoid X receptor (FXR; NR1H4)^[30-32]. Therefore, bile acids may be important regulators of gene expression in the liver and intestines. To date, the genes that have been shown to be responsive to regulation by FXR encoded proteins are involved in the biosynthesis and transport of bile acids^[33]. Bile acids have been shown to modulate a variety of other cellular functions, such as secretion of lipoproteins

from hepatocytes^[34,35] and translocation of bile acid transporters to the hepatocyte canalicular membrane^[36]. Our results indicate that HCV core protein interacts with bile acid-binding proteins. Maybe it is a way that HCV core protein affects cellular lipid metabolism.

Our results revealed a number of novel and known genes that responded to HCV core. The 6 unknown nucleotide sequences of SSH fragments are deposited in GenBank under accession numbers of AY038359, AY038361, AY039041, AY039042, AY039043, and AY039044.

Abstract

AIM: The pathogenesis of delayed gastric emptying in patients with non-ulcer dyspepsia (NUD) remains unclear. We aimed to examine whether gastric emptying rate in NUD patients was associated with *Helicobacter pylori* (*H pylori*) infection and whether it was affected by eradication of the infection.

METHODS: Gastric emptying rate of a mixed solid-liquid meal was assessed by the paracetamol absorption method in NUD patients and asymptomatic controls ($n=17$). *H pylori* status was assessed by serology and biopsy urease test. *H pylori*-positive NUD patients ($n=23$) received 10-day triple eradication therapy. *H pylori* status was re-assessed by biopsy urease test four weeks later, and if eradication was confirmed, gastric emptying rate was re-evaluated.

RESULTS: Thirty-three NUD patients and 17 controls were evaluated. NUD patients had significantly delayed gastric emptying compared with controls. The mean maximum plasma paracetamol concentration divided by body mass (C_{max}/BM) was 0.173 and 0.224 mg/L·kg respectively ($P=0.02$), the mean area under plasma paracetamol concentration-time curve divided by body mass (AUC/BM) was 18.42 and 24.39 mg·min/L·kg respectively ($P=0.01$). Gastric emptying rate did not differ significantly between *H pylori*-positive and *H pylori*-negative NUD patients. The mean C_{max}/BM was 0.172 and 0.177 mg/L·kg respectively ($P=0.58$), the mean AUC/BM was 18.43 and 18.38 mg·min/L·kg respectively ($P=0.91$). Among 14 NUD patients who were initially *H pylori*-positive, confirmed eradication of the infection did not significantly alter gastric emptying rate. The mean C_{max}/BM was 0.171 and 0.160 mg/L·kg before and after *Hp* eradication, respectively ($P=0.64$), the mean AUC/BM was 17.41 and 18.02 mg·min/L·kg before and after eradication, respectively ($P=0.93$).

CONCLUSION: Although gastric emptying is delayed in NUD

patients compared with controls, gastric emptying rate is not associated with *H pylori* status nor it is affected by eradication of the infection.

INTRODUCTION

Dyspepsia is defined as pain or discomfort centered in the upper abdomen, according to the Rome II criteria^[1]. Discomfort refers to a subjective, unpleasant feeling that the patient does not interpret as pain and which can include any of the following: upper abdominal fullness, early satiety, bloating, or nausea. Functional or non-ulcer dyspepsia (NUD) is defined as persistent or recurrent dyspepsia for at least 12 wk, which need not to be consecutive, within the preceding 12 mo of persistent or recurrent dyspepsia, with no evidence of organic disease that is likely to explain the symptoms, and no evidence that symptoms are exclusively relieved by defecation or associated with the onset of a change in stool frequency or stool form (*i.e.*, not irritable bowel syndrome)^[1].

NUD is a common healthcare problem: The estimated annual prevalence in Western countries is 15%^[2]. Despite a great deal of scientific attention, little is known about the pathogenesis of NUD. *Helicobacter pylori* (*H pylori*) infection and delayed gastric emptying have both been documented to have higher prevalence in patients with NUD compared with asymptomatic controls^[3, 4]. However, it is unknown if *H pylori* infection and/or delayed gastric emptying are involved in the pathogenesis of NUD. Furthermore, it is still unclear whether there is a causal association between these two factors in patients with NUD.

Therefore, we designed this study to investigate whether gastric emptying rate in patients with NUD was associated with the presence of *H pylori* infection, and whether the eradication of the infection affected the gastric emptying rate in these patients. We also sought to confirm in our population the well-known finding of delayed gastric emptying in patients with NUD compared with asymptomatic controls.

MATERIALS AND METHODS

Subjects

Consecutive patients with dyspeptic symptoms who attended the self-referred out-patient clinic of the 2nd Department of Internal Medicine, General Regional Hospital of Alexandroupolis were candidates for inclusion in the study. Inclusion criteria were: (1) age between 18 and 65 years; (2) presence of dyspeptic symptoms, defined as upper abdominal pain, upper abdominal discomfort, upper abdominal fullness, early satiety, or nausea/vomiting, continuously or intermittently for at least three mo; (3) no relevant findings revealed by physical examination other

than epigastric tenderness; (4) normal gastroscopy except mild erythema of gastric or duodenal mucosa; (5) normal abdominal ultrasound scan; (6) normal full blood count, liver function tests, fasting glucose, urea, creatinine, electrolytes, amylase and thyroid function tests. Exclusion criteria were: (1) presence of any organic or psychiatric disease that could affect the evaluation, treatment or compliance of the patient; (2) heartburn as the predominant symptom; (3) predominant symptoms being compatible with the diagnosis of irritable bowel syndrome or functional constipation as defined by Rome I criteria^[5]; (4) pregnancy or breast feeding; (5) chronic alcoholism or drug abuse; (6) past medical history of peptic ulcer disease, oesophagitis, pancreatitis, abdominal trauma, or abdominal surgery other than uncomplicated appendectomy; (7) intake of antibiotics 4 wk prior to inclusion; (8) regular intake of non steroidal anti-inflammatory drugs, including aspirin, or other medications that could cause dyspepsia during the 3 mo prior to inclusion.

The asymptomatic controls were recruited from the employees of General Regional Hospital of Alexandroupolis. Eligibility criteria were: (1) age between 18 and 65 years; (2) absence of dyspeptic symptoms; (3) absence of any organic or psychiatric disease that could affect the evaluation, treatment or compliance of the participant; (4) intake of antibiotics 4 wk prior to inclusion.

Proton pump inhibitors and H₂-receptor antagonists were withheld from all participants for 7 d before gastroscopy or gastric emptying testing. Paracetamol and all medications with any known potential effect on gastrointestinal motility were withheld for, respectively, two and three days before gastric emptying testing.

Study protocol

Study procedures were timed as follows: NUD patients underwent gastroscopy and two biopsy specimens were collected, one from the antrum and one from the corpus, for urease testing for *H. pylori* (CLOtest®, Delta West Ltd, Australia). The presence of *H. pylori* IgG antibodies in serum was assessed by ELISA (*H. pylori* GVE 573II IgG, PLK, Italy). On the following day, gastric emptying rate was assessed by the paracetamol absorption method as described below. *H. pylori*-positive NUD patients received 10 d of *H. pylori* eradication therapy consisting of omeprazole 20 mg twice daily, amoxicillin 1 000 mg twice daily and clarithromycin 500 mg twice daily. Four weeks later, *H. pylori* status was re-assessed by biopsy urease test. If eradication of *H. pylori* infection was confirmed, gastric emptying rate was re-evaluated. Asymptomatic controls were tested for *H. pylori* infection by serology (*H. pylori* IgG ELISA) and had gastric emptying rate assessed by the paracetamol absorption method.

The study protocol conformed to the World Medical Association Helsinki Declaration in 1964 as amended in 1996 and was approved by the regional Ethics Committee. Informed consent was obtained from all study subjects. This work was not financially supported by any outside agency or pharmaceutical company.

Assessment of gastric emptying rate

Gastric emptying rate was assessed by the paracetamol absorption method, which was conceived by Heading *et al.*^[6,7] and recently re-evaluated^[8,9]. The test meal was administered following overnight fasting and consisted of: (1) three cream crackers (total mass is 35 g); (2) a 200-mL carton of Fortimel® (Nutricia Clinical, Holland; liquid nutritional supplement; 410 mOsm/L; 4.184×10³ kJ/L; containing 19.4 g of protein, 4.2 g of fat and 20.8 g of carbohydrates per carton); (3) 1 g of paracetamol as two tablets 500 mg Depon®, Bristol-Myers Squibb; (4) 100 mL of tap water. Peripheral venous blood samples were obtained *via* a heparinised cannula immediately after the

ingestion of paracetamol (time 0) and at 30 min intervals over a 3-h period (7 samples in total). During the 3-h test period, the subjects were free to sit, stand or walk; they were not allowed to eat, drink or smoke.

Paracetamol plasma concentration was determined with the TDxFLx® System (Abbott, IL, USA) by using fluorescence polarization immunoassay technology. The following parameters were calculated: time to detect paracetamol in plasma (lag phase), maximum plasma paracetamol concentration divided by body mass (C_{\max}/BM); time to reach maximum plasma paracetamol concentration (T_{\max}), area under the plasma paracetamol concentration – time curve divided by body weight (AUC/BM).

Primary outcomes were the absolute difference in gastric emptying rate as assessed by C_{\max}/BW and AUC/BW in *H. pylori*-positive and *H. pylori*-negative NUD patients, and in *H. pylori*-positive NUD patients before and after eradication.

Secondary outcomes were the absolute difference in gastric emptying rate as assessed by C_{\max}/BM and AUC/BM in NUD patients compared to asymptomatic controls. We also assessed gastric emptying lag phase and T_{\max} in all study groups.

Sample size calculation

Sample size was calculated *a priori* with the Altman nomogram^[10]. A pilot study of five *H. pylori*-positive NUD patients provided an estimate of mean C_{\max}/BM (19.0 mg·min/L·kg) and standard deviation (5.0 mg·min/L·kg). We calculated that at least 10 subjects were required in each study group (*H. pylori*-negative NUD patients, *H. pylori*-positive NUD patients, post-eradication NUD patients, asymptomatic controls) in order to detect a clinically important relative difference (*a priori* set as $\geq 25\%$) between two study groups or within person comparison before and after *H. pylori* eradication ($1-\beta=0.8$, $\alpha=0.05$, two tailed significance).

Statistical analysis

Statistical analysis was carried out according to a pre-established analysis plan. Proportions were compared by χ^2 test with Fisher's exact test when appropriate. Regarding continuous outcomes, study groups were compared by the Mann-Whitney *U* test, while differences before and after *H. pylori* eradication were assessed by Wilcoxon matched pairs signed rank test. Two sided significance tests were used throughout. The software used was Statistical Package for the Social Sciences 10.0.1 for Windows (release 1999, SPSS Inc., Chicago, IL). Confidence intervals were calculated with Confidence Interval Analysis software 2.0.0 (release 2000, T. Bryant, Univ. of Southampton).

RESULTS

Thirty-three patients with NUD and 17 asymptomatic volunteers were included in the study during two recruitment periods (January to March 1997 and March to April 1998). All participants were Caucasian. Twenty-three of the NUD patients (70%) had both a positive serum anti-*H. pylori* IgG and biopsy urease test and were considered *H. pylori*-positive. The remaining 10 NUD patients had both tests negative and were considered *H. pylori*-negative. The baseline characteristics of the study groups are displayed in Table 1. The only significant difference found was a difference in age between control group and NUD group ($P=0.02$). Nevertheless multiple regression (ANOVA) revealed that age had no effect on any of the study outcomes. There was, therefore, no need for adjustment for age.

All study subjects underwent evaluation of gastric emptying. There was no significant difference in gastric emptying rate between *H. pylori*-positive and *H. pylori*-negative NUD patients as assessed by the primary study parameters C_{\max}/BM and

AUC/BM (Table 2). NUD patients had significantly delayed gastric emptying compared with asymptomatic controls as assessed by C_{\max} /BM and AUC/BM (Table 3). Gastric emptying lag phase and T_{\max} did not differ significantly in any comparison (data not shown).

All 23 *H. pylori*-positive NUD patients received eradication therapy. Of those, 18 completed the 10-d course and 4 wk later underwent repeat gastroscopy and biopsy urease test, eradication was confirmed in 14 patients (per protocol eradication rate 77.8%). Of the remaining five patients who received eradication therapy, 4 did not consent to repeat gastroscopy and 1 discontinued the course on the third day due to severe diarrhea (*C. difficile* toxin negative). No other side effects of the eradication regimen were reported on direct questioning.

All 14 NUD patients with confirmed *H. pylori* eradication underwent repeat assessment of gastric emptying. No significant difference was found in the gastric emptying parameters C_{\max} /BM and AUC/BM compared with the values prior to eradication (intra-individual comparisons) as shown in Table 4. Neither gastric emptying lag phase nor T_{\max} differed significantly compared with the values prior to eradication (data not shown).

DISCUSSION

This study confirmed that gastric emptying is significantly delayed in patients with NUD compared to asymptomatic controls (Table 3). This has been well established for years^[3, 11].

In fact, our results showed that the 95% confidence interval (CI) for the absolute difference between the medians of gastric emptying parameters, C_{\max} /BW and AUC/BW, was compatible with a relative difference encompassing the predefined limit of clinical importance (*i.e.* 25%). Consequently, our results need to be interpreted as evidence of a statistically significant difference in gastric emptying rate between patients with NUD and asymptomatic controls, which however is unclear if it is clinically relevant. The above comparison was not the primary outcome of our; Nonetheless the fact that these results are in agreement with the current medical literature corroborates the methodological validity of our study and the credibility of the main outcomes.

The pathophysiology of delayed gastric emptying in patients with NUD, as well as its clinical implications, remains unknown. *H. pylori* gastritis - which was also more prevalent in patients with NUD^[3] - has been suggested as a causal factor for the gastric motility disorders found in these patients. There is no solid evidence supporting this hypothesis although there is some biological plausibility since a mucosal inflammatory reaction could affect the function of enteric nerves and smooth muscle^[12].

In our attempt to investigate the potential role of *H. pylori* in the above mentioned motility disorders, we found that the gastric emptying rate in patients with NUD did not differ significantly between *H. pylori*-positive and *H. pylori*-negative patients (Table 2). Furthermore, eradication of *H. pylori* infection in patients with NUD did not induce any significant modification

of the gastric emptying rate (Table 4). However, for both comparisons, the 95% CI for the absolute difference between the medians of gastric emptying parameters was marginally compatible with the pre-defined level of a clinically important relative difference of 25%. This should be interpreted, therefore, as insufficient evidence to confirm or exclude a clinically important difference in gastric emptying rate between *H. pylori*-positive and *H. pylori*-negative patients with NUD. The same conclusion applies to the changes of gastric emptying rate following eradication of *H. pylori* infection in patients with NUD.

Our results are in agreement with most previous publications, which did not detect any influence of *H. pylori* status on gastric emptying rate in patients with NUD^[13-23]. However, it is possible that some of these studies were not adequately powered to detect the targeted difference. Some investigators were able to demonstrate significant differences, but their conclusions differed. For example, Fock *et al.*^[24] found that gastric emptying was slower in *H. pylori*-positive NUD patients compared to *H. pylori*-negative NUD patients, while Tucci *et al.*^[25] found the opposite. No meta-analysis has yet addressed this issue.

Regarding the effect of the eradication of *H. pylori* infection on gastric emptying rate in NUD patients, our results are in line with three other trials, which were unable to detect any changes in gastric emptying rate after a follow up period of one^[26], six^[27] and 12 mo^[28]. Nonetheless, other investigators found that eradication of the infection significantly increased gastric emptying rate after a follow-up of 1 mo^[29] or "normalised" previously abnormal (*i.e.* rapid or delayed) gastric emptying after a 2-mo follow up^[30]. There was considerable methodological heterogeneity among these trials, which complicates any attempts to draw a conclusive answer.

Further larger trials would be helpful. These would be facilitated by using safe and non-invasive methods of gastric emptying assessment, such as the paracetamol absorption method, ultrasonography^[31], or ¹³C octanoic acid breath test. Utilization of urea breath testing for confirmation of *H. pylori* eradication^[32], which was not available to us at the time of the research, might improve the compliance of participants and could allow investigators to lengthen the post-eradication follow-up time without a significant dropout rate. Future studies should also explore whether specific *H. pylori* characteristics, such as CagA phenotype^[19], or differences in host response are implicated in the pathogenesis of gastric emptying disorders in patients with NUD.

In conclusion, gastric emptying is delayed in patients with NUD but is unrelated to *H. pylori* status. Eradication of *H. pylori* infection in *H. pylori*-positive patients with NUD does not significantly alter the gastric emptying rate. Although our results are not definitive, they will contribute to a better understanding of the pathogenesis of NUD - especially when quantitatively synthesised with analogous data in future meta-analyses.

ACKNOWLEDGMENTS

The authors thank Professor Nikolaos Gotsis for his help in the design of the study, Professor Colin Howden for helpful discussions, Associate Professor Areti Hitoglou-Makedou for performing the *H. pylori* serology and expert technical advice and Ms. Vasiliki Katsilaki for her excellent technical assistance.

Abstract

AIM: To demonstrate the effect of lactose as an inducer on expression of the recombinant proteins encoded by *Helicobacter pylori* ureB and hpaA, and *Escherichia coli* LTB and LTKA63 genes and to determine the optimal expression parameters.

METHODS: By using SDS-PAGE and BIO-RAD gel image analysis system, the outputs of the target recombinant proteins expressed by *pET32a-ureB-E.coliBL21*, *pET32a-hpaA-E.coliBL21*, *pET32a-LTKA63-E.coliBL21* and *pET32a-LTB-E.coliBL21* were measured when using lactose as inducer at different dosages, original bacterial concentrations, various inducing temperatures and times. The results of the target protein expression induced by lactose were compared to those by isopropyl- β -D-thiogalactoside (IPTG). The proteins were expressed in *E.coli*.

RESULTS: Lactose showed higher efficiency of inducing the expression of rHpaA, rUreB, rLTB and rLTKA63 than IPTG. The expression outputs of the target recombinant proteins induced at 37 °C were remarkably higher than those at 28 °C. Other optimal expression parameters for the original bacterial concentrations, dosages of lactose and inducing time were 0.8, 50 g/L and 4 h for rHpaA; 0.8, 100 g/L and 4 h for rLTKA63; 1.2, 100 g/L and 5 h for both rUreB and rLTB, respectively.

CONCLUSION: Lactose, a sugar with non-toxicity and low cost, is able to induce the recombinant genes to express the target proteins with higher efficiency than IPTG. The results in this study establish a beneficial foundation for industrial production of *H pylori* genetic engineering vaccine.

INTRODUCTION

In China, chronic gastritis and peptic ulcer are two most common

gastric diseases^[1], and gastric cancer is one of the malignant tumors with high mortalities and morbidities.

Helicobacter pylori (*H pylori*), a microaerophilic, spiral and Gram-negative bacterium, is recognized as a human-specific gastric pathogen that colonizes the stomachs of at least half of the world's populations. Most infected individuals are asymptomatic. However, in some subjects, *H pylori* infection causes acute, chronic gastritis and peptic ulceration^[2-4], and acts as a high risk factor on development of gastric adenocarcinoma^[5-10], and mucosa-associated lymphoid tissue (MALT) lymphoma^[10-13].

It is generally considered inoculation of *H pylori* vaccine is a most efficient measure for prevention and control of *H pylori* infection^[14]. However, high nutrition requirements, poor growth for a long time, easy contamination during the cultivation and difficulty of bacterial strain conservation make whole cell vaccine of *H pylori* impracticable. Genetic engineering vaccine seems to be a possible pathway for developing *H pylori* vaccine.

Isopropyl- β -D-thiogalactoside (IPTG), a highly stable and effective inducer on T7lac promoter for target recombinant protein expression, is widely used in laboratories. However, IPTG is a reagent with potential toxicity and high cost^[15], which limited it as a practical inducer for industrial production of genetic engineering vaccines. It was reported that lactose, a common disaccharide, is also able to induce T7lac promoter after it is transformed into allolactose^[16]. The low-cost and non-toxicity make lactose a practical potential for engineering products. In comparison with IPTG, the parameters of lactose inducing different recombinant protein expression vary greatly and its optimal working conditions are established usually by a large number of laboratory tests^[17]. In our previous studies, urease subunit B (UreB) and *H pylori* adhesin (HpaA) were demonstrated as fine candidates in *H pylori* engineering vaccine^[18,19]. For improving immunogenicity of the vaccine, heat-labile enterotoxin subunit A mutant at the 63rd position (LTKA63) and subunit B (LTB) of *Escherichia coli* were selected as adjuvants^[20]. In this study, 4 constructed prokaryotic expression systems of ureB, hpaA, LTKA63 and LTB were used as the target genes to determine the inducing effects with different lactose dosages, temperatures and times, and original bacterial concentrations on expression of the recombinant proteins.

MATERIALS AND METHODS

Materials

Four prokaryotic expression systems of *pET32a-ureB-E.coliBL21*, *pET32a-hpaA-E.coli BL21*, *pET32a-LTKA63-E.coliBL21* and *pET32a-LTB-E.coliBL21* were constructed and offered by our laboratory. Tryptone, yeast extract for LB medium were purchased from OXOID (Basingstoke, Hampshire, England). IPTG and lactose used for inducement, and SDS, glycine and DTT were offered by BBST (Shanghai, China). Acrylamide, N, N'-methylene-bis-acrylamid and TEMED were obtained from Serva (Heidelberg, Germany).

Methods

Determination of optimal inducing concentrations of lactose

and temperatures A colony of each the four engineering bacteria in LB agar plates was inoculated into 5 mL of LB liquid medium and then incubated on rotator with 200 r/min at 37 °C for 12 h. The values at A_{600} measured by spectrophotometry were used to indicate the bacterial concentrations. Lactose at the final concentrations of 5, 10, 50 and 100 g/L were added into the cultures of the 4 strains with the A_{600} values of 1.2, respectively, and then incubated on 200 r/min shaking at 28 °C or 37 °C for 4 h. The bacteria in the medium were collected by centrifugation. By using SDS-PAGE, the expression and outputs of the target recombinant proteins (rUreB, rHpaA, rLTKA63 and rLTB) were examined and estimated, respectively. BIO-RAD gel image analysis system was applied to measure the outputs of target protein fragments by their area percentages in the total bacterial proteins. 0.5 mmol/L IPTG was simultaneously used as an inducer control, which inducing effects for the four recombinant proteins had been confirmed in our previous studies^[18-20].

Determination of optimal original bacterium concentrations for inducement Four engineering bacterial strains were inoculated with proportion of 1:100 (V/V) into LB liquid medium and then incubated on 200 r/min shaking at 37 °C. According to the results obtained above, lactose at the final concentrations of 100, 50, 100 and 100 g/L for inducement of rUreB, rHpaA, rLTKA63 and rLTB expression was added into the cultures with the A_{600} values of 0.2, 0.4, 0.8, 1.2, 1.6, 2.0 and 2.4, respectively. The lactose added cultures were continuously incubated on 200 r/min shaking at 37 °C for 4 h. The outputs of rUreB, rHpaA, rLTKA63 and rLTB were examined by SDS-PAGE and BIO-RAD gel image analysis system.

Effects of the target protein expression by using different inducing time According to the results obtained above, the optimal original bacterial concentration for inducement was 1.2 (A_{600}). The four different bacterial cultures ($A_{600}=1.2$), which expressing rUreB, rHpaA, rLTKA63 or rLTB, were added with lactose at the final concentrations of 100, 50, 100, 100 g/L, respectively. The cultures were continuously incubated on 200 r/min shaker at 37 °C for 1, 2, 3, 4, 5, 6 and 7 h, respectively. The outputs of rUreB, rHpaA, rLTKA63 and rLTB were examined by SDS-PAGE and BIO-RAD gel image analysis system.

SDS-PAGE A vertical discontinuous plate polyacrylamide gel electrophoresis was applied^[21]. The isolation gels with 8%, 10%, 12% and 15% concentrations (W/V) were used to detect the expressed rUreB, rLTKA63, rHpaA and rLTB, respectively, based on their different molecular weights. The start voltage was 8 V/cm and then changed to 15 V/cm while the samples went into isolation gels. The gels after electrophoresis were stained by Coomassie brilliant blue and then decolorized with methanol-acetic acid solution.

RESULTS

Optimal inducing concentrations and temperatures of lactose

Lactose with multiple appropriate concentrations could

effectively induce expression of 4 target recombinant proteins (Figure 1). Beginning with the original bacterial concentrations of 1.2 A_{600} values, the outputs of rUreB, rHpaA, rLTKA63 and rLTB at the inducing temperature of 37 °C were 27.3-53.9%, 7.4-30.9%, 0.8-79.8% and 12.7-119.1% increased as compared with those of 28 °C, respectively (Table 1). When the concentrations of lactose were 100, 50, 100 and 100 g/L inducing at 37 °C for 4 h, outputs of the 4 recombinant proteins reached the highest (Table 1). In comparison with the inducing expression effects of 0.5 mmol/L IPTG, the highest outputs of rUreB, rHpaA, rLTKA63 and rLTB induced by lactose were 203.2%, 98.4%, 114.0% and 245.1% increased, respectively (Table 1).

Figure 1 Effects of lactose on inducing expression of target recombinant proteins compared to IPTG. A: rUreB; Lane 1: Marker; Lane 2: Induced with 0.5 mmol/L IPTG; Lane 3: Induced with 100 g/L lactose; Lane 4: Non-induced. B: rHpaA; Lane 1: Marker; Lane 2: Induced with 0.5 mmol/L IPTG; Lane 3: Induced with 50 g/L lactose; Lane 4: Non-induced. C: rLTKA63 expression; Lane 1: Marker; Lane 2: Induced with 0.5 mmol/L IPTG; Lane 3: Induced with 100 g/L lactose. Lane 4: Non-induced; D: rLTB; Lane 1: Marker; Lane 2: Induced with 0.5 mmol/L IPTG; Lane 3: Induced with 100 g/L lactose; Lane 4: Non-induced.

Effects of the target protein expression of original bacteria with different A_{600} values under inducement by lactose

By using the inducing concentrations of lactose with 100, 50, 100 and 100 g/L inducing at 37 °C for 4 h, the expression outputs of the 4 recombinant proteins with the different original bacterial concentrations (0.2-2.4 A_{600} values) are showed in Figure 2. The results indicated that a better expression effect for any of the 4 recombinant proteins was present when the original bacterial concentration used was higher ($A_{600}=0.8-1.2$).

Table 1 Expression outputs of rUreB, rHpaA, rLTKA63 and rLTB proteins induced by different concentrations of lactose and temperatures

Concentrations of lactose(g/L) and IPTG(mmol/L)	Expression outputs (% of total bacterial proteins)							
	rUreB		rHpaA		rLTKA63		rLTB	
	(37 °C)	(28 °C)	(37 °C)	(28 °C)	(37 °C)	(28 °C)	(37 °C)	(28 °C)
Lactose (50)	40.59	26.38	50.35	44.72	23.36	22.41	39.55	21.91
(10)	50.52	39.70	57.61	44.86	35.84	27.09	42.66	26.17
(5)	30.51	22.17	60.80	46.42	35.64	22.09	26.99	23.94
(1)	27.33	18.92	54.00	50.29	21.91	21.73	23.33	10.65
(0.5)	20.78	13.63	42.29	36.05	22.01	12.24	14.72	10.31
IPTG (0.5)	16.66	14.72	30.65	22.61	16.75	14.48	12.36	10.06

Effects of the target protein expression using different inducing time

When the original bacterial concentrations as A_{600} values of 1.2 and the lactose concentrations of 100, 50, 100 and 100 g/L, the outputs of rUreB, rHpaA, rLTKA63 and rLTB were shown in Figure 3. The results indicated that a higher output for any of the 4 recombinant proteins was present when the inducing time was 4-5 h.

DISCUSSION

H pylori causes a local superficial infection in human stomach and duodenum^[22]. So orally inoculating of *H pylori* vaccine has a good protective effect^[23]. So far, no commercial *H pylori* engineering vaccine has been available. An engineering vaccine has many advantages but its immunoprotective effect is usually poor because of the unitarity for antigen components. Using adjuvant is an efficient measure to improve immune effect of engineering vaccines^[24]. UreB and HpaA were demonstrated to be excellent antigen candidates as their stable and high expression, strong antigenicity, universal distribution in different *H pylori* isolates and exposure on the surface of the bacterium^[25,26]. *E. coli* LTKA63 and LTb were recently found and were generally considered as the most efficient adjuvants for mucosal immunization so far^[27,28]. So we planned to use the rUreB and rHpaA as antigens and LTb or LTKA63 as adjuvants to develop an oral-taken double-valence genetic engineering vaccine of *H pylori*.

Almost of all the recombinant proteins show a very low expression or non-expression without inducement. IPTG is a routinely laboratory used inducer with high efficiency on recombinant protein expression in *E. coli* but it must be removed by complicated methods from the induced products because of its toxicity. When at the efficient inducing dosages, the cost of IPTG is approximate hundredfold of lactose. Therefore, lactose as an inducer has industrially remarkable advantages. Lactose, differs from IPTG, is unable to enter the bacterial body. It must

be helped by a special enzyme called as primase to be transported into host bacterium. The lactose in bacterial cell must be transferred into allolactose by β -galactosidase and the latter is able to start T7 Lac promotor. In the process inducing expression of recombinant protein, lactose is much more complex than IPTG. So lactose, if used it as an efficient inducer, must be clarified its inducing parameters such as dosage, temperature, time and original bacterial concentration.

It was proved by our study that lactose at the multiple tested concentrations could efficiently induce the expression of rUreB, rHpaA, rLTKA63 and rLTb. The effects of lactose on inducing expression of the 4 recombinant proteins were much stronger than that by IPTG, which demonstrated by 98.4-245.1% increased outputs (Table 1). Furthermore, it was reported that lactose is a carbon source for bacteria to promote growth and increase number of bacteria in culture, which results in the increase of output of the target recombinant protein.

The results of this study indicated that at 37 °C for 4 h inducement the lactose concentration to obtain the highest expression outputs of rUreB, rHpaA, rLTKA63 and rLTb were 100, 50, 100 and 100 g/L, respectively. It was found in the study that inducing temperatures can obviously affect the expression of the recombinant proteins. For example, with the original bacterial concentration of 1.2 A_{600} value for 4 h inducement, using 37 °C as the inducing temperature could increase the expression outputs of rUreB, rHpaA, rLTKA63 and rLTb with 27.3-53.9%, 7.4-30.9%, 0.8-79.8% and 12.7-119.1% of those induced by 28 °C. The original bacterial concentrations when lactose addition was found to affect the outputs of the recombinant proteins. There were preferable expression effects of the recombinant proteins to add lactose when the original bacterial concentrations with the A_{600} values of 0.8-1.2. With the original bacterial concentration of 1.2 A_{600} values and at temperature 37 °C, the outputs of the recombinant proteins for 4-5 h inducement by the optimal concentrations of lactose were relatively higher.

Summarily, using lactose as an inducer on the expression of *pET32a-ureB-E.coliBL21*, *pET32a-hpaA-E.coli BL21*, *pET32a-LTKA63-E.coliBL21* and *pET32a-LTB-E.coliBL21*, the optimal temperature was 37 °C. The rest optimal parameters for the original bacterial concentrations, dosages of lactose and inducing time were 0.8, 50 g/L and 4 h for rHpaA; 0.8, 100 g/L and 4 h for rLTKA63; 1.2, 100 g/L and 5 h for both rUreB and rLTb, respectively. The results from this study established a beneficial foundation for industrial production of *H pylori* genetic engineering vaccines.

Abstract

AIM: To detect the telomerase activity and c-Myc expression in gastric diseases and to examine the relation between these values and *Helicobacter pylori* (*H pylori*) as a risk factor for gastric cancer.

METHODS: One hundred and seventy-one gastric samples were studied to detect telomerase activity using a telomerase polymerase chain reaction enzyme linked immunosorbent assay (PCR-ELISA), and c-Myc expression using immunohistochemistry.

RESULTS: The telomerase activity and c-Myc expression were higher in cancers (87.69% and 61.54%) than in noncancerous tissues. They were higher in chronic atrophic gastritis with severe intestinal metaplasia (52.38% and 47.62%) than in chronic atrophic gastritis with mild intestinal metaplasia (13.33% and 16.67%). In chronic atrophic gastritis with severe intestinal metaplasia, the telomerase activity and c-Myc expression were higher in cases with *H pylori* infection (67.86% and 67.86%) than in those without infection (21.43% and 7.14%). c-Myc expression was higher in gastric cancer with *H pylori* infection (77.27%) than in that without infection (28.57%). The telomerase activity and c-Myc expression were coordinately up-regulated in *H pylori* infected gastric cancer and chronic atrophic gastritis with severe intestinal metaplasia.

CONCLUSION: *H pylori* infection may influence both telomerase activity and c-Myc expression in gastric diseases, especially in chronic atrophic gastritis.

INTRODUCTION

Gastric cancer is one of the most common malignant tumors in the world. Gastric carcinogenesis is a multi-step process progressing from chronic gastritis to glandular atrophy, metaplasia, and dysplasia^[1-3]. Genetic analyses of gastric

cancers suggest alterations are involved in the structures and functions of several oncogenes and tumor suppressor genes as well as genetic instability^[3,4]. However, in addition to these genetic changes, cell immortality is important for the sustained growth properties of gastric cancer cells^[4,5]. The ribonucleoprotein enzyme telomerase that synthesizes the G-rich strand of telomeric DNA in germline tissues and in immortal tumor cells plays a critical role in the maintenance of telomeres^[6]. By using a highly sensitive PCR-based TRAP assay, telomerase activity has been observed in a wide range of human cancers, including cancers of breast, bladder, stomach, colon, prostate, and liver, so telomerase may be regarded as a molecular marker for cancer diagnosis and therapeutic strategies^[7-13]. Telomerase activity is also positive in gastric preneoplastic lesions^[14]. Therefore it is thought that reactivation of telomerase may occur at an early stage of carcinogenesis^[14].

Myc network proteins are known to be oncoproteins, which are involved in the control of cell proliferation, differentiation and apoptosis^[15,16]. The c-Myc oncogene is implicated in the transformation and progression of mutated cells^[17-19]. Deregulation of Myc genes is usually caused by chromosomal translocation involving the c-myc gene as well as by gene amplification. Overexpression of Myc is frequently observed in a wide variety of tumor types, and affects both the development and progression of hyperproliferations^[20,21].

It is well known that *Helicobacter pylori* (*H pylori*), the main cause of chronic gastritis, is a class I gastric carcinogen^[22]. It contributes to the induction of chronic gastritis to cancer through precursor lesions, such as atrophy, metaplasia and dysplasia^[23]. Precancerous phenotypic expression is generally associated with acquired genomic instability and activation of telomerase activity^[24]. *H pylori* inoculation into Mongolian gerbils has been reported to induce chronic gastritis and intestinal metaplasia. Chronic infection with *H pylori* induces activations of telomerase in gastric mucosa exhibiting intestinal metaplasia^[25]. In patients with intestinal-type gastric cancer, telomerase activity was higher in intestinal metaplasia with *H pylori* infection than in that without infection^[25,26]. These data indicate that *H pylori* infection may contribute to the precancerous stage through induction of telomerase activity, and that telomerase activation in intestinal metaplasia with *H pylori* infection may be correlated with oncogenesis, though the mechanism remains to be defined. To our knowledge, little is known about whether *H pylori* infection induces both genetic alterations and cell immortality in gastric mucosa. Recent evidence suggested that Myc protein was implicated in the regulation of hTERT^[27-29]. Therefore we measured telomerase activity and c-Myc expression in *H pylori* infected gastric cancer, chronic atrophic gastritis and chronic superficial gastritis. The results indicate that *H pylori* infection may induce telomerase activity and c-Myc protein expression in the process of carcinogenesis.

MATERIALS AND METHODS

Tissue samples

Samples were obtained from upper gastrointestinal endoscopy or surgical operation during the period of September 2000 to May 2001. It included 20 of chronic superficial gastritis (CSG),

30 of chronic atrophic gastritis(CAG) with mild intestinal metaplasia(IM), 42 of chronic atrophic gastritis with severe intestinal metaplasia, 14 of dysplasia(Dys) and 65 of gastric cancer(GC). Haematoxylin and eosin stains were used for the histopathological diagnosis. Degree of inflammatory reaction and glandular atrophy, intestinal metaplasia, and cellular dysplasia were evaluated according to the criteria of the updated Sydney system. The diagnosis of each sample was based on agreement between two pathologists.

H pylori infection

H pylori infection was detected by rapid urease test and bacteria culture. Infection was defined as positive when *H pylori* was detected and/or urease test was positive.

Immunohistochemistry

For each case, 4- μ m thick serial sections were cut from paraffin wax blocks, mounted on acid-cleaned glass slides, and heated at 55 °C for 60 min. Slides were dewaxed and rehydrated, then endogenous peroxidase activity was inhibited by incubation with 30 mL/L H₂O₂ in methanol for 20 min at room temperature. To reduce non-specific background staining, slides were incubated with 50 mL/L goat serum for 15 min at room temperature. To enhance immunostaining, sections were treated with an antigen retrieval solution (10 mmol/L citric acid monohydrate, pH 6.0, adjusted with 2 mol/L NaOH) and heated three times in a microwave oven at high power for five min. Finally, slides were incubated with appropriate primary antiserum in a moist chamber overnight at 4 °C. The monoclonal primary antibody, anti-c-Myc, was purchased from Maxim Biotech, Inc. (USA). S-P kit was purchased from Fujian Maixin Ltd (China). Samples were detected according to manufacturer's instructions. The degree of immunopositivity was evaluated semi-quantitatively. A total of 300 cells were counted in random fields from representative areas of the lesions, and the immunoreactive cells were roughly assessed and expressed as percentages. The scoring system for the antibody tested was: 0-5%(negative), 5-25%(low positivity), 25-50%(moderate positivity), >50%(high positivity).

Telomerase assay

Telomerase activity was measured by a modified version of the standard TRAP method, using PCR-ELISA detection kit (Roche Molecular Biochemicals), according to its manufacturer's instructions. Five 10- μ m thick cryostat sections of were transferred into a sterile reaction tube containing 200 μ L ice-cold lysis reagent. The lysates were homogenized and incubated on ice for 30 min. After centrifuged at 16 000 g for twenty minutes at 4 °C, 175 μ L of the supernatant was collected and transferred to a fresh tube. Three micro-litter of tissue extract was incubated with 25 μ L of reaction mixture including a biotin labeled P1-TS primer and P2 primer, telomerase substrate, and Taq polymerase for 20 min at 25 °C. After further incubation at 94 °C for 5 min for telomerase inactivation, the resulting mixture

was subjected to PCR for 30 cycles at 94 °C for 30 s, at 50 °C for 30 s, and at 72 °C for 90 s, the reaction was held at 72 °C for 10 min.

PCR products were denatured and hybridized with a digoxigenin labeled, telomeric repeat specific detection probe. The resulting product was immobilized through the biotin labeled TS primer to a streptavidin coated microtitre plate and detected with antidigoxigenin antibody conjugated with peroxidase. Absorbance values were measured using a microtitre (ELISA) reader at 450 nm with a reference wavelength of approximately 690 nm within 30 min after addition of the stop reagent. Heat-treatment of the cell extract for 10 min at 65 °C prior to the TRAP reaction was used to inactivate telomerase protein for producing negative controls. Positive controls were the 293 cells that expressed the telomerase activity. Samples were regarded as telomerase-positive if the difference in absorbance (ΔA) was higher than 0.2 ($A_{450\text{ nm}} - A_{690\text{ nm}}$ units).

Statistical analyses

The correlations between qualitative data were studied with the χ^2 and Fisher tests. A probability *P* value <0.05 was considered statistically significant.

RESULTS

H pylori infection

One hundred and twelve of 171 cases were *H pylori* positive. The *H pylori* infection rate was 65%(13/20) in CSG, 63.89%(46/72) in CAG, 64.29%(9/14) in Dys, and 67.69%(44/65) in GC. It had no significant difference among these groups.

Telomerase activity

Telomerase activity was measured by a telomerase polymerase chain reaction (PCR) enzyme linked immunosorbent assay, which does not require radioactive PCR amplification and yields a semiquantitative measurement. Telomerase activity was detected in 57(87.69%) of 65 gastric carcinomas examined, 46(63.89%) of 72 CAG and 9(64.29%) of 14 Dys. No telomerase activity was detected in all the 20 CSG. The mean telomerase activity was higher in gastric cancer than in CAG, CSG and Dys ($P < 0.01$ or $P < 0.05$). Based on intestinal metaplasia, CAG was classified into two groups, severe IM and mild IM. The telomerase activity was higher in CAG with severe IM than that in mild IM ($P < 0.01$).

Twenty-nine gastric cancers with complete clinical data were classified by histologic parameters such as gender, tumor location, tumor size and microscopic morphology. The telomerase activity among these groups had no significant difference (data not shown).

H pylori infection and telomerase activity in patients with gastric cancer and CAG are shown in Table 1. The mean telomerase activity was higher in CAG with severe intestinal metaplasia and *H pylori* infection than in that without infection ($P < 0.05$), but there was no significant difference between those with and without *H pylori* infection in gastric cancer and CAG with mild intestinal metaplasia.

Table 1 Telomerase activity and c-Myc expression in *H pylori* infected gastric diseases

Diagnosis	Samples number	<i>H pylori</i> infection	Telomerase activity + (%)	<i>P</i>	c-Myc expression + (%)	<i>P</i>
GC	65	+(44)	38 (86.36)	>0.05	34 (77.27)	<0.05 ^a
		-(21)	19 (90.48)		6 (28.57)	
CAG with MM	30	+(18)	3 (16.67)	>0.05	4 (22.22)	>0.05
		-(12)	1 (8.33)		1 (8.33)

		-(14)	3 (21.43)		1 (7.14)	

χ^2 test and Fisher's exact test. ^a $P < 0.05$ vs c-Myc expression from samples without *H pylori* infection. ^b $P < 0.01$ vs telomerase activity from samples without *H pylori* infection. ^d $P < 0.01$ vs c-Myc expression from samples without *H pylori* infection. MM, mild intestinal metaplasia SM, severe intestinal metaplasia.

Figure 1 c-Myc protein expression in chronic superficial gastritis, chronic atrophic gastritis and gastric adenocarcinoma. A: c-Myc protein expression in chronic superficial gastritis. B: c-Myc protein expression in chronic atrophic gastritis. C: c-Myc protein expression in gastric adenocarcinoma.

c-Myc expression

c-Myc was expressed in 40 of 65 (61.5%) gastric cancers, 20 of 42 (47.62%) CAG with severe IM, 5 of 30 (16.67%) CAG with mild IM, 8 of 14 (57.14%) Dys and 1 of 20 (5%) CSG. The expression of c-Myc was highest in gastric cancer, and c-Myc expression in CAG with severe IM was significantly higher than that in CAG with mild IM. The c-Myc immunoreactivity was localized in both cytoplasm and nucleus (Figure 1).

H pylori infection and c-Myc expression in patients with gastric cancer and CAG are shown in Table 1. The expression of c-Myc was higher in *H pylori* infected gastric cancer and CAG with severe IM than in those without infection ($P < 0.01$), but there was no significant difference between those with and without *H pylori* infection in CAG with mild IM.

Coordinate up-regulation of telomerase activity and c-Myc expression in *H pylori* infected gastric cancer and CAG with severe intestinal metaplasia

The telomerase activity and c-Myc expression were coordinately increased in *H pylori* infected gastric cancer and CAG with severe IM (Figure 2). The rate of co-expression was 89.47% (34/38) and 100% (19/19), respectively.

Figure 2 Coordinate increase of telomerase activity and c-Myc expression in *H pylori* infected gastric cancer and CAG with severe intestinal metaplasia. The rate of co-expression was 89.47% (34/38) and 100% (19/19), respectively. (CAG-MM: chronic atrophic gastritis with mild metaplasia; CAG-SM: chronic atrophic gastritis with severe metaplasia.).

DISCUSSION

In the present study, we demonstrated that most gastric tumors displayed telomerase activity, regardless of histological types. Telomerase activity was highest in cancer tissue, followed by chronic atrophic gastritis with complete intestinal metaplasia, dysplasia, chronic atrophic gastritis with mild intestinal metaplasia and chronic superficial gastritis. Telomerase activity was higher in CAG with severe metaplasia and *H pylori* infection than in that

without *H pylori* infection ($P < 0.01$). Our results indicate that telomerase activity is one of the most common and fundamental events of gastric cancers. What is more important is that telomerase was activated in precursor lesions, such as chronic atrophic gastritis with intestinal metaplasia and dysplasia. It suggested that there were a certain number of immortal cells existing in these lesions. In addition, *H pylori* infection might induce telomerase activity in chronic atrophic gastritis with intestinal metaplasia.

Recently, it was reported that *H pylori* infection played a role in activation of telomerase. Chronic infection with *H pylori* induced the activation of telomerase in gastric mucosa exhibiting intestinal metaplasia^[25]. In patients with intestinal-type gastric cancer, telomerase activity was higher in intestinal metaplasia with *H pylori* infection than in that without infection^[26]. We found that telomerase was activated in *H pylori* infected precursor lesions, such as chronic atrophic gastritis and dysplasia, and telomerase activity rose higher during the progression of the lesions. These data indicate that *H pylori* infection may contribute to gastric tumorigenesis through induction of telomerase activity, and that telomerase activation in *H pylori* infected chronic atrophic gastritis with intestinal metaplasia and dysplasia may be correlated with oncogenesis. It remains to be defined how *H pylori* infection activates telomerase. *H pylori* infection might influence the negative regulator of telomerase activity during early stages of stomach carcinogenesis^[26]. In addition, inflammatory gastric mucosa caused by *H pylori* infection could produce free radicals and cytokines that may induce telomerase activity^[30].

Frequent genetic alterations, such as c-myc proto-oncogene have been found in gastric pre-malignant lesions^[31,32]. Amplified c-Myc, which controls cell growth and cellular differentiation^[33,34], has been reported in small percent of gastric carcinomas^[35,36]. Expression of c-Myc was proved to be more frequent in poorly differentiated gastric cancer cells, and more frequent in gastric adenocarcinoma than in adenoma and has also been proposed as an aid to differentiate between the two conditions^[37,38]. In the present study, c-Myc was expressed in 61.54% (40/65) of gastric cancers, 47.62% (20/42) of chronic atrophic gastritis with severe IM, 16.67% (5/30) of CAG with mild IM, and 5% (1/20) of chronic superficial gastritis patients. The expression of c-Myc was highest in gastric cancers, and c-Myc expression in CAG with severe intestinal metaplasia was significantly higher than that in CAG with mild intestinal metaplasia. The expression of c-Myc was higher in *H pylori* infected gastric cancer and CAG with severe intestinal metaplasia than in that without infection ($P < 0.01$). We found that c-Myc expression in both gastric cancer and chronic atrophic gastritis with severe intestinal metaplasia is correlated with *H pylori* status. Previously, a study by Nardone *et al* showed that *H pylori* infection affected the expression of c-Myc in chronic gastritis, but the positive rate was very low (15%). The expression of c-Myc was very high in *H pylori* infected CAG in our study because we classified chronic gastritis as CSG

and CAG, the latter was further classified as CAG with mild intestinal metaplasia and with severe intestinal metaplasia.

Recent evidence suggested that the Myc protein could bind to the promotor of human telomerase reverse transcriptase (hTERT), the catalytic subunit of telomerase^[27-29]. It has been shown that hTERT is the determinant of telomerase activity control. A study by Hiyama *et al.* demonstrated a close association between a high level of telomerase activity and amplification of the myc locus in neuroblastomas. Thus, up-regulation of Myc due to gene alterations leading to subsequent activation of hTERT expression, may be one cause for telomerase activation in tumors. Interestingly, we found that telomerase activity and c-Myc were co-expressed in *H pylori* infected chronic atrophic gastritis. The correlation was not significant in patients without *H pylori* infection or in patients with *H pylori* infection but without gastric atrophy. Therefore, it is suggested that the presence of both gastric atrophy and chronic *H pylori* infection is essential for cell immortality and genomic instability.

Abstract

AIM: Colonic epithelium is known to secrete both Cl^- and HCO_3^- , but the secretory mechanisms of different colonic cell types are not fully understood. The present study aimed to investigate the differential activation of Cl^- and HCO_3^- secretion by tetramethylpyrazine (TMP) in human crypt-like cell line, T84, and villus-like cell line, Caco-2, in comparison to the TMP-induced secretory response in freshly isolated rat colonic mucosa.

METHODS: Colonic epithelial anion secretion was studied by using the short circuit current (I_{sc}) technique. RT-PCR was used to examine the expression of $\text{Na}^+/\text{HCO}_3^-$ cotransporter in different epithelial cell types.

RESULTS: TMP produced a concentration-dependent I_{sc} which was increase in both T84 and Caco-2 cells. When extracellular Cl^- was removed, TMP-induced I_{sc} was abolished by 76.6% in T84 cells, but not in Caco-2 cells. However, after both Cl^- and HCO_3^- were removed, TMP-induced I_{sc} in Caco-2 cells was reduced to 10%. Bumetanide, an inhibitor of $\text{Na}^+/\text{K}^+/\text{Cl}^-$ cotransporter, inhibited the TMP-induced I_{sc} by 96.7% in T84 cells, but only 47.9% in Caco-2 cells. In the presence of bumetanide and 4, 4'-diisothiocyanostilbene-2, 2'-disulfonic acid, an inhibitor of $\text{Na}^+/\text{HCO}_3^-$ cotransporter, inhibited the TMP-induced current in Caco-2 cells by 93.3%. In freshly isolated rat colonic mucosa, TMP stimulated distinct I_{sc} responses similar to that observed in T84 and Caco-2 cells depending on the concentration used. RT-PCR revealed that the expression of $\text{Na}^+/\text{HCO}_3^-$ cotransporter in Caco-2 cells was 4-fold more greater than that in T84 cells.

CONCLUSION: TMP exerts concentration-dependent differential effects on different colonic cell types with stimulation of predominant Cl^- secretion by crypt cells at a lower concentration, but predominant HCO_3^- secretion by villus cells at a higher concentration, suggesting different roles of these cells in colonic Cl^- and HCO_3^- secretion.

INTRODUCTION

Colonic epithelium, which lines the surface of both crypts and villi, plays an important role in the maintenance of water and electrolyte balance. While it is well established that colonic fluid secretion is driven by electrogenic colonic Cl^- secretion^[1], HCO_3^- secretion has also been shown to be important in the human colon. In many diarrhea disorders, a high concentration of HCO_3^- was frequently found in stool water and patients with severe diarrhea often suffered from metabolic acidosis due to sustained HCO_3^- losses in the stool^[2]. However, the contribution of crypts and villus epithelia to colonic Cl^- and HCO_3^- secretion is not known. Although it has been generally believed that colonic villus (or surface) epithelium is mainly involved in NaCl and water absorption while crypt epithelium is involved in secretion^[1,3]. There is now clear evidence that electrolyte secretion is located in both^[1,4]. The cystic fibrosis transmembrane conductance regulator (CFTR), a cAMP-dependent Cl^- channel known to mediate both Cl^- ^[5] and HCO_3^- secretion^[6,7], has been shown to be present in both crypt and villus epithelial cells although higher expression level of CFTR was found in crypts than in villi^[8,9]. Human colonic cell lines have been derived to provide useful models in studying electrolyte transport properties of colonic crypts and villus epithelial cells. T84 cell line is a well-characterized colonic epithelial model that maintains a secretory phenotype similar to crypt base cells, and has been widely used to examine the regulation of intestinal Cl^- secretion since CFTR and $\text{Na}^+/\text{K}^+/\text{Cl}^-$ cotransporter (NKCC) are highly expressed in this cell line^[1,10,11]. The properties of human colonic Caco-2 cells are mostly close to those of mature absorptive villus/surface cells but they possess a certain CFTR characteristic of secretory cells^[1,12,13]. However, few studies have been conducted to compare the secretory properties of these cell lines.

Tetramethylpyrazine (TMP, also named ligustrazine), a compound purified from *Ligustium Wollichii Francha*, is a widely used active ingredient in Chinese herbal medicine for the treatment of cardiovascular diseases due to its vasodilatory actions and antiplatelet activity^[14-16]. TMP has been proposed to act as an inhibitor of phosphodiesterase (PDE) and thereby it increases intracellular cAMP^[15]. We have recently demonstrated a stimulatory effect of a TMP-containing herbal formula on the anion secretion in human colonic^[17] and pancreatic duct cell lines^[18], indicating the involvement of cAMP and activation of CFTR. The present study aimed to compare the stimulatory effects of TMP on colonic anion secretion in different colonic cell types, T84 and Caco-2, as well as freshly isolated rat colonic mucosa, in an attempt to assess the different contribution of these two cell types to colonic anion secretion.

MATERIALS AND METHODS

Chemicals and solutions

Tetramethylpyrazine was purchased from Beijing Fourth

Pharmacy (Beijing, China). Diphenylamine-2, 2'-dicarboxylic acid (DPC) was obtained from Riedel-de Haen Chemicals (Hannover, Germany). Amiloride hydrochloride was obtained from Sigma Chemical Company (St. Louis, MO). Calbiochem (San Diego, CA) was the source for 4, 4'-diisothiocyanostilbene-2, 2'-disulfonic acid (DIDS), bumetanide, tetrodotoxin (TTX), indomethacin and glybenclamide. Dulbecco's modified Eagle's medium (DMEM)/F12, Hanks' balanced salt solution (HBSS) and fetal bovine serum were from Gibco Laboratory (New York, NY). Krebs-Henseleit solution (K-HS) had the following compositions (mmol/L): NaCl, 117; KCl, 4.5; CaCl_2 , 2.5; MgCl_2 , 1.2; NaHCO_3 , 24.8; KH_2PO_4 , 1.2; glucose, 11.1. The solution was gassed with 950 mL/L O_2 and 50 mL/L CO_2 , and kept the pH at 7.4. In some experiments gluconate was used to replace anions Cl^- or $\text{Cl}^-/\text{HCO}_3^-$ for making a Cl^- free or $\text{Cl}^-/\text{HCO}_3^-$ free K-HS. For $\text{Cl}^-/\text{HCO}_3^-$ -free K-HS, HEPES and Tris were used and the solution was gassed with absolute O_2 .

Cell culture

Human colonic T84 and Caco-2 cells were purchased from American Type Culture Collection (Rockville, MD). The cells were routinely maintained in DMEM/F12 for T84 or in DMEM for Caco-2 with 100 mL/L fetal bovine serum, 100 kU/L penicillin and 100 mg/L streptomycin. The cells were fed 3 times a week, and $(2-3) \times 10^5$ cells were plated on to the floating permeable support, which was made of a Millipore filter with a silicone rubber ring attached on top of it for confining the cells (0.45 cm^2). Cultures were incubated at 37°C in 950 mL/L O_2 - 50 mL/L CO_2 for 4-5 d before experiments.

Colonic mucosa preparation

Adult male Sprague-Dawley rats (Laboratory Animal Services Center, the Chinese University of Hong Kong) ranging in age from 8 to 12 wk had free access to standard rodent laboratory food and water until the day of the experiments. The animals were killed by exposure to absolute CO_2 . Segments of distal colon about 8 cm proximal to the anus were quickly removed, cut along the mesenteric border into flat sheets and flushed with ice-cold K-HS bubbled with 950 mL/L O_2 - 50 mL/L CO_2 . The tissues were pinned flat with the mucosal side down in a Sylgard-lined petri dish containing ice-cold oxygenated solution. The serosa, submucosa, and muscular layer were stripped away with fine forceps to obtain a mucosa preparation which was pretreated with indomethacin ($10 \mu\text{mol/L}$), a synthesis inhibitor of prostaglandins (PG), and $1 \mu\text{mol/L}$ of tetrodotoxin (TTX), a blocker of neuron sodium channel, 30 min before treatment with TMP. Three or four of these stripped mucosal preparations were obtained from each animal.

Short-circuit current measurements

The measurement of I_{SC} was described previously^[19]. Between the two halves of the Ussing chamber, in which the total cross-sectional area was 0.45 cm^2 , monolayers of cell lines grown on permeable supports were clamped and flat sheets of rat stripped colonic mucosa were mounted, which were bathed in both sides with K-HS and maintained at 37°C by a water jacket enclosing the reservoir. K-HS was bubbled with 950 mL/L O_2 - 50 mL/L CO_2 to maintain the pH of the solution at 7.4. Drugs could be added directly to apical or basolateral side of the epithelium. Transepithelial potential difference for every monolayer or colonic mucosa was measured by the Ag/AgCl reference electrodes (World Precision Instrument, USA) connected to a preamplifier that was in turn connected to a voltage-clamp amplifier DVC-1000 (World Precision Instrument, USA). In most of the experiments, the change in I_{SC} was defined as the maximal rise in I_{SC} following agonist stimulation and it was normalized to current change per unit area of the epithelial monolayer

($\mu\text{A}/\text{cm}^2$). The total charge transported for 15 min (the area under the curve of the agonist-induced I_{SC} response) was also used to describe the agonist-induced response ($\mu\text{C}/\text{cm}^2$). Experiments were normally repeated in different batches of culture to ensure that the data were reproducible.

Reverse transcription PCR (RT-PCR) analysis

Total RNA ($15 \mu\text{g}$) was extracted from T84, Caco-2 cells and rat colonic mucosa. Human pancreatic duct epithelial cells, CAPAN-1, were used as a positive control. Expression of NBC was analyzed by competitive RT-PCR. The specific oligo nucleotide primers for NBC were CCT CAG CTC TTC ACG GAA CT for sense and AGC ATG ACA GCC TGC TGT AG for antisense corresponding to nucleotides 333-949 with expected cDNA of 616 bp^[20]. Internal marker, GAPDH was used for semi-quantitative analysis of NBC expression in Caco-2 and T84 cells. The specific oligo nucleotide primers for GAPDH were TCC CAT CAC CAT CTT CCA G for sense and TCC ACC ACT GAC ACG TTG for antisense corresponding to nucleotides 249-764 bp with expected cDNA of 515 bp^[20].

Statistical analysis

Results were expressed as mean \pm SE. The number of experiments represented independent measurements on separate monolayers. Comparisons between groups of data were made by either the Student's *t*-test (2-group comparison) or one-way ANOVA with Newman-Keuls *post-hoc* test (3-group comparison). A *P* value less than 0.05 was considered statistically significant. EC_{50} values were determined by nonlinear regression using GraphPad Prism software.

RESULTS

TMP-induced I_{SC} responses in T84 and Caco-2 cells

TMP stimulation increased I_{SC} in both T84 and Caco-2 cells when the drug was added to either the apical or basolateral membrane. However, greater responses were achieved when TMP was added to apical membrane of T84 and basolateral membrane of Caco-2. The TMP-induced responses were concentration-dependent with an apparent EC_{50} at 0.5 and 5.1 mmol/L for T84 and Caco-2 cells respectively (Figure 1A). The TMP-induced changes in I_{SC} were calculated as the total charge transported for 15 min (the area under the curve of the TMP-induced I_{SC} response for the given time period) since the current kinetics was different in the two cell types. TMP produced a fast and sustained increase of I_{SC} in T84 cells with averaged total charge of $6100 \pm 451 \mu\text{C}/\text{cm}^2$ ($n=8$, Figure 1B) transported over 15 min in response to TMP at a concentration close to corresponding EC_{50} (1 mmol/L). However, TMP produced a I_{SC} response in Caco-2 cells with a fast transient peak followed by a lower but sustained plateau with averaged total charge of $2293 \pm 214.7 \mu\text{C}/\text{cm}^2$ ($n=7$) in response to TMP at corresponding EC_{50} (5 mmol/L, Figure 1C). Similar TMP-induced I_{SC} characteristics were observed in the same cell type at all concentrations of TMP used.

Involvement of Cl^- and HCO_3^- in TMP-induced I_{SC} responses in colonic cell lines

Removal of Cl^- from the bathing solution inhibited TMP-induced I_{SC} increase by 76%, from $6100 \pm 451 \mu\text{C}/\text{cm}^2$ to $1375 \pm 103 \mu\text{C}/\text{cm}^2$ in T84 cells ($n=7$, $P<0.001$, Figure 2). In Caco-2 cells the TMP-induced current in Cl^- -free solution was not reduced, but rather increased to $3700 \pm 388 \mu\text{C}/\text{cm}^2$ ($n=6$, $P<0.001$, Figure 3). However, the TMP-induced I_{SC} in Caco-2 was reduced by 90%, to $228.9 \pm 27.6 \mu\text{C}/\text{cm}^2$ ($n=6$, $P<0.001$) when both extracellular Cl^- and HCO_3^- were removed (Figure 3). Apical addition of Cl^- channel blockers, DPC (2 mmol/L) or

glibenclamide (1 mmol/L), could completely abolish the TMP-induced response in T84 (Figure 2A,B) and Caco-2 cells (Figure 3A,B). Basolateral addition of $\text{Na}^+\text{-K}^+\text{-2Cl}^-$ cotransporter (NKCC) inhibitor, bumetanide (100 $\mu\text{mol/L}$), inhibited TMP-induced I_{SC} in T84 cells by 96.7%, from $6\,100 \pm 451\ \mu\text{C/cm}^2$ ($n=8$) to $200 \pm 71\ \mu\text{C/cm}^2$ ($n=5$, $P<0.001$, Figure 4A), but only 47.9% in Caco-2 cells, from $2\,720 \pm 144\ \mu\text{C/cm}^2$ ($n=6$) to $1\,304 \pm 200\ \mu\text{C/cm}^2$ ($n=5$, $P<0.001$, Figure 4B). However, when an inhibitor of NBC, DIDS (200 $\mu\text{mol/L}$), was combined with bumetanide, it reduced TMP-induced current in Caco-2 cells to $181 \pm 41\ \mu\text{C/cm}^2$ by 93.3% ($n=5$, $P<0.001$, Figure 4B). Pretreatment with epithelial Na^+ channel (ENaC) blocker, amiloride (10 $\mu\text{mol/L}$) ($n=5$, $P>0.05$) or removal of Na^+ from apical solution ($n=4$, $P>0.05$) did not significantly affect the TMP-induced I_{SC} (data not shown), indicating that TMP-produced responses were mediated by $\text{Cl}^-/\text{HCO}_3^-$ secretion, but not Na^+ absorption.

TMP-induced I_{SC} response in colonic mucosa

In freshly isolated rat colonic mucosa, TMP induced different I_{SC} responses depending on the concentration used. One mmol/L of TMP evoked a sustained I_{SC} increase (Figure 5A) similar to that observed in T84 cells, with averaged total charge of $5\,133 \pm 465\ \mu\text{C/cm}^2$ (Figure 5C, $n=11$). However, at the concentration greater than 5 mmol/L, TMP induced a I_{SC} response similar to that observed in Caco-2 cells, a transient peak followed by a more sustained phase (Figure 5B), with averaged total charge of $18\,945 \pm 2\,023\ \mu\text{C/cm}^2$ (Figure 5C, $n=11$). Removal of extracellular Cl^- inhibited 65.5% of the I_{SC} induced by 1 mmol/L TMP (Figure 5C, $n=10$, $P<0.001$). However, the I_{SC} induced by 5 mmol/L of TMP was not significantly reduced by Cl^- removal ($n=6$, $P>0.05$) but was reduced by 71.6% in Cl^- and HCO_3^- -free solution (Figure 5, $n=5$), indicating a greater extent of the involvement of HCO_3^- in the response to 5 mmol/L TMP as compared to the response

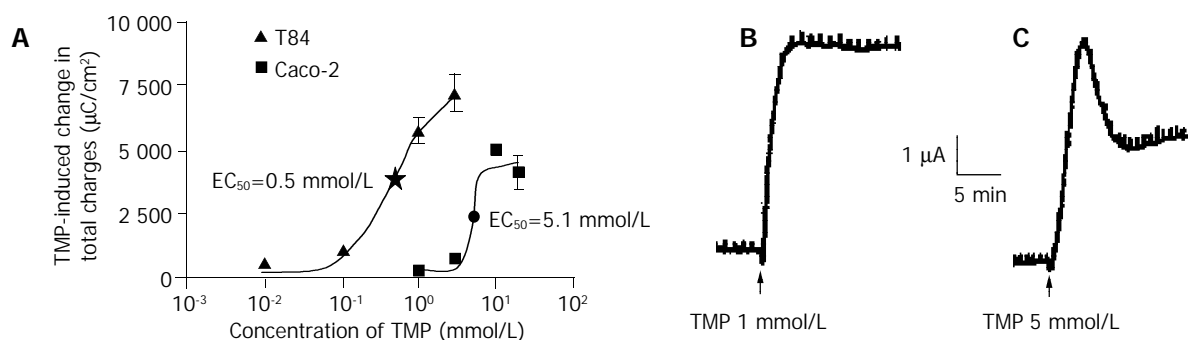

Figure 1 TMP-induced I_{SC} response in T84 and Caco-2 cell lines. The concentration-response curve for TMP-induced response in T84 and Caco-2 cells, and each datum was obtained from at least 4 individual experiments. A: Values are mean \pm SE of maximal I_{SC} increase; B: Representative I_{SC} recordings in response to apical addition of TMP (1 mmol/L) in T84 cells; C: Basolateral application of TMP (5 mmol/L) in Caco-2 cells.

Figure 2 Cl^- dependence of TMP-induced I_{SC} increase in T84 cells. Representative I_{SC} recording with arrows indicating TMP (1 mmol/L) added apically, which was blocked by apical adding DPC. Values are mean \pm SE; $^cP<0.001$. A: Normal; B: Cl^- -free; C: K-HS, comparison of TMP-induced total charge transferred in normal and Cl^- -free K-HS.

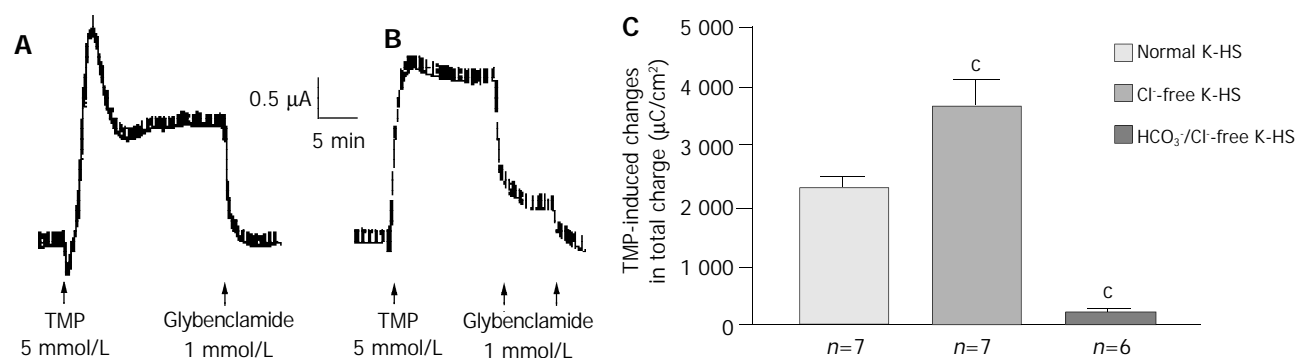

Figure 3 HCO_3^- dependence of TMP-induced I_{SC} increase in Caco-2 cells. Representative I_{SC} recording with arrows indicating TMP (5 mmol/L) added basolaterally, which was abolished by apical application of glibenclamide. Values are mean \pm SE; $^aP<0.05$, $^bP<0.01$ and $^cP<0.001$. A: Normal; B: Cl^- -free; C: K-HS, comparison of TMP-induced total charges transferred in normal and Cl^- -free K-HS.

to 1 mmol/L TMP. Basolateral addition of bumetanide (100 μ mol/L) blocked 80.9% responses induced by 1 mmol/L TMP, from $5\,133 \pm 465\ \mu\text{C}/\text{cm}^2$ to $978 \pm 357\ \mu\text{C}/\text{cm}^2$ ($n=9$, $P<0.001$, Figure 5D), but only blocked 43.2% of the responses induced by 5 mmol/L of TMP, from $18\,945 \pm 2\,023\ \mu\text{C}/\text{cm}^2$ to $10\,762 \pm 513\ \mu\text{C}/\text{cm}^2$ ($n=7$, $P<0.05$). Basolateral addition of

DIDS (100 μ mol/L) had no significant effect on the response induced by 1 mmol/L of TMP ($n=7$, $P>0.05$), but inhibited 66.5% of the responses induced by 5 mmol/L of TMP, from $17\,143 \pm 2\,408\ \mu\text{C}/\text{cm}^2$ to $8\,248 \pm 328\ \mu\text{C}/\text{cm}^2$ ($n=7$, $P<0.001$), indicating possible involvement of NBC in the 5 mmol/L TMP-induced response.

A: Comparison of TMP (1 mmol/L)-induced I_{sc} responses in T84 cells in the absence and presence of basolateral addition of bumetanide (100 μ mol/L); B: Comparison of TMP (5 mmol/L)-induced I_{sc} responses in Caco-2 cells in the absence and presence of basolateral addition of inhibitors indicated.

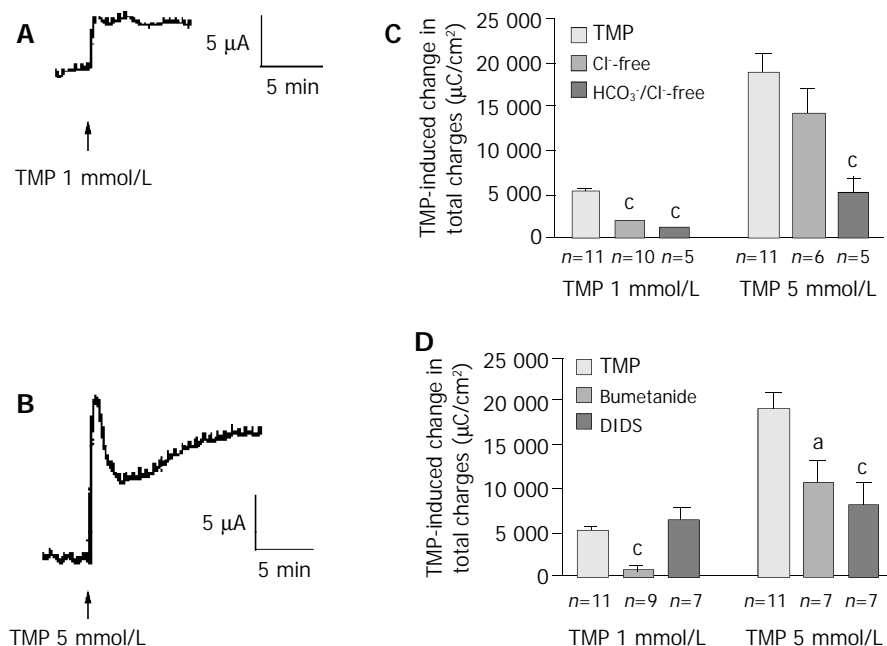

Figure 5 TMP-induced anion secretions in rat colonic mucosa. Representative I_{sc} recording values are mean \pm SE; ^a $P<0.05$, ^b $P<0.01$, ^c $P<0.001$. A: 1 mmol/L; B: 5 mmol/L of TMP added basolaterally in normal K-HS; C: Comparison of TMP (1 and 5 mmol/L)-induced I_{sc} obtained in normal and Cl^- -free as well as both of Cl^- and HCO_3^- -free solutions; D: Comparison of TMP (1 and 5 mmol/L)-induced I_{sc} obtained in basolateral pretreatment of colonic mucosa with bumetanide (100 μ mol/L) and DIDS (100 μ mol/L).

Figure 6 RT-PCR analysis of mRNA expression of $\text{Na}^+/\text{HCO}_3^-$ cotransporter (NBC) in colonic cells. A: RT-PCR results with products as expected of NBC found in rat colon (1), T84 (2) and Caco-2 (3) with positive control (4) using pancreatic duct cells (CAPAN-1) and negative control (5) where cDNA was omitted. B: Semi-quantitative analysis of NBC expression in Caco-2 (1); C: T84 (2) cells with NBC to GAPDH (internal marker) ratio shown.

RT-PCR analysis of NBC expression in T84, Caco-2 cells and colonic mucosa

NBC was expressed in all cells and tissues examined by RT-PCR (Figure 6A). However, semi-quantitative analysis showed that the nucleotide expression level in Caco-2 cells was 4.8-fold over that of T84 (Figure 6B). The NBC nucleotide fragment was confirmed by nucleotide sequencing (Figure 6C).

DISCUSSION

The present study has demonstrated for the first time the effects of TMP on the colonic anion secretion and revealed that the different doses of TMP could induce differential Cl^- and HCO_3^- -mediated anion secretion by different colonic cell types. The differential effects of TMP on T84 and Caco-2 cells were not only reflected by the differences in the concentration-dependent I_{SC} responses and the I_{SC} kinetics, but also in the extents to which Cl^- and HCO_3^- were involved in mediating the TMP responses. This was supported by the observation that the TMP-induced response in T84 was sensitive to extracellular Cl^- replacement or an inhibitor of basolateral NKCC, bumetanide, while the response in Caco-2 cells was relatively insensitive to these treatments, at least to a much less extent. Instead, the response in Caco-2 cells was sensitive to the removal of extracellular HCO_3^- and an inhibitor of basolateral NBC, which has been shown to mediate HCO_3^- entry into the cells in a number of tissues including the pancreas^[21,22], intestine^[23], kidney^[24] and endometrium^[25]. Although DIDS is also known to inhibit $\text{Cl}^-/\text{HCO}_3^-$ exchanger (AE), the involvement of AE in this case was unlikely since it was not electrogenic. The high expression of NBC in Caco-2 cells but not T84 cells was also consistent with the DIDS sensitivity profiles in the two cell types, suggesting the involvement of NBC in mediating basolateral HCO_3^- transport in Caco-2 cells. The observed predominant Cl^- secretion elicited by TMP in T84 cells was consistent with the Cl^- -secreting characteristics of this colonic crypt-like cell model. Although secretory properties were less well characterized in Caco-2 cells, a previous study^[26] has demonstrated I_{SC} increases in response to cAMP-evoking agents including PDE inhibitor, 3-isobutyl-1-methylxanthine (IBMX), in Caco-2 cells with biphasic current kinetics and DIDS sensitivity similar to that of the TMP-induced I_{SC} response observed in the present study. Interestingly, in the same study alkalization of the apical solution could be induced which was also inhibited by basolateral addition of DIDS. Similar HCO_3^- -dependent and DIDS-sensitive I_{SC} was also observed in the intestine^[27-29]. Together with the presently demonstrated NBC expression in Caco-2 cells, these results strongly indicate a role of villus-like Caco-2 cells in HCO_3^- -potentiated secretion. Thus, it appears that colonic Cl^- and HCO_3^- -potentiated secretion may be differentially mediated by different colonic cell types.

The observed difference between T84 and Caco-2 cells in their I_{SC} responses to different concentrations of TMP suggested that colonic Cl^- and HCO_3^- -mediated secretions might be differentially elicited by the same agent depending on the concentrations used, probably due to differential expression of receptors, cotransporters, exchangers and ion channels^[10-13] leading to differential responses to TMP. This notion is supported by the observation that TMP at different concentrations could elicit different I_{SC} responses from freshly isolated rat colon mucosa with distinct current characteristics. Interestingly, the colonic mucosal I_{SC} response elicited by 1 mmol/L of TMP had characteristics similar to the TMP-induced response in T84 cells (e.g. sensitive to Cl^- removal and bumetanide but insensitive to DIDS), indicating predominant Cl^- secretion, whereas the colonic mucosal I_{SC} response elicited by TMP at

concentrations greater than 5 mmol/L resembled the response observed in Caco-2 cells (e.g., more sensitive to DIDS than to Cl^- removal and bumetanide), indicating predominant HCO_3^- -potentiated secretion at this concentration range. The fact that distinct TMP-induced I_{SC} responses with characteristics similar to those observed in human colonic T84 and Caco-2 cells could be observed in intact rat colonic mucosa suggests that the secretory activities of T84 and Caco-2 cells may reflect the secretory properties of the colon, which may be similar in rats and humans. The present findings suggest that by having different sensitivities to stimulation in distinct colonic cell types, the colon in rats or humans, may be able to secrete either Cl^- -rich fluid or HCO_3^- -rich fluid. In other words, colonic Cl^- and HCO_3^- -mediated secretions may be differentially regulated by the same physiological regulator depending on its local concentration. Possible candidates of physiological regulators may include prostaglandins, VIP and secretin, all of which are known to be present in the colon and able to increase intracellular cAMP^[30-32]. In fact, secretin has been shown to stimulate Cl^- secretion in the colon^[33] and HCO_3^- secretion in Caco-2 cells^[26]. It should be noted that TMP has been shown to be a cAMP-evoking agent having an action similar to PDE inhibitor in antiplatelet activity^[15]. The further study is required to identify the signaling pathway in mediating TMP effects on colonic cells.

The present finding of predominant HCO_3^- -mediated secretion by villus-like Caco-2 cells is of physiological interest. Although a constant pH microclimate at the luminal surface has been considered to have a decisive influence on the reabsorption of Cl^- and absorption of weak electrolytes such as short-chain fatty acids^[34], the mechanisms involved in the maintenance and regulation of the pH microclimate are poorly understood. A recent study has demonstrated that HCO_3^- is the most important factor in maintaining a constant pH microclimate at the luminal surface^[35]. However, the origin of HCO_3^- responsible for this was not demonstrated although a continuous secretion of HCO_3^- at the luminal surface of the colonic epithelium has been observed^[36]. The present study suggested that the villus/surface-like epithelial cells were capable of secreting HCO_3^- upon stimulation, and thus, they are likely to contribute to the maintenance and regulation of the pH microclimate observed at the luminal surface of the colon. Being situated at the luminal surface, villus epithelial cells have the advantage over crypt cells in that they can sense the small variations in the pH microclimate at the luminal surface and secrete HCO_3^- directly adjusting the luminal microclimate. This suggests that the secretory role of villus/surface epithelium is distinct from that of crypts which are mainly responsible for Cl^- secretion on which colonic fluid secretion depends. The differential expression of NBC, the major basolateral transport mechanism for HCO_3^- entry^[23], in the two human colonic cells lines also supports this contention.

The mechanism(s) by which Cl^- and HCO_3^- exit through the apical membrane remains to be elucidated. The fact that both Cl^- and HCO_3^- secretions could be completely blocked by DPC and glibenclamide, both of which are known to inhibit CFTR, suggest that a common mechanism may be involved. CFTR appears to be a possible candidate since its involvement in Cl^- and HCO_3^- secretion has been demonstrated^[5-7]. The investigation of detail mechanism involved in mediating the TMP-stimulated anion secretions is currently undertaken in our laboratory.

It should be noted that while TMP has been used clinically to treat cardiovascular disorders^[14], no study has been reported, at the time of writing, on its effect on colonic secretion. The present results suggest that potential application of TMP as an alternative treatment of GI disorders may be further explored, considering its natural origin and differential effects on colonic Cl^- and HCO_3^- secretion.

Abstract

AIM: To investigate Time- and pH-dependent colon-specific drug delivery systems (CDDS) for orally administered diclofenac sodium (DS) and 5-aminosalicylic acid (5-ASA), respectively.

METHODS: DS tablets and 5-ASA pellets were coated by ethylcellulose (EC) and methacrylic acid copolymers (Eudragit® L100 and S100), respectively. The *in vitro* release behavior of the DS coated tablets and 5-ASA coated pellets were examined, and then *in vivo* absorption kinetics of DS coated tablets in dogs were further studied.

RESULTS: Release profile of time-dependent DS coated tablets was not influenced by pH of the dissolution medium, but the lag time of DS release was primarily controlled by the thickness of the coating layer. The thicker the coating layer, the longer the lag time of DS release is. On the contrary, in view of the pH-dependent 5-ASA coated pellets, 5-ASA release was significantly governed by pH. Moreover, the 5-ASA release features from the coated pellets depended upon both the combination ratio of the Eudragit® L100 and S100 pH-sensitive copolymers in the coating formulation and the thickness of the coating layer. The absorption kinetic studies of the DS coated tablets in dogs demonstrated that *in vivo* lag time of absorption was in a good agreement with *in vitro* lag time of release.

CONCLUSION: Two types of CDDS, prepared herein by means of the regular coating technique, are able to achieve site-specific drug delivery targeting at colon following oral administration, and provide a promising strategy to control drug release targeting the desired lower gastrointestinal region.

INTRODUCTION

Currently, a novel oral colon-specific drug delivery system

(CDDS) has been developing as one of the site-specific drug delivery systems. This delivery system, by means of combination of one or more controlled release mechanisms, hardly releases drug in the upper part of the gastrointestinal (GI) tract, but rapidly releases drug in the colon following oral administration. The necessity and advantage of CDDS have been well recognized and reviewed recently^[1-3]. In view of CDDS specifically delivering drug to the colon, a lot of benefits would be acquired in terms of improving safety and reducing toxicity when treating local or systemic chronic diseases. First, as for treating localized colonic diseases, i.e. ulcerative colitis, Crohn's disease and constipation *etc.*, the optimal drug delivery system, such as CDDS, should selectively deliver drug to the colon, but not to the upper GI tract^[1]. For this reason, the drug concentration was significantly lessened in the upper GI tract, while increased considerably in the colon, resulting in alleviated GI side effects. Second, the colon is referred to as the optimal absorption site for protein and polypeptide after oral administration, because of the existence of relatively low proteolytic enzyme activities and quite long transit time in the colon^[2,3]. To our knowledge, CDDS could provide reliable protection against GI enzymatic degradation by releasing the polypeptide and protein nearly unchanged and fully efficacious in the preferred colon, thereafter resulting in remarkably increased bioavailability for protein and polypeptide. Finally, CDDS would be advantageous when a delay in absorption is desirable from a therapeutic point of view, as for the treatment of diseases that have peak symptoms in the early morning and that exhibit circadian rhythms, such as nocturnal asthma, angina and rheumatoid arthritis^[1,4,5].

There were currently a few strategies to achieve colonic specificity, such as bacterially triggered and pressure-controlled CDDS^[6]. The aim of this study was to explore the feasibility of the time- and pH-dependent CDDS, diclofenac sodium (DS) and 5-aminosalicylic acid (5-ASA) being selected as model drugs, respectively. Besides, we were intended to exploit the typical pharmaceutical coating technology to attain the time- and pH-dependent colon-specific drug delivery. Time-dependent colon-specific DS coated tablets consisted of a tablet core and a coating layer composed of a water-insoluble ethylcellulose (EC) and a water-soluble channeling agent. pH-dependent colon-specific 5-ASA coated pellets consisted of a pellet core and a coating layer of the pH-sensitive methacrylic acid copolymers (Eudragit® L100 and S100).

DS was frequently used for treating rheumatoid arthritis^[2], which had apparent circadian rhythms and peak symptoms in the early morning. When orally administering DS conventional formulation, it was difficult to achieve the desired clinical effect, because it elicited patients' incomppliance of administration in the early morning to coordinate the rhythm of rheumatoid arthritis, due to rapid absorption of the conventional formulation. However, colon-specific DS delivery was not only effective, but also more convenient for administration than the conventional formulation. On the other hand, 5-ASA was usually used to effectively treat ulcerative colitis and Crohn's disease in clinical practice^[7]. It was unstable in the stomach, and readily absorbed in the small intestine, eliciting the undesirable adverse effect. Thereby, 5-ASA was prepared as

the CDDS in this study, which protected 5-ASA from the upper GI conditions^[1] and allowed for 5-ASA rapid release in the designated colonic region.

