The age of the gastric cancer group and control group both expressed abnormal distribution with the mid-value being 60.5 and 61.5 years respectively. The χ^2 was performed ($\chi^2 = 22.265$, $P = 0.0002$), suggesting that the age distribution in the two groups was overbalanced. The result from the χ^2 detection for the sex distribution was $\chi^2 = 25.138$ and $P = 0.0003$, showing that the sex distribution in the two groups was out of balance as well. Tables 1 and 2 respectively show the co-variance analysis results.

The age and nature of gastric cancer patients had a linear correlation with the CHE level ($r = 0.8$, $P = 0.031$), suggesting that the difference in CHE level between gastric cancer patients and controls was significant ($F = 79.069$,

$P = 0.0004$). The serum CHE level of gastric cancer patients ($81.6 \pm 31.5 \mu\text{kat/L}$) was significantly lower than that in the control group ($114.8 \pm 30.8 \mu\text{kat/L}$), indicating that age was also an important factor affecting the incidence of gastric cancer ($F = 18.481$, $P = 0.0003$).

With the age distribution, χ^2 was performed ($\chi^2 = 5.281$, $P = 0.383$), showing that the age was evenly distributed. In gastric cancer patients and controls, CHE had a normal distribution and the variance was in order. Therefore, single-factor variance analysis could be made. The average value, standard deviation and single-factor variance are listed in Tables 1 and 2.

The difference in CHE levels of the two groups was significant ($F = 29.884$, $P = 0.0006$). The serum CHE level in gastric cancer patients ($85.0 \pm 34.5 \mu\text{kat/L}$) was significantly lower than that in the control group ($111.4 \pm 25.8 \mu\text{kat/L}$, Figure 1).

Table 1 Serum CHE distribution in gastric cancer patients ($\mu\text{kat/L}$)

Multi-factor logistic regressive analysis

The three variables (sex, age, and CHE) were put into the Logistic model. After being fitted with the backward method, the final model was expressed (Table 3). The factors put into the model were only sex and CHE. The adaptive regressive equation was $P(1) = 1/[1 + e^{-(0.129) + 2.542X_1 + 1.006X_3}]$ or $\text{CHE} = 12.701$. Therefore, after removing the influence of other factors, the reduction of the CHE activity was a dangerous factor for gastric cancer.

DISCUSSION

Cholinesterase can be divided into true cholinesterase (acetylcholinesterase, AChE) and pseudocholinesterase (PCHE). AChE exists mainly in the vesicles of cholinergic nerve peripheral synapse where there is a comparatively large amount of AChE in the folding of the terminal synapse back membranes. It also exists in the cholinergic neurons^[13,14], red cells^[15], sera^[16], livers^[17], kidneys^[18], intestines, white mass of brain^[19], *etc.* In the activity center on the surface of the molecules of CHE protein, there are two places to be combined with acetylcholine, namely the anion place with negative charges and the place with ester decomposition. The place with ester decomposition has an acidic action point formed by serine hydroxide and an alkaline action point formed by histidine imidazole ring. They are combined by means of hydrogen bonds. PCHE reduces when the parenchymal cells are damaged, as the liver synthesizes PCHE^[20-22]. Organophosphorus toxicant is a powerful inhibitor of AChE and PCHE^[23-26]. Measuring serum CHE activity can help diagnose organophosphorus poisoning and evaluate the condition after recovery. The results of this experiment indicate that human serum CHE activity has a significant correlation with gastric cancer.

Anic *et al.*^[27], discovered that the serum CHE activity in hepatitis B patients is relatively low. Khan *et al.*^[28], detected serum CHE and lactic dehydrogenase (LDH) activity in 40 cases of mammary cancer patients, 25 cases of benign tumor patients and 30 cases of healthy persons, and found that there is a significant difference in serum CHE activity between malignant and benign tumor patients.

If the ratio between CHE activity and serum CHE activity is less than 0.42, the malignant source should be considered^[29]. A number of studies have been conducted on the relation between serum CHE activity and acute leukemia and cervical cancer^[30,31].

Among the 81 cases of gastric cancer in the present study, there were 39 cases (48.2%) whose serum CHE activity was less than $75.0 \mu\text{kat/L}$. Among the 80 cases of

controls, there were only five cases (6.3%) whose serum CHE activity was less than 50.0 μ kat/L. In the gastric cancer group, there were 14 cases whose serum CHE activity was less than 75.0 μ kat/L. However, in the control group, there were no such cases. The results suggest that if a patient with gastric pathological changes whose serum CHE activity is less than 50.0 μ kat/L, sharp vigilance on the existence of gastric cancer should be maintained after organophosphorous poisoning and damages of parenchymal cells, etc., are excluded.

In conclusion, the determination of serum CHE activity is a rapid, simple, convenient, inexpensive and reliable method to diagnose gastric cancer. Its exact mechanism remains to be further explored.

Abstract

Symptomatic hepato-diaphragmatic interposition of a bowel loop or Chilaiditi's syndrome is a peculiar anatomical condition most often found by chance. Its described symptoms range from intermittent, mild abdominal pain and dyspepsia to acute intestinal obstruction. We report a case of hepato-diaphragmatic migration of the hepatic flexure of the colon associated to an unusual, heretofore unreported, angina-like pain exclusively evoked by the left lateral decubitus. To maximize the chance of observing anatomical changes in different postures, computed tomography of the chest and abdomen was performed after air insufflation into the colon. While frank herniation into the chest was excluded, the scan showed that the hepatic flexure-with the interposition of the diaphragm-came in contact with the right side of the heart in the left lateral, but not in the supine, decubitus. This finding was reproduced by echocardiography which also showed virtually unaltered hemodynamics after the change of posture. ECG, left and right ventricular global and regional function as well as cardiac injury markers also remained unchanged during the maneuver, indicating that the pain evoked by the latter was unlikely due to myocardial ischemia. This case suggests that Chilaiditi's syndrome should be included among the possible, although rare, causes of unexplained angina-like symptoms.

INTRODUCTION

The radiological finding of hepato-diaphragmatic

interposition of a bowel segment, also known as Chilaiditi's sign, defines an uncommon and typically asymptomatic anatomical abnormality. When associated with symptoms, it is termed as Chilaiditi's syndrome^[1]. Although a number of different symptoms have been attributed to this condition they are almost always related to the digestive tract itself such as, most commonly, abdominal pain, dyspepsia and intestinal obstruction due to volvulus.

In the case described in this paper, the hepato-diaphragmatic migration of the hepatic flexure of the colon was associated with an angina-like pain, exclusively evoked by the left lateral decubitus. The investigations conducted in our patient clearly showed that the symptom was associated to the contact between the heart and the intestine. Although the precise mechanism at the basis of this phenomenon remains unknown it is, to our knowledge, the first time that precordial pain has been attributed to such a peculiar anatomical condition.

CASE REPORT

A 69-year-old white male was admitted to the hospital with a history of retrosternal oppressive pain radiating to the left arm, mild dyspnea, and a state of prostration for the past 2 years.

These symptoms were present with the patient lying on his left side, and subsided in the supine position and in orthostatism.

For this reason, he had been previously referred to a cardiologist. However, an ECG failed to show overt signs of ischemia; a stress test and a Holter monitoring were within limits and a trial with calcium antagonists proved ineffective. At this point, a diagnosis of anxiety/depression syndrome was considered likely but a therapeutic trial with benzodiazepines was without effect.

The only relevant episodes in his past medical history were an apparent pleural effusion at the age of 18 which spontaneously resolved; and an NSAID-related gastric ulcer at the age of 46 which was treated with H₂-antagonists with complete healing.

On admittance, the patient was in good general condition. He was overweight (BMI 27.5 kg/m²) but physical examination was otherwise unremarkable. The pulse rate was 72, and the blood pressure was 130/70 mmHg. Laboratory tests showed increased values of ferritin (635 ng/dL), γ -GT (75 U/L) and total cholesterol (295 mg/dL). The ECG tracing at rest was normal. During the hospital stay, the symptoms mentioned above took place on two separate episodes: in each occasion they immediately subsided by changing decubitus. The physical examination during the crisis was unremarkable; the ECG and cardiac injury markers remained unchanged. Cardiac involvement at this point seemed unlikely. Since he reported, during his symptoms, the subjective feeling of a mass moving from the abdomen

toward the chest, subsequent studies focused on the gastrointestinal tract.

An abdominal ultrasound showed a severe hypotrophism of the liver with marked stretching of the intrahepatic vessels, while the portal hilum and the gallbladder were not identifiable at all. The general picture was not incompatible with chronic liver disease, even in the absence of parenchymal and focal lesions. However, liver disease became unlikely once the diagnosis of Chilaiditi's sign was established by a double contrast barium enema (not shown) and a CT scan of the abdomen which showed the interposition of the hepatic flexure of the colon between the right liver lobe and the homolateral rib cage (Figure 1) while excluding frank herniation into the chest.

Subsequently, we sought a correlation between this anatomic finding and the patient's symptoms. To maximize the chances of observing anatomical changes in different postures, a CT scan of the abdomen and chest was performed with a Toshiba Aquilion 16 Multi-Slice CT (Toshiba AMS, Tustin, CA, USA) after air insufflation into the colon. The latter involved an amount of air (approximately 800 cm³) that caused mild discomfort to the patient, roughly equivalent to the sensation provoked by naturally occurring meteorism. The scan demonstrated

Figure 1 Axial CT scan of the abdomen. The image shows interposition of the colon (with fecal content) between the rib cage and the liver (Chilaiditi's sign). The latter appears compressed and dislocated in the absence of parenchymal and focal lesions.

Figure 2 CT scan of the chest after air insufflation into the colon. **A:** Supine position: the arrow shows the close vicinity of the hepatic flexure (asterisk) to the right side of the heart with the interposition of the diaphragm. However, the pericardium and the intestinal wall are clearly demarcated. The left hemithorax appears symmetrical compared to the right one; **B:** Left lateral decubitus: upon changing position the colon moves forward and medially, coming into contact with the vena cava and the right side of the heart (arrow). Compared to the

the close vicinity of the colon to the right side of the heart in the supine position (Figure 2A, arrow). When the same scan was taken with the patient lying on his left side (Figure 2B) it showed that the colon had moved forward and medially, coming into contact with the vena cava and the right side of the heart. In this position, the patient complained of his typical precordial pain. The change of posture also caused migration of the diaphragm and its attached organs (i.e., the heart) toward the left side of the chest (Figures 2A and B). At the same time, the left hemithorax anteroposterior diameter increased, while the transverse diameter decreased (Figures 2A and B).

Finally, the patient was subjected to multiplane trans-esophageal echocardiography (SONOS 5500, Philips, Best, Holland) before and after air insufflation into the colon as above. The latter did not produce echos different from the exam conducted under basic conditions. However, the change of posture from the supine (Figure 3A) to the left lateral decubitus (Figure 3B) resulted again in frank contact between the heart and the colon with blurring of each other's contours. Blood pressure, heart rate, right and left ventricular global and regional function and oxygen saturation remained unchanged indicating no alteration in cardiac hemodynamics.

Thus, the mechanism provoking pain, as well as being reversible, did not appear to involve true ischemia. In addition, the patient refused to take surgery into consideration. Therefore, we opted for careful observation recommending the patient to lose weight. After 8 mo he did lose 8 kg of body weight and his symptoms have now become much less frequent and intense.

DISCUSSION

Hepato-diaphragmatic interposition of a bowel loop, usually the hepatic flexure of the colon, described by Chilaiditi^[2] in 1910, is a peculiar anatomical condition most often found by chance. When associated with symptoms-usually from mild abdominal pain and dyspepsia to acute intestinal obstruction-it is termed Chilaiditi's syndrome^[1].

Congenital anatomical abnormalities such as colonic

supine position, the left hemithorax anteroposterior diameter is increased while the transverse diameter is decreased. This phenomenon may, at least in part, be associated to partial migration of the diaphragm and its attached organs and vessels toward the left side of the chest. This is also underlined by the change in the position of the heart in this radiogram in relation to the broken line (drawn from the sternum to the vertebra) compared to the radiogram in Figure 1. In this posture the patient complained of his typical precordial pain.

Figure 3 Multiplane trans-esophageal echocardiography after air insufflation into the colon. **A:** supine position; **B:** left lateral decubitus. Confirming the CT scan findings, the change of posture resulted in frank contact (arrow) between the heart and the colon with blurring of each other's contours. However, blood

pressure, heart rate and oxygen saturation remained unchanged during the maneuver, indicating no alteration in cardiac hemodynamics. (RV: right ventricle; S: interventricular septum; C: air space corresponding to the colon).

elongation and laxity of colonic and hepatic suspensory ligaments have been postulated as the principal predisposing factors^[3]. Other predisposing situations can be acquired such as an enlarged lower thoracic outlet (e.g., in pregnancy, emphysema, and cirrhosis with ascites), or organ shrinkage (e.g., atrophic cirrhosis of the liver)^[4]. Fat deposition between the liver and the colon, in obese individuals, widens the space between the two organs and can also favor the migration of the colon^[5].

The case of Chilaiditi's syndrome reported in this paper is peculiar with regard to its symptoms angina of like pain with left arm irradiation and their likely origin, i.e., the motion of the colon into the chest. Although a case of *right* rib cage pain has been attributed to Chilaiditi's syndrome^[6] the latter has never been causally associated to precordial pain.

Our patient had a few known predisposing factors for the migration of the hepatic flexure, i.e., he was overweight and, likely, had an abnormally thin and lax diaphragm. In addition, he had a hypotrophic liver even though the latter could have been a consequence rather than the cause of his bowel displacement.

Guided by the absence of cardiologic abnormalities and by the patient's subjective feeling of a moving abdominal mass, we made an initial diagnosis of Chilaiditi's sign by barium enema and CT scan. We then elected to perform both CT scan and cardiac ultrasound after air insufflation into the colon to study in detail the expected anatomical changes associated with the patient's symptom. It should be emphasized that the amount of insufflated air was small and only produced a typical subjective feeling of meteorism. Although the colon (with the interposition of the diaphragm) was very close to the heart in the supine position (Figures 2A and 3A) it was in the left lateral decubitus, that the two organs clearly touched each other and the heart moved to the left of the chest (Figures 2B and 3B). Since the ECG, the cardiac function and the cardiac enzymes remained within limits during the maneuver, it is unlikely that the pain originated from true cardiac ischemia. Blood pressure, heart rate, and oxygen saturation also did not change. Indeed, cardiac hemodynamics were not expected to be affected since the pressure inside the heart chambers far exceeds

that inside the colon. Thus, it is possible that the pain felt by the patient, concomitant to the migration of the hepatic flexure, was simply due to the transient stimulation of cardiac nervous fibers or to the internal compression of the chest or to overstretching of the major vessels-including the aorta and vena cava, or to a combination of these last two factors^[7]. Indeed, the CT scan showed a movement of the heart with the diaphragm toward the left side of the chest upon changing position (Figures 2A and B). This partial migration might have caused the hypothetical stretching of the vessels as well as (at least in part) the change in the anteroposterior and transverse diameters of the left hemithorax.

Based on patient's choices and given the apparent absence of a life threatening situation, we did not recommend surgery but only careful observation and weight loss. Indeed, losing weight has gradually decreased the frequency and intensity of the patient's symptoms.

In conclusion, we have shown a case of Chilaiditi's syndrome presenting with an unusual symptom-precordial pain-associated to the unusual contact between the colon and the heart and the movement of the heart to the left of the chest. Hence, Chilaiditi's syndrome should be included among the possible, although rare, causes of unexplained angina-like symptoms.

Abstract

This paper deals with all aspects of liver alveolar echinococcosis (AE) including epidemiology, pathology, clinical manifestations, imaging examinations, diagnosis and differential diagnosis, surgical treatment and chemotherapy. The review is not only based on personal clinical experiences but also in combination with relative basic research such as proliferation and growth of alveococcus, preclinical studies of a novel compound extracted from TCM for treatment of liver AE, and molecular immunology used for specific AE diagnosis, etc.

INTRODUCTION

Echinococcosis is a parasitic zoonosis, consisting of cystic echinococcosis (CE) and alveolar echinococcosis (AE). These two types differ in parasitology, epidemiology, pathology, clinical aspects, treatment and prognosis. They are respectively caused by the larval stage of *Echinococcus granulosus* (Eg) and *E. multilocularis* (Em) (Figure 1). Over one hundred years, the disease had been misdiagnosed as liver colloid cancer. The cause of AE was not confirmed until 1856. In China, liver AE was reported respectively in Ningxia, Xinjiang autonomous regions and Gansu Province during 1950s to 1970s^[1-3]. Up to now, at least one thousand cases of AE have been reported throughout China, but most of them

were mistaken as liver cancer. In order to improve the diagnostic level of AE, a review is comprehensively introduced as follows.

Figure 1 Adult of *E. multilocularis*.

EPIDEMIOLOGY

Em needs two mammalian hosts for completion of its life cycle. They are respectively called the definite host, arnivore and the intermediate host, mainly rodents. Proglottid containing eggs or free eggs are excreted in the feces of the definite hosts, e.g. dog or fox. Once eggs are ingested by the intermediate hosts including rodents and human beings, AE may occur in liver or other organs. In China, fox, dog and wolf have been found to be as definite hosts and a few species of the rodent such as *Citellus dauricus*, *Myospalax fontanieri*, *Microtus brandti*, were confirmed to be as intermediate hosts. Human body affected by AE is chiefly due to contacting the animals: fox, dog, or occasionally cat. Especially, ladies, herdsman and hunters are higher risk populations. AE has been found mainly in the west of China including eight provinces or autonomous regions (Figure 2)^[4].

Gansu province

During a period from 1985 to 2000, of 89 AE cases originating from Gansu Province, 63 came from Zhang County, which may be considered as a hyper-endemic area^[5]. In the three neighbouring counties of central eastern Gansu (Figure 3), human AE epidemiological surveys were conducted four times respectively in three counties^[6-9] (Table 1). The results of comparative analysis showed that the prevalent rate was higher in Zhang County and Ming County than in Lintao County. Factors were also investigated regarding natural geographical condition, local climate, parasitic life cycle, and our experimental study^[10].

Xinjiang uygur autonomous region

AE was more common in northern Xinjiang with a total of 100 cases.

Figure 2 Distribution of AE in eight provinces in west China.

Figure 3 AE endemic counties in central eastern Gansu. (1) Zhang County, (2) Ming County, (3) Lintao, (4) Jinyuan.

Table 1 Human AE epidemiological survey in three counties of central eastern Gansu

Yr	County	Persons investigated	Positive rate of immuno-test(%)		Ultrasonic morbidity(%)
			Intradermal test	ELISA	
1986 ^[6]	Zhang County	380	19.2		2.4
1992 ^[7]	Zhang County	1 312		2.8	5.0
1998 ^[8]	Ming County	1 200		2.2	5.6
2003 ^[9]	Lintao	1 071	1.8		0.7

Ningxia Hui autonomous region

Distribution of AE was limited to a specific endemic area, and chiefly found in Xi Hai Gu's three Counties which were situated bilaterally along branches of Liupan Mountain. In 1989 during human ultrasonic investigation in Xiji County, AE morbidity was 5.9%(141/2 389). The positive rate by ELISA was 5.8%(138/2 389). In 2003, 263 cases of AE in the past 17 years were followed up in Xiji, of whom the positive rate of intradermal test was 90.2%(174/193) and ELISA in 137 patients were all positive^[11].

Qinghai province

Until 2000, 1 748 cases with echinococcosis were reviewed and 143 of them belonged to AE (8.3%). Another survey was made in 3 702 individuals, of whom 23 (0.62%) were ultrasonically diagnosed as liver AE. The distribution of AE appeared with a scattered tendency. During an investigation of human AE in three counties under the jurisdiction of Qingnan plateau, the average morbidity was 0.35%. From 1959 to 1998, 111 cases of AE were surgically treated^[12].

West Sichuan province

AE severely affected three counties of Ganzi, Shiqu, and Seda. According to investigations of 3 998 individuals in Ganzi and Shiqu from 1997 to 1998, AE morbidity was 7.78% and 2.33% respectively.

Tibet autonomous region

In 1993, 12 cases of AE originating from Larsa and three prefectural hospitals of Naqu, Shannan, and Changdu were discovered surgically and pathologically.

Inner Mongolia autonomous region

Although animals of definite host and intermediate host

were found in Hulunbeier grassland in 1988, the patient of AE was not clinically reported until 1998^[13].

Heilongjiang province

Two scattered patients of liver AE were identified surgically and pathologically. One of them was a native of Nahe County^[14] and another case was from Jiamusi city^[15].

PROLIFERATION AND GROWTH OF ALVEOCOCCUS AND HISTOGENESIS OF PROTOSCOLEX

Proliferation and growth of alveococcus is very significant as it bears practical relation with clinical aspects especially chemotherapy. As early as in 1950s to 1980s, a few Euroamerican authors^[16-21] observed the proliferation and growth phenomenon of experimental alveococcus respectively in white mice, cotton mice, and jirds (*Meriones unguiculatus*). Our study was partially carried out microscopically on the pathological sections of human AE^[22]. Two modes of proliferation were found, i.e. endogenous budding and exogenous budding (Figure 4). The former (Figure 4A) was characterized by internally protrusive hyperplasia from the mother alveolar wall into the alveolar cavity and then proliferation extending continuously to reach the opposite wall of the cavity. So, septum-like budding was named. Sometimes two or more proliferative sites on the alveolar wall propagated simultaneously into the cavity in opposite directions, and mingled with each other to form a septum dividing the mother to form two or more small alveoli (Figure 4B). Externally protrusive proliferation occurred at one or several sites of the mother alveolar wall, producing single or multiple daughter and granddaughter alveoli under the name of exogenous budding (Figure 4C). These two buddings may coexist not only in one

Figure 4 Modes of proliferation. **A:** Endogenous budding of alveococcus (HE stain $\times 200$). Arrow: Septum; **B:** One mother alveolus (left lower side)

dividing into four daughter alveoli (HE stain $\times 400$); **C:** Exogenous budding of alveococcus (HE stain $\times 400$); **D:** Model of alveococcus exogenous budding.

Figure 5 The entire process of mouse AE protoscolex histogenesis (HE stain $\times 200-800$). **A:** local cellular hyperplasia of germinal membrane of alveococcus wall; **B:** re-arrangement of hyperplastic cells and formation of brood capsule; **C:** local cellular hyperplasia of brood capsule wall; **D:** elliptical protrusion into cavity; **E:** mushroom protrusion; **F:** lingual protrusion; **G:** showing rostellum and suckers of protoscolex; **H:** Hooklets on rostellum; **I:** mature protoscolex (right: evaginated type. Left: invaginated type).

section of liver AE but also in that of metastatic lung or brain AE and metastatic lymph node AE. To date, the mechanism of AE proliferation and growth is not understood completely although it has been studied for decades. In the exogenous proliferative course of liver AE, the daughter alveoli of 1st grade budding and the granddaughter alveoli of 2nd grade budding were respectively named. Proliferating grade by grade, a mother alveolus may propagate into numerous new alveoli of multi-grades just like infiltrative dissemination of carcinoma, or it further affects neighbouring organs such as porta hepatis, inferior vena cava or pancreas, rendering radical surgical operation impossible. Euzeby^[21] explained that exogenous budding was due to discontinuity of the alveolar cuticular layer, allowing the germinal membrane to escape from the mother alveolus (Figure 4D). As concerns the entire

Figure 6 Histogenesis process of brood capsule of liver AE protoscolex in *Mus musculus* (HE stain $\times 200$). **A:** local hyperplasia of alveococcus wall into the cavity, looking like a reversed pocket; **B:** gradually approximating and finally closing of two pocket edges; **C:** formation of brood capsule; **D:** local cellular hyperplasia of brood capsule wall.

process of protoscolex histogenesis, a stage of the formation of brood capsule must be passed through. Local cellular hyperplasia began in the wall of brood capsule, and elliptical, mushroom-shaped or lingual protrusion protruded into the cavity of brood capsule. After that, the protrusion gradually developed into rostellum and suckers, finally changing from embryonic protoscolex to mature protoscolex of evaginated or invaginated type (Figure 5). The formation of brood capsule expressed two modes. The first was local hyperplasia of germinal membrane of alveococcus wall, forming cellular group. By means of cellular rearrangement, the cells accumulated towards the periphery and a cell-free space appeared in the center, developing further into brood capsule^[23] (Figure 5). This is basically similar to other reports at home and abroad^[19,25]. The second mode of brood capsule formation was found by us from liver AE of *Mus musculus* in Zhang County, Gansu Province^[24] (Figure 6). Similar report has not been seen yet.

PATHOLOGY (Figure 7)

Macroscopical appearance

The lesion was yellowish or gray and felt as firm as cartilage. Superficially, it showed numerous noduli or minute cysts

Figure 7 Pathology. **A:** A cross section of human liver AE showed alveolate appearance; **B:** Types of liver AE. ↑: Nodular type, ↑↑: Mixed type; **C:** Protoscolices inside brood capsule (HE stain×100); **D:** Alveococcus nodule

(HE stain×200); **E:** Three arrows indicating metastatic bilateral lung AE; **F:** ↑: metastatic right brain AE; **G:** lymph node metastasis near porta hepatis (HE stain×200). ↑: AE. The left upper side: Metastatic lymph nodes.

without definite encapsulation, but with alveolate structure on cross section (Figure 7A). It was usually classified into three types, of which large circumscribed mass type was more common (67.8%) and the other two were nodular type (16.7%) and mixed type (15.5%) (Figure 7B)^[26]. The central area of alveococcus may be complicated by coagulated necrosis due to poor blood supply.

Microscopic finding The lesion was characterized by many alveoli with different sizes and shapes. Observation of alveolus wall showed that the thick, acellular, laminated outer layer looked bank-like, sometimes folding within the alveolar cavity. The thin, germinal inner membrane lined by a single-layer cell was usually deficient due to detachment. Brood capsule or protoscolices were occasionally seen (Figure 7C). The lesion may be complicated by central necrosis, producing a cavity or pseudocyst after liquidization. In the

periphery of alveoli group it showed hyperplasia of fibro-connective tissue and cellular infiltration of eosinocytes, lymphocytes, plasma cells and giant cells, forming a typical alveococcus nodule (Figure 7D).

Metastasis According to a collective analysis of 270 cases with liver AE from five provinces of China (Table 2)^[27], general metastatic rate was 3.7%(10/270). The commonest metastatic organ was lung (4.7%)(Figure 7E) and the next one was brain (3.3%)(Figure 7F).

Three modes of metastasis were found. The first was direct infiltrative dissemination. The alveococcus lesion infiltrated gradually into the liver parenchyma and formed a large mass. The neighbouring organs outside the liver such as the porta hepatis, diaphragm, pancreas or inferior vena cava were further involved. The second was blood metastasis. A small portion of detached proliferating bud, if involving

Figure 8 The size of upper abdominal mass with the largest reaching the umbilicus level. **A:** After external drainage of pseudocyst, the patient survived for 23 years. **B:** The patient survived only for 3 years.

Figure 9 Imaging examinations. **A:** Ultrasonic scanning of liver AE showed a central necrotic pseudocystic cavity, but the cystic wall was irregular; **B:** Liver CT showed partial AE calcification (left) and pseudocyst (right) on the left upper side. The patient was confirmed surgically and pathologically.

the branches of portal vein, extensively disseminated within the liver parenchyma resulted in multiple noduli. Involving the branches of hepatic vein, the alveococcus spread along systemic circulation to distal organs such as lung or/and brain. The third was lymphatic metastasis. The liver alveococcus may spread to lymph nodes of the porta hepatis (Figure 7G), peritoneal cavity and colonic mesentery. According to the results of animal experiment in Japan^[28], the mechanism of metastasis was due to the detached proliferated bud, even very small or only a few nuclei entering the blood vessels. Nevertheless, it was incapable of causing metastasis if protoscolices were injected into the vessels.

CLINICAL MANIFESTATIONS

Generally speaking, sex difference is not obvious, sometimes males slightly outnumbered females. Most patients were young and in robust years of their life. According to clinical features^[29], four types, i.e. simple hepatic enlargement, obstructive jaundice, liver giant node (cancer-like) and remote metastasis were classified. According to clinical course, we divided AE into the early stage with only mild hepatic enlargement, middle stage with progressive hepatomegaly and the advanced stage associated with impaired liver function, portal hypertension, or metastasis^[30]. The main symptom was upper abdominal mass or liver mass with stiff and nodular feeling on palpation. The size of the mass varied, with the smallest being not felt or only palpated below right sub-costal margin and the largest reaching the umbilicus level (Figures 8A and B). Another symptom was abdominal pain, but usually not severe. Jaundice was found

in some cases, usually due to the impairment of liver function or the invasion and compression of bile duct by liver mass at the advanced stage. Extensive infiltration of the alveococcus lesion or fibrosis caused liver cirrhosis with subsequent portal hypertension such as the superficial varicosity of the thoracic or abdominal wall, ascites and splenomegaly. In case of liver AE associated with lung or brain metastasis, the patient manifested corresponding respiratory or neuropathic symptoms and signs.

IMAGING EXAMINATIONS (Figure 9)

X-ray films

Enlargement of liver and elevation of right diaphragm were shown on abdominal plain film. The shadows of spotted or clustered calcification were visible in the hepatic region. But they must be carefully observed as their appearances were usually not distinct. If multiple shadows of bilateral lung showed on chest film, the possibility of liver AE associated with lung metastasis ought to be considered.

Ultrasonic scanning

In a series of 141 cases with liver AE^[31], the ultrasonic features revealed solid mass in 96 and solid-cystic degeneration in 45. The former comprised 23 cases with local type, 21 with diffuse nodular type and 52 with large circumscribed mass type. If the liver alveococcus was complicated by central necrotic pseudocyst, the ultrasonic scanning showed echo-free area with irregular cystic wall (Figure 9A).

Computerized tomography (CT)

Liver CT showed single or multiple, intrahepatic, hypodense areas with irregular margin, or occasionally partial calcification of alveococcus (Figure 9B).

IMMUNOLOGICAL EXAMINATIONS

As hydatid intradermal test was simple and cheap, it was commonly used, especially in our country. Although the sensitivity was high, false positive reaction may occur. Therefore indirect hemagglutination test and ELISA were reliable methods for immunological diagnosis due to their higher specificity. Along with current advancement of molecular immunology, purification of a specific antigen from *Echinococcus multilocularis* (Em) has been successful. As early as in 1983, Gottstein *et al.*^[32,33], prepared an antigen fraction (Em2) from alveococcus tissue using affinity chromatography. Owing to a high specificity of Em2 for *E. multilocularis*, a correct serological differential diagnosis was achieved in 95% of 57 confirmed cases of human CE or AE. However, Em2 was isolated from laminated layer of alveococcus, a higher or lower level of antibody titer did not reflect whether the focus was active or not. Em2-ELISA test still showed positive result with a high titer even though the focus became stable or calcified after chemotherapy. As the protoscolex is the most active component of the alveococcus tissues, it was used to isolate protoscolex antigens designated as Em16 and Em18 using Western blotting in a cooperative study between China and Japan^[34]. Em18 and Em16, especially the former showed not only a higher sensitivity but also stronger specificity for immunodiagnosis

Table 2 Remote metastases of 270 cases with liver AE in China

Province or autonomous region (yr)	n	Number of cases of blood-stream metastasis (%)				Number of cases of lymphatic metastasis (%)		
		Lung	Brain	Lung+brain	Spleen	Lymph node of porta hepatis	Lymph node of peritoneal cavity	Lymph node of colonic mesentery
Xinjiang (1985)	43	3	2					
Ningxia (1991)	22						1	
Sichuan (1994)	24	2		1				
Gansu (1995)	70	3	2	1		1		1
Qinghai (2000)	111	2	7		2		1	
Total	270	10 (3.7)	11 (4.1)	2 (0.7)	2 (0.7)	1 (0.4)	2 (0.7)	1 (0.4)

of human AE. We also used the alveococcus protoscolices for isolating Em16 and Em18 by isoelectric focusing analysis^[35]. These protein antigens could not show the best diagnostic value and cross reaction which possibly occurred between AE and CE or between AE and cysticercosis^[36]. In short, molecular immunological diagnosis for human AE needs further studies.

DIAGNOSIS

Until now, liver AE is always mis-diagnosed. To make a correct diagnosis of liver AE, we should not ignore the past histories of the patients. First, where did the patient come from, AE endemic area? Next, did the patient contact dog, cat, or fox-fur? Thirdly, what is the occupation of the patient, fox-hunter or dog-raiser? These data would be helpful for the diagnosis of liver AE.

DIFFERENTIAL DIAGNOSIS

Liver cancer

In our collective review of 274 cases with liver AE, the determination of serum AFP was negative in all the patients^[27]. So it is significant for differential diagnosis of AE. As a rule, liver AE pursues a slow, but progressive course. It obviously differs from liver carcinoma which develops faster or very rapidly, leading to patient death in a short time. AFP test is a reliable differential diagnostic method. Sometimes, gross findings of liver AE may be confused with carcinoma on the operation table and frozen section is necessary. When the diagnosis of liver AE is still difficult before operation, liver needle biopsy may be considered (Figure 10). Occasionally liver AE also needs to be differentiated from cystic echinococcosis (CE) or some nonparasitic diseases such as tuberculosis. If chest X-ray film showed multiple shadows of bilateral lung or brain CT showed cerebral lesion, it might be possible that liver AE was associated with lung or/and brain metastasis^[37]. Clinically unknown nature of malignant tumor was always determined.

TREATMENT

Surgical operation

The rational treatment for liver AE is radical hepatectomy and the prognosis of the patient may be good. An individual case had been postoperatively followed up for 21 years without recurrence^[2]. However, the rate of hepatectomy is very low due to the difficulty of early diagnosis. According

Figure 10 Liver needle biopsy. Arrow: alveococcus (HE stain×200).

to our collective analysis of 258 cases of liver AE in China^[27], only 27(10.5%) and 16 (6.2%) had performed radical liver lobectomy and partial hepatectomy respectively. In order to increase the percentage of hepatectomy, an epidemiological survey in AE endemic area is very significant to screen out early cases. For liver unresectable case, a palliative operation may be indicated such as surgical drainage for a large pseudocyst in order to decompress pericystic liver tissues. As in Figure 8A, the patient was alive for 23 years after external drainage of liver pseudocyst.

Chemotherapy

Albendazole (ABZ) is considered by WHO as the best anti-AE drug. Experimental studies showed that ABZ was able to inhibit alveococcus proliferation and growth. Considering the clinical effects, it was shown to alleviate the symptoms, to prolong the survival, and diminish lung or/and brain metastasis after therapy. In our 23 cases of liver AE treated with ABZ, symptoms were improved, appetite increased, jaundice relieved, and liver enlargement decreased in 15 (65.2%)^[38] cases. Liu *et al.*^[39], reported that in 11 cases of liver AE followed-up for 2-7 years after long-term continuous ABZ therapy, 7 showed calcification on liver CT film. Thus ABZ may be lethal to the parasite. In addition, we found a novel compound extracted from traditional Chinese medicine, Xiao-Bao capsule for treatment of AE. Experimental results showed that the inhibitory rate of mouse AE was 65.7% and 80.6% respectively in two groups of mice, i.e., 1-week and 10-weeks after inoculative infection^[40]. In our 21 cases of liver AE, symptoms improved in 16 (76.1%)^[27] cases. Both acute toxicity test in mice and chronic toxicity test in rats showed no toxic reactions^[41]. We

postulate that combination of Xiao-Bao capsule and ABZ would be more effective than single medication.

Abstract

AIM: To observe the variation of DNA polymerase β (pol β) in esophageal carcinoma.

METHODS: Thirty specimens containing adjacent normal epithelial tissues were collected from patients in Linzhou region (a high risk area for esophageal squamous carcinoma) and 25 specimens were from a non-high risk area. Total RNA was extracted from the samples and reverse transcription polymerase chain reaction (RT-PCR) was performed. PCR products were cloned and sequenced to investigate the pol β gene with DNASIS and OMIGA. Statistical significance was evaluated using the χ^2 test.

RESULTS: High-incidence area group: pol β gene variation was detected in 13 of 30 esophageal carcinoma tissue specimens, and only one variation was found in 30 corresponding adjacent normal tissue specimens. Non high-incidence area group: pol β gene variation was detected in 5 of 25 esophageal carcinoma tissue specimens, and no variation was found in 25 corresponding adjacent normal tissue specimens. The incidence of pol β gene variation observed in the high-incidence area group was significantly higher than in the non-high incidence area group. Two mutation hot spots (454-466 and 648-670 nt) and a 58 bp deletion (177-234 nt) were found.

CONCLUSION: Variations of pol β perform different functions between the high-incidence areas and the other areas, and may play a more important role in the high-incidence areas.

INTRODUCTION

Esophageal carcinoma occurs frequently in China, especially in the mountainous Taihang area. Epidemiology and laboratory studies suggest that the carcinogenesis and progression of esophageal carcinoma are probably associated with some gene mutations^[1,2]. Some researches indicate that the ability of pol β to repair DNA damage reduces in peripheral blood of esophageal carcinoma patients and that obvious chromosome changes occur in tumor cells^[3-5]. Therefore, there must be DNA damage repair in the development of esophageal carcinoma. However, variations of DNA replication and repair enzymes in esophageal carcinoma, especially the mutation of pol β is rare. Thus, we made a preliminary analysis on the mutation of pol β in esophageal carcinoma.

MATERIALS AND METHODS

Specimens

High-incidence area group: Specimens of 30 esophageal squamous carcinomas (serial numbers H1-H30) and matched adjacent normal tissues were obtained from patients in Linzhou region of northern China, a well-recognized high-risk area for esophageal carcinoma.

Non-high incidence area group: Specimens of 25 esophageal squamous carcinomas (serial numbers N1-N25) and corresponding adjacent normal tissues were obtained from patients who underwent surgery at Cancer Hospital of Henan Province and the First Affiliated Hospital of Zhengzhou University.

All patients were histopathologically diagnosed to be infiltrative squamous carcinoma cases. The tissues were frozen in liquid nitrogen immediately after surgery.

RT-PCR

A pair of primers for PCR was designed to amplify the total pol β gene according to the sequence of M13140 in GenBank. Primer P1 (sense): 5' ATGAGCAAACG GAG-GGCGCCG 3'; Primer P2 (antisense): 5' TCATTCGCT-CCGTCCTTGG 3'. The primer was synthesized by Shanghai Sangon Co., Ltd.

Total RNA was extracted with the QIAGEN RNA extraction kit. Five microliters of total RNA was transcribed into cDNA using 0.2 μ mol/L primer P2, 0.2 μ mol/L dNTP,

RNasin 40 U, 1 \times buffer (Promega), and 2 U AMV in a final volume of 30 μ L. In PCR assay, the PCR reaction mixture consisted of 1 \times PCR buffer (PE), 200 μ mol/L dNTP, 20 pmol of each primer, 2 U of Golden Taq DNA polymerase (PE). The mixture was pre-incubated for 5 min at 94 $^{\circ}$ C, followed by amplification at 94 $^{\circ}$ C for 50 s, 56 $^{\circ}$ C for 50 s, and at 72 $^{\circ}$ C for 60 s, for 30 cycles. A final extension was performed at 72 $^{\circ}$ C for 7 min.

DNA cloning and sequencing

The PCR products from all specimens were excised from 0.8% agarose gels, and the desired fragments were purified using a DNA gel extraction kit (Promega). The purified fragments were cloned into a pGEM-T plasmid vector, and then transformed into *E. coli* JM109 competent cells. Plasmid DNA was extracted from the positive clones and sequenced using a PE 377 sequencer. The sequences were analyzed by DNASIS and OMEGA.

Statistical analysis

Statistical significance was evaluated using the χ^2 test. $P < 0.05$ was considered statistically significant. Statistical analysis was performed with SPSS 11.0.

RESULTS

PT-PCR analysis of whole $\text{pol}\beta$ gene

In the high-incidence group, PCR products were obviously smaller than 1 008 bp in six carcinoma specimens. The correct length of $\text{pol}\beta$ gene was obtained by amplifying the other specimens (Figure 1).

Figure 1 RT-PCR amplification of $\text{pol}\beta$ gene. Lanes 1, 2 and 7: Normal size of PCR products of H1, H2 and H3; lanes 3-6: shorter size of PCR product of H5, H8, H10, and H16; M: DNA marker (from top to bottom: 1 000, 900, 800, 700, 600, 500, 400, 300, 200, 100 bp).

Result of sequencing

Point mutations and deletion of $\text{pol}\beta$ gene were detected in the high-incidence area group (Table 1 and Figure 2). Overall, $\text{pol}\beta$ gene variations were found in 13 of 30 esophageal carcinoma tissue specimens. A 58 bp(177-234 nt) deletion was detected in six tumor tissue specimens (Figure 3). Only one variation was found in the corresponding adjacent normal tissue (Table 1).

$\text{Pol}\beta$ gene point mutations were detected in 5 of 25 esophageal carcinoma tissue specimens, and no variation was found in corresponding adjacent normal tissues in the non-high incidence area group (Table 2).

The incidence of $\text{pol}\beta$ gene variation observed in the high-incidence area group was significantly higher than that

in the non-high incidence area group ($P = 0.007$, χ^2 test).

Variation of amino acid caused by gene mutations

Twelve kinds of variation in the $\text{pol}\beta$ gene were found in the present study, including 11 point mutations and a 58 bp deletion (Table 3). The translation of $\text{pol}\beta$ was interrupted due to the emergence of a termination codon at 117 nt caused by 462 nt G→T mutation. Mutations at 665, 737, and 740 nt were synonymous mutations, which would not change the amino acids. The other seven point mutations caused replacement of amino acids.

Figure 3 Comparison between wild type polβ gene fragment and six gene fragments with deletion (177→234 nt).

DISCUSSION

DNA pol β is one of the four recognized, vertebrate, cellular, DNA polymerizing enzymes. Two features of pol β from various species may play a key role. First, the structure of pol β is highly conserved from the standpoint of both polypeptide size and amino acid sequence. Second, in cultured mammalian cells, the level of pol β enzymatic activity is low and independent of cell-cycle stage^[6,7]. Hence, pol β is considered as a constitutively expressed “housekeeping” enzyme required for DNA metabolic events other than replicative synthesis of genomic DNA. DNA synthesis during DNA repair and recombination are examples of such events, and the idea that pol β is involved in some types of DNA repair is supported by various studies with DNA polymerase inhibitors^[8-11]. Recent observations have shown that the variation of pol β occurs in some tumors such as colorectal carcinoma, bladder carcinoma, breast carcinoma, prostate carcinoma and non-small cell lung cancer. The variation rate is particularly high in colon carcinoma, being more than 80% (5/6)^[12-17,20]. Some studies indicate that the accumulation of proto-oncogene and tumor suppressor gene variations perhaps leads to tumor. However, the initial molecular defects causing accumulated mutations and inducing cancer are not well understood. Interestingly, there is a higher mutation rate of pol β , p53 and ras in colorectal carcinoma. A genetic disease, xeroderma pigmentosum, is associated with ERCC, a kind of DNA repair gene^[18-21], and these patients are more susceptible to skin carcinoma^[22,23]. The above findings suggest that there is a correlation between human tumors and the damage, maladjustment and defects in the DNA repair system.

The present results showed that some mutations, such as 462 nt G \rightarrow T and deleting 177-234 nt, could lead to the abnormal amino acid of pol β followed by abnormal protein structure and lack of DNA repair activity. From the histopathological diagnosis, we found that cancer cells involving the two mutations were more malignant. In addition, there were three synonymous mutations at 665 nt (T \rightarrow G), 737 nt (A \rightarrow T) and 740 nt (A \rightarrow G), which may be the single nucleotide polymorphism (SNP)^[24-29].

Pol β gene variation in the high-incidence area group was detected in 13 of 30 esophageal carcinoma tissue specimens. The mutation rate of this group was 43.3%. Pol β gene variation in the non-high incidence area group was found in 5 of 25 esophageal carcinoma tissue specimens, and the mutation rate was 20%. Thus, there was a significant difference in mutation rates between these two groups ($P < 0.05$). Twelve types of pol β gene variation were found in high-incidence area, but only three types were found in the non-high incidence area, suggesting that damage of the DNA repair system via alteration of this gene may contribute to the development of esophageal carcinoma, and that pol β may play a more important role in the high-incidence area.

By analyzing the variation site of pol β , we found that three point mutations were located in one region (454-466 nt), and four point mutations were located in another region (648-670 nt). The two regions are probably the mutation hot spots of the pol β gene of esophageal carcinoma. Moreover, the deletion of 58 bp was found in 6 of 20 specimens

from the high-incidence area (31.6% frequency), but was not found in the non-high incidence area. Hence, this deletion may be one of the main variations of pol β gene in esophageal carcinoma. Our results prove that pol β mutations do exist in esophageal carcinoma, and are probably correlated to the development of esophageal carcinoma.

It is suggested that during such genetic evolution, the DNA repair system plays an important role in cancer development^[30-32]. Although the relationship between mutations of pol β and alterations in proto-oncogenes or tumor suppressor genes is currently not clear, pol β gene mutation is involved in a subset of human esophageal carcinoma, especially in the high-incidence area.

Abstract

AIM: To explore the feasibility of performing gastrectomy with D2 lymphadenectomy in gastric cancer patients with liver cirrhosis.

METHODS: A total of 7 178 patients were admitted with a diagnosis of liver cirrhosis from January 1993 to December 2003. We reviewed the records of 142 patients who were diagnosed with liver cirrhosis and gastric adenocarcinoma during the same period. Gastrectomy with D2 lymph node dissection for carcinoma of the stomach was performed in 94 patients with histologically proven hepatic cirrhosis.

RESULTS: All but 12 patients were classified as Child's class A. Only 35 patients (37.2%) were diagnosed with cirrhosis before operation. Seventy-three patients underwent a subtotal gastrectomy (77.7%) and 21 patients (22.3%) underwent a total gastrectomy, each with D2 or more lymph node dissection. Two patients (3.8%) who had prophylactic intra-operative drain placement, died of postoperative complications from hepatorenal failure with intractable ascites. Thirty-seven patients (39.4%) experienced postoperative complications. The extent of gastric resection did not influence the morbidity whereas serum aspartate aminotransferase level ($P = 0.011$) and transfusion did ($P = 0.008$). The most common postoperative complication was ascites (13.9%) followed by wound infection (10.6%).

CONCLUSION: We concluded that the presence of compensated cirrhosis, i.e. Child class A, is not a contraindication against gastrectomy with D2 or more lymph node dissection, when curative resection for gastric cancer is possible. Hepatic reserve and meticulous hemostasis

are the likely determinants of operative prognosis.

INTRODUCTION

Although the prognosis of gastric cancer has improved significantly as a result of early diagnosis, radical operation, and advances in adjuvant therapy, gastric cancer remains the most common cause of cancer-related death in Korea^[1]. Extended lymph node dissection is regarded as an essential criterion for the treatment of gastric cancer^[2-4]. It not only makes the surgical therapy more radical but also provides adequate lymph node staging.

Liver cirrhosis is another major health problem in Korea, where it is the fourth most common cause of death, and is probably linked to the high prevalence of HBV infection and a culture that encourages high alcohol consumption^[5]. Because of the high prevalence, cirrhosis of the liver is not infrequently encountered among candidates for gastric cancer surgery in Korea. Most surgeons are reluctant to perform a D2 lymph node dissection in patients with liver cirrhosis due to the risk of liver dysfunction^[6].

Recent advances in peri-operative patient care and surgical techniques, however, have reduced the morbidity and mortality rates associated with gastric cancer surgery even after a D2 lymph node dissection. This study was conducted to explore the feasibility of performing gastrectomy with D2 lymphadenectomy in gastric cancer patients with liver cirrhosis, in terms of the morbidities and mortalities.

MATERIALS AND METHODS

Patients

A total of 7 178 patients were admitted with a diagnosis of liver cirrhosis to Yonsei University Medical Center from January 1993 to December 2003. We reviewed the records of 142 patients who were diagnosed with liver cirrhosis and gastric adenocarcinoma at the Department of Surgery, Yonsei University College of Medicine during the same

period. All patients had no previous history of abdominal surgery or other malignancies. Thirty-four patients who had palliative surgery and 14 patients who did not have surgery due to impaired liver function were excluded from the study. The remaining 94 gastric cancer patients with liver cirrhosis who underwent curative gastric resection for gastric cancer were included in this study.

Cirrhosis was diagnosed primarily by liver biopsy. In patients in whom liver biopsy was not performed, the diagnosis was made by gross findings during the operation, a history of liver disease, with impaired liver function tests and CT scan or ultrasonography imaging.

Characteristics of the patients including age, sex, Child-Pugh classification, extent of gastric resection, stage of the tumor, and postoperative outcomes including operation time, the number of retrieved lymph nodes, complications, hospital stay, survival rates were analyzed. The χ^2 test was used for discrete variables and Student's *t* test for continuous variables. Survival rates were estimated using the Kaplan-Meier method and the difference between the curves was assessed using the log-rank test. *P* values less than 0.05 indicated statistical significance.

Operative technique

Gastric cancer surgery in our institution is done according to the following standardized operative protocol: (1) A total or distal subtotal gastrectomy is performed depending on the location and the macroscopic type of gastric cancer. (2) A D2 or more lymph node dissection is preferred regardless of the clinical stage^[7]. Lymph nodes along the hepato-duodenal ligament and common hepatic artery were retrieved and tied with #3 silk. After gastric resection, the gastrointestinal continuity is restored by either a gastro-duodenostomy or a gastro-jejunostomy, depending on the location of the tumor after a distal subtotal gastrectomy. A Roux-en-Y esophago-jejunostomy is done after a total gastrectomy. Gastro-duodenostomy is done using interrupted 3-0 silk Lembert

sutures for the outer layer and interrupted 3-0 polyglycolic sutures for the transmural inner layer. The gastro-jejunostomy is performed using interrupted 3-0 silk Lembert sutures for the outer layer and a running 3-0 polyglycolic suture for the transmural inner layer. Esophago-jejunostomy is done using an EEA stapler (Ethicon, Somerville, NJ, USA). Before the abdominal wall is closed, a two-armed suction drain (Hemovac, Sewoon Medical Co., Seoul, South Korea) is inserted through a new stab wound on the right flank toward the subhepatic area after a subtotal gastrectomy. An additional suction drain is inserted through the left flank toward the left sub-diaphragmatic space after a total gastrectomy. The abdominal fascia is closed with continuous polydioxanone sutures reinforced by interrupted 1-0 silk sutures. The subcutis and cutis are restored with interrupted 3-0 silk sutures and skin staplers.

RESULTS

Characteristics of the patients, tumors, and surgeries

There were 73 (77.7%) males and 21 (22.3%) females. The median age was 59 years (range, 36-76 years). All but 12 patients were classified as Child's class A. Thirty-five patients (37.2%) were diagnosed with cirrhosis before the operation and the other 59 (62.8%) patients were diagnosed with liver cirrhosis during the operation. Cirrhosis was related to HBV in 52 (55.3%) patients, HCV in 8 (8.5%) patients, and alcohol abuse in 30 (31.9%) patients. Cirrhosis was cryptogenic in 4 (4.3%) patients.

Seventy-three (77.7%) patients had a subtotal gastrectomy and 21 (22.3%) patients underwent a total gastrectomy. All patients underwent D2 or more lymph dissection. The mean number of the retrieved lymph nodes was 35 (range, 15-71). The mean operation time was 195 min (range, 110-345 min). Prophylactic drainage was done in 51 (73.9%) patients. The median hospital stays in this cohort of 94 patients was 13.5 d (range, 7-90 d). The characteristics of patients, tumors, and surgeries are summarized in Table 1.

Table 1 Characteristics of patients, tumors, and surgeries

Patients				
Variables	Number	%	Variables	
Sex			Age (yr)	
Male	73	77.7	Median	59
Female	21	22.3	Range	36-76
Diagnosis of cirrhosis			Retrieved nodes	
Preoperative	35	37.2	Median	35
Intraoperative	59	62.8	Range	15-71
Cause of cirrhosis			Positive nodes	
HBV-related	52	55.3	Mean	3.5
Alcohol	30	31.9	Range	0-27
HCV-related	8	8.5	Operation time (min)	
Cryptogenic	4	4.3	Mean	194.6
Extent of gastric resection			Range	110-345
Subtotal	73	77.7	Hospital stay (d)	
Total	21	22.3	Median	13.5
TNM stage			Range	7-90
I	51	54.3		
II	25	26.6		
III	10	10.6		
IV	8	8.5		

Mortality and morbidity

Two patients who had prophylactic intra-operative drains died after the operation (2.1%) as a result of hepato-renal failure related with intractable ascites. One patient was classified as Child's class B and the other patient as Child's class C. The most common post-operative complication was ascites (13 patients, 13.9%) followed by wound infection (10 patients, 10.6%). Ascites was well controlled with medications in nine patients (six patients had prophylactic intra-operative drain placement and three patients had not) and with paracentesis in four patients who had prophylactic intra-operative drain placement. All the patients who experienced post-operative bleeding (four patients) and anastomotic leakage (two patients) were managed conservatively (Table 2).

Table 2 Morbidities and mortalities

	Patients		Total (%)
	No drainage (n = 37, %)	Drainage (n = 57, %)	
Morbidities			
Absent	27 (73.0)	30 (52.6)	57 (60.6)
Present	10 (27.0)	27 (47.4)	37 (39.4)
Wound infection	2 (5.4)	8 (14.0)	10 (10.6)
Ascending infection	0 (0.0)	3 (5.3)	3 (3.2)
Pneumonia	2 (5.4)	3 (5.3)	5 (5.3)
Bleeding	1 (2.7)	3 (5.3)	4 (4.3)
Anastomosis leakage	1 (2.7)	1 (1.8)	2 (2.1)
Ascites	3 (8.1)	10 (17.5)	13 (13.9)
Mortalities	0 (0.0)	2 (3.8) ¹	2 (2.1)

¹Mortalities were caused by hepatorenal syndrome.

The association between clinico-pathological parameters and the risk of post-operative complications are summarized in Table 3. Transfusion and serum aspartate aminotransferase levels were the independent predictive factors of morbidity ($P < 0.05$) (Table 4). The extent of gastric resection or tumor stage did not influence the morbidity, while intra-operative drain placement showed marginal significance ($P = 0.055$). Ten out of the thirty-seven patients, who had no prophylactic drains (27.0%) experienced postoperative complications, whereas 27 out of the 57 patients who had prophylactic drains (47.4%) experienced complications.

Survival of the patients

The overall 5-year survival rate of the patients was 65.9%. The overall 5-year survival rate of the Child's class A patients was 69.1% and 44.4% for the Child's class B and C patients. There was a significant difference between the survival rates at Child's class ($P = 0.0195$).

DISCUSSION

Postoperative complications in cirrhotic patients after gastrectomy with D2 lymph node dissection were associated with serum aspartate aminotransferase levels and transfusion. We observed that the post-operative morbidity was more common among patients with prophylactic drains after gastrectomy with D2 lymph node dissection, than among patients without prophylactic drains. Two patients who had

prophylactic intra-operative drain placement died of postoperative complications from hepato-renal failure with intractable ascites.

The prevalence of gastric cancer among cirrhotic patients in this study was higher than other reports (2.0%, 142 patients out of 7 178 cirrhotic patients). Gastric cancer among cirrhotic patients have been rarely reported in the literature^[8]. A recent nationwide cohort study from Denmark revealed that the risk of gastric carcinoma in cirrhotic patients is not low compared to other cancers, except for hepatocellular carcinoma^[9]. The study identified 40 gastric carcinoma patients (0.34%) among 11 605 cirrhotic patients during a 12-year follow-up. A group of Italian endoscopists has made similar observations^[10]. Zullo *et al.*, reported that the prevalence of latent gastric cancer in liver cirrhosis patients could be significantly higher than that expected in the general population (a 2.6-fold increase). The reasons for the high prevalence of gastric cancer in our study remain unclear but probably are associated with the generally high prevalence of gastric cancer and a culture that encourages high alcohol consumption in Korea^[5,11].

The data presented here demonstrates that gastrectomy with D2 lymph node dissection in cirrhotic patients is feasible. Abdominal operations in cirrhotic patients have been a technical challenge with mortality rates around 30%^[12-14]. Therefore, gastric cancer surgery for cirrhotic patients remains controversial. Our peri-operative morbidity and mortality rates compared favorably with most series on abdominal procedures in the literature. The Child-Pugh classification has proven to be a reliable tool in identifying patients at risk of post-operative complications. In our series, the morbidity rate was related to serum aspartate aminotransferase levels and peri-operative transfusion status. Peri-operative transfusion has been reported to be associated with morbidities in gastric cancer patients due to immunosuppressive effects^[15]. Lowering the serum aspartate aminotransferase levels and meticulous hemostasis during operation are probably the best way to decrease post-operative complication rate in patients with liver cirrhosis.

Our data showed that D2 lymph node dissection in cirrhotic patients is feasible without drains, if the hepatic reserve is not severely compromised and no usage of prophylactic drain. All the patients underwent D2 lymph node dissection and the mean number of retrieved lymph nodes was 35 in this study. This result is comparable to the results of other studies concerning D2 lymph node dissection^[3,6]. Prophylactic drain placement showed no beneficial effect in terms of post-operative morbidity in this study. Although three patients, who did not have intraoperative drain placement, developed ascites after surgery, they were easily controlled with medications. Three out of ten patients who needed paracentesis were all patients who had intra-operative drain placement. Similar results were reported by Urbach *et al.*, who performed a metaanalysis on colorectal cancer patients and concluded that they could not find any benefit of routine intra-operative drain placement after colon and rectal anastomoses in reducing the rate of anastomotic leakage or other complications^[16].

by the Japanese Research Society on Gastric Cancer) and common hepatic artery (station number 8) in cirrhotic gastric cancer patients has been reported to be limited^[6,17]. The lymphatic systems in these two lymph node stations are

extensive and well developed, making these two lymph node stations as the frequent sites of lymphorrhea especially after lymph node dissection that is not easy to control^[6]. Cirrhotic patients often suffer from ascites after gastric cancer surgery,

which can be aggravated by insertion of a drainage catheter [12,18]. Two patients who had prophylactic intra-operative drain placement died of post-operative complications from hepato-renal failure with intractable ascites. Downstaging Child's class B and C patients to Child's class A patients and meticulous tying of the lymphatic systems should be attempted first, instead of limiting the extent of lymph node dissection.

Since more than half of the patients in our study were diagnosed with liver cirrhosis during the operation and this study was a retrospective study with inherent sampling bias, the association of Child's class with morbidities and mortalities was not always clear. Therefore, it is difficult to compare our results against other reports in the literature. The reason why more than half of the patients in this study had been diagnosed as liver cirrhosis during the operations is unclear.

In conclusion, patients with compensated cirrhosis, i.e., Child's class A, may safely undergo gastrectomy with D2 lymph node dissection. Downstaging the Child's class and performing a D2 lymph node dissection with meticulous hemostasis and without a prophylactic drain placement appear to be the most reasonable treatment plan for gastric cancer patients with liver cirrhosis.

Abstract

AIM: To find and identify specific nuclear matrix proteins associated with proliferation and differentiation of carcinoma cells, which will be potential markers for cancer diagnosis and targets in cancer therapy.

METHODS: Nuclear matrix proteins were selectively extracted from MGc80-3 cells treated with or without hexamethylamine bisacetamide (HMBA), and subjected to 2-D gel electrophoresis. The resulted protein patterns were analyzed by Melanie software. Spots of nuclear matrix proteins differentially expressed were excised and subjected to *in situ* digestion with trypsin. Peptide masses were obtained by matrix-assisted laser-desorption/ionization time of flight mass spectrometry (MALDI-TOF-MS) analysis and submitted for database searching using Mascot tool.

RESULTS: The MGc80-3 cells were induced into differentiation by HMBA. There were 22 protein spots which changed remarkably in the nuclear matrix, from differentiation of MGc80-3 cells compared to control. Eleven of which were identified. Seven proteins - actin, prohibitin, porin 31HL, heterogeneous nuclear ribonucleoprotein A2/B1, vimentin, ATP synthase, and heat shock protein 60 were downregulated, whereas three proteins - heat shock protein gp96, heat shock protein 90-beta, and valosin-containing protein were upregulated, and the oxygen-regulated protein was only found in the differentiated MGc80-3 cells.

CONCLUSION: The induced differentiation of carcinoma cells is accompanied by the changes of nuclear matrix proteins. Further characterization of those proteins will show the mechanism of cellular proliferation and differentiation, as well as cancer differentiation.

INTRODUCTION

Nuclear matrix (nuclear skeleton) is the filamentous protein framework in eukaryotic cell nucleus. Nuclear matrix plays an important role in life activities such as maintaining the cell morphology, dimensional localization, DNA replication and transcription. Thereby, it is intensely associated with cell proliferation and differentiation, as well as carcinogenesis^[1,2].

The role of nuclear matrix in cell activities has drawn increasing attention recently. Most of its components, besides the fibrins, are proteins and/or enzyme in DNA replication, transcription and gene expression^[3,4]. The nuclear matrix in cancer cells is not only abnormal in morphology, but also apparently different in its composition. Tumor-associated nuclear matrix proteins have been identified in cancers of the breast, colon, bone, bladder, and larynx using 2-D gel electrophoresis^[5-9]. But nuclear matrix proteins associated with the differentiation of carcinoma cells were unexplored.

Previously, we found that the morphology of nuclear matrix in differentiated human gastric cancer cells, induced by hexamethylamine bisacetamide (HMBA) and retinoic acid^[10], showed similar characteristics with that in normal cells. It is implied that further study on the differential expressed nuclear matrix proteins in response to differentiation reagent will be able to reveal the mechanism of carcinogenesis and phenotypic reversion, as well as cell growth and differentiation.

This study was designed to find and identify specific nuclear matrix proteins, associated with the proliferation and differentiation of carcinoma cells. The human gastric mucous adenocarcinoma MGc80-3 cell was selected as a subject to undergo differentiation induced by HMBA. The nuclear matrix proteins from MGc80-3 cells were selectively extracted, and subjected to 2-D gel electrophoresis. The changed nuclear matrix proteins during the differentiation process were identified by matrix-assisted laser-desorption/ionization time of flight mass spectrometry (MALDI-TOF-MS) combined with database searching.

MATERIALS AND METHODS

Materials

HMBA (Sigma Chemical Company) were used to induce the differentiation of MGc80-3 cells. Sequence grade, modified trypsin (Promega) and iodoacetamide (Sigma) were used in the in-gel digestion. ReadyStrip IPG strips (pH 3-10, 11 cm) and IPG buffer pH 3-10 were from Amersham Biosciences. Other reagents used in 2-D gel electrophoresis and Coomassie blue R250 were from Shanghai Sangon Biological Engineering Technology and Service Co., Ltd.

Cell culture

MGc80-3 cells were cultured in the RPMI-1640 supplemented with 15% new born bovine serum at 37 °C. The cells were seeded in a constant density overnight, and treated with 5 mmol/L HMBA for 7 d. Fresh culture media were added to the cells every 48 h, and cells were harvested at subconfluency. The obtained cells were then stored at -80 °C.

Purification of nuclear matrix proteins

The nuclear matrix proteins were extracted by a method of Fey *et al.*^[11]. The MGc80-3 cells were washed with PBS and extracted with cytoskeleton buffer (CSK100) (10 mmol/L PIPES pH 6.8, 300 mmol/L sucrose, 100 mmol/L NaCl, 4 mmol/L CaCl₂, 1.0 mmol/L PMSF, 0.5% Triton X-100) at 0 °C for 10 min. The nuclei were sheared through a 16-gauge needle, and subjected to centrifugation for 5 min at 400 r/min. The deposition was washed twice with CSK50 (10 mmol/L PIPES pH 6.8, 300 mmol/L sucrose, 50 mmol/L NaCl, 4 mmol/L CaCl₂, 1.0 mmol/L PMSF, 0.5% Triton X-100) and digested for 30 min at 25 °C in the same buffer containing 500 U/mL DNase I. One mole per liter ammonium sulfate was added dropwise to a final concentration of 0.25 mmol/L. After incubation for 15 min, the nuclear matrix proteins were pelleted by centrifugation at 1 000 r/min for 5 min, and washed once with the CSK50 buffer, then stored at -80 °C. Protein concentrations were determined by Bradford's method.

Two-dimensional gel electrophoresis

To solubilize nuclear matrix proteins, the pellet of purified nuclei was resuspended in 2-D buffer containing 7 mol/L urea, 2 mol/L thiourea, 4% CHAPS, 50 mmol/L DTT and ultrasonicated for 2 min. The supernatant was centrifuged for 30 min at 16 000 g at 4 °C. IEF was performed in ReadyStrip IPG strips. ReadyStrip IPG strips were rehydrated overnight in a reswelling tray with 2-D buffer containing 0.5% IPG buffer pH 3-10 and nuclear matrix proteins in a final volume of 250 µL (200 µg). IEF was carried out on a Protean IEF Cell (Investigator) at 19 °C with a maximum current setting of 80 mA/strip. Focusing was performed for a total of 70 000 V·h.

Before carrying out second dimensional SDS-PAGE, the strips were equilibrated in an equilibration buffer consisting of 20% glycerol, 2% SDS, 65 mmol/L Tris-HCl, pH 6.8 and 20 mmol/L DTT for 10 min at room temperature, then transferred into the second equilibration buffer consisting of 20% glycerol, 2% SDS, 65 mmol/L Tris-HCl, pH 6.8 and 2.5% iodoacetamide. The strips were transferred onto 1-mm thick SDS-PAGE gels and sealed in place with

1% agarose. SDS-PAGE was performed on a 12.5% acrylamide/bisacrylamide gel at 50 V for 30 min followed by 170 V for 8 h. The gels were run in the following electrode buffer: 25 mmol/L Tris, 192 mmol/L glycine, 0.1% SDS. SDS-PAGE standards were used for gel calibration. The gels were stained with Coomassie blue R250 and destained with 5% methanol, 7.5% acetic acid. 2-DE maps of nuclear matrix proteins were subjected to analysis with Melanie software. Protein spots were manually excised for mass spectrometry.

Protein identification by matrix-assisted laser-desorption/ionization time of flight mass spectrometry (MALDI-TOF-MS) analysis

In-gel digestion Spots were cut into about 1 cm×1 cm×1 cm pieces, and washed twice with 80 µL of 25 mmol/L NH₄HCO₃, 50% acetonitrile for 5 min, then dehydrated with 80 µL of acetonitrile. Gel pieces were completely dried. Reduction was achieved by 1 h treatment with 10 mmol/L DTT/100 mmol/L NH₄HCO₃ at 57 °C. Alkylation was performed with 25 mmol/L iodoacetamide/100 mmol/L NH₄HCO₃ for 45 min in the dark at 25 °C. Finally, gel pieces were washed thrice for 5 min alternatively with 100 mmol/L ammonium carbonate and acetonitrile, and then completely dried with a Speed Vac before trypsin digestion. Appropriate volumes of trypsin (12.5 ng/µL, freshly diluted in 50 mmol/L NH₄HCO₃) were added to the dried gel pieces. The digestion was performed at 37 °C overnight. After being centrifuged for 5 min in a Speed Vac, the gel pieces were incubated in 10 µL 20 mmol/L NH₄HCO₃ for 20 min at room temperature, and then incubated in 10 µL 5% TFA/50% acetonitrile for 5 min at room temperature. The supernatant was mixed, and completely dried with a Speed Vac.

MALDI-TOF-MS analysis For MALDI-TOF-MS analysis, samples were dissolved in 2 µL 0.1% TFA. Mass measurements were carried out on a Bruker ULTRAFLEX™ TOF/TOF mass spectrometer. This instrument was used at a maximum accelerating potential of 20 kV (in positive mode) and was operated in reflector mode. 0.5 µL of saturated solution of α -cyano-4-hydroxy cinnamic acid in 0.1% TFA/30% acetonitrile was mixed with 0.5 µL sample solution, and added to the target. Internal calibration was performed with tryptic peptides coming from autodigestion of trypsin (monoisotopic masses at m/z 842.51, and m/z 2 211.10). Monoisotopic peptide masses were assigned and used for database search.

Database search

The MALDI-TOF-MS data were searched against a NCBI nonredundant protein sequence database using Mascot tool from Matrix Science. All proteins present in the NCBI database were taken into account without any pI or M_r restrictions. Search parameters included a maximum allowed peptide mass error of 100 ppm with a consideration of one incomplete cleavage per peptide. Accepted modifications included carbamidomethylation of cysteine residues (from iodoacetamide exposure) and methionine oxidation, a common modification occurring during SDS-PAGE. Protein identifications were assigned when three criteria were met:

(1) Statistical significance ($P < 0.05$) of the match when tested by Mascot (matrixscience.com); (2) $> 20\%$ sequence coverage by the tryptic peptides; (3) Concordance ($\pm 15\%$) with the molecular weight and pI of the parent 2-D PAGE protein spot; and (4) Protein identifications not fulfilling criterion 2 were still assigned, if criteria 1 and 3 were fulfilled and no other *Homo sapiens* proteins with peptide mass-matched P values < 0.05 were identified by Mascot; identified protein was inferred.

RESULTS

Changes in nuclear matrix proteins upon addition of 5 mmol/L HMBA

Samples of nuclear matrix proteins extracted from MGc80-3 cells treated with or without 5 mmol/L HMBA were subjected to 2-D gel electrophoresis for at least three repeats per experimental condition. Analysis of proteins was based on evaluation of at least two gels. Typical 2-DE map of nuclear matrix proteins from MGc80-3 cells in the presence or absence of HMBA is shown in Figure 1. There were 22 protein spots that were changed remarkably, whereas most of the spots were similar in the expression patterns of nuclear matrix proteins from differentiated MGc80-3 cells compared to that from control. Among the changed spots,

12 spots were downregulated, one spot disappeared in the differentiated MGc80-3 cells, whereas 8 spots were upregulated, and 1 spot emerged as a new protein spot that appeared in the differentiated cells (Figures 1 and 2). Relative expression levels of the changed proteins were shown using Melanie software (Figure 3), relative volume (%vol) of spot was employed to make the data independent of uninteresting variation between gels, such as differences in protein loading or staining (Table 1).

Identification of the altered proteins

In the 22 differentially expressed protein spots, 15 were identified as 11 proteins by peptide mass fingerprinting according to the criteria, while 8 spots failed to be identified by peptide mass fingerprinting. The Spot C33 that disappeared in the HMBA-treated MGc80-3 cells was identified as hnRNP A2/B1. Nine of the twelve spots downregulated in the HMBA-treated cells were actin, vimentin, prohibitin, porin 31HL, hnRNP A2/B1, ATP synthase and heat shock protein 60. The new spot present after HMBA treatment was oxygen-regulated protein. In the eight upregulated spots, four spots were matched with heat shock protein gp96, heat shock protein 90-beta, ubiquitin thiolesterase (EC 3.1.2.15) and valosin-containing protein individually.

DISCUSSION

In the present study, nuclear matrix proteins extracted from differentiated MGc80-3 cells induced by HMBA were compared with those from MGc80-3 cells using 2-D gel electrophoresis. 2-D gel image analysis software was used to confirm the identification of specific nuclear matrix proteins associated with the differentiation of carcinoma cells combined with the visual observation. The protein patterns were highly reproducible. There were 22 spots that were changed remarkably during the differentiation process. Most of interested proteins differed qualitatively between control and differentiated MGc80-3 cells, except for two proteins, in which one was absent, while the other was only present in the HMBA-treated cells. The differentially expressed proteins confirm that specific nuclear matrix proteins are accompanied with the differentiation of MGc80-3 cells.

Fifteen of the twenty-two changed proteins were identified. The identified proteins that associated with proliferation and/or differentiation of MGc80-3 cells were grouped into six classes: (1) common nuclear matrix proteins:

Figure 2 Enlarged maps of changed nuclear matrix proteins from MGc80-3 cells, Coomassie blue-stained **A-H**: nuclear matrix from control cells; **I-P**: nuclear matrix from HMBA-treated cells. Arrows pointed to changed proteins. C33 disappeared, while C19, C20, C23, C27, C28, C29, C30, C38, C39, C40,

C41, C70 were downregulated in the HMBA-treated cells; S78 was a new protein, whereas S4, S44, S53, S54, S72, S74, S75 were upregulated after HMBA treatment.

Figure 3 Relative expression level of changed nuclear matrix proteins. **A:** Relative expression level of disappeared or downregulated proteins in the nuclear matrix fractions of MGc80-3 cells treated with HMBA; **B:** Relative expression level of new or upregulated proteins in the nuclear matrix fractions of MGc80-3 cells treated with HMBA. C33 was disappeared, while C19, C20, C23, C27, C28, C29, C30, C38, C39, C40, C41, C70 were downregulated in the HMBA-treated cells; S78 was a new protein, whereas S4, S44, S53, S54, S72, S74, S75 were upregulated after HMBA treatment. Relative expression levels were shown using Melanie software. Values are mean \pm SE for two experiments.

vimentin and actin; (2) heterogenous nuclear ribonucleoprotein family: hnRNP A2/B1; (3) heat shock proteins; heat shock protein 60, heat shock protein gp 96, heat shock protein 90-beta, oxygen-regulated protein; (4) enzymes: ATP synthase, ubiquitin thiolesterase, and valosin-containing protein; (5) tumor suppressor protein: prohibitin; and (6) chloride channel protein: porin 31HL^[12].

Previously, several nuclear matrix proteins identified in this study, such as hnRNP A2/B1^[13], vimentin, actin^[14], prohibitin^[15], heat shock protein 60^[16], heat shock protein gp96^[17], and heat shock protein 90-beta^[18], were reported previously to be associated with cell growth and/or differentiation, although the roles they played in cell differentiation remain unclear.

In the downregulated proteins, vimentin and hnRNP A2/B1 have drawn intense attention to their relationship with cellular differentiation^[12,13]. In accordance to the result in this study, vimentin and hnRNP A2/B1 were highly expressed in cancer cell lines, but not detected or expressed in a lower level in well differentiated cells. Low expression of vimentin was reported to be correlated with the decreased mobility of cell, while the expression level of hnRNP A2/B1 was associated with cell proliferation ability. Inhibition on mobility and proliferation ability are the characteristics of differentiated cells, it is sure that vimentin and hnRNP A2/B1 are involved in the differentiation process, but the roles they play in cell growth and differentiation remain unknown.

In the upregulated or newly-emerged five proteins, there were three belonging to the heat shock protein family, while another member of the family, HSP60, was downregulated in the differentiated MGc80-3 cells. All the involved HSP proteins were reported to be associated with cell growth and differentiation^[16-19]. The deep involvement of heat shock protein family in the differentiation of MGc80-3 was consistent with the reports that heat shock proteins played an important role in the gastric tumors.

The proteins found in this study may be directly or indirectly involved in altered gene expression associated with the differentiation of carcinoma cells.

The findings described here will facilitate the understanding of the signal pathways and the mechanism of HMBA-induced differentiation. Further characterization of these proteins is now underway. These specific proteins are potential markers for tumor development or therapeutic target.

In this study, proteomic methods were used to systematically analyze the altered protein profiles in differentiated cancer cells. Specific nuclear matrix proteins associated with the differentiation of carcinoma cells were found and identified. It is of significance for revealing the signal pathway and mechanism of cell growth and differentiation, as well as carcinogenesis. Further characterization of those proteins will show the mechanism of cellular proliferation and differentiation, as well as cancer differentiation.

Abstract

AIM: To characterize the histochemical type and pattern of intestinal metaplasia (IM) adjacent to gastric cardia adenocarcinoma (GCA) and distal gastric cancer (GC) in Linzhou, Henan Province, China.