MATERIALS AND METHODS

Preparation of time-dependent colon-specific DS coated tablets and in vitro/in vivo tests

Preparation of DS core tablets Core tablets consisted of 40% (w/w) diclofenac sodium (Yanzhou Pharm., China), 40% (w/w) sodium carboxymethyl starch sodium, 8% (w/w) sodium chloride, 2% (w/w) other excipients. Drug and excipients were blended and sieved (mesh 80); the mixtures were granulated with adhesives and dried 1 h at 55 °C. Core tablets with average weight of 100 mg were prepared using a single punch tablet machine (Type-TDP, 1st Pharm Machine Manu. Co., Shanghai, China). The diameter of core tablets was 6 mm.

Tablet coating The core tablets were coated in a conventional rotating pan. For the coating process, the rotation speed was adjusted to 36 r/min with the coating pan set at an angle of 45°, nozzle port size 0.8 mm; inlet air temperature was 35 °C; tablet bed temperature was 25 °C; the coating solution was sprayed onto the tablets at a flow rate of 0.8 mL/min. The coating solution was 30 g/L EC (Colorcon Co., China) in ethanol solution which contained diethyl phthalate (20% of EC, w/w) as plasticizer, and PEG 400 (15% of EC, w/w, Pharm. Med. Supply Ltd. Co., China) as channeling agent.

Dissolution test Dissolution studies were carried out with paddle method at a rotation speed of 100 r/min and 900 mL distilled water as medium at 37 °C ($n=6$). Samples were collected at predetermined time points, analyzed for DS contents using a UV-spectrophotometer (UV-9100, Ruili Co., China) at 276±1 nm and calculated cumulative release amounts of DS over the sampling times.

Absorption kinetics of time-dependent colon-specific DS coated tablets

Experimental protocol Six male dogs (weight 20±2.5 kg) were randomly assigned to one of two crossover experiments with a 7-d washout period. Dogs were fasted overnight for 12 h before administration and free access to water was allowed. Each dog was orally administered either reference formulation (four enteric coated tablets, Liaodong Pharm. Ltd. Co., batch: 010910, tablet containing 25 mg of DS) or test formulation (four EC coated tablets, each tablet containing 25 mg of DS with 7.5% coating level), respectively. Blood samples were collected at predetermined times for each protocol, respectively: (1) 1, 2, 2.5, 3, 3.5, 4, 4.5, 5, 6, 7, 8, 10, and 24 h for the reference; (2) 1, 3, 4, 5, 5.5, 6, 6.5, 7, 7.5, 8, 9, 10, 12, and 24 h for the test. Plasma was immediately obtained by centrifuging the blood samples at 3 000 r/min for 10 min. The plasma samples were maintained in a freezer at -20 °C until analysis.

Chromatographic conditions The quantitative determination was performed on a high-performance liquid chromatograph equipped with a PU-1580 pump (Jasco, Japan) and 970/975 UV detector (Jasco, Japan). The column was a Hypersil ODS C-18 (250 mm×4.6 mm, 5 µm). The mobile phase consisted of methanol: water: triethylamine: glacial acetic acid (68:22:0.044:0.044, v/v)^[8]. The eluate was monitored at 274 nm, with a sensitivity of 0.001 AUFS. A flow rate was 1.0 mL/min, and the column temperature was maintained at 35 °C.

Sample preparation A 0.5 mL plasma sample was mixed with 20 µL of 4.8 mmol/L inuprofen (internal standard) and 0.6 mL of 1.0 mol/L phosphate buffer in a glass centrifuge tube. The solution was mixed on a vortex mixer for 2 min, and then added 3 mL of a solution of hexane and isopropyl alcohol (4:1, v/v). The mixture was mixed on a vortex mixer for 2 min

again and centrifuged at 3 000 r/min for 5 min. The organic layer was transferred into a clean tube and evaporated to dryness under nitrogen at 35 °C. The residue was dissolved in 100 µL of mobile phase and 20 µL of the solution were injected into the HPLC system.

Data analysis C_{max} represents the maximum drug concentration, t_{max} the time to reach peak concentration, and t_{lag} the lag time of drug. These values were obtained as directly measured values. The elimination rate constant (K_e) was calculated from the slope of the logarithm plasma concentration to time at the end four points. The areas under the plasma concentration-time curve (AUC_{0-t_n}) were calculated by the trapezoidal method. The relative bioavailability ($F\%$) was calculated by the equation: $F(\%) = (AUC_{Test\ formulation} \cdot Dose_{Reference\ formulation}) / (AUC_{Reference\ formulation} \cdot Dose_{Test\ formulation})$. The percentages of absorption *in vivo* were calculated by the Wagner-Nelson method.

Preparation of pH-dependent colon-specific 5-ASA coated pellets

Preparation of 5-ASA pellets Pellets (1.0-1.2 mm in diameter) consisted of 5-aminosalicylic acid (5-ASA, Genlou Chem. Ltd. Co., China), microcrystalline cellulose (MCC, Avicel PH101, Asahi Chem. Ind. Ltd. Co., Japan) and lactose. Drug and excipients were blended and sieved (mesh 80); the mixtures were prepared as wet mass with adhesives. Pellets were prepared by extruder and spheronizer (Institute of Machinery for Chemical Industry East China University of Science and Technology, Shanghai, China). The speed of the extrusion was 30 r/min. The speed of the spheronization was 1 200 r/min and the time of the spheronization was 5 min^[9,10].

Pellet coating The pellets were coated in a fluidized-bed coating apparatus (Shenyang Pharm. Univer., China). For the coating process, nozzle port size was 0.8 mm; inlet air temperature 45 °C; atomizing pressure 1.2 kg/cm²; coating solution was sprayed onto the pellets at a flow rate of 0.8 mL/min. The coating solution was aqueous dispersions of various proportions of Eudragit® L100 and Eudragit® S100 (Röhm Pharma GmbH, Germany). The plasticizer TEC was added directly to the polymer dispersions^[11].

Dissolution test Dissolution studies were carried out with a basket method at a 100 r/min rotation speed and 37 °C, 900 mL dissolution medium according to ChP 2000. The dissolution tests were performed in HCl pH 1.2, phosphate buffer solution pH 6.0, 6.8, 7.2 or 7.5, respectively. Samples were collected at predetermined time points, analyzed for 5-ASA content using a UV-spectrophotometer (UV-9100, Ruili Co., China) at 302 nm and 330 nm for 5-ASA assay in 0.1 mol/L HCl and the phosphate buffer solutions, respectively.

In order to simulate the pH changes along the GI tract, three dissolution media with pH 1.2, pH 6.0, and pH 7.2, were sequentially used, referred to as the sequential pH change method (Table 1). pH 6.0, and pH 7.2 media were 0.05 mol/L phosphate buffer solution. When performing release experiments, the pH 1.2 medium was first used for 2 h, then removed, and the fresh pH 6.0 dissolution medium was added. After 1 h, the medium was removed again, and fresh pH 7.2 dissolution medium added. The UV readings were taken at 302 nm and 330 nm for 5-ASA measurement in 0.1 mol/L HCl and the buffer media, respectively^[12,13]. And then the 5-ASA cumulative release percentage was calculated over the sampling times.

Table 1 Dissolution conditions of 5-ASA coated pellets

pH	λ_{max} (nm)	Time (h)	Simulated GI region
1.2	302	2	Stomach
6.0	330	1	Duodenum
7.2	330	5	Lower small intestine and colon

RESULTS

Time-dependent colon-specific DS coated tablets

The DS core tablets were coated by the coating formulation, consisting of 30 g/L EC, diethyl phthalate (20% of EC, w/w) as a plasticizer and PEG 400 (15% of EC, w/w) as a channeling agent in ethanol solution. The *in vitro* release behavior of the DS coated tablets with different coating levels (3%, 5%, 7%, 9%, and 11%, w/w), was studied. As shown in Figure 1, the coating level exercised a significant effect on the lag time of DS release from the coated tablets. Manifestly, the greater the coating level, the longer the lag time of DS release from the coated tablets. However, once the coating layer was broken up, DS then was rapidly released from the coated tablets (Figure 1). The effects of dissolution medium pH on the release profiles of the DS coated tablets at 7.5% coating level are shown in Figure 2. To be evident, the pH values of media did not exert a significant effect on the DS release pattern from the coated tablets. The *in vitro* release profile of test DS coated tablets at 7.5% coating level was compared with the marketed DS enteric tablets, as shown in Figure 3.

Figure 1 Effect of different coating levels on the DS release from the coated tablets in distilled water. The tablets were coated at five levels of 3% (◇), 5% (○), 7% (△), 9% (□), 11% (×) (w/w, total solid applied) ($n=6$).

Figure 2 Effect of pH of the dissolution medium on DS release from the coated tablets. The tablets were coated at 7.5% (w/w, total solid applied) level ($n=6$). pH1.0 (◇), pH2.0 (■), pH5.0 (▲), pH6.8 (○), pH7.6 (△) of the dissolution media.

Figure 3 DS dissolution profiles of test coated tablets (○) and the reference enteric coated tablets (◆) ($n=6$).

The reference enteric tablets started DS release at 2 h, while the test DS coated tablets began to release DS at 4 h, after being put in the dissolution medium. The lag time of DS release from the test tablets was significantly longer than that of reference enteric tablets. Moreover, the cumulative DS release percentage of test tablet was nearly 100% within 7 h.

pH-dependent colon-specific 5-ASA coated pellets

The 5-ASA pellets were coated with combination of Eudragit® L100-Eudragit® S100 methacrylic acid pH-sensitive copolymers, and their release characteristics were examined by three sequential dissolution media with different pH values in order to mimic pH changes along GI tract. We investigated the effect of combination ratios of Eudragit® L100-Eudragit® S100 in the coating formulation on the release profiles of 5-ASA coated pellets, as shown in Figure 4.

The combination ratios of Eudragit® L100-Eudragit® S100 in the coating formulation played a significant role in regulating the release behavior of 5-ASA coated pellets. When employing 1:4 (w/w) combination ratio of Eudragit® L100-Eudragit® S100 as the coating formulation, 5-ASA was released less than 1.0% in pH 1.2 dissolution medium (simulated gastric fluid) until 2 h, and less than 3.0% in pH 6.0 (simulated duodenum fluid) at 1 h after changed to fresh medium, and more than 80% in pH 7.2 (simulated lower small intestinal and colonic fluid) at 1.5 h after changed to fresh medium. When the pellets were coated with Eudragit® L100-Eudragit® S100 combination (w/w) ratios of 1:0, 4:1, and 1:1, the cumulative release percentage of 5-ASA was 1.0-3.6% in pH 1.2 until 2 h, 11-37% in pH 6.0 at 1 h, and more than 80% in pH 7.2 at 1.5 h, the results indicating that the earlier measurable release occurred. Pellets coated with Eudragit® S100 alone displayed the slowest release rate, the cumulative release percentage of 5-ASA was less than 0.5% in pH 1.2 up to 2 h, was less than 1.0% in pH 6.0 at 1 h, and was not more than 10% in pH 7.2 at 1.5 h.

The effects of the coating level on the release properties of 5-ASA coated pellets were also examined, with the coating level ranging from 0% to 25% and the combination ratio of Eudragit® L100-Eudragit® S100 set at 1:4 (w/w), as shown in Figure 5. As the coating level and thickness of coating layer increased, the acid-resistant property of coating layer was enhanced. The coating level being 25% (w/w), almost none of the 5-ASA was released from coated pellets in pH 1.2 and pH 6.0 dissolution media. By contrast, the cumulative release percentage of 5-ASA was more than 80% in pH 7.2 at 1.5 h, regardless of the coating levels. Accordingly, this formulation, with the combination ratio Eudragit® L100-Eudragit® S100 being 1:4 (w/w) and the coating level being 25%, would be a promising candidate for designed DS pH-dependent CDDS.

Moreover, we examined the influences of medium pH values on the release characteristics of the 5-ASA coated pellets, utilizing 1:4 (w/w) combination ratio Eudragit® L100-Eudragit® S100 as the coating formulation and setting the coating level at 25%. Five pH values (1.2, 6.0, 6.8, 7.2 and 7.5) of dissolution media were utilized. As shown in Figure 6, pH values of medium notably affected 5-ASA release profiles from the pH-dependent coated pellets. When pH increased from 1.2 to 7.5, the release rate of 5-ASA from the coated pellets was outstandingly enhanced.

In vivo absorption kinetics of time-dependent colon-specific DS coated tablets

Either DS reference formulation (four 25 mg enteric coated tablets) or DS test formulation (four 25 mg EC coated tablets) was orally administered in the two crossover experimental design in dogs at a dose of 100 mg/body, respectively. The concentration-time curve of DS in plasma is illustrated in Figure 7. The pharmacokinetic parameters are calculated and listed in Table 2. The mean lag time of DS absorption from the test

formulation was as long as 5.80 h, while that for the reference formulation was 2.80 h after oral administration. This result was well consistent with the mean *in vitro* lag time of DS release from two formulations, the test tablets being 4 h versus reference enteric tablets being 2 h. In addition, C_{max} of the test and the reference formulations was 8.17 mg/L and 10.05 mg/L, respectively. The relative bioavailability of test formulation versus reference formulation was 86.38%.

Absorption percentage *in vivo* of DS for test formulation was assessed by the Wagner-Nelson method. Both absorption percentage *in vivo* of DS ($F(t)$) and the cumulative release percentage *in vitro* of DS ($f(t)$) versus time profiles, demonstrate a similar contour curve in Figure 8. Furthermore, there existed a significant correlation between $F(t)$ and $f(t)$ ($r=0.95$) for test formulation, indicative of the good relationship between *in vitro* release and *in vivo* absorption processes.

Figure 4 5-ASA release profile of pellets coated at 25% level with various Eudragit® L100-Eudragit® S100 combination ratios of 1:0 (◆), 4:1 (□), 1:1 (△), 1:4 (○) and 0:1 (●) (w/w), using the sequential pH change method ($n=6$).

Figure 5 5-ASA release profile of pellets coated at 5 levels of uncoated (◆), 5% (□), 10% (△), 15% (○), 25% (●) (w/w, total solid applied) with Eudragit® L100-Eudragit® S100 combinations of 1:4 (w/w), using the sequential pH change method ($n=6$).

DISCUSSION

It has been well found that gastric emptying of a preparation was variable and depended primarily upon whether subjects were fed or not, and upon the properties of the preparation. On the contrary, the transit time in small intestine for the preparation was surprisingly constant at 3 ± 1 h and appeared to be independent of the types of the preparations and whether subjects were fed or not^[14]. On the basis of the above understandings, we designed the time-dependent colon-specific drug delivery to achieve no measurable drug release in the upper part of GI tract and a considerable drug release after arrival at colon.

The time-dependent DS coated tablets were prepared by means of the coating technology, with the coating formulation consisting of the water-insoluble EC, the water-soluble channeling agent PEG 400 and the membrane plasticizer diethyl phthalate. Generally, the coating layer of EC was mainly hydrophobic and was moderately impermeable to water molecules. And the water-soluble channeling agent was rapidly dissolved in water, resulting in the formation of numerous micro-channels across the coating layer. Then, water molecules

could penetrate into the tablet core via these channels to cross the hydrophobic EC membrane. Water uptake caused the expansion of the disintegrating agent within the tablet core, resulting in a gradual build-up of pressure within the coated tablets. Once the inside pressure exceeded the critical disrupted value that the coating layer resisted most, the coating layer would be ruptured and release drug in a manner of burst, thus forming the delay effect of drug release from the coated tablets. Taken together, the formation of micro-channels was the first crucial step, and the critical disrupted pressure governed by the coating layer and the expansibility of the disintegrating agent were the key factors for time-dependent controlled release^[15].

The release profiles of the DS coated tablets at 7.5% coating level were not affected by the pH values of media (Figure 2). This was reasonably expected, since the channeling agent PEG 400 was pH-insensitive and formation of the micro-channels was not affected by pH. The effects of the coating level on the lag time of DS release from the coated tablets were tested, indicating that the coating level played a significant role in controlling the lag time of release. To increase the coating level would extend the lag time of DS release from the coated tablets (Figure 1). There were two possible mechanisms contributing to this phenomenon. For one thing, since the hydrophobic EC membrane was relatively impermeable to water molecules, substantial effect on the rate of the water molecules diffusion and water uptake, was exerted by the number, size, length and tortuosity of the aqueous micro-channels in the coating layer. The coating level and thickness of the coating layer certainly determined the rate of water uptake, by controlling the formation rate and physical characteristics of the aqueous channels. To be evident, the increase of the coating level would elicit the longer and more tortuous aqueous micro-channels, severely impairing the rate of water uptake. Alternatively, the thicker coating layer developed the higher critical resistant pressure to be surpassed for disrupting the coating membrane, required the greater water uptake to gradually build up inside pressure by the disintegrating agent's expansion and prolonged the lag time of drug release from the coated tablets^[16].

The mean *in vivo* lag time of the DS absorption from coated tablets was significantly longer than that from enteric tablets, being 5.80 h vs 2.80 h (Figure 7 and Table 2). The results were in accordance with the *in vitro* lag time of DS release from two formulations, and the lag time of DS release from test tablets was nearly 2 h longer than that from the enteric tablets (Figure 3). Furthermore, the *in vivo* absorption kinetics of the time-dependent DS coated tablets was assessed by the typical Wagner-Nelson method. The absorption percentage *in vivo* versus time profile was analogous to the cumulative release percentage *in vitro* versus time profile, which validated the *in vitro* dissolution conditions and verified the utility of the time-dependent CDDS (Figure 8). The good correlation coefficient ($r=0.95$) between *in vivo* absorption and *in vitro* release percentages, further confirmed this conclusion.

To our knowledge, there exists a pH gradient along the GI tract, a fact that pH in the stomach is approximately 1.5 in the fasted state, ranges roughly from 5.0 to 7.0 in the small intestine, and from 6.0 to 7.2 in the colon^[1]. The pH values at the end of ileum and in the colon are notably higher than the upper GI tract, therefore providing the rationale for developing pH-dependent CDDS. In addition, a novel dosage form, pellets, is the multiple units' drug delivery system, and it is superior to the conventional preparation, such as tablets, for the following reasons. The pellets appear to be less influenced by the physiologic factors, such as the gastric emptying, intestinal transit, than tablets. Moreover, the pellets could be widely and evenly distributed in the GI tract surfaces, which increase the drug-tract contact surface and thus improve bioavailability.

Finally, the release failure of the individual unit hardly affects the total release behavior due to the multiple units, whereas tablets do not^[17].

Eudragit® L100 and S100 were methacrylic acid pH-sensitive copolymers and began to be dissolved from pH 6.0 and pH 7.0, respectively. The combination utilization of L100 and S100 would be capable of designing the suitable copolymers intended to begin being dissolved from the desired pH environment in the lower GI tract (pH variation range of 6.0-7.0). Clearly, the combination ratio of L100 and S100 exerted a great effect on the 5-ASA release characteristic from the coated pellets. The combination ratios (1:0, 4:1, 1:1, and 1:4, 0:1) of L100 and S100 hardly released drug in pH 1.2 until 2 h, indicating the acid-resistant properties of the coated polymers (Figure 4). After changing to pH 6.0 fresh medium, L100 could to be dissolved and the channels were then quickly created in the coating membrane; conversely, S100 did not. Therefore, the higher the proportion of L100 in the coating formulation, the more channels formed, thus allowing for the higher 5-ASA release^[12]. After converting into the pH 7.2 fresh medium, both L100 and S100 could be dissolved; by contrast, the dissolution rate of L100 was faster than S100. Thus the higher amount of L100 in the coating formulation, the faster dissolution and disappearance of the coating layer, leading to rapid release of 5-ASA (Figure 4). The dissolution profile for the 0:1 coating formulation at pH 7.2 demonstrated that the dissolving process of the coating layer of S100 alone was rather slow, resulting in very slow drug release.

Fixing the combination ratio of Eudragit® L100 and S100 at 1:4, the coating level remarkably influenced the 5-ASA release from coated pellets (Figure 5). When the coating level was less than 25%, a measurable 5-ASA release was observed in pH 1.2 and 6.0 media. The coated pellets at 25% coating level scarcely released 5-ASA in pH 1.2 and 6.0 media, and rapidly released in pH 7.2 medium. This coating level of pellets (25%) was significantly higher than that of tablets (10%) in this study, because of the ratio of surface area of pellets considerably greater than tablets. The lower coating level for pellets would form an incomplete closed membrane around pellets, and elicited a measurable drug release in pH 1.2 and 6.0 media (Figure 5). The coating level of pellets 25%, however, could form uninterrupted and homogenous coating layer, swiftly released 5-ASA in pH 7.2, but not in pH 1.2 and 6.0 media. On the other hand, the higher coating level would require the longer processing time, escalation of cost and further 5-ASA was incapable of being rapidly released from pellets in pH 7.2 medium (the coating level $\geq 35\%$, unpublished data). Since the coating copolymers were pH-sensitive, 5-ASA release from the coated pellets was expected to be influenced by the dissolution medium pH, as confirmed in Figure 6.

In summary, two controlled release mechanisms, i.e. time- and pH-dependent, could achieve colonic-specific drug delivery following oral administration. In addition, both CDDS were relatively inexpensive and easy to be manufactured using conventional pharmaceutical coating technique, and provided the promising candidates for specifically delivering drug to the targeted colon region, in particular for DS and 5-ASA in this study, respectively.

Abstract

AIM: Bicyclol, 4,4'-dimethoxy-5,6,5',6'-dimethylene-dioxy-2-hydroxymethyl-2'-carbonyl biphenyl, is a new anti-hepatitis drug. The aim of the present study was to investigate the protective effect of bicyclol on concanavalin A (Con A)-induced immunological liver injury in mice and its mechanism.

METHODS: Liver injury was induced by injection of Con A via tail vein of mice and assessed biochemically and histologically. Serum transaminase and tumor necrosis factor alpha (TNF- α) were determined. Liver lesions were observed by light microscope. Expressions of TNF- α , interferon gamma (IFN- γ), Fas and Fas ligand (FasL) mRNA in the livers were measured by RT-PCR.

RESULTS: Serum transaminase level and liver lesions in Con A-induced mice were markedly reduced by oral administration of 100, 200 mg/kg of bicyclol. TNF- α level in serum was also reduced by bicyclol. Con A injection induced up-regulation of TNF- α , IFN- γ , Fas and FasL mRNA expression in liver tissues. Bicyclol significantly down-regulated the expression of IFN- γ , Fas and FasL mRNA, but only slightly affected TNF- α mRNA expression in liver tissues.

CONCLUSION: Bicyclol protects against Con A-induced liver injury mainly through inhibition of Fas/FasL mRNA expression in liver tissues and TNF- α release in mice.

INTRODUCTION

Viral hepatitis is a serious health problem worldwide, as more than two billion people alive today have been infected by hepatitis B virus, and 170 million people have been infected by hepatitis C virus^[1]. Although a number of drugs such as interferon- 2α and lamivudine have been used in the treatment of viral hepatitis, the efficacy of these drugs is still limited and some side effect are severe^[2,3]. Therefore, it is necessary to develop new anti-hepatitis drugs. Bicyclol is new synthesized anti-hepatitis drug, chemically named 4, 4'-dimethoxy-5, 6,

5', 6'-dimethylene-dioxy-2-hydroxymethyl-2'-carbonyl biphenyl. Our previous studies demonstrated that bicyclol has anti-liver injury, anti-liver fibrosis and anti-hepatitis virus activities^[4]. Clinical trials indicated that bicyclol markedly normalized the elevated level of serum transaminase in patient with viral hepatitis B, and also inhibited HBV-DNA replication^[5]. It is known that the liver injury induced by CCl₄, acetaminophen and D-galactosamine is mainly caused by free radicals and oxidative stress^[6,7]. The protection of bicyclol against CCl₄, acetaminophen-induced liver injury, is closely related to its elimination of free radicals and inhibition of oxidative stress. However, the pathogenesis of human viral hepatitis is different from hepatotoxicants induced liver injury. Human viral hepatitis is a disease resulting from destruction of virus-infected hepatocytes through immune-mediated mechanism^[8,9]. Thus, it is necessary to further investigate if there are other mechanisms involved in the protective effect of bicyclol against liver injury in addition to its anti-oxidative activity. Recently, a model of immune-mediated liver injury in mice was established by injection of T cell mitogen Con A, which is an available animal model relevant to human hepatitis and hepatocellular damage^[10]. Previous studies demonstrated that activated T cell-mediated cellular immunity is responsible for the liver damages in Con A model. TNF- α released from activated T lymphocytes and Kupffer cells plays a critical role in the process of liver damage and hepatocyte apoptosis^[11-13]. In addition, Fas and Fas ligand (FasL) pathway is involved in the pathogenesis of hepatocytes apoptosis and necrosis^[14]. Therefore, the present study was to investigate the effect of bicyclol on Con A induced immune-mediated liver injury and its mechanisms. Figure 1 shows the chemical structure of bicyclol.

Figure 1 Chemical structure of bicyclol.

MATERIALS AND METHODS

Animals

Male C57BL/6 mice weighing 21-25 g were obtained from the Animal Center of Chinese Academy of Medical Sciences. They were fed standard maintenance diet and water throughout the experiments. All animals received care in compliance with the guidelines of China Ministry of Health.

Reagents

Bicyclol was kindly provided by Professor Zhang CZ in the Department of Pharmaceutical Chemistry of our institute. The purity of bicyclol was over 99% and not dissolved in water. Type IV Con A was purchased from Sigma Chemical Co. (St. Louis, MO, USA). ALT kit was purchased from BHKT Chemical Reagent Co., Ltd (Beijing, China). ELISA kit for

TNF- α determination was provided by Jingmei Biotechnology Co, Ltd (Beijing, China).

Con A-induced hepatitis in mice and drug administration

Control mice were injected pyrogen-free phosphate-buffered saline (PBS). A dose of 23 mg/kg of Con A was injected via tail vein. Bicyclol was suspended in 5 g/L sodium carboxymethylcellulose (Na-CMC) just before use. The 200 mg/kg and 100 mg/kg of bicyclol were administered orally three times, 24, 12, 1 h before Con A injection.

Assay for serum ALT activity and TNF- α levels

Serum from individual mouse was obtained at various intervals after Con A injection. Alanine aminotransferase (ALT) level was determined by a biochemical kit according to the manufacturer's instruction. The assay of serum TNF- α level was performed with specific ELISA kit.

Histopathological examination of liver tissue

Liver samples from individual mouse were fixed in 40 g/L neutral formaldehyde solution, embedded in paraffin, sliced into sections 5- μ m of thickness and stained with hematoxylin and eosin for histological examination. The degrees of liver injury were graded based on a score of 0-3^[15] and expressed as the mean of 10 different fields of each slide.

Detection of Fas, Fas ligand (FasL), TNF- α , and IFN- γ expression by semiquantitative RT-PCR

Total RNA from mouse liver was extracted by TRIzol reagent (Gibco USA)^[16]. RT-PCR was conducted to detect Fas, FasL, TNF- α and IFN- γ gene expression. The primers for Fas were as follows: 5'-TGCACAGAAGGGAAGGAGTA-3' and 5'-ATG GTTTCACGACTGGAGGT-3'; for FasL: 5'-GACAGCAGTG CCACTTCATC-3' and 5'-TTAAGGCTTTGGTTG GTGAA-3'; for IFN- γ : 5'-CTCAAGTGGCATAGATGTGG-3' and 5'-ACT CCTTTTCCGCTTCCTGA-3'; for TNF- α : 5'-GGCGGTGCCT ATGTCTCAG-3' and 5'-GGGCAGCCTTGTC CCTTGA-3'; and for Cu/Zn SOD: 5'-TCTGCGTGCTGAAG GGCGAC-3'; and 5'-CTCCTGAGAGTGAGATCACA-3'. mRNA was reversely transcribed with AMV reverse transcriptase and then amplified using *T7* DNA polymerase for 35 cycles as follows: at 94 °C for 30 s (dissociation), at 60 °C for 60 s (annealing), and at 72 °C for 90 s (primer extension). PCR amplification products were visualized in 2% agarose gels after staining with ethidium bromide. The density of the PCR products was compared with Cu/Zn SOD, which was used as an internal control. Briefly, the spot density of each band in the gel was measured with the Kodak digital imaging system (Kodak DC120, Digital science 1D system, USA). The percentage of gene expression was calculated by the following equation: (density of cytokine product/density of SOD product) \times 100.

Statistical analysis

All data are expressed as mean \pm SD and analyzed by Student's *t*-test.

RESULTS

Effect of bicyclol on Con A-induced aminotransferase elevation in serum

Injection of Con A to mice caused a time dependent increase in serum ALT levels (Figure 2). ALT levels increased significantly and reached a maximum at 6 h and maintained at plateau for 16 h after Con A injection. Administration of 200 mg/kg and 100 mg/kg of bicyclol to mice for three times significantly reduced the elevated serum ALT levels at 12 h and 16 h after Con A administration (Table 1).

Effect of bicyclol on liver histology

Twelve hours after Con A injection, histological analysis of the liver sections of Con A-treated mice showed widespread areas of necrosis and inflammation within the liver lobules and around the central veins and portal tracts (Figure 3A,B). Extensive lesions were characterized by massive hepatocytes coagulative necrosis, and cytoplasmic swelling of most living hepatocytes and nuclear chromatin condensation were found frequently, which indicated hepatocytes apoptosis. A moderate infiltration of lymphocytes and mononuclear cells in the portal area and around the central vein were also observed. As shown in Figure 3C, bicyclol reduced the areas of lesions and the extent of liver injury induced by Con A. The extent of lymphocyte infiltration in bicyclol treated mice also reduced significantly. The extent of liver necrosis was classified using a four degree score as shown in the footnote of Table 2.

Figure 2 Time-course of Con A-induced liver serum ALT elevation in mice. ^b*P* < 0.01 vs other time.

Figure 3 Light micrographs of livers from mice treated with Con A alone or in combination with bicyclol. Original magnification \times 200. A: normal control mouse. B: Con A injected mouse; C, mouse treated with bicyclol 200 mg/kg.

Table 1 Protection of bicyclol against Con A induced liver injury in mice as determined by ALT(U/L)

Time	Con A alone	Con A+bicyclol 200 mg/kg	Con A+bicyclol 100 mg/kg
12 h	161.5±63.11	27.1±10.8 ^b	50.1±15.9 ^a
16 h	165.8±8.76	10.6±12.8 ^b	30.7±27.4 ^b

Data are mean±SD of 8 mice per group. ^a $P<0.05$, ^b $P<0.01$. vs Con A alone. Serum ALT levels were measured 12 h and 16 h after Con A injection, respectively.

Table 2 Effect of bicyclol on liver histology by evaluation the degree of liver injury 12 h after Con A injection

Group	Grade of liver injury			
	0	1	2	3
Normal (n=7)	7	0	0	0
Con A alone (n=7)	0	0	0	7
ConA+bicyclol 200 mg/kg (n=8)	3	2	1	2
ConA+bicyclol 100 mg/kg (n=7)	1	2	3	1

Histological degree of liver injury is classified according to the area of coagulative necrosis in hepatic lobules as follows: grade 0, no coagulative necrosis; grade 1, coagulative necrosis area <10%; grade 2, coagulative necrosis area between 10% and 25%; grade 3, coagulative necrosis area >25%.

Lowering effect of bicyclol on serum TNF- α level in Con A-injected mice

Mice were killed at the indicated time points after injection of 23 mg/kg Con A. As shown in Figure 4, serum TNF- α level increased significantly 1–2 h after Con A injection, and then showed a marked decline at 4 h. At 24 h, the level of TNF- α level was still slightly higher than the normal mice but not significantly (Figure 4).

The treatments of mice with bicyclol 200 mg/kg caused a decrease of the elevated TNF- α level by about 50% two hours after Con A injection ($P<0.05$). Bicyclol 100 mg/kg also decreased serum TNF- α concentration about 25% but not significantly statistically (Figure 5).

**Figure 4** Dynamic changes of serum TNF- α level after Con A injection in mice. Each point represents mean±SD of six mice.

Effect of bicyclol on expressions of liver TNF- α , IFN- γ , Fas and FasL mRNA in Con A-treated mice

One hour after the last administration of bicyclol, mice were injected 23 mg/kg of Con A. The livers were removed 2 h later. Total liver RNA was isolated, reversely transcribed, and amplified by PCR using primers for TNF- α , IFN- γ , Fas and FasL, respectively. Cu/Zn SOD was used as an internal control. As shown in Figure 6, TNF- α and IFN- γ mRNA were undetectable in livers from normal control mice, while the mice injected with Con A showed TNF- α and IFN- γ mRNA expression

apparently. Prior administration of bicyclol 200 mg/kg reduced about 40% IFN- γ mRNA expression induced by Con A, but had slight influence on up-regulation of TNF- α mRNA in Con A injected mice.

Although Fas and FasL mRNA levels were detectable in normal control mice, significant increase of both Fas and FasL mRNA levels was demonstrated in Con A challenged mice. Mouse liver Fas mRNA level was more than that of FasL both in normal control and Con A injected groups. Administration of bicyclol down-regulated Fas and FasL mRNA expression to approximately normal level.

**Figure 5** Lowering effect of bicyclol on the elevated serum TNF- α Level induced by Con A injection in mice. Each bar represents mean±SD of 6 mice per group ^b $P<0.01$ vs Con A alone.**Figure 6** Effect of bicyclol on Con A induced TNF- α , IFN- γ , Fas and FasL mRNA expression determined by RT-PCR. A: Photograph of ethidium bromide-stained amplification products. Lane 1, molecular mass markers; lane 2 and lane 3, control liver; lane 4 and lane 5, liver 2 h after Con A administration alone; lane 6 and lane 7, liver 2 h after injection of Con A in combination with 200 mg/kg bicyclol. B: Relative band intensity of amplification products compared with Cu/Zn SOD mRNA. Data represent the mean of two lanes. Each lane corresponds to the pooled livers from two mice. ^a $P<0.05$ vs Con A alone.

DISCUSSION

The immune cell-mediated liver injury is a critical event in the pathogenesis of human viral hepatitis^[17–19]. Cell immunity is involved in the immune clearance of virus-infected hepatocytes and at the same time damage virus-infected hepatocytes. This conclusion came from the findings that infiltrating T cells were

observed in the liver tissue of hepatitis patients^[20,21]. Con A induced liver injury is a T-cell-dependent hepatitis model, which situation is relevant to human liver injury^[22]. In Con A induced hepatitis, T cell activation plays a crucial role in the process of liver injury, because lymphocytes depleted mice or severe combined immunodeficiency disease (SCID) mice can not develop liver injury after Con A injection, and pretreatment of mice with a monoclonal antibody which *in vivo* destroys Th1.2 antigen-bearing T cells abrogated the susceptibility of these animals toward the hepatotoxicity induced by Con A^[10]. In the present study lymphocyte infiltration was observed in the portal area and around the central vein of damaged liver tissue. Biochemical and histological data showed that prior administration of bicyclol, a new anti-hepatitis drug has protective effect against Con A induced liver injury in mice. In order to elucidate how bicyclol exerts its protective effect against Con A induced liver injury, mice were pretreated with bicyclol. The results showed that bicyclol markedly decreased lymphocyte accumulation into liver.

Cytotoxic T lymphocytes play an important role in the pathogenesis of viral hepatitis by inducing hepatocyte apoptosis^[23,8]. In the study of Moriyama *et al.*^[24] transfer of HBV-specific cytotoxic T lymphocytes can mediate liver cell necrosis in the HBV transgenic murine. As viral hepatitis, hepatocytes apoptosis is a dominant feature of Con A induced hepatitis as measured by DNA fragmentation and morphological observation. The apoptosis cascade can be initiated by a ligand, which binds to its receptors on the cell surface. Ligands such as FasL and TNF- α play an important role in Con A induced hepatitis. Interaction of Fas and FasL is an important pathway that mediates the target cytolysis by cytotoxic T lymphocytes^[25]. In *gld/gld* mice, in which FasL is defective, the development of the disease is completely suppressed and in *lpr/lpr* mice, the suppression of Fas mRNA is incomplete, the hepatitis is partially suppressed. Antibody against Fas can block the development of hepatitis^[14]. When FasL binds to Fas, the receptor molecules trimerize, leading to clustering of death domains, activation of a series of caspases and the final apoptosis of liver cells^[26]. In chronic hepatitis B (CHB), the intensity of FasL mRNA showed a positive correlation with the histological activity and serum alanine aminotransferase level^[27]. Immunohistochemical study suggested that Fas antigen expression plays an important role in inflammation in the hepatitis C virus-infected liver^[28]. In our previous study, we found that bicyclol inhibited Con A induced DNA fragmentation^[29]. To further investigate the mechanism of bicyclol in protection against liver injury, we measured the expression of Fas/FasL in Con A-induced liver injury.

In our study, we found that both FasL and Fas mRNA expressions were up-regulated significantly after Con A injection. Bicyclol down-regulated the expression of FasL and Fas close to normal level. The results explained why bicyclol could inhibit apoptosis of hepatocytes in Con A hepatitis model in our previous experiment^[29]. It is known that Fas expression can be activated by IFN- γ to enhance apoptosis. Fas mRNA expression was reduced by 50% in the liver of IFN- γ ^{-/-} mice compared with that in IFN- γ ^{+/+} mice^[30]. Because IFN- γ can affect the expression of Fas, we further investigated the effect of bicyclol on IFN- γ mRNA expression. Our results indicated that bicyclol reduced the expression of IFN- γ mRNA by about 40% in the livers of Con A treated mice, which was associated with the inhibition of Fas.

TNF- α is another important ligand to induce hepatocyte apoptosis. Activated lymphocytes stimulated the macrophages to release TNF- α and the activated lymphocyte itself is the potential source of TNF- α ^[31]. This proinflammatory cytokine can produce a direct cytotoxic effect to transcription-inhibited hepatocytes *in vitro* when bound to TNF-R^[32]. In addition to

the effect on Fas/FasL pathway, bicyclol significantly inhibited the release of TNF- α . Con A significantly increased the release of serum TNF- α and mRNA expression in liver tissue. Bicyclol reduced the serum level of TNF- α by about 50%. It, however, showed a slight effect (10%) on the mRNA expression in liver. It seems that bicyclol inhibited TNF- α release mostly at posttranscriptional level, which needs further investigation.

In conclusion, bicyclol protects mice against Con A-induced liver injury through at least two mechanisms: down-regulation of the expression of Fas/FasL mRNA, and prevention of proinflammatory cytokine TNF- α release.

ACKNOWLEDGEMENTS

We thank Ms. Yong-Rong Zhang and Ms. Yan Liu from the Department of Pathology of our institute for their support in the examination of liver morphology by light microscopy. We also thank Ling-Hong Yu for her helpful advice and excellent technical assistance.

Abstract

AIM: To investigate the expression of gonadotropin-releasing hormone (GnRH) receptor and the effects of GnRH analog (alarelin) on proliferation of cultured gastric smooth muscle cells (GSMC) of rats.

METHODS: Immunohistochemical ABC methods and *in situ* hybridization methods were used to detect protein and mRNA expression of GnRH receptor in GSMC, respectively. Techniques of cell culture, OD value of MTT test, measure of ³H-TdR incorporation, average fluorescent values of proliferating cell nuclear antigen (PCNA) and flow cytometric DNA analysis were used in the experiment.

RESULTS: The cultured GSMC of rats showed immunoreactivity for GnRH receptor; positive staining was located in cytoplasm. GnRH receptor mRNA hybridized signals were also detected in cytoplasm. When alarelin (10^{-9} , 10^{-7} , 10^{-5} mol/L) was administered into the medium and incubated for 24 h, OD value of MTT, ³H-TdR incorporation and average fluorescent values of PCNA all decreased significantly as compared with the control group ($P < 0.05$). The maximum inhibitory effect on cell proliferation was achieved a concentration of 10^{-5} mol/L and it acted in a dose-dependent manner. Flow cytometric DNA analysis revealed that alarelin could significantly enhance ratio of G₁ phase and decrease ratio of S phase of GSMC of rats ($P < 0.05$). The maximum inhibitory effect on ratio of S phase was at the concentration of 10^{-5} mol/L and also acted in a dose-dependent manner.

CONCLUSION: Our data suggest that GnRH receptor can be expressed by GSMC of rats. GnRH analogue can directly inhibit proliferation and DNA synthesis of rat GSMC through GnRH receptors.

INTRODUCTION

Gonadotropin releasing hormone (GnRH), a decapeptide synthesized by the neuroendocrine cells in the pro-optic area of brain, plays an important role in regulation of reproductive function. After released from the hypothalamus, GnRH binds to a specific receptor on the plasma membrane of the pituitary gonadotroph, resulting in stimulation of FSH and LH biosynthesis and release. There is evidence that GnRH and its receptors are expressed in numerous extrapituitary tissues, such as syncytiotrophoblast cells^[1], human granulosa-Luteal cells^[2], human peripheral lymphocytes^[3,4] and so on. They are not only expressed in normal tissues, but also widely exist in various carcinoma that derived from reproductive (ovary cancer^[5] and prostate cancer^[6]) or non-reproductive tissues (breast cancer^[7], lung cancer^[8], pancreas cancer^[9] and hepatocellular carcinoma^[10], *et al*). Our previous studies have shown the presence of GnRH and its receptor in rat digestive tract^[11], submaxillary gland^[12], thyroid gland^[13] and pancreas^[14] and proposed that GnRH could be classified as a kind of brain-gut hormone. Presently, we first investigated the expression of GnRH receptor in cultured rat gastric smooth muscle cells (GSMC) and investigate the effect of GnRH analogue (alarelin) on the proliferation of cultured GSMC of rats.

MATERIALS AND METHODS

Materials

GnRH anti-idiotypic antibody was prepared by our department^[15]. ABC kit was the product of Vector Company (Vector Laboratories Burlingame, CA, U.S.A.). MTT (3-(4, 5-dimethylthiazol-2-yl)-2, 5-diphenyltetrazolium), collagenase I, PPO (2, 5-diphenyloxazole) and POPOP (1, 4-bis (5-phenyloxazol-2-yl) benzene) were purchased from Sigma Company (Staint Louis, Missouri, U.S.A.). DMEM and Trypsin were the products of Gibco Company (Carlsbad, California, U.S.A.). Alarelin was purchased from Shanghai Lizhu Biochemical and Pharmaceutical Company, Shanghai, China. PCNA (Proliferating cell nuclear antigen) antibody and immunofluorescent kit were purchased from Boster Company (Wuhan, China). ³H-TdR was purchased from Academy of Atomic Energy Sciences of China (Shanghai, China). The 1-3-day-old male Sprague-Dawley rats were purchased from the Center of Laboratory Animal Medicine, the Fourth Military Medical University, (Xi'an, China).

Preparation and culture of GSMC of rats

The culture of GSMC of rats was performed as described previously with modifications^[16,17]. 1-3-day-old immature male Sprague-Dawley rats were sterilized by 750 mL/L alcohol; removed the stomachs and put them into cool Hanks solution (mmol/L: CaCl₂ 1.3, KCl 5.4, KH₂PO₄ 0.4, MgCl₂·6H₂O 0.4, MgSO₄·7H₂O 0.4, NaCl 137, glucose 5.6) immediately. The mucosas were

removed by scraping with razorblade. The gastric smooth muscle tissues were minced into 1.0 mm³ pieces with tissue chopper, then put them into DMEM containing 1 mg/L collagenase I at 37 °C for 30-60 min, and the GSMCs were collected at an interval of 20 min. The cell suspension was centrifuged at 500 r/min for 5 min, washed 2 times in DMEM, then cultured in DMEM containing 100 mL/L calf serum, 100 U/mL penicillin G and 100 U/mL streptomycin under a humidified atmosphere of 50 mL/L CO₂ in air. To obtain pure GSMC and remove the fibroblasts, the cells were preattached in flasks with 10% calf serum under DMEM in a humidified atmosphere of 5% CO₂ or 90 min at 37 °C. Afterwards, the cells were maintained in fresh DMEM containing 100 mL/L calf serum and removed it per 3 d and subsequently subcultured per 4-5 d by treatment with trypsin (2.5 g/L). The GSMC were identified by "valley and hill appearance"^[17] and showed α -actin immunoreactivity, which was located in cytoplasm. The experiments were performed with monolayer of cells from passage 3-5.

Immunocytochemical procedure

The GSMCs (1×10⁵/mL) were seeded in a six-well plate containing the coverglasses inside. The cells of passage 3-5 were fixed in 4% paraformaldehyde solution for 30 min at room temperature. The coverglasses were washed 3 times with phosphate-buffered saline (PBS, pH 7.2), and put into methanol-H₂O₂ for 30 min to remove endogenous peroxidase activity. Then they were stained using immunohistochemical ABC method. They were incubated with first antibody, rabbit GnRH anti-idiotypic antibody (1:200 dilution) at 4 °C for 18-24 h. Then they were incubated with second antibody, biotin labeled goat anti-rabbit IgG antibody (1:400 dilution), at room temperature for 2 h, followed by incubation with ABC complex (1:400 dilution), at room temperature for 1 h. Finally, DAB (diaminobenzidine) was used for color developed, and then the slides were washed in distilled water to stop the reaction, dehydrated in alcohol, hyalinized in xylene, and mounted on Canada balsam. The first antibody was replaced by normal and diluted rabbit serum for the negative control.

In situ hybridization

The probe was produced according to the cDNA sequence of the rat's pituitary GnRH receptor^[12,18]. The sequence was: 5'-ATGTATGCCCCAGCCTTCATGATGGTGATTAGCC TGGATC-3'. The digoxigenin was labeled at 5'-end by the TaKaRa Biotechnology Company, (Dalian, China). The *in situ* hybridization was carried out on the coverglasses after the cells were fixed in 40 g/L paraformaldehyde containing 1 g/L DEPC (Diethyl pyrocarbonate) for 30 min. Then they were processed as follows: The coverglasses were rinsed in 0.01 mol/L PBS (pH 7.2) for 5 min×3, in Proteinase K (1 µg/mL) for 2 min at 37 °C. They were post-fixed in 40 g/L paraformaldehyde for 5 min, washed in distilled water for 5 min×3. After being dried in the air, each coverglass was applied with the hybridization buffer containing GnRH receptor oligonucleotide probe (2.0 µg/mL), and hybridization was carried out in sealed humid box at 42 °C for 20 h. After that the slides were washed with 2×SSC at 37 °C for 5 min×3, 0.1×SSC at 37 °C for 10 min×2, they were incubated with mouse-anti-dig antibody at room temperature for 2 h. Thereafter, the slides were washed with 0.5 mol/L TBS for 5 min×3, followed by incubation with biotin-labeled goat-anti-mouse IgG antibody for 1 h at 37 °C. The slides were washed with 0.5 mol/L TBS for 5 min×3 and incubated with SABC-AP for 30 min at 37 °C. The sections were rinsed in 0.5 mol/L TBS for 5 min×4, and the alkaline phosphatase reaction was conducted by incubation with complex solution of NBT (Nitro-blue tetrazolium) and BCIP (5-bromo-4-chloro -3-indo-lyl phosphate) for 20-30 min.

Finally, the slides were washed in distilled water to stop the reaction, and then dehydrated in alcohol, hyalinized in xylene, and mounted on Canada balsam. The slides were incubated with normal mouse serum instead of the mouse-anti-dig antibody in absence of the labeled probe for the negative controls.

MTT assay

The cells were trypsinized in a solution of 2.5 g/L trypsin and seeded in a 96-well plate at a density of 10⁴ cells/(0.1 mL/well). After the cells were grown for 24 h to approximately 800 g/L subconfluent state, 0.1 mL medium containing 2.5% calf serum and various concentrations (10⁻⁹, 10⁻⁷, 10⁻⁵ mol/L) of alarelin was added to each well, respectively, and incubated for 24 h in a CO₂ incubator. Each concentration was tested in at least 12 wells. The MTT assay was performed as described previously with modifications^[19]. Briefly, 15 µL of MTT solution (5 g/L, PBS, pH 7.2) was added to each well and incubated for 4 h. Then, the medium and MTT were removed and 150 µL of DMSO was added to each well and shaken for 10 min to dissolve the crystal. The OD was determined at 490 nm using an ELISA reader.

³H-TdR incorporation

To observe the role of GnRH analogue in growth regulation of GSMC, a ³H-TdR incorporation assay was performed as previously described^[20]. The cells were plated into a 96-well plate at a density of 10⁴ cells/(0.1 mL/well). After the cells were grown for 24 h, 0.1 mL medium containing 2.5% calf serum and various concentrations (10⁻⁹, 10⁻⁷, 10⁻⁵ mol/L) of alarelin was added to each well, respectively, and incubated for 16 h in a CO₂ incubator. Then the ³H-TdR (2 µCi/mL) was added to each well and continuously incubated for 8 h. Incubation was stopped by adding 1 vol of cold 100 mL/L trichloroacetic acid (TCA) which disrupted cells and precipitated the macromolecules. After being washed with a methanol, the precipitate was collected in 9999 fiberglass filter paper, respectively. When the filter paper was dried, 0.5 mL scintillant liquid were mixed and the radioactivity was estimated with a scintillation counter (Backman LS5801). Each concentration was tested in at least 6 wells.

Fluorescent immunocytochemical reaction of PCNA in GSMC

The cells were seeded in six-well plate containing the coverglasses inside. After the cells were grown for 24 h to approximately 800 g/L subconfluent state, 2 mL medium containing 25 mL/L calf serum and various concentrations (10⁻⁹, 10⁻⁷, 10⁻⁵ mol/L) of alarelin was added to each well, respectively, and incubated for another 24 h in a CO₂ incubator. Then the monolayers were fixed in 40 g/L paraformaldehyde solution for 30 min. The cell coverglasses were washed 3 times with PBS (pH 7.2), and then put into methanol-H₂O₂ for 30 min to remove endogenous peroxidase activity. Then PCNA immunofluorescence reaction was carried out according to the manufacturer's instructions. The coverglasses were incubated with the first antibody (mouse antibody, 1:200 dilution) at 4 °C overnight, followed by incubation with the second antibody, biotin labeled goat anti-rabbit IgG antibody (1:200 dilution), at room temperature for 2 h. Then the coverglasses were incubated with SABC-fluo Cy3 (1:100 dilution) at room temperature for 1 h. At last, the cells were detected by using the laser confocal microscopy, and scanned the average fluorescent values of PCNA of GSMC. For the negative controls, the first antibody was replaced by normal rabbit serum.

Cell-cycle analysis by flow cytometry

The cells were seeded in 12-well plate at a density of 10⁷ cells/(1.5 mL/well). After the cells were grown for 24 h to approximately 800 g/L subconfluent state, 2 mL medium containing 25 mL/L calf serum and various concentrations (10⁻⁹-10⁻⁵ mol/L) of alarelin was added to each well, respectively,

and incubated for another 48 h in a CO₂ incubator. Then the cells were trypsinized in a solution of 2.5 g/L trypsin, fixed in 700 mL/L ethanol and stained by PI (propidium iodide) for DNA analysis. The flow cytometric analyses were performed using EPICS Profile II. DNA content was measured and ratio of each DNA period of cell proliferation was analyzed.

Data analysis

In the proliferation study, the data were expressed as mean±SD. The data were analyzed by SPLM statistical software. $P<0.05$ was considered statistically significant.

RESULTS

Expression and localization of GnRH receptor

Immunocytochemical reaction showed a dark-brown staining in cytoplasm for GnRH receptor immunoreactivity; background was light yellow or no staining; positive cells were identified easily. The two negative controls showed no staining for GnRH receptor. All cultured GSMCs showed immunoreactivity for GnRH receptor in the cytoplasm, but with variations in degrees of intensity of the immunoreactivity (Figure 1).

In situ hybridization showed GnRH receptor mRNA hybridized signal was blue, and the background was not stained. The GnRH receptor mRNA hybridization signals could be detected in all cultured GSMCs, but with variation in signal strength between them. The signals were only distributed in the cytoplasm with hybridization negative nuclei (Figure 2). The two negative controls did not show GnRH receptor mRNA hybridized signal.

Figure 1 Gastric smooth muscle cells showed GnRH receptor immunoreactivity in cytoplasm. (×200).

Figure 2 Gastric smooth muscle cells showed GnRH receptor mRNA hybridized signal in cytoplasm. (×400).

Effect of alarelin on GSMC viability

The influence of alarelin on GSMC viability was assessed using the MTT assay. The cell viability in the presence of alarelin was significantly lower than that in the absence of alarelin ($F=59.083$, $P<0.01$). The maximum stimulatory effect on cell viability was achieved at a concentration of 10^{-5} mol/L and it acted in a dose-dependent manner (Table 1).

Table 1 Effects of alarelin on A value of MTT of rat GSMC

Group	MTT/A value (n=12)
Control	0.728±0.100
10^{-9} mol/L alarelin	0.533±0.073
10^{-7} mol/L alarelin	0.368±0.029
10^{-5} mol/L alarelin	0.243±0.042

³H-TdR Incorporation assay

To evaluate the functional role of GnRH in GSMC, the cells were treated with different concentrations of alarelin and incubated for 16 h, and then ³H-TdR (2 μCi/mL) was added. After 8 h, ³H-TdR incorporation assays were performed. As shown in Table 2, alarelin inhibited the growth of GSMC in a dose-dependent manner. A significant inhibition of proliferation was detected in the different groups, and the antiproliferative effect was the most evident when the concentration of alarelin at 10^{-5} mol/L ($F=22.33$, $P<0.05$).

Table 2 Effects of alarelin on ³H-TdR Incorporation of rat GSMC

Group	³ H-TdR Incorporation (n=6)
Control	1 936.50±440.99
10^{-9} mol/L alarelin	1 448.17±327.72
10^{-7} mol/L alarelin	945.83±374.32
10^{-5} mol/L alarelin	385.83±184.66

The average fluorescent values of PCNA assay

The cells were treated with different concentrations of alarelin (10^{-9} , 10^{-7} , 10^{-5} mol/L) and incubated for another 24 h, and the average fluorescent values of PCNA assays were performed. As shown in Table 3, alarelin significantly inhibited the average fluorescent value in a dose-dependent manner compared with the control group ($F=15.86$, $P<0.01$).

Table 3 Effects of alarelin on average fluorescent values of PCNA in GSMC

Group	Average fluorescent values of PCNA (n=5)
Control	13.48±1.31
10^{-9} mol/L alarelin	11.37±1.99
10^{-7} mol/L alarelin	9.35±1.38
10^{-5} mol/L alarelin	7.37±1.06

Effects of alarelin on GSMC cell cycles

Table 4 showed the ratio of G₁ phase and S phase of DNA period of cell proliferation of each group. The ratio of G₁ phase of DNA in group II- VI were markedly higher than that of the control, but did not increase in a dose-dependent manner ($F=74.94$, $P<0.05$). Moreover, the ratio of S phase of DNA was significantly lower in group II-VI than that in the control and acted in a dose-dependent manner ($F=32.5$, $P<0.05$, except the Group III, V compared with their border groups).

Table 4 Effects of alarelin on GSMC cell cycles (n=4)

Group	Concentration of alarelin	G ₁ phase (%)	S phase (%)
Group I	Control	70.80±11.30	17.50±3.40
Group II	10^{-9} mol/L alarelin	80.00±9.42	9.93±1.73
Group III	10^{-8} mol/L alarelin	76.60±8.99	7.10±1.05
Group IV	10^{-7} mol/L alarelin	79.60±7.43	6.60±1.54
Group V	10^{-6} mol/L alarelin	78.50±10.66	5.10±1.01
Group VI	10^{-5} mol/L alarelin	80.20±10.03	3.20±1.20

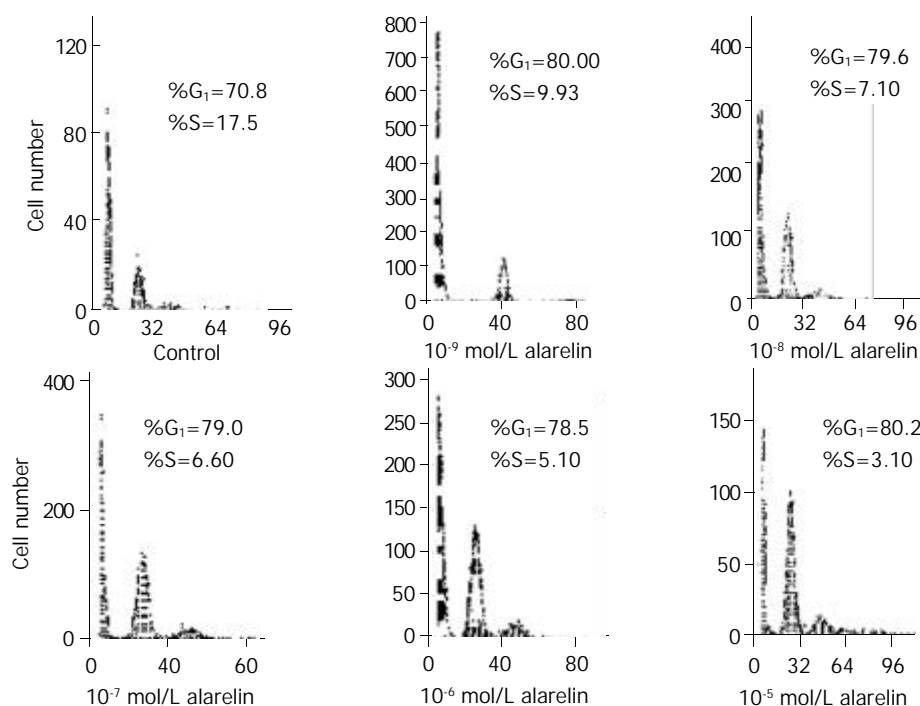

Figure 3 Effects of alarelin on DNA content of GSMCs cell cycles.

DISCUSSION

GnRH anti-idiotypic antibody has been widely applied in immunohistochemical studies of GnRH receptors^[11,12,21]. GnRH and its receptor mainly exist in hypothalamus-pituitary axis, and also expressed in extra- hypothalamically, and has extra-pituitary activity. Studies have reported that pancreatic islets have GnRH immunoreactivity^[14]. Jan *et al.*^[22] reported that GnRH was a possible transmitter in sympathetic ganglion in frog, and our previous studies^[4,5] revealed that both GnRH and GnRH receptor were all existed in digestive tract. Our present study revealed, for the first time, that GnRH receptor mRNA was expressed in cultured GSMC of rats. These findings have raised intriguing questions which concern the physiological function of GnRH and its receptor.

GnRH has been suggested to regulate cell growth and proliferation through its receptor in exipituitary tissues. GnRH analogues not only have been used and proven to be efficient in treating GnRH receptor-bearing tumors, including carcinomas of the ovary, breast, and endometrium^[23-25], but also inhibited the growth and proliferation of normal cell, such as granulosa cells and myometrial smooth muscle cells^[26,27]. MTT assays and ³H-TdR assays are considered to be the most reliable techniques for measurement of the cell population. Using MTT assays and ³H-TdR assays, we demonstrated that GnRH analogue inhibited growth of normal GSMC of rats in a dose-dependent manner. This inhibitory effect is consistent with the results of Minaretzis *et al.*^[26] in granulosa-lutein cells and Chegini *et al.*^[27] in myometrial smooth muscle cells. This inhibitory effect of GnRH analogue appears to be receptor-mediated and its exact mechanism of growth inhibitory effect at the receptor level is unclear.

To examine whether GnRH receptor (GnRHR) mediates direct antiproliferative effects, we attempted to assess the effects of alarelin on average fluorescent values of PCNA and cell cycle of GSMC. PCNA, a protein which functions as a cofactor to DNA polymerase delta, has many characteristics which make it an effective marker for evaluating cell proliferation, particularly in S phase^[28]. PCNA is a stable cell-cycle regulated nuclear protein, expressed differentially during the cell cycle^[29,30], and it is believed to reflect the different

stages of the cell cycles, which begins to increase in terminus of G₁, reaches at peak in S phase, and decreases in G₂ and M phases, and this is corresponded with the change of DNA content^[28]. In the present study, we found that alarelin inhibited the average fluorescent values of PCNA, and acted in a dose-dependent manner. These might cause by the binding of GnRH analogue with its receptor, which induced the activation of phosphatidylinositol kinase activity, known to stimulate mitogenic response in plasma membranes^[31]. By flow cytometry, we demonstrated the GnRH analogue improved the ratios of G₁/G₀ which did not act in a dose-dependent manner, and inhibited the ratios of S phase which acted in a dose-dependent manner. So, the reason of growth inhibition might be that GnRH analogue arrested at G₁/S phase, which inhibits DNA synthesis. These results are consistent with the results of MTT assay, ³H-TdR incorporation and fluorescent value of PCNA.

In summary, we have demonstrated for the first time that GnRH receptor is expressed in GSMC and GnRH analogue has a direct growth inhibitory effect on GSMC of rats that is mediated through GnRH receptor. Our findings strongly suggest that GnRH play an important role in digestive tract.

Abstract

AIM: To evaluate the viability and energy metabolism of long warm ischemically damaged pancreas during preservation by the UW solution cold storage method.

METHODS: The pancreas grafts subjected to 30-120 min warm ischemia were preserved by the UW solution cold storage method for 24 h. The tissue concentrations of adenine nucleotides (AN) and adenosine triphosphate (ATP) and total adenine nucleotides (TAN) were determined by using high performance liquid chromatography (HPLC) and the viability of the pancreas graft was tested in the canine model of segmental pancreas autotransplantation.

RESULTS: The functional success rates of pancreas grafts of groups after 30 min, 60 min, 90 min, 120 min of warm ischemia were 100%, 100%, 67.7%, 0%, respectively. There was an excellent correlation between the posttransplant viability and tissue concentration of ATP and TAN at the end of preservation.

CONCLUSION: The UW solution cold storage method was effective for functional recovery of the pancreas suffering 60-min warm ischemia. The tissue concentration of ATP and TAN at the end of 24 h preservation by the UW solution cold storage method would predict the posttransplant outcome of pancreas graft subjected to significant warm ischemia.

INTRODUCTION

Preservation is necessary if organs for transplantation are removed from donors prior to preparation of the recipient^[1-3]. The methods used for preservation of pancreas grafts for experimental transplantation have produced variable results^[4,5].

As warm ischemic injury of pancreas graft before and during procurement strongly influences the results of pancreas transplantation, it is important to predict the viability of the ischemically damaged pancreas graft before transplantation^[6,7]. Recently we preserved the segmental pancreas in the UW solution after 30-120 min, and our experimental model was heterotopic segmental (left limb) pancreas autotransplantation in totally pancreatectomized dogs, and demonstrated that the UW solution cold storage method was effective for functional recovery of the pancreas suffering 60-min warm ischemia^[8]. There are some qualitative differences between warm and cold ischemic injuries^[9-12]. In this study we examined the viability and energy metabolism of the pancreas graft after significant warm ischemia and cold storage, and found tissue concentrations of ATP and TAN after preservation by the UW solution cold storage method were excellent markers to predict the posttransplant outcome^[13,14].

MATERIALS AND METHODS

Animals

Mongrel dogs of both sexes, weighing 10-15 kg were used for the experiments. UW solution was from China Pharmaceutical Corporation Guangzhou Branch. Chemicals were from Sigma Co.Ltd.

Operative procedures are as follows. Anesthesia was induced and maintained with sodium pentobarbiturate (25 mg/kg). The pancreas was exposed through a midline abdominal incision, and the left limb (tail) was removed with the splenic vessels in preparation for grafting, followed by splenectomy. The segmental pancreas graft was unflushed and left *in situ* for 30-120 min. After warm ischemia the pancreas was flushed with 30-50 mL heparinized cold UW solution (10 000 units/L heparin) and preserved in 50 mL heparinized cold UW solution for 24 h. A splenectomy was performed. The remainder of the pancreas was excised at the time of transplantation. The pancreatic tail was autotransplanted heterotopically, immediately or after preservation, with anastomosis of the splenic vessels to iliac vessels. A proper delicate tube was inserted into the pancreatic duct to drain the pancreatic juice. After operation, the dogs received saline with 100 g/L glucose (30 mL/kg) and 3.2 Mu penicillin for 3-5 days, then standard kennel diets were given.

Experimental protocol

There were two groups of control dogs: group 1, sham-operated group, abdomen was only opened and closed; group 2, no warm ischemia, pancreatic tail was flushed and preserved immediately after being harvested. The experimental group (group 3) was divided into 4 subgroups according to the warm ischemia time: group 3a, 30 min warm ischemia; group 3b, 60 min warm ischemia; group 3c, 90 min warm ischemia; group 3d, 120 min warm ischemia.

Functional studies

Blood glucose concentration was determined daily during the first postoperative week after autotransplantation. An

intravenous glucose tolerance test (IVGTT) was performed one week after transplantation. Glucose, 0.5 g/kg, was administered as a bolus and blood samples were collected serially over a 2-h period for plasma glucose. IVGTT K values were calculated from the plasma glucose levels at the end of 5 to 60 min^[15]. Maintenance of normoglycemia for at least five days after transplantation or a key value of IVGTT more than 1.0 one week after transplantation was considered a functional success of pancreas graft. The plasma insulin levels in splenic and peripheral vein one hour after transplantation were examined. The pancreatic juice was collected every day and amylase in the pancreatic juice of the first and the seventh days were determined.

Tissue extraction method for adenine nucleotides: After preservation, a part of pancreas was rapidly frozen in liquid nitrogen, lyophilized overnight, and kept at -80 °C until analysis. The dry tissue powder was weighed (200 mg) and homogenized in 3 mL of ice cold 0.5 mol/L perchloric acid. The precipitated protein was removed by centrifugation, and 500 µL of supernatant was neutralized by the additions of 50 µL 1 mol/L KOH and 50 µL Tris. Following centrifugation, 10 µL of supernatant was injected into HPLC for analysis.

Measurement of adenine nucleotides

High-performance liquid chromatography (HPLC, Waters, 510 Pump, 486 Detector) was performed on a reverse-phase column of Shim-pack, CLC-ODS (15 cm×3.96 mm, 4 µm) which was equilibrated with 100 mmol/L sodium phosphate buffer (pH 6.0) according to the method of Wynants *et al.*

TAN was calculated as the sum of ATP, adenosine diphosphate (ADP) and adenosine monophosphate (AMP).

Histological studies

Biopsies of the pancreas grafts were taken after cold preservation and one hour after transplantation. For light microscopy, the tissues were fixed in 100 ml/L formalin and stained with hematoxylin and eosin. For electron microscopic studies the tissues were prefixed in 25 g/L glutaraldehyde, postfixated in 25 g/L osmium tetroxide, sectioned at 1 µm, and stained with uranyl acetate and lead citrate.

Statistical analysis

All data were expressed as mean±SD. *F* test was used to compare values of different groups, χ^2 test for comparison of viability. A value of *P*<0.05 was considered statistically significant.

RESULTS

Graft function

Pancreatic graft endocrine function Plasma glucose and IVGTT K values in groups 1, 2, 3a and 3b recovered to normal 2-3 days after transplantation, while groups 3c and 3d did not one week after transplantation (Table 1). The plasma insulin levels in splenic and peripheral veins in groups 1, 2, 3a, and 3b were much higher than those in groups 3c, and 3d (*P*<0.05, Table 2).

Pancreatic graft exocrine function The pancreatic juice flow over the pancreatic duct 30 min after transplantation increased gradually and came to a climax on the fourth day after transplantation, and then declined gradually. The daily amounts of pancreatic juice of groups 1, 2, 3a and 3b were much more than those of groups 3c and 3d (*P*<0.05). The amylase activities in the pancreatic juice of the first and seventh days in groups 1, 2, 3a and 3b were much more than those in groups 3c and 3d (*P*<0.05, Tables 2, 3).

Tissue ATP, ADP, AMP and TAN after preservation The tissue concentrations of ATP, ADP, AMP and TAN after 24-hour preservation in groups 1, 2, 3a and 3b were much higher than those in groups 3c and 3d (*P*<0.05, Table 4).

Viability of canine pancreas autografts after preservation After significant warm and cold preservation, the functional success rates of groups 2, 3a, 3b, 3c and 3d were 5/5(100%), 6/6(100%), 6/6(100%), 4/6(66.7%) and 0/4(0%), respectively (Table 3). The UW cold preservation method was effective for functional recovery of the pancreas after 30 to 60-min warm ischemia (Table 3).

Relationship between posttransplantation viability and tissue ATP and TAN There was no overlap between the lowest ATP in the viable grafts and highest ATP in the nonviable grafts. If ATP level of 4.0 µmol/g dry weight was determined as a critical

value for the viability following transplantation, the specificity, sensitivity, predictive value and efficacy were all 100%. And there was also no overlap between the lowest TAN in the viable grafts and highest TAN in the nonviable grafts. If TAN level of 7.0 $\mu\text{mol/g}$ dry weight was determined as a critical value for the viability following transplantation, specificity, sensitivity, predictive value and efficacy were all 100%. Both ATP and TAN were reliable markers for determining the transplantation.

Histologic studies

Under light microscope, the pancreas in groups 1 and 2 stored for 24 h showed normal architecture. After 24 h, preservation vacuolization of the acinar cells and interstitial edema were seen in grafts of groups 3a and 3b, and only mild edema of the islets was evident. Grafts of groups 3c and 3d showed severe edema, and after revascularization there was hemorrhage in the interstitial space.

Under electron microscope, the pancreas in groups 1 and 2 stored for 24 h showed well preserved cells. In grafts of groups 3a and 3b, acinar cells showed no nuclear changes, but rough endoplasmic reticulum (RER) cisternae were dilated. In grafts of groups 3c and 3d, irreversible cell damage was seen in most, but not all, specimens.

DISCUSSION

Pancreas graft injury due to warm ischemia strongly affects the posttransplant outcome^[16,17]. Therefore, resuscitation of an ischemically damaged pancreas is essential to enlarge the donor pool using the pancreas graft from the cardiac arrest donor^[18]. We have demonstrated that canine pancreases subjected to 60 min of warm ischemia can be resuscitated during preservation by the UW solution preservation method at 4 °C for 24 h.

Restoration of cellular function of the pancreas graft subjected to significant warm ischemia by the UW solution cold preservation method will make it possible to use pancreas

grafts from cadaver with cardiac arrest^[19,20], wait safely for the excision of the pancreas and enlarge the donor pool. Cerra^[21,22] reported that the canine pancreatic allografts tolerated warm ischemia up to one hour. Florack *et al.*^[23,24] demonstrated that the canine pancreatic autografts tolerated warm ischemia up to 60 min.

On the other hand, the assessment of a pancreas graft viability before transplantation is very important to prevent transplantation of a nonfunctioning allograft especially after significant warm ischemia because there is progressive depletion of ANs during warm ischemia^[25], ultimately leading to ischemic damage. But the relationship between the tissue concentration of ANs before transplantation and organ viability after transplantation is controversial^[26,27]. In human liver preservation, Lanir *et al.*^[28,29] demonstrated a direct correlation between a high ATP concentration and good posttransplant outcome. On the contrary, correlation between the ATP level at the end of cold preservation and viability following transplantation was not proved in the rat liver^[30,31].

We have also demonstrated that correlation between high ATP tissue concentration, which is necessary to maintain cellular integrity, and good posttransplant outcome of a canine pancreas graft after preservation by the UW solution cold preservation method^[32,33]. It is suggested that tissue concentration of ATP and TAN at the end of 24-h preservation by the UW solution cold preservation method will predict the posttransplant outcome of pancreas graft subjected to significant warm ischemia^[34,35]. But the mechanism responsible for the effectiveness of the UW solution cold preservation method in restoration of function of the pancreas graft subjected to significant warm ischemia remains unclear and is under investigation^[35-38].

We conclude that the tissue concentration of ATP and TAN at the end of 24-h preservation by the UW solution cold storage method will predict the posttransplant outcome of pancreas graft subjected to significant warm ischemia.

Abstract

AIM: To study the effect of cholecystokinin-octapeptide (CCK-8) on lipopolysaccharide (LPS) -induced pulmonary artery smooth muscle cell (PASMCS) injury and the role of heme oxygenase-1 (HO-1), and to explore the regulation mechanism of c-Jun N-terminal kinase (JNK) and activator protein-1 (AP-1) signal transduction pathway in inducing HO-1 expression further.

METHODS: Cultured PASMCS were randomly divided into 4 or 6 groups: normal culture group, LPS (10 mg/L), CCK-8 (10^{-6} mol/L) plus LPS (10 mg/L) group, CCK-8 (10^{-6} mol/L) group, zinc protoporphyrin 9 (ZnPPiX) (10^{-6} mol/L) plus LPS (10 mg/L) group, CCK-8 (10^{-6} mol/L) plus ZnPPiX and LPS (10 mg/L) group. Seven hours after LPS administration, ultrastructural changes and content of malondialdehyde (MDA) of PASMCS in each group were investigated by electron microscopy and biochemical assay respectively. HO-1 mRNA and protein of PASMCS in the former 4 groups were examined by reverse transcriptase polymerase chain reaction (RT-PCR) and immunocytochemistry staining. Changes of c-fos expression and activation of JNK of PASMCS in the former 4 groups were detected with immunocytochemistry staining and Western blot 30 min after LPS administration.

RESULTS: The injuries of PASMCS and the increases of MDA content induced by LPS were alleviated and significantly reduced by CCK-8 ($P < 0.05$). The specific HO-1 inhibitor-ZnPPiX could worsen LPS-induced injuries and weaken the protective effect of CCK-8. The expressions of c-fos, p-JNK protein and HO-1 mRNA and protein were all slightly increased in LPS group, and significantly enhanced by CCK-8 further ($P < 0.05$).

CONCLUSION: HO-1 may be a key factor in CCK-8 attenuated injuries of PASMCS induced by LPS, and HO-1 expression may be related to the activation of JNK and activator protein (AP-1).

INTRODUCTION

Lipopolysaccharide (LPS), a main component of Gram-negative bacterial endotoxin, is the main factor to induce endotoxic shock (ES). ES is a common and serious syndrome in clinic and its mortality is very high. The lung is one of the target organs easily insulted in ES. It was demonstrated that lung injury in ES was associated with oxygen free radicals (OFR)^[1,2] and the content of cholecystokinin (CCK) in serum was increased when ES occurred. Our previous *in vivo* and *in vitro* studies demonstrated that CCK-8 could protect animals from LPS-induced ES and lung injury, which may be related to its effect on reducing the production of OFR^[3-7].

There is a rapid increase in those substances that provide protection against oxidative stress. Among them one is heme oxygenase (HO)-1, which has generated much interest as a novel stress protein that is highly induced by many factors which induce oxidative injury and protect against oxidative stress^[8-12]. However, the regulation mechanism of HO-1 expression was still unclear and there were no reports about the relationship between HO-1 and the protection of CCK-8 in LPS-induced ES and lung injury. One of the earliest responses to LPS and CCK-8 is the activation of mitogen-activated protein kinases (MAPKs), including p38, p42/p44 extracellular signal-regulated kinase (ERK) and c-Jun NH₂-terminal kinase (JNK)^[13,14]. A slightly later cellular response is the activation of activator protein (AP)-1. AP-1 is a dimeric protein complex containing 2 members of the real family of transcription factors, c-fos and c-Jun. Recent studies showed that, one or more members of AP-1 were likely involved in HO-1 gene transcription^[15-18]. The relationship between the activation of these signaling molecules and downstream HO-1 expression represents an active line of investigation. This can provide experimental evidences to elucidate whether the protective mechanism of CCK-8 is associated with HO-1.

Pulmonary artery hypertension (PAH) is the typical pathological change in the early phase of ES. It was reported that the degree and duration of PAH were the important factors of ES accompanied by acute lung injury, and pulmonary artery smooth muscle cells (PASMCS) played an important role in maintaining the tone of pulmonary artery. In the present study, the effect of CCK-8 pretreatment on the injuries of PASMCS induced by LPS was observed, and further investigated the role of HO-1 and the regulation mechanism of c-Jun N-terminal kinase (JNK) and AP-1 signal transduction pathway in inducing HO-1 expression were further investigated.

MATERIALS AND METHODS

Materials

CCK-8 (sulfated), LPS (*E.coli* LPS, serotype 0111:B4), ZnPPIX and Triton X-100 were all purchased from Sigma. Mouse anti-rat phosphorylate JNK(p-JNK) monoclonal antibody, rabbit anti-rat c-fos and HO-1 polyclonal antibody were all purchased from Santa Cruz. DMEM and fetal calf serum (FCS) were purchased from GibcoBRL. Total RNA isolation system and access RT-PCR system were purchased from Promega (USA). SABC kit was purchased from Boshide(China). All other reagents used were of analytic grade.

Methods

Cell isolation and culture Rat PSMCs were prepared as previously described^[19]. Briefly, male healthy Sprague-Dawley rats (100-150 g BM, Experimental Animal Center of Hebei Province) were anesthetized with intraperitoneal administration of pentobarbital sodium (35 mg/kg), and pulmonary arteries were obtained. The isolated pulmonary arteries were cleaned of connective tissues, and aseptically opened longitudinally. The adventitia was carefully removed and the luminal surface was scraped with forceps to remove endothelial cells and then minced into 1 mm² pieces and plated on culture flasks at 37 °C in humidified air containing 50 mL/L CO₂ for 2-3 h, and then cultured in Dulbecco modified Eagle medium (DMEM) supplemented with heat-inactivated 10 mL/L FCS and antibiotics (100 U penicillin, 100 µg/mL streptomycin) and grew until confluence. The medium was changed every 3-4 d, and confluent cells were passaged with 1.25 g/L trypsin solution every 5-7 d, and experiments were performed in an 80% confluent state on the sixth- to eighth-passages from primary culture. Cells were made quiescent by incubation in each medium without FCS for 24 h before LPS or CCK-8 addition. PSMCs in culture were elongated and spindle shaped, grown with the typical hill-and-valley appearance, and characterized by immunocytochemical assay with anti-α-actin monoclonal antibody, demonstrating positive staining in >95% of cells. The cultured PSMCs were randomly divided into 4 or 6 groups: normal culture (control) group, LPS (10 mg/L) group, CCK-8 (10⁻⁶ mol/L) group, CCK-8 (10⁻⁶ mol/L) plus LPS (10 mg/L) group, ZnPPIX (10⁻⁶ mol/L) plus LPS (10 mg/L) group, and CCK-8 (10⁻⁶ mol/L) plus ZnPPIX (10⁻⁶ mol/L) and LPS (10 mg/L) group.

Observation of ultrastructural changes with transmission electron microscopy After treated with LPS, CCK-8 or ZnPPIX, the cells were washed rapidly with PBS and harvested, then fixed with 40 g/L paraformaldehyde/5 g/L glutaraldehyde and postfixed with 40 g/L OsO₄/potassium hexacyanoferrate. After embedded in Epon, thin sections were cut, contrasted with uranyl acetate (20 g/L)/lead citrate (27 g/L) and examined with an EM10 electron microscope as described previously^[20].

Assessments of PSMCs malondialdehyde (MDA) content

The cells were harvested after treated with LPS or CCK-8 or ZnPPIX and washed rapidly with PBS, then immediately homogenized on ice in 9 volumes of saline. The homogenates were centrifuged at 4 000 r/min at 4 °C for 10 min. The MDA content in the supernatants was measured using a MDA assay kit (Nanjing Jiancheng Corp. China).

Analysis of c-fos and HO-1 protein expression by immunocytochemistry Confluent cells were passaged with 2.5 g/L trypsin solution onto 20 mm×20 mm glass sheets in a 6-well plate. After treatment with LPS, CCK-8 or both LPS and CCK-8 for 30 min or 7 h, the cells were treated with 3 mL/L H₂O₂ in methanol to block endogenous peroxidase activity. Immunocytochemical staining was performed using rabbit polyclonal antibody against c-fos and HO-1 by an indirect streptavidin/peroxidase technique. Experiments were performed

following the manufacturer's recommendations. The cells were incubated with polyclonal anti-rat c-fos and HO-1 antibody for 12 h at 4 °C after antigen repair. Biotinylated IgG was added as the second antibody. Horseradish peroxidase labeled streptomycin-avidin complex was used to detect the second antibody. Slides were stained with DAB and examined under a light microscope. The brown or dark brown stained cytoplasm or cell nucleus was considered as positive. Phosphate-buffered saline (PBS) solution was used as negative control. The result of immunocytochemistry was analysed by using the CMAS-8 image analysis system.

Analysis of HO-1 mRNA by RT-PCR After treatment with LPS, CCK-8 or both LPS and CCK-8 for 7 h, total RNA was extracted from PSMCs. The concentration of RNA was determined from absorbent at 260 nm. The primers for HO-1 and β-actin were as follows: HO-1 (309 bp), 5' -CTT TCA GAA GGGTCAGGTGTCCA-3', 5' -CTGAGAGGTCACCCAGGT AGCGG-3'; β-actin (224 bp), 5' -CGTGGGCCGCCCTAGGCA CCA-3', 5' -CGG TTG CCT TAG GGT TCA GAG GGG-3'. Polymerase chain reactions(PCR) were performed in a 50 µL reaction volume. Reverse transcriptase polymerase chain reaction (RT-PCR) was run in the following procedures: at 42 °C for 45 min, 1 circle; at 95 °C for 3 min, at 60 °C for 30 s, at 72 °C for 30 s, 1 circle; at 94 °C for 30 s, at 60 °C for 30 s, at 72 °C for 30 s, 30 circles; at 94 °C for 30 s, at 60 °C for 30 s, at 72 °C for 6 min, 1 circle. A 10 µL PCR product was placed on to 15 g/L agarose gel and observed by EB staining using a Gel-Pro analyzer.

Western blot analysis of p-JNK protein in PSMCs After treatment with LPS or CCK-8 or both LPS and CCK-8 for 30 min, the cells were harvested and then lysed with ice-cold lysis buffer [50 mmol/L Tris (pH 7.5), 150 mmol/L NaCl, 10 g/L Triton X-100, 5 g/L deoxycholic acid, 1 g/L sodium dodecyl sulfate, 1 mmol/L phenylmethanesulfonyl (PMSF), 10 mmol/L NaF, 1 mmol/L sodium vanadate, 5 mmol/L EDTA (pH 8.0) and a 40 µg/mL protease inhibitor cocktail] as described previously for 1 h and then centrifuged at 12 000 g at 4 °C for 10 min. After precipitated unsolubilized fraction was discarded, protein concentration in the supernatant was determined by Coomassie blue dye-binding assay (Nanjing Jiancheng Corp. China). The supernatant containing 30 µg protein was treated with 2×Laemmli buffer, then subjected to SDS-PAGE using 100 g/L running gel for 3 h at 100 V. Protein was transferred to nitrocellulose membrane, and immunoblot analysis was performed as described previously. Briefly, the membrane was incubated successively with 3 mL/L milk in TPBS at room temperature for 1 h, with 1:1 000 diluted mouse anti-rat specific antibody of p-JNK at 37 °C for 2 h, and then with horseradish peroxidase-labeled secondary antibody at 37 °C for 30 min. After each incubation, the membrane was washed extensively with TPBS and the immunoreactive band was stained with diaminobenzidine (DAB). The brown or dark brown stained strap was considered as positive.

Statistical analysis

Data were reported as mean±SD. Statistical differences between values from different groups were determined by one way ANOVA and Newman-Keuls *q* test. Significance was set at *P*<0.05.

RESULTS

CCK-8 alleviated PSMC injury induced by LPS

PSMCs were harvested at 7 h. There were significantly ultrastructural injuries in LPS group such as seriously swollen mitochondria and mitochondria without or partly without cristallins. CCK-8 could significantly alleviate the above-mentioned changes. While the ultrastructural injuries induced

by LPS were aggravated and the protective effect of CCK-8 on cells was weakened by ZnPPiX. There was no significant difference between CCK-8 group and control group (Figure 1).

CCK-8 inhibited MDA production

The MDA content of PSMCs was significantly increased in LPS group when compared with control group ($P<0.05$). Compared with the LPS group, the MDA content was further increased in LPS+ZnPPiX group but markedly decreased in CCK-8+LPS group, however the protective effect of CCK-8 was weakened by ZnPPiX. There was no significant difference between CCK-8 group and control group ($P<0.05$) (Table 1).