METHODS: Alcian-blue-periodic acid Schiff and high iron diamine-Alcian blue histochemical methods were performed on 142 cases of IM, including 49 cases of GCA and 93 cases of GC. All the patients were from Linzhou, Henan Province, China, the highest incidence area for both GCA and squamous cell carcinoma. Radio- or chemotherapy was not applied to these patients before surgery.

RESULTS: The detection rate of IM in tissues adjacent to GCA tissues was 44.9%, which was significantly lower than that in GC tissues (80.64%, $P < 0.01$). The rates of both incomplete small intestinal and colonic IM types identified by histochemistry in GCA tissues (31.82% and 63.64%, respectively) were significantly higher than those in GC (5.33% and 21.33%, respectively, $P < 0.01$).

CONCLUSION: IM in GCA and GC should be considered as a separate entity. Further research is needed to evaluate whether neoplastic progression of IM is related to its mucin profile in GCA.

INTRODUCTION

In China, epidemiologically, gastric cardia adenocarcinoma (GCA) shares a very similar geographic distribution with esophageal squamous cell carcinoma (SCC), especially in Linzhou (formerly Linxian County), Henan Province, north China, the highest incidence area of SCC in the world^[1,2]. However, the incidence of adenocarcinoma arising from the distal stomach is very low in this area^[3,4]. In the last two decades, the incidence of primary adenocarcinoma of the lower esophagus, esophagogastric junction and GCA has increased dramatically in North America and Western European countries^[5-6]. In contrast, the incidence of gastric cancer (GC) has decreased steadily in recent years.

In Linzhou, China, GCA has been classified as esophageal cancer by the local registry for the past several decades, because of their similar clinical symptoms, such as dysphagia^[7]. Approximately 60% of patients with dysphagia are found to have a diagnosis of SCC, the remaining 40% are found to have adenocarcinomas of the lower esophagus or gastric cardia^[8]. A case-control study performed on patients with presumed distal esophageal or gastric cardia cancer in Linzhou found that one-third of all these tumors are adenocarcinomas of the gastric cardia^[9].

The histogenesis and carcinogenesis for malignant transformation of GCA, however, are still not clear. Intestinal metaplasia (IM) is documented in the gastro-esophageal junction and cardia, but the etiology remains unclear^[10,11]. It has been believed that IM is closely related with the distal stomach cancer^[12]. However, whether IM is a premalignant lesion for GCA is still not clear. Studies on the histochemical features of IM arising from gastric cardia

Table 1 Criteria for IM classification based on histology and histochemistry

Types of IM	Histology			Histochemical staining		
	Structure of glands	Columnar cell	Paneth cell	AB	PAS	HID
Complete	Regular	-	+	+	-	-
Incomplete	Irregular	+	-	+	+	-
Complete colonic	Regular	-	-	+	-	+
Incomplete colonic	Irregular	+	-	+	+	+
Incomplete gastric	Irregular	+	-	-	+	-

Revised from Ref. [11].

and distal stomach and their relationship are very limited. Thus, the present study was undertaken to characterize the histological and histochemical types of IM in tissues adjacent to GCA and GC from patients in Linzhou, a high-incidence area of SCC and GCA in north China with Alcian-blue-periodic acid Schiff (AB-PAS) and High Iron Diamine-Alcian blue (HID-AB) staining methods.

MATERIALS AND METHODS

Collection and processing of surgically resected GCA and GC specimens

One hundred and forty-two surgically resected GCA and AC specimens were collected from Linzhou People's Hospital, Linzhou Center Hospital and Yaocun Esophageal Cancer Hospital in Henan Province from 2000 to 2001. All the patients were from Linzhou, Henan Province, the highest incidence area of both GCA and SCC. There were 49 patients with GCA, including 26 males and 23 females with an average age of 59.96 ± 10.29 years (range 36-80 years) and 93 patients with GC, including 49 males and 44 females with an average age of 58.96 ± 9.38 years (range 33-82 years). None of the cases received chemotherapy or radiotherapy before surgery. The surgically resected specimens were immediately fixed in 85% ethanol, and embedded with paraffin. Ten to fifteen pieces of tissue adjacent to cancer foci were obtained from each sample, dehydrated routinely with graded ethanol, embedded with paraffin, and cut into 5- μ m-thick sections. For each block, three slides were prepared, one slide was stained with hematoxylin and eosin (HE) for pathological diagnosis and another two slides were histochemically stained for histochemical analysis.

AB-PAS and HID-AB staining

The protocols for AB-PAS and HID-AB staining established previously in our laboratory were used^[11]. Briefly, for AB-PAS staining, the paraffin slides were deparaffinized with xylene. One hundred microliters of AB staining solution (Fluka Company) was added to the slides for staining in wet boxes for 20-30 min, washed with distilled water for 3-5 min; 100 mL 0.5% periodic acid solution was applied for oxidation for 10 min, washed with distilled water for 3-5 min; Schiff solution staining for 10 min, washed with distilled water for 5-10 min. Finally, the slides were sealed with neutral gum. For HID-AB staining (Sigma Company, USA), the paraffin slides were deparaffinized with xylene. The slides reacted with high iron diamine solution at room temperature for 24 h and then were washed with distilled water. One hundred

microliters of AB solution was applied for staining in wet boxes for 20-30 min and washed with distilled water, 0.5% neutral red solution (No. 3 Reagent Factory, Shanghai) was stained for 1-2 min and then washed with distilled water for 3-5 min. Finally, the slides were sealed with neutral gum.

Criteria for diagnosis and classification of IM

Based on the morphology and histochemistry findings, IM was classified as five types: complete intestinal IM, incomplete intestinal IM, complete colonic IM, incomplete colonic IM, and incomplete gastric IM (Table 1). In complete IM, the epithelial cells were composed of goblet cells, Paneth cells, mucous columnar cells, and absorptive cells; in incomplete IM, the epithelial cells were composed of goblet and mucous columnar cells.

Statistical analysis

The data were processed with SPSS 8.0 and χ^2 test was used for the difference among different IM types. $P < 0.05$ was considered statistically significant.

RESULTS

Histological findings

The histological analysis showed that the detection rate in both complete and incomplete IM adjacent to GCA (44.9%) was lower than that in both complete and incomplete IM adjacent to GC (80.64%, $P < 0.01$, Table 2). IM could be identified in a single acinus, or in several acini (Figure 1A).

Table 2 Prevalence and distribution of different types of IM in tissues adjacent to GCA and GC in Linzhou, Henan Province, China

Type	Incomplete IM		
	Complete IM n (%)	Small intestinal n (%)	Colonic n (%)
GCA (44.90%, 22/49)	1/22 (4.55)	7/22 (31.82)	14/22 (63.64)
GC (80.64%, 75/93)	55/75 (73.33)	4/75 (5.33)	16/75 (21.33)

Histochemical findings

By AB-PAS staining, complete type of IM was stained blue (Figure 1B), the incomplete type of IM was stained blue and red (Figure 1C), the gastric type of IM was stained red, the intestinal type of IM was stained blue. But, by HID-AB staining, the intestinal type of IM was stained blue (Figure 1D), the colonic type of IM was stained brown or black (Figure 1E).

Figure 1 Histological and histochemical findings in different types of IM. **A:** Microphotograph of chronic carditis with IM; **B:** Microphotograph of histochemical stain on complete IM at gastric cardia; **C:** Microphotograph of histochemical

stain on incomplete IM at gastric cardia; **D:** Microphotograph of histochemical stain on intestinal type of IM at gastric cardia; **E:** Microphotograph of histochemical stain on colonic type of IM at gastric cardia.

The histochemical pattern and type of IM were different between GCA and GC and most types of IM in GCA were incomplete type (95.45%), especially in the incomplete colonic type (63.64%); In contrast, complete IM occurred more frequently in GC (73.33%, $P < 0.01$, Table 2). Incomplete colonic and small intestinal IM could be observed in the same microscopic field or different fields on the same sample. In other words, blue acid mucous and brown-black sulfuric acid mucous co-existed in one acinus in some cases. The detection rate of co-existence for both colonic and small intestinal types on the same slide was 22.73% ($n = 5$). IM mostly occurred in the deep glands of gastric cardia.

DISCUSSION

The present study showed that IM was a frequent event in gastric cardia non-cancerous tissue adjacent to GCA (44.9%) in Linzhou, Henan Province, the highest incidence area of SCC and GCA. Goblet cells were invariably identified on HE-stained specimens. Only 0.7% symptom-free subjects in Linzhou are identified with IM in gastric cardia biopsies^[4]. These results suggest that IM may be a precancerous lesion

of GCA in this area.

Another interesting observation in the present study is that incomplete type of IM, especially the colonic type, is the predominant form of IM found in the gastric cardia. In contrast, the complete type of IM is the major form of IM found in GC. These results suggest that IM in GCA and GC should be considered as a separate entity. In stomach, IM frequently forms at the antrum (22.9%) but rarely at the fundus (2.8%)^[13]. Likewise, most GCs arise from the distal part of the stomach and infrequently from the near part. It is believed that GC correlates with IM closely, particularly with the intestinal type of GC based on the fact that the risk for GC and IM shares the same epidemiological characteristics^[14]. It was reported that the incomplete IM in which columnar cells secrete sulfuric acid mucous relates with GC^[12,15,16]. The present study indicated that the detection rate of IM adjacent to GCA was lower than that adjacent to GC. But the IM adjacent to GCA belonged to the incomplete IM, and the percentage of incomplete IM is much higher, suggesting that GCA correlates with incomplete IM closely and incomplete IM may be precancerous lesions of GCA. Reports with respect to the relationship between

IM and GCA are inconsistent^[17]. Further characterization of molecular changes of IM in nearby cancer foci and cancer tissue will shed light on the relationship of IM and GCA.

The prevalence of IM in gastric cardia is an understudied subject, especially in symptom-free subjects at the high-risk area of GCA. Only 0.7% symptom-free subjects in Linzhou, Henan Province, the high incidence area for GCA are identified with IM in gastric cardia biopsy, which is much lower than that in gastric cardia tissue adjacent to GCA (64-folds lower, 44.9% *vs* 0.7%)^[4]. The possibility for this difference may be that the prevalence of IM in symptom-free subjects is lower than that in GCA patients. Recent studies in Western countries indicate that IM in Barrett's esophagus and at the gastroesophageal junction seems to occur more apparently in old subjects. GCA patients are usually 5-10 years older at the time of diagnosis than symptom-free subjects in the same area. Another reason may be due to the sampling procedure. IM occurs with a patchy, irregular distribution in flat mucosa that is usually invisible at endoscopy. Presently, we lack methods to target biopsy for IM lesions, the chance to identify IM lesions in small biopsy is much less than that in surgically resected GCA specimen. Methylene blue selectively stains specialized columnar epithelia in Barrett's esophagus with a high accuracy. Chromoendoscopy with methylene blue stain may help to direct biopsies in subjects with IM in gastric cardia^[17-19].

IM has been recognized as a key point in Barrett's esophagus. Goblet cells are invariably identified on HE-stained Barrett's esophagus. It has been hypothesized that Barrett's adenocarcinoma follows the metaplasia-dysplasia-adenocarcinoma sequence^[10]. At present, however, the importance of IM at gastric cardia remains unclear. Apparently, reflux esophagitis is not correlated with IM at gastric cardia in Chinese population. Chronic carditis may contribute to the development of IM at gastric cardia. Further research in large scale and long-term follow-up are needed to evaluate whether neoplastic progression of GCA is related to IM and its mucin profile.

The present study showed that incomplete IM and colonic IM coexisted in the same area or different areas of one sample. Some stomach glands presented blue acid mucous of intestinal IM and brown-black sulfuric acid mucous of colonic IM. The possible explanation is the multipotent stem cells in the neck of gastric glands are to differentiate different types of epithelium due to the irritation of various initial agents, leading to different mucous reaction.

Abstract

AIM: To investigate the association of cyclooxygenase-2 (COX-2) expression with angiogenesis and the number and type of inflammatory cells (macrophages/Kupffer cells; mast cells) within primary hepatocellular carcinoma (HCC) tissues and adjacent non-tumorous (NT) tissues.

METHODS: Immunohistochemistry for COX-2, CD34, CD68 and mast cell tryptase (MC_T) was performed on 14 well-characterized series of liver-cirrhosis-associated HCC patients. COX-2 expression and the number of inflammatory cells in tumor lesions and surrounding liver tissues of each specimen were compared. Moreover, COX-2, CD34 staining and the number of inflammatory cells in areas with different histological degrees within each tumor sample were comparatively analyzed.

RESULTS: The percentage of COX-2 positive cells was significantly higher in NT tissues than in tumors. COX-2 expression was higher in well-differentiated HCC than in poorly-differentiated tissues. Few mast cells were observed within the tumor mass, whereas a higher number was observed in the surrounding tissue, especially in peri-portal spaces of NT tissues. Abundant macrophages/Kupffer cells were observed in NT tissues, whereas the number of cells was significantly lower in the tumor mass. However, a higher cell number was observed in the well-differentiated tumor and progressively decreased in relation to the differentiation grade. Within the tumor, a positive correlation was found between COX-2 expression and the number of macrophages/Kupffer cells and mast

cells. Moreover, there was a positive correlation between CD34 and COX-2 expression in tumor tissues. Comparison between well- and poorly-differentiated HCC showed that the number of CD34-positive cells decreased with dedifferentiation. However, COX-2 was the only independent variable showing a positive correlation with CD34 in a multivariate analysis.

CONCLUSION: The presence of inflammatory cells and COX-2 expression in liver tumor suggests a possible relationship with tumor angiogenesis. COX-2 expressing cells and the number of macrophages/Kupffer cells and mast cells decrease with progression of the disease.

INTRODUCTION

Cyclooxygenase-2 (COX-2) is an inducible immediate early gene associated with inflammation, cell growth and differentiation, prevention of apoptosis and tumorigenesis^[1]. A substantial body of evidence supports the role of COX-2 in the angiogenesis of a variety of human malignancies^[2-3]. Recent studies have already shown an increased expression of COX-2 in patients with liver disease, suggesting the role of COX-2 in chronic liver disease and during the progression of HCC^[6-8]. In addition, COX-2 expression is reported to correlate with tumor angiogenesis in patients with hepatitis C or B virus-associated HCC^[9,10].

Macrophages are an important source of angiogenic activity in wound healing, cancer, and chronic inflammation. They can produce various growth factors and cytokines that promote angiogenesis. The presence of infiltrating macrophages is closely associated with angiogenesis in several types of malignancies, including melanoma^[11], breast^[12], prostate^[13] and lung^[14] cancer, glioma^[15], cervical^[16] and esophageal carcinoma^[17]. In the liver, infiltrating macrophages

and Kupffer cells which are considered as resident macrophages, play an essential role not only in host defense but also in homeostatic responses of tissue^[18-20]. However, their role in the process of tumor progression and angiogenesis is not well understood.

Mast cells (MCs) circulate in blood as progenitors and undergo terminal differentiation into mature cells only when they enter the tissues. Mast cells release a variety of factors known to enhance angiogenesis, namely heparin, histamine and tryptase, as well as cytokines, such as transforming growth factor- β (TGF- β), tumor necrosis factor- α (TNF- α), interleukin-8 (IL-8), fibroblast growth factor-2 (FGF-2) and vascular endothelial growth factor (VEGF). MC density is highly correlated with the extent of both normal and pathological angiogenesis in chronic inflammatory diseases and tumors^[21,22]. MCs are present in both normal and pathological livers^[23,24]. Their role in tumor angiogenesis is not entirely clear, although MCs are of primary importance in the transition from sinusoidal to capillary-type endothelial cells during HCC growth.

Although, as quoted above, some studies on the liver have evaluated the relationship between COX-2 and angiogenesis, or the relationship between the presence of macrophages and mast cells and the different liver pathologies, no studies are available to date on the possible relationship between the various parameters. Therefore, we investigated the association of COX-2 expression with the number of microvessels, the number and type of inflammatory cells in primary hepatocellular carcinoma and adjacent non-tumorous tissues; compared within the same tumor specimen of the two areas with the greatest difference in differentiation grade, and evaluated which of the parameters analyzed could play a prominent role in the neoangiogenesis of HCC.

MATERIALS AND METHODS

Patients and tissue samples

The study included 14 primary HCC patients whose main clinical characteristics are shown in Table 1. Diagnosis was made according to the pathological findings in all cases. All the patients with known cirrhosis were enrolled in a prospective study for HCC screening. The disease was associated with the presence of serum HCV antibodies in all cases. None of the patients was positive for HBsAg. HCC was histologically

graded by two pathologists (AMF and CT) and divided into well-differentiated (WD), moderately-differentiated (MD) or poorly-differentiated (PD) types. Nine of the fourteen patients showed different histological grades (WD+MD+PD) in a single nodule (Table 1). However, a total of 23 tumor sites (11 well-differentiated and 12 poorly-differentiated) were analyzed (Table 1). In order to analyze the different parameters during tumor progression and to avoid variability between the different patients, we compared the two areas with the greatest difference in differentiation grade (i.e. well-differentiated *vs* poorly-differentiated, $n = 9$) within the same tumor specimen.

Histochemical staining

Specimens were fixed in formalin and embedded in paraffin. Four micrometer-thick sections were cut, dewaxed and hydrated. In the case of COX-2 and mast cell tryptase (MC_T) staining, the sections were first heated in a microwave oven (3-4 cycles of 5 min each) in 10 mmol/L citrate buffer (pH 6.0) and then washed twice with PBS for 5 min. All sections were incubated with 30 mL/L hydrogen peroxide in methanol for 5 min to inhibit endogenous peroxidase. Immunohistochemistry was performed by the streptavidin-biotin complex (StreptABC) using the following antibodies: rabbit polyclonal antibody against COX-2 (Cayman, Chemical, MI, USA) at a dilution of 1:100 for 2 h at 37 °C, and mouse mAb against CD68 (clone PG-M1, Dako, Copenhagen, Denmark) at a dilution of 1:50 and CD34 (Clone Qbend/10, Menarini, Florence, Italy) at a dilution of 1:30, or anti-human mast cell tryptase (clone AA1, Dako, Copenhagen, Denmark) at a dilution of 1:150 for 30 min at room temperature. Sections were then incubated for 30 min at room temperature with biotinylated anti-rabbit or anti-mouse immunoglobulin diluted in PBS and streptavidin-biotin complex for 30 min at room temperature. The color was developed with 3-amino-9-ethyl-carbazole (AEC) (Dako, Copenhagen, Denmark) for 5-10 min at room temperature and counterstained with Mayer hematoxylin for 3 min.

Evaluation of COX-2 expression, determination of the number of macrophages/Kupffer cells, mast cells and microvessels

Immunohistochemical staining for COX-2 was semi-quantitative

Table 1 Patient characteristics and histological features of HCC

TR: trabecular; PS: pseudoglandular; COM: compact. WD: well-differentiated; MD: moderately-differentiated; PD: poorly-differentiated.

tatively evaluated by two independent observers (AMF, CT) using a scale of 0-5, according to both degree and intensity of staining, in which 0: negative, 1: positive staining in 1-20% of cells, 2: in 21-40%, 3: in 41-60%, 4: in 61-80% and 5 \geq 81%.

When the number of macrophages and mast cells was determined, the CD68-positive and MC_T-positive cells were counted respectively. Intra-tumoral microvessels were assessed by immunostaining with anti-CD34. All stained endothelial cells or cell clusters were counted as one microvessel. Branching structures were counted as a single vessel. The same two evaluators (AMF and CT) performed the counts. Briefly, stained sections were observed at 100 \times magnification to identify the areas with the highest number of positive cells. Counts were performed in five regions at 200 \times magnification. A scale of 0-5 was used for CD68, in which 0: negative, 1: 1-15 positive cells, 2: 16-30, 3: 31-45, 4: 46-60 and 5 \geq 61. In the case of CD34, a scale of 0-4 was used, in which 0: negative, 1: 1-20 microvessels, 2: 21-40, 3: 41-60, 4: \geq 61. For MC_T, the mean of the five counts was used directly because a small number of cells were observed.

Statistical analysis

Data were expressed as median and range (min-max). The Mann-Whitney *U* test and Spearman's rank correlation test were used when appropriate. Multiple linear regression analysis was used to study the association between increased values of CD34 and values of COX-2, CD68, and MC_T. The linear regression equation was used to describe a linear

relationship between the dependent variable (CD34) and one or more explanatory variables. $P < 0.05$ was considered statistically significant.

RESULTS

Expression of COX-2

COX-2 expression was detected in all the HCCs studied by immunohistochemical analysis. The percentage of COX-2 positive cells was significantly higher in non-tumor (NT) tissues than in tumors ($P < 0.0001$) (Figure 1 and Table 2). COX-2 showed a diffuse cytoplasmic localization in NT hepatocytes, whereas it showed a cytoplasmic dot-like pattern in tumor cells. COX-2 expression tended to be higher in well-differentiated than in poorly-differentiated HCC tissues ($z = 4.2$, $P < 0.0001$). As shown in Figures 1B and C, a clear difference in COX-2 staining was observed at the boundary of HCC tissues with different histological grades.

Immunostaining of macrophages

In this study, anti-CD68, an anti-human macrophage antibody, was used to identify the macrophages. However, in the CD68-positive (CD68+) cells, short spindle cells were considered to be Kupffer cells, whereas migrating macrophages were those with oval shape and abundant cytoplasm. The total number of CD68+ cells was calculated in all cases. The expression of CD68+ cells was significantly higher in non-tumor tissue than in tumor itself ($P < 0.0001$, Figure 2 and Table 2). In addition, the number of CD68+ cells reduced as the histological grade decreased

Figure 1 Immunohistochemical expression of COX-2 in cirrhotic liver area (A), well- and moderately-differentiated HCC areas (B), well-differentiated

HCC with trabecular arrangement and poorly-differentiated HCC with loose cohesive pattern (C) ($\times 250$).

Figure 2 Immunohistochemical staining with anti-CD68 highlights the number of histiocytes in cirrhotic liver cells (A), well-differentiated HCC (B) and poorly-

differentiated HCC (C). (A, C $\times 250$; B $\times 400$).

Table 2 Mann-Whitney analysis of score representing immunostaining for COX-2, CD68 and number of MCs in liver cirrhosis and HCC tissues

	LC	HCC	z	P
COX-2	5 (3-5)	1 (0-5)	3.7	<0.0001
CD68	5 (3-5)	3 (0-4)	4.2	<0.0001
MC _T	4 (2-18)	1 (0-10)	4	<0.0001

LC: liver cirrhosis; HCC: hepatocellular carcinoma.

(Figures 2B and C) and was completely absent in some cases of poorly-differentiated HCC.

Immunostaining of mast cells

Mast cells were recognized by using anti-human tryptase mAb. Tryptase is a neutral protease contained in the secretory granules of MCs. Tryptase-positive mast cells (MC_T) were abundant and mainly localized in the portal tracts of non-tumorous liver tissues (Figure 3A). The number of MCs was significantly lower in HCC tissue than in surrounding cirrhotic liver tissue ($P<0.0001$, Figure 3A and Table 2). However, different histological grades of HCC showed different number of MCs (Figure 3B), well-differentiated HCC showed the highest number of MCs which tended to decrease in less-differentiated HCC ($z = 4.1$, $P<0.0001$).

Figure 3 Immunohistochemical staining with anti-human mast cell tryptase in cirrhotic and HCC tissues (A) and in well-differentiated HCC and moderately-differentiated HCC (B). (x 250).

Immunostaining of endothelial cells

The presence of microvessels inside the tumor mass was evaluated by staining endothelial cells with anti-CD34 antibody. In the surrounding cirrhotic tissue CD34-positive

cells were found only in the portal tracts and septa. As shown in Figure 4, CD34+ cells were clearly found in well-differentiated HCC, whereas poorly-differentiated HCC showed few or no vessels (Figure 4B). The mean score was 2 (0-14) in well- and 0 (0-2) in poorly-differentiated HCC ($z = 3.3$, $P<0.001$).

Figure 4 Immunohistochemical expression of CD34 underlining striking differences between well-differentiated HCC (A) and poorly-differentiated HCC (B). (x250).

COX-2 expression as evaluated in all HCC sites (WD-HCC+PD-HCC, $n = 23$) significantly correlated with the presence of macrophages ($P<0.001$), mast cells ($P<0.0001$) and CD34 expression ($P<0.0001$). The presence of CD68+ cells significantly correlated with the number of MC_T ($P<0.0001$) and CD34 expression ($P<0.001$). The number of MC_T in HCC significantly correlated with CD34 expression ($P<0.001$).

To confirm the relationship between angiogenesis expressed as CD34 (dependent variable) and other parameters (independent variables), multiple linear regression analysis was performed. A close association was found between CD34 and COX-2 ($\beta = 0.69$, $P<0.002$, $R^2 = 0.65$), while no association was found between CD68 ($P<0.07$) and MC_T ($P = \text{not significant}$).

DISCUSSION

Tumor angiogenesis is essential for tumor growth, and depends on angiogenic factors produced by tumor cells and/or infiltrating cells in tumor tissue. The tumor microenvironment largely orchestrated by inflammatory cells is an indispensable participant factor in the neoplastic process. The inflammatory component of a developing neoplasm includes a varied leukocyte population, e.g., macrophages, neutrophils, eosinophils, and mast cells, all of which are variably loaded

with an assorted array of cytokines, cytotoxic mediators including reactive oxygen species, serine-, cysteine-, and metalloproteases, membrane-perforating agents, and soluble cell killing mediators, such as TNF- α , interleukines, and interferons^[24,25].

In recent years, a number of studies have correlated COX-2 expression with tumor angiogenesis^[2-5]. In addition, accumulation of inflammatory cells, macrophage and mast cells coupled with angiogenesis can be found in the literature^[11-17,20,21].

In this study, we evaluated the association of COX-2 expression with angiogenesis and the number and type of inflammatory cells in primary HCC and surrounding NT tissues, as well as their association with differentiation grades in HCC tissues. A previous study demonstrated that dedifferentiation occurs with time and tumor growth^[26]. In our study, a single tumor node showing areas with different histological grades was found in most HCC tissues. This allowed us to compare well-differentiated tumors with poorly-differentiated tumors in the same subject, and therefore to determine the role of molecules and cells analyzed during HCC progression.

We found that COX-2 expression and the number of macrophages/Kupffer cells and MCs were higher in adjacent NT tissues than in tumors. However, due to our limited patient population ($n = 14$) no correlation was observed by comparing each parameter in NT and tumor tissues in the same patient (data not shown). In addition, no correlation was found between the presence of inflammatory cells and COX-2 expression in peri-tumorous cirrhotic liver (data not shown).

We found that COX-2 was expressed in all HCC cases, which is in agreement with the results reported by Koga^[6] and Bae^[8]. COX-2 expression was higher in well-differentiated HCC than in poorly-differentiated HCC, suggesting that COX-2 may be involved in the early stages of hepatocarcinogenesis. The reduction of COX-2 expression during tumor progression is not common in all types of cancer. A possible explanation of this different behavior is that, in some cell types COX-2 over-expression may cause a growth disadvantage during tumor progression. This is in agreement with the results of Trifan *et al.*^[27], who reported that COX-2 overexpression is able to induce cell cycle arrest in a variety of cell types.

Although the functions of intra-tumor macrophages/Kupffer cells and MCs are still unclear, two hypotheses have been advanced about their possible role in tumor lesions. One hypothesis suggests that both cell types are important in the host defense mechanism and anti-tumor effects, the other postulates that they may directly promote tumor growth, invasion and neovascularity. Our results, in agreement with previous observations, show that there is a significant difference in the number of CD68+ cells between well- and poorly-differentiated HCC, and that the latter contains few of these cells. Similarly, the number of MC_T decreases significantly with tumor dedifferentiation. These results suggest that the decrease in inflammatory cells is closely related to the differentiation grade and tumor progression. In view of these results, it is reasonable to hypothesize that both cell types may have an inhibitory effect on HCC cell proliferation.

Moreover, the data of this study seem to suggest a correlation between both cell types and COX-2 expression and tumor angiogenesis, although COX-2 expression is the only independent variable that shows a significant positive correlation with CD34.

In conclusion, there is a relationship between COX-2 expression and the neovasculature of human HCC. Therefore, it is likely that COX-2 inhibition may block HCC-associated angiogenesis, thus providing a rationale for the use of selective COX-inhibitors in the treatment of this malignancy.

HIF-1 α co-localized in cancerous tissues. Notably, the formation of 8-oxodG was correlated significantly with lymphatic invasion ($r = 0.386$ and $P = 0.018$). Moreover, 8-nitroguanine and 8-oxodG in non-cancerous tissues were associated significantly with neural invasion ($P = 0.042$ and $P = 0.026$, respectively). These results suggest that reciprocal activation between HIF-1 α and iNOS mediates persistent DNA damage, which induces tumor invasiveness via mutations, resulting in poor prognosis.

CONCLUSION: The formation of 8-nitroguanine and 8-oxodG plays an important role in multiple steps of genetic changes leading to tumor progression, including invasiveness.

Abstract

AIM: Nitrative and oxidative DNA damage such as 8-nitroguanine and 8-oxo-7,8-dihydro-2'-deoxyguanosine (8-oxodG) formation has been implicated in initiation and/or promotion of inflammation-mediated carcinogenesis. The aim of this study is to clarify whether these DNA lesions participate in the progression of intrahepatic cholangiocarcinoma.

METHODS: We investigated the relation of the formation of 8-nitroguanine and 8-oxodG and the expression of hypoxia-inducible factor-1 α (HIF-1 α) with tumor invasion in 37 patients with intra-hepatic cholangiocarcinoma.

RESULTS: Immunohistochemical analyses revealed that 8-nitroguanine and 8-oxodG formation occurred to a much greater extent in cancerous tissues than in non-cancerous tissues. HIF-1 α could be detected in cancerous tissues in all patients, suggesting low oxygen tension in the tumors. HIF-1 α expression was correlated with inducible nitric oxide synthase (iNOS) expression ($r = 0.369$ and $P = 0.025$) and 8-oxodG formation ($r = 0.398$ and $P = 0.015$). Double immunofluorescence study revealed that iNOS and

INTRODUCTION

Intra-hepatic cholangiocarcinoma (ICC), an adenocarcinoma originating from intra-hepatic bile duct epithelium, presents in most cases with an extremely poor prognosis^[1]. The highest proportional incidence of ICC is observed in the north-east region of Thailand, in which *Opisthorchis viverrini* (OV) infection is endemic^[2,3]. Thus, molecular markers serving as predictive factors are needed to provide effective therapy as well as to understand the underlying mechanisms of ICC carcinogenesis.

Infections are well accounted for association with several types of cancer including ICC through chronic inflammation^[4,5]. Production of a large amount of reactive oxygen species (ROS) and reactive nitrogen species (RNS), such as nitric oxide (NO), is associated with an increased risk of human cancer^[6-8]. 8-Oxo-7,8-dihydro-2'-deoxyguanosine (8-oxodG), a marker of DNA damage by ROS^[9], is a mutagenic lesion leading to G \rightarrow T transversions^[10,11], which are frequently found in tumor relevant genes in a variety of cancers. NO generation by inducible nitric oxide synthase (iNOS) is triggered

during infection and inflammation^[12]. Overproduction of NO leads to the generation of various RNS, causing nitrative DNA damage such as 8-nitroguanosine formation^[13]. 8-nitroguanine undergoes spontaneous depurination, which leads to apurinic sites in DNA^[13]. The resulting apurinic sites in DNA can also lead to G→T transversions^[14]. Recently, we have reported 8-nitroguanine formation in the liver of hamsters re-infected with OV^[15-17]. We have also demonstrated the accumulation of 8-nitroguanine in human gastric epithelium induced by *Helicobacter pylori* infection, which is associated with gastric cancer^[18]. Thus, we have proposed that 8-nitroguanine and 8-oxodG can be biomarkers of initiation and/or promotion in cases of carcinogenesis mediated by inflammation. However, the role of 8-nitroguanine and 8-oxodG in tumor progression in ICC has not been elucidated.

Tumor growth induces hypoxia, which is associated with poor prognosis^[19]. Tumor cells adapt to hypoxia by increasing the synthesis of hypoxia-inducible factor-1 α (HIF-1 α), which mediates transcription of various genes, including vascular endothelial growth factor, glucose transporter 1, lactate dehydrogenase and iNOS^[19], in solid tumors. It remains to be clarified whether HIF-1 α is associated with DNA base lesions and tumor invasion, resulting in poor prognosis with ICC patients.

To evaluate prognostic factors in ICC carcinogenesis, we investigated the formation of 8-nitroguanine and 8-oxodG, and the expression of iNOS and HIF-1 α in the liver of ICC patients by immunohistochemistry. We raised a highly specific antibody against 8-nitroguanine without cross reaction by immunizing with an 8-nitroguanine-aldehyde-rabbit serum albumin conjugate. We investigated the association of DNA damage in the liver tissue with neural and lymphatic invasion in ICC patients.

MATERIALS AND METHODS

Subjects

This study was approved by the Ethics Group of the Human Research Committee, Khon Kaen University, Thailand. Patients undergoing surgical resection of hepatogastrointestinal cancer in 1998 and 1999 at the Department of Surgery, Faculty of Medicine, Khon Kaen University, Thailand, were asked to volunteer for this study. Informed consent was obtained from each subject. Gross appearance of 37 surgical specimens was classified as periductal-infiltrating (11 patients) or mass-forming (26 patients) types. In addition, nine healthy individuals of accidental cause of death were used as controls.

Specimen collection and storage

ICC cases were clarified by physicians using clinical finding and laboratory investigation such as tumor markers, including α -fetoprotein, carcinoembryonic antigen and carbohydrate antigen 19-9, X-ray and histological examination. Liver tissues in both cancerous and adjacent non-cancerous region were obtained from the same patients in all cases. Sections were immediately frozen in liquid nitrogen and stored at -80 °C until analysis. The International Union against Cancer TNM classification and staging system were used for tumor assessment. Liver function test and complete blood count were performed

by the hospital laboratory using standard protocols.

Reagents

Highly sensitive and specific anti-8-nitroguanine rabbit polyclonal antibody was raised as described previously^[17]. Mouse monoclonal anti-8-oxodG antibody was purchased from Japan Institute for the Control of Aging (Fukuroi, Japan). Rabbit polyclonal anti-iNOS antibody and mouse monoclonal anti-HIF-1 α antibody were purchased from Calbiochem-Novabiochem Corporation (Darmstadt, Germany). Alexa 594-labeled antibody against rabbit IgG and Alexa 488-labeled antibody against mouse IgG were obtained from Molecular Probes Inc. (Eugene, OR, USA).

Immunohistological staining

Immunohistochemical staining was performed by using immunoperoxidase methods. Sections (thickness, 6 μ m) were deparaffinized in xylene and rehydrated in descending gradations of ethanol. To enhance the immunostaining, sections were placed in citrate buffer (pH 6) and microwaved intermittently for up to 10 min for antigen unmasking. Endogenous peroxidase was quenched by immersion in 30 mL/L hydrogen peroxide (H₂O₂) for 30 min, and then blocked with 10 mg/L skimmed milk for 30 min. These sections were treated with the primary antibodies (2 μ g/mL for 8-nitroguanine and 5 μ g/mL for 8-oxodG) overnight at room temperature. The slides were then washed, and incubated for 3 h with goat anti-rabbit IgG antibody, followed by the treatment with peroxidase-anti-peroxidase complex (1:200) for 1 h for detection of 8-nitroguanine. To detect 8-oxodG, the slides were treated with HRP-conjugated goat anti-mouse IgG antibody (1:200). The immunostaining were developed by using 3,3-diaminobenzidine tetrahydrochloride as a chromogen for 15 min.

The expression of iNOS and HIF-1 α was assessed by using double immunofluorescence technique as described previously^[18]. Briefly, the sections were treated with anti-iNOS antibody (1:300) and anti-HIF-1 α antibody (1:500) and then treated with Alexa 594-labeled antibody against rabbit IgG and Alexa 488-labeled antibody against mouse IgG (1:400 each). The results were analyzed by using a laser scanning microscope.

The following scores were assigned to each specimen according to the degree of staining: 0, negative; +, less than 25% (minimal); ++, 25-50% (moderate); and +++, more than 50% (strong) in the cells of tissue sections.

Histopathological study

Histopathological study was performed by hematoxylin and eosin staining in paraffin sections as described previously^[20]. Neural invasion and lymphatic invasion were assessed by standard method^[21].

Examination of specific IgG antibody against OV antigen and OV eggs

OV-specific IgG antibody was determined by ELISA technique^[22]. Crude somatic antigen of OV was prepared from hamsters infected with 100 metacercariae after 4 mo as described previously^[20]. The OV egg count was determined from 1 g of feces using the formalin-ethyl acetate concentration technique^[22].

Statistical analysis

Significant differences were analyzed by the χ^2 -test. Spearman's rank correlation coefficient served to analyze correlations for qualitative data, while Pearson's correlation coefficient was used for quantitative data. *P* values less than 0.05 were considered to be statistically significant.

RESULTS

Clinical data of ICC patients

ICC samples, comprising 37 matched cancerous and adjacent noncancerous tissues and 9 healthy subjects who died from accidental cases, were collected at the time of surgery. ICC patients included 26 men and 11 women with the mean age 53 ± 11 years. These subjects were verified by histopathological study and comprised of well (15 patients, including 2 patients of papillary), moderately (11 patients) and poorly (11 patients) differentiated adenocarcinoma. The gross appearance was periductal infiltrating (11 patients) and mass forming (26 patients). Tumor size was 3-6 cm (22 patients), 7-10 cm (4 patients) and >10 cm (4 patients). The average of hemoglobin and hematocrit of all patients was $11.7 \pm 2.3\%$ and $34.7 \pm 6.5\%$, respectively. Most of the patients (22 out of 37, 59.5%) had total bilirubin less than 1 mg% without jaundice, and other patients had total bilirubin of 1-10 mg% (5 patients) and >14 mg% (10 patients). Sixty percent was positive for OV antibody and 30% was positive for OV egg, without adult worm in the liver. All patients had no history of infection with hepatitis virus and exposure to aflatoxin.

Formation of 8-oxodG and 8-nitroguanine

Immunohistochemical staining demonstrated that 8-oxodG and 8-nitroguanine formation was observed in inflammatory cells within the liver to a greater extent in cancer patients than in healthy subjects. 8-oxodG and 8-nitroguanine were formed to a much greater extent in cancerous tissues than that in non-cancerous tissues. 8-oxodG formation was observed in tumor cells and inflammatory cells, whereas 8-nitroguanine was formed mainly in inflammatory cells and weakly in tumor cells in cancerous tissues (Figure 1). We have confirmed that the anti-8-nitroguanine antibody is highly sensitive and specific by a dot immunobinding assay and absorption test^[17].

Expression of HIF-1 α and iNOS

Double immunofluorescence staining revealed that HIF-1 α and iNOS expression could be detected in all cancerous tissues and was found to a greater extent than in non-cancerous tissues. Expression of HIF-1 α and iNOS was found in the tumor tissues especially bile duct epithelial cells (Figure 2). Slight immunoreactivity of iNOS was observed in inflammatory cells, especially Kupffer cells, in healthy subjects.

The correlation of 8-oxodG and 8-nitroguanine formation and iNOS expression with tumor invasion

Table 1 exhibits the relationship of DNA damage with lymphatic and neural invasion in ICC patients. Immunoreactivity for 8-oxodG and 8-nitroguanine was stronger in

Figure 1 Localization of 8-oxodG and 8-nitroguanine in cancerous and noncancerous liver tissues in an ICC patient with a well-differentiated adenocarcinoma. Formation of 8-oxodG and 8-nitroguanine was assessed by immunohistochemistry using an immunoperoxidase method. Paraffin sections (6 μ m thickness) were incubated with a rabbit polyclonal anti-8-nitroguanine antibody and a mouse monoclonal anti-8-oxodG antibody. The original magnification is 200 \times .

cancerous tissues than in the adjacent non-cancerous tissues ($P < 0.05$). HIF-1 α could be detected in all cancerous tissues. HIF-1 α expression was correlated with iNOS expression ($r = 0.369$ and $P = 0.025$) and 8-oxodG formation ($r = 0.398$ and $P = 0.015$) in cancerous tissues. Furthermore, iNOS expression was significantly correlated with the formation of 8-oxodG ($r = 0.584$ and $P = 0.00015$) and 8-nitroguanine ($r = 0.328$ and $P = 0.047$). 8-oxodG formation in cancerous tissues was also significantly correlated with increased lymphatic invasion ($r = 0.386$, $P = 0.018$). The formation of 8-nitroguanine and 8-oxodG in non-cancerous tissues was significantly associated with neural invasion ($P = 0.042$ and $P = 0.026$, respectively). Neural invasion was associated with poor survival by generalized Wilcoxon test ($P = 0.021$) using the Kaplan-Meier method (Figure 3). In addition, in cancerous tissues, formation of 8-oxodG and 8-nitroguanine was positively correlated with serum ALT, AST and alkaline phosphatase (ALP) ($r = 0.76$, 0.58 , and 0.96 for 8-oxodG and $r = 0.63$, 0.58 , and 0.86 for 8-nitroguanine, respectively). Moreover, iNOS expression was also associated with ALT, AST, ALP ($r = 0.71$, 0.97 and 0.82 , respectively).

DISCUSSION

Our results showed that both 8-nitroguanine and 8-oxodG were formed in cancerous tissues to a much greater extent than the adjacent non-cancerous tissues. Moreover, the formation of these DNA lesions was correlated with neural and lymphatic invasion. 8-oxodG was formed in tumor cells and inflammatory cells, whereas 8-nitroguanine was observed mainly in inflammatory cells and weakly in tumor cells. These results are consistent with a model in which tumor cells encourage inflammatory cell infiltration in cancerous areas; inflammatory cells then induce 8-nitroguanine and 8-oxodG formation via NO and superoxide anion radical production^[23].

The present study revealed that 8-nitroguanine and 8-oxodG formation was related with serum ALT, AST, and

Figure 2 Localization of iNOS and HIF-1 α in cancerous liver tissues in an ICC patient with poorly-differentiated adenocarcinoma. The expression of iNOS and HIF-1 α was assessed by using double immunofluorescence technique. Paraffin

sections were treated with anti-iNOS and anti-HIF-1 α antibodies. The original magnification is 400 \times .

ALP activity. This result is supported by the report showing that the number of 8-oxodG-positive hepatocytes was correlated with ALT and AST in liver diseases^[24]. These findings can be explained by assuming that increase in NO and ROS not only causes DNA damage, but also induces epithelial bile duct and hepatocyte injury, resulting in an increase in hepatobiliary enzyme activities.

Our results showed that HIF-1 α was associated with iNOS expression and 8-oxodG formation in cancerous tissues. This result is confirmed by immunohistochemistry showing that iNOS and HIF-1 α co-localized in cancerous tissues. HIF-1 α could be detected in all cancerous tissues, suggesting low oxygen consumption in tumor tissues. Tumor cells adapt to hypoxia by increasing the synthesis of HIF-1 α ,

which mediates transcription of various genes, including iNOS^[19]. iNOS expression was correlated with both 8-nitroguanine and 8-oxodG formation. Therefore, we hypothesize that tumor hypoxia induces HIF-1 α expression, and then HIF-1 α mediates iNOS expression, resulting in nitrative and oxidative DNA damage. On the other hand, an increase in NO production through iNOS expression not only causes DNA damage^[25] but also induces the accumulation and activation of HIF-1 α ^[26,27]. Therefore, these findings lead to an idea that reciprocal activation between HIF-1 α and iNOS mediates persistent DNA damage. Hypoxia in tumor cells increases the generation of mitochondrial H₂O₂ at complex III^[28], which may lead to 8-oxodG formation. Interestingly, we found that 8-oxodG formation in cancerous

Non-cancer = noncancerous tissues. 0 = no positive cell, + = positive in few areas or cells, ++ = moderately positive and +++ = predominately positive. ICC samples, comprising 37 matched cancerous and adjacent noncancerous tissues and 9 healthy subjects who died from accidental cases were collected at the time of surgery. ICC patients included 26 men and 11 women with the mean age 53 \pm 11 years. These subjects were verified by histopathological study and comprised well- (15 patients, including 2 patients of papillary), moderately- (11 patients) and poorly (11 patients) differentiated adenocarcinoma. The International Union Against Cancer TNM classification and staging system were used for tumor assessment.

Figure 3 Overall survival curve of ICC patients. *Thin line*, neural invasion evaluated as -; *thick line*, neural invasion evaluated as + (Kaplan-Meier method).

tissues was significantly correlated with lymphatic invasion. In addition, the formation of 8-nitroguanine and 8-oxodG in non-cancerous tissues was significantly associated with neural invasion. These results suggest that DNA damage participates in tumor invasion and/or poor survival. The accumulation of DNA base lesions may contribute to genetic instability and mutations, leading to tumor progression^[14,29]. Recent data have expanded the concept that inflammation is a critical component of tumor progression^[4]. It has been reported that iNOS expression is associated with poor survival in cancer patients^[30,31]. Tumor-derived NO promoted tumor growth and metastasis by enhancing invasive, angiogenic and migratory capacities of tumor cells^[32-34]. Our findings raise the idea that NO-mediated DNA damage plays the key role in tumor progression and poor survival. Together, HIF-1 α may contribute to tumor progression^[35] and subsequent poor prognosis^[36] via a nitrative and oxidative DNA damage-dependent mechanism. Therefore, our results and these reports lead to an idea that tumor hypoxia mediates HIF-1 α expression, followed by iNOS expression, and nitrative and oxidative DNA damage, which induces tumor invasiveness via mutations. Tumor growth facilitates tumor hypoxia and subsequent expression of HIF-1 α and iNOS to cause DNA damage in addition to DNA damage mediated by inflammatory cells, resulting in tumor development. Tumor tissues may undergo development through repetition of this process, resulting in invasion and metastasis, leading to poor prognosis.

The combination of previous data with the results of this study, proposes a model in which 8-nitroguanine and 8-oxodG induced by inflammation and hypoxia may participate in tumor invasion, functioning in combination with DNA damage-independent mechanisms, including NO-mediated promotion of migratory, invasive and angiogenic properties^[37]. We previously reported that OV infection induced the formation of 8-oxodG and 8-nitroguanine through chronic inflammation at the initiation and/or promotion step of carcinogenesis^[16]. In addition, we hypothesize that 8-nitroguanine and 8-oxodG may also contribute to progression of carcinogenesis mediated by chronic OV infection. In this study, we demonstrated earlier that 8-nitroguanine was formed by cancerous tissues in humans, and this observation strongly supports our hypothesis. In conclusion, the formation of 8-nitroguanine and 8-oxodG is mediated by reactive

species generated endogenously in the process of tumor hypoxia. These DNA lesions could contribute to multiple steps of carcinogenesis, leading to tumor progression, including invasiveness.

Abstract

AIM: To detect the expression of a proliferation-related ligand on human hepatocellular carcinoma (HCC) cell lines (SK-Hep1, HLE and HepG2) and in culture medium.

METHODS: APRIL expression was analyzed by Western blotting in HCC cell lines. Effects of APRIL to cell count and angiogenesis were analyzed, too.

RESULTS: Recombinant human APRIL (rhAPRIL) increased cell viability of HepG2 cells and, in HUVEC, rhAPRIL provided slight tolerance to cell death from serum starvation. Soluble APRIL (sAPRIL) from HLE cells increased after serum starvation, but did not change in SK-Hep1 or HepG2 cells. These cells showed down-regulation of VEGF after incubation with anti-APRIL antibody. Furthermore, culture medium from the HCC cells treated with anti-APRIL antibody treatment inhibited tube formation of HUVECs.

CONCLUSION: Functional expression of APRIL might contribute to neovascularization via an upregulation of VEGF in HCC.

INTRODUCTION

Cytokines regulate cellular proliferation and differentiation by binding to their specific receptors on target cells^[1]. Tumor necrosis factor (TNF) is the prototypic member of a family of cytokines playing an important role in immune regulation and cancer^[2,3].

A proliferation-inducing ligand (APRIL), a new member of the TNF family, is reported to stimulate tumor cell growth^[4-6], modulate tumor cell apoptosis^[7-9], or activate nuclear factor-kappa B (NF- κ B)^[10,11]. APRIL also is associated with regulation of humoral immunity^[6,12]. APRIL is a type II membrane protein, which is typical of the TNF ligand family member^[4]. The sequence of the extracellular domain of APRIL shows homology with FasL, TNF α , LT β , TRAIL, TWEAK, and TRANCE^[4]. In particular, APRIL shares significant homology with B-lymphocyte stimulator (BLys)^[13]. Though the TNF ligand family is synthesized into membrane-bound proteins, of which several are cleaved into a soluble form, APRIL is processed intracellularly and secreted from the cell surface^[14].

The expression of APRIL mRNA or protein has been detected in many tumor cells and tissues^[4,5,7], but is almost undetectable in normal tissues^[5]. Hence, APRIL may provide a significant growth advantage to malignant cells. Because soluble APRIL can stimulate tumor cell growth^[1], APRIL may provide its signal in an autocrine and/or paracrine mode^[5].

APRIL binds to two TNF receptor families, transmembrane activator and CAML interactor (TACI) and B cell maturation antigen (BCMA) with relatively high affinity^[6,10,15]. It is clear that TACI and BCMA intracellular signaling is similar to that of other TNF receptor homologs without a death domain^[16,17]. However, the signaling transduction pathway triggered by APRIL that prolongs lymphocyte survival is still not characterized^[18]. A soluble form of BCMA inhibits APRIL activity and decreases tumor cell proliferation^[19]. NZB/WF1 mice, which develop chronic autoimmune disease, can inhibit development of proteinuria and prolongation of survival after being treated with soluble TACI-Ig fusion protein treatment^[20]. These observations imply the importance of APRIL via these receptors with tumor cell or lymphocyte survival. However, in Jurkat cells, APRIL induces cell death and binds to other TNF family receptors^[7]. An additional APRIL-specific receptor expressed on cell surfaces other than TACI or BCMA, is implied adenocarcinoma or fibroblast tumor cells lacking any detectable BCMA or TACI expression even though

these cells respond to growth stimulatory effects of APRIL^[5,19]. However, the function of APRIL in tumor cells is not well elucidated.

Therefore, we investigated the function of APRIL in HCC cell lines and human umbilical vein endothelial cells (HUVEC). We further investigated the expression of APRIL in HCC cells and evaluated the effects of APRIL on neovascularization.

MATERIALS AND METHODS

Cell lines and reagents

Human umbilical vein endothelial cells (HUVECs), and human HCC cell lines, HepG2 and SK-Hep1 cells were purchased from American Type Culture Collection (Rockville, MD, USA). Human HCC cell line, HLE was purchased from the Health Science Research Resource Bank (Osaka, Japan). HCC cell lines were cultured in Dulbecco's modified Eagle's medium (Dainippon Pharmaceutical Co., Ltd., Osaka, Japan) at 37 °C. All media were supplemented with 1% penicillin/streptomycin (GIBCO BRL, Grand Island, NY, USA) and 10% heat-inactivated fetal calf serum (GIBCO BRL). HUVECs were cultured in HuMedia-EG2 (KURABO, Osaka, Japan). Recombinant human APRIL (rhAPRIL) was purchased from ALEXIS Biochemicals (Switzerland). Anti-APRIL polyclonal antibody was purchased from Ψ ProSci Incorporated (Poway, CA, USA). Anti-vascular endothelial growth factor (VEGF) mAb and anti- α -tubulin mAb were purchased from Oncogene Research Products (Boston, MA, USA). Normal rabbit IgG was purchased from Santa Cruz Biotechnology, Inc. (Santa Cruz, CA, USA). Recombinant human VEGF (rhVEGF) was purchased from Peprotech EC Ltd. (London, UK).

Assessment of count of HCC cells and HUVECs

To assess the viability of HCC cells and HUVECs, the 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl tetrazolium bromide (MTT) assay was performed. The cells were plated at a density of 5×10^3 cells/well in 96-well microtiter plates (Corning Glass Works, Corning, NY, USA) and each plate was incubated for 24 h at 37 °C in 50 mL/L CO₂. Reagents were added and the plates were incubated for the indicated time. The live-cell count was determined using a Cell Titer 96 assay kit (Promega, Madison, WI, USA) according to the manufacturer's instructions. The absorbance of each well was measured at 570 nm with a microtiter plate reader (Bio-Rad Laboratories, Hercules, CA, USA).

Western blotting

Expression of APRIL was analyzed by Western blotting. HCC cells were harvested and lysed in lysis buffer (50 mmol/L Tris-HCl, pH 8, 150 mmol/L NaCl, 5 mmol/L EDTA, 1% NP-40, 1 mmol/L phenylmethyl-sulfonyl fluoride) on ice. Protein content was measured using a Bio-Rad protein assay kit (Bio-Rad Laboratories). Equal amounts of protein from each extract were separated by 14% sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE) and transferred onto nitrocellulose membranes (Toyo Roshi, Tokyo, Japan). Blots were blocked by incubation in 5% non-fat dried milk in Tris buffered saline (TBS)

overnight at 4 °C and probed for 2 h at room temperature with primary antibody. The immunoblots were then probed with horseradish peroxidase-conjugated immunoglobulin (Ig) G (1:2 000 diluted with 5% non-fat dried milk in Tris-HCl; pH 7.5 and 0.05% Tween 20). Signal was detected with an ECL kit (Amersham Pharmacia Biotech, Buckinghamshire, UK).

Angiogenesis assay

Matrigel (BD Biosciences, MA) was placed in an 8-well Lab-tek II chamber slide (NUNC™ Brand Products, Denmark) (100 μ L/well) and allowed to set at 37 °C for 30 min. HUVECs were added to each well (4×10^4) and incubated in the culture medium of HCC cells with rabbit IgG or anti-APRIL polyclonal antibody at 37× for 6 h in a 50 mL/L CO₂ atmosphere. Tube formation was observed by microscopy (OLYMPUS, Tokyo, Japan).

RESULTS

APRIL expressions in human HCC cell lines

APRIL expression in 3 human HCC cell lines (SK-Hep1, HLE, HepG2) was investigated. Bands corresponding to the expression in 42 ku unprocessed form of APRIL were observed in all human HCC cell lines (Figure 1). SK-Hep1 or HepG2 cells, were similar, but weaker in HLE cells. In addition to the unprocessed form, a lower molecular weight form (17 ku) was observed in HCC cell lysates and supernatants (Figure 1). This was thought to be a soluble form of APRIL. The soluble form of APRIL was observed in the three HCC cell lysates and supernatants. The soluble form of APRIL was most strongly expressed in supernatant from SK-Hep1 cells.

Figure 1 APRIL expression in human HCC cell lines and their supernatants by Western blotting. Closed arrowhead indicates the expression of unprocessed form of APRIL (42 ku) and open arrowhead indicates the soluble form of APRIL (17 ku).

Effect of recombinant human APRIL (rhAPRIL) in human HCC cell lines and HUVECs

We analyzed the effect of rhAPRIL on proliferation of human HCC cells. After 72-h incubation, the HCC cell counts slightly increased at the concentrations of 1, 10, or 100 ng/mL (Figure 2A), the greatest effects were observed at concentration of 1 ng/mL in HepG2 cells.

Since HCC is generally a hypervascular tumor^[21] and gains its hypervascularity during dedifferentiation and progression^[22], we investigated the effect of rhAPRIL stimulation on the proliferation of HUVECs.

Figure 2 Effects of rhAPRIL stimulation on viability of human HCC cells (A) and

HUVECs (B and C) incubated at different time periods.

An increase in proliferation at the concentration of 100 ng/mL rhVEGF was observed in the presence or absence of FBS and EGF (Figure 2B). In particular, rhVEGF effectively inhibited cell death induced by cell starvation. The cell viability of HUVECs slightly increased with the stimulation of 1 ng/mL rhAPRIL and the same concentration of rhAPRIL inhibited cell death with starvation (Figure 2C). From these results, we confirmed that APRIL could induce cell proliferation and cell death inhibition in HCC cells and HUVECs, but we also observed that the effect of APRIL on HCC cell lines was not so potent.

APRIL could mediate regulation of cell growth, induce XIAP expression and decrease caspase activity^[23]. We examined the expression of apoptosis-related proteins, including FLICE/caspase-8 inhibitory protein (FLIP), X-chromosome-linked inhibitor of apoptosis (XIAP), BclxL, Apaf-1, and smac in HCC cell lines and HUVECs after APRIL stimulation. However, these apoptosis-related proteins did not show changes in expression levels after APRIL stimulation (data not shown).

Regulation of APRIL in human HCC cell lines

We examined the expression of APRIL after serum starvation in HCC cells and HUVECs (Figure 3). Serum starvation increased the expression of both the unprocessed and soluble forms of APRIL in HLE. In SK-Hep1 and HepG2 cells, serum starvation did not induce upregulation of APRIL, however its expression was maintained. sAPRIL eventually disappeared after 24 h of serum starvation in SK-Hep1 cells, whereas HepG2 cells maintained sAPRIL expression.

APRIL was associated with VEGF expression in HCC cell lines

We observed APRIL expression and regulation by serum starvation in human HCC cell lines. In particular, the serum starvation induced APRIL expression in HLE cells. VEGF might be associated with angiogenesis or tumor progression^[24-31] and VEGF expression could be induced by stress, for example hypoxia or ischemia, in HCC cells^[24,25,28,29]. All HCC cell lines showed expression of VEGF with serum starvation, although the modulation of VEGF expression differed among three cell lines (Figure 4A). In SK-Hep1 and HepG2 cells, VEGF expression was stable for 12 h. In contrast, VEGF expression in HLE cells was not observed until 48 h and was less than that in SK-Hep1 or HepG2 cells.

Because APRIL was expressed constitutively in SK-Hep1 and HepG2 and upregulated in HLE cells after starvation,

we considered that APRIL might be associated with VEGF expression in HCC cells. So, we used anti-APRIL antibody to bind to sAPRIL in culture medium and to inhibit APRIL effects mediated by an autocrine or paracrine system. As shown in Figure 4B, blockade of APRIL by anti-APRIL antibody induced downregulation of VEGF expression in SK-Hep1 and HepG2 cells, compared to controls with normal IgG.

Figure 3 Regulation of APRIL expression in HCC cells. Closed arrowhead indicates the expression of unprocessed form of APRIL. Open arrowhead indicates soluble form of APRIL.

Figure 4 Regulation of VEGF expression with starvation in HCC cells incubated with FBS-negative culture (A) and 10 μg/mL anti-APRIL polyclonal antibody or normal rabbit IgG (B).

Finally, we observed that culture medium from the HCC cells incubated with anti-APRIL polyclonal antibody inhibited endothelial cell tube formation in matrigel (Figure 5).

Figure 5 Effect of APRIL on *in vitro* endothelial cell tube formation.

DISCUSSION

Though HCC is the most common primary cancer of the liver and preceded by chronic hepatitis and cirrhosis, the mechanism of hepatocarcinogenesis or tumor progression is complex and not well understood. Cell killing and stimulation of mitosis leading to cell transformation or chromosomal instability induced by recombinogenic proteins during chronic hepatitis may cause carcinogenesis of HCC^[32].

HCC is resistant to conservative chemotherapy and difficult to induce apoptosis with TNF family members^[33]. On the other hand, TNF families, including TNF, TRAIL or Fas, can induce activation of NF- κ B^[33-41] and the tumor itself expresses these ligands^[42,43]. These phenomena suggest that TNF families contribute to tumor progression by autocrine or paracrine systems. In this study, we demonstrated that APRIL, a TNF family member, expressed in HCC cell lines, including SK-Hep1, HLE and HepG2, and sAPRIL was detected in culture medium of these HCC cell lines. However, addition of rhAPRIL did not induce any significant effect on viability of HCC cell lines, except for HepG2 cells stimulated with 1 ng/mL rhAPRIL. Because APRIL can induce both cell proliferation^[4,5,19] and death^[7] of malignant tumors, the result of present study may reflect that APRIL does not induce cell death so much as proliferation in HCC cells. In contrast to other TNF members, which are processed from the cell surface, APRIL is processed intracellularly and sAPRIL is purified^[14]. sAPRIL is used to stimulate tumor cells and induce cell proliferation in previous studies^[4,14]. The unprocessed form of APRIL may have less ability to induce tumor cell proliferation than sAPRIL.

APRIL enhances the growth of several tumor lines, however, the effect is more prominent at the point of tumor implantation than established tumor^[23]. Because expanding solid tumors, including HCC, are advanced with insufficient nutrition or oxygen, they have to get new vascular support to grow. In this study, HUVECs did not show significant cell proliferation or apoptosis inhibition after APRIL

stimulation. But HLE cells showed upregulation of APRIL after 24 h starvation, and further prolonged starvation induced upregulation of VEGF. In SK-Hep1 and HepG2 cells, starvation did not significantly induce the expression of APRIL, however, starvation promptly induced upregulation of VEGF. These results suggest that APRIL may be associated with expression of VEGF and induction of neovascularization in HCC. Further more, blockade of APRIL activity by anti-APRIL antibody induced downregulation of VEGF and inhibited tube formation of HUVECs. These results support the notion that neovascularization and progression of HCC may be induced by APRIL via VEGF expression.

Until now, some factors including VEGF have been identified as mediators of angiogenesis associated with tumors. With regard to HCC, recent studies indicate that angiopoietin^[44,45] is a target of angiogenesis. APRIL may not be critical for HCC progression as a direct effector, but plays an important role in neovascularization of HCC.

Abstract

AIM: To investigate the clinical values of serum free insulin-like growth factor II (IGF-II) levels and IGF-II mRNA in hepatocellular carcinoma (HCC) tissues and peripheral blood for diagnosis of HCC and monitoring of extrahepatic metastasis.

METHODS: Total RNAs were extracted from HCC tissues or peripheral blood mononuclear cells from patients with HCC, liver diseases devoid of cancer, non-hepatic tumors, and healthy controls, respectively. IGF-II cDNAs were synthesized through random primers and reverse-transcriptase, amplified by polymerase chain reaction (PCR), and confirmed by DNA sequencing analysis. Serum free IGF-II levels in patients with different liver diseases were analyzed by an enzyme-linked immunosorbent assay.

RESULTS: The amplified fragments of IGF-II mRNA by RT-PCR were identical to originally designed ones with a size of 170 bp and confirmed by sequencing analysis. The dilution experiments revealed that the lowest sensitivity of our system was 2 ng/L of total RNA. The positive frequencies of IGF-II mRNA were 100% in HCC tissues, 53.3% in para-cancerous tissues, and 0% in non-cancerous tissues, respectively. The serum free IGF-II levels were significantly higher in HCC than those in chronic hepatitis or liver cirrhosis. The positive frequency of circulating IGF-II mRNA was 34.2% in HCC, no amplified fragment

was found in other liver diseases, extrahepatic tumors, and normal controls, respectively. The circulating IGF-II mRNA correlated with the stage of HCC, and its positive rate was 100% in HCC with extrahepatic metastasis and 35.5% in HCC with AFP-negative. No significant correlation was found between tumor sizes and circulating IGF-II mRNA fragment.

CONCLUSION: The abnormal expressions of free IGF-II and IGF-II mRNA are useful tumor markers for HCC diagnosis, differentiation of extrahepatic metastasis and monitoring postoperative recurrence.

INTRODUCTION

Hepatocellular carcinoma (HCC) is one of the most common and rapidly fatal malignancies worldwide, and has been ranked as the second cancer killer in China since the 1990s, particularly in the eastern and southern areas, including the inshore area of the Yangtze River^[1,2]. Major risk factors for HCC in these areas are exposure to aflatoxin B1 (AFB1) and infection by hepatitis viruses^[3]. HCC prognosis is poor and early detection is of utmost importance^[4]. Treatment options are severely limited by the frequent presence of metastases^[2]. Although serum α -fetoprotein (AFP) is a useful tumor marker for the detection and monitoring of HCC development, the false-negative rate with AFP level alone may be as high as 40% for patients with small size HCC^[5]. However, if hepatocyte-specific mRNAs are detected in the circulation, it is possible to infer the presence of circulating, presumably malignant liver cells and to predict the likelihood of hematogenous metastasis^[6,7].

Insulin-like growth factor II (IGF-II) is a mitogenic polypeptide closely related to insulin. Its gene has complex regulation of transcription, resulting in multiple mRNAs initiated by different promoters^[8,9]. IGF-II is speculated to

serve as an autocrine growth factor in various cancers, because they often coexpress IGF-II and IGF-I receptors. IGF-II is a kind of fetal growth factor and highly expressed during hepatocarcinogenesis^[10,11] and reexpression of IGF-II gene has recently been described in HCC^[12,13]. HCC is generally considered to be a hypervascular tumor. Although hepatic arterial embolization is widely used as an effective treatment of HCC on the basis of hypervascularization of HCC, IGF-II may play an important role in the development of neovascularization of HCC, because IGF-II substantially increases vascular endothelial growth factor (VEGF) mRNA and protein levels in a time-dependent manner in human hepatoma cells^[14]. The induction of VEGF by IGF-II was further increased by hypoxia, and IGF-II may be a hypoxia-inducible angiogenic factor in HCC and stimulates the growth of HCC cells *in vitro*^[15,16]. Park *et al.*, reported that most of the cirrhotic and HCC tissues express IGF-II^[17]. However, little is known of the circulating IGF-II in HCC.

In order to investigate the expression of IGF-II-mRNA in patients with liver diseases, we analyzed IGF-II-mRNA in tissues and peripheral blood of patients with HCC by reverse-transcriptase polymerase chain reaction (RT-PCR), and estimated the clinical values of circulating IGF-II mRNA as a peripheral blood tumor marker in diagnosis, differential diagnosis, and hematogenous metastasis of HCC.

MATERIALS AND METHODS

Patients

We studied 111 patients (100 males and 11 females) with HCC treated at Affiliated Hospital of Nantong University, China. The patients' ages ranged from 25 to 80 years (median, 48.3 years). Ninety patients (81%) had a history of cirrhosis, and 32 (29%) had a history of chronic hepatitis. Moreover, 85.6% (95/111) had hepatitis B surface antigen (HBsAg) carriers, 10.8% (12/111) had antibody to hepatitis C virus (anti-HCV, second generation antibody, Shanghai, China) and 14.4% (16/111) antibody to hepatitis G virus by enzyme-linked immunosorbent assay (ELISA, Beijing, China), respectively. Other cases studied included 30 patients with chronic viral hepatitis (23 males and 7 females), 30 patients with acute hepatitis (18 males and 12 females), 25 patients with cirrhosis (16 males and 9 females), 25 patients with non-liver tumors (6 with lung cancer, 6 with gastric cancer, 3 with esophageal cancer, 3 with breast cancer, 3 with colon cancer, 2 with cervical cancer, 2 with pancreatic cancer), and 25 healthy individuals with hepatitis B markers (HBsAg, HBcAb, HBV-DNA, and anti-HCV)-negative and normal serum alanine aminotransferase (ALT) levels from the Nantong Central Blood Bank as a control group.

All patients were diagnosed by blood biochemical tests, viral histology and B-ultrasonic examination. All peripheral blood samples were collected in the morning, with anti-clot heparin, and peripheral blood mononuclear cells were separated immediately, according to the method as described previously^[18]. Serum AFP concentrations ranged from 30 to 2 600 µg/L (median, 418 µg/L) and exceeding 50 µg/L was taken as a positive result. AFP-mRNA in peripheral blood

was also detected in this study as described elsewhere^[7]. The diagnosis of HCC and viral hepatitis was based on the criteria proposed by Chinese National Collaborative Cancer Research Group^[19] and the 2000 Prevention and Cure Scheme of Viral Hepatitis^[20], respectively.

Tissue specimens

Fresh tissue specimens including cancerous, paracancerous, and non-cancerous tissues were collected from 30 patients who underwent operations for liver cancers at the Affiliated Hospital of Nantong University, China. The tissue specimens were immediately frozen in liquid nitrogen and kept at -85 °C until used. The patients included 25 men and 5 women, ranging from 22 to 70 years.

Isolation of total RNA and synthesis of cDNA

Total RNAs were isolated from peripheral blood mononuclear cells and from liver tissues by the guanidine thiocyanate method with RNazole reagent (Promega) and purified as described elsewhere^[21]. RNAs were dissolved in tromethamine-HCl buffer (10 mmol/L, pH 8.0) containing EDTA 10 mmol/L. The concentration of total RNAs was measured by optical density at 260 nm in an ultraviolet spectrophotometer (Shimadzu UV-2201 type, Kyoto, Japan), and calculated µg/mg wet tissue, and it was stored at -85 °C. For synthesis of cDNA, 2 µg of total RNAs was denatured in the presence of random hexamers (200 pmol/L, Promega, Madison, WI, USA) at 95 °C for 5 min and incubated with moloney murine leukemia virus reverse-transcriptase (GIBCO, BRL) at 23 °C for 10 min, 42 °C for 60 min and 95 °C for 10 min, then on ice for 5 min, and stored at -20 °C for PCR analysis.

Amplification of nested polymerase chain reaction

The resulting cDNA was amplified by a nested PCR with two pairs of primers. The oligonucleotides were designed according to IGF-II sequence^[22] and synthesized with synthesizer (Model 381 A, Applied Biosystems, Foster City, CA, USA). The sequences of the 2 external primer pairs used for the initial PCR amplification were IGF-II-1(sense), 5'-ATGGGAATGCCAATGGGGAAG-3' (nt 251-271) and IGF-II-2(antisense), 5'-CTTGCCACGGGGTATC-TGGG-3' (nt 566-586), the size of amplified gene fragment was 336 bp. The sequences of the two internal primer pairs used for the second PCR amplification were IGF-II-3 (sense), 5'-TGCTGCATTGCTGCTTACCG-3' (nt 311-330) and IGF-II-4 (anti-sense), 5'-AGGTCACAGCTGCGG AAACA-3' (nt 461-480). PCR amplification consisted of initial denaturation at 94 °C for 5 min, followed by 94 °C for 25 s, 55 °C for 30 s, and 72 °C for 90 s for 30 cycles. The final product of nested PCR was 170 bp. Human glyceraldehyde-3-phosphate dehydrogenase (GAPDH) genome^[23] was used as a control. Primer sequence for GAPDH was GAPDH-1 (sense), 5'-ACCACAGT-CCATGCCATCAC-3' (nt 601-620) and GAPDH-2 (antisense), 5'-TCCACCACCCTGTTGCTGT A-3' (nt 1 033-1 052), the product of PCR was 452 bp (GAPDH gene transcript, 40 pmol/L). The PCR products were electrophoresed on 2% agarose gels with ethidium bromide staining. The fragment sizes were evaluated using PCR markers (Promega) as molecular weight standards.

Sequencing of PCR products

The 170 bp amplified product of human IGF-II genome was purified with the Montage PCR centrifugal filter devices (Millipore, MA, USA) according to the instruction of protocol. One microgram DNA was used for preparation of sequencing reaction and directly sequenced using the MegaBACE DNA analysis system in MegaBACE DNA sequencer with the DYEnamic ET Dye Terminator Cycle Sequencing Kit (Amersham Biosciences, NJ, USA), following their protocol. The sequences were edited using the MegaBACE Sequence Analyzer Version 3.0 program (Amersham Biosciences) and aligned with the amplified sequences of IGF-II genome, HCC tissue and circulating IGF-II.

Detection of serum free IGF-II protein level

The levels of serum free IGF-II protein in patients with chronic diseases were detected by an enzymatically amplified two-step sandwich-type immunoassay (ACTIVE™ Free IGF-II ELISA, TX). In this assay, standards, controls and serum samples were incubated in microtitration wells, which had been coated with anti-IGF-II antibody. After incubation and washing, the wells were treated with another anti-free IGF-II detection antibody labeled with the enzyme horseradish peroxidase (HRP). After a second incubation and washing step, the wells were incubated with the substrate tetramethylbenzidine (TMB). An acidic stopping solution was then added and the degree of enzymatic turnover of the substrate was determined by dual wavelength absorbance measurement at 450 nm and 620 nm. The absorbance measured was directly proportional to the concentration of free IGF-II present. A set of free IGF-II standards was used to draw a standard curve of absorbance *vs* free IGF-II concentration from which the free IGF-II concentrations in the serum samples can be calculated according to the ELISA routine method.

Statistical analysis

All patients were divided into six groups: HCC, acute hepatitis, chronic hepatitis, cirrhosis, extrahepatic tumor, and normal subjects. Hepatoma tissues were divided into three groups: cancerous, para-cancerous and non-cancerous tissues. Results are expressed as mean \pm SD. Differences between different groups were assessed by the Student's *t* test or the χ^2 test. *P* < 0.05 was considered to be significant.

RESULTS

Amplification of IGF-II mRNA and sensitivity of detection

The fragments of IGF-II genome were amplified by a nested PCR assay from human hepatoma tissues and circulating blood of patients with HCC (Figure 1). The sizes of amplified fragments were identical to the original designed ones, which were 336 bp in single-step PCR, and 170 bp in nested-PCR. Differences between single-step PCR and nested PCR for amplified IGF-II mRNA were compared in 111 peripheral blood samples. The detecting frequency of IGF-II-mRNA was 6.3% (7/111) by single-step PCR and 34.2% (38/111) by nested-PCR. The incidence of nested PCR for IGF-II mRNA amplification was significantly higher than that in single-step PCR (*P* < 0.05). Total RNAs (2 ng/L) extracted from hepatoma tissues were

diluted 10^{-2} - 10^{-8} times and amplified by nested-PCR, and the lowest sensitivity of the assay was 2 ng/L of total RNA (Figure 1A). The positive fragments of IGF-II genome were found distinctly from HCC tissues or peripheral blood of patients with HCC (Figure 1C) and could not be detected from non-cancerous tissues of HCC patients or from peripheral blood of patients with acute hepatitis, chronic hepatitis, liver cirrhosis, and extrahepatic tumors. By sequence analysis, the nucleotide homologies of amplified IGF-II gene fragments from HCC tissue and peripheral blood were identical to the cited sequence of human IGF-II genome (Figure 2)^[22].

Figure 1 Amplification of IGF-II genomes from human hepatoma tissues or circulating blood samples of patients with hepatocellular carcinoma. IGF-II mRNAs were synthesized according to IGF-II cDNA with random hexamers and moloney murine leukemia virus reverse-transcriptase, and detected with different primer pairs by nested PCR (170 bp). The positive fragments of IGF-II genome were found distinctly in hepatoma tissues or in peripheral blood of patients with hepatocellular carcinoma. **A**: the sensitive limitation of our detection system (2 ng/L), using total RNA with 10^{-2} - 10^{-8} fold dilution and then amplified by nested PCR; **B**: the amplified fragments (452 bp) of glyceraldehyde-3-phosphate dehydrogenase genome from liver tissues or peripheral blood as controls; **C**: the amplification of IGF-II genomes in liver tissues (No. 1-4) or circulating blood (No. 5-6). No. 1-2, the positively amplified fragments of IGF-II mRNA from cancerous tissues of patients with hepatocellular carcinoma; No. 3, the positively amplified fragments of IGF-II mRNA from para-cancerous tissue of patients with hepatocellular carcinoma; No. 4, no positively amplified fragment from non-cancerous tissue of patients with hepatocellular carcinoma; No. 5, no positively amplified fragment from circulating blood of patients with liver cirrhosis, and No. 6, the positively amplified fragment from peripheral blood of patients with hepatocellular carcinoma. GAPDH: glyceraldehyde-3-phosphate dehydrogenase. M: DNA molecular weight marker.

Figure 2 Alignment of nucleotide sequences of the amplified fragments of IGF-II genome from cancerous tissue or circulating blood in patients with HCC by sequence analysis. Origin: the cited sequence (170 bp, nt 311-480) of human IGF-II genome²²; Hepatoma: the amplification fragment of IGF-II genome from human hepatoma tissue; PB: the amplified fragment of peripheral blood IGF-II genome from patients with hepatocellular carcinoma.

Expression of total RNA and IGF-II mRNA in HCC

Different expression of total RNA was found in different parts of HCC tissues. The total RNA concentrations were significantly lower in HCC tissues than in self-control surrounding tissues ($P<0.05$) or non-cancerous tissues ($P<0.01$), respectively (Table 1). However, the expression of IGF-II mRNA amplified by nested-PCR was 100% in cancerous tissues, 53.3% in its surrounding tissues, and 0% in its non-cancerous tissues, respectively. The positive frequencies of IGF-II mRNA in HCC tissues or its para-cancerous tissues were significantly higher than those in its non-cancerous tissues ($P<0.01$), respectively.

Table 1 Alterations of total RNA (mean \pm SD) and amplification of IGF-II mRNA in cancerous, para-cancerous, and non-cancerous liver tissues

Groups	n	Total RNA level (μ g/mg wet tissue)	IGF-II mRNA	
			Positive	%
Cancerous tissues	30	13.4 \pm 8.4	30	100
Para-cancerous tissues	30	20.7 \pm 14.6 ^a	16	53.3 ^b
Non-cancerous tissues	30	25.0 \pm 20.2 ^b	0	0 ^b

^a $P<0.05$, ^b $P<0.01$ vs the cancerous tissue group.

Circulating free IGF-II level in patients with chronic liver diseases

The levels of serum free IGF-II protein in patients with chronic liver diseases were investigated in this study, and the results are shown in Table 2. Of the 166 cases with chronic liver disease, the level of circulating free IGF-II protein was significantly higher ($P<0.01$) in HCC patients (75.7%, 84/111) than in patients with liver cirrhosis (28%, 7/25) or with chronic hepatitis (26.7%, 8/30). Also, the levels of serum AFP in patients with HCC (64.9%, 72/111) were significantly higher ($P<0.01$) than in patients with liver cirrhosis (36%, 9/25) or with chronic hepatitis (23.3%, 7/30).

Table 2 Levels of serum free IGF-II and AFP in patients with chronic liver diseases

Groups	n	Free IGF-II (μ g/L)		AFP (μ g/L)	
		mean \pm SD	>6.0 (%)	mean \pm SD	>50 (%)
CH	30	4.1 \pm 2.4	8 (26.7)	32.0 \pm 23.7	7 (23.3)
LC	25	5.5 \pm 1.7	7 (28.0)	34.7 \pm 39.8	9 (36.0)
HCC	111	6.7 \pm 1.8	84 (75.7) ^b	417.5 \pm 274.1	72 (64.9) ^b

^b $P<0.01$ vs the chronic hepatitis group or the liver cirrhosis group. HCC: hepatocellular carcinoma; LC: liver cirrhosis; CH: chronic hepatitis.

Detection of circulating IGF-II mRNA in HCC

Amplification of IGF-II mRNA in peripheral blood of patients with liver diseases or with extrahepatic tumors in comparison with AFP mRNA is shown in Table 3. Although the serum free IGF-II level increased in patients with chronic hepatitis or with liver cirrhosis, the circulating IGF-II mRNAs only were detected in HCC patients. The frequency of peripheral blood IGF-II mRNA was 34.2% in patients with HCC, no amplified fragments of circulating IGF-II

mRNA could be detected in patients with benign liver diseases, extrahepatic tumors, and normal controls, respectively. The incidence of circulating IGF-II mRNA was lower than that of AFP mRNA in patients with HCC, but it was a more specific circulating marker for HCC diagnosis. Of the 111 cases with HCC, both of AFP mRNA and IGF-II mRNA were detected in 28 patients (25.2%, 28/111), and only 27.0% of HCC cases were positive for AFP mRNA (30/111) or only IGF-II mRNA was detected in 10 patients (9%, 10/111). The combined analysis of circulating AFP mRNA and IGF-II mRNA was useful for diagnosis and differential diagnosis of HCC.

Table 3 Analysis of IGF-II-mRNA and AFP-mRNA in peripheral blood of patients with different liver diseases or non-liver tumors

Groups	n	IGF-II mRNA		AFP mRNA		Both	
		Positive	%	Positive	%	Positive	%
HCC	111	38	34.2	58	52.3	68	61.3
LC	25	0	0 ^b	5	20.0 ^b	5	20.0 ^b

^b $P<0.01$ vs the hepatocellular carcinoma group. HCC: hepatocellular carcinoma; LC: liver cirrhosis; CH: chronic hepatitis; AH: acute hepatitis; ET: extrahepatic tumor; NC: normal control.

Circulating IGF-II mRNA in HCC metastasis

Of the 111 patients with HCC, the relationship between circulating IGF-II mRNA and HCC stages and metastasis is analyzed in Table 4. The fragments of circulating IGF-II mRNA could be detected in any stage of HCC development. No significant differences of IGF-II mRNA were found between HCC stage I and II. The incidence of IGF-II mRNA in HCC stage III was 45.5% (30/66), significantly higher than that in early-stage (stage I or II) HCC. The fragments of IGF-II mRNA could be detected in all HCC patients with extrahepatic metastasis (100%). However, no significant difference of peripheral blood IGF-II mRNA was found between HCC with intra-hepatic metastasis and without intra-hepatic metastasis ($P>0.05$).

Table 4 Relationship between peripheral blood IGF-II mRNA or AFP mRNA and HCC stage or metastasis

Groups	n	IGF-II mRNA		AFP mRNA	
		Positive	%	Positive	%
HCC Stage I	14	2	14.3 ^a	5	35.7 ^a
Stage II	31	6	19.4 ^a	8	25.8 ^a
Stage III	66	30	45.5	47	71.2
Intra-hepatic metastasis					
With	67	27	40.3	44	65.7 ^c
Without	44	11	25.0	18	40.9
Extrahepatic metastasis					
With	13	13	100 ^b	13	100 ^b
Without	98	25	25.5	53	54.1

^a $P<0.05$ vs the HCC stage III group. ^b $P<0.01$, ^c $P<0.05$ vs the non-metastasis group. HCC: hepatocellular carcinoma.

Circulating IGF-II mRNA with AFP level and tumor size

We divided the 111 HCC patients into two groups according to serum AFP level: the positive frequency of circulating IGF-II mRNA fragment was 35.3% (6/17) in cases with AFP less than 50 µg/L, and 34.0% (32/94) in cases with AFP more than or equal to 50 µg/L, without significant differences between the two groups ($P>0.05$). In addition, we found that the incidence of peripheral blood IGF-II mRNA was 31.8% (7/22) in cases with diameters of tumor less than 5 cm, and 34.8% (31/89) in cases with diameters of tumor more than or equal to 5 cm, respectively.

DISCUSSION

Hepatocellular carcinoma is one of the most common forms of malignant cancer with the 4th highest mortality rate worldwide^[24]. Major risk factors for the development of HCC include chronic infections with hepatitis B or C virus, alcohol consumption, exposure to dietary aflatoxin B1, hereditary liver disease or liver cirrhosis of any etiology^[25]. Recent studies have discovered changes in the IGF axis that affect the molecular pathogenesis of HCC, including the autocrine production of IGFs, IGF binding proteins (IGFBPs), IGFBP proteases, and IGF receptor expression. Characteristic alterations detected in HCC and hepatoma cell lines comprise the overexpression of IGF-II and IGF-I receptor emerging as critical events in malignant transformation and growth of tumors^[26,17]. IGF-II is a polypeptide hormone secreted by many organs of the fetus. Very little information is available on the expression of IGF-II mRNA in HCC. In the present study, the total RNA levels and IGF-II mRNA in different parts of HCC tissues, the expression of peripheral blood IGF-II mRNA, and the level of serum free IGF-II protein were investigated in patients with various liver diseases.

The sinusoidal cells in para-cancerous cirrhotic nodule tissues and the malignant hepatocytes in HCC tissues expressed IGF-II. As we know, liver cirrhotic nodules are the precancerous lesion of HCC, so it is suggested that, in the precancerous condition, IGF-II mediated hepatocyte proliferation mainly via IGF1R by a paracrine mechanism. IGF-II mRNA was distributed in the cytoplasm of hepatocytes and overexpressed in HCC tissues^[27,28]. IGF-II could be secreted by hepatoma cells themselves and stimulate their proliferation via an autocrine mechanism^[29,30]. In order to analyze IGF-II expression, the fragments of IGF-II genome in HCC tissues were amplified by the sensitive nested PCR and confirmed by analysis of IGF-II sequences. Although different expression levels of total RNA were found in different parts of HCC tissues, the expression of IGF-II mRNA was detected in all of HCC tissues, half in its para-cancerous cirrhotic tissues, and none in its non-cancerous tissues (Table 1), respectively. Some differences in RNA level between tumor and cirrhotic tissues were quite informative.

The observations that HCC cells expressed less IGF-I than control liver cells, whereas IGF-II expression was higher in a high proportion of HCC cells^[31,32], are consistent with previous reports^[33,34] which showed that IGF-I mRNA levels were lower in HCC as compared with adjacent non-tumorous hepatic tissue, whereas IGF-II mRNA was higher in tumor tissues compared with normal liver tissues. The molecular

mechanisms responsible for reduction in IGF-I and reactivation of IGF-II in HCC remain to be determined. These results support growth factor-dependent HCC development and provide novel prognosis markers after HCC surgery.

IGFs are potent autocrine and paracrine mitogens for liver cancer cell proliferation, and their bioactivity is reduced by IGFBP-3. Human embryonic liver cell lines expressed IGF-II also, suggesting that hepatoma cells may regain some embryonic development characteristics like AFP secretion^[35,36]. A smaller proportion of IGF-II is associated with other IGFBPs, while less than 5% of IGF-II exists as unbound or free IGF-II that is believed to be the biologically active fraction of IGF-II^[37], capable of binding the type 2 IGF receptor^[38]. IGF-II present in the ternary complex is not easily dissociated, however IGF-II contained in low molecular weight binding complexes has a rapid turnover and may be the source of much of the detected free IGF-II. The levels of serum free IGF-II protein were significantly higher in HCC group than those in liver cirrhosis or in chronic hepatitis group (Table 2). The data indicated that serum free IGF-II secreted from HCC cells may act as an angiogenic factor for the hypervascularization of HCC.

Serum AFP is a diagnostic marker of HCC, but its significance in the early diagnosis of HCC is unclear and the positive rate is not high^[5,7,39]. The fragments of peripheral blood IGF-II mRNA were amplified by PCR and its clinical significances in patients with liver diseases were analyzed in the present study (Table 3). Although the serum free IGF-II level increased in patients with chronic hepatitis or liver cirrhosis, the circulating IGF-II mRNA only was detected in HCC patients. The frequency of IGF-II mRNA was not so high in patients with HCC, yet it was more specific (100%) for HCC diagnosis than that of peripheral blood AFP mRNA. No amplified fragments of circulating IGF-II mRNA could be detected in patients with benign liver diseases, extrahepatic tumors, and normal controls. The fragments of circulating IGF-II mRNA could be detected in all HCC patients with extrahepatic metastasis (100%), and like circulating AFP mRNA, could provide markers of severity and prognosis after HCC resection. The analyses of peripheral blood AFP-mRNA and IGF-II mRNA were more specific and more sensitive tumor markers for detecting and monitoring a few of circulating HCC hepatocytes.

In conclusion, the present data indicate that the expression levels of IGF-II mRNA were different in different parts of HCC liver tissues, and IGF-II mRNA could only be detected in peripheral blood of HCC patients. The frequency of circulating IGF-II mRNA and its diagnostic value increased with clinical stage of HCC and with distant metastases of HCC. The circulating IGF-II mRNA could be a useful molecular marker for HCC diagnosis, especially in monitoring extrahepatic metastases of tumor cells. Further studies will allow us to quantitate IGF-II mRNA in liver tissues and peripheral blood, and to explore the molecular mechanisms responsible for reactivation of IGF-II in development of HCC.

Abstract

AIM: To investigate the relation between MUC1 expression, distribution, and prognosis in hepatocellular and cholangiocarcinoma (HCC and CC) and cirrhotic liver tissues, and their significance in HCC and CC diagnosis.

METHODS: Expression and distribution of MUC1 were examined by immunohistochemical assay with anti-MUC1 mAb in 59 samples of HCC and 37 samples of CC, 20 samples of cirrhotic liver tissues, and 10 samples of normal liver tissues, seeking possible associations between MUC1 positive expression, distribution in HCC and CC (primary liver cancer, PLC) cases and the studied clinical data.

RESULTS: Immunohistochemical analysis of MUC1 expression showed that in the 96 PLC samples, 68 (70.8%) were strong positive, and 6 (6.2%) were weak positive. Only 4 in the 20 cirrhotic liver tissues were found to be weak positive, while no expression of MUC1 was detected in normal liver tissues. Apparently, the high expression rate of MUC1 in PLC tissues was statistically significant in comparison to that in cirrhotic and normal liver tissues. The expressed MUC1 protein, stained in dark brownish or brownish-yellow particles, chiefly localized on the cancer cell membranes or in cytoplasm. In the 68 strong positive samples, 40 were detected on cell membrane and the other 28 were in cytoplasm. In addition, follow-up studies of those PLC cases demonstrated that MUC1 expression on cell membrane or in cytoplasm was closely associated with PLC prognosis. The expression of MUC1 in PLC had little statistical significance in respect of the pathological types and sizes of the tumors, but a strong

relationship regarding histological differentiation, metastasis of lymph nodes, portal canal emboli, and post-operational recurrence of the carcinomas. After 3 years of tumor excision, the metastasis rate in MUC1 positive expression group (67.6%) was much higher than that in MUC1 weak expression group (33.3%) and negative expression group (31.8%), and thus the survival rate in MUC1-positive expression group was significantly different from that in weak and negative expression groups.

CONCLUSION: Expression and localization of MUC1 proteins in primary liver carcinomas (PLCs) may act as prognostic markers, and MUC1 molecules might be helpful in differential diagnosis.

INTRODUCTION

Primary liver carcinoma (PLC) is one of the most frequent malignant tumors in clinics, and its tendency to invade and metastasize is the paramount reason for high recurrence after excision, greatly affecting the survival rate of PLC suffers. Even with the developments in PLC therapies, the overall effect is far from radical cure on demand^[1]. Thus, it is quite necessary and important to explore new approaches for early diagnosis and immunological treatment of PLC.

MUC1, also known as polymorphic epithelial mucin, is a group of glycoproteins with high molecular mass. One important characteristic of MUC1 gene is the polymorphism. The second expressed exon within the MUC1 coding genes contains a variable number of tandem repeats (VNTRs), and every VNTR is composed of a 20-amino acid peptide motif as VTSAPDTRPAPGSTAPPAAHG, constituting main antigenic determinants in this region. Usually MUC1 is expressed at a very low level on normal adenocytes, chiefly localized on gland cell surfaces or in gland cavities by excretion, and thus not recognized by the host immune system^[2-4]. It has been found that MUC1 is aberrantly expressed in the forms of misglycolization or incomplete

glycolization, in many tumor tissues like breast, stomach, and colon cancers. These abnormal MUC1 molecules reveal new protein epitopes or carbohydrate antigens, distributed all around the cancer cell surface, and may be recognized by the immune system as notable tumor-associated antigens^[5-9]. As a tumor marker, MUC1 has been applied in breast cancer and other tumors for their diagnosis and biological treatment^[10-13].

During the process of malignant transformation and invasion of tumor cells, the changes of MUC1 glycolization influence the biological behavior of tumor cells^[14]. It was also reported that MUC1 positive expression is an important prognostic indicator in breast cancer and other tumor patients^[15-17]. However, the expression levels of MUC1 in PLC and cirrhotic liver tissues and their correlation with carcinogenesis still remain to be elucidated. In this study, we used immunohistochemical assay to detect MUC1 expression in PLC and cirrhotic liver tissues, and further investigated the potential significance of MUC1 in PLC diagnosis and immunological treatment.

MATERIALS AND METHODS

Clinical data

Ninety-six paraffin-embedded PLC samples were collected from patients undergoing surgery in our hospital from 1990 to 2001. Hepatocellular carcinoma (HCC) was found in 59 patients, and cholangiocarcinoma (CC) in 37 patients. Sixty-six samples were from male patients and 30 from female patients, aged 35-68 years (averaged 41.5 years). Lymph node metastasis was confirmed by pathological examination. No chemotherapy or radiotherapy was given before tumor excision. In the 20 samples of cirrhotic tissues, 12 were from male patients and 8 female patients, aged 19-70 years (averaged 40.7 years). Ten samples of normal liver tissues from 10 cases of hepatic angiomas served as normal controls. All tissue sections were stained with hematoxylin and eosin (H&E).

The diagnosis of HCC was primarily based on history of chronic hepatitis, results of AFP detection, and space occupying lesions in the liver on ultrasonography and CT. The pathological diagnosis of HCC and CC was confirmed by H&E staining of the tissue sections. Patients were regularly examined by ultrasonography and CT after PLC surgery. Tumor recurrence was defined as new focus was detected, and metastasis was defined when lymph nodes of hepatic portal vein became swollen or new foci were found in distal organs.

Preparation of tissue samples

For routine sections, tissue samples were immersion-fixed in 40 g/L buffered formaldehyde for hours, and dehydrated through graded alcohols. After paraffin wax embedding, sections of 5 μ m thickness were cut and mounted on coated glass slides. Then H&E as well as immunohistochemical staining were performed.

Immunohistochemical assay

Endogenous peroxidase blocker and normal house serum were added to all sections for 30-min incubation at room

temperature to minimize non-specific staining, and antigen restoration was performed by microwave method. Mouse anti-human MUC1 mAb working at 1:100 dilution was purchased from Antibody Diagnostica Inc., USA, and ABC diagnostic kit was purchased from Santa Cruz, USA. Detection procedures were performed according to the kit instructions. The cover slide was treated with goat anti-mouse bridging antibody (1:200) for 30 min at 37 °C. Finally, diaminobenzidine tetrachloride was used for color development and the slides were counterstained with hematoxylin. Dehydration, clearing, covering, and light microscopy were performed routinely. Blank test and replacement test were set for negative controls.

Result determination

Brownish-yellow particles under light microscope were considered positive. Three positive levels according to positive cell percentage in five high power, randomized, observation fields were classified: Level 0: cells without stained particles (negative MUC1 expression, -), Level 1: positive cell percentage less than 25% (weak MUC1 expression, +), and Level 2: positive cell percentage more than 25% (strong MUC1 expression, ++).

Statistical analysis

All data were analyzed by SPSS 11.0 (SPSS Inc., USA). Statistical methods included χ^2 -test, Fisher's exact test, and the Kruskal-Wallis test. $P < 0.05$ was considered statistically significant.

RESULTS

MUC1 expression in primary liver carcinoma, cirrhotic liver, and normal liver tissues

In the 96 tested PLC samples, 68 were strong positive (Figures 1A and B) and 6 were weak positive. Only 4 in the 20 cirrhotic liver tissues were found to be weak positive (Figure 1C), while no expression of MUC1 was detected in normal liver tissues (Figure 1D). Apparently, the high expression rate of MUC1 in PLC tissues was statistically significant in comparison to that in cirrhotic and normal liver tissues ($P < 0.05$, Table 1).

Table 1 Expression of MUC1 in PLC, cirrhotic, and normal liver tissues

Group	n	Expression of MUC1		
		-	+	++
Normal liver	10	10	0	0
Cirrhotic liver	20	16	4	0
PLC	96	22	6	68 ^a

^a $P < 0.05$ vs cirrhotic and normal liver tissues.

MUC1 expression was associated with PLC pathology

MUC1 was both expressed in HCC (Figure 2) and CC tissues with no statistical difference between them ($P > 0.05$), demonstrating that MUC1 gene expression was not associated with histological classification of the hepatic tumors. The

sizes of solid tumors were not different in the MUC1 expression either ($P > 0.05$). However, MUC1 expression in well differentiated tumor tissues were significantly different from that in moderately and poorly differentiated tissues ($P < 0.05$), and so did in lymph node metastases, portal vein embolism, and 3-year post-operation recurrence ($P < 0.05$). The association of MUC1 expression and PLC clinical pathology behavior is illustrated in Table 2.

Localization of MUC1 in PLC tissues and prognosis

By immunohistochemical assay, the expressed MUC1 proteins in liver carcinoma tissues were stained as dark brownish or brownish-yellow particles, and mainly localized on the cancer cell membranes (Figure 1A) or in cytoplasm (Figure 1B). Table 3 shows the association of strong MUC1

expression and the prognosis of 68 cases of hepatic tumor.

MUC1 expression and PLC metastasis

Three years after surgery, metastasis occurred in 55 out of

DISCUSSION

To investigate the possible correlation among MUC1 expression and localization and prognosis in PLC and cirrhotic liver tissues, we carried out immunohistochemical assay to detect the MUC1 expression in 96 samples of PLC hepatic tissues. The results showed that MUC1 was strongly expressed on PLC cell membrane or in cytoplasm, while weak and negative expressions were found in human

cirrhotic liver tissues, and no expression was found in normal liver tissues. The difference was of statistical significance. In addition, MUC1 expression increased during the process of transformation from benign cells to malignant cells, which is in accordance with the common understanding of hepatic carcinoma resulting from liver cirrhosis.

There are discrepant results in reports on MUC1 expression and PLC histological differentiation types. Sasaki and Nakanuma^[18] reported that MUC1 core protein is expressed in intrahepatic bile duct carcinoma, but not in HCC. Cao *et al.*^[19] demonstrated that MUC1 is remarkably expressed in HCC cells and can be considered as an indicator of HCC prognosis. In our test, MUC1 expression was not associated with either histological classification or size of the tumors. Based on our testing data, we take it that MUC1 can be used as one of the helping indicators early diagnosis of PLC, by hepatic puncture biopsy before PLC surgery.

In previous studies, it was suggested that high-level MUC1 expression is reversely correlated with prognosis of tumor patients. For example, MUC1 expression is closely related with prognosis of breast cancer sufferers^[3,20]. However, possible association(s) of MUC1 expression levels in PLC liver tissues with the prognosis still remains uncertain. From our test results, it is clear that MUC1 expression levels are quite different in well-differentiated tumor tissues and moderately- or poorly-differentiated tumor tissues, and so are the differences among MUC1 expression and lymph node metastasis, portal vein embolism, and post-operation recurrence. Expression and localization of MUC1 proteins in PLC may act as different prognostic markers of PLC. We also found that the prognosis was worse in cytoplasm expression group than in cell surface expression group. It is reasonable to deduce that MUC1 molecule on cell surface may stimulate protective immunities (for instance, specific cytotoxic T lymphocytes) from the body to fight against the tumor cells.

Intra-hepatic tumor invasion in portal vein system with subsequent metastasis is the major cause of morbidity and mortality in patients with PLC. In our work, it was apparent that MUC1 expression was associated with PLC cell infiltration and metastasis as well. The possible mechanisms might be as follows. (1) E-cadherin is a transmembrane glycoprotein that mediates calcium-dependent, inter-cellular adhesion and is specifically involved in epithelial cell-to-cell adhesion. In cancers, decreased E-cadherin expression is one of the alterations that characterize the invasive phenotype, and the data support its role as a tumor suppressor. Studies have shown that aberrant E-cadherin expression is associated with the acquisition of invasiveness and more advanced tumor stage for many cancers including lung cancer, prostate cancer, gastric cancer, and breast cancer, indicating that MUC1 promotes tumor metastasis by downregulating E-cadherin expression and its binding to beta-catenin^[21-23]. (2) MUC1 acts as anti-cell adhesion molecules. High density of filamentous MUC1 molecules expressed on tumor cell surface might prevent binding between membrane-anchored ligands and corresponding receptors, minimize intercellular interactions induced by integrin in extracellular matrix, thus facilitating cancer cell invasion^[24,25]. (3) Sialyl Lewis epitopes on MUC1 molecules function as

ligands to E-selectin in injured or inflammatory vascular endothelial cells, and facilitate tumor cell adhesion, infiltration, and metastasis^[26].

Currently, carcinectomy is still one of the major treatments for PLC, but has limitations for PLC patients of life expansion and quality promotion. MUC1 molecules play a double role in tumor genesis and development^[4]. On one hand, aberrant MUC1 expression influences inter-cellular adhesions via surface molecule interactions, and makes easier for tumor cell growth and metastasis. On the other hand, as a hapten with newly formed glycan or peptide epitopes because of incomplete glycolization, MUC1 induces anti-tumor immune responses, and may be a target for tumor immunotherapy. It was reported that clinical MUC1 vaccination trials for breast cancer are in progress^[27]. We also discovered that MUC1 gene vaccination induces specific cytotoxic T lymphocyte responses in mice^[28]. MUC1-targeted tumor therapeutical vaccination may be effective for PLC treatment.

To conclude, we used immunohistochemical assay to detect MUC1 expression in PLC, cirrhotic and normal liver tissues, and the results show that MUC1 may be an indicator for PLC diagnosis and prognosis. As HCC is common in China^[29-31] and most Asian countries^[32-35], further investigations on MUC1 roles in PLC genesis and development are of particular significance in providing new ways of PLC treatment.

Abstract

AIM: Cell adhesion molecules and their signal molecules play a very important role in carcinogenesis. The aim of this study is to elucidate the role of these molecules and the signal molecules of integrins and E-cadherins, such as (focal adhesion kinase) FAK, (integrin linked kinase) ILK, and β -catenin in hepatocellular carcinoma cell apoptosis.

METHODS: We first synthesized the small molecular compound, *S*-(1,2-dichlorovinyl)-L-cysteine (DCVC), and identified it, by element analysis and ^1H NMR. To establish the apoptosis model of the SMMC-7721 hepatocellular carcinoma cell, we treated cells with DCVC in EBSS for different concentrations or for various length times in the presence of 20 $\mu\text{mol/L}$ *N,N*-diphenyl-*p*-phenylenediamine, which blocks necrotic cell death and identified this model by flow cytometry and DNA ladder. Then we studied the changes of FAK, ILK, β -catenin, and PKB in this apoptotic model by Western blot.

RESULTS: We found that the loss or decrease of cell adhesion signal molecules is an important reason in apoptosis of SMMC-7721 hepatocellular carcinoma cell and the apoptosis of SMMC-7721 cell was preceded by the loss or decrease of FAK, ILK, PKB, and β -catenin or the damage of cell-matrix and cell-cell adhesion.

CONCLUSION: Our results suggested that the decrease of adhesion signal molecules, FAK, ILK, PKB, and β -catenin, could induce hepatocellular carcinoma cell apoptosis.

INTRODUCTION

Apoptosis or programmed cell death is critical for normal development and tissue homeostasis^[1]. However uncontrolled apoptosis may occur after treatment with cytostatic chemicals. It is a pathophysiological process and is associated with the occurrence of various human diseases^[2]. Maintenance of cell-matrix or cell-cell contact is an important cell survival factor^[3-6] and loss of these contacts, or rounding up, is a hallmark of apoptosis. Cell-matrix interactions occur at the closest contact between the cell and the substratum. It was called as focal adhesion. Integrins are mainly engaged in cell-matrix adhesion. Integrin ligated with the extracellular matrix results in activation of focal adhesion kinase (FAK) and integrin linked kinase (ILK). FAK is a 125-ku protein tyrosine kinase, that is critical in transmission of signals from the focal adhesion to the cytoplasm after cell attachment^[7,8]. ILK is another integrin cytoplasmic-binding protein that has been implicated in the regulation of cell adhesion and extracellular matrix deposition as well as the activation of cell survival and proliferative pathways, including those involving MAP kinase, PKB/Akt and GSK-3 β ^[9,10]. Similarly, E-cadherin is a calcium-dependent transmembrane cell-cell adhesion protein, mainly involved in cell-cell adhesion^[11]. When the homophilic interaction in their specific extra-cellular regions occurred, their intra-cellular linked protein, β -catenin, was activated and mediated signal transduction^[12,13]. It seems clear that FAK, ILK, and β -catenin are important for signaling, cell attachment and cell survival. Despite the importance of these proteins in signal transduction and cell survival, there is little evidence about the role of FAK, ILK, and β -catenin in chemically induced models of apoptotic cell death. Therefore, we have investigated the role of FAK, ILK, β -catenin and other related signal molecule such as PKB in SMMC-7721 hepatocellular carcinoma cell using the characterized nephrotoxicant, *S*-(1,2-dichlorovinyl)-L-cysteine (DCVC)^[14,15]. DCVC is metabolized by a β -lyase to a reactive acylating metabolite that covalently modifies cellular macromolecules^[16-18]. The apoptosis of renal proximal tubule epithelial cell (RPTE) induced by DCVC had been reported. Cell death of primary cultured RPTE caused by DCVC treatment is preceded by disorganization of the cytoskeletal network and dissolution of focal adhesion^[14,15]. Thus, this compound is a useful agent to study the role of

cell-cell or cell-matrix adhesion in apoptosis of epithelial cells.

To study the relationship between the cell adhesion signal molecules and cell apoptosis, we found the apoptosis model of the SMMC-7721 hepatocellular carcinoma cell using DCVC and examined the role of FAK, ILK, β -catenin and other related signal molecules in this model.

MATERIALS AND METHODS

Chemicals and antibodies

SMMC-7721 cells were obtained from the Department of Pathology, Shanghai No. 2, Military Medical University (Shanghai, China)^[19]. Anti-FAK and anti-ILK polyclonal antibodies were purchased from Santa Cruz. Anti- β -catenin and anti-PKB mAb were purchased from Sigma. Secondary antibodies conjugated with HRP were purchased from Watson Biotech. (Shanghai). *N,N'*-Diphenyl-*p*-phenylenediamine (DPPD) was from Sigma-Aldrich (St. Louis, MO, USA). DCVC was synthesized by us.

Cell culture and DCVC treatment

SMMC-7721 cells were grown in RPMI medium 1640 supplemented with penicillin and 10% heat inactivated fetal bovine serum in 37 °C and 50 mL/L CO₂. Confluent monolayers of SMMC-7721 in 10-cm dishes were washed with Earle's balanced salt solution (EBSS) twice. Thereafter, cells were treated with DCVC in EBSS for different concentrations or for various lengths of time. To find the apoptosis model, cells were treated with DCVC in the presence of 20 μ mol/L DPPD (stocked in dimethyl sulfoxide), which blocks necrotic cell death but allows the onset of apoptosis^[15,20]. Following treatment with DCVC, cells were allowed to recover in a complete medium containing 20 μ mol/L DPPD.

Western blot analysis

After treatment of DCVC and recovery in complete medium, confluent cells were washed twice with ice-cold PBS and lysed in modified loading buffer containing 50 mmol/L Tris-HCl, pH 6.8, 2% SDS, 10% glycerol and protease inhibitors (1 mmol/L PMSF). The samples were boiled for 10 min and centrifuged at 12 000 *g* for 10 min, and insoluble material was removed. Equal amount of protein were separated on a SDS-PAGE and transferred to PVDF membrane. After being blocked with 3% BSA in PBS (containing 0.05% Tween 20), the membrane was incubated with the appropriate primary antibodies, followed by HRP-conjugated secondary antibodies. Proteins were visualized by fluorography using an enhanced chemiluminescence system (Perfect Biotech, Shanghai).

Synthesis and identification of *S*-(1,2-dichlorovinyl)-L-cysteine (DCVC)

Dry L-cysteine (0.1 mol) and sodium were added in portions to 300 mL of dry ammonia contained in a flask equipped with a magnetic stirrer and a drying tube. The reaction flask was set in a dish, so that alcohol could be applied to prevent frosting. Sodium was added first to give the characteristic blue color, which disappeared when cysteine was added to form the disodium salt. Trichloroethylene (8.96 mL, 0.1 mole) was dissolved slowly in liquid ammonia (25 mL). After 30 min, a stream of air was directed on the reaction flask to

speed up evaporation of ammonia, which required about 2 h. The slightly colored residue was dissolved in 300 mL of water, free from traces of ammonia *in vacuo* and, by the addition of glacial acetic acid, adjusted to pH 5.0 from an initial pH 11.9. The resulting copious precipitate was diluted with one volume of ethanol, cooled overnight in a refrigerator and isolated by filtration. The crude precipitate was dissolved in 600 mL of water at 70 °C, 1 g of activated carbon was added, and the mixture was filtered while it was still hot. An equal volume of ethanol was added to the clear filtrate and, after overnight at 4 °C, 9.1 g of needle-like crystals were obtained. MP 158-159 °C.

DCVC analysis, calculated for C₅H₇NO₂SCl₂: C, 27.79; H, 3.27; N, 6.48; S, 14.84; Cl, 32.82. Found: C, 27.82; H, 3.28; N, 6.47; S, 14.94; Cl, 32.80. ¹H NMR (deuterium replaced DMSO as solvent 300 mol/L) δ : 3.35 (*t*, *J* = 15.50 Hz, *J* = 7.42 Hz, 1 H), 3.53 (*t*, *J* = 15.50 Hz, *J* = 4.05 Hz, 1 H), 3.91 (*t*, *J* = 4.05 Hz, *J* = 7.42 Hz, 1 H), 6.71 (*s*, 1 H). FAB MS: 217 ([MH⁺]).

Detection of cell apoptosis

DNA laddering was determined by agarose gel electrophoresis. Cells were harvested by scraping the adherent cells which were then combined with floating cells present in the culture medium. After centrifugation, the cell pellet was washed once with ice-cold PBS by centrifugation, lysed with lysis buffer (10 mmol/L Tris, 1 mmol/L EDTA, and 2 g/L Triton X-100, pH 7.4), and incubated on ice for 20 min. Cell debris was removed by centrifugation; the supernatant was treated with RNase (60 μ g/mL) for 1 h at 50 °C. The DNA was precipitated with 0.5 mol/L NaCl and equal volume of isopropyl alcohol and separated by electrophoresis on 1% agarose gels.

SMMC-7721 hepatocellular carcinoma cell nuclear fragmentation treated with DCVC was stained with 1 μ g/mL Hoechst 33258 in PBS. After washing with PBS, coverslips were mounted and viewed using a Nikon epifluorescence microscope.

Apoptosis was also determined by cell cycle analysis. Both floating and adherent cells that were trypsinized were pooled and fixed in 100% ethanol (-20 °C). After washing the cells twice with PBS, cells were resuspended in PBS containing 10 μ g/mL RNase A and 7.5 μ mol/L propidium iodide. After 30 min incubation at room temperature, the cell cycle was analyzed by flow cytometry (FAC Scan, Becton Dickinson) and the percentage of cells present in sub-G₀/G₁ was calculated using the LYSIS software (Becton Dickinson).

RESULTS

DCVC induces apoptosis of SMMC-7721 hepatocellular carcinoma cell

SMMC-7721 hepatocellular carcinoma cells were induced into apoptosis in the presence of DCVC (Figure 1). When SMMC-7721 hepatocellular carcinoma cells were treated with 0.02 mmol/L DPPD and various DCVC concentrations for 6 h and then harvested for flow cytometry assay, it was found that the cell apoptosis was induced by DCVC in a dose-dependent manner in the presence of DPPD and when the concentration of DCVC is larger than 0.05 mmol/L, the percentage of cell apoptosis increased rapidly (Figure 2).

Figure 1 Measurement of apoptosis by DNA fragmentation upon treatment with DCVC/DPPD. **A:** SMMC-7721 Hepatocellular carcinoma cells were treated with 0.1 mmol/L DCVC and 0.02 mmol/L DPPD for various time duration, then harvested for DNA fragmentation assay to estimate apoptosis. Lane 1, DNA marker; lane 2, absent DCVC; lanes 3–6 represent tumor cells treated for 1, 2, 4, 6, and 8 h, respectively; **B:** SMMC-7721 hepatocellular carcinoma cells were treated with 0.02 mmol/L DPPD and various DCVC concentrations for 6 h, then harvested for DNA fragmentation assay to estimate apoptosis. Lane 1, DNA marker; lane 2, absent DCVC; lanes 3–6 represent tumor cells treated for 0.02, 0.05, 0.1, and 0.2 mmol/L, respectively.

Similarly, the effect of DCVC on apoptosis was also time-dependent. At the first 4 h, the percentage of cell apoptosis was very low and after that it increased rapidly (Figure 3).

These data demonstrate that the effective apoptosis had not happened until the DCVC concentration and treatment time was high and long enough. We also demonstrate that DPPD alone could not cause cell apoptosis (Figure 4).

DCVC-induced loss of FAK expression in SMMC-7721 hepatocellular carcinoma cell

FAK, as an important cell survival factor, has been implicated in apoptosis induced by various stimuli^[21–23]. Until now, no reports have described the role of FAK in DCVC/DPPD-induced malignant cell apoptosis. We investigated the FAK expression in DCVC-induced SMMC-7721 hepatocellular carcinoma cell by Western blot analysis and found that the level of FAK protein was almost lost (Figure 5).

Interestingly, we found that the FAK expression decreased in a dose-dependent and time-dependent manner. When the cells were treated for 1 h, the protein level of FAK began to decrease, but at that time the percentage of cell apoptosis had no significant decrease. After the treatment time gets

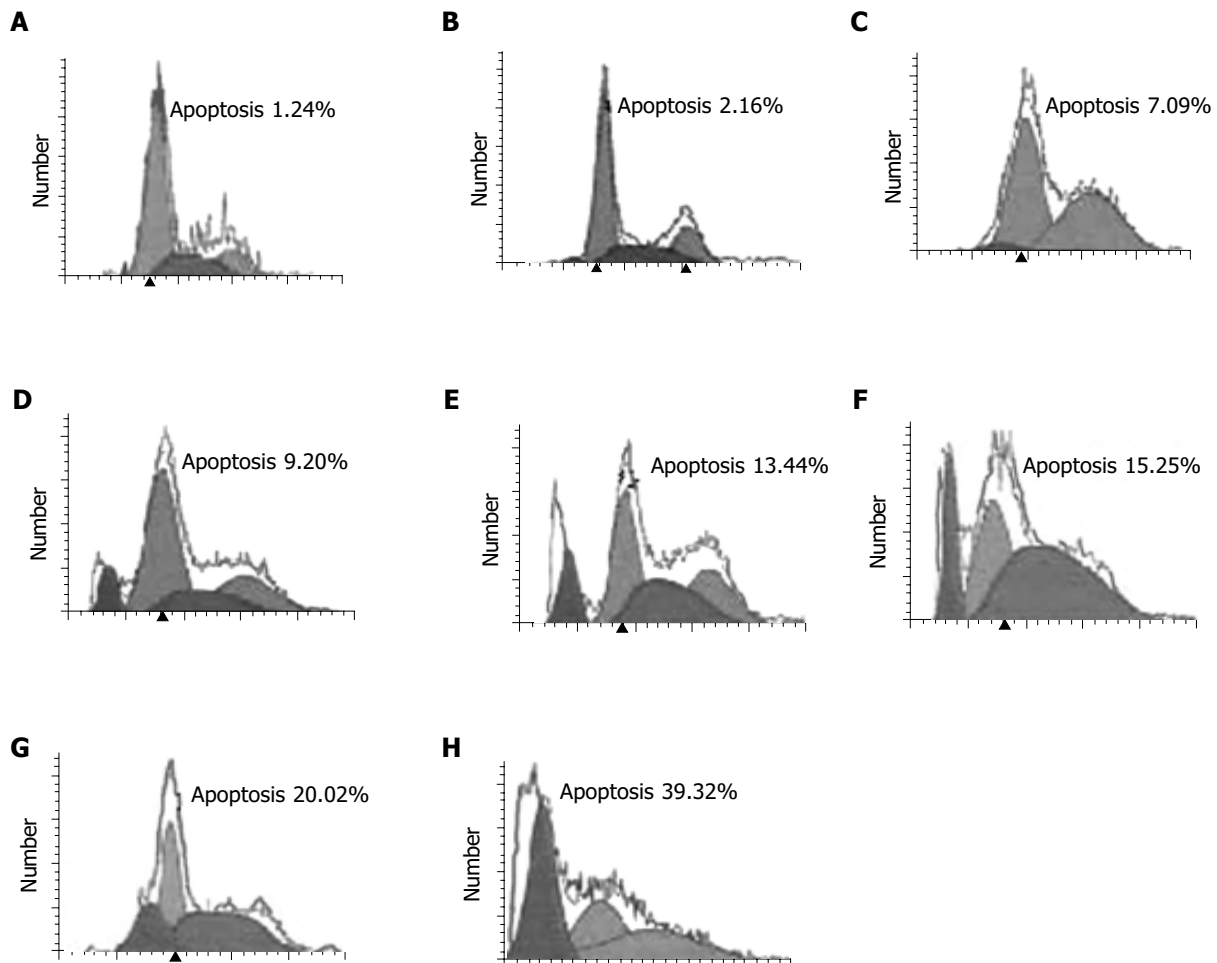

Figure 2 Dose effect on cell apoptosis induced by DCVC co-treated with DPPD. SMMC-7721 hepatocellular carcinoma cells were treated with 0.02 mmol/L DPPD and various DCVC concentration for 6 h, then harvested for flow cytometry

assay to estimate apoptosis. **A:** Absent both DCVC and DPPD; **B:** absent DCVC; **C:** DCVC (0.005 mmol/L); **D:** DCVC (0.01 mmol/L); **E:** DCVC (0.02 mmol/L); **F:** DCVC (0.05 mmol/L); **G:** DCVC (0.1 mmol/L); **H:** DCVC (0.2 mmol/L).

assay to estimate apoptosis. A: absent DCVC, for 8 h; B: for 1 h; C: 2 h; D: 4 h; E: 6 h; F: 8 h.

Figure 4 Role of DPPD in apoptosis of SMMC-7721 hepatocellular carcinoma cell. Cells were cultured in completed medium for 12 h. A: In the absence of DPPD; B: in the presence of 0.02 mmol/L DPPD, then cells were carried out in FMC to estimate apoptosis.

longer than 4 h, the FAK protein was almost lost (Figure 5A) and the percentage of cell apoptosis began to increase rapidly. When the concentration of DCVC was larger than 0.05 mmol/L, the FAK expression almost was not observed (Figure 5B). These results were consistent with the process of cell apoptosis and suggested that cell apoptosis occurred after the cleavage of FAK and the damage of cell-matrix interaction or the focal adhesion.

Figure 5 DCVC effects on FAK protein expression. A: SMMC-7721 hepatocellular carcinoma cells were treated with 0.1 mmol/L DCVC and 0.02 mmol/L DPPD for various time duration; B: SMMC-7721 hepatocellular carcinoma cells were treated with 0.02 mmol/L DPPD and various DCVC concentrations for 6 h, from right the first lane both DCVC and DPPD were absent, the second lane had DPPD but no DCVC. Cells were harvested with 1× SDS loading buffer, followed by Western blot analysis. Equal amounts of cell protein (60 μg) were added to each lane, these studies were repeated thrice with similar results.

ILK level was decreased after the DCVC treatment

ILK is another newly identified, integrin cytoplasmic-binding protein. Overexpression of ILK in cultured intestinal and mammary epithelial cells has been previously shown to induce changes characteristic of oncogenic transformation, including anchorage-independent growth, invasiveness, suppression of anoikis and tumorigenicity in nude mice^[9]. For this reason, we measured the expression of ILK in DCVC-induced SMMC-7721 hepatocellular carcinoma cell by Western blot analysis and found that the level of ILK was also decreased (Figure 6). These findings further demonstrated that the disruption of focal adhesion was taking place in this apoptosis model.

Figure 6 DCVC effects on ILK protein expression. **A:** SMMC-7721 hepatocellular carcinoma cells were treated with 0.1 mmol/L DCVC and 0.02 mmol/L DPPD for various time duration; **B:** SMMC-7721 hepatocellular carcinoma cells were treated with 0.02 mmol/L DPPD and various DCVC concentrations for 6 h, from left the both DCVC and DPPD were absent, the second lane had DPPD but no DCVC. Cells were harvested with 1× SDS loading buffer, followed by Western blot analysis. Equal amounts of cell protein (60 μg) were added to each lane, these studies were repeated thrice with similar results.

β-catenin level was down-regulated in the apoptosis induced by DCVC

E-cadherin-mediated cell-cell adhesion plays a crucial role in intercellular communication, which is related to the regulation of cell proliferation, differentiation, and apoptosis^[24]. β-Catenin regulates cadherin-mediated cell-cell adhesion and also functions as a signaling molecule^[25]. For this reason, we measured the expression of β-catenin in DCVC-induced SMMC-7721 hepatocellular carcinoma cell by Western blot analysis and interestingly found that the level of β-catenin began to decrease for an hour of DCVC treatment and after that, the level of β-catenin decreased further (Figure 7A). Similarly when the dose of DCVC was larger than 0.05 mmol/L, β-catenin also decreased (Figure 7B). These findings suggest that, the cell apoptosis occurred after the decrease of β-catenin and the damage of intercellular adhesion.

Figure 7 DCVC effects on β-catenin protein expression. **A:** SMMC-7721 hepatocellular carcinoma cells were treated with 0.1 mmol/L DCVC and 0.02 mmol/L DPPD for various time duration; **B:** SMMC-7721 hepatocellular carcinoma cells were treated with 0.02 mmol/L DPPD and various DCVC concentrations for 6 h, from left the first lane both DCVC and DPPD were absent, the second lane had DPPD but no DCVC. Cells were harvested with 1× SDS loading buffer, followed by Western blot analysis. Equal amounts of cell protein (60 μg) were added to each lane, these studies were repeated thrice with similar results.

PKB level was downregulated in the apoptosis induced by DCVC

PKB has been demonstrated to play a suppressive role in cell apoptosis^[26]. We therefore investigated the PKB level in

response to DCVC in the presence of DPPD. We found when the time of DCVC treatment was longer or the dose of DCVC was increased, the level of PKB decreased. Particularly, after 4 h of DCVC treatment, PKB obviously decreased and after 8 h, PKB protein almost disappeared (Figure 8).

Figure 8 DCVC effects on PKB protein expression. **A:** SMMC-7721 hepatocellular carcinoma cells were treated with 0.1 mmol/L DCVC and 0.02 mmol/L DPPD for various time duration; **B:** SMMC-7721 hepatocellular carcinoma cells were treated with 0.02 mmol/L DPPD and various DCVC concentration for 6 h, from left both DCVC and DPPD were absent in the first lane, the second lane had DPPD but without DCVC. Cells were harvested with 1× SDS loading buffer, followed by Western blot analysis. Equal amounts of cell protein (60 μg) were added to each lane, these studies were repeated thrice with similar results.

DISCUSSION

In this study, we investigated the level of FAK, ILK, PKB, and β-catenin during apoptosis of SMMC-7721 hepatocellular carcinoma cell induced by DCVC in the presence of DPPD. It was found that the level of each protein mentioned above dramatically decreased. These results suggest that the loss or decrease of cell adhesion signal molecules is an important reason in apoptosis of SMMC-7721 hepatocellular carcinoma cell. The apoptosis of SMMC-7721 was preceded by the loss or decrease of FAK, ILK, PKB, and β-catenin or the damage of cell-matrix and cell-cell adhesion.

FAK has been shown to play a suppressive role in apoptosis induced by various stimuli including H₂O₂ and c-myc, and apoptosis induced by keeping cell in suspension, termed anoikis, which disrupts the interactions between normal epithelial cells and the extracellular matrix^[21,27,28]. Our findings strongly support the view that FAK play a suppressive role in apoptosis. Furthermore, decrease of FAK seems to precede cell apoptosis.

ILK is another integrin cytoplasmic-binding protein that has been identified as a potential PDK-2. ILK is capable of phosphorylating PKB/Akt on Ser-473 and stimulating its activity. Attwell found that overexpression of ILK in SCP2 mouse mammary epithelial cells results in a profound inhibition of anoikis^[29]. Until the present day, no reports have described the role of ILK in the apoptosis of human hepatocellular carcinoma cell. We found that the level of ILK was decreased in DCVC/DPPD-induced apoptosis. This finding is in accordance with that of Attwell's reports^[29].

β-catenin has emerged as an important oncogene in the transformation of a number of epithelial cancers^[30]. It acts as a downstream transcriptional activator of the Wntless-Wnt signaling pathway. The β-catenin-Tcf complex transactivates the downstream genes that regulate cell proliferation or inhibit

apoptosis^[31]. But Kim *et al.*, reported that overexpressed β -catenin induces apoptosis in NIH 3T3 fibroblasts, corneal fibroblasts, corneal epithelia, uveal melanoma cells, and several carcinoma cell lines^[32]. In this study, we found that the level of β -catenin was dramatically decreased in DCVC-induced SMMC-7721 cell apoptosis and the reason needs to be elucidated by further research.

PKB acted as a common downstream signal protein of FAK, and ILK has been demonstrated to play a suppressive role in cell apoptosis^[21,26,29]. Our results showed that the PKB level was decreased with increased DCVC concentration or treatment time, as well as the percentage of apoptotic cells during the apoptosis induced by DCVC in the presence of DPPD.

Our findings indicate that DCVC cause the cleavage of FAK, ILK, β -catenin, and PKB. Cleavage of these proteins may actually ensure that the cell does not attach to matrix or other cells. It blocks the cell-matrix and cell-cell adhesion-mediated signal transduction and gives rise to cell apoptosis. It demonstrates the importance of cell adhesion signal molecules in cell survival. However, the exact way of cleavage of these proteins is still unclear. FAK and β -catenin may be cleaved by caspases, as both have been identified as substrates for caspases^[33,34]. Whether ILK and PKB are also cleaved by caspases or other enzymes, remains to be determined.

In conclusion, the present findings demonstrate that the cell apoptosis occurred after the damage of cell-matrix interaction and cell-cell contact. Cell-matrix and cell-cell adhesion-mediated signal transduction is fundamental for cell survival and many cell adhesion signal molecules such as FAK, ILK, and β -catenin have oncogenic potential and have anti-apoptotic function.

ACKNOWLEDGMENTS

We gratefully appreciate Dr. Hong-Xing Zhang for the assistance of DCVC synthesis. We thank all people in the Flow Cytometry Core Facility of Tumor Hospital at Fudan University for processing the cell apoptosis analysis.

Abstract

AIM: Oligomeric proanthocyanidins (OPC), natural polyphenolic compounds found in plants, are known to have antioxidant and anti-cancer effects. We investigated whether the anti-cancer effects of the OPC are induced by apoptosis on human colorectal cancer cell line, SNU-C4.

METHODS: Colorectal cancer cell line, SNU-C4 was cultured in RPMI 1640 medium supplemented with 10% fetal bovine serum. The cytotoxic effect of OPC was assessed by 3-(4, 5-dimethylthiazol-2-yl)-2, 5-diphenyltetrazolium bromide (MTT) assay. To find out the apoptotic cell death, 4, 6-diamidino-2-phenylindole (DAPI) staining, terminal deoxynucleotidyl transferase (TdT)-mediated dUTP nick end labeling (TUNEL) assay, reverse transcription-polymerase chain reaction (RT-PCR), and caspase-3 enzyme assay were performed.

RESULTS: In this study, cytotoxic effect of OPC on SNU-C4 cells appeared in a dose-dependent manner. OPC treatment (100 µg/mL) revealed typical morphological apoptotic features. Additionally OPC treatment (100 µg/mL) increased level of *BAX* and *CASPASE-3*, and decreased level of *BCL-2* mRNA expression. Caspase-3 enzyme activity was also significantly increased by treatment of OPC (100 µg/mL) compared with control.

CONCLUSION: These data indicate that OPC caused cell death by apoptosis through caspase pathways on human colorectal cancer cell line, SNU-C4.

INTRODUCTION

Oligomeric proanthocyanidins are some of the most abundant polyphenolic substances in the plant kingdom. Proanthocyanidins are an integral part of the human diet, found in high concentration in fruits, vegetables and seeds as well as in most types of tea and red wine^[1]. Numerous studies have reported that flavonoids have potent antioxidant effects through scavenging of superoxide and hydroxyl radicals^[2] and anti-proliferative actions via inhibition of metabolic pathways and inhibition of intra-cellular signal transduction^[3]. In addition, a variety of proanthocyanidins have been shown to be anti-bacterial, anti-viral^[4], anti-carcinogenic^[3-6], anti-inflammatory^[7,8], anti-allergic^[9-11] and consequently reduce the concentration of reactive oxygen species^[12] and low density lipoprotein oxidation^[13], and cardioprotective effects in human beings^[14].

Despite their beneficial effects, the great extent of polyphenolics are not absorbed and metabolized easily due to their chemical structures and the glycosylation, acylation, conjugation, polymerization and the solubility of the compound. Monomeric flavonoids are absorbed in the small intestine. However, polymeric polyphenolics may be degraded by intestinal and colonic microflora, and then excreted in the feces, and the monomers appear to be absorbed in a dose-dependent manner^[15].

Apoptosis, a programmed cell death, also plays an essential role as a protective mechanism against cancer cells^[16]. Induction of apoptosis is a highly desirable mode as a therapeutic strategy for cancer control. In fact, many chemopreventive agents act through the induction of apoptosis as a mechanism to suppress carcinogenesis^[17]. Recently, cancer chemotherapy has gradually improved with the development and discovery of novel anti-tumor drugs, but sometimes these drugs have been limited in clinical application by drug resistance of tumor and by serious damage to the normal tissues and cells.

Oligomeric proanthocyanidins incubated with several human cancer cell lines (breast, lung, gastric, and skin) revealed a selective cytotoxicity for the cancerous cells.

However OPC has not been tested for colorectal cancer which is one of the major cause of cancer-related mortality in the West.

In this study, we examined the inhibitory effects of OPC on cancer cell proliferation, and pharmacological mechanism for anti-tumor effects on human colorectal cancer cell line SNU-C4.

MATERIALS AND METHODS

Materials

Grape seed OPC was donated by Doosan Biotech (Yongin, Korea). According to the manufacturer, this OPC extract contained essentially, dimeric (17.4%), trimeric (16.3%), tetrameric (13.3%) and oligomeric (5-13 Units) (53.0%) proanthocyanidins. DAPI and caspase-3 assay kit were obtained from Sigma (St. Louis, MO, USA). MTT and TUNEL assay kits were purchased from Roche (Roche, Basel, Switzerland).

Cell culture

The SNU-C4 cell line was obtained from Korean Cell Line Bank (KCLB, Seoul, Korea). Cells were cultured in RPMI 1640 medium (Gibco, Grand Island, NY, USA) supplemented with 10% heat-inactivated fetal bovine serum (Gibco). Cultures were maintained in a humidified incubator with 5% CO₂-95% O₂ air at 37 °C, and the medium was changed every 2 d.

MTT assay

Cell viability was determined using the MTT assay kit according to a previously described protocol^[18]. In order to detect the cytotoxicity of OPC, SNU-C4 cells were treated with OPC at the concentrations of 10, 50, 100, and 500 µg/mL for 24 h. The control group was treated with the same amount of vehicle. After the MTT, labeling reagent (5 mg/mL) was added to each group and incubated for 4 h at 37 °C, they were incubated for 12 h with the solubilization solution in which the formazan crystals formed by MTT will be dissolved. The absorbance was measured with a microtiter plate reader (Bio-Tek, Winooski, VT, USA) at a test wavelength of 595 nm with a reference wavelength of 690 nm. The optical density (*A*) was calculated as the difference between the reference wavelength and the test wavelength. Percent viability was calculated as (*A* of drug-treated sample/*A* of none-treated control) ×100.

DAPI staining

The nucleic condensation of apoptosis was determined by DAPI staining. SNU-C4 cells treated with OPC (100 µg/mL) for 24 h were cultured on four-chamber slides (Nalge Nunc International, Rochester, NY, USA). The cells were fixed in 40 g/L paraformaldehyde for 30 min, and were incubated for 30 min in the dark, including 1 µg/mL DAPI solution. They were observed through a fluorescence microscope (Zeiss, Oberkochen, Germany).

TUNEL assay

For detection of apoptotic cells, TUNEL assay was performed by ApoTag[®] peroxidase *in situ* cell death

detection kit (Roche, Basel, Switzerland). After 24 h exposure to OPC (100 µg/mL), cultured SNU-C4 cells were fixed in acetic acid at -20 °C for 5 min. Incubated with digoxigenin-conjugated dUTP in a terminal deoxynucleotidyl transferase-catalyzed reaction for 1 h at 37 °C in a humidified atmosphere. The fixed cells were immersed in stop/wash buffer for 10 min at room temperature, and the cells were again incubated with an anti-digoxigenin antibody conjugating peroxidase for 30 min. The nuclei fragments were stained using 3,3'-diaminobenzidine (DAB) as a substrate for the peroxidase.

RT-PCR analysis

Total RNA was isolated from SNU-C4 cells with RNazolTMB (TEL-TEST, Friendswood, TX, USA) according to the manufacturer's instruction. cDNA was produced using random hexamer primers and reverse transcriptase (Promega, Madison, WI, USA). The corresponding cDNA was amplified in PCR reactions with following primers for *BCL-2* (5'-TCC GTG CCT GAC TTT AGC AAG CTG-3'; 5'-GGA ATC CCA ACC AGA GAT CTC AA-3'), *BAX* (5'-AGA TGA ACT GGA TAG CAA TAT GGA-3', 5'-CCA CCC TGG TCT TGG ATC CAG ACA-3'), and for *CASPASE-3* (5'-CTT GGT AGA TCG GCC ATC TGA AAC-3'; 5'-GGT CCC GTA CAG GTG TGC TTC GAC-3'). *CYCLOPHILIN* (5'-ACC CCA CCG TGT TCT TCG AC-3', 5'-CAT TTG CCA TGG ACA AGA TG-3') was used as an internal standard. The annealing temperature was 50 °C for *BCL-2* and *BAX*, 57 °C for *CASPASE-3*, and 56 °C for *CYCLOPHILIN*. The amplified fragment sizes were respectively 333 bp (for *BCL-2*), 260 bp (for *BAX*), 405 bp (for *CASPASE-3*), and 300 bp (for *CYCLOPHILIN*). The PCR products were electrophoresed on a 1.2% agarose gel, and stained with ethidium bromide. The PCR amplification was performed in 30 cycles for *BCL-2*, *BAX*, *CASPASE-3*, and 24 cycles for *CYCLOPHILIN*.

Caspase-3 enzyme activity

Because caspase-3 is a key step in the regulation of apoptosis, caspase-3 activity was measured using a commercially available kit. Cells were incubated with OPC (100 µg/mL) for 24 h, and were washed with phosphate-buffered saline (PBS) and lysed. Then the lysates were incubated overnight with caspase-3 substrate (Ac-DVED-*p*NA) at 37 °C, and absorbance at 405 nm was measured using a 96-well microtiter plate reader. As a positive control, recombinant caspase-3 protein was incubated with a substrate. As an inhibitor of caspase-3, Ac-DVED-CHO was used.

Statistical analysis

Results were expressed as mean±SE. All experiments were done in triplicate. The data were analyzed by one-way ANOVA followed by Dunnett's post-hoc analysis using SPSS. Differences were considered significant at *P*<0.05.

RESULTS

Cytotoxic effects of OPC on colorectal cancer cell line, SNU-C4

The MTT assay was used to measure the viability of SNU-

C4 cells exposed to OPC. As shown in Figure 1, the viabilities of cells exposed to OPC at concentrations of 10, 50, 100, and 500 $\mu\text{g/mL}$ for 24 h, were $94.03 \pm 0.21\%$, $81.17 \pm 0.35\%$, $35.61 \pm 5.53\%$, and $21.24 \pm 1.31\%$ of control value, respectively. The cytotoxic effect of OPC on SNU-C4 cells appeared in a dose-dependent manner (Figure 1).

Figure 1 Cytotoxic effects of OPC. SNU-C4 cells were treated with various concentrations of OPC for 24 h prior to the determination of cellular viability. Results are presented as mean \pm SE. ^a $P < 0.05$ vs control group.

Morphological changes in OPC-induced cytotoxicity

The morphological changes, DAPI staining, and TUNEL reaction were studied to investigate whether cell death was a result of apoptosis in SNU-C4 cells. Cells treated with OPC (100 $\mu\text{g/mL}$) for 24 h revealed shrinkage of cells through phase-contrast microscope (Figure 2B). To

characterize the cell death induced by OPC, nuclear morphology of dying cells were examined with a fluorescent DNA-binding agent, DAPI. Cells treated with OPC displayed typical morphological features of apoptotic cells, with condensed and fragmented nuclei (Figure 2D). The induction of apoptosis by OPC was examined by *in situ* apoptosis detection. TUNEL assay, based on labeling of DNA strand breaks generated during apoptosis, confirmed that OPC induces apoptosis in SNU-C4 cells (Figure 2F).

Involvement of BCL-2 and BAX genes in OPC-induced cytotoxicity

To examine the role of these BCL-2 family genes in OPC-induced apoptosis, the expression of BCL-2 and BAX genes were evaluated in SNU-C4 cells using RT-PCR. As shown in Figure 3, BCL-2 gene expression was markedly decreased and BAX gene expression was highly increased with OPC treatment.

Involvement of caspase-3 in OPC-induced cytotoxicity

Since caspase-3 plays the critical role in apoptosis, the CASPASE-3 gene expression and caspase-3 enzyme activity were determined through RT-PCR and caspase-3 activity assay. The expression of CASPASE-3 was markedly increased after OPC treatment (Figure 3). The caspase-3 activity was measured using specific substrate (Ac-DEVD-pNA). Caspase-3 protein was used as the positive control, and a caspase inhibitor, Ac-DEVD-CHO was the negative control. As illustrated in Figure 4, caspase-3 specific activity was increased by OPC treatment.

Figure 2 Characterization of OPC-induced cell death in SNU-C4 cells. Cells were cultured without OPC (A, C and E) or with 100 $\mu\text{g/mL}$ OPC (B, D and F). Morphology (top): phase-contrast microscopy shows cell shrinkage, bubble

like bleb in cell membrane and cellular detachment in OPC-treated cultures (B). SNU-C4 cells stained with DAPI staining (D). SNU-C4 cells stained with TUNEL staining (F): Scale bar, 10 μm .

Figure 3 Results of RT-PCR analysis of *BCL-2*, *BAX*, and *CASPASE-3*. As internal control, *CYCLOPHILIN* mRNA was also reverse-transcribed and amplified. (A) Control, (B) 100 µg/mL OPC treated group.

Figure 4 Result of caspase-3 enzyme activity assay. The rate of Ac-DEVD-pNA cleavage was measured at 405 nm. OPC was used as concentration of 100 µg/mL. Caspase-3 was a positive control and Ac-DEVD-CHO was a caspase inhibitor. ^a $P < 0.05$ vs control group.

DISCUSSION

Colorectal cancer is the most common of visceral malignancies with the third most common cause of cancer-related mortality in the West^[19]. Despite improvements in the management of the colon cancer patient, there is little change in survival rates over the past 50 years^[20]. Tumor cells differ from normal cells in their non-responsiveness to normal growth-controlling mechanisms. Current chemotherapeutic drugs try to change the biological properties of cancer cells that continuously divide and grow^[21].

In the present study, we investigated the effect of OPC-induced apoptosis on human colorectal cancer cell line SNU-C4 to define the pharmacological basis for anticancer effects and its mechanism of OPC. OPC, extracted from grape seed showed potent anti-oxidant effects in numerous studies^[22-25]. Additionally, proanthocyanidins exhibit anti-carcinogenic^[3-6], anti-inflammatory^[7,8], anti-allergic^[9,10], cardioprotective activities^[14], as well as being inhibitors of the phospholipase A2, cyclooxygenase and lipooxygenase^[26].

Recently, Carnesecchi *et al.*^[6], reported anti-proliferative effects of procyanidins from cocoa extracts on the growth inhibition of human colonic cancer cell with a blockade of the cell cycle at the G2/M phase. OPC have demonstrated the anti-proliferative effect in murine Hepa-1c1c7^[26],

cytotoxic effects on selected human cancer cells, including cultured MCF-7 breast cancer, CRL 1739 gastric adenocarcinoma and A-427 lung cancer cells^[5]. These reports demonstrated that OPC influences cancer cell proliferation and growth.

The results of present study demonstrated that OPC induce cytotoxic effect measured by the cell viability on SNU-C4 cells in a dose-dependent manner (Figure 1). SNU-C4 cells also showed apoptotic morphological change of nuclear shrinkage, chromatin condensation, irregularity in shape and retraction by the OPC treatment (Figure 2). In this study, we observed the apoptotic morphology of cellular bodies and the chromatin condensation by DAPI staining (Figure 2). It is known that DNA strand breaks occur during the process of apoptosis, and the nicks in DNA molecules can be detected by the apoptotic status of cells through TUNEL assay^[27]. In the present study, typical TUNEL distinction of apoptosis was observed in OPC-treated cells (Figure 2).

In a number of studies, it has been documented that the progress of apoptosis is regulated by the expression of several genes, one of these genes is a member of the *BCL-2* family^[28]. The *BCL-2* family can be classified into two functionally different groups: anti-apoptotic genes and pro-apoptotic genes. *BCL-2*, an anti-apoptotic gene, is known for regulating the apoptotic pathways and protecting cell death, while *BAX*, a pro-apoptotic gene of the family, is expressed abundantly and selectively during apoptosis, promoting cell death^[29]. Our data showed that OPC altered the expression of apoptosis-regulating genes. *BCL-2* gene expression decreased and *BAX* gene expression increased after OPC-treatment (Figure 3).

At the execution phase of apoptosis, a series of morphological and biochemical changes appear to have resulted from the action of caspases^[30]. Caspase-3, in particular, is believed to be most commonly involved in the execution of apoptosis in various cell types^[31], because it cleaves most of caspase-related substrates, including key proteins such as the nuclear enzyme PARP^[32]. In our data, it is shown that the *CASPASE-3* gene expression was increased (Figure 3) and the activity of caspase-3 was increased after OPC treatment (Figure 4). Based on the results, OPC appears to activate intracellular death-related pathways, leading to caspase-3 activation in SNU-C4 cells. Ye *et al.*^[5], revealed cytotoxicity of proanthocyanidins from grape seed compared between the human cancer cells with two normal cells, proanthocyanidins demonstrated selective cytotoxicity toward several cancer cells at the concentration of 25, 50 mg/L, while it enhances the growth and viability of the normal cells at the same concentration. Moreover, Joshi *et al.*^[33], demonstrated that grape seed proanthocyanidin, ameliorates the toxic effects associated with chemotherapeutic agents such as, 30 nmol/L idarubicin and 1 µg/mL 4-hydroxyperoxycyclophosphamide (4-HC) on normal human hepatocyte, Chang liver cells. These findings suggest that the treatment with OPC show low toxicity on normal cells, and it might have a novel anti-tumor effect on human colorectal cancer cells.

In conclusion, inhibitory effect of OPC on the proliferation of human colorectal cancer cells, SNU-C4 is mainly through apoptosis induced by *CASPASE-3* related to *BCL-2* families.

Abstract

AIM: To conduct the proteomic analysis of human colorectal carcinoma cell line, SW480 by using two-dimensional electrophoresis (2-DE) and matrix-assisted laser desorption/ionization-time of flight mass spectrometry (MALDI-TOFMS).

METHODS: The total proteins of human colorectal carcinoma cell line, SW480 were separated with 2-DE by using immobilized pH gradient strips and visualized by staining with silver nitrate. The gel images were acquired by scanner and 2-DE analysis software, Image Master 2D Elite. Nineteen distinct protein spots were excised from gel randomly and digested in gel by TPCK-trypsin. Mass analysis of the tryptic digest peptides mixture was performed by using MALDI-TOF MS. Peptide mass fingerprints (PMFs) obtained by the MALDI-TOF analysis were used to search NCBI, SWISS-PROT and MSDB databases by using Mascot software.

RESULTS: PMF maps of all spots were obtained by MALDI-TOF MS and thirteen proteins were preliminarily identified.

CONCLUSION: The methods of analysis and identification of protein spots of tumor cells in 2-DE gel with silver staining by MALDI-TOF MS derived PMF have been established. Protein expression profile of SW480 has been obtained. It is demonstrated that a combination of proteomics and cell culture is a useful approach to comprehend the process of colon carcinogenesis.

INTRODUCTION

Colorectal cancer (CRC) is one of the three leading causes of morbidity and mortality worldwide^[1]. It is believed that CRC develops through a multistep process involving the accumulation of genetic alterations. The genetic changes involved in colon carcinogenesis, including changes in proto-oncogenes, tumor suppressor genes, and DNA repair genes were well studied. But the exact mechanisms involved in this process are not well understood. Recently, changes in the transcriptome of colon tissues were studied by using DNA microarray analysis^[2]. However, the value of mRNA changes may be limited in terms of understanding changes in cellular physiology. Instead, genetic alterations lead to altered expression patterns, modifications in protein structures and functions. Alterations in the proteome may reflect cellular changes more accurately since proteins are the actual mediators of intracellular processes as opposed to mRNAs. Proteomics is the study and analysis of the proteins of living organisms. In recent years, the development of research entailing the protein complement of the genome, the proteome, has evolved significantly as a result of improved technology for two-dimensional gel electrophoresis (2-DE) and mass spectrometry (MS) for protein identification. With these technologies, it is now possible to obtain a more holistic view of protein changes associated with colon carcinogenesis. Here, for the first time, a proteomic approach is used to display the protein profile of human colorectal carcinoma cell line, SW480 to understand the basis of colon carcinogenesis.

MATERIALS AND METHODS

Chemicals and materials

Immobilized pH gradient (IPG) strips (pH3-10, linear, 13 cm), IPG buffer (pH3-10, linear) were purchased from Amersham Biosciences (Uppsala, Sweden). Dithiothreitol (DTT),

iodoacetamide (IAA), TPCK-trypsin, Trifluoroacetic acid (TFA), CHAPS, α -cyano-4-hydroxycinnamic acid (CHCA) were purchased from Sigma company (St. Louis, MO, USA). All the buffers were made by using high purity MilliQ water. IPGphor electrophoresis unit, Hoefer SE 600 vertical chambers, electrophoresis apparatus, Image Master 2D Elite 4.01 software and image scanner were purchased from Amersham Biosciences. Voyager-DE MALDI-TOF MS was product of Applied Biosystems (USA).

Cell line culture and sample preparation

The cell line, SW480 was purchased from Institute of Biochemistry and Cell Biology, Chinese Academy of Sciences (Shanghai, China). The cells were cultured in RPMI 1640 medium supplemented with 10 mL/L fetal bovine serum (FBS) and antibiotics. The cells were maintained in an incubator at 37 °C in 50 mL/L CO₂ humidified atmosphere. The cells grown at the exponential growth phase were harvested with trypsinization. After washing in Hanks' solution and ice-cold PBS, the cells were counted, lysated in a cocktail of 9 mol/L urea, 40 g/L CHAPS, 40 mmol/L Tris and 40 mmol/L DTT and centrifuged at 12 000 *g* in for 1 h at 4 °C. Protein concentrations were determined by the method of Bradford.

2-Delectrophoresis

2-DE was performed by using IPG strips. Briefly, first-dimensional isoelectric focusing (IEF) was performed on 13 cm strips (pH 3-10, linear) by using an Amersham IPGphor unit. IEF was carried out by using an IPGphor electrophoresis unit (Amersham Biosciences). Separation in the second dimension (SDS-PAGE) was carried out on a 1.0 mm-thick 125 g/L polyacrylamide gels at a constant current (20 mA/gel) and temperature (15 °C) by using the Hoefer SE 600 vertical chambers. After 2-D separation, the gels were stained with silver nitrate. Image analysis was performed by using the Image Master 2D Elite software 4.01.

In-gel trypsin digestion of proteins

Proteins were in-gel digested as previously described by Wilm *et al.*, (Nature 1996; 379: 466-469) with some modification. Silver-stained spots were excised and washed with a 50 μ L fresh bleaching liquid (100 mmol/L Na₂S₂O₃; 30 mmol/L K₃Fe (CN)₆ = 1:1). Gel spots were dried in a vacuum centrifuge and reswelled in 50 μ L of solution containing 10 mol/L DTT/100 mol/L NH₄HCO₃ and incubated at 57 °C for 1 h. This solution was subsequently replaced with 50 μ L of solution containing 55 mol/L IAA/100 mol/L NH₄HCO₃ and incubated at room temperature for 30 min. The gel spots were dried again and digested with TPCK-trypsin at 37 °C overnight. After the incubation, the liquid was removed from the gel piece and the liquid was transferred to a new-labeled tube. This solution contains the extracted tryptic peptides.

MALDI-TOF -MS analysis of tryptic peptide

Mass analysis was performed by using a Voyager-DE MALDI-TOF MS (Framingham, MA, USA), operated in the delayed extraction and linear mode. The tryptic digest mixture was mixed with CHCA matrix. The MALDI spectra

averaged over 50 laser shots. All mass spectra were calibrated externally by using a standard peptide mixture (angiotensin II and ACTH 18-39). Internal calibration was performed by using auto digestion peaks of trypsin.

Database searching and identification of proteins

Peptide mass fingerprints obtained by the MALDI-TOF MS were used to search NCBIInr, SWISS-PROT and MSDB databases by using Mascot software (<http://www.matrixscience.com>). The parameters used for the search were as follows: peptide mass ranged from 1 000 to 3 000 U; modifications were allowed for carboxy-amidomethylation of cysteine and oxidation of methionine; one missed cleavage site was allowed; mass accuracy was ± 1 U; restriction was placed on the species of *Homo sapiens*. The criteria for positive identification of proteins were set as follows: (1) the MS match consisted of a minimum of four peptides; (2) the matched peptides covered at least 20% of the whole protein sequence; (3) 50 ppm or better mass accuracy.

RESULTS

Proteomic pattern of SW480 by 2-DE

Proteins of human colorectal cancer cell line SW480 was separated by 2-DE. Spots were visualized with silver staining. Three pairs of gels from SW480 were analyzed by using the Image Master 2D Elite software 4.01. Figure 1 shows a representative example of cell proteins separated on a 2-DE gel, where 100 μ g of total protein was applied. Nearly 1 000 proteins spots were obtained in the range of *M_r* 14 400-9 4000 u, *PI* 3-10.

Figure 1 2-DE map of human colorectal cancer cell line SW480 proteome (silver staining).

MALDI-TOF MS analysis of proteins

Nineteen distinct protein spots were excised from gels randomly and marked with Arabic numbers at the corresponding sites in Figure 1. All spots obtained the PMF maps by MALDI-TOF MS following in-gel digestion with TPCK-trypsin. Figure 2 shows the spectrum of trypsin digestion of protein spot 2.

Database searching and identification of proteins

PMFs obtained by the MALDI-TOF MS were used to search NCBIInr, SWISS-PROT and MSDB databases by using

Figure 2 PMF of protein spot 2 in SW480 2-DE map.

Mascot software (<http://www.matrixscience.com>). Figure 3 shows the searching result of spot 2.

Thirteen proteins were preliminarily identified on the basis of peptide mass matching by database searching. Some PMFs such as 1, 8, 9, 10, 11, 16 were not searched by the satisfactory proteins. Table 1 lists the identified proteins. Among these proteins, some were correlated with signal transduction (e.g. zinc finger protein 79 and PR-domain zinc finger protein 7

isoform B), some with cell metabolism (e.g. enolase 1, phosphopyruvate hydratase, carboxypeptidase A5 precursor and peptidylprolyl isomerase), some with cell growth and adhesion (e.g. paired box transcription factor and intermediate filament-binding fragments of Desmoplakin), and some with the immunological function of tumor cells (e.g. MHC class I promoter binding protein, immunoglobulin heavy chain VHDJ region and human B7-1 CTLA-4 co-stimulatory complex).