Table 1 Change of MDA content in PSMCs (mean \pm SD, $n=8$)

Group	MDA content (nmol/mL)
Control	4.02 \pm 2.18
LPS	23.44 \pm 1.25 ^a
LPS+CCK-8	14.66 \pm 1.66 ^c
CCK-8	3.00 \pm 2.18
LPS+ZnPP	34.97 \pm 1.54 ^{ae}
LPS+CCK-8+ZnPP	29.68 \pm 2.18 ^{ec}

^a $P<0.05$ vs Control group, ^c $P<0.05$ vs LPS+CCK-8 group, ^e $P<0.05$ vs LPS group.

Change of c-fos and HO-1 protein expression

The expressions of c-fos and HO-1 protein in PSMCs were demonstrated by immunocytochemical staining. The results showed that in control group, no brown deposits were present in PSMCs. In contrast, LPS slightly increased the expressions of c-fos and HO-1 protein, some strong positive signals were observed in PSMCs from LPS group. CCK-8 could further enhance the increased expressions of c-fos and HO-1. The dimension and intensity of positive signals were increased also in CCK-8 group (Figure 2).

Table 2 Changes of HO-1 and c-fos protein expression by immunocytochemistry in PSMCs (mean \pm SD, $n=6$)

Group	Area (%)		(A)	
	HO-1	c-fos	HO-1	c-fos
Control	2.10 \pm 0.01	1.18 \pm 0.02	0.02 \pm 0.009	0.03 \pm 0.021
LPS	20.18 \pm 0.08 ^a	18.95 \pm 0.07 ^a	0.19 \pm 0.07 ^a	0.20 \pm 0.01 ^a
LPS+CCK-8	28.91 \pm 0.36 ^c	29.87 \pm 0.33 ^c	0.47 \pm 0.04 ^c	0.45 \pm 0.02 ^c
CCK-8	21.27 \pm 1.05	20.16 \pm 0.98	0.31 \pm 0.02	0.33 \pm 0.01

^a $P<0.05$ vs Control group, ^c $P<0.05$ vs LPS group.

RT-PCR detection of HO-1 mRNA

HO-1 mRNA in PSMCs was detected by RT-PCR analysis. The results showed that the PSMCs of rats 7 h after LPS administration expressed the gene coding for HO-1, because RT-PCR generated a DNA fragment corresponding to the predicted length, 309 bp, of the HO-1 amplification product. The expression of HO-1 increased significantly in LPS and CCK-8 groups compared with control group. The rate of β -actin was (11 \pm 2) % in control group, while it increased to (30 \pm 6) % and (47 \pm 7) % respectively in LPS and CCK-8 groups. The expression of HO-1 increased further in LPS+CCK-8 group compared with LPS group, it increased to (80 \pm 8) % in LPS+CCK-8 group. In each cell sample, all β -actin amplification products were 224 bp in length and there was no significant difference in β -actin expression (Figure 3).

Western blot analysis of p-JNK protein

There were a few of activated JNK proteins in control group. JNK could be activated by LPS, significant phosphorylation of JNK was observed in PSMCs 30 min after LPS administration. CCK-8 could significantly enhance LPS-induced phosphorylation of JNK. Phosphorylation of JNK was also observed in cells receiving CCK-8 (Figure 4).

Figure 1 Mitochondria ultrastructural changes shown in EM photograph of PSMCs ($\times 25\,000$). A: Control group, B: LPS group, C: CCK-8+LPS group, D: CCK-8 group, E: LPS+ZnPP group, F: CCK-8+LPS+ZnPP group.

DISCUSSION

CCK is a member of the gastrin-CCK family, first isolated from hog intestine, and shows a widespread distribution in different organs and tissues. The sulfated carboxy-terminal octapeptide (CCK-8), isolated from the central nervous system and digestive tract, is the predominant active form. Our previous *in vivo* and *in vitro* studies demonstrated that CCK-8 could protect animals from LPS-induced ES. Treatment of ES rats and rabbits with CCK-8 could lead to an increase in decreasing mean arterial pressure and a reduction in increasing pulmonary artery pressure. Pathological changes of lung could be ameliorated when CCK-8 was via vessel in advance. CCK-8 could protect pulmonary artery endothelia against detrimental effects and then reverse the inhibition of endothelia-dependent relaxation of pulmonary artery induced by LPS, which might be associated with the above-mentioned protective effect of CCK-8^[5-10]. Despite convincing data indicating the protective function of CCK-8 to the organisms in endotoxic shock or to the cells exposed to LPS, the precise mechanism remains unclear.

During stress state induced by administration of LPS, inflammation or therapeutic doses of inhaled oxygen, the bodies would evolve a complex, and redundant network of antioxidants. It has been found that an important arm of the antioxidant response consists of antioxidant enzymes and stress-response proteins^[21-23]. One such stress-response protein is HO-1, the rate-limiting enzyme in the oxidative degradation of heme into bilirubin, carbon monoxide (CO) and free iron. HO exists in three isoforms, whereas HO-2 and HO-3 are primarily constitutive. HO-1 also known as heat shock protein 32, has been found to be the only inducible HO isoform^[24-27]. There is a strong evidence to support the emerging paradigm that HO-1 is essential in maintaining cellular and tissue homeostasis in various *in vitro* and *in vivo* models of oxidant-induced injury. Recent analyses of HO-1 null mice as well as the first reported

HO-1-deficient human have strengthened the emerging paradigm that HO-1 is indeed an important molecule in the host's defense against oxidant stresses such as hypoxia, hyperthermia, and inflammation. It has been considered as one of the most sensitive indicators of cellular injury^[28-31]. Recent studies showed that HO-1 was an important regulator of the vascular response to injury. In this experiment we used the specific HO-1 inhibitor-ZnPPiX to study the relationship between induced HO-1 and injuries of PSMCs. The results showed that HO-1 mRNA and protein expression increased after LPS administration and ZnPPiX could worsen LPS-induced injuries, indicating that overexpression of HO-1 in PSMCs can attenuate their injuries induced by LPS. It is undoubtedly one of the adaptive and self-protective responses to the injury.

Given the overall consistency of data that show HO-1 expression is generally a protective response, it is necessary to study the relationship between HO-1 expression and the protection of CCK-8. We found that CCK-8 could ameliorate the ultrastructural injuries of PSMCs induced by LPS. However, the protective effect of CCK-8 was impaired by ZnPPiX. To further demonstrate the role of HO-1 in CCK-8 attenuated injury of PSMCs induced by LPS, the HO-1 expression and signal pathway of HO-1 induction in PSMCs were studied. The candidate upstream signaling pathways for HO-1 regulation were MAPKs, a group of protein kinases that could mediate the nuclear responses of cells to a wide variety of extracellular stresses such as inflammatory cytokines, growth factors, ultraviolet light, and osmotic stress^[32-34]. The "classical" MAPKs are the p44 and p42 isoforms. Recently, two novel MAPK-related enzymes have been identified, one is JNK and the other is p38^[35]. Although three distinct subfamilies have been described, there is a significant cross talk between the pathway and common downstream target^[36]. In our experiment, we found that CCK-8 significantly enhanced LPS-induced overexpression of HO-1 mRNA and protein. We also observed that LPS could also activate c-fos (one of the two members of the real family of AP-1) and JNK in PSMCs, while CCK-8 could further enhance the activation of c-fos and JNK induced by LPS. From all above, the role of MAPKs was potential in HO-1 signal pathway after LPS and CCK-8 administration to PSMCs, HO-1 might be the key for CCK-8 to exert its protective effect.

In summary, administration of CCK-8 can prevent injuries of PSMCs induced by LPS through overexpression of HO-1 mRNA and protein, which may involve c-fos and JNK.

Abstract

AIM: To evaluate the incidence of regurgitation and other symptoms of gastroesophageal reflux in Indonesian infants.

METHODS: In a cross-sectional study at the University Outpatient Clinic for vaccination in Jakarta, 138 mothers of healthy infants less than 12-mo old were prospectively asked to report the frequency of regurgitation.

RESULTS: Whatever the age was, some infants did not regurgitate (from 10% during the first month of life to 67% in 1-year-old infants). Regurgitation of at least once a day was reported in 77% of infants younger than 3 mo. Daily regurgitation decreased to 12% in the 9-12 mo old group. Reported peak prevalence was 81%(26/32) during the first month of life. Regurgitation decreased sharply between the 4-6 and 7-9 mo old groups (from 44% to 9%). The longer the regurgitation persisted, the more frequently the mother perceived regurgitation as a problem. Volume and frequency of regurgitation, back arching, irritability, crying and refusal of feeding were the symptoms causing maternal anxiety. The longer the regurgitation persisted, the more frequently the mothers viewed it as a health problem.

CONCLUSION: Regurgitation occurs frequently in Indonesian infants, and is a frequent cause of concern to mothers.

INTRODUCTION

Regurgitation is the effortless return of gastric contents into the mouth, and the most common symptom of infantile gastroesophageal reflux (GER). Few attempts have been made to determine the prevalence of regurgitation and its natural course in infants. In the Western world, evaluation of the natural progression of symptoms of GER at any age has become virtually impossible because of widespread self-treatment and a lack of medical referral. It is not clear how important genetic, racial and ethnic factors may be in the clinical presentation, the prevalence and the natural history of GER disease. In the Eastern

part of the world, it is commonly thought that regurgitation is less frequent than in the United States and Europe. For these reasons, determining the prevalence of GER in Indonesian infants is of interest.

MATERIALS AND METHODS

Data were collected from mothers bringing their healthy infants to the Outpatient Clinic of the Cipto Mangunkusumo Hospital, Jakarta, for routine immunization. All infants were born at term and in good general health with adequate nutritional status (P50-97 NCHS). Most of the mothers were from the middle-low socioeconomic class and worked as housewives. The data were obtained by prospectively interviewing mothers using a standard questionnaire about the prevalence of regurgitation during the previous two wk and other descriptive information.

The same author (BH) interviewed 138 consecutive mothers, presenting to the outpatient clinic of one of the local authors. Each interview lasted for 15 to 20 min. All mothers agreed to participate in the study. Age distribution of the infants is listed in Table 1. There were 75 male and 63 female infants. Mothers were asked the number of episodes of regurgitation per day, and whether they considered regurgitation as a health problem, whether the frequency or volume of emesis was a health problem and whether the infant had such symptoms as crying, back arching, irritability, or refusal to feed, as well as whether the symptoms had an adverse impact on the baby's quality of life.

The two-tailed unpaired *t*-test was used, statistical significance was set at $P < 0.05$.

Table 1 Age distribution of studied infants

Age (mo)	Infants (n)
0-3	74
4-6	34
7-9	21
10-12	9
Total	138

RESULTS

Table 2 summarizes the prevalence and frequency of regurgitation in the infants by month of age. Up to the age of 3 mo, about half of the infants regurgitated more than two times a day, the number was slightly higher in the first mo of life and smaller at 3 mo. In the group regurgitating 1 to 4 times a day, there was a sharp decrease in the number of episodes of regurgitation to almost zero by the age of 7 to 8 mo. Twenty-five percent of the infants regurgitated more than 4 times a day during the first month of life, but from the age of 6 mo all infants regurgitated less than 4 times a day. Table 3 shows the number of mothers who were concerned about regurgitation. The evolution of concern was inversely related to the persistence of regurgitation. During the first month of life, many infants regurgitated, and few mothers expressed their concerns. However, the mothers of older infants with persistent vomiting became concerned about the symptom. Among infants regurgitating more than once a day, about 40% of the mothers asked for medical advice about

the symptom. The reasons for maternal concern are listed in Table 4, and included the excessive volume and frequency of regurgitation, and symptoms suggesting a decreased quality of life of the infants such as food refusal, crying, back arching and irritability. The volume of regurgitation was less frequently considered as a problem than the frequency of regurgitation (9% vs 66%). Crying and irritability were the second most frequent reasons for concern among the mothers (57%). Food refusal and back arching were reported as reasons for concern in 26% and 20%, respectively. Mothers of regurgitating infants estimated their infants had an impaired quality of life (75 vs 15 %, $P<0.05$). Infants of unconcerned mothers had much less frequent symptoms than infants of concerned mother ($P<0.05$).

Table 2 Daily frequency of regurgitation in 138 healthy infants

Age (mo)	Infants	Daily frequency of regurgitation (%)			
		0	<1	1-4	>4
1	32	3 (10)	3 (10)	18 (55)	8 (25)
2	25	3 (12)	2 (8)	13 (15)	7 (28)

6	10	6 (60)	1 (10)	3 (30)	0 (0)
7	10	6 (60)	2 (20)	2 (20)	0 (0)
8	3	1 (33)	2 (67)	0 (0)	0 (0)
9	8	8 (10)	0 (0)	0 (0)	0 (0)
10	5	4 (80)	0 (0)	1 (20)	0 (0)
11	1	1 (100)	0 (0)	0 (0)	0 (0)
12	3	2 (67)	1 (33)	0 (0)	0 (0)
	138	48(35)	15 (11)	54 (39%)	21 (15%)

Table 3 Number of mothers considering regurgitation as a health problem

	Daily regurgitation frequency (%)			
	<1	1-4	>4	
With concern	3	24	8	35 (25)
Without concern	60	30	13	103 (75)

Table 4 Symptoms of gastroesophageal reflux and number of mothers showing concern

Symptom	n (%)
Crying and irritability	20 (57)
Food refusal	9 (26)
Back arching	7 (20)
Excessive frequency of regurgitation	23 (66)
Excessive volume of regurgitation	3 (9)

DISCUSSION

Recent studies have suggested that GER may in part be genetically determined. Thus, its prevalence and severity might be expected to vary according to racial or ethnic background. Radiology is not recommended in the diagnosis of GER. The radiological method of GER evaluation showed a specificity of 50% and a sensitivity of 29%, as compared to 24-h pH monitoring^[1]. A genetic influence on the prevalence of GER was supported by the finding that GER symptoms are more frequently encountered in the relatives of GER disease patients^[2]. Moreover, the concordance for GER is higher in monozygotic than dizygotic twins^[3]. A locus on chromosome 13q, between microsatellite D13S171 and D13S263, has been linked with severe GER in 5 families with multigenerational histories^[4], but the

same abnormal locus was not found in 5 other families, possibly due to the genetic heterogeneity of GER and different clinical presentations among patients studied^[5]. The incidence of hiatal hernia was reported to be much lower in Korea (1.4%) than in Western world (2.3-50%)^[6]. Several studies have confirmed the familial segregation of hiatal hernia, Barrett's esophagus, esophageal carcinoma and GER.

There are only a few studies that have attempted to describe the natural history of GER in children. In some of these studies, infantile GER was excluded^[7]. Orenstein developed a questionnaire to identify infants with GER^[8]. At least regurgitation occurred once a day in half of 0- to 3-mo-old white non-Hispanic infants, and increased up to two thirds at 4 mo and decreased to 5% at 10-12 mo of age^[9]. Daily regurgitation was present in 50% of infants younger than 3 mo, in more than 66% at 4 mo, but only in 5% at 1 year of age^[8-10]. Nelson and coworkers documented the prevalence of regurgitation in a white non-Hispanic infant population in USA^[9]. However, as the authors stated, their findings could not be generalized and investigations of different racial/ethnic and socioeconomic groups are needed to determine differences in prevalence of symptoms in other populations. Also in Japanese infants, regurgitation was common and decreased with age^[11].

Our questionnaire intended to report the incidence of regurgitation, not of symptoms suggesting gastro-esophageal reflux (disease). Regurgitation occurred frequently in our small sample size of Indonesian infants. The sample size was relatively small for an epidemiological survey. In fact, the prevalence of regurgitation in our population was the highest ever reported. In the study by Nelson and coworkers, the prevalence of regurgitation peaked at 4 mo of age^[9], whereas in our population the prevalence was highest during the first month of life. In a study from northern India, the prevalence of regurgitation in 1-6-mo-old infants was 55%^[12]. In our study, 75% of 0-6-mo-old infants regurgitated at least once a day.

Complete resolution of regurgitation was the most common outcome in infant reflux, with a resolution by 10 mo of age in 55%, by 18 mo of age in 60-80% and by 2 years of age in 98%^[13,14]. In the study by Nelson and coworkers, and in our study, regurgitation was almost completely disappeared by 7 mo^[9]. In 6-12-mo old infants, the prevalence of regurgitation was 15% in North India^[12], which was similar to the findings in our population if all infants regurgitating at least once per day were considered. If the infants regurgitating less than once a day were included, then the prevalence of regurgitation among 6-12-mo old Indonesian infants was as high as 30%. In all studies evaluating the natural evolution of infant regurgitation, there was a sharp decline around 6-7 mo towards a disappearance at the age of 12 mo^[9,12,15].

According to epidemiological data from France, Australia and the United States, excessive regurgitation was a cause of concern and medical consult in about 25% of parents^[8-10]. Spilling in infancy was very common, but the majority of children settled by 13 to 14 mo of age. However, those with frequent spilling (>90 d) were more likely to have GER symptoms at 9 years of age^[16]. Esophagitis occurred in one quarter of infants with persistent distress^[17]. There was a subgroup of otherwise healthy infants, presenting with wheeze and/or stridor, who had isolated swallowing dysfunction and silent aspiration as the cause of their respiratory symptoms^[18]. Our findings were similar, 30% of the mothers showed concern over regurgitation. Symptoms causing parental perception that regurgitation might be a problem were comparable in both studies, and included the volume and frequency of regurgitation and symptoms suggesting decreased quality of life such as crying, back-arching and irritability^[9]. Parental reports about reflux-related behaviors were similar in Nelson's study and in ours^[9]. Despite the concern of parents, pediatricians generally stated

that intervention was not needed^[19]. Although a prospective follow-up of 63 regurgitating infants reported a complete disappearance of regurgitation by 12 mo of age, it is interesting that these same infants were reported on a long-term follow-up to have a significant increase in feeding refusal, prolonged eating time, parental distress about feeding and impaired quality of life when compared to non-regurgitating controls^[15].

In conclusion, the severity and incidence of GOR were significantly higher in symptomatic than asymptomatic infants^[20]. Food allergy might be common in regurgitating infants^[21,22]. Recommendations for a diagnostic workup have been published^[23,24]. Hydrolysates might treat regurgitation by improving gastric emptying^[25]. GER frequently caused apnea in infants^[26,27]. GER and regurgitation decreased the quality of life^[28] in infants, and increased hospital stay and cost^[29,30]. Worldwide, racial differences in the prevalence and persistence of infantile regurgitation seem minimal. Regurgitation in Indonesian infants tends to be very frequent, with more than 75% of 0-3-mo-old infants regurgitating at least once a day. Symptoms viewed as being related to GER and causing maternal concern are also similar. For one in three mothers worldwide, the symptom of regurgitation is a cause for concern. Mothers in Indonesia are no exception.

Abstract

AIM: To assess the relationship between severity of gastroesophageal reflux disease and Epworth sleepiness scale as an indicator of daytime somnolence.

METHODS: One hundred and thirty-four patients underwent an upper panendoscopy as indicated by the typical reflux symptoms and were also investigated with regard to somnolence. Sleepiness was evaluated by Epworth Sleepiness Scale, which was compared to the severity of endoscopic findings (Savary-Miller/modified by Siewert). Patients with psychiatric disorders or being on sedato-hypnotics as well as shift workers were excluded from the study. The relationship between the severity of the reflux disease and daytime somnolence was analyzed with the help of multivariate regression analysis.

RESULTS: A positive tendency was found between the severity of the reflux disease and the corresponding Epworth Sleepiness Scale. In the case of the more severe type - Savary-Miller III - at least a mild hypersomnia was found. For this group daytime somnolence was significantly higher than in the case of the non-erosive type of Gastroesophageal Reflux Disease representing the mildest stage of reflux disease.

CONCLUSION: The severity of Gastroesophageal Reflux Disease influences daytime somnolence.

INTRODUCTION

Sleep is potentially conducive to the gastro-esophageal reflux events. The physiological antireflux mechanisms – swallowing rate, salivation, the pressure of the upper and the lower esophageal sphincter, gastric emptying - are reduced as well as the “heartburn-signal” is depressed during the state of sleep^[1-6]. Moreover, the typical lying position facilitates the

flow of the gastric content towards the esophagus due to the forces of gravitation^[2]. Studies of parallel 24 h pH-metry and polysomnography amongst obstructive sleep apneic patients showed that some reflux events coincide with arousals^[3]. At the same time, it was also found that some apneic periods contribute to considerable reflux events, while others not. On the other hand, earlier investigations focusing on the relationship between sleep related breathing disorders and Gastroesophageal Reflux Disease (GERD) have indicated the adverse effect of nocturnal reflux events on the sleep structure^[4,5]. In this respect some epidemiological studies have suggested a relationship between GERD and daytime sleepiness^[6-9]. In 2003 the ProGERD study has established that the effective treatment of GERD reduces sleep disturbances^[10]. The results of a Gallup Telephone Survey – conducted on behalf of the American Gastroenterological Association – have shown that the nocturnal heartburn and the regurgitation of gastric content caused frequent awakenings and sleep disturbances, which could affect daytime performance and the quality of life^[11]. Therefore it appears that the nighttime reflux could have a considerable impact on the quality of sleep and it can also play a significant role in the developing of restless sleep experienced widely by the patients.

The influence of GERD on daytime cognitive functions has not been analyzed yet. In this study we focused on one of the important cognitive functions, on daytime sleepiness and its relation to the severity of GERD. The aim of the study was to describe the association between the severity of GERD and daytime somnolence.

MATERIALS AND METHODS

The database

The study was conducted by a gastroenterologist in two centers. The patients were referred for upper panendoscopy with the typical symptoms of GERD untreated. Psychiatric patients or those who took sedato-hypnotics and shift workers were excluded. The classification of GERD was based on endoscopic findings and the severity of the esophagitis^[12]. We used the conventional Savary-Miller classification of the disease modified by Siewert. The Epworth Sleepiness Scale (ESS) was used as an indicator of daytime somnolence, which is a simple questionnaire measure to assess daytime somnolence amongst patients suffering of sleep-awake disorders^[13-15]. The patient data were collated on an Excel 9.0 worksheet, including the severity grades of GERD (0-IV), the Epworth scale (0-24), age, gender and Body Mass Index (BMI).

Statistical methods

The extent and statistical strength of the potential relationship between GERD severity and daytime somnolence was captured by estimating the impact of diagnosed GERD categories on the indicators of sleepiness relative to the two endpoints of the reflux disease severity scale. We relied on the conventional $P < 0.05$ critical values regarding the statistical tests of the results. At the same time, we also took into account a somewhat weaker, 10% significance level when evaluating the observed

associations, given the relatively small size of the available sample. We used the SPSS 9-software package for the statistical procedures.

RESULTS

Basic descriptions of the study population

The total available population covered 134 patients the descriptive statistics are given in Table 1. This population was characterized by an average age of 52.9 years (std. dev. 16.7), a male/female ratio of 65: 69, and an average BMI of 26.4 (std. dev. 5.1). Using the Savary-Miller definitions as modified by Sievert, our patients displayed the following distribution alongside the endoscopic categorization of reflux disease: 24 (18.9%) GERD 0 subjects, 29(21.6%) GERD I subjects, 56 (41.8%) GERD II subjects, 13(9.7%) GERD III subjects, and 12 (8.9%) GERD IV subjects. Note that we included only the sample of GERD cases with 122 patients into the detailed statistical analysis. The exclusion of GERD IV group was justified on the basis of the consideration that this set of patients is inherently heterogeneous regarding the anatomic abnormalities as well as the severity of the reflux disease itself. Obviously, this could be a confounding factor in relation to the effect on our analyzed dependent variable, the daytime sleepiness.

Table 1 Descriptive statistics of the total study population

Variable	Minimum	Maximum	Mean	SD
Age (yr)	17.00	83.00	52.940	16.752
Male	0	1	0.485	-
BMI	17.54	43.94	26.420	5.133
GERD 0	0	1	0.179	-
GERD I	0	1	0.216	-
GERD II	0	1	0.418	-
GERD III	0	1	0.097	-
GERD IV	0	1	0.089	-
EPWORTH	1.00	24.00	7.440	4.226

n=134

Note: The mean values of the dichotomous variables (with cases taking values 0 or 1) refer to frequencies and thus the standard deviation is not an applicable measure for them.

The population means of the Epworth sleepiness scale used as a direct measure of somnolence here was 7.4 (SD. 4.2) (while slightly higher -7.6 (SD4.3) – for the sample covering the GERD 0 and GERD I-IV patients). We created a further dependent variable, "abnormal Epworth", for the observations with an index value greater than 8 taking into account that at least a mild form of hypersomnia could be diagnosed above this level. Since our sample was not primarily directed at patients suffering from sleep disorders, it did not seem to be reasonable to select a higher limit. Nevertheless, the detectable tendencies did not differ qualitatively for the critical Epworth value of 10 from the one, which is presented here. The "abnormal Epworth" took the frequency of 44.8% (and 44.3% after dropping the GERD IV group).

Table 2 shows the patterns for the two above described dependent variables by GERD diagnosis. It is evident that the means for the Epworth indices exhibited increasing values alongside the severity of GERD taking the sub-groups of GERD 0 and GERD I-III together. Whereas GERD I exceeded by 0.5 (6.2% of the population average) and GERD II by 0.7(9.2% of the population average) the 6.7 mean value of our GERD 0 cluster, this difference was already 4.1(54.5% of the population average) in the case of the GERD III group. This increasing tendency reflecting the severity of GERD appeared to be even

more characteristic with respect to the frequencies of "abnormal Epworth". Compared with the 29.1% ratio calculated for GERD 0, the observed percentage increments in the presence of hypersomnia were: 8.8% (19.7% of the population average) for GERD I, 17.3%(38.7% of the population average) for GERD II, and 47.8%(106.9% of the population average) for the GERD III group. For information, the table gives our observations for the GERD IV patients as well: we found the lowest group mean value with respect the Epworth index, but the occurrence of hypersomnia went above the population average. This seems to provide a further aspect regarding the heterogeneity of patients diagnosed with GERD IV.

Table 2 Measures of daytime somnolence by GERD groups

GERD	<i>n</i>	EPWORTH index Mean (Std. dev.)	"Abnormal" EPWORTH >8 Frequency
GERD 0	24	6.708 (4.639)	0.291
GERD I	29	7.172 (4.036)	0.379
GERD II	56	7.393 (3.706)	0.464
GERD III	13	10.769 (5.890)	0.769
GERD IV	12	6.166 (2.588)	0.500
Total sample	134	7.440 (4.226)	0.447

Notes: 1. The equality of the mean values for the Epworth indices could be rejected at 5% significance level on the basis of the Student *t*-tests for the following pairs of GERD groups: GERD III vs GERD II, GERD III vs GERD I, GERD III vs GERD 0, and GERD III vs GERD IV. 2. The Pearson chi-square tests for the frequencies of "abnormal" Epworth indices indicated significant differences at 5% critical value in the case of the following 2x2 tables : GERD III vs GERD II, GERD III vs GERD I, GERD III vs GERD 0.

Statistical analysis and results

To evaluate our observations indicating a positive association between severity of GERD and somnolence more precisely, we performed linear regressions for the variation of the Epworth index and logistic regressions for the probability of "abnormal Epworth" over the sample comprising the GERD 0 and GERD I-III cases. Apart from the categorical variables constructed for the reflux disease classifications, we also included the BMI values, and the observations for gender and age as explanatory variables. Since our estimated models typically gave a better overall fit when measuring age above 50 rather than the number of years directly, we present our result with the former control variable below.

Table 3 summarizes our linear regression analysis. The first two blocks of the table present the results with the inclusion of the additional control variables. Although the sign of the regression coefficient (B) obtained for BMI was positive as expected, the contribution of the variable did not emerge to be statistically significant. At the same time, the higher age was found to reduce the expected value of the Epworth index at $P<0.05$ critical values. As far as the estimates for the GERD categories were concerned, the multivariate regression seemed to support the direct observation that reflux disease severity incurs a positive effect on the extent of the Epworth index. When choosing GERD 0 as the reference category (that is the indicator for this group was excluded), the coefficients for the sub-groups of GERD I-III took positive and increasing values as it is shown by the figures of the first model. These coefficients reached a critical magnitude at the GERD III group, which already proved to be significant at 5% level. In numeric terms, this implied that after filtering out the joint effect of the control variables the Epworth index was estimated to be lifted up by 47.5% of the population mean relative to GERD 0 in the case of the third sub-group of GERD I-III. n=122

signed coefficients with decreasing absolute values that were estimated relative to GERD III directly mirrored the results of the first model, but this regression exercise gave an opportunity for further statistical tests (see the second block). Thus, the coefficients obtained for GERD 0 as well as for GERD I, II were significantly ($P<0.05$) different from zero, and consequently indicated statistically relevant deviations from the expected Epworth value at GERD III serving as the baseline. These two estimations above were repeated without the additional control variables as well (see the third and fourth blocks of Table 3). The coefficients in this case were of course equivalent with the differences of the Epworth means grouped in Table 2. At the same time, the corresponding t -values confirmed our previous results indicating that GERD III was associated with a significantly greater sleepiness scale relative to GERD 0, while GERD 0, GERD I and GERD II were associated with a significantly smaller one relative to the GERD III group.

We could reach essentially similar conclusions on the basis of the logistic regressions investigating the occurrences of the "abnormal Epworth" as it is presented in Table 4. The sign of the coefficients (B) obtained for the additional control variables was the same as in the case of the linear regression, but we could not identify a separate significant effect in this case on the basis of the Wald-tests. At the same time, the Wald-statistic referring to the joint effect of the GERD categories (i.e. the "GERD" row of the table) already displayed a weakly significant ($P<0.1$) value. The estimates relative to GERD 0 gave again increasing coefficients with odds ratios greater than one (see the parameters of the first model). The odds ratio computed for GERD III was different from one at $P<0.05$. Correspondingly, we found in absolute terms that the estimated ratio of hypersomnia to the normal cases *ceteris paribus* increased by 7.4 times in the GERD III group compared with

the least severe reflux disease cluster. At the same time, the increasing odds ratios with values lower than one derived from the logistic regression using GERD III as the reference category showed statistically significant differences in the case all less severe reflux disease groups (the second block of the table). (In this respect, GERD II could be regarded as a "transitory" category between GERD III and the milder disease classes as far as this difference appeared to be only weakly significant.) The regressions re-run without the control variables produced the odds ratios that could be directly calculated from the frequencies of Table 2 (see the third and fourth models of Table 4). The Wald-tests performed on these coefficients indicated again that the probability of hypersomnia to occur was significantly higher for GERD III relative to GERD 0, and significantly lower for GERD 0, GERD I and GERD II relative to GERD III.

DISCUSSION

We raised the question whether the well-known nocturnal symptoms of patients suffering from GERD results in the deterioration of daytime cognitive functions. Daytime sleepiness was chosen to relate the severity of GERD assessed by panendoscopy to the measure of ESS. Our results indicate that the more severe GERD groups categorized by the Savary-Miller classification exhibit a gradually increasing, more "somnolent" result by the ESS. Moreover, while in the group GERD 0 only 29% of patients reaches the mild somnolence value of 8 on ESS, in GERD I this rate grows up to 39% and in GERD II it reaches 46%. In the group of GERD III more than 77% of the subjects suffered of significant somnolence. This relationship was confirmed by the multivariate regression analysis when estimating the ESS result directly as well as

when examining the probability of at least mild hypersomnia, especially with regard to significantly higher somnolence observed in the most severe GERD population.

Our findings seem to imply that there is a significant fragmentation in the sleep structure in the case of severe GERD. Previous investigations already indicated that arousals, which play a major role in the fragmentation of the sleep structure, could be generated by some reflux events^[4,16]. The higher positioned and longer than 5 min reflux events are more likely to cause arousals. If the reflux content leaves the esophagus and migrates into the upper respiratory tract, it could irritate the acid sensitive receptors, which are located in the mucus layer^[17]. This irritation would lead to the change in muscle tone as a manifestation of arousal producing a motoric restless sleep. In addition, the regurgitation of the acidic gastric fluid may cause discomfort, choking, aspiration, and disturbed sleep with multiple awakenings. The motoric restless sleep is more likely to happen even independently of the pH value of the gastric content, if the refluxate reaches the sensitive pharyngeal level. We, however only assessed patients with the classical self-reported GERD. In fact, patients with extra esophageal symptoms may develop daytime somnolence even earlier and without visible esophagitis.

Finally, it should be noted that GERD is not the dysfunction of acid production but the insufficiency of the LES. So it is important to explore daytime somnolence in the cases of severe and therapy refractory GERD^[18]. These cases can be caused by sleep-related breathing disorders, which can augment the symptoms of GERD and cause daytime sleepiness as well.

Abstract

AIM: It has been noticed that gastroenteritis or dysentery plays a role in pathogenesis of irritable bowel syndrome (IBS), and antibiotics can increase functional abdominal symptoms, both of which may be partly due to intestinal flora disorders. This study was to determine the change of gut flora of IBS, a cluster of abdominal symptoms. Because of the chronic course and frequent occurrence of the disease, IBS patients suffered much from it. So the quality of life (QoL) of IBS patients was also evaluated in this study.

METHODS: Twenty-five Rome II criteria-positive IBS patients were recruited, and 25 age and gender-matched healthy volunteers were accepted as control. The fecal flora, including *Lactobacillus*, *Bifidobacterium*, *Bacteroides*, *C. perfringens* *Enterobacteriaceae* and *Enterococcus*, were analyzed quantitatively and qualitatively. We also calculated the ratio of *Bifidobacterium* to *Enterobacteriaceae* (B/E ratio) in both IBS patients and controls. In both groups, the data were further analyzed based on age difference, and comparisons were made between the younger and elder subgroups. We also evaluated the quality of life (QoL) of IBS patients and the control group using the Chinese version of SF-36 health questionnaire.

RESULTS: In IBS patients, the number of fecal *Bifidobacterium* was significantly decreased and that of *Enterobacteriaceae* was significantly increased compared with that in healthy controls (both $P < 0.05$). The mean microbial colonization resistance (CR) of the bowel in IBS patients was smaller than 1, making a significant difference compared with that in control which was more than 1 ($P < 0.01$). There was no significant difference in gut flora between two subgroups. While in control, the elder subgroup presented more *Enterobacteriaceae* than the younger one ($P < 0.05$). Compared with the control group, IBS patients had significantly lower scores on all SF-36 scales, with the exception of physical functioning. However, there was no significant correlation between quality of life and enteric symptoms in IBS patients.

CONCLUSION: There are intestinal flora disorders in IBS patients, which may be involved in triggering the IBS-like symptoms. IBS patients experience significant impairment

in QoL, however, the impairment is not caused directly by enteric symptoms.

INTRODUCTION

Many patients with typical irritable bowel syndrome (IBS) blamed all their bowel symptoms for acute gastroenteritis or dysentery, and it has been shown that intestinal infection does play an important role in the pathogenesis of IBS^[1,2]. Although the mechanisms underlying postinfectious IBS are not clear, microbiological environmental alterations may be partly responsible for the pathogenesis. There is even evidence showing that antibiotics can increase functional abdominal symptoms^[3]. In some cases, this is due to the colonization of pathogenic bacteria such as *Clostridium difficile*. In others it may be due to changes in bowel flora, which have been shown to persist for many months after a single antibiotic course.

In this study, the changes of intestinal microecology were investigated. Since age or sex may influence the composition of gut flora^[4,5], age and sex-matched controls were recruited and the gut flora was also studied. Furthermore, the impact of IBS on quality of life (QoL) was evaluated using SF-36 health questionnaire (Chinese Version). Finally, the correlation between enteric symptoms scores and QoL in IBS patients was analyzed.

MATERIALS AND METHODS

Subjects

From September 2002 to March 2003, 25 Rome II criteria-positive^[6] IBS patients diagnosed at the Department of Gastroenterology, Sir Run Run Shaw Affiliated Hospital of Zhejiang University were recruited (8 males, 17 females, mean age 45.40 ± 10.56 years, ranging from 26 to 64 years). Subjects were excluded if they had any organic disease and those who had taken antibiotics or microecological modulators within 2 weeks before study were also ruled out. Twenty-five healthy volunteers (age and gender-matched) were accepted as control. All procedures were approved by the Ethical Committee of Medical College of Zhejiang University.

Bacteriological analysis of intestinal flora

Selective culture medium for *Lactobacillus* (LBS), *Bifidobacterium* (Bs), *Bacteroides* (NBGT), *Enterococcus* (EC) and *Enterobacteriaceae* (EMB) was prepared by the Institute of Infectious Diseases, the First Affiliated Hospital of Zhejiang University. The culture medium for *C. perfringens* (TSN) was bought from Biomerieux (French). Glove box (Forma Scientific, Lnc., USA) was also needed.

Bacteriological analysis of intestinal flora was performed using the method that was essentially the same as that established by Okusa *et al*^[7]. In brief, 10 g fresh stool was collected and sent to laboratory within 30 min in an anaerobic

jar. After 1 g fresh stool was aseptically quantified and homogenized, then diluted with an anaerobic solution in an anaerobic chamber (decimal dilutions up to 10^{-7} were prepared). Fifty μL of serial dilution volume (10^{-1} , 10^{-3} , 10^{-5} , 10^{-7}) of the specimens was spread over the above agar media with a L-shape stick. Aerobic bacteria were cultivated at 37°C in an incubator for 48 h and anaerobic bacteria were cultivated in glove box (800 mL/L nitrogen, 100 mL/L hydrogen, and 100 mL/L carbon dioxide) at 37°C for 48–72 h. After incubation, morphologically distinct colonies were described, calculated, isolated, and identified by morphology, Gram reaction and API fermentation tests, *etc.* The results were expressed as \log_{10} of the number of bacteria per gram wet weight of feces (colony forming units/g, CFU/g). In our study, 2×10^2 (CFU) were set as the lowest detection limit. The incidence of each bacterial group recorded as the percentage of each bacterial group relative to the total bacteria was calculated. Furthermore, the ratio of *Bifidobacterium* to *Enterobacteriaceae* (B/E ratio) was calculated as the microbial colonization resistance (CR) of the bowel according to literature^[8].

Evaluation of enteric symptoms

IBS patients were evaluated by enteric symptom questionnaire^[9] which included 6 scales concerning abdominal pain, mucous stool and distention, *etc.* (Table 1). Each scale was scored as “0” to “3” according to the severity and frequency of symptoms, whereas a higher score meant a more severe and frequent occurrence. The sum of each score was regarded as the general assessment of enteric symptoms.

Assessment of quality of life

The quality of life (QoL) of IBS patients and controls was evaluated with the Chinese version of short form 36 (SF-36) established by Wang *et al.*^[10], which included 8 multiple dimensions as physical functioning (PF), role physical (RP), bodily pain (BP), general health (GH), vitality (VT), social functioning (SF), role emotional (RE) and mental health (MH). Scores were calculated according to corresponding formula and rules. Each dimension was scored from 0 to 100, with higher scores indicating better QoL.

Statistical analysis

Quantitative data were compared using different *t* test according to different situations, with the results expressed as mean \pm SD. The detection frequency was analyzed by Chi-squares test. The correlation between enteric symptom scores and QoL in IBS patients was detected by Pearson's correlation analysis. A *P* value less than 0.05 was considered statistically significant. All analysis was conducted using SPSS10.0 statistical package.

RESULTS

Gut flora and microbial colonization resistance and detection frequency

Compared with the control group, IBS patients showed a significant decrease in *Bifidobacterium* but an increase in

Enterobacteriaceae (both $P < 0.05$). The mean microbial colonization resistance (CR) of the bowel in IBS patients was smaller than 1, which was significantly different from that in control ($P < 0.01$). There were no significant differences in *Lactobacillus*, *Bacteroides*, *Enterococcus* between two groups. The detection frequency of *C. perfringens* in IBS group was much lower than that in the control group ($P < 0.01$, Table 2).

Table 2 Number of bacteria and B/E value in two groups (mean \pm SD, LgN/g stool)

Bacteria (%)	IBS patients (n=25)	Controls(n=25)
<i>Lactobacillus</i>	6.79 \pm 1.73 (92)	6.79 \pm 1.94 (84)
<i>Bifidobacteria</i> ^a	8.14 \pm 2.14 (96)	9.32 \pm 1.22 (100)
<i>Bacteroides</i>	10.49 \pm 0.56 (100)	10.62 \pm 0.79 (100)
<i>C. perfringens</i> ^d	7.32 \pm 2.12 (40)	6.66 \pm 1.68 (80)
<i>Enterococcus</i>	7.96 \pm 1.53 (100)	7.49 \pm 1.29 (100)
<i>Enterobacteriaceae</i> ^a	9.02 \pm 1.04 (100)	8.44 \pm 0.95 (100)
B/E value ^b	0.91 \pm 0.27 (96)	1.12 \pm 0.23 (100)

The data in the bracket mean positive rate (This is applicable for the following tables including flora.). ^a $P < 0.05$ flora vs control, ^b $P < 0.01$ B/E value vs control, ^d $P < 0.01$ detection frequency vs control.

The data were further analyzed based on age difference. Both groups were sorted on ascending order, the first 12 persons were chosen as younger subgroup (mean age 36.25 \pm 5.17) and the rest 13 (mean age 53.85 \pm 6.14) as elder one. We found that in IBS group, there was no significant difference in gut flora between two subgroups, but CR was smaller than 1 in both subgroups. While in control, the elder subgroup presented more *Enterobacteriaceae* than the younger subgroup ($P < 0.05$), but smaller CR (Tables 3, 4).

Table 3 Number of bacteria and B/E value in younger subgroup and elder subgroup in IBS group (mean \pm SD, LgN/g stool)

Bacteria (%)	Younger subgroup (n=12)	Elder subgroup (n=13)
<i>Lactobacillus</i>	6.63 \pm 1.83 (100)	6.98 \pm 1.70 (84)
<i>Bifidobacteria</i>	7.60 \pm 2.65 (100)	8.68 \pm 1.38 (92)
<i>Bacteroides</i>	10.52 \pm 0.42 (100)	10.47 \pm 0.72 (100)
<i>C. perfringens</i>	8.84 \pm 1.07 (25)	6.89 \pm 2.20 (54)
<i>Enterococcus</i>	8.26 \pm 1.58 (100)	7.69 \pm 1.50 (100)
<i>Enterobacteriaceae</i>	9.16 \pm 1.22 (100)	8.90 \pm 0.88 (100)
B/E value	0.85 \pm 0.33 (100)	0.98 \pm 0.19 (92)

QoL of IBS patients

IBS patients experienced significant impairment in QoL (Table 5). Compared with control group, IBS patients had significantly lower scores on all SF-36 scales, with the exception of physical functioning. Decrements in QoL were most pronounced in general health (GH, mean score 41.40), role physical (RP, mean score 52.00) and vitality (VT, mean score 53.40). Others like mental health (MH), role emotional (RE), bodily pain (BP) and social functioning (SF) were also impaired.

Table 1 Enteric symptom scales

Symptoms	0	1	2	3
Duration of abdominal pain (h/d)	None	<1	2-8	>8
Frequency of abdominal pain (d/wk)	None	1-2	3-5	6-7
Ratio of abnormal shape of stool	None	<1/4	1/4-3/4	>3/4
Ratio of abnormal passage of defecation	None	<1/4	1/4-3/4	>3/4
Ratio of mucous stool	None	<1/4	1/4-3/4	>3/4
Distention or gastrectasia when defecation	None	<1/4	1/4-3/4	>3/4

Table 4 Number of bacteria and B/E value in younger subgroup and elder subgroup of control group. (mean±SD, LgN/g stool)

Bacteria (%)	Younger subgroup (n=12)	Elder subgroup (n=13)

Correlation between QoL and enteric symptoms in IBS patients

Although IBS patients presented a negative correlation between bodily pain (BP) and enteric symptoms (correlation coefficient: 0.347), the difference was not significant ($P>0.05$). While vitality (VT), role emotional (RE), general health (GH) and physical functioning (PF), showed no significant difference with QoL in IBS patients (Table 6).

Table 6 Correlation between enteric symptoms and QoL in IBS (mean±SD)

	Score of QoL	Score of enteric symptoms	Correlation coefficient (r)
PF	74.40 (26.78)	7.56 (2.31)	-0.062
RP	52.00 (44.44)	7.56 (2.31)	0.060
BP	73.33 (17.57)	7.56 (2.31)	-0.347
GH	41.40 (15.04)	7.56 (2.31)	-0.137
VT	53.40 (16.94)	7.56 (2.31)	-0.280
SF	75.00 (12.50)	7.56 (2.31)	0.018
RE	61.33 (41.59)	7.56 (2.31)	-0.257
MH	58.24 (16.21)	7.56 (2.31)	0.001

DISCUSSION

The etiology of IBS is still unclear and the pathogenetic mechanisms are only partly understood. Intestinal motility alteration, visceral hypersensitivity, disturbed intestinal reflexes, psychological disorders, food intolerance and gastrointestinal infection and imbalance of gut flora were involved in the pathogenesis of IBS^[11]. IBS patients presented various intestinal motility alterations, which were recognized as the basic pathophysiological factor. Evidences have shown that there were gastroparesis and small bowel dysmotility in IBS^[12]. The motility index (MI), mean number and peak amplitude of high amplitude propagating contractions (HAPCs) in IBS patients were significantly greater than those in controls. These abnormalities might be related to shortened colonic transit time^[13]. The migrating motor complex (MMC) was found to be an

important mechanism controlling bacterial growth in the upper small bowel. Its disruption could promote duodenal bacterial overgrowth and bacterial translocation^[14].

Food-related microbial alteration of the bowel might be partly responsible for the occurrence of IBS, since many IBS symptoms might be triggered or aggravated by food intake^[15]. King and his colleagues found that colonic-gas production, particularly hydrogen, was greater in IBS patients, and both symptoms and gas production were reduced by an exclusion diet. This reduction might be associated with alterations in the activity of hydrogen-consuming bacteria^[16]. It has been shown that IBS patients have abnormal lactulose breath test (LBT), suggesting the presence of small intestinal bacterial overgrowth (SIBO) or an increased number of enteric organisms. Normalization of LBT could lead to a significant reduction in IBS symptoms^[17]. On the other hand, some studies reported that the incidence of IBS was increased after acute gastroenteritis or dysentery. Under the circumstance of infection, an alterant microbiological environment might influence the number of lymphocytes, mast cells and enteroendocrine cells in the mucosa, rapid transit and a tendency to a secretory state was often found^[1].

In this study, we found that IBS patients had a decrease of beneficial *Bifidobacteria* and overgrowth of potentially pathogenic *Enterobacteriaceae*. The ratio of B/E was smaller than 1, suggesting impairment of microbial colonization resistance (CR) of the bowel in IBS. Once CR was destroyed by antibiotics or other reasons, bacterial infection or dysbacteriosis might emerge^[18].

Intestinal dysbacteriosis may be related to the occurrence of symptoms of IBS, since *Bifidobacteria* are considered to be beneficial to health. It involves in the production of essential mucous nutrients, such as short-chain fatty acids (SCFAs) and lactic acid, by lactose fermentation. They have been shown to eliminate toxins and unnecessary substances, such as hydroxybenzene, ammonia and steroids. They may also participate in the regulation of intestinal functions, such as nutrient synthesis and absorption. *Bifidobacteria* could prevent the overgrowth of potentially pathogenic organisms by bacterial barrier or by producing antibiotics^[5,19]. *Enterobacteriaceae*, the main cause of endotoxin, may produce toxins such as ammonia, sulfured hydrogen^[5]. Endotoxin could temporarily impair canine gut absorptive function both in colon and in jejunum, with decreased absorption of water, glucose and electrolytes, including sodium, chloride, and potassium^[20]. When endotoxin of Gram-negative bacteria was administered intravenously in rats, the migrating myoelectric complex was replaced by spike bursts accompanied by rapid transit^[21]. These effects may contribute to the occurrence of diarrhea. Microecological modulators could prominently relieve IBS-like enteric symptoms, suggesting the close relationship between gut flora and IBS^[22,23].

Ageing may affect the flora residing in the gut and outside of it^[5]. In our study, we found that the intestinal microecology showed an overgrowth of *Enterobacteriaceae* with age in normal control, implying that age may interact with the gut flora. The overgrowth of *Enterobacteriaceae* may also account for the susceptibility to intestinal infection and endotoxemia in elderly people. *Bifidobacteria* have been shown to have a close relationship with human longevity^[5]. While in IBS group, age had no influence on gut flora, since there was intestinal dysbacteriosis in both younger and elder subgroups.

There was a high detection frequency of *C. perfringens* in normal control, without any apparent pathogenic effect. It was supposed that changes of gut flora in IBS might result in a relatively high detection frequency of *C. perfringens*. Therefore, further studies are needed to elucidate this phenomenon.

Anyway, microbial metabolic processes have been going on like in a black box^[24]. Although almost all organic compounds and nutrients, fiber, digestive secretions and desquamated

epithelial cells of the host can enter into microorganismic metabolic chains and processes, little is known about this metabolic chain and process. Further studies are still needed. However, there was dysbacteriosis in IBS patients. Whether it is the effect or just cause of IBS remains unclear.

The purpose of focusing on health-related quality of life (HRQL) is to go beyond the presence and severity of symptoms of disease and to examine how patients perceive and experience these manifestations in their daily lives^[25]. Briefly, HRQL concerns more about the physical, psychological and social functioning.

IBS is not a life-threatening disease. Its impacts include costs associated with diagnosis and treatment, production losses due to morbidity and pain and diarrhea, *etc.*^[26]. With a questionnaire, Silk^[27] found that IBS impacted significantly on personal relationships and working practices. Some even complained that IBS prevented them from applying for promotion or a new job. IBS patients had impaired quality of life in general health, vitality, social functioning, *etc.*^[9,28]. According to the research of Gralnek *et al.*^[29], IBS patients experienced significantly worse HRQL in some aspects than those with gastroesophageal reflux disease (GERD) or diabetes mellitus (DM). IBS patients had even worse bodily pain, fatigue, and social functioning when compared with dialysis-dependent end-stage renal disease patients.

In our study, we also found that IBS patients had significantly lower scores on all SF-36 scales with the exception of physical functioning, when compared with the age and sex-matched control group. Decrements in QoL were most pronounced in general health, role physical and vitality. However, there was no significant correlation between QoL and enteric symptoms, which might be due to the frequent presence of anxiety, depression, fatigue and anorexia in IBS patients^[11,30]. Compared with the control, neuroticism, hypochondriasis and depression were significantly more prevalent in IBS patients attending a clinic, which would have a prominently negative influence on QoL. Hypnotherapy was effective in treating IBS, suggesting that psychological factors may play an important role in IBS. Thus the general impacts of IBS may go far beyond those of enteric symptoms, implicating that IBS is a psychosomatic disease.

Abstract

AIM: To more clearly define the clinical and pathological characteristics and appropriate diagnosis and treatment of nonfunctioning (NFICTs) islet cell tumors, and to review our institutional experience over the last 30 years.

METHODS: The records of 43 patients confirmed to have nonfunctioning islet cell tumors of pancreas were retrospectively reviewed. Survival was estimated by the Kaplan-Meier methods and potential risk factors for survival were compared with the log-rank tests.

RESULTS: The mean age was 31.63 years (range, 8 to 67 years). There were 7 men and 36 women. Twenty-eight patients had a confirmed diagnosis of nonfunctioning islet cell carcinoma (NFICC) and benign islet cell tumors were found in 15 patients. The most common symptoms in patients with NFICTs were abdominal pain (55.8%), nausea and/or vomiting (32.6%), fatigue (25.6%) and abdominal mass (23.3%). Preoperative ultrasonic and computed tomography localized the tumors in all patients. Forty-three NFICTs were distributed throughout the pancreas, with 21 located to the right of the superior mesenteric vessels, 10 in the body of the pancreas, 6 in the tail of the pancreas, and multiple tumors were found in one patient. Thirty-nine of 43 patients (91%) underwent surgical resection. Surgical treatment was curative in 30 patients (70%) and palliative in 9 (21%). The resectability and curative resection rate in patients with NFICC of pancreas were 89% and 61%, respectively. The overall cumulative 5- and 10-year survival rates for patients with NFICC were 58.05% and 29.03%, respectively. Radical operation and diameter of cancer small than 10 cm were positive prognostic factors in females younger than 30 years old. Multivariate Cox regression analysis indicated that radical operation was the only independent prognostic factor, $P=0.007$.

CONCLUSION: Nonfunctioning islet cell tumors of pancreas are found mainly in young women. The long-term results for patients undergone surgery, especially curative resection are good.

INTRODUCTION

Tumors arising from the pancreatic islet cell are rare and represent a heterogeneous group of benign or malignant lesions. Most tumors present with well characterized syndromes, whereas others appear to be nonfunctioning. Functioning tumors, such as gastrinomas, insulinomas, and vasoactive intestinal peptide-secreting tumour (VIPomas), are characterized by extensive production of single polypeptide hormones which lead to specific clinical syndromes. Nonfunctioning tumors, which account for 15% and 52% of tumors, are not associated with clinical syndromes, as they do not produce an excess of any active polypeptide hormones^[1,2]. These lesions tend to occur later and have a different clinical course from their functioning counterparts.

The purpose of this study was to analyze the clinical presentations, diagnosis, management, and prognosis of a large group of patients with nonfunctioning islet cell tumors (NFICTs) of pancreas managed at a single cancer center to determine the natural history and optimum management of such lesions.

MATERIALS AND METHODS

Patients

A total of 43 patients with NFICTs were treated between 1972-2002. The diagnosis of islet cell tumors of pancreas was established by histopathologic examination. Tumors were considered nonfunctional if no clinical symptoms of excess hormone were present.

The disease was considered regional if no evidence of metastases in the liver or elsewhere was found either during surgery or by imaging techniques. Metastases in the liver or elsewhere were considered distant.

Methods

Clinical records were reviewed with regard to patient demographics, clinical features, diagnostic procedures, pathologic findings, operative details, medical treatment, and long-term survival. All patients were followed up by return visits, letters from the follow-up department, correspondence with primary surgeons, or telephone contact within the last months from the conclusion of this study. Survival rate was estimated by the Kaplan-Meier methods, and potential risk factors for survival were compared with the log-rank tests and Cox methods. Ninety-five percent confidence intervals were calculated for specific estimates of survival.

RESULTS

Clinical characteristics

There were 36 females and 7 males with a mean age of 31.63 years and a range of 8 to 67 years and the details are shown in Figure 1. At the time of diagnosis, the median age of male and female patients was 33.57 and 31.25 years, respectively ($P>0.05$). The clinical presentations are illustrated in Table 1. The predominant presentations were abdominal pain, nausea and/or vomiting, fatigue and abdominal pain. None of the patients displayed the clinical features of an endocrine disorder. The duration from the onset of symptoms to diagnosis for all patients ranged from 3 d to 10 years (median 6 mo). Only three patients were asymptomatic, with the tumor found incidentally.

Figure 1 Age distribution in 43 NFICTs patients.

Abdominal ultrasonography (US) and spiral CT were the most commonly employed to detect the primary tumor in all but the patient with emergency operation. Correct prediction of an islet cell tumors based on CT and US results was achieved only in 6(20%) patients. The common diagnosis of CT was carcinoma of pancreas (in 20 patients). Endoscopic retrograde cholangiopancreatography(ERCP) was performed in 6 patients to determine the cause of obstructive jaundice. Magnetic resonance imaging (MRI) and endoscopic ultrasonography (EUS) localized the tumor and the local extension correctly in 5 and 4 patients, respectively.

Table 1 Clinical presentations

Symptoms	Patients(n=43)	(%)
Abdominal pain	24	55.8
Nausea and/or vomiting	14	32.6
Fatigue	11	25.6
Abdominal mass	10	23.3
Back pain	9	21.0
Jaundice	8	18.6
Weight loss	5	11.6
No symptoms	3	7.0
Acut abdomen	1	2.3

Pathological findings

Confirmation of malignancy was mainly based on the demonstration of local invasion, microscopic vascular or perineural invasion, lymph node metastases, hepatic metastasis or distant metastases. Twenty-eight patients were histopathologically diagnosed as nonfunctioning islet cell carcinoma (NFICC) of pancreas.

The size of islet malignant and benign tumors ranged from 2.5 cm to 15 cm (mean 10 cm) and from 4 cm to 30 cm (mean 9.9 cm), respectively ($P>0.05$). Metastases were presented in 6 patients at the time of operation. There were 21 tumors located in the head of the pancreas, 10 in tail, 6 in the body, 5 in body and tail (Table 2). Multiple tumors were presented only in one patient.

Table 4 Primary operative procedures

Procedure	Malignant (n=28)	(%)	Benign (n=15)	(%)
Pancreatoduodenectomy	8	28.5	2	13.3
Pylorus-preserving pancreatoduodenectomy	0	0	1	6.7
Distal pancreatectomy + splenectomy	7	25.0	5	33.3
Subtotal pancreatectomy + splenectomy	4	14.3	2	13.3
Distal pancreatectomy	2	7.1	0	0
Enucleation	1	3.6	4	26.7
Double bypass	1	3.6	0	0
Biliary bypass	3	10.7	1	6.7
Gastric bypass	1	3.6	0	0
Biopsy only	1	3.6	0	0

Table 2 Location of the tumors

Location	Malignant (n=28)	Benign (n=15)
Head	13	8
Tail	8	2
Body	2	4
Body+Tail	4	1
Multiple	1	0

Operative detail and outcome

We performed 30(70%) potentially curative resections, 9(21%) palliative resections, and 4(9.3%) bypass procedures, resulting in a resection rate of 91%. Of the 28 patients with islet cell carcinoma of pancreas, potentially curative resection, palliative resection, palliative bypass and biopsy were performed in 17(61%), 8(28.6%), 3(10.7%) and 1(3.6%), respectively (Table 3). The potentially curative resection was performed in 87% of patients with benign islet cell tumors compared to only 61% of those with NFICC ($P<0.05$). Table 4 shows the type of operative procedures for patients with benign and malignant islet cell tumors. There was no 30-day mortality.

Table 3 Nature operative procedures

Nature	Malignant (n=28)	(%)	Benign (n=15)	(%)
Curative resection	17	61.0	13	87.0
Palliative resection	8	28.6	1	6.7
Palliative bypass	2	5.1	1	6.7
Biopsy only	1	3.6	0	0

Other treatment modalities

A total of 13 cases of NFICC received adjuvant therapy after curative operation, of them 9 patients with NFICC underwent chemotherapy (5 of them with the regimen of FAM and 4 others with 5-FU only) after a curative operation. One of them developed liver metastasis one year later, the another patient died 23 mo postoperatively. The remaining 7 patients were alive with no evidence of disease for a median 45.5 mo (range 15-96 mo). Another 4 patients with malignant tumors underwent radiation plus chemotherapy (three with FAM, and one with 5-FU). All these 4 patients were alive with no evidence of disease for 55.6 mo in average (range 14-124 mo).

Among the patients with NFICC who underwent palliative resection, 4(50%) were given chemotherapy with 5-FU and CF, one developed multiple liver metastasis 13 mo later.

Survival

The cumulative 5- and 10-year survival rates for all patients with NFICC were 58.05% and 29.03%, respectively (Figure 2). Table 5 demonstrates the survival in detail. The median survival of female patients was 120 mo, which was better than the survival for male patients (45 mo, $P=0.312$, Figure 3). Patients who were

younger than 30 years had a better long-term survival than those elder than 30 years, but the difference was not statistical significant (Figure 4, $P=0.758$). Figure 5 compares survival curves for the curative operations and noncurative groups. Survivals at 5- and 10-years were significant better for patients who underwent PD and STRP than those who underwent palliative operation, $P=0.007$. As demonstrated in Figure 6, survivals were better for patients with smaller tumors than those with larger ones, but the difference was not statistically significant, $P=0.1169$.

DISCUSSION

NFICTs are developmentally and histologically identical to functioning tumors but differ in their clinical course and outcome. In this group, the mean age at diagnosis (31.63 years) was 20 years younger than those reported by other researchers^[3-5], but it was similar to some domestic reports^[6-8]. The mean age of the females was 31.25 years, a little bit younger than that of males (33.57 years). It was considered that more male than female patients suffered from islet cell tumors. The ratio of males: females was 1.29:1^[9-12]. In contrast to other reports, we found there were more females than males with this disease (F:M=36:7). It was similar to domestic reports^[6-8]. The reason is unknown. The difference races may be responsible for this phenomenon.

The clinical presentations of NFICTs were mainly due to mass effects. When tumors were smaller than 5 cm in diameter, most patients were asymptomatic^[16]. The symptoms or signs at the time of diagnosis were abdominal pain, weight loss, nausea/vomiting, jaundice and abdominal mass^[5-7,10].

Abdominal US and contrast-enhanced spiral CT were used. In this series, abdominal US and CT were used to detect the primary tumor in all but the patients with emergency operation. Correct prediction of a NFICT based on CT and US results was

achieved only in 6(20%) patients. It is believed that the following features appear to be characteristic for NFICTs: a well defined pancreatic mass with a unusually large size, moderate to strong mass hyperdense in the arterial contrastographic phase of either the primary or the hepatic metastases, and no infiltration of vessels of the celiac axis or the proximal superior mesenteric artery^[4,13]. A recent report showed that in patients with NFICT, a hypoechoic mass with an irregular central echogenic area on EUS or complete obstruction of the main pancreatic duct on ERCP suggested a malignancy^[14].

EUS and laparoscopy could provide accurate preoperative and intraoperative localization to enhance laparoscopic or open operation^[15]. Magnetic resonance imaging, angiography, transabdominal sonography and portal venous sampling could yield an additional accuracy for the diagnosis.

NFICTs of pancreas were believed to be malignant in the presence of distant metastases, or histologic evidence of vascular, lymphatic, or perineural invasion^[3,10]. However, because all NFICTs had a similar histologic appearance, the absence of lymphovascular or perineural invasion could not exclude the potential for malignant behavior. Patients who had locally advanced nonmetastatic diseases at diagnosis subsequently died of complications of the primary tumor^[11]. It was believed that neither vascular or perineural invasion nor electron microscopy and any other histologic criteria could accurately predict whether tumor behavior was benign or malignant^[5]. Most previous reports have suggested that NFICTs are biologically very aggressive, with a malignancy rate ranging from 82% to 100%^[1,11]. However, our findings do not support these previous observations, as we found that the evidence of malignancy based upon evidence of local invasion or presence of metastases could accurately predict the clinical outcome. We believe that the diagnosis of malignancy in NFICTs should be mainly based upon gross findings of local tumor invasion or the presence of metastases. Some reports showed that patients with benign islet tumors were alive at the follow-up time point^[16]. The 5 year survival rate of patients with benign tumors in our group was 100%.

Despite of advances in the multidisciplinary management of NFICC of pancreas in recent decades, surgery plays still an important role in providing potentially curative resections, relieving symptoms, and improving long-term survival. The resectable rate of this disease was 24% to 100%^[3,4,17] and curative resection was performed only in 61% patients^[5]. In current series, the resectable rate was 91%, the curative resection rate for the patients was 61%, which was comparable to that in literature reports. Radical operation could yield a best survival for patients with NFICC, palliative debulking could reduce the mass of tumor, enhance other treatment modalities, it might also prevent other complications such as recurrent pancreatitis, intestinal obstruction, and gastrointestinal bleeding due to direct tumor invasion or varices secondary to splenic vein obstruction^[7]. For this reason, noncurative debulking of tumors might improve survival. Repeated resections for respectable recurrences or metastases might be indicated to improve survival also^[8].

Tumor size is not included in the diagnostic criteria, but when NFICC is definitely diagnosed, it is helpful to predict the survival. When the diameter was larger than 10 cm, the long-term survival would be poor. On the other hand, female and younger (≤ 30 years) patients would have a better survival.

One third of our patients received adjuvant chemotherapy after radical resection of the primary tumors. Obviously, this was too small a number to make any meaningful observations

regarding the efficacy of any specific chemotherapy regimen. Moertel and colleagues^[18] reported a large prospective, randomized multi-institutional trial of two regimens using 162 patients with advanced islet cell carcinomas. They concluded that the combination of streptozotocin and 5-fluorouracil could produce a response rate of 63%, which was significantly higher than 34% seen with streptozotocin alone.

Abstract

AIM: To clarify whether -238G/A polymorphism of tumor necrosis factor- α (TNF- α) gene promoter region was associated with outcomes of hepatitis B virus (HBV) infection in Han population of northern China, and to analyze the gene-environment interaction between -238G/A polymorphism and cigarette smoking or alcohol consumption.

METHODS: A case-control study was conducted to analyze the association of TNF- α gene promoter polymorphism with HBV infection outcomes. A total of 207 patients with chronic hepatitis B (HB) and 148 cases of self-limited HBV infection from Ditan Hospital and Shunyi District Hospital in Beijing, respectively were recruited. History of smoking and alcohol drinking was inquired by a questionnaire. The -238G/A polymorphism of TNF- α gene promoter was genotyped by polymerase chain reaction-restricted fragment length polymorphism (PCR-RFLP).

RESULTS: The frequencies of GG and GA genotypes were 98.07% and 1.93% in chronic HB patients and 93.24% and 6.76% in self-limited HBV infection individuals, respectively ($\chi^2=5.30$, $P=0.02$). The frequency of G allele was significantly higher in patients with chronic HB than in individuals with self-limited HBV infection (99.03% vs 96.62%, $\chi^2=5.20$, $P=0.02$). Only modestly increased risk of onset of chronic HB was found in smokers ($OR=1.40$, 95% CI : 0.87-2.28, $P=0.14$) and drinkers ($OR=1.26$, 95% CI : 0.78-2.05, $P=0.32$). There was a positive interaction between genotype GG and cigarette smoking with an interaction index (II) of 2.95, or alcohol consumption with an II of 1.64.

CONCLUSION: The -238G/A polymorphism of TNF- α gene promoter region is independently associated with different outcomes of HBV infection.

INTRODUCTION

Human beings are susceptible to HBV. HBV infection in adults is usually clinically inapparent, and the virus is cleared after infection. Only about 5-10% of them become persistently infected and develop chronic liver disease with varied severity^[1], which could not be explained completely by the virus itself and environmental factors. Progress of HBV infection might be affected by host genetic susceptibility^[2].

Since HBV is not cytolytic for hepatocytes, and hepatocellular injuries caused by HBV infection are predominantly immune-mediated^[3-6]. Immune attacks by host against HBV are mainly mediated by a cellular reaction. Cytokines produced by immune cells, such as TNF- α , might play a role in immune pathogenesis of HBV infection.

TNF- α is secreted by macrophages, monocytes, neutrophils, T-cells and NK-cells following the stimulus by bacterial lipopolysaccharides and shows a broad spectrum of biological activities, causing cytolysis and cytostasis in many tumor cell lines *in vitro*. Several lines of evidence suggest the importance of TNF- α in HBV. Patients with acute and chronic hepatitis B have an elevated plasma concentration of TNF- α ^[7,8]. Some individual differences in cytokine production may be related to genetic components, and certain polymorphism alleles may be associated with higher or lower levels of TNF- α production, which has been ascribed to polymorphisms within the regulatory regions of cytokine genes^[9-14].

There were some studies about the association of TNF- α gene promoter polymorphism with progress of the disease^[13,15], but ethnic difference could lead to different results. The aim of the present study was to investigate whether the TNF- α promoter polymorphism at position -238 was associated with outcomes of HBV infection in Han people of northern China.

MATERIALS AND METHODS

Study design

Case-control study was used to analyze the association between the polymorphism at position -238 of TNF- α gene promoter and outcomes of HBV infection, as well as the interaction between the gene and smoking or alcohol drinking.

Subjects

The clinical diagnosis for all subjects in this study was based

on references^[16,17]. Two hundred and seven patients with chronic HB from Ditan Hospital in Beijing, China during November 2001 to August 2002 were recruited, with inclusion criteria as follows: hepatitis B surface antigen (HBsAg) seropositive, anti-HBs antibodies (anti-HBs) seronegative, abnormally elevated serum alanine aminotransferase level, and duration of chronic HB ≥ 2 years. One hundred and forty-eight subjects with self-limited HBV infection were from Shunyi District Hospital in Beijing, China during the same period, with inclusion criteria as positive for both anti-HBs and anti-HBc antibodies only, definitely negative for HBsAg, normal liver function tests, and no history of HBV vaccination. All subjects were Chinese Han people and they were recruited with their informed consent for genetic analysis. Venous blood was drawn from all subjects after an overnight fasting. Serum was separated immediately to detect ALT and blood corpuscles were stored at -70 °C to extract DNA and analyze genotypes.

Serological tests

Enzyme-linked immunosorbent assay (ELISA) was used for detection of serum HBsAg, anti-HBs, and anti-HBc (IMX; Abbott Diagnostics, North Chicago, IL).

Analysis of TNF- α gene promoter polymorphism

Genomic DNAs were obtained from peripheral blood leukocytes by standard phenol-chloroform extraction^[18]. The -238G/A polymorphism in the promoter region of TNF- α gene was detected by PCR-RFLP as described by Miyazoe *et al.*^[19]. A 152-bp fragment was amplified using primers (5' : 5' AGAAG ACCCCCCTCGGAACC3' and 3' : 5' ATCTGGAGGAAGCG GTAGTG3'). Amplification was performed in a Perkin Elmer thermocycler (2700; Applied Biosystems, Foster City, CA) with 50 ng of genomic DNA, 20 pmol/L of each primer, 200 μ mol/L each dNTP, 1.5 mmol/L MgCl₂, standard polymerase chain reaction (PCR) buffer and 1U Taq polymerase (Shanghai Biocolor) to 25 μ L reaction system. PCR procedure was as follows: predenaturation at 94 °C for 2 min, followed by 30 cycles of denaturation at 94 °C for 1 min, annealing at 59 °C for 1 min and extension at 72 °C for 1 min, with a final extension at 72 °C for 5 min to terminate the reaction. After amplification, 10 μ L PCR product was digested with restriction endonuclease (Msp-I 3U, Takara Bio Cor Dalian) at 37 °C for 5 h after addition of appropriate incubation buffer and ddH₂O to 20 μ L. The digestion products were separated on 3% agarose gel and visualized directly under UV light with ethidium bromide staining. One base-exchange substitution from A to G position at position -238 created the Msp-I restriction site, resulting in 20- and 132-bp fragments with Msp-I digestion, where -238A allele could not create the Msp-I restriction site, which resulted in an 152-bp fragment.

Cigarette smoking and alcohol consumption

Cigarette smoking and alcohol consumption of the subjects were assessed by their self-report in a questionnaire.

Evaluation of the interaction

The gene-environment interaction was defined according to Rothman *et al.*^[20], with a formula to estimate interaction index (II)=OR₁₁/OR₀₁×OR₁₀. II>1 was defined as positive, and II<1 as negative.

Statistical analysis

The frequencies of TNF- α promoter region alleles and genotypes were estimated. The Hardy-Weinberg equilibrium and frequencies of the alleles and genotypes between two groups were compared by χ^2 tests with two-tailed *P* values^[21].

Odds ratios and their 95% confidence intervals were also calculated as measures of association of the polymorphism with outcomes of HBV infection. All the statistical procedures were performed with SAS version 6.12.

RESULTS

Characteristics of subjects

The main characteristics of study subjects are summarized in Table 1. The average age of the patients with chronic HB and subjects with self-limited HBV infection was 40.06(40.06±14.55) and 37.75(37.75±13.35) years, respectively, without significant difference (*t*=1.53, *P*=0.40). The number of men was more in the group of patients with chronic HB than in the group of subjects with self-limited HBV infection ($\chi^2=36.54$, *P*<0.01). The proportion of married subjects was also different between the two groups ($\chi^2=6.29$, *P*=0.01), whereas their education level was not statistically different ($\chi^2=5.66$, *P*=0.06).

Table 1 Main characteristics of study groups

Variable	Chronic HB <i>n</i> =207(%)	Self-limited HBV infection <i>n</i> =148 (%)	<i>P</i>
Age (mean±SD)	40.06±14.55	37.75±13.35	0.40
Male/Female	162/45	70/78	<0.01
Marital status			0.01
Married	162 (78.26)	131 (88.51)	
Unmarried	45 (21.74)	17 (11.49)	
Education level			0.06
Lower than high school	13 (6.28)	18 (12.16)	
High school	126 (60.87)	94 (63.51)	
Above high school	68 (32.85)	36 (24.32)	

Association of -238G/A polymorphism of TNF- α promoter and behavior factors with outcomes of HBV infection

The distribution of genotype frequencies in patients with chronic HB and subjects with self-limited HBV infection was coincident with Hardy-Weinberg equilibrium ($\chi^2=0.02$, *P*=0.89; $\chi^2=0.02$, *P*=0.89).

The genotype distribution and allele frequencies of the -238 polymorphism in both groups are shown in Table 2. The homozygous AA genotype was not found in the study. Two hundred and three (98.07%) patients with chronic HB had GG genotype, significantly increased as compared with subjects with self-limited HBV infection ($\chi^2=5.30$, *P*=0.02). The frequency of G allele in patients with chronic HB was significantly higher than that in subjects with self-limited HBV infection (99.03% vs 96.62%, $\chi^2=5.20$, *P*=0.02).

The frequency of exposure to cigarette smoking or alcohol consumption in patients with chronic HB was significantly higher than that in subjects with self-limited HBV infection (*OR*>1), but there was no significant difference between the two groups ($\chi^2=2.13$, *P*=0.14 and $\chi^2=0.99$, *P*=0.32).

Multivariate unconditional logistic regression model was used to analyze the association of outcomes of HBV infection with age, sex, cigarette smoking, alcohol consumption and genotypes. It indicated that genotype GG was independently associated with chronic HB after the other factors were controlled (Table 4).

Gene-environmental interaction

As GG genotype was defined as positive exposure in this study, the results of gene-environmental interaction analysis between GG genotype and smoking or alcohol drinking are shown in Tables 5, 6. The odds ratios for smoking exposure alone and GG genotype alone were 0.50 (*P*=1.00) and 2.60 (*P*=0.19), respectively, whereas the odds ratio for combination of smoking and GG genotype was 3.84 (*P*=0.07) in a synergic pattern

Table 2 Genotype and allele frequencies in subjects with chronic HB and self-limited HBV infection

Group	n	Genotype (%) ¹			Allele (%) ²

DISCUSSION

It is estimated that HBV is present in about 130 million chronic carriers, accounting for 10% of Chinese population^[22]. HBV infection can result in acute hepatitis, HBV carriage, chronic hepatitis, liver cirrhosis, even primary hepatocellular carcinoma. One reason of broad spectrum of HBV infection could be attributed to the interaction of genetic and environmental factors. The majority of human genetic studies on HBV

infection focused on human leucocyte antigen (HLA) in recent years^[23-27]. Several pro-inflammatory cytokines such as interleukin-2 and interferon- γ and TNF- α , have been identified to participate in the process of viral clearance and host immune response to HBV^[28,29]. In addition, TNF- α /TNF- α receptor system has an important role in the pathogenesis of liver damage and viral clearance^[30].

TNF- α is a principal mediator of inflammation and cellular immune response regulated both transcriptionally and posttranscriptionally^[31]. In the past years -238G/A polymorphism in a putative regulation box of the TNF- α gene promoter region has been identified. Genetic polymorphisms in the regulatory regions of various cytokine genes could influence the amount of cytokines produced in response to inflammatory stimuli.

In our study, chronic HB patients and self-limited HBV infection individuals (the same as the patients recovered from HB in other studies) were recruited to examine the TNF- α promoter polymorphism at position -238. The results demonstrated that 98.07% of the patients carried genotype GG, significantly higher than the frequency in those with self-limited infection, suggesting that genotype GG could increase the risk of chronic HB and was different from the report of Hohler^[32]. Fifty-three (75%) of 71 subjects with chronic HB were homozygous in TNF- α G/G, lower than the frequency of those with self-limited HBV infection (94%). Ethnic difference could play a certain role in these conflicting results, because the results from several studies suggested that the distribution of TNF promoter polymorphisms in the study subjects was different from those with other racial origins^[7,32,33].

The difference in genotype and allele frequency between patients with chronic HB and subjects with self-limited HB infection in our study suggested that GG genotype might have no advantage to antigen presenting, but further study would be needed to demonstrate its significance as a susceptible gene. This difference may be due to the fact that the TNF- α promoter polymorphism at position -238, likely serving as a marker, was in linkage disequilibrium with neighboring genes encoding HLA or other undefined genes, thus possibly influencing the

outcomes of diseases.

Some studies suggested that the TNFA-A allele falling within a putative Y regulation box of the TNF- α promoter, was associated with increased TNF- α expression^[34-36], which was inconsistent with other studies^[37-40]. It is necessary to carry out the experimental study to confirm the causality between the -238G/A polymorphism of TNF- α promoter gene and the outcome of HBV infection, based on the population study.

The gene of TNF- α is located in the HLA class III region in the short arm of chromosome 6. Some single nucleotide polymorphism (SNP) loci have been found in the promoter region of TNF- α gene. It is speculated that these loci would be in linkage disequilibrium with other unknown mutations or HLA genes. It is important to further demonstrate the association of their constructed haplotypes with outcomes of HBV infection.

Epidemiological findings indicated that alcohol consumption and viral hepatitis could act synergistically to promote the development and progression of liver disease. Patients with viral hepatitis and alcohol consumption accelerated their liver injury with a higher risk of liver cirrhosis and primary hepatocellular carcinoma than those with viral hepatitis alone or alcohol consumption alone^[41,42]. Wang^[43] reported cigarette smoking and alcohol consumption were independently associated with elevated ALT levels among anti-HCV-seropositive individuals. Our study showed cigarette smoking and alcohol consumption might be risk factors of chronic HB (OR>1), but further study is needed due to lack of evidence that could reveal statistically significant differences between groups of chronic HB and self-limited HBV infection.

The analysis of gene-environmental interaction in this study showed there was a synergic effect between GG genotype and cigarette smoking or alcohol consumption. The very wide confidence interval was due to only one subject who smoked or drank without GG genotype in patient group, which needs a larger sample size to be confirmed.

In summary, different outcomes of HBV infection are independently associated with TNF- α promoter polymorphism at position -238, and there might be a synergic effect between TNF- α promoter gene and cigarette smoking or alcohol consumption in the development of chronic HB.

Abstract

AIM: To investigate the relationship between methylation of Syk (spleen tyrosine kinase) gene in promoter region and oncogenesis, metastasis of gastric carcinoma. The relation between silencing of the Syk gene and methylation of Syk promoter region was also studied.

METHODS: By using methylation-specific PCR (MSP) technique, the methylation of Syk promoter region in specimens from 61 gastric cancer patients (tumor tissues and adjacent normal tissues) was detected. Meanwhile, RT-PCR was used to analyse syk expression exclusively.

RESULTS: The expression of the Syk gene was detected in all normal gastric tissues. Syk expression in gastric carcinoma was lower in 14 out of 61 gastric cancer samples than in adjacent normal tissues ($\chi^2=72.3$, $P<0.05$). No methylation of Syk promoter was found in adjacent normal tissues. hypermethylation of Syk gene in promoter was detected 21 cases in 61 gastric carcinoma patients. The rate of methylation of Syk promoter in gastric carcinoma was higher than that in adjacent normal tissues ($\chi^2=25.1$, $P<0.05$). In 31 patients with lymph node metastasis, 17 were found with Syk promoter methylation. A significant difference was noted between two groups ($\chi^2=11.4$, $P<0.05$).

CONCLUSION: Hypermethylation leads to silencing of the Syk gene in human gastric carcinoma. Methylation of Syk promoter is correlated to oncogenesis and metastasis of gastric carcinoma. Syk is considered to be a potential tumor suppressor and anti-metastasis gene in human gastric cancer.

INTRODUCTION

Gastric cancer development and progression are thought to occur through a complex, multistep process, including oncogene activation and mutation or loss of tumor suppressor genes. Determining the function of genetic alterations in gastric carcinoma tumorigenesis and metastasis has been the focus of

intensive research efforts for several decades. One group of proteins that play a critical role in gastric cancer cell signaling pathways is tyrosine kinases. The decrease or loss of spleen tyrosine kinase (Syk) expression seems to be associated with increased motility and invasion of malignant phenotype^[1-5].

Syk, a non-receptor type of protein-tyrosine kinase that is widely expressed in hematopoietic cells, is one of the two members of the Syk family (Syk and ZAP-70). Syk is activated upon the binding to its tandem Src homology 2 (SH2) domains to immunoreceptor tyrosine-based activation motif (ITAM) and plays an essential role in lymphocyte development and activation of immune cells. Emerging evidence indicates that Syk may be a potent modulator of epithelial cell growth and a potential tumor suppressor in human breast carcinoma^[6,7]. But the role of Syk in gastric carcinoma remains unclear, so we examined Syk mRNA expression in human gastric cancer and the adjacent non-cancerous tissues, and explored whether methylation of Syk promoter region was associated with the loss of Syk expression in gastric cancer and the relationship between Syk mRNA expression in gastric cancer tissue and clinicopathological factors in the present study.

MATERIALS AND METHODS

Tissues

Gastric cancer and matched adjacent non-cancerous tissues were obtained during surgical excision from 61 patients with gastric cancer in our department between March 2001 and October 2002. The age of 38 male and 23 female patients was rang from 26 to 78 (mean, 58.1) years. All samples were placed in liquid nitrogen immediately after resection and stored at -70 °C until RNA extraction. No patient had received chemotherapy or radiation therapy prior to surgery. All patients were confirmed to have gastric carcinoma by pathologic test.

RNA extraction and semi-quantitative reverse transcription (RT)-polymerase chain reaction (PCR)

Total RNA was isolated from each specimen by Trizol reagent according to the manufacturer's recommendations. Samples were ground into a fine powder using a mortar and pestle, incubated in Trizol solution (100 g/L) for 15 min, and then 1/5 volume of choloform was added. After vigorous agitation for 5 min, the inorganic phase was separated by centrifugation at 12 000 g for 20 min at 4 °C, RNA was then precipitated in the presence of 1 volume of isopropanol and centrifuged at 10 000 g for 15 min at 4 °C. RNA pellets were washed with 700 ml/L ice-cold ethanol and then dissolved in diethyl pyrocarbonate (DEPC) - treated H₂O. Total RNA concentration and quantity were assessed by absorbency at 260 nm by using a nucleic acid and protein. Semi-quantitative RT-PCR of 40 pairs of gastric cancer tissues and 15 pair of benign fibroadenoma tissues was performed for intergrin beta1 displaying expression alterations. Five micrograms of total RNA in each hybridization sample was used to synthesize the first strand cDNA with SuperScript preamplification system for first strand cDNA synthesis kit. Then 1 mL product was used as the template to amplify specific fragments in 25 mL reaction mixture under the following conditions:

denaturation at 94 °C (3 min); 40 cycles at 94 °C (45 s), at 60 °C (45 s) and at 72 °C (60 s), then extensions at 72 °C (3 min). The PCR primers of Syk were as follow: Syk forward, 5' -CATGTCAAGGATAAGAACATCATAGA-3'; reverse: 5' -AGTTCACCACGTCATAGTAGTAATT-3'. A 514 bp nucleotide fragment of the human Syk cDNA was amplified. In each PCR reaction, primers for the human glyceraldehyde-3-phosphate dehydrogenase (*GAPDH*) gene were used as an internal control. *GAPDH* primer sequences were as forward: primer 5' -AGAAGGCTGGGGCTCATTTCAGGG-3' reverse primer 5' -GTCACCTGGCGTCTTACCACCATG-3'. Ten mL RT-PCR reaction product was analyzed by electrophoresis on a 15 g/L agarose gel. The electrophoresis images were scanned by Fluor-S MultiImager and the original intensity of each specific band was quantitated with the software Multi-Analyst. The data were compared after normalized by the intensity of *GAPDH*. After normalization, the adjusted intensities were calculated for the amplified gene products, and the ratios were calculated. The sequences of PCR primer pairs of intergrin beta1 and *GAPDH* were designed using Primer3 Internet software program. Their specificity was confirmed by a BLAST Internet software assisted search for a nonredundant nucleotide sequence database.

DNA extraction, purification, bisulfite modification and Sequencing

Genomic DNA from cell lines or frozen gastric tissues was extracted by using a Dneasy kit. Genomic DNA was treated with sodium bisulfite. DNA (20 mg/L) was denatured by NaOH (concentration 0.2 mol/L) for 10 min at 37 °C. Thirty μ L of 10 mmol/L hydroquinone and 520 μ L of 3 mol/L sodium bisulfate were added, followed by incubation at 50 °C for 16 h. The modified DNA was purified using Wizard DNA purification columns. The purified DNA was treated again with NaOH and precipitated. DNA was resuspended in 30 μ L of TE buffer (3 mmol/L Tris (pH8.0)/0.2 mmol/L EDTA) and subjected to PCR amplification using a primer set (forward 5' -GATTAA GATATATTTTAGGGAATATG-3; reverse 5' -CACCTATA TTTTATTCACATAATTTC-3) that spanned the Syk CpG island. Fifteen μ L reaction containing 30 ng of bisulfite-treated DNA and 1xRDA buffer (67 mmol/L Tris (pH8.8)/16 mmol/L (NH₄)₂SO₄, 100 mmol/L 2-mercaptoethanol, 1 g/L BSA) was processed in 30 thermal cycles at 94 °C for 45 s, at 58 °C for 45 s, and at 72 °C for 45 s. One aliquot (2 μ L) of diluted PCR Product (40-fold) was subjected to PCR amplification in a 15- μ L volume.

Methylation-specificPCR (MSP)

Methylation-specific primers were designed to cover 9 CpG dinucleotides numbered 17-21 (forward) 47-50 (reverse). Similarly, unmethylation-specific primers were designed cover 8 CpG dinucleotides numbered 18-22 b, (forward) and 35-37 (reverse). Primers specific for methylation DNA (forward) 5' -CGATTTTCGCGGGTTTCGTTC-3; (reverse) 5' -AAAACGAACGCAACGCGAAAC-3; and unmethylation DNA (forward) 5' -ATTTTGTGGGTTTGTGTTGGTG-3, reverse 5' -ACTTCCTTAACACACCCAAAC-3 were added to the same reaction and PCR products were subjected to electrophoresis on a 10 g/L agarose gel. The m-specific primer set yielded a band at 243 bp and the u primer set yielded a band at 140 bp. PCR conditions were 24 cycles at 94 °C for 30 s, at 67 °C for 30 s, and at 72 °C for 30 s.

Statistical analysis

t-test was used to compare the Syk mRNA expression levels with primary gastric cancer, the adjacent non-cancerous tissues. χ^2 test was also used to estimate the relationship between the silencing of Syk mRNA and methylation of Syk promoter region.

Values of $P < 0.05$ were considered statistically significant.

RESULTS

Expression of Syk in gastric cancer and adjacent non-cancerous tissues

The expression of Syk was found in 14 out of 61 gastric cancer tissues, Syk mRNA expression was detected in all adjacent normal gastric tissue (Figure 1). The rate of expression of Syk in gastric cancer tissue was significantly lower than that in adjacent non-cancerous normal gastric tissues ($\chi^2=72.3$, $P < 0.05$).

Figure 1 Syk mRNA expression in human gastric cancer and adjacent non-cancerous tissue (RT-PCR detection of Syk mRNA). T: tumor tissue; N: adjacent non-cancerous normal gastric tissue; M: marker.

Syk mRNA expressions were found in 11 out of the 30 gastric cancer patients without lymph node metastasis, but in 3 out of the 31 gastric cancer patients with lymph node metastasis. Expression of Syk mRNA in patients having lymph node metastasis was significantly lower than that in those having no lymph node metastasis ($\chi^2=4.85$, $P < 0.05$). Meanwhile no significant difference was found between Syk mRNA expression in the gastric cancer patients and age, tumor size, clinicopathological stage, histological type (data not shown).

Semi-quantitative RT-PCR

A total of 10 μ L RT-PCR products were electrophoresed on 15 g/L agarose gel contacting ethidium bromide. The level of *GAPDH* was used as internal control (Figure 2). The relative expression levels of Syk normalized to the expression level of *GAPDH*, in the primary gastric cancer tissues and adjacent mammary tissues were, 1.71 ± 1.28 and 3.19 ± 0.59 (mean \pm SD). A significant difference was found between the level of Syk mRNA expression in the primary gastric cancer tissues and adjacent mammary tissues ($t=2.1$, $P < 0.05$). Furthermore, the level of Syk mRNA in patients having lymph node metastasis was significantly lower than that in patients having no lymph node metastasis (1.18 ± 1.13 vs 2.14 ± 1.27 , $t=3.4$, $P < 0.05$).

Figure 2 Partial semi-quantitative RT-PCR results in 40 gastric cancer tissues and adjacent non-cancerous tissues. T: tumor tissue; N: adjacent non-cancerous normal gastric tissue; M: marker.

Correlation between methylation of Syk gene in promoter region and oncogenesis, metastasis of gastric carcinoma

MSP was used to analyze the Syk methylation status of gastric carcinoma and its matched normal gastric tissues. Forty nonselective gastric cancers were screened. Among the 61 carcinomas examined, 21 exhibited strong Syk methylation. Representative examples are shown in Figure 3. In contrast to their corresponding carcinomas, the Syk gene of the 61 matched neighboring normal gastric tissues remained unmethylated. The

rate of methylation of Syk promoter in gastric carcinoma was higher than that of adjacent normal tissues ($\chi^2=25.1$, $P<0.05$).

Figure 3 Representative examples of Syk methylation (neighboring normal gastric tissues unmethylated).

As shown in Table 1, of the 31 cases of lymph node metastasis, 17 were found with Syk promoter methylation. Syk promoter methylations in 4 out of 30 without lymph node metastasis were detected. A significant difference was noted between two groups ($\chi^2=11.4$, $P<0.05$). Correlation between methylation of Syk promoter region and clinicopathologic factors was shown in Table 1.

Table 1 Correlation between methylation of Syk promoter region and clinicopathologic factors (n)

Factor	Frequency of Syk promoter region methylation	P
Gender		
Male	14/38	0.26
Female	7/23	
Tumor size		
<3cm	8/26	0.61
3	13/35	
Depth of invasion		
Mucosa and submucosa	2/9	0.075
Muscle and subserosa	7/29	
Serosa	12/23	
Lymph node metastasis		
Present	17/31	0.0016
Absent	4/30	
Stage		
I-II	6/25	0.24
III-IV	15/36	
Tumor location		
Lower third	6/15	0.83
Middle third	11/35	
Upper third	4/11	

Relationship between Syk promoter region hypermethylation and loss of its expression in gastric carcinoma

Syk promoter methylation was found in 21 of 61 gastric tumors. They did not show any detectable Syk. In 40 cases without Syk promoter methylation, Syk mRNA expression was found in 13 cases. Syk promoter methylation was significantly related with loss of Syk expression in gastric carcinoma ($\chi^2=4.2$, $P<0.05$).

DISCUSSION

Syk is ubiquitously expressed in hematopoietic cells and has been extensively studied as effectors of B cell receptor (BCR) signaling^[8-10]. It has been found to be involved in coupling activated immunoreceptors to downstream signaling events that mediate diverse cellular responses including proliferation, differentiation and phagocytosis^[11-16]. Some reports are of opinions that Syk is a candidate suppressor gene.

In this paper, we explored expression of Syk mRNA in gastric

cancer and its adjacent non-cancerous tissues. Our results showed that the level and rate of Syk mRNA expression in gastric cancer tissues were significantly lower than those in adjacent non-cancerous tissues, especially invasive gastric cancer tissues did not show any detectable Syk mRNA expression, indicating that loss of Syk mRNA expression may be correlated to gastric carcinogenesis. Our findings were in agreement with the results of Goodman *et al.*^[17,18].

Furthermore, we observed that only four gastric cancer tissues from 31 patients with lymph node metastasis had Syk mRNA expression which was negatively correlated to lymph node metastasis. In B cells, Syk activity was a key regulator of Akt kinase activity after BCR engagement, because Syk induced PI3-K-dependent Akt activation and inhibition of apoptosis^[18]. Numerous studies have demonstrated deregulated Akt activity in gastric cancer cells. It is tempting to speculate that Syk may also regulate Akt activity in gastric cells. Syk mRNA expression was reduced during human gastric cancer progression, and then it was unlikely that Syk-dependent signaling contributed to the increased Akt activity observed in gastric cancer cells^[19-21]. Findings by Okamura *et al.*^[23] suggest that Syk mRNA expression was positively correlated to p53 expression. They found that Syk gene expression was repressed in a p53-dependent manner in human colon carcinoma cells, indicating that loss of p53 function during tumorigenesis could lead to deregulated Syk activity^[7,22]. Study by Mahabeshwar *et al.*^[19] suggested Syk suppressed cell motility and inhibited PI-3 kinase activity and uPA secretion by blocking NF- κ B activity through tyrosine phosphorylation of I κ B α . So loss of Syk expression might contribute to gastric oncogenesis and metastasis^[18,23].

However, the mechanism of Syk expression loss remains unclear. A number of cancer-associated genes have been shown to be inactivated by hypermethylation of CpG islands during gastric tumorigenesis. About 50% of human genes have clusters of CPG dinucleotides (CPG islands) in their 5' -regulatory sequences. Gene silencing through methylation of these sites has been observed in early developmental stages and aging. Aberrant methylation may lead to deregulation of gene expression. Most notably, tumor suppressor genes, mismatched repair genes, and others such as estrogen receptor, E-cadheria, death-associated protein kinase, and thrombospondin-I, were repressed by CPG island hypermethylation in cancer tissues, inhibition of the transcription of these genes could provide an epigenetic mechanism of clonal selection during tumorigenesis^[24,25].

In this study, the 5' CpG island methylation status of the Syk gene in gastric cancer tissues was examined. We found Syk 5' CpG hypermethylation in 35% (21/60) of unselected gastric tumors, whereas all of the matched neighboring normal gastric tissues exhibited unmethylated DNA. We found that the rate of methylation of Syk promoter in gastric carcinoma was significantly higher than that in adjacent normal tissues, suggesting that hypermethylation of Syk promoter region may be associated with oncogenesis of gastric cancer. In addition, the rate of Syk promoter region methylation in the patients with lymph node metastasis is significantly higher than that in the patients without lymph node metastasis, indicating that methylation of Syk promoter methylation is related to lymph node metastasis of gastric cancer. The absence of Syk protein was reflected by the loss of its mRNA expression in gastric cancers, suggesting that the loss of Syk mRNA expression occurs at the transcriptional level. 5' CpG hypermethylation of Syk was reported to be associated with loss or reduction of Syk gene expression, which may provide a new way to treat gastric cancer^[26,27].

However, we did not observe any significant correlation between Syk methylation and tumor grade. This may be attributable to a relatively small sample size and the complexity of unselected patient population. Additional detailed studies

using patient cohort should be done needed to examine the value of Syk methylation as a diagnostic or prognostic marker^[28,29].

The recent identification of Syk as a potent modulator of gastric epithelial cell growth has generated a need for further exploration of the role of nonreceptor tyrosine kinases in gastric cancer progression and metastasis^[28-30]. These initial results offer the promise that novel molecular targets may be identified both for the prevention of gastric cancer development and for inhibition of metastatic gastric cancer spread. The continual elucidation of novel targets such as Syk is a critical part of the endeavor to eradicate gastric cancer. These findings may provide promise molecular targets for the prevention of gastric cancer development^[31-33].

Abstract

AIM: To study the alteration of nuclear matrix proteins (NMPs) in gastric cancer.

METHODS: The NMPs extracted from 22 cases of gastric cancer and normal gastric tissues were investigated by SDS-PAGE technique and the data were analyzed using Genetools analysis software.

RESULTS: Compared with normal gastric tissue, the expression of 30 ku and 28 ku NMPs in gastric cancer decreased significantly ($P=0.002$, $P=0.001$, $P<0.05$). No significant difference was found in the expression of the two NMPs between the various differentiated grades ($P=0.947$, $P=0.356$) and clinical stages of gastric cancer ($P=0.920$, $P=0.243$, $P>0.05$).

CONCLUSION: The results suggested that the alteration of NMPs in gastric cancer occurred at the early stage of gastric cancer development.

INTRODUCTION

Nuclear matrix (NM) is the structural framework of the nucleus comprising the peripheral lamins and pore complexes, an internal ribonucleic protein outside nucleoli^[1]. Nuclear matrix proteins (NMPs) are important for a variety of cell functions, including nuclear assembly, replication, transcription, and nuclear integrity^[2]. Specific changes of NMPs are associated with many cancers^[3-6]. However, the alteration of NMPs in gastric cancer has not been reported. In this paper, the NMPs in gastric cancer and normal gastric tissue were studied by SDS-PAGE and Genetools quantitative analysis software.

MATERIALS AND METHODS

Materials

Twenty-two cases of gastric cancer specimens (with no history

of radio- or chemotherapy preoperatively) and normal gastric mucosa were collected from the First Affiliated Hospital of Medical College of Zhengzhou University and the People's Hospital of Henan Province. All the specimens were diagnosed pathologically (well and moderately differentiated cancers in 10 cases, poorly differentiated cancers in 12 cases). According to the PTNM of International Alliance of Anticancer in 1987, the specimens were divided into 4 clinical stages, Nine were at stage I and II, and 13 at stage III and IV.

Preparation of nuclei

The gastric cancers and normal gastric tissues were minced and mixed with STM (0.25 mol/L sucrose, 10 mmol/L Tris-HCl pH 7.4, 5 mmol/L MgCl₂) and homogenized with a homogenizer. Nuclei were initially separated by low speed centrifugation at 750 r/min for 10 min. The pellet was suspended with STM containing 5 g/L Triton X-100 for 10 min and centrifuged at 750 r/min for 10 min. The crude nuclei were resuspended with 2 mol/L sucrose and centrifuged at 12 000 g for 10 min. The pellet containing purified nuclei was washed with STM.

Extraction of NMPs

The purified nuclei were digested with DNase I (200 U/mL) at room temperature for 45 min prior to low salt (LS) buffer (10 mmol/L Tris-HCl pH 7.4, 0.2 mmol/L MgCl₂) extraction and centrifuged at 1 000 r/min for 15 min. The pellet was extracted twice with high salt (HS) buffer (10 mmol/L Tris-HCl pH 7.4, 2 mol/L NaCl, 0.2 mmol/L MgCl₂) and centrifuged at 6 000 r/min for 15 min. Washed with LS buffer, the pellet was resuspended with 2×loading buffer and detected for the concentration of proteins in the sample.

SDS-PAGE

A 100 µg proteins were loaded in each well of 100 g/L SDS-polyacrylamide gel. The proteins were electrophoresed at constant voltage of 200 V. The gel was stained with Coomassie brilliant blue R-250 over 4 h. The protein bands were photoed with gel photography system and quantitatively analyzed with Genetools software.

Statistic analysis

Data were analyzed using nonparametric statistics with SPSS 10.0 statistic software and $P<0.05$ was considered statistically significant.

RESULTS

On the gel stained with Coomassie brilliant blue R-250, many bands were exhibited in both gastric cancer and normal gastric tissue, which suggested that NMPs were abundant in these tissues. The bands of 30 ku and 28 ku NMPs in the gastric cancer were stained more lightly than those in the normal gastric tissue (Figure 1). Analyzed with Genetools quantitative software, the expression of 30 ku and 28 ku NMPs in normal gastric tissues was significantly higher than those in gastric cancer ($P<0.05$). The difference of the expression of 30 ku and 28 ku NMPs between well and moderately differentiated and

poorly differentiated gastric cancers was not significant ($P>0.05$). There was no significant difference in the expression of the two NMPs between stage I, II and stage III, IV ($P>0.05$) (Table 1).

Figure 1 SDS-PAGE of nuclear matrix 1 gastric carcinoma tissue; 2 adjacent cancer tissue; 3 normal tissue; 4 marker.

Table 1 Comparison of the 30 ku, 28 ku bands between gastric cancer tissues and normal tissues

Group	30 ku			28 ku	
	<i>n</i>	<i>T</i>	<i>Z</i>	<i>T</i>	<i>Z</i>
Normal tissue group ^a	22	7.25	-3.165	4.33	-3.263
Gastric cancer group	22	12.44		14.19	
Well and moderately differentiated	10	11.60	-0.066	12.90	-0.923
Poorly differentiated	12	11.42		10.33	
Stage I, II	9	11.33	-0.100	13.44	-1.169
Stage III, IV	13	11.62		10.15	

T: mean of rank sum, *Z*: *z* value ^a $P<0.05$ vs gastric cancer.

DISCUSSION

NM is the structural framework of the nucleus^[7], and is involved in a variety of cell functions, including DNA replication^[8], RNA transcription^[9], architecture of chromatin^[10], carcinogenesis^[11] and apoptosis^[12]. The study on the relationship between NMPs and carcinogenesis has been carried out for a few years. In the experiment of Spencer *et al.*^[13], specific changes in NMPs of breast cell line were identified by two-dimensional gel electrophoresis. NMP66 was evaluated as a potential biomarker for early breast cancer in large-scale clinical trials^[11]. The extent of chromosomal rearrangements correlates positively with the level of expression of the nuclear matrix high mobility group (HMG) proteins HMG I (Y) when tested in three human prostate cancer cell lines (PC-3>DU145>LNCaP)^[14]. Using both one-dimensional and high-resolution two-dimensional immunoblot analyses, Leman *et al.*^[15] found that, in the transgenic adenocarcinoma of mouse prostate (TRAMP) model, HMG I (Y) was an NMP expressed as two protein bands with a molecular mass of 22-24 ku and HMG I (Y) expression was correlated with neoplastic and malignant properties in late stage of prostate tumor TRAMP model. In 26 pairs of human prostate cancer and normal tissue, Ishiguro *et al.*^[16] identified a specific upregulated gene encoding a 55 ku nuclear matrix protein (nmt55) by RT-PCR and real time quantitative PCR. nmt55 gene expression in human prostate cancer tissue was higher (20/26) than that in normal prostate tissue.

NMP22 has been identified as a tumor marker for transitional cell carcinoma of urinary tract^[17] and bladder cancer^[18-21]. Eissa *et al.*^[22] evaluated the diagnostic efficacy of NMP22, fibronectin and urinary bladder cancer antigen (UBC) in comparison with voided urine cytology on the detection of bladder cancer. They

found that NMP22 and fibronectin had superior sensitivities compared to UBC and voided urine cytology, while NMP22 and voided urine cytology had the highest specificities. Xu^[23] reported that the examination of NMP22 in urine was a rapid and effective way to detect the recurrence of bladder cancer. The urinary NMP22 levels were significantly higher in the renal cell carcinoma group than in the control group. The urinary NMP22 might be used in the evaluation of patients at risk of renal cell carcinoma^[24]. Konety *et al.*^[25] reported that the BLCA-4 was a very sensitive and specific marker for bladder cancer.

NMPs alterations were also associated with the cancer of digestive tract. Chen *et al.*^[26] found that the interaction between HPV-16 E6 and nuclear matrix might contribute to virus induced carcinogenesis in esophageal carcinoma. Brunagel *et al.*^[27] analyzed the NMPs expression by high-resolution two-dimensional gel electrophoresis, and found that the NMP composition was able to differentiate liver metastases from normal liver tissue and normal hepatocytes. In 2003, they identified an NMP, calreticulin, which was expressed much more strongly in colon cancer compared to adjacent and normal colon tissue^[28]. In our study, we found that the expression of 30 ku, 28 ku NMPs was significantly reduced in gastric cancer when compared with that in the normal gastric tissue ($P<0.05$). There were no significant differences in the expression of these two proteins between the various differentiation grades and clinical stages of the gastric cancer. The results suggested that the changes of NMPs in gastric cancer might occur at early stage of the tumor development.

Matrix attachment regions (MARs) are postulated to anchor chromatin onto the NM, thereby organizing genomic DNA into topologically distinct loop domains that are important in replication and transcription^[29]. The p300-SAF-A interactions at MAR elements of nontranscribed genes might pose these genes for transcription^[30]. NM was a key locus for CK2 signaling in the nucleus^[31]. Expression of p16 gene was significantly reduced in gastric cancer. The down-regulated expression of 30 ku, 28 ku NMPs in gastric cancer might be related to the down-regulated expression of p16 gene. In our previous study, we found the hypermethylation, mutation and microsatellite instability of p16 gene in gastric cancer. The binding of NMPs to the upstream of p16 gene and its relation to the down regulated expression of p16 gene in gastric cancer will be studied further.

Abstract

AIM: To investigate the apoptosis in primary gastric cancer cells induced by genistein, and the relationship between this apoptosis and expression of bcl-2 and bax.

METHODS: MTT assay was used to determine the cell growth inhibitory rate *in vitro*. Transmission electron microscope and TUNEL staining were used to quantitatively and qualitatively detect the apoptosis of primary gastric cancer cells before and after genistein treatment. Immunohistochemical staining and RT-PCR were used to detect the expression of apoptosis-associated genes *bcl-2* and *bax*.

RESULTS: Genistein inhibited the growth of primary gastric cancer cells in dose- and time-dependent manner. Genistein induced primary gastric cancer cells to undergo apoptosis with typically apoptotic characteristics. TUNEL assay showed that after the treatment of primary gastric cancer cells with genistein for 24 to 96 h, the apoptotic rates of primary gastric cancer cells increased time-dependently. Immunohistochemical staining showed that after the treatment of primary gastric cancer cells with genistein for 24 to 96 h, the positivity rates of Bcl-2 proteins were apparently reduced with time and the positivity rates of Bax proteins were apparently increased with time. After exposed to genistein at 20 $\mu\text{mol/L}$ for 24, 48, 72 and 96 respectively, the density of *bcl-2* mRNA decreased progressively and the density of *bax* mRNA increased progressively with elongation of time.

CONCLUSION: Genistein is able to induce the apoptosis in primary gastric cancer cells. This apoptosis may be mediated by down-regulating the apoptosis-associated *bcl-2* gene and up-regulating the expression of apoptosis-associated *bax* gene.

INTRODUCTION

Genistein is a planar molecule with an aromatic A-ring, has a second oxygen atom 11.5 Å from the one in the A ring, a molecular weight similar to those of the steroidal estrogens. It has estrogenic properties in receptor binding assays^[1,2], cell culture^[3,4], and uterine weight assays^[5-7]. Genistein inhibits

topoisomerase II^[8], platelet-activating factor- and epidermal growth factor-induced expression of c-fos^[9], diacylglycerol synthesis^[10], and tyrosine kinases^[11]. It also inhibits microsomal lipid peroxidation^[12] and angiogenesis^[13]. Genistein exhibits antioxidant properties^[14-16] and was reported to induce differentiation of numerous cell types^[17-19]. Moreover, a recent report shows that genistein is a potent cancer chemopreventive agent^[20-22]. The anti-tumor activity of genistein might be related to induce the apoptosis of tumor cells but the precise mechanism of antitumor activity is not well understood.

The Bcl-2 family plays a crucial role in the control of apoptosis. The family includes a number of proteins which have homologous amino acid sequences, including anti-apoptotic members such as Bcl-2 and Bcl-x_L, as well as pro-apoptotic members like Bax and Bad^[23-26]. Overexpression of Bax has the effect of promoting cell death^[27-31]. Conversely, Overexpression of antiapoptotic proteins such as Bcl-2 will repress the function of Bax^[32-36]. Thus, the ratio of Bcl-2/Bax appears to be a critical determinant of cell apoptosis^[37].

In this study, MTT assay was used to determine the cell growth inhibitory rate. Transmission electron microscope and TUNEL staining method were used to quantitatively and qualitatively detect the apoptosis status of primary gastric cancer cells before and after the genistein treatment. Immunohistochemical staining and RT-PCR were used to detect the expression of apoptosis-associated genes *bcl-2* and *bax*.

MATERIALS AND METHODS

Materials

Genistein and MTT were obtained from Sigma Chemical Co, Ltd. *In situ* cell detection kit, anti-Bcl-2 monoclonal antibody and anti-Bax monoclonal antibody were purchased from Beijing Zhongshan Biotechnology Co, Ltd. Stock solution of genistein was made in dimethylsulfoxide (DMSO) at a concentration of 40 $\mu\text{mol/L}$. Working dilutions were directly made in the cell culture medium.

Methods

Cell culture Fresh sample from a patient with gastric cancer was obtained in operating room. A single-cell suspension of tumor cells with the concentration of $5 \times 10^5/\text{mL}$ was prepared for seeding. Primary gastric cancer cells were purified after culture.

MTT assay Cells $1 \times 10^5/\text{well}$ in a 96-well plate after incubation for 24 h were treated with different concentrations of genistein (5, 10, 20, 40 $\mu\text{mol/L}$) for 24, 48 and 72 h respectively. A 10 μL of 5 g/L of MTT was added to the medium triplicate at each dose and incubated for 4 h at 37 °C. Culture media were discarded followed by addition of 0.2 mL DMSO and vibration for 10 min. The absorbance (A) was measured at 570 nm using a microplate reader. The cell growth inhibitory rate was calculated as follows: $\{(A \text{ of control group} - A \text{ of experimental group}) / (A \text{ of control group} - A \text{ of blank group})\} \times 100\%$.

Transmission electron microscopy Cells treated with 20 $\mu\text{mol/L}$ genistein were harvested after incubation for 24 h. Subsequently

the cells were fixed in 40 g/L glutaral and immersed with Epon 821, imbedded for 72 h at 60 °C. After that the cells were prepared into ultrathin section (60 nm) and stained with uranyl acetate and lead citrate. Cell morphology was observed by transmission electron microscopy.

TUNEL assay Apoptosis of primary gastric cancer cells was evaluated by using an *in situ* cell detection kit. The cells were treated in the presence or absence of 20 µmol/L genistein for 24 to 96 h and fixed in ice-cold 800 mL/L ethanol for up to 24 h, treated with proteinase K and then 3 mL/L H₂O₂, and labeled with fluorescein dUTP in a humid box for 1 h at 37 °C. Cells were then combined with POD-horseradish peroxidase, colored with DAB and counterstained with methyl green. Controls received the same treatment except the labeling of omission of fluorescein dUTP. Cells were visualized under light microscope. The apoptotic index (AI) was calculated as follows: AI=(Number of apoptotic cells/Total number)×100%.

Immunohistochemical staining Immunohistochemical staining was done by an avidinbiotin technique. Primary gastric cancer cells treated in the presence or absence of 20 µmol/L genistein for 24 to 96 h were grown on six-well glass plates and were fixed by acetone. After washed in PBS, the cells were incubated in 3 mL/L H₂O₂ solution at room temperature for 5 min. The cells were then incubated with anti-Bcl-2 or anti-Bax monoclonal antibody at a 1:300 dilution at 4 °C overnight. After wash of cells in PBS, the second antibody, biotinylated antirat IgG was added and the cells were incubated at room temperature for 1 h. After wash of cells in PBS, ABC compound was added and the cells were then incubated at room temperature for 10 min. DAB was used as the chromagen. After 10 min, the brown color signifying the presence of antigen bound to antibodies was detected by light microscopy and photographed at ×200. Controls were treated the same as the experimental group except the incubation of the primary antibody instead of second antibody. The positive rate (PR) was calculated as follows: PR=(Number of positive cells/Total number)×100%.

RT-PCR The primary gastric cancer cells were treated in the presence or absence of 20 µmol/L genistein for 24 to 96 h and total RNA was extracted. The concentration of RNA was determined by absorption at 260 nm. The primers for Bcl-2, Bax and β-actin were as follows: β-actin (500 bp): 5' GTGGG GCGCCCCAGGCACCA 3', 5' CTCCTTAATGTCACG CACGATTTC 3'; bcl-2 (716 bp): 5' GGAAATATGGCGC ACGCT 3', 5' TCACTTGTGGCCCAGAT 3'; bax (508 bp): 5' CCAGCTCTGAGCAGATCAT 3', 5' TATCAGCCCA TCTTCTTCC 3'. Polymerase chain reactions were performed in a 25 µL reaction volume. PCR for Bcl-2 and β-actin was run in the following procedures: at 94 °C for 7 min, 1 circle; at 94 °C for 1 min, at 72 °C for 1 min, 30 cycles; at 72 °C for 7 min, 1 circle. PCR for Bax was run in the following procedure: 94 °C for 1 min, 60 °C for 45 s, 72 °C for 45 s, 35 cycles. Ten µL PCR product was placed onto 15 g/L agarose gel and observed by EB staining using Gel-Pro analyzer.

Statistical analysis

Data were analyzed by the paired two-tailed Student's *t* test, and significance was considered when $P < 0.05$.

RESULTS

MTT assay

Primary gastric cancer cells were exposed to increasing concentrations (5 µmol/L to 40 µmol/L) of genistein for 24 to 72 h, respectively. Primary gastric cancer cells showed death in a dose- and time-dependent manner. The data are summarized in Table 1.

Table 1 A value of primary gastric cancer cells treated with different concentrations of genistein

	24 h	48 h	72 h
Control	0.400±0.008	0.406±0.007	0.404±0.008
5 µmol/L genistein	0.361±0.002 ^a	0.334±0.012 ^b	0.305±0.004 ^b
10 µmol/L genistein	0.325±0.004 ^d	0.313±0.003 ^b	0.248±0.004 ^d
20 µmol/L genistein	0.308±0.003 ^d	0.249±0.002 ^d	0.206±0.003 ^d
40 µmol/L genistein	0.265±0.004 ^d	0.215±0.004 ^d	0.159±0.002 ^d

^a $P < 0.05$; ^b $P < 0.01$; ^d $P < 0.001$ vs control group.

Morphological changes

After treatment of primary gastric cancer cells with genistein (20 µmol/L) for 24 h, some cells presented apoptotic characteristics including chromatin condensation, appearance of chromatin crescent, nuclear fragmentation that could be seen by transmission electron microscope (Figure 1).

Figure 1 Ultra-microscopic structure of gastric cancer cells induced by genistein. A: Primary gastric cancer cells; B: apoptotic gastric cancer cells (Original magnification: ×4 800).

TUNEL assay

Apoptotic cells were determined by TUNEL assay according to the manufacture's instructions. Positive staining located in the nucleus. After treatment with genistein (20 µmol/L) for 24 to 96 h, Apoptotic index of the cells was apparently increased with the increase of treatment time ($P < 0.05$) (Table 2).

Expression of Bcl-2 proteins

Positive staining located in the cytoplasm. After treatment with genistein (20 µmol/L) for 24 to 96 h, Positivity rate of the cells of Bcl-2 proteins was apparently reduced with the increase of treatment periods ($P < 0.05$) (Table 3). This suggested that genistein could down-regulate the expression of Bcl-2.

Expression of Bax proteins

Positive staining located in the cytoplasm. After treatment with genistein (20 µmol/L) for 24 to 96 h, PRs of Bax proteins were apparently increased with increase of treated time ($P < 0.05$).

(Table 4). This suggested that genistein could up-regulate the expression of Bax.

Table 2 Apoptotic index (AI) of primary gastric cancer cells treated by genistein

	Control	24 h	48 h	72 h	96 h
AI (%)	1.25±0.30	4.97±0.80	18.44±1.92	35.18±0.35	43.93±1.11
<i>t</i>		-6.13	-13.82	-180.16	-52.80
<i>P</i>		<i>P</i> <0.05	<i>P</i> <0.05	<i>P</i> <0.05	<i>P</i> <0.05

P<0.05 vs control group; AI: Apoptotic index.

Table 3 Positivity rate (PR) of Bcl-2 in primary gastric cancer cells treated by genistein

	Control	24 h	48 h	72 h	96 h
PR(%)	36.34±0.72	21.62±0.08	10.60±0.49	7.21±0.45	4.54±0.36
<i>t</i>		31.93	44.67	73.80	59.32
<i>P</i>		<i>P</i> <0.01	<i>P</i> <0.01	<i>P</i> <0.01	<i>P</i> <0.01

P<0.01 vs control group; PR: Positivity rate.

Table 4 Positivity rate (PR) of Bax in primary gastric cancer cells treated by genistein

	Control	24 h	48 h	72 h	96 h
PR(%)	10.73±0.57	20.63±0.86	34.3±0.81	45.96±0.42	58.61±1.46
<i>t</i>		-57.49	-41.23	-69.53	-51.31
<i>P</i>		<i>P</i> <0.001	<i>P</i> <0.001	<i>P</i> <0.001	<i>P</i> <0.001

P<0.01 vs control group; PR: Positivity rate.

RT-PCR

After exposed to 20 µmol/L genistein for 24, 48, 72 and 96 h respectively, the density of bcl-2 mRNA decreased progressively and the density of bax mRNA increased progressively with elongation of time by RT-PCR. It suggested that genistein could down-regulate the expression of Bcl-2 and up-regulate the expression of Bax.

DISCUSSION

Populations who consume a diet high in soy are reported to have a lower incidence of breast and prostate cancer. The activity of the soy-derived phytoestrogen, genistein, is thought to account for a portion of the chemopreventative properties of soy; these include an inhibitory effect on tyrosine kinases^[11], DNA topoisomerases I and II^[8], and ribosomal S6 kinase, antiestrogenicity, antioxidant activity, anti-angiogenesis activity^[12], suppression of cell proliferation, induction of differentiation^[17-19], and modulation of apoptosis^[20-22].

In this study, we found that primary gastric cancer cells showed death in a dose- and time-dependent manner in MTT assay. This suggested genistein was able to restrain the growth of primary gastric cancer cells. It was found that genistein was able to induce the apoptosis of primary gastric cancer cells by transmission electron microscope assay and TUNEL assay. After treatment with 20 µmol/L genistein for 24 to 96 h, PRs of Bcl-2 proteins were apparently reduced and PRs of Bax proteins were apparently increased with increase of treated time by Immunohistochemical staining. After exposed to 20 µmol/L genistein for 24, 48, 72 and 96 h respectively, the density of bcl-2 mRNA decreased progressively and the density of bax mRNA increased progressively with elongation of time by RT-PCR.

Genistein could reduce Bcl-2 expression and enhance bax

expression. The ratio of Bcl-2/Bax was decreased when primary gastric cancer cells were treated with genistein, which could trigger the apoptosis of primary gastric cancer cells.

The present study demonstrated that genistein was able to induce the apoptosis in primary gastric cancer. This apoptosis may be mediated by down-regulating the expression of apoptosis-associated gene *bcl-2* and up-regulating the expression of apoptosis-associated gene *bax*. Genistein may be used as a potential chemotherapeutic drug in the anti-gastric carcinoma chemotherapy.

Abstract

AIM: To investigate the relationships between polymorphisms of interleukin-1B (IL-1B) promoter region -511C/T and interleukin-1 receptor antagonist gene (IL-1RN) and susceptibility to chronic hepatitis B in Chinese population.

METHODS: Genomic DNA was extracted from the peripheral blood of 190 patients with chronic hepatitis B and 249 normal controls and then subjected to polymerase chain reaction (PCR) amplification. The PCR products were digested by restriction endonuclease *Ava*I. The products of digestion were subjected to 20 g/L gel electrophoresis and ethidium bromide staining.

RESULTS: The frequencies of IL-1B (-511) genotypes CC, CT and TT in patients with chronic hepatitis B were 23.7%, 49.5% and 26.8%, while 26.1%, 47.4% and 26.5% respectively in controls. The results showed that there was no significant difference in the frequencies of alleles or genotypes in IL-1B between patients with chronic hepatitis B and controls. The distributions of IL-1B (-511) genotype CC were significantly different between the two subgroups (HBV-DNA $\leq 1 \times 10^3$ copies/mL as subgroup I, HBV-DNA $> 1 \times 10^3$ copies/mL as subgroup II) of chronic hepatitis B ($P=0.029$). Only four of the five kinds of polymorphism (1/1, 1/2, 2/2 and 1/4) were found in this study. The frequencies of IL-1RN genotypes 1/1, 1/2, 2/2 and 1/4 were 88.9%, 9.0%, 0.5% and 1.6% in patients with chronic hepatitis B respectively, while were 81.1%, 16.9%, 0.4% and 1.6% respectively in controls. The frequencies of genotype 1/2 and IL-1RN allele 2 in patients with chronic hepatitis B were lower than those in controls ($P=0.016$ and $P=0.029$, respectively).

CONCLUSION: There is an association between polymorphisms of the promoter region -511C/T of IL-1B and IL-1RN intron 2 and chronic hepatitis B virus infection. Subjects with IL-1RN allele 2 may be resistant to HBV infection, and IL-1B(-511) genotype CC is closely related with HBV-DNA replication, which gives some new clues to the study of pathogenesis of chronic hepatitis B.

INTRODUCTION

Hepatitis B virus (HBV) infection is one of the most important chronic viral diseases in the world. An estimated 400 million people worldwide are carriers of HBV, and approximately 250 000 deaths occur each year as a consequence of fulminant hepatic failure, cirrhosis, and hepatocellular carcinoma^[1]. When HBV is acquired in adulthood, the majority of infections are cleared, with chronic infection occurring in 5% to 10% of cases. However, the dynamic interaction of the host inflammatory response with HBV, and the subsequent impact of this interaction on the clinical outcome of HBV infection, are not yet fully understood, nor are the underlying mechanisms for persistence of the virus.

Cytokines play an important role in defense against viral infection, indirectly through determination of the predominant pattern of the host response, and directly through inhibition of viral replication^[2]. Interleukin(IL)-1 is one of the most proinflammatory agents, and has a central role in inflammation and destruction^[3]. The most important members of the IL-1 family are the IL-1 α , IL-1 β and IL-1 receptor antagonists (ra). IL-1ra is an IL-1 natural competitive inhibitor, acting by occupancy of cell surface receptor without triggering signal transduction^[4]. IL-1ra plays a role as an important regulator of inflammation and is currently evaluated in clinical trials. Genes encoding IL-1 are located on the 430 kb region of chromosome 2q13-21, consisting of three homologous genes: IL-1A, IL-1B and IL-1ra (IL-1RN)^[5]. Biallelic polymorphisms at positions IL-1A -889, IL-1B -511, and +3 953 have been described, all representing a C/T single nucleotide polymorphism (SNP). IL-1RN contains an 86 bp variable number tandem repeat (VNTR) polymorphism in intron 2^[6]. These polymorphisms are located within the regulatory regions of the genes and have potential functional importance by modulating IL-1 protein production, and are related with the development of some diseases^[7].

This research was to discuss the relationship between polymorphisms of IL-1 gene and susceptibility to HBV in the Chinese population, and tried to reveal the correlation between the genotype and phenotype distributions, in order to provide a certain scientific basis for prevention and treatment of chronic hepatitis B.

MATERIALS AND METHODS

Subjects

A total of 190 patients with chronic hepatitis B (130 males, 60 females) aged 11-68 years were recruited in Remin Hospital of Wuhan University. The diagnosis of all the patients was confirmed according to the criteria for chronic hepatitis B, and the patients did not have other viral hepatitis. Two hundred and forty-nine control subjects (150 males, 99 females) aged 18-82 years were selected in Wuhan area (HBsAg negative, anti-HBe negative, and anti-HBc negative), and liver, renal, endocrine and cardiovascular disorders were excluded.

PCR preparation

Two microliter peripheral venous blood was collected in an EDTA tube. Genomic DNA was extracted from peripheral

blood leukocytes and frozen at -20 °C. Each PCR was carried out in 25 µL reaction mixture containing 100-200 ng genomic DNA, 100 µmol/L dNTP, 25 mmol/L MgCl₂, 20 pmol/L primers and 1U TaqDNA polymerase (Promega).

IL-1B and IL-1RN polymorphisms

SNP at position -511 in the promoter region (-702-398) of IL-1B was analyzed by the PCR-restriction fragment length polymorphism (RFLP) method^[8]. A 304 bp PCR fragment of the IL-1B promoter region was amplified using the following primers: 5'-TGGCATTGATCTGGTTCATC-3' and 5'-GTTTAGGATCTTCCCACTT-3'. PCR conditions were as follows: denaturation at 95 °C for 5 min, then 35 cycles at 94 °C for 30 s, at 55 °C for 30 s, at 72 °C for 1 min, and final extension at 72 °C for 5 min. twenty µL of PCR products was digested with 5 U of *Ava*I (TaKaRa, shiga, Japan) at 37 °C for 3 h and run on a 20 g/L agarose gel stained with ethidium bromide.

IL-1RN intron 2 contained a VNTR of an 86 bp length of DNA. Oligonucleotides 5'-CTCAGCAACACTCCTAT-3' and 5'-TCCTGGTCTGCAGGTAA-3' flanking this region were used as primers^[8]. Amplification conditions were same as the above. The PCR products were analyzed by electrophoresis on a 20 g/L agarose gel stained with ethidium bromide.

HBV-DNA measurement

Serum HBV-DNA level in patients with chronic hepatitis B was detected with the real-time fluorescent quantitative PCR method (reagents supplied by Shanghai Fosun Co. Ltd.) using a Lightcycler PCR system. Results were considered abnormal when HBV-DNA >1×10³ copies/mL.

Statistical analysis

IL-1B(-511) and IL-1RN(intron 2) allelic and genotype frequencies were calculated in patients with chronic hepatitis B and control subjects. Comparison of allelic and genotypes between groups, and association of IL-1B and IL-1RN polymorphisms with HBV-DNA replication were examined

for statistical significance with chi-square test. Analysis was completed with SPSS 9.0, and $P < 0.05$ was considered statistically significant.

RESULTS

Genotypes of IL-1B and IL-1RN

C/T transition polymorphism of IL-1B(-511) was analyzed by PCR-RFLP. *Ava*I digestion of the PCR products of IL-1B resulted in three genotypes, consisting of TT (intact, 304 bp), CT (three fragments of 304, 190 and 114 bp) and CC (two fragments of 190 and 114 bp), (Figure 1). The intron 2 of IL-1RN polymorphism contained VNTR of 86 bp. There were five alleles in humans, including allele 1 (four repeats, 410 bp), allele 2 (two repeats, 240 bp), allele 3 (five repeats, 500 bp), allele 4 (three repeats, 325 bp) and allele 5 (six repeats, 595 bp). Only four of the five kinds of polymorphism of IL-1RN(1/1, 1/2, 2/2, and 1/4) were found in this study (Figure 2).

Frequencies of IL-1B and IL-1RN genotypes in both groups

The genotype and allele frequencies of IL-1B and IL-1RN in patients with chronic hepatitis B and control subjects were determined, and explored with 2×2 χ^2 test under the Hardy-Weinberg law and shown to represent all population (Tables 1, 2). The frequencies of IL-1B genotypes CC, CT and TT in patients with chronic hepatitis B were 23.7% (45/190), 49.5% (94/190) and 26.8% (51/190), while those in controls were 26.1% (65/249), 47.4% (118/249), and 26.5% (66/249) respectively. The results showed that there was no significant difference in the frequencies of alleles ($\chi^2=0.16$, $P=0.69$) or genotypes ($\chi^2=0.35$, $P=0.84$) in IL-1B between patients with chronic hepatitis B and control subjects.

Only four of the five kinds of polymorphism of IL-1RN (1/1, 1/2, 2/2 and 1/4) were found in this study. The frequencies of 1/1, 1/2, 2/2 and 1/4 were 88.9%, 9.0%, 0.5% and 1.6% in chronic hepatitis B patients, while those in controls were 81.1%, 16.9%, 0.4% and 1.6% respectively. IL-1 RN allele 1 was

detected in 94.2% of chronic hepatitis B patients and 90.4% of controls, while IL-1RN allele 2 was detected in 5.0% of the patients and 8.8% of controls. The frequencies of genotype 1/2 and IL-1RN allele 2 in patients with chronic hepatitis B were lower than those in controls ($\chi^2=5.81$, $P=0.016$ and $\chi^2=4.76$, $P=0.029$ respectively).

Association of IL-1B and IL-1RN polymorphism with HBV-DNA replication

For further analysis of the relationship between IL-1B, IL-1RN polymorphisms and HBV-DNA replication in patients with chronic hepatitis B, the patients were divided into two subgroups (HBV-DNA $\leq 1 \times 10^3$ copies/mL as subgroup I, HBV-DNA $> 1 \times 10^3$ copies/mL as subgroup II). As shown in Table 3, the distributions of IL-1B(-511) genotype CC were of significant difference between the two subgroups ($\chi^2=4.77$, $P=0.029$).

DISCUSSION

HBV infection is a major global health problem with an estimated 300 million people chronically infected worldwide^[9,10]. Individuals with an inadequate primary immune response to HBV are at increased risk of developing chronic hepatitis B. Age is the strongest host feature associated with chronic infection with 90% infants and 5-10% of adults developing chronic hepatitis B after exposure. In addition, people with the same age, sex and ethnical group were exposed to the same HBV strain, which could cause a broad spectrum ranging from no infection to different clinical outcomes^[11]. These data suggest that host genetic factors are responsible for the clinical outcomes of HBV infection. Clearance of HBV requires a coordinated innate and adaptive humoral and cell-mediated immune response. Cytokines are soluble polypeptide molecules that mediate cell-to-cell communication and regulate the intensity and duration of the immune response. Previous studies have shown that the maximal capacity of cytokine production

varies among individuals and correlates with SNP in the promoter region of various cytokine genes^[12,13]. Furthermore, cytokine gene polymorphisms were associated with liver disease severity in patients with viral hepatitis^[14]. In the present study we compared the distributions of IL-1B(-511) and IL-1RN intron 2 VNTR polymorphisms between patients with chronic B and control subjects.

IL-1B is one of the IL-1 gene family members, and located in the proximal region of chromosome 2q13-21. Different polymorphisms have been described in IL-1B, and at least two of them could influence the protein production. One is located in the promoter region at position -511, and the other in exon 5. Pociot *et al.*^[15] reported that IL-1B polymorphisms were correlated with IL-1 β expression. IL-1B allele T carrier had higher productions of IL-1 β than IL-1B allele C carrier. In the study, genotype distributions and allelic frequencies for IL-1B(-511) promoter polymorphisms in patients with chronic hepatitis B and control subjects were not statistically different. Further analysis of the relationship between IL-1B polymorphism and HBV-DNA replication in patients with chronic hepatitis B showed that IL-1B(-511) genotype CC was associated with HBV-DNA replication.

IL-1ra is a naturally occurring anti-inflammatory protein, competitively blocks the binding of IL-1 α and IL-1 β type I and type II IL-1 receptors, but exerts no agonist activity, despite sharing 30% amino acid sequence homology with IL-1 β , and 19% with IL-1 α . IL-1ra has been shown to inhibit the effects of IL-1 both *in vitro* and *in vivo*^[16]. Increasing evidence showed that IL-1RN polymorphisms were related with susceptibility to individual diseases, including psoriasis, systemic lupus erythematosus, and inflammatory bowel disease^[4]. By the study of IL-1RN intron 2 polymorphisms, our results suggested that the distributions of IL-1RN 1/2 genotype and IL-1RN allele 2 in patients with chronic hepatitis B were significantly lower than those in control subjects. A possible explanation of this result could be provided by the fact that carriage of IL-1RN allele 2 of each of these polymorphisms was related with high production of IL-1 β ^[17], which may augment the production of other cytokines, such as IL-2, IL-6 and TNF- α , and trigger the complex immunological processes to eliminate the virus and its complex.

In summary, the findings of this study and others may provide further evidence that genetic factors are important in the pathogenesis of HBV infection. Our results suggest that the carriage of IL-1RN allele 2 may play a protective role in the development of HBV infection and IL-1B CC genotype may be associated with HBV-DNA replication. However, the real roles of IL-1 polymorphisms in the pathogenesis of developing chronic hepatitis B should be further investigated by large population-based studies.

Abstract

AIM: To investigate the mechanisms of tegaserod, a partial 5-HT₄ agonist, in reducing visceral sensitivity by observing Fos, substance P (SP) and calcitonin gene-related peptide (CGRP) expression in the lumbar sacral spinal cord induced by colonic inflammation in rats.

METHODS: Twenty-four male rats with colonic inflammation induced by intraluminal instillation of trinitrobenzenesulfonic acid (TNBS) were divided into 3 groups. Treatment group 1: intra-gastric administration of tegaserod, 2 mg/kg·d; Treatment group 2: intra-gastric administration of tegaserod, 1 mg/kg·d; Control group: intra-gastric administration of saline, 2.0 mL/d. After 7 d of intra-gastric administration, lumbar sacral spinal cord was removed and processed for Fos, SP and CGRP immunohistochemistry.

RESULTS: In rats of the control group, the majority of Fos labeled neurons was localized in deeper laminae of the lumbar sacral spinal cord (L₅-S₁). SP and CGRP were primarily expressed in the superficial laminae of the spinal cord after TNBS injection. Intra-gastric administration of tegaserod (2 mg/kg·d) resulted in a significant decrease of Fos labeled neurons (22.0±7.7) and SP density (12.5±1.4) in the dorsal horn in the lumbar sacral spinal cord compared to those of the control group (62.2±18.9, 35.9±8.9, $P<0.05$). However, CGRP content in dorsal horn did not significantly reduce in rats of treatment group 1 (1.2±1.1) compared to that of the control group (2.8±2.4, $P>0.05$). Neither Fos expression nor SP or CGRP density in the dorsal horn significantly declined in rats of treatment group 2 compared to those of the control group ($P>0.05$).

CONCLUSION: Tegaserod can significantly reduce Fos labeled neurons in the lumbar sacral spinal cord induced by colonic inflammation. Tegaserod may reduce visceral sensitivity by inhibiting SP expression in the dorsal horn of spinal cord.

INTRODUCTION

Irritable bowel syndrome (IBS) is a common functional gastrointestinal disorder. Its typical feature is recurrent abdominal discomfort or pain associated with disordered defecation. Studies have shown that visceral sensitivity plays an important role in the pathophysiology of IBS^[1]. Tegaserod, a partial 5-HT₄ agonist, acts selectively on 5-HT₄ receptors in the gut. Tegaserod can relieve symptoms in IBS patients with abdominal discomfort or pain and significantly decrease visceral sensitivity^[2]. The objectives of the present study were to identify regions of the Fos protein, substance P (SP) and calcitonin gene-related peptide (CGRP) expression in the lumbar sacral spinal cord in response to colonic inflammation induced by intraluminal instillation of TNBS, and to compare the effects of tegaserod on the spinal Fos, SP and CGRP expression induced in the same animal model.

MATERIALS AND METHODS

Animals

Twenty-four adult male Sprague-Dawley rats (The Fourth Military Medical University) weighing 220-250 g were used in this study. The animals were housed in a quiet room with a constant ambient temperature of 20 °C with free access to rat chow and water.

Experimental protocol

After 24 h fast, TNBS (100 mg/kg in 300 mL/L ethanol) was administered intrarectally through a silicone rubber catheter introduced 7 cm into the anus under light diethyl-ether anesthesia. To keep TNBS in the colon for a longer time and to avoid leakage, the catheter was slowly withdrawn and the tail of the rat was kept elevating for 8-10 min.

Tegaserod (20 mg, Beijing Novartis Pharmacy Company) was dissolved in 100 mL distilled water. After one day of TNBS instillation, the rats were randomly divided into 3 groups. Each group had eight rats. Treatment group 1: intra-gastric administration of tegaserod 2 mg/kg; Treatment group 2: intra-gastric administration of tegaserod 1 mg/kg; Control group: intra-gastric administration of saline 2.0 mL. Tegaserod or saline was administered once daily (10:00AM) for consecutive 7 d after TNBS instillation.

Fos, SP and CGRP immunohistochemistry

One day after the last time of tegaserod or saline administration, the rats were deeply anesthetized with pentobarbital Na (80 mg/kg, i.p.) and perfused with 100 mL saline followed by 500 mL fixative of 40 g/L paraformaldehyde in 0.1 mol/L phosphate buffer (PH 7.4). L₃-S₂ segments of the spinal cord were removed, post-fixed in the same fixative at 4 °C for 2-4 h and then cryoprotected in 200 g/L sucrose overnight. Serial frozen sections of 40-μm thickness cut on a Leitz cryostat. Sections were collected in 0.01 mol/L PBS for immunohistochemistry.

The spinal cord sections were stained for Fos, SP and CGRP using avidin-biotin-peroxidase complex (ABC) method. Free

floating tissue sections were treated in 800 mL/L methanol containing 30 mL/L H_2O_2 to block endogenous peroxidase activity for 30 min at room temperature. They were treated with 0.01 mol/L PBS containing 1 g/L Triton $\times 100$ for 20 min at room temperature. The sections were then incubated with a polyclonal rabbit anti-Fos serum (1:3 000, Santa Cruz), polyclonal rabbit anti-SP serum (1:500, Boster) and polyclonal rabbit anti-CGRP serum (1:500, Boster) respectively for 48 h at 4 °C. After the step, the sections were incubated with biotinylated goat anti-rabbit IgG (1:500, Sigma), and subsequently with the ABC complex (1:500, Sigma) at room temperature for 2 h each. The antigen-antibody reaction sites were visualized by incubation with glucose oxidase-DAB-nickel method for 15-30 min at room temperature. The sections were rinsed in 0.01 mol/L PBS for 3 \times 10 min between transition of these steps. Finally, the sections were mounted onto gelatin-coated slides, dried, dehydrated, cleared and coverslipped.

Fos immunoreactive neuronal counts and measurement of the density of dorsal horn SP and CGRP staining

The number of neuronal nuclear profiles expressing Fos was analyzed with computer assisted QUIC menu system. Precise regional localization was done by outlining specific regions and then particles (stained nuclei) were counted in the outlined regions. The number of profiles counted in five sections was averaged for each animal, and comparisons were made between the groups^[3].

The density of SP and CGRP staining in the dorsal horn of spinal cord was also measured in specific outlined regions using computer assisted QUIC menu system. The ratio of the area of stained SP or CGRP to the area of the outlined regions was presented as the density of SP or CGRP. The averages were obtained for density measurements from five randomly selected spinal cord sections for each animal, and comparisons were

made between treatment and control groups^[3].

Statistical analysis

Pictures were taken under BX-60 microscopy with the support of IM50 software. All results are expressed as mean \pm SD. An unpaired *t*-test was used to compare Fos-IR (immunoreactive) cell count data, SP and CGRP density between the groups. A difference was accepted as significant if the probability was less than 5% ($P < 0.05$).

RESULTS

Effect of tegaserod on Fos expression in spinal cord

In animals of the control group, Fos protein was expressed bilaterally in the nuclei of cells of the dorsal horn in L₅, L₆ and S₁ of lumbarsacral spinal cord. The nuclei of Fos-IR neurons were black and there was no cytoplasmic staining. Among 62.2 \pm 18.9 neurons exhibited Fos-IR, most of them were distributed in the deeper laminae (III-IV, V-VI) of the dorsal horn. Only few Fos-IR neurons were sparsely distributed in the superficial laminae (I-II) of the dorsal horn (Figure 1A).

After intra-gastric administration of tegaserod 1 mg/kg·d for 7 d, Fos-IR cells in the dorsal horn decreased to 42.6 \pm 7.5, but was not significantly different with that of the control group (62.2 \pm 18.9, $P > 0.05$). After intra-gastric administration of tegaserod 2 mg/kg·d for seven days, Fos-IR neurons in the dorsal horn decreased to 22.0 \pm 7.7, a significant difference ($P < 0.05$) (Table 1, Figure 2A).

Effect of tegaserod on SP and CGRP expression in spinal cord

In rats of the control group, SP was expressed bilaterally in the superficial laminae (I-II) in the dorsal horn. The density of SP

Figure 1 Sections from the control rats. $\times 10$. A: Fos-IR neurons induced by TNBS administration were observed as black spots in the dorsal horn. Note that most Fos-IR neurons were distributed in the deeper laminae of the dorsal horn. B: SP was mainly distributed in the superficial laminae of the dorsal horn. C: CGRP was primarily localized in the superficial laminae of the dorsal horn.

Figure 2 Sections from rats treated with tegaserod 2 mg/kg·d. $\times 10$. A: After treatment with tegaserod, the number of Fos-IR cells was decreased significantly compared with that of the control group. B: Note that the density of SP in rats treated with tegaserod was decreased significantly compared with that of the control rats. C: The density of CGRP was not different between the treatment group and the control group.

was 35.9 ± 8.9 . After 7 d of intra-gastric injection of tegaserod $1 \text{ mg/kg} \cdot \text{d}$, the density of SP in the superficial laminae did not significantly reduce (33.3 ± 3.4 , $P > 0.05$). However, after intra-gastric administration of tegaserod $2 \text{ mg/kg} \cdot \text{d}$ for 7 d, the density of SP decreased to 12.5 ± 1.4 , a significant difference compared to that of the control group ($P < 0.05$) (Table 1, Figures 1B, 2B).

In animals of the control group, most CGRP were expressed in the superficial laminae of the dorsal horn. A few CGRP were distributed in the deeper laminae. The density of CGRP in rats of the control group was 2.8 ± 2.4 . The density of CGRP did not significantly decrease in rats treated with tegaserod $1 \text{ mg/kg} \cdot \text{d}$ for 7 d (2.2 ± 2.3 , $P > 0.05$). After treatment with tegaserod $2 \text{ mg/kg} \cdot \text{d}$ for 7 d, the density of CGRP decreased 56.7% compared to that of the control group (1.2 ± 1.1), but there was no significant difference ($P > 0.05$) (Table 1, Figures 1C, 2C).

Table 1 Number of Fos-IR neurons and density of SP, CGRP (%) in dorsal horn of rats in various groups

	Fos	SP	CGRP

DISCUSSION

Irritable bowel syndrome is a common functional gastrointestinal disorder. Its typical feature is recurrent abdominal discomfort or pain associated with disordered defecation or a change in bowel habit. Routine investigation revealed no evidence of structural or biochemical abnormality. There is evidence that patients with IBS showed a lower threshold for discomfort and/or pain, increased sensitivity to stimuli, or altered viscerosomatic referral^[4]. Therefore, visceral hypersensitivity could play an important role in the pathophysiology of IBS^[1].

Tegaserod is a partial 5-HT₄ agonist. The absence of blood-brain barrier permeation makes it selectively bind to 5-HT₄ receptors in the gastrointestinal tract. Tegaserod has been shown to modulate both gastrointestinal motility and visceral sensitivity^[2]. Studies demonstrated that tegaserod produced rapid and sustained improvements of the abdominal pain/discomfort and constipation in IBS patients, especially in female IBS patients^[5,6]. These improvements were seen within the first week, and maintained throughout the treatment period. A randomized, double-blind, placebo-controlled study showed that tegaserod reduced the sensitivity to rectal distension in healthy subjects^[7].

Fos, one of the inducible transcription factors, serves as a quantifiable marker to identify neuronal populations activated by noxious somatic and visceral stimulations. Noxious stimulation of hollow viscera induced a specific pattern of Fos expression in rat spinal cord that reflected the intensity of the stimulation^[8]. Recently, the anti-nociceptive effects of some drugs have been studied in animal models of persistent visceral pain using Fos expression as an independent measure. Lu reported that baclofen, a selective GABA_B receptor agonist, specifically reduced Fos expression in the superficial dorsal horn of spinal cord induced by mustard oil irritation of the colon^[3]. A recent study has demonstrated that opiate receptor agonists, especially morphine, attenuate pain related behavior and Fos expression in rat spinal cord neurons following noxious visceral stimulation^[9]. Thus, localization of Fos expression can be a useful tool to examine the effectiveness of different analgesic drugs after nociceptive stimulation.

In rats of the control group, Fos protein expression became bilaterally evident as nuclear staining in cells in L₅, L₆ and S₁ of

lumbar-sacral spinal cord. In the rats, the descending colon was innervated by sensory afferent fibers in the pelvic nerve projecting bilaterally to the lumbar-sacral (L₆-S₂) spinal cord^[10]. The result was consistent with the viscerotopic organization of the afferent fibers that innervate the descending colon. Most of the Fos-IR neurons were distributed in the deeper laminae (III-IV, V-VI) of the dorsal horn. Few Fos expressed in the superficial laminae (I-II) of the dorsal horn. Imbe demonstrated that Fos-IR cells had the tendency to spread from the superficial laminae to the deeper laminae when deep tissue inflammation became persistent^[11]. From the segment and laminae distribution of Fos-IR neurons, we conclude that neurons in the dorsal horn of lumbar-sacral spinal cord are activated via sensory afferent fibers in the pelvic nerve by noxious stimulation induced by persistent colonic inflammation. Therefore, tegaserod can dose-dependently prevent sensory neurons in the dorsal horn from being activated by colonic inflammation.

Substance P was released from primary sensory nociceptive neurons in response to noxious stimuli. Up to 80% of dorsal root ganglion (DRG) neurons supplying viscera contained SP, suggesting the importance of SP in transmission of signals from the viscera to the spinal cord^[12]. Study of Kishimoto demonstrated that high concentrations of SP were significantly related to abdominal pain^[13]. SP could play a pivotal role at the spinal cord level in postsynaptic sensitization, particularly during and after gut inflammation^[14]. In the spinal cord, SP releasing from the primary afferents could activate the dorsal horn neurons by inducing an influx of Ca²⁺ throughout voltage-gated Ca²⁺ channels^[15]. The results of this study showed that the density of SP in the dorsal horn decreased significantly compared to the control group after treatment with tegaserod $2 \text{ mg/kg} \cdot \text{d}$ for 7 d. Therefore, tegaserod can inhibit SP expression in the dorsal horn of the spinal cord.

CGRP is one of the major neuropeptides expressed in the spinal cord sensory processing region and is widely distributed in the nervous system, particularly in sensory neurons. CGRP, which is generally colocalized with SP in the primary afferent nociceptors, is likely to be involved in pain transmission. CGRP may produce a direct nociceptive effect. CGRP might also enhance SP-induced nociceptive sensation by facilitating the release of SP in the spinal dorsal horn^[16]. Compared with that of the control group, the density of CGRP decreased 21.4% in treatment group 1 and 57.1% in treatment group 2, showing an insignificant difference ($P > 0.05$). The results suggest that tegaserod may not act on CGRP expression to reduce visceral nociceptive transmission. However, whether a much larger dose of tegaserod can significant decrease CGRP expression in the spinal cord still needs more studies.

The results of the present study showed that tegaserod could significantly decrease Fos and SP expression in the dorsal horn of the spinal cord. Tegaserod can exert antinociceptive effect. This effect is related to SP expression inhibition in the spinal cord. The study of Schikowski showed that in decerebrated cats the static discharge rate of the afferents evoked by rectal distension decreased significantly after intravenous administration of tegaserod. They proposed that 5-HT₄ receptor activation had an inhibitory effect on intramural mechanoreceptors in cat rectum^[17]. Today there is considerable evidence that serotonin influences nociceptive reflexes at different anatomic levels. For example, intrathecal and iontophoretic applications of serotonin to the dorsal horn produced pain relief, and serotonin antagonists produced hyperalgesia^[18]. Ghelardini found that BIMU1 and BIMU8, two 5-HT₄ agonists, exerted an antinociceptive effect by centrally potentiating endogenous cholinergic activity^[19]. Since there are serotonin-SP and serotonin-Ach neurotransmitter links, we conclude that tegaserod, acting on 5-HT₄ receptors in the gut, produces an antinociceptive effect by inhibiting the expression of SP in spinal dorsal horn.

Abstract

AIM: To review the characteristics of esophageal carcinoma in recent 30 years in the epidemiological investigation.

METHODS: A total of 1 520 cases of esophageal carcinoma in the First Affiliated Hospital of Zhejiang University Medical College admitted from 1970 until now were reviewed. Their age, gender, position of carcinoma and histological type were analyzed.

RESULTS: The morbidity of esophageal carcinoma was increasing during the observation period. Compared with the 1970s (9.5%), the ratio of adenocarcinoma significantly increased after the 1980s (19.1%). The difference was significant ($P \leq 0.05$).

CONCLUSION: The morbidity of esophageal adenocarcinoma was increasing and advanced clinical study should be strengthened.

INTRODUCTION

Carcinoma of esophagus is one of the most common cancers with a high mortality. Squamous cell carcinoma and adenocarcinoma account for more than 95% of esophageal tumors^[1]. The incidence rate of squamous cell carcinoma of the esophagus in the pathological feature is more frequent compared with adenocarcinoma. Increasing prevalence of adenocarcinoma of the esophagus has been reported from western countries in recent years and its incidence since the 1970s in China is unknown. Our study aimed to make an epidemiological investigation of carcinoma of esophagus and compare the incidence rate of adenocarcinoma and squamous cell carcinoma of the esophagus.

MATERIALS AND METHODS

Medical records of all patients ($n=1\ 520$) with adenocarcinoma or squamous cell carcinoma of the esophagus seen at the the First Affiliated Hospital of Zhejiang University Medical College between 1970 and 2001 were reviewed. The following data were retrieved: age, gender, tumor location, history of surgery and pathological features. The patients were divided into 3 groups:

group A (211 patients) were patients seen from 1970 to 1979, group B (451 patients) were patients from 1980 to 1989 and group C (858 patients) were from 1990 to 2001.

RESULTS

The data of the 1520 patients with adenocarcinoma or squamous cell carcinoma were analyzed. Among them, 236 (15.5%) were female and 1 284 (84.5%) were male. In group A there were 184 (87.2%) male patients and 27 (12.8%) female patients, in group B there were 380 (84.3%) male and 71 (15.7%) female, in group C there were 720 (83.9%) male and 138 (16.1%) female. No differences were found between the groups in gender. Among 240 cases of adenocarcinoma of esophagus, 195 (81.3%) were male and 45 (18.7%) were female. And among 1280 cases of squamous cell carcinoma of the esophagus, 1 089 (85.1%) were male and 191 (14.9%) were female. No significant difference of sex ratios were found in patients with adenocarcinoma of esophagus and squamous cell carcinoma of the esophagus.

The age distribution of the patients is shown in Table 1. Patients in their 50s are at highest risk for carcinoma of the esophagus in the 1970s. And patients in their 60s are at highest risk for carcinoma of the esophagus since 1980s.

From clinical pathological data, 20, 80, 134 cases with adenocarcinoma and 191, 365, 724 cases with squamous cell carcinoma were found in groups A, B, C, respectively. The proportion of esophageal adenocarcinoma of all groups were 9.5% (20/211), 19.1% (86/451) and 15.6% (134/858), respectively. The difference was significant between groups A and B ($P=0.002$) and also between groups A and C ($P=0.023$). And there was no significant difference between groups B and C ($P=0.113$).

We investigated the location of adenocarcinoma of esophagus (193 cases), whose pathological findings showed the definite location. Two (1.0%) cases were located at the upper esophagus, 15 (7.8%) at the middle and 176 (91.2%) located at the lower esophagus.

Table 1 Age distribution of all patients with carcinoma of esophagus: n (%)

Age (yr)	A	B	C
≤ 30	3 (1.4)	2 (0.4)	5 (0.6)
30-	15 (7.1)	20 (4.3)	26 (3.0)
40-	47 (22.3)	72 (16.0)	162 (18.9)
50-	103 (48.8)	160 (35.5)	250 (29.1)
> 60	43 (20.4)	197 (43.7)	415 (48.4)

DISCUSSION

Esophageal cancer is one of the most deadly forms of gastrointestinal cancer in China and death rate from carcinoma of esophagus ranked the third annually. Epidemiological data defined a certain geographical distribution^[2]. In high mortality areas of China, Iran and Africa, the incidence of esophageal tumors is approximately equal in men and women^[3]. By comparison, in low-incidence regions such as the United States and parts of Europe, there is a significant predilection for males^[4]. It was reported that the incidence rate in male is higher than that of female, and the sex ratios (male/female) was 5-10:1. In our study, the male to female

ratio was 5.5:1 and the difference was not significant among groups.

Although squamous cell carcinoma was traditionally considered synonymous with esophageal cancer, the incidence of adenocarcinoma of the esophagus is increasing in most Western industrialized nations in recent years^[5,6]. The incidence of esophageal adenocarcinoma increased from 1.5 to 7.0 per 100 000 men and from 0.4 to 1.5 per 100 000 women between 1971 and 1998 in England and Wales^[7]. The proportion of adenocarcinomas has increased, probably in connection with the increasing incidence of Barrett's esophagus. But the risk of Barrett's esophageal mucosa advancing to esophageal adenocarcinoma is not well established^[8]. Even though the incidence of esophageal adenocarcinoma has been rising in Western populations over the past two decades and squamous cell carcinoma has been declining^[9,10], esophageal squamous cell carcinoma remains the predominant type of esophageal malignancy in the remainder of the world.

The mechanism of increased incidence of adenocarcinoma remained to be unclear. Gastroesophageal reflux disease (GERD), Barrett's esophagus, smoking, alcohol drinking and disfunction of esophageal motivation may be associated with the increase of incidence of adenocarcinoma. Adenocarcinoma is an uncommon cause of mortality in patients with Barrett's esophagus. Forty-four patients were confirmed to have Barrett's esophagus and were followed up for 209 patient-years. Only 2 patients developed esophageal adenocarcinoma, resulting in an incidence of one case in 209 patient-years, a 55-fold risk compared with age- and sex-matched population in Scotland^[11]. Gastric juice that refluxes into the esophagus can injure esophageal squamous epithelium. When the injury heals through a metaplastic process in which an abnormal columnar epithelium replaces the injured squamous one, the resulting condition is called Barrett's esophagus^[12]. Barrett's esophagus is the major risk factor for the development of esophageal adenocarcinoma, which is increasing in incidence faster than any other cancer in the Western world. Barrett's adenocarcinomas are increasing in epidemic proportions for as yet unknown reasons, approximately 0.5-1% of patients with Barrett's will develop adenocarcinoma^[13,14]. Although GERD symptoms precede the development of adenocarcinoma of esophagus in many patients, fewer than 50% of patients have pathologic evidence of esophagitis or Barrett's epithelium at presentation.

There are clear racial, gender and site predilections for esophageal adenocarcinoma^[15,16]. Our study demonstrated that 176 cases (91.2%) of adenocarcinoma of esophagus were located at the lower esophagus, being different from squamous cell carcinoma of the esophagus which were located mainly at the middle of the esophagus. Adenocarcinoma of esophagus shared with the same location with Barrett's esophagus.

Further study is required to determine the risk factors such

as food^[17] for the development of esophageal cancer and epidemiological investigation will prove important developing methods of detection and therapeutic intervention of this disease.

INTRODUCTION

Mansonic schistosomiasis is the main cause of portal hypertension in Brazil. Hepatosplenic (HS) form is manifested by hepatomegaly mainly on the left hepatic lobe associated with large splenomegaly and bleeding due to esophageal varices with high mortality rates^[1,2].

Pulmonary hypertension in the HS form of mansonic schistosomiasis is described in association with both the acute and chronic forms of the disease, with a prevalence of 5% and may be a serious complication in the evolution of the disease. It can also be the triggering factor for serious complications associated with any form of surgical approach^[3,4].

Surgical treatment is indicated for patients with a history of bleeding due to esophageal varix rupture based on world previous experience with endoscopic treatment results^[5]. At present, techniques vary in azigo-portal disconnection and splenectomy (APDS) and distal splenorenal shunt (DSRS) for surgical treatment of such patients. All patients submitted to DSRA were carefully evaluated pre-operatively with eletrocardiography, chest X-ray and transthoracic echocardiography to rule out pulmonary hypertension. We report two fatal cases of pulmonary hypertension arising after DSRS.

Case Reports

Case 1 A 33-year-old man was admitted to the Liver and Portal Hypertension Surgical Unit, Hospital das Clínicas, University of São Paulo Medical School for surgical treatment of portal hypertension due to hepatosplenic mansonic schistosomiasis after previous episode of bleeding esophageal varices. Ultrasound scan of the abdomen revealed discrete hepatomegaly, mainly on the left hepatic lobe associated with splenomegaly. Esophagogastroduodenoscopy revealed four large variceal vessels. The results found in routine laboratory

tests were alanine amino transferase (ALT) of 29 U/L (normal: 10-30), aspartate amino transferase (AST) of 20 U/L (normal: 10-36), bilirubin of 0.8 mg/dL (normal: 0.2-1.0), gamma-glutamyl transferase of 86 U/L (normal: 7-32), and alkaline phosphatase of 241 U/L (normal: 32-104). The electrocardiogram, chest X-ray and echocardiography were within normal limits. The patient was submitted to DSRS. On the 4th postoperative day he developed progressive dyspnea and dyed 3 h later. The necropsy showed severe pulmonary hypertension, right ventricular dilatation and secondary myocardial infarction. The shunt was pervious.

Case 2 A 25-year-old woman was admitted to the Liver and Portal Hypertension Surgical Unit, Hospital das Clínicas, University of São Paulo Medical School for surgical treatment of portal hypertension due to hepatosplenic mansonic schistosomiasis after an episode of bleeding esophageal varices. Ultrasound scan of the abdomen revealed discrete hepatomegaly, mainly on the left hepatic lobe associated with splenomegaly. Esophagogastroduodenoscopy revealed two large variceal vessels. The results found in routine laboratory tests were alanine amino transferase (ALT) of 25 U/L (normal 7-45), aspartate amino transferase (AST) of 38 U/L (normal 7-45), bilirubin of 1.0 mg/dL (normal 0.2-1.0), gamma-glutamyl transferase of 31 U/L (normal 7-32), and alkaline phosphatase of 96 U/L (normal 32-104). The electrocardiogram, chest X-ray and echocardiography were within normal limits. The patient was submitted to DSRA. One the 7th postoperative day he developed progressive dyspnea and cardiogenic shock. A pulmonary artery catheter was inserted and showed high pulmonary mean artery pressure (64 mmHg) and a reduced cardiac index (CI = 1,2 L/min/m²). The patient died before the shunt could be occluded. The necropsy showed severe pulmonary hypertension, right ventricular dilatation and secondary myocardial infarction. The shunt was pervious.

DISCUSSION

The treatment of portal hypertension in hepatosplenic schistosomiasis is very different in cirrhotic patients mostly because hepatic function is well preserved in Manson's disease. The surgical treatment has been considered the best alternative for schistosomotic patients with a history of bleeding from esophageal varix rupture because these patients had normal liver function and the only severe complication of the disease was digestive bleeding^[2-6].

The two modalities of elective surgical treatment are selective shunt surgery (Warren procedure) or an esophagogastric devascularization procedure with splenectomy (EGDS). Shunt surgeries have been found to be effective for bleeding control, but were associated with postoperative encephalopathy and higher operative mortality rates when compared to devascularization procedures^[2,5,6].

Although recognizable as a complication of shunt procedures, acute and fatal pulmonary hypertension have never been previously reported since Warren procedure for treatment of portal hypertension in mansonic schistosomiasis. Some groups in Brazil performed thousands of shunt surgeries for schistosomal portal hypertension, but have never described this important

complication^[7-11]. Our group routinely performed a transthoracic echocardiography in order to evaluate pulmonary hypertension. The two patients had a normal pre-operative evaluation and were submitted to DSRS. The necropsy revealed typical findings of acute pulmonary hypertension, suggesting that sub-clinical elevated pulmonary artery pressure be present before surgery. The hyperflow determined by shunt surgery aggravated a previously unsuspected pulmonary hypertension, leading to death. This observation suggests that shunt surgeries should be employed very cautiously in young patients with portal hypertension due to hepatosplenic mansonic schistosomiasis and should be performed only after measurement of pulmonary artery pressure, if indicated.

Abstract

Liver penetration is a rare but serious complication of peptic ulcer disease. Usually the diagnosis is made by operation or autopsy. Clinical and laboratory data were no specific. A 64-year-old man was admitted with upper gastrointestinal bleeding. Hepatic penetration was diagnosed as the cause of bleeding. Endoscopy showed a large gastric ulcer with a pseudotumoral mass protruding from the ulcer bed. Definitive diagnosis was established by endoscopic biopsies of the ulcer base.

INTRODUCTION

Penetration into the liver is a rare complication of peptic ulcer disease and may lead to unusual complications such as abscess formation or upper gastrointestinal hemorrhage^[1,2]. The absolute frequency of this complication in patient with peptic ulcers is not known.

We reported on a patient who presented with upper gastrointestinal bleeding due to a gastric ulcer penetrating into the liver. Diagnosis was based on histologic examination of endoscopic biopsy materials. We also reviewed 13 other reported cases of endoscopically and histologically diagnosed peptic ulcer penetration into the liver^[2-13].

CASE REPORT

A 64-year-old man was admitted because of a 2-wk history of weakness, dizziness, and melena. One week before his admission, the patient noted intermittent mild mid-epigastric pain and nausea after meals. He had undergone a highly selective vagotomy and primer suture 13 years before for peptic ulcer perforation.

Physical examination demonstrated that he was afebrile with a regular heart rate at 88 beats/min and a blood pressure of 110/60 mm Hg. The abdomen was soft, nontender, nondistended, and without organomegaly or masses. Bowel sounds were hyperactive. Rectal examination revealed no masses and the stool was melanic. A nasogastric tube was passed in emergency room, "coffe grounds" material were aspirated from the stomach. Initial laboratory evaluation showed mild leukocytosis (white blood cell counts, 15 800/mm³; normal, 4-10 10³/mm³) and severe anemia (hemoglobin, 4.7 g/dL; normal hemoglobin, 14.1-17.2 g/dL; hematocrit, 13.8%; normal hematocrit, 36.1-50.3%; mean red cell

volume, 68.2 fL; normal red cell volume, 82.2-99 fL). The stool was positive for occult blood. Coagulation parameters and liver function tests were within normal limits. The patient had no gastrointestinal symptoms and was not receiving aspirin or nonsteroidal antiinflammatory drugs (NSAIDs). Emergency endoscopy showed a large (4.5 cm) ulcer on the anterior wall of the gastric antrum, with malignant appearance (Figure 1). The ulcer base was covered with fibrin, and the margins were irregular. No active bleeding was present at the time of investigation, but stigmata of recent hemorrhage were detected. Sonographic examination demonstrated the "target" sign of the gastric antral area with suggestion of eccentric "tumour" extension into liver (Figure 2). The center of the target was echogenic. Multiple biopsies were taken separately from the ulcer margins and the pseudotumoral mass. Histologic examination of the specimens showed gastric mucosa with granulation tissue and also normal-appearing hepatocytes (Figure 3).

Figure 1 Endoscopic photograph showing a giant deep ulcer (about 4.5 cm in diameter) with malignant appearance (arrow).

Figure 2 Longitudinal ultrasound scan showing the target like appearance (arrows) representing the giant ulcer seen on gastroscopy.

Figure 3 Endoscopic biopsy showing granulation tissue (arrowhead) adjacent to normal-appearance hepatocytes (arrow) (HE $\times 20$).

Urease (CLO test) for *Helicobacter pylori* was negative. Treatment was started with 40 mg of omeprazole twice per day. He received 4 units of packed red blood cells by transfusion. The symptoms improved. The surgery service was then consulted for potential resection, however the patient and family refused surgical intervention. On the 17th d of hospitalization, he died of gastrointestinal bleeding.

DISCUSSION

We reported a very rare case of an endoscopically and histologically proven liver penetration by a gastric ulcer in an older man. In general, penetration into the liver by a peptic

ulcer is not a frequent event. We have found only a few reports of liver penetration by gastric ulcer diagnosed by endoscopy. None of them was clinically or radiologically recognised prior to endoscopy. There were thirteen previous case reports of liver penetration in patients with peptic ulcer disease. Four of these cases were for duodenal ulcer and nine were for gastric ulcer. Three of these cases could be diagnosed at the time of surgery, but the other cases were diagnosed on the basis of histologic finding of hepatic tissue on endoscopic biopsies. All of the patients, including ours, showed severe gastrointestinal bleeding. Abdominal pain was described in only 4 patients^[7,8,11,13], thus in our case, abdominal pain did not seem to be a common finding. These case reports, including the present one, are summarized in Table 1.

Endoscopically, 3 of the patients had a large ulcer crater with a pseudotumoral mass protruding from the ulcer bed, however no histologic signs of malignancy were seen^[2,6,7]. Another patient had only a mass without any ulcer^[5]. The rest of them had ulcers ranging from 2.5 cm to 9 cm \times 3 cm in diameter.

The correct diagnosis was established in all the cases by the presence of liver tissue in the histologic examination of endoscopic biopsies. In contrast to the cases, described by Guerrieri and Waxman^[9], the liver tissue in this case did not show severe inflammation or inflammatory atypia. The hepatic histological changes found in our case were consistent with those reported by others. All reported cases except two^[6,9] had normal liver function tests. This may reflect that local hepatic injury does not cause abnormalities in liver functions. The diagnostic value of liver function tests in cases of ulcer penetration into the liver is very limited.

Table 1 Comparison of published reports of liver penetration by peptic ulcer

Source	Age/Gender	Epigastric Pain/tenderness	Main clinical feature	Location	Endoscopic appearance	NSAIDs	Treatment
Martinez-onsurbe (10)	91/Female	-	GI bleeding	Anterior wall of antrum	ulcer	?	?

Jimenez-Perez(2)	61/Male	Tenderness	GI bleeding	Lesser curve of corpus	ulcer with mass	?	Op
Castellano (11)	77/Male	-	GI bleeding	posterior wall of duodenal bulb	ulcer	+	Op (BII)
Castellano (11)	70/ Male	Epigastric pain	GI bleeding	posterior wall of antrum	ulcer	?	Op (BII)
Matsuoka (12)	53/Male	Tenderness	GI bleeding	Lesser curve of corpus	Giant ulcer	?	H ₂ RA, Op
Novacek(8)	33/Female	Epigastric pain	GI bleeding	Posterior wall of duodenal bulb	ulcer	+	PPI, Op
PaddaS (5)	78/Male	-	GI bleeding	Anterior wall of duodenal bulb	Mass without ulcer	+	H ₂ RA, Op
Brullet (7)	89/Female	Epigastric Pain	GI bleeding	Anterior wall of gastric antrum	ulcer with mass	?	Op (BII)
Mostbeck(13)	53/Male	Epigastric pain	-	Anterior wall of duodenal bulb	ulcer	?	?
Present case	61/ Male	-	GI bleeding	Anterior wall of gastric antrum	giant ulcer	-	PPI

GI Bleeding: gastrointestinal bleeding; Op (BII): subtotal gastrectomy with Billroth II reconstruction; H₂RA: histamine H₂- receptor antagonist; PPI: proton pump inhibitor.

Larger lesions of the upper gastrointestinal tract have some characteristic sonographic patterns. These have been described variously as ring sign, pseudo-kidney, target-like and bull's-eye^[13,14]. Ultrasonographic examination of the present case showed a 'target' lesion with echogenic centre in the gastric antral area with suggestion of exogastric extension into the liver, leading to the suspicion of hepatic penetration by a gastric tumor as described by Sperber^[3]. The center of the ulcer appeared as cavity lesions (hypoechoic area) which were considered secondary to fluid secretions within the cavity of the giant ulcer. Endoscopic ultrasonography is useful for the diagnosis and treatment of a variety of gastrointestinal diseases. We could not perform endoscopic ultrasonography because of its absence in our unit. Endoscopic ultrasonography may be helpful for the diagnosis of gastric ulcer complications such as penetration into an adjacent structure^[15]. Only one of the patients was treated successfully with a histamine H₂-receptor antagonist^[4], but an operation was necessary for all other patients. A subtotal gastrectomy with Billroth II reconstruction was performed in 5 cases^[6,7,9,11]. In the present case, the patient did not require an emergency operation and was initially treated with a proton pump inhibitor. All patients had uneventful postoperative courses except for 2 patients, of them one died of a sepsis^[7], and the other died of pulmonary embolism^[11]. The outcome was not given in 3 cases^[3,10,13]. These reports indicate that penetration as a serious complication of peptic ulcer disease often required operative treatment. Results of a recent study have not shown a decrease in severe ulcer complications despite the use of histamine- H₂ receptor antagonists^[16]. This was likely due to the increase, mean population age in developed countries and the high prevalence of nonsteroidal anti-inflammatory drug use. Lanas *et al*, found that NSAID use was the most important independent risk factor for upper and lower gastrointestinal perforation^[17]. Endoscopic studies have shown an increase in the prevalence of peptic ulcers and gastrointestinal perforation in patients who took NSAIDs regularly^[18]. Only three of these cases were regularly using NSAIDs^[5,8,11]. Nonsteroidal antiinflammatory drugs, therefore, seem to be the most important risk factor for ulcer penetration into the liver.