DISCUSSION

To further understand cellular functioning, the next logical level of analysis is proteomics. Proteomics is the study of global protein expression patterns in a cell, tissue, or organism. In general, it deals with the large-scale determination of gene and cellular function directly at the protein level^[3]. The most commonly used method is a combination of two-dimensional electrophoresis (2-DE) and mass spectrometry (MS)^[4]. Protein mixtures from cells are separated by 2-DE, stained, and each observed protein spot is quantified by its staining intensity. Selected spots are excised, digested and

Probability Based Mowse Score: Score is $-10 \log(P)$, where P is the probability that the observed match is a random event. Protein scores greater than 63 are significant ($P < 0.05$).

analyzed by MS^[5]. 2-DE was the first technique capable of supporting the concurrent quantitative analysis of large numbers of gene products. Proteins are separated by charge in the first dimension and then by size in the second dimension, yielding spots on a polyacrylamide gel. Then, each protein spot was individually recovered and cleaved into short peptide fragments. 2-DE has been a mature technique for more than 25 years. Compared to classical 2-DE with carrier ampholytes (O' Farrell 1975), the employment of immobilized pH gradient (IPG) gel strips as the first dimension, isoelectric focusing (IEF), has produced significant improvements in 2-D electrophoretic separation, permitting higher resolution and greater reproducibility. It become an effective method for separation of complex proteomes such as human cancer cells and tissues, facilitating spot identification by peptide mass fingerprinting (PMF), MALDI or tandem mass spectrometry, amino acid composition analysis, N-terminal and/or internal peptide microsequencing. We have developed a comprehensive strategy for reproducible, robust, gel-based separation of >1 000 protein components for quantitative protein profile. This strategy uses improved sample preparation methods and an optimized in-gel proteolysis protocol.

Protein identification is the most important step in expression proteomics. MS has increasingly become the method of choice for analysis of complex protein samples. MS-based proteomics is a discipline made possible by the availability of gene and genome sequence databases and technical and conceptual advances in many areas, most notably the discovery and development of protein ionization methods, as recognized by the 2002 Nobel prize in chemistry.

The two most widely used ion-producing methods are called Electro Spray Ionization (ESI) and Matrix-Assisted Laser Desorption Ionization (MALDI)^[6]. The method of choice for rapid, high-volume sequence analysis is MALDI, developed in 1987 by Hillenkamp and Karas^[7]. In this process, peptides are first made soluble in a solvent containing an organic acid, such as nicotinic acid, and are then deposited onto a metal stage, as the solvent is evaporated. The organic acid plays a dual role - it is capable of absorbing light energy and it serves as a matrix that holds the protein molecules in place. Energy from a short laser pulse is absorbed by the matrix, which vaporizes, releasing stable precharged peptide ions into the ion chamber. Ionized molecules released in this manner may remain intact or break down into smaller pieces en route to the detector. MALDI's tendency to deliver intact protein masses to the detector is very useful for determining the full molecular weight of a protein, but provides little information about the amino acid sequence that composes it. This limitation can be overcome by enzymatically or chemically cleaving the protein to obtain a mixture of peptides that is then analyzed by mass spectrometry. The peptide mass pattern obtained in this manner is characteristic of the original protein and constitutes a sort of "fingerprint" that can aid in its identification. Each peptide in the fingerprint can be further analyzed by fragmentation to yield complex patterns of ion mass that may be used to identify the molecule. Once a suitable mass spectrum is obtained, it is compared against a protein mass spectral database to see if the sample pattern matches the fingerprint of any known peptides. Commonly used protein sequence

databases include the SWISSPROT, OWL and NCBI nr databases, which are publicly available. Several software programs for protein identification are available online such as Mascot (<http://www.matrixscience.com>), MOWSE (<http://srs.hgmp.mrc.ac.uk/cgi-bin/mowse>), PeptIdent2, and ProFound (<http://prowl.rockefeller.edu/cgi-bin/ProFound> or <http://www.proteometrics.com/prowl-cgi/ProFound.exe>), Prowl (<http://prowl.rockefeller.edu/contents/resource.htm>), and Protein Prospector (<http://prospector.ucsf.edu/>). PMF by MALDI-TOF has become highly efficient in the identification of gel-separated proteins^[8].

The identified proteins were abundantly expressed in SW480 cells including enzymes (enolase), cytoskeletal components (intermediate filaments, IF), transcription factors (PR-domain family), and immunological molecules (MHC class and human B7-1 CTLA-4 co-stimulatory complex). These proteins maybe involved in colorectal carcinogenesis. Enolase is a key enzyme of glycolysis related with the energy metabolism^[9]. This gene encodes one of three enolase isoenzymes found in mammals. It encodes alpha-enolase, a homodimeric soluble enzyme, and also encodes a shorter monomeric structural lens protein, tau-crystallin. The two proteins are made from the same message. The full-length protein, the isoenzyme, is found in the cytoplasm. The shorter protein is produced from an alternative translation start, is localized to the nucleus, and has been found to bind to an element in the c-myc promoter. A pseudogene has been identified, that is located on the other arm of the same chromosome. Intermediate filaments are the most abundant cytoskeletal proteins in cells and regulate the migration of normal and transformed epithelial cells and can be used to define a specific cancer tissue^[10]. The PR domain (PRDI-BF1-RIZ homology region), a distant relative of the SET

domain functioning in chromatin-mediated gene expression, defines a small family of zinc-finger type DNA-binding transcription factors. Three human members are presently known, and they are RIZ, MDS1-EVI1, and PRDI-BF1 or BLIMP1. A characteristic feature of these genes is the unusual yin-yang involvement in human cancers. Two products are normally produced from PR-domain family members who differ by the presence or absence of the PR domain; the PR-plus product is disrupted or under expressed whereas the PR-minus product is present or over expressed in cancer cells. This imbalance in the amount of the two products, a result of either genetic or epigenetic events, appears to be an important cause of malignancy^[11].

Cancer cells can be detected and destroyed by cytotoxic T lymphocytes in many tumors. In humans however, most diagnosed tumors are not eliminated by T cells but grow steadily, invading and metastasizing until the host is destroyed. Evidence is accumulating that progressive tumor growth occurs not because the immune system is defective or deteriorated, but because the cancer cell is capable of developing a variety of strategies to escape immune recognition. Major histocompatibility complex (MHC) molecules are of central importance in regulating the immune response against tumors. Proper HLA class I antigen processing and presentation is a prerequisite for the recognition of tumor cells by cytotoxic T lymphocytes^[12]. MHC II molecules are designated DP, DQ or DR and consist of two transmembrane polypeptides: an alpha (α) chain and a beta (β) chain. HLA-DPB1 is located on chromosome 6p12.3 and codes for Human Leukocyte Antigen, a Major Histocompatibility Class II (MHC II) molecule. MHC II molecules are heterodimeric, having α and β chains, DPB1 codes for the β chain. These molecules are responsible for initiation of the immune

response through antigen presentation to T cells^[13,14]. B7 family members play a central co-stimulatory role in T cell activation^[15]. These two signals are necessary for T cell activation. It is generally accepted that human and experimental tumor cells can lose Major Histocompatibility Complex (MHC) class I molecules and this represents the major mechanism of tumor escape from T-cell immune responses. This is now mandatory, considering the high frequency of total or partial MHC class I losses observed in different tumor types as a result of escape mechanism from infiltrating-infiltrating lymphocytes: 90% in cervical carcinomas^[16], 73% in colorectal carcinomas^[17], 88% in breast carcinomas^[18,19], 51% in melanomas^[20,21], and 66% in laryngeal carcinomas^[22] and renal cell carcinoma^[23]. The expression of MHC I, MHC II and B7-1 molecules by SW480 cells might imply that such a kind of tumor cells had all the components necessary for evoking T lymphocyte activation and generating a positive anti-tumor immune response. Why the hosts cannot eliminate the malignancies? Recent findings discovered that the lymphocyte population of a patient with CRC contained at least two types of lymphocytes with tumor specificity, i.e., CTLs and regulatory T cells. They might be induced by a tumor-associated self antigen(s)^[24,25]. However, the exact immunological pathomechanism(s) of these immunological molecules remains to be established. The regulatory T cells may suppress autologous CTL functions, resulting in escape of the tumor from immune surveillance by CTLs. This may explain why tumors often grow despite the presence of CTLs in the same individual.

Peptide mass fingerprinting (PMF) is a powerful tool for identification of proteins separated by 2-DE. However, there are several limitations to peptide mass fingerprinting, including a lack of complete and accurately annotated genome- and protein-sequence databases for a great number of highly homologous human proteins. Beyond identification, confirmation and validation of the protein of interest are also important steps in proteomic approaches.

Abstract

AIM: To determine whether any changes have occurred on the patterns of colorectal cancer in China.

METHODS: Data from 21 Chinese articles published from 1980 to 1999, were used to analyze the time trend of colorectal cancer according to the patients' age at diagnosis, sex, the site of the tumor, stage, and the pathology.

RESULTS: From 1980s to 1990s, the mean age of the colorectal cancer patients has increased. The percentage of the female patients rose. The distribution of colorectal carcinoma shows a predominance of rectal cancer. However, the proportion of proximal colon cancer (including transverse and ascending colon) increased significantly accompanied by a decline in the percentage of rectal cancer. Similarity in the percentage of distal colon cancer between two decades was revealed. In the 1990s, statistically more Stage B patients were found than those in 1980s. In addition, databases show a significant decrease in the Stage D cases. The proportion of adenocarcinoma increased, but the mucinous adenocarcinoma decreased during two decades.

CONCLUSION: These findings indicate that the pattern of colorectal cancer in China has been changing. Especially, a proximal shift due to the increasing proportion of ascending and transverse colon cancer has occurred in China.

INTRODUCTION

Colorectal carcinoma (CRC) is one of the most common

tumor types in the world, with approximately 400 000 deaths annually^[1]. It is a frequent cause of cancer death in the developed world^[2]. For example, in the USA, despite a slight decrease in its incidence and mortality during the past two decades, CRC has remained the third most common cancer, affecting approximately 140 000 people and causing approximately 50 000 cancer-related deaths per year^[3]. In China, the incidence rate was initially low, but in recent years, due to the changes of life style and nutritional habits, the rate is increasing. The most impressive increase in the incidence rates of CRC was observed from 1972-1974 to 1987-1989, being 85% in males and 79% in females. The average rate of increase in incidence is 4.2% per year^[4]. According to the report of the Ministry of Health PR China in 2002, the incidence rate of CRC has ranked third in 1990s, from the sixth most common cancer in 1970s, and the death rate of CRC has increased to 10.25/10⁵ annually, which is the fifth leading cause of cancer mortality^[5].

Recent epidemiologic studies have suggested that the anatomic distribution of colorectal cancer may have undergone a distal to proximal shift over several decades. Lev^[6] has reported that during 1986 to 1992, cecal and ascending colon tumors increased in incidence from 33.9% to 36%, tumors of the transverse colon increased from 15.8% to 17.2%, and tumors of the sigmoid colon decreased from 36.0% to 33.4%.

So besides the increasing incidence rate and mortality rate, we still want to know whether there are some changes on patterns of CRC in China. But because a National Colorectal Cancer Registry system has not been established yet in China, so we compiled all the Chinese articles on CRC in order to compare the changing patterns between 1980s and 1990s. These articles were published on the journals included by the Chinese S&T Journal Citation Reports (CJCR). It is difficult to collect only articles in SCI, because in 1980s, few Chinese journals were included by SCI.

MATERIALS AND METHODS

Data were obtained from 21 Chinese articles published from 1980 to 1999 in CJCR. The articles involved 25 hospitals and 11 geographic areas of China. The study was based on the records of 10 201 patients reported during 20 years. According to the time of falling ill, they were divided into two groups, 1980s and 1990s. The former included 3 420 patients, and the latter had 6 781. These cases were recorded under sex, age, the subsites distribution of the CRC, Dukes' classification and the pathologic data. The distribution of the CRC was categorized into five segments: rectum (excluding

anal canal cancer), sigmoid, descending colon, transverse colon, and ascending colon (including cecum cancer but excluding appendicular neoplasm). On the other hand, we classified as proximal colon (ascending and transverse colon), distal colon (descending and sigmoid colon) and rectum. The patients without these detailed data were excluded.

Statistical analysis

Statistical analysis was performed using the SPSS 10.0 program. Independent samples' *t* test was used to compare the difference of age between two groups. Other data was examined by χ^2 test and statistical significance was accepted at $P < 0.05$.

RESULTS

Incidence and patient characteristics

In the 1980s group, 3 420 patients were reported, including 2 053 men and 1 367 women. The ratio was 1.50:1. But in the 1990s group, 6 781 patients were registered, among them there were 3 780 men and 3 001 women, and the ratio was 1.26:1. There is a significant difference between the two groups on the gender constituent ratio ($P < 0.05$). The mean age of 1980s group was 56.83, which was lower than 59.66 in 1990s (Table 1).

Table 1 Epidemiologic results

	1980s (%)	1990s (%)	<i>P</i>
Total number of CRCs	3 420	6 781	
Male	2 053 (60.03)	3 780 (55.74)	
Female	1 367 (39.97)	3 001 (44.26)	
Male/female ratio	1.50:1	1.26:1	0.02
Mean age (yr)	56.83	59.66	

Distribution of CRC

The CRC localization changed in the two decades. The distribution of CRC shows a predominance of rectal cancer. However, the proportion of rectal cancer in CRC has decreased significantly from 71.2% in 1980s to 66.7% in 1990s ($P < 0.001$). The proportion of transverse colon and ascending colon individually increased significantly ($P < 0.001$). Meanwhile, the percentage of patients with proximal colon cancer among those with colorectal cancer certainly increased significantly (10.9% *vs* 15.2% $P < 0.001$). But the data revealed similarity in the percentage of distal colon cancer between two groups ($P > 0.05$, Table 2).

Table 2 Distribution of CRC

Localization	1980s (%)	1990s (%)	<i>P</i>
Rectum	2 484 (72.6)	4 539 (66.9)	<0.001
Colon	936 (27.4)	2 242 (33.1)	<0.001
Distal			
Sigmoid	337 (9.9)	844 (12.4)	<0.001
Descending colon	226 (6.6)	366 (5.4)	0.02
Total distal CRCs	563 (16.5)	1 210 (17.85)	
Proximal			
Transverse colon	87 (2.5)	275 (4.1)	<0.001
Ascending colon	286 (8.4)	757 (11.2)	<0.001
Total proximal CRCs	373 (10.9)	1 032 (15.2)	<0.001
Others			
Total number of CRCs	3 420	6 781	

Dukes' classification

Of all CRCs, complete tumor staging is available in 2 300 and 3 772 patients in 1980s and 1990s respectively. Distributions among different categories of the Dukes' classification are shown in Table 3. In 1990s statistically more Stage B CRCs were found than in 1980s ($P < 0.001$) and databases show a statistically significant decrease in the Stage D cases.

Table 3 Dukes' staging

Stage	1980s (%)	1990s (%)	<i>P</i>
A	306 (13.3)	416 (11.0)	0.01
B	679 (29.5)	1 399 (37.1)	<0.001
C	823 (35.8)	1 379 (36.6)	
D	492 (21.4)	578 (15.3)	<0.001
Total	2 300	3 772	

Pathologic classification

The pathologic data of the CRCs were classified into adenocarcinoma, mucinous adenocarcinoma and others which mean carcinoid, adenosquamous carcinoma, and so on. We can see in Table 4, that recent pathologic classification in CRC in China has significantly changed. The proportion of adenocarcinoma increased but the mucinous adenocarcinoma decreased ($P < 0.001$).

Table 4 Pathologic classification

Pathologic classification	1980s (%)	1990s (%)	<i>P</i>
Adenocarcinoma	1 251 (82.1)	3 838 (85.6)	<0.001
Mucinous adenocarcinoma	231 (15.2)	465 (10.4)	<0.001
Others	42 (2.8)	180 (4.0)	
Total	1 524	4 483	

DISCUSSION

Rates of CRC vary considerably with geography. The disease is common in USA, Australia, Western Europe, and Scandinavia and is relatively uncommon in Asia, Africa, and South America^[7,8]. In recent years, there were some changes on the pattern of CRC, such as increasing incidence rate in Japan and Eastern Europe^[9-11], continued rightward shift of CRC^[11-13] and so on. Compared with Western countries, the incidence of CRC in China is low, but the dietary habits and lifestyle of Chinese have changed greatly, and the incidence is increasing rapidly. Thus, it is worthwhile to study the time trends for the changing patterns on CRC in China. This study collected 10 201 cases to investigate the age, male/female ratio, subsite distribution and pathologic changes on CRC in China over a period of 20 years.

CRC is primarily a cancer of the older population and risk for it increases with age^[7,8]. The increase of mean age may contribute to the population aging during 20 years in China. But we failed to show that there is a significance between the two decades.

It is clearly shown that the proportion of the female patients on CRC in China increased significantly from 1.50:1 in 1980s to 1.26:1 in 1990s. One possible explanation for the role of

gender may be the effect of female hormones^[14]. Some suggested that hormonal replacement therapy may decrease the incidence of CRC in females^[15,16]. Female sex hormones are known to affect cholesterol metabolism, which in turn affects bile acid production, a pathway linked to the development of colorectal cancer^[17].

In low-risk countries, rectal cancer accounts for the largest proportion of all colorectal cancers^[18]. The proportion of rectal cancer among all colorectal cancers is generally less than 40% in Europe and North America, in contrast to the 50% or more in Asia^[19]. In our study, rectal cancer is the main part of the colorectal cancer in China, no matter what was in 1980s or 1990s. However, the ratio of patients with colon cancer to all CRC cases has increased greatly in both sexes. In 1980s, the proportion of the colon cancer is 27.4%, but 33.1% in 1990s. Correspondingly, the percentage of rectal cancer decreased obviously. Likewise, several recent studies reported consistent results^[19-24]. The reason for this is not clear. It may be continued anatomic rightward shift of CRC, which were mentioned as follows, improved diagnostic accuracy for lesions in colon^[19], and varying etiologic factors^[21,23,24].

In the past 40 years, since the first description on CRC shift toward the proximal colon by Axtell and Chiazze^[25], many investigators confirmed it from various countries^[14,24,26-34]. The present study indicates the distribution of colon cancer in China changed greatly in 20 years, a significant increase in proximal colon cancer including transverse and ascending colon. The ratio of proximal colon cancer to all CRCs increased about 4.3%. Nevertheless the proportion of total distal colon cancer (sigmoid and descending) remains static. To exclude the possible question that the rightward shift may be due to the decreasing proportion of rectal cancer among all CRC, we limited our further analysis to data for the colon alone. It also concluded that there was an actual increase in right-sided cancer. So the proximal shift may be a reason for the increased ratio of colon cancer to rectal cancer as mentioned before.

There may be several potential causes for the rightward shift in CRC. The proximal and distal colon has different embryologic origins, morphology, physiology, and function^[35]. Cecum, ascending colon, and proximal two-thirds of the transverse colon derives from the midgut, whereas the segment comprising the splenic flexure to the upper anal canal derives from the hindgut. The distinct embryologic origins of each segment are reflected in the dual blood supply of the normal colon. The proximal colon is primarily involved with water absorption and solidification of fecal contents, but the distal colon functions primarily for storage^[19]. The metabolic pathways such as that of glucose, butyrate, and polyamines are also different. It has therefore been hypothesized that proximal and distal colons are two different organs^[36]. It may mean differences in differential sensitivities and exposures to carcinogens for the proximal and distal sections of colon and rectum.

The colon cancer is associated with genetic factors. Some studies reported that high-frequency microsatellite instability was significantly associated with tumors occurring in the proximal colon^[37,38]. Also Gervaz showed that distal colon cancer were more likely to express a nonfunctional p53

protein and a p53 gene mutation than proximal tumors^[31]. In the future, such genetic variations by cancer site may provide more clues to understanding the reasons of rightward shift of CRC.

The fecal occult blood test, digital examination of rectum, rigid and flexible sigmoidoscopy, barium enema X-ray as well as colonoscopy are particularly geared toward the diagnosis and screening of colorectal cancer. In 1980s, the colonoscopy was not popular in China especially in the suburban. So the rectal and sigmoid cancers are inclined to be found and diagnosed. Following the increased use of colonoscopy, more and more was the detection of proximal lesions with the observed time trends in 1990s. Although sigmoidoscope has been proven as an effective tool for screening against colorectal cancer^[39,40] and detects almost 80% CRC in China, it has the limitation that it would miss the proximal cancer for 20%. Accompanying the continuing rightward shift, the miss rate (meaning the ratio of miss out diagnosis cases to all CRC patients) may rise, especially on symptomatic patients. The miss rate may even be higher when one takes into account that approximately 25% of all patients who underwent sigmoidoscopy, the entire sigmoid is not adequately visualized^[41]. So the use of barium enema X-rays and total colonoscopy appears more appropriate for symptomatic patients, especially elderly people and women.

There are some other theories to explain the rightward shift of CRC. Gonzalez^[14] considered that five co-morbid conditions were associated with a greater likelihood of proximal lesions: congestive heart failure, cerebrovascular disease, chronic pulmonary disease, ulcer disease, and diabetes mellitus. West *et al.*^[42] demonstrated that a high-fat diet increased the risk for proximal colon cancer, whereas a high-protein diet increases the risk for distal neoplasm.

Screening seems attractive because of the difference in prognosis between early and late stage of CRC. During 20 years, China has developed the screening system. So the Dukes' D stage CRC has shrunk significantly and Dukes' B has been the main part of all cases.

Finally, our data indicated that the proportion of adenocarcinoma increased, correspondingly, mucinous adenocarcinoma decreased. The reasons for it needs further study.

Future studies should examine the subsites of CRC to clarify further analytical epidemiological findings, carcinogenic mechanisms, various risk factors, and prognosis to reduce the mortality.

Abstract

AIM: To investigate the role of survivin expression in the pathogenesis of colorectal carcinoma.

METHODS: Immunohistochemistry S-P method and terminal deoxynucleotidyl transferase-mediated dUTP nick end labeling (TUNEL) were used to detect the expression of survivin and apoptotic cell *in situ* in colorectal cancerous tissues, para-cancerous tissues and normal tissues of 48 cases of colorectal carcinoma.

RESULTS: The survivin positive unit (PU) was higher in cancerous tissues (38.76 ± 5.14) than in para-cancerous (25.17 ± 7.26) or normal tissues (0.57 ± 0.03) ($P < 0.05$). The apoptosis index (AI) of para-cancerous tissues was ($7.51 \pm 2.63\%$) higher than cancerous tissues ($4.65 \pm 1.76\%$). The expression of survivin was associated with pathological grade, lymph node metastasis and Dukes stage of colorectal carcinoma.

CONCLUSION: Survivin expression may play an important role in carcinogenesis of colorectal carcinoma and may be associated with malignant biological behaviors of colorectal carcinoma.

INTRODUCTION

Survivin is a new member of inhibitors of apoptosis proteins (IAP) gene family that has been found recently. The survivin

gene lies in the 17q25 of human chromosome with unique structure and characteristics, coding a 16.5 KD protein^[1]. Survivin protein contains only one BIR (baculovirus IAP repeat) domain and does not have the zinc-binding fold terminated with carboxyl. Furthermore, under normal circumstances survivin is expressed in embryonic and fetal tissues, but completely downregulated in normal adult tissues. Interestingly, this protein is found to be prominently reexpressed in a variety of human malignant transformation cell lines and tumorous tissues^[2,3]. And its unique structure and biological function have interested so many scholars during their researches on the molecular biology of tumors.

Colorectal carcinoma has a high incidence in China. The deficiency of cell apoptosis plays an important role in the pathogenesis of this carcinoma. It is still uncertain about the role of survivin expression in colorectal carcinoma. In the present study, the expression of survivin and cell apoptosis were detected. The correlation between survivin expression and cell apoptosis and the role of survivin in the pathogenesis of colorectal carcinoma were also investigated.

MATERIALS AND METHODS

Study materials

Forty-eight cases of colorectal carcinoma who received rectectomy were obtained from the Department of General Surgery, Renmin Hospital of Wuhan University. Twenty-six of them were male and 22 female. The mean age was 55.8 years ranged from 37 to 75 years. All the cases did not receive radiation treatment or chemotherapy before surgery and had been diagnosed by two doctors at the department of pathology. Three pieces of tissues were taken respectively from cancerous tissues, para-cancerous tissues (5 cm away from cancerous tissues) and normal tissues (10 cm away from cancerous tissues). All the specimens were fixed in 10% neutral-buffered formalin, dehydrated in ascending series of ethanol and routinely embedded in paraplast. Sections were cut at 4 μ m, stained with hematoxylin and eosin for histopathological and immunohistochemical evaluation as well as TUNEL. The clinicopathological parameters are summarized in Table 1.

Immunohistochemical analysis

All the specimens were incubated in 3% hydrogen peroxide for 15 min to inactivate the endogenous peroxidase and then heated in 0.01 mol/L citrate buffer for antigen retrieval through 12 min microwave pre-treatment. Incubated with 10% goat serum, all the specimens were subsequently reacted with rabbit-anti-human survivin polyclonal antibody (Neomarkers, USA, 1:1 000 dilution) at 4 °C overnight.

Table 1 Relationship between survivin PU and pathological parameter in 48 cases with colorectal carcinoma (mean±SD)

Subjects	Clinical pathological index	n	Survivin PU	P
Gender	Male	26	42.95±16.87	P>0.05
	Female	22	30.96±16.06	
Age (yr)	<55	14	36.95±19.86	P>0.05
	≥55	34	38.96±15.37	
Tumor Diameter	<3 cm	14	36.15±16.29	P>0.05
	≥3 cm	34	38.28±18.16	
Pathological	High and intermedium differentiated	24	33.16±14.28	P<0.05
Grade	Cannular adenocarcinoma	10	51.93±20.89	
	Low differentiated tubular adenocarcinoma			
	Other types			
Lymph node	Negative	26	30.12±13.33	P<0.05
	Positive	22	56.21±11.95	
Dukes stage	A	16	20.16±5.16	P<0.05
	B	4	24.85±3.12	
	C	10	45.13±10.21	
	D	14	59.66±10.21	

Immunohistological staining was performed according to SP detection kit.

TUNEL staining

Apoptotic cells were detected, according to the procedure recommended by *in situ* cell apoptosis detection kit (Boehringer Mannheim Company, Germany).

Evaluation criteria

Immunohistochemical quantitative evaluation All the analyses were performed using the HIPAS-2000 computer image analysis system (produced by Tongji Qianping Image Engineering Company). Images were captured at ×400 magnification by micrographic system. Image analysis system separated staining positive area from background. Then the gray level units as well as areas of positive staining and background could be measured. According to Shen's method, positive unit represents the relative concentration of positive staining^[4]. Each section was observed randomly at five areas and the mean PU was calculated.

Evaluation criteria for cell apoptosis

The apoptotic cells were located sporadically with nuclei stained yellow or brownish yellow. A mean percentage of positive cells among 500 cells was determined in five areas at ×400 magnification. The results could be recorded as apoptosis index (AI).

Statistical analysis

All analyses were performed with *t* test and ANOVA using SPSS 9.0 software (Statistical Package for Social Science). *P* values<0.05 were considered to indicate statistical significance.

RESULTS

Survivin PU and apoptosis index of cancerous, paracancerous and normal tissues

Survivin PU were mainly in the cytoplasm of para-cancerous or cancer cells. The nuclei could be stained equally light yellow or brownish yellow, located sporadically or in the

form of sheets (Figure 1A). Survivin PU was rarely expressed in normal large intestinal mucosa (Figure 1B). Quantitative analysis of immunohistochemistry is summarized in Table 2. The apoptotic cells were distributed sporadically or in clusters with brownish yellow nuclei. apoptotic cells were found to be rare and weak stained in normal large intestinal mucosa, most of which were located in epithelium (Figure 2A), but scattered sporadically in cancerous (Figure 2B) and para-cancerous tissues. Survivin PU in cancerous tissues 38.76±5.14 was significantly higher than in para-cancerous 25.17±7.26 and normal tissues 0.57±0.03 (*P*<0.05). And the AI in para-cancerous tissues, (7.51±2.63)% was significantly higher than in cancerous tissues, (4.65±1.76)%(*P* = 0.0075).

**Figure 1** Expression of survivin in colorectal cancerous and normal tissues by S-P method. (x400). **A:** colorectal cancerous tissues; **B:** normal colorectal tissues.**Table 2** The comparison of survivin PU and AI in cancerous, paracancerous and normal tissues (mean±SD)

Subjects	Cancerous tissues	Paracancerous tissues	Normal tissues	P
Survivin PU	38.76±5.14	25.17±7.26 ^a	0.57±0.03 ^a	P
AI (%)	4.65±1.76	7.51±2.63	1.75±0.49	P

^a*P*<0.05, Survivin PU of cancerous tissue vs paracancerous or normal tissue; *P* = 0.0075, AI of paracancerous tissue vs cancerous tissue.

Relationship between survivin PU and clinicopathological parameters

Survivin PU was not correlated with sex, age and tumor diameter of patients, but correlated with pathological grade, lymph node and Dukes stage. Survivin PU in cancerous tissues with low differentiation, lymph node positive and Dukes C/D stage was higher than in cancerous tissues with high differentiation, lymph node negative, and Dukes A/B stage.

Figure 2 Apoptotic cells in normal colorectal epithelial and cancerous tissues by TUNEL method. (x400). **A:** normal colorectal epithelial tissues; **B:** colorectal epithelial tissues.

DISCUSSION

According to recent clinical and statistical data, there was a gradually increasing incidence in colorectal carcinoma. carcinogenesis can be regarded as a complex process with multi-gene participation and multi-steps. As we all know, most colorectal carcinomas originate from adenoma. Abnormalities in the control of programmed cell death (apoptosis) play an important role in the pathogenesis of colorectal carcinoma during the process from adenoma to cancer. It has been proved that the genes closely related with the control of colorectal cell apoptosis include bcl-2, c-myc, p53 and IAP gene family. So the research and application of those apoptosis-related genes is of great importance in the diagnosis, treatment and prognosis judgement of colorectal carcinoma.

Survivin is a new member of IAP gene family, which was obtained by Altieri in Yale University through hybridization and filtration of human genome^[5]. It can combine with microtubules of mitotic spindle, and through interaction with caspases it can inhibit cell apoptosis^[6]. Survivin affects various terminal effect factors and might be one of the strongest apoptosis inhibitory factors till now. This research using immunohistochemical staining showed that survivin was very weak in normal epithelial cells and partially expressed in para-cancerous tissues. But positive cells in para-cancerous tissues were less than in cancerous tissues with a weaker staining, suggesting that survivin expression could be an early event during the pathogenesis of colorectal carcinoma. This is in accordance with the researches on pancreatic and hepatocellular cancers. Evidence showed that survivin could be expressed in early stage of pancreatic cancer or precancerous lesions^[6,7]. Sarela found survivin mRNA mainly existed in survivin positive cancerous tissues,

but hardly in survivin negative cancerous tissues^[8]. Thus, it is proposed that, survivin is an oncogene, and also a marker with great potential for tumor diagnosis. Survivin antibody could also be taken as a common marker for early diagnosis of colorectal carcinoma^[9,10].

This research proved that survivin PU had no significant correlation with sex, age, and tumor diameter, but correlated with differentiation stage, lymph node and Dukes stage of colorectal carcinoma. Survivin PU in cancerous tissues with low differentiation, lymph node positive and Dukes C/D stage was higher than in cancerous tissues with high differentiation, lymph node negative and Dukes A/B stage. It indicated that survivin PU was related with malignant biological behaviors. Its continuous expression might be associated with the development of malignant tumor. Researches on gastric carcinoma, lung cancer, breast cancer revealed that survivin PU was not only correlated with malignant biological behaviors such as invasion, metastasis, etc, but also correlated with recurrence, reduced survival time after surgery. It might be taken as an independent index for judging the prognosis^[11-13]. Therefore, survivin is of great value for diagnosis and prognosis judgement of malignant tumors.

Survivin has the feature of selective expression in various malignant tumors, which might be essential for carcinogenesis of those tumors. But the mechanism for survivin to contribute to carcinogenesis of tumors is not clear yet. It is probably involved in cell apoptosis, proliferation, etc.^[14]. Our research showed that the apoptotic cells mainly located in epithelium of normal large intestinal mucosa, but distributed sporadically in cancerous and para-cancerous tissues. AI of paracancerous tissues was higher than cancerous tissues, indicating that survivin could inhibit apoptosis of colorectal carcinoma cells. This might be regarded as part of mechanisms for its participation in carcinogenesis of colorectal carcinoma. But the precise pathway for survivin to inhibit apoptosis still needs further investigation. According to the present study, survivin had various pathways to inhibit apoptosis, which could also be found in other malignant tumors^[15]. It might play an important role in the carcinogenesis of various tumors.

Abstract

AIM: To elucidate the relationship between the frequency of core mutations and the clinical activity of hepatitis B virus (HBV)-related liver disease and to characterize the amino acid changes in the core region of HBV.

METHODS: We studied 17 Chinese patients with chronic hepatitis B according to their clinical courses and patterns of the entire core region of HBV.

RESULTS: Amino acid changes often appeared in the HBV core region of the HBV gene in patients with high values of alanine aminotransferase (ALT) or with the seroconversion from HBeAg to anti-HBe. The HBV core region with amino acid changes had high frequency sites that corresponded to HLA I/II restricted recognition epitopes reported by some investigators.

CONCLUSION: The core amino acid changes of this study occur due to influence of host immune system. The presence of mutations in the HBV core region seems to be important for predicting the clinical activity of hepatitis B in Chinese patients.

INTRODUCTION

Individuals infected with hepatitis B virus (HBV) may display asymptomatic, acute, fulminant, or chronic hepatitis. Previous studies have suggested that liver disorders due to HBV are immune-mediated and that hepatitis B envelope antigen (HBeAg) and hepatitis B core antigen (HBcAg) could be immunological targets^[1-3]. Furthermore, several antigenic regions have been identified in the HBV core region using recombinant antigens or synthetic peptides. Some reports have revealed that amino acids (aa) 78-83 and aa 127-133 are exposed on the surface of HBcAg^[4,5]. Others have also reported that aa 120-140 are related to the recognition of helper T-cells, and forms of the HBV core and e antigens influence cytokine release in mouse models^[6-8]. Thus, liver disorder in hepatitis B is influenced by the host immune system, which attacks core peptides as the main target. Given this, the pattern of amino acid changes in the HBV core region might predict the clinical course according to the level of serum ALT (sALT) values and the presence of HBeAg. In other words, mutations in the HBV core region may help to predict the outcome of liver disorders. To identify one cause of hepatitis B activity, we analyzed the HBV core sequence and the frequency of core mutations.

MATERIALS AND METHODS

Patients

Serum samples were taken from 17 Chinese patients, who were consistently positive for hepatitis B surface antigen (HBsAg). HBsAg and anti-hepatitis B surface antibody (HBsAb) were determined by immunoassay, while HBeAg, anti-hepatitis B envelope antibody (HBeAb), and HBcAb were determined by passive hemagglutination (PHA) assay. Patients were first divided according to the presence of HBeAg into positive (eAg-Po) and negative (eAg-Ne) groups, and then divided, according to the sALT values measured twice or thrice a year into high activity (HA) and low activity (LA) groups. The HA group had sALT over 100 IU/L at least once a year and the LA group had sALT consistently below 100 IU/L. This study was approved by the ethics committee and informed consent was obtained from all patients.

Extraction and amplification of HBV DNA by polymerase chain reaction (PCR)

HBV DNA was extracted from 100 µL of serum. In brief, after the serum samples were diluted to 400 µL with distilled water, the DNA was extracted with 1 mL of phenol/

chloroform (1/1:v/v) and precipitated with 1/10 volume of 3 mol/L sodium acetate and 2 volumes of 100% ethanol. The precipitates were dried under vacuum and dissolved with 20 μ L of Tris-HCL and EDTA buffer (pH 7.4). PCR was performed to amplify a 609-bp DNA fragment using specific primers (the 1st PCR primers: sense primer H: 5'-GGGAGGAGATTAGGTTA-3', anti-sense primer I: 5'-GTACAGTAGAAGAATAAAG C-3'; /the 2nd PCR primers: sense primer D: 5'-CAAGCCTCCAAGCTGTG-CCT-3', anti-sense primer F: 5'-ACCTTATG AGTCCA-AGGGAT-3') corresponding to the outside of the core region in the HBV genome. A reaction mixture containing 50 mmol/L KCl, 10 mmol/L Tris-HCl (pH 8.0), 2.5 mmol/L MgCl₂, 1 μ mol/L each of the two primers, 200 μ mol/L dNTP, 200 μ g/mL gelatin, and 5 U of *Taq* DNA polymerase (Amersham Life Science, Cleveland, OH, USA) was added into a 200- μ L tube containing 10 μ L DNA solution. Amplification was performed for 35 cycles as follows: denaturation at 94 °C for 1 min, annealing at 58 °C for 1 min, extension at 72 °C for 2 min. In the last cycle, incubation at 72 °C was continued for 10 min to complete the extension. Electrophoresis of 10- μ L aliquots of PCR products was performed on a 3.5 % agarose gel subsequently stained with ethidium bromide. To avoid contamination, we performed amplification under the stringent conditions recommended by Kwok and Higuchi, with one positive and one negative control for each sample^[9].

Cloning and DNA sequencing

After the primers were removed from the amplification products by the commercial product SUPREC-02™ (TAKARA, Otsu, Japan), the products were ligated to pT7BlueT vectors (Novagen Inc., WI, USA). The ligated phagemid vector was transfected into competent JM109 cells (Toyobo, Osaka, Japan). Several independent colonies were examined to find appropriate clones from PCR using D and F primers. At least three clones for each case were subjected to 2 mL of liquid culture and small-scale preparation of phagemid DNA. Each clone was reacted with the DyeDeoxy™ terminator cycle sequencing kit and sequenced with a DNA sequencing system (Model 373A, Perkin Elmer, Urayasu, Japan), and the consensus sequences were adopted. The amino acid (aa) sequences deduced from the DNA consensus sequences in the HBV core region were compared to the wild type, subtype adr^[10] for all subjects.

Statistical analysis

Data values were presented as mean \pm SD. Statistical studies were achieved by Fisher's exact probability test and unpaired Student's *t*-test or Welch's *t*-test. *P*<0.05 was considered statistically significant.

RESULTS

Clinical and laboratory data on 17 patients with chronic hepatitis B

Of the 17 patients in the study, 7 were in the eAg-Po group and 10 were in the eAg-Ne group. Similarly, 10 were in the HA group and 7 were in the LA group. The percentage of HBeAg/anti-HBe seroconversion was 80% in the HA group and 28.6% in the LA group. The percentage of females in

HA group (50%) was greater than that in LA group (28.6%). More eAg-Po members were found in the HA group than in the LA group.

Mutation at HBV core region

The DNA sequences in the HBV core region samples from 17 patients were analyzed and compared to the adr subtype (Figures 1A and B). Figure 1A shows the HBV core regions in the eAg-Po and eAg-Ne groups, whereas Figure 1B shows those in the HA and LA groups. As shown in Figures 1A and B, many amino acid changes were detected in the HBV core regions of the eAg-Ne group and the HA group. The frequency of DNA mutations and the amino acid changes in the HBV core region are summarized in Table 1. No significant difference was found in the number of DNA mutations between the LA and HA groups, whereas the number of DNA mutations in the eAg-Ne group tended to be higher than that in the eAg-Po group (*P* = 0.06). The number of amino acid changes in the HA group was significantly greater than that in the LA group (*P*<0.05). The number of amino acid changes in the eAg-Ne group was also significantly greater than that in the eAg-Po group (*P*<0.05).

Table 1 Comparison of DNA mutation number and amino acid changes (mean \pm SD)

Group	DNA mutations	Amino acid changes
eAg-Po (<i>n</i> = 7)	8.9 \pm 3.7	0.9 \pm 0.9
eAg-Ne (<i>n</i> = 10)	13.7 \pm 5.4	5.0 \pm 2.4 ^b
HA (<i>n</i> = 10)	12.8 \pm 5.8	4.3 \pm 2.6 ^a
LA (<i>n</i> = 7)	10.1 \pm 4.1	1.7 \pm 2.1

^a*P*<0.05 eAg-Po group, ^b*P*<0.001 vs LA group.

Hot mutation spots of amino acid changes in HBV core region

As shown in Figures 1A and B, unique amino acid changes were detected in 30 of the 183 residues of the HBV core region. Of these 30 residues, six had an especially high mutation rate (more than 30%). The amino acid changes included replacements. Proline (Pro)-5 was replaced by threonine (Thr)-5, valine (Val)-5, and histidine (His)-5. Serine (Ser)-87 was replaced by glycine (Gly)-87 and asparagine (Asn)-87. Isoleucine (Ile)-97 was replaced by leucine (Leu)-97. Pro-130 was replaced by glutamine (Gln)-130 and Thr-130. Pro-135 was replaced by Gln-135 and Gly-153 was replaced by cysteine (Cys)-153.

DISCUSSION

Several virus factors and host factors have been reported to affect the activity of chronic hepatitis B^[11-14]. In this study, we analyzed Chinese patients with chronic hepatitis B according to the level of sALT values and the presence of HBeAg, and then investigated the entire core region of HBV to characterize the amino acid changes in this region and to elucidate the relationship between the frequency of core mutations and the clinical activity of HBV-related liver diseases. We found that many amino acid changes in the HBV core region occurred in the HBV DNA of patients with high sALT values and with the seroconversion from

Figure 1 Comparison of core amino acid sequences between eAg-Po and eAg-Ne groups. (A) and between HA and LA groups (B). The top line is the core amino acid sequence of the HBV adr subtype. Core amino acid sequences of the HA group are C-1, C-2, C-3, C-11, C-16, C-22, C-29, C-35, C-36, and C-39, and those of the LA group are C-4, C-6, C-8, C-9, C-13, C-17, and C-21,

Each dot denotes an identical match to the top sequence. An asterisk denotes that this codon is a stop codon. a,b,c are HLA class II-restricted T cell recognition sites. d, e, f are HLA class I-restricted CTL epitopes. g, h are the lesion exposed at the surface of HBcAg.

HBeAg to anti-HBe. Increased activity of hepatitis and decreased time of seroconversion from HBeAg to anti-HBe may be attributed to increased immunological attacks against the HBV core region. Indeed, it has been reported that both B and T lymphocytes [helper T lymphocytes and cytotoxic T lymphocytes (CTL)] recognize core peptides. Some studies have reported that aa 78-83 and aa 127-133 are exposed on the surface of HBcAg^[4,5]. Penna *et al.*^[15], and Ferrari *et al.*^[16], have identified three major HLA class II-restricted T cell recognition sites within HBcAg: aa 1-20, aa 50-69, and aa 117-131. Furthermore, it has been reported that the HLA-A2.1-restricted CTL epitope is mapped to aa 18-27, HLA-A31- and HLA-AW68-restricted-CTLs recognize aa 141-151^[17], and HLA-A11-restricted-CTLs including HLA-A11 binding motifs recognize aa 88-96^[18]. To our surprise, these recognition epitopes correspond to the HBV core region involving the most sites of amino acid changes, suggesting that the amino acid changes are not randomly distributed, but selectively generated. From these data, we can also suggest that core amino changes are influenced by the host immune system. Regarding the mechanism of the relationship between virus mutations and host immunity, it has been recently reported that amino acid changes in epitopes of T and B lymphocytes in the HBV core region may markedly influence T lymphocyte function or subsequent cytokine release. Therefore, we speculate that such amino acid changes affect the viral antigenicity against the host immunity and may be associated with the clinical severity of hepatitis. This study suggests that the frequency of core mutations may be associated with the severity of hepatitis and the HBV seroconversion from HBeAg to anti-HBe. On the other hand, we could not find any difference in the HBV core protein among several HBV viruses. To differentiate HBV among groups, it may be necessary to examine not only various HBV proteins including surface protein and polymerase protein, but also the type of HLA in the host. Further investigation is needed regarding other causes of activity in chronic hepatitis B.

We conclude that identifying mutations in the HBV core region is important for predicting the clinical course of hepatitis B.

CONCLUSION: The levels of Zn, Se, Cu, and oxidative stress (MDA), as well as related anti-oxidative enzymes (GR and GPX) in blood have important impact on the viral factors in chronic hepatitis C. The distribution of these parameters might be significant biomarkers for HCV.

Abstract

AIM: To assess the extent of micronutrient and oxidative stress in blood and to examine their linkages with viral loads in chronic hepatitis C patients.

METHODS: Hepatitis C virus (HCV)-RNA levels were quantified in the serum from 37 previously untreated patients with chronic hepatitis C. The plasma and erythrocyte micronutrients (zinc, selenium, copper, and iron) were estimated, and malondialdehyde (MDA) contents were determined as a marker to detect oxidative stress. Antioxidant enzymes, superoxide dismutase (SOD), glutathione peroxidase (GPX) and glutathione reductase (GR) activities in blood were also measured. The control group contained 31 healthy volunteers.

RESULTS: The contents of zinc (Zn), and selenium (Se) in plasma and erythrocytes were significantly lower in hepatitis C patients than in the controls. On the contrary, copper (Cu) levels were significantly higher. Furthermore, plasma and erythrocyte MDA levels, and the SOD and GR activities in erythrocytes significantly increased in hepatitis C patients compared to the controls. However, the plasma GPX activity in patients was markedly lower. Plasma Se ($r = -0.730$, $P < 0.05$), Cu ($r = 0.635$), and GPX ($r = -0.675$) demonstrated correlations with HCV-RNA loads. Significant correlation coefficients were also observed between HCV-RNA levels and erythrocyte Zn ($r = -0.403$), Se ($r = -0.544$), Cu ($r = 0.701$) and MDA ($r = 0.629$) and GR ($r = 0.441$).

INTRODUCTION

Essential micronutrients are involved in many metabolic pathways in the liver, such as enzymatic functions and protein synthesis, oxidative damage and anti-oxidant defense, immunological competence, interferon therapy response regulations, and alterations of the virus genomes^[1-3]. Reactive oxygen species (ROS) have also been implicated in a number of hepatic pathologies in exacerbating liver diseases^[6-10]. The oxidant production associated with immune reactions against viral hepatitis leads to the formation of hepatocellular carcinoma (HCC)^[8]. Therefore, the changes in micronutrients and their demolishing effects against oxidative stress are factors for viral hepatitis pathogenesis.

HCV is a major cause of chronic liver disease. HCV infection frequently leads to chronic hepatitis with increasing risk of developing liver cirrhosis and HCC. Interferon with or without ribavirin is the only drug with proven efficacy in treating chronic HCV infections^[11-13]. Unfortunately, these therapeutic models maintain the rate of sustained virologic response (SVR) to approximately 10-40%^[14-16]. The effective advancement in the antiviral treatments against chronic hepatitis C is necessary.

There are several factors that attribute to the failure in achieving a SVR for the majority of patients^[17-19]. Hepatic iron deposit has been identified as one of these factors^[20-23]. Iron depletion and zinc supplementation^[24,25] may improve the response of chronic hepatitis C patients to interferon treatment. Moreover, viral factors may affect the outcome of the therapy. Zhang *et al.*^[26], indicated that selenium-dependent glutathione peroxidase (GPX) modules are

encoded in the RNA viruses. The presence of zinc ion also decreases the HIV-1 reverse transcriptase activity^[27]. It is conceivable that the micronutrient status may affect the HCV load and viral replication, leading to significant changes in reported SVR rates. However, there is limited information about the distribution of micronutrients and their effects on viral production.

Our present study aimed to examine the levels of micronutrients (zinc, copper, iron, selenium), and malondialdehyde (MDA) which is an indirect marker for oxidative stress in blood. Moreover, superoxide dismutase (SOD), glutathione reductase (GR) and GPX activities were assessed. In addition, the relationships among these parameters and HCV-RNA levels in patients with chronic hepatitis C were investigated.

MATERIALS AND METHODS

Subjects

This study contained 33 patients with chronic hepatitis C including 20 men and 13 women (from 2002 to 2003). The mean age of the patients was 49.5 ± 2.4 years. All patients underwent serological and biochemical analyses. Diagnosis of chronic hepatitis C was based on elevated serum alanine aminotransferase levels for at least 6 mo, and consistent detection of serum HCV-RNA. All patients were negative for hepatitis B surface antigen and HIV, and none had liver cirrhosis or renal disease.

A control group of 31 healthy volunteers (17 men and 14 women) was recruited from blood donors aged 43.2 ± 1.7 years. They underwent a routine medical examination prior to the blood collection.

Biochemical determinations and HCV-RNA analysis

Venous blood samples were collected from patients prior to treatment. Erythrocytes were pelleted by centrifugation and washed thrice with cold isotonic saline. The plasma and erythrocyte zinc (Zn), copper (Cu), and iron (Fe) levels were determined by flame atomic absorption spectrophotometry (932 plus, GBC, Australia) as previously described^[28]. The accessory hydride formation system (HG3000), also from GBC, was used for determining selenium (Se) concentrations. All samples were analyzed in triplicate. Serum "second-generation" reference materials (Seronorm™ Trace Elements Serum) were purchased from Nycomed, Oslo, Norway.

Thiobarbituric acid substances reacted with products of lipid peroxidation, mainly MDA, producing a pink color compound that could be measured at 535 nm. Following the protocol in Richard *et al.*^[29], thiobarbituric acid levels were determined in plasma and erythrocytes of patients and controls. Results were expressed as nanomoles of MDA per milliliter in plasma and as nanomoles of MDA per gram protein in erythrocytes. Protein concentration was determined using the Coomassie protein assay (Pierce, Rockford, IL, USA) with bovine serum albumin as the standard.

Erythrocyte SOD and GPX activities in plasma were determined with RANSOD kits (Randox, San Diego) and Cayman GPx assay kits (Cayman Chemical, USA) respectively. All values were expressed as units per gram hemoglobin or

units per milliliter. One unit of SOD was defined as the amount of enzyme necessary to produce 50% inhibition in the *p*-iodonitrotetrazolium reduction rate. The activity of GR in erythrocytes was also measured at 340 nm using the commercial kits (GR340, OxisResearch). One GR activity unit was defined as the amount of enzyme catalyzing the reduction of 1 mmol of GSSG.

Additionally, viral RNA was detected and quantitative HCV-RNA was determined by Amplicor (Roche Molecular Diagnostics) and expressed as the log of copies of RNA per milliliter. RNA was extracted from serum samples following the manufacturer's instructions (QIAamp viral RNA kit from Qiagen Inc.). This assay had a lower limit of 100 copies/mL.

Statistical analysis

Data were expressed as mean \pm SE. Significant differences in variables between two groups were tested by Student's *t*-test. $P < 0.05$ was considered statistically significant. Linear regressions were used to analyze the correlation among variables.

RESULTS

Blood micronutrient levels

Table 1 shows the values of specific micronutrients in plasma of chronic hepatitis C patients and healthy subjects. There was a significant decrease in Zn and Se and a statistical increase in Cu concentrations of the patients ($P < 0.05$). However, plasma Fe levels revealed no significant difference ($P > 0.05$).

The erythrocyte concentration of Cu in the patients was significantly higher than that in the healthy controls, and the Fe concentrations were not significantly different between two groups. Furthermore, Se and Zn levels were significantly lower in erythrocytes of the patients (Table 2).

Table 1 Plasma concentrations of Zn, Cu, Fe, and Se in patients with chronic hepatitis C and healthy controls (mean \pm SE)

Groups	Plasma			
	Zn (mg/L)	Cu (mg/L)	Fe (mg/L)	Se (μ g/L)
Patients	0.13 ± 0.01^a	1.68 ± 0.08^a	0.56 ± 0.04	159.12 ± 5.30^a
Healthy controls	0.55 ± 0.06	0.53 ± 0.03	0.57 ± 0.03	216.69 ± 7.44

^a $P < 0.05$ vs healthy controls.

Table 2 Erythrocyte levels of Zn, Cu, Fe, and Se in patients with chronic hepatitis C and healthy controls (mean \pm SE)

Groups	Erythrocytes			
	Zn (mg/L)	Cu (mg/L)	Fe (mg/L)	Se (μ g/L)
Patients	0.79 ± 0.05^a	0.52 ± 0.05^a	$1\ 369.8 \pm 88.6$	55.09 ± 3.79^a
Healthy controls	1.40 ± 0.10	0.09 ± 0.01	$1\ 075.9 \pm 96.7$	139.08 ± 5.76

^a $P < 0.05$ vs healthy controls.

Evidence of oxidative stress

Table 3 summarizes the values of parameters related to oxidative stress. Erythrocyte and plasma MDA increased

Table 3 MDA levels, SOD, GR, and GPX activities in patients with chronic hepatitis C and healthy controls (mean±SE)

Group	MDA		Parameters ¹		
	Plasma (nmol/mL)	RBC (nmol/g protein)	SOD (U/g Hb)	GR (mU/g Hb)	GPX [nmol/(min·mL)]
Patients	0.41±0.02 ^a	0.33±0.02 ^a	17.95±0.51 ^a	40.10±2.48 ^a	38.95±1.99 ^a
Healthy controls	0.15±0.01	0.19±0.02	15.24±0.45	30.15±2.69	51.26±2.66

^a*P*<0.05 vs healthy controls. ¹MDA: malondialdehyde; SOD: superoxide dismutase; GR: glutathione reductase; GPX: glutathione peroxidase.

significantly in patients. Also, the erythrocyte Cu, Zn-SOD, and GR activities increased significantly in the patients compared to the controls. In contrast, the plasma Se-dependent GPX activity in hepatitis C patients was markedly lower.

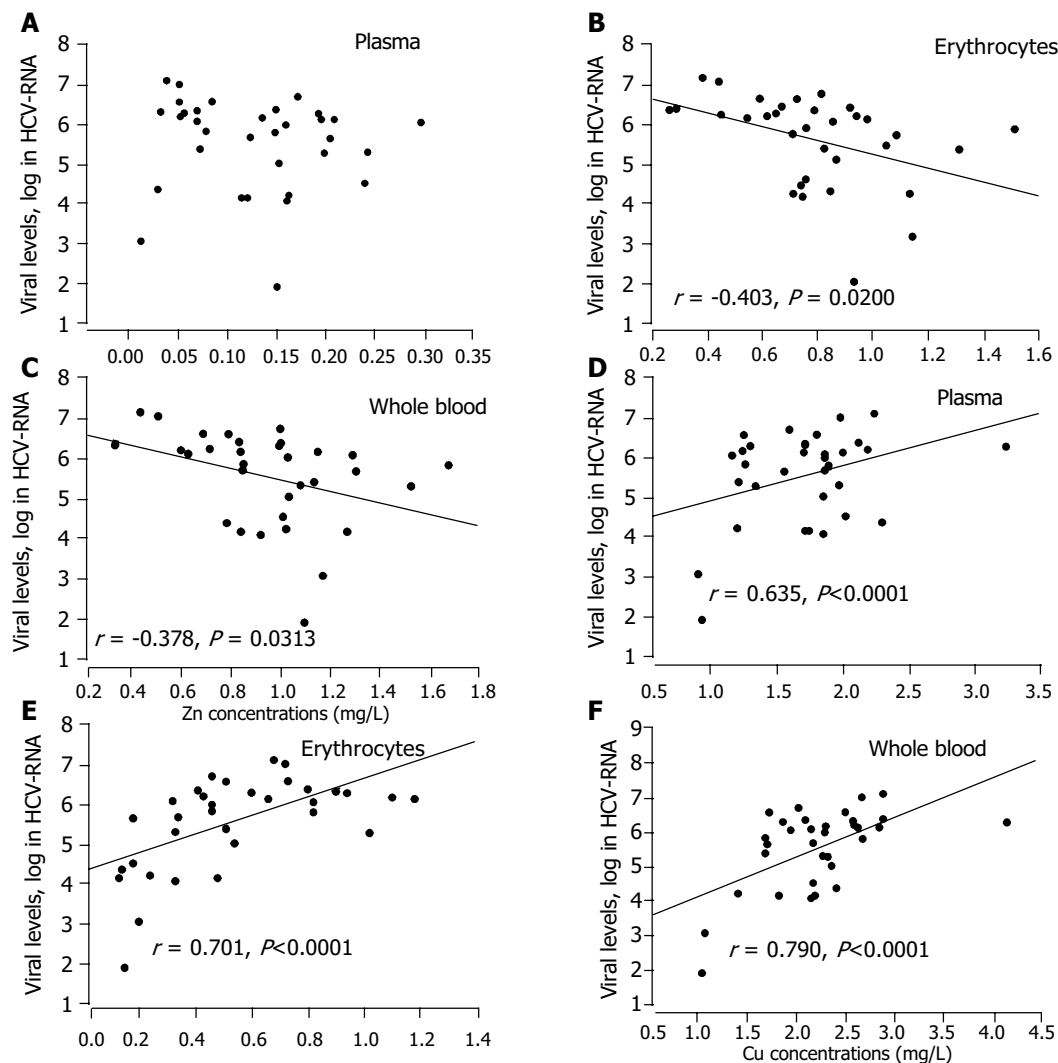

Correlation of micronutrient concentrations with HCV-RNA levels

Figures 1A-C shows that there was a significant negative relationship between Zn contents in erythrocytes/whole blood and HCV-RNA levels (by log) in patients. In plasma, however, no significant correlation was observed. A positive correlation was noted between plasma Cu and HCV-RNA levels in patients, and an even stronger correlation between the Cu in erythrocytes/whole blood and HCV-RNA levels (Figures 1D-F).

The Se levels in plasma/erythrocytes/whole blood had a statistically significant negative correlation with HCV-RNA levels, whereas a better correlation was found in plasma or whole blood (Figures 1G-I, *r* = -0.730, -0.742, *P*<0.0001).

Relationship between oxidative stress and HCV-RNA levels

No significant correlation was found between MDA in plasma and HCV-RNA levels (*P*>0.05, data not presented). However, erythrocyte MDA production was positively correlated with HCV-RNA concentration (Figure 1J, *r* = 0.629, *P*<0.0001). Additionally, HCV-RNA levels correlated with both erythrocyte GR (Figure 1K, *r* = 0.441, *P* = 0.01) and plasma GPX (Figure 1L, *r* = -0.675, *P*<0.0001) activities. The activities of SOD did not correlate with the HCV-RNA levels (*P*>0.05, data not shown).

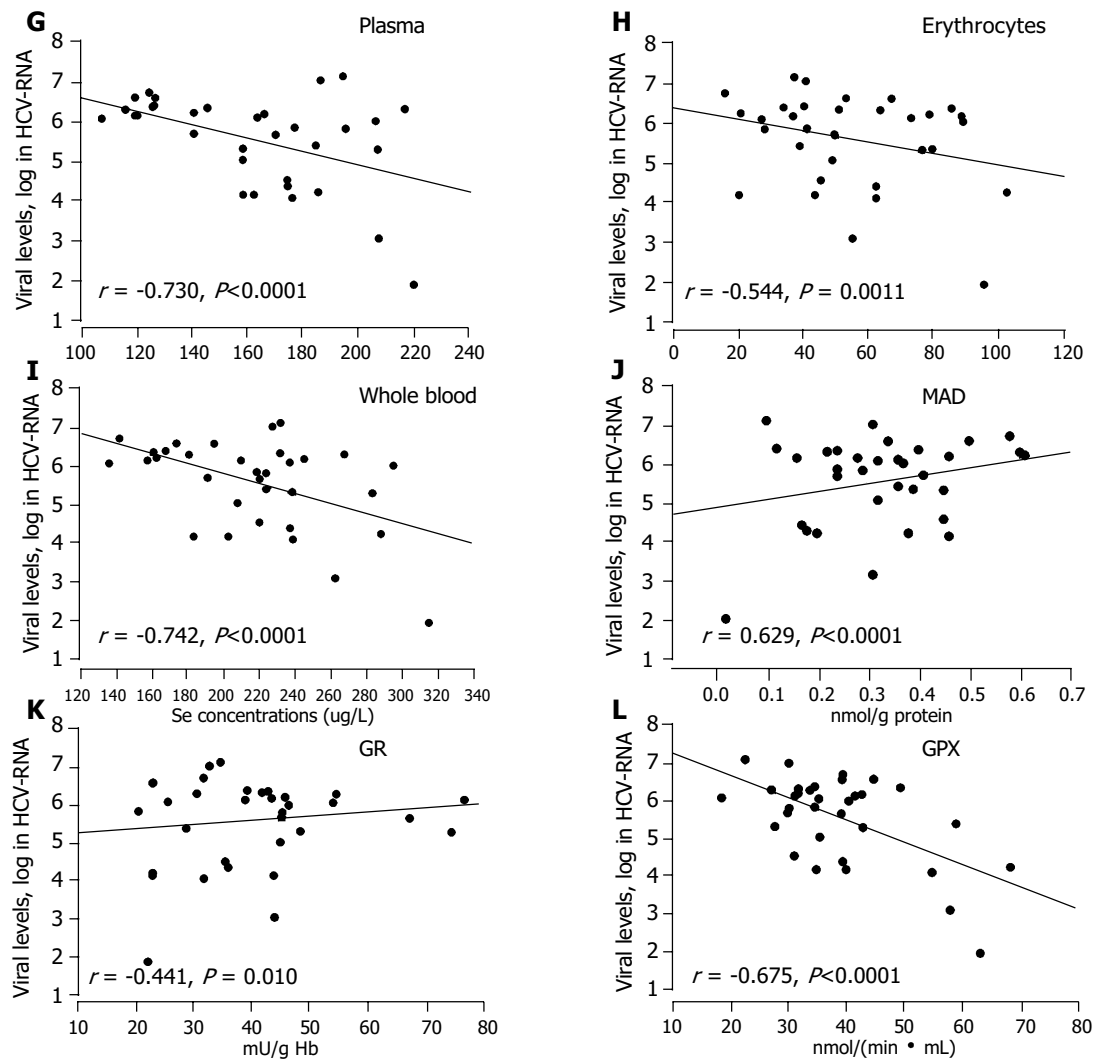

Figure 1 Correlations between viral levels and plasma zinc (A), erythrocytes zinc (B), or whole blood zinc (C), plasma copper (D), erythrocyte copper (E), whole blood copper (F), plasma selenium (G), erythrocyte selenium (H), whole

blood selenium (I), erythrocyte MDA (J), GR (K), and plasma GPX activities (L) in chronic hepatitis C patients.

DISCUSSION

The purpose of our study was to find the levels of blood micronutrient and oxidative stress in patients with chronic hepatitis C, and to search for linkages between the HCV-RNA levels and micronutrient status, as well as between oxidative stress and the presence of antioxidant enzymes.

The essential micronutrients (Zn, Cu, Fe, and Se) might exacerbate liver disease in case of deficiency, imbalance, or toxicity^[5,30]. They are also linked to the process of oxidation during chronic liver damage^[6,7,31]. In the present investigation, the levels of Zn and Se in plasma and erythrocytes of HCV-infected patients decreased significantly compared to healthy subjects. On the contrary, the Cu levels in patients were significantly higher than those in the control group. Nevertheless, alterations of these micronutrients in plasma and erythrocytes varied in different magnitudes.

Decreasing levels of Zn, Se, or increasing Cu levels were also noted in sera of hepatitis cases^[31-33]. HCV- and HIV-co-infected patients showed markedly lower blood Se levels compared to HIV-infected patients without concomitant HCV infection^[34]. However, no significant difference in blood Zn and Se concentrations was observed between chronic

hepatitis C patients and controls^[35,36]. One possible explanation for this discrepancy is that, the subjects in the above two studies could not be distinguished by the type of hepatitis, and patients with hepatitis A-D may have different blood concentrations of Zn and Se. The present study did not find significantly higher values of erythrocyte Fe in the patients to coincide with the results in Loguercio *et al.*^[36], whereas some data in the literature show an obvious increase of Fe contents both in the liver and in the serum of these patients^[37,38]. Thus, the pretreatment levels of blood Fe might not be a proper marker for the iron status in patients with chronic hepatitis C infection.

Although the precise causes remain to be elucidated, there is evidence that cytokines might alter the levels of serum trace elements in viral hepatitis^[32]. It was reported that inflammatory cytokines are higher in HCV-infected individuals than in normal individuals^[39,40]. Increased Cu levels might result from inflammatory responses^[32]. Therefore, the present results suggest that changes of Zn, Cu, and Se levels in plasma and erythrocytes of patients with chronic hepatitis C are directly related to the pathology developed in the liver.

ROS plays a crucial role in the induction and progression of liver disease, and are involved in the transcription and activation of a large series of cytokines that could induce production of ROS. Some studies indicate that treatment of high serum Se and Zn levels leads to reduction of inflammatory reaction in hepatitis patients^[41,42]. In addition to the anti-inflammatory reaction, Se or Zn has antioxidant and immuno-modulatory effects^[43-45]. Copper is also associated with the inflammatory response and oxidative stress^[46,47]. In the present study, decreased activity of Se-dependent GPX and increased Cu, Zn-SOD, and GR activities either in plasma or in erythrocytes suggest that anti-oxidative capability is limited during circulation. The presence of significant increase in MDA levels also indicates a possible oxidative insult in these patients. Liver cirrhosis induces a significant decrease in Se and Zn levels, another indication of presence of oxidative stress^[36]. The levels of MDA have been correlated with the severity of chronic hepatitis^[45]. There is evidence that the production of free radicals increases while anti-oxidant defense decreases significantly in all types of liver damage^[6-9]. Therefore, supportive nutrients, Zn, Cu, and Se, and oxidative stress might be sensitive indicators for the degree of liver injuries and the sustained response to therapy in chronic hepatitis C patients.

The outcome of HCV infection is also thought to depend on the balance between the rate of viral replication, rapidity, and specificity and the effectiveness of the host immune response. Few studies have focused on the relationship between circulating pool of these immune-regulated micronutrients and HCV-RNA contents. Our present results suggest that there is a markedly negative relationship between HCV-RNA titer (in log) and either erythrocyte or whole blood Zn concentrations. Similarly, the inverse correlations between HCV-RNA and blood Se levels observed in this study suggest that significant higher viral loads are correlated with lower blood Zn and Se levels in HCV-infected patients.

In addition, higher levels of blood Cu are markedly correlated with higher HCV-RNA concentrations. Little is known about the possible regulatory mechanism of micronutrients in the pathogenesis of HCV infection. However, these nutrients are known to assist in immune-mediated response and involve in the alteration of virus genomes^[5,27,45,48]. It is suggested that the distribution of Zn, Se, and Cu might affect sustained response to therapy in patients with chronic hepatitis C. Therefore, these micronutrients may be involved in multiple points in the immune pathogenesis of HCV infection that is essential for viral clearance.

The oxidative stress is high in hepatitis patients, and there are significant correlations among HCV-RNA and erythrocyte MDA, erythrocyte GR and plasma GPX activities. Zhang *et al.*^[26], reported that Se-dependent GPX modules are encoded in a number of RNA viruses, including HIV-1, HCV, Cocksackie's virus B3, and HIV-2 virus. A HCV-encoded GPX gene might demonstrate that oxidant stress is associated with HCV disease progression. In HIV-infected patients, the decline in Se levels is greater than that in those with HCV co-infection^[34]. Se deficiency increases the virulence of CVB3 infection, which is encoded

by the GPX gene within Keshan disease's cofactor^[26,49]. It has been proposed that Se-dependent GPX participates directly in immune cytotoxicity, enabling neutrophils and macrophages to complete intracellular lysis of phagocytosed cells. In previous investigations, an inverse relationship between Se level and HBV infection incidence was found^[50]. Zn has also been studied for its antiviral effect against HIV, rhinovirus, and herpes virus^[24]. Moreover, Zn supplementation enhances the response to interferon therapy in chronic hepatitis C patients^[25]. Zn is necessary for the dimerization of interferon, which activates the interferon receptor^[51]. It is apparent that erythrocyte and plasma Zn, Se, and Cu levels and oxidative stress are associated with HCV-RNA levels.

In conclusion, the distribution of Zn, Cu, Se levels and MDA product, GPX and GR activities in blood may be an additional host-specific parameter (outside of predictive viral factors) with a predictive value for the responsiveness of patients to interferon/ribavirin therapy. Furthermore, these results may be affected by immunocytokines as a host-defense system during HCV infection.

ACKNOWLEDGMENT

Great appreciation is extended to Miss Anna Hsu of Oregon State University for the English editing of the manuscript.

Abstract

AIM: To investigate the biological impacts of "hot-spot" mutations on genotype B and C HBV X proteins (HBx).

METHODS: Five types of "hot-spot" mutations of genotype B or C HBV X genes, which sequentially lead to the amino acid substitutions of HBx as I127T, F132Y, K130M+V131I, I127T+K130M+V131I, or K130M+V131I+F132Y, respectively, were generated by means of site-directed mutagenesis. To evaluate the anti-proliferative effects, HBx or related mutants' expression vectors were transfected separately to the Chang cells by lipofectamine, and the cells were cultured in hygromycin selective medium for 14 d, drug-resistant colonies were fixed with cold methanol, stained with Giemsa dyes and scored (increase of the colonies indicated the reduction of the anti-proliferation activity, and vice versa). Different types of HBx expression vectors were co-transfected separately with the reporter plasmid pCMV β to Chang cells, which were lysed 48 h post-transfection and the intra-cellular β -galactosidase activities were monitored (increase of the β -galactosidase activities indicated the reduction of the transactivation activity, and vice versa). All data obtained were calculated by paired-samples *t*-test.

RESULTS: As compared to standard genotype B HBx, mutants of I127T and I127T+K130M+V131I showed higher transactivation and anti-proliferative activities, while the mutants of F132Y, K130M+V131I, and K130M+V131I+F132Y showed lower activities. As compared to standard genotype C HBx, I127T mutant showed higher transactivation activity, while the other four types of mutants showed no differences. With regard to anti-proliferative activity, compared to standard genotype C HBx, F132Y and K130M+

V131I mutants showed lower activities, and K130M+V131I+F132Y mutant, on the other hand, showed higher activity, while the mutants of I127T and I127T+K130M+V131I showed no differences.

CONCLUSION: "Hot-spot" mutations affect the anti-proliferation and transactivation activities of genotype B and/or C HBx, and the biological impacts of most "hot-spot" mutations on HBx are genotype B and C differentiated.

INTRODUCTION

HBV belongs to the hepadnaviridae family, which has a double-stranded DNA genome with a single-stranded gap. The genome of HBV encodes four kinds of proteins including the envelope protein (S/Pre-S), the core protein (C/pre-C), the polymerase (P), and the X protein (HBx). HBx is a multi-functional transcriptional transactivator^[1] and has been shown to be crucial in the pathogenesis of HBV-related diseases^[2].

Based on an intergroup divergence of 8% or more in the complete or partial nucleotide sequences, HBV can be classified presently into eight genotypes^[3,4], termed A-H, in which B and C genotypes are prevalent in East Asia including China^[5]. Recent studies^[6,7] revealed that the infection of genotype B or C HBV brought about quite different clinical manifestations and liver histological changes, yet the exact mechanisms involved remain largely obscure. Considering the important role HBx plays in the pathogenesis of HBV, it is reasonable to speculate that the clinical and histological differences of the infection of genotype B and C HBV may be partially related with the functional differentiations between these two genotypes of HBx due to the genetic variability.

Genetic variability^[8] of HBx includes both of the genotype-specific variations and the mutations emerged during chronic infection. We had shown in our previous study^[9] that there were 16 amino acid genotype-specific

variations between genotype B and C HBx, and the biological functions including transactivation activities and anti-proliferation capacities were different between these two HBx genotypes. It was also demonstrated that during chronic infection, genotype B and C HBx shared the same “hot-spot” mutations in the amino acid positions of 127, 130, 131, and 132^[10], we wondered whether these “hot-spot” mutations effected HBx, and more importantly, whether the influences of the same type of mutation on HBx showed genotype B or C specificity. To address these issues, we constructed HBx mutants of each genotype (B or C) with the same “hot-spot” mutations, and comparatively analyzed their differences in biological functions.

MATERIALS AND METHODS

Plasmids

pcDNA3.1-XB and pcDNA3.1-XC were recombinant pcDNA3.1/Hygro(-) (Invitrogen, USA) vectors harboring either genotype B or genotype C HBV X gene with conserved sequences (the amino acid alignment of these two genotypes of HBx is shown in Figure 1) and could express HBx in transfected Chang cells, as detected by immunohistochemistry.

Generation of genotype B or C HBV X mutants with “hot-spot” mutations

pcDNA3.1-XB or pcDNA3.1-XC was used as the template and the mutagenesis was carried out using GeneTailor site-directed mutagenesis system (Invitrogen, USA) following the manufacturer's instructions. In brief, 200 ng of pcDNA3.1-XB or pcDNA3.1-XC DNA was methylated by 8 U methylase in a total volume of 32 μ L, and 2 μ L of methylated DNA was used as the template for PCR using paired primers (reverse primer R was used together with one of the forward primers F1-F5 to generate nucleotide mutation, sequentially resulting in amino acid substitution) (Table 1). After amplification, 5 μ L of PCR product was used to transform *E. coli* DH α -T1, and transformants were screened by growth on bacterial culture plates with ampicillin for selection. All mutants were sequenced to confirm the correctness of the induced mutations.

Cell culture and transfection

The human liver cell line, CCL13 (Chang cells) was cultured in Dulbecco's modified Eagle minimal essential medium with penicillin (100 U/mL) and streptomycin (100 μ g/mL), supplemented with 10% fetal calf serum. Recombinant plasmid DNA was extracted and purified with Qiagen maxiprep kits, and used to transfect Chang cells in 60-mm plates or six-well plates by lipofectamine 2000. Duplicate plates/wells were used for all samples. Empty vector pcDNA3.1/Hygro(-) was used as a mock transfection control.

Colony formation assay

Chang cells (3×10^5) in six-well plates were transfected with 2.5 μ g of HBx constructs or empty vector. Forty-eight hours after transfection, the cells were subcultured at a ratio of 1:3, and cultured in 200 μ g/mL hygromycin (Roche, Germany) selective medium for 14 d. Drug-resistant colonies were fixed with cold methanol, stained with Giemsa, and then scored.

β -galactosidase test

Two micrograms of HBx constructs and 2.0 μ g reporter pCMV β plasmids (Promega, USA) were co-transfected into Chang cells in 60-mm plates (5×10^5 cells per plate). Cells were harvested and lysed at 48 h post-transfection. After protein normalization by the Bradford assay (Bio-Rad Laboratories, Hercules, CA, USA), equal amounts of protein (30 ng) were used for β -galactosidase assay following the manufacturer's instructions.

Statistical analysis was performed using a paired *t*-test. $P < 0.05$ was taken as significant.

RESULTS

Generation of genotype B or C HBx mutants

Mutations at HBV nucleotides 1 753, 1 762, 1 764, and 1 768 resulted in amino acid substitution of HBx at positions 127, 130, 131, and 132, respectively. In this study, nucleotide mutations were generated in each genotype of HBx with five types of combinations as 1 753^{T→C}, 1 762^{A→T}+1 764^{G→A}, 1 753^{T→C}+1 762^{A→T}+1 764^{G→A}, 1 762^{A→T}+1 764^{G→A}, 1 762^{A→T}+1 764^{G→A}.

Figure 1 There were 16 amino acid variations between genotype B and C HBx, which were located at amino acid positions 5, 30, 31, 34, 36, 39, 40, 42, 43, 44, 47, 87, 88, 116, 118, and 119, respectively. Four boxed amino acids, located at the positions of 127, 130, 131, 132, respectively, were to be substituted by site-directed mutagenesis.