Finally, as in other reported cases, results of the liver function tests in our patient were unremarkable and so did not focalise our attention on the probability of liver process. Endoscopic view of the lesion did not make us suspect penetrating peptic ulcer disease. However, ultrasound was the first procedure to raise suspicion of hepatic penetration by a gastric ulcer. This diagnosis was subsequently confirmed by endoscopic biopsy. A high index of suspicion to make the diagnosis is necessary.

Abstract

Inflammatory pseudotumor of the liver is a rare benign lesion that can mimic a malignant liver neoplasm. A case of inflammatory pseudotumor of the liver found in association with a malignant gastrointestinal stromal tumor (GIST) of the small bowel was reported. The inflammatory pseudotumor was misdiagnosed as a metastasis from the GIST by frozen section. A correct diagnosis was made only after histopathological examination of the paraffin section of the resected specimen. This case is particularly interesting because of the association of the two rare pathological entities and the diagnostic dilemma that arose from the similarity of their histological appearances. To our knowledge, this association has not been reported in the literature.

Lo OS, Poon RT, Lam CM, Fan ST. Inflammatory pseudotumor of the liver in association with a gastrointestinal stromal tumor: A case report. *World J Gastroenterol* 2004; 10(12): 1841-1843
<http://www.wjgnet.com/1007-9327/10/1841.asp>

INTRODUCTION

Inflammatory pseudotumors of the liver are rare benign lesions characterized by proliferating fibrovascular tissue mixed with inflammatory cells. They are associated with fever, pain and a mass effect, and are commonly mistaken for malignant tumors or liver abscesses. Usually the radiological or cytological examinations fail to differentiate hepatic pseudotumors from liver neoplasms. We report a patient with an inflammatory tumor of the liver who was found to have a malignant gastrointestinal stromal tumor (GIST) of the small bowel at the same time, with special emphasis on their possible etiological association and the diagnostic dilemma.

CASE REPORT

A 46-year-old housewife was admitted to our hospital in January 1998 with right upper quadrant abdominal pain and low grade fever for one week. Blood tests showed leukocytosis ($16.7 \times 10^9/L$) and raised erythrocyte sedimentation rate (ESR) (92 mm/h). Serum alkaline phosphatase (138 IU/L) was slightly increased but hepatic parenchymal enzymes were normal. The levels of serum alpha-fetoprotein (AFP) and carcinoembryonic antigen (CEA) were within normal ranges. Hepatitis B and C

viral serology tests were negative. Repeated blood culture did not reveal any bacterial growth.

In view of the mildly deranged liver function, an abdominal ultrasonography was performed which showed a space-occupying lesion in the right hepatic lobe. No dilated intrahepatic or common bile ducts were noted. Helical computer tomography (CT) scan showed a heterogeneous lesion of 10 cm in size in the right lobe of the liver (Figure 1). The right portal vein was displaced anteriorly. Radiologist commented that it could be a large multi-septated liver abscess, but the possibility of a liver tumor could not be excluded.

Figure 1 Contrast CT scan showing heterogeneous contrast enhancement in the lesion with a multi-septated appearance.

The patient was treated initially with intravenous cefotaxime and metronidazole, and the fever subsided after 1 wk of antibiotics treatment. However, due to the large size of the lesion and the worry about possible malignancy, surgical exploration was decided. Intraoperatively, in addition to the liver mass, a 10 cm soft tissue tumor was found in the ileum at 15 cm from the ileocecal valve. The tumor and a segment of the small bowel were resected and frozen section examination showed a spindle cell tumor. Trucut biopsy of the liver mass and frozen section suggested a metastatic spindle cell tumor. In view of an isolated hepatic metastasis without lymph node involvement or other evidence of metastasis, an extended right hepatectomy with a 1 cm resection margin from the tumor was performed (Figure 2).

Figure 2 Yellowish firming well-circumscribed mass in the right hepatectomy specimen.

Histopathological examination of the paraffin section of the small bowel tumor confirmed the diagnosis of a malignant GIST. Microscopic examination of the paraffin section of the liver "tumor" showed that it was composed of fascicles of spindle fibroblasts and myofibroblasts admixed with chronic inflammatory cells, which were mainly lymphocytes and plasma cells. The overall pathological features were those of an inflammatory pseudotumor of the liver.

The patient recovered well after the operation and was discharged without complication. The patient had regular follow-up in our outpatient clinic with yearly CT scan. After 4 years of follow-up, the patient was in good health and there was no evidence of tumor recurrence or further liver lesion.

DISCUSSION

Inflammatory pseudotumor of the liver is a rare clinical and pathological entity. Pack and Baker first described it in a patient after right hepatic lobectomy in 1953^[1]. To date, there have been fewer than 80 cases reported in the literature^[2-7]. These "tumors" were so named because of the difficulty in distinguishing them from malignant lesions preoperatively, as in the case of our patient. Histologically, these tumors are composed of densely hyalinized collagenous tissue infiltrated by a variety of cells, mainly plasma cells and the enigmatic plump spindle cells, although monocytes and lymphocytes have also been found^[3]. The pathogenesis and etiology of inflammatory pseudotumors of the liver are uncertain. Some authors suggested that they might be attributed to a septic origin from aberrant inflammatory reaction to migrating microorganisms from large bowel^[2]. Though bacterial culture growths, such as *Escherichia coli* and *Klebsiella pneumoniae*, have been reported in a few cases^[8], no definite microorganism could be isolated from the specimens in most cases. Other authors suggested that Epstein Barr viral infection might play a role in the pathogenesis of inflammatory pseudotumors^[9], but this still needs to be verified by further studies.

In the reported cases, patients with an inflammatory pseudotumor of the liver usually complained of non-specific symptoms at first presentation, such as abdominal pain, fever, weight loss and malaise. Elevated ESR, leukocytosis and mildly elevated hepatic transaminases and bilirubin were typical. Inflammatory pseudotumor has been reported in children as young as 3 mo of age and in adults up to 83 years of age^[4,5], with male preponderance. Schmid reported that more patients with inflammatory pseudotumors were observed in Southeast Asians (54.7%) when compared with other Western counterparts^[4]. As hepatitis B infection is common in Southeast Asia, hepatocellular carcinoma is the most common liver tumor encountered in this area. However, inflammatory pseudotumor should be included in the differential diagnosis of a hepatic mass, especially in those patients with normal hepatitis B screening and AFP level.

The recommended therapeutic approach for inflammatory pseudotumors of the liver is still controversial, though surgical resection is generally considered as an overtreatment^[8,10]. Spontaneous regression of the lesion was reported in some cases, and cases that regressed with the use of antibiotics^[11] or nonsteroidal anti-inflammatory drugs^[12] have also been reported. When the inflammatory pseudotumors caused major complications, such as biliary obstruction^[13] and portal hypertension^[14], the patients might need surgical resection or even liver transplantation^[15]. Although most authors believed that inflammatory pseudotumors had a benign behavior, there have been some reports of invasive course and mortality^[2].

To our knowledge, this is the first patient reported to have an inflammatory pseudotumor in association with a small bowel

GIST. The exact etiological link between the two is uncertain. However, the presence of an ileal GIST could potentially enhance entry of enteric bacteria into the portal circulation, which could then result in an inflammatory pseudotumor if the hypothesis of an infective etiology is true. In our patient, frozen section examination of the hepatic mass suggested that it was a metastasis from the malignant small bowel GIST, but we proceeded with hepatic resection in view of the absence of other obvious extrahepatic metastasis. In the past, patients with hepatic metastases from malignant GIST or leiomyosarcoma were considered to have poor prognosis even after surgical resection^[16,17]. Hence, hepatic resection was usually not offered to patients with liver metastasis from gastrointestinal leiomyosarcoma. However, recently some authors advocated that aggressive surgical resection for liver metastasis might provide survival benefit to the patients^[18,19]. In a recent report from a single institution, a median survival of 40 mo and a 5-year survival rate of 33% were observed after hepatic resection for hepatic metastases from leiomyosarcoma^[17]. We adopted a similar approach and performed a major hepatectomy. The final pathology of the liver lesion turned out to be an inflammatory pseudotumor, and the patient had survived without any disease recurrence for four years by the time of writing the manuscript. Our case illustrated the difficulty in differentiating an inflammatory pseudotumor from a malignancy not only in the preoperative imaging but also even by frozen section examination. The histological appearance of an inflammatory pseudotumor and a GIST is particularly difficult to differentiate. The surgeons should be aware of their possible association as illustrated in this case. A favorable long-term outcome may be expected with resection of the GIST together with hepatic resection for the inflammatory pseudotumor in the liver.

Abstract

Six patients infected with *Cyclospora cayetanensis* who sought medical care at three different hospitals in Turkey are herein presented. Four patients were male and the others were female and their ages ranged from 7 to 62 years. The first patient was HIV-positive and presented with watery diarrhea with a frequency of up to 18 times a day for more than ten months and diagnosed as cyclosporiasis in Kayseri, 1996. The second patient was also HIV positive and diagnosed as cyclosporiasis in Kayseri, 2000. The third patient was an acute myeloblastic leukemia (AML) patient and diagnosed in Istanbul, 2000. The fourth patient was idiopathic hepatic cirrhosis complaining of diarrhea and weakness and diagnosed in Kayseri, 2001. The fifth and sixth patients were immunocompetent patients complaining of diarrhea and diagnosed in Izmir and Kayseri, 2002. Diarrhea occurring from one to ten times a day continued for 7 to 70 d in the last 5 patients. Treatment with a trimethoprim/sulfamethoxazole compound was done for all patients. Both symptomatic and parasitologic improvements were quickly observed. In summary, *C. cayetanensis* infection is rare in Turkey and most patients infected with this pathogen tend to be immunosuppressive individuals at present.

INTRODUCTION

The genus *Cyclospora* is in the subclass Coccidia, phylum Apicomplexa. This genus is taxonomically related to coccidian genera in humans. This organism is a unilocular parasite previously known as cyanobacterium-like or coccidian-like body (CLB) and, in recent years, a new coccidian pathogen, *Cyclospora*, has been putatively identified^[1,2]. The organisms are seen as nonrefractile spheres and are acid-fast variable with the modified Kinyoun's acid-fast stains, those are unstained appear as glassy, wrinkled spheres. Modified acid-fast stains stain the oocysts from light pink to deep red, some of which may contain granules or have a bubbly appearance. The oocysts autofluoresce (strong green or intense blue) under UV epifluorescence^[3]. The first known human cases of illness caused by *Cyclospora* infection (i.e., cyclosporiasis) were reported in the medical literature in 1979^[4]. Our aim in this study was to present cases of human cyclosporiasis in Turkey and to review the literature.

MATERIALS AND METHODS

We evaluated all of the human cases in our country

retrospectively which were belongs to Kayseri (three cases), Istanbul (one case) and Izmir (one case) regions between 1996 and 2002^[5-9]. Following these, we determined a new case with *C. cayetanensis* in December 2002. In this study, we discuss all of the six cases with cyclosporiasis in Turkey.

RESULTS

Case 1^[5]

A 50 year-old woman with acquired immune deficiency syndrome (AIDS) was admitted in December 1996 for chronic diarrhea, vomiting, and fever to the Erciyes University Medical Faculty Hospital. There was preceding history of episodic watery diarrhea, vomiting, and weight loss along with intermittent fever over a period of one year. She was cachectic, with mild abdominal tenderness and alert, thrush and palpable small cervical lymph nodes. She had anemia (Hb 8.4 g/L). Enzyme immunoassays for HIV antibodies were positive and the T4/T8 ratio was 0.6 in serum. *E. coli* and *Proteus* spp. were found at 10⁴ cfu/mL from urine specimens. Microscopical analysis of the stool revealed numerous spherical double walled microorganisms 8-9 µm in diameter, some with internal granulation. After Kinyoun's acid fast staining of the stool, the organisms appeared faint pink to red in colors, some cysts not taking up the stain and appearing as "ghosts". Empty cysts varied in shape but had generally collapsed into crescents. The organisms were identified as *Cyclospora* sp. The patient was treated with TMP/SMZ (160/800 mg) bid for three weeks. Following treatment, re-examination of a stool sample revealed no more organisms and diarrhea stopped. This case was the first report of *Cyclospora* infection in Turkey.

Case 2^[6]

A 40-year old man with AIDS was evaluated parasitologically for the etiologic agent of his persistent diarrhea for two months in Erciyes University Medical Faculty Hospital in 2000. Stool samples were examined by conventional coprological methods such as fresh preparation, iodine stain, and flotation. Suspicious organisms (8-10 µm in diameter) were seen in stool, which were stained with Kinyoun's acid-fast stain and identified as *C. cayetanensis*. He was treated with TMP/SMZ (160/800 mg) bid for two weeks. We could not find the organism in the stool samples after the treatment and diarrhea stopped.

Case 3^[7]

In 2000, at the Istanbul University Medical Faculty Hospital there was another 7 year-old male patient with acute myeloblastic leukemia (AML). A sudden diarrhea developed while bone marrow transplantation was being planned. The patient's stool samples were examined with respect to pathogen bacteria and fungi and rotavirus. None of them was determined, isolated and/or seen. Two stool specimens, which were taken in one-week interval, also were examined with modified trichrome, acid fast and safranin staining methods. In microscopic examinations, *C. cayetanensis* oocysts were seen with all three staining methods. After four weeks of therapy with trimethoprim-sulphamethoxazole (15 mg/kg.d) diarrhea stopped and in the new stool specimens, *C. cayetanensis* oocysts were not encountered.

Case 4^[8]

A 52 year-old male patient with idiopathic hepatic cirrhosis

complaining of diarrhea and weakness was accepted to the gastroenterology clinic of Erciyes University Medical Faculty Hospital in 2001. In the patient's history, there were watery, bad smelling, bloodless episodes of diarrhea, fever, cold, sweating, and a 10 kg lost of weight which all began three weeks prior to hospitalization. The patient had never traveled to a foreign country. Physical examination did not reveal any abnormalities except subicteric conjunctivas and a hyperemic tongue. The patient was afebrile. In laboratory examination, blood values were found as Hb: 14.2 g/dL, white blood cells: 4 900/mm³, platelets: 69 000/mm³. Biochemical values were as follows: K: 2.9 mmol/L (↑), P: 1.7 mg/dL (↑), Ca: 7.6 mg/dL (↑), Mg: 0.9 mg/dL (↑), uric acid: 9.3 mg/dL (↑), total bilirubin: 4.2 mg/dL (↑), AST: 165 U/L (↑), ALT: 76 U/L (↑), CK-MB: 120 U/L (↑), albumin: 2.8 gr/dL (↑), acetone, protein and bilirubin were (+) in urine. Anti-HBs Ag and Anti-HAV were positive and other hepatitis markers were negative. Anti-HIV antibodies were found to be negative by ELISA test. In abdominal USG, liver with lobule contour was smaller than normal size, and its echo was increased. Widespread intraperitoneal exudate was seen.

In order to find out the causative etiologic agent of diarrhea, stool samples were examined by different methods and stained using modified Kinyoun's acid-fast stain. Following examination, acid-fast variable wrinkled spheres approximately 9 µm in diameter, were seen and diagnosed as *C. cayetanensis*. Confirmation of the diagnosis was established by fluorescent microscope (380 to 420 nm excitation filter), which showed bright green to intense blue autofluorescent oocysts.

Consequently, this organism was diagnosed as *C. cayetanensis*. The patient was treated with TMP/SMZ (160/800 mg) bid for 7 d. Following treatment, re-examination of a stool sample, however, did not reveal the presence of any organisms.

Case 5^[9]

A 30 year-old female patient complaining of diarrhea and weakness was admitted to the gastroenterology clinic of Atatürk State Hospital in Izmir, 2002. In the patient's history, there were watery diarrhea, fever, nausea which all began one week prior to admission to hospital. Stool samples were examined by conventional coprological methods such as fresh preparation, iodine stain, flotation, modified Ritchie's method and modified Kinyoun's acid-fast stain. Acid-fast variable wrinkled spheres were seen and diagnosed as oocysts of *C. cayetanensis*. Confirmation of the diagnosis was established by fluorescent microscope. After one-week therapy with trimethoprim-sulphamethoxazole for 7 d, diarrhea stopped and in the new stool specimens, *C. cayetanensis* oocysts were not seen. This patient was different from the other four cases in Turkey because there were no abnormalities in immunologic tests of the patient. That is, she was an immunocompetent patient.

Case 6

A 62-year-old male patient complaining of diarrhea was admitted to the Erciyes University Medical Faculty Hospital in October 2002. This case was not reported anywhere. In the patient's history, there were watery, bad smelling diarrhea, fever, sweating, which all began one week before admission to hospital. Stool samples were examined by conventional coprological methods. Acid-fast variable oocysts were seen and diagnosed as oocysts of *C. cayetanensis* (Figure 1).

After one-week therapy with trimethoprim-sulphamethoxazole (160/800 mg) bid for 7 d diarrhea stopped and in the new stool specimens, *C. cayetanensis* oocysts were not encountered and all the symptoms disappeared. This patient was also immunocompetent similar to case 5. There were no abnormalities in immunologic tests of the patient.

Figure 1 *Cyclospora* oocysts in stool smear preparations. A: *Cyclospora* oocysts in native preparation (original magnification. $\times 1\,000$). B: Acid-fast stained *Cyclospora* oocysts (Modified Kinyoun's acid-fast stain: original magnification. $\times 1\,000$). C: Acid-fast stained and unstained *Cyclospora* oocysts (Modified Kinyoun's acid-fast stain: original magnification. $\times 1\,000$). D: *Cyclospora* oocysts' autofluorescence in wet preparation with fluorescent microscope of 380-420 nm wavelength. ($\times 400$).

DISCUSSION

Cyclospora organisms were first reported in the intestines of moles in 1870 by Eimer, and Schneider introduced the genus *Cyclospora* in 1881. The first report of human *Cyclospora* infection came from Papua New Guinea in 1979^[4].

Cyclospora oocysts in freshly excreted stool are non-infectious. The oocysts are thought to require days to weeks outside the host under favorable environmental conditions to sporulate and thus to become infectious. Direct person-to-person transmission by fecal exposure is unlikely, because excreted oocysts must sporulate to become infective^[10].

C. cayetanensis constitutes a significant cause of chronic and intermittent diarrhea in immunocompromised patients especially those with AIDS. A study in Haiti has documented the occurrence of chronic diarrhea in most patients with AIDS^[11]. *Cyclospora* infection has also been reported in patients with severe AIDS in other areas^[12,13]. Lontie *et al.*^[14] reported 2 cases of intestinal *Cyclospora* infection in immunocompetent Belgians. In Turkey, there were 6 cases between 1996 and 2002, 2 of them were AIDS patients^[5,6], 1 of them was an AML patient^[7], 1 of them was idiopathic hepatic cirrhosis^[8] and the last two patients were immunocompetent individuals^[9,10].

Both epidemiological and environmental data suggested that the organism be waterborne^[1]. The transmissibility of *Cyclospora* through water depends on the probability that the water source of interest could become contaminated and that the water treatment would kill or remove oocysts. *Cyclospora* oocysts, like *Cryptosporidium* oocysts, probably are highly chlorine resistant, but they could be more easily removed by conventional filtration because they are about twice as big as *Cryptosporidium* oocysts^[10].

In 1994, an outbreak of *Cyclospora* occurred among British soldiers and dependents stationed in a small military base detachment in Pokhara, Nepal. That outbreak was epidemiologically

Table 1 Similarities and differences between *Cryptosporidium parvum* and *Cyclospora cayetanensis*^[10]

Similarities	<i>C. cayetanensis</i>	<i>C. parvum</i>
Acid-fast staining of oocysts	Variable acid-fast	Acid-fast
Number of infective units (sporozoites) per sporulated oocyst	4	4
Completion of life cycle within humans	Yes, except for sporulation	Yes
Multiplication outside the host (e.g. in water or food)	No	No
Differences		
Size of oocysts	8-10 µm in diameter (intermediate in size between <i>Cryptosporidium parvum</i> and <i>Isospora belli</i>)	Average width of 4.5 µm and average length of 5 µm
Number of organisms in stools of symptomatic nonimmune hosts	Typically excreted in low to moderate number	Often excreted in somewhat higher numbers
Autofluorescence of oocyst wall	Yes	No
Internal morphology of sporulated oocysts	Each oocyst has 2 internal sporocysts, each contains 2 sporozoites	The 4 sporozoites are naked within the oocyst
Infectivity of oocysts in freshly excreted stool	Must sporulate outside host to become infectious	Fully sporulated and infectious when excreted (sporozoites can be visualised when oocysts are excreted)
Zoonotic potential	Host range unknown	Infects virtually all commonly known wild and domestic mammals
Location in enterocytes of small bowel	Intracytoplasmic within a parasitophorous vacuole in apical supranuclear region	Intracellular, extracytoplasmic, within a parasitophorous vacuole at luminal surface of enterocyte
Susceptibility to antimicrobial agents	Treatment with TMP-SMZ leads to both clinical and parasitologic cure	Some antimicrobial agents (e.g. paromomycin) may cause clinical improvement, but no agents has been consistently demonstrated to provide parasitologic cure

linked to drinking water, because the organism was identified in the water source^[15].

In the 1990s, at least 11 definite and probable food born outbreaks of cyclosporiasis, affecting at least about 3 600 people, were documented, all of which occurred in North America^[10]. The outbreak that brought cyclosporiasis to prominence in North America and definitively established that *Cyclospora* was transmissible through food, occurred in 1996 in the United States and Canada and was linked to a third country, Guatemala, which was the source of implicated fresh raspberries^[16].

The symptoms presenting in one patient (watery diarrhea, nausea, weight loss, and abdominal pain) were similar to those classically *Cyclospora* infection^[11,13,17]. Since the oocysts of *Cyclospora* are acid-fast like those of *Cryptosporidium*, we recommend that all laboratories screening for the latter parasite include precise measurements of oocysts. *Cyclospora* oocysts are 8-10 µm in diameter (intermediate size between *Cryptosporidium parvum* and *Isospora belli*). *Cryptosporidium parvum* oocysts have an average width and length of 4.5 µm 5 µm, respectively. It is possible that many cases of diarrhea reported to be due to *Cryptosporidium* might actually be due to *Cyclospora* because size discriminations are not often made. *Cyclospora* organisms have now been isolated in chronic diarrhea and this infection should be carefully distinguished from cryptosporidiosis^[11,11,18]. A list of some of the similarities and differences between these two organisms is shown in Table 1.

The treatment for *Cyclospora* infections cotrimoxazole (TMP-SMZ) was given for 7-10 d (longer, if symptoms persist)^[19]. The adult dosage was 160 mg TMP plus 800 mg SMZ orally twice daily. In a double blind, placebo controlled trial among Peruvian children, a three-day course of TMP (5 mg/kg.d) plus SMZ (25 mg/kg.d) decreased the duration of oocyst

excretion, but few symptomatic children were treated to address the effect on duration of diarrhea^[20]. Alternative treatments have not yet been identified. Limited data suggest that the following drugs are ineffective: albendazole, azithromycin, nalidixic acid, norfloxacin, tinidazole, metronidazole, quinacrine, tetracycline, and diloxanide furoate. Approaches to alternative treatment of patients who could not tolerate TMP-SMZ therapy include observation and symptomatic treatment^[21-25]. In a small, randomized, controlled-trial comparing oral TMP-SMZ and ciprofloxacin for treatment of and secondary prophylaxis for *Cyclospora* infection in HIV infected Haitians, ciprofloxacin (500 mg twice daily for 7 d as therapy and thrice weekly for 10 wk as secondary prophylaxis) was moderately effective, though it was less active than TMP-SMZ^[26]. These results suggest that ciprofloxacin might be an alternative for patients who cannot tolerate TMP-SMZ. However, these results should be confirmed in a large number of patients as well as in non-HIV population.

Sporadic cases of infection may be part of widespread outbreaks and should in any case be reported to public health officials. Public health personals and clinicians should also be aware that stool examination for *Cyclospora* should be specifically required in case of clinical suspicion of *Cyclospora* infection (protracted or relapsing diarrheal episode)^[10]. In conclusion, this organism should be considered in the differential diagnosis of unexplained diarrhea in both immunosuppressive and immunocompetent patients. However, further studies are needed to confirm the causative association with other diseases and to determine the incidence and epidemiological features of this organism.

Abstract

To date, dozens of melanoma-associated antigens (MAGEs) have been identified and classified into 2 subgroups, I and II. Subgroup I consists of antigens which expression is generally restricted to tumor or germ cells, also named as cancer/testis (CT) antigen. Proteins and peptides derived from some of these antigens have been utilized in promising clinical trials of immunotherapies for gastrointestinal carcinoma, esophageal carcinoma, pulmonary carcinoma and so on. Various MAGE family members play important physiological and pathological roles during embryogenesis, germ cell genesis, apoptosis, etc. However, little is known regarding the role of MAGE family members in cell activities. It is reasonable to speculate that the genes for subgroup I MAGEs, which play important roles during embryogenesis, could be later deactivated by a genetic mechanism such as methylation. In the case of tumor formation, these genes are reactivated and the resultant proteins may be recognized and attacked by the immune system. Thus, the subgroup I MAGEs may play important roles in the immune surveillance of certain tumor types. Here, we review the classifications of MAGE family genes and what is known of their biological functions.

INTRODUCTION

In 1991, researchers first isolated a melanoma-associated antigen (MAGE) gene, MAGE-A1^[1]. This antigen, isolated from an MZ-2 human melanoma cell line, could be recognized by cytotoxic T lymphocytes (CTLs). In the following years, dozens of new MAGE gene were identified. MAGE proteins act as anti-tumoral immune targets, making these antigens a popular focus of immunotherapy researches on gastrointestinal carcinoma and other cancers^[2]. Although much work has investigated the expression of MAGE genes and HLA-restricted epitopes, relatively little is known about the functions of the MAGE proteins. In this paper, we review the classifications of MAGE family genes and what is known of their biological functions.

CLASSIFICATIONS OF THE HUMAN MAGE PROTEIN FAMILY

In 1991, Terry Boon's laboratory established a method for identifying tumor antigens based on tumor-specific CTLs recognition^[1]. Using this method, the group identified a new tumor antigen which they called MAGE-1. Subsequently, this

and other screening methods were used to identify a large number of tumor-specific and tumor-related antigens, including dozens of MAGEs (Table 1)^[3-7]. The MAGE family proteins share certain homologous regions, including the MAGE homology domain (MHD). Sequence comparison and analysis revealed 3 subgroups of acidic MAGEs, termed A, B, and C, and one basic subgroup, MAGE-D, which includes Necdin, Restin and others^[8]. Based on expression patterns, the MAGEs were further classified as belonging to either subgroup I or II. Members of subgroup I, including MAGE-A, -B, and -C, are expressed in malignant tumors and testis, but not in other normal tissues. These members are also named as cancer/testis (CT) antigen and tumor-specific antigen. In contrast, subgroup II MAGEs are expressed in various normal adult human tissues^[4,9]. Interestingly, testis germ cells do not express MHC I/II molecules and cannot present the MAGE proteins, so testis tissue is generally immune-exempt. Based on this, tumor-expressed MAGE-A, -B, and -C proteins have become important targets for cancer immunotherapy, and some clinical trials are ongoing for treating gastrointestinal carcinoma, esophageal carcinoma, pulmonary carcinoma and so on. Now researchers are continuing to identify additional MAGE genes in the hope of identifying better therapeutic targets.

CELLULAR FUNCTIONS OF MAGE PROTEINS

Regulation of subgroup I MAGE gene expression in normal somatic cells

In normal mature somatic cells, subgroup I MAGE genes are static. When cells become neoplastic, MAGE genes are activated and the corresponding proteins are expressed. Interestingly, some non-MAGE-A1-expressing tumor cells have been found to contain transcription factors capable of activating the MAGE-A1 promoter^[10]. This suggests that the presence of the relevant transcription factor is not sufficient to trigger expression, indicating that alternative regulatory mechanisms may exist in terms of MAGE-1 gene activation.

Recent studies have shown that MAGE gene activation may be related to promoter demethylation^[11]. The promoter of the MAGE-A1 gene contains several cis-regulatory sequences located from nt -792 to +47. Among them, the B and B' domains are critical for MAGE-1 gene expression. Both domains contain Ets transcription factor binding sites, including a critical CpG bi-nucleotide site. When this CpG is methylated, the Ets transcription factor cannot bind to the B and B' domains, and expression of MAGE-1 is inhibited. Therefore, promoter methylation inhibits the expression of MAGE-1^[10]. Indeed, when non-MAGE-A1-expressing tumor cells were treated with the demethylating reagent, 5-aza-2-deoxycytidine (5DC), MAGE-A1 expression was induced^[11]. When normally non-MAGE-expressing cells (i.e. fibroblasts) were treated with 5DC, some cells expressed MAGE genes^[11], while others did not^[12]. In explanation of this, the authors proposed that most normal cells possess strong methylating actions, and that demethylating reagents such as 5DC are insufficient to demethylate MAGE promoters to a degree that would allow for MAGE gene expression. Taken together, these studies suggest that both normal and tumor cells contain the transcription factors that activate subgroup I MAGEs, and that expression of these genes is regulated by promoter demethylation.

Table 1 The MAGE family genes

Subtype	Gene name	Access number	Expression status	Length of amino acids
MAGE-A	MAGE-A1	JC2358 ^[27-29]	T	280

T: Only expressed in tumor cells or germ cells. P: Pseudogene; N: Expressed in normal cells. -: Unknown.

The functions of MAGE genes in germ cells

Most MAGE genes are expressed in germ cells under physiological conditions, but their functions remain unclear. Early work has focused on the functions of the mouse MAGE-b4 gene during embryonic development^[13]. The mouse MAGE-b4 gene is expressed in adult and fetal reproductive gland cells and shares high homology with members of the human MAGE-B sub-

type. The MAGE-b4 protein is located in the cytoplasm but not in the nucleus. In male testes, germ cells (gonocytes) continuously proliferate until they arrest at the G0/G1 stage, differentiate into foot cells and form the spermatogenic cords. After birth, the gonocytes differentiate into spermatogonia, which in turn undergo meiosis during adolescence and differentiate into sperm cells. The MAGE-b4 gene is highly expressed in germ cells suspended in G0/G1; in contrast, the gene is barely expressed in meiotic spermatogonia. Thus, MAGE-b4 likely plays an important role in male germ cells, perhaps by maintaining gonocytes in a non-proliferative state.

In female germ cells, MAGE-b4 is expressed prior to meiosis, and also during the pachytene and telophase portions of meiosis. Other cell cycle proteins have shown similar differences in expression in the two sexes. For instance, cyclin A1 deficiency in male germ cells inhibits meiosis but does not affect that in female germ cells^[14]. Similarly, deficiencies of Hsp70-2 or A-myb suppress the development of male germ cells and male fertility but do not affect female development^[15]. Therefore, we speculate that MAGE-b4 may similarly play an important role in the control of the cycle of male germ cells, while playing a less dramatic role in female germ cells.

Another member of the MAGE family Magphinin plays an important role in germ cell development. Mouse Trophinin is a membrane protein that plays an adhesive role in the process of zygotic implantation into the uterine endometrium; an alternative transcript of the Trophinin gene encodes Magphinin^[16]. Although the Trophinin protein is not homologous with the MAGE family members, the mouse Magphinin protein shares high homology with Necdin, Dlxin and NRAGE. Of these, Necdin can bind transcription factor E2F-1, which is responsible for inducing the expression of cyclin and promoting cell cycle progression from G1 to S. Thus, it is possible that the Necdin homolog, Magphinin, acts similarly to bind E2F-1 and inhibit cell proliferation. Magphinin has three alternatively spliced forms: magphinin-a, β and γ . Northern blot analysis reveals that Magphinin protein is expressed in mouse brain, ovary, testis, and epididymis. Western blot analysis indicates that in mouse ovary and epididymis, Magphinin is derived from alternative translation of the Trophinin transcript beginning at the second start codon (AUG). The Magphinin protein sequence contains a nuclear localization signal that allows it to enter the nucleus and inhibit cell proliferation. Immunohistochemical studies suggest that the localization of Magphinin protein varies between male and female germ cells at various stages of the cell cycle. Before meiosis, Magphinin- β is mainly distributed in the cytoplasm of male germ cells. After the first meiosis, when primary spermatocytes differentiate into secondary spermatocytes, Magphinin is localized in both the cytoplasm and the nucleus, and after this nuclear translocation, cell division terminates. Based on this, we speculate that Magphinin regulates the cell cycle during the formation of male spermatocytes. In the female germ cell, the distribution of Magphinin is somewhat different. When the oocyte has only single- or double-layer vesicles, intracellular Magphinin (especially Magphinin- γ) is strictly cytoplasmic. When the oocyte has divided into multi-layer vesicles, the protein is only located in nucleus. In this case, meiosis terminates at stage G2, suggesting that Magphinin also controls the formation of the female ovum.

May these expression patterns and functional roles be generalized to other members of the MAGE family? This remains to be shown. Indeed, at present, little is known about the functions of MAGE family proteins inside germ cells. Further studies will show whether human MAGE proteins control the cell cycle in manners similar to the actions of MAGE-b4 and Magphinin.

Below, we will discuss several specific examples of MAGEs and what is known of their cellular functions.

MAGE-A4

In terms of cancer biology, yeast two-hybrid studies identified binding between the MAGE-A4 protein and a cancer protein: the gann ankyrin repeat protein (also called Gankyrin, PSMD10 or p28). This MAGE-A4-specific binding is mediated by its C-terminus^[17]. Gankyrin, which consists of six gann ankyrin repeats and a 38 amino acid N-terminus, can bind the cancer-suppressing protein Rb, the S6 ATP enzyme subunit of the 26S protein, and cell cycle-dependent kinase 4 (Cdk4). Gankyrin expression is increased in the livers of hepatocellular carcinoma patients; this increase is seen at the earliest stages of tumor genesis^[18,19]. Overexpression of Gankyrin can increase the phosphorylation and degradation of Rb, as well as immortalization of NIH/3T3 cells. In addition, the binding of Gankyrin to Cdk4 counteracts the cancer-inhibiting functions of p16^{INK4A} and p18^{INK4C}^[20]. Therefore, Gankyrin plays an important role in controlling cell cycle during liver cancer tumorigenesis. Studies have shown that exogenous MAGE-A4 can partly inhibit the adhesion-independent growth of Gankyrin-overexpressing cells *in vitro* and suppress the formation of migrated tumors from these cells in nude mice. This inhibition is dependent upon binding between MAGE-A4 and Gankyrin, suggesting that interactions between Gankyrin and MAGE-A4 inhibit Gankyrin-mediated carcinogenesis^[17].

Necdin

Necdin, first identified in 1991, is the best-characterized member of the MAGE protein family. The gene was isolated from P19 neural cells; the encoded protein consists of 325 amino acids and shares about 30% homology with other MAGE proteins^[21]. Studies have shown that overexpression of Necdin may induce cell cycle arrest in NIH3T3 and SAOS2 cell lines, suggesting that Necdin functions in cell cycle arrest and maintenance of cell stability. *In vivo*, Necdin can interact with cell cycle promoting proteins such as the SV40 big-T protein, adenovirus E1A and transcription factor E2F-1, which acts as a cell cycle regulator by trans-activating the relevant genes in an Rb-regulated pathway. The latter binds to E2F-1 protein during G1 stage and inhibits the binding ability of E2F-1, leading to inhibition of gene activation. Similarly, Necdin can bind to E2F-1 and initiate conformational changes to decrease E2F-1 binding and inhibit cell growth^[22]. In addition, Necdin can bind to and inhibit p53, which normally induces cell cycle arrest and cell death^[23]. Thus, Necdin plays important roles in inhibiting cell growth and apoptosis through its interactions with E2F-1 and p53.

The human Necdin gene is localized at 15q¹¹⁻¹³, an area genetically associated with the neurological behavior disorder, Prader-willi Syndrome (PWS). Newborn PWS patients generally suffer respiratory failure and myasthenia, and adolescent PWS patients show psychonosema, sexual dysfunction and obesity. The PWS chromosomal region contains several genes, including Necdin and MAGE-L2. Indeed, knockouts of the mouse Necdin homolog show symptoms similar to human PWS^[24], suggesting that Necdin plays a role in proper development, and that lack of Necdin may be involved in the pathogenesis of PWS.

MAGE-D1

The MAGE-D1, also named as NRAGE or Dlxin, plays important roles in mediating apoptosis and transcription. NRAGE interacts with p75^{NTR}, a TNF receptor responsible for binding the Trk receptor and forming a complex that facilitates binding of neurotrophin, which in turn activates the Trk receptor. p75^{NTR} is also capable of mediating cell death. NRAGE-p75^{NTR} binding, identified by yeast two-hybrid screening, occurs through an 80 amino acid intracellular segment of p75^{NTR} located near the plasma membrane.

Overexpression of NRAGE inhibited the interaction between p75^{NTR} and the Trk receptor and induced cell apoptosis. In contrast, overexpression of the Trk receptor increased binding between Trk and p75^{NTR}, leading to inhibition of NRAGE-p75^{NTR} complex-induced cell death. This indicates that NRAGE-p75^{NTR} and Trk receptor-p75^{NTR} binding are mutually exclusive.

Another NRAGE-binding protein, XIAP, can inhibit apoptosis by binding to activated Caspases. The NRAGE-XIAP complex accelerates the decomposition of XIAP, suggesting that NRAGE accelerates cell death by degrading XIAP and activating Caspases^[4].

Indeed, members of the MAGE-D1 subgroup can bind to several proteins that control apoptosis and cell cycle^[4]. The MAGE-D1 repeat regions can directly interact with Msx2, Dlx7 and Dlx5. Msx generally acts as a transcription inhibitor, whereas Dlx acts as a transcriptional activator. In addition, Msx1 and Msx2 play roles in the control of cell cycle, and Msx2 can promote cell death. The effect of MAGE-D1 on Msx remains unknown, but MAGE-D1 is necessary for Dlx5 to promote transcription.

CONCLUSION

Although subgroup I and II MAGE genes are expressed in different tissue-specific patterns, all family members contain the MAGE homology domain (MHD), suggesting some functional conservation. Biochemical analyses of these two subgroups have provided some insights into the physiological effects of the MAGE genes. Embryonic cells have much less CpG methylation at the MAGE genes than do somatic cells^[25,26]. Similarly, MAGE genes in tumor cells are hypomethylated; indeed, the entire tumor genome is generally hypomethylated^[10]. Thus, it is likely that MAGE gene expression in tumor tissues is the result of tumor genesis, not a cause. It is reasonable to speculate that this family of proteins functions during embryonic development, and that the genes are subsequently deactivated, perhaps by methylation. During neoplastic transformation, these genes are re-activated, expressed, and may become antigenic targets that are recognized and attacked by the immune system^[8]. Therefore, MAGE genes take part in the immune process by targeting some early tumor cells for immune destruction. Consequently, these genes should be studied further in terms of their various functions as they relate to the pathogenic mechanism of tumors, immunotherapy, and other important fields.

Abstract

Traditional Chinese medicine, including herbal medicine and acupuncture, as one of the most important parts in complementary and alternative medicine (CAM), plays the key role in the formation of integrative medicine. Why do not the modern drugs targeting the specificity of diseases produce theoretical effects in clinical observation? Why does not the traditional Chinese medicine targeting the Zheng (syndrome) produce theoretical effects in clinic? There should have some reasons to combine Western medicine with Chinese herbal medicine so as to form the integrative medicine. During the integration, how to clarify the impact of CAM theory on Western medicine has become an emergent topic. This paper focuses on the exploration of the impact of theory of traditional Chinese medicine on the therapy of diseases in Western medicine.

INTRODUCTION

More than one third of patients in the United States use complementary and alternative medicine (CAM)^[1], and more and more scientists are interested in integrative medicine research in USA. Recent research showed that integrative medicine (also complementary and alternative medicine) could contribute to primary health care^[2,3]. Traditional Chinese medicine (TAM), including herbal medicine and acupuncture, as one of the most important parts in CAM, should play the key role in the formation of integrative medicine. During the integration, how to clarify the impact of CAM theory on Western medicine has become the emergent topic.

TCM was formed two thousand years ago, and developed in the following centuries. TCM recognizes human body by system discrimination and cybernetic way. TCM can be characterized as holistic with emphasis on the integrity of the human body and the close relationship between human and its social and natural environment. TCM focuses on health maintenance and in the treatment of disease emphasizes on

enhancing the body's resistance to diseases. For improving health, TCM applies multiple natural therapeutic methods.

Zheng (syndrome) is the basic unit and key term in TCM theory. Zheng is an outcome after analyzing all symptoms and signs. All therapeutic methods in TCM come from the differentiation of Zheng. The methods have been used for thousands of years, which proves that TCM therapeutic approach is effective. From this point of view, Zheng should play an important role in determining the effect. Combined with modern medicine, Zheng should have an impact on disease pathogenesis that directly influences the therapeutic effect.

HISTORICAL BACKGROUND

At the time when TCM formed, there was nothing modernized in medical and biological fields, but there was something developed in Chinese philosophy, astronomy and literature. Also at that time, people got a great amount of experiences on how to deal with the disorders by natural methods, such as puncture, Qigong (mind controlling), taking plants. Some talents in China began to summarize those phenomena and sublimated to theory based on their philosophical and social knowledge at that time. The theory is the original TCM. Thus TCM handles human physiology and pathology following old Chinese philosophical thinking. In the following centuries, accumulation of experiences and addition of relative knowledge (such as clinical observation data and less anatomical experience) made TCM developed. The terminology TCM is partially originated from Chinese philosophy. Other terms in TCM, even same as those in modern medicine, have completely different meanings. It is believed that to understand the physiology of TCM, to some extent, should have some knowledge about Chinese philosophy.

PHYSIOLOGY AND PATHOLOGY IN TCM

During the formation and development of TCM, there are two ideological ideas that fully penetrate into the whole process. The first is the homeostasis idea that focuses on the integrity of human body, and emphasizes the close relationship between human body and its social and natural environment (integrity between human and cosmos). The second is the dynamic balance idea that takes emphasis on the movement in the integrity. Physiologically TCM recognizes human body by system discrimination and cybernetic way. In system discrimination approach, the intrinsic activities of human body can be clarified by analyzing the audio-visual information. The human body, a complicated system, could be identified as different closely related systems that form a network (integrity). The external information should reflect something intrinsic because of the integrity between human body and its social and natural environment. For example, the heart as a center, together with blood, vessel, mind, tongue, small intestine, consists of the heart system in TCM. Any information from any parts in the system can demonstrate the system's activity even the structure of the part is unclear. In cybernetic approach, TCM takes human body as a self-controlled system network. The network is connected by the meridian that exists in whole body. Blood

and vital energy flow also contributes to the connection. The Five elements theory in TCM, named as wood, fire, earth, metal and water, divides human body into five systems. Each system has its own specific features that can be inferred by analyzing those natural materials. The movement and interchange among the five elements are used to explain human body's physiology.

Since TCM has its unique physiology in understanding human body, it has its special understanding on human body's disorders. Pathologically, TCM focuses on the pathogenicity of social and natural factors. The factors have a close relationship with humans to consist of the integrity. Mostly they are non-direct and non-specific factors if we say bacteria or viruses are direct and specific ones. TCM is not completely to seek the specific pathogen, and pathological changes in a specific organ, while it is to seek the disturbances among the self-controlled systems by analyzing all symptoms and signs. In the heart system, any disturbance in any part of the system is useful to clarify the pathology. At the same time, comparison of the disturbance happened in different period is also important in pathological analyses. TCM takes emphasis on the dynamic changes in any parts and any connections in the self-controlled system.

THERAPEUTIC MECHANISM IN TCM

Physiology in TCM is featured with self-controlled system discrimination and its pathology is featured with dynamic changes in the system (whether direct or indirect, specific or non-specific). The therapeutic mechanism in TCM focuses on enhancing human body's resistance to diseases and prevention by improving the inter-connections among self-controlled systems. To reach the approach, TCM uses different therapeutic methods, such as mind-spiritual methods (such as Qigong, Taiji boxing), natural methods (acupuncture, moxibustion, herbal medicine). These therapeutic methods are characterized by fewer side effects since they are natural. TCM evaluates the therapeutic results by comparing the symptoms before and after the treatment. The treatment is based on the differentiation of symptoms to clarify what is wrong in the self-controlled system. TCM seeks the therapeutic mechanism from the integrity. The integrity includes the human itself as integrity, and the integrity between human and its social and natural environment. The therapeutic mechanism can be achieved by activating systems, improving system connection and enhancing human resistance. The mechanism in TCM is not like modern medicine that seeks the mechanism from cellular or molecular level (such as killing bacteria and virus, antagonistic method). If someone lives well (no symptoms), she is healthy in TCM, whether she has some signs in cellular and molecular level such as high blood pressure.

KEY TERM IN TCM THERAPEUTIC APPROACH: DIFFERENTIATION OF ZHENG

Zheng (syndrome), a basic unit in TCM, decides the therapeutic methods. Zheng is the outcome after a careful analysis of all symptoms and signs (tongue appearance and pulse feeling included). Zheng outcome might change since the symptoms and signs might change. There are many Zhengs in TCM, either simple Zheng or combined ones.

Zheng, as the key term and basic unit in TCM therapeutic theory, develops following the progress in disease theory progress. Tens of years ago, Zheng did not include any signs from modern diagnostic instruments, and nowadays, Zheng is combined with or referred to disease diagnosis during the therapeutic process to some content.

The process of how to get the outcome is called differentiation

of Zheng, which is based on the physiology and pathology of TCM.

IMPACT OF ZHENG ON DISEASE TREATMENT

Disease's key units usually contain etiology, pathology and disease location. Modern medicine is trying to get the specificity of the cause, pathology and location, and as a result, the therapeutic approach is targeting on the specificity. New drugs in modern medicine are developed from strictly designed scientific pharmacological tests that are targeting on the specificity. Pharmacological tests show better effect than the effect shown in clinic.

In differentiation of Zheng, clinical effect should be better if the theory of differentiation of Zheng and physiology of TCM are followed. Unfortunately the effect in practice, even completely following the differentiation of Zheng, is not as good as the theoretical one. There should have some reasons to explain the difference between theoretical and clinical effects in TCM practice.

As summarized, there are two questions about the therapeutic problem in medical science. One is why is there difference between the pharmacological and clinical effects in modern medicine? The other is why is there difference between the theoretical and clinical effects in traditional Chinese medicine?

The questions refer to that there are some shortages of therapeutic approach both in modern medicine and in traditional Chinese medicine.

Any disease (morbidity) could contain two parts of appearance. One is the so-called specificity to the realities of morbidity, such as the pathological change. The other is the non-specificity that refers to the reactions caused by interactions between personal physique and environments, such as heterogeneous manifestations. Modern medicine is aimed to explore the specificity of morbidity, while traditional Chinese medicine is mainly aimed to explore the reality of the morbidity by checking the external appearance (that is the differentiation of Zheng). It is believed that the non-specificity sometimes could influence or change the process of morbidity, and only targeting the specificity is not enough to stop the progress of morbidity^[4].

Disease mainly refers to the specificity of cause and pathology with less emphasis on the non-specificity. Non-specificity includes all symptoms and signs not directly induced by the specific cause and pathology. Usually the specificity decides the process of diseases. Drugs in modern medicine are targeting the specific cause and pathology, and it usually gives good effect even though the effect is not as good as the pharmacological effect. Since the specific cause and pathology cannot be found in all diseases, the effect of modern drugs depends on whether the cause and pathology are clear or not. In reality, modern drugs are good at curing those diseases with clarified cause and pathology, and not good at curing those diseases due to multiple factors in the pathogenesis, which have become more common in medical science.

However, whenever the non-specificity influences on the specificity, drugs targeting the specificity have no good effect. That is the main reason why modern drugs sometimes are not effective in some cases in the treatment of a disease with a clarified cause and pathology.

Zheng mainly refers to the non-specificity and part of specificity that is only obtained from symptoms and signs by asking, watching and feeling since there are no modern diagnostic instruments. Chinese herbal medicine, based on the Zheng which is taken as an outcome of differentiation of symptoms and signs, targets to the non-specificity and part of the specificity. The effect of herbal medicine is not so good in curing a disease with specific signs, which can be only obtained

by modern diagnostic instruments since Zheng does not refer to those signs. However, the effect of herbal medicine is better in treating some cases when the non-specificity decides the process of a disease. Thus, the reason why there is a difference between the theoretical effect based on Zheng differentiation and the clinical effect is that Zheng differentiation can not exactly differentiate the specificity of a disease.

COMBINING ZHENG WITH DISEASE: NEW STRATEGY IN THERAPEUTIC APPROACH

Following TCM Zheng theory, different diseases may be treated by a same therapeutic approach if they show same Zhengs. One herbal preparation can be used to treat different diseases, a common phenomenon in TCM. Similarly, the same disease may be treated by different therapeutic approaches if the disease shows different Zhengs. It is common in TCM that one kind of disease is treated with different therapies. As mentioned above, Zheng is the outcome of differentiation of symptoms and primary signs obtained by getting from watching (tongue watching) and feeling (pulse feeling), and definitely Zheng is not so accurate. The following example can be used to explain the shortage of Zheng information. Gastritis and stomach cancer could show similar symptoms and primary signs, suggesting that they could be differentiated as the same Zheng in TCM, and could be treated by the same TCM approach. The effect, there is no doubt, should be different since stomach cancer is difficult to be cured by herbal medicine. Thus, the differentiation of Zheng would not give any good effect when the specificity is not clarified resulting from the decisive factor in the evaluation of effects.

It was reported that the effects of two herbal preparations that targeted on coronary heart disease with different Zhengs were at least partially dependent on the Zhengs. The results showed that for coronary heart disease cases with Qi deficiency, Zheng could be alleviated by herbal medicine to reinforce Qi deficiency at effective rate of 89%, while the cases could be alleviated by herbal medicine targeting coronary heart disease and nourishing Yin at effective rate of 60%. For the coronary heart disease cases with Yin deficiency, Zheng could be alleviated by herbal medicine to nourish Yin at the effective rate of 87%, while the cases could be alleviated by herbal medicine to reinforce Qi at effective rate of 65%. Thus, the differentiation of Zheng plays an important role in the therapeutic process and affects the therapeutic result of a specific disease.

Following the disease theory there should have a specific therapy targeting the specific cause, pathology and location. If the specificity is clarified, the disease would be cured. Actually, there might not be so good effect in alleviating some diseases or symptoms even the specificity is clarified. The reason is that the non-specificity influences the specificity. Thus, targeting the specificity of a disease may not result in a good effect or give no effect at all when the non-specificity is decisive in the effect evaluation. The example about drugs in lowering blood pressure would be helpful to explain the reason. In patients with hypertension, there are some good drugs in decreasing blood pressure, and the real thing is that there always have some cases showing any effect after taking drugs. The partial reason is that, in some cases of hypertension, the non-specific appearance could play a key role in influencing the effect of

drugs. At this point, new anti-hypertension drugs for the cases in which the non-specificity is a decisive factor need to be developed.

Combining the differentiation of Zheng with diagnosis of disease, which is combining herbal medicine mainly targeting non-specificity with modern drugs targeting the specificity, would achieve the best therapeutic effect.

Many clinical studies have shown that combining modern drugs with herbal medicine would dominantly increase the effect. For example, the effect rate in treating coronary heart disease with modern drugs (routine therapy) was 45.5%, while combining with herbal medicine it was up to 87.3%^[5]. The importance is to explore how to combine the two therapies.

More double-blinded clinical trials need to be conducted, both for modern drugs and herbal medicine. All specific and non-specific information needs to be collected for further analysis.

Any new drug, even targeting the exact specific pathology, does not act on all cases of diseases since the effect of non-specificity may affect the process of pathogenesis. Any herbal medicine originating from the exact differentiation of Zheng does not act on all cases with Zheng since lack of enough specificity may lose the decisive factor in the treatment.

After the information about new drug classification is obtained, the best effect could be achieved by either combination of drugs targeting the specificity with herbal medicine targeting the non-specificity, or by complex new drug development focusing both on specificity and non-specificity.

TCM focuses on the integrity of human body and the close relationship with its social and natural environments. It recognizes human physiology by analyzing external information by system discrimination and cybernetic approach, and regards that any disorders are caused by the disturbance in any part of the self-controlled system in the integrity. In therapeutics, TCM targets the non-specificity and part of specificity by natural ways.

Why modern drugs cannot achieve the effect as the pharmacological study and the same effect in a same disease is that Zheng in TCM contributes to the progress of a disease. It is important to clarify that in what situation drugs targeting the disease specificity would be effective and how to make the drug become more effective.

Abstract

Cytomegalovirus (CMV) remains one of the most frequent viral infections and the most common cause of death after liver transplantation (LT). Chronic allograft liver rejection remains the major obstacle to long-term allograft survival and CMV infection is one of the suggested risk factors for chronic allograft rejection. The precise relationship between cytomegalovirus and chronic rejection remains uncertain. This review addresses the morbidity of cytomegalovirus infection and the risk factors associated with it, the relationship between cytomegalovirus and chronic allograft liver rejection and the potential mechanisms of it.

Gao LH, Zheng SS. Cytomegalovirus and chronic allograft rejection in liver transplantation. *World J Gastroenterol* 2004; 10(13): 1857-1861

<http://www.wjgnet.com/1007-9327/10/1857.asp>

INTRODUCTION

Chronic allograft liver transplantation, also termed vanishing bile duct syndrome (VBDS), develops slowly over a period of months or years and is a main cause of late graft loss. In fact, the onset is usually within several months after transplantation. Diagnostic criteria for chronic rejection are (1) the presence of bile duct atrophy/pyknosis, affecting the majority of bile ducts, with or without bile duct loss; (2) convincing foam cell obliterative arteriopathy; or (3) bile duct loss affecting greater than 50% of the portal tracts^[1]; (4) total fibrous obliteration of main portal vein and portal foam cell venopathy^[2]. Risk factors for chronic liver rejection include transplantation for primary sclerosing cholangitis (PSC)^[3], primary biliary cirrhosis (PBC)^[4], certain patterns of HLA match between donor and recipient^[5-7], positive lymphocyte cross-match^[8], cytomegalovirus infection, transplantation between donor and recipient of different ethnic origins^[9], sex mismatch^[10], and absence of azathioprine from the immunosuppressive regimen^[11]. Not all these risk factors have subsequently been confirmed. Cytomegalovirus infection is one of the suggested risk factors for chronic allograft liver rejection. Some results showed there was no direct correlation between them, others demonstrated CMV infection somehow implicated in mechanisms of chronic rejection and played a key role in the pathological changes of atrophy of bile duct and generation of graft arteriosclerosis, characteristic of chronic rejection.

The review addresses several questions. First, CMV infection and risk factors associated with it in liver transplantation. Second, CMV infection and cytokines. Third, relation between CMV infection and chronic liver rejection, potential etiological mechanism of CMV infection in chronic liver transplantation. Is the actual incidence of CMV infection a cause of VBDS?

CMV INFECTION AND RISK FACTORS

Human cytomegalovirus (HCMV) infection occurred in 30-65% of liver transplantation recipients, of which 18-40% were symptomatic infection and mostly developed 1 to 3 mo after transplantation. HCMV infection has two pathways: primary infection and infection activated by latent infection. Many factors are involved in HCMV infection. A prospective study of 218 LT recipients by Paya CV showed that 55% of patients developed CMV infection during the 1st year post-transplantation^[12]. Symptomatic CMV infection developed in 25% of all patients, being a major cause of death (21% of all deaths). Of the 62 episodes of documented organ invasion, liver was the major site (38 episodes), followed by lung, gastrointestinal tract and retina. Multivariate statistical analysis of risk factors indicated that the R-/D+ group was the main risk factor for CMV infection and symptomatic infection. Use of antilymphocyte preparations, retransplantation, donor CMV seropositivity, use of antilymphocyte preparations, and retransplantation were risk factors for the development of CMV diseases following liver transplantation^[13]. A higher incidence of cytomegalovirus infection was seen in the liver recipients of alcoholic sclerosis^[14]. Intraoperative hypothermia during liver transplantation increased the risk of CMV infection in the 1st month postoperation and active warming seemed to reduce this risk^[15]. Early application of OKT-3 was the risk factor for development of spreading HCMV diseases; FK506 could reverse rejection effectively, but increased the incidence of HCMV diseases^[16]. Others found that immunosuppressant FK506 after liver transplantation augmented inducible NK cell activity and alleviated CMV infection^[17]. Among immunosuppressive drugs, only anti-interleukin-2Rab was proved to significantly reduce the incidence of CMV^[18]. The role of antirejection therapy may be particularly important, since it could suppress CMV specific cytotoxic T-cell responses and result in prolonged viraemia, which in turn could cause a prolonged alloreactive cytotoxic response. HCMV infection is associated with human herpesviruses (HHV) 6 and 7. Lautenschlager *et al.*^[19] analyzed it in consecutive 34 adult liver allograft recipients, CMV disease was diagnosed in 12 patients, in which 10 patients had concurrent HHV-6 infection and 9 had HHV-7 infection. A prolonged prothrombin time, acute fulminant hepatitis diagnosed as the underlying liver disease and hepatic artery thrombosis were found to be significant risk factors for CMV infection^[20]. Total number of units of blood transfusion and transfusion of seropositive CMV blood had no effect on primary CMV infection after liver transplantation, though it had an influence on the severity of CMV infection and seropositive CMV recipients. The study about the effect of cytomegalovirus infection status on the first-year mortality among orthotopic liver transplantation recipients showed^[21]:

seronegative donors and recipients (11%), seronegative donors and seropositive recipients (22%), seropositive donors and recipients (30%), and seropositive donors and seronegative recipients (44%). Multivariate analysis showed that retransplantation, total number of units of blood products administered during transplantation, CMV infection and bacteremia were associated with higher mortality rates. Thus donor and recipient CMV serologic status is a significant pretransplantation determinant for death in liver transplant recipients.

HCMV INFECTION AND CYTOKINES

The significance of some cytokines highly expressed in grafts and blood serum after liver transplantation with HCMV infection remains unknown. Vascular adhesion molecules and their ligands are important both in leukocyte-endothelial cell interactions and in T-cell activation of rejection cascade. A significant induction of intercellular adhesion molecule-1 and vascular cell adhesion molecule-1 was seen in vascular and sinusoidal endothelium associated with both CMV and rejection, and induction of endothelial leukocyte adhesion molecule-1 in vascular endothelium was seen in rejection only. In both cases, the number of leukocytes expressing leukocyte function antigen-1 was significantly increased, but very late antigen-4-positive cells were more characteristic for CMV^[22]. IL2-receptor (IL2R) positivity was practically seen in rejection only, but both IL2R and CD8 were increased in cytomegalovirus hepatitis. Simultaneously increased IL2R and CD8 may mean the development of cytomegalovirus hepatitis on the basis of acute rejection. Vascular adhesion protein-1 (VAP-1), an adhesion molecule involved in lymphocyte adhesion, was up-regulated in acute liver rejection of sinusoids, hepatocytes in bile duct and this up-regulation was prolonged by RCMV infection^[23]. Thus the severity of acute rejection was intensified. Tumor necrosis factor- α (TNF- α) plays a key role in regulating reactivation of CMV infection. TNF- α could activate CMV-IE enhancer and result in high CMV-IE antigen expression in peripheral blood mononuclear cells particularly in monocytes. Increased tumor necrosis factor- α (TNF- α) could lead to occurrence of cachexy after CMV infection and mediate development of vanishing bile duct syndrome. Inhibition of TNF- α release or action might be an alternative strategy for preventing CMV-associated morbidity in allograft recipients^[24].

CMV-IE protein could activate transforming growth factor- β 1 (TGF- β 1) promotor during CMV infection and result in early high expression of TGF- β 1 mRNA^[25]. In chronic human allograft rejection, increased infiltrated macrophages and up-regulated platelet-derived growth factor (PDGF), fibroblast growth factor (FGF) could lead to transformation of lipocytes to myofibroblast-like cells, which would lead to increase secretion of extracellular matrix and were engaged in hepatic fibrosis^[26]. TGF- β 1 increased levels of FGF and FGF receptor mRNAs in myofibroblast cells and expression levels of PDGF mRNA^[27]. Thereafter CMV infection may implicate in chronic rejection by secretion of chronic fibroblast factors. Whether by regulating some of the cytokines which were thought to be involved in chronic rejection, skewing of immunity towards Th2 cytokines (TGF- β , IL-4, IL-10) and humoral response, expression of adhesive molecules and antigens can be induced in graft, to mediate occurrence of chronic rejection, needs further research.

HCMV INFECTION AND CHRONIC REJECTION IN TRANSPLANT LIVER

Many studies have demonstrated a close relationship between HCMV infection and chronic liver rejection. Analysis of ten

liver transplants whose graft was lost due to histologically confirmed chronic rejection showed^[28] that there was at least one episode or many times of rejection early after transplantation. All patients had a history of CMV infection usually following acute rejection. Persistent CMV-DNA was found in all of those grafts examined by DNA-hybridization *in situ*, CMV-DNA was strongly expressed in the remaining bile ducts and moderately expressed in endothelial cells of the vascular structures. Persistent CMV genome was found in those structures that were the major targets of chronic rejection process in the liver. These findings support the suggestion that CMV infection is one of the risk factors for chronic allograft rejection. Arnold *et al.*^[29] found that CMV-DNA was identified in hepatocytes in 10 of 12 patients with VBDS, of whom 1 had no serological evidence of CMV infection, 9 developed cytomegalovirus infection at 1 wk until death or retransplantation. Cytomegalovirus DNA was identified in hepatocytes and never identified in either biliary or endothelial tissue. CMV-DNA was identified in all 18 patients with HCMV infection but no bile duct was injured. However in those with uncomplicated cytomegalovirus, infection occurred earlier but was eliminated more quickly, and the number of infected hepatocytes was greater when compared with those with vanishing bile duct syndrome. The data indicated that vanishing bile duct syndrome was associated with persistent cytomegalovirus replication within hepatocytes. Further study showed^[30] that interferon- α (IFN- α) was identified more frequently and patients developed VBDS after a longer period in the bile duct cytoplasm compared with those with acute HCMV infection without evidence of VBDS. These indicate that persistent CMV infection of bile duct cells resulting in increased IFN- α is likely a co-factor linked to progression to VBDS. Martelius *et al.*^[31] performed liver transplantations in a rat strain combination with PVG (RT1c) \rightarrow BN (RT1n). One group of animals was infected with RCMV intraperitoneally. They found in liver allografts undergoing acute rejection, CMV significantly increased portal inflammation and caused more severe bile duct damage linked to the induction of VCAM-1 in endothelial cells. The ongoing infection was found to vary over time in different structures of liver grafts. These results support an association between CMV infection and the immunological mechanisms of rejection, as well as the role of CMV in the development of bile duct damage in liver allografts. In the same rat strain combination, Martelius *et al.*^[32] examined CMV infection of the graft at various time points and found that rat cytomegalovirus (RCMV) caused an active infection in the graft from 5 d to 2 wk after transplantation. Thereafter the cultures were negative. RCMV antigens and DNA were found in hepatocytes, endothelial, inflammatory, and bile duct cells during the active infection. At 4 wk, RCMV DNA positive cells decreased. IE-1 mRNA expression was, however, only detected during the active infection, but not at 4 wk postinfection. They concluded the CMV-induced graft damage did not require the continued expression of IE-1. Halme *et al.*^[33] demonstrated that CMV infection was a risk factor for development of biliary complication after liver transplantation.

A variety of risk factors for VBDS have been postulated, but they are controversial. O'Grady *et al.*^[34] confirmed A 1-2 antigen matched for HLA DR antigens, a zero matched for HLA A/B antigens, and active CMV infection were independently associated with an increased risk of VBDS. Hoffmann *et al.*^[35] examined 120 liver transplants retrospectively and analyzed the risk factors for VBDS. Ten patients (8.3%) developed VBDS. Seventeen patients had hepatitis C virus infections after liver transplantation. In this group, the incidence of VBDS was the highest (4 of 17, or 23.5%) and reached statistical significance. They found hepatitis C infection predisposed one to the development of VBDS after OLT.

The potential mechanisms of CMV cause VBDS. (1) Virus itself directly destroys or liquefies the infected structure. (2) Cytotoxic T lymphocyte plays a role in inducing VBDS. CMV infection may trigger an immune response by inducing MHC antigens and adhesion molecules on the bile ductal cell surface and make the ductal cells a target for immunological attack. For example, a cross-reaction between the viral protein and MHC molecules is possible because CMV has been shown to code a protein homologous to MHC class I antigen^[36], and a CMV IE₂ protein has been found to share an epitope with the HLA-DR β chain^[37]. CMV is known to increase expression of class II human leukocyte antigens on bile duct epithelial cells. After immune recognition of these foreign antigens by host antigen-presenting cells, CD₄⁺T would release cytokines and stimulate differentiation and proliferation of cytotoxic T cells (CD₈⁺T). The activated CD₈⁺T then plays a immune killing role. CMV has been shown to induce proinflammatory cytokines, such as IFN- γ and TNF- α , which could lead to other immunological events. (3) Dystrophy and ischemic sequelae caused by obliterative arteriopathy. Although CMV-DNA can not be detected on some bile duct epithelial cells in VBDS, CMV might play a pathogenetic role in the development of VBDS^[38]. The sequelae of clearing infection, host immune response would selectively kill these bile duct epithelial cells with CMV infection. CMV infection of hepatocytes would in some way up-regulate the expression of HLA antigens on biliary epithelial cells. CMV viral antigens are present and bound to HLAs on the surface of bile duct cells. So even though CMV was cleared *in vivo*, they could exhibit their episode role.

Few studies about the relation of CMV infection and angiopathy are available. Grefte *et al.*^[39] demonstrated that in patients with active CMV infection, distinctive large cells were present in peripheral blood. Moreover, these cells were shown to express CMV antigens and to have endothelial origin with immunologic staining, indicating an association between CMV infection and widespread occult vascular damage. CMV-induced endothelial damage may be a potent antigenic stimulus, leading to the production of anti-endothelial cells autoantibodies. Anti-endothelial cell autoantibodies may represent not only a marker of cell injury but also contribute to the progression of inflammatory response leading to the exposure of tissue-privileged self-antigens and induction of other autoantibodies such as SMA. These would further aggravate pathological damages. Analysis of autoantibody was carried out in sequential sera from 40 liver transplantation patients by Varani *et al.*^[40]. Ten out of 23 antigenemia-positive and none of antigenemia-negative patients developed serum autoantibodies. Anti-endothelial cell autoantibodies were found in 9 cases and SMA in 4 patients. Antinuclear antibodies were detected in 1 autoantibody-negative patient. All but 1 case of autoantibody positivity were observed in the high antigenemia group and detected in blood during the antigenemia phase and in most cases in coincidence with or after the antigenemia peak.

In the arteries of an allografted organ, endothelial injury may arise from immune injury, ischemia/reperfusion injury, and injuries due to dyslipidemia, hypertension, or infectious agents. The injured endothelial cells can elaborate small molecules and cytokines that can activate macrophages and smooth muscle cells to express functions that may contribute to arterial lesion formation. The precise immunological mechanisms underlying chronic vascular rejection are unknown. Three potential effector mechanisms have been implicated in allograft rejection^[41]: alloreactive CD₄⁺ cytokine-producing "helper" T (TH) lymphocytes, alloreactive CD₈⁺ cytolytic T lymphocytes (CTL), and alloreactive antibodies (produced by B lymphocytes). Chronic delayed-type hypersensitivity mediated by host CD₄⁺ T cells activated by graft alloantigens presented directly by graft endothelial and

dendritic cells or indirectly by host dendritic cells, is likely a candidate. All of which contribute to atherosclerotic vascular disease, and chronic vascular rejection.

CMV infection might directly increase MHC antigens on the surface of graft cells through the induction of release of mediators such as interferon and may activate cytotoxic T cells, which can trigger acute rejection in association with concurrent alloantigen stimulation. Acute rejection results in a generalized inflammatory response. Kas-Deelen and colleagues have postulated that the occurrence of acute rejection at the allograft site could sensitize the endothelial surface of the host to CMV-induced damage^[42]. These endothelial cells then became a target for alloreactive T cells. According to these *in vitro* studies, even a few CMV-infected endothelial cells in a transplanted organ might trigger autoreactivity^[43]. CMV infection enhances several steps, with ensuing chronic rejection. Endothelial adhesion molecule expression, in particular, could provoke influx of inflammatory cells and smooth muscle cell proliferation. In addition, CMV infection could induce vascular wall changes resembling fatty streaks reported in the early stages of classic atherosclerosis^[44].

There is still a controversy concerning the relationship between CMV infection and chronic allograft rejection. Paya *et al.*^[45] studied 81 liver transplant recipients and found that cytomegalovirus infection developed in 46 recipients (57%), and VBDS occurred in 9 recipients (11%). CMV infection developed in only 5 of the 9 patients with VBDS. Univariate analysis of pretransplantation recipient/donor CMV serological tests and human leukocyte antigen typing showed they were not significant risk factors for the development of VBDS. The data indicated no association was found between CMV infection alone or in relation to class I or II human leukocyte antigen match and the subsequent development of VBDS. van den Berg *et al.*^[46] in a retrospective study confirmed there was no association among CMV infection, HLA-DR and VBDS. Wright TL in an editorial postulated that CMV was indeed an innocent bystander rather than a culprit. In the pathogenesis of VBDS, it is the immune responsiveness of the patient that is important. It is quite possible that patients with VBDS have an inherent defect in immune response that allows persistence of CMV infection, and CMV is unrelated to destruction of bile ducts. On the other hand, if CMV infection is really an etiological factor for VBDS, antiviral therapy would be effective in decreasing incidence of the chronic rejection. Unfortunately, many studies about antiviral therapy for CMV failed to show an association between the development of CMV disease and the occurrence of rejection^[47].

CONCLUSION

Many studies have demonstrated a close association between CMV infection and chronic allograft liver transplantation, but it did not prove an etiological role for the virus in this syndrome. CMV infection may be one of the risk factors for development of VBDS. A better understanding of the etiologic role of CMV in VBDS, is important for designing effective therapeutic strategies to ameliorate this process.

Abstract

AIM: To assess the expression of cyclooxygenase-2 (COX-2), nitric oxide synthase (iNOS), p53 and Ki-67 in gastric mucosa-associated lymphoid tissue (MALT) lymphoma and clarify the relationship between COX-2 expression and iNOS or p53 expression in these patients.

METHODS: The expressions of COX-2, iNOS, p53 and Ki-67 were detected in 32 gastric MALT lymphoma specimens and 10 adjacent mucosal specimens by immunohistochemical Envision method.

RESULTS: COX-2 and iNOS expressions were significantly higher in gastric MALT lymphoma tissues than those in adjacent normal tissues. The expression of COX-2 was observed in 22 of 32 cases of MALT lymphoma tissues (68.8%). A positive cytoplasmic immunoreactivity for iNOS was detected in 17 of 31 cases (53.1%). COX-2 expression in gastric MALT lymphoma tissues was positively correlated with iNOS expression ($r=0.448$, $P=0.010$) and cell proliferative activity analyzed by Ki-67 labeling index ($r=0.410$, $P=0.020$). The expression of COX-2 protein did not correlate with age, sex, stage of disease, lymph node metastasis or differentiation. The accumulation of p53 nuclear phosphoprotein was detected in 19 (59.4%) of tumors. p53 protein was expressed in 11 of 23 assessed LG tumors and in 8 of 9 assessed HG tumors. The difference of p53 positivity was found statistically significant between LG and HG cases ($P=0.0302$). The p53 accumulation correlated with advanced clinical stage (stage III+IV vs stage I+II, $P=0.017$). There was a significant positive correlation between COX-2 expression and p53 accumulation status ($r=0.403$, $P=0.022$). The mean PI of Ki-67 in each grade group were $36.0 \pm 7.73\%$ in HG and $27.4 \pm 9.21\%$ in LG. High-proliferation rate correlated with HG tumors ($r=0.419$, $P=0.017$). The correlation coefficient showed a significant positive correlation between PI and COX-2 expression in MALT lymphoma patients ($r=0.410$, $P=0.020$).

CONCLUSION: COX-2 expresses in the majority of gastric MALT lymphoma tissues and correlates with cellular proliferation and iNOS expression. COX-2 overexpression is closely associated with p53 accumulation status. iNOS and COX-2 may play a synergistic role in the pathogenesis of gastric MALT lymphoma.

INTRODUCTION

Lymphomas of mucosa-associated lymphoid tissue (MALT) are a distinct subgroup of extranodal B-cell non-Hodgkin's lymphomas. Gastric MALT lymphomas are the majority of the cases and account for 1-10% of all gastric malignant neoplasms^[1]. Epidemiological and clinical studies demonstrated a link between gastric MALT lymphoma and chronic infection with *Helicobacter pylori* (*H. pylori*)^[2,3]. Cyclooxygenase-2 (COX-2) and nitric oxide synthase (iNOS) are important enzymes that mediate inflammatory processes. In recent years, it has been demonstrated that both COX-2 and iNOS play important roles in various tumors, including gastric MALT lymphoma^[4,5]. COX-2, a key isoenzyme in conversion of arachidonic acid to prostaglandins, is inducible by various agents such as growth factors and tumor promoters, and is frequently overexpressed in various tumors^[6,7]. iNOS are isoenzymes that catalyze the synthesis of nitric oxide (NO). Overexpression of iNOS has been demonstrated in various human neoplasms, such as breast cancer^[8], colorectal cancer^[9], and gastric cancer^[10]. The p53 tumor suppressor protein is a critical mediator of apoptosis and tumorigenesis. Although studies have suggested interactions between COX-2 and iNOS or p53 in different tumors, the relationship between COX-2 expression and a variety of other molecular markers of tumor progression has not been reported for gastric MALT lymphomas. In the present study, we conducted to determine the expressions of COX-2, iNOS and p53 expression as well as cell proliferative index (Ki-67) in 32 gastric MALT lymphomas by using immunohistochemistry.

MATERIALS AND METHODS

Specimens

Thirty-two gastric MALT lymphoma specimens and 10 adjacent specimens were obtained from surgical resection. The patients underwent surgery at Xijing Hospital of the Fourth Military Medical University (Xi'an, China) between January 1996 and September 2002. The tumor specimens were retrieved from the archives of the Department of Pathology, Xijing Hospital. The mean age of the gastric MALT lymphoma group was 52.8 years (range 29-70 years), and there were 22 males and 10 females. All cases were of B-cell origin as immunohistochemistry showed CD20 expression in all MALT cases. The cases were categorized in two basic groups, according to (REAL) Classification^[11] and the WHO Classification^[12] for MALT lymphomas: low-grade lymphoma of MALT (composed of centrocyte-like cells, lymphoid follicles and plasma cell differentiation) and high-grade lymphoma of MALT (diffuse large B cell lymphoma (DLBCL) with or without low grade MALT +lymphoma component). Of the 32 patients, 23 were low grade MALT lymphoma (LG) and 9 high grade MALT lymphoma (HG). Patients were staged according to the Ann Arbor system. All specimens

were fixed in 40 g/L buffered formaldehyde, and embedded in paraffin wax.

Immunohistochemical assay for expression of COX-2, iNOS, p53 and Ki-67

The expression of COX-2, iNOS, p53 and Ki-67 was studied by immunohistochemical Envision method according to the manufacturer's instructions. H-62 (COX-2) is a rabbit polyclonal antibody raised against a recombinant protein corresponding to amino acids 50-111 mapping near the amino terminus of COX-2 of human origin (sc-7951, Santa Cruz Biotechnology, dilution 1:50). M-19 (iNOS) was provided as a rabbit affinity-purified polyclonal antibody raised against a peptide mapping at the carboxyl terminus of iNOS of mouse origin (sc-650, Santa Cruz Biotechnology, dilution 1:50). The Ki-67 antibody recognizes the Ki-67 antigen of paraffin-embedded tissues. To detect the p53 protein, a mouse monoclonal antibody (sc-126, Santa Cruz Biotechnology, dilution 1:50) was used which recognizes an epitope in the N-terminus of the human p53 protein. Staining for Ki-67 was performed by using an anti-Ki-67 monoclonal mouse antibody (ZM-0166, Zhongshan Biotechnology, dilution 1:50). Briefly, 5- μ m sections cut from formalin-fixed, paraffin-embedded specimens were deparaffinized in xylene and rehydrated in graded alcohol. For antigen retrieval, the deparaffinized slides were microwaved in 0.01 mol/L sodium citrate buffer (pH 6.0) for 10 min. Endogenous peroxidase activity was then blocked by incubating the sections with 30 mL/L H₂O₂ in 0.05 mol/L phosphate buffer (pH 7.4), containing 0.45 mol/L NaCl for 15 min. Non-specific antibody binding was blocked by pretreatment with PBS containing 5 g/L bovine serum albumin. The sections were then incubated with the primary antibodies diluted as described above. After incubation, these sections were washed with 0.02 mol/L sodium phosphate buffer. The slides were then incubated with a secondary antibody for 30 min. Diaminobenzidine was used as chromogen and the sections were counterstained with hematoxylin. Negative controls were established by replacing the primary antibody with PBS.

Assessment of immunohistochemical results

The slides were evaluated independently by two observers who were unknown to the histological status. At the cellular level, COX-2 and iNOS staining was cytoplasmic in most cases, however, p53 and Ki-67 staining was nuclear. COX-2 is cytoplasmic enzyme detectable in tumor cells, epithelial cells, endothelial cells, smooth muscle cells and inflammatory cells. For final analysis, the expression of COX-2 was scored in the tumor cells. Staining for COX-2 and iNOS was considered positive only when more than 10% of the tumor cells in the entire tumor area were judged to be positive. The level of p53 was calculated by expressing the number of p53-positive cancer cells as a percentage of the total number of cancer cells in a high-power field. For analysis, tumors were classified as p53-negative (less than 10% positive nuclei) or p53-positive (more than 10% positive nuclei). The Ki-67 labeling index (proliferation index, PI) was determined by counting the percentage of positive cells among 1 000 tumor cells in 10 random regions in 400-fold fields.

Statistical analysis

Statistical comparisons for significance were made with the Student's *t* test and Chi-square test. Spearman correlation test was used for the correlation between positive rates. A *P* value <0.05 was considered statistically significant.

RESULTS

Expression of COX-2 and iNOS in gastric MALT lymphoma

The expression of COX-2 was observed in 22 of 32 cases of MALT lymphoma tissues (68.8%). Immunohistochemically, COX-2 was stained diffusely in cytoplasm of the tumor cells (Figure 1A). In contrast, no or very faint signal was found in neighboring normal tissues. A positive cytoplasmic immunoreactivity for iNOS was detected in 17 of 31 cases (53.1%, Figure 1B). However, no staining could be observed in neighboring normal tissues.

There was a significant correlation between COX-2 and iNOS expression ($r = 0.448$, $P = 0.010$). The positive expression

Figure 1 Results of immunohistochemical staining (Original magnification: $\times 400$). A: Expression of COX-2 in gastric MALT lymphoma; B: Expression of iNOS in gastric MALT lymphoma; C: Expression of p53 in gastric MALT lymphoma; D: Expression of Ki-67 in gastric MALT lymphoma.

rate of iNOS (88.2%) in the COX-2 positive group was significantly higher than that in the COX-2-negative group (46.7%, $P=0.011$).

Correlation between COX-2 expression and clinicopathological factors

The correlation between COX-2 expression and the clinicopathologic findings was analyzed by Spearman correlation test. All the parameters analyzed in COX-2 positive cases, including age, gender, stage of disease, lymph node metastasis and differentiation degree of the tumor, did not reached statistical significance ($P>0.05$, Table 1).

Expression of p53 in gastric MALT lymphoma

The accumulation of p53 nuclear phosphoprotein was detected in 19(59.4%) of tumors (Table 1, Figure 1C), whereas the p53 accumulation was undetectable in normal gastric tissues. A relationship between p53 status and several clinicopathological characteristics was investigated. p53 protein was expressed in 11 of 23 assessed LG tumors and in 8 of 9 assessed HG tumors. The difference of p53 positivity was found statistically significant between LG and HG cases ($P=0.033$). The p53 accumulation correlated with advanced clinical stage (stage III+IV vs stage I+II, $P=0.017$). The other parameters, such as age, gender and lymph node metastasis did not show any significant relation to the expression of p53.

There was a significant positive correlation between COX-2 expression and p53 accumulation status ($r=0.403$, $P=0.022$). Tumors that overexpressed p53 had higher expression levels of COX-2 than those without p53 overexpression ($P=0.022$, Table 1).

Expression of Ki-67 in gastric MALT lymphoma

Ki-67 staining was nuclear (Figure 1D). Very few cells were positive for Ki-67 in non-neoplastic gastric tissues. The mean PI of Ki-67 in the tumors was $29.81\pm9.54\%$ (mean \pm SD). Mean values in each grade group were $36.0\pm7.73\%$ in HG and $27.4\pm9.21\%$ in LG. A significant correlation was observed between the high-proliferation rate and HG tumors ($r=0.419$, $P=0.017$).

The PI in COX-2 positive group was significantly higher than that in COX-2 negative group ($P=0.031$). The correlation coefficient showed a significant positive correlation between PI and COX-2 expression in MALT lymphoma patients ($r=0.410$, $P=0.020$). However, no significant correlation between PI and iNOS expression was found ($r=-0.037$, $P=0.839$).

Table 1 Correlation between expression of COX-2 and iNOS/p53 and clinicopathological factors in gastric MALT lymphoma (n, %)

Variable		Total	COX-2 positive	COX-2 negative	P value
Gender	Male	22	15(68.2)	7(31.8)	0.918
	Female	10	7(70.0)	3(30.0)	
Age (yr)	≤ 50	9	6(66.7)	3(33.3)	0.874
	> 50	23	16(69.6)	7(30.4)	
Lymph node	+	10	8(80.0)	2(20.0)	0.355
Metastasis	-	22	14(63.6)	8(36.4)

DISCUSSION

Gastric MALT lymphoma is a unique disease. Normal human gastric mucosa is devoid of MALT. MALT accumulates within gastric mucosa as a result of long-standing *H pylori* infection in a subset of infected patients, and from this acquired MALT, low-grade B cell MALT lymphoma may eventually develop^[13]. *H pylori* can be demonstrated in the gastric mucosa of the majority of cases of gastric MALT lymphoma^[14,15]. Additionally, eradication of *H pylori* was reported to result in the complete regression of the majority of these tumors^[16,17]. However, the exact mechanism responsible for the development of MALT lymphoma still remains obscure.

The contribution of COX-2 to carcinogenesis and the malignant phenotype of tumor cells have been thought to be related to its abilities: (1) increase production of prostaglandins^[18]; (2) convert procarcinogens to carcinogens^[19]; (3) inhibit apoptosis^[20]; (4) promote angiogenesis^[21]; (5) modulate inflammation and immune function^[22,23]; (6) increase tumor cell invasiveness^[24,25]. Like COX-2, iNOS is also involved in the process of carcinogenesis. Sustained induction of iNOS in chronic inflammation may be mutagenic through NO-mediated DNA damage or hindrance to DNA repair, and thus potentially carcinogenic. In addition, NO can favour tumor growth and development by stimulating angiogenesis^[10,26-28] and causing immunosuppression^[29].

In the current study, we demonstrated that a high positive immunostaining rate for COX-2 and iNOS was observed in gastric MALT lymphoma. Our results agree with the findings of previous investigations^[4,5,14,17]. The present results indicated that the increased expression of COX-2 and iNOS might be important molecular events that contribute to gastric MALT lymphoma carcinogenesis. We speculate that *H pylori* infection might induce gastric carcinogenesis via overexpression of COX-2. These processes may be completed by the expression of COX-2 as an inflammation enzyme to release excessive amounts of prostaglandins, leading to further proliferation, reduction in apoptosis, angiogenesis and tumor growth.