Anti-proliferation activities of genotype B or C HBx mutants

To study the anti-proliferation activities of HBx mutants, we performed colony formation assay^[11], in which the increasing anti-proliferation activities should be paralleled with the reduction of cell colonies, and vice versa. Chang cells were transfected separately with parental vector pcDNA3.1/Hygro(-) or recombinant vectors harboring different types of HBx; cells were subcultured in hygromycin selective medium 48 h post-transfection, and the drug-resistant colonies formed 14 d later were stained with Giemsa and scored. The results showed that, as compared with XB (standard genotype B HBx), expression of mutants XB-127 and XB-127-130-131 caused the reduction in the number of colonies, and expression of mutants XB-132, XB-130-131, or XB-130-131-132 caused the elevation (Figure 2). As for genotype C HBx, expression of mutant XC-130-131-132 caused the sharp reduction of colonies to zero, and mutants of XC-132 and XC-130-131, on the other hand, caused the elevation in the number of colonies as compared with XC (standard genotype C HBx), while XC-127 and XC-127-130-131 showed no differences from XC (Figure 3). It indicated that effects of three types of “hot spot” mutations, i.e., I127T, I127T+K130M+V131I, and K130M+V131I+F132Y, on anti-proliferation of HBx were

Figure 2 Chang cells were transfected by genotype B X gene expression vectors and screened by hygromycin, the drug-resistant colonies formed 14 d

post-transfection were fixed by cold methanol, stained with Giemsa (A) and counted (B). The results are shown as mean±SD of six separate experiments.

Figure 3 Chang cells were transfected by genotype C X gene expression vectors and screened by hygromycin, the drug-resistant colonies formed 14 d

post-transfection were fixed by cold methanol, stained with Giemsa (A) and scored (B). The results are shown as mean±SD of six separate experiments.

Figure 4 Chang cells were co-transfected by pCMV β together with the X gene or related mutants with genotype B (A) or genotype C (B). Forty-eight hours post-transfection, the cells were lysed and the intracellular β -galactosidase

activities were monitored after protein normalization. The results are shown as mean \pm SD of six separate experiments.

genotype B and C differentiated. In addition, it was also demonstrated that all HBx caused dramatic reduction of colonies as compared with the empty vector pcDNA3.1/Hygro(-), irrespective of genotypes (B or C) or the types (the standard or the mutants), indicating the retaining of anti-proliferation activities of all HBx.

Transactivation activities of genotype B or C HBx mutants

It was reported previously that HBx could transactivate the CMV immediate early promoter^[12], so plasmid pCMV β containing the CMV immediate early promoter and expressing β -galactosidase was used as the indicator to evaluate the transactivation activities of HBx mutants. In our study, pCMV β was co-transfected with an HBx construct to Chang cells, which were lysed 48 h post transfection, and intra-cellular β -galactosidase activities were monitored. The results showed that, as for genotype B HBx, expression of mutants XB-127 and XB-127-130-131 induced increase in β -galactosidase activities as compared with XB, and three other mutants, i.e., XB-132, XB-130-131, and XB-130-131-132 induced decreased activities (Figure 4A and Table 2), as for genotype C HBx, XC-127 induced the increase in β -galactosidase activities as compared with XC, while the other four types of mutants showed no differences (Figure 4B and Table 2). The results revealed that effects

of four types of “hot spot” mutations, i.e., I127T+K130M+V131I, K130M+V131I, K130M+V131I+F132Y, and F132Y, on transactivation of HBx were genotype B and C differentiated. In addition, the results also showed that expression of HBx, irrespective of genotypes (B or C) or the mutant types, induced the increase in intra-cellular β -galactosidase activities as compared with the empty vector pcDNA3.1/Hygro(-), indicating the retaining of transactivation activities of all HBx.

DISCUSSION

There are increasing evidences that the clinical manifestations, the long-term prognosis, the liver histological changes, and the response to treatment of interferon and nucleosidic inhibitors may differ depending on which genotype of HBV the patient has been infected with^[13]. In Taiwan, where the genotypes of HBV were predominantly B and C, genotype C is associated with more severe liver disease and genotype B is associated with the development of hepatocellular carcinoma (HCC) in young non-cirrhotic patients^[6]. In contrast, genotype B has a relatively good prognosis in Japan and China and is rarely associated with the development of HCC^[7]. However, the impact of genotypes on HBV pathogenesis remains largely obscure.

HBx is a promiscuous activator^[1] and considered to be of importance in the pathogenesis of HBV, it can indirectly activate miscellaneous viral and cellular genes^[14], induce or block apoptosis of the infected cells^[15,16], and induce HCC in certain lines of transgenic mice^[17,18]. We demonstrated previously that there were 16 amino acid differences between standard genotype B and C HBx, and the activities including transactivation and anti-proliferation were different between these two genotypes of HBx. These results indicated that the B, C genotype-specific structural and functional differentiations of HBx may partially contribute to the different clinical outcomes and histological changes of the infection with genotype B or C HBV.

In addition to the genotype-specific variations, both of B and C genotypes of HBx also showed the same gene mutations within their coding regions (nt1 376-1 840), i.e., nt1 753^{T→C}, nt1 762^{A→T}, nt1 764^{G→A}, and nt1 768^{T→A}, which accordingly led to the amino acid variations as I127T, K130M, V131I, and F132Y. These “hot-spot” mutations

I127T+K130M+V131I	↑	↑	–	–
K130M+V131I	↓ ⁴	↓	–	↓
K130M+V131I+F132Y	↓	↓	–	↑
F132Y	↓	↓	–	↓

¹Changes of biological functions were compared with XB; ²Changes of biological functions were compared with XC. ³, ⁴, and ⁵ accordingly indicate increased, decreased and equal activities of HBx mutants as compared with XB/XC.

emerged due to the error-prone reverse transcriptase activity of HBV polymerase^[19] and the long-term virus-host interaction, and occurred mainly during chronic infection including different clinical stages of chronic hepatitis^[20] and HBV-associated HCC as well^[21]. In fact, these “hot-spot” mutations appeared predominantly in five types: I127T, F132Y, K130M+V131I, I127T+K130M+V131I, or K130M+V131I+F132Y. Our results demonstrated that these mutations affected the anti-proliferation and transactivation activities of genotype B and/or C HBx, and more importantly, the impacts of most types of the “hot-spot” mutations on HBx were genotype B and C differentiated, i.e., as concerning the anti-proliferation activities, impacts of HBx mutants of I127T, I127T+K130M+V131I, and K130M+V131I+F132Y showed genotype B and C differentiated, and regarding the transactivation activities, impacts of mutants of I127T+K130M+V131I, K130M+V131I, K130M+V131I+F132Y, and F132Y showed genotype B and C differentiated (Table 3).

It was also revealed that all HBx mutants, irrespective of genotypes or mutant types, retained their biological functions. It may be therefore concluded that the effects of the mutations on HBx was relatively mild and was in strong contrast to the distal COOH-terminal deletion mutants isolated from the integrated chromosomes of HCC tissues, which completely abrogated the transactivation or anti-proliferation activities^[22,23]. In addition, it was previously reported that the transactivation activities of HBx are often linked to anti-proliferation function^[24]. Our results strikingly showed that the linkage of these two activities only occurred in genotype B HBx, in which the increasing activation activities of HBx mutants were coupled with the enhanced anti-proliferation activities, and vice versa, while it seemed that the activities of anti-proliferation and transactivation were completely separated in genotype C HBx (Table 3). Therefore, it was concluded that association of transactivation with anti-proliferation activities was a common feature of HBx with genotype B rather than genotype C.

There is no indisputable evidence showing that the transactivation activity of HBx contributes to liver disease. However, reduction of the anti-proliferation effect may endow a growth advantage on cells containing these particular HBx mutants, while increase of anti-proliferation effects will lead to cell disruption and hence accelerate intracellular spread of HBV^[25]. So in this point, any functional changes of anti-proliferation are pathogenic.

In summary, “hot-spot” mutations affect the anti-proliferation and transactivation activities of genotype B

and/or C HBx, and the biological impacts of most “hot-spot” mutations on HBx are genotype B and C differentiated. Together with our previous findings demonstrating the different biological functions between genotype B and C HBx^[9,26], we conclude that genetic variability results in functional differentiations between genotype B and C HBx. Nevertheless, considering the sophisticated mechanism of HBV pathogenesis^[27], whether these genotype B and C specific functional differentiations of HBx are responsible for the different clinical outcomes and liver histological changes between two genotypes of HBV, and more importantly, the exact mechanisms involved await further studies.

Abstract

AIM: To investigate the biological function of p7 protein and to look for proteins interacting with p7 protein in hepatocytes.

METHODS: We constructed p7 protein bait plasmid by cloning the gene of p7 protein into pGBKT7, then transformed it into yeast AH109 (a type). The transformed yeast was mated with yeast Y187 (α type) containing liver cDNA library plasmid, pACT2 in 2 \times YPDA medium. Diploid yeast was plated on synthetic dropout nutrient medium (SD/-Trp-Leu-His-Ade) containing x- α -gal for selection and screening. After extracting and sequencing of plasmids from blue colonies, we performed sequence analysis by bioinformatics.

RESULTS: Fifty colonies were selected and sequenced. Among them, one colony was *Homo sapiens* signal sequence receptor, seven colonies were *Homo sapiens* H19, seven colonies were immunoglobulin superfamily containing leucine-rich repeat, three colonies were spermatid peri-nuclear RNA binding proteins, two colonies were membrane-spanning 4-domains, 24 colonies were cancer-associated antigens, four colonies were nucleoporin 214 ku and two colonies were CLL-associated antigens.

CONCLUSION: The successful cloning of gene of protein interacting with p7 protein paves a way for the study of the

physiological function of p7 protein and its associated protein.

INTRODUCTION

Hepatitis C virus (HCV) is a major cause of chronic hepatitis, liver cirrhosis, and hepatocellular carcinoma throughout the world. Although HCV cannot be incubated efficiently *in vitro*, several of its key features have been elucidated in the past few years. HCV, cloned successfully via molecule biological technology^[1,2], is an enveloped, positive single-stranded RNA (9.6-kb) virus belonging to the Flaviviridae. The HCV genome has only one ORF which is flanked by a 5' and 3' noncoding region. The ORF encodes for a large polyprotein precursor of about 3 000 amino acid residues, and this precursor protein is cleaved by the host and viral proteinases to generate at least 10 proteins in the following order: NH2-C-E1-E2-p7-NS2-NS3-NS4A-NS4B-NS5A-NS5B-COOH. HCV proteins not only function in viral replication but also affect a variety of cellular functions^[3-6]. HCV p7, which is located between the E2 and NS2 proteins, is a 63 residue peptide encoded by HCV genome between 2 580-2 768 nt^[7]. Although there are studies on the genomic structure, synthesis and function of p7 protein, the role of the HCV p7 protein in the virus life cycle is not known. To gain more information on the HCV p7 protein, and provide some new clues for elucidating the potential biological function of p7, we looked for proteins interacting with p7 protein by screening human liver cDNA library with yeast two-hybrid system.

MATERIALS AND METHODS

Bacteria, yeast strains and plasmids

All yeast strains and plasmids for yeast two-hybrid experiments

were obtained from Clontech (Palo Alto, CA, USA) as components of the MATCHMAKER two hybrid system 3. Yeast strain AH109 (MATa, *trp1-901*, *leu2-3,112*, *ura3-52*, *his3-200*, *gal4Δ*, *gal80Δ*, *LYS2:GAL1_{UAS}-GAL1_{TATA}-HIS3*, *GAL2_{UAS}-GAL2_{TATA}-ADE2*, *URA3: MEL1_{UAS}-MEL1_{TATA}-LacZ*) containing pGBKT7-53, coding for DNA-BD/mouse p53 fusing protein and AH109 was used for cloning of bait plasmids, yeast strain Y187 (MATa, *ura3-52*, *his3-200*, *Ade2-101*, *trp1-901*, *leu2-3, 112*, *gal4Δ*, *gal80Δ*, *met-*, *URA3: GAL1_{UAS}-GAL1_{TATA}-lacZ MEL1*) containing pTD1-1, in which pACT2 codes for AD/SV40 large T antigen fusing protein and Y187 was used for cloning of library plasmids. Bacterial strain DH5a was used for cloning of every shuttle plasmid. pGBKT7 DNA-BD cloning plasmid, pGADT7 AD cloning plasmid, pGBKT7-53 control plasmid, pGADT7, pGBKT7-Lam control plasmid, pCL1 plasmid were from Clontech Ltd Company (K1612-1). pGEM T vector was from Promega Company, USA.

Chemical agents and culture media

Taq DNA polymerase was purchased from MBI Company. T4 DNA ligase, *Eco*RI and *Bam*HI restriction endonuclease were from Takara. c-Myc mAb secreted by 1-9E10.2 hybridoma (ATCC), and goat anti-mouse IgG conjugated with horseradish peroxidase were from Zhongshan Company, China. Lithium acetate, semi-sulfate adenine, acrylamide, and *N*, *N'*-bis-acrylamide were from Sigma. TEMED was from Boehringer Mannheim. Tryptone and yeast extracts were from Oxoid. X-α-gal and culture media: YPDA, SD/-Trp, SD/-Leu, SD/-Trp/-Leu, SD/-Trp/-Leu/-His, SD/-Trp/-Leu/-His/-Ade were from Clontech Ltd Company. Protein-G agarose were from Roche. pEGM-T vector was from Promega. RT-PCR kit was from Isotope Company of China. Others were from Sigma Company.

Construction of "bait" plasmid and expression of HCV p7 protein

To make the bait plasmid, HCV-p7 sequences were generated by PCR amplification of HCV plasmid (HCV strain 1b). The plasmid containing coding sequences of all the structural and non-structural proteins was used as the template. The sequence of the primers containing the *Eco*RI and *Bam*HI restriction enzyme sites are sense primer: 5'-GAA TTC ATG GCT TTG GAG AAC CTC G-3' and anti-sense primer: 5'-GGA TCC TTA CGC GTA CGC CCG CTG G-3'. The PCR conditions were as follows: at 94 °C for 30 s, at 60 °C for 30 s, at 72 °C for 30 s. Ten nanograms of the 189-bp PCR product were cloned with pGEM-T vector. The primary structure of insert was confirmed by direct sequencing. The fragment of encoding p7 was released from the pEGM-T-p7 by digestion with *Eco*RI and *Bam*HI, and ligated to pGBKT7. Vector pGBKT7-expressing proteins were fused with amino acids 1-147 of the GAL4 DNA binding domain (DNA-BD), pGADT7-expressing proteins were fused with amino acids 768-881 of the GAL4 activation domain (AD). Plasmid pGBKT7-p7 (Figure 1) containing full-length HCV p7 gene could directly express DNA binding domain, c-Myc and p7 fusion protein. The plasmid was transformed into yeast strain AH109 by using lithium acetate method^[8]. Transformed AH109 (bait) was cultured on quadruple dropout media to exclude the auto-activity.

Figure 1 Map of "bait" plasmid pGBKT7-p7.

Western blot analysis

A single isolated colony (1-2 mm in diameter, not older than 5 d) of yeast AH109 transformed with pGBKT7-p7 selected by lithium acetate method was inoculated into 5 mL of SD/-Trp and incubated at 30 °C overnight with shaking at 220-250 r/min. The entire overnight culture was inoculated into 50 mL YPDA medium and incubated at 30 °C with shaking at 220-250 r/min until the *A*₆₀₀ reached 0.4-0.6. The culture was chilled and centrifuged for cell pellets. The yeast protein extracts of p7 were prepared according to urea/SDS method. A part of protein extract was resolved on SDS-polyacrylamide gel and transferred onto nitrocellulose membrane. After being blocked with nonfat dried milk, the membrane was treated with c-Myc mAb for 90 min, then with HRP-goat anti-mouse IgG at the dilution of 1:500 for 60 min. Subsequently the blot was developed by 4-chloro-1-naphthol and H₂O₂. The yeast AH109 cells with transformed pGBKT7 were used for positive control and the untransformed yeast, AH109 cells were used for negative control.

Screening of liver cell cDNA library by yeast two-hybrid system

One large (2-3 mm), fresh (<2 mo old) colony of AH109 (bait) was inoculated into 50 mL of SD/-Trp and incubated at 30 °C overnight (16-24 h) with shaking at 250-270 r/min. Then the cells were spun by centrifuging the entire 50 mL culture at 1 000 r/min for 5 min. After supernatant was decanted, the cell pellet was resuspended in the residual liquid by vortexing. A human liver cDNA library was cloned into pACT2 and yeast reporter strain Y187 (Clontech Co.). The entire AH109 (bait) culture and 1 mL human liver cDNA library (1×10⁶ CFU/mL) were combined and cultured in a 2-L sterile flask and 45 mL of 2 YPDA/Kan was added and swirled gently. After 20 h mating, the cells were spun re-suspended and spread on 50 large (150 mm) plates containing 100 mL of SD/-Ade/-His/-Leu/-Trp (QDO). After growth for 6-15 d, the yeast colonies were transferred onto the plates containing X-α-gal to check for expression of the MEL1 reporter gene (blue colonies).

Plasmid isolation from yeast and transformation of E. coli with yeast plasmid

Approximately 1×10⁶ colonies were screened and 50 positive clones were identified. Yeast plasmid was isolated from

positive yeast colonies with lyticase method (Clontech Co.), and transformed into super-competence *E. coli* DH5 α by a chemical method. Transformants were plated on ampicillin SOB selection media and grown under selection. Subsequently, pACT2-cDNA constructs were re-isolated following the standard protocol, analyzed by restriction digestion and sequencing in.

Bioinformatic analysis

After the positive colonies were sequenced, the sequences were blasted with GenBank to analyze the function of the genes (<http://www.ncbi.nlm.gov.blast>).

Confirmation of the true interaction in yeast

To confirm the true protein–protein interaction and exclude false positives, the plasmids of positive colonies were transformed into yeast strain Y187, and then mating experiments were carried out by mating with yeast strain AH109 containing pGBKT7-p7 or pGBKT7-Lam. After mating, the diploids of yeast were plated on SD/-Ade-His-Leu-Trp (QDO) covered with X- α -gal to test the specificity of interactions.

RESULTS

Identification of recombinant plasmid

The full length sequences of HCV p7 were generated by PCR amplification of HCV plasmid (HCV strain 1b), sequenced and analyzed by comparing to vector NTI 6 and BLAST database homology search (<http://www.ncbi.nlm.nih.gov/blast>). After being cut by *EcoRI*/*Bam*HI, the fragment was in-frame ligated into pGBKT7 *EcoRI*/*Bam*HI site. Restriction enzyme analysis of pGBKT7-p7 plasmid with *EcoRI*/*Bam*HI yielded two bands: 7 300 bp empty pGBKT7 and 189 bp HCV p7. The product of plasmid was amplified by PCR. Analysis of the PCR reaction products by agarose gel electrophoresis showed the clear bands with the expected size (189 bp of p7). Sequences of the PCR products were correct (Figures 2A and B).

Figure 2 Fragment-p7 amplified by PCR (A) and pGBKT7-p7 cut by *EcoRI*/*Bam*HI (B).

Expression of “bait” fusion protein

Yeast strain AH109 transformed with pGBKT7-p7 could stably express the fusion protein at high level (Figure 3) and could only grow on SD/-Trp medium but not on QDO medium. Thus, the transformed yeast could be used for yeast hybrid analysis.

Figure 3 Expression of HCV p7 in yeast shown by Western blotting. Lane 1: HCV p7 protein; lane 2: positive control; lane 3: negative control.

Screening of liver cell cDNA library

We isolated the plasmids from the blue colonies containing only pGBKT7-p7 and one library plasmid other than other plasmids. Because plasmid pACT2-cDNA contains two restriction endonuclease sites of *Bgl*II on both sides of multiple cloning sites, the gene fragments of the liver cell cDNA library (pACT2-cDNA) screened were released by *Bgl*II digestion (Figure 4). The gene fragments of different lengths in Figure 4 proved, that these screened clones were positive colonies growing on SD/-Trp/-Leu/-His/-Ade culture medium after mating.

Figure 4 Identification of different colonies with *Bgl*II digestion.

Analysis of cDNA sequence and homology

We obtained a total of 50 positive colonies growing on the selective SD/-trp-leu-his-ade/X- α -gal medium. These colonies were prescreened by *Bgl*II digestion to make sure that only colonies with different inserts were subjected to sequencing. Fifty colonies from cDNA library were sequenced. Using the BLAST program at the National Center for Biotechnology Information, the 50 sequences had a high similarity to known genes. The data are presented in Table 1.

DISCUSSION

The precise mechanism of early HCV infection remains largely unknown. We tried to obtain a sufficient amount of free virions from the plasma of infected individuals and to establish a robust *in vitro* system for virus propagation. In HCV polyprotein, HCV p7 is located downstream of the envelope glycoprotein, E2 and upstream of the NS2 protein and begins at the position 747 of HCV H strain polyprotein. The generation of HCV p7 is supposed to be catalyzed by

Table 1 Comparison between positive clones and similar sequences in GenBank

High similarity to known genes	Number of similar	Homolog (%)
<i>Homo sapiens</i> signal sequence receptor, delta	1	100

<i>Homo sapiens</i> membrane-spanning 4-domains, subfamily A, member 6A (MS4A6A)	2	97-98
<i>Homo sapiens</i> colon cancer-associated antigen	24	94-100
<i>Homo sapiens</i> nucleoporin 214 ku	4	86
<i>Homo sapiens</i> CLL-associated antigen KW-13	2	99

a host signal peptidase localized in the endoplasmic reticulum^[9]. The p7 polypeptide of HCV is a small hydrophobic polyprotein of unknown function and contains 63 amino acids. Its encoding gene is present between structural and non-structural proteins, but it is still not clear whether p7 is a structural protein or a non-structural protein. Studies on the subcellular localization of HCV proteins indicate that most of them associate with ER membranes^[10-12]. HCV p7 comprising two transmembrane alpha helices linked by a small charged cytoplasmic loop, is indeed membrane-associated and mostly located in the endoplasmic reticulum^[7]. HCV p7 is an integral membrane polypeptide. Pulse-chase analysis showed that a large proportion of p7 stays in an early compartment of the secretory pathway. Carrere-Kremer *et al.*'s studies^[7] showed that p7 has a double membrane-spanning topology, the amino- and carboxyl-terminal tails are oriented toward the ER and should therefore also be accessible from the extracellular environment. The C-terminal transmembrane domain of p7 is a signal sequence and the amino- and/or carboxyl-terminal intraluminal tails of p7 contain sequences with genotype-specific function^[13]. The data indicate that p7 is a polytopic membrane protein that could play a functional role in several compartments of the secretory pathway.

At present, studies are carried on the biological functions of HCV p7 protein in the virus life cycle. HCV p7 protein forms hexamer cation ion channels in black lipid membranes. The function of p7 is supposed to be similar to viroporin, which mediates cation permeability across membranes and are important for virion release or maturation^[14,15]. Mutants with deletions of all or part of p7 and a mutant with substitutions of two conserved residues in the cytoplasmic loop are not viable. Thus, p7 is essential for infectivity of HCV^[13]. HCV p7 regulates the internalization properties of HCV structural proteins^[16]. It has been hypothesized that lack of p7 may lead to conformational changes of envelope proteins, as reported for closely related virus, that are perhaps important for cell binding and entry of the HCV virion. Studies of HCV subgenomic replicons showed that p7 is not critical for RNA replication^[17,18].

Transfection with RNA transcripts from an infectious BVDV cDNA clone with in-frame deletions or point mutations of p7 could not produce infectious virus, but the infectivity could be restored by providing p7 in transmembrane. HCV p7 has characteristics similar to those of a group of proteins called viroporins^[13,15]. These proteins form ion channels that might be of importance for virus assembly and/or release or maturation. Mutation of a conserved basic loop located between the two predicted

transmembrane alpha helices rendered HCV p7 non-functional as an ion channel. The intra-cellular localization of p7 was unaffected by this mutation^[19,20]. The HCV-like particles (HCV-LPs) without p7 (p7-HCV-LP) have been shown to be more potent in inducing cellular immune responses with a Th1 bias than HCV-LP with p7^[21]. The study showed that p7-HCV-LP can also induce both humoral and cellular immunities in AAD mice^[22].

Protein-protein interactions occur in a wide variety of biological processes and essentially control the cell fate from division to death. Yeast two-hybrid assays represent a versatile tool to study protein interactions *in vivo*. Yeast two-hybrid system 3 based on the system originally designed by Fields and Song, takes advantage of the properties of the GAL4 protein of the yeast *Saccharomyces cerevisiae*. GAL4-based assay uses yeast transcription factor, GAL4 for detection of protein interactions by transcriptional activation. GAL4 possesses a characteristic phenomenon that the transactivation function can be restored when the factor's DNA-binding domain (DBD) and its transcription-AD are brought together by two interacting heterologous proteins. GAL4-yeast two-hybrid assay uses two expression vectors, one uses DBD and the other uses AD. The GAL4-DBD fuses to a protein 'X' and a GAL4-AD fuses to a protein 'Y' to form the bait and the target of the interaction trap, respectively. A selection of host cells with different reporter genes and different growth selection markers provides a means to detect and confirm protein-protein interactions and has significantly fewer false positives^[23-26].

To investigate the role of HCV p7 in pathogenesis of HCV and physiologic function in hepatocytes, yeast two hybrid system 3 is used to screen the proteins interacting with p7 protein. In this study, the "bait" plasmid pGBKT7-p7 was transformed into yeast strain AH109. In order to further confirm the expression of HCV p7 protein in AH109 yeast strain, we performed the experiment of Western blot and a strong expression of the HCV p7 protein was observed. After the "bait" plasmid pGBKT7-p7 yeast strain AH109 was mated with liver cDNA library yeast strain Y187, the diploid yeast cells were plated on QDO media containing X- α -gal, 50 true positives were obtained. By sequencing analysis of isolated library plasmids, we got the sequences of 50 genes with known functions. Eight of them were respectively associated with genesis of tumor and immunity, regulation of cell life cycle, and the way of signal transmission.

We screened *Homo sapiens* membrane-spanning 4-domains, subfamily A (MS4A6A). Tetraspanins are a large superfamily of cell surface membrane proteins characterized by their

four transmembrane domains, and expressed in a wide variety of cell types and formed two different circularity structures outside cellular membrane. Tetraspanins interact with diverse important proteins, such as integrins, immunoreceptors, and signaling molecules and have functional roles in processes. They promote cellular growth and signal transduction and are possibly related to viral adhesion and entry, cellular cancerization, tumor cell invasion, and metastasis^[27,28]. The tetraspanin web refers to a network of molecular interactions involving tetraspanins and other molecules. The functions of net are complex and multiple. The CD81 is one of the tetraspanins and widely expressed in a variety of cell types. Todres *et al.*^[29], and Bartosch *et al.*^[30], showed that CD81 is likely to be the receptor protein of HCV infecting target cells, and the structures of CD81 and other subfamilies of tetraspanins are partly homologous. Because CD37 can regulate directly B cell function and interact between T and B cells, and regulate humoral immunity^[31,32]. CD53 relates to apoptosis and tumor formation. CD63 relates to maturation of human dendritic cells and modulates differential distribution of associated MHC class II molecules during maturation of dendritic cells^[33]. Migration of activated hepatic stellate cells (HSC) is a key event in the progression of liver fibrosis. The tetraspanin CD151 molecule plays a key role as a regulator of $\alpha 6 \beta 1$ integrin adhesion strengthening and involves in HSC migration, adhesion, and proliferation^[34,35]. Human CD81 directly enhances Th1 and Th2 cell activation, but preferentially induces proliferation of Th2 cells upon long-term stimulation. CD81 cross-linking can also induce adhesion in B and T cells and decrease the threshold for B cell activation via the immunoglobulin (Ig) receptor, which produces autoantibodies and form corresponding immunopathologic damage^[36]. In this study, it was shown that HCV p7 could bind to tetraspanins and the functions of p7 are complex.

Another important protein interacting with p7 protein from liver cDNA library is *Homo sapiens* nucleoporin 214 ku (NUP214). Nuclear pore complexes (NPCs) are large protein structures spanning the double membrane of the eukaryotic nucleus that serves as a site for translocation of macromolecules between the nucleus and the cytoplasm. NPCs include a family of 50-100 proteins termed as nucleoporins (Nups). Studies in the past several years have demonstrated that individual Nups play a unique role in regulating NPC function and nucleo-cytoplasmic transport of proteins and RNAs. The functions of individual Nups are associated with specific human diseases. NUP214, also named as CAN protein, is an oncogene and one of the components of NPCs in eukaryotic cells. It contains FG repeat sequences of special proteins of NPCs, which bind directly to receptors that transport substrates through the NPC. NUP214 is located at cytoplasmic side of the NPC and plays a role in numerous pathways, including cell cycle progression, control of gene expression, oncogenesis, and transport of nucleoplasmic. 3' extremity of the gene forms an integral gene with DEK gene on chromosome 6, which is correlative to acute myelocytic leukemia and myelodysplastic syndrome^[37-39].

We also screened *Homo sapiens* Ig superfamily (IgSF) containing leucine-rich repeat. The IgSF is one of the largest families of protein domains in this genome and one of the

major families in other multicellular eukaryotes. The members of the superfamily are involved in a variety of functions including cell-cell recognition, cell-surface receptors, muscle structure and the immune system^[40]. The IgSF containing a leucine-rich repeat (LRR) is named as ISLR. The ISLR gene is mapped on human chromosome 15q23-q24 by fluorescence *in situ* hybridization. It is a protein with a molecular mass of 46 ku and contains a LRR, with conserved flanking sequences and a C2-type Ig-like domain. These domains are important for protein-protein interaction or cell adhesion, therefore it is possible that the ISLR may also interact with other proteins or cells^[41].

HCV p7 protein also interacts with *Homo sapiens* signal sequence receptor δ , *Homo sapiens* H19, imprinted maternally-expressed untranslated mRNA, *Homo sapiens* spermatid perinuclear RNA binding protein, *Homo sapiens* colon cancer-associated antigen and *Homo sapiens* CLL-associated antigen KW-13. The significance of interactions of the proteins with HCV p7 should be further studied *in vivo* and *in vitro*.

Abstract

AIM: To develop a serum or histological marker for early discovery of gastric atrophy or intestinal metaplasia.

METHODS: This study enrolled 44 patients with gastric adenocarcinoma, 52 patients with duodenal ulcer, 14 patients with gastric ulcer and 42 consecutive healthy adults as controls. Each patient received an endoscopy and five biopsy samples were obtained. The degrees of histological parameters of gastritis were categorized following the Updated Sydney System. Anti-parietal cell antibodies (APCA) and anti-*Helicobacter pylori* (*H. pylori*) antibodies (AHPA) were analyzed by immunoassays. *H. pylori* infection was diagnosed by rapid urease test and histological examination.

RESULTS: Patients with gastric cancer and gastric ulcer are significantly older than healthy subjects, while also displaying higher frequency of APCA than healthy controls. Patients with positive APCA showed higher scores in gastric atrophy and intestinal metaplasia of corpus than patients with negative APCA. Patients with positive AHPA had higher scores in gastric atrophy, intestinal metaplasia, and gastric inflammation of antrum than those patients with negative AHPA. Elderly patients had greater prevalence rates of APCA. Following multivariate logistic regression analysis, the only significant risk factor for antral atrophy is positive AHPA, while that for corpus atrophy is positive APCA.

CONCLUSION: The existence of positive APCA correlates

INTRODUCTION

Statistics from the American Cancer Society indicated around 22 000 new cases of gastric carcinoma in the USA for 2001^[1]. Gastric cancer, a disease with high mortality, is the second leading cause of cancer death worldwide^[2]. An important factor concerning the high mortality rate is the high frequency of advanced gastric cancer at diagnosis. Early diagnosis is difficult because gastric cancer tends to manifest initially with non-specific symptoms and signs.

Helicobacter pylori (*H. pylori*) was categorized as class I carcinogen of gastric cancer by the International Agency for Research on Cancer in 1994^[3]. However, most patients with *H. pylori* gastritis are clinically silent and only a fraction of them will develop gastric cancer^[4]. Which histological elements would raise the risk of gastric cancer is disputable. Chronic atrophic gastritis was reported in 80-90% and intestinal metaplasia appeared in 70% of patients with gastric carcinoma^[5]. Glandular atrophy and intestinal metaplasia are now considered as risk factors for gastric cancer. The identification of both conditions, however, demands invasive procedures and biopsy. To develop a non-invasive, diagnostic tool is an important challenge to all gastroenterologists.

There are no sufficiently sensitive serum markers to enable an early diagnosis of gastric cancer^[6]. A low serum pepsinogen I and raised serum gastrin levels were found in patients with gastric cancer^[7,8]. However, they lack adequate sensitivity and specificity. The levels of anti-parietal cell antibody (APCA) expression were associated with the

histological degree of atrophy^[9]. The presence of APCA may represent an early marker of gastric atrophy.

This study attempted to assess differences in histological parameters of gastritis among patients with gastric cancer and other controls. The effectiveness of serum APCA and anti-*H pylori* antibodies (AHPA) in predicting glandular atrophy and even gastric cancer was also assessed.

MATERIALS AND METHODS

Patients

This study enrolled 152 consecutive subjects with epigastric discomfort between July 2002 and June 2003. The subjects comprised 44 patients with histologically documented gastric adenocarcinoma, 52 patients with duodenal ulcer, 14 patients with gastric ulcer, and 42 consecutive healthy adults as controls. Those subjects with history of major systemic diseases including diabetes mellitus, adrenal insufficiency, iron deficiency anemia, thyrotoxicosis, myxedema, and Hashimoto's thyroiditis were excluded.

All subjects were recruited at our hospital and gave informed consent for endoscopic biopsies. Biopsies were executed with jumbo forceps from cancer and non-cancer sites. At least six specimens were obtained from the neoplastic lesions for histological verification. Only those who were histologically documented as gastric adenocarcinoma were included in this study.

In addition, five specimens were collected from antrum and corpus following the standard protocol. These five specimens were classified with a visual analog scale proposed by the Updated Sydney System^[10]. This study was approved by the Human Medical Research Committee of the Kaohsiung Veterans General Hospital, Kaohsiung, Taiwan.

Biopsy protocol

A standardized biopsy protocol was done in all subjects. All subjects underwent endoscopic biopsies and five specimens were extracted from A3 (lesser curvature site of angularis), A1 (lesser curvature site of antrum), A4 (greater curvature site of antrum), B5 (lesser curvature site of mid-body), and B6 (greater curvature site of mid-body). Only cases from whom all five specimens were available were included in this study.

Histology

The specimens for histological examinations were fixed in 10% buffered formalin, embedded in paraffin, and sectioned. The sections were stained with a hematoxylin and eosin stain and a modified Giemsa stain^[11,12]. The biopsied specimens were assessed by a histopathologist who was unaware of the endoscopic features and clinical data. The morphological variables, including *H pylori* density, neutrophils (AIS: acute inflammatory score), monocytes (CIS: chronic inflammatory score), lymphoid follicles, glandular atrophy and intestinal metaplasia, were graded with a visual analog scale according to the Updated Sydney System. The scores of all histological parameters in antrum were calculated from means of A1 and A4 and those in corpus from B5 and B6.

Rapid urease test

The rapid urease test was performed according to our

previous studies^[13]. Each biopsied specimen was placed immediately in 1 mL of a 10% solution of urea in deionized water (pH 6.8) to which two drops of 1% phenol red solution had been added and incubated at 37 °C for up to 24 h. If the yellowish color around the area of inserted specimen changed to bright pink within the 24-h limit, the urease test was considered positive. In our laboratory, the sensitivity and specificity of the rapid urease test were 96% and 91%, respectively^[14].

Questionnaire

Complete medical history and demographic data was gathered from each patient, comprising age, sex, blood type, residence area, marital status, cigarette and alcohol consumption, beverage of tea or coffee, and drug history.

Helicobacter pylori infection

The presence of *H pylori* infection was defined as both positivity of rapid urease test and histology.

Anti-parietal cell antibodies (APCA)

Serum APCA was determined with indirect fluorescent antibody tests employing the commercial kit FLUORO-KIT™ (DiaSorin Inc. Stillwater, USA) test systems utilizing rat stomach for detection and differentiation of circulating autoantibodies in human serum. Patient's serum samples were diluted in phosphate buffered saline and overlaid onto tissue cryostat sections fixed on a microscope slide. If APCA appeared in patients' serum, stable antigen-antibody complexes would be formed. The complexes bound fluorescein labeled anti-human immunoglobulin. The consequent positive reaction, observed with a properly equipped fluorescence microscope, appeared as apple green fluorescence.

Anti-*Helicobacter pylori* antibodies (AHPA)

Immunoglobulin G (IgG) antibodies to *H pylori* were measured with an inhouse enzyme immunoassay (EIA). The antigen employed was an acid glycine extract from *H pylori* strain NCTC 11637. Absorbance readings were converted to reciprocals of the end point titers.

Statistical analysis

Statistical tests were performed with SPSS system. The χ^2 test or the Fisher exact test was used for nominal scale and between groups. Two independent samples were compared by the Student test or the Mann-Whitney/Wilcoxon rank sum test. The stepwise logistic regression analysis was performed with various items and a *P* value < 0.05 was considered to be significant.

RESULTS

Demographic data

The demographic data for all groups of patients are shown in Table 1. The mean age of patients with gastric cancer (68.8±13.7) and gastric ulcer (71.6±10.7) was significantly higher than that in healthy controls (48.2±13.3). Males had distinctively higher rates of gastric cancers than females. (84% *vs* 45%, *P* < 0.05) Patients with gastric ulcer had greater

rates of smoking than controls. (71% *vs* 29%, $P<0.05$) No significant differences emerged in other demographic variables between patients with gastric cancer and controls.

Helicobacter pylori infection

H. pylori infection was defined as, both positivity of rapid urease test and histology. The positive rates of *H. pylori* infection of patients with gastric cancer (53%), gastric ulcer (57%), and duodenal ulcer (75%) were notably higher than in controls (24%, Table 2).

Anti-parietal cell antibodies (APCA)

The prevalence rates of APCA in patients with gastric cancer (70%) and gastric ulcer (79%) were much higher than those of controls (36%, $P<0.05$, Table 2). Host and bacterial factors related to the presence of APCA in serum were also evaluated. (Table 3) Old age (≥ 60 years) was the only significant factor correlated with the presence of APCA.

Anti-*Helicobacter pylori* antibodies (AHPA)

The presence of AHPA was detected by serum IgG. The investigation assessed host and bacterial factors associated with the presence of AHPA in serum. (Table 4) No significant difference was found between patients with and without AHPA.

APCA and scores of histological gastritis (Figure 1)

All degrees of histological parameters of gastritis were graded with a visual analog scale according to the Updated Sydney System. The correlation between APCA and histological

gastritis is shown in Figure 1. For the histological parameters in antrum, the scores of CIS and atrophy were significantly higher in patients with positive APCA than in those with negative APCA. For the parameters in corpus, the scores of CIS, glandular atrophy, and intestinal metaplasia were significantly higher in patients with positive APCA than in those without. There were no significant differences in scores of other parameters.

AHPA and scores of histological gastritis (Figure 2)

The correlation between AHPA and histological gastritis is shown in Figure 2. For the histological parameters in antrum, the scores for AIS, CIS, glandular atrophy, intestinal metaplasia, and *H. pylori* density were significantly higher in patients with positive AHPA than in those without. ($P<0.05$) For parameters in corpus, the scores of CIS and *H. pylori* density were significantly higher in patients with positive AHPA than in those without. There were no significant differences in other parameters.

Multivariate logistic regression analysis (Tables 5 and 6)

Multivariate logistic regression analysis of factors affecting severe atrophy (score of glandular atrophy > 2) was also executed. The only factor affecting severe atrophy in antrum was positive AHPA and that in corpus was positive APCA.

DISCUSSION

Discovery of *H. pylori* led to a widely accepted hypothesis of a multi-step sequence that begins with gastritis and, through atrophy, metaplasia, dysplasia, finally leads to gastric cancer^[15]. An odds ratio of 3.6 was reported for gastric cancer among patients infected with *H. pylori* vs those non-

infected^[16]. The seropositive rate of *H. pylori* infection ranged from 65% to 84% in patients with gastric cancer^[17]. In the present study, the infection rate with *H. pylori* was significantly higher in the gastric cancer group (53%) than in controls (24%). ($P < 0.05$) The positive rate was lower than that reported previously. The reason may relate to the strict policy that presence of *H. pylori* infection was defined as both positivity of rapid urease test and histology.

Glandular atrophy and intestinal metaplasia have been demonstrated to be linked with gastric cancer^[5]. An earlier study claimed that in patients with intestinal-type early gastric cancer, more severe glandular atrophy and intestinal metaplasia was noted in all biopsy sites of the stomach^[18].

However, another study revealed that both glandular atrophy and intestinal metaplasia were more severe in distal stomach^[19,20]. The present study disclosed that scores for glandular atrophy were statistically higher in antrum and corpus of patients with gastric cancer. These results imply that if glandular atrophy occurs, either in antrum or corpus, the risk of developing gastric cancer is greater. The investigation also discovered that scores of intestinal metaplasia and CIS in antrum were significantly higher in patients with gastric cancer. Scores of AIS, CIS, glandular atrophy, intestinal metaplasia, and lymphoid follicles were also higher in corpus. All these results imply that severe degrees of CIS, glandular atrophy and intestinal metaplasia may herald the development of gastric cancer.

Strickland and Mackay even reported in 1973 that APCA was associated with chronic atrophic gastritis of corpus^[21]. The levels of APCA expression are connected with the histological degree of atrophy^[9], whose presence closely paralleled gastric atrophic status. In the present study, the presence of APCA was significantly higher in patients with gastric cancer than among controls. Evaluation of the histological parameters revealed that the scores of CIS, intestinal metaplasia and glandular atrophy were markedly higher in patients with positive APCA, particularly in corpus. Following multivariate logistic regression analysis, positive APCA was the only significant factor affecting severe atrophy in corpus. These results suggest that the presence of APCA represents an early marker for glandular atrophy in corpus and even for the development of gastric cancer.

When assessing host factors related to the presence of APCA, this study identified old age (>60 years) as the only factor for developing APCA. Although host factors have been thought important for the promotion of atrophic gastritis, the factor that actually triggers these changes remains unknown^[22]. Results of this study suggest that age may be the factor promoting atrophic changes. However, the small sample size precludes a definite conclusion at this stage.

The correlations between AHPA and histological gastritis indicated that AHPA correlated well with AIS, CIS, glandular atrophy, intestinal metaplasia, and *H. pylori* density in the antrum. ($P < 0.05$) These correlation results conform to many previous studies^[23]. Following multivariate logistic regression analysis, AHPA emerged as the only significant factor affecting severe atrophy in the antrum. The occurrence of AHPA may act as a predictive marker for glandular atrophy in antrum.

Chronic atrophic gastritis is an independent risk factor for gastric cancer. Timely recognition of these patients was difficult without endoscopic biopsy. If any factor predicting gastric atrophy can be found, these high-risk patients may be diagnosed earlier. Patients with gastric cancer were found to have higher prevalence of APCA and AHPA. (Table 2) The existence of positive APCA correlates well with glandular atrophy in corpus, whereas the presence of positive AHPA correlates with atrophy in antrum. The results of the present work imply that both APCA and AHPA can predict glandular atrophy in corpus and antrum. However, this sample size is small and large-scale age-matched prospective studies are

awaited to determine the definite correlation between APCA, AHPA and glandular atrophy.

ACKNOWLEDGMENTS

The authors would like to express their deep appreciation to Dr. Chang-Bih Shie, Yuh-Chyi Chou, Chia-Lin Yeh, Chao-Ming Wu, Lung-Chih Cheng, Miss Yu-San Chen for their invaluable support in this study.

Abstract

AIM: To study the effect of proton pump inhibitor (PPI) treatment on patients with reflux esophagitis and its *in vivo* effect on apoptosis, p53- and epidermal growth factor receptor (EGFR) expression.

METHODS: After informed consent was obtained, gastric biopsies of the antrum were taken from patients with reflux oesophagitis prior to and after 6 mo of 20 mg omeprazole ($n = 14$) or 40 mg esomeprazole ($n = 12$) therapy. Patients did not take any other medications known to affect the gastric mucosa. All patients were *Helicobacter pylori* negative as confirmed by rapid urease test and histology, respectively. Cell proliferation, apoptosis, EGFR, and p53 expression were measured by immunohistochemical techniques. At least 600 glandular epithelial cells were encountered and results were expressed as percentage of total cells counted. Was considered statistically significant.

RESULTS: Although there was a trend towards increase of cell proliferation and EGFR expression both in omeprazole and esomeprazole treated group, the difference was not statistically significant. Neither apoptosis nor p53 expression was affected.

CONCLUSION: Long-term PPI treatment does not significantly increase gastric epithelial cell proliferation and EGFR expression and has no effect on apoptosis and p53 expression.

INTRODUCTION

Long-term PPI therapy is suggested to be the best treatment for gastro-esophageal reflux disease. Administration of PPI causes profound and continuous hypochlorhydria by selective inhibition of the proton pump ($H^+/K^+-ATPase$) in gastric parietal cells^[1]. It has been shown in animal studies that long-term omeprazole treatment reversibly increases epidermal cell proliferation and suppresses its differentiation in rats^[2,3].

Apoptosis normally plays a role complementing proliferation and is also considered to be essential for the maintenance of gastro-intestinal homeostasis and health^[4]. Disturbance in the balance between these two processes may predispose to either cell loss with mucosal damage or cell accumulation and cancer development^[5].

However, several studies have investigated the effects of omeprazole on gastric mucosa, but there is no information available about the effect of the first single-isomer, esomeprazole, on gastric epithelial cell proliferation, apoptosis, p53- and EGFR expression.

The proliferating cell nuclear antigen (PCNA) technique is an accepted method for measurement of cell proliferation. PCNA is the co-factor of DNA-polymerase and can be detected mostly in the late G₁ and S phases, but it is also present in every phase of the cell cycle.

The terminal deoxynucleotidyl (TdT)-mediated deoxyuridine triphosphate (dUTP) nick end labelling (TUNEL) method has been accepted for the detection of apoptotic cells^[6].

Abnormalities in p53 expression represent the most common molecular change not only in cancer, but also in precancerous gastric lesions, including gastric dysplasia^[7,8]. An increased wild-type p53 expression may also represent a cellular response to DNA damage.

Epithelial growth factor (EGF) is a potent mitogenic peptide, which plays a crucial role in promoting gastric epithelial cell migration, proliferation and differentiation. The increased local production of EGF leads to over expression of EGFR^[9-11].

The aim of the present study was to measure the cell turnover (cell proliferation and apoptosis), p53- and EGFR expression by immunohistochemistry in gastric biopsy samples during long-term omeprazole and esomeprazole treatment.

MATERIALS AND METHODS

Patients

To analyze the effect of PPI therapy on cell kinetics pattern of the gastric mucosa, we studied patients with gastro-esophageal reflux disease. A total of 26 patients (14 males and 12 females, mean age 46.2 ± 16.5 years) took part in the study. All patients gave written informed consent.

Biopsies were taken in each subject during upper endoscopy from the antrum (lesser curvature, 3 cm from the pylorus). Additional biopsies were taken during endoscopy for the histological evaluation of their *Helicobacter pylori* (*H. pylori*) status^[12].

Patients were treated in an open label study continuously with omeprazole (20 mg/d) or esomeprazole (40 mg/d) for 6 mo. Fourteen patients were on omeprazole and 12 patients on esomeprazole therapy.

Patients did not receive any other medication known to affect the gastric mucosa, but stable medication for hypertension or other diseases such as hypercholesterinemia, non-insulin dependent diabetes mellitus, *etc.* was allowed.

Patients were classified by the Los Angeles classification (15 patients had grade A, and 11 had grade B). None of the patients had Los Angeles grades C, D, or Barrett esophagus. Exclusion criteria were active *H. pylori* infection and presence of intestinal metaplasia, since it has been established in previous studies that gastric epithelial cell proliferation is enhanced, if intestinal metaplasia or *H. pylori* infection is present^[13-15]. Since histology may miss initial focal microscopical lesions of intestinal metaplasia, small intestine mucus antigen (SIMA) and large intestine mucus antigen (LIMA), each indicates intestinal metaplasia in the gastric biopsy samples, were measured by immunohistochemical technique in all samples. To exclude *H. pylori* infection, in addition to histology, both rapid urease test during endoscopy and urease breath test were performed.

Biopsies taken at 0 and 6 mo in both the omeprazole- and esomeprazole-treated groups were assessed.

Neither patients treated with omeprazole nor patients on esomeprazole therapy had endoscopic changes in the stomach or duodenum or *H. pylori* infection when biopsy was taken. No intestinal metaplasia was found in the samples.

For immunohistochemistry, all biopsy specimens were fixed in buffered formalin and embedded in paraffin. Four micron thick sections were cut and mounted on glass slides.

Proliferation-PCNA immunohistochemistry

The four micron thick tissue sections were dewaxed and rehydrated. Antigen unmasking was carried out in citrate buffer pH 6.0 by microwave heat treatment (3 min 750 W

and 3 min 370 W), and samples were cooled down in PBS for 20 min. Endogenous peroxidase activity was blocked by incubation for 30 min at room temperature in 3% hydrogen peroxide. After being washed thrice in PBS for 3 min, the slides were incubated with optimally diluted PCNA antibody (Clone: PC10, DAKO) for 15 min at room temperature in a humidified chamber. After being washed thrice in PBS, signal conversion was carried out with the LSAB2 system (DAKO: K0672) as described in the manual. Hematoxylin co-staining was done.

Apoptosis-TUNEL immunohistochemistry

After deparaffinization in xylene and rehydration through graded ethanol, antigen unmasking was carried out in citrate buffer pH 6.0 by microwave heat treatment (5 min 750 W), and samples were cooled down in PBS for 20 min. Samples were digested with nuclease free proteinase K for 20 min at room temperature. After being washed twice in PBS, samples were covered with 30 μ L TUNEL dilution label and 50 μ L TUNEL reaction mixture (5 μ L Tdt enzyme solution and 45 μ L dUTP label solution). Samples were incubated for 120 min at 37 °C in a dark humidified chamber. After being washed thrice in PBS, endogenous peroxidase activity was blocked by incubation for 30 min in 3% hydrogen peroxide at room temperature in a dark humidified chamber. After being washed twice in PBS, non-specific blocking was carried out with 1% BSA-PBS solution for 10 min at room temperature in a dark humidified chamber. After redundant BSA was removed with pipette, samples were covered with 50 μ L converter-POD antibody and incubated for 60 min at 37 °C in a dark humidified chamber. After being washed thrice with PBS, 50 μ L DAB solution (5 μ L DAB substrate and 45 μ L peroxide buffer) was added to each sample and signal conversion was checked by light microscopy. Finally, haematoxylin co-staining was done.

P53 immunohistochemistry

The four micron thick tissue sections were deparaffinized in xylene, rehydrated through graded ethanol. Antigen unmasking was carried out by microwave heat treatment (samples in plastic jars containing citrate buffer pH 6.0 were put into a preheated (95-99 °C) plastic water bath and heated with 500 W for 15 min), and samples were cooled down in PBS for 20 min. Endogenous peroxidase activity was blocked by incubation for 30 min at room temperature in 3% hydrogen peroxide. After being washed thrice in PBS for 3 min, the slides were incubated with optimally diluted p53 antibody (Clone: DO-7, DAKO) at 37 °C for 30 min in a humidified chamber. After being washed thrice in PBS, signal conversion was carried out with the LSAB2 system (DAKO) as described in the manual. Hematoxylin co-staining was done.

EGFR immunohistochemistry

After deparaffinization, antigen unmasking was carried out by nuclease free proteinase K digestion for 20 min at room temperature. After being washed twice in PBS, endogenous peroxidase activity was blocked by incubation for 30 min at room temperature in 3% hydrogen peroxide. After being washed thrice in PBS for 3 min, non-specific blocking was

done with 1% BSA-PBS solution for 10 min at room temperature. Then, the slides were incubated with diluted EGFR antibody (1 μ L EGFR antibody and 40 μ L PBS) (Clone: H-11, DAKO) at 37 °C for 60 min in a humidified chamber. After being washed thrice in PBS, signal conversion was carried out with the LSAB2 system (DAKO) as described in the manual. Hematoxylin co-staining was done.

Counting

Known immunohistochemically-positive tissue sections were used as positive controls, and negative control sections were processed immunohistochemically after the primary antibody was replaced by PBS. None of these control sections exhibited immunoreactivity.

Axially, at least 800 (mainly 1 000) crypt epithelial cells within well-oriented crypts were counted in each sample under light microscope (40X objective). The labelling index (LI) was defined as a percentage of the positive nuclei over the total nuclei counted. The evaluation of staining intensity (i.e. number of positive cells) for PCNA, TUNEL, p53 and EGFR was performed by two investigators independently, without knowledge of the histology and the results of the other investigator. There was less than 5 % variance between the results of two counts.

SIMA, LIMA immunohistochemistry

The four micron thick tissue sections were dewaxed and rehydrated, reacted with anti-SIMA and -LIMA mAbs, stained by indirect immunoperoxidase methods, and counterstained with hematoxylin, including appropriate controls. The deparaffinized sections were blocked with 5% BSA (diluted in PBS) for 5 min, drained and incubated with the diluted mouse antibodies for 20 min. After two 5-min washings with PBS, the sections were covered with horseradish-peroxidase-labelled rabbit anti-mouse immunoglobulin (Serotec, UK), then washed twice for 5 min with PBS. Sections from all blocks were also stained with hematoxylin-eosin (H&E) for 2-10 min.

The immunoperoxidase-stained slides were then viewed under a light microscope, and assessed under code, by two observers. Scores of 0-3 were assigned to intensity of reactivity (weak, 1; moderate, 2; strong, 3) and distribution (restricted, <25% positive, 1; patchy, 25-75%, 2; and diffuse, >75%, 3) for each of the antibodies, in serial sections of specimens.

Statistical analysis

Statistical analysis with one-way ANOVA, LSD test and

correlation analysis were performed by the Statistica for Windows 4.3 program package. $P < 0.05$ was considered statistically significant.

RESULTS

Proliferation index, apoptosis, p53- and EGFR expression prior to and after 6 mo of omeprazole or esomeprazole therapy are shown in Tables 1 and 2, respectively.

Table 1 Effect of long-term omeprazole therapy on gastric epithelial cell kinetics (mean \pm SD)

Omeprazole (n = 14)		
Endoscopy (mo)	0	6
Proliferation index (%)	40.9 \pm 13.8	54.1 \pm 16.6
Apoptosis (%)	45.3 \pm 8.7	49.5 \pm 10.3
P53 (%)	28.7 \pm 4.3	28.9 \pm 12.7
EGFR (%)	17.6 \pm 11.9	21.9 \pm 7.9

Table 2 Effect of long-term esomeprazole therapy on gastric epithelial cell kinetics (mean \pm SD)

Esomeprazole (n = 12)		
Endoscopy (mo)	0	6
Proliferation index (%)	39.6 \pm 8.7	52.8 \pm 10.4
Apoptosis (%)	43.5 \pm 9.8	48.9 \pm 9.8
P53 (%)	29.2 \pm 10.7	29.6 \pm 11.5
EGFR (%)	16.8 \pm 8.1	22.3 \pm 8.1

There was no difference between the effects of omeprazole and esomeprazole therapy on gastric epithelial cell kinetics (Figure 1). There was no statistically significant difference in any of the investigated parameters between the samples taken at the beginning and those taken after 6 mo of PPI treatment. Cell parameters were not significantly affected by age and sex (data not shown).

Although there was a trend towards increase of cell proliferation and EGFR expression in both omeprazole- and esomeprazole-treated groups, the difference was not statistically significant.

We found alterations only in the localization of immunohistochemical staining density prior to and after PPI therapy.

In a non-affected normal gastric mucosa, the greatest density of PCNA positive cells was found in the neck cell compartment (Figure 2). The greatest increment in cell

Figure 1 No difference between the effects of omeprazole and esomeprazole on cell turnover of gastric mucosa.

Figure 2 Greatest density of PCNA positive cells (brown colored cells) found in neck cell compartment of non-affected gastric mucosa (400x magnification).

Figure 3 Greatest increase in PCNA positive cells (brown colored cells) observed in gland compartment of gastric mucosa after PPI therapy (400x magnification).

Figure 4 Positive EGFR immunoreactivity (brown color) in parietal cells and mucus neck cells of fundic glands (200x magnification).

proliferation in response to PPI therapy, occurred in the gland compartment of the gastric mucosa. The increase was limited to the deepest portions of the crypts (Figure 3). In both, prior to and after PPI administration, parietal cells did not express PCNA.

In a non-affected normal gastric mucosa, positive EGFR immunoreactivity was observed in parietal cells and mucous neck cells of the gastric fundic glands. EGFR was localized to the basolateral cell membrane, but not to the apical luminal membrane (Figure 4). After PPI administration, a strong positive EGFR immunoreactivity was observed at the basolateral membrane, in cytoplasm and supranuclear area of mucosal cells (Figure 5A). Positive EGFR expression was also found in some parietal cells (in cytoplasm and plasma membrane), but it was generally weaker compared to the neck cells (Figure 5B).

No dysplasia was observed after 6 mo of follow-up in any of the patients receiving either omeprazole or esomeprazole therapy.

DISCUSSION

Maintaining cell turnover is a key feature in organs with high metabolism such as the gastric mucosa. Higher cell turnover may lead to tumor formation while the suppressed state results in ulcer development^[4].

Omeprazole-induced potent acid suppression may lead to sustained and profound hypochlorhydria, which is often associated with hypergastrinemia^[16]. In majority of animal studies, it has been shown that long-term omeprazole

treatment reversibly increases epithelial cell proliferation and suppresses its differentiation^[2,3]. In other studies, however, neither cell proliferation is higher^[17,18], nor increased gastrinoma or other tumor formation is observed during long-term PPI treatment^[19]. Additional data suggest that gastrin enhances growth of normal and malignant colonic cells *in vitro* and may be linked to the development of colorectal cancer^[20-24]. On the other hand, animal and clinical studies do not support the role of omeprazole-induced hypergastrinemia in gastro-intestinal neoplasia development^[25,26] and no increased incidence of colon cancer has been found in patients with either pernicious anemia or gastrinomas^[27-29].

The risk of hypergastrinemia induced by long-term PPI therapy is still ambiguous and of concern to many clinicians.

This study analyzed the gastric epithelial cell kinetics in patients with gastro-esophageal reflux disease during long-term PPI treatment using immunohistochemical techniques. We investigated the effect of two different proton pump inhibitors: omeprazole and esomeprazole.

Although esomeprazole has a higher bio-availability than omeprazole and provides more pronounced inhibition of acid secretion compared to all other clinically available proton pump inhibitors, we found no difference between these drugs in terms of their effects on the gastric epithelium.

Our results confirmed the previous observations^[17,18] that cell proliferation is not significantly altered during long-term PPI therapy. Although there was a trend towards increase of both cell proliferation and EGFR expression, the difference was not statistically significant. Previous studies

Figure 5 EGFR immunostaining (A) and immunoreactivity (B) after PPI therapy

(200x magnification).

have indicated that PCNA positive cells are nearly always positive for EGFR^[10]. The accompanied increase of EGFR expression to a higher PCNA activity in this study has therefore been expected.

The fact that the trend towards increase in gastric cell proliferation and EGFR expression is not accompanied with a parallel increase in apoptosis and p53 expression also supports the conclusion that there is no significant change in cell turnover during chronic administration of any PPI. No dysplasia or neoplasia was observed in any of the samples obtained during this study.

In the present study, in a non-affected normal gastric mucosa, positive EGFR immunoreactivity was identified in the mucous neck cells and parietal cells of the fundic glands, and the staining was localized only on the basolateral cell membrane, which is in agreement with previous studies^[3,11].

Gray *et al.*^[3], suggested that the greatest increment in cell proliferation in response to the increased gastrin drive occurs in the gland compartment of gastric mucosa. Our findings have confirmed their observations. After long-term PPI administration, we observed the greatest increase in PCNA positive cells mainly in the gland compartment. Although there is a proportionally greater increase in proliferation in the gland compartment compared to that in the mucous neck cell compartment, the neck cell compartment remains the main source of new cell formation.

Several studies have shown an intense EGFR expression during ulcer healing^[10,11]. In our study, after administration of PPI a strong positive EGFR immunoreactivity was observed predominantly in some mucous neck cells of the proliferative zone compared to the weaker staining density in parietal cells. The EGFR immunoreactivity was localized not only on the basolateral membrane of these cells, but also appeared in cytoplasm and supranuclear area.

EGFR is a good immunohistochemical marker for the detection of altered gastric epithelial cell function. The presence of EGFR on cells of the proliferative zone clearly indicates that they are the targets for the proliferation-stimulating action of EGF.

Parietal cells express EGFR but not PCNA. Presence of EGFR in the parietal cells is not associated with cell proliferation, but is consistent with a potent inhibitory action of EGF on gastric acid secretion.

We demonstrated that long-term PPI treatment did not significantly increase gastric epithelial cell proliferation and EGFR expression and had no effect on apoptosis and p53 expression. We found alterations only in the localization of immunohistochemical staining density during chronic PPI administration.

Our results have confirmed the previous observations that cell proliferation is not significantly altered during long-term PPI therapy. In addition no alterations in cellular response and no disturbance in the balance between cell proliferation and apoptosis are found, the maintenance of gastro-intestinal hemostasis is ensured and there is no risk for progression of hyperplasia to dysplasia in patients during chronic PPI administration.

These data suggest that 6-mo treatment with proton pump inhibitors is not associated with cell proliferation abnormalities of the gastric antral mucosa, which is a further

argument for the safety of PPIs.

Abstract

AIM: To determine the prevalence of porcine endogenous retrovirus (PERV) in various pig breeds raised in China including Chinese experimental mini-pigs by PERV-reverse transcriptase (PERV-RT enzyme). Moreover, the potential for infection of PERV was investigated in patients treated with a bioreactor based on porcine liver cells ($n = 3$).

METHODS: Pig serum, liver and muscle cell-free supernatants were collected from various Chinese pig breeds. Porcine hepatocytes were isolated with a two-step perfusion method. Three patients with acute or chronic liver failure were treated with a bioartificial liver support system (BALSS) for 8-12 h and serum samples were collected from the patients before, immediately after and 30 d after treatment.

RESULTS: The activities of PERV-RT enzyme in pig liver and muscle cell-free supernatants were higher than in normal human controls. PERV-TR enzyme activity did not increase in patients before and after 1 mo of treatment. PERV-RT activities were not significantly different when compared with pre-treatment group (1.544 ± 0.155576), the post-treatment groups (1.501 ± 0.053507 , 1.461 ± 0.033808 and 1.600667 ± 0.01963 for 0, 14 and 30 d post-treatment, respectively, $P > 0.05$), and normal control group (1.440 ± 1.0641 , $P > 0.05$). RT enzyme activity in Chinese experimental mini-pigs was higher than in normal human control group (1.440 ± 1.0641 U/mL, $P < 0.05$), and not significantly different ($P > 0.05$) when compared with the pig breeds except in the muscle supernatants. All the samples including muscle and liver cell supernatants from the Chinese mini-experimental pigs and the four domestic Chinese pig breeds contained PERVs.

CONCLUSION: These results suggest that the risk of PERV infection through BALSS containing porcine liver cells without immunosuppressants may be quite low. Although

there were PERVs in Chinese experimental mini-pigs and porcine liver cell culture suspensions, we did not find any evidence of persistent PERV infection in patients treated with this porcine hepatocyte-based bioartificial liver.

INTRODUCTION

Acute or chronic liver failure is still one of the most challenging clinical syndromes in modern medicine. Survival rate in patients with acute or chronic liver failure caused by hepatitis B virus (HBV) is less than 20%^[1]. Various non-biological approaches including plasma exchange, hemodialysis and hemofiltration have had limited success, presumably because of the role of the synthetic and metabolic functions of the liver that are inadequately replaced in these systems. The liver is an organ with an extensive regenerative potential and has a remarkable capacity to meet replacement demands of cellular loss^[2]. If a system is designed to maintain normal liver functions for a bridging period until liver transplantation or liver recovery, then the survival rate of patients with acute liver failure (ALF) could be dramatically improved. Bioartificial liver support systems, which combine living cells of the liver in an extracorporeal circuit, have been successfully used in primary clinical trials and serve as a potent therapy and bridge to liver transplantation^[3]. The shortage of human organs to be used for bioreactors and the lack of safe and effective human liver cell lines have resulted in pigs becoming an important hepatic cell source. Primary porcine hepatocytes are most commonly used in devices undergoing pre-clinical and clinical evaluation. However, using these cells may be associated with the risk of transmission of PERVs^[4]. PERVs are present in the genome of all pigs and are able to infect human cells *in vitro*^[5]. However, the prevalence of PERV in Chinese pig breeds and whether PERVs infect patients who undergo bioartificial liver treatments based on Chinese experimental mini-pig liver

cells remains unclear. The objective of the study was to detect the prevalence of PERVs in the serum, liver and muscle cell-free supernatants of different pig breeds and in the serum of patients with acute or chronic liver failure, treated with a bioreactor based on porcine liver cells

MATERIALS AND METHODS

Samples collection and treatment

Pig liver and muscle cell-free supernatant collection

Muscle and liver samples (20 g) were collected from three Chinese experimental mini-pigs (the Institute of Experimental Animals, Beijing Agriculture University, China), weighing 10-15 kg each and from four domestic Chinese pigs of different breeds (Taihu pig, Wuzhishan pig, Dabai pig and Dahei pig-Beijing pig market), weighing approximately 60 kg each. The samples were taken and ground, pulverized with an SPS-3 Ultrasonic Pulverizer (working frequency 23 kHz; pulse 50% for 5 min). The pulverized samples were collected and centrifuged for 3 min at 80 r/min at room temperature. The cell-free supernatant was collected and resuspended in a solution provided by the C-type RT activity kit (Cavidi Tech AB, Uppsala, Sweden). The solution was then incubated for 30 min at room temperature and stored at -70 °C until used.

Serum samples collection Serum samples (1.5 mL) were collected from domestic Chinese pigs ($n = 4$) and Chinese experimental mini-pigs ($n = 3$). Human serum samples (1.5 mL) were collected from normal adult controls ($n = 4$) and from patients ($n = 3$) undergoing bioartificial liver treatments with samples taken at pre-treatment, d 0, 14 and 30 post-treatment. All serum samples were stored at -70 °C until used.

Liver cell isolation

Pig hepatocytes were harvested from three Chinese experimental mini-pigs using a two-step *in situ* collagenase perfusion technique that was modified from the original method developed by Aiken^[6]. The pig was initially anesthetized with ketamine (40 mg/kg). The liver was first perfused *in vivo* with oxygenated perfusion solution I (143 mmol/L sodium chloride, 6.7 mmol/L potassium chloride, 10 mmol/L Hepes, and 1 g/L EDTA, pH 7.4) at 300 mL/min for 20-40 min. The liver was then perfused *ex vivo* at 300 mL/min with oxygenated perfusion solution II (100 mmol/L Hepes, 67 mmol/L sodium chloride, 6.7 mmol/L potassium chloride, 4.8 mmol/L calcium chloride, 10 mL/L bovine albumin, and 1 g/L collagenase-D (Sigma), pH 7.6). Once the liver was visually dissolved (after 20-30 min), it was broken and irrigated with cold William's E medium (Gibco) supplemented with 15 mmol/L Hepes, 0.2 U/mL insulin, 2 mmol/L L-glutamine (Gibco), 100 U/mL penicillin, and 100 mg/mL streptomycin. The released cells were filtered through nylon mesh with 100- μ m openings and washed via three centrifugations (50 r/min) and resuspended in William's E medium. Viability for the harvests as determined using trypan blue exclusion ranged from 90% to 95%.

Patients

Three patients (2 males, 1 female, age 32-54) suffering from

acute on chronic liver failure were recruited into the study. Informed consent was obtained from all the patients or their relatives and approved by the Beijing Youan Hospital Ethics Committee. All the patients involved in the study were treated with HBL (*Cell Biotech Bioartificial Liver BIOLIV A3 device*) in our center from March 2000 to June 2001. The criteria^[7] for acute or chronic liver failure are as follows: (1) Evidence of chronic liver disease (chronic hepatitis and cirrhosis; cutaneous features of chronic liver disease; investigations demonstrating splenomegaly and hypoalbuminemia; evidence of chronic hepatitis/cirrhosis; chronic HBV carrier status by liver biopsy; chronic HBV/HCV overlapping with HAV, HDV, HEV or other viral infection). (2) All of the following: Prolonged prothrombin time and PTA < 40%, bilirubin rise > 17.1 μ mol/L per day or total bilirubin > 171 μ mol/L, Grade III/IV hepatic encephalopathy and ascites alone, or both simultaneously.

PERV-RT activity

Liver and muscle cell-free supernatants and serum samples filtered through membranes (0.45- μ m pore size) were analyzed for RT activity using the C-type RT activity assay (Cavidi Tech AB, Uppsala, Sweden) according to the instructions of the manufacturer (protocol B). One hundred and sixty microliters of sample dilution buffer was added to all wells of 96-well microtiter plate. Then 40 μ L of various samples was added to wells. A series of MuLV RT standard dilutions served as the positive controls, with normal human serum and sample dilutions as the negative controls. The PolyA Plate was sealed with adhesive tape. The plate was incubated at 33 °C for 3 h for the first plate and overnight for the second plate on an orbital shaker set at gentle agitation. The PolyA Plate was washed according to the protocol. Residual fluid in the wells was removed by tapping the plate upside down on absorbing cloth or paper. Two hundred microliters of AP substrate solution was added to each well of the PolyA plate and incubated at room temperature under dark cover on an orbital shaker set at gentle agitation. The filter of the plate reader was set at 405 nm. The absorbance of every well in the plate was read.

Statistical analysis

Data were expressed as the mean \pm SD. An unpaired Student's *t* test was used to compare mean between two groups and ANOVA was used for multiple comparisons. $P < 0.05$ was considered significant.

RESULTS

Yield and survival rate of porcine hepatocytes

Freshly isolated porcine hepatocytes were assessed for viability and function by trypan blue dye exclusion. The yield of cells was 5×10^9 cells/liver and cell viability was (95 \pm 5)%. During HBL treatment, porcine hepatocyte viability was monitored every 30 min and viability was maintained at 80%.

Enzymatic activity of PERV-RT

Standard curve and regression analysis The regression line was calculated with the use of SPSS10.0 software. A

Table 1 PERV-RT activities of patient's sera and Chinese experimental mini-pig tissues (U/mL)

	Pre-treatment	0 d after treatment	14 d after treatment	30 d after treatment
Patient 1	1.366	1.540	1.500	1.612
Patient 2	1.612	1.440	1.440	1.612
Patient 3	1.654	1.523	1.443	1.578
Mean±SD	1.544±0.155576 ¹	1.501±0.053507 ¹	1.461±0.033808 ¹	1.6006667±0.01963 ¹
Normal control (Mean±SD)	1.441±0.10 ²	1.451667±0.119801 ²	1.525667±0.085031 ²	1.468333±0.085031 ²

¹PERVs-RT activities before treatment were not significantly different when compared with post-treatment; ²normal control groups ($P>0.05$).

strong correlation was found between absorbance (A_{405}) and the various concentrations of MuLV RT standard dilution (Figure 1). The regression equation was obtained as follows: $Y = 0.098\ 617 - 0.131\ 297X$, the relative coefficient (r) was 0.954 91, the regression coefficient comparison was done by an unpaired Student's t test ($t = 3.795$, $P < 0.0035$) and both the absorbance and concentrations of MuLV RT were linear. RT activity for wells giving an A_{405} within the linear measuring range of the reader was determined by taking the A values of the samples into the regression equation. The results of each sample's RT activity are shown in Tables 1 and 2.

**Figure 1** Correlation between absorbance of A_{405} (Y) and the various concentrations of MuLV RT standard dilution (X).

PERV-RT activities in patients' serum and Chinese experimental mini-pig tissues

Serum RT activities result from the three patients were: 1.544 ± 0.155576 pre-treatment, 1.501 ± 0.053507 at 0 d post-treatment, 1.461 ± 0.033808 at 14 d post-treatment and 1.6006667 ± 0.01963 at 30 d post-treatment. The difference of PERV-RT activities was not significant between the pre-treatment, post-treatment and normal control groups (Table 1). The patients treated for acute hepatic failure with a bioreactor based on porcine cells were shown to be free of PERV infections, with a follow-up period of 1 mo.

PERV-RT activities of pig tissues from Chinese experimental mini-pigs and domestic pig breeds

RT activities results from the Chinese experimental mini-pigs were 2.443333 ± 0.09609 U/mL in muscle cell-free supernatants, 2.256667 ± 0.188237 U/mL in liver cell-free supernatants and 2.503333 ± 0.032146 U/mL in serum, respectively. RT activities in the four domestic pig breeds were 3.645 ± 0.205 U/mL in muscle cell-free supernatants,

3.6375 ± 0.523983 U/mL in liver cell-free supernatants and 3.0425 ± 0.378979 U/mL in serum, respectively. Serum RT activity in the Chinese experimental mini-pigs was higher than in normal human control group 1.440 ± 1.0641 U/mL ($P < 0.05$), but not significantly different from the domestic pig breeds ($P > 0.05$). RT activity in the muscle cell-free supernatant in the Chinese experimental mini-pigs was higher than that of the domestic pig breeds ($P < 0.05$) (Table 2). All of the samples including muscle and liver cell-free supernatants from either the Chinese mini-experimental pigs or the four domestic Chinese pigs demonstrated high PERV-RT activity, implicating that PERVs not only existed in these tissues but was also actively replicating.

Table 2 PERV-RT activities of pig tissues of Chinese experimental mini-pig and domestic pig breeds (U/mL)

	Muscle supernatants	Liver supernatants	Serum
Chinese experimental mini-pig 1	2.34	2.04	2.49
Chinese experimental mini-pig 2	2.53	2.35	2.48

^a $P < 0.05$ vs normal human control group.

DISCUSSION

According to the literature published from 1964 to 2000, a total of 270 patients worldwide with acute, sub-acute or chronic liver failure have been treated by 527 extracorporeal liver perfusions in 49 medical centers with livers from six different animal species, the pig being the most frequently used source^[8]. In addition, swine organs are amongst the most likely source species of xenografts for clinical use to date^[9-12]. The extracorporeal pig liver perfusion might provide the opportunity for a virus to evolve into a pathogen that can be transmitted from one individual to another efficiently enough to create a new epidemic disease. PERVs are a special risk, because they are part of the normal genetic material of mammalian cells except humans. Laboratory assays have been developed which target many aspects of the PERV replication/transmission cycle: PERV pro-viral DNA sequences, mRNA expression, RT activity, and the presence

of proteins, as well as the detection of anti-PERV immune responses^[13-15]. Among various assays, only enzymatic RT-activity is highly sensitive and specific for all PERV-A, PERV-B and PERV-C types, since RT is a generic marker of retroviruses. The presence of RT activity can be used to identify the presence of virus particles and, failure to detect it in these patient's sera points to the absence of any other, unrecognized retrovirus of porcine origin^[16].

This study showed that the RT activities from four domestic pig breeds were 2.445 U/mL in muscle cell-free supernatants, 2.508 U/mL in liver cell-free supernatants and 2.264 U/mL (range 2.048-2.387 U/mL) in serum respectively. All samples from the Chinese experimental mini-pigs and four domestic pig breeds contained PERVs that actively replicated in the tissues.

Breeding and keeping pigs under specific-pathogen-free or qualified-pathogen-free conditions is generally assumed to reduce the potential risk of transmitting exogenous viral, bacterial, fungal, and parasitic agents by xenotransplantation. Viral transmission, in a particular PERV is still a major obstacle, since PERVs are capable of infecting human cells *in vitro*. In a worse scenario, it is feared that PERV transmission to humans might be the starting point of a man-made pandemic threatening the health not only of BLASS patients, but also of the general public. A recent example of a rapid worldwide spread of an animal-borne disease was highlighted with the outbreak of severe acute respiratory syndrome (SARS), which spread in a matter of weeks from mainland China and Hong Kong to Vietnam, Singapore, Australia, Europe, and North America. This virus was the "common cold" virus of the Himalayan masked palm civet, an exotic species sold at live-animal markets in southern China where their meat is considered as a traditional delicacy. The transmission of SARS from animal to humans was traced back to civet chefs from Guangdong Province who contracted the disease, while handling infected meat.