It has been reported that COX-2 overexpression in tumors significantly correlates with iNOS overexpression^[4,5]. In the current study, we also discovered that COX-2 expression was positively correlated with iNOS expression, suggesting a link between the COX-2 and iNOS pathways. In addition, iNOS and COX-2 may play a synergistic role in the pathogenesis of gastric MALT lymphoma. Because the product of iNOS catalysis, NO, is an important regulator of COX-2 activity and expression^[30,31], and the products of COX-2 (diverse prostaglandins) may also influence iNOS expression^[32]. Furthermore, prostaglandins and NO have been proposed to be involved in angiogenesis *in vivo*^[33]. The inhibition of NO production by COX-2 inhibitors suggests NO-COX cross-talk between COX-2 and iNOS pathways^[34].

Our results demonstrated that COX-2 expression in MALT lymphoma tissues was positively correlated with cell proliferative activity analyzed by Ki-67 labeling index. Ki-67 is expressed in cells that undergo active proliferation and have left the G₀ phase of the cell cycle^[35]. These results suggest that COX-2 expression may be actively associated with the modulation of cellular proliferation and transformation during the evolution of *H pylori*-associated gastritis to MALT lymphoma.

So far, there have been some ambiguous points with regard to relationships between COX-2 overexpression and clinicopathological characteristics of tumors. Several reports have demonstrated that COX-2 expression in various tumors influences tumor cell differentiation, invasiveness, size, and survival^[36]. However, we found no significant relation between COX-2 expression and clinicopathological characteristics in our study, which was compatible with previous reports on other organs^[37].

Low-grade MALT lymphoma can transform into high-grade lymphoma and is associated with other genetic events such as p53 inactivation^[38,39]. In the current study, p53 positivity increased significantly as the histological grade advanced. The results of our study support the concept that the expression of p53 in gastric lymphomas may be associated with transformation from low-grade to high-grade disease. In addition, there have been many workers reporting that high-proliferation rate is associated with the presence of a large cell component of MALT lymphoma^[40,41]. The results of our experiments showed that high proliferation rate expressed by Ki-67 was correlated with HG tumors. These suggested that high proliferation index in MALT lymphoma may help in identifying a population of patients with an increased risk of developing MALT lymphoma.

Consistent with the findings of others^[40], we found that COX-2 overexpression was closely associated with p53 accumulation status. With regard to the negative regulation of COX-2, it has recently been shown that wild-type p53 suppresses promoter activities of COX-2 and the expression of COX-2 protein. Wild-type p53 was shown to suppress COX-2 promoter activity by competing with TATA-binding proteins^[41]. Han *et al.*^[42] identified that COX-2 expression was inducible by wild-type p53 and DNA damage. They also found that p53-induced COX-2 expression resulted from p53-mediated activation of the Ras/Raf/MAPK cascade, as demonstrated by suppression of COX-2 induction in response to p53 by dominant-negative Ras or Raf1 mutants. Furthermore, heparin-binding epidermal growth factor-like growth factor (HB-EGF), a p53 downstream target gene, induced COX-2 expression, implying that COX-2 is an ultimate effector in the p53→HB-EGF→Ras/Raf/MAPK→COX-2 pathway.

In conclusion, COX-2 is expressed in the majority of gastric MALT lymphoma tissues and correlates with cellular proliferation and iNOS expression. iNOS and COX-2 may play a synergistic role in the pathogenesis of gastric MALT lymphoma. COX-2 overexpression is closely associated with p53 accumulation status. The molecular basis for the expression of COX-2 and iNOS and their roles in the evolution of *H. pylori*-associated gastritis to gastric MALT lymphoma requires to be carefully investigated in follow-up studies.

Abstract

AIM: To investigate the expression of adenovirus-mediated human endostatin (Ad/hEndo) gene transfer and its effect on the growth of hepatocellular carcinoma (HCC) BEL-7402 xenografted tumors.

METHODS: Immunohistochemistry analysis with an anti-endostatin antibody was performed to detect endostatin protein expression in HCC BEL-7402 cells infected with Ad/hEndo. MTT assay was used to investigate the effects of Ad/hEndo on proliferation of human umbilical vein endothelial cells (HUVEC). Intra-tumoral injections of 1×10^9 pfu Ad/hEndo was given to treat BEL-7402 xenografted tumors in nude mice once weekly for 6 wk. Mice received injections of Ad/LacZ and DMEM were regarded as control groups. After intra-tumoral administration with Ad/hEndo, the endostatin mRNA expression in tumor tissue was analyzed by Northern blotting, and plasma endostatin levels were determined using enzyme-linked immunosorbent assay (ELISA).

RESULTS: High level expression of endostatin gene was detected in the infected HCC BEL-7402 cells. Ad/hEndo significantly inhibited HUVEC cell proliferation by 57.2% at a multiplicity of infection (MOI) of 20. After 6-week treatment with Ad/hEndo, the growth of treated tumors was inhibited by 46.50% compared to the Ad/LacZ control group ($t=2.729$, $P<0.05$) and by 48.56% compared to the DMEM control group ($t=2.485$, $P<0.05$). The ratio of mean tumor volume in treated animals to mean tumor volume in the control animals (T:C ratio) was less than 50% after 24 d of treatment. Endostatin mRNA in tumor tissue was clearly demonstrated as a band of approximately 1.2 kb, which was the expected size of intact and functional endostatin. Plasma endostatin levels peaked at 87.52 ± 8.34 ng/mL at d 3 after Ad/hEndo injection, which was significantly higher than the basal level (12.23 ± 2.54 ng/mL). By d 7, plasma levels dropped to nearly half the peak level (40.34 ± 4.80 ng/mL).

CONCLUSION: Adenovirus-mediated human endostatin

gene can successfully express endogenous endostatin *in vitro* and *in vivo*, and significantly inhibit the growth of BEL-7402 xenografted liver tumors in nude mice.

INTRODUCTION

Increasing evidence suggests that solid tumors and their metastasis are angiogenesis dependent^[1]. Angiogenesis, the formation of new microvessels generated by vascular endothelial cells, provides essential nutrition for rapid growth of malignant cells. Without angiogenesis, neoplasm might remain in dormancy^[2]. Anti-angiogenesis therapies, which block the blood supply of a growing tumor by inhibiting proliferation of endothelial cells, provide a new strategy for treatment of solid tumors^[3]. Vascular endothelial cells, the target of anti-angiogenic treatment are genetically stable. So it is unlikely that anti-angiogenic agents would induce the drug resistance^[4].

Transcatheter arterial embolization (TAE) has been widely practiced in the treatment of unresectable hepatocellular carcinoma (HCC)^[5]. However, the obstruction of hepatic artery induces extensive ischemic necrosis or hypoxia which are strongly correlated with increased expression of angiogenic factors, such as vascular endothelial growth factor (VEGF), basic fibroblast growth factor (bFGF)^[6]. The proliferative activity of vascular endothelial cells and tumor cells was increased in residual tumor following arterial embolization^[7]. Combination of antiangiogenesis and TAE therapy could inhibit increased proliferation of vascular endothelial cells and capillary vessel formation induced by arterial embolization, and improve the therapeutic effect^[5].

Endostatin, a carboxyl-terminal proteolytic fragment of collagen XVIII, was regarded as one of the most potent inhibitors of tumor angiogenesis^[8]. Several studies have shown that recombinant endostatin protein generated from *Escherichia coli* and *Pichia pastoris* yeast significantly inhibited growth and metastasis of xenografted tumor in different tumor models with no drug resistance and side effects^[9,10]. However, its widespread application has been hampered by difficulties in the large-scale production of high bioactive protein^[11,12].

In this study, we constructed a replication-defective recombinant adenoviral vector harboring a human endostatin gene (Ad/hEndo), and demonstrated efficient expression of endostatin gene *in vivo* and its antitumoral effect on BEL-7402 xenografted liver tumors in nude mice.

MATERIALS AND METHODS

Materials

Cells and adenoviruses BEL-7402 cells (Hepatocellular

carcinoma, HCC) and human umbilical vein endothelial cells (HUVEC) were maintained in RPMI 1640 supplemented with 100 mL/L fetal bovine serum (FBS). The culture medium contained 100 U/mL of penicillin and 100 µg/mL of streptomycin (GIBCO BRL, Gaithersburg, MD).

Recombinant adenovirus vectors carrying the human endostatin gene (Ad/hEndo) and *LacZ* gene (Ad/*LacZ*) were generated as described previously^[12,13]. All virus particles were amplified in 293 cells and purified by cesium chloride gradient centrifugation. Viruses were titered using a standard plaque-forming unit (pfu) assay.

Animals Four to 6-week-old male BALB/c nude mice (with body weight of 19 to 23 g) were purchased from Animal Experiment Center (Medial College, Sun Yat-sen University) and maintained in a specific pathogen-free (SPF) environment (certificate: 26-99S029).

Agents Human endostatin protein accucyte EIA (Oncogene Research Products, Boston, MA), rabbit anti-human endostatin polyclonal antibody (Chemicon International, Temecula, CA).

Methods

Immunohistochemistry for expression of endostatin protein *in vitro* BEL-7402 cells were infected with Ad/hEndo at a multiplicity of infection (MOI) of 10. At 2 h postinfection, the medium was replaced with Dulbecco's minimal essential medium (DMEM) containing 100 mL/L FBS. After 72-h incubation, cells were collected and plated on slides. The slides were washed, fixed and blocked for 20 min in Tris-buffered saline (TBS) containing 10 mL/L goat serum, then incubated with rabbit anti-human endostatin polyclonal antibody diluted 1:50 in PBS overnight. After washing 3 times, biotinylated goat anti-rabbit secondary antibody (Dako Corp., Carpinteria, CA) diluted 1:200 in PBS was added, and slides were incubated for an additional 30 min. Slides were then washed 3 times with PBS and stained with streptavidin-biotinylated horseradish peroxidase complex.

HUVEC cells proliferation assay Human umbilical vein endothelial cells (HUVEC) were seeded in a 96-well plate at a density of 1×10^4 /well and allowed to adhere overnight. Cells were then infected for 2 h with Ad/hEndo at MOIs of 0.05, 0.5, 1.0, 5.0, 10 and 20, and with Ad/*LacZ* at an MOI of 20. Cells were washed 3 times with PBS and incubated at 37 °C in fresh medium. Seventy-two hours later, 20 µL of 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl-2H-tetrazolium bromide (MTT) (Fluka Biochemika, Buchs, Switzerland) was added to the wells and the plate was incubated for an additional 4 h at 37 °C. Then, 100 µL DMSO was added to the wells and the plate was incubated for 10 min at 37 °C. Absorbance was read using a Bio-Rad 550 microplate reader (Bio-Rad Laboratories, Hercules, CA) at 570 nm. The value of the treated cells was calculated as percent of the untreated control.

***In vivo* tumor growth inhibition** BEL-7402 cells were subcutaneously inoculated into the flanks of 6-week-old female BALB/c nude mice (5×10^6 cells in 200 µL). Ten days after tumor cell inoculation, intra-tumoral injections of virus (Ad/hEndo or Ad/*LacZ*; 1×10^9 pfu in 100 µL) was given once weekly for 6 wk. An additional 7 animals received injections of 100 µL of DMEM as a negative control. Tumors were measured with a caliper gauge twice a week over a 6-week period following the initial virus injections. Tumor volume was calculated according to the formula: volume = width² × length × 0.52^[10]. One week after the 6th injection of Ad/hEndo, the mice were sacrificed and the xenografted tumors were excised and weighed. The inhibition rates of growth of BEL-7402 xenografted tumors were calculated according to the formula: Inhibition rate (%) = (1 - mean Weight_(Ad/hEndo) / mean Weight_(control)) × 100.

Northern blotting for expression of endostatin mRNA *in vivo* On d 1, 4 and 8 after intra-tumoral administration with 100 µL

of 1×10^9 pfu Ad/hEndo, the mice were sacrificed. The xenografted tumors were excised and snap frozen in liquid nitrogen. Total RNA was isolated from tumor tissues using the Trizol reagent (Invitrogen) according to the manufacturer's instructions. RNA isolated from the tumors injected with DMEM was used as a negative control. Total RNA of 15 µg was resolved on a 10 g/L formaldehyde agarose gel, and transferred to nylon membrane. The RNA was fixed onto the membrane by UV cross-linking. The membrane was prehybridized in DIG Easy Hyb hybridization solution (Roche, Basel, Switzerland) at 68 °C for 30 min, then hybridized in DIG Easy Hyb hybridization solution containing digoxin (DIG)-labeled endostatin probe at 68 °C overnight. The membrane was incubated with anti-DIG antibody for 30 min and stained with NBT/BCIP for 10 min.

Plasma endostatin levels detected by ELISA Blood samples were harvested on d 0, 3 and 7 after intra-tumoral administration with 100 µL of 1×10^9 pfu Ad/hEndo. Samples were centrifuged, and plasma endostatin levels were determined using a human endostatin enzyme-linked immunosorbent assay (ELISA) kit (Oncogene Research Products, Boston, MA), according to the manufacturer's instructions.

Pathological observation One week after the 6th course of treatment, the animals were sacrificed. The major organs including heart, liver, spleen, kidney, lung and brain were extracted from the nude mice, fixed in 40 g/L buffered formaldehyde phosphate, cut into 4 µm thick for tissue section and stained with haematoxylin and eosin.

RESULTS

High level transgene expression in BEL-7402 cells infected with Ad/hEndo

Three days after transfection with Ad/hEndo at a MOI of 10, BEL-7402 cells were probed with rabbit anti-human endostatin antibody. Immunohistochemistry with an anti-endostatin antibody clearly demonstrated that endostatin protein was expressed in the transduced BEL-7402 cells. Extensive positive staining was observed in the cytoplasm of transduced cells (Figure 1). This indicated that human endostatin gene mediated by recombinant adenovirus was highly expressed in BEL-7402 cells and provided evidence for the feasibility of local gene therapy for HCC BEL-7402 xenografted tumors.

Figure 1 Immunohistochemistry analysis for endostatin protein *in vitro* (×100). Extensive positive staining was observed in the cytoplasm of transduced cells. This indicated that human endostatin gene mediated by recombinant adenovirus was highly expressed in BEL-7402 cells.

Inhibition of proliferation of HUVEC cells by Ad/hEndo

In order to investigate the effects of this secreted endostatin on proliferation of HUVEC cells, cell proliferation assays were performed by MTT assay. Ad/hEndo inhibited HUVEC cell proliferation by 7.61%, 12.61%, 24.8%, 29.86%, 38.78% and 57.2% at MOIs of 0.05, 0.5, 1.0, 5, 10 and 20, respectively. The

Ad/LacZ control group showed inhibition of cellular proliferation by 7.25% at a MOI of 20 (Figure 2). These results indicated that the endostatin protein secreted by the transduced cells was highly bioactive and inhibited the proliferation of vascular endothelial cells *in vitro* in a dose-dependent manner, while the viral vector alone did not.

Figure 2 Effect of Ad/hEndo on the proliferation of HUVEC cells.

Inhibition of the growth of BEL-7402 xenograft tumors by Ad/hEndo

In order to observe the effect of Ad/hEndo on the growth of tumors, we established a BEL-7402 xenograft tumor model in BALB/c nude mice. After 6 wk of treatment, the growth of treated tumors was inhibited by 46.50% compared to the Ad/LacZ control group ($t=2.729$, $P<0.05$) and by 48.56% compared to the DMEM control group ($t=2.485$, $P<0.05$). The ratio of mean tumor volume in treated animals to that of the control animals (T:C ratio) was <50% after 24 d of treatment (Figure 3). These results showed that Ad/hEndo significantly inhibited the growth of BEL-7402 xenografted tumors.

Figure 3 Effect of Ad/hEndo on growth of BEL-7402 xenografted liver tumors.

Figure 4 Northern blotting of endostatin mRNA *in vivo*. Lanes 1-3: RNA extracted from tumors on d 1, 4 and 8 after Ad/hEndo injection, respectively; Lane 4: RNA extracted from control tumors injected with DMEM.

Full-length expression of endostatin mRNA *in vivo*

Northern blotting was performed to test whether the *in vivo* expressed endostatin mRNA was of full-length. After hybridization, the membrane was stained with NBT/BCIP, and endostatin mRNA was clearly demonstrated as a band of

approximately 1.2 kb (Figure 4), which was the expected size of intact and functional endostatin. The highest level of endostatin mRNA *in vivo* was detected 1 d after intra-tumoral administration of Ad/hEndo. On d 4 and 8, endostatin mRNA levels significantly decreased. Therefore, Northern blotting showed that adenovirus-mediated human endostatin gene transfer resulted in expression of intact endostatin mRNA *in vivo*.

Plasma levels of endostatin protein

ELISA was used to measure the plasma endostatin levels. Plasma endostatin levels peaked at 87.52 ± 8.34 ng/mL on d 3 after Ad/hEndo injection, which was significantly higher than the basal level (12.23 ± 2.54 ng/mL). By d 7, plasma levels dropped to half the peak level (40.34 ± 4.80 ng/mL) (Figure 5). These results showed that intra-tumoral delivery of the endostatin gene resulted in high plasma endostatin concentrations.

Figure 5 Detection of endostatin concentration in plasma by ELISA.

Pathological changes of main organs

All animals were survived and appeared to be physically normal. There were no histological changes in main organs of DMEM control animals. However, histological examination in several mice of the Ad/hEndo (3/8) and Ad/LacZ (3/8) groups revealed slight to modest hepatocyte fatty degeneration, cloudy swelling and occasional necrosis companied with infiltration of lymphocyte and inflammatory cells. (Figure 6) One mouse in Ad/hEndo group (1/8) and 1 in Ad/LacZ (1/8) group demonstrated slight cloudy swelling in some proximal renal tubule cells and distal renal tubule cells. No histological changes were found in spleen, lung, heart and brain of both these groups. There was no significant difference in histological changes between Ad/hEndo group and Ad/LacZ group. These results suggested that it was the recombinant adenoviruses, not endostatin protein that caused the liver and kidney toxicity.

Figure 6 Pathological changes of liver 1 wk after 6 wk of treatment with Ad/hEndo (HE, original magnification: $\times 200$).

DISCUSSION

Animal experiments on angiogenesis have frequently been conducted on tumors recently implanted in mice. However, in

the human situation, tumors are often established for months or years and may possess mature vasculature that is less sensitive to anti-angiogenic therapy^[1,2]. Indeed, antiangiogenesis therapies, which inhibit the growth and metastasis of neoplasms by blocking the formation of new blood vessels from existing vessels, appear to require long-term administration of the angiogenic inhibitor to ensure tumor growth suppression^[3]. Endostatin protein derived from yeast (*Pichia pastoris*) had been introduced into clinical trials as a possible antiangiogenic tumor fighting drug^[15]. The clinical studies showed that the mean half-life of recombinant human endostatin was only 10.7 ± 4.1 h in the human body, suggesting that this protein-based therapy was likely to require repeated daily or long-term administration of high-quality protein for optimal therapeutic benefits^[16].

It is hoped that these difficulties of protein-based therapy may be overcome by direct expression of therapeutic gene in the body^[17]. Endostatin gene therapy is a promising strategy for anti-angiogenic therapy, for a single transduction of endostatin gene could achieve a relatively long-term and high-quality protein expression *in vivo*^[17,18]. Adenoviral vectors are commonly used as carriers for gene transfer due to their high efficiency and high capacity^[19,20]. We cloned the human endostatin gene into an adenoviral shuttle plasmid and generated an adenoviral expressing system which resulted in highly efficient expression of endostatin gene and demonstrated high level of bioactivity by significantly inhibiting the proliferation of endothelial cells. In our studies, endostatin gene therapy using a recombinant adenovirus delivery significantly inhibited the growth of BEL-7402 xenografted liver tumors. Since d 24 of treatment with intra-tumoral injection with Ad/hEndo, the T:C ratio of mean tumor volume was less than 50%. After 6 courses of treatment, the growth of xenografted tumors treated with Ad/hEndo was markedly inhibited as compared with the control group.

Adenovirus can infect dividing and nondividing cells and obtain high efficiency of transgene expression^[21,22]. These properties of adenoviral vector provide the possibility of local treatment, such as intra-tumoral injection and transcatheter arterial infusion of recombinant adenovirus^[23]. In this study, we investigated the possibility of tumor-targeted endostatin gene therapy for liver cancer. First, we demonstrated high level transgene expression in BEL-7402 cells infected with Ad/hEndo. Then, intra-tumoral endostatin mRNA expression was clearly detected by Northern blotting on d 1 after injection with Ad/hEndo. Northern blotting indicated that the endostatin mRNA expressed inside tumor tissue was intact, thus the resultant endostatin protein could be biologically active *in vivo*. These positive results had provided solid evidence for local endostatin gene therapy for liver cancer.

The tumor-targeted gene therapy produced endostatin protein mostly inside the tumors^[23,24], however, some of the protein entered the circulation, resulting in the peak of plasma endostatin concentration of 87.52 ± 8.34 ng/mL by d 3 post-administration. Although this plasma level was considerably lower than those reached by intravenous delivery of recombinant adenoviral vector for endostatin gene therapy^[19,20], it had been shown that circulating endostatin levels of 35–40 ng/mL was sufficient to exert an antiangiogenic effect *in vivo*^[24], suggesting that our delivery system was able to induce therapeutically relevant circulating endostatin levels.

The transient expression is a key problem for any therapeutic use^[23,25], while the reason for the transient *in vivo* transgene expression is unclear^[26,27]. Repetition of administration with therapeutic gene *in vivo* using a transgene vector was recommended to achieve better therapeutic effect^[23,28,29]. However, multiple injections of immunogenic transgene vector will get an immune response to the vector which not only make

expression even worse, but also cause systemic toxicity^[30,31]. Indeed, we observed slight liver and renal damage in mice after 6 courses of endostatin gene therapy using a recombinant adenovirus delivery. Histological examination in several mice administrated with adenoviral vector revealed slight to modest hepatocyte and renal tubule cell degeneration and some degree of inflammatory reaction. It was the recombinant adenovirus, not endostatin protein that caused the liver and kidney toxicity^[27,32]. Our results suggested that cautions should be taken for clinical repeated administration within a short time of the recombinant adenoviral vector carrying endostatin gene.

In conclusion, a recombinant adenoviral vector carrying human endostatin gene can be successfully constructed, with highly efficient expression of endostatin gene both *in vitro* and *in vivo*, thereby significantly inhibiting the growth of BEL-7402 xenografted liver tumors in nude mice.

Abstract

AIM: To obtain human recombinant Fv-immunotoxin hscFv₂₅-mTNF α (mutant human TNF α fused to human scFv₂₅) against hepatocellular carcinoma (HCC).

METHODS: Two relevant sites of enzymatic digestion were added to mTNF α by PCR. mTNF α was linked to the 3' end of hscFv₂₅ in pGEX4T-1 vector. This anti-HCC recombinant Fv-immunotoxin hscFv₂₅-mTNF α was expressed in *Escherichia coli* and purified from inclusions. After purified by glutathione-S-transferase affinity chromatography and thrombin digestion, it was identified by electrophoresis and Western blot. And then, the purified recombinant Fv-immunotoxin was injected into nude mice with HCC xenografts through their tail veins. mTNF α protein and PBS were used as control at the same time. After treated for two weeks, nude mice were executed. The bulk and weight of tumors were observed. The tumor tissues were stained by immunohistochemical method with TNF α antibody.

RESULTS: The expression ratio of recombinant Fv-immunotoxin hscFv₂₅-mTNF α was 12% of bacterial protein. The result of tumor restraining trials of hscFv₂₅-mTNF α showed 2/5 complete remission and 3/5 partial remission. mTNF α restraining trials showed 5/5 partial remission. The therapeutic result of hscFv₂₅-mTNF α was better than that of mTNF α ($F=8.70$, $P<0.05$). The hscFv₂₅-mTNF α remedial tumor tissues were positive for TNF α by immunohistochemical staining. The positive granules mainly existed in the cytoplasm of tumor cell.

CONCLUSION: Recombinant Fv-immunotoxin hscFv₂₅-mTNF α has better therapeutic effect than mTNF α . It can inhibit the cellular growth of HCC and has some potential of clinical application.

INTRODUCTION

Hepatocellular carcinoma (HCC) is a common malignant tumor

in China with poor prognosis^[1,2]. Its diagnosis and therapy are still major challenges^[3,4]. The single chain Fv (scFv) is consisted of heavy-chain and light-chain variable region of the antibody, linked with a peptide chain. They have shown a various application value in tumor therapy^[5-7]. Our laboratory, through collaboration with the Academy of Military Medical Science, constructed human scFv₂₅ against HCC (hscFv₂₅) several years ago^[8]. In this study, we fused human mutant tumor necrosis factor- α (mTNF α) to hscFv₂₅ and constructed prokaryotic expressing vector pGEX4T-1/hscFv₂₅-mTNF α . After recombinant Fv-immunotoxin hscFv₂₅-mTNF α was expressed, purified and identified, we used it in tumor restraining trials of the HCC (SMMC-7721) xenografts in nude mice.

MATERIALS AND METHODS

Main materials

Isopropyl-1-thio-D-galactopyranoside (IPTG), PCR marker, T4 ligase and thrombin were purchased from Promega. Glutathione-S-transferase affinity chromatogram and low molecular weight marker were purchased from Pharmacia. The plasmid extracting reagent kit was purchased from Huashun Biologic Co. (Shanghai, China). EnVision™ System was purchased from Dako. The mTNF α protein produce was offered by Biologic Center of the Fourth Military Medical University. The mouse anti-human TNF α monoclonal antibody was purchased from Santa Cruz, USA.

Vector construction

According to cDNA of mTNF α , Sal I site was added to its 5' -end and Xho I site to its 3' -end. The 5' primer was: ACTCTCGAG TCAGAAGGCAATGATCCCAAAGTA; and the 3' primer was: ACGCGTCGACCGCAAACGTAAGCCTGTA.

The primers were synthesized by Sangon (Shanghai, China). After digested by Sal I and Xho I restriction enzymes, mTNF α PCR products were linked to 3' -end of pGEX4T-1/hscFv₂₅, which was digested by the same restriction enzymes. And then, pGEX4T-1/hscFv₂₅-mTNF α was transformed into *E. coli* JM109. *E. coli* were cultivated in the Amp^r/LB medium at 37 °C for 16-22 h. The positive clones were selected and identified by EcoR I and Sal I, EcoR I and Xho I, Sal I and Xho I restriction enzymes analysis and 10 g/L agarose gel electrophoresis.

Recombinant Fv-immunotoxin expression and purification

E. coli were cultivated at 37 °C in LB medium containing 50 g/L ampicillin. When their density reached $A_{650}=1.0$, bacteria were induced by 1.0 mmol/L IPTG for 3-4 h. And then they were harvested by centrifugation and their inclusions were isolated, purified, denatured and re-natured. After purified by glutathione-S-transferase affinity chromatography, glutathione-S-transferase (GST) was removed by thrombin digestion. The immunotoxin was analyzed by 120 g/L SDS-PAGE.

Western blot

When 120 g/L SDS-PAGE electrophoresis was completed, stacking gel was removed and equilibrated in transfer buffer

(25 mmol/L Tris, 190 mmol/L glycocine, 200 mL/L methanol). The expressing proteins were transferred from gel to NC membrane by electrophoresis. The membrane in heat-sealable plastic bag was blocked with buffer (TBS with 30 g/L bovine serum albumin, BSA) overnight at 4 °C. After the blocking buffer was removed, the solution with TNF α antibody was added, which was diluted with TBS (containing 10 g/L BSA). And then the membrane was incubated for 1h at 37 °C. After washed 3 times with TBS, the membrane was transferred to fresh plastic bag containing goat anti-mouse IgG antibody for one hour at 37 °C and stained with DAB for 10-20 min.

Tumor therapy

The SMMC-7721 cells were cultivated in RPMI 1640 containing 100 mL/L fetal bovine serum, which was obtained from Gibco BRL. Fifteen immunodeficient nude mice BALB/nu, purchased from our Experiment Animal Center and Shanghai Cellular and Biologic Center, were implanted s.c. 2×10^6 SMMC-7721 cells (PBS suspended) at right rear flank respectively. When tumors grew to a palpable size about 2 mm subcutaneously, fifteen mice were divided into three groups randomly. Each group had five mice. PBS was injected to the first group of mice. Twelve μ g mTNF α was injected to each mouse in the second group and 16 μ g hscFv₂₅-mTNF α was injected to each mouse in the third group. All mice were injected through their tail veins. Fourteen days were one course of therapy. At the end of the second week, the mice were dissected. Their tumors were weighed and examined for morphological evidence of damage, along with lungs and livers. The paraffin sections were prepared for histological examination and immunohistochemical staining.

Immunohistochemical staining

The sections were stained by immunohistochemical method. Those in the control groups were stained according to the same method, with the first antibody substituted by PBS, normal mouse serum and an irrelevant antibody IB₃ respectively. All paraffin embedded samples were deparaffined and rehydrated, pretreated for 20 min at 95 °C in a microwave oven. After being treated with 3 mL/L H₂O₂ for 30 min to block the endogenous peroxidase, the sections were incubated with 20 mL/L fetal calf serum for 30 min to reduce nonspecific binding, and then the primary TNF α antibody was applied to sections at 4 °C overnight. The sections were subsequently incubated with horseradish peroxidase (HR)-labeled goat anti-mouse immunoglobulin at 37 °C for 1 h, and stained with DAB-H₂O₂ for 5-10 min and counterstained with hematoxylin.

Statistical methods

The *F* test was used for statistical analysis of tumor bulk and weight among three groups. The criterion of significance was set at *P*<0.05.

RESULTS

Vector construction and verification

One ladder was observed at 450 bp, with the same size as mTNF α . After PCR products were digested by *Sal* I, *Xho* I and linked to 3' -end of pGEX4T-1/hscFv₂₅, which was digested by the same restriction enzymes, the prokaryotic expressing vector pGEX4T-1/hscFv₂₅-mTNF α was constructed. Then it was transformed to *E. coli* JM109. The bacteria were cultivated in the Amp^r/LB medium at 37 °C for 16-22 h. Six clones were selected at random. Three clones had one ladder about 450 bp digested by *Sal* I and *Xho* I restriction enzymes. After subsequently digested by *Eco*R I and *Xho* I, *Eco*R I and *Sal* I, 1 180 bp and 730 bp ladders were observed,

corresponding well with the size of hscFv₂₅-mTNF α and hscFv₂₅ (Figure 1).

Figure 1 The result of enzyme digested pGEX4T-1/hscFv₂₅-mTNF α . Lane1: mTNF α ; Lane 2: hscFv₂₅; Line 3: hscFv₂₅-mTNF α ; Lane 4: DNA ladder (100, 250, 500, 750, 1 000, 2 000 bp).

Fv-immunotoxin expression, purification and identification

The bacteria containing pGEX4T-1/hscFv₂₅-mTNF α were induced by IPTG. Compared with the same bacteria without induction by IPTG, there was a new transcript of *M_r* 68 000, corresponding well with the size of fusion protein GST-hscFv₂₅-mTNF α (GST *M_r* 26 000, hscFv₂₅ *M_r* 26 000, mTNF α *M_r* 16 000). The result of absorbance scanning showed that the expressing amount of GST-hscFv₂₅-mTNF α was 12% bacterial protein. The fusion protein existed in the form of infusibility inclusions. After the inclusions were denatured, renatured, purified by affinity chromatography, only 2 mg preliminarily purified GST-hscFv₂₅-mTNF α was obtained from 100 mL bacteria. Digested by thrombin subsequently and purified by GST affinity chromatography again, hscFv₂₅-mTNF α protein was obtained. The result of SDS-PAGE showed that proteins were accorded to electrophoresis purification (Figure 2). The GST-hscFv₂₅-mTNF α studied by Western blot was seen as a new transcript of *M_r* 68 000, the same as the fusion protein GST-hscFv₂₅-mTNF α .

Figure 2 GST-hscFv₂₅-mTNF α and hscFv₂₅-mTNF α SDS-PAGE. Lane 1: Low molecular mass marker (20.1, 31.0, 43.0, 66.2, 97.4 KD); Lane 2: Preliminarily purified GST-hscFv₂₅-mTNF α ; Lane 3: Purified hscFv₂₅-mTNF α .

hscFv₂₅-mTNF α targeting therapy

Fifteen nude mice, weighing 16-24 g, were implanted s.c. 2×10^6 SMMC-7721 cells at their right rear flanks and received drug treatment on the tenth day. The tumor of bulk and weight of 15 nude mice were shown in Table 1. The tumor restraining trials of hscFv₂₅-mTNF α to HCC xenografts showed 2/5 complete remission (CR) and 3/5 partial remission (PR). The therapeutic result of mTNF α showed 5/5 PR. The therapeutic effectiveness of mTNF α was less than that of hscFv₂₅-mTNF α (*F*=8.70, *P*<0.05). In the PBS group, tumors showed no remission

Table 1 Targeting therapy of hscFv₂₅-mTNF α for HCC xenografts

		Tumor bulk (mm×mm)	Tumor weight (mg)	Regression rate of tumor bulk (%)	Regression rate of tumor weight (%)	Curative effect
PBS	1	9×5	119	0	0	NR
	2	7×7	87	0	0	NR
	3	9×4	51	0	0	NR
	4	5×3	26	0	0	NR
	5	5×4	30	0	0	NR
hscFv ₂₅ - mTNF α	1	0.8×0.5	2	99.2	96.8	PR
	2	2×3	10	81.8	84.0	PR
	3	2×3	15	81.8	76.0	PR
	4	0	0	100	100	CR
	5	0	0	100	100	CR
mTNF α	1	2×2	11	87.9	82.4	PR
	2	3×3	22	72.7	64.9	PR
	3	2×4	5	75.8	76.0	PR
	4	2×3	10	81.8	84.0	PR
	5	2×3	10	81.8	84.0	PR

NR: non-remission; PR: partial remission; CR: complete remission.

(NR). After the liver and lung specimens were sliced up continuously and examined, no metastatic tumors and surviving tumor cells were seen in CR xenografts. The tissues of PR xenografts showed a large number of necrotic areas.

Immunohistochemical staining

The remnant tumor tissues treated by hscFv₂₅-mTNF α showed diffusely positive for TNF α . The positive granules mainly existed in the cytoplasm of tumor cells (Figure 3). Immunohistochemical staining with the irrelevant antibody IB₃, PBS and normal mouse serum was negative. The tumor tissues treated by PBS showed negative or weak positive for TNF α .

Figure 3 The remnant tumor tissues treated by hscFv₂₅-mTNF α were positive for TNF α . The positive granules mainly existed in the cytoplasm of tumor cells. EnVision™ ×200.

DISCUSSION

In the past 20 years, the antibody study has passed through 3 stages: polyclonal antibody, monoclonal antibody and genetic engineering antibody. Among them, the genetic engineering antibody was the most arresting focus of research because of its prominent advantage, such as lower molecular weight, better specificity and affinity^[9-12]. It had minimal antigenicity of human against mouse immunoglobulin antibody (HAMA)^[13]. Many scFvs against tumors have been used in the phase I-III clinical therapy trials^[14-16]. HAB₂₅ is a kind of the monoclonal antibody against HCC constructed by our laboratory. The hscFv₂₅ against HCC is constructed from HAB₂₅. Previous experiment showed that it had better targeting action compared to HAB₂₅^[17-19].

The recombinant Fv-immunotoxin was constructed if the

scFv C' end was linked to protein toxins, such as pseudomonas exotoxin (PE)^[20]. Once bound to the target cells, immunotoxins could kill the tumor cells. Due to PE being nonhuman, to produce effect, it must be internalized into endocytic vesicles where the catalytic protein of the toxin was processed and released into cytosol. Some results of clinical trials using such exotoxin were not satisfactory. Here, we have constructed the single chain recombinant Fv-immunotoxin hscFv₂₅-mTNF α . The mTNF α we used was a mutant from natural human TNF α .

The TNF α is one of the strongest active factors in organisms which can kill tumor cells directly. It has severe side effects and is often used in local therapy or targeting therapy by antitumor antibodies^[21,22]. Some studies found that the toxicity of TNF α could be reduced by genic fix point mutation or polymeric alteration^[23,24]. When natural TNF α 's N-end seven amino acids were cut out and Pro⁸Ser⁹Asp¹⁰ changed to ArgLysArg, and its C-end 157th amino acid of Leu changed to Phe, mTNF α was attained. Compared with natural TNF α , the toxicity of mTNF α was reduced evidently and its cytotoxicity was enhanced greatly^[25].

Our study showed the hscFv₂₅-mTNF α could kill tumor cells effectively. Compared with dosage of mTNF α and the former experimentation^[17], the dosage of hscFv₂₅-mTNF α was reduced markedly. Those results revealed that mTNF α could concentrate in tumor tissues and killed tumor cells by the targeting of hscFv₂₅. The anti-HCC recombinant Fv-immunotoxin with TNF α replaced by mTNF α could increase its cytotoxicity. Furthermore, we found tumor cells were positive for TNF α in immunohistochemical staining. It also indicated hscFv₂₅ had better targeting action.

All these showed the hscFv₂₅-mTNF α had better distributive ratio in HCC tissues. It could help local tumor cells to attain a high level of mTNF- α and reduce dose-limiting toxicity. The recombinant Fv-immunotoxin hscFv₂₅-mTNF α might have potentiality of clinical application. Due to few nude mice in our study, it maybe lacked rigorous statistical signification. The experimental results need be approved in the future.

Abstract

AIM: To evaluate whether cell apoptosis and regeneration
were existed in normal liver cells adjacent to carcinoma
after transarterial chemoembolization (TACE).

METHODS: Fifty rabbits with hepatic carcinoma were
divided into 5 groups at random: group A (control group),
groups B and C (TACE treatment groups), groups D and E
(partial hepatectomy groups). There were 10 rabbits in
each group. Rabbits in groups B-E were treated by transarterial
chemoembolization (TACE) and partial hepatectomy (PH)
respectively. The changes of S-phase cell fraction (SPF),
proliferation index (PI) and cell apoptosis in the normal liver
tissue were determined with flow cytometry (FCM) after
operations on the first and third days. We determined the
mitosis index (MI) with histo-pathological method and the
apoptosis index (AI) with TUNEL method at the same time.

RESULTS: Twenty-four hours after operations, compared
with control group, the rabbits in TACE group had much
higher index of SPF, PI and MI (MI: $t=4.89$, $P<0.001$; SPF:
 $t=5.27$, $P<0.001$; PI: $t=4.87$, $P<0.001$). Moreover, the
proliferation of liver cells in TACE group was much weaker
than that of the cells treated by partial hepatectomy, and
the differences were significant (MI: $t=7.02$, $P<0.001$; SPF:
 $t=4.06$, $P<0.001$; PI: $t=2.70$, $P<0.05$). Seventy-two h after
operations, FCM showed a small sub-G1 peak in TACE
group and PH group, compared with the control group, but
there was no difference between them ($t=0.41$, $P>0.05$).
TACE showed that AI in the treated rabbits was higher
than that in control group ($t=3.07$, $P<0.05$), and there were
no differences between TACE group and PH group, either
($t=0.93$, $P>0.05$).

CONCLUSION: Cell apoptosis and regeneration exist in
rabbit liver tissues after TACE in some degree, which may
be associated with the selective embolization of iodised
oil, chemotherapeutic drug and free radical damage.

apoptosis and regeneration of hepatocellular carcinoma after
transarterial chemoembolization. *World J Gastroenterol* 2004;
10(13): 1876-1880

<http://www.wjgnet.com/1007-9327/10/1876.asp>

INTRODUCTION

The efficacy of transarterial chemoembolization (TACE) is
greatly determined by the liver function reserve of liver cancer
patients. More than 40% patients died of liver failure after TACE,
in which most of them were accompanied by poor liver function
and damage due to chemotherapy. Therefore, it is important to
study the effects of TACE on non-neoplastic liver tissue to
decrease the death rate. We have established the animal model
of rabbit VX2 hepatic carcinoma. All the rabbits were treated
by TACE to detect the effect on cell cycle of non-neoplastic
liver tissues after operations^[1].

MATERIALS AND METHODS

Establishment of the animal model

Fifty Japanese alpine hares, weighing 2.5-3.3 kg, provided by
the Experiment Animal Center of Tongji Medical College were
used in this experiment. The rabbits were implanted hepatocellular
carcinoma cell VX2, and observed for 3 wk before experiment^[2].

Treatment and radiological examination^[3,4]

Fifty rabbits with VX2 hepatic carcinoma were randomly divided
into 5 groups: Group A (control group), groups B and C (TACE
treatment groups), groups D and E (partial hepatectomy groups),
10 rabbits in each group. Three weeks later, at laparotomy of the
rabbits, the feeding artery of liver carcinoma was punctured and
arteriography was made^[5]. A 1 mL of physiological saline was
administered to group A. Groups B and C were treated with 0.6-
0.8 mL of a mixture of iodine oil (10 mL) and mitomycin (10 mg)^[6,7].
Groups D and E were treated by hepatectomy. Groups B and C
were performed CT and MRI after TACE^[8,9].

Flow cytometry analysis

Rabbits in groups A, B and C were killed on the first day after
the procedure, and those in groups D and E were killed on the
third day after the procedure. As soon as the rabbits died, a
piece of non-neoplastic liver tissue was cut from each rabbit
and digested with enzymes. The cells were fixed by 800 mL/L
ice ethanol, hatched by 40 μ L PC on ice for 30 min, and washed
in 1 g/L PBS. At last, they were stained by at 100 μ L PI 10 mg/L
and 50 μ L 1 g/L RNA enzyme for 20 min, then flow cytometry
was performed. The cells were detected by FAC Sort FCM
machine (Becton Dickinson Co, USA). The fluorescence of cells
was analyzed with Cellquest software and the cell cycle was
studied. The other liver tissues were photographed, fixed with
40 g/L formaldehyde, and stained by HE^[10].

Groups B and C were performed CT after TACE, and
accumulation of iodized oil was observed. General pathological
changes of carcinoma were detected in all the rabbits. Under the
microscope, we calculated the number of liver cells in the mitosis

phase per 1 000 liver cells, which was called mitosis index (MI).

FCM analysis

S phase cell fraction (SPF) was calculated according to the equation: $SPF = S / (S + G1/G0 + G2/M) \times 100\%$. Proliferation index (PI) was calculated according to the equation: $PI = (S + G2/M) / (S + G1/G0 + G2/M) \times 100\%$. Apoptosis index (AI) was analyzed by TUNEL method^[11], the number of apoptotic cells was calculated under microscope^[12].

Statistic analysis

All the data were analyzed by *t* test.

RESULTS

General pathological and radiological findings

Three wk after tumor implantation, the size of VX2 liver carcinoma was 3.5 ± 1.6 cm on average, and appeared as white nodules near the liver surface. There were no definite margins between carcinomas and normal liver tissues. On DSA, there was increased and irregular angiogenesis of the tumor vessels, with tumor stained mainly at the periphery (Figure 1). On MR, the signal of cancer was slightly lower than that of normal liver tissue on T1WI and slightly higher on T2WI (Figure 2). The iodized oil deposited well after TACE on CT^[13] (Figure 3).

Figure 1 Hepatic arteriography of rabbits. There was increased angiogenesis with thickening and irregularity of the vessels. There was also tumor staining mainly in the periphery of the tumor.

Figure 2 MRI of rabbit liver. The tumor appeared hypointense on T1WI (A) and hyperintense on T2WI (B).

Figure 3 CT scan shows massive retention of iodized oil in tumor after TACE.

Cytological changes

Red fluorescent light could be seen in the cells under laser confocal microscope (Figure 4). Under light microscope (Olympus), we could find cell mitosis clearly, and mitosis index (MI) could be calculated. Flow cytometry showed that S phase and G2/M phase cells in TACE groups and partial hepatectomy groups increased much more on the first day after operations than that in the control group (Figure 5). On the third day after operations, the amount of S-phase and G2/M phase cells in TACE group and partial hepatectomy group was about the same as control group (Figure 6). In the cell apoptosis index (AI) determined by TUNEL method, no significant difference existed between TACE group (Figure 7) and partial hepatectomy group.

Figure 4 Cells giving out red fluorescent light under laser confocal microscope.

The *t* test values of MI, SPF and PI of TACE groups and control group are listed in Table 1. The *t* test values of MI, SPF and PI of TACE groups and partial hepatectomy groups are listed in Table 2.

Table 1 *t* test value of MI, SPF and PI of TACE groups and control group on the first day after operations

Index	TACE group	Control group	<i>t</i> value	<i>P</i> value
MI (%)	1.42 ± 0.55	0.51 ± 0.21	4.89	$P < 0.001$
SPF (%)	12.46 ± 4.18	4.90 ± 1.76	5.27	$P < 0.001$
PI (%)	23.38 ± 8.31	9.93 ± 2.68	4.87	$P < 0.001$

Table 2 *t* test value of MI, SPF and PI of TACE groups and partial hepatectomy group on the first day after operations

Index	TACE group	Partial hepatectomy group	<i>t</i> value	<i>P</i> value
MI (%)	1.42 ± 0.55	3.13 ± 0.54	7.02	$P < 0.001$
SPF (%)	12.46 ± 4.18	21.76 ± 5.92	4.06	$P < 0.001$
PI (%)	23.38 ± 8.31	32.51 ± 6.75	2.70	$P < 0.05$

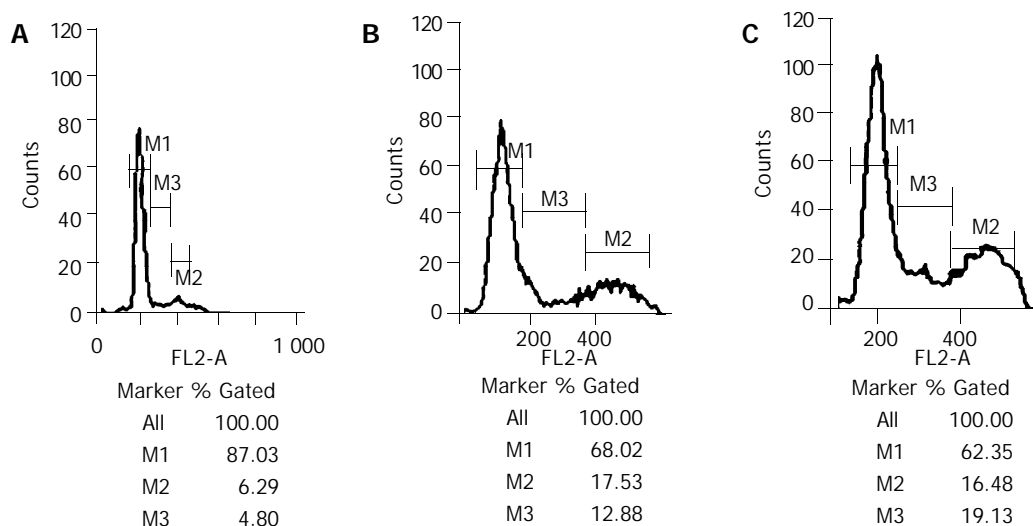

Figure 5 A: Shows the S phase and G2/M phase cells were small in proportion on the first day after operations (4.80%, 6.29%) in control group. B: Shows the S phase and G2/M phase cells grew much more on the first day after operations (17.53%, 12.88%) in TACE group. C: Shows the S phase and G2/M phase cells grew much more on the first day after operations (16.48%, 19.13%) in PH group. *M1 is G0/G1 phase cell ratio/M2 is G2/M phase cell ratio, M3 is S phase cell ratio.

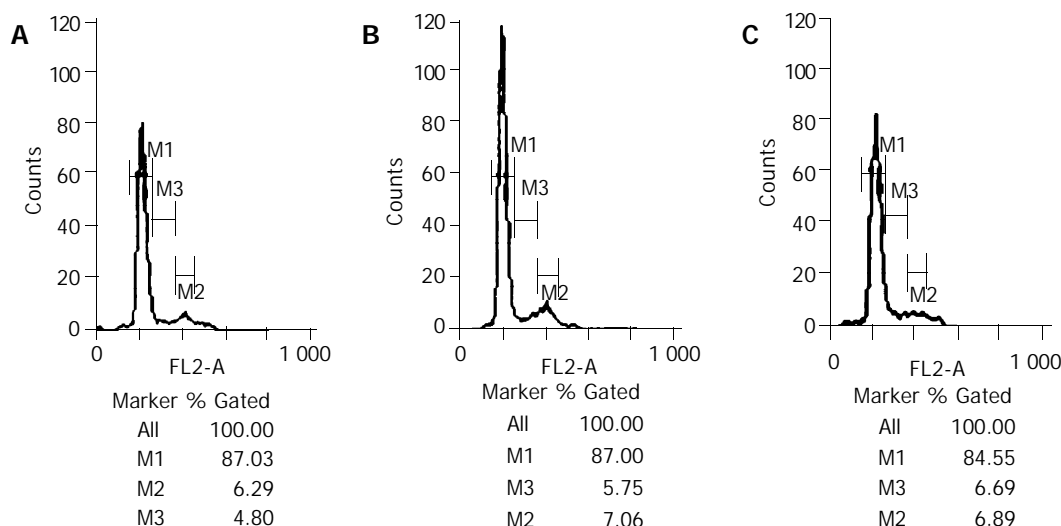

Figure 6 A: Shows the S phase and G2/M phase cells were small in proportion on the third day after operations (4.80%, 6.29%) in control group. B and C: Show the S phase and G2/M phase cells had slight changes on the third day after operations in TACE group and PH group.

Figure 7 Analysis of apoptosis cells by TUNEL method in TACE group. The nuclei of apoptosis cells appeared brown while those of normal cells appeared blue. It was found that part of the cells were apoptotic cells.

The *t* test values of MI, SPF of TACE groups and control group are listed in Table 3. There was no significant difference between the two groups ($P > 0.05$). However, the *P* value of AI and sub-G1 was less than 0.05. The *t* test values of MI, SPF, AI and PI of TACE groups and partial hepatectomy groups are listed in Table 4.

Table 3 *t* test value of MI, SPF, AI, Sub-G1 and PI of TACE groups and control group on the third day after operations

Index	TACE group	Control group	<i>t</i> value	<i>P</i> value
MI (%)	0.62±0.33	0.51±0.21	0.88	$P > 0.05$
SPF (%)	5.70±1.93	4.90±1.76	0.95	$P > 0.05$
PI (%)	11.69±1.74	9.93±2.68	1.68	$P > 0.05$
Sub-G1 (%)	2.31±1.57	1.18±0.45	2.18	$P < 0.05$
AI (%)	20.33±2.36	13.68±1.97	3.07	$P < 0.05$

Table 4 *t* test value of MI, SPF, sub-G1 and PI of TACE groups and partial hepatectomy group on the third day after operations

Index	TACE group	Partial hepatectomy group	<i>t</i> value	<i>P</i> value
MI(%)	0.62±0.33	0.81±0.30	1.28	$P > 0.05$
SPF(%)	5.70±1.93	6.62±1.56	1.34	$P > 0.05$
PI(%)	11.69±1.74	11.85±2.00	0.17	$P > 0.05$
Sub-G1 (%)	2.31±1.57	2.05±1.07	0.41	$P > 0.05$
AI(%)	20.33±2.36	22.69±3.79	0.93	$P > 0.05$

DISCUSSION

Transarterial chemoembolization (TACE) has been one of the most important and commonly used methods for treatment of hepatocarcinoma^[14]. Because most patients died of liver failure after TACE^[15,16], it is important to study the condition of postoperative normal liver tissues^[17]. The most precise method to evaluate hepatocyte reproduction and apoptosis has been the study of cell cycle^[18]. In our research, normal hepatocytes were isolated, fixed and stained, flow cytometry (FCM) was performed and DNA was analyzed. Results showed SPF, PI and MI value of TACE group was much higher than that of control group ($P < 0.001$, Table 1). We could conclude that there existed liver regeneration after TACE. From Table 2 at the same time, we could find that hepatocyte regeneration in PH group was stronger than that in TACE group on the first day ($P < 0.05$). On the third day after TACE, the difference between TACE group and control group was not significant in all indexes. Furthermore, the difference between TACE group and PH group was not significant either on the third day. From these data, we could conclude that the regeneration process stopped, most of the cells entered the dormancy phase (G_0 phase). However, the value of hypodiploid peak (sub-G1) increased on the third day after TACE ($t = 2.18$, $P < 0.05$). The difference of sub-G1 between TACE group and PH group was obvious ($P > 0.05$, Tables 3, 4). The apoptosis index (AI) became greater on the third day after TACE.

Cell apoptosis (programmed cell death) means the maintenance of stability of internal environment, i.e. the process of autonomic programmed cell death has been controlled by gene^[19]. After partial hepatectomy, the hepatocytes would regenerate soon. At the peak of regeneration, cell apoptosis begins. Accompanying cell reproduction, cell apoptosis would eliminate the overgrown cells, and rebuilding of the tissue constitution is achieved. Some authors^[20] pointed out that the process was mitogen \rightarrow cell reproduction \rightarrow regeneration \rightarrow cell apoptosis. It was different from the necrosis caused by liver cytotoxic material, which was in the order of cytotoxic material \rightarrow necrosis \rightarrow compensatory hyperplasia \rightarrow cell regeneration. Liver tissue regeneration after PH has been studied comprehensively. When the liver is resected less than 70%, the regeneration is proportional to the volume of the resected portion. Mitosis reaches the peak in 24 h, and completes in 72 h. Liver tissue regeneration exists also after TACE, this is due to the effect of super-selective embolization with iodized oil. The liver regeneration in TACE group was weaker than that in PH group, the reason was that the extent of "medical hepatectomy" was much smaller^[21]. However, from Tables 3 and 4, we could find the apoptosis levels between TACE and hepatectomy groups. The apoptosis level following liver regeneration was directly proportional to the regeneration level. It is easy to draw the conclusion that there must exist a new mechanism, which promotes cell apoptosis after TACE. The mechanism might be that mitomycin depressed DNA synthesis and promoted cell apoptosis^[22]. Some authors^[23] pointed out that mitomycin (5 mg/mL) could cause cell apoptosis after 24 h. Almost all chemotherapeutic drugs could induce cell apoptosis by different ways^[24]. For example, vincristine (VCR) and colchicine could induce cell apoptosis by disturbance of microtubule function \rightarrow loss of hepatocyte function \rightarrow identification of the injury by hepatocytes \rightarrow decrease of protein synthesis \rightarrow increase of $[Ca^{2+}]$ activation of endonuclease and protein kinase \rightarrow DNA split \rightarrow cell apoptosis^[25]. On the other hand, there were ischemia and hypoxia of locally embolized tissue, and release of a large amount of free radicals and cell toxins^[26,27]. They could induce cell apoptosis^[28,29]. For example, free radicals could injure DNA which would lead to activation of polydiadenosine phosphate pibotransferase^[30] and accumulation of p53. A cell calcium ion would cause cell apoptosis. It could activate nucleus transcription factors such

as NF- κ B which would induce cell apoptosis^[31]. Normal hepatocyte apoptosis was mainly resulted from the effects of chemotherapeutic drugs and free radical injury rather than from normal tissue repair^[32,33].

The regeneration and apoptosis level of normal hepatocytes usually determine the patients' prognosis after transarterial chemoembolization. The obvious apoptosis after TACE was due to chemotherapeutic drugs and free radicals, which made the normal process of apoptosis more rapid. Therefore, excessive dosage of chemotherapeutic drugs may promote apoptosis and injury of normal hepatocytes in non-neoplastic area of the liver, and deteriorate the liver function of patients. We can draw the conclusion that it is important to use chemotherapeutic drugs, because they can protect the liver function of patients and improve their survival rate after treatment.

Abstract

AIM: To evaluate the palliative therapeutic effects of transjugular intrahepatic portosystemic shunt (TIPS) in portal vein tumor thrombosis (PVTT) complicated by portal hypertension.

METHODS: We performed TIPS for 14 patients with PVTT due to hepatocellular carcinoma (HCC). Of the 14 patients, 8 patients had complete occlusion of the main portal vein, 6 patients had incomplete thrombosis, and 5 patients had portal vein cavernous transformation. Clinical characteristics and average survival time of 14 patients were analysed. Portal vein pressure, ascites, diarrhoea, and variceal bleeding and circumference of abdomen were assessed before and after TIPS.

RESULTS: TIPS was successful in 10 cases, and the successful rate was about 71%. The mean portal vein pressure was reduced from 37.2 mmHg to 18.2 mmHg. After TIPS, the ascites decreased, hemorrhage stopped and the clinical symptoms disappeared in the 10 cases. The average survival time was 132.3 d. The procedure failed in 4 cases because of cavernous transformation in portal vein and severe cirrhosis.

CONCLUSION: TIPS is an effective palliative treatment to control hemorrhage and ascites due to HCC complicated by PVTT.

INTRODUCTION

TIPS is effective in treating patients with hemorrhage, intractable ascites and portal hypertensive gastropathy, and many favorable results and experiences have been obtained as well^[1-7]. TIPS has been widely used for portal hypertension with portal vein thrombosis (PVT), type-III Budd-Chiari syndrome, even bile duct occlusive diseases, and other portal hypertension^[8-17]. But how to treat primary hepatocarcinoma

with secondary portal hypertension is a challenge. In 1995, Zhang^[18] first reported the clinical experiences that TIPS procedure was applied to HCC patients with variceal hemorrhage, but the portal vein must be opened before TIPS. There were no reports about whether TIPS could be a palliative method for portal vein tumor thrombosis (PVTT). Since 1998 we have tried to study TIPS in the treatment of portal hypertension secondary to PVTT.

MATERIALS AND METHODS

Clinical data

There were 14 patients with end-stage HCC in our hospital from December 1998 to May 2001, 13 men and one woman. The patients aged from 28 to 75 years, and the average age was 56.3 years. Three patients did not receive any treatment before TIPS and the others were treated with transarterial chemoembolization (TACE) and other procedures. One patient survived for 6 years after 8 times of TACE, and 2 patients emerged ascites and hemorrhage after they were treated by radiofrequency ablation. Of the 14 patients, there were three patients with intractable ascites, one patient with simple hemorrhage and 10 patients with hemorrhage and ascites (Tables 1, 2). Their hepatic function was poor and assigned to Child-Pugh class C. The diagnosis of PVTT was based on contrast-enhanced CT and color Doppler sonography while the cavernous transformation in the portal vein was detected by color Doppler sonography, contrast-enhanced CT and angiography.

TIPS procedure

TIPS was performed by using the RTPS 100 (Cook, America) portal venous puncture set. After administration of local anesthetic (20 g/L lidocaine hydrochloride) the Colapinto needle (Cook, America) was advanced into the right hepatic vein, and then the right portal vein was punctured. A wire guide (hydrophilic coating wire guide, Terumo) was introduced through the needle. Because of stenosis, occlusion and cavernous transformation of portal vein trunk and its right and left branches, puncture was difficult. So small branches were also available. With a guiding wire the catheter was advanced into the portal vein trunk. After measurement of the portal venous pressure, the needle track was dilated with a balloon (10 mm-diameter, 40 mm-length). Then an expandable stent (8-10 mm-diameter, 6-8 cm-length) was placed. The number of stents was based on the length of the shunt tract to ensure the stents covering all along stenosis segments arising from tumor emboli. The portal venous pressure was also measured after shunt was established.

RESULTS

The portosystemic shunt was successful in 10 of 14 patients. Shunt tract was achieved with a single stent in four patients, two stents in four patients, and four stents in two patients. The mean portal pressure was 37.2 mmHg and 18.2 mmHg before

and after TIPS. The mean abdomen circumference was 86.3 cm and 77.65 cm before and after the procedure (Table 1). TIPS could be performed for four patients with incomplete occlusion of portal vein trunk as standard TIPS (Figure 1), while it could be performed for six patients with complete occlusion of portal vein trunk by introducing hydrophilic coating wire guide through the potential vascular lumen to superior mesenteric vein (Figure 2). The 4 patients with cavernous transformation in portal vein and severe cirrhosis failed to TIPS procedure, no portal vein trunk and branches but vascular plexus sign was displayed on angiogram. They had no improvement in clinical symptoms and their mean survival time was 34 days, shorter than the successful ones. The needles were punctured out of liver and into the peritoneum cavity in two patients, but they had no severe complications during and after the procedure. The needle tract was passed through the tumor in one patient, but no metastasis was found in 3 mo of follow-up. In all patients the mean content of serum bilirubin and aminotransferase increased transiently after TIPS procedure,

and improved after one week of treatment.

Table 1 Clinical characteristics of 14 patients assigned to treatment with transjugular intrahepatic portosystemic stent-shunt procedure

Characteristic	Value
Age (yr)	
Range	28-75
mean±SD	53.6±12.7
Sex (M/F)	13/1

Figure 1 TIPS procedure in patient with incomplete occlusion of portal vein trunk. A: Main portal vein dilation with eccentric tumor thrombi shown on enhanced Ctgram. B: Superior mesenteric vein dilation with eccentric filling defect and main portal vein occlusion shown on superior mesenteric vein angiogram. C: Open shunt shown on superior mesenteric vein angiogram after stent implantation. D: Recurrence of symptoms of ascites and diarrhoea 30 d after TIPS and shunt stenosis as well as segmental filling defects shown on follow-up angiogram.

DISCUSSION

The incidence of PVTT in end-staged HCC was very high, about 20-30% in small hepatoma (2-3 cm in diameter) and 50-75% in those above 5 cm in diameter, and 86% of HCC patients with variceal bleeding had PVTT^[18]. The tumor emboli resulting in portal hypertension and high resistance made the patients tend to have variceal bleeding and ascites. Tumor thrombosis in main portal vein was more prone to variceal bleeding and more difficult to be treated than that in branches and hepatic vein. Therefore some conservative measures were taken to relieve the patients' ailments, such as endoscopic sclerotherapy and ligation. But these measures were less effective. Because of low efficacy and huge cost, many patients abandoned treatment.

Current status and application of TIPS in PVTT

TIPS procedure is an effective and safe treatment for patients with variceal hemorrhage and intractable ascites, but its use is limited due to its complications of encephalopathy and poor long-term efficacy^[19-25]. It was reported that the rate of stenosis of shunt was 33-66% within 1 year and that of encephalopathy was 10-30%^[1-2,19,22]. In recent years some scholars applied TIPS to portal hypertension secondary to portal thrombosis to ensure the patients to have time for further treatments including liver transplantation^[26-29]. But the thrombus must be newly happened because old emboli possibly led to cavernous transformation and made the TIPS and liver transplantation difficult. Some authorities applied TIPS to HCC patients with esophagogastric variceal bleeding, but they thought that patients must be with hepatic function class A or B (Child-Pugh classification), under-controlled or small nodular type hepatoma and without PVTT^[18,30-34].

Key skill points in TIPS procedure for PVTT

Of the 14 cases, 10 cases were technically successful and the ratio of success was consistent with that reported^[1-2]. It was very difficult to puncture the right main portal branch directly because of portal occlusion, stenosis and cavernous transformation. Even a small branch of portal vein was punctured with good blood regurgitation, and hydrophilic coating wire guide could be introduced into the superior mesenteric vein or splenic vein through the loose thrombus (Figure 2). The stent should cover all the thrombus to prevent tumor from growing into the shunt. The slower the blood flow passing the stent, the more easily the shunt is thrombosed. Esophagogastric vein should be embolized after TIPS procedure because low blood flow tended to form thrombosis in the shunt^[8,25]. The embolism of esophagogastric vein could also prevent variceal bleeding, keep high flow and reduce thrombosis in the stent. But esophagogastric vein was not displayed very well because of PVTT in most cases.

Figure 2 Occlusive portal vein, dilated superior mesenteric vein, portal vein cavernous transformation, and esophagogastric varices shown on portal vein angiogram after introducing a catheter into superior mesenteric vein.

Experiences and clinical effect

TIPS procedure is very effective for diarrhoea secondary to PVTT. A male patient with PVTT had mechanical diarrhoea 12-15 times a day and it lasted for a month with no abnormality in stool examination. Following the decrease of portal pressure after TIPS, ascites and diarrhoea decreased. The causes of diarrhoea were similar to those of ascites. Too high portal vein pressure could make fluid leak out of vessels not only into peritoneal cavity but also into intestinal tract as watery stool.

All patients who failed to TIPS procedure had cavernous transformation. Two patients with tumor thrombus in portal vein had no dilation in superior mesenteric vein and the pressure was not high as well (Figure 3). Considering that the effect was probably not very well in patients with little pressure gradient, we did not continue further procedure. In these portal hypertension patients there were areas with both a portal and a systemic venous drainage including esophagus, anal canal, retroperitoneum and umbilical region. Partial spleen artery embolization or gastric coronary vein embolization was not effective and variceal rebleeding was inevitable in the following months. In this study only one patient had a successful procedure in five patients with cavernous transformation, so it should be careful to carry out TIPS procedure in such cases.

Figure 3 Main portal vein occlusion, hepatic arteric portal shunt and portal cavernous transformation in a 64-year-old patient with refractory ascites and hematemesis. A: Thin splenic and superior mesenteric vein shown on enhanced CT gram. B: Thin superior mesenteric vein and disordered drainage vein shown on angiogram.

A suitable size of stent is important to improve shunt flow, prevent esophagogastric variceal bleeding and decrease ascites^[23-34]. Too large a stent could lead to encephalopathy and we used stents of 10 mm in diameter. The shunt stenosed in one patient with a stent of 8 mm in diameter 15 days after TIPS and died of rebleeding after 20 d. Another patient was placed 4 stents because the shunt was too long. Stenosis of the shunt happened 30 d after the stents were placed and the angiogram displayed shunt rugged and segmental filling defects (Figure 1D). Treatment of the shunt stenosis was similar to that of standard TIPS. The rate of shunt stenosis was relatively low in these patients, partly because of short-term follow-up and abnormal coagulation. By actively preventing encephalopathy and closely

monitoring condition change, patients in this study did not have encephalopathy of stage II and only 5 patients had transitory encephalopathy of stage I. Although patients died of dyscrasia or liver failure, their quality of life was improved.

Abstract

AIM: To investigate the effect of transcatheter arterial embolization (TAE) on angiogenesis of hepatic tumor.

METHODS: Twenty New Zealand White rabbits were randomly divided into two groups of 10 each and VX2 carcinoma was implanted in the left medial lobes of the livers. Fourteen days later, a silicon catheter was inserted into the left hepatic artery of rabbit with VX2 hepatic tumor and infusion was performed via the hepatic artery using Lipiodol (the TAE group) or saline (the control group). Rabbits were sacrificed 7 d after treatment and tumor tissues were excised. Expression of vascular endothelial growth factor (VEGF) protein and microvessel density (MVD) of tumors were examined using immunohistochemistry. The staining intensity of VEGF was evaluated with a computer-assisted image-analyzer. Reverse transcription-polymerase chain reaction (RT-PCR) was used to detect the VEGF mRNA expression of tumors.

RESULTS: MVD was higher in the TAE group compared with the control group (28.6 ± 10.6 vs 16.3 ± 6.9 , $P < 0.01$). Expression of VEGF protein was enhanced after TAE. The staining intensity of VEGF in the TAE group was 0.162 ± 0.018 , significantly higher than in the control group (0.142 ± 0.01 , $P < 0.01$). At mRNA level, VEGF165 mRNA was significantly higher in the TAE group compared with the control group (2.58 ± 0.42 vs 1.99 ± 0.21 , $P < 0.001$). MVD was well correlated to VEGF expression in both the TAE group ($r = 0.69$, $P < 0.05$) and the control group ($r = 0.72$, $P < 0.05$).

CONCLUSION: TAE promotes the development of neovascularization of residual tumors through up-regulation of VEGF expression, possibly due to hypoxic insult.

INTRODUCTION

Hepatocellular carcinoma (HCC) is one of the most common malignant tumors in Asia, including China. Surgical resection is still the treatment of first choice for patients with HCC

nowadays^[1]. However, because of tumor extension, poor hepatic functional reserve due to underlying liver cirrhosis, or both, only a small portion of patients are suitable candidates for surgery^[2-4]. Transcatheter arterial chemoembolization (TACE) is considered to be an effective treatment for patients with HCC who are not candidates for surgical resection^[5,6]. TACE could reduce tumor size^[7-8]. However, intrahepatic or extrahepatic metastasis after TACE is the major factor limiting its overall therapeutic effect^[9].

Angiogenesis, the process leading to the formation of new blood vessels from preexisting vessels, plays a central role in the survival of tumor cells, in local tumor growth, and in the development of distant metastasis^[10]. Microvessel density (MVD) has been the gold standard for the quantification of tumor angiogenesis, showing a good correlation with the prognosis in a variety of cancers including HCC^[11-15]. Among the known angiogenic factors produced by tumor cells, vascular endothelial growth factor (VEGF) is one of the most potent angiogenic factors involved in tumor development. VEGF is a specific mitogenic factor for vascular endothelial cells, which stimulates endothelial cells proliferation, promotes neovascularization and increases vascular permeability. Evidence from preclinical and clinical studies indicates VEGF is associated with formation of metastases and poor prognosis in various cancers^[16-18].

VEGF protein is produced by alternative splicing of the primary transcript leading to the production of at least four major isoforms of VEGF: 121, 165, 189, and 206^[19]. VEGF189 and VEGF206 contain heparin-binding domains and are highly concentrated in the extracellular matrix. VEGF165 and VEGF121 are diffusible and predominate in most tissues, lacking this particular domain. The presence or absence of these domains affects the properties, actions, and distribution of the isoform produced^[19].

Little is known of the changes of angiogenesis and VEGF expression in HCC after TACE. Thus, we established a rabbit model of transcatheter arterial embolization (TAE) with hepatic VX2 carcinoma, and examined MVD and VEGF expression in the hepatic tumors after TAE.

MATERIALS AND METHODS

Implantation procedure

The rabbit VX2 carcinoma was selected for implantation in the liver because of the similarities of its blood supply to that of human hepatomas^[20,21]. The VX2 strain (obtained from Dr. Li Xin of Department of Radiology, the Union Hospital, Tongji Medical College of Huazhong University of Science and Technology, Wuhan, China) was maintained by serial passage in rabbit hindlimbs. Twenty male New Zealand White rabbits (3.0 to 3.5 kg) were used for all experiments. Studies with these animals were approved by the Animal Care and Use Committee of Tongji Medical College of Huazhong University of Science and Technology and carried out according to their guidelines. Tumor implantation was performed as described previously^[22] with a slight modification. Briefly, rabbits were anesthetized by i.v. injection of sodium pentobarbital (30 mg/kg) via a marginal ear vein. The abdominal area was shaved and

sterilized, and a midline subxyphoid incision was made. The left medial lobe of rabbit liver was gently exposed, and one piece of the VX2 tumor tissue excised from the carrier rabbit and broken into fine pieces (1 mm×1 mm×1 mm in size per piece) in Hanks' solution was implanted into the subcapsule of the left medial hepatic lobe. The implanted site was closed with gelatin sponge to prevent the leakage of tumor cells into the peritoneal cavity. The hepatic lobe was then returned to the abdominal cavity. This method allows the growth of a single solitary, well-demarcated tumor in the liver of each recipient rabbit. The incision was closed in two layers. The tumors were allowed to grow for 2 wk, and studies were performed when the tumors reached 1 to 2 cm in diameter.

TAE procedure

Twenty rabbits were divided into two groups of 10 rabbits each randomly. The animals were relaparotomized through a midline abdominal incision under the general anesthesia as described above, and a silicone catheter (outer diameter 0.8 mm) with a tip in the shape of a hockey-stick was inserted retrogradely into the left hepatic artery via the gastroduodenal artery under the operating microscope (Zeiss OPMI 6-S, Aalen, Germany). The catheter was tightly secured and hepatic arterial infusion was made, with 0.5 mL/kg of lipiodol in TAE group or with the same volume of saline in control group. After the injection, the catheter was removed and the gastroduodenal artery was ligated. The incision was closed in two layers. CT scan was performed 2 d after TAE, and confirmed that the lipiodol had been retained in the tumors of all cases (Figure 1).

Figure 1 CT scan 2 d following lipiodol infusion.

Tissue preparation

The rabbits were sacrificed 7 d after treatment, and the tumor was removed. Part of the specimen was flash-frozen at -70°C for RT-PCR, and the rest was fixed in 40 g/L formaldehyde and embedded in paraffin for immunohistochemical study.

Immunohistochemistry

Consecutive 4- μm sections were cut and mounted on glass slides. Sections were stained with H&E. VEGF expression was examined immunohistochemically with an anti-VEGF mouse monoclonal antibody (JH121, Neomarkers, Inc., Fremont, CA) at a dilution of 1:80, and by using streptavidin-peroxidase technique with SPtm kit (Zymed Laboratories, Inc., USA). The JC/70 monoclonal antibody (Dako, Glostrup, Denmark) against CD31 was used for microvessel staining using the LSAB method (Dako LSAB kit; Glostrup, Denmark). Negative controls were prepared by PBS substitution for the primary antibodies staining, and known positive controls were included in each staining run.

Morphometric analyses

The positive expression cells of VEGF were ones with brown-

yellow granular patterns in the cytoplasm. In intensively positive staining area, three fields of vision were selected at $\times 400$ magnification. Staining intensity of VEGF was assessed morphometrically with a computer-assisted image-analyzer (HPIAS-1 000 high precision color-image measure system, Tongji Qiangping Image Engineer Company). The image analyzer is an integrated system of Windows-based software specially designed for immunohistochemical analysis.

Determination of MVD

MVD was evaluated according to the method described by Gasparini *et al.*^[23] The stained sections were screened at low power field ($\times 40$), and five areas with the most intense neovascularization (hot spots) were selected. Microvessel counts of these areas were performed at high power field ($\times 200$). Any brown-stained endothelial cell or endothelial cell cluster clearly separated from adjacent microvessels, tumor cells, and other connective-tissue elements was counted as one microvessel, irrespective of the presence of a vessel lumen. The mean microvessel count of the five richest vascular areas was taken as the MVD, which was expressed as the absolute number of microvessels per 0.74 mm^2 ($\times 200$).

RNA preparation and reverse transcription-polymerase chain reaction (RT-PCR)

Total RNA was extracted using TriZol reagent (Life Technologies, Grand Island, NY) according to the manufacturer's recommendations. Briefly, the tissue was homogenized with a Polytron homogenizer in 1 mL TriZol per 100 mg tissue. The suspension was left at room temperature for 10 min before being centrifuged at $12\,000\text{ g}$ at 4°C for 10 min. The aqueous supernatant containing the RNA was carefully removed and transferred to a fresh tube. Total RNA was precipitated by addition of isopropanol and centrifuged at $12\,000\text{ g}$ at 4°C for 10 min. The RNA pellet was washed with 750 mL/L ethanol and re-dissolved in DEPC-treated water. Before being used in RT-PCR these samples were phenol/chloroform extracted and phenol precipitated. The RNA concentration and quality were determined by UV spectrophotometer at absorbances of 260 and 280 nm.

cDNA was synthesized from total RNA with Avian Myeloblastosis Virus and oligo dT-Adaptor Primer (TaKaRa RNA PCR Kit, TaKaRa Bioteth., Dalian, CHN) according to the manufacturer's instructions. Amplification of cDNA was performed using published sense and antisense primers for rabbit β -actin and VEGF^[19,24,25]. The primer sequence for β -actin sense was 5'-CCT TCC TGC GCA TGG AGT CCT GG-3', and the primer sequence for β -actin antisense was 5'-GGA GCA ATG ATC TTG ATC TTC-3'. The sense primer sequence for VEGF was 5'-CAG TGA ATT CGA GAT GAG CTT CCT ACA GCA C-3', and the antisense primer sequence was 5'-CCT GGA ATT CTC ACC GCC TCG GCT TGT CAC-3'. The PCR cycle profile was at 94°C for 30 s, 59°C for 60 s and 72°C for 60 s, with 30 cycles.

After visualization of the PCR products by 20 g/L agarose gel electrophoresis with ethidium bromide staining gel, images were obtained and the densities of the products were quantified using a digital gel image analysis system (GDS8 000, UVP Co., UK). The PCR fragments were identified according to their molecular mass using a DNA marker (DL2 000 marker, TaKaRa Bioteth., Dalian, China). The relative expression levels were calculated as the density of the product of the respective target genes after normalization with the β -actin internal control.

Statistical analysis

All data are expressed as mean \pm SD. Differences in staining

intensity of VEGF, quantity of variant VEGF isoforms and MVD between the TAE group and the control group were compared with Student's *t* test. The correlation of VEGF and MVD was performed with linear regression analysis. $P < 0.05$ was considered statistically significant. Statistical analysis was done using SPSS 10.0 for Windows.

RESULTS

MVD and its pathologic features

Figure 2A shows microvessels were stained in brown color. Microvessels were heterogeneously distributed inside the tumor, and, in general, maximal density was observed near the margins of the invasive tumor or in the central regions of tumor where necrosis could be seen. The MVD was 28.6 ± 10.6 in the TAE group, and 16.3 ± 6.9 in the control group. The MVD was significantly higher in the TAE group than that of the control group ($P < 0.01$).

Expression of VEGF protein

Immunoreactive products of anti-VEGF antibody were positively detected in the cytoplasm of hepatoma cells and scarcely detected in endothelial cells. In general, hepatoma cells showed stronger VEGF immunoreactivity than endothelial cells. The intensity of immunoreactive products was heterogeneous (Figure 2B). The staining intensity of VEGF in the TAE group was 0.162 ± 0.018 , significantly higher compared to the control group (0.142 ± 0.01 , $P < 0.01$).

There was a significant correlation between MVD and VEGF protein expression in both the TAE group ($r = 0.69$, $P < 0.05$) and the control group ($r = 0.72$, $P < 0.05$).

Figure 2 Immunohistochemical staining in hepatic tumor tissues obtained from a rabbit underwent TAE. A: CD31, original magnification $\times 200$; B: VEGF, original magnification $\times 400$.

Expression of VEGF mRNA

PCR amplification of cDNA prepared from frozen sections showed the expression of three bands of 110, 242 and 314 bp corresponding to VEGF121, VEGF165 and VEGF189, respectively (Figure 3A). The band corresponding to VEGF206 was not detected. In both the TAE group and the control group, VEGF165 was strongly detected (Figure 3B). The intensity of

VEGF165 mRNA was significantly higher in the TAE group (2.58 ± 0.42), as compared with the control group (1.99 ± 0.21 , $P < 0.001$). Although the signal of VEGF121 mRNA was slightly higher in the TAE group (1.14 ± 0.19) than that of the control group (0.99 ± 0.11), there was no statistical significance. No significant difference between VEGF189 mRNA in the TAE group (1.03 ± 0.14) and the control group (1.01 ± 0.11) was demonstrated (Figure 3B).

Figure 3 Expression of VEGF mRNA in hepatic tumor tissues. A: Results of RT-PCR of VEGF mRNA in TAE (lane 1), control (lane 2) and M (molecular mass marker); B: quantification of RT-PCR data.

DISCUSSION

TACE has been accepted as one of the most effective palliative treatments for patients with unresectable HCC on the basis of the characterization of its blood supply. Since the blood supply of HCC is derived almost exclusively from hepatic arteries, hepatoma cells undergo ischemic necrosis in TAE. The addition of chemotherapy aimed to enhance the antitumor effect of the ischemia. However, it was only a small proportion of HCC that occurred complete necrosis after TACE^[26]. We have occasionally noticed rapid growth and extensive metastasis after multiple TACE treatments. TACE prior to surgical resection may facilitate recurrence of HCC^[27]. The recurrence rate after 3 years of treatment is 30-60%^[28,29]. It is possible that in addition to the limited ability of chemoembolization to eliminate cancer cells, it may play a role in enhancing the malignant potential of the tumor and the ability of some cells to escape necrosis after treatment^[30]. Huang *et al.*^[26] and Kim *et al.*^[31] reported that the proliferative activity of tumor cells was increased after TACE.

In the present study, we investigated the change of angiogenesis in VX2 hepatic tumor that underwent TAE using immunohistochemical techniques. The results showed that MVD of the tumors markedly increased after TAE. MVD is currently considered the gold standard for histological assessment of the degree of angiogenesis within a tumor. It is an independent predictor for the growth, metastasis and prognosis of tumor. Increasing evidence suggests that there is a clear relationship between the MVD and HCC prognosis^[1,14,32,33]. These findings thus provide evidence that the development of neovascularization

in hepatic residual tumors after TAE may be one of the reasons why the majority of tumor nodes do not show complete necrosis and why tumors have an increased tendency to metastasize after TAE.

Until recently, VEGF was the only growth factor proven to be specific and critical for blood vessel formation^[34]. Many studies have indicated that VEGF is not only correlated with HCC angiogenesis, but also closely correlated with the invasion and metastasis of HCC. The levels of VEGF in tumor and peripheral blood of patients with HCC might be a useful indicator for both HCC metastasis and poor prognosis^[18,35-41]. In our study, the expression of VEGF protein was well correlated to MVD, and the level of VEGF expression in TAE group was increased significantly compared with the control. These findings show that VEGF plays a vital role in the process of angiogenesis in hepatic tumors after TAE.

It has been known that four alternatively spliced products can be generated from the single VEGF gene, yielding different protein products composed of 121, 165, 189 and 206 amino acids, designated as VEGF121, VEGF165, VEGF189 and VEGF206, respectively. Among them, only VEGF121 and VEGF165 are secreted and can induce mitogenesis of endothelial cells; VEGF189 and VEGF206 are membrane anchored and act as vascular permeability factors. To identify the changes of VEGF mRNA isoform expression in hepatic tumors after TAE, we performed RT-PCR. In our study three bands of 110, 242 and 314 bp were shown, corresponding to VEGF121, VEGF165 and VEGF189, respectively. The major VEGF isoform expressed in VX2 hepatic tumor was VEGF165. The significantly enhanced expression of VEGF165 mRNA in the TAE group was observed compared with the control group. Although VEGF121 mRNA was slightly higher in the TAE group than in the control group, there was no statistical significance. We detected no VEGF206 mRNA, consistent with the very restricted expression of this splice variant.

The possible reason for up-regulation of VEGF expression after embolization was anoxia and ischemia of tumor tissues. Hypoxia is known to be a very important stimulus for the new vessel formation seen in tumor angiogenesis by stimulating the expression of VEGF^[42,43]. Kim *et al.*^[44] reported that hypoxia might induce HCC cells to secrete more VEGF and IGF-II. Moreover, the combination of hypoxia and IGF-II brought an additional induction of VEGF. In the current study, it was found that more microvessel was observed in the tumor margins or areas around the necrotic tissues, which might be resulted from more severe local anoxia in these areas.

Song *et al.*^[45] reported that plasma IGF-II level was increased after TACE, which implied that expression of other angiogenic factors besides VEGF might also be changed after TACE.

In conclusion, these results indicate that TAE is involved in the development of neovascularization of hepatic residual tumors after TAE through up-regulation of VEGF expression, possibly due to hypoxic insult. Therefore, the combination of TAE and antiangiogenic therapy may be superior to TAE alone in the treatment of HCC.

Abstract

AIM: To examine the calcium metabolism of colorectal cancer (CRC) in patients with colorectal cancer and control patients.

METHODS: Seventy newly diagnosed CRC patients were included. The healthy control group was age and gender matched ($n=32$). Particular attention was devoted to the relationship between serum calcium of patients, and levels of AFP, CEA, carbohydrate antigen 19-9 (CA 19-9) (that could be considered as prognostic factors). Furthermore, the Ca-sensing receptor (CaSR) gene A986S polymorphism was investigated in these patients, as well as the relationship between different CaSR genotypes and the data stated above.