The diameter of the 3A bioreactor membrane pore is about 200 nm and the diameter of PERV RNA is about 100 nm. Thus, it is quite possible for the PERV to pass through the bioreactor membrane. However, we did not find any evidence of infection with PERV in the patient's serum soon after treatment or within 1 mo of follow-up. Like all investigations published to date, in patients who have been treated with porcine cells, tissues and organs, there has been no evidence for PERV infection. Although the results are encouraging, it has to be stated that the human immune system through a variety of specific and non-specific mechanisms can clear PERV particles effectively. As humans do not express functional α 1, 3-galactosyl transferase, high titers of natural anti-gal-antibodies develop in their circulation because of continuous contact with gal- α 1, 3-gal bearing microorganisms. These pre-formed or natural antibodies also effectively neutralize the α -gal-bearing γ -retroviruses including PERV. Since PERVs are produced by pig cells that have gal- α 1, 3-gal-epitopes, they are sensitive to serum-mediated virolysis via the classical complement pathway *in vivo*. Thus, if immunosuppressed patients are treated with porcine liver cell bioreactor therapy then the potential risk of PERV infection will enhance. In this study the patient's sera were not in direct contact with the pig cells and the time of treatment was limited to only 8-10 h. Clearly, with an increase in the duration of

treatment by BLASS, the potential for PERV transmission will also increase. Therefore, it remains to be determined whether PERV transmission might occur in future trials and necessitates the continuation of strict monitoring regimens. The ability to monitor clinical trials closely using these assays will be of great benefit to the microbiological safety of clinical BLASS and xenotransplantation. This study sets one possible standard for laboratory surveillance of PERV infection after exposure to cellular xenografts from pigs.

Abstract

AIM: To investigate the prevalence of advanced polyps in asymptomatic Chinese and to determine the risk of proximal advanced colonic polyps in subjects with and without polyps in the distal colon.

METHODS: Data were collected prospectively during colonoscopic examinations performed in 5 973 subjects as part of health evaluation at our unit from December 1997 to December 2003. Polyps were considered advanced, if they were larger than 10 mm or were tubovillous, villous or malignant. Proximal colon was defined as the splenic flexure and more proximal portions of the colon.

RESULTS: Colon polyps were detected in 971 (16.3%) subjects (613 males and 358 females) with their mean age being 56.6±10.7 years. Advanced polyps were noted in 199 (3.3%) individuals. Subjects were sub-classified according to the location of polyps into three groups: distal (569, 58.6%), proximal (284, 29.2%), and combined proximal and distal (118, 12.2%) groups. Subjects with advanced polyps in these three groups were 95 (9.8%), 56 (5.8%), and 48 (4.9%) respectively. In the 48 subjects with advanced combined polyps, 13 advanced polyps were distributed at the distal colon, 17 at the proximal colon, and 18 at both. Eighteen colon cancers including 12 at sigmoid and 6 at ascending colon were confirmed by final pathology. The relative risk for advanced proximal polyp according to distal findings was 3.1 (95%CI: 1.3-7.4) for hyperplastic polyp, 2.7 (95%CI: 1.4-5.3) for tubular polyp and 13.5 (95%CI: 5.1-35.4) for advanced polyp as compared to that for no polyp. However, 56 (28.2%) of 199 subjects with advanced polyps had no index polyps at the distal colon and might go undetected under sigmoidoscopic screening.

CONCLUSION: Although distal lesions can predict the risk of advanced proximal polyps, a substantial portion of

INTRODUCTION

Colorectal cancer (CRC) is an important health problem that carries high morbidity and mortality in the developed and Western countries^[1]. The majority of CRCs arise from pre-existing adenomas^[2]. This adenoma-adenocarcinoma sequence in colorectal carcinogenesis has provided an opportunity for screening asymptomatic individuals to prevent CRC. Indeed, accumulating evidence has indicated that the screening policy may greatly reduce the mortality and incidence of CRC^[3]. Currently, CRC screening is suggested for those with 50 years of age and above. Standard recommendations include annual testing for fecal occult blood and periodic sigmoidoscopy. Colonoscopy is generally reserved for patients with positive screening tests or those with a high average risk^[4].

Early detection and removal of potentially malignant polyps is the central element of CRC screening^[3]. In this respect, efforts to control and prevent CRC lie in the reliable detection and resection of advanced adenomas before they become malignant. Atkin *et al.*^[5], investigated the long-term risk of CRC after excision of recto-sigmoid adenomas and found that 88% of cancers develop in patients with high risk (namely villous, tubovillous histology, or >10 mm in diameter) recto-sigmoid adenomas. This study has led them to propose that a single examination with a sigmoidoscopy leading to full colonoscopy in patients with high risk recto-sigmoid adenomas is a cost effective and safe screening protocol^[6]. The UK flexible sigmoidoscopy screening trial further supports that population screening by sigmoidoscopy is a worthwhile screening tool^[7]. However, sigmoidoscopy is a sub-optimal approach for colon screening, and proximal adenomas without associated distal polyps may not benefit from early detection. The intrinsic risk of underdiagnosis by sigmoidoscopy has been illustrated by evidence of an increasing rightward trend of colon polyps and CRC^[8]. It was also reported that 46-52% of proximal advanced adenomas are not accompanied with distal polyps^[9,10]. Even

addition of fecal occult blood testing to sigmoidoscopy cannot significantly increase the detection of advanced neoplasia^[11]. Similar observations have also been reported from other countries^[12-15]. Therefore, another school of thought has advocated use of an ordinary colonoscope instead of a sigmoidoscope for screening^[16].

Racial differences in the anatomical distribution of colorectal neoplasia exist between Western and Oriental countries. Variations in prevalence of proximal adenomas could influence the choice of colonoscopy *vs* sigmoidoscopy for screening in different populations. It remains uncertain whether clinical findings from Western countries are applicable to Chinese. In Taiwan, CRC ranks the third leading cancer death and its incidence has increased rapidly due to westernization of lifestyle^[17]. The information regarding the prevalence of colorectal polyps in asymptomatic Chinese remains limited^[14,15]. Our unit has provided self-paid screening for CRC since December 1997^[18]. Taking this advantage, we performed a prospective study to investigate the prevalence of advanced polyps in asymptomatic subjects and to determine the risk of proximal advanced polyps in subjects with and without distal polyps.

MATERIALS AND METHODS

Since December 1997, our center has started to provide full colonoscopic service for all subjects who attended health checkup with a request for a colonoscopy. All colonoscopies were performed with Olympus Model CF200 or CF240 colonoscopes by experienced colonoscopists^[18]. Patients were prepared by oral administration of balanced electrolyte solution with polyethylene glycol on the day before the examination. All lesions identified were removed for histologic examination by either biopsy, polypectomy, or conventional surgery. The exact size of the polyp was determined immediately after polyp removal or by comparing the known width of opened biopsy forceps. The location and size of all polypoid lesions were recorded. The distal colon was defined as the rectum, sigmoid, and descending colon, whereas proximal colon was splenic flexure and more proximal portions of the colon. Polyps were considered advanced, if they were larger than 10 mm or were tubovillous, villous, or malignant.

The exclusion criteria included presence of colorectal symptoms, previous history of colorectal neoplasia, colonic surgery, inflammatory bowel disease, family history of colon cancer or first-degree relatives with related neoplasms of the breast, ovary or uterus, inability to give informed consent, and incomplete colonoscopic examinations. From December 1997 to December 2003, a total of 5 973 subjects who fulfilled the above criteria were enrolled for further analysis. Categorical data were analyzed by χ^2 test and relative risk of advanced proximal polyps was evaluated by logistic regression analysis.

RESULTS

Colonoscopy was successfully performed in the cecum in 5 973 subjects. The baseline characteristics of patients and colonoscopic findings are described in Table 1. Colon polyps were detected in 971 (16.3%) subjects (613 males and 358

females) with a mean age of 56.6 ± 10.7 years. Among them, 199 (3.3%) subjects had advanced polyps. The prevalence of colorectal polyps in relation to demographic parameters is listed in Table 2. The prevalence of polyps (682/3 317, 20.6% *vs* 289/2 656, 10.9%, $P < 0.01$) and advanced polyps (165/3 317, 3.0% *vs* 34/2 656, 1.3%, $P < 0.01$) was significantly higher in subjects older than 50 years as compared to those younger than 50 years. Overall, male subjects had a significantly higher prevalence of polyps (613/3 125, 19.6% *vs* 358/2 848, 12.6%, $P < 0.01$) and advanced polyps (124/3 125, 3.9% *vs* 75/2 848, 2.6%, $P < 0.01$) than female subjects. The 971 subjects with polyps were subclassified according to the location of polyps into distal (567, 58.6%), proximal (284, 29.2%) and combined proximal and distal (118, 12.2%) groups. Advanced polyps in these three groups were 95 (9.8%), 56 (5.8%), and 48 (4.9%), respectively. In the 48 subjects with advanced combined groups, 13 advanced polyps were distributed at the distal colon, 17 at the proximal colon, and 18 at both. Eighteen colon cancers including 12 at sigmoid and 6 at ascending colon were confirmed by final pathology. The relative risk for advanced proximal polyp according to distal findings was 3.1 (95%CI: 1.3-7.4) for hyperplastic polyp, 2.7 (95%CI: 1.4-5.3) for tubular polyp and 13.5 (95%CI: 5.1-35.4) for advanced polyps as compared to that for no polyp (Table 3).

No polyp	5 002 (83.7)
Proximal polyp	284 (4.8)
Distal polyp	569 (9.5)
Combined	118 (2.0)

DISCUSSION

The reported prevalence of colonic polyps varies widely due to differences in structure of the studies and sensitivities of the test used to define prevalence^[19]. Referred and symptomatic patients cannot represent screening setting, but true incidence is difficult to calculate in symptom-free and unselected populations. It was estimated that 30% of the Western population have colonic polyps while a lower rate (10-15%) is noted in Asia and Africa^[16]. Cross-sectional studies indicate that 5-10% of asymptomatic subjects (50-75 years old) have advanced colonic neoplasia^[9,10]. Colonoscopy is the most sensitive imaging study for assessment of colonic polyps. Prior to our study, there were two studies dealing with the prevalence of colonic polyps in asymptomatic Chinese. Sung *et al.*^[14], enrolled 505 subjects older than 50 years through health exhibitions and documented

Table 2 Prevalence of colorectal polyps in relation to demographic parameters, *n* (%)

Distal finding	Total	Advanced proximal polyp	Relative risk
No polyp	5 286	56	1.0
Hyperplastic polyp	181	6	3.1 (1.3-7.4)
Tubular adenoma	380	11	2.7 (1.4-5.3)
Advanced adenoma	126	18	13.5 (5.1-35.4)

12.5% of advanced polyps in Hong Kong Chinese. In contrast, Cheng *et al.*^[15], detected only 1.3% of advanced polyps in Taiwanese Chinese. We found 16.3% of colonic polyps and 3.3% of advanced polyps respectively in 5 973 asymptomatic subjects older than 40 years. All these three studies were performed by colonoscopy, indicating that factors other than screening methods are responsible for the difference. The low prevalence in the later two studies may in part reflect the relatively large number of individuals younger than 50 years. In addition, inherent selection bias of enrolled subjects, geographic or dietary factors, and different incidence rates are among the plausible explanations but remain to be investigated by future studies.

Results from previous studies have shown that colonic polyps are more common in men than in women and increase in frequency with increasing age^[13,19]. In agreement with these observations, subjects ≥50 years old and males tend to have a higher prevalence of both colonic polyps and advanced adenoma. To our knowledge, none of the studies have addressed the prevalence of colonic polyps in asymptomatic Chinese younger than 50 years. Overall, in subjects aged ≥50 years, colonic polyps and advanced adenomas are present in 20.6% and 3.0%, respectively, whereas 10.9% and 1.3% are found in patients aged <50 years. Taken together, these studies support the notion that age and gender may also influence the prevalence of colonic polyps^[13,19]. Furthermore, our data suggest that in Chinese the optimal cut-off point of age for screening of average risk is similar to Western guideline because the incidence of colorectal polyps begins to rise above the age of 50 years^[4].

From the standpoint of screening accuracy, colonoscopy is the only reliable way for detection of all colorectal polyps. However, current guidelines recommend sigmoidoscopy as the first-line CRC screening in view of expense, complication and patient's acceptability^[4]. A crucial assumption underlying the practice of sigmoidoscopy is that, there exists an association between distal and proximal colonic neoplasia. Therefore, sigmoidoscopy may function as a gatekeeper and colonoscopy could be reserved for individuals with index polyps at the distal colon. Two recent systematic reviews

support this notion and point out that distal polyps, irrespective of size or histology, are associated with an increased prevalence of synchronous proximal neoplasia^[20,21]. In keeping with these observations, our results have demonstrated that distal hyperplastic, tubular, and advanced polyps are associated with 3- to 13-fold risk of synchronous, proximal advanced polyp.

Although distal colonic polyps can predict the risk of advanced proximal lesion, a clean rectum and sigmoid colon cannot guarantee any significant adenomas in the proximal colon. The proximal colon is not routinely examined when an index lesion is not detected in sigmoidoscopy. Consequently, the proportion of patients with adenoma in the proximal colon but without distal colonic neoplasia may influence the effectiveness of screening sigmoidoscopy^[20,21]. The issue is becoming increasingly important, since several reports have revealed a rightward shift of CRC^[8]. Moreover, available data from recent colonoscopic screening indicate that 46-52% of proximal advanced adenomas are not accompanied with distal polyps^[9,10]. In the present study, we found 199 subjects had advanced polyps and 56 (28.1%) were isolated proximal lesions. Taken together, these findings implicate that a substantial portion of individuals with proximal neoplasia will go undetected by screening sigmoidoscopy and are at increased risk of cancer.

In summary, this study provides data on the background prevalence of colonic polyps in asymptomatic Chinese aged ≥40 years. The varied prevalence as compared to previous studies may be explained by variation of screening methods, selection criteria of enrolled subjects and different etiologic factors. About 30% of advanced proximal polyps are not associated with sentinel lesions, and might be missed by screening sigmoidoscopy. For the motivated individuals older than 50 years, whole colon screening by colonoscopy will detect more proximal lesions and give the greatest reassurance. The cost-effectiveness of colonoscopy needs to be evaluated further in future studies.

Abstract

AIM: To study the effect of rosiglitazone, which is a ligand of peroxisome proliferator-activated receptor gamma (PPAR γ), on the expression of PPAR γ in hepatic stellate cells (HSCs) and on the biological characteristics of HSCs.

METHODS: The activated HSCs were divided into three groups: control group, 3 μ mol/L rosiglitazone group, and 10 μ mol/L rosiglitazone group. The expression of PPAR γ , α -smooth muscle actin (α -SMA), and type I and III collagen was detected by RT-PCR, Western blot and immunocytochemical staining, respectively. Cell proliferation was determined with methylthiazolyltetrazolium (MTT) colorimetric assay. Cell apoptosis was demonstrated with flow cytometry.

RESULTS: The expression of PPAR γ at mRNA and protein level markedly increased in HSCs of 10 μ mol/L rosiglitazone group (t value was 10.870 and 4.627 respectively, $P < 0.01$ in both). The proliferation of HSCs in 10 μ mol/L rosiglitazone group decreased significantly ($t = 5.542$, $P < 0.01$), α -SMA expression level and type I collagen synthesis ability were also reduced vs controls (t value = 10.256 and 14.627 respectively, $P < 0.01$ in both). The apoptotic rate of HSCs significantly increased in 10 μ mol/L rosiglitazone group vs control ($\chi^2 = 16.682$, $P < 0.01$).

CONCLUSION: By increasing expression of PPAR γ in activated HSCs, rosiglitazone, an agonist of PPAR γ , decreases α -SMA expression and type I collagen synthesis, inhibits cell proliferation, and induces cell apoptosis.

INTRODUCTION

It is well established that hepatic fibrosis is the pathological basis on which chronic liver diseases further progress to hepatic cirrhosis^[1]. Multiple factors produce hepatic lesions, contributing to hepatic fibrosis^[2]. Studies show that reversing hepatic fibrosis may block the progression of hepatic cirrhosis^[3]. Hepatic stellate cell (HSC) is now well established as the key cellular element involved in the development of hepatic fibrosis^[4]. When the liver is attacked by pathogenic factors, HSCs, a pericyte-like mesenchymal liver cell population, transform from a "quiescent" status ("resting" HSC) into myofibroblast-like cells ("activated" HSC) with the latter synthesizing and secreting extracellular matrix (ECM), tissue inhibitor of matrix metalloproteinases and multiple cytokines, which contribute to collagen deposition, leading to fibrosis^[5-7]. Recently, it has been reported that resting HSC expresses peroxisome proliferator-activated receptor gamma (PPAR γ); the expression of PPAR γ gradually decreases during the course of activation of HSC cultured *in vitro*, indicating that certain expression level of PPAR γ may be a crucial element that inhibits the natural activation of HSC^[8-14]. The present study was designed to investigate whether activated HSCs (myofibroblast-like cells) treated by PPAR γ -specific ligands were able to enhance the expression of PPAR γ and its effect on HSC proliferation, collagen secretion, and cell apoptosis.

MATERIALS AND METHODS

HSCs of rats

HSCs of rats were obtained from HSC strain rHSC-99 produced by the Department of Hepatobiliary Surgery, Peking University People's Hospital and this strain had the characteristics of activated HSCs^[15].

Rosiglitazone

A high-affinity specific ligand of PPAR γ , was purchased from GlaxoSmithKline Investment Co., Ltd.

Experimental groups

Three groups were set up in the study, blank control group, 3 μ mol/L rosiglitazone, and 10 μ mol/L rosiglitazone groups, respectively.

Semi-quantitative RT-PCR detection of PPAR γ

The extraction and reverse transcription of RNA were performed according to the directions of the kits (Taq PCR MasterMix, TW-Biotech Co.); PPAR γ primer was synthesized by Shanghai Bioengineering Co., Ltd, with an upstream fragment of CCCTGGCAAAGCATTGTAT, a downstream fragment of ACTGGCACCCCTTGAAAAATG and an extension fragment of 222 bp. The internal reference β -actin was designed with an upstream fragment of TGGGACG-ATATGGAGAAGAT, a downstream fragment of ATTG-CCGATAGTGATGACCT and an extension fragment of 522 bp. PCR reaction is as follows. PPAR γ primers were added to reaction systems, which conditions were set at 95 °C for 5 min; 94 °C for 20 s, 55 °C for 30 s, 72 °C for 40 s, totally 29 cycles; finally at 72 °C for 5 min. The products of PCR were photographed after electrophoresis on 2% agarose gel and the gray scale values determined through image analysis. The sample quantities were adjusted to make the gray scale value in each β -actin group stay at a relatively identical level and then the gray scale values of PPAR γ between groups were compared.

Detection of PPAR β protein by western blot

In each electrophoresis lane, a sample of 30 μ g protein was added and after polyacrylamide gel electrophoresis at a volume fraction of 30%, the electrophoretic proteins were transferred onto nitrocellulose membranes, blocked with 5% fat-free milk in TBST buffer (20 mmol/L Tris-HCl, 137 mmol/L NaCl, and 0.05% Tween 20). The membranes were incubated with the first and second antibody, respectively. Antigen-antibody complexes were visualized using the enhanced chemiluminescence detection system according to the manufacturer's instructions (Santa Cruz Biotechnology, Inc.). Membranes were exposed to autoradiography, and signals were scanned for quantitation. Image analysis was done on the straps to determine the gray scale value. The expression quantity of PPAR γ by HSC in each group was expressed relative to that of the control group.

Detection of PPAR γ protein by immunocytochemistry method

After HSCs were cultured on the slides, they were fixed in neutralized 40 g/L formaldehyde, then detected with SP method (Santa Cruz Biotechnology, Inc.) and examined under a microscope. Those cells whose nuclei were brown were defined as positive.

Effect of rosiglitazone on HSC proliferation

Cells were incubated in a 96-well plate. The cells grew in DMEM culture medium containing a volume fraction of 16% calf serum until the logarithmic growth phase, and were then incubated for 24 h in DMEM culture medium that contained a volume fraction of 1% calf serum, which could stop the growth of cells. After that, cells were incubated in culture media respectively containing a volume fraction of 16% calf serum, as blank control group, and rosiglitazone groups of a final concentration of 3 and 10 μ mol/L. And the absorbance value of A570 was read on the microplate reader for each well using MTT colorimetric assay at 0, 24, and 48 h.

Effect of rosiglitazone on the synthesis of α -SMA of HSCs, and collagen I and III

HSCs from control group, 3 μ mol/L rosiglitazone group and 10 μ mol/L rosiglitazone group were detected by Western blot and immunocytochemistry respectively.

Effect of rosiglitazone on HSCs apoptosis

The apoptotic index was determined by flow cytometry (Applied Biosystems). A total of 1×10^6 /mL cells in a suspension were fixed with precooled 70% ethanol solution and stained, and analyzed by a flow cytometer and the apoptotic index was determined by Multicycles software.

Statistical analysis

t-Test and χ^2 test were employed to analyze all the data concerned. $P < 0.05$ was taken as significant.

RESULTS

10 μ mol/L rosiglitazone enhanced the expression of HSC PPAR γ mRNA

At 3 μ mol/L of rosiglitazone, no significant difference was seen in the expression of PPAR γ mRNA in HSCs compared with the control group. There was a significant increase in the expression of PPAR γ mRNA in HSCs by 10 μ mol/L rosiglitazone compared with the control group ($t = 10.87$, $P < 0.01$, Figure 1). Meanwhile obvious expression of all β -actin was observed.

Figure 1 PPAR γ mRNA level. **A:** Expression of PPAR γ mRNA. Lane 1, 10 μ mol/L rosiglitazone group; lane 2, 3 μ mol/L rosiglitazone group; lane 3, control group; **B:** Expression of β -actin.

Western blot demonstrated that the expression of PPAR γ protein increased by 10 μ mol/L rosiglitazone

At 3 μ mol/L rosiglitazone, no significant difference was seen in the expression of PPAR γ protein in HSCs compared with control group. The expression of PPAR γ protein in HSCs by 10 μ mol/L rosiglitazone was significantly increased compared with that of the control group ($t = 4.627$, $P < 0.01$, Figure 2).

Immunocytochemistry demonstrated enhanced expression of PPAR γ protein in HSCs in 10 μ mol/L rosiglitazone group

In the blank control group and 3 μ mol/L rosiglitazone

group, no evident expression of PPAR γ protein was found by immunocytochemistry. In the 10 $\mu\text{mol/L}$ rosiglitazone group, there was a relatively increased expression of PPAR γ protein in the nucleus of most HSCs and in the cytoplasm of some HSCs (Figure 3A). The expression of PPAR γ protein seen in the cytoplasm in some of the HSCs might be proteins not entering into the cell nucleus, and the precursor of PPAR γ proteins in cytoplasm.

10 $\mu\text{mol/L}$ rosiglitazone markedly inhibited HSCs proliferation

There was no significant difference in the proliferation activity of HSCs between 3 $\mu\text{mol/L}$ rosiglitazone group and the control group. After a 24 and 48 h culture period, the proliferation activity of 10 $\mu\text{mol/L}$ rosiglitazone group was lower than that in both the control group (t value = 5.542 and 19.293, respectively, $P < 0.01$ in both) and the 3 $\mu\text{mol/L}$ rosiglitazone group (t value = 6.880 and 10.502 respectively, $P < 0.01$ in both, Table 1).

Table 1 Effect of rosiglitazone on proliferation of rHSC-99

Groups	0 h	24 h	48 h
Controls	0.21 \pm 0.041	0.62 \pm 0.088	1.00 \pm 0.045
3 $\mu\text{mol/L}$	0.22 \pm 0.038	0.63 \pm 0.060	0.93 \pm 0.049
10 $\mu\text{mol/L}$	0.22 \pm 0.064	0.33 \pm 0.085 ^b	0.49 \pm 0.060 ^b

^b $P < 0.01$ vs controls or 3 $\mu\text{mol/L}$ treatment group.

10 $\mu\text{mol/L}$ rosiglitazone decreased synthesis of α -SMA, collagen I in HSCs

Detection of synthesis of α -SMA, collagen I and III in HSCs by immunocytochemistry indicated that cytoplasmic

Figure 2 PPAR γ protein was assessed with Western blotting. Lane 1, 10 $\mu\text{mol/L}$ rosiglitazone group; lane 2, 3 $\mu\text{mol/L}$ rosiglitazone group; lane 3, control group.

staining of α -SMA and collagen I and III in both the blank control group and 3 $\mu\text{mol/L}$ rosiglitazone group was strongly positive. In 10 $\mu\text{mol/L}$ rosiglitazone group, the expression of α -SMA and collagen I decreased significantly while there was no distinct change in the expression of collagen III. Through gray-scale scanning analysis, the quantity of α -SMA and collagen I decreased 48% and 42%, respectively compared with the blank control group (t value = 10.256 and 14.627, respectively, $P < 0.01$ in both). Western blot detection of α -SMA showed that there was no significant difference between 3 $\mu\text{mol/L}$ rosiglitazone group and blank control group. The gray-scale value of α -SMA strap of 10 $\mu\text{mol/L}$ rosiglitazone group significantly decreased compared with the blank control group ($t = 4.627$, $P < 0.01$).

10 $\mu\text{mol/L}$ rosiglitazone accelerated HSC apoptosis

Flow cytometry analysis revealed that HSC apoptosis index in 10 $\mu\text{mol/L}$ rosiglitazone group was 23.8%, significantly higher than that in the control group (3.6%, $\chi^2 = 16.682$, $P < 0.01$).

DISCUSSION

Excessive production and deposition of extracellular matrix is one of the main characteristics of hepatic fibrosis, in which type I collagen is an essential component^[16]. Type I collagen mainly comes from activated myofibroblast HSC^[17]. At present, studies on hepatic fibrosis are increasingly concentrating on HSC, in order to find specific and efficient approaches to inhibit and reverse hepatic fibrosis^[1,2,18,19].

Several studies demonstrated that resting HSCs express PPAR γ and when resting HSCs are activated to become myofibroblast HSCs, they lose the ability to transcribe and express PPAR γ ^[8,9,12,20,21]. PPAR γ is a member of nuclear receptor superfamily^[22]. When combined with its ligand, PPAR γ forms heterodimer with retinoid X receptor, which is then combined with peroxisome proliferator response element (PPRE) at the upstream of regulated gene promoter to play a role in transcription and regulation^[23]. Rosiglitazone is widely used in clinical practice as an insulin sensitizer, and at present, it is identified as a high-affinity specific ligand of PPAR γ , which can promote the expression of PPAR γ in cells and enhance the transcription activity of PPAR γ ^[24-28]. According to the change of blood drug level after rosiglitazone is taken, 2-3 $\mu\text{mol/L}$ rosiglitazone is believed

Figure 3 Immunocytochemistry of rHSC-99 $\times 100$. A: Positive of PPAR γ in 10 $\mu\text{mol/L}$ rosiglitazone group; B: positive of α -SMA in control group; C: weak

positive of α -SMA in 10 $\mu\text{mol/L}$ rosiglitazone group.

to be at a relatively high level, but in a preliminary experiment, only 10 $\mu\text{mol/L}$ rosiglitazone displayed a notable effect. Therefore, we set up a blank control group, 3 $\mu\text{mol/L}$ rosiglitazone group, and 10 $\mu\text{mol/L}$ rosiglitazone group. It was shown that 10 $\mu\text{mol/L}$ rosiglitazone markedly increased the transcription activity and expression level of PPAR γ in HSC, indicating that using PPAR γ -specific ligand was able to recover the expression and transcription activity of PPAR γ to a certain extent.

HSC strain rHSC-99 has been established by serial passage of rat HSC. This strain has the characteristics of activated myofibroblast HSC and highly expresses α -SMA and collagen I and III^[15]. The results of our experiment demonstrate that while 10 $\mu\text{mol/L}$ rosiglitazone remarkably enhances the transcription activity and expression level of PPAR γ in HSCs, the PPAR γ inhibits the expression of α -SMA and collagen I and the proliferation of HSCs.

At present, the mechanism that enhances the transcription activity and expression level of PPAR γ in HSC can inhibit the expression of α -SMA and collagen I and HSC proliferation has not been well elucidated^[30]. PPAR γ has a regulatory effect on multiple genes, but little research has been done regarding the effect of changes in PPAR γ expression and transcription activity on related genes of HSCs^[9,12,13,21,29]. Researches have shown that the enhancement of PPAR γ transcription activity can inhibit the expression of TGF- β 1 mRNA induced by TGF- β 1, suggesting that the activation of PPAR γ might block the autocrine loop of TGF- β 1 and further reduce TGF- β 1 induced secretion of collagen and HSCs proliferation^[30-32]. In researches on human and mouse macrophages^[33-36], it was found that there existed an interaction between PPAR γ and AP-1 signal pathway and the activation of PPAR γ could inhibit the activity of transcription factor AP-1, STAT, and NF- κ B. It is assumed that, there may be similar mechanism in HSC that PPAR γ , through inhibiting the activity of transcription factor AP-1, STAT, and NF- κ B, further plays an inhibitory role in HSC proliferation and expression of collagen.

HSC apoptosis can reduce the absolute quantity of activated HSC, thus not only reducing the synthesis of collagen, but also weakening the inhibitory effect on collagen degradation through decreasing activated HSCs to reduce the expression of matrix tissue inhibitor of metalloproteinases^[5]. Therefore, induction of HSC apoptosis has been considered as an efficient countermeasure to postpone or reverse hepatic fibrosis^[19]. Rosiglitazone, as a specific ligand of PPAR γ , can significantly increase HSC apoptosis rate.

The results of our experiment indicate that PPAR γ -specific ligand rosiglitazone, through activating the expression of PPAR γ , can inhibit the expression of α -SMA and collagen I in activated HSCs, the proliferation of activated HSCs and induce apoptosis of activated HSCs.

Abstract

AIM: To explore the expression of p53, bcl-2, bax, survivin and the cell apoptosis during the development of tree shrew hepatocellular carcinoma (HCC), the relationship between expression of these genes, its impact on HCC development, and its relation to cell apoptosis.

METHODS: Tree shrew HCC was induced with aflatoxin B1 (AFB1), and regular biopsy of liver tissues was carried out and the biopsy tissues were collected during cancer inducement. Liver biopsy tissue and HCC tissue were collected from 35 pre-cancerous experimental animals at wk 30 and 60 and at the 30th-, 60th-, and 90th-wk. Liver biopsy tissues were collected from 13 blank control animals at wk 30, 60, and 90. Expression of p53, bcl-2, bax, and survivin at each stage was examined by immunohistochemistry method. Apoptotic cells were detected *in situ* by the terminal deoxynucleotidyl transferase-mediated nick end labeling (TUNEL) technique.

RESULTS: The apoptosis rate of normal hepatic cells was extremely low, whereas it increased during the formation of HCC. Expression of the apoptosis-related genes p53, bcl-2, bax, and survivin during the formation of HCC presented an increasing tendency. Expression of p53 did not noticeably relate to that of bcl-2, bax, and survivin, whereas expression of bcl-2 and bax was closely related. In HCC, p53 did not present a distinct relation to cell apoptosis, whereas its high level expression was probably related to liver cell proliferation. Survivin negatively correlated apoptosis index, and its overexpression could inhibit cell apoptosis.

CONCLUSION: Apoptosis-related genes p53, bcl-2, bax, and survivin are all related to the occurrence of HCC. The

INTRODUCTION

Occurrence and biological characteristics of tumors are related not only to over-proliferation of carcinoma cells but also to decrease of apoptosis. Investigation of apoptosis helps to disclose the biological characteristics of tumors, and seeks new methods of diagnosis and treatment for tumors. Product of gene bax (bcl-2 associated X gene) expression is a 21-ku protein, which is able to combine bcl-2 protein to form a heterogeneous dimer, thus inhibiting the function of bcl-2 and promoting the occurrence of apoptosis. p53 is universally accepted as a tumor suppressor, whose mutation and deficiency accelerate cancer growth. Survivin is a new member of the inhibitor of apoptosis inhibiting protein family. It is believed that cell apoptosis induced by most of apoptosis signals is realized through the effect of a cascade proteinase, namely caspase. Survivin can act directly on caspase, thus inhibiting the activity of caspase-3 and caspase-7^[1] and eventually blocking the terminal pathway of apoptosis. In this research, expression of p53, bcl-2, bax, survivin, and cell apoptosis in different stage liver tissues during the development of laboratory tree shrew HCC were explored by the immunohistochemistry method and the terminal deoxyn-ucleotidyl transferase-mediated nick end labeling (TUNEL) technique. The relationship between expression of these genes, its impact on HCC formation, and its relation to cell apoptosis were discussed.

MATERIALS AND METHODS

Animal experiment

Adult laboratory tree shrews, weighing 100-160 g, were raised in separate stainless cages under a laboratory temperature of 25±2 °C. After 2-4 wk of feeding, all animals were examined for serum ALT and HBsAg. Thus, 61 healthy animals were

selected and divided into experimental group and control group.

Forty-eight tree shrews in the experimental group received aflatoxin B1 (AFB1) at the beginning of the experiment, 150 µg/(kg·d), five times/wk. AFB1 was solved into dimethyl sulfoxide, then added into milk for lapping by the animals. The animals received AFB1 for 105 wk then common animal food for 45 wk when the experiment was completed.

Thirteen tree shrews in the control group did not receive AFB1 but common animal food, milk and fruits.

Liver tissue biopsy

During the whole experiment, liver tissue biopsy was carried out in both groups of tree shrews once in every 15 wk. Biopsy tissues were fixed in 10% formaldehyde solution.

Tissue specimens

Specimens of liver biopsy tissues taken at wk 30 and 60 and HCC tissues from the experimental animals and those of the liver biopsy tissues taken at wk 30, 60, and 90 were embedded with paraffin wax and cut into 5-µm consecutive sections, then subjected to the routine HE staining. Expression of p53, bcl-2, bax, and survivin was detected by immunohistochemistry method. Apoptotic cells were subjected to *in situ* detection by the TUNEL technique.

Reagents

Mouse anti-human p53, bcl-2, bax, and survivin mAbs were from Beijing Zhongshan Company. Streptavidin-peroxidase (S-P) kits and DAB developers were from Fuzhou Maixin Company; TUNEL staining kits (Cat. No. 1684809) were from Boehringer Mannheim GmbH, Deutschland. DNAase I, proteinase K, and 3% bovine serum albumin were from Dalian Baosheng Company.

Immunohistochemistry staining and in situ detection of apoptosis

S-P method was applied. Sections before addition of mAb were subjected to microwave antigen repairing, all other procedures were according to the kit manual. PBS was substituted for the first antibody to act as the negative contrast, and the positive contrast sections from Fuzhou Maixin Company were used as the positive contrast. *In situ* detection of apoptosis was carried out as previously described^[2]. Positive contrast sections were subjected to a 30-min digestion with DNAase I before TUNEL reacting solution was added, whereas negative contrast sections were subjected to TDT-free TUNEL reacting solution.

Result assessment and statistical analysis

p53 and survivin protein positive reactions were located in nuclei, presenting light or dark brown. Bcl-2 and bax protein positive reactions were located in cytoplasm, appearing as dark brown.

Immunohistochemical staining was divided into five grades: grade 0: <5%; grade I: 5-25%; grade II: 25-50%; grade III: 50-75%; and grade IV: >75%. Five percent was taken as the criterion for the judgment of positive cells.

Staining intensity of positive cells was divided into three grades: grade I: low; grade II: medium; grade III: strong. The staining intensity of all the positive contrast sections was

determined as grade III for reference. Immunohistochemical staining score = grading for percentage of positive cells × staining intensity^[3].

Apoptotic cells were calculated under five high power fields randomly selected, at least than 1 000 cells per field. Percentage of positive cells to total cells was taken as apoptosis index.

Statistical analysis was carried out by variance analysis, χ^2 test, etc., with the statistical software package PEMS.

RESULTS

Occurrence of HCC

At the 150th wk of the experiment, all dead animals were subjected to etiological diagnosis of HCC. The result showed that occurrence of HCC was seen in 35 of 48 experimental tree shrews, with an incidence rate of 72.9%, and in none of 13 control tree shrews. The earliest time of carcinoma occurrence was 88 wk, and the latest time was 150 wk. The average time was 117 wk.

Pathological tissues' change at each stage

In the liver biopsy tissues from the control animals at each stage, liver cells were arrayed in good order, lobular structure was clear and complete, and no inflammation and hepatocyte hyperplasia appeared. In the experimental animals, the liver biopsy tissues taken at wk 30 and 60 appeared with hepatocellular degeneration and hyperplasia change. The former was primarily vacuole degenerative, the latter presented hepatocyte array in two lines, multi-lines, even pieces, with clear lobular structure. In HCC animals, liver cells were poorly and moderately differentiated presenting diffusive, nodular, or girder-like types.

Expression of apoptosis-related genes and cell apoptosis

The expression of p53, bcl-2, bax, and survivin in HCC and other liver tissues is listed in Table 1; the apoptosis indices in HCC and other liver tissues are shown in Table 2; the relationship between expression of p53, bcl-2, bax, survivin, and cell apoptosis in HCC tissues is summarized in Table 3.

DISCUSSION

Studies^[3,15,18,20] have shown that genes p53, bcl-2, bax, and survivin play an important role in HCC formation, but these studies are confined to the resected HCC, employing carcinoma-adjacent tissues as control liver tissues. This study was carried out in the tree shrew HCC model established at the Department of Pathology of the Affiliated Tumor Hospital of Guangxi Medical University. The HCC model allows repeated biopsy with no animals being killed during the induction of HCC, so that liver tissues at different stages of carcinogenesis are available. These tissues were utilized for the investigation on the dynamic expression of p53, bcl-2, bax, and survivin during the development of HCC, and for the exploration of its impact on HCC development.

Relationship between cell apoptosis and HCC

Apoptosis is a process of programmed cell death under certain physiological or pathological conditions. This process is active, highly ordered, multi-gene controlled, and serial-

enzyme catalyzed^[4]. As an important modulating mechanism maintaining the stability of organ itself, apoptosis not only plays a role in physiological courses such as embryo developing, tissue shaping, hematopoiesis modulating, growing and ageing, but also has a close relation to cancer occurrence and development^[5]. The occurrence of cancer is related to the over-proliferation of carcinoma cells and the relative destitution of apoptosis.

It was reported that the apoptosis index in HCC is apparently lower than that in tissues of normal liver, chronic hepatitis, hepato-cirrhosis, and adjacent cancer tissues^[6-9]. It has also been found that the cell proliferation augment usually accompanies increased apoptosis during HCC development^[10]. The result of this study is consistent with the latter case with a result indicating that the natural incidence rate of apoptosis in normal hepatic cells is low (1-0.3%). The averaged apoptosis indices of pre-HCC tissues and carcinoma-adjacent tissues taken at wk 30 and 60 were 0.57, 0.70%, and 0.71% respectively. Though no significant

difference was found when intra-group comparison was made, these indications were higher than those at the same stage of the control group suggesting that cell apoptosis during the development of HCC increases. The possible reason for the different reports mentioned above is that invariableness of cell number of multi-cell organisms depends upon the dynamic equilibrium between cell proliferation and apoptosis. Cancer occurrence and development are the results of destruction of the equilibrium. Therefore, besides the blockade of cell proliferation and apoptosis, cell apoptosis may increase. In the latter case, the speed of apoptosis is lower than that of malignant cell proliferation, thus resulting in a net augment of cell number. It is believed that this is related to blood supply deficiency that results in anoxemia of tumor cells and induces apoptosis increment.

Relationship between p53, bcl-2, bax, and survivin expression, HCC, and apoptosis

Fifty percent of human tumors are related to p53 mutation.

The wild-type p53 has a very short half life, and cannot be detected by immunohistochemistry method. The half life of mutant p53 is long enough to allow detection by the same method^[11]. The possible reason is that the control animals are free from cancer-inducible factors so that the liver tissues do not present any substantial change. At the late stage of our experiment, p53 was significantly expressed (0.60% and 71.4%), showing that the mutant p53 participate in occurrence of liver cancer. It is also found that p53 protein expression does not relate to apoptosis index level. The reason may be that during the development of idiopathic HCC, liver cell apoptosis increases with the augment of liver cell proliferation. In addition, in this experiment p53-positive tissues accompanied the expression of the apoptosis-promoting gene bax, which may counteract the influence of p53 on apoptosis. Therefore, in AFB1-induced HCC p53 expression does not inhibit cell apoptosis but stimulates cell proliferation, thus promoting the malignant conversion of cells.

It was reported that bax can significantly promote cell apoptosis^[12], yet bcl-2 has anti-apoptosis effects. Bax distributes in tissues and cells in human body, and its expression is high in liver and kidney tissues, but low in most carcinoma tissues. This study found that bax did not express in tissues of the control animals, but expressed apparently with an increasing tendency in tissues of the HCC-infected animals. Presently, there are still some controversies over the relationship between bcl-2 and HCC. Results from this study indicate that bcl-2 is significantly expressed in HCC tissues but not in tissues of control animals. The scores of bcl-2 expression present an increasing trend, suggesting that both bax and bcl-2 proteins take part in the formation of HCC.

The anti-apoptosis effect of bcl-2 is affected by bax. The bcl-2/bax ratio is a key factor for determining apoptosis. When bcl-2 expresses excessively, bcl-2-bax heterogeneous dimer predominates, thus inhibiting apoptosis^[13]. When bax expresses excessively, bax-bax homogeneous dimer or monomer predominates, thus promoting apoptosis. This study found that apoptosis index for bcl-2-positive HCC tissues was higher than that for bcl-2-negative tissues. In bcl-2-positive tissues, bax appeared positive. Because of the overexpression of bax, bax-bax homogeneous dimer predominates, thus speeding up apoptosis.

Survivin, a recently discovered anti-apoptosis gene, bears the following anti-apoptosis mechanisms: (1) directly inhibiting the activity of the terminal-responsive enzymes caspase-3 and caspase-7, which act during the apoptosis process, thus blocking up apoptosis^[14]; (2) combining the cell cycle modulator CDK4 to form survivin-CDK4 complex, thus causing CDK4 complex releasing p21 that further combines with caspase-3 within mitochondrion, so as to inhibit the activity of caspase-3, eventually blocking apoptosis^[15].

Although survivin inhibits various kinds of stimulant-induced apoptosis through a direct action on caspase, survivin does not significantly present any anti-apoptosis effect in HCC. This study found that survivin rendered high expression in normal liver tissues, experimental animal liver tissues, and HCC tissues, showing no significant difference between these three tissues. This is in accordance

with the previous report^[16]. In HCC, apoptosis index for survivin-positive tissues is higher than that for survivin-negative tissues, suggesting that during the formation of HCC, enhancement of survivin expression is a late incident. The possible reason is that tumor formation activates through a certain mechanism, then holds down apoptosis of carcinoma cells, and at last results in consecutive proliferation and differentiation of carcinoma cells. Therefore, the primary effect of survivin in HCC is to inhibit cell apoptosis and promote cell proliferation and malignant conversion.

Interrelationship between p53, bcl-2, bax, and survivin in HCC

Carcinoma occurrence is an extremely complicated course. Though it is known that genes have a close relation to carcinoma occurrence, but whether they relate to each other is still unknown. p53 is an important apoptosis-regulating gene and modulates apoptosis through many pathways. It was reported that p53 serves as a very important regulator bax, that promotes apoptosis through the bax pathway^[17,18]. p53 also causes downregulation of bcl-2^[19,20] and survivin^[21] at protein and mRNA level. This study showed that there was no significant interrelation between p53, bcl-2, bax, and survivin in HCC. This may result from the fact that the mutation of p53 has lost effect on expression of bax, bcl-2, and survivin. In HCC tissues of 14 bcl-2-positive cases, bax was positive for all cases; in HCC tissues of 21 bcl-2-negative cases, bax was positive for 10 cases; in HCC tissues of 25 bax-positive cases, bcl-2 was positive for 14 cases; in HCC tissues of 11 bax-negative cases, bcl-2 negative for all cases. Inter-group comparison showed that the difference was rather significant, suggesting that there is a mechanism of co-transcript or mutual activation between bcl-2 and bax.

In conclusion, apoptosis rate in normal liver cells is extremely low and increases during the development of HCC. Apoptosis-related genes p53, bcl-2, bax, and survivin are all related to HCC occurrence, and their expression renders an increasing tendency during the formation of HCC. There is no distinct relationship between bcl-2, bax, and survivin, but there is a close relationship between bcl-2 and bax. Bax can facilitate apoptosis, and the anti-apoptosis effect of bcl-2 is affected by bax. Therefore, the bax/bcl-2 ratio reflects more accurately the extent of cell apoptosis. Survivin relates negatively to the apoptosis index, and its expression inhibits apoptosis. In HCC, p53 is not noticeably related to cell apoptosis, and its high expression may relate to the proliferation of liver cells.

Abstract

AIM: To study the immuno-modulatory effect of resveratrol (RES) on allograft rejection after liver transplantation in rats.

METHODS: Male Sprague-Dawley (SD) rats were selected as donors and male Wistar rats as recipients for a rejection model. The recipients were divided into four groups after orthotopic liver transplantation (OLTx). In the RES A, B, and C groups, RES was given intra-peritoneally once a day (25, 50, and 100 mg/kg, respectively) after OLTx, whereas in the control group, vehicle buffer was given intra-peritoneally once a day. The survival time, serum chemistry, production of cytokines, activation of transcription factor NF- κ B, and histopathologic findings were then compared among these groups.

RESULTS: The mean survival time after OLTx in the RES C group was significantly longer than that in the control group (16.7 ± 1.2 d vs 9.3 ± 0.6 d, $P < 0.01$). On the 7th post-transplant day the serum albumin level significantly improved in the RES C group, the serum total bile acid and alanine aminotransferase (ALT) levels were significantly lower in the RES C group, the serum IL-2 and INF- γ levels were significantly lower in the RES C group, and the activation of transcription factor NF- κ B in peripheral blood T lymphocytes was significantly suppressed in the RES A, B, and C groups in comparison to those in the control group. On the 7th post-transplant day, a histological examination revealed apparent difference in the severity of rejection between the RES C group and control group.

CONCLUSION: RES has an immuno-suppressive property as well as protective effect on hepatocytes under allograft rejection. It might serve as a novel agent for reducing the severity of hepatic allograft rejection in rats.

Key words: Resveratrol; Liver; Transplantation; Rat

INTRODUCTION

Since the introduction of cyclosporine and tacrolimus for the control of post-operative rejection, liver transplantation has become an established surgical technique and is now performed on patients with various terminal liver diseases. Most instances of mortality after liver transplantation are still attributed to infection, and such infection is apt to occur as a result of over-immunosuppression to severe rejection^[1-3]. Rejection is still a leading cause of morbidity and mortality after liver transplantation. To improve the survival after liver transplantation, novel strategies are still needed for the treatment of the rejection.

Resveratrol (3,5,4'-trihydroxystilbene, RES) is a polyphenol present in a limited number of plants^[4], mainly in grapes with levels up to tens of grams per kg^[5], where it is synthesized in response to stress conditions such as fungal infections and trauma^[4]. Many studies have demonstrated that this molecule exhibits a wide range of biological and pharmacological activities both *in vitro* and *in vivo*^[6]. A series of studies showed that resveratrol has anti-oxidant properties^[7], anti-inflammatory properties^[8,9], and cancer-chemopreventive activity^[10,11]. Many of the biological activities of resveratrol, like the inhibition of cyclooxygenase^[8], induction of CD95 signaling-dependent apoptosis^[12], effects on the cell division cycle^[13] and modulation of NF- κ B activation^[14], indicate a possible effect on immune response and many *in vitro* experiments have proven that resveratrol has immuno-modulatory activity^[15-17].

To our knowledge, there has not been a report on the *in vivo* immuno-modulatory effect of RES on hepatic allograft after transplantation. We therefore investigated whether RES might have any beneficial effect on hepatic allograft after transplantation.

MATERIALS AND METHODS

Materials

Male Sprague-Dawley (SD) rats 9-10 wk old weighing 190-210 g as donors and male Wistar rats 7-8 wk old weighing 190-210 g as recipients were purchased from the Animal Center of Xi'an Jiaotong University (Xi'an, China) and Animal Center of Shanxi Medical College (Shanxi, China), respectively. All rats were allowed free access

to water and standard laboratory chow. Before operation the rats were fasted for 12 h and only allowed free access to water. All animal protocols were approved by the Xi'an Jiaotong University Institutional Animal Care and Use Committee.

Resveratrol, dimethyl sulfoxide (DMSO), and IL-2 and INF- γ ELISA kits were purchased from Sigma Chemical Co. RPMI-1640, HEPES, EDTA, EGTA, DTT, PMSF, and NP-40 were from Gibco BRL. NF- κ B consensus oligonucleotide and single base pair mutant were from Promega. Fetal bovine serum was from SiJiQing Co., Hangzhou, China. 32 P-ATP was from Beijing Isotope Co., China.

Orthotopic liver transplantation

Orthotopic rat liver transplantation (OLTx) was performed by the cuff technique as described by Kamada and Calne^[18], with some slight modifications. With the rat under ketamine anesthesia (75 mg/kg), the liver was gently skeletonized and flushed with chilled lactated Ringer's solution through the abdominal aorta. Special care was taken for minimal manipulation of the graft and portal vein and bile duct for reconstruction. The liver was harvested and stored at 4 °C in lactated Ringer's solution until transplantation. OLTx was performed without hepatic artery reconstruction. The suprahepatic vena cava was anastomosed with 7-0 Prolene continuous suture (Ethicon, Somerville, NJ) and portal vein and inferior vena cava reconstruction was performed by the cuff technique. The bile duct connection was made with an intra-luminal epidural catheter stent. In rat liver transplantation, the cold ischemic time and anhepatic phase were 40-50 min and 14-16 min, respectively, and no significant difference was recognized among these groups.

RES administration and graft survival

The RES was dissolved and sterilized in DMSO and then diluted in RPMI-1640 to 5, 10, and 20 mg/mL. The recipients were randomly divided into four groups after OLTx. In the RES A, B, and C groups, 1 mL of these preparations was administered by intra-peritoneal route once a day after OLTx (25, 50, and 100 mg/kg, respectively) and in the control group, vehicle buffer was given by intraperitoneal route once a day after OLTx.

Six rats were left in each group until they died. The rats used to evaluate graft survival were given RES or vehicle buffer until they died.

Liver function test and ELISA

Six animals in each group were killed on the 7th posttransplant day for blood collection. A 6-mL blood sample was obtained from the vena cava. Two milliliters blood was centrifuged immediately at 3 000 r/min at 4 °C for 10 min and stored at -80 °C until analysis. Albumin, total bile acid, and alanine aminotransferase (ALT) were assayed by standard enzymatic methods, while serum IL-2 and INF- γ levels were assayed by ELISA.

EMSA

The remaining 4 mL of blood was used for the detection of NF- κ B activation in peripheral blood T lymphocytes. First, the peripheral blood mononuclear cells were separated

by standard Ficoll-Hypaque gradient centrifugation, and then incubated in RPMI-1640 culture medium containing 10% calf serum. The cell suspension was separated from the adherent cells the next day and T-lymphocyte subpopulation was obtained by magnetic separation column according to the instructions of the manufacturer (Miltenyi Biotec, Germany). The purity of the cell population was confirmed by FACScan analysis and cell viability was determined by trypan blue dye exclusion.

Then T-lymphocyte nuclear extracts were prepared by the modified procedure of Dignam *et al.*^[19]. Following treatment, cells were washed thrice with PBS, resuspended, and incubated on ice for 15 min in hypotonic buffer A (10 mmol/L HEPES, pH 7.9, 10 mmol/L KCl, 0.1 mmol/L EDTA, 0.1 mmol/L EGTA, 1 mmol/L DTT, 0.5 mmol/L PMSF, and 0.6% NP-40). Cells were vortexed gently for lysis, and nuclei were separated from cytosolic components by centrifugation at 12 000 *g* for 1 min at 25 °C. Nuclei were resuspended in buffer C (20 mmol/L HEPES, pH 7.9, 25% glycerol, 0.4 mol/L NaCl, 1 mmol/L EDTA, 1 mmol/L EGTA, 1 mmol/L DTT, 0.5 mmol/L PMSF) and shaken for 30 min at 4 °C. Nuclear extracts were obtained by centrifugation at 12 000 *g* for 10 min at 25 °C. Protein concentration was measured by the Bradford assay (Bio-Rad).

For binding reactions, nuclear extracts (10 μ g of protein) were incubated in a 25- μ L total reaction volume containing 20 μ mol/L HEPES, pH 7.9, 60 mmol/L NaCl, 0.1 mmol/L EDTA, 1 mmol/L DDT, 8% glycerol, and 2.55 μ g/mL of poly (dl-dC, Pharmacia). Double-stranded radiolabeled NF- κ B oligonucleotide probe (5'-CGCTT-GATGAGTCAGC-CGGAA-3') was added to the mixture after pre-incubation for 15 min at 4 °C, and the reaction mixture was then incubated for 20 min at room temperature. Samples were loaded on 6% polyacrylamide gels in low-ionic-strength 0.25 \times TBE buffer (22.3 mmol/L Tris, 22.2 mmol/L borate, 0.5 mmol/L EDTA) and run at 150 V/cm with cooling. The gels were dried and analyzed by autoradiography.

Histopathologic examination

Liver specimens were collected from five animals in each group on the 7th post-transplant day and fixed in 10% neutral buffered formalin. Then, the specimens were embedded in paraffin and 3 μ m thick sections were cut and stained with hematoxylin and eosin (H&E). A single blinded pathologist examined the liver graft specimens.

Statistical analysis

All data were expressed as mean \pm SD, and Student's *t*-test was used to evaluate the significance of the difference between experimental groups and control group. The survival time were compared according to the Kaplan-Meier and log rank analysis. *P*<0.05 was considered statistically significant.

RESULTS

Graft survival

The mean survival time was 8.3 \pm 0.6, 11.7 \pm 1.5, and 16.7 \pm 1.2 d in the RES A, B, and C groups, respectively,

and 9.3 ± 0.6 d in the control group. The difference between the RES C group and control group was statistically significant ($P < 0.01$). The survival rates in the four groups are shown in Figure 1.

Figure 1 Survival rate of rats after liver transplantation.

Liver function tests

Table 1 shows the serum chemistry data that reflected the liver functions after OLTx. On the 7th posttransplant day the albumin level was 2.0 ± 0.1 , 2.2 ± 0.1 , and 2.7 ± 0.2 g/dL in the RES A, B, and C groups, respectively, whereas it was 2.1 ± 0.3 g/dL in the control group. The difference between the RES C group and control group was statistically significant ($P < 0.05$). The total bile acid was 314.7 ± 97.5 , 270.4 ± 93.7 , and 155.4 ± 34.2 μ mol/L in the RES A, B, and C groups respectively, whereas it was 353.9 ± 84.4 μ mol/L in the control group. The difference between the RES C group and the control group was significant ($P < 0.05$). ALT was 1112.1 ± 159.4 , 806.5 ± 135.2 , and 482.7 ± 101.2 U/L in the RES A, B, and C groups respectively, whereas it was 1137.5 ± 235.4 U/L in the control group. The difference between the RES C group and the control group was significant ($P < 0.05$).

Table 1 Effect of RES on liver function in rats after OLTx (mean \pm SD)

Group	Dose (mg/kg)	n	Albumin level (g/dL)	Total bile acid (μ mol/L)	ALT (U/L)
Control	0.0	6	2.1 ± 0.3	353.9 ± 84.4	1137.5 ± 235.4
RES A	25.0	6	2.0 ± 0.1	314.7 ± 97.5	1112.1 ± 159.4
RES B	50.0	6	2.2 ± 0.1	270.4 ± 93.7	806.5 ± 135.2
RES C	100.0	6	2.7 ± 0.2^a	155.4 ± 34.2^a	482.7 ± 101.2^a

^a $P < 0.05$ vs control.

ELISA

The IL-2 level was 305.1 ± 82.8 , 241.7 ± 38.1 , and 195.7 ± 42.4 ng/L in the RES A, B, and C groups respectively, whereas it was 294.4 ± 38.0 ng/L in the control group. The difference between the RES C group and the control group was significant ($P < 0.05$). The INF- γ level was 96.5 ± 6.5 , 82.8 ± 14.9 , and 66.6 ± 15.7 ng/L in the RES A, B, and C groups respectively, whereas it was 101.3 ± 14.1 ng/L in the control group. The difference between the RES C group and the control group was

significant ($P < 0.05$). The serum cytokine levels on the 7th post-transplant day in the four groups are shown in Table 2.

Table 2 Effect of RES on IL-2 and INF- γ production in rats after OLTx (mean \pm SD)

Group	Dose (mg/kg)	n	IL-2 (ng/L)	INF- γ (ng/L)
Control	0.0	6	294.4 ± 38.0	101.3 ± 14.1
RES A	25.0	6	305.1 ± 82.8	96.5 ± 6.5
RES B	50.0	6	241.7 ± 38.1	82.8 ± 14.9
RES C	100.0	6	195.7 ± 42.4^a	66.6 ± 15.7^a

^a $P < 0.05$ vs control.

Activation of NF- κ B

The activation of NF- κ B DNA binding activity in peripheral blood T lymphocytes was 57.00 ± 3.00 , 52.33 ± 2.08 , and 41.67 ± 1.53 U in the RES A, B, and C groups respectively, whereas it was 100.33 ± 7.57 U in the control group, being significantly lower in the RES A, B, and C groups than in the control group ($P < 0.05$). Figure 2 demonstrates the measurable NF- κ B DNA binding activity in the four groups on the 7th post-transplant day.

Figure 2 Levels of NF- κ B in peripheral T lymphocytes analyzed by EMSA (A) AND quantitation of NF- κ B activity by PhosphorImager (B).

Histopathologic examination

All the four groups showed the typical signs of severe graft rejection with intense portal infiltrate. There was an apparent difference in the severity of rejection between the RES C group (Banff score 4.3 ± 1.5) and control group (Banff score 7.3 ± 0.6) on the basis of Banff schema by a blinded pathologist ($P < 0.05$). Figure 3 shows the H&E staining of histologic sections in the RES C group and control group on the 7th posttransplant day.

DISCUSSION

The immuno-modulatory effect of resveratrol has been reported

Figure 3 Typical signs of severe graft rejection in control group (A) and RES C group (B).

with use of mouse splenic lymphocytes, lymphokine activated killer (LAK) cells, mouse macrophage-like cell line RAW 264.7, and human peripheral blood T lymphocytes^[15,20-23]. Gao *et al.*^[15], reported that RES inhibits splenic lymphocyte proliferation, induction of cytotoxic T lymphocytes, and cytokine production, at least in part through the inhibition of NF- κ B activation. Yu *et al.*^[20], reported that RES can suppress notably the proliferation and transformation of human lymphocytes and the combination of resveratrol at a given concentration with cyclosporine-A can enhance immune suppression. Although most of these studies focused on the immunosuppressive effects of RES, a few experiments showed that low dose RES could enhance cell-mediated immune response. Feng *et al.*^[23], reported that RES (4 mg/kg, ig) promotes DTH response of mouse. However, the detailed mechanisms of the bi-phasic modulatory effects of RES remain to be studied. Our study revealed that RES could downregulate NF- κ B activation of peripheral T lymphocytes and IL-2 and INF- γ serum levels and decrease portal infiltrate of T lymphocytes in rats with severe rejection. RES has also been shown to promote albumin synthesis and prevent elevation of total bile acid and ALT and prolong the survival time of rats after liver transplantation.

As rejection occurs in the graft, hepatocytes are destroyed by infiltrating T lymphocytes. Hepatic function deteriorates as the number of hepatocytes decreases, and rejection eventually kills the recipient unless immuno-suppressants are given. In this hepatic allograft rejection model, RES decreased the number of accumulated mononuclear cells around the Glissonian triad in the H&E stained section on the 7th posttransplant day. RES may influence lymphocytes in the

hepatic allograft because of its influence on NF- κ B of T lymphocytes^[24].

Transcription factor NF- κ B, and other members of the Rel homology family of transcription factors play a pivotal role in the transcription of genes involved in immune and inflammatory responses^[25], and in cell proliferation and transformation^[26,27]. It is possible that suppression of lymphocyte infiltration and cytokine production by resveratrol may result from suppression of NF- κ B activation. In resting cells, NF- κ B remains sequestered in the cytoplasm in a functionally inactive form, non-covalently bound to an inhibitory protein, I κ B. Upon stimulation of cells with mitogens, antigens, or cytokines, I κ B dissociates from the NF- κ B complex, allowing NF- κ B to translocate to the nucleus where it binds to κ B motifs in the promoter region of the response genes. In our study, peripheral T lymphocytes expressed high levels of activated NF- κ B. However, after administration of RES, the NF- κ B activation due to the stimulation of heterogeneous antigens was blocked partly. These results are consistent with those of other investigators^[14,28].

It has been generally accepted that the immune response leading to graft rejection is accompanied with an increase of cytokine production by the primed T cells. Cytokines are essential for the differentiation, proliferation and amplification of the T cells^[29]. The most important cytokine is IL-2, which is essential for activated T cell proliferation^[30,31], and INF- γ is mainly secreted by activated T cells^[32] and induces MHC class I antigen expression in several kinds of cells such as lymphocytes^[33], myocytes^[34], endothelial cells^[35] and fibroblasts^[36]. Some studies have shown that the gene expression of IL-2 and INF- γ by intra-graft is specific to acute rejection, which precedes histopathologic manifestations in liver transplantation^[37,38]. We also investigated the effect of resveratrol on the production of INF- γ and IL-2, and found that RES could suppress the serum IL-2 and INF- γ levels in rats after liver transplantation when it was administered at a dosage of 100 mg/kg body weight. The results are consistent with other reports^[15,22].

In conclusion, resveratrol downregulates the serum IL-2 and INF- γ levels, decreases the lymphocyte infiltration in allograft liver, prolongs the mean survival time after OLTx. Suppression of the activation of transcription factor NF- κ B in peripheral T lymphocytes appears to be a part of the mechanism by which resveratrol inhibits the *in vivo* development of immunological responses.

Abstract

AIM: To investigate the expression of interferon inducible protein-10 (IP-10) in pancreas of mice and to discuss its possible role in the pathogenesis of type 1 diabetes.

METHODS: Non-obese diabetic (NOD) mice were used as experiment group and BALB/c mice as non-diabetic prone model. Immunohistochemistry method was used to evaluate the expression of IP-10 in the pancreas of NOD mice and BALB/c mice. Immunoelectron microscope was used to show the location of IP-10 in pancreatic islet β cells.

RESULTS: Pancreatic islets were positively stained in all the NOD mice. Insulinitis could be found in mice at the age of 4 wk. The weakly positive results were found in control group with no insulinitis. Immunoelectron microscopy further demonstrated that IP-10 was produced by pancreatic β cells and stored in cytoplasm of the cells.

CONCLUSION: IP-10 can be largely produced in pancreatic islets of NOD mice at the age of 2 wk when there is no significant insulinitis, and may play an important part in the pathogenesis of type 1 diabetes by attracting immune cells to infiltrate the pancreatic islets.

INTRODUCTION

Type 1 diabetes has been recognized as an organ specific autoimmune disease due to the immune destruction of pancreatic islet β cells in genetically susceptible individuals^[1]. In both human and rodent models of Type 1 diabetes, the disease has a distinct stage characterized by infiltration of immune cells in the pancreas (insulinitis). The major populations of infiltrating cells are macrophages and lymphocytes. Therefore, immune cell infiltration in pancreatic islets may be a crucial step in the pathogenesis of type 1 diabetes^[2]. Experiments have shown that interferon induced protein-10 (IP-10), an important member of CXC chemokine subfamily, has chemoattractant effects on monocytes and activated lymphocytes^[3]. Thus, we hypothesize that IP-10 may recruit immune cells into the pancreas by binding to the chemokine receptor, CXCR4 expressed on the target cells, thus leading to type 1 diabetes. In this study, we evaluated the expression of IP-10 in the pancreas of animal model of type 1 diabetes and discussed its possible role in the pathogenesis of type 1 diabetes.

MATERIALS AND METHODS

Experimental animals and samples

Experimental NOD mice were obtained from Shanghai Laboratory Animal Center, Chinese Academy of Sciences. Pancreatic islet infiltration of immune cells appeared and insulinitis developed in the mice at the age of 4 wk. Insulinitis became most serious at the age of 9-10 wk. The remaining pancreatic β cells decreased to 10% of normal levels and diabetes developed. The incidence of diabetes in female NOD mice was higher than that in males. BALB/c mice were used as non-diabetes and non-autoimmune-prone control. Blood glucose in all the mice was measured before death. If the blood glucose concentrations exceeded 300 mg/L, diabetes could be considered.

The mice were killed by decollation. Pancreases were fixed in 40 g/L formaldehyde and embedded in paraffin. Paraffin-embedded tissues were sectioned and stained with hematoxylin-eosin and analyzed by light microscopy.

Expression of IP-10

Dewaxed sections were stained using streptavidin-biotin-peroxidase complex (SABC) method (Wuhan Boster Biological Technology Co., Ltd). Primary antibody was goat -anti-mouse polyclonal antibody (Santa Cruz Biotechnology, Inc.). The color of the complex was developed using 3,3'-diaminobenzidine tetrahydrochloride (DAB) kit (AR1022). The sections were counterstained with hematoxylin, dehydrated and mounted, examined microscopically.

Immunoelectron microscopy

The samples were fixed with 1% osmic acid, after the color reaction using DAB. Sections were dehydrated in graded ethanol solutions and embedded in Epon 872. Ultra-thin (70 nm) sections were made and stained with uranyl acetate, and then examined under JEM-1200EX (JEOL) electron microscope.

RESULTS

Expression of IP-10 in NOD mice

Pancreatic islets were positively stained in all NOD mice. Insulinitis could be found at the age of 4 wk (Figures 1A-D)

Expression of IP-10 in BALB/C mice

Weakly positive results were found in the pancreatic islets of BALB/c mice, which were stained light brown (Figure 2). No insulinitis could be found.

Immunoelectron microscopy in NOD mice

Immunoelectron microscopy demonstrated that IP-10 was

produced by pancreatic β cells and stored in cytoplasm of the cells (Figure 3).

DISCUSSION

Type 1 diabetes is a chronic disease, severely affecting the health of children. Its incidence has been increasing continuously from 1980s. In both human and rodent models of Type 1 diabetes, the disease has a distinct stage characterized by immune cell infiltration in pancreas (insulitis). The major populations of infiltrating cells are macrophages and lymphocytes. Therefore, the infiltration of macrophages and lymphocytes may be a crucial step in the auto-immune response of type 1 diabetes. IP-10 is a member of CXC chemokine subfamily and has chemoattractant effects on monocytes and activated lymphocytes. Thus, we suppose that it may play an important part in the immune cell infiltration of pancreatic islets.

We demonstrated in this study that the expression of IP-10 was positive in the pancreas of both NOD mice and

Figure 1 Expression of IP-10 in pancreatic islets of NOD mice at the age of 2

wk (A), 4 wk (B), 8 wk (C), and 14 wk (D).

Figure 2 Expression of IP-10 in pancreatic islets of BALB/C mice at the age of 4 wk.

Figure 3 Various shapes of IP-10 crystal in pancreatic islet β cells.

BALB/c mice, which agrees well with the findings of Arimilli *et al.*^[4], suggesting that IP-10 is constitutively produced by the pancreatic islets in mice. But the production of IP-10 is small because weak expression of IP-10 has been shown in BALB/c mice, and IP-10 produced has no chemoattractant effect as no infiltration of immune cells could be found in the control group. It has long been known that chemokines have many functions in addition to chemo-attractant effect. IP-10 is involved in delayed-type allergy and the suppression of angiogenesis. Therefore, IP-10 has other biological functions in normal pancreatic tissues other than chemoattractant effect. Few studies on expressions of IP-10 in pancreas are available. The acute functions of the constitutive expressions of IP-10 in pancreatic tissues need further study. But, the pancreatic islets of diabetic mice produce high level of IP-10 and accompanied insulinitis, which supports our hypothesis that abundant IP-10 can be produced in a pathological environment and attract immune cells into pancreatic tissues. Our study also proved that IP-10 could be found in the pancreatic islets of NOD mice at the age of 2 wk when there was no significant insulinitis, suggesting that IP-10 is produced at the onset of diabetes. Its concentration may not be high enough to cause insulinitis at first. As IP-10 accumulates, more immune cells can be recruited into the pancreatic islets and finally result in insulinitis.

Viral infections and inflammatory cytokines including IL-1 β and interferon- γ are important factors triggering type 1 diabetes. Double stranded RNA (dsRNA) produced by virus cooperated with IL-1 β and Interferon- γ or IL-1 β could induce high levels of IP-10 in human and NOD mice pancreatic β cells *in vitro*^[5,6]. Our study also showed that IP-10 existed in the pancreatic β cells. These results indicate that pancreatic β cells can produce IP-10, and that virus and inflammatory cytokines can initiate expression of IP-10 *in vivo*. Pancreatic β cells are possibly one of the main sources of IP-10. It has been reported that pancreatic islet specific Th1 cells can produce IP-10 and may be another source^[7].

We can speculate about the possible mechanism of viral infections causing diabetes based on the present studies. Viruses induce the expression of IP-10 in pancreatic β cells, and IP-10 is secreted into the pancreatic islets. Then, peripheral

immune cells migrate into the pancreatic islets along with the IP-10 concentration gradient and result in insulinitis.

Since few studies on the role of IP-10 in type 1 diabetes are available, our data are necessary to be confirmed by more studies. There is no study on the expression of IP-10 in the pancreas of patients with type 1 diabetes. Although the serum IP-10 levels in newly diagnosed patients with type 1 diabetes are much higher than those in healthy subjects^[8], chemokines tend to form high concentration grade in local secretion point that attract target cells. The serum chemokine level cannot reflect the true conditions of expressions of chemokine in human pancreas.

In conclusion, IP-10 may play an important part in the pathogenesis of type 1 diabetes by attracting immune cells to infiltrate the pancreatic islets.

Abstract

AIM: To investigate the influence of HLA-DRB1 alleles and HBV genotypes on interferon- α therapy for chronic hepatitis B.

METHODS: HLA-DRB1*03, *07, *09, *12, *15 alleles were determined using polymerase chain reaction/sequence specific primer (PCR/SSP) technique in 126 patients with chronic hepatitis B and 76 normal control subjects in Shandong Province, and HBV genotypes were determined by nested-PCR analysis using type-specific primers in 126 patients.

RESULTS: The positivity of HLA-DRB1*07 allele in chronic hepatitis B group was significantly higher than that in normal control group ($\chi^2 = 6.33$, $P < 0.025$, $RR = 2.37$). Among the 126 patients, genotype B was found in 38 (30.2%), genotype C in 69 (54.8%), and mixed genotype (B+C) in 19 (15.0%), genotypes D-F were not found. Among the 46 DRB1*07(+) patients, 7 were responders and 39 were non-responders among them ($\chi^2 = 6.71$, $P < 0.05$). The positivity of HLA-DRB1*07 and prevalence of HBV genotype C were significantly higher in non-responders than in responders.

CONCLUSION: High positivities of HLA-DRB1 *07 allele and HBV genotype C are closely associated with the lower response to interferon- α therapy for chronic hepatitis B.

INTRODUCTION

Hepatitis B virus (HBV) is a well-known agent of acute and

chronic hepatitis. Seventy-five percent of the estimated 400 million patients with chronic HBV infection in the world are Asians^[1]. Transient infections may cause fatal, fulminant hepatitis and chronic infections may lead to liver cirrhosis and even hepatocellular carcinoma.

Interferon- α (IFN- α) has anti-viral, immuno-modulatory, anti-proliferative, and gene induction properties. Treatment with interferon- α results in the clearance of HBeAg, and is associated with improved clinical outcomes^[2]. It is well-known that several factors influence the response, including viral factors (particularly serum HBV-DNA loads), host factors, which may be genetic (sex, cytokine polymorphism), other factors such as age, serum aminotransferase activities, grade of inflammatory activity in liver, presence of cirrhosis, and race. The aim of this study was to identify the influence of HLA-DRB1 alleles and HBV genotypes on the response to interferon- α therapy.

MATERIALS AND METHODS

Subjects

A total of 126 patients (94 males, 32 females, mean age: 33.2 ± 10.6 years) with chronic hepatitis B and 76 healthy controls (54 males, 22 females, mean age: 33.8 ± 9.8 years) were enrolled in this study. These patients received treatment in the Department of Infectious Diseases, Qilu Hospital of Shandong University, China. The diagnoses of these patients were made according to the criteria established in the National Viral Hepatitis Conference of China (2000). All the patients and controls were Chinese Han people from Shandong Province. HCV infection, auto-immune hepatitis and metabolic disorders were excluded by appropriate clinical and laboratory evaluations. They had no histories of malignancy or depression, immunodeficiency virus infection, liver cirrhosis, decompensated liver diseases, use of IFN and thyroid abnormality, chemotherapy, or other agents that could influence treatment outcomes. HLA-DRB1*03, *07, *09, *12, *15 alleles were determined in all patients and healthy controls. HBV genotypes were detected only in patients.

The 126 patients received IFN- α treatment subcutaneously at a dose of 3 MU thrice weekly for 24 wk. The response to IFN- α therapy was defined as loss of HBeAg, sero-conversion to anti-HBe, normalization of serum ALT levels and HBV-DNA (-). The patients with a response were described as 'responders' and those without response as 'non-responders' in this report.

Serological tests

Sera were tested for ALT, HBeAg, anti-HBeAg, and HBV-

DNA. The remaining sera were stored at -70 °C.

Genotyping of HLA alleles

Genomic DNA was extracted from frozen blood clots by proteinase K digestion followed by phenol/chloroform extraction and ethanol precipitation. DNA was typed for HLA class II alleles DRB1*03, *07, *09, *12, *15 by polymerase chain reaction (PCR), using published sequence-specific primers^[2]. A total amount of 50 µL PCR reaction solution contained 1 µL of each sequence specific primer (10 µmol/L), 2 µL of genomic DNA (60-80 ng/µL), 5 µL of 10× buffer, 5 µL of MgCl₂ (15 mmol/L), 5 µL of dNTP (2 mmol/L), 0.4 µL of Taq polymerase (5 U/µL) and 30.6 µL of deionized H₂O. The PCR cycling parameters of HLA-DRB1 alleles were as follows: pre-denaturation at 94 °C for 5 min, denaturation at 94 °C for 30 s, annealing at 55 °C for 1 min, extension at 72 °C for 50 s, repetition for 30 cycles and final extension at 72 °C for 5 min.

Genotyping of HBV

Nucleic acid of HBV was extracted from 200 µL serum samples by heating at 100 °C for 10 min and the HBV genome was amplified by nested PCR using universal primers for the outer primers, followed by two different mixtures containing type-specific inner primers^[3]. The first round of PCR was carried out in a tube containing 40 µL of a reaction buffer containing 4 µL of HBV-DNA, 4 µL of 10× buffer, 4 µL of MgCl₂ (15 mmol/L), 4 µL of dNTPs (10 mmol/L), 0.2 µL of Taq polymerase (5 U/µL), 4 µL of each outer primer (12.5 µg/mL), and 15.8 µL of deionized H₂O. The thermocycler was programmed to incubate the samples for 2 min at 94 °C, followed by 35 cycles, each at 94 °C for 15 s, at 58 °C for 30 s, at 72 °C for 30 s, and final extension at 72 °C for 7 min. Two second rounds of PCR were performed for each sample, with the common universal anti-sense primers for mixA and mixB. Two microliters of the first PCR product was added to two tubes containing the second sets of each of the inner primer pairs, each of the deoxynucleotides, Taq polymerase and PCR buffer, as in the first reaction, then amplified with the following parameters: preheating at 94 °C for 2 min, then followed by 35 cycles, each at 94 °C for 15 s, at 60 °C for 30 s, at 72 °C for 30 s, and final extension at 72 °C for 7 min.