RESULTS: A lower level of ionized calcium (also corrected for albumin) was found in the serum of CRC patients with normal 25(OH) vitamin D levels. The ionized calcium concentration was inversely correlated with the serum level of CA 19-9. There was no difference in the distribution of CaSR genotypes, between CRC patients and general population. The genotypes did not correlate with other data examined.

CONCLUSION: Based on these results, lower levels of serum calcium might be a pathogenic and prognostic factor in colorectal cancer.

INTRODUCTION

Mortality statistics of the developed countries show that colorectal cancer (CRC) is the second leading cause of death. Even though tumorigenesis is a complex process, epidemiological and experimental data indicate that beside the genetic factors, eating habits (and thus the calcium intake) also play a key role in the development of CRC^[1]. In the past few years, we have learned more and more about the process, but not every possible factor has been uncovered yet.

Several *in vitro* and *in vivo* studies have confirmed the chemopreventive role of calcium in CRC^[1-5]. The experimental

data showed that there was a definite connection between low calcium and vitamin D intake and the prevalence of CRC^[6,7]. Some researchers described a protective effect against the development of CRC, when the calcium intake was 1 200 mg daily^[8]. Alimentary calcium (among others) together with bile acids creating insoluble calcium-soaps inhibit the cytotoxic effect of fatty acids in the bowel, thus protecting the mucus membrane^[9-12].

According to twin studies, serum calcium level was mostly determined by genetic factors^[13]. One of the key factors of this determination is the calcium-sensing receptor (CaSR), which by sensing the concentration of calcium in target organs could respond to the changes of calcium level, thus regulating calcium homeostasis^[13]. Also, a connection has been found between the CaSR gene A986S genotypes (986 Ala/Ser) and serum calcium concentrations within the normal range in healthy adult population^[14].

In our work, we examined the calcium metabolism of 70 recently diagnosed CRC patients and analyzed its possible role in the pathogenesis of CRC, and also the relationship between serum levels of AFP, CEA, CA 19-9 (that could be considered as prognostic factors) and parameters of calcium metabolism. Furthermore, we examined the genotype frequencies (CASR A986S) of our patients and the relationship between genotypes and laboratory parameters of calcium homeostasis and tumor markers.

MATERIALS AND METHODS

Patients

Seventy newly diagnosed CRC patients were examined. All the subjects were in good general conditions. Colonoscopy was performed partly for screening purposes ($n=10$), partly due to symptoms ($n=60$), such as abdominal pain, discomfort and flatulence, anemia, hematochezia, changes in bowel habits, and partly to search for primary tumor (for example in cases of hepatic metastasis). In each selected case, the histological diagnosis was adenocarcinoma. Clinical stage was Dukes A: 20, B: 32, C: 18. Five patients had liver metastasis at presentation. The clinical data of the patients are presented in Table 1. An age and gender adjusted healthy control group ($n=32$) was selected for comparison of the laboratory data. The CASR genotype frequency was compared to the genotype frequency of our previously determined control group, consisting of 201 healthy adults. Written informed consent was obtained from all subjects. The study was approved by the Semmelweis University Regional and Institutional Committee of Science and Research Ethics (141/2003).

Laboratory parameters

To analyze the calcium metabolism of the subjects, serum calcium, phosphate and albumin levels were determined by photometric analysis (Roche, Mannheim, Germany). Ionized calcium levels were also measured in a similar way (Easy-Lite, Bedford, USA). The calcium levels were also corrected to the serum albumin levels (corrected calcium). HPLC (Biorad,

Hercules, USA) was used to measure the serum 25(OH) vitamin D levels, while serum levels of parathyroid hormone (PTH) were determined by chemiluminescence assay (ElecSys/Roche, Basel, Switzerland). To measure AFP, CEA and CA 19-9, immunoassays (Axxym/Abbott, North Chicago, USA) were utilized.

Sampling and histology

In each case, the diagnosis was established by colonoscopy (Fujinon, Japan), and tissue samples were taken for histological analysis.

Genotyping

The polymorphic region of *CaSR* gene was amplified by allele specific PCR technique. The following primers were used: primer M: 5' ACG GTC ACC TTC TCA CTG ACG TTT GAT GAG CCT CAG AAG TAC T 3' 43-mer; primer W: 5' GCT TTG ATG AGC CTC AGA AGA TCG ' 24-mer; and primer R: 5' CTC TTC AGG GTC CTC CAC CTC T 3' 22-mer (10 µmol/L final concentration). PCR reaction was carried out in 20 µL final volume containing: 2 µL 10× Mg free reaction buffer, 4 µL dNTP (1 mmol/L), 1.2 µL 25 mmol/L MgCl₂, 1 µL DNA (25 ng/mL), 3-2-1 µL (primer R, -W, -M), 0.1 µL (0.5 U/µL) Taq (Promega, Madison, USA) and 5.7 µL 2D PCR water. The PCR conditions were at 94 °C for 12 min, 35 cycles at 94 °C for 20 min, at 55 °C for 20 min, at 72 °C for 30 min and at 72 °C for 5 min. There were two types of *CaSR* alleles, the allele A and allele S, so the genotypes were AA, AS, SS. Electrophoretic separation was carried out in a 70 g/L Spreadex/acrilamide-bis (29:1) gel (Elchrom, Cham, Switzerland). For the PCR reaction; Hybaid express thermocycler (Teddington, Middlesex, UK) was used.

Statistics

As the first step, the distribution of continuous parameters was analyzed (Kolmogorov-Smirnov test). Logarithmic transformation was performed as needed. However, results were presented using the original units for easier understanding. The average values for CRC and the control population as well as difference between patients with different genotypes were compared using Student *t* test with separate variance estimates. χ^2 test was used to describe the relation between the allele frequency and tumor localization. Finally, we used parametric correlation (Pearson) to describe the relationship between tumor markers and the calcium homeostasis. A *P* value <0.05 was considered statistically significant. All the statistical analyses were performed using SPSS 9.0 for Windows.

RESULTS

By examining the calcium metabolism of CRC patients, we found that the serum calcium, ionized and corrected calcium levels of our patients were significantly lower, than those of controls. These calcium levels were at the lower limits of the normal range. Serum phosphate and albumin levels were also determined, which were in the lower end of the normal range (Table 1).

There was no difference in serum 25(OH)-vitamin D and PTH values between patients and controls (Table 1). When examining the correlation between calcium metabolism and CEA, AFP, CA 19-9 tumor markers, we found that the ionized calcium levels of our patients were inversely correlated with the serum level of CA 19-9 tumor marker (Table 2).

There was no significant difference in the *CaSR* A986S genotype frequency between healthy population and CRC patients [(CRC: AA=51/70(73%), AS=19/70(27%), SS=0/70(0%); control group: AA=145/201(72%), AS=54/201(27%), SS=2/201(1%)].

In case of the different *CaSR* A986S genotypes of CRC patients, no difference was observed in the examined biochemical parameters and tumor markers (Table 3). Different alleles or genotypes did not show any correlation with the localization of tumor.

Table 1 Laboratory data of CRC patients (mean±SE)

	CRC	Control	<i>P</i>	Normal value
Calcium (Ca)	2.26±0.17	2.45±0.09	0.0001	2.25-2.61 mmol/L

Age (yr)	66.18±10.96	64.8±11.2	NS

NS=no significant difference.

DISCUSSION

The results of our study support the role of low serum calcium in the pathogenesis of CRC. Contrasting to previous data of others, we found that beside normal vitamin D values the level of calcium and the concentration of serum phosphate were both lower than that of controls^[7], suggesting that in CRC the function of vitamin D receptor (VDR) might be damaged. Our previous study corroborates this hypothesis since we showed that oncogene (HER-2) expression correlated with VDR genotypes in CRC patients^[15].

Western style diet (low in calcium and vitamin D and high in fat) has been shown to induce hyperproliferation in colonic epithelial cells. This cell proliferation could be inhibited by calcium and vitamin D supplementation^[10,16,17]. By increasing calcium intake, the number of apoptotic cells in colon epithelium increased,

as well^[18]. Based on several human studies, high calcium and vitamin D intake might prevent CRC development^[11,3,5,6]. A prospective study claimed that the frequency of CRC was three times less in those patients whose serum vitamin D level was above 20 ng/mL^[7]. More than 3.75 µg daily vitamin D intake appeared to reduce 50% incidence of CRC, while 1 200 mg daily calcium intake decreased 75% of its incidence^[7,8].

Low calcium level may influence CRC pathogenesis in several ways. Calcium ion (Ca²⁺) is needed for cell proliferation and differentiation. On the other hand, Ca²⁺ could play an important role in intercellular connections and signal-transduction cascades^[19-24]. Furthermore, it has an influence on the cell-cycle regulatory genes (p53, K-ras, epidermal growth factor) that had a well-documented role in CRC pathogenesis^[25,26]. The functions mentioned above are mediated partly through CaSR. Similarly to other tissues, CaSR could be detected in normal colon epithelial cells as well. Besides, stimulation of the CaSR could increase the expression of E-cadherin and decrease that of beta-catenin. E-cadherin is the inducer of cell differentiation while beta-catenin is responsible for the genesis of malignant phenotype. The fundamental question is whether the low serum calcium level influencing CRC development is present during a life-long period or emerges only in a phase of the patient's life right before the appearance of cancer. Answering this question is crucial in deciding when to start chemoprevention.

A986S polymorphism of the CaSR gene has been suggested to have a role in the development of parathyroid adenoma. Others have demonstrated that healthy women with CaSR 986 AA homozygote had lower levels of serum calcium compared to women having AS heterozygote and SS homozygote CaSR 986 alleles^[14]. Earlier, we demonstrated that CaSR A986S allele frequencies in CRC patients were not different from those in healthy subjects. However, patients with homozygote AA genotype had a significantly higher UICC stage at the time of discovery compared to the heterozygote AS patients. We could not find an association between serum calcium concentrations and CaSR A986S genotypes in our CRC subjects. We also could not detect a correlation between CaSR polymorphism and CRC. The role of CaSR A986S polymorphism in CRC development requires further investigation.

A large array of evidence indicates that CA 19-9 tumor marker had a prognostic role in CRC. Elevated serum levels were associated with the recurrence of CRC or the presence of metastasis. In our patients, serum calcium levels inversely correlated with CA 19-9 concentration, which could support the significance of serum calcium not only as a pathogenic factor but also as a prognostic factor.

In conclusion, our results further strengthen the possibility that serum calcium might be a pathogenic and prognostic factor in the development of colorectal cancer. Our data draw attention to the possibility that by increasing calcium intake, the multi-leveled pathogenic process leading to tumorigenesis might be influenced. In order to prove this, further studies are necessary.

Abstract

AIM: To clarify the effect of SEN virus (SENV) infection on a combination therapy including interferon alfa (IFN- α) or pegylated-IFN with ribavirin in patients with chronic hepatitis and the effect of a combination therapy on SENV.

METHODS: SENV DNA was determined by polymerase chain reaction in serum samples from 95 patients with chronic hepatitis C. Quantitative analysis was done for SENV H DNA.

RESULTS: Twenty-one (22%) of 95 patients were positive for SENV DNA. There was no difference in clinical and biochemical parameters between patients with HCV infection alone and coinfecting patients. The sustained response rate for HCV clearance after combination therapy did not differ between patients with SENV (52%) and without SENV (50%, n.s.). SENV DNA was undetectable in 76% of the initially SENV positive patients at the end of follow-up. SENV H response to combination therapy was significantly correlated with SENV DNA level ($P=0.05$).

CONCLUSION: SENV infection had no influence on the HCV sustained response rate to the combination therapy. Response rate of SENV to the combination therapy depends on SENV DNA level.

INTRODUCTION

Five hepatitis viruses (A-E) are responsible for more than 80% of cases of viral hepatitis. Recently, a new family of DNA viruses was discovered and designated as "SEN virus" (SENV)^[1]. SENV is a single-stranded circular virus of approximately 3 800 nucleotides. By phylogenetic analysis, 8 different strains of SENV have been identified. SENV is a member of the *Circoviridae* family, a group of small, single-stranded,

nonenveloped circular DNA virus that includes TT virus, TUSO1, SANBAN, and YONBAN^[2].

Two strains of SENV (SENV D and SENV H) have been extensively studied and have been shown to be present in approximately 2% of blood donors in the United States, 2% in Italy and 10% in Japan and to be readily transmitted by blood transfusion and other common parenteral routes^[3]. Although SENV infection is cleared spontaneously in the majority of patients, approximately 45% develop persistent infection that exceeds 1 year and has been documented as long as 12 years. Hypervariable regions with mutation rates of 7.32×10^{-4} per site per year may be involved in the persistence^[4]. Although SENV D and SENV H infections were strongly associated with transfusion-associated non-A to non-E hepatitis in one study, this association does not establish causality and the vast majority of patients infected with SENV did not develop hepatitis at the time of transfusion^[3]. However, the clinical role of SENV infection is not yet clear.

HCV is a major cause of post-transfusion hepatitis and chronic liver disease^[5]. More than half of patients with HCV infection develop chronic hepatitis that leads to liver cirrhosis, and hepatocellular carcinoma (HCC)^[6]. The prevalence of SENV in patients with chronic hepatitis was reported to be between 24% and 40%^[3,7]. There is no evidence that SENV infection affects the progression of HCV infection, but the influence of SENV on HCV response to interferon alfa (IFN- α) is not clear^[3]. Three studies investigated the influence of SENV on the response to interferon therapy in HCV infected patients^[8-10]. Rigas *et al.* and Kao *et al.* investigated the patients with chronic hepatitis treated for 6 mo with 3 million units interferon (IFN) 2 alfa 3 times per week plus 1 000-1 200 mg ribavirin daily. The morning dose was reduced to 400 mg for those weighing less than 72 kg. Rigas *et al.* could demonstrate a negative effect of SENV coinfection on the outcome of therapy^[8]. Kao *et al.* showed that SENV infection has no effect on response to combination therapy^[10]. The third study investigated 104 patients who were treated with IFN at a dosage of 9 million units (MU) daily for 2 wk, followed by 9 MU 3 times a week for 22 wk (total dose, 720 MU). There was no effect of SENV coinfection on interferon response in this study^[9].

None of the studies represent the current therapy scheme. Therapy duration depends on HCV genotype. Patients with HCV genotype 2 or 3 are treated for 24 wk with IFN 3 MU 3 times a week plus ribavirin at a dosage of 1 200 mg or 1 000 mg daily. Patients with genotypes other than 2 or 3 are treated for 48 wk^[11,12].

The aim of this study was to determine the prevalence of SENV infection in chronic HCV infected patients, the influence on clinical and virological characteristics and the effect of SENV coinfection on HCV response to combination therapy including IFN and ribavirin.

MATERIALS AND METHODS

Subjects

Ninety-five patients with chronic hepatitis C virus infection

were seen at the outpatient department of the University of Düsseldorf. Diagnosis of chronic hepatitis C was based on the following criteria: (1) detectable HCV-RNA; (2) absence of detectable hepatitis B surface antigen; (3) exclusion of other liver diseases (autoimmune hepatitis, hemochromatosis, Wilson disease). All patients received combination therapy with IFN α or pegylated-interferon (PEG-IFN) α plus ribavirin, and treated for 24 or 48 wk with IFN α 2a (Intron) or 2b (Roferon)- or PEG-IFN α 2a (PEG-Intron) or 2b (Pegasys), and oral ribavirin (Rebetol, Schering Plough) at a dose of 1 000 mg (weight<75 kg) or 1 200 mg (weight>75 kg) daily. Patients infected with HCV genotype 1 or 4 were treated for 48 wk. Patients with HCV genotype 2 or 3 were treated for 24 wk. Blood samples were taken at baseline, at the end of treatment and six months after the treatment. HCV RNA was detected at baseline, 24, 48 and 24 wk after treatment.

Responders were defined as patients who had undetectable levels of HCV RNA in serum and normal ALT 6 mo after the treatment. Patients, who were positive for HCV-RNA at wk 24 discontinued the treatment and were defined as nonresponders. Patients who relapsed after end of treatment were defined as nonresponders. No patient had a history of or developed decompensated cirrhosis or HCC during the study period and all were negative for the antibody to human immunodeficiency virus.

Ninety-five patients entered the study between 1999 and 2002. Forty-nine patients were treated in combination with IFN and 46 patients in combination with PEG-IFN. Fifty-nine of them were men and 36 women with mean age of 42 \pm 12 years. Sixty-eight (71%) of them were infected with HCV genotype 1 or 4 and 26(27%) with genotype 2/3 and HCV genotype of 2(2%) patients were undetermined. Mean ALT was 72 \pm 73 U/L.

SENV-detection and quantification

The presence of SENV D and SENV H DNA was determined by PCR. Total DNA was extracted from 200 μ L serum with the QIAamp blood kit (QIAGEN) and resuspend in 200 μ L of elution buffer. The oligonucleotide primers were synthesized according to the published SENV sequences. The selection of the real-time PCR primers for SENV H-virus and SENV D was done with the support of the Primer Express Software (PE Applied Biosystems, Weiterstadt, Germany).

The primer for the SENV H were designated SENV H-F1 (GGTTAACCKSAGCTGACTTCA (K=G/T; S=G/C)) and SENV H-R1 (GGAAGGTGTAGCAAGGGTTGTC), the fluorogenic TaqMan[®]probe (5' FAM TTTCCGTTCTGCTCACCACAAA 3' TAMRA). A 69-base pair amplicon in a conserved region of the ORF 1 gene was amplified and detected. The primers for the SENV D were designated SENV D-F1 (CCAGACTTGTGC AAAGTTCCTCTTG (R=A/G)) and SENV D-R1 (GTGGTGAG CAGAACGGATGTT), the fluorogenic TaqMan[®]probe (5' FAM AACTTTGCGGTCAACTGCCGCTG 3' TAMRA). A 76-base pair amplicon in a conserved region of the ORF 1 gene was amplified and detected. Each PCR contained 5 μ L sample DNA, 300 nmol/L forward and reverse primer, 200 nmol/L fluorogenic Taq-man probe, 200 μ mol/L (each) dATP, dCTP, and dGTP, 400 μ mol/L dUTP, 10 mmol/L Tris-HCl (pH 8.3), 5 mmol/L MgCl₂, 0.5 U uracyl-N-glycosylase (UNG) and 1.25 U Taq Gold polymerase in a final volume of 50 μ L. Following inactivation of the UNG (2 min, 50 °C) and activation of the AmpliTaq Gold for 10 min at 95 °C, 40 cycles (15 s at 95 °C and 1 min at 60 °C) were performed with an thermocycler 5 700 system (PE Applied Biosystems). As a DNA standard for the SENV H-PCR, a SENV H-coding plasmid (pSGSEN-H), encompassing the amplified region of the TaqMan[®]-PCR, was created by PCR-cloning and serially diluted. The sensitivity of the TaqMan PCR was

determined as <5 copies/assay. A standard graph of the C_T values obtained from serial dilutions of the standard was constructed by the software and the C_T values of the unknown samples were plotted on the standard curves and the number of SENV H genomes were calculated. For the SENV D-PCR no standard-plasmid was created and the results were only determined qualitatively.

Serologic testing of hepatitis B and C

The qualitative analysis of HCV-RNA was tested by a commercial PCR assay (Amplicor HCV Amplification 2.0, Roche Diagnostics, Indianapolis, IN). The quantitative analysis of HBV-DNA was made by a commercial assay (Digene Hybrid Capture System HBV DNA Assay). HBs-Ag as a serologic marker of HBV-infection was detected by a commercial immunoassay (AxSYM HBs-Ag, Abbott Laboratories, North Chicago, IL).

Genotyping of HCV

The genotype analysis of HCV was performed by a commercial hybridization assay (Inno-Lipa HCV II, Innogenetics, Ghent, Belgium) using HCV-positive amplification products from the PCR assay (Amplicor HCV Amplification 2.0, Roche Diagnostics, Indianapolis, IN).

Statistical analysis

Data were entered in SPSS (version 11.0, Inc., Munich, Germany). A χ^2 or Fisher's exact test (F-test) was used for the comparison of categorical variables, and a Mann-Whitney test was used for the comparison of continuous variables. The significance level was set at 0.05, and all *P* values were two tailed. All statistical analyses were performed using of SPSS.

ULTS

SENV was detected in 21 (22%) of 95 patients. Of the 21 patients, 16 were infected with SENV H, 4 with SENV D, and one with both strains. The mean SENV H DNA level in serum was 461 \pm 381 copies/mL. The mean age and the proportion of men and women were similar in the SENV positive and SENV negative group. There was no significant difference between both groups concerning serum levels of ALT, HCV genotype, number of patients who received PEG-IFN, and the proportion of pretreated patients (Table 1). Therefore, many confounding variables known to influence the outcome of the therapy were excluded. Sustained response rates did not differ significantly between the 21 SENV positive patients and 74 SENV negative patients. Eleven of the 21 SENV positive and 37 of the 74 SENV negative patients were responders (52% vs 50%, *P*=1.0).

Table 1 Characteristics of SENV positive and SENV negative patients

	SENV positive (n=21)	SENV negative (n=74)	<i>P</i> value
Median age (yr)	42 \pm 12	42 \pm 12	0.99 ¹
Male, m (%)	13 (62%)	46 (62%)	1.0 ²
Median baseline ALT (IU/L)	81 \pm 109	69 \pm 60	0.56 ¹
Pretreated, n (%)	3 (14%)	10 (14%)	1.0 ²
Hepatitis C genotype, n (%)			
1,4	16 (76%)	51 (69%)	0.6 ²
2,3	5 (24%)	21 (28%)	0.79 ²
Undetermined	0 (0%)	2 (3%)	
PEG-IFN	11 (52%)	35 (47%)	0.81 ²
Sustained HCV response to therapy	11 (52%)	37 (50%)	1.0 ²

¹Mann-Whitney test; ²Fisher's exact test.

Of the 95 patients receiving combination therapy, 48 were sustained responders, who lost detectable HCV RNA for more than 24 wk after completing the therapy (51%). Of these 48 patients, 30 were infected with HCV genotype 1 or 4 and 16 with HCV genotype 2 or 3 and in 2 patients HCV genotypes were undetermined. Sustained responders were found to be independent in relation to gender, ALT before treatment, HCV genotype, and SENV DNA positivity. Sustained HCV response rate to the combination therapy was correlated inversely with age of the patients ($P < 0.01$). A higher mean SENV H DNA level was observed in the nonresponder group, but the difference was not statistically significant (393 ± 297 vs 523 ± 452 , $P = 0.48$) (Table 2).

Table 2 Clinical, biochemical and viral characteristics in relation to HCV response to combination therapy

	Sustained response (n=48)	No sustained response (n=47)	P value
Male, n (%)	30 (63%)	29 (62%)	0.34 ¹
Age (yr)	39±11	45±11	<0.01 ²
ALT	70±78	74±68	0.54 ²
HCV genotype, n (%)			
1 or 4	30 (63%)	37(79%)	
2 or 3	16 (33%)	10 (21%)	0.16 ¹
Undetermined	2 (4%)		
SEN positive, n (%)	10 (21%)	11 (23%)	0.81 ¹
SENV H-DNA (copies/mL)	393±297	523±452	0.48 ²

¹Fisher's exact test; ²Mann-Whitney test.

We analysed the response of SENV to the combination therapy in 20 of the 21 SENV positive patients. The clinical and virological characteristics are shown in Table 3. Of the 21 patients with SENV DNA, 16 were infected with SENV-H, 3

with SENV-D, and 1 with both. Fifteen (75%) of 20 patients had no detectable SENV DNA after treatment. Two (66%) of the 3 patients infected with SENV D responded to the combination therapy, 12 (75%) of the 16 patients infected with SENV H, and the patient who was infected with both strains responded to combination therapy. SENV response to the combination therapy did not correlate with sex, age, or ALT level (Table 4). SENV H response rates correlated with the SENV-DNA titer before treatment. SENV H-DNA level was significantly lower in patients who responded to the combination therapy (371 ± 276 copies/mL vs 820 ± 497 copies/mL, $P = 0.05$).

Of the five patients who failed to eradicate SENV, two lost HCV-RNA, one of these two patients did not have ALT normalized.

Table 4 Clinical and virological parameter of SENV response to combination therapy in 20 HCV/SENV-coinfecting patients

	SENV response (15)	SENV nonresponse (5)	P
Age (yr, mean)	41±12	48±13	0.23 ¹
Male	10 (63%)	3 (60%)	1.0 ²
ALT	85±61	80±123	0.35 ¹
SENV H-DNA (copies/mL)	371±276 (n=13)	820±497 (n=4)	0.05 ¹

¹Mann-Whitney test; ²Fisher's exact test.

DISCUSSION

SENV D or SENV H-DNA was detectable in 22% of the patients, which is comparable to recent reports^[13]. The observed frequency of HCV and SENV infection is not surprising because these agents are transmitted by similar routes. SENV has been shown to be associated with blood transfusion and intravenous drug abuse^[3,14]. Dual infection with HCV and other

Table 3 Clinical and virological characteristics of patients coinfecting with HCV and SENV

hepatitis virus (HAV, HBV) has been reported to be associated with a more severe and rapidly progressing liver disease^[15-17]. In our study no clinical or biochemical difference was found between patients with HCV infection alone and those coinfecting with HCV and SENV. In this and previous studies, there was no evidence to suggest that SENV coinfection leads to increased severity or persistence of chronic hepatitis C^[7]. It was demonstrated that infection with SENV in patients with non-A to non-E liver disease has no effect on disease progression^[18].

Five independent factors could be identified which are significantly associated with response to antiviral therapy: genotype 2 or 3, viral load less than 2 million copies/mL, age 40 years or less, minimal fibrosis stage, and female sex^[11]. Of these five factors, we studied sex, age, ALT, and HCV genotype and found a significant correlation for response of age ($P=0.006$) but not of sex, ALT, or HCV genotype. This result may reflect the patient selection. We observed on an average, 1.3 times higher SENV DNA level in patients who failed to the therapy compared with patients with sustained response. Nevertheless, this difference was not statistically significant (393 ± 297 vs 523 ± 452 , $P=0.48$) and may be due to the small cohort studied.

Response rates to antiviral therapy in hepatitis C has increased after combination therapy consisting of IFN and ribavirin was used. Further increase was observed after introduction of PEG-IFN. Sustained response rates of up to 80% in HCV genotype 2/3 are described^[12]. Patients coinfecting with other hepatotropic viruses are still difficult to treat. Coinfection with hepatitis B virus impairs sustained rate^[15]. On the other hand, it could be demonstrated that coinfection with TT virus has no influence on response rates to IFN therapy in patients with chronic hepatitis C infection^[19,20]. Three studies tried to clarify the influence of SENV on chronic hepatitis C. Rigas *et al.* reported that coinfection with HCV and SENV adversely affected the HCV response to combination therapy with interferon and ribavirin^[8]. This cohort was treated for 6 mo with 3 million units IFN 2ab three times per week plus 1 000/1 200 mg ribavirin/day depending on body mass more or less than 72 kg. They did not take into account that antiviral therapy duration in hepatitis C depends on HCV genotype. In contrast, Umemura *et al.* found no influence of SENV coinfection on HCV therapy^[9]. They investigated the patients with chronic hepatitis C virus infection, who underwent an IFN-monotherapy. Kao *et al.* studied 100 patients with chronic hepatitis C who were treated with IFN and ribavirin. These patients were treated for 24 wk independent of HCV genotype. They showed that coinfection with SENV has no effect on response to the therapy. However, none of the studies represented the current standard in the therapy of HCV infection.

In our study, patients received combination therapy for a duration depending on HCV genotype. We found no significant difference in sustained response rates between patients with HCV and SENV coinfection and those who had HCV infection alone (52% vs 50%, $P=1.0$). Therefore, our data are in concordance with the results from Umemura *et al.* and Kao *et al.* Overall sustained response rates were higher in our study as compared with the study by Umemura. This results from the higher efficiency of combination therapy compared with IFN-monotherapy.

Sixteen of 20 coinfecting patients lost SENV DNA after treatment. There was no influence of the SENV strain on the response rates. SENV D and SENV H response to the combination therapy was not different (2/3 (66%) vs 12/16 (75%), $P=1.0$). This result is in contrast to the results published by Umemura *et al.* The authors reported a response rate of SENV D to a IFN- α therapy of 73% (11/15 patients) and 33% (1/3 patients) for SENV H. This discrepancy may be a result of our cohort. In contrast to their studies we detected more often SENV H than SENV D.

It is well known that virus load is a predictive factor for response to treatment in different virus infections. For example, sustained response rate of HCV therapy correlates with the virus load at initiation of therapy^[21]. Patients with high HBV-DNA levels fail more often to antiviral therapy than patients with low HBV-DNA levels^[22]. Similarly, a significant difference in SENV DNA levels between patients who lost SENV DNA and those who did not respond was found. SENV H-DNA levels were significantly lower in the group who lost SENV ($P=0.05$).

In conclusion, SENV infection is common in patients with HCV infection. SENV coinfection does not influence the clinical course of hepatitis C or the response rates of HCV to the combination therapy. SENV is sensitive to IFN- α , and additional medication with ribavirin does not improve response to IFN- α . The SENV response rate is correlated with the SENV DNA level prior to treatment. Higher levels influence response rate adversely.

Abstract

AIM: To study the effect of siRNA expressed from DNA vector on HBV replication.

METHODS: Human U6 promoter was amplified from genomic DNA and cloned into plasmid pUC18 to construct a mammalian siRNA expression vector pUC18U6. Then oligonucleotides coding for a short hairpin RNA against HBV were cloned into pUC18U6 to form pUC18U6HBVsiRNA which was introduced into 2.2.15 cells by using liposome-mediated transfection. 2.2.15 cells transfected by pUC18U6 and pUC18U6GFPsiRNA which expressed siRNA against green fluorescent protein and mock-transfected 2.2.15 cells were used as controls. Concentration of HBsAg in the supernatant of the transfected cells was measured by using solid-phase radioimmunoassay.

RESULTS: A mammalian siRNA expression vector pUC18U6 was constructed successfully. Compared with controls, pUC18U6HBVsiRNA which expressed siRNA against HBV decreased concentration of HBsAg significantly by 44% ($P < 0.05$).

CONCLUSION: HBV replication in 2.2.15 cells is inhibited by siRNA expressed from the DNA vector.

INTRODUCTION

RNA interference (RNAi) is a potent gene silencing mechanism conserved in all eukaryotes, in which double-stranded RNAs suppress the expression of cognate genes inducing degradation of mRNAs or blocking mRNA translation^[1-3]. The physiological functions of RNAi are not very clear as yet, but it has been used successively as a potent method of gene knockdown in study of gene function and in experimental treatment of some diseases^[4-19]. In mammalian cells, double-stranded RNAs inducing RNAi must be short in length (<30 bp) so that they would not activate nonspecific interferon reactions. These short

interfering RNAs (siRNAs) can be produced by four different ways: chemical synthesis, *in vitro* transcription, enzymatic digestion of dsRNAs and transfection of DNA vectors encoding siRNAs. Among the four ways, transfection of DNA vectors has some advantages such as low cost, lasting expression of siRNA, easiness of preparation, which make it the preferential method when siRNAs are used in treatment of diseases.

Hepatitis B virus (HBV) is a small enveloped DNA virus which belongs to hepadnaviridae. Human beings are HBV's natural host, though some primates can be infected in laboratory. Liver is the primary target organ of infection and persistent infection of HBV usually leads to severe diseases, such as chronic hepatitis, cirrhosis and hepatocellular carcinoma. Current treatment regimens for chronic HBV infection, namely administration of interferon- γ , lamivudine, adefovir, or different combinations of these drugs have only limited long-term efficacy and many adverse effects or drug resistance^[20,21]. Considering the huge population infected by HBV (more than 350 million people are infected by HBV around the world), the exploration of novel treatment strategies is both necessary and urgent. Many ingenious treatment strategies have been tested for inhibition of HBV replication, such as antisense nucleotides, ribozymes, intracellular antibodies, and targeted ribonucleases^[22], and all of them have been demonstrated to inhibit HBV replication to various degrees.

To explore RNAi as a novel alternative strategy for treating HBV, we constructed a DNA vector which can express siRNAs in mammalian cells, and then the vector was used to express in 2.2.15 cells a siRNA against HBV to study its effect on HBV replication.

MATERIALS AND METHODS

Cell culture

Human hepatoblastoma Hep G2 cell line 2.2.15 cells stably transfected by HBV genome, were cultured in Dulbecco's modified Eagle's medium (DMEM, from Gibco Life Technologies, Grand Island, NY) supplemented with 100 mL/L fetal calf serum (Sijiqing Biotech Company, Hangzhou, China).

Construction of mammalian siRNA expression vector-pUC18U6

Human genomic DNA was extracted from HepG2 cells with DNeasyTM tissue kit (Qiagen, Germany) according to the manufacturer's protocol. Purified human genomic DNA was used as the template in PCR to obtain human U6 promoter. The sequences of the primers are as follows: Forward primer: 5' GCGATCTAGAAAGGTCGGGCAGGAAGAG3', reverse primer: 5' GCGAGGTACCGGTGTTTCGTCCTTTCCACAAG3'.

The underlined bases in forward and reverse primers have recognition sites for *Xba* I and *Kpn* I, respectively. The condition of PCR was at 94 °C for 5 min, then 35 cycles at 94 °C for 30 s, at 60 °C for 30 s, and at 72 °C for 1.5 min followed by extension at 72 °C for 7 min. The PCR product was analyzed with 100 g/L agarose gel electrophoresis and then purified by PCR fragment recovery kit as recommended by the manufacturer (Takara, Dalian, China). The purified PCR product was digested by *Xba* I and *Kpn* I, ligated with pUC18,

and transformed into competent *E. coli*. The recombinant plasmid was then purified from transformed *E. coli*, and verified by *Xba* I/*Kpn* I digestion analysis and DNA sequencing.

Construction of HBV-siRNA expression vector-pUC18U6HBVsiR

Two oligodeoxyribonucleotides encoding shRNA against HBV were synthesized by Bioasia Company (Shanghai) and their sequences are as follows: Oligo 1:5' CAGGCTTTCACCTTCTCGCTCGAGCGAGAAAGTGAAAGCCTGCTTTTTTG3', Oligo2:5' AATTCAAAAAGCAGGCTTTCACCTTCTC GCTCGAGCGAGAAAGTGAAAGCCTG3'.

The underlined bases are spacer region and recognition site for *Xho* I. The target of shRNA was 1 086-1 103 nt of HBV genome. To clone the two oligodeoxyribonucleotides, downstream of U6 promoter into pUC18U6, 400 nmol/L for each of the two oligodeoxyribonucleotides was mixed, heated at 100 °C for 5 min, and cooled gradually to room temperature to anneal. pUC18U6 was digested with *Kpn* I, blunt-ended with T4 DNA polymerase, then digested with *Eco*R I, purified and ligated with the annealed oligodeoxyribonucleotides. The ligation mixture was transformed into competent *E. coli*. The recombinant plasmid was then purified from transformed *E. coli*, and verified by *Hind* III/*Xho* I digestion analysis. A control vector, pUC18U6GFPsiR, which expressed a siRNA against green fluorescent protein (GFP), was constructed with the same methods and the sequences of the two oligodeoxyribonucleotides encoding the siRNA were synthesized as previously described^[23]: Oligo1:5' GGCGATGCCACCTACGGCAAGCTCGAGCTTGCCGTAGGTG GCATCGCCCCCTTTTTTG3', Oligo2:5' AATTCAAAAAG GGCGATGCCACCTACGGCAAGCTCGAGCTTGCCG TAGGTGGCATCGCCC3'.

The underlined bases are spacer region and recognition site for *Xho* I.

Transfection

Twenty-four hours before transfection, 2.2.15 cells were seeded

into the culture plate at a density of 2×10^8 /L. LipofectamineTM 2000 reagent (Gibco Life Technologies, Grand Island, NY) was used for the transfection of 2.2.15 cells by pUC18U6HBVsiR, pUC18U6, pUC18U6GFPsiR, or mock solution (DMEM plus LipofectamineTM 2000 reagent containing no plasmid) according to the manufacturer's protocol.

Quantification of HBsAg in supernatant of cell culture

Forty-eight hours after the transfection, the supernatant of the cell culture was collected, and HBsAg in the supernatant was quantified using the solid phase radio-immunoassay kit for quantification of HBsAg (Beimian Dongya Biotech Institute, Beijing) according to the manufacturer's protocol. Briefly, 200 μ L of the supernatant was incubated with a plastic tube coated by anti-HBs antibody at 45 °C for 1.5 h. After the tube was thoroughly washed with deionized water, 200 μ L of ¹²⁵I-labelled secondary antibody was added and incubated at 45 °C for 2 h. The tube was thoroughly washed, and cpm was measured. The concentration of HBsAg of each sample was calculated by comparing the cpm of each sample with a standard curve.

Statistical analysis

One-way ANOVA was used for data analysis. Differences were considered significant when $P < 0.05$.

RESULTS

Construction of pUC18U6 and pUC18U6HBVsiR

Agarose gel analysis showed that human U6 promoter was amplified from genomic DNA (Figure 1A). Restriction digestion analysis and DNA sequencing indicated a vector suitable for siRNAs expression in mammalian cells, pUC18U6, was successfully constructed (Figure 1B and Figure 2A). We then cloned into pUC18U6, downstream of U6 promoter, the annealed two oligodeoxyribonucleotides encoded a short-hairpin RNA (shRNA) against HBV. shRNAs could be

Figure 1 Construction of mammalian siRNA expression vector pUC18U6 and HBV-siRNA expression vector pUC18U6HBVsiR. A: Amplification of human U6 promoter by PCR. 1: DNA marker (2 000, 1 000, 750, 500, 250, 100 bp from top to bottom); 2: PCR product. B: Restriction digestion analysis of recombinant vector pUC18U6. 1: pUC18; 2: pUC18U6; 3: DNA marker (2 000, 1 000, 750, 500, 250, 100 bp from top to bottom). C: Restriction digestion analysis of recombinant vector pUC18U6HBVsiR. 1: pUC18U6HBVsiR; 2: pUC18; 3: DNA marker (2 000, 1 000, 750, 500, 250, 100 bp from top to bottom).

Figure 2 Maps of pUC18U6 and pUC18U6HBVsiR. A: pUC18U6. B: pUC18U6HBVsiR.

processed into siRNA in cells^[24,25]. Since there was no *Xho* I site in pUC18U6, we designed the spacer (CTCGAG) in shRNA recognized by *Xho* I. Therefore, the recombinant vector pUC18U6HBVsiR containing the shRNA coding sequence could yield a new 310 bp fragment compared with pUC18U6 after digested with *Xho* I and *Hind* III (Figure 2B), and this was verified by agarose gel analysis (Figure 1C). This indicated that pUC18U6HBVsiR which could express a siRNA against HBV, was successfully constructed (Figure 2B).

Effect of pUC18U6HBVsiR expressed siRNA on HBV replication

pUC18U6HBVsiR and its control plasmids were transfected into 2.2.15 cells by using liposome. Forty-eight hours after the transfection, the supernatant of the cell culture was collected, and HBsAg in the supernatant was quantified as described in Materials and Methods. As shown in Figure 3, transfection of pUC18U6HBVsiR reduced HBsAg significantly as compared with the controls ($P < 0.05$), suggesting that siRNA expressed by pUC18U6HBVsiR suppressed the replication of HBV, and this suppression was specific because transfection of pUC18U6GFPsiR, which expressed siRNA against GFP, had no effect on HBV replication.

Figure 3 HBsAg concentrations in supernatants of transfected 2.2.15 cells. Groups A-D represent mock-transfected 2.2.15 cells or 2.2.15 cells transfected by pUC18U6, pUC18U6GFPsiR and pUC18U6HBVsiR, respectively. The concentration of HBsAg in the supernatant of 2.2.15 cells transfected by pUC18U6HBVsiR was decreased by 44% as compared with that of mock-transfected 2.2.15 cells.

DISCUSSION

The aim of the present study was to explore siRNAs as a novel strategy in the treatment of HBV infection. Firstly, we first constructed a vector which was suitable to express siRNAs in mammalian cells. siRNAs could be produced *in vitro* and *in vivo*. *In vitro*, siRNAs could be produced by chemical synthesis, *in vitro* transcription, or by enzymatic digestion of dsRNAs^[26-29]. siRNAs produced *in vitro* could be transfected directly into mammalian cells to knockdown gene expression. However, *in vitro* produced siRNAs have several shortcomings, such as transient effect, and high cost. To overcome these shortcomings, several groups have developed a couple of DNA-vectors which could express siRNAs *in vivo*^[11,23-25,27,28]. These vectors had different promoters and different backbones, and expressed siRNAs via two approaches: sense and antisense strands of siRNAs transcribed from tandem promoters and then combined to form siRNAs, or short hairpin RNAs transcribed from a single promoter and then processed by Dicer, a key enzyme in RNA interference, to yield siRNAs. The mammalian siRNAs expression vector constructed by us used human U6 promoter, a pol III promoter, to drive the expression of shRNAs. Compared with other reported vectors, our vector has some features which make the cloning of shRNA expression cassettes easy. The *Kpn* I and *Eco*R I sites downstream of the U6 promoter

were used for directional cloning of shRNA expression cassettes and the first nucleotide of the *Kpn* I site was guanosine, just the required nucleotide for the +1 position of the U6 promoter. Therefore, there was no need to consider this requirement when we designed shRNA sequences by using our vector. Additionally, our vector has no *Xho* I site. By incorporating *Xho* I site as the spacer in the shRNA sequences, it is easy to identify positive shRNA expression vectors containing shRNA expression cassettes by routine agarose gel analysis of *Xho* I/*Hind* III digestion products of the vectors. Positive vectors should reveal a new small fragment of about 300 bp which was absent from the negatives (Figures 1C and 2B). Some reported vectors also identify positive shRNA expression by double enzyme digestion. However, the double enzyme digestion sites in these vectors are just the sites used for cloning of shRNA expression cassettes. Therefore, for these vectors it is not easy to identify the positive shRNA expression vectors by routine agarose gel analysis, especially minigel analysis widely used in laboratories, since shRNA expression cassettes are generally 50-60 bp in length, almost the limit of resolving power of routine agarose gel analysis. The same constraint of routine agarose gel analysis also requires shRNA expression cassettes without double enzyme digestion sites, and limit siRNA target site selection. In contrast, there was no such limitation when using our vector to express siRNAs.

Several groups have reported using siRNAs to inhibit HBV replication in cell cultures and animal models^[12-19]. Although all of these reports showed that HBV replication was inhibited to various degrees by siRNAs, several factors must be taken into account before siRNAs are used to treat HBV infection. One is target selection. siRNAs target at different sites of the same gene can vary from strong to less inhibition of the gene expression. Up to now, little is known about the mechanism of this selection. Therefore, it is still an empirical matter to design the most effective siRNAs. In our study, we chose 1 086-1 103 nt of HBV genome as the target, different from other groups. Our results suggested that siRNA targeting this site specifically inhibited HBV replication. Considering that HBV genome is 3.2 kb and there are no general rules to predetermine the most effective siRNAs, a systematic comparison by experiments of the efficiency of siRNAs against different targets of HBV genome in inhibiting HBV replication should be done to pick out the most effective siRNAs for treating HBV infection. Another concern of using siRNAs for treatment of HBV infection is viral mutants. RNAi is so specific in gene silencing that even a single-base mismatch between siRNAs and cognate genes can significantly reduce the silencing effect. Since viruses evolve very rapidly, they can gain the resistance to once-effective siRNA molecules in short time. In fact, two recent studies reported HIV and poliovirus escape mutants after extended siRNAs treatment^[30,31]. To overcome this obstacle, multiple viral sequences must be targeted simultaneously. In this aspect, our study adds another target when designing multi-target siRNAs to inhibit HBV replication. Further studies are needed to determine the optimal combination of these targets.

Abstract

AIM: To explore how to improve the immunogenicity of HBcAg CTL epitope based polypeptides and to trigger an HBV-specific HLA I-restricted CD8⁺ T cell response *in vitro*.

METHODS: A new panel of mimetic therapeutic peptides based on the immunodominant B cell epitope of HBV PreS2 18-24 region, the CTL epitope of HBcAg18-27 and the universal T helper epitope of tetanus toxoid (TT) 830-843 was designed using computerized molecular design method and synthesized by Merrifield's solid-phase peptide synthesis. Their immunological properties of stimulating activation and proliferation of lymphocytes, of inducing T_{H1} polarization, CD8⁺ T cell magnification and HBV-specific CD8⁺ CTL mediated cytotoxicity were investigated *in vitro* using HLA-A2⁺ human peripheral blood mononuclear cells (PBMCs) from healthy donors and chronic hepatitis B patients.

RESULTS: Results demonstrated that the therapeutic polypeptides based on immunodominant HBcAg18-27 CTL, PreS2 B- and universal T_H epitopes could stimulate the activation and proliferation of lymphocytes, induce specifically and effectively CD8⁺ T cell expansion and vigorous HBV-specific CTL-mediated cytotoxicity in human PBMCs.

CONCLUSION: It indicated that the introduction of immunodominant T helper plus B-epitopes with short and flexible linkers could dramatically improve the immunogenicity of short CTL epitopes *in vitro*.

INTRODUCTION

Despite the existence of effective vaccines against hepatitis B virus (HBV) for many years and massive prophylactic vaccination campaigns, HBV infection remains an important health problem worldwide. HBV can evade the immune defence system and present consistently in hepatocytes. Patients carrying the virus can develop chronic hepatitis, liver cirrhosis,

and ultimately hepatocellular carcinoma^[1-3]. Currently, the two approved therapies for chronic hepatitis with definite clinical beneficial effects are IFN- α and lamivudine. IFN- α therapy combines antiviral and immunostimulant properties and can result in sustained suppression of HBV replication in one-third of patients. Lamivudine leads to a rapid and almost absolute discontinuation of HBV replication as well as a rapid improvement of the necro-inflammatory activity of the liver disease and to a lesser extent of fibrosis. However, short-term treatment leads to a frequent relapse of HBV replication. On the other hand, long-term treatment has shown to result in virological breakthrough related to the selection of resistant viral variants with a yearly incidence of 15-25%. These outcomes emphasize the need for novel therapeutic approaches^[4]. And it is known that cytotoxic T lymphocytes (CTLs) recognize short peptides derived from the intracellular processing of viral antigens in association with HLA class I molecules on the surface of the infected cells, and HLA-I restricted T cell mediated responses, especially virus antigen specific CTL mediated cytotoxicity, play the key role in controlling HBV infection and in the clearance of infected cells^[5-7]. Since HBV does not efficiently infect human cells *in vitro*, the use of short synthetic peptides comprised of a set of immunodominant epitopes of virus antigens mimicking the processed antigen fragments can be a rational strategy to stimulate the HBV specific CTL response and break to some extent the immune tolerance to HBV antigens^[8-12]. Based on this concept, a new panel of short polypeptides (mimogens) representing the immunodominant CTL, B- and T helper epitopes of the HBcAg, pre-S2 and tetanus toxoid was designed and used for CTL-mediated response analysis. This issue was addressed *in vitro* with HLA-A2⁺ human peripheral blood lymphocytes (PBMCs) from healthy donors and chronic hepatitis B patients.

MATERIALS AND METHODS

Materials

HLA-A2⁺ human peripheral blood mononuclear cells (PBMCs) from 9 healthy donors and 9 chronic viral hepatitis B patients were kindly donated by Southwest Hospital, Chongqing municipality, China. Amino acids used for peptide synthesis were purchased from PE & ACT companies. Na₂⁵¹GrO₄ for target cell labeling in standard ⁵¹Gr release assay and ³H-TdR were both from New England Nuclear (NENTM), Boston, USA. Other materials used in this study were as the following: RPMI 1640 medium (Gibco), fetal calf serum (FCS) (HyClone), HLA-A*0201/FLPSDFFPSV tetramer kit (ProImmune, UK) and human IFN- γ ELISpot kit (DiaClone, France).

Methods

Mimetic polypeptides The immunodominant B- and CTL epitopes of HBV pre-S2 and HBcAg were identified on the basis of the HLA-A2.1 binding motifs^[13-15]. Peptide1 was chosen from the immunodominant HBcAg₁₈₋₂₇ CTL epitope (FLPSDFFPSV). The N-termini of peptide 1 linking to the universal T helper sequence of TT 830-843 through a linker of “-Gly-Gly-Gly-” was named as peptide 2 (QYIKANSKFIGITE GGG FLPSDFFPSV). The universal T helper epitope of tetanus

toxoid and the Pre-S₂₁₈₋₂₄ B-epitope were linked to the N- and C-termini of the HBcAg₁₈₋₂₇ sequence respectively with the linker of “-Ala-Ala-Ala-” and “-Gly-Gly-Gly-” as peptide 3 (QYIKANSKFIGITE AAA FLPSDFFPSV GGG DPRVRGLYFPA). Melanoma associated MART-1₂₇₋₃₅ CTL epitope peptide (AAGIGILTV) was used as irrelevant control. All mimogens were calculated and optimized using computerized molecular design theories and methods in O2 workstation (SGI).

The above peptides were synthesized with a Merrifield's solid-phase peptide synthesis method (PE431A synthesizer), purified by RP-HPLC (WATERS 600) and analyzed by MS/MS (API 2000). All peptides with a purity over 95% were solved in DMSO at the concentration of 10 mg/mL and preserved at -70 °C.

Lymphocytes proliferation assay

Human PBMCs were separated from peripheral blood by centrifugation on Ficoll-Hypaque gradients and used as fresh samples^[16]. PBMCs were plated at a concentration of 2×10^6 /mL in 96-well microplates in PRMI 1640 medium supplemented with 100 mL/L fetal bovine serum, 5×10^{-5} mol/L α -mercaptoethanol, and in the presence of 10 μ g/mL mimetic peptides respectively. Eighteen to 24 h later, 1 μ Ci/well of ³H-TdR was added into the medium. Four to 6 h later, lymphocytes were collected and counted using a β -counter. Non-stimulated PBMCs were used as negative control. Results of samples were considered positive if the stimulation index (SI) > 2.1.

T_{H1} polarization assay

For the assay of T_{H1} polarization induced by mimetic peptides, IFN- γ ELISPOT kit was used. Briefly^[16,17], 96-well PVDF membrane-bottomed plates were coated with capture anti-human IFN- γ mAb at 4 °C overnight. Fresh PBMCs were stimulated with 10 μ g/mL of mimetic peptide 1, 2 and 3 respectively, and then added to triplicated wells at 5×10^3 /well and the plates were incubated for 18 h at 37 °C in 50 mL/L CO₂. At the end of incubation, cells were washed off and a second biotinylated anti-IFN- γ mAb was added, followed by streptavidin-alkaline phosphatase conjugate and substrates. After the plates were washed with tap water and dried overnight, spots were counted under a stereomicroscope. The number of T_{H1} polarized cells (HBcAg₁₈₋₂₇-specific CD8⁺ T cells), expressed as IFN- γ secreting cells (ISCs) /10⁶ PBMCs, was calculated after subtracting negative control values (non-stimulated PBMCs). Results of samples were considered as positive if above the mean by three standard deviations and with a cut off of 50 ISCs /10⁶ PBMCs above mean background.

Cytotoxicity assay

Peptide-specific CTL lines were primed as follows: at d 0, fresh PBMCs were plated at a concentration of 2×10^5 /mL in 24-well microplates (2 mL /well) in RPMI 1640 medium supplemented with 100 mL/L fetal bovine serum and L-glutamine, and in the presence of 10 μ g/mL mimetic peptides respectively. Two days later, 30 IU/mL rhIL-2 was added to the medium. Lymphocytes were then re-stimulated weekly for 2 wk as follows: Cells were harvested, washed once, and replated in 24-well plates at the concentration of 2×10^5 /mL in the above medium, and restimulated respectively with 10 μ g/mL mimetic polypeptides. Twenty hours after last stimulation, cells were harvested, and used as fresh effectors.

CTL-mediated cytotoxicity was detected by standard 4 h ⁵¹Cr release assay^[17]. T2(HLA-A2) cells were used as targets and pre-incubated with 10 μ g/mL of HBcAg₁₈₋₂₇ peptide 2 h before use. The 1×10^6 target cells were labeled with 3.7×10^6 Bq Na₂⁵¹CrO₄ in 1.0 mL RPMI 1640 medium supplemented with 150 mL/L fetal bovine serum and in the presence of 10 μ g/mL of HBcAg₁₈₋₂₇ peptide for 60 min at 37 °C, and then

washed three times before the addition of effectors. Various concentrations of effector cells were mixed with 1×10^4 targets at effector/target (E/T) ratios of 12.5, 25, 50 and 100 in 200 μ L of culture medium in 96-well V-bottomed microplate in triplicate. The microplate was centrifuged for 3 min at 500 r/min, and then incubated for 4 h at 37 °C in 50 mL/L CO₂. After the incubation terminated, 100 μ L of supernatants was harvested and counted on a γ -counter. Percentage of target cell specific lysis was determined as: (average sample counts-average spontaneous counts/average maximum counts-average spontaneous counts) $\times 100\%$. Maximum and spontaneous counts were measured using supernatants from wells receiving 50 g/L SDS or culture medium alone, respectively. In all experiments, spontaneous counts should be less than 30% of maximum counts. CTL responses were considered positive if they exceeded the mean of specific lysis caused by irrelevant mimetic antigen by three standard deviations and by 10%.

HBcAg₁₈₋₂₇-specific CD8⁺ CTL quantitative detection

HLA class I^{PEP} tetramer-binding assay was used to quantify the HBcAg₁₈₋₂₇-specific CD8⁺ T cells from the fresh effectors produced^[18]. Briefly, fresh effectors were collected, washed twice with 0.02 mol/L, pH7.2 phosphate buffered saline (PBS), counted and separated equally into different tubes in 1.0 mL of PBS each. The effectors were stained with 2 μ L of R-PE-conjugated HLA-A*0201/FLPSDFFPSV and 20 μ L of Cy-Chrome-conjugated mouse anti-human CD8 mAb for 30 min at room temperature. R-PE-conjugated avidin and Cy-Chrome-conjugated mouse IgG_{1,k} antibodies were used as isotype control, and non-stimulated PBMCs were used as negative controls. All samples were collected, washed twice, dissolved into 300 μ L of PBS and FACS-sorted on a FACStar (Beckton-Dickson) with Cell Quest software. Results were expressed as percentages of tetramer-binding cells in the CD8⁺ population. A total of 50 000 events were acquired in each analysis. Results were considered as positive for tetramer-binding cells when above negative controls and by 0.1% CD8⁺ T cells.

Statistical analysis

All data were expressed as mean \pm SD. Statistical analysis was performed using a two-tailed Student's *t* test.

RESULTS

Lymphocytes proliferation assay

Fresh PBMCs were stimulated respectively with three mimetic peptides we designed, and ³H-TdR was used to detect the proliferation of lymphocytes. Data demonstrated that peptide 3 pulsed the most vigorous activation and proliferation of lymphocytes, and with SI > 4.1 by average in healthy PBMCs and > 3.3 in PBMCs from chronic hepatitis patients. Peptide 2 could also induce weak lymphocytes proliferation, with the mean of SI > 2.3 and 2.1 respectively in the PBMCs from healthy donors and chronic hepatitis patients. No activation and proliferation of lymphocytes were detected in peptide 1 stimulated PBMCs (Table 1).

T_{H1} polarization induced by mimetic peptides

HLA-A2⁺ human PBMCs were pulsed respectively with three mimetic peptides we initially designed and synthesized, and the T_{H1} polarization induced was detected using IFN- γ ELISPOT method. Spots of IFN- γ secreting cells can be observed in each of the mimetic peptide samples. Peptide 1 could induce peptide-specific CD8⁺ T cells magnification up to approximately $1\ 667 \pm 231$ ISCs /10⁶ PBMCs in PBMCs from healthy donors and $1\ 420 \pm 253$ ISCs /10⁶ PBMCs in PBMCs from chronic hepatitis B patients, which were dramatically weaker than those of Peptide 2 and 3, which induced

A: Non-stimulated HLA-A2⁺ PBMCs from healthy donors; B: Irrelevant peptide pulsed HLA-A2⁺ PBMCs from healthy donors; C: Peptide1 pulsed HLA-A2⁺ PBMCs from healthy donors; D: Peptide2 pulsed HLA-A2⁺ PBMCs from healthy donors; E: Peptide3 pulsed HLA-A2⁺ PBMCs from healthy donors; F: Non-stimulated HLA-A2⁺ PBMCs from chronic hepatitis patients; G: Irrelevant peptide pulsed HLA-A2⁺ PBMCs from chronic hepatitis patients; H: Peptide1 pulsed HLA-A2⁺ PBMCs from chronic hepatitis patients; I: Peptide2 pulsed HLA-A2⁺ PBMCs from chronic hepatitis patients; K: Peptide3 pulsed HLA-A2⁺ PBMCs from chronic hepatitis patients.

approximately 4 133±416 and 9 200±1 638 ISCs/10⁶ PBMCs respectively in PBMCs from healthy donors, and 3 915±685 and 8 966±1 435 ISCs/10⁶ PBMCs in PBMCs from chronic hepatitis B patients. These results suggest that all the 3 peptides could pulse T_{H1} polarization of T cells, and peptide 3 was more vigorous than peptide 2 and 1 ($P<0.01$). It showed no difference between the PBMCs from healthy donors and chronic hepatitis patients (Table 2).

Cytotoxicity assay

HLA-A2⁺ human PBMCs were pulsed with the 3 mimetic peptides and the irrelevant control peptide respectively, and the CTL-mediated cytotoxicity induced was tested by standard 4 h ⁵¹Cr release assay against HBcAg₁₈₋₂₇ peptide pre-incubated T2 targets. The results demonstrated that all the 3 mimetic peptides could induce positive HBV-specific CTL response, among which peptide 3 induced the most vigorous CTL activity and as high as (68.4±15)% target cell lysis was observed at E/T=100. The percentages of target cells lysed between peptide 1 and 2 pulsing groups were of statistically no difference, and both were dramatically lower than that of peptide 3 ($P<0.01$). The targets lysis observed in both healthy donors and chronic hepatitis

patients showed no statistical difference (Tables 3 and 4).

HBcAg₁₈₋₂₇-specific CD8⁺ CTL detection

HLA-A2⁺ human PBMCs were pulsed respectively with the above three mimetic peptides and the irrelevant peptide MART-1₂₇₋₃₉, the HBcAg₁₈₋₂₇-specific CD8⁺ T cells induced were quantified using HLA-A*0201/FLPSDFFPSV tetramer-binding assay. No HBcAg₁₈₋₂₇-specific CD8⁺ T cells could be detected in the PBMCs pulsed with MART-1₂₇₋₃₅ peptide, and the tetramer staining was almost the same as control background (0.02% in PBMCs from healthy donors, and 0.04-0.14% in PBMCs from chronic hepatitis patients). In PBMCs stimulated with peptide 1, 2 and 3, the frequencies of HLA-A*0201/FLPSDFFPSV-CD8 double-positive T cells were on average 0.35% (3 500/10⁶ PBMCs), 0.38% (3 800/10⁶ PBMCs) and 1.05% (10 500/10⁶ PBMCs) respectively in the PBMCs from healthy donors, and 0.39% (3 900/10⁶ PBMCs), 0.43% (4 300/10⁶ PBMCs) and 0.93% (9 300/10⁶ PBMCs) respectively in the PBMCs from chronic patients. Data showed no statistical differences between the PBMCs from healthy donors and chronic hepatitis patients, and between the effects induced by peptide1 and peptide 2 (Figure 1).

DISCUSSION

HBV-specific CD8⁺ cytotoxic T cells play a critical role in viral clearance. Low HBV-specific CTL responses in chronic HBV infection may favor the persistence of virus, whereas stimulation and expansion of HBV-specific CTL activity may assist elimination of HBV infection^[1-3]. Natural HBV antigens generally contain inappropriate epitopes which could elicit T_H/T_{H2} disequilibrium, immune deviation or immune deficiency, and the conserved amino acid sequences might interfere with intercellular communication and thus elicit immune subversion. Thereby some viruses may evade the immune defence system and present consistently in hepatocytes, and result in chronic hepatitis, liver cirrhosis, and even hepatocellular carcinoma. Thus new generations of therapeutic vaccines should induce CTL responses different from that induced by natural virus infection, and at the same time hold the specificity of HBV antigens^[19-22]. According to modern immune theories, effective protection relies on the appropriate match of a set of epitopes^[8,23]. Thus, natural antigens should be redesigned or modified using molecular design techniques on the basis of immunodominant epitopes.

Among the different CTL epitopes of HBV core, envelope, and polymerase so far identified, the sequence 18-27 of the HBV core antigen is immunodominant and subdominant in the different supertype of HLA-A2 molecules, and could induce HBV-specific CTL responses in patients of different HLA-A2 subtypes with indistinguishable frequency and magnitude, and represents the main component of a peptide-based therapeutic vaccine aiming at stimulating the antiviral CTL response in patients with chronic hepatitis B. Furthermore, this epitope was also found to stimulate HLA class II restricted T-cell responses. These data illustrate its potential usefulness for the development of therapeutic vaccines^[24-26].

As in other infections with noncytopathic viruses, helper T cells control the intensity of CD8⁺ T-cell responses and helper T-cell responses might be compromised in chronic carriers of

HBV, and according to *in vivo* studies, administration of single CTL epitope vaccine could initiate CTL activity, but the magnitude was lower, and the low-level CTL activity was considered not associated with viral clearance^[26-30]. In this study, we chose the immunodominant B cell epitope of HBV PreS₂ region and the CTL epitope of HBcAg, and introduced the universal T_H epitope of tetanus toxoid to strengthen the T_H response. Three mimetic peptides based on the above epitopes were initially designed and synthesized, and their immunological properties of pulsing lymphocyte activation and proliferation, of inducing T_{H1} polarization and HBV-specific CD8⁺ CTL-mediated cytotoxicity were preliminarily investigated using human PBMCs from HLA-A2⁺ healthy donors and chronic hepatitis B patients.

After *in vitro* stimulation, a direct tetramer-binding assay was used to detect the frequencies of HBV-specific CD8⁺ T cells. The results varied according to the peptides used. The highest frequencies were from peptide3 pulsing group, about 1.05% (10 500/10⁶ PBMCs) and 0.93% (9 300/10⁶ PBMCs) HLA-A*0201/HbcAg₁₈₋₂₇ CD8⁺ CTLs produced in the PBMCs from healthy donors and chronic hepatitis patients respectively, remarkably higher than those of peptide 2 and peptide 1 (*P*<0.01). No HBcAg₁₈₋₂₇-specific CD8⁺ T cells could be detected in the PBMCs pulsed with irrelevant peptide, the tetramer staining was almost the same as control background. These data demonstrated the specificity of the therapeutic peptides we designed.

The tetramer-binding assay detects only the number of cells with an appropriate TCR but not their function^[31], so chromium release assay, IFN-γELISpot assay and lymphocyte proliferation assay were used to detect the function of the effectors pulsed. And a highly significant correlation was found between the frequencies of peptide-specific CD8⁺ T cells and the functions of responding T cells. All the three mimetic polypeptides designed were potent to induce *in vitro* cultured human PBMCs activation and proliferation, T_{H1} polarization, CD8⁺ T cell expansion and generation of cytotoxicity. Peptide 3 with the immunodominant B-, CTL and T helper epitope was the most potent. After introduction of T helper epitope into peptide 1, CTL frequency was not remarkably improved, and cytotoxic activity remained low suggesting that this conformation was not sufficient to drive proliferation of CTLs, and its differentiation into mature killer cells. The comparatively higher immunogenicity of peptide 3 was attributed to its molecular structure: the introduction of T helper and B-epitopes, and the design of short linkers “-A-A-A-” and “-G-G-G-”. The linker was designed and proved to be highly flexible and might act as “hinges”. We surmise that this peptide might be recognized by MHC-I/II restricted molecules, and be presented to CD4⁺ T cells and CD8⁺ T cells, and ultimately T helper and Tc cells should be activated and function interactively. The results demonstrate that the peptides designed are highly immunogenic and HBV-specific, and the introduction of short and flexible linker and immunodominant T_H plus B- epitopes into short CTL epitopes may dramatically improve the therapeutic peptides’ immunogenicity and the possibility of being presented to antigen presenting cells (APCs).

According to reports as yet, the vast majority of polypeptides, especially short epitope peptides can not induce CTL responses vigorously by *in vivo* because of poor immunogenicity^[32-35]. Little knowledge is known so far on the molecular mechanisms leading to the difference between the peptides’ *in vitro* and *in vivo* functions. In our opinion, *in vivo* induction of cytotoxic activity relies on the efficient presentation by APCs, and the crucial point is how to improve the antigenicity of short peptides and to meet the needs for efficient antigen presentation *in vivo*. In the present study, we redesigned and modified the structure of linear short peptides on the basis of immunodominant

epitopes, changed the molecular properties of the natural peptides, and triggered the direct recognition of the peptides by T_H and T_H cells, and the mimogens sieved were proved to be highly immunogenic *in vitro*. Whether this conformation can meet the needs for efficient antigen presentation *in vivo* needs to be addressed in HLA-A2 transformed HBV transgenic mice.

Abstract

AIM: To prospectively assess the sensitivity, specificity and time to positivity of the Ultra-rapid urease test (URUT) for *Helicobacter pylori* (*H pylori*), and compare the results of one with those of two biopsies.

METHODS: Five antral biopsies were taken in consecutive patients undergoing upper endoscopy: one and two biopsies for URUT, and one each for *H pylori* culture and histology. URUT was read at 1, 5, 10, 20 and 30 min, 1, 2, 3 and 24 h after biopsy insertion into the reagent. A positive histology and/or culture was used as positive reference "gold standards".

RESULTS: URUT was more sensitive for detecting *H pylori* with two biopsies rather than one, at all time points up to 120 min. The sensitivity improved from 3.6% to 82.1% for one biopsy and 10.7% to 85.7% for two biopsies from 1 to 120 min. The sensitivity reached 96.4% at 24 h for both, but the specificity reduced from 100% to 96% and 92% for one and two biopsies, respectively.

CONCLUSION: Development of a positive URUT result is hastened by doubling the number of gastric biopsies. We recommend taking two instead of one biopsy to achieve an earlier positive URUT result so that *H pylori* eradication therapy can be initiated before patient is discharged from the endoscopy suite.

INTRODUCTION

The biopsy urease test was introduced as a simple and convenient method for diagnosing *Helicobacter pylori* (*H pylori*) infection. The biopsy urease test is based on the presence of large amounts of preformed urease enzymes in *H pylori*. The breakdown of urea by urease produces a high local concentration of ammonia, which raises the gastric pH. A phenol indicator that changes

the color from yellow at pH 6.8 to magenta at pH 8.4 can detect this pH alteration. The color change with the introduction of the gastric biopsy is an indication for the presence of *H pylori*.

Despite many advances on the study of *H pylori*, the use of the biopsy urease test still remains invaluable in the diagnosis and management of gastroduodenal disease^[1,2]. The rapid urease test is able to offer a sensitivity of 80-99% and a specificity of 92-100%^[3-5] in untreated patients when compared with histology as the gold standard in the diagnosis of *H pylori* infection.

Since McNulty and Wise first described the biopsy urease test in 1985^[6], several modifications of this test have been developed and validated. A test kit (CLOtest, Delta West Limited, W Australia) is commercially available but its costs and the time taken to positive results, which may be up to 24 h, limits its usefulness. The detection rate of *H pylori* at 20 min was 75% and 92% at 3 h and 98% at 24 h^[7]. The length of time it takes for CLOtest still poses a hindrance to those clinicians wishing to treat infected patients while they are still in the endoscopy room.

The ultra-rapid urease test (URUT), as described by Arvind^[8] is reported to overcome the latter shortcoming by enabling most positive tests to be apparent even before the end of the endoscopy^[8].

We had previously reported the sensitivity, specificity, and the time to positivity for the URUT^[9]. We found that better sensitivity could be obtained if the test continued to be read over a 24-h period although this was achieved at the expense of an increase in the number of false positive cases. We used only one antral biopsy for the URUT. In the CLOtest, the use of two biopsy specimens has been shown to hasten the time to a positive reaction^[10]. Taking two specimens also may theoretically improve the sensitivity and specificity of the test.

The aim of this study was to assess prospectively the sensitivity, specificity and time to positivity for the URUT and compare the results of one biopsy and those of two biopsies in patients undergoing upper endoscopy.

MATERIALS AND METHODS

Patients

From September 1999 to June 2000, 53 consecutive patients who were given routine diagnostic upper gastrointestinal endoscopic examinations by one of the authors (KYH) and who had not been exposed to antibiotics, proton pump inhibitor or bismuth compounds within the past four weeks, and in whom gastric antral biopsies were clinically indicated, were prospectively studied. Patients who had been previously treated for *H pylori* infection and those with an abnormal coagulation profile were excluded from the study.

After an overnight or six-hour fast, each patient underwent esophagogastroduodenoscopy, during which five antral biopsies were taken from within 2 cm of the pylorus using sterilised biopsy forceps (Olympus 16K; Olympus Corp., Tokyo, Japan). Three of the biopsies were used for URUT

wherein the tests were done using one and two of the biopsies, respectively. The remaining two biopsies were sent for culture and histologic examination for *H pylori*. Biopsy specimens for the urease test and culture were taken before those used for histologic examination to avoid contamination with formalin. All patients gave informed consent before endoscopy. The study was conducted in accordance with the provisions of the Declaration of Helsinki and was approved by the Hospital Research & Ethics Committee.

Ultra-rapid urease test

The ultra-rapid urease test kit is composed of a capped polypropylene tube containing 0.5 mL aliquot of 100 g/L unbuffered solution of urea in deionised water (pH 6.8). The solution contains two drops of 10 g/L phenol red, which acts as the indicator^[11]. The biopsy specimens for the URUT were removed from the biopsy forceps with a sterile toothpick and placed immediately into the polypropylene tube. Particular care was taken not to shake the tube after placing the biopsy into it so that a rapid positive result could be achieved^[12]. The reagent was prepared in large batches, frozen, and was ready for thawing just before use. A positive test result was indicated when there was a color change in the medium surrounding the biopsy from yellow to magenta. The test tube was left at room temperature and examined by experienced observers without knowing the clinical details at pre-determined intervals over 24 h. Convenient times chosen were 1, 5, 10, 20, 30 min and 1, 2, 3 and 24 h after insertion of the biopsy specimen into the urease test reagent.

Histologic assessment

The gastric biopsies for histologic assessment were fixed in 40 g/L neutral buffered formaldehyde paraffin processed and stained with haematoxylin and eosin (H&E) in the normal way. Experienced pathologists without knowledge of the clinical data and URUT results assessed the presence or absence of *H pylori* by examining 3 sets of tissue levels within 12 consecutive sections. Histologic diagnosis of *H pylori* infection with H&E stain was compared with the use of Giemsa^[13,14] and thus the Giemsa stain was used only when a few organisms were identified with H&E stain, always confirming the original diagnostic impression.

Culture assessment

For *H pylori* culture, gastric biopsies were smeared on pre-

reduced chocolate blood agar plates and incubated in a humidified carbon dioxide incubator at 37 °C with 50 mL/L carbon dioxide for 3-4 d. The identity of any colonies grown was confirmed using Gram's stain and biochemical tests. Experienced microbiologists without knowledge of the clinical data and URUT results assessed the presence or absence of *H pylori*^[15,16].

Statistical considerations

Only patients with both culture and histology results were analyzed. Results from the URUT were compared with those from culture and histology of biopsy specimens obtained from the same patient. *H pylori* was considered as positive if either culture or histology demonstrated *H pylori*, and negative if *H pylori* was not detected in both culture and histology. Based on these results, the sensitivity and specificity of the URUT at various time points were determined. For this study, sensitivity was defined as the frequency of a positive URUT in patients with either gastric histology or culture positive for *H pylori*. Specificity was the frequency of a negative test in patients with both negative histology and culture for *H pylori*.

RESULTS

Of the 53 patients included in this study, 39(74%) were Chinese, 7(13%) were Malays, 6(11%) were Indians and 1(2%) was of another race. There were 29(55%) males and 24(45%) females. Their ages ranged from 23 to 85 (median, 52) years. The indications for the endoscopy included abdominal pain in 33 patients (62.2%), anemia or drop in hemoglobin in 6(11.3%), atypical chest pain in 5(9.5%), gastric ulcer follow-up in 1(1.9%), and other symptoms in 8(15.1%). The findings during esophagogastroduodenoscopy were esophagitis in 15(28%), duodenal ulcers in 14(26%), gastric ulcers in 8(15%), gastritis in 8(15%), duodenitis in 3(6%), and others in 5(10%).

H pylori was positive in 28 of the 53 patients (53%), in whom either the histology or culture demonstrated the organism. Twenty-four patients were *H pylori* positive in histology and 28 patients were culture positive.

The results of sensitivity and specificity of URUT at various time points are shown in Table 1. URUT was more sensitive for detecting *H pylori* when two biopsies rather than one were used, at all time points up to 120 min. At 1 min, the sensitivity was 3.6% for one biopsy and 10.7% for two biopsies. At 5 min, the sensitivities improved to 32.1% and 50% respectively. At

Bx=Biopsy, m=minutes, h=hours, PPV=positive predictive value, NPV=negative predictive value.

60 min, the sensitivity was 82.1% for one biopsy and 85.7% for two biopsies. Thereafter there was still some increase in sensitivity with either one or two biopsies, reaching 96.4% at 24 h in each case, but with a reduction in the specificity from 100% to 96% and 92%, for one and two biopsies respectively. Using the receiver operating characteristic curve (Figure 1), the optimal times to read the test appeared to be 1 h when two biopsies were used and 3 h when only a single biopsy was used, and at these time points, the optimal combination of sensitivity and specificity was obtained.

Figure 1 Receiver operating characteristic curve plot of urease test for detection of *H. pylori* infection. Bx=Biopsy.

DISCUSSION

The ultra-rapid urease test, as described by Arvind^[8] is reported to overcome the shortcoming of the CLOtest which takes a while to become positive. Using this home-made URUT preparation, we had found the test to be highly specific but not very sensitive when interpreted at one minute^[9]. However, if the test continued to be read, the sensitivity improved to 87% at 24 h. This was however achieved at the expense of a longer reading time and a reduction in specificity to 90% at 24 h^[9]. The development of false positives with delayed reading of the urease tests has previously been noted and attributed to other urease-producing bacteria, or to relatively small numbers of *H. pylori*, which are not identified histologically, i.e., false-negative histology^[17].

We previously used only one antral biopsy for the ultra-rapid urease test^[9]. We hypothesize that if more gastric tissue was sampled, a positive test result might appear earlier, thus improving the test sensitivity without compromising its specificity. The present study confirmed this hypothesis. The URUT was more sensitive in detecting *H. pylori* when two biopsies instead of one, were used at all time points up to 60 min. In this study a receiver operating characteristic curve analysis was used to select the optimal time for reading the test. The 1-h reading was found to give the optimal sensitivity/specificity combination when two biopsies were used, this does not automatically ensure that it is the best time to read the test. In many centers in the Asia Pacific region, the URUT is used as an initial screening test, with an additional sample taken for histology, which is sent only if the URUT is negative and when there is a strong clinical suspicion of *H. pylori* infection. This approach is of great benefit to avoid the additional cost of the histology. Despite the fact that the *H. pylori* infection is a chronic disease, the necessity to treat it soon after endoscopy is desirable to minimize the cost as well as the inconvenience of a second clinic visit. If this is the practice, then the most appropriate time point at which to read the test is 30 min when there is maximal specificity (as false positives will not be checked by histology) and minimal gain in sensitivity by reading the test beyond this time. Most importantly, reading the test at 30 min allows the physician to prescribe *H. pylori* eradication treatment to the patient before discharging him or

her from the endoscopy suite.

We are unable to explain the initial low sensitivity of the URUT test results found in this study when compared with the original study^[9]. One possible explanation is the reduced size of the biopsy specimens using smaller biopsy forceps as compared with the original study. However, the discrepancy is unlikely to be caused by the difference in the study populations, the incubation temperature of the biopsy specimens, and the volume and concentration of the phenol red used to make the test reagents since these parameters were similar to our previous study^[9]. The initially low test sensitivity might not be a major problem as test sensitivity difference between one and two biopsies, and not the initial test sensitivity was the primary concern of this study. The conclusions reached by this study therefore, should remain valid.

There may be additional yield in taking biopsy specimens from different sites of the stomach due to the differences in the geographical distribution of *H. pylori*, for example from the gastric body, in addition to the antral biopsies. However, we do not believe the addition of these biopsies would add significantly to the sensitivity of the tests. As part of another protocol (personal communication, KYH), two antral and two body biopsies were taken from 115 consecutive patients, and the specimens stained with H&E to assess the presence or absence of *H. pylori*. Of a total of 66 histology positives, only three (4.5%) were correctly identified by the body biopsies while negative in the antral biopsies. Thus body biopsies contributed to an increased yield of only 4.5% in identifying histology positives. Previous other studies to determine the topographic distribution and density of *H. pylori* to provide the maximum yield and to reduce the fallacious results due to sampling error have also concluded that biopsies taken from the antrum was sufficient^[18-20].

Increasing the number of biopsies to more than two biopsies from the antrum, that is three or even four antral biopsy specimens, may increase the sensitivity given that this probably increases the *H. pylori* load and therefore the amount of urease. However, this will prolong the endoscopy time and add inconvenience to the patient.

In our study, *H. pylori* positivity was 53% based on either culture or histology result, which is in agreement with the local background *H. pylori* colonization rate from our previously published data^[9,21]. There were 24 patients who were *H. pylori* positive on histology and 28 patients who were culture positive. This difference may reflect the difference in *H. pylori* density. In this case, culture appears more sensitive than histology in identifying *H. pylori*.

In conclusion, this study showed that the development of a positive URUT result could be hastened by doubling the gastric tissue samples. We recommend to take two biopsies instead of one for the URUT to achieve an earlier positive test result so that appropriate *H. pylori* eradication therapy can be prescribed before the patient is discharged from the endoscopy suite.

Abstract

AIM: Liver fibrosis is a common pathological process of chronic liver diseases. Activation of hepatic stellate cells (HSCs) is the key issue in the occurrence of liver fibrosis. In this study, we observed the inhibitory action of rat serum containing Biejiajian oral liquid (BOL), a decoction of turtle shell, on proliferation of rat HSCs, and to explore the anti-hepatofibrotic mechanisms of BOL.

METHODS: A rat model of hepatic fibrosis was induced by subcutaneous injection of CCl_4 . Serum containing low, medium and high dosages of BOL was prepared respectively. Normal and fibrotic HSCs were isolated and cultured. The effect of sera containing BOL on proliferation of HSCs was determined by ^3H -TdR incorporation.

RESULTS: The inhibitory rate of normal rat HSC proliferation caused by 100 mL/mL sera containing medium and high dosages of BOL showed a remarkable difference as compared with that caused by colchicine (medium dosage group: $34.56 \pm 4.21\%$ vs $29.12 \pm 2.85\%$, $P < 0.01$; high dosage group: $37.82 \pm 1.32\%$ vs $29.12 \pm 2.85\%$, $P < 0.01$). The inhibitory rate of fibrotic rat HSC proliferation caused by 100 mL/L serum containing medium and high dosages of BOL showed a remarkable difference as compared with that caused by colchicine (medium dosage group: $51.31 \pm 3.14\%$ vs $38.32 \pm 2.65\%$, $P < 0.01$; high dosage group: $60.15 \pm 5.36\%$ vs $38.32 \pm 2.65\%$, $P < 0.01$). The inhibitory rate of normal rat HSC proliferation caused by 100 mL/L and 200 mL/L sera containing a medium dosage of BOL showed a significant difference as compared with that caused by 50 mL/L (100 mL/L group: $69.02 \pm 9.96\%$ vs $50.82 \pm 9.28\%$, $P < 0.05$; 200 mL/L group: $81.78 \pm 8.92\%$ vs $50.82 \pm 9.28\%$, $P < 0.01$). The inhibitory rate of fibrotic rat HSC proliferation caused by 100 mL/L and 200 mL/L sera containing a medium dosage of BOL showed a significant difference as compared with that caused by 50 mL/L (100 mL/L group: $72.19 \pm 10.96\%$ vs $61.38 \pm 7.16\%$, $P < 0.05$; 200 mL/L group: $87.16 \pm 8.54\%$ vs $61.38 \pm 7.16\%$, $P < 0.01$).

CONCLUSION: Rat serum containing BOL can inhibit proliferation of rat HSCs, and the inhibition depends on the dosage and concentration of BOL. The inhibitory effect on

HSC proliferation is one of the main anti-hepatofibrotic mechanisms of BOL.

INTRODUCTION

Liver fibrosis is a common pathological process of chronic liver diseases. Injury factors would cause an unbalance between synthesis and degradation of extracellular matrix (ECM), which results in excessive collagen deposition in the liver^[1]. Liver fibrosis could be reversed before developing into liver cirrhosis. Therefore, it is fundamental to prevent and treat cirrhosis to arrest its progression to liver cancer.

There are several steps in treating liver fibrosis in Western medicine, namely to inhibit activation of HSCs and proliferation of fibroblast-like HSCs and/or synthesis of matrix protein, to promote degradation of matrix protein, to impair activation of cytokines which lead to liver fibrosis, and to give gene therapy^[2,3]. At the same time, the wide application of Western drugs should be restricted due to their toxicity and side effects.

The anti-hepatofibrotic effect of Biejiajian oral liquid (BOL) has been confirmed in our previous studies^[4-6]. At present, we investigated the effect of rat serum containing BOL on the proliferation of rat hepatic stellate cells (HSCs) to further explore its anti-hepatofibrotic mechanisms.

MATERIALS AND METHODS

Materials

One hundred and forty male Wistar rats, weighing (360 ± 20) g, were supplied by Animal Center of Academy of Medical Sciences of Zhejiang Province. Fodder was maize powder (Hangzhou Sijiqing Feed Factory). Lard (commercially available) and cholesterol were produced by Chemical Branch of Guangzhou Medicinal Company (batch number: 980503). Ethanol (A.R) was purchased from Changyuan Chemical Plant of Changshu City (batch number: 980630). BOL was prepared by the Pharmaceutical Laboratory, Zhejiang College of Traditional Chinese Medicine.

Methods

Animal model Except 30 rats for normal control, the rest of 60 Wistar rats received sc 5 mL/kg CCl_4 in the first day of experiment, followed by sc 400 mL/L CCl_4 -liquid paraffin mixture 3 mL/kg daily for 3 d. The normal group received an equal amount of 9 g/L NaCl (NS) daily for 6 wk. Except the normal group, each rat was fed with mixed fodder (maize powder with 5 g/L cholesterol and 200 g/L lard) and drank 200 g/L ethanol only. The normal group was fed with general fodder and water. The time required to complete the induction of model was 6 wk^[7].

Serum containing BOL preparation Eighty Wistar rats were divided into NS group, colchicine (0.1 mg/kg) group, groups

receiving high (9.2 g/kg), medium (4.6 g/kg) and low dosages (2.3 g/kg) of BOL. Each group received the drug once a day for 7 d. Venous blood was collected from inferior vena cava under asepsis 1 h after the last ig, then serum was separated (3 000 r/min, 20 min, 4 °C), inactivated at 56 °C for 30 min, and stored at -70 °C for use.

HSC isolation and culture HSCs were isolated from the livers of normal rats and those with liver fibrosis. Isolation and culture were performed according to the modified Freidman method.

HSC proliferation determination Monolayer HSCs appeared in the 24-well culture plate after they were cultured in 1640 culture medium (Gibco BRC) with sera containing different dosages and concentration of BOL for 48 h. ³H-TdR (Shanghai Institute of Atomic Energy) was added on 92.5 µgBq/well. HSCs were collected after cultured again for 24 h. The HSCs were digested with 2.5 g/L trypsinase-1.1 g/L EDTA (Sigma), fixed by 100 mL/L trichloroacetic acid, dehydrated by alcohol, and then oven dried. Dimethylbenzene solution containing 5 mL/L ppo (Amersham) and 0.2 mL/L PoPop was added to measure CPM value of every sample.