HLA-DRB1*03, *07, *09, *12, *15 alleles and genotypes of HBV for each sample were determined by identifying the genotype-specific DNA bands. All the primers were synthesized by Shanghai Branch, Canadian Sangon Company.

Taq DNA polyanzyme and dNTPs were also purchased from Shanghai Branch, Canadian Sangon Company. pUC19 DNA/*Msp*I (*Hpa*II) marker 23 was purchased from MBI Fermentas. Amplifications of all samples were performed in a GeneAmp PCR system (GeneAmp PCR system 9600; Perkin Elmer).

Detection of PCR products

PCR products were electrophoresed on 2% agarose gel, stained with ethidium bromide, and evaluated under ultraviolet light. The sizes of PCR products were estimated according to the pUC19 DNA/*Msp*I (*Hpa*II) marker 23.

Statistical analysis

The positivity of HLA-DRB1 alleles was calculated by direct count. The positive number (PN) of the study group was compared with that of the control group using χ^2 -test. Relative risk frequencies (RR) were calculated according to Wolf formula. $P < 0.05$ was considered statistically significant.

RESULTS

HLA-DRB1 alleles in patients with chronic hepatitis B and healthy controls

The distribution of HLA-DRB1*03, *07, *09, *12, *15 alleles in patients with chronic hepatitis B and healthy controls is shown in Table 1. The positivity of HLA-DRB1*07 allele in patients with chronic hepatitis B group was markedly higher than that in normal controls, there was a significant difference between them. The positivity of HLA-DRB1*03, *09, *12, *15 alleles in patients with chronic hepatitis B was not different from that in normal controls. The electrophoresis of HLA-DRB1*03, *07, *09, *12, *15 alleles is shown in Figure 1.

Figure 1 Electrophoresis of HLA-DRB1*03, *07, *09, *12, *15 alleles. M: pUC19 DNA/*Msp*I (*Hpa*II) marker 23; 1: DRB1*0701/0702, 232 bp; 2: DRB1*0901, 236 bp; 3: DRB1*1201/1202, 248 bp; 4: DRB1*1501/1502, 197 bp; 5: DRB1*0301/0302, 151 bp.

Prevalence of HBV genotypes in patients with chronic hepatitis B

The prevalence of different HBV genotypes in patients with chronic hepatitis B is shown in Table 2. Genotype B was found in 38 patients (30.2%), genotype C in 69 (54.8%), mixed genotype (B+C) in 19 (15.0%), genotypes D- F were not found. Genotypes C and B were the major genotypes in this area. The electrophoresis of HBV genotypes is shown in Figure 2.

Table 2 Prevalence of different HBV genotypes in patients with chronic hepatitis B

Genotype	Number	%
B	38	30.2
C	69	54.8
B+C	19	15.0
D	0	0
E	0	0
F	0	0

**Figure 2** Electrophoresis of HBV genotypes. M: pUC19 DNA/*MspI* (*HpaII*) marker 23; lane 1: genotype B (281 bp); lane 2: genotype C (122 bp); lane 3: genotype B+C; lane 4: negative control.**No response of HLA-DRB1*07 to IFN- α therapy**

Among the 46 DRB1*07(+) patients, 7 were responders and 39 were non-responders. Compared with the DRB1*07 (-) patients, the positivity of DRB1*07 in responder group was significantly lower than that in non-responder group ($\chi^2 = 4.51$, $P < 0.05$), indicating that DRB1*07 had no response to IFN- α therapy (Table 3).

Table 3 Correlation between DRB1*07 and IFN- α therapy, n (%)

	Responder ($n = 33$)	Non-responder ($n = 93$)	Total (126)	χ^2	P
HLA-DRB1*07(+)	7 (15.2)	39 (84.8)	46	4.51	<0.05
HLA-DRB1*07(-)	26 (32.5)	54 (67.5)	80		

Response of HBV genotypes C and B to interferon- α therapy

Patients with HBV genotype C had a significantly lower response to IFN- α , only 13% *vs* 50% among patients with genotype B and 26.3% with genotype B+C ($\chi^2 = 17.3$, $P < 0.005$, Table 4).

Response to interferon- α therapy in patients with HLA-DRB1*07 (+) and genotype C (+)

The patients with both HLA-DRB1*07(+) and genotype C (+) were compared with those with HLA-DRB1*07(+) or

genotype C(+), significant difference was found among them ($\chi^2 = 6.71$, $P < 0.05$, Table 5).

Table 4 Response to interferon- α therapy in patients with different genotypes, n (%)

	Responder	Non-responder	Total	χ^2	P
Genotype				17.3	<0.005

-	14 (32.6)	29 (67.4)	43		

DISCUSSION

Currently, two therapeutic agents, interferon and lamivudine, are used in treatment of chronic hepatitis B in most countries, and the only agent known to have a lasting beneficial effect on chronic hepatitis B is interferon- α . It was reported that IFN treatment can result in sustained clearance of HBeAg in approximately 25-40% of patients, and a loss of HBsAg in 10% of Western patients^[4]. The response of chronic hepatitis B to IFN- α is generally determined by a combination of virological factors, host immunological factors and genetic factors^[5-10].

The present study aimed to investigate the role of HBV genotypes and HLA-DRB1 alleles in response to IFN- α in Chinese Han hepatitis B patients. Until now, HBV can be classified into eight genotypes (A-H)^[11-14]. HBV genotypes have a characteristic geographic distribution^[13-18]. Genotype A is more common in North America and northwestern Europe, genotypes B and C are the two most common genotypes prevailing in Asia. Genotype D is predominant in the Mediterranean area, the Middle East, and in India. The distribution of genotype H is less studied. Studies suggested that genotype A is associated with a higher rate of IFN- α -induced HBeAg sero-conversion than genotype D^[19], and genotype B is associated with a higher rate of IFN- α -induced HBeAg clearance than genotype C^[20,21]. Our study showed that HBV genotype C was associated with a lower rate of anti-viral response to IFN- α treatment in Chinese Han patients with HBeAg-positive chronic hepatitis B than genotype B and genotype B+C (50% *vs* 13% *vs* 26.3%, $P < 0.005$). Further studies are needed to determine if HBV genotypes also play a role in response to IFN- α treatment of chronic hepatitis B patients from other geographic regions where other HBV genotypes prevail.

Great inconsistencies exist in studies about the association between HLA-DRB1 alleles and chronic hepatitis B. Jiang *et al.*, suggested that the allele frequencies of HLA-DRB1*0301

in chronic hepatitis B group (17.31%) are markedly higher than those in normal control group (5.67%), and that HLA-DRB1*0301 is closely associated with susceptibility to chronic hepatitis B. They also found that the allele frequencies of HLA-DRB1*1101/1104 in chronic hepatitis B group were markedly lower than those in acute hepatitis B group, and that HLA-DRB1*1101/1104 is closely associated with resistance to chronic hepatitis B. Shen *et al.*^[9] suggested that susceptibility to chronic hepatitis B is strongly associated with HLA-DRB1*10 allele in northern Chinese patients. Cotrina *et al.*^[22] reported that HLA-DRB1*1301 and -DRB1*1302 alleles are associated with the clearance of HBV infection and protect people against chronic hepatitis B. Diepolder *et al.*^[10] found that a strong virus-specific CD4⁺ and CD8⁺ T lymphocyte response to HBV is associated with viral clearance, patients with acute hepatitis B carrying HLA-DR13 have a more vigorous CD4⁺ T cell response to HBV core than patients not carrying HLA-DR13, suggesting that HLA-DR13 is associated with a self-limited course of HBV infection. In the present study, we did not examine HLA-DRB1*11 and HLA-DRB1*13, but there was no significant difference in HLA-DRB1*03 between the control group and the chronic hepatitis B group, which is inconsistent with Jiang's report. On the contrary, we found that HLA-DRB1*07 was significantly higher in chronic hepatitis B group than in control group, the response to IFN- α therapy was significantly lower in HLA-DRB1*07(+) group than in HLA-DRB1*07(-) group ($P < 0.05$), suggesting that susceptibility to persistent infection and lower response to interferon- α are significantly associated with the presence of HLA-DRB1*07^[23-25].

It is more important that the response to IFN- α therapy in patients with both HLA-DRB1*07(+) and genotype C (+) was even lower than that in patients with HLA-DRB1*07 (+) or genotype C (+, $P < 0.05$), suggesting that HBV genotype C and HLA-DRB1*07 are closely associated with lower response of chronic hepatitis B to IFN- α therapy. Therefore, early exclusion of their existence before anti-viral therapy is very important for selection of patients and judgment of their prognosis.

ACKNOWLEDGMENTS

The authors thank XR Song and AQ Zheng (Tumor Research Center, Shandong Tumor Hospital) for their assistance with the PCR and serologic assays, and all patients for participating in this research.

Abstract

AIM: NONI juice (*Morinda citrifolia*) is an increasingly popular wellness drink claimed to be beneficial for many illnesses. No overt toxicity has been reported to date. We present two cases of novel hepatotoxicity of NONI juice. Causality of liver injury by NONI juice was assessed. Routine laboratory tests and transjugular or percutaneous liver biopsy were performed. The first patient underwent successful liver transplantation while the second patient recovered spontaneously after cessation of NONI juice. A 29-year-old man with previous toxic hepatitis associated with small doses of paracetamol developed sub-acute hepatic failure following consumption of 1.5 L NONI juice over 3 wk necessitating urgent liver transplantation. A 62-year-old woman without evidence of previous liver disease developed an episode of self-limited acute hepatitis following consumption of 2 L NONI juice for over 3 mo. The most likely hepatotoxic components of *Morinda citrifolia* were anthraquinones. Physicians should be aware of potential hepatotoxicity of NONI juice.

INTRODUCTION

Due to the known side effects of approved pharmaceuticals, patients often turn to alternative medicine which is considered “natural” and “healthy”. Herbal medicine is thus gaining popularity, but lack of knowledge of the mechanisms and

side effects of these preparations as well of safety regulations for their preparation may have serious consequences^[1]. Reports of hepatotoxicity associated with the use of herbal medicines are accumulating, ranging from mild elevations of liver enzymes to fulminant liver failure requiring liver transplantation^[2]. Healthcare professionals should be made aware of the potential dangers of herbal preparations. We present two cases of acute drug-induced hepatitis associated with the consumption of NONI juice.

CASE REPORT

Case 1

A 29-year-old male patient presented in March 2003 with acute hepatitis following treatment of an upper respiratory tract infection with paracetamol (4 g daily for 5 d followed by lower doses over 4 wk, cumulative dose of 40 g) associated with reduced food intake. Laboratory abnormalities included a bilirubin concentration of 26.3 mg/dL (normal: 0.1-1.2 mg/dL), ASAT 2 926 U/L (normal: <35 U/L), ALAT 2 665 U/L (normal: <45 U/L), γ -glutamyl transpeptidase 75 U/L (normal: <55 U/L), and alkaline phosphatase 209 U/L (normal: 40-130 U/L). Besides, the patient had allergic asthma treated with inhalative β_2 -agonists and glucocorticoids and eosinophilia of up to 12% in his peripheral blood smear. During military service at the age of 18, liver function tests were normal except for bilirubin (1.8 mg/dL) attributed to Gilbert's syndrome. Viral hepatitis, autoimmune hepatitis, hemochromatosis, α_1 -antitrypsin deficiency, Wilson's disease as well as other infections (leptospirosis, toxoplasmosis, coxsackie, and brucellosis) were ruled out and his abnormal liver tests were interpreted as low-dose paracetamol toxicity facilitated by fasting. Three months later, aminotransferase and bilirubin levels improved (ASAT 222, ALAT 300 U/L, bilirubin 4.8 mg/dL) and the patient was lost to follow-up. From April 2003 until June 2004, he treated himself with various homeopathic preparations containing small amounts of ethanol (<1 g/d). In June 2004 he was readmitted with acute liver failure. During the 3 wk prior to readmission, he ingested 1.5 L Tahitian NONI[®] juice and for 9 d prior to admission, approximately 7 g/d of a Chinese herbal mix containing bupleuri, pinellia, scutellaria, codonopsis, glycyrrhizae, schizonepeta, and paeonia. He denied any other medication over the past year. Other etiologies for acute liver failure such as fulminant hepatitis A or B, acute Wilson's disease, mushroom poisoning, and Budd-Chiari syndrome were ruled out. On re-admission, he showed grade 1 hepatic encephalopathy, ASAT 1 557, ALAT 1 626 U/L, bilirubin 45.3 mg/dL, INR 1.4 (normal: 0.85-1.15), albumin 3.3 g/dL (normal: 3.5-5.3 g/dL), and ammonia 90 μ mol/L (normal: 15-55 μ mol/L). A transjugular liver biopsy was performed and revealed acute hepatitis consistent with an

idiosyncratic drug reaction (Figure 1A). Over the next 3 d, liver failure progressed rapidly. On d 4, the patient fulfilled King's College criteria for emergency liver transplantation and was listed for urgent liver transplantation. During the waiting time, he underwent two consecutive sessions of extra-corporeal liver support using fractionated plasma separation, adsorption and dialysis (FPAD, Prometheus™, Fresenius Medical Care, Bad Homburg, Germany) which resulted in temporary improvement of hepatic encephalopathy from grade 3 to grade 2 and a decrease of arterial ammonia levels from 144 to 97 $\mu\text{mol/L}$. On d 6, liver transplantation was performed. On d 11, hepatic artery thrombosis necessitated re-transplantation. Thereafter, the patient recovered completely and was discharged on d 30.

Case 2

A 62-year-old woman was admitted in September 2003 with vomiting and diarrhea. On admission, routine laboratory tests revealed acute hepatitis (ASAT 1 415, ALAT 2 381 U/L, γ -glutamyl transpeptidase 241, alkaline phosphatase 292 U/L, bilirubin 2.9 mg/dL). In 1999, she was diagnosed with chronic B-cell leukemia which was treated with fludarabine in 2002 resulting in remission. Throughout that time, liver function tests were normal and the patient did not take any other regular medication. From April to July 2003, she ingested 2 L of Tahitian NONI® juice. Viral hepatitis, auto-immune hepatitis, hemochromatosis, α_1 -antitrypsin deficiency, and Wilson's disease were

ruled out. There was no evidence of biliary obstruction or Budd-Chiari syndrome on ultrasound. The patient did not take any other potentially hepatotoxic drugs during that period. A percutaneous liver biopsy revealed acute hepatitis consistent with an idiosyncratic drug reaction (Figure 1B). Laboratory values peaked at ASAT 2 022, ALAT 3 570 U/L, and bilirubin 4.9 mg/dL and gradually improved over the next 30 d (ASAT 194, ALAT 645 U/L, and bilirubin 3.9 mg/dL). Nine months later, aminotransferases and bilirubin normalized and the patient remained asymptomatic.

DISCUSSION

We present two cases of toxic hepatitis associated with NONI juice (*Morinda citrifolia*) which represent the first reports of hepatotoxicity of this herbal preparation. To our knowledge, only one further case of NONI hepatotoxicity observed at the Medical University Innsbruck, Austria, has been published to date^[3]. Case 1 developed fulminant liver failure requiring emergency liver transplantation while liver function was preserved in case 2 and the patient recovered spontaneously after cessation of NONI juice. The temporal relationship between NONI intake and liver dysfunction (Figures 2A and B) and extensive exclusion of alternative causes of acute hepatitis confirmed herbal hepatotoxicity in both cases. Causality of liver injury by NONI juice was assessed using the Council for International Organizations of Medical Sciences scale^[4]

Figure 1 Confluent liver cell necrosis (asterisk), ductular reaction and metaplasia as well as mild inflammatory infiltrate (arrow head) in case 1 (A) and centrilobular

area with liver cell necrosis, ballooned hepatocytes and mild inflammatory infiltrate in case 2 (B).

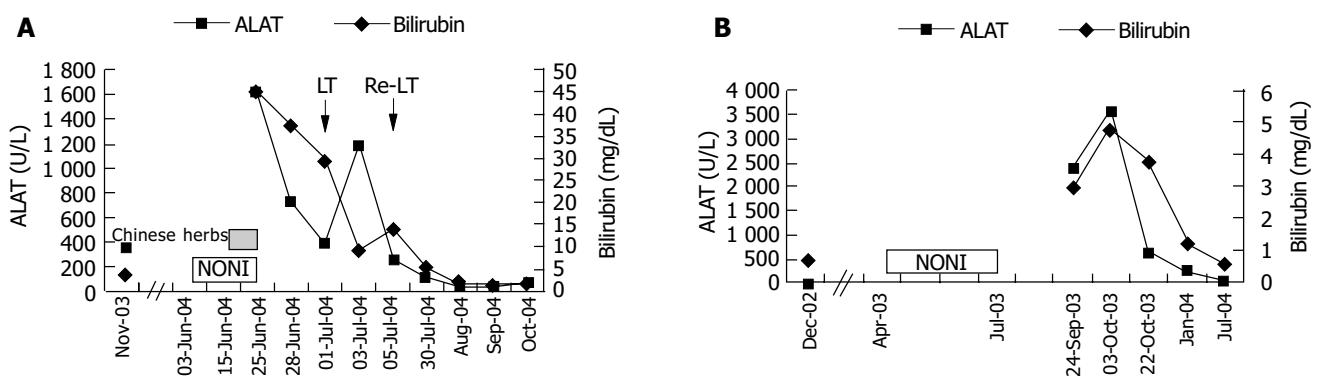

Figure 2 Time course of NONI intake and elevation of ALAT and bilirubin in

case 1 (A) and case 2 (B). LT: Liver transplantation.

and yielded a score of +5 (“possible”) in case 1 and a score of +7 (“probable”) in case 2. Histology revealed acute hepatitis with centrilobular necrosis consistent with acute drug-induced hepatotoxicity of idiosyncratic type in both cases (Figures 1A and B). However, we could not exclude concomitant pre-existing liver damage by paracetamol and/or an additional hepatotoxic effect of components of the Chinese herbal mix in case 1.

NONI juice is prepared from the fruit of *Morinda citrifolia*, a Polynesian plant with a long history of medicinal applications^[5]. Since 1996, various preparations of NONI juice have been sold as wellness drinks. Short-term safety studies in rats have not yielded overt toxicity^[5]. One case of hyperkalemia due to self medication with NONI juice is reported in a patient with renal failure^[6]. So far, no detailed pharmacological studies were reported on the putative active ingredients of the NONI plant, which include scopoletin, including scopoletin, potassium, ascorbic acid, terpenoids, alkaloids, anthraquinones, β -sitosterol, carotene, vitamin A, flavone glycosides, linoleic acid, alizarin, amino acids, acubin, L-asperuloside, caproic acid, caprylic acid, ursolic acid, rutin, and several volatile components such as acids (mainly octanoic acid and hexanoic acid), alcohols, esters, ketones, and lactones^[5,7]. The most likely hepatotoxic components are anthraquinones such as nordamnacanthal, moridone, and rubiadin. Anthraquinones in other herbal remedies have been reported to cause hepatotoxicity^[8-12]. A possible mechanism of hepatotoxicity of anthraquinones has been described for rhein (4,5-dihydroxyanthraquinone-2-carboxylic acid) which produces oxygen-derived free radicals by redox cycling resulting in depletion of intracellular reduced glutathione, decreased mitochondrial membrane potential, initiation of lipid peroxidation, and cell death^[13]. Further studies are required to evaluate the exact mechanism of toxicity. Physicians should be aware of potentially serious hepatotoxicity of NONI juice.

Abstract

Mucocele of the appendix is a rare lesion, characterized by distension of the lumen due to accumulation of mucoid substance. This disease is often asymptomatic and pre-operative diagnosis is rare. If untreated, one type of mucocele may rupture producing a potentially fatal entity known as pseudomyxoma peritonei. The type of surgical treatment is related to the dimensions and to histology of the mucocele. Appendectomy is used for simple mucocele or for cystadenoma. Right hemi-colectomy is recommended for cystadenocarcinoma. In this paper, we report a case of a 51-year-old woman with a mobile, painless mass in the right lower quadrant of abdomen caused by a giant appendiceal mucocele. Imaging showed a large, tubular, cystic structure extending below from the inferior wall of the cecum. Surgery revealed a giant retro-cecal appendix measuring 17 cm in length and 4 cm in diameter. The final pathologic diagnosis was mucocele caused by mucinous cystadenoma.

INTRODUCTION

Mucocele is a rare pathology of the appendix, characterized by a cystic dilation of the lumen with stasis of mucus. The incidence ranges between 0.2% and 0.3% of all appendectomies, with a higher frequency in females (4/1) and in people more than 50 years^[1]. It demonstrates an inflammatory or a tumoral cause; most important for the surgeon, however, the mucoceles are caused by mucinous cystadenomas and cystadenocarcinomas. In the latter case, a possible rupture of the mucocele, either spontaneous or accidental, may result in the clinical condition of pseudomyxoma peritonei, a spread of malignant

cells throughout the peritoneal cavity in the form of multiple mucinous deposits^[2,3]. A correct diagnosis may help to avoid iatrogenic rupture during surgery. We describe a case of a giant appendiceal mucocele and present the diagnostic aspects, surgical options and prognosis of this disease.

CASE REPORT

A 51-year-old woman was admitted to our department on April 21, 2004 due to the appearance of a mass in the right lower quadrant of abdomen, with nausea and decreased appetite. No urinary dysfunction or changes in her intestinal transit was reported. Her blood pressure was 130/80 mmHg with regular pulse of 80/min. She had a body temperature of 36.8 °C. On admission, physical examination of chest revealed no abnormalities and superficial lymph nodes were not palpable. A mobile, painless mass was palpated at the right lower abdomen. No liver or spleen enlargements were noted.

Laboratory tests, including CEA, CA 19-9, CA 125, CA 15-3 and CA 72-4, were unremarkable.

Abdominal ultrasonography revealed the presence of a non-homogeneous oval mass. Computed tomography scan of the abdomen showed a large, hypodense, tubular, cystic structure extending below the inferior wall of the cecum (Figure 1). Coronal view of computed tomography disclosed a mass, which measured about 13 cm in length (Figure 2).

Figure 1 Large, hypodense, tubular, cystic structure extending below the inferior wall of the cecum revealed in a computed tomography scan of the abdomen.

On April 24 the patient had a laparotomy. At surgery, a giant retro-cecal appendix was found (Figure 3). There was no lymphadenopathy or hepatic metastases. No other tumors were noted in the abdominal or pelvic cavities. The appendix was bent behind the ascending colon. After adhesiotomy, a standard appendectomy was performed.

The mass, which measured 17 cm in length and 4 cm in diameter, showed a thin fibrous wall and viscous hemorrhagic mucoid content without any mucosal lesion. The final pathologic diagnosis was mucocele caused by mucinous cystadenoma. There was no evidence of malignancy. The patient's post-operative course was unremarkable and she was discharged 5 d post-operatively.

At present, about 7 mo post-operatively, the patient is asymptomatic, and abdominal ultrasonography did not reveal any abdominal lesion.

Figure 2 Mass of about 13 cm in length disclosed in a coronal view of computed tomography scan.

Figure 3 Intraoperative finding of a giant appendix, which measured 17 cm in length and 4 cm in diameter.

DISCUSSION

The term mucocele is often used as a general descriptive term for dilatation of the appendiceal lumen by mucinous secretions. Four subgroups of the disease can be identified, according to the characteristics of the epithelium: (1) simple or retention mucocèles resulting from obstruction of the appendiceal outflow, usually by a fecalith, and characterized by normal epithelium and mild luminal dilatation up to 1 cm. (2) Mucocèles with hyperplastic epithelium where luminal dilatation is also mild; these constitute 5-25% of mucocèles. (3) Benign mucocèles, the most common form, accounting for 63-84% of cases. These exhibit mostly epithelial villous adenomatous changes with some degree of epithelial atypia, and are characterized by marked distention of the lumen

up to 6 cm. Our patient belongs to this group. (4) Malignant mucinous cystadenocarcinomas, representing 11-20% of cases. They are distinguished from the previous group by their glandular stromal invasion and/or presence of epithelial cells in the peritoneal implants. The luminal distention is usually severe^[1-4].

Mucinous cystadenomas and cystadenocarcinomas are often referred to as neoplastic mucocèles. In cystadenomas, which are the most common form, the luminal dilatation reaches up to 6 cm and is associated with appendiceal perforation in 20% of instances. This results in mucinous spillage into the peri-appendicular area and peritoneal cavity. Histological examination of the mucus does not reveal any neoplastic cells and appendectomy is usually curative^[5]. Mucinous cystadenocarcinomas, on the other hand, are less common than mucinous cystadenomas and may present with spontaneous rupture in 6% of cases. Macroscopically, they produce mucin-filled cystic dilatation of the appendix indistinguishable from cystadenomas. However, neoplastic cells may penetrate the appendiceal wall and spread beyond the appendix in the form of peritoneal implants. In its fully developed state, the peritoneal cavity becomes distended with adhesive, semi-solid mucin in which neoplastic adenocarcinomatous cells can be found; this condition is termed as pseudomyxoma peritonei. The intraperitoneal spread of this mucin-secreting cancer is identical to that of intra-peritoneal ovarian mucinous cystadenocarcinomas^[2-5].

Symptomatology of appendiceal mucocèles is not specific: very large lesions are asymptomatic in 25% of patients. The most common presentation is right lower quadrant pain, similar to an acute appendicitis; a palpable mass can be found in 50% of cases, whereas urinary dysfunction or hematuria is rarely related^[6]. Increase of tumor markers indicate a probable neoplastic origin^[7,8]. The rare complications include intestinal obstruction, frequently caused by intussusception, or intestinal bleeding. Pseudomyxoma is the worst complication, characterized by peritoneal dissemination caused by spontaneous or iatrogenic perforation of the appendix. In benign mucocele, the pseudomyxoma is confined to the peri-appendicular area. In malignant cases, this dissemination is considered a real metastatic entity; retro-peritoneal or pleural implants are occasionally reported^[7-9].

Preoperative diagnosis is difficult, due to the nonspecific nature of the disease. The lesion may be identified by radiologic, sonographic, or endoscopic means. Elevated carcino-embryonic antigen levels have been described in neoplastic mucocèles^[10,11].

Computed tomography scan of the abdomen is important in the diagnosis and evaluation of the extent of the disease. A typical computed tomography scan finding of an appendiceal mucocele is a round, low-density, thin-walled, encapsulated mass, communicating with the cecum. Ultrasonography shows a cystic, encapsulated lesion, firmly attached to the cecum, with liquid content and an internal variable echogenicity related to mucus density. Colonoscopy may show a pathognomonic image, the 'sign of the volcano', i.e., an erythematous, soft mass with a central crater, from which mucus is discharged^[12-15].

Therapy is surgical, but laparoscopic approach is not advised because of the risk of rupture^[16].

The type of surgical treatment is related to the dimensions and to histology of the mucocoele. Appendectomy is used for simple mucocoele or for cystoadenoma, when the appendiceal base is intact. Cecal resection is indicated for cystoadenoma with a large base, and a right hemi-colectomy is recommended for cystadenocarcinoma. Intra-operative histologic examination is not always definitive. An accurate exploration of the abdomen during laparotomy is advised, because of the association between the appendiceal mucocoele and other tumors, particularly carcinoma of the colon (11-20 %) and tumors of the ovary^[17].

If exploration reveals a ruptured appendiceal mucocoele, the primary resection should be accompanied by removal of all gross implants ^[16,17].

Postoperatively, patients with simple or benign neoplastic mucocoeles have shown an excellent prognosis with 5-year survival rates of 91-100%, even in cases with extension of mucus into the extra-appendiceal spaces. In malignant mucocoeles, however, the 5-year survival rate is markedly diminished (25%) due to complications of pseudomyxoma peritonei^[18].

In conclusion, patients with mucocoeles can present with various symptoms, but may also be asymptomatic. Preoperative diagnosis is rare, but it is possible using appropriate tests. These uncommon and potentially lethal entities are usually surgically curable, if diagnosed in an early phase. Therefore, pre-operative recognition with a carefully planned resection to remove the mass is required.

Abstract

Biloma is an encapsulated bile collection outside the biliary tree due to a bile leak. It is occasionally found following traumatic liver injury or iatrogenic injury to the biliary tract, induced either during an endoscopic or surgical procedure. It is a rare complication of transcatheter arterial embolization (TAE). Although biloma can be shrunk by appropriate aspiration or drainage in majority of cases, we report a case of intrahepatic biloma following repeated TAE for hepatocellular carcinoma (HCC) and complicated by infection and intrahepatic stones. This particular constellation of problems has not been reported before and the intrahepatic stones need to be removed by percutaneous procedure.

CASE REPORT

A 69-year-old woman was diagnosed with cryptogenic liver cirrhosis 15 years ago, but had well-compensated liver function. In October 2000, she was found to have a 8-cm tumor in the left lobe of the liver. HCC was diagnosed on pathological examination. Surgical resection was not attempted because of the large size of the tumor and atrophy of the right lobe. Therefore, she was treated with transcatheter arterial

embolization (TAE) and percutaneous ethanol injection (PEI). TAE was performed with 6 cm³ of iodized oil (lipiodol) injected through the catheter and embolization with gelfoam sponge. Four weeks after TAE, enhanced CT was used to access the effects. If the response was not satisfactory, pure ethanol was injected under ultrasound guidance. By May 2003, the patient received five courses of combined TAE and PEI. Her cirrhosis was assessed as Child-Pugh class A, and HCC was maintained at 7 cm in diameter. No major complications were noted till that point.

Three weeks after the sixth TAE procedure, the patient complained of nausea, epigastric pain, and poor appetite. She denied fever or chills. A tender mass was palpable in the epigastric area. Her bilirubin was elevated at 2.8 mg/dL. An abdominal CT disclosed an encapsulated fluid collection in the left lobe of the liver. Echo-guided aspiration of bile from the lesion confirmed the diagnosis of biloma. Several days later, the culture of the aspirated bile culture was reported as growing *K. pneumoniae*. On the same day, the patient developed fever and leukocytosis. She was treated with intravenous antibiotics, and a 10 F pig-tail catheter was placed percutaneously to drain the biloma. Two days later, contrast media was injected through the catheter for a fluoroscopic evaluation. A communication was found between the biloma and the left biliary tree (Figure 1). Small filling defects were seen in one dilated branch of the IHD, consistent with stones. Some of these fell into the biloma. The biloma drain continued to put out a large volume of bile along with sandy stones for 5 d, without any shrinkage the size of the cavity. However, the fever did subside. Concerned that the stones were preventing collapse of the biloma, we decided to remove the stones percutaneously. The fistula track was gradually dilated to 16 F by changing the drainage

Figure 1 Communication between the biloma and the left biliary tree (short arrows) on injection contrast via the percutaneous pig-tail catheter and small filling defects (long arrow) seen in one dilated branch of the IHD, consistent with stones.

catheter. The IHD stones were removed with a basket over several sessions. Two months later, the biloma shrunk.

DISCUSSION

Biloma is occasionally found following traumatic liver injury or iatrogenic injury to the biliary tract, induced either during an endoscopic^[1] or surgical procedure. Peripheral bile duct necrosis caused by microvascular damage and ductal stenosis after TAE might lead to a bile leak^[2,3]. Our patient has already undergone five courses of TAE and PEI before, and the biloma developed 3 wk after the sixth TAE. We do not think that the PEI could directly influence this biloma, although there is one case report in the literature of a biloma after PEI^[4]. The incidence of biloma after TAE in several series has been reported to be around 0.8–1.1%^[5–7]. These often occurred only after more than five courses of TAE^[5,6]. Recent reports indicate the advantage of the usage of embolization materials which have a suitable size only for the feeding artery, but largely for occlusion of bile duct microplexus. It is in terms of effective tumor embolization as well as prevention of possible complications.

Biloma is usually a simple cyst without septum. Percutaneous needle aspiration with chemical analysis could confirm the diagnosis. It may be asymptomatic or present with a variety of manifestations, such as gastric outlet obstruction, jaundice, or fever. The presentation depends on the size and location of the lesion and the presence or absence of infection. Asymptomatic patients may be treated conservatively. In a series reported by Kohno *et al.*^[4], in 15 of 20 patients, the biloma shrank spontaneously during a 6-mo follow-up period. A biloma that fails to decrease in size should be drained, as infection is a common complication if the condition persists. If there is no communication with the biliary tree, and the proximal biliary tree has neither stricture nor stones, percutaneous drainage and intravenous antibiotics may achieve resolution. Intra-hepatic duct strictures may require insertion of a stent in order to relieve pressure that might reopen a tract to the biloma. However, IHD stones are often difficult to be removed. A biloma connected to a biliary tree containing stones has not been previously reported. It appeared in our patient that peripheral bile outflow was blocked by the IHD stones, causing a high pressure in biliary system and thus, led to a persistent bile leak. Given the difficulty of reaching IHD stones endoscopically, percutaneous removal of the stones seemed advisable, and ultimately, the biloma did shrink.

The proposed therapies for HCC, beyond TAE and PEI are increasing and include hepatic artery infusion of chemotherapy agents^[8], microwave coagulation^[9], and high frequency radioablation. Any of these may cause peripheral bile duct damage, so that it is conceivable that the incidence of biloma will increase. Clinicians must be aware of this possible complication. The prophylactic administration of antibiotics may be employed in these procedures, since biloma can be a result of focal infection. But the real necessity of prophylactic antibiotics remains to be identified.

Abstract

Acute pancreatitis as an initial symptom of systemic lupus erythematosus (SLE) is rare. We present a report of a 46-year-old female patient who had fever, abdominal pain and vomiting, elevated pancreatic enzyme levels, hypocalcemia, hypoxemia, and various other laboratory abnormalities. She was first diagnosed with acute severe pancreatitis and then with SLE after further investigations. After a 2-mo treatment with somatostatin, the patient recovered.

<http://www.wjgnet.com/1007-9327/11/4766.asp>

INTRODUCTION

Systemic lupus erythematosus (SLE) is a multi-system, autoimmune disorder characterized by a broad range of manifestations, including presence of antibodies against cell nuclei. The initial manifestations of SLE, however, can involve many organ systems either singly or in combination, which frequently makes diagnosis difficult. The American Rheumatism Association recommends that the diagnosis of SLE can be confirmed if it meets 4 of the following 11 revised criteria: malar rash, discoid rash, photo-sensitivity, oral ulcers, arthritis, serositis, renal disorder, neurologic disorder, hematologic disorder, immunologic disorder, and antinuclear antibodies.

We report a 46-year-old female patient with fever, abdominal pain and vomiting, elevated levels of pancreatic enzyme, hypocalcemia, hypoxemia, and other laboratory

abnormalities. She was first diagnosed with acute severe pancreatitis and then with SLE, after further investigations.

CASE REPORT

A 46-year-old woman came to the Sixth Hospital attached to Shanghai Jiaotong University, complaining of a 6-d history of persistent abdominal pain, loss of appetite, occasional nausea and vomiting without obvious reasons. She also had a 3-d history of fever and generalized weakness.

She reported bilateral thigh pain, finger pain and swelling 5 mo ago, which were abated after 7-d treatment with hydroxy-chloroquine. Four months ago, she had elevated alanine aminotransferase, and received no treatment. She also reported some thinning of her hair and a weight loss of 5 kg in the past 2 mo. Her family history was unremarkable for auto-immune disorders.

Her body temperature was 38 °C, pulse rate 100 beats per minute, blood pressure 120/80 mmHg. She had no skin lesions, but had swollen and painless lymph nodes. She had fine rales on bilateral lungs, and 3-degree systolic murmur in the mitral valve area and a pericardial friction sound. Her abdomen was soft with mild epigastric tenderness, minimal guarding, and no rebound tenderness.

Her blood chemistry was as follows: 126 mmol/L sodium, 4.4 mmol/L potassium, 97 mmol/L chloride, 22.5 mmol/L bicarbonate, 1.6 mmol/L blood urea nitrogen, 31 µmol/L creatinine, 5.1 mmol/L glucose, 83 U/L aspartate aminotransferase, 16 U/L alanine aminotransferase, 66 g/L protein, 37 g/L albumin, 1.70 mmol/L calcium, and 18 µmol/L total bilirubin. A complete blood count showed a white cell count of $3.0 \times 10^9/L$ with 78.9% neutrophils, 19.8% lymphocytes, 2.3% monocytes. Hemoglobin was 89 g/L, hematocrit 33.8%, and platelets $112 \times 10^9/L$. Pancreatic enzyme determinations disclosed a blood amylase level of 1 000 U/L (normal 20-115 U/L) and urine amylase level of 830 U/L, and a lipase level of 690 U/L. Urinalysis showed cloudy urine with a protein level of 260 mg/dL, a white cell count of 3-4/µL, granular casts 0. Nitrite and leukocyte esterase were negative. Blood culture was negative.

Computed tomographic (CT) scan and ultrasonic scan of the abdomen with contrast, showed swollen pancreas but no gallbladder stones (Figure 1A). Another CT scan of the bosom showed effusion both in right and in left pleurae (Figure 1B).

Connective tissue showed an antinuclear antibody (ANA) titer of 1:640, positive anti-double-stranded DNA (dsDNA) antibody, negative anti-Smith antibody, anti-ribonucleoprotein, anti-SSA, and anti-SSB. The erythrocyte sedimentation rate was 92, complement 3 (C₃) was 0.75 g/L (normal 1.0-1.8 g/L),

anti-cardiolipin antibodies and lupus anti-coagulant were negative.

Figure 1 Swollen pancreas (A) and pleural effusion (B) before treatment with somatostatin.

After a 2-mo treatment with somatostatin, the pancreatic enzyme was 29 U/L. Repeated CT scan revealed a less swollen pancreas (Figure 2A) and still bilateral pleural effusion (Figure 2B). But the patient still had fever and palpitation. A diagnosis of SLE pancreatitis was made on the 66th d of admission, and 40 mg methylprednisolone intravenous injection qd was started. Once steroid therapy began, the heart rate declined to 90 beats per minute. Two weeks after continuous steroid therapy, the heart rate was 78 beats per minute and the temperature was 36.6 °C. Pleural effusion disappeared.

Figure 2 Less swollen pancreas (A) and pleural effusion (B) after treatment with somatostatin.

DISCUSSION

Although the patient on admission was positive for ANA and anti-dsDNA, arthritic, serositis and blood cells reduced, which fulfills the American Rheumatism Association criteria for the diagnosis of SLE. Our case illustrates the protean manifestations of SLE and a rare initial manifestation as acute pancreatitis. Over 50% SLE patients have manifestations of digestive system, but pancreatitis is few, and such acute pancreatitis as an initial manifestation is even rare. The association between SLE and pancreatitis was first documented in 1939^[1]. Since then, only 70 cases of SLE pancreatitis have been documented in the literature, and only 10 of these cases, including this one, have pancreatitis as their initial manifestation^[2-5].

The mechanisms involved in the origin of SLE pancreatitis are not clear. SLE pancreatitis might result from vasculitis, microthrombi, anti-pancreas autoantibody, side-effects of medicine, intimal thickening and virus infection. Most lupus

pancreatitis is found in patients with long-standing SLE who have multi-organ involvement and are already on steroid, diuretic, or immunosuppressive therapy, all of which have been implicated in the etiology of pancreatitis. Since the initial description of SLE pancreatitis, whether steroid or SLE is the primary cause has been controversial. Recent studies support that SLE is the primary etiologic factor of SLE pancreatitis, and drug toxicity may also play a role^[5-9].

Pathological changes of SLE pancreatitis bear similarities to those of pancreatitis due to other causes. SLE pancreatitis can occur during a generalized flare-ups and disease quiescence, though the latter seems more likely^[3]. Its manifestation can be acute, severe, or chronic, self-limiting or fulminant. It is believed that subclinical pancreatitis which has an elevation of pancreatic enzymes without clinical symptoms is much more frequent than symptomatic pancreatitis^[10-14]. About 30.5% of asymptomatic SLE patients have hyperamylasemia; therefore subclinical pancreatic damage might occur very frequently in SLE^[15].

Within the context of SLE, the diagnosis of SLE pancreatitis is usually based on clinical findings as abdominal pain, nausea, and vomiting as well as laboratory findings like abnormal pancreatic enzymes and suggestive tomographic findings. Etiology diagnosis is fairly important, which decides whether steroid can be used. If drug toxicity is not considered as the origin, SLE pancreatitis is treated with steroid. Of course, steroid or other drugs should be stopped once they are regarded as the cause^[16,17].

In conclusions, it is important to determine whether drug toxicity is the cause of SLE pancreatitis. If the condition of patients with SLE pancreatitis can be improved with somatostatin, steroid might not be necessary during the acute episode.

TO THE EDITOR

In a recent issue of *World Journal of Gastroenterology*, Demeter *et al.*^[1], reported that in patients having both gastro-esophageal reflux disease (GERD) and obstructive sleep apnea (OSA), there was a positive correlation between endoscopic findings of GERD and the number of apneas and hypopneas per hour, namely apnea hypopnea index. They proposed that the severity of OSA and GERD are parallel to each other. The study of Demeter and colleagues is very important, not only for assessing reflux-induced esophageal damage in OSA, but also for determining therapeutic approaches for patients with OSA and GERD. Because both conditions are very common in general population and are associated with morbidity and deterioration of quality of life^[2,3].

However, causative relationship underlying the association may be complicated. One proposed mechanism is that greater respiratory effort increases the pressure gradient across the lower esophageal sphincter and eventually facilitates the retrograde movement of gastric content^[4]. The point is that classification of OSA is traditionally based on the apnea-hypopnea index (AHI) and, severity of OSA, which is defined by higher score of AHI, does not necessarily reflect the magnitude of respiratory effort during obstruction. Therefore, it is not easy to conclude that the occurrence of gastro-esophageal reflux is related to the number of apneas

and hypopneas rather than respiratory effort during each breathing cessation period. Besides the magnitude of respiratory effort, repetitive stimulation of lower esophageal sphincter via phreno-esophageal ligament may also be linked with a threshold value of respiratory effort. Interestingly, there is another sleep-disordered breathing called “Upper Airway Resistance Syndrome”, which is described by excessive daytime sleepiness, increased respiratory effort without oxyhemoglobin desaturation during sleep and absence of apneas or hypopneas. Inspiratory effort is an important characteristic and determinant of sleepiness and other symptomatology in UARS patients^[5]. Considering the same mechanism, patients with UARS should also complain from reflux-related symptoms. We are not aware of any study reporting GERD in UARS. Another mechanism involves increased arousals in patients with OSA, together with reduced sleep efficiency, which may trigger transient lower esophageal sphincter relaxation and thus, promote acid reflux^[6]. We have recently reported that there is no sufficient evidence to accept arousals and obstructive respiratory events during sleep as primary causes of gastroesophageal reflux and vice versa^[7]. Indeed, we failed to find any timely relation between reflux episodes and respiratory events on the simultaneous recordings of dual probe esophageal pH monitoring and polysomnography. We think that controversy will remain until placebo-controlled studies focusing on the timely relation between respiratory effort and reflux episodes will be performed.

Abstract

Fecal incontinence is a disabling disease, often observed in young subjects, that may have devastating psycho-social consequences. In the last years, numerous evidences have been reported on the efficacy of bio-feedback techniques for the treatment of this disorder. Overall, the literature data claim a success rate in more than 70% of cases in the short term. However, recent controlled trials have not confirmed this optimistic view, thus emphasizing the role of standard care. Nonetheless, many authors believe that this should be the first therapeutic approach for fecal incontinence due to the efficacy, lack of side-effects, and scarce invasiveness. Well-designed randomized, controlled trial are eagerly awaited to solve this therapeutic dilemma.

<http://www.wjgnet.com/1007-9327/11/4771.asp>

INTRODUCTION

Fecal incontinence is a common health care problem, with modest physical but important psychosocial consequences that can be distressful and incapacitating, up to complete social isolation^[1]. Fecal incontinence is one of the fields in which bio-feedback techniques are thought to be most

successful, and owing to the fact that bio-feedback procedures have had a strong impact in gastro-enterology, behavioral research in this area has greatly increased in recent years^[2,3]. The term bio-feedback training refers to the use of various devices (mechanical, electrical) that are supposedly able to increase the awareness of a biological response, so that patients can learn, through a process of "trial and error", to improve their voluntary control of this response^[4]. Bio-feedback training sessions are usually supplemented by home practice training (Kegel exercises), with the purpose of enforcing muscle strength through an increase of the number of muscle fibers innervated by existing nerves. It is commonly thought that bio-feedback is not able to repair or generate new neural pathways.

The increase of patient's awareness of somatic sensations, and the improvement of motor skills, which represent the basis of biologic self-regulation, are critical points for bio-feedback training. For instance, a cause of fecal incontinence is the loss of the ability to feel rectal fullness, a major point for contracting the pelvic floor muscles to avoid incontinence^[5]. In these patients, the goal of bio-feedback training is to improve the ability to detect rectal filling through sensory re-training^[6,7].

Types of bio-feedback training for fecal incontinence

Bio-feedback treatment of fecal incontinence was proposed by Engel and coworkers, 30 years ago^[8]. Patients were taught to improve their ability to voluntarily contract the external anal sphincter during rectal filling, either by improving the strength of the sphincter (motor skills training) or by increasing the ability to perceive weak rectal distention (discrimination training) or by combining the previous two mechanisms (training in the coordination of sphincter contractions with rectal sensation). No side effects were reported and the treatment was generally well accepted. Further trials had shown that therapeutic goals can be achieved through training, that employs measurements of pressures (manometry) or electrical activity (electromyography, EMG) in the anal canal^[2,3].

Manometric bio-feedback

Bio-feedback training aimed at increasing the strength of the external anal sphincter has usually been carried out by recording anal canal pressures, coupled to visual/auditory signals proportional to the pressures themselves. Anal pressure may be recorded by balloon probes or by perfused catheters^[4]. During manometric recording, the patient is required to squeeze as to prevent defecation while being given visual feedback and verbal guidance on how to reach

this goal. The patients may also be taught to inhibit wrong responses such as contraction of the abdominal muscles. Asking the patient to squeeze may be obtained in response to balloon distention of the rectum^[9] or without rectal distention^[10]. Some authors have suggested that improving squeeze duration is more important than maximizing anal strength. Therefore, patients are taught to pursue this therapeutic goal as a part of the bio-feedback protocol^[10,11].

EMG bio-feedback

Strengthening the pelvic floor muscle may also be achieved by showing the patient, a recording of the integrated (average) EMG activity from the striated muscles which surround the anal canal^[12]. In EMG training, the patient is asked to squeeze and relax without rectal distention, and home exercises in which the patient is required to repeatedly squeeze the pelvic floor muscles (Kegel exercises) are usually added to the training to further strengthen these muscles. Other methods of EMG recording of the pelvic floor employ an anal plug with surface electrodes^[13], very easy to use and requiring no preparation.

Sensory discrimination training

This is aimed at increasing the patient's ability to perceive and respond to rectal distention^[14]. After inserting within the rectum a catheter-mounted balloon, the latter is inflated with different air volumes; the patient is then asked to signal when the feeling of distention is perceived, or to contract the pelvic floor muscles in response to the distention. For these purposes, easily perceived distention with large volumes of air is firstly given, the volumes of distention are gradually decreased until the patient is able to perceive them with difficulty. Repeated distention slightly above and below the sensory threshold of the patient, coupled to the investigator's feedback on the accuracy of detection, teach the patient to recognize distention of even weaker intensity^[3,4]. This type of sensory training is often coupled to sphincter strength training, asking the patient always to contract (as strongly as possible) in response to rectal distention and providing feedback on the strength of contraction and accuracy of detection^[3,4]. Several evidences suggest that sensory discrimination training (aimed at reducing the threshold for perception of rectal distention) is very important for an effective bio-feedback procedure^[6-8,15]. We have recently evaluated 24 patients with severe, solid-stool fecal incontinence^[16] by teaching them to squeeze in response to rectal distention; the patients were evaluated 3 mo after bio-feedback training, and were classified as responders (>75% decrease of incontinence episodes) or non-responders. Comparison of the two groups showed that responders displayed significantly lower sensory thresholds after training with respect to non-responders, but squeeze pressures were not significantly different between groups. Sensory thresholds measured before bio-feedback training were good predictors of which patients would respond to it; in fact, patients with more severe sensory impairment had poor response to bio-feedback training^[16]. Sphincter strength and severity of fecal incontinence before bio-feedback training were not useful as predictors of outcome.

METHODS

An internet-based comprehensive search strategy of the Medline and Science Citation Index was performed using the keywords bio-feedback and fecal incontinence, in various combinations with the Boolean operators AND, OR, and NOT. Only articles related to human studies were used, and manual cross-referencing was also performed. Articles published in English between January 1965 and September 2004 were selected; however, a search in non-English languages and in journals was also older than 1965 performed in our library. Letters were excluded, and abstracts were quoted only when the full papers were unavailable.

Usefulness of bio-feedback in fecal incontinence

Most of the available studies concerning the use of bio-feedback to treat fecal incontinence have been carried out by manometric means; however, a clear superiority of pressure *vs* EMG feedback has not surfaced^[17], and only one study aimed at comparing pressure *vs* EMG feedback training showed no significant differences between the two techniques^[18].

Looking at all the studies available in literature regardless of etiology, it is found that about 2/3 of patients display at least a 75% decrease of their episodes of fecal incontinence^[19,20], although only about 50% of them developed complete continence. However, it must be stressed that (1) no uniform criteria for defining improvement or assessing outcome have been adopted; (2) inclusion criteria differed; (3) treatment protocols varied and (4) only few prospective, randomized, parallel-group studies have been published, not enough to draw conclusions on the overall efficacy of bio-feedback training. In addition, recent randomized studies have not confirmed the optimistic outcome of previous open studies. These trials will be examined in detail in the following paragraph.

In a first randomized controlled study, bio-feedback plus behavioral management was compared to behavioral management alone in children with fecal incontinence due to myelomeningocele^[21]; both groups displayed significant improvement, suggesting that bio-feedback has the same effects as behavioral management for most children with myelomeningocele. However, it must be stressed that patients with spinal cord defects show commonly worst responses to bio-feedback than patients with incontinence due to other causes^[22]. In a second controlled study, van der Plas and coworkers studied 71 children with fecal incontinence without constipation and randomized them to standard care and laxatives or standard care and laxatives plus bio-feedback. At 12-18 mo follow-up, approximately 50% of children in both groups showed significant symptoms improvement. A trend toward better outcome was shown in the bio-feedback group, but statistical significance was not reached^[23]. In the first randomized study of bio-feedback in adults with fecal incontinence, a complex cross-over design was employed making interpretation of results quite difficult^[24]. Twenty-five patients were initially randomized to either three sessions, sensory discrimination training without bio-feedback on sphincter strength or equivalent distention without feedback on the accuracy of their

detection of the strength of contractions. Patients in the sensory training group had significant decrease of frequency of episodes of incontinence with respect to controls, but between-group differences did not reach statistical significance (probably due to small sample size). Control patients were then given sensory training, and displayed improvement in continence. Thereafter, all patients were randomized again to sphincter-strengthening exercises without bio-feedback or to squeeze in response to rectal distention with feedback. Overall, the patients had further improvement of continence in this second step of the study, but no significant differences were observed between groups, suggesting that sensory training is important for the treatment of incontinence, although the results are not definitive due to the small size samples. Recently, the St. Mark group reported a large, randomized, controlled study on 171 adults with fecal incontinence^[25]. Patients were randomized into four groups: (1) standard care with advice; (2) standard care with advice plus anal sphincter exercises taught verbally and via digital examinations; (3) same as group 2 plus bio-feedback therapy run at the clinic; (4) same as group 3 plus sphincter exercises guided by a home bio-feedback device. Approximately half of patients in all groups reported improvement of symptoms at one year follow-up. Interestingly, quality of life measurements, bowel symptoms and anal sphincter pressures were improved in similar percentage in all groups. Bio-feedback therapy yielded no greater benefit than did standard care with advice on an intention-to-treat analysis.

This trial appears methodologically sound in most instances with few, relevant limitations mostly related to the lack of details of the bio-feedback protocol used. Type and dosage of anti-diarrheal medications used in all the groups were also not provided. The results of this trial are at variance with a previous open study coming from the same Center, where bio-feedback therapy was reported to improve symptoms in the majority of patients with fecal incontinence^[26]. Moreover, another prospective, randomized, controlled study comparing pelvic floor exercises plus anal exercises taught via digital examination with either manometry or anal ultrasound-guided bio-feedback in 120 adults with fecal incontinence had failed to show any additional benefit of behavior therapy over Kegel exercises in terms of clinical outcome, quality of life measurements, and anal pressures^[27]. In this trial, a clinical benefit was evident in the short term in approximately 70% of all patients. The same group then reported this clinical benefit as substantially preserved in the long term follow-up^[28]. Interestingly, quality of life measurements and subjective perception of “catching up” with incontinence improved even in patients whose incontinence scores worsened. Therefore, intervention “*per se*” seems to improve subjective symptoms perception in fecal incontinence.

Do predictors of outcome exist

Although it is traditionally thought that subgroups of patients (demented, mentally retarded, young children, severely depressed, mobility impaired) are less prone to respond to bio-feedback training, there are few data to support these concepts as guidelines^[29]. The available data may be

summarized as follows: (1) severe mechanical damage of the anal sphincters is generally associated with poor bio-feedback responses^[30,31]; (2) major sensory impairment determines a poor response to bio-feedback training^[16,26,32]; (3) although many studies have not found the response to bio-feedback predictable on the basis of pretreatment findings^[33–35], there are reports showing that a low basal pressure of the internal anal sphincter is associated with poor outcomes^[36]; (4) abnormally prolonged pudendal nerve conduction times are employed to identify subjects with pudendal nerve injuries as a cause of incontinence; these measurements correlate poorly with the response to bio-feedback^[37]; (5) there is no significant association between fecal incontinence and anxiety or depression^[38,39], the latter, however, may decrease the patient’s ability to learn and to comply with home practice^[40]; (6) the association of constipation by outlet dysfunction may affect outcome unfavorably^[41].

Associate treatments

There are several reports of miscellaneous combinations of bio-feedback with surgical procedures to treat fecal incontinence. Results described as positive have been reported for high imperforate anus repair^[42], gracilis muscle transposition^[43], and anterior resection of the rectum and total colectomy with ileo-anal anastomosis^[44]; however, all these were uncontrolled studies, and the patient sample’s were small. Other studies associated electrical stimulation with pelvic floor bio-feedback in a miscellaneous group of patients (including subjects with fecal incontinence and subjects with constipation due to pelvic floor dysfunction), and claimed that this association was more effective than a single approach^[45]. Real-time ultrasonographic imaging of the pelvic floor muscles has also been employed to teach patients with fecal incontinence to squeeze the external anal sphincter^[46], but the trials with this technique are still ongoing. Loening-Baucke implemented standard medical care with a pressure bio-feedback protocol in a small group of adults with fecal incontinence. No additional benefit could be evidenced compared to standard medical care alone^[47].

Conclusions

Although fecal incontinence is a socially devastating disorder, many physicians are still unaware that it is often amenable to treatment^[48]. Recently, well-designed, randomized trials have shown that standard medical care implemented with simple pelvic floor exercises is effective in a large percentage of patients with fecal incontinence. Attention to diet, scheduled defecations and judicious use of anti-diarrheal medications seem to preserve a relevant role in this “untreatable” disease. Traditionally, bio-feedback techniques have been rated to offer a suitable non-invasive method of approaching the problem superior to conservative simpler therapeutic measurements. This has not been confirmed by randomized, controlled trials. Notwithstanding the reported symptoms improvement in over 2/3 of fecally incontinent patients shown in open trials, and the common belief that behavior therapy is a safe and effective therapeutic option for many patients with fecal incontinence, experimental evidence is giving conflicting results. Properly

designed and carefully analyzed bio-feedback trials are actually needed to prove the effectiveness of this treatment in fecal incontinence. Meanwhile, it is reassuring to know that simple therapeutic measurements may effectively help these individuals affected by such a disabling disorder.

Abstract

AIM: To assess the efficacy of metoclopramide (Met) for prevention of prolonged post-operative ileus in advanced gastric cancer patients undergoing D2 gastrectomy and intra-peritoneal chemotherapy (IPC).

METHODS: Thirty-two advanced gastric cancer patients undergoing D2 gastrectomy and IPC were allocated to two groups. Sixteen patients received Met immediately after operation (group A), and 16 did not (group B). Another 16 patients who underwent D2 gastrectomy without IPC were enrolled as the control group (group C). All patients had received epidural pain control. The primary endpoints were time to first post-operative flatus and time until oral feeding with a soft diet without discomfort. Secondary endpoints were early complications during hospitalization.

RESULTS: Gender, the type of resection, operating time, blood loss, tumor status and amount of narcotics were comparable in the three groups. However, the group C patients were older than those in groups A and B (67.5 ± 17.7 vs 56.8 ± 13.2 , 57.5 ± 11.7 years, $P = 0.048$). First bowel flatus occurred after 4.35 ± 0.93 d in group A, 4.94 ± 1.37 d in group B, and 4.71 ± 1.22 d in group C ($P > 0.05$). Oral feeding of a soft diet was tolerated 7.21 ± 1.92 d after operation in group A, 10.15 ± 2.17 d in group B, and 7.53 ± 1.35 d in group C (groups A and C vs group B, $P < 0.05$). There was no significant difference in respect to the first flatus among the three groups. However, the time of tolerating oral intake with soft food in groups A and C patients was significantly

shorter than that in group B patients. Levels of C-reactive protein (CRP) were significantly lower in group C and there was a more prominent and prolonged response in CRP level in patients undergoing IPC. The incidence of post-operative complications was similar in the three groups except for prolonged post-operative ileus. There was no increased risk of anastomotic leakage in patients receiving Met.

CONCLUSION: The results suggest that a combination of intravenous Met and epidural pain control may be required to achieve a considerable decrease in time to resumption of oral soft diet in advanced gastric cancer patients who underwent gastrectomy and IPC. Furthermore, the administration of Met did not increase anastomotic leakage. Met has a role in the prevention of prolonged post-operative ileus.

INTRODUCTION

The long-term results of treatment for resectable gastric cancer have not shown any significant improvement in recent decades^[1]. Analyses of surgical treatment failure after curative resection have indicated intra-peritoneal recurrence is the major pattern of tumor recurrence^[2]. Large randomized trials of intravenous or radiotherapy have failed to demonstrate any benefit for lowering intra-peritoneal recurrence^[3,4].

Therefore, intra-peritoneal chemotherapy (IPC) as an adjuvant to surgery, may be considered as a rational therapeutic modality.

Although the role of IPC in treating peritoneal seeding or preventing peritoneal recurrence for advanced gastric cancer is still controversial, its use in prophylactic treatment in potentially curative gastric cancer resection has shown improved survival and lower peritoneal recurrence rates in Japan and Korea^[5,6]. There are some prospective randomized trials that have shown a patient with surgery plus IPC was

1.3 more times more likely to survive 5 years than a patient with surgery alone^[6]. However, prolonged post-operative ileus (POI) is one of the most commonly reported complications of IPC^[7-9]. In the situation of an immunocompromised condition induced by surgical trauma, cancer, and chemotherapy, prolonged gastro-intestinal (GI) tract stasis can increase the potential for bacterial overgrowth and translocation, potentially leading to systemic sepsis and multiple organ failure, both of which are the most prevalent post-operative complications causing death^[10,11].

To our knowledge, there are few reports concerning aggressive treatment or prevention of POI in patients undergoing IPC. Most treatments for this problem are largely supportive, including naso-gastric (NG) decompression, intravenous hydration and parenteral nutrition.

Metoclopramide (Met) antagonizes central and peripheral dopamine receptors and sensitizes GI tract receptors to acetylcholine^[12-14]. These actions increase peristalsis in the antrum, duodenum, and jejunum and increase the lower esophageal pressure. In previous studies about the effect of Met on intestinal motility, major surgical procedures have not been combined with intensive regional chemotherapy. The incidence of prolonged POI was reported as relatively low and the prophylactic use of Met as seemingly unnecessary or ineffective^[15-19].

The present study was a prospective, controlled trial in which only gastric cancer patients who underwent sub-total or total gastrectomy were enrolled. The aim of the study was to assess the effects of Met on the IPC-induced ileus.

MATERIALS AND METHODS

This study was approved by the institutional review board of Tri-Service General Hospital and informed consent was obtained from patients and family members. It was a prospective, controlled study conducted in the above hospital from March 2001 to October 2004, involving patients lesser than 70 years who had undergone R0 curative gastrectomy with D2 lymph node, i.e., N1 and N2, dissection^[20] followed by IPC for advanced gastric cancer, including T3 (serosal penetration) or T4 (invasion of adjacent organs), according to the Japanese Classification of Gastric Carcinoma^[21]. The type of resection, total or sub-total gastrectomy, depended on the location and Bormann type of primary tumor. After the potentially curative operation was performed, the peritoneal cavity was extensively washed, using seven liters of physiologic saline (1 L, seven times), followed by IPC with mitomycin-C (MMC) 10 mg in 1 L normal saline, for 60 min for all patients. The patients were allocated into two groups of 16 patients each. Patients in group A received intravenous Met 10 mg, every 8 h, commencing immediately after completion of the operation and continued until oral feeding with soft diet was resumed or abdominal cramping pain developed. Patients in group B received an equivalent volume of 5% dextrose in water, and did not receive Met. A control group (group C) of further 16 patients did not receive IPC and Met. All patients had received epidural pain control for the first three post-operative days, and then pain control was changed to intramuscular meperidine

on post-operative day (POD) four in three groups.

Epidural pain control

Before surgery, a thoracic epidural catheter was inserted at T₈-T₁₀ and advanced 5 cm into the epidural space. A test dose of 3 mL of 2% lidocaine containing epinephrine (5 µg/mL) was administered to rule out intra-thecal or intravascular misplacement. After pre-operative assessment of the epidural block, general anesthesia was induced with fentanyl (2 µg/kg), cisatracurium (2 mg), thiamylal (3-5 mg/kg), and lidocaine (1.5 mg/mg) by intravenous (IV) administration, and tracheal intubation was facilitated with succinylcholine (1.5 mg/mg). General anesthesia was maintained with desflurane in oxygen (300 mL/min) in a totally closed circuit system where the end-tidal desflurane concentration was maintained at 7.5±0.5%. Cisatracurium was used for muscle relaxation. No additional intravenous opioid was given during operation. Standard monitors included pulse oximetry, electrocardiography, central venous pressure measurement, and intra-arterial pressure measurement via a radial artery catheter. At the end of surgery, the residual neuromuscular block was antagonized with edrophonium (4 mg) and atropine (0.6 mg); the endotracheal tube was removed when the patient breathed spontaneously. After surgery, all patients received a uniform epidural pain control regimen consisting of morphine (1 mg) in 10 mL of 0.095% bupivacaine every 8 h until 72 h. If pain relief was insufficient, meperidine (50 mg every 6 h) was given. Acetaminophen tablets or meperidine were administered after termination of epidural pain control.

Postoperative care

Serum electrolytes were monitored and corrected in the first seven post-operative days for all patients. Serum C-reactive protein (CRP) levels and abdominal drainage fluid amylase levels were determined post-operatively in all patients. Pancreatic leakage was suspected if the amylase levels of abdominal drainage fluid rose to more than 4 000 U/L^[22]. NG tubes were removed immediately after operation in patients receiving a total gastrectomy and maintained for one day in patients receiving a sub-total gastrectomy. Indication of NG tube reinsertion was biliary vomiting or abdominal distension. Oral intake with 5% glucose solution resumed immediately after the first bowel flatus, and then progressed to a soft diet two days later, if no abdominal discomfort developed. Patients who could not resume oral intake of a soft diet beyond the seventh POD and have generalized ileus shown in plain abdominal x-ray film (KUB) (Figure 1), were defined as having prolonged POI. The epidural catheter was removed routinely on the third POD (approximately 72 h after surgery). The main aim of the study was to compare the length of time of IPC-induced ileus. Therefore, data collected included time to the first post-operative bowel flatus, and number of days required for patients to tolerate a soft oral diet. Narcotic use was recorded for comparison among the three groups. Other information analyzed included operation time, type of resection, blood loss, and complications.

Student's *t*-test, Fisher exact test or the Mann-Whitney *U*-test were used in the statistical analysis. Probabilities of less than 0.05 were accepted as significant.

RESULTS

There were no major differences among the three groups with regard to clinico-pathological characteristics (Table 1). However, patients receiving IPC were younger than those not receiving IPC (56.8 ± 13.2 , 57.5 ± 11.7 years *vs* 67.5 ± 17.7 years, $P = 0.048$). All three groups had an increase of serum CRP post-operatively (Figure 2). Group A and B patients, however, had much higher levels of CRP, which were significantly raised at the first day post IPC, compared with the group C patients ($P < 0.05$). There was a more prominent and prolonged response in patients undergoing IPC.

The mean time of first flatus and resumption of glucose solution was not different among the three groups (Table 2). Regarding a soft oral diet, however, there was a significantly shorter mean time in group A patients compared with group

B patients (7.21 ± 1.92 d *vs* 10.15 ± 2.17 d, $P < 0.05$) and no difference between group A and group C (7.21 ± 1.92 d *vs* 7.53 ± 1.35 d, $P > 0.05$). There was one death (6.25%) secondary to aspiration pneumonia and sepsis in group B. Several complications (prolonged POI, wound infection, pneumonia, anastomotic leakage, pancreatic leakage) are shown in Table 3. The patients in group B have a higher incidence of prolonged POI. All complications were successfully treated with medical therapy, except for one case of aspiration pneumonia leading to the only death.

DISCUSSION

Prolonged POI is a significant problem after abdominal surgery, especially when accompanied by IPC. This study indicates that intravenous Met, combined with thoracic epidural pain

Table 1 Clinicopathological characteristics of patients in three groups

	Group A (n = 16)	Group B (n = 16)	Group C (n = 16)	P

Table 3 Postoperative complications and mortality

	Group A ^b (n = 16)	Group B ^b (n = 16)	Group C ^b (n = 16)	P
Death	0	1 ¹	0	NS
Prolonged POI	1 (6.25)	9 (56.26)	1 (6.25)	<0.01
Wound infection	2	1	2	NS
Pneumonia	2	3	2	NS
Anastomotic leak	0	0	1	NS
Pancreatic leak	3	3	2	NS

¹The patient died of aspiration pneumonia and sepsis. Significant difference in prolonged POI ($^bP < 0.01$) between group B and groups A and C. Prolonged POI was defined as intolerance to oral soft diet more than 7 d and generalized ileus shown in KUB. Pancreatic leakage was defined as amylase level of abdominal fluid more than 4 000 U/L. POI: post-operative ileus. NS: not significant.

Figure 1 One patient in group B developed biliary vomiting on the 7th post-operative d. The supine abdominal plain x-ray film showed generalized ileus. (Arrow: dilated colonic air; arrow head: water-soluble contrast media retention in proximal jejunum).

Figure 2 Serial measurement of CRP levels in three groups of patients (group A, with IPC and Met treatment; group B, with IPC but without Met treatment; group C, without IPC and Met) at eight different time points. The change of serum CRP were found to be prominent and prolonged in groups A and B. The data are expressed as mean±SD.

control, could effectively prevent prolonged IPC-induced ileus in gastric cancer patients. Further it is indicated that the administration of intravenous Met in patients receiving GI resection does not increase the risk of leakage of the newly constructed GI anastomosis.

IPC, with or without hyperthermia, has been used successfully for a variety of intra-abdominal malignancies, especially ovarian and GI tract cancer^[23,24]. Although it has many advantages, such as a high cytotoxic level of intra-peritoneal drug and less systemic toxicity, it is associated with morbidity. Prolonged POI is one of the most consistent and common side effect^[7,8,25,26]. Prolonged POI was also observed in our study in which intra-peritoneal infusion of MMC was performed in 32 patients. Of these patients, 10 (31.2%) developed prolonged POI, especially in group B (56.25%). This is a higher incidence compared with a previous report that indicated an incidence of 42%. The reason of the higher incidence might partly be due to us giving a more clear definition of prolonged POI in our study.

POI is a poorly understood complication in post-surgical patients. The autonomic nervous system, inflammatory mediators, neurotransmitters, and opioid receptors have all been implicated in the pathophysiology of POI^[27-32]. With

respect to the inflammatory response to surgery, Cannon and Murphy demonstrated in 1906 that opening the peritoneum in dogs and surgical manipulation of the bowel resulted in decreased peristalsis^[33]. More recently Kalfff *et al.*^[31], showed an association between bowel manipulation and impaired contractile activity, noting increased neutrophil infiltration of the muscularis. Surgical manipulation of the bowel and subsequent ileus has been linked to the release of inflammatory mediators from WBC. The inflammatory mediators released as part of a stress response contributes to the development of POI. In general, it is characterized as a temporary impairment of intestinal motility after surgery. Usually different areas of the GI tract resume function at different times. The stomach can take 24-48 h to recover, whereas the colon requires 72-120 h to resume normal motility patterns. Thus, uncomplicated POI resolves spontaneously after approximately 3-5 d^[34,35]. Moreover, some studies indicated that after 7 d of fasting, the intestinal mass decreased by nearly 50%, which might increase the risk of bacterial translocation and septic complications^[36-38]. Therefore, we made a definition of prolonged POI as intolerance of soft diet exceeding 7 d after operation and generalized ileus in KUB. Abdominal surgical procedures may be responsible for the uncomplicated POI. However, extensive surgical procedures, IPC, or a combination of both, may be responsible for prolonged ileus. Stimulation in the small intestine, such as mechanical inflammation after surgical manipulation, may be enhanced by chemical inflammation after IPC, and thus prolong reasonably predictable uncomplicated POI. This was clearly observed in our study which indicated that more patients receiving IPC developed prolonged POI than patients not receiving IPC. Indeed, the concentration of acute phase protein (CRP) in the blood samples of the patients receiving IPC exceeded the level in patients not receiving IPC, suggesting IPC may worsen POI by increasing an inflammatory response.

Prolonged POI and GI tract stasis, in the situation of an immuno-compromised condition induced by cancer, surgical trauma and chemotherapy, will increase the potential for bacterial overgrowth and translocation, which could lead to systemic sepsis and multiple organ failure. Both these post-operative complications are the most prevalent causes of death^[9,10]. Clearly, it is important to find a strategy for preventing or treating these problems.

Met has been used as a prokinetic agent for many years and may potentially influence motility throughout the GI tract^[11-13]. It has both a central and peripheral anti-dopamine effect as well as a direct and indirect stimulatory effect on cholinergic receptors. Dopaminergic receptors have been identified throughout the GI tract. It has also been suggested that the prokinetic effect of Met may be due to the stimulatory effect on cholinergic receptors and the blockade of dopamine receptors that inhibit the release of acetylcholine. This inhibition of dopamine and augmentation of acetylcholine release are thought to sensitize the muscarinic receptors of the GI smooth muscle, allowing for coordinated intestinal motor function. However, results of several studies on the effect of Met on POI have been varied. Some studies have supported the hypothesis that Met reduces the length of POI^[39,40], whereas others refute it^[14-19]. In this study, the effect of Met on preventing prolonged POI was obvious. There

were some differences in our study compared to previous studies about the effect of Met on POI. Firstly, our study focused on prolonged POI, not uncomplicated POI. Moreover, we have a more clear definition of prolonged POI. Met may not change the course of uncomplicated POI, however, it could prevent IPC-induced prolonged POI. Theoretically, prolonged POI has more important and deleterious effect on clinical outcome than uncomplicated POI. However, there was no obvious effect of Met on clinical outcome. Small sample of this study might be the reason. Secondly, all our patients received thoracic epidural pain control. Thoracic epidural analgesia shortens POI via this mechanism by not only blocking pain and lessening stress, but also by inhibiting sympathetic efferent nerve transmission to the gut while preserving motility-promoting parasympathetic stimulation in the sacral region. Parasympathetic innervation via both the vagus nerve and sacral nerve roots can be spared, while sympathetic innervations to the gut (T5-L2) can be selectively blocked when local anesthetics are delivered through a mid-thoracic epidural catheter^[41-43]. In our study, however, most of the patients in group B who received IPC without Met administration developed prolonged ileus, even though they all had epidural pain control. This might be due to epidural anesthesia could not completely abolish IPC-induced inflammatory inhibition of intestinal motility. In contrast, additional administration of Met in group A patients can sensitize the muscarinic receptors of the GI smooth muscle, allowing for coordinated intestinal motor function even though these patients had underwent IPC and vagotomy. Therefore, the time to resumption of soft diet was significantly reduced by Met when compared without Met (Table 3). It is believed that the combination of Met and epidural pain control has a synergic effect on the motility of the GI tract.

An important consideration is whether it is safe to promote intestinal motility by epidural anesthesia or intravenous Met immediately after operation. Some authors have questioned whether Met or epidural anesthesia might be harmful to healing of GI anastomoses because of the increased bowel motility^[44,45]. In the present study, however, no patient developed anastomotic leakages after administration of Met and epidural anesthesia. Our findings do not support the common fear that disturbance to healing of GI anastomoses and an increased risk of anastomotic leakages are linked with early increase of GI motility. Similar results to ours have been reported by some authors^[46,47]. Moreover, early removal or no use of an NG tube after operation is safe in patients receiving Met, only one patient needed reinsertion of the tube in our patients. The concept has been speculated by some investigators^[48,49].

Prolonged POI occurs frequently in patients undergoing extended gastrectomy and IPC, increasing the time needed to achieve nutritional goals, and limiting the benefit of early enteral feedings. This study was the first to examine the role of Met in a group of advanced gastric cancer patients undergoing extended gastrectomy and IPC. Our results demonstrated a clear improvement in the resumption of oral soft diet in the Met-treatment group during the 1st wk post-operatively compared with the no-treatment group (7.21 ± 1.92 d *vs* 10.15 ± 2.17 d, $P < 0.05$). There is a theoretical

possibility that improvement in nutritional intake might improve outcome. We found no significant differences among three groups in infectious risk, or mortality. This study, however, was not powered to detect small differences in outcome. Further studies with more patients are needed to determine whether patient outcomes can be improved by the administration of Met in clinical outcome.

In conclusion, Met with epidural pain control prevents prolonged POI at an early post-operative stage in advanced gastric cancer patients undergoing gastrectomy and IPC. We conclude that Met can be used as a safe prokinetic drug for post-operative intestinal dysmotility worsened by IPC.

Abstract

AIM: Human β -defensin (HBD)-1 and HBD-2 are endogenous antimicrobial peptides. Unlike HBD-1, the HBD-2 expression is augmented by *Helicobacter pylori* (*H. pylori*). We sought to determine HBD-1 and HBD-2 concentrations in gastric juice during *H. pylori* infection.

METHODS: HBD-1 and HBD-2 concentrations were measured by radioimmunoassay in plasma and gastric juice of 49 *H. pylori*-infected and 33 uninfected subjects and before and after anti-*H. pylori* treatment in 13 patients with *H. pylori*-associated gastritis. Interleukin (IL)-1 β and IL-8 concentrations in gastric juice were measured by enzyme-linked immunosorbent assay (ELISA). Histological grades of gastritis were determined using two biopsy specimens taken from the antrum and corpus. Reverse phase high performance liquid chromatography (RP-HPLC) was used to identify HBD-2.

RESULTS: HBD-2 concentrations in gastric juice, but not in plasma, were significantly higher in *H. pylori*-positive than -negative subjects, albeit the post-treatment levels were unchanged. Immunoreactivity for HBD-2 was exclusively identified in *H. pylori*-infected mucosa by RP-HPLC. HBD-2 concentrations in gastric juice correlated with histological degree of neutrophil and mononuclear cell infiltration in the corpus. IL-1 β levels correlated with those of IL-8, but not HBD-2. Plasma and gastric juice HBD-1 concentrations were similar in *H. pylori*-infected and uninfected subjects.