Statistical analysis

Statistical analysis was performed with ANOVA. Data were presented as mean±SD. Significant differences were determined by using ANOVA. Results were considered statistically significant when $P<0.05$.

RESULTS

Effect of BOL on rat HSC proliferation

We used 100 mL/L sera containing different dosages of BOL to culture HSCs from normal and hepatofibrotic rats. Results showed that ³H-TdR incorporated into rat HSCs was inhibited obviously by each dosage group, and the higher the dose, the better the effect (Tables 1, 2).

Table 1 Effect of different BOL dosage sera on ³H-TdR incorporation of normal rat HSCs (mean±SD)

Effect on rat HSC proliferation caused by different concentration sera containing medium dosage of BOL

We used 50 mL/L, 100 mL/L and 200 mL/L sera containing

an intermediate dosage of BOL to culture normal and hepatofibrotic rat HSCs, which were controlled with normal rat sera at the same concentration. We observed that ³H-TdR incorporation increased gradually as normal serum concentration increased. ³H-TdR incorporation decreased gradually as drug serum concentration increased. ³H-TdR incorporation in drug serum group at the same concentration was significantly lower than that in control group ($P<0.05$, Tables 3, 4).

Table 3 Effect of different concentration sera containing intermediate dosage of BOL on ³H-TdR incorporation of normal rat HSCs (mean±SD)

Concentration	n	Control group (cpm/well)	BOL group (cpm/well)	Inhibitory rate (%)

DISCUSSION

Mechanism of liver fibrosis

The cells synthesizing extracellular matrix (ECM) in the liver were mainly active HSCs^[8]. HSCs are situated in the Disse's spaces. As liver cells were injured, HSCs would be activated and might increase, and then converted into myofibroblast-like cells (MFBLC), which could express cytokines, receptors, smooth muscle alpha-actin (alpha-SMA) and synthesize a great deal of ECM. Therefore, activation of HSCs is a key step in the pathogenesis of liver fibrosis^[9-13]. Activation of local renin-angiotensin system might relate to hepatic fibrosis. Active HSCs could synthesize angiotensin II, which could participate in tissue remodeling in human liver^[14]. It is the main source of collagen formation. HSC apoptosis could relieve experimental liver fibrosis in rats. Thus, it is an important pathway for preventing liver cirrhosis that inhibits HSC proliferation and collagen synthesis. Moreover, HSC proliferation is a key phase in liver fibrosis. Inhibiting proliferation of HSCs had an important sense for anti-hepatofibrosis^[15,16]. Basement membrane-like matrix could inhibit proliferation of HSCs, estrogen could relieve liver fibrosis, and lipid could induce HSC proliferation^[17,18].

Recognition of liver fibrosis in TCM

Researches on preventing and treating liver fibrosis in TCM have been increasing^[4-7]. According to the theory of TCM, liver fibrosis is manifested as weakened body resistance while pathogenic factors prevail, damp-heat and blood stasis coexist, and the liver is depressed due to deficiency of Qi and blood in the spleen and kidney. Liver depression and Qi stagnation can result in blood stasis, blood fails to nourish the liver, and the

key pathogenetic mechanism is blood stasis. At beginning, the pathogenetic mechanism is Qi stagnation and blood stasis. If treated improperly, the disease would evolve into blood stasis, so that body resistance is weakened and excessive superficiality is present. The therapy is to promote the circulation and relieve the stasis, and to strengthen the body resistance to eliminate pathogenic factors, to resolve and soften the hard masses.

Anti-hepatofibrotic mechanism of BOL

BOL is an improved preparation from Biejiajian Pill that was recorded in an ancient medical book (*Jinkui Yaolue*). Its ingredients include more than twenty herbs, they are Carapax trionycis, Blackberrylily rhizome, Baical skullcap root, Zingiberis, rhizoma, Radix et rhizoma rhei, Ramulus cinnamomi, Folium pyrosiae, Magnoliae cortex, Lilac pink herb, Lagerstroemia indica L, Colla corii asini, Radix bupleuri, Catharsius, Paeonia, Ppaonia suffruticosa, Pruni persicae, semen, Radix ginseng, Pinelliae tuber, Tansymustard seed, Nitrum, Beehive. The combination of ingredients has the effect on promoting circulation and relieving stasis, strengthening body resistance and eliminating pathogenic factors, as well as resolving and softening the hard masses, which is conformable with the principle of treating liver fibrosis. Our previous experiments indicated the mechanisms of anti-hepatofibrosis of BOL as follows. It can prevent hepatocytes from degeneration and necrosis, eliminate liver fibrosis, inhibit the synthesis and secretion of ECM, relieve the capillarization of hepatic sinusoids, and improve the microcirculation of liver. HSCs are sensitive to oxygen and hypoxia could enhance liver fibrosis^[19-22]. BOL could also regulate the immune function, and reduce the damage of liver cells^[4-6].

In conclusion, serum-containing BOL can inhibit HSC proliferation and the inhibition may be dependent with the dosage and concentration of BOL.

Abstract

AIM: To investigate the effects of traditional Chinese medicinal enema (TCME) on inflammatory and immune response of colonic mucosa of rats with ulcerative colitis (UC), and to observe the pathogenic mechanism.

METHODS: Thirty UC rats, induced by intestinal enema together with 2,4-dinitrochlorobenzene (DNCB) and acetic acid, were randomly divided into 3 groups, i.e., GI, GII and GIII. Groups GI and GII were administered with TCME and salazosulfapyridine enema (SASPE), respectively. Group GIII was clystered with only normal saline (NSE), served as control. Group GIV was taken from normal rats as reference, once daily, from the 7th day after the establishment of UC for total 28 d. Interleukin-6 (IL-6) in the colonic mucosa was assayed by ³H-TdR incorporation assay. Colonic mucosal lymphocyte subpopulation adhesive molecules, CD₄⁺CD_{11a}⁺, CD₄⁺CD₁₈⁺, CD₈⁺CD_{11a}⁺, CD₈⁺CD₁₈⁺ (LSAM), tumor necrosis factor (TNF)- α , and interferon- γ (IFN- γ), were detected by enzyme linked immunosorbent assay (ELISA). Moreover, the expression of TNF- α mRNA and IFN- γ mRNA in colonic mucosa were detected by polymerase chain reaction (RT-PCR).

RESULTS: Before therapies, in model groups, GI, GII and GIII, levels of IL-6, TNF- α , IFN- γ , CD₈⁺CD_{11a}⁺ and CD₈⁺CD₁₈⁺ were significantly different (38.29 \pm 2.61 U/mL, 16.54 \pm 1.23 ng/L, 8.61 \pm 0.89 ng/L, 13.51 \pm 2.31% and 12.22 \pm 1.13%, respectively) compared to those in GIV group (31.56 \pm 2.47 U/mL, 12.81 \pm 1.38 ng/L, 5.28 \pm 0.56 ng/L, 16.68 \pm 1.41% and 16.79 \pm 1.11%, respectively). After therapeutic enemas, in GI group, the contents of IL-6 (32.48 \pm 2.53 U/mL), TNF- α (13.42 \pm 1.57 ng/L) and IFN- γ (5.87 \pm 0.84 ng/L) were reduced; then, the contents of CD₈⁺CD_{11a}⁺ (16.01 \pm 1.05%) and CD₈⁺CD₁₈⁺ (16.28 \pm 0.19%) were raised. There was no significant difference between groups GI and GIV, but the difference between groups GI and GII was quite obvious (P <0.05). The expressions of TNF- α mRNA and IFN- γ mRNA in group GIII were much higher than those of group GIV, but those in group GI were significantly suppressed by TCME therapy.

CONCLUSION: Ulcerative colitis is related to colonic regional mucosal inflammatory factors and immune imbalance. TCME

can effectively inhibit regional mucosal inflammatory factors and improve their disorder of immunity.

<http://www.wjgnet.com/1007-9327/10/1914.asp>

INTRODUCTION

Ulcerative colitis (UC) is a refractory, chronic and non-specific disease. Its pathogenesis is probably related to the deficiency of autoimmunity and imbalance of immunoregulation^[1-3]. The relationship between pathogenesis and immunity of colonic mucosa remains a focus at present^[6-11]. In view of poor curative effect and high recurrence rate, traditional Chinese medicinal formulae were used to treat the disease in recent years, and the therapeutic effectiveness is quite satisfactory^[12]. In order to explore the mechanism of UC and pharmacological action of the traditional Chinese medicinal formulae, rat models were established to observe the effect of traditional Chinese medicinal enema on immunological and inflammatory factors in colonic mucosa of rats with UC.

MATERIALS AND METHODS

Materials

Six-week-old Wistar rats ($n=56$), half of male and half of female were purchased from Shanghai Laboratory Animal Center of Chinese Academy of sciences (SLAC. CAS), calf serum, ConA and PHA (Institute of Cell Research of CAS) and mRNA reagent kit and PCR reagent (Promega), IL-6, TNF- α , IFN- γ reagent kit and PE marked CD_{11a}⁺, CD₁₈⁺ monoclonal antibody (Sigma). ³H-TdR was from Shanghai Atomic Nuclear Institute of CAS. Cell factor primer-detonator was purchased from Shanghai Biological Engineering Center of CAS. The formulae of traditional Chinese medicinal herbs for enema consisted of Huangqi (*astragalus*), Dahuang (*caulis fibraureae*), Huangbai (*cortex phellodendri*), Wubeizi (*galla chinensis*) and Baiji (*rhizoma bletillae*), mixed with 1g crude drug per milliliter by Medicament Section of Shanghai Tongji Hospital. Salazosulfapyridine (SASP, batch No.921101, Shanghai Sine Pharmaceutical Factory) was prepared as suspension (20 mg/mL) at the same section.

UC model establishment

The models were prepared in reference to literature^[13]. Fifty six Wistar rats weighing 200 \pm 20 g, were fed for 1 week before experiment. Then 38 rats were randomly taken as subjects for experiment. After depilation on back and neck, the rats were administered 0.3 mL of DNCB acetone liquid (DNCB 2.0 g: acetone 100 mL) solution on their bare backs and necks once daily for total 14 d. At the 15th day, 0.25 mL of 0.04 mmol/L DNCB ethanol (500 mL/L) solution was infused through a nylon hose inserted into the colon of rat 8 cm depth. At the 16th day, 2 mL of 80 mL/L-1 acetic acid solution was infused at the same depth. Then, the colon was rinsed with 5 mL normal

saline after 15 s of retention. The remaining 18 rats acted as controls after infusion of normal saline (NS) at 1 week since the preparation of the models, 8 rats were taken respectively from the group of model and group for reference to detect the levels of colonic mucosa lymphocytes: IL-6, TNF- α , IFN- γ and LSAM. The remaining 30 rats were randomly divided into 3 groups of 10 each: GI, GII and GIII were clystered daily with 2 mL of TCM, SASP and NS for 28 d respectively. Another group (GIV) of 10 rats, administered 2 mL of NS daily for 28 d, was taken as reference of normality. At the end of 4 wk experimental period, the lymphocytes were again detected and also the expressions of TNF- α mRNA and IFN- γ mRNA were examined.

Assay of cytokines and immunological factors

Separation and culture of intestinal theca mucosa cells

Mucosa cells were separated and routinely cultured to prepare monolayer culture cells suspension of colonic mucosa, and the suspension was adjusted to 5×10^9 /L in RPMI 1640 containing 100 mL/L calf serum. Then, 1.0 mL of suspension, was put in 24-well plate, then 1.0 mL of ConA (final density 5 mg/L) was added, and cultured at 37 °C for 24 h in a humidified atmosphere containing 50 mL/L CO₂. The supernatant of the culture was centrifuged at 3 000 r/min and preserved at -20 °C for detection of IL-6, TNF- α , IFN- γ and LSAM levels according to the manufacturer's instructions.

RNA extraction

Total RNA from colonic mucosa tissue of rats was extracted as previously described^[14-16]; using single-step method of RNA isolation (acid guanidinium thiocyanate-phenol-chloroform extraction). Formaldehyde denatured electrophoresis stained with ethidium bromide (EB) was used to examine infect RNA. Reverse transcription reaction was performed as previously described^[17-19]: a total amount of 1 μ g of RNA as template was mixed with RNasin (40 U/ μ L) 0.5 μ L, 25 μ mol/L oligo (dT) 1 μ L, 5 \times RT buffer 5 μ L, dNTP (10 mmol/L) 1 μ L and AMV (9 U/ μ L) 1 μ L to a total reaction volume of 25 μ L, followed by incubation at 37 °C for 1 h and at 94 °C for 5 min. PCR reaction was carried out as described previously^[20-22]: 10 μ L cDNA was added with 0.1 μ g of primer, 0.05 μ g of β -action primer and 2.5 U of *Taq* enzyme (5 U/ μ L). Total PCR reaction volume was 100 μ L. PCR condition was as follows: deraturation at 94 °C for 1 min; primer annealing at 54 °C for 40 s, and extension at 72 °C for 40 s, followed a further extension at 72 °C for 7 min. Other cycles were as follows: after 30 cycles of amplification, 20 μ L of PCR product was electrophoresed on 20 g/L agarose gel, then recorded with camera under ultraviolet for density scanning and calculated the relative expression of the gene.

Statistical analysis

Experimental results were expressed as mean \pm SD. $P < 0.05$ was considered statistically significant. All statistical calculations were performed using the SPSS for Windows version 9.0 software package.

RESULTS

Expression of colonic mucosal cytokines and adhesion molecules in rats of model group (MG) and control group (CG)

At 1 week after setting of models, the expression of cytokines in MG was found to be significantly higher than that in CG ($P < 0.01$, Table 1). The expressions of lymphocyte T subpopulation surface adhesive molecules, CD₈⁺CD_{11a}⁺ and CD₈⁺CD₁₈⁺, were remarkably lower in MG than those in CG ($P < 0.01$, Table 2).

Colonic mucosal TNF- α mRNA and IFN- γ mRNA

In group GI clystered with TCME, the levels of IL-6, TNF- α

and IFN- γ were obviously reduced. Levels of CD₈⁺CD_{11a}⁺ and CD₈⁺CD₁₈⁺ were remarkably raised, which were no obvious differences compared with those in GIV group (i.e., control group) ($P > 0.05$, Tables 3 and 4), but, there were significant differences between groups GI and GII ($P < 0.05$, Tables 3 and 4).

Table 1 Expression of colonic mucosal cytokines in MG and RG before therapy (mean \pm SD)

Group	<i>n</i>	IL-6 (U/mL)	TNF- α (ng/L)	IFN- γ (ng/L)
Model	8	38.29 \pm 2.61 ^b	16.54 \pm 1.23 ^b	8.61 \pm 0.89 ^b
Control	8	31.56 \pm 2.47	12.81 \pm 1.38	5.28 \pm 0.56

^b $P < 0.01$ vs control group.

Figure 1 Analysis of TNF- α mRNA expression in UC mice after a 4-week treatment. A 550-bp fragment was amplified by PCR. M: Marker; Lane 1: Group GIV (control); Lane 2: Group GI (TCME); Lane 3: Group GII (SASPE); Lane 4: Group GIII (NSE). The primers used were: upstream, 5' -GGAGCTGCTCA GAGTAAATCAC-3'; and the downstream, 5' -GCACGAGTCA CTCTCGTTTTC-3' [23].

Expression of TNF- α mRNA and IFN- γ mRNA in colonic mucosal tissue

The expression of TNF- α mRNA and IFN- γ mRNA in colonic mucosal tissue, was higher in GIII group than those in GIV group (Figures 1, 2). After treatment, TNF- α mRNA and IFN- γ

mRNA levels were obviously suppressed in groups GI and GII, especially in group GI.

Figure 2 Analysis of IFN- γ mRNA expression in UC mice after a 4-week treatment. A 430-bp fragment was amplified by PCR. M: Marker; Lane 1: Group GIV (control); Lane 2: Group GI (TCME); Lane 3: Group GII (SASPE); Lane 4: Group GIII (NSE). The primers used were: upstream, 5'-TTTGGGTCTCTTGGCTGTT-3'; and the downstream, 5'-CTCCTTTTCGCTTCCCTGT-3' [23].

DISCUSSION

The pathogenesis of colonic colitis remains unclear up to now. It is believed that colonic colitis results from the interaction of many factors, such as environment, immunity and heredity, etc. Probably, susceptible population in heredity is affected by environmental factors, such as water, food and infection, which trigger excessive reaction of intestinal immunity. The reaction can cause an inflammatory stimulation to intestinal mucosa and damage it [24,25]. More and more attention has been paid to autoimmunity. An opinion suggests that there exists an inevitable correlation between the immunity system of intestinal mucosa and its integrity [26-28]. It has been reported that IL-6, a mononuclear macrophage, is a cytokine secreted by T and B cell. IL-6 can promote proliferation of T cell and enhance T cell reaction to cell toxicity. Our experimental result showed that IL-6 was high active in colonic mucosal tissue of UC models, the higher level of IL-6 can further aggravate the injury on colonic tissue by antigen-antibody reaction and complement activation [29,35]. More endogenous IFN- γ and TNF- α produced by colonic epithelia of UC models cause the changes in epithelia, which may lead directly to scatches of inflammatory epithelia [36,37]. Disorder of autoimmunity is closely related to the imbalance of Th₁ and Th₂ cells. For IFN- γ being on Th₁ cell, abnormal expressions of IFN- γ and IFN- γ mRNA cause inevitably the imbalance of Th₁/Th₂ and result in immune disorder [38-40]. CD_{11a}⁺/CD₁₈⁺ are cell surface adhesive albumin, also known as lymphocyte function antigen-1 (LFA-1), a representative of β_2 integrants. It possesses a series of functions, such as introduction of adhesion, chemotaxis of cell and homing of lymphocytes, etc. It expresses on surfaces of white cells, phagocytes and large granular lymphocytes, acting as a key channel in interaction and information between cells. A few of cellular factors, affected by them, such as IL-6, IFN- γ , TNF- α and endotoxin, can affect their expressions [41-43]. CD₈⁺CD_{11a}⁺ and CD₈⁺CD₁₈⁺ (on T_s cell) were found in suffers with moderate and severe ulcerative colitis, and significantly lower than those in normal control rats [44]. This is in conformity to our findings.

Our study showed that expressions of IL-6, TNF- α , TNF- α mRNA, IFN- γ , IFN- γ mRNA were found to be obviously higher and the levels of lymphocyte T surface adhesive molecules, CD₈⁺CD_{11a}⁺ and CD₈⁺CD₁₈⁺ were lower than those in normal rats in colonic mucosal tissue of UC models. The results were in agreement with the findings of others [45]. The results indicated that ulcerative colitis was correlated with disfunction and disorder of autoimmunity. The abnormal expressions of local inflammatory factors and adhesive albumin of cell surface in colonic tissue play a critical role in regulation of immunity. The mutual affects of these factors and

abnormality of regulation of immune system are regarded as the core of pathogenesis. The imbalance of regulation between pre-inflammation cytokines and anti-inflammation cytokines is considered an important mechanism of intestine inflammation, including ulcerative colitis.

At present, ulcerative colitis lacks more effective therapy for radical cure. Principally, steroid hormones and salicylic acid preparation are used to control and suppress the inflammation. In recent years, along with the development of immunology and molecular biology, the accumulation of knowledge about the disease and further understanding of the mechanism of drug action, new methods of treatment have come up into being one after another. But the ordinary UC sufferers can not afford remedies due to the exorbitant price of drugs, and the safety of the remedies needs to be further identified. Our study demonstrated that salazosulfapyridine (SASP) is still the principal remedy for ulcerative colitis. It can improve the conditions of patients in mild and moderate states. But the side-effect and high relapse rate after the remedy are unsatisfactory. Traditional Chinese medicine is popular in China. It is characteristic of TCM to treat intestinal diseases with TCM herbs enemas [12]. The study showed that the treatment of TCME was better on UC than SASPE. Our TCME could effectively inhibit the activity of granulocyte, macrophage and monocyte. Also it could reduce immune response and formation of inflammation in colonic mucosal tissue, which might be due to that our TCME could reduce the expressions of IL-6, TNF- α , IFN- γ and raise the levels of surface adhesive molecules (CD₈⁺CD_{11a}⁺ and CD₈⁺CD₁₈⁺), could also suppress the abnormal expressions of IFN- α and IFN- γ mRNA, improve the disorder of immunity in UC and the Baiji could protect colonic mucosa, Bahuang and Huangbai could promote cruror. SASP suspension has more side-effects than the formulae of TCM herbs, although it has a certain effect in treatment of ulcerative colitis clinically. Therefore, the retention enema prepared from TCM herbs may be an ideal choice to manage the disease.

Abstract

AIM: Cyclooxygenases (COX) are key enzymes for conversion of arachidonic acid to prostaglandins. Nitric oxide synthase (NOS) is the enzyme responsible for formation of nitric oxide. Both have constitutive and inducible isoforms. The inducible isoforms (iNOS and COX-2) are of great interest as regulators of tumor angiogenesis, tumorigenesis and inflammatory processes. This study was to clarify their role in pancreatic adenocarcinomas.

METHODS: We investigated the immunohistochemical iNOS and COX-2 expression in 40 pancreatic ductal adenocarcinomas of different grade and stage. The results were compared with microvessel density and clinicopathological data.

RESULTS: Twenty-one (52.5%) of the cases showed iNOS expression, 15 (37.5%) of the cases were positive for COX-2. The immunoreaction was heterogeneously distributed within the tumors. Staining intensity was different between the tumors. No correlation between iNOS and COX-2 expression was seen. There was no relationship with microvessel density. However, iNOS positive tumors developed more often distant metastases and the more malignant tumors showed a higher COX-2 expression. There was no correlation with other clinicopathological data.

CONCLUSION: Approximately half of the cases expressed iNOS and COX-2. These two enzymes do not seem to be the key step in angiogenesis or carcinogenesis of pancreatic adenocarcinomas. Due to a low prevalence of COX-2 expression, chemoprevention of pancreatic carcinomas by COX-2 inhibitors can only achieve a limited success.

INTRODUCTION

Cancer of the pancreas is still one of the most dismal malignant

diseases with a death to incidence rate of 0.99^[1]. In Germany alone, more than 11 000 patients die of this disease per year^[2]. The only effective therapy is surgical excision^[3]. Adjuvant chemo- and radiotherapy provide only a minimal survival advantage without consistent improvement in outcome^[4]. Until now, the molecular biology of pancreatic cancer still is relatively unknown. A number of studies have focused on genetic changes^[3,5,6]. But also inflammation has been identified as a significant factor in the development of pancreatic cancer^[7]. Both hereditary and sporadic forms of chronic pancreatitis may be associated with increased cancer risk^[8]. Cytokines, reactive oxygen species and mediators of the inflammatory pathway have been identified to increase cell cycling, cause loss of tumor suppressor function and stimulate oncogene expression^[7]. These cytokines are also part of angiogenesis, being an important step for tumor development and could be a therapeutic target also for pancreatic adenocarcinomas.

Nitric oxide (NO) is a pleiotropic biomolecule with a short half time. It has part in the signal transduction in a great variety of mechanisms including neural transmission, vasodilatation, immunoregulation and defense mechanism as well as influencing cancerogenesis^[9]. NO is a product of the conversion of L-arginine to L-citrulline by nitric oxide synthase (NOS)^[10]. This enzyme exists in three isoforms, namely the constitutively expressed calcium-dependent endothelial (eNOS) and neuronal (nNOS) nitric oxide synthase and the calcium independent inducible or immunological (iNOS or NOS-2) isoforms^[11].

iNOS expression in human diseases has long been a matter of investigation. NO production by iNOS in tumor infiltrating macrophages may be part of their antitumoral cytotoxic potential^[12]. On the other hand, expression of iNOS in endothelial cells of tumor vessels and in cancer cells itself supports the assumption that the cancer uses this isoform to regulate the tumor vascularisation and blood flow^[13,14].

Cyclooxygenases (COX) are enzymes which are involved in the synthesis of prostaglandines (PGs) from arachidonic acid. They catalyze the insertion of molecular oxygen into arachidonic acid to form the unstable intermediate PG-G2 being rapidly converted to PGH2. PGH2 is the source of several biological active PGs, thromboxanes and prostacyclines which contribute to many physiological and pathological processes like hemostasis, kidney and gastric function, pain, inflammation and tumor defense and also tumorigenesis^[15].

The two isoforms of COX (COX-1 and COX-2) differ in many respects^[16]. COX-1 is constitutively expressed in most tissues and seems to be responsible for the baseline production of PG. COX-2 is not detected in most normal tissues but is highly inducible by inflammatory and mitogenic stimuli. COX-2 is strongly implicated in tumorigenesis and COX-2 inhibitors are discussed as the target for cancer prevention and therapy^[17].

Current knowledge regarding the rate of iNOS and COX-2 expressions and their relationship to MVD in pancreatic cancer is rather limited. We investigated therefore iNOS and COX-2 expression in pancreatic adenocarcinomas in comparison to microvessel density to clarify the influence of these mediators in pancreatic carcinomas.

MATERIALS AND METHODS

Tissue specimens

All tissues used in this study were surgical resection specimens obtained from the files of the Department of Pathology, Johannes Gutenberg- University, Mainz, Germany. All pancreatic adenocarcinomas were of ductal origin. Carcinomas from 18 women and 22 men with a mean age of 62.2 years (range 45- 81 years) were investigated. Thirty-three tumors were located in the head of the pancreas, 3 in the corpus and 5 in the tail of the pancreas. TNM- classification according to the TNM classification of malignant tumors was as follows: 5× T1, 27× T2, 7× T3, 1× T4. Twenty-three patients showed lymph node metastases and in 5 patients, distant metastases were known. There were 3 well differentiated, 15 moderately differentiated and 22 poorly differentiated pancreatic carcinomas.

Immunohistochemistry

Resected specimens were fixed overnight in 40 g/L buffered formaldehyde, embedded in paraffin and further processed.

For iNOS detection, 4-µm thick sections were deparaffinized and rehydrated, washed in tap water and distilled water and finally in 0.05 mol/L Tris buffer (pH 7.6). After blocking of nonspecific binding sites (Protein blocking agent, Ultratech, Coulter-Immunotech, Marseille, France), sections were washed and incubated with the primary polyclonal rabbit antibody (Transduction Laboratories, Biomol, Hamburg, Germany) with a dilution of 1:1 200 overnight at 4 °C. This antibody is directed against the mouse iNOS C-terminal peptide (1 131-1 144) plus additional N-terminated Cys conjugated to KLH (CKKGSALKEPKATRL). According to the manufacturer, the antibody could recognize the human, mouse and rat iNOS 130 kDa protein without cross reaction to eNOS or nNOS. A biotinylated goat anti-rabbit antibody (Vectastain, ABC-AP Elite Kit, Vector Laboratories, Burlingame, USA) served as secondary antibody. After incubation with the avidine-biotin-complex with alkaline phosphatase, as described by the manufacturer, Fast Red chromogen system (Coulter Immunotech) was used for visualization.

For COX-2 immunohistochemistry, antigen retrieval was achieved by microwave treatment 3 times for 5 min with 600 watt in 0.01 mol/L citrate buffer pH 6.0. The monoclonal antibody COX-2 (h-62 sc-7951; Santa Cruz, Santa Cruz, CA USA) was used as primary antibody in a dilution of 1:50. According to the producer, this antibody reacts with COX-2 of mouse, rat and human origin with no cross reaction with Cox-1. For visualization, the envision kit (DAKO, Glostrup, Denmark) was used.

The results of MVD were retrieved from a previous study [18]. In brief, it was determined using a monoclonal mouse anti-CD34 antibody (Biogenex, San Ramon, Calif, USA). After the endogenous peroxidase was blocked with 30 mL/L hydrogen peroxide the staining procedure was automated including detection with DAB (Ventana, Strassbourg, France).

Nuclear counterstaining was done in all sections with hematoxyline. For every staining procedure sections were incubated without the primary antibody as negative controls. Tissues from colorectal cancer were used as positive controls for all three antibodies.

Evaluation

Semiquantitative analysis of the immunostainings for iNOS and COX-2 was performed for the whole tissue sections considering staining intensity and percentage of positive tumor cells. Using a light microscope (Aristoplan, Leitz, Wetzlar, Germany), in ten randomly selected tumor areas the amount of positive tumor cells and the amount of all tumor cells were determined using an ocular grid at 400×. A case without

positive tumor cells was considered negative. A case with less than 10% positive tumor cells was scored 1, 10-50% was scored 2, 50-80% was scored 3 and more than 80% was scored 4. The staining intensity was divided in weak (I), moderate (II) and strong (III). An immunoreactive score was calculated by multiplication of staining intensity with the amount of positive cells (lowest end score 0, highest end score 12). This evaluation was performed according to Remmele [19]. Specimens with a grade of more than 1 were regarded as positive.

Intratumoral MVD was measured as previously described [18]. In brief, stained sections were screened at 50× magnification to identify the highest vascular area within the tumor. In these hot spots, individual microvessel count was evaluated at 200× magnification using an ocular grid. Every cluster of cells stained with CD34 was counted as a vessel. Branching structures were counted as single vessels. Vascular counts for each case were calculated.

Statistics

Statistical analysis was performed with the Statistical Program for Social Science (SPSS, Chicago, Ill., USA). The Pearson's chi-square test and Fischer's exact test were used to examine the association with the clinicopathological parameters. Nonparametric correlation with Spearman's rho correlation coefficient was used to compare iNOS and COX-2 expressions as well as MVD. A *P*-value <0.05 was considered statistically significant.

RESULTS

iNOS

Positive iNOS immunostaining was detected in 21 (52.5%) of all 40 cases of pancreatic carcinoma. Immunoreactive tumor cells were both diffusely and focally distributed throughout the tumor. The immunoreaction was seen in the cytoplasm with completely unstained nuclei (Figure 1). Nine cases (22.5%) showed a mild staining intensity (grade I), 8 cases (20%) a moderate staining intensity (grade II) and 4 cases (10%) a strong staining intensity (grade III). One case (2.5%) expressed iNOS only focally in less than 10% of tumor cells. Eight cases (20%) showed immunoreaction in 10- 50% of tumor cells, 11 cases (27.5%) in 50-80% of positive tumor cells. In one case (2.5%) more than 80% of tumor cells were stained (Table 1).

There was no correlation with tumor stage (*P*=0.971), histological grade (*P*=0.591), location within the pancreas (*P*=0.184), lymph node metastases (*P*=0.652), age (*P*=0.651) or sex (*P*=0.546) of the patients. A relationship between iNOS expression and distant metastases was seen, but the low amount of cases with distant metastases did not allow statistical evaluation.

In the surrounding tissue the islets of Langerhans showed positive reaction in several cells. The original acini were negative. In the negative controls, immunoreactivity was completely lacking while the positive controls displayed a clear cut immunopositivity.

COX-2

Positive COX-2 staining was seen in 15 out of the 41 (37.5%) pancreatic carcinomas. The immunoreactivity here was also focally distributed throughout the tumor with cytoplasmic reaction only. Nuclear staining was not observed (Figure 2). The staining intensity in the positive cases differed. Among them, 5 cases (12.5%) were slightly stained (grade I), 4 cases (10%) were moderately stained (grade II) and 6 cases (15%) were intensely stained (grade III). The amount of positive cells was as follows: 3 cases (7.5%) with less than 10% positive tumor cells, 7 cases (17.5%) with 10-50% positive tumor cells, 4 cases (10%) with 50-80% positive tumor cells and 1 case with more than 80% (2.5%) positive tumor cells (Table 1).

Table 1 Comparison between expression of iNOS and COX-2 and clinicopathological features in pancreatic adenocarcinomas (n=40)

Variables	No. of patients (%)	iNOS positive	iNOS negative	P value	COX-2 positive	COX-2 negative	P value
Tumor stage							
I	5 (12.5)	1	4	0.971	1	4	0.983
II	27 (67.5)	15	12		11	16	
III	7 (17.5)	4	3		3	4	
IV	1 (2.5)	1	0		0	1	
Nodal stage							
n=0	17 (42.5)	10	7	0.652	6	11	0.945
n=1	23 (57.5)	11	12		9	14	
Distant metastases							
M0	35 (87.5)	18	17	0.043	13	22	0.459
M1	5 (12.5)	3	2		2	3	
Grade							
G1	3 (7.5)	2	1	0.591	1	2	0.000
G2	15 (37.5)	10	5		6	9	
G3	22 (55)	9	13		8	14	
MVD		5.7 (+/-2.4)	6.4 (+/-2.9)		6.4 (+/-3)	5.8 (+/- 2.4)	

**Figure 1** Immunohistochemical demonstration of iNOS expression in cases of pancreatic adenocarcinomas with moderate (A) and strong (B) staining intensity. There was a cytoplasmatic staining pattern with distribution within the tumor. No nuclear staining was observed. Cells of the islets of Langerhans were also positive (C). Original magnification $\times 200$, Hematoxylin counterstaining.**Figure 2** COX-2 immunohistochemistry in pancreatic adenocarcinomas shown in a case with (A) moderate and (B) strong staining intensity. Immunostaining was restricted to the cytoplasm. Even in the case with high staining only a portion of tumor cells expressed COX-2. Cells of the islets of Langerhans were also stained (C). Original magnification $\times 200$, Hematoxylin counterstaining.**Figure 3** Comparison of iNOS or COX-2 expression with microvessel density. No statistically significant correlation could be noted.

Comparing the immunoreactive score of COX-2 expression with histological grade, a significant relationship could be seen. The more malignant tumors (grade 3) showed a higher COX-2 expression ($P=0.000$). This association depended stronger on the amount of positive cells ($P=0.000$). Considering staining intensity alone, no relationship was seen ($P=0.118$). The carcinomas in the head of the pancreas showed more often COX-2 expression than in other locations ($P=0.006$).

COX-2 did not correlate with tumor stage ($P=0.983$), lymph node ($P=0.945$) or distance metastases ($P=0.459$), age ($P=0.369$) or sex ($P=0.331$) of the patients.

In the surrounding tissue, the islets of Langerhans had positive reaction in several cells. The original acini were negative. In the negative control, immunoreactivity was completely lacking while the positive control displayed a clear cut immunopositivity.

MVD

The mean MVD in pancreatic carcinoma was 6.08 vessels per mm² (range 1.6 to 11.8 vessels per mm², standard derivation of 2.67 vessels per mm², median value of 5.25 vessels per mm²).

MVD analysis demonstrated a significant relationship to the age groups (younger or older than 60 years) with higher MVD in the older patients ($P=0.024$). There was no statistically significant trend regarding the histological grade with more malignant carcinomas (grade 3) having higher MVD ($P=0.056$).

MVD had no association with tumor stage ($P=0.154$), location within the pancreas ($P=0.678$), lymph node ($P=0.325$) or distance metastases ($P=0.137$) or sex ($P=1.000$) of the patients.

Correlation between iNOS, COX-2 and MVD

There was no statistically significant correlation between INOS and COX-2 expression in pancreatic adenocarcinomas ($P=0.137$, Figure 3). MVD did neither depend on iNOS expression ($P=0.160$) nor COX-2 expression ($P=0.989$). Considering only COX-2 positive cases, no correlation of COX-2 with MVD could be found ($P=0.459$). Also, considering iNOS positive cases alone, there was no relationship between iNOS expression and MVD ($P=0.436$) noticeable.

DISCUSSION

Folkman *et al.* suggested that the step from prevascular to vascular phase was the prerequisite for the growth and spread of many solid tumors^[20]. Thus, angiogenesis contributes significantly to the progression of carcinomas. Intratumoral microvessel density is believed to reflect the overall degree of tumor angiogenesis. It has been accepted as an independent prognostic factor for several types of tumors like breast cancer, colon cancer or lung adenocarcinomas^[21-23]. For pancreatic carcinoma, we could not find a correlation with parameters linked to survival^[18].

Both COX-2 and iNOS, were play- markers of tumor angiogenesis^[24]. Hypoxia induces iNOS together with erythropoietin, the molecule leading to erythropoiesis and improvement of oxygen supply. COX-1 could regulate angiogenesis in endothelial cells, whereas COX-2 could regulate the production of nearly all angiogenetic factors in cancer cells^[24].

We could show that iNOS was inconstantly expressed in pancreatic adenocarcinomas. This is in concordance with other studies^[25,26]. INOS expression has been observed also in other carcinomas such as urothelial carcinomas^[27], gynecological cancers^[28], breast carcinomas^[29], colon cancers^[14], and lung tumors^[30].

The role of iNOS in cancerogenesis is still not clear. NO, the product of NOS, has several properties in addition to angiogenesis, which might enhance tumor growth. NO has been

found to be a mediator of angiogenesis and blood flow^[31]. Also, high concentrations of NO could lead to apoptosis, low concentrations might protect many cells from cell death^[32-34]. It could be shown that NO induces a G1-arrest followed by apoptosis in pancreatic carcinoma cell lines^[35].

Multiple lines of evidence suggest that COX-2 is important in carcinogenesis. For example, COX-2 was upregulated in various forms of cancers^[36]. A null mutation for COX-2 caused marked reduction in intestinal polyposis in a murine model of familial adenomatous polyposis^[37]. Newly developed selective inhibitors of COX-2 were reported to protect against gastrointestinal tumor formation.

We found COX-2 expression in 15 out of 40 cancer cases. This is slightly lower than that reported in the literature, which was up to 74% by using different methods including Northern and Western blot as well as immunohistochemistry^[38-40]. Okami reported a weak staining in most of the investigated carcinoma specimens^[41]. COX-2 staining in pancreatic carcinoma was very heterogeneous and there were great variations between specimens.

For pancreatic carcinoma, Koshiba *et al.* suggested that COX-2 might be associated with the degree of malignancy comparing intraductal papillary mucinous adenomas, intraductal papillary carcinomas and intraductal carcinomas^[42]. We and others could show that in the group of carcinomas the expression of COX-2 depended on the histological grading, and higher malignant tumors showed more enhanced COX-2 expression. A dependence of histological grade was also described by Nijima^[43]. With a higher expression in more malignant tumors COX-2 seems to be a late or bystander effect. In our cohort, we could not prove a positive or negative correlation of COX-2 expression with MVD.

In chronic pancreatitis COX-2 overexpression was also recently observed^[44]. The enzyme was found in atrophic acinar cells, hyperplastic ductal cells and islets cells. As chronic pancreatitis is a risk factor for pancreatic cancer, this opens whether COX-2 is involved in the tumorigenesis via chronic inflammation. Apart from positive islets cells, we could not see any COX-2 expression in normal tissues, especially in the surrounding tissue of the tumor. If COX-2 is constantly expressed in chronic inflammation of pancreas one would expect enzyme induction also in the inflamed peritumoral region. Other reports mentioning the nonneoplastic tissue also found no COX-2 expression. It seems therefore unlikely that this enzyme is involved in early tumor development via inflammation.

In summary, approximately half of pancreatic adenocarcinomas express iNOS and COX-2. Both enzymes are heterogeneously distributed in the tumors without any correlation to each other nor to MVD. COX-2 is a phenomenon of higher malignant tumors. Both enzymes do not appear to be a key step in the angiogenesis of pancreatic adenocarcinomas.

Abstract

AIM: To determine the role and effect of nitric oxide synthase type II (NOSII) in cirrhotic rats.

METHODS: Expression of NOSII mRNA was detected by real time RT-PCR. The activity of nitric oxide synthase and serum levels of NO, systemic and portal hemodynamics and degrees of cirrhosis were measured with high sensitive methods. Chinese traditional medicine tetrandrine was used to treat cirrhotic rats and to evaluate the function of NO. Double-blind method was applied during the experiment.

RESULTS: The concentration of NO and the activity of NOS were increased markedly at all stages of cirrhosis, and iNOSmRNA was greatly expressed. Meanwhile the portal-venous-pressure (PVP), and portal-venous-flow (PVF) were significantly increased. NO, NOS and iNOSmRNA were positively correlated to the quantity of hepatic fibrosis. Tetrandrine significantly inhibited NO production and the expression of iNOSmRNA.

CONCLUSION: Increased hepatic expression of NOSII is one of the important causes of hepatic cirrhosis and portal hypertension.

INTRODUCTION

Nitric oxide (NO) is a vasodilator formerly detected in vascular system, but is currently recognized as a multifunctional molecule widely distributed in many other tissues, such as immune and neuronal systems. NO is synthesized from L-arginine by the NO synthase isozyme family of which three different members have been characterized, namely NOSI, NOSII and NOSIII. NOSI and NOSIII are constitutive and Ca^{2+} /calmodulin-independent. The first was initially discovered in neurons and the second in endothelial cells^[1-2]. NOSII is Ca^{2+} -independent, and is located in macrophages and smooth muscle cells, and is induced by appropriate proinflammatory stimuli and bacterial lipopolysaccharides^[3]. Its activity can be competitively inhibited

by several L-arginine analogues such as N^{ω} -nitro-L-arginine.

However, proinflammatory cytokines, endotoxins, and bacterial infections in various pathologic entities are associated with enhanced production of NO, hyporesponsiveness to vasoconstrictors, and development of a hyperdynamic state^[4-7]. Vallance and Moncada hypothesized that bacterial endotoxin might account for hemodynamic changes in severe cirrhosis by stimulating the expression of inducible NO synthase (iNOS) to produce NO^[8].

Recently, numerous studies have focused on NO as a possible major causative agent of the decreased vascular resistance in cirrhosis. In fact, most investigations are coincident in reporting an increased NO activity in the vasculature of patients and rats with cirrhosis^[9-12], a phenomenon in which both NOSII and NOSIII seem to be involved^[13]. There is, however, little information on the progress in liver diseases affecting the L-arginine/NO pathway in organs other than the systemic vasculature. This is particularly intriguing in the liver, as it largely affects the consequence of the derangement under pathologic conditions. Whereas most investigations consider NO as an important mediator of hemodynamic alterations in experimental cirrhosis^[14].

Chinese traditional medicine tetrandrine has the function of inhibiting calcium influx^[15,16], and effect in treatment of liver fibrosis^[17]. We postulated that if NO was a key mediator in cirrhosis and portal hypertension, Tetrandrine would affect the level of NO by inhibiting the expression of NOSmRNA and the activity of NOS. Therefore, in this study, mRNAs of NOSII and NOSIII were determined in liver tissue of rats with CCL₄-induced cirrhosis to assess the level of NO. In addition, the NOS activity of liver tissue and the serum levels of NO, hemodynamic changes of portal vein and pathologic changes at all stages of cirrhosis were also investigated.

MATERIALS AND METHODS

Induction of cirrhosis in rats

Hepatic injury and fibrosis were induced in male retired breeder Sprague-Dawley rats (450-550 g) by intragastric administration of carbon tetrachloride as described previously^[18]. CCL₄ (1.0 mL/kg) in a 1:1 mixture with corn oil was administered by gavage at 7-day intervals. After the second intragastric administration of carbon tetrachloride, Tetrandrine group inhaled the suspension of Tetrandrine (1 mL/0.1 kg). Animal weight was monitored, and the dosage of CCL₄ and Tetrandrine was adjusted accordingly. Portal hypertension (portal venous dilation with portal pressure >10 cm H₂O) was documented in all animals after 10 doses of CCL₄. Controls received corn oil on the same schedule as experimental animals.

In vivo effects of tetrandrine administration

There were 90 conscious rats in this study. Animals were anesthetized with ketamine (100 mg/kg.bm) and prepared with P-50 catheters in portal vein and inferior vena cava. The catheter was connected to a highly sensitive transducer and a multichannel recorder (MX4P and MT4, Lectromed Ltd, Jersey, Channels Islands, UK) and portal venous pressure and portal venous

flow were recorded. Then, a 2-mL blood sample was taken to measure NO. Blood was immediately centrifuged at 4 °C and serum was frozen at -20 °C until further analysis. Tissue specimens were obtained from the middle liver lobe in each animal. Liver specimens were fixed in 40 g/L buffered formaldehyde and stained with hematoxylin and eosin, reticulin, and Masson's trichrome for histological examination. Moreover, additional liver tissues were immediately frozen in dry ice and stored in liquid nitrogen until further analysis. Serum NO and liver NOS activity were determined.

Expression of inducible and constitutive NOS mRNA

mRNAs of NOSII and NOSIII were assessed in liver tissues of all groups. Under anesthesia with ketamine (100 mg/kg) animals were exsanguinated by cardiac puncture. Liver tissue was dissected, placed in a Petri dish containing a diethyl pyrocarbonate (0.01%) -treated PBS buffer solution, total RNA was extracted by the guanidine isothiocyanate method^[19].

NOSII and NOSIII mRNA expression was assessed by real-Time RT-PCR

Reverse transcription (RT) reaction was performed with cDNA synthesis kit (Promega, Madison, WI) and followed the attached protocol with reaction kit. The final volume of the reaction (20 µL) was completed with RNase free water. First strand cDNA synthesis was carried out at 42 °C for 30 min in a DNA thermal cycler (PTC-100, MJ Reserch Inc, Watertown, MA). Afterwards, the tubes were incubated at 99 °C for 5 min to terminate the reaction. Then each tube was kept at 4 °C until PCR was performed.

Real-time RT-PCR

Expression of the target genes (NOSII and NOSIII) was quantified. The primers were designed using the software Primer Express (Applied Biosystems) (Table 1).

RT- PCR was performed according to a TaqMan 2-step method using an ABI PRISM 7 700 sequence detection system (Applied Biosystems). PCR cycling conditions included an initial phase at 50 °C for 2 min, followed by at 95 °C for 10 min for AmpErase, 40 cycles at 95 °C for 15 s, and at 60 °C for 1 min. Quantification of the PCR products was based on the TaqMan 5' nuclease assay using the ABI PRISM 7 700 sequence detection system. The starting amount of a specific mRNA in an unknown sample was determined. The standard curve was generated on the basis of the linear relationship between the Ct value and logarithm of the starting quantity. Ct value was the cycle number at which a significant increase in the fluorescence signal was initially detected. The unknown samples were quantified by the software of the ABI PRISM 7 700 sequence detector system, which calculated the Ct value for each sample and then determined the initial amount of the target using the standard curve. The amount of the target was normalized to the reference.

Table 1 Oligonucleotides used for PCR

Gene	Quantification method	Primer sequence	cDNA
NOSII	Forward primer	5' -CCCTTCCGAAGTTTCTGGCAGCAG-3'	2 793-2 817
	Reverse primer	5' -GGGCTCCTCCAAGGTGTTGCCC-3'	3 424-3 446

	Reverse primer	5' -GAAGATGGTGTATGGGA-3'	
	Probe	5' -(JOE)CAAGCTTCCCGTTCTCAGCC(TAMRA)-3'	

Statistical analysis

One-way ANOVA, Newman-Keuls's, and unpaired Student's *t* tests were used for statistical analysis. Data are expressed as mean±SE, *P* level at 0.05 or less was considered statistically significant.

RESULTS

The cirrhotic liver treated with CCL₄ had a finely granulated surface. Histological examination showed the distinct features of three-grade fibrosis. Tetrandrine group had slight fibrosis in the third grade of cirrhosis.

Pathologic examination

Pathologic examination indicated that tetrandrine had an obvious effect on preventing the necrosis of hepatic cells and delaying the development of hepatic fibrosis (Figure 1).

Serum NO and NOS activity of liver tissue

Serum NO and NOS activity in cirrhotic group were significantly higher than those in normal control, and had no difference between the normal and therapeutic groups (Tables 2, 3).

Table 2 Effects of tetrandrine and on serum NO in cirrhotic rats (µmol/L, mean±SD)

Grade	Tetrandrine (n=8)	Cirrhosis (n=8)	Negative control (n=8)
Earlier period	6.51±0.56 ^b	10.27±0.71	5.91±0.67
Metaphase	6.87±0.78 ^b	10.88±0.82	6.04±0.98
Late period	6.49±0.83 ^b	6.35±1.48 ^b	6.17±0.73

^b*P*<0.01 vs cirrhosis.

^a*P*<0.05 vs cirrhosis.

Hemodynamics

High hemodynamics was observed in cirrhotic rats. Portal-venous-pressure (PVP) and portal-venous-flow (PVF) were significantly increased. But PVP in tetrandrine groups was significantly decreased in all stages of cirrhosis. PVF was only decreased in the metaphase of cirrhosis (Table 4).

Figure 1 Histological images of three-grade fibrosis and tetrandrine treated group (200×). A: normal group, B: earlier cirrhosis group, C: earlier tetrandrine group, D: metaphase cirrhosis group, E: metaphase tetrandrine group, F: late cirrhosis group, G: late tetrandrine group.

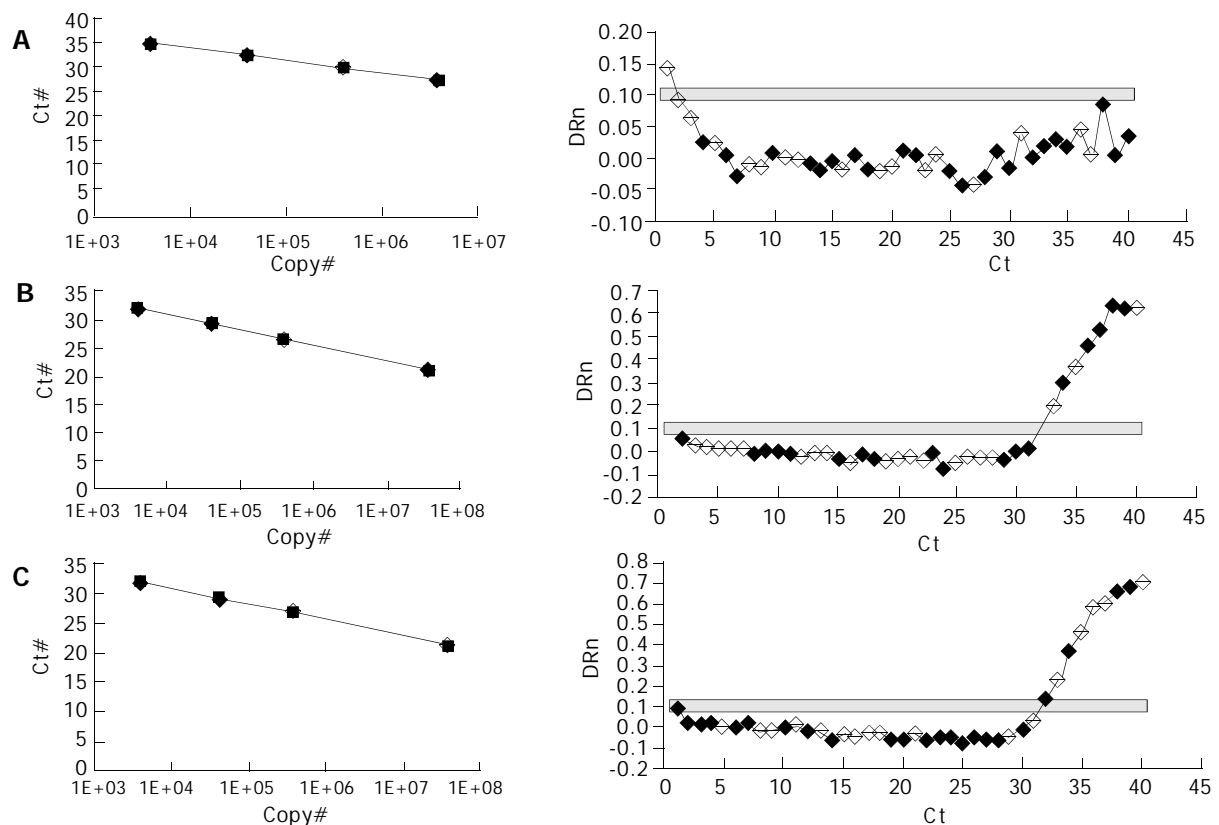

Figure 2 Real-time RT-PCR images: Expression of iNOS in normal hepatic tissue (A), Expression of iNOS in Tetrandrine therapeutic hepatic tissue (B), Expression of iNOS in cirrhotic tissue (C). NOSII was not expressed in normal rat tissue, but highly expressed in cirrhotic rat tissue and NOSII in therapeutic groups was significantly decreased than that in cirrhosis.

	PVR	7.44±1.08	8.01±0.79	6.76±0.34

^a*P*<0.05, ^b*P*<0.01 vs cirrhosis.

Relationship between NO and hemodynamics

NO concentration correlated significantly with PVP ($r=0.69$, $P<0.01$) and PVF ($r=0.72$, $P<0.01$), but inversely with PVR ($r=-0.63$, $P<0.01$).

Quantitative RT-PCR

Quantification of the PCR products showed that NOSII was highly expressed in cirrhotic rat tissue (Figure 2C), and NOSII in therapeutic groups was significantly decreased than cirrhosis (Figure 2B) ($P<0.01$). NOSII was not found in normal rat tissue (Figure 2A). NOSIII expression was not different among all groups ($P>0.05$) (Table 5).

Table 5 Quantification of PCR products

Stage	Index	Tetrandrine (n=8)	Cirrhosis (n=8)	Negative control (n=8)
Earlier period	NOSII	0.1723±0.0014	0.5635±0.0104	-
	NOSIII	0.2578±0.0076	0.2694±0.0043	0.2786±0.0107
Metaphase	NOSII	0.1679±0.0093	0.7521±0.0098	-
	NOSIII	0.3210±0.0084	0.3412±0.0113	0.2916±0.0089
Late period	NOSII	0.1876±0.0065	0.6987±0.0078	-
	NOSIII	0.2917±0.0102	0.3002±0.0091	0.2815±0.0098

Quantification of cirrhosis

Quantification of cirrhosis showed that cirrhosis significantly decreased in Tetrandrine group than in cirrhotic group (Figure 3).

DISCUSSION

The function of NO in human beings or experimental animals is

invariably associated with marked systemic and portal venous hemodynamic effects, including arterial hypotension, portal hypertension, increased portal venous perfusion. The intensity and full manifestation of this response depend on the expression of NOS and the NOS activity. To ascertain which isoforms of NOS displayed a differential effect on cirrhotic liver of rats, the expressions of NOSII and NOSIII were determined. The study showed that NOSII was markedly increased in cirrhotic rat liver tissues. However, we did not find the expression of NOSII in normal liver tissues. Because macrophages were of central importance in the initiation and regulation of nonspecific and specific immune responses^[20], it was considered that NO from these cells was implicated in the nonspecific defense against parasitic diseases and participated in the production of free radicals that are toxic to bacteria and parasites^[21]. Rodent macrophages were extremely sensitive to agents promoting NOSII expression^[22]. In this study, no difference in NOSIII expression between cirrhotic and normal rats was found. We postulated that NOSIII expression in cirrhotic liver had no effect on portal hypertension. But it might have a great function in cirrhosis due to its expression in big blood vessels^[23-25]. Intrahepatic endothelial NO mediated by shear stress-dependence seems impaired by shunt.

Chinese traditional medicine Tetrandrine had a good therapeutic effect for fibrosis^[16,17]. It is often used to treat hepatitis of HBV. In a recent study, it was tested to inhibit calcium influx. We therefore postulated that if NO played a role in the mechanism of cirrhosis and portal hypertension, Tetrandrine would have the effect on the inhibition of NO production. This study approved our hypothesis and showed NOSII mRNA was markedly expressed in cirrhotic liver tissues. NOSIII was mainly distributed in endothelial cells and its function was relied on calmodulin(CaM)^[26]. Tetrandrine affected NOSIII expression, however, had no effect on NOSIII expression. Thus, we reason the changes of NOSIII could be stimulated by shear stress. NOSII was mainly distributed in microphages and endothelial cells. NOSII did not express in normal physiological conditions. Amino acid sequence analysis showed that NOSII had the conjugated site of calmodulin, and rodent NOSII could be conjugated tightly with CaM without calcium^[27]. In this study, an important finding in cirrhotic liver exposed to Tetrandrine was an NO antagonist. Moreover, tetrandrine could also affect NOS enzymatic activity. The results of the present study indicated that portal-venous-pressure and portal-venous-flow decreased by tetrandrine were mediated by lower level NO and cirrhotic blood vessel.

In conclusion, NOSII is markedly expressed in cirrhotic liver, inducing a high hemodynamic change of portal vein and pathologic changes in all stages of cirrhosis. Tetrandrine inhibits NOSII expression, decreases NOS activity and reduces the NO production. The mechanism of fibrosis and portal hypertension is NO mediated, and tetrandrine is effective for improving portal hypertension by reducing NO in cirrhotic patients.

Abstract

AIM: To choose an appropriate methods for the isolation of hepatic lymphocytes between the mechanical dissection and the enzymatic digestion and investigate the effects of two methods on phenotype and function of hepatic lymphocytes.

METHODS: Hepatic lymphocytes were isolated from untreated, poly (I:C)-stimulated or ConA-stimulated mice using the two methods, respectively. The cell yield per liver was evaluated by direct counting under microscope. Effects of digestive enzymes on the surface markers involved in hepatic lymphocytes were represented by relative change rate [(percentage of post-digestion - percentage of pre-digestion)/percentage of pre-digestion]. Phenotypic analyses of the subpopulations of hepatic lymphocytes and intracellular cytokines were detected by flow cytometry. The cytotoxicity of NK cells from wild C57BL/6 or poly (I:C)-stimulated C57BL/6 mice was analyzed with a 4-h ⁵¹Cr release assay.

RESULTS: NK1.1⁺ cell markers, NK1.1 and DX5, were significantly down-expressed after enzymatic digestion and their relative change rates were about 28% and 32%, respectively. Compared with the enzymatic digestion, the cell yield isolated from unstimulated, poly (I:C)-treated or ConA-treated mice by mechanical dissection was not significantly decreased. Hepatic lymphocytes isolated by the mechanical dissection comprised more innate immune cells like NK, NKT and $\gamma\delta$ cells in normal C57BL/6 mice. After poly (I:C) stimulation, hepatic NK cells rose to about 35%, while NKT cells simultaneously decreased. Following ConA injection, the number of hepatic NKT cells was remarkably reduced to 3.67%. Higher ratio of intracellular IFN- γ (68%) or TNF- α (15%) NK1.1⁺ cells from poly (I:C)-treated mice was obtained using mechanical dissection method than control mice. There was no difference in

viability between the mechanical dissection and the enzymatic digestion, and hepatic lymphocytes obtained with the two methods had similar cytotoxicity against YAC-1 cells.

CONCLUSION: There is no difference in the cell yield and viability of the hepatic lymphocyte isolated with the two methods. The mechanical dissection, but not the enzymatic digestion, may be suitable for the phenotypic analysis of hepatic NK1.1⁺ cell.

INTRODUCTION

In recent decades, isolated lymphocytes from human or murine liver were universally used to explore the immune mechanisms in the defense of pathogens such as hepatitis virus^[1,2] and in the pathogenesis of liver diseases, especially in the autoimmune hepatitis^[3] and liver transplantation^[4]. Several lymphocyte subpopulations reside in the normal adult human liver. These cells mainly include a large number of T cells, B cells, natural killer (NK) cells and natural killer T (NKT) cells, which are distinct from the peripheral blood lymphocytes (PBL)^[5-7]. Up to now, mechanical dissection and enzymatic digestion are two main techniques for isolation of hepatic lymphocytes. The former method started in the early of 1980 and has been used yet. Reportedly, the viability of lymphocyte with this method is poor, and this method also leads to low yield. The latter methods was through incubation with digestive enzymes, 0.5 g/L collagenase IV and 0.01 g/L DNAase I^[8] and was considered to have a relative low contamination of PBL. Because the manipulation of the method is difficult to handle for tenderfoots, the prevalent use is limited. Some investigators also discovered that two digestive enzymes used could influence and decrease the percentage of surface markers of human hepatic lymphocytes such as CD56 molecule^[9]. However, the effects of two digestive enzymes on the surface markers of murine hepatic lymphocytes especially NK1.1⁺ cells, remain obscure. Yet there was not any report exclusively focused on the difference between these two methods. To compare these two methods for suitably selecting an appropriate method to analyze the NK1.1⁺ cells in the liver, we used these methods to isolate the murine hepatic mononuclear cells for the phenotypic and functional analysis.

MATERIALS AND METHODS

Animal

Female C57BL/6 (H-2^b), 6 to 8 week-old, was purchased from Shanghai Experimental Animal Center, Chinese Academy of Sciences (Shanghai, China). All mice were maintained under controlled conditions (22 °C, 55% humidity, and 12-h day/night

rhythm) in compliance with the regulations of animal care of University of Science and Technology of China.

Reagent

Collagenase IV and DNase I were purchased from Sigma Chemical Co. (St. Louis, MO) and dissolved in the pyrogen-free RPMI 1640 at the concentration of 0.5 g/L and 0.01 g/L, respectively.

Poly (I:C) or ConA treatment

Polyinosinic-polycytidylic acid sodium [Poly (I:C)] and Concanavalin A (Con A) were purchased from Sigma Chemical Co. (St. Louis, MO) and dissolved in the pyrogen-free saline at the concentration of 1 mg/mL. For *in vivo* stimulation of NK cells, mice were intraperitoneally injected with Poly (I:C) (7.5 µg/g·b.m.) for 6 h. For *in vivo* stimulation of NKT cells, mice were intravenously injected with ConA (7.5 µg/g·b.m.) for 6 h.

Protocols for isolation of mononuclear cells (MNC) from liver

Under deep ether anesthesia, mice were euthanized by exsanguinations from the subclavian artery and vein. A needle was inserted into the portal vein. The liver was perfused with 20 mL pH 7.0 PBS, and then the liver was removed. Isolation of hepatic lymphocytes with the mechanical dissection was carried out as follows: step 1, the liver was thoroughly dissected and gently passed through a 200-gauge stainless steel mesh and then suspended in RPMI 1640 medium containing 100 mL/L fetal calf serum (FCS). Step 2, the above cell suspension was centrifuged at 1 500 r/min. The pellet was resuspended in 40% Percoll solution containing 100 U/mL heparin, and then loaded on the layer of 70% Percoll solution followed by centrifugation at 2 000 r/min for 20 min at room temperature. Step 3, the cells were aspirated from the Percoll interface and harvested by centrifugation and washed twice with Hanks' balanced salt solution (HBSS) containing 50 mL/L FCS before use. The procedures for the enzymatic digestions were as follows: step 1, the liver was dissected into 1 mm³ pieces and 5 mL digestive solution was added. The mixture was incubated at 37 °C for 1 h. The supernatant was collected and diluted 1/2 in complete RPMI 1640. Step 2 and 3 were similar to the mechanical dissection.

Assessment of yield and viability of hepatic lymphocytes

Isolated hepatic lymphocytes from different groups (4 mice per group) were diluted 1:20 with 20 mL/L acetic acid, and cell numbers were assessed by direct counting under microscope. Cell viability was assessed by staining with trypan blue, and the stained-positive cells were enumerated to dead cell, while negative cells to viable lymphocyte.

Effects of digestive enzymes on the surface markers

Effects of digestive enzymes, collagenase IV and DNase I, on the surface markers were determined by the percentage in the pre-digestion and post-digestion. It was represented as relative change rate (%). Relative change rate=[(percentage of post-digestion - percentage of pre-digestion)/percentage of pre-digestion].

Immunofluorescence

The phenotype of lymphocytes was analyzed using monoclonal antibody (mAb) in conjunction with two-color or three-color immunofluorescence. The mAb used in this study included fluorescein isothiocyanate (FITC)-, phycoerythrin (PE)-, or Cy5-conjugated gamma/delta T cell receptor (γδ TCR), anti-CD3e, anti-CD25, anti-CD69, anti-IFN-γ, anti-DX5, and anti-NK1.1 mAb (PharMingen, San Diego, CA). For Intracellular cytokine staining, liver mononuclear cells were incubated in the presence of brefeldin A (5 µg/mL; BD PharMingen) and phorbol myristate

acetate (PMA) (20 ng/mL; BD PharMingen) for 3 h, and then stained with FITC-conjugated anti-NK1.1 mAb and Cy-5 conjugated anti-CD3e mAb. After fixation with fixation solution and permeabilization with permeabilization solution (Bioscience, Camarillo, USA), intracellular cytokine staining was performed using PE-conjugated anti-IFN-γ or anti-TNF-α mAb. To prevent nonspecific binding, respective isotype antibodies were used as control. Stained cells were acquired by FACSCalibur and analyzed with WinMDI2.8.

Cytotoxicity assay

Target cells used in NK cytotoxicity assay were YAC-1 cells, which were propagated in RPMI 1640 medium supplemented with 100 mL/L heat-inactivated FCS, 2 mmol/L L-glutamine and 25 mmol/L NaHCO₃ in a humidified atmosphere containing 50 mL/L CO₂ at 37 °C. Cytotoxicity assay was carried out as described previously [10]. Labeled target cells (10⁴/well) were incubated in a total volume of 200 µL with effector cells in RPMI 1640 containing 100 mL/L FCS in 96-well round-bottom microtiter plates at various cell densities in order to achieve effector-to-target (E/T) ratios. The plate was incubated for 4 h, and the supernatant was collected after centrifugation and then counted in a gamma counter. The cytotoxicity was calculated as the percentage of releasable counts after subtraction of spontaneous release. The spontaneous release was less than 15% of the maximum release.

Statistical analysis

Data were expressed as mean±SD. Statistical analysis was performed using *t* test. Difference between the groups was considered statistically significant when *P* value was less than 0.05.

RESULTS

Effects of enzymatic digestion on surface molecules of hepatic lymphocytes

To understand the effect of collagenase IV and DNase I on murine hepatic lymphocytes, we detected the percentage of lymphocyte-related markers, CD3, CD4, CD8e, CD25, CD69, NK1.1, DX5 and γδ TCR in the enzyme-treated and untreated hepatic lymphocytes. Surface markers, CD3, CD4, CD8e, CD25, CD69 and γδ-TCR, remained unchanged and two markers associated with NK and NKT cells, NK1.1 and DX5, were significantly decreased in the enzyme-treated group compared to untreated group and their relative change rates were about 28% and 32% in NK1.1 and DX5 groups respectively (Figure 1). The percentages of NK and NKT cells isolated with the mechanical dissection were higher than those in the enzymatic digestion (Table 1, *P*<0.05). This finding suggested that the enzymatic digestion might decrease the proportion of NK1.1⁺ cells in murine hepatic lymphocytes by decreasing the NK or NKT-related surface molecules, and should be avoided in the study of NK1.1⁺ in the liver.

Table 1 Subpopulations of hepatic lymphocytes isolated by two the methods (%)

Group	T cell	NK cell	NKT cell	γδ T cell
Mechanical dissection	38.56±5.63	13.35±4.61	20.42±4.65	13.6±3.15
Enzymatic digestion	36.96±4.68	8.35±2.69 ^a	13.48±4.25 ^a	12.6±2.74

^a*P*<0.05 vs dissection.

Cell yield of the two methods

In normal C57BL/6 mice, the total cell number obtained with the mechanical dissection was about 2.6×10⁶ per liver and that

obtained with the enzymatic digestion was 2.9×10^6 per liver, showing no significant difference (Figure 2A). To further investigate the cell yield in the stress condition, two stimuli, Poly (I:C) and ConA, were used to trigger hepatic lymphocytes, respectively. About 7×10^6 hepatic lymphocytes per liver were obtained in Poly (I:C)-stimulated or ConA-stimulated mice using either the mechanical dissection or the enzyme digestion, without any significant difference between the two isolation methods (Figures 2B,C). These results suggested that the mechanical dissection was as effective as the enzymatic digestion in the cell yield.

Figure 1 Effects of enzymatic digestion on surface molecules of hepatic lymphocytes. ^a $P < 0.05$, NK1.1 vs other groups except DX5; ^b $P < 0.01$, DX5 vs other groups except NK1.1.

Hepatic lymphocytes isolated with mechanical dissection were suitable for phenotypic analysis

Using mechanical dissection, we isolated the hepatic lymphocytes for analyzing the subpopulations of hepatic lymphocytes. Different from other immune organs, hepatic

lymphocytes of normal C57BL/6 mice comprised more innate immune cells like NK, NKT and $\gamma\delta$ cells, which accounted for 18.60%, 16.62% and 18.60% respectively (Figure 3A). Following Poly (I:C) stimulation, hepatic NK cells increased to about 35% and NKT cells simultaneously decreased, which was consistent with other reports^[11] (Figure 3B). Following ConA injection, hepatic NKT cells were remarkably reduced to 3.67%. In addition, after Poly (I:C) stimulation intracellular IFN- γ and TNF- α were significantly augmented to about 68% and 25% within NK (CD3⁺NK1.1⁺) cells, respectively (Figure 3C). Taken together, the results indicated that hepatic lymphocytes obtained with the mechanical dissection could be used for the antibody-based phenotypic analysis of NK1.1⁺ cells. On the other hand, the liver had the predominance of more innate immune cells.

Hepatic lymphocytes isolated with mechanical dissection were suitable for the functional analysis

In order to understand whether hepatic lymphocytes obtained with mechanical dissection were suitable for functional assays, cell viability was assessed through staining with trypan blue. The cell viability of hepatic lymphocytes from normal C57BL/6 mice accounted for 90% using mechanical dissection method, which was similar to enzyme digestion method (Figure 4A). Next, we examined NK cells cytotoxic function against an NK-sensitive cell line, YAC-1 cells, and found that there was no difference between the two methods (Figure 4B). In the absence of Poly (I:C) stimulation, the cytotoxicity of NK cells to YAC-1 cells was about 15% at the E:T ratio of 1:12.5. After Poly (I:C) stimulation, it increased to 35% at the same E:T ratio. These results indicated that the isolated lymphocytes with the two different methods had the similar viability and were suitable for functional analysis of hepatic lymphocytes prior to or after immune stimulation.

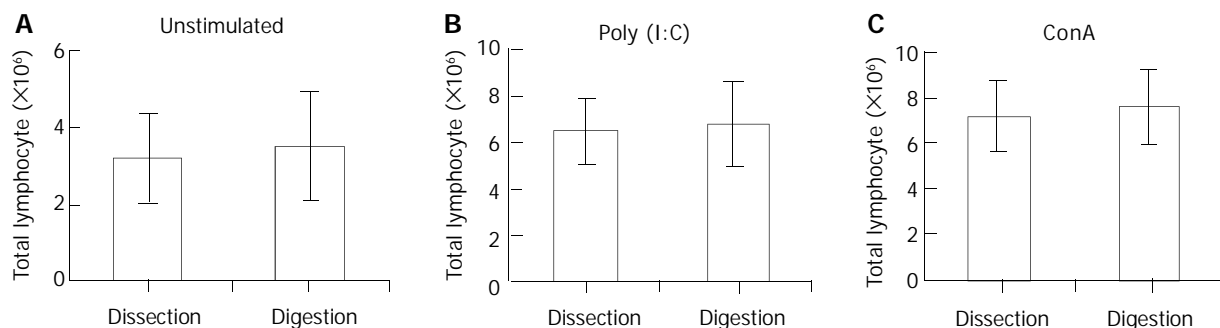

Figure 2 Cell yields between the two isolating methods. Hepatic lymphocytes were isolated using mechanical dissection method and the enzymatic digestion method, respectively, from normal C57BL/6 mice (A), Poly (I:C)-treated C57BL/6 mice (B) or ConA-treated C57BL/6 mice (C).

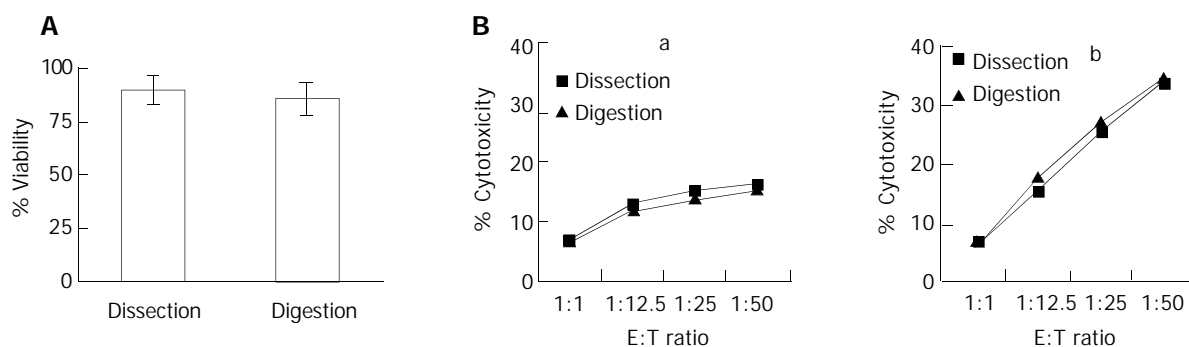

Figure 4 Hepatic lymphocytes isolated with mechanical dissection were suitable for the functional analysis of NK1.1⁺ cells. A: Viability of hepatic lymphocytes isolated with two methods; B: Cytotoxicity analysis of hepatic lymphocytes. Hepatic lymphocytes were isolated by two different methods, respectively, from control B6 mice (a) or Poly (I:C)-treated B6 mice (b). Their cytotoxicity against YAC-1 cells was tested at the (E/T) ratios.

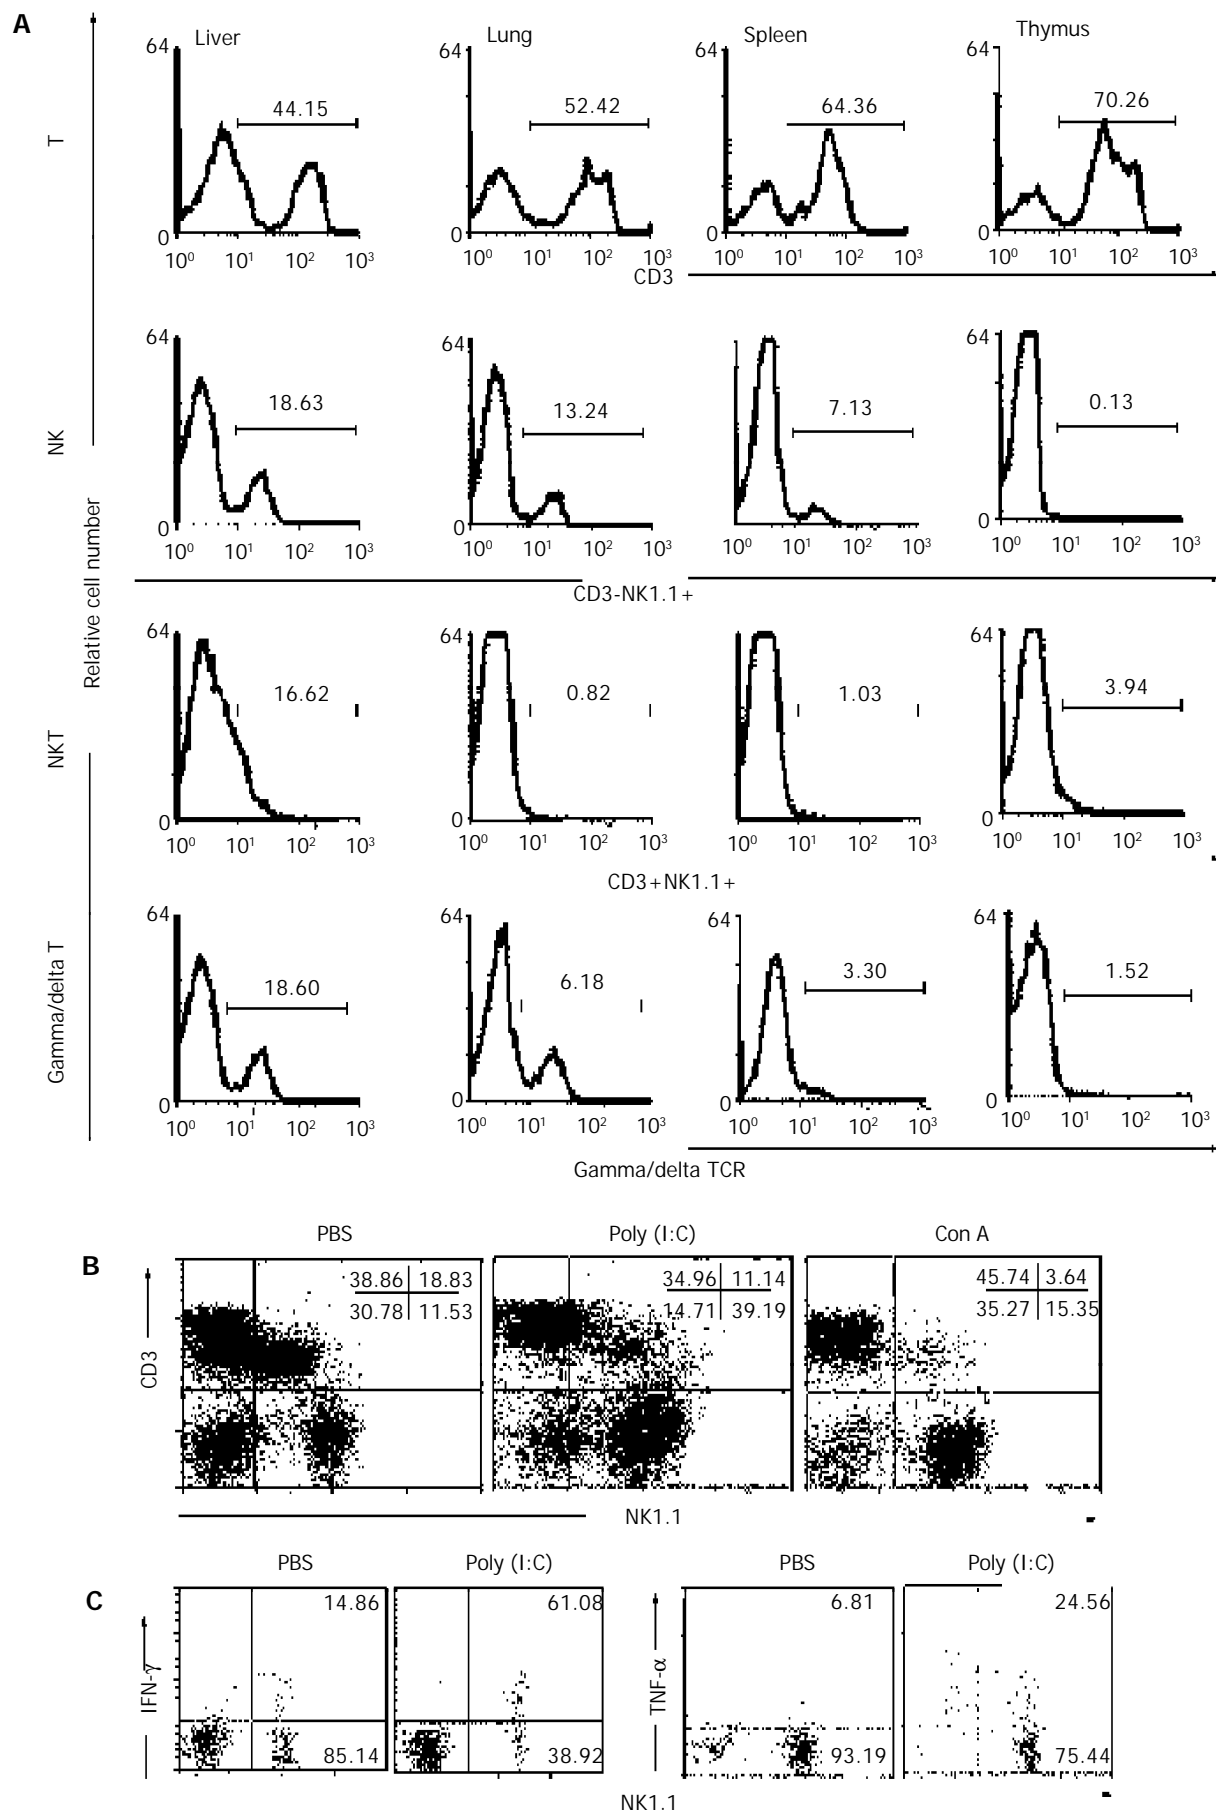

Figure 3 Hepatic lymphocytes isolated with mechanical dissection were suitable for phenotypic analysis of NK1.1⁺ cells. A: Lymphocytes from liver, lung, spleen and thymus of normal C57BL/6 mice were labeled with two-color immunofluorescence; B, C: C57BL/6 mice were injected with PBS, Poly (I:C) or ConA, respectively. Hepatic lymphocytes were isolated and labeled for phenotype (CD3 and NK1.1) and intracellular cytokine (IFN- γ and TNF- α) detection.

DISCUSSION

Liver has a unique dual blood supply with venous blood from the gut via the portal veins and arterial blood delivered via the hepatic arteries. In view of this distinct anatomy character, liver is thus constantly exposed to gut-derived antigens and infectious organisms in the portal blood. So many unidentified mechanisms have been involved to allow rapid and selective immune responses within this tissue^[12,13]. Structurally and functionally, qualification of liver as a lymphoid organ has been reflected by many studies^[14,15], and therefore a new term "hepatoimmunology" was emerged in 2002^[16]. Liver harbors many innate immune cells, such as NK, NKT and $\gamma\delta$ T cells. The predominance of these cells in the liver endows liver with the character of innate immune organ^[17], which was supported by the response of NK cells to the innate immune stimulus, Poly (I:C) in our study. However, the exact roles of these cells in the liver remain unclear. NK1.1 molecule is a member of NKR-P1 family, also named as CD161 in human^[18], and NK1.1⁺ cells often have DX5 molecule on their membrane in mice^[19]. Their remarkable distinction was that NK1.1 was only expressed by certain strain of mice, such as C57BL/6 and NZB, but not BALB/c^[20]. Conventionally, NK1.1⁺ cells mainly included NK cells and NKT cells. However, upon certain stimulation, activated cytotoxic T cell could also upregulate NK1.1 molecule. NK and NKT cells are two important subpopulations in the liver. They exerted their versatile roles in the defense of pathogens like murine cytomegalovirus (MCMV)^[21,22]. Several studies also reported that hepatic NK and NKT cell took part in the antimetastasis of tumor^[23-25]. NK1.1⁺ cells were reported to involve in the pathogenesis of many diseases, like human immunodeficiency virus (HIV) infection and liver disease^[26,27]. The demonstration that NK cell or NKT cell could give rise to liver injury had been confirmed by different groups, including our laboratory^[28-30]. Accurate assessment of these NK1.1⁺ cells in the liver required an appropriate technique to purify the hepatic lymphocytes. Various enzymatic or mechanical methods were proposed in the past to isolate lymphocytes from human or murine liver^[9]. The Enzymatic digestion was considered to be a satisfied method in the preparation of human organ-specific lymphocytes^[31]. In addition, this method has been used to isolate cells like hepatocytes^[32]. However, results from different studies appeared to be inconsistent. For example, Trobonjaca *et al.* reported that NKT cells accounted for 35.9% of the total hepatic lymphocytes in normal mice^[8], while Osman *et al.* reported that NKT cell accounted for only 16%^[33]. This difference may contribute to the different isolating methods taken by them. The roles of collagenase on surface makers of peripheral blood lymphocytes were investigated in 1996. They found collagenase could disrupt the surface markers, such as CD3, CD4, CD8, $\alpha\beta$ and $\gamma\delta$ TCR by about 20-40%^[34]. It was also reported that isolation of intestinal lymphocytes using collagenase released cytotoxic factors, which were found to suppress NK cell activity of isolated cell^[35]. Although the mechanical dissection for preparation of hepatic lymphocytes has been used for many years and still used yet, this technique has a defect in cell yield. To make sure the extent, in this study we found that there was no difference in cell yields and viability between the mechanical dissection method and the enzymatic digestion method. We did not observe any decrease in the surface molecules of hepatic lymphocytes in all cases except NK1.1 and DX5, suggesting that enzymatic digestion using collagenase IV and DNase is unsuitable for isolating hepatic lymphocytes for NK1.1⁺ cell analysis.

ACKNOWLEDGEMENT

We are thankful to Dr. Jing Wang and Dr. Yong-Yan Cheng for their continuous technical helping during this work.