CONCLUSION: Our results place the β -defensins, especially

INTRODUCTION

Helicobacter pylori (*H. pylori*) infection is the major cause of chronic gastritis and peptic ulcer disease and is a risk factor for gastric cancer^[1,2]. The non-invasive organism colonizes the gastric epithelium and elicits specific antibodies against various immunogenic proteins derived from the bacteria^[3]. *H. pylori*-associated gastritis is characterized by intense infiltration of neutrophils and mononuclear cells into the lamina propria^[4,5]. However, despite these humoral and cellular immune responses, the infection usually lasts a lifetime in the absence of antibiotic treatment^[5]. Moreover, current anti-*H. pylori* combination regimens are rather complicated and do not always result in cure of the infection because *H. pylori* strains often develop resistance to antibiotic drugs^[3,6].

Recently, various endogenous anti-microbial peptides have been identified as key elements of innate host defence against infection^[7,9]. Defensins, single chain cationic peptides of molecular weight ranging from 3 000 to 4 500 Da, are one of the most extensively studied classes of such naturally occurring antibiotics^[7,9]. They exhibit a wide variety of microbicidal activities against Gram-positive and -negative bacteria, mycobacteria, fungi and certain enveloped viruses^[7,9]. Human defensins are divided into α - and β -defensins, based on the arrangements of three intra-molecular disulfide bridges^[7,9]. At present, four members of β -defensins have been isolated in humans^[7-11]. They are essentially synthesized in the epithelial compartment at various mucosal sites^[7-11].

Recent *in vitro* studies showed the constitutive expression of human β -defensin (HBD)-1 and induced expression of HBD-2 in several gastric cancer cell lines in response to

H. pylori infection^[12-14]. Exclusive enhancement of HBD-2 expression upon *H. pylori* infection was also noted in patients with chronic gastritis^[15,16]. However, there is no information on the secretion of HBD-2 into the gastric lumen *in vivo* or its concentrations in gastric juice during *H. pylori* infection.

We have developed a sensitive, specific radioimmunoassay (RIA) for HBD^[17]. Employing this assay system, we measured HBD-2 concentrations in gastric juice of *H. pylori*-infected and uninfected individuals. This study paves the way for further understanding of the mechanisms involved in host immune response to this pathogen.

MATERIALS AND METHODS

Patients and sampling

A total of 82 patients referred for diagnostic upper gastro-intestinal endoscopy between September 2002 and August 2003 were enrolled in the present study. The following exclusion criteria were applied for enrollment in the study. (1) The use of non-steroidal anti-inflammatory drugs, proton pump inhibitors, histamine H₂-receptor antagonists or antibiotics within 4 wk prior to the present study; (2) History of severe concomitant diseases, upper gastro-intestinal surgery, peptic ulcer diseases and gastric cancer. On the day of endoscopy, blood samples were taken, transferred into tubes containing EDTA-2Na and aprotinin, centrifuged, plasma separated, and stored at -80 °C until assay.

At the beginning of endoscopy (XQ 200; Olympus Optical Co., Tokyo, Japan), a sample of the gastric juice was aspirated into collection tube containing EDTA-2Na and aprotinin using an aspiration instrument (PW-6P-1, Olympus) under endoscopic guidance. Gastric juice samples were immediately neutralized to pH 7.0 with 1 N NaOH and frozen at -80 °C until measurement. Two biopsy specimens were endoscopically obtained from both the antrum within 2 cm of the pyloric ring and the middle portion of the corpus along the greater curvature, fixed in 10% buffered formalin and embedded in paraffin. One was used for rapid urease test (Helicocheck, Otsuka Pharmaceutical Co., Tokushima, Japan) and another for histopathological and immunohistochemical assessments.

Fourteen patients with *H. pylori*-associated gastritis were treated with eradication therapy consisting of lansoprazole (30 mg twice daily), amoxicillin (750 mg twice daily) and clarithromycin (400 mg twice daily) for 7 d^[18]. Four weeks after cessation of the treatment, patients were examined by endoscopy again, and gastric juice and biopsy specimens were taken in a similar fashion to that performed before treatment.

Eradication of *H. pylori* was considered successful when ¹³C-urea breath test was negative^[18].

Histopathological examination

Paraffin-embedded biopsy specimens were cut into 4- μ m thick sections and stained with hematoxylin and eosin. Each histological parameter of activity (neutrophils), chronic inflammation (mononuclear cells), glandular atrophy and intestinal metaplasia in the antrum and corpus of patients with *H. pylori* infection was scored as 0, 1, 2 or 3 corresponding to none, mild, moderate or severe, respectively, based on

the Sydney system^[19,20]. Intestinal metaplasia was defined by the presence of goblet cells in glandular mucosa with Alcian blue (pH 2.50)/periodic acid-Schiff staining^[21].

Furthermore, the density of *H. pylori* colonization assessed with Giemsa staining was also scored from 0 to 3, based on the above classification system^[19,20]. The biopsy specimens were examined blindly without knowledge of the results of β -defensins measurement.

Diagnosis of H. pylori infection

H. pylori status was assessed by serology (anti-*H. pylori* immunoglobulin G antibody, HEL-p TEST, AMRAD Co., Melbourne, Australia), rapid urease test and histology with Giemsa staining. Patients were considered positive for *H. pylori* infection when at least two of these examinations yielded positive results^[20,22]. On the other hand, patients were defined as *H. pylori*-negative, if all test results were negative^[23].

Measurement of interleukin (IL)-1 β and -8 levels in gastric juice

The concentrations of interleukin (IL)-1 β and -8 in gastric juice were measured as described previously^[20,22,24]. The samples were assayed for total protein by a modified Lowry method, diluted to 0.5 mg/mL total protein concentration, and frozen at -80 °C until assay. Measurement of the two cytokines in the aliquots was performed using commercially available assay kits (Research and Diagnostics, Minneapolis, MN, USA), which employ the quantitative immunometric sandwich enzyme immunoassay technique. These assays were performed in duplicate according to the instructions provided by the manufacturer. In our study, inter- and intra-assay variabilities were <10%, respectively^[20,22].

Measurement of HBD-1 and -2 levels in plasma and gastric juice

The concentrations of HBD-2 in plasma and gastric juice samples were measured by RIA established in our laboratory^[17]. Briefly, full-length HBD-2 was synthesized using a peptide synthesizer (model 430, Applied Biosystems, Foster City, CA, USA) and purified by reverse phase high performance liquid chromatography (RP-HPLC). Synthetic HBD-2 was used for immunizing New Zealand white rabbits by multiple intracutaneous and subcutaneous injections. It was radio-iodinated and the ¹²⁵I-labelled peptide was purified by RP-HPLC on a TSK ODS 120A column (Tosoh Co., Tokyo). The diluted sample or a standard peptide solution (100 μ L) was incubated for 24 h with 100 μ L antiserum diluent (final dilution 1:4 200 000). The ¹²⁵I-labelled solution (16 000 cpm in 100 μ L) was added and the mixture was incubated again for another 24 h. Normal rabbit serum and anti-rabbit IgG goat serum were then added and stored for 16 h. Bound and free ligands were separated by centrifugation. All procedures were performed at 4 °C and duplicate assays were carried out. Volumes of 0.5 mL plasma and 1-2 mL gastric juice were used to determine the levels of HBD-2. The concentrations of HBD-1 were also measured in similar fashions. The intra-assay and inter-assay coefficients of variation were <10%, respectively, in both the RIA analyses^[15,23].

Chromatographic characterization of HBD-2

Chromatographic characterization of HBD-2 was performed as described previously^[26,27]. Each 10 mg wet weight of non-cancerous mucosal tissue was sampled from surgically resected stomach of three patients with gastric cancer and *H. pylori* infection. The samples were immediately homogenized and aliquots of homogenate supernatants, obtained by centrifugation (10 000 g for 10 min), were used for RP-HPLC on a TSK ODS SIL 120A column (Tosoh Co.). A linear gradient of acetonitrile (CH₃CN) from 10% to 60% in 0.1% trifluoroacetic acid (pH 2.0) was used at a flow rate of 1.0 mL/min for 50 min. All fractions were analyzed for HBD-2 employing RIA.

Statistical analysis and ethical considerations

Statistical analyses were performed using Fisher's exact, χ^2 , Student's *t*, Mann-Whitney *U*, Kruskal-Wallis, Spearman rank and Wilcoxon signed ranks tests, as appropriate. A *P* value of less than 0.05 was accepted as statistically significant. Data were expressed as mean \pm SD.

All examinations were conducted according to Good Clinical Practice and the Declaration of Helsinki, and were approved by the university ethics committees. All samples were obtained with written informed consent of the patients prior to their inclusion in the study. All experiments involving animals were approved by the ethics review committees for animal experimentation of participating universities.

RESULTS

Patient demographics

The study population consisted of 49 *H. pylori*-positive and 33 *H. pylori*-negative subjects. They included 38 men and 44 women, with mean age of 50 years (range, 25-78 years). There were no significant differences between the *H. pylori*-positive and -negative groups in background data on age, sex, body mass index, current tobacco use and alcohol intake (Table 1).

Table 1 Baseline characteristics

	<i>H. pylori</i> -positive (n = 49)	<i>H. pylori</i> -negative (n = 33)
Mean age, ys (range)	49.9 (25-72)	49.6 (28-78)
Male/female	24/25	14/19
Smoker	17 (34.7%)	12 (36.4%)
Alcohol drinker	16 (32.7%)	10 (30.3%)

Plasma and gastric juice β -defensins concentrations according to *H. pylori* status

HBD-2 levels in gastric juice of patients with *H. pylori* infection were significantly higher than those of *H. pylori*-negative subjects ($P < 0.0005$, Table 2), whereas infection had no significant impact on plasma concentrations of HBD-2 (Table 2). There were no significant differences in HBD-1 concentrations both in plasma and gastric juice with respect to *H. pylori* status (Table 2). The levels of β -defensins in gastric juice did not correlate with those in plasma

(correlation coefficient, $r = 0.036$ and -0.005 for each HBD-1 and HBD-2). In addition, there were no significant correlations between HBD-1 and HBD-2 levels in plasma ($r = -0.077$) and gastric juice ($r = -0.092$).

Correlation between HBD-2 and cytokine levels in gastric juice

There were significant differences in IL-1 β and IL-8 concentrations in gastric juice between *H. pylori*-positive and -negative subjects ($P < 0.05$ and $P < 0.005$, respectively, Table 2). HBD-2 concentrations in gastric juice did not correlate with IL-1 β and IL-8 levels ($r = -0.055$ and $r = 0.121$, respectively). There was a positive correlation between IL-1 β and IL-8 concentrations ($r = 0.575$, $P < 0.0001$).

Table 2 Plasma and gastric juice HBD-1 and HBD-2 levels and gastric juice IL-1 β and -8 concentrations

	<i>H. pylori</i> -positive (n = 49)	<i>H. pylori</i> -negative (n = 33)	<i>P</i>
Plasma			
HBD-1 levels (ng/mL)	10.1 \pm 0.9	9.6 \pm 1.8	NS
HBD-2 levels (pg/mL)	276.2 \pm 61.0	257.2 \pm 56.0	NS
Gastric juice			
HBD-1 levels (pg/mL)	384.2 \pm 101.5	357.9 \pm 79.6	NS
HBD-2 levels (pg/mL)	230.3 \pm 77.4	118.1 \pm 87.7	<0.0005
Interleukin 1 β levels (mg/mL)	53.6 \pm 16.9	5.3 \pm 4.4	<0.05
Interleukin 8 levels (pg/mL)	17.9 \pm 3.1	8.6 \pm 1.7	<0.005

¹Human β -defensin, NS: not significant.

Correlation between gastric juice HBD-2 concentrations and histopathological parameters

As shown in Table 3, HBD-2 concentrations in gastric juice correlated positively with the scores of activity and chronic inflammation in the corpus ($P < 0.005$ and $P < 0.05$, respectively), but not with glandular atrophy and intestinal metaplasia scores in the corpus. On the other hand, there were no significant correlations between HBD-2 concentrations and each score of gastritis in the antrum. In addition, *H. pylori* density in the antrum and corpus did not correlate with HBD-2 concentrations in gastric juice.

Table 3 Correlation coefficients between gastric human- β -defensin 2 levels and each histological parameter

	Correlation coefficient	<i>P</i>
Antrum		
Activity	0.048	NS
Chronic inflammation	0.258	NS
Glandular Atrophy	0.148	NS
Intestinal Metaplasia	-0.063	NS

Effects of eradication treatment on gastric juice concentrations of HBD-2, IL-1 β and IL-8

Successful eradication of *H. pylori* was achieved in 10 of 14 (71%) with the triple therapy. At 4 wk after completion of the 7-d treatment, HBD-2 concentrations in gastric juice of these patients were not significantly different from those measured before eradication therapy (Table 4). However, *H. pylori* eradication was associated with a significant fall in IL-1 β , and IL-8 levels of gastric juice compared with pre-treatment levels ($P < 0.05$ and $P < 0.005$, respectively, Table 4).

In patients who were still infected with *H. pylori* after antibiotic treatment, HBD-2, IL-1 β and IL-8 levels in gastric juice remain unchanged compared to the pre-treatment concentrations (Table 4).

Chromatographic characterization of HBD-2

Immunoreactive HBD-2 was identified in the gastric mucosa infected with *H. pylori* on RP-HPLC coupled with RIA (Figure 1). The peak was situated at a position identical to that of synthetic HBD-2 peptide. Each sample prepared yielded the same chromatographic pattern.

Figure 1 Representative RP-HPLC profiles of the HBD-2 molecules in *H. pylori*-infected gastric mucosa.

DISCUSSION

Recent studies have shown the inducible expression of HBD-2 messenger ribonucleic acid (mRNA) in response to *H. pylori* infection in cultured gastric epithelial cells^[12-14]. In clinical setting of gastritis, the HBD-2 mRNA and peptide expression is evidently increased in gastric mucosa infected with the organism^[15,16]. There are a few *in vitro* observations of the secretion of HBD-2 peptide upon *H. pylori* infection. George *et al.*^[26], showed its enhanced release in supernatants from

infected gastric cancer cell lines by Western blotting. However, the actual concentrations of such antimicrobial peptides at the local site of human stomach during *H. pylori* infection remain unknown. Our sensitive RIA system allowed us to determine the HBD-2 concentrations in gastric juice, as well as in other body fluids and blood^[17,25]. Thus, we demonstrated, for the first time, that the HBD-2 levels in gastric juice of *H. pylori*-infected patients were significantly higher than those of uninfected ones, suggesting its physio-pathological significance in the bacterial infection. In contrast, *H. pylori* status did not have a significant impact on plasma HBD-2 levels. Immunoreactivity for HBD-2 was identified in *H. pylori*-infected gastric mucosa by RT-HPLC combined with RIA. In agreement with the results of previous studies^[15,16], immunohistochemical staining against anti-HBD-2 antibody within the infected mucosa was confined to the superficial epithelial cells. Taken together, we believe that *H. pylori* infection stimulates the biosynthesis of HBD-2 in gastric mucosa, primarily in epithelia confronting this organism^[15], and the product is mainly released into the gastric lumen.

In the present study, however, there was no significant difference in gastric juice, HBD-2 levels before and 4 wk after cure of the infection, and in certain cases, post-treatment HBD-2 levels were rather increased compared to the pre-treatment ones. In contrast, Hamanaka *et al.*^[15], reported that epithelial HBD-2 expression assessed by immunohistochemistry was markedly decreased in gastric specimens obtained 4 wk after eradication of *H. pylori*, concomitant with the pronounced reduction of its transcripts to undetectable levels by reverse transcription-polymerase chain reaction (RT-PCR). These results must be interpreted within the context of studies' limitations including their small sample sizes, differences in samples assessed-gastric biopsy tissues *vs* gastric juice- and diverse methodological approaches to HBD-2. Nevertheless, one might postulate the mingling of HBD-2 secreted by the other cells than gastric epithelial cells, such as esophageal squamous cells, in the gastric juice. In fact, more than 95% of biopsy specimens from the esophagus were positive for the β -defensin mRNA on RT-PCR analysis^[16]. Several recent studies have shown that elimination of *H. pylori* infection would lead to the development of gastro-esophageal reflux disease, probably in some cases, in association with post-treatment increase in acid secretion^[27-29]. At present, however, there is no information available as to whether the esophageal HBD-2 expression is altered during this condition or upon such stimuli as refluxates with increased acidity.

We found the association of HBD-2 concentrations in gastric juice with histological degree of mucosal infiltration of neutrophils and mononuclear cells in the corpus, but not in the antrum. In line with this, Wehkamp *et al.*^[16], reported that *H. pylori* colonization was significantly related to higher percentage of positive biopsies taken from the corpus with respect to HBD-2 transcripts. The sparse distribution and confined localization to cells of the apical foveolae of this peptide^[15,16] may be attributable to the topographical differences in HBD-2 expression. In addition to the direct anti-microbial activity, evidence is accumulating for the role of defensins as immune and inflammatory mediators^[7-9,30]. In fact, β -defensins display chemotactic activities for dendritic cells and T lymphocytes through the chemokine receptor CCR6^[30]. It is possible that β -defensins, especially HBD-2, may be involved in the pathogenesis of *H. pylori*-associated gastritis, in part, via their action as chemoattractant. Again, the HBD-2 levels in gastric juice can provide useful information on histological severity of corporal mucosal inflammation.

Recent *in vitro* studies have demonstrated that HBD-2 mRNA expression is stimulated by pro-inflammatory cytokines such as IL-1 β and tumor necrosis factor α in various cell lines including gastric epithelial cells^[9,12,13]. We have also reported a positive correlation between IL-1 β and HBD-2 concentrations in broncho-alveolar lavage fluid of patients with pneumonia and diffuse panbronchiolitis^[17,23]. In the present study, however, there was no significant correlation between gastric juice HBD-2 and IL-1 β concentrations, whereas the IL-1 β levels strongly correlated with those of IL-8. IL-1 β is known to activate nuclear factor kappa B (NF- κ B)^[31], an important transcription factor regulating a plethora of genes including those of IL-8 and HBD-2^[9,31,32]. In this regard, we demonstrated that mucosal IL-8 levels of patients with *H. pylori*-associated gastritis correlated strongly with the grades of activated NF- κ B expression in gastric epithelial cells^[20,22]. Considered together, these data suggest that IL-8 expression is probably enhanced by IL-1 β -induced NF- κ B activation within the *H. pylori*-infected mucosa. On the other hand, we suggest that the increased expression of HBD-2 in the gastric epithelium may result from the direct contact between this pathogen and epithelial cells *in vivo*.

H. pylori status had no impact on HBD-1 concentrations in gastric juice, providing further evidence for its constitutive nature^[12-14,16]. Since ingestion of contaminated food or water exposes the gastric mucosa to a wide variety of microbial pathogens, the constitutive expression of HBD-1 could play a 'surveillance-like' role during normal homeostasis of human stomach^[33].

The *in vitro* minimal inhibitory concentrations against a panel of micro-organisms range from 0.1 to 100 μ g/mL for defensin peptides^[9]. Hamanaka *et al.*^[15], reported that the growth rate of cultured *H. pylori* was suppressed by 50% on incubation with 0.3 μ g/mL of HBD-2 and was completely inhibited at 30 μ g/mL of this peptide. It remains to be determined whether β -defensins are microbicidal for the organism in gastric milieu *in vivo*. However, it is tempting to speculate that the *H. pylori* strains that are able to establish persistent infection may be rather insensitive to such innate

mucosal defense machinery.

In conclusion, we demonstrated the presence of significantly high levels of HBD-2 in gastric juice in patients with *H. pylori* infection. The enhanced production/release of HBD-2 may contribute to the perpetuation of mucosal inflammation of the corpus. Our results highlight the importance of β -defensins, especially HBD-2, not only in innate defense but also in adaptive immune response to the organism.

Abstract

AIM: To study the effect of IL-10 on the expression of growth factors - transforming growth factor- β 1 (TGF- β 1), epidermal growth factor (EGF), hepatocyte growth factor (HGF) and platelet-derived growth factor (PDGF) of hepatic stellate cells (HSCs) of hepatic fibrosis rat and the anti-fibrogenic role of exogenous IL-10.

METHODS: Hepatic fibrosis was induced by CCl₄ administration intra-peritoneally. Sixty clean male Sprague-Dawley (SD) rats were randomly divided into three groups: normal control group (GN, 8 rats), hepatic fibrosis model group (GC, 28 rats) and IL-10 treated group (GI, 24 rats). At the beginning of the 7th and 11th wk, rats in each group were routinely perfused with pronase E and type IV collagenase through a portal vein catheter and the suspension obtained from the liver was spun by centrifugation with 11% Nycodenz density gradient to isolate HSCs. Histological examination was used to determine the degree of hepatic fibrosis. RT-PCR was employed to analyze mRNA expression from freshly isolated cells. Immunocytochemistry was performed to detect protein expression in primary cultured HSCs.

RESULTS: Rat hepatic fibrosis was developed with the increase of injection frequency of CCl₄, and HSCs were successfully isolated. At the 7th and 11th wk, TGF- β 1, EGF, and HGF mRNA in GC increased obviously compared with GN ($P = 0.001/0.042$, $0.001/0.001$, $0.001/0.001$) and GI ($P = 0.001/0.007$, $0.002/0.001$, $0.001/0.001$). For TGF- β 1, no difference was observed between GI and GN. For EGF, mRNA level in GI increased compared with GN during the 7th wk ($P = 0.005$) and 11th wk ($P = 0.049$). For HGF, mRNA level in GI decreased compared with GN at the 7th wk ($P = 0.001$) and 11th wk ($P = 0.021$). Between these two time points, TGF- β 1 expression at the 7th wk was higher than that of the 11th wk ($P = 0.049$), but for EGF, the former was lower than the latter ($P = 0.022$). As for PDGF mRNA, there was no significant difference between these

groups, but difference seemed to exist in protein levels. Results by immunocytochemistry of TGF- β 1 and EGF were paralleled with the above findings.

CONCLUSION: The expression of TGF- β 1, EGF and HGF increased in HSC of hepatic fibrosis rat and decreased after treatment with IL-10. IL-10 plays an anti-fibrogenic role by suppressing growth factors expression.

INTRODUCTION

Hepatic fibrosis, which represents the wound healing response of the liver is a common sequel to diverse liver injuries, characterized by increased deposition and altered composition of extracellular matrix (ECM). Hepatic stellate cells (HSCs) are the major source of ECM, and believed to be the crucial cell type in the development of hepatic fibrosis^[1,2] and growth factors were considered to exert their effects through autocrine or paracrine on HSCs during the process^[3]. It has been reported that interleukin-10 (IL-10) could relieve the degree of rat hepatic fibrosis induced by carbon tetrachloride (CCl₄). In the present study, based on the established hepatic fibrosis rat model and IL-10 treated model, we isolated HSCs, detected the expression of TGF β 1, EGF, HGF and PDGF of HSC, and tried to explore the relationship between growth factors and hepatic fibrosis and the possible mechanisms of the anti-fibrogenic activities of exogenous IL-10 *in vivo*.

MATERIALS AND METHODS

Establishment of animal models

Sixty clean male SD rats, weighing 200-300 g, were divided randomly into three groups: normal control group (GN, 8 rats), hepatic fibrosis model group (GC, 28 rats) and IL-10 treated group (GI, 24 rats). All rats were bred under routine conditions (room temperature, 22 \pm 2 °C; humidity, 55 \pm 5%; light, 12 h per day; drinking tap water and food

ad libitum. Animal food was provided by BK Company in Shanghai, China. Rats in GN were injected intra-peritoneally with saline at a dose of 2 mL/kg twice a wk; rats in the other two groups received intra-peritoneal injection of 500 mL/L CCl₄ dissolved in castor oil 2 mL/kg twice a week as described previously^[4]. From the 3rd wk, rats in the treated group were given intra-peritoneally IL-10 dissolved in saline 4 µg/kg, 20 min before CCl₄ administration, as proposed by Nelson *et al.*^[5]. The intervention stated above lasted to the end of the experiment.

Histological examination

At the beginning of the 7th and 11th wk, two rats of each group were selected randomly for histological examination. The liver tissues were fixed in 40 g/L formaldehyde and embedded with paraffin. Sections were stained with hematoxylin and eosin (HE) and examined under a light microscope.

Isolation, culture and identification of HSCs

Isolation, culture and identification of HSCs have been described thoroughly in our previous experiments^[6]. Briefly, at the beginning of the 7th and 11th wk, five rats of each group were selected randomly to perfuse successively with 0.13% pronase E and 0.025% type-IV collagenase through a portal vein catheter. The liver tissue suspension was incubated with 0.02% pronase E and 0.025% type-IV collagenase with agitation. Then the suspension obtained from the digested liver was spun by centrifugation with 11% Nycodenz density gradient to purify HSCs. Thereafter, HSCs were seeded at approximately 1×10⁶ cells/mL of Dulbecco's modified eagle medium (DMEM) with 20% fetal calf serum in 96-well plates. Then HSCs were kept in culture at 37 °C in a 50 mL/L CO₂ atmosphere for 72 h. They were identified by their typical phase-contrast microscopic appearance and by immunocytochemistry using antibody directed against desmin. Cell vitality was checked by trypan blue exclusion.

RNA extraction and RT-PCR

Total RNA was extracted from freshly isolated HSCs, according to the RNA isolation kit instructions (Jingmei Biotechnology Company of Shenzhen). Its quantity and purity were assessed by measuring the optical density at 260 and 280 nm. After measurement of RNA amount, samples were either used immediately for reverse transcription (RT) or stored at -70 °C.

For RT, 1 µg total RNA was reversely transcribed following the instructions of first strand cDNA synthesis kit (Jingmei Biotechnology Company of Shenzhen). Reaction mixtures of 20 µL were transcribed using the following program: at 42 °C for 60 min, 99 °C for 5 min, and stored at -20 °C.

For PCR, primers coding for the house-keeping gene β-actin was added to the reaction mixture spontaneously to standardize the results. Reactive systems contained cDNA 2 µL, 10×buffer 5 µL, 25 mmol/L MgCl₂ 5 µL, 10 mmol/L d NTP 1 µL, 20 mmol/L target gene sense and anti-sense primers 1 µL, 20 mmol/L β-actin primer pairs 1 µL, Taq DNA polymerase 3 U, with a total volume of 50 µL by adding aqua. Then PCR was performed with cycle parameters of 45 s at 94 °C, 30 s at 55 °C (TGF-β1) or 58 °C (EGF) or 66 °C (HGF) or 62 °C (PDGF) and 60 s at 72 °C after pre-denaturation for 5 min at 94 °C; final elongation time was 7 min at 72 °C. The number of corresponding cycles for TGF-β1, EGF, HGF and PDGF were 30, 32, 34 and 34, respectively. Primers were designed with reference to GenBank (Table 1). PCR products were immediately analyzed by 2% agarose gel electrophoresis and the density of resultant bands was semi-quantified by scanning densitometry with the ratio of TGF-β1/β-actin2, EGF/β-actin1, HGF/β-actin1 and PDGF/β-actin2.

Immunocytochemistry

Most of HSCs were attached to the dishes after 72 h of primary culture. Then the 96-well plates were washed twice with 0.1 mol/L PBS and fixed with poly-formaldehyde at 4 °C overnight. The following procedures were performed according to the instructions of streptavidin-peroxidase (S-P) kit (Beijing Zhongshan Company). Briefly, cells were washed with PBS, incubated with bovine serum albumin in PBS, reacted with primary antibody dissolved in PBS, washed, incubated with peroxidase-conjugated second antibody, washed, and reacted for 20 min with S-P. Color reaction was developed by incubation with DAB. For negative controls, the primary antibody was replaced by PBS. Table 2 summarizes the characteristics of the antibodies used in this study.

Statistical analysis

All data were expressed as mean±SE. The significance for the difference between the groups was analyzed with SPSS10.0 by one-way ANOVA.

RESULTS

Histological examination

Hepatic fibrosis, as shown histologically, became remarkable with the treatment of CCl₄. During the 7th wk, specimens from GC showed steatosis and ballooning degeneration, the collagen fibers increased and began to extend to the parenchyma, a great number of mononuclear cells and unusual neutrophils surrounded the centrilobular veins and fibrotic septa (Figure 1A), while only a few inflammatory

cells infiltrated around centrilobular veins without evident changes of lobular structure in GI (Figure 1B). At the 11th wk, the reticular fibers extended into hepatic plate and full delimitation was developed in GC (Figure 1C), while less fibrous and inflammatory infiltrates were seen in GI (Figure 1D). Specimens from GN showed normal lobular structure (Figure 1E). Due to the limit of samples, no statistical data could be obtained to present disparity between the two groups, but it still illustrated the trend that fibrogenesis of GI was much less severe than that of GC.

Isolation and identification of HSCs

Totally 2.45×10^7 cells per rat were harvested by the present

method. HSCs were identified by immunoreaction for desmin (Figure 2), the mean purity of freshly isolated HSCs was $(95 \pm 5)\%$. Cell vitality checked by trypan blue exclusion was higher than 95%.

Expression of mRNA

RNA purity was determined by the ratio of A_{260}/A_{280} , which ranged from 1.8 to 2.0. At the 7th and 11th wk, TGF-β1, EGF, and HGF mRNA in GC increased obviously compared with GN and GI ($P < 0.01$). For TGF-β1, no difference was seen between GI and GN. For EGF, mRNA level in GI increased compared with GN at the 7th wk ($P < 0.01$) and 11th wk ($P < 0.05$). For HGF, mRNA level in GI

Figure 2 Desmin expression of HSCs from primary culture for 5 d by immunochemistry (SP×100).

decreased compared with GN at the 7th wk ($P<0.01$) and 11th wk ($P<0.05$). Between these two time points, TGF- β 1 expression at the 7th wk was higher than that of the 11th wk; but for EGF, the former was lower than the latter. As for PDGF mRNA, there was no significant difference between these groups (Tables 3-5, Figure 3 A-C).

Protein expression and immunophenotyping of cells

TGF- β 1, EGF and PDGF positive expressions were localized in cytoplasm and nuclei of HSCs in all groups by immunocytochemistry after primary culture for 72 h. By then, most of the cells were attached and spread over the plastic sub-stratum. At the 7th wk, the size of HSCs in GC and GI was slightly larger than GN, as well as the number and length of pseudopodium. At the 11th wk, cell phenotype in GI was in the form of a circle or an ellipse and slightly smaller than the 7th wk, no obvious change of phenotype was seen in GC compared to the 7th wk. Despite the small number of samples and lack of statistical data, we could still find the tendency that the expression of TGF- β 1, EGF and PDGF in GC was higher than that of GN and decreased after treatment with IL-10 (Figure 4A-F).

DISCUSSION

Although significant progress has been made in understanding the pathogenesis of hepatic fibrosis, a rational therapy that prevents the progression or even reverses established fibrosis remains elusive^[7-9]. IL-10 is produced mainly by TH₂ cells and inhibits functions of TH₁ cells. It downregulates pro-cytokine synthesis and is associated with amelioration of the inflammatory response^[10-12] and fibrosis. The present study also found the trend of IL-10 relieving the degree of inflammation. Then, except for anti-inflammation, is there any other mechanism to fulfill its anti-fibrotic role? In this experiment, we detected the mRNA level of TGF- β 1, EGF, HGF and PDGF of HSCs of rat in hepatic fibrosis group and IL-10 treated group at the 7th and 11th wk.

TGF- β 1 is the most important growth factor involved in the fibrotic and cirrhotic liver. It is known to promote the development of liver fibrosis by inducing synthesis of ECM proteins and downregulating the expression of matrix degrading enzymes and stimulating the synthesis of their respective inhibitors^[13-16]. The present study showed that with the development of hepatic fibrosis, TGF- β 1 mRNA increased in GC compared to GN, and decreased after treatment with IL-10. Specifically, TGF- β 1 mRNA level did not parallel with the progression of hepatic fibrosis. These illustrated further that TGF- β 1 correlated closely with hepatic fibrosis, and it could not be regarded as a predictable factor of the degree of hepatic fibrosis and HSCs' capacity of producing TGF- β 1 declined when fibrosis developed to

a certain extent and that IL-10 exerted its anti-fibrotic activities by attenuating the expression of TGF-β1 of HSCs.

EGF is a potent mitogen for many cells. EGF up-regulation is a characteristic feature of fibrotic liver disease^[17]. Apart from stimulating hepatocyte and bile duct epithelial proliferation, EGF also has a chemotactic mitogen effect on HSCs^[18]. A recent study demonstrated that direct stimulation with TGF-β1 and EGF results in an increased migratory response of activated HSCs^[19]. In the present study, EGF level increased with the presence of hepatic fibrosis or cirrhosis and dropped after intervention with IL-10. It showed that IL-10 inhibited HSCs from proliferating and migrating by reducing autocrine secretion of EGF, thus it limited the spread of disease, and retarded the progression of hepatic fibrosis.

HGF is secreted as a precursor polypeptide that requires proteolytic cleavage to a disulfide-linked heterodimer and binds to a specific receptor known as c-Met^[20] for biological activity. Physiologically, HGF has potent hepatotrophic and cytoprotective functions^[21]. Reports have shown treatment with HGF suppressed the increase of TGF-beta1, reduced

mRNA levels of procollagen, inhibited fibrogenesis and cell apoptosis, and produced complete resolution of fibrosis in the cirrhotic liver, thereby improving the survival rate of rats with this severe illness^[22-26]. In the present experiment, HGF mRNA level of HSCs increased in hepatic fibrosis rats which might reflect intra-hepatic inflammation or the compensation of steatosis of hepatocytes. After intervention with IL-10, HGF mRNA level dropped. So we postulated that IL-10 probably suppressed some cytokines that positively regulated HGF expression by anti-inflammation or immunoreaction or that it indicated normal liver function, or a manifestation of decreased degree of steatosis and degeneration.

PDGF has been identified as the most potent-polypeptide growth factor able to stimulate the proliferation of HSCs^[27-29], which play a critical role in the development of hepatic fibrosis. Although no statistical data were obtained to prove any difference of PDGF mRNA in these groups, which probably resulted from the difference in experimental animals, drugs, reagents and methods, PDGF protein level seemed to show the disparity that it increased in GC and

decreased in GI compared to GN.

Our experiment showed IL-10 exerted anti-fibrotic effect not only by anti-inflammatory reaction but by suppressing the expression of growth factors. Whether IL-10 plays an adverse role in liver regeneration by downregulating the expression of HGFmRNA awaits further studies. Based on the biological effect model of HGF, it is necessary to elucidate its activities at protein and receptor levels, which should provide a promising prospect for the therapy of hepatic fibrosis.

Abstract

AIM: Recent laboratory and epidemiological studies suggest that vitamin D is a potential agent for colorectal cancer prevention. Its function is partially mediated by the vitamin D receptor (VDR). The aim of this study was to investigate whether a novel G (allele 'U')>A (allele 'u') polymorphism (*Tru9I*) in the VDR intron 8 region is associated with risk for colorectal adenoma in a colonoscopy-based case-control study.

METHODS: Genotyping for a total of 391 subjects was carried out through PCR and restriction fragment length polymorphism.

RESULTS: The frequencies of 'U' and 'u' alleles were 89.3% and 10.7%, respectively. The 'Uu' and 'uu' genotypes were associated with decreased risk for adenoma (OR, 0.71; 95%CI, 0.40-1.25). The inverse association was more pronounced for multiple adenomas and adenomas that were larger had moderate or greater dysplasia, or were sessile: the odds ratios (ORs) were, 0.51 (95%CI, 0.21-1.24), 0.37 (95%CI, 0.11-1.28), 0.68 (95%CI, 0.33-1.41), and 0.36 (95%CI, 0.13-0.97) respectively. In joint/combined analyses, inverse associations were more obvious among those who had at least one 'u' allele and also were younger (OR, 0.60; 95%CI, 0.26-1.37), women (OR, 0.38; 95%CI, 0.17-0.88), did not smoke (OR, 0.39; 95%CI, 0.13-1.23), or took NSAID (OR, 0.38; 95%CI, 0.12-1.25), but no evidence existed for interactions with calcium or vitamin D intake.

INTRODUCTION

Colorectal cancer (CRC) is one of the most common cancers in the USA, with an annual incidence of 146 940 cases and 56 730 deaths^[1]. It has been reported that in USA, CRC morbidity is greater in northern latitudes, which may in part be due to lower sun exposure^[2]. Several epidemiological studies support the hypothesis that dermal vitamin D synthesis mediated by sunlight may protect against colorectal cancer; several found decreased risk for this disease with higher serum levels of vitamin D or with increasing dietary vitamin D intake^[3-5]. The vitamin D receptor (VDR), a member of the steroid/thyroid receptor family, mediates genomic actions of the active metabolite of vitamin D [1, 25(OH)₂D₃], and thus regulates cellular proliferation and differentiation^[6-8] and induces apoptosis^[9]. Recent studies show that VDR functions as a sensor of the colorectal carcinogen, lithocholic acid (LCA), inducing *in vivo* expression of the CYP3A family that detoxifies LCA in the liver and intestine^[10]. Based on such findings, there has been increased interest in an interaction between vitamin D and the VDR gene and risk for colorectal cancer. Although contradictory results have been reported^[11-13], evidence suggests that at least some VDR gene polymorphisms are related to the risk of CRC or adenoma^[14-17].

Recently, a novel G>A polymorphism in the 3'-UTR region of the VDR gene was identified and designated as VDR *Tru9I*^[18]. It is thought that the polymorphisms in this region of the VDR gene may affect its mRNA stability, possibly through linkage to other variants^[19]. So far, no previous study has been reported on investigating the function of this polymorphism. In a epidemiological

study, Gyorffy *et al.*^[20], found that the presence of the variant 'u' allele, combined with VDR *ApaI* 'a' and *BsmI* 'b' alleles, is associated with increased risk for type I diabetes mellitus in girls. To our knowledge, there has been no previously published study on a potential association between the VDR *Tru9I* polymorphism and colorectal adenoma risk. Previously, we found that different genetic polymorphisms might affect risk for colorectal adenoma: the *cyclinD1 A/G* polymorphism was associated with increased risk^[21], and the p53-inducible ribonucleotide reductase small subunit 2 (p53R2) 'AA' genotype was strongly associated with increased risk in those with lower dietary nutrients including vitamins and calcium intakes (paper submitted). Herein, we report data from this same North Carolina case-control study on the association of the VDR *Tru9I* polymorphism and colorectal adenoma risk, alone and in interaction with various environmental risk factors for colorectal neoplasms.

MATERIALS AND METHODS

Study design

From 1994 to 1997, the markers of adenomatous polyps (MAP) case-control study were conducted to assess the validity of colonic epithelial cell proliferation as a biomarker of risk for incident sporadic colorectal adenomatous polyps. Prior to beginning the study, MAP was approved by the Institutional Review Board of Wake Forest University, Bowman Gray School of Medicine in accordance with an assurance filed with and approved by the Department of Health and Human Services. Informed consent was obtained from each participant. Eligibility criteria for study subjects consisted of English speaking adults from 30 to 74 years of age, either sex or any race who were scheduled for elective outpatient colonoscopy by four large gastro-enterology practices in Winston-Salem and Charlotte, North Carolina. Patients were recruited for over 24 mo. Cases were identified as eligible colonoscopy patients who were determined to have study index pathologist-confirmed incident adenomatous polyps according to criteria adapted from the National Polyp Study^[22]. Controls consisted of all eligible colonoscopy patients with no previous history of adenomatous polyps and who were found to be free of adenomatous polyps. Persons with familial polyposis, Gardner's syndrome, ulcerative colitis, Crohn's Disease, bowel resection, newly diagnosed recurrent adenomatous polyps, and incident colon cancer were excluded, as they were patients with past or prevalent cancer other than non-melanoma skin cancer.

Patients completed mailed questionnaires prior to their colonoscopies (to avoid bias) regarding family history of polyps or colon cancer, medical history, dietary information (via a semi-quantitative Willett 153-item Food Frequency Questionnaire), physical activity (via a modified Paffenbarger questionnaire), reproductive variables, body fat distribution, and their reasons for and the sequence of events leading to colonoscopy. Blood was drawn and stored at -70 °C for possible later measurement of various genotypes.

Preparation for colonoscopy included a 12 h fast and bowel cleansing with polyethylene glycol (GoLYTELY). Subjects willing to undergo biopsies had four quadrant

biopsies taken from normal appearing mucosa in the rectum (10 cm above the anus), sigmoid colon, and cecum for a total of 16 biopsies. Information recorded included number of polyps, polyp size, polyp type (adenoma, hyperplastic, or mixed), adenoma subtype (tubular, villous, tubulo-villous), and the degree of dysplasia.

Subjects

Among all four clinical sites, 2 246 colonoscopy patients were identified. Of these, 669 were eligible on initial screening (eligibility rate 29.8%), and of these 633 were willing to discuss the study, 617 of these were contacted, and 417 of these signed consent and had study colonoscopies (consent rate 63.1%). Of the 417 participants, 259 had some type of polyp, and of these 179 had adenomatous polyps. Nine of the 417 patients were subsequently determined ineligible for the study, and an additional eight patients had incident colon cancer and were not eligible for the primary case-control analyses; thus, 400 possible patients were available for genotypic analysis. Of these 400 patients, viable DNA was isolated from 391 (171 cases and 220 controls) for genotyping.

Genotyping

Genomic DNA was obtained from stored WBCs digested in 500 µL of lysis buffer (50 mmol/L Tris-HCl, pH 8.5, 1 mmol/L EDTA, 0.2% SDS, 200 g/mL proteinase K) over night at 55 °C with shaking. The digestion was precipitated directly with isopropanol and the pellets were washed with 70% ethanol. The genomic DNA pellets (50-100 µg) were dissolved in 300-800 µL of TE buffer, of which about 1 µL was used for each PCR reaction. DNA was amplified following the primers designed for the exon 8 region of the VDR gene following the published DNA sequence (GenBank number: AY342401). An isoschizomer of *Tru9I*, *MseI*, was used in this study. The PCR (50 µL volume) was carried out in 20 mmol/L Tris-HCl, pH 8.4, 50 mmol/L KCl, 1.5 mmol/L MgCl₂, 0.2 mmol/L dNTP, 0.5 mmol/L of each primer (5'-GCA GGG TAC AAA ACT TTG GAG -3' as forward and a 5'-CCT CAT CAC CGA CAT CAT GTC -3' as reverse), 80-120 ng of DNA template, and 2.5 units Taq polymerase (Gibco-Invitrogen). The solution was heated to 94 °C for 2 min, followed by 35 cycles of 30 s at 94 °C, 30 s at 69 °C, and 30 s at 72 °C. The final reaction was extended 7 min at 72 °C. The PCR products (5 µL) were loaded onto a 3% 2:1 NuSieve-SeaKem gel for confirmation. The PCR products (10 µL) were then subjected to *MseI* restriction enzyme at 37 °C overnight. Bands for the wild-type ('UU') allele were not cut (177 bp); the 'uu' genotype was showed at 91 and 86 bp; and the heterozygote ('Uu') allele was cut into 177-, 91-, and 86-bp fragments.

Statistical analysis

Allelic frequencies for polymorphic VDR *Tru9I* G>A alleles were compared to those in previous study populations. VDR *Tru9I* G>A genotype (UU, Uu, uu) distributions for cases and controls were tested for adherence to the Hardy-Weinberg equilibrium.

All statistical inquiries were conducted using R language

version 1.9.0 from <http://www.R-project.org>. Descriptive comparisons (i.e., mean \pm SD, frequencies as percents) of cases and controls were conducted utilizing χ^2 tests for categorical variables, and *t* test for continuous variables.

Multiple logistic regressions were utilized to calculate odds ratios (ORs) and corresponding 95%CI, adjusted for potential confounding factors, to estimate the strength of an association between VDR *Tru9I* genotype and risk for incident sporadic colorectal adenomas. The effect of VDR *Tru9I* genotype was analyzed utilizing a priori hypothesized low risk, common 'UU' genotype as the referent group. A 'P' test for trend was calculated across genotypes to detect a pattern of association.

Several risk factors were scrutinized as possible confounders or effect modifiers of the VDR *Tru9I* genotype-colorectal adenoma association. Among these were age, sex, race, body mass index, family history of colon cancer (FHCC), smoking, alcohol consumption, non-steroidal anti-inflammatory drug (NSAID) use, and total dietary intake of calcium and vitamin D. Criteria for inclusion of any covariate in the final model included: (1) biological plausibility; (2) whether it fits the model at $P \leq 0.1$; and (3) whether it altered the OR for the primary exposure variable by 10% or more. Final models for genotype main effects included age, sex, smoking status, drinking status, and FHCC.

Models involving in the assessment of possible interactions between genotypes and various anti- and pro-proliferative and other key risk factors included age, sex, FHCC, NSAIDs, smoking status, and total intake of calcium and alcohol.

To examine potential gene-environment interactions of VDR *Tru9I* genotype and certain risk factors, stratified analyses were conducted. Continuous variables were dichotomized on median values for controls; furthermore, continuous dietary variables were categorized as sex-specific. Criteria for assessing effect modifiers were based on previous literature, biological plausibility, and whether or not risk estimates differed substantially across strata.

RESULTS

Adenoma cases were similar to the controls in respect to race, education status, and most dietary intakes (Table 1). However, cases were more likely to be a little older, male, and current drinkers or smokers. Controls were more likely to have histories of colon cancer in first-degree relatives.

There were significant differences in NSAID use and dietary calcium intake between cases and controls. The polymorphism distribution in present population was in Hardy-Weinberg equilibrium ($\chi^2 = 3.41$, $P = 0.07$).

genotypes and colorectal adenoma risk. The frequencies of VDR *Tru9I* 'UU', 'Uu', and 'uu' genotypes were 84.2%, 13.5%, and 2.3% in cases, and 77.8%, 20.3%, and 1.9% in controls, respectively. There were equivalent allele distributions for cases ('U' = 90.9%, 'u' = 9.1%) and controls ('U' = 88%, 'u' = 12%). A 29% decreased multivariable-adjusted OR (0.71; 95%CI, 0.40-1.25) was observed in 'Uu' and 'uu' carriers, compared to 'UU' carriers.

We investigated the association of the polymorphism with colorectal adenoma risk according to characteristics

of adenomatous polyps (Table 3). The inverse association of having at least one 'u' allele with risk for colorectal adenoma was more pronounced for adenoma that were multiple (OR, 0.51; 95%CI, 0.21-1.24), larger (OR, 0.37; 95%CI, 0.11-1.28), sessile (OR, 0.36; 95%CI, 0.13-0.97), and perhaps for adenomas with higher levels of dysplasia (OR, 0.68; 95%CI, 0.33-1.41).

Potential interactions of VDR *Tru9I* polymorphism and other risk factors for colorectal neoplasms and risk for adenomas are shown in Table 4. Compared to the 'UU'

genotype carriers, having a 'u' allele was inversely associated with risk for colorectal adenoma among those who were younger (OR, 0.60; 95%CI, 0.26-1.37), women (OR, 0.38; 95%CI, 0.17-0.88), did not smoke (OR, 0.39; 95%CI, 0.13-1.23), or took NSAID (OR, 0.38; 95%CI, 0.12-1.25). Dietary calcium and vitamin D intake were observed to be related to decreased risk for adenoma; however, there was no evidence suggesting an interaction with the VDR *Tru9I* polymorphism.

DISCUSSION

VDR polymorphisms have been evaluated as risk factors for CRC or adenoma; however, their impact remains unclear. In the present study, we assessed, for the first time, VDR *Tru9I* variants as risk factor for colorectal adenoma. Our data suggest that the *Tru9I* mutant 'u' allele was associated with decreased risk for colorectal adenoma, particularly for adenomas that were larger, multiple, had moderate or greater dysplasia, or were sessile. Also, the 'u' allele was related to decreased risk for adenoma, particularly among persons who were younger, female, NSAID users or did not smoke.

Vitamin D is obtained from the diet or sunlight-induced synthesis, and hydroxylated first in the liver [forming 25-(OH)D], then subsequently in the kidney [forming 1,25-(OH)₂D]. The hypothesis that vitamin D may provide reduced colorectal adenoma risk was first proposed in the early 1980s in light of an inverse ecologic association between CRC morbidity and solar exposure^[23]. *In vivo* and *in vitro* studies found that vitamin D₃ promotes differentiation of colon carcinoma cells by inducing E-cadherin and inhibiting β-catenin signaling^[7]. Experimental data also suggest that the active metabolite of vitamin D and its analogs can induce apoptosis in a colorectal adenoma cell line^[9]. Vitamin D interacts with the VDR, which upregulates CYP3A expression, which in turn increases detoxification of secondary bile acids, including LCA^[10]. Recent epidemiological studies have suggested inverse associations among calcium, vitamin D and CRC or adenoma risk; but results are mixed. In the present study, higher calcium and vitamin D intake were associated with lower risk for colorectal adenomas; however, there was no support for the hypothesis that the VDR *Tru9I* polymorphism may interact with these dietary micronutrients.

VDR is thought to mediate most vitamin D effects, and six common polymorphisms of the VDR gene have been identified. It has been reported that the polymorphisms in the 3'UTR-region (*BsmI*, *TaqI*, *ApaI*, *Tru9I* and *Poly-A*) might alter transcriptional activity and mRNA degradation^[19]; and *FokI*, located at the VDR start codon, affects the length of the N-terminal VDR transactivation domain, resulting in a three-amino acid longer protein^[24]. Several epidemiological studies have addressed associations between VDR polymorphisms and different cancer types including colorectal cancers^[11-15,25-31]. The *FokI* polymorphism, which is a potential functional variant, has been extensively studied. Under various exposures, inconsistent results were obtained from different investigators: Wong *et al.*^[14], reported, that the mutant 'f' allele was associated with increased risk of colorectal cancer; while another study by Ingles *et al.*, found that the 'f' allele was related to decreased risk^[13]; but null associations

also have been observed^[12,17]. The association of VDR *BsmI* polymorphism with cancer risk has also been investigated. Two previous studies found that the VDR *BsmI* 'BB' genotype may reduce risk for colorectal adenoma; in one, the association was modified by NSAID use, and in the other, the association was associated with reduced risk among those who had lower calcium intake and used NSAIDs^[11,16]. Also, we previously reported that the VDR *BsmI* variant 'b' allele was associated with colorectal adenoma risk in the same study population as the current study^[32]. The VDR *Poly-A* polymorphism has been associated with decreased risk for colorectal adenoma, modified by NSAID use^[11]. So far, there have been no previous reports of investigations of an association of the *Tru9I* polymorphism with any cancer.

Many studies have reported that the VDR polymorphisms are associated with susceptibility for and prognosis of different cancers^[13,33,34]. Hutchinson *et al.*^[33], found that the VDR 'ttff' genotype (according to *TaqI* and *FokI* polymorphisms) was significantly associated with thicker malignant melanoma tumors. It has also been reported that the *FokI* polymorphism was more strongly related to large adenoma risk among subjects with lower dietary calcium intake^[13].

Some limitations in this study should be considered in interpreting our results. First, the small sample size and consequent low power preclude drawing strong conclusions. Second, this study is colonoscopy-based, and the population may not be representative of the general population. People who worried about their positive family history were more likely to seek colonoscopy examination, leading to a family history bias that may have attenuated associations. Another potential limitation is that ultraviolet radiation exposure was not assessed in the present study; therefore, the dietary vitamin D intake may not reflect the true exposure to vitamin D. In light of the relationship between vitamin D and calcium, this may also impact the estimated calcium-adenoma association.

In conclusion, this is the first study to investigate an association between the VDR *Tru9I* polymorphism and risk for incident sporadic colorectal adenoma. Our data suggest that the VDR *Tru9I* polymorphism may be more related to progression than initiation of colorectal adenoma. Our study also focused on the interaction between the VDR gene polymorphism, *Tru9I*, and dietary calcium and vitamin D intakes; however, no such interaction was found. On the other hand, our data suggest possible interactions of VDR *Tru9I* genotypes with age, sex, smoking, drinking, and NSAID use. Further, larger studies are needed to verify the present data, to understand the biological mechanisms of VDR gene/calcium/vitamin D interactions.

Abstract

AIM: To observe different histomorphologic changes of ulcerative colitis (UC) rats that were treated with four regulating-intestine prescriptions (FRIP), to investigate the curative effects of FRIP and to analyze their treatment mechanism.

METHODS: The UC rat model was made by the method of 2,4-dinitro chloro benzene (DNCB) immunity and acetic acid local enema. Ninety-eight SD rats were randomly divided into seven groups, namely, the normal control group, model group, salicylazosulfapyridine (SASP) group, Wumeiwan (WMW) group, Baitouwengtang (BTWT) group, Senglingbaishusan (SLBSS) group, and Tongxieyaofang (TXYF) group. Each group had 14 rats (with equal ratio of male and female). The six animal model groups of UC -SASP, TXYF, WMW, BTWT, SLBSS, TXYF-were treated by distilled water except the normal control group. Changes of the rat's general conditions after treatment were respectively observed, the colon tissue damage scores were given out, the pathology of colonic mucosa and changes of ultrastructure were analyzed.

RESULTS: Different pathological changes on histology were shown after treatment by FRIP. The colon tissue damage score in model group was higher than that of FRIP groups and SASP group ($q = 4.59, 4.77, P < 0.05$ or $q = 5.48, 6.25, 5.97, P < 0.01$). The scores of WMW group, BTWT group and SLBSS group were lower than that of SASP ($q = 4.13, P < 0.05$ or $q = 5.31, 5.12, P < 0.01$). There was no remarkable difference between the damage score of TXYF group and SASP group ($q = 3.75, P > 0.05$). In addition, some apoptosis cells were found in the pathologic control group.

INTRODUCTION

Ulcerative colitis (UC) is a non-specific inflammatory intestinal disease. The pathogenesis of UC is affected by a variety of factors, but its pathogenesis is still unknown at present^[1]. A rat model of UC was established by the methods of DNCB immunity and acetic acid local enema. This subject is about the treatment effect of four regulating-intestine prescriptions (FRIP) by making rat model of UC, especially they were observed by scoring the gross morphologic damage and the change on the pathological section of colon tissue under light and electron microscope by treating with traditional Chinese medicine (TCM), and compared the different curative effect of Wumeiwan (WMW) group, Baitouwengtang (BTWT) group, Senglingbaishusan (SLBSS) group and Tongxieyaofang (TXYF) group.

MATERIALS AND METHODS

Materials

Herbs in FRIP (WMW, BTWT, SLBSS, TXYF) and their quantity are as follows: WMW: 16 g dark plum, 6 g asarum herb, 10 g dried ginger, 16 g Chinese goldthread, 4 g Chinese angelica root, 6 g aconite root, 4 g pricklyash peel, 6 g cassia twig, 6 g sun-dried ginseng, 6 g bark of cork tree; BTWT: 30 g Chinese pulsatilla root, 24 g bark of amur corktree, 10 g Chinese goldthread, 24 g ash bark; SLBSS: 10 g pulp of lotus seed, 10 g coix seed, 10 g dried amomum fruit, 10 g balloon flower root, 15 g bean of white hyacinth, 20 g white Tuckahoe, 20 g sun-dried ginseng, 20 g licorice root, 20 g big head atractylodes rhizome, 20 g Chinese yam; TXYF:

30 g parched white atractylodes rhizome, 20 g white peony root, 15 g dried old orange peel, 20 g ledebouriella root.

Salicylazosulfapyridine (SASP) with batch no. 200111002 is produced by Shanghai Sanwei Pharmaceutical Company (250 mg/tablet).

TNF- α ISH detection kit, ISH special cover glass, DBA chromogenic kit, poly-L-lysine, DEPC and 20% glycerin were supplied by Wuhan Boster Biological Technology Co., Ltd.

Transmission electron microscope (Hitachi H-600), photomicroscope (Japan), ultramicrotome (LKB-V), magnifier and microscope, *etc.*, were used.

Ninety-eight SD rats (male rats and female rats separately account for 50% and a rat weighed 300 ± 50 g) were supplied by Test Animal Center of Tongji Medical School, Huazhong University of Science and Technology. They were raised in the SPF environment (constant temperature, humidity and sterilized water, food and padding) and acclimatized to the surrounding for 7 d before the experiments.

Methods

Animal groups Ninety-eight SD rats (male rats and female rats separately account for 50%) were randomly divided into seven groups as males and females, and each group contained 14 rats (male rats and female rats separately account for 50%), of which group 7 was normal group. Groups 1-6 were modeled, which were respectively WMW group, BTWT group, SLBSS group, TXYF group, SASP group, and model group. Body weight of rats in each group showed no significant difference on statistics ($P > 0.05$).

Preparation of the animal model Model of UC rat was established with 2,4-dinitro chloro benzene (DNCB) immunity and acetic acid local enema^[1-5]. After hair on the rats' nape was removed with Na₂S of 100 g/L, 0.25 mL acetone solution with DNCB content of 20 g/L (five drops) was dripped on the rats' back once a day and continuously dripped for 14 d. On the 15th d, a ϕ 3-mm urinary catheter was put into at 8 mm of a rat's colon via its anus to fill 0.25 mL ethanol containing 0.1% DNCB. On the 16th d, 2 mL 8% acetate solution was filled in the same position. After accurately timing for 10 s, this position was flushed with 5 mL physiological saline. After that, they were fed for 2 wk, to continue observing the rats' stool characters, dietetics, hair and activity conditions, *etc.*, every day. It could be seen from observation that the rats gradually produced typical symptom of UC active period. After 30 d, the modeling was finished. After modeling was finished (after the 30th d), two rats were randomly taken in each group and their colons were examined after they were killed to pathologically confirm a series of changes occurring in their colons such as hyperemia, hydrops, inflamed cellular infiltration, crypt abscess, fewer goblet cells, body of gland destroyed and aphthous formed.

Means for drugs For each rat in WMW group, BTWT group, SLBSS group, TXYF group, gastric lavage was conducted respectively with 3 mL prepared WMW liquid (0.515 g/mL), BTWT liquid (0.562 g/mL), SLBSS liquid (0.987 g/mL) and TXYF liquid (0.216 g/mL) once a day. For each rat in SASP group, gastric lavage was conducted with 3 mL SASP suspension (0.026 g/mL) liquid once a

week. For each rat in model control group and normal group, gastric lavage was conducted with 3 mL distilled water. The drug feeding period was 15 d.

Collection and treatment of specimens After the feeding of drugs in all groups of rats ended, they were weighed and killed by the mode of cutting off their heads. After that, they were immediately dissected to take 6-8 mm colons upward at 2 mm of the anus. The intestine cavities were opened along the longitudinal axis of the intestinal mucosa and cleaned thoroughly with 0.9% saline and pure water, and assigned a code number. Then they were spread on the wax plate with the intestinal mucosa pointing upward. After they were fastened with the pins, occurring conditions of inflammation and ulcer were observed with a dissecting microscope. The colon was immediately examined under a stereomicroscope and any visible damage was scored on a 0-5 scale (Table 1).

Table 1 Criteria for scoring the gross morphologic damage of colon tissue^[6-9]

Score	Gross morphology
0	No damage
1	Localized hyperemia with no ulcers
2	Linear ulcers with no significant inflammation
3	Linear ulcers with inflammation at one site
4	More site of ulcers and inflammation, the size of ulcers <1 cm
5	Multiple inflammation and ulcers, the size of ulcers ≥ 1 cm

After modeling was finished (30 d), two rats were randomly selected from each group and killed by the mode of cutting off their heads to take part of the intestine tissues, which were immobilized with 40 g/L formaldehyde, embedded with paraffin, pathological section was taken and HE staining was performed. And then, colon conditions after modeling were observed and investigated.

After ending of the above tests (45 d), a small piece of colon tissue (3 mm) was taken from the colon of each rat. They were immobilized with 40 g/L formaldehyde (grouped and numbered with the penicillin bottles), embedded with paraffin, pathological section was taken and HE staining was performed. And then, pathological changes in each group of colons were observed (the above work was finished with the help of Pathology Department of Hubei Hospital of Traditional Chinese Medicine).

A rat was randomly selected in each group and the above procedures were executed until cleaning procedure. The colonic mucosa with ulcer was taken immediately and cut into 1-mm bits, which was immobilized with 2.5% glutaraldehyde, washed with 1% paraformaldehyde and immobilized after it was put in 1% osmic acid. Then, they were dehydrated in steps with ethanol and acetone, embedded with vegetable wax, cut into super-thin sections and doubly stained with uranium acetate and lead nitrate. After that, they were observed with a transmission electron microscope (finished with the help of Electron Microscope Department of Medical School of Wuhan University).

Statistical analysis

The weights of rats and tissue damage scores were expressed

as mean \pm SD, and analyzed with the Student's *t*-test or *F* test (*q* test).

RESULTS

Changes of symptoms and signs

The study of the rats in the model had symptoms of mucous thin stool after about 2 wk and worsened gradually. After about 4 wk, the symptoms were more serious and some symptoms such as pus and blood stool, thinner, less weight, hair having no gloss, significantly less appetite, intolerance of cold and action and less movement occurred. After gastric lavage was conducted with FRIP and SASP, their symptoms were improved differently (no statistical analysis except for weights). Weight changes are shown in Table 2.

Table 2 Effect on weights in rats of FRIP (mean \pm SD)

Group	Case (n)	Weights (g)
Normal control group	12	352.5 \pm 20.7 ^b
Model group	10	307.8 \pm 15.3 ^d
SASP group	9	321.5 \pm 18.7 ^{a,d}
WMW group	11	340.3 \pm 16.8 ^{b,c}
BTWT group	10	331.4 \pm 13.8 ^{b,d}
SLBSS group	9	325.6 \pm 18.4 ^{a,d}
TXYF group	10	328.7 \pm 10.5 ^{a,d}

^a*P*<0.05, ^b*P*<0.01 vs model group; ^c*P*<0.05, ^d*P*<0.01 vs normal control group.

Visual observing results of colonic mucosal damage

The degree of colonic mucosal damage in rats of FRIP was scored according to the criteria in Table 1. The colon tissue damage score in model group was higher than that of FRIP groups and SASP group (*P*<0.05 or *P*<0.01). The scores of WMW group, BTWT group, and SLBSS group was lower than that of SASP (*P*<0.05 or *P*<0.01). There was no remarkable difference between the damage score of TXYF group and SASP group (*P*>0.05). The scores were roughly given out according to the inflammation and injury level, observation results of which are shown in Table 3.

Table 3 Scoring the gross morphologic damage of colon tissue in rats of FRIP (mean \pm SD)

Group	Case (n)	Scoring the gross morphologic damage
Normal control group	12	0 ^b
Model group	10	5.5 \pm 0.45
SASP group	9	3.8 \pm 0.39 ^a
WMW group	11	1.8 \pm 0.34 ^{b,d}
BTWT group	10	2.5 \pm 0.38 ^{b,d}
SLBSS group	9	1.9 \pm 0.35 ^{b,c}
TXYF group	10	3.7 \pm 0.47 ^a

^a*P*<0.05, ^b*P*<0.01 vs model group; ^c*P*<0.05, ^d*P*<0.01 vs SASP group.

Observation results of pathological sections (HE dye)

Normal control group: The colonic mucosa of rats was in good condition without inflammatory cell infiltration or ulceration of mucosa; the epithelial mucosae was intact and continuous; the bodies of gland arranged regularly with clear

structure and active secreting function; the epithelial mucosae, the blood vessel in the membrana propria and fibers were normal; muscularis had no abnormal conditions. Model group: The colonic mucosa of the rats showed erosion and ulcers; the most of mucosa produced coloboma and some produced deep and large erosions, mucous gland bodies were destroyed; remaining mucosa was hyperemic and dropsical and formed polyp-like appearance (false polyp) due to hyperplasia; a lot of inflammatory cells (lymphocytes, plasma cells, and macrophages) infiltrated; some cells were scattered and were in multiplication conditions (more plasma, large nucleus, and sparse chromatin); mucous layer became thinner and the lamina propria beneath the mucosa showed local hyperemia, dropsy, and fiber hyperplasia. SASP group: The epithelial mucosae of the rat colon produced the local defects; the bodies of gland arranged less regularly with slight hyperemia beneath the mucosa and more inflammatory cells infiltrated. WMW group: The epithelial mucosae of the rat was basically sound; the bodies of gland arranged more regularly without significant hyperemia beneath the mucosa; a few inflammatory cells infiltrated. BTWT group: The epithelial mucosae of the rat was basically sound; the bodies of gland arranged more regularly without significant hyperemia beneath the mucosa; and inflammatory cell infiltration could be seen. SLBSS group: The epithelial mucosae of the rat was basically sound; the bodies of gland arranged more regularly without significant hyperemia beneath the mucosa; and a few inflammatory cell infiltration could be seen. TXYF group: The epithelial mucosae of the rat was less sound; the bodies of gland arranged less regularly with significant hyperemia beneath the mucosa; and inflammatory cell infiltration could be seen (Figures 1A-H).

Observation results of ultrastructure

Normal control group: The microvilli on the surface of the mucosal epithelium of the rat colon was integral with neat arrangement, identical sizes, and regular mitochondrion shape and showed approximate roundness and ellipse, inner matrixes of which were of medium density; endoplasmic reticulum and nucleus were all up to snuff; epithelia linked tightly; space between cells was found to be wider (normal linking); the intestine gland was composed of the goblet cells. Model group: The microvilli on the surface of the mucosal epithelium of the rat colon were sparse, became shorter and irregularly curled with visible vacuoles, even epithelium cell membrane produced defects; organelles became fewer; cytoplasm liquefied and dissolved; inner matrixes in the mitochondria were clear with fewer inner cristae and significant swelling; endoplasmic reticulum expanded; chromatic agglutination and pyknosis could be seen; nucleoplasm proportion became less, some congregated beneath karyolemma and showed goblet with clear boundaries, even apoptosis corpusculum, karyo-pyknosis, and lymphocyte infiltration could be seen. SASP group: The microvilli on the surface of the mucosal epithelium of the rat colon partly dropped off and became less regular; mitochondria shape became less regular and some were with slight swelling with destroyed cytoarchitecture; fat particles and endoplasmic reticulum expanding could be seen. WMW group: The microvilli on the surface of the mucosal

group; **H:** TXYF group (HE $\times 200$).

epithelium of the rat colon were basically intact with normal cytoarchitecture; after observing under the electron microscope ($\times 12\,000$), it could be found that their endoplasmic reticulum and mitochondria were clearer, and the organelles such as mitochondria and elder with cytotocytes could be seen with clear cytoarchitecture as well as dropping-off of the microvilli could be seen. BTWT group: The microvilli on the surface of the mucosal epithelium of the rat colon was basically regular and intact; mitochondria in the cytoplasm was abundant with regular mitochondria and showed approximate roundness or ellipse; the matrixes were basically even. SLBSS group: The microvilli on the surface of the mucosal epithelium

of the rat colon were less irregular and a few microvilli dropped off; mitochondria were swelling with normal cytoarchitecture. TXYF group: More microvilli on the surface of the mucosal epithelium of the rat colon dropped off or they were sparse and expanding; staining of nucleus was a little dark; destroyed cytoarchitecture and wider chromatin margin could be seen; cellular nucleus became smaller (Figures 2A-G).

The results of pathological sections under electron microscope showed that UC was related to apoptosis and the curative effect of WMW was better than that of the other groups and SASP groups.

DISCUSSION

Normal colonic tissue consists of mucous membrane layer (including epidermis layer, lamina propria, muscular layer of mucous membrane), mucous membrane substrate layer, muscular layer (inner ring and outer race), chorion layer and so on. Pathological changes of UC affects mucous membrane and substrate layer. The best characteristic changes of histology included diffuse and severe inflammatory cell infiltration in all layers of inhesion membrane, serious and comprehensive mucous configuration abnormality, crypt lymph in recess (namely crypt abscess), inhesion membrane with a great number of plasma cells, lymphocyte, mononuclear cells, neutrophils and eosinophils infiltration. Because of inflammatory irritation, there were epithelial hyperplasia of gland, which were shown as goblet cells and mucilage in the body of the gland reduced but nucleus expanded and nuclear fusion increased in various extents. Cytoplasm had a liking for alkalinescence; epithelial hyperplasia of gland sometime

became false compound. Further observation showed that the capillary vessel dilatation caused congestion and blood vessel swelling further. In a serious case, the inflammation could develop into the mucous membrane substrate layer, even perforation, which broke to form the pilosity granular light ulcer or merged into various sizes and shapes to become irregular ulcer. Serious cases had large range of mucous membrane peeling. More normal mucous membrane between the ulcer turn into prowling form (there are boundary between sick mucous membrane and normal mucous membrane), taking on hydronics and polyp (false polyp), so the mucous membrane took the form of particle coarsely, the blood vessels were so fuzzy and fragile that they were apt to bleed with purulence secretion when touched. But there was seldom involvement of the deep layer of intestine wall, so the incrassation and fibrosis intestine wall were not remarkable, but few breaking out types and poisoning type colon cases come out of a hole because of

piercing through intestine wall.

In recent years, many studies to the change of colonic mucus were carried out. It was suggested that it might be the prodromal change of carcinoma of large intestine. As we all know, UC is a pre-cancerous lesion of colon carcinoma. The mucosa in this region also showed certain histologic characteristics: the goblet cells in the glandular body decreased remarkably or disappeared with appearance of simple columnar cells, which lack mucin secretion. The lumen of some mucosal glands became dilated, branched or irregularly arranged. We found that the important characteristic of UC was inflammation in this experiment and cell apoptosis under electron microscope. We also found that the presentation was hyperemia and edema with a great number of plasma cells, lymphocytes, mononuclear cells, neutrophils, and eosinophils infiltration^[10-12], the characteristic that pathology changes and ultrastructure was different in all groups was associated with the treatment.

This model made with DNCB and acetic acid was successful by the changes of symptoms and signs, damage scores of the colonic mucosa and the pathology sections and ultrastructure of colon tissue. At the same time, their symptoms and signs and pathology differently improved after treatment (not statistically significant, $P>0.05$). In this study, we discovered that FRIP had better curative effect on UC and WMWs was the best, BTWs and SLBSSs were the second of best. TXYFs were worst (they were as same as SASPs). At the same time, this implies, that we must have BianzhengLunzhi in the treatment of UC^[13]. According to TCM, UC belongs to the category of "Xiouxili" (diarrhea), the mucosal inflammatory lesions result from not only deficiency and hypofunction of spleen and stomach, but also accumulation of damp heat, the pathogenesis of UC is similar with the prescription characteristic of WMW. Therefore, in this study, the best curative effect was achieved by the treatment of the WMW. The results showed that this WMW had the function of strengthening the spleen and reinforcing Qi and eliminating damp-heat pathogen, promoting flow of Qi and blood, improving luminal blood circulation, and was helpful for hemostasis and the absorption of inflammatory products, eventually attained the goal of the neogenesis of granulated tissue in the region of ulceration, and the repair of mucosal epithelium. But BTW concentrated on eliminating damp-heat pathogen, SLBSS was good at strengthening the spleen and reinforcing Qi, the former had the function of reducing the excess, the latter had the function of reinforcing the deficiency, so two

formulae of BTW and SLBSS had some therapeutic effects, and they were the second curative effect; the prescription characteristic of TXYF, which had the function of smoothing the liver-Qi to normalize the stomach, was different with the pathogenesis of UC and it had the worst curative effect.

In addition, we discovered that apoptosis was possibly related to UC^[13] and FRIP could decrease apoptosis, block inflammation and induce remission.

Abstract

AIM: To identify the proteins interacting with nucleostemin (NS), thereby gaining an insight into the function of NS.

METHODS: Yeast two-hybrid assay was performed to screen a human placenta cDNA library with the full length of NS as a bait. X-Gal assay and β -galactosidase filter assay were subsequently conducted to check the positive clones and the gene was identified by DNA sequencing. To further confirm the interaction of two proteins, the DNA fragment coding NS and the DNA fragment isolated from the positive clone were inserted into the mammalian expression vector pcDNA3 and pcDNA3-myc, respectively. Then, two plasmids were cotransfected into the COS-7 cells by DEAE-dextran. The total protein from the cotransfected cells was extracted and coimmunoprecipitation and Western blot were performed with suitable antibodies sequentially.

RESULTS: Two positive clones that interacted with NS were obtained from human placenta cDNA library. One was an alpha isoform of human protein phosphatase 2 regulatory subunit B (B56) (PPP2R5A) and the other was a novel gene being highly homologous to the gene associated with spondylo paralysis. The co-immunoprecipitation also showed that NS specifically interacted with PPP2R5A.

CONCLUSION: NS and PPP2R5A interact in yeast and mammalian cells, respectively, which is helpful for addressing the function of NS in cancer development and progression.

INTRODUCTION

There is evidence that cancer originates from cancerous stem cells^[1-7]. Nucleostemin (NS) is a novel protein found in the nucleoli of CNS stem cells, embryonic stem cells, and several cancer cell lines, and plays a critical role in controlling the proliferation of stem cells and some cancer cells^[7]. NS contains a N-terminal basic domain and two GTP-binding motifs. Mutation analysis indicates that excessive NS, particularly mutant NS that lacks the GTP-regulatory domain, prevents cells from mitosis and causes apoptosis in a p53-dependent manner. The N-terminal basic domain specifies nucleolus localization, p53 interaction, and is required for cell death caused by NS overexpression. To investigate the function of NS in cancer development and progression, yeast two-hybrid assay was used to screen the proteins associated with NS from a human placenta cDNA library, and the interaction between the alpha isoform of human protein phosphatase 2 regulatory subunit B (B56) known as PPP2R5A and NS was identified in yeast and COS-7 cells, thus providing new clues to the functional study of NS as well as related proteins.

MATERIALS AND METHODS

Cell culture and reagents

Monkey *Cercopithecus Aethiops* COS-7 cells provided by American Type Culture Collection (Manassas, VA, USA) were cultured in Dulbecco's modified Eagle's medium (Invitrogen Corporation, Carlsbad, CA, USA) supplemented with 10% fetal bovine serum (Sigma Chemical Co., St. Louis, MO, USA), and maintained in a humidified chamber with 50 mL/L CO₂ at 37 °C.

Plasmid pGBKT7, matchmaker 3 pretransformed human placenta cDNA library, X-Gal and all other yeast two-hybrid components were purchased from Clontech. Various restriction endonucleases were products of New England Biolabs. T4 DNA ligase was purchased from Promega. The kits for PCR and purification reagents of PCR products were obtained from Qiagen. Antibody against NS or c-myc tag and other reagents were all kept in our laboratory.

Plasmid construction

The full length of NS cDNA was cut by *Bam*HI and *Xba*II restriction endonucleases from pCDNA3-NS, then inserted into the downstream of the Gal4 DNA-binding domain of the bait vector pGBKT7 (Clontech Laboratories) with T4 DNA ligase. The recombinant vector pGBKT7-NS was sequenced and NS protein was in the reading frame. The expression of NS fusion protein with yeast Gal4 DNA-binding domain was checked by Western blot with antibody against NS.

To construct the eukaryotic vector expressing the protein

of the positive clone, DNA of the positive clone was digested by restriction endonucleases *Bam*HI and *Xho*I, and the DNA fragment was inserted into the pCDNA-myc vector.

Screening of clones interacted with NS

The experiments were carried out according to the protocols described in the MATCHMAKER Libraries User Manual (PT3042-1)^[8-11]. Briefly, the pGBKT7-NS plasmid was initially introduced into the AH109 yeast strains using a modified lithium acetate protocol and the transformed clones were selected on SD/-Trp plates. The mating between the selected AH109 and human placenta cDNA library was performed and co-transformed clones were selected on SD/-Leu-Trp-His plates and SD/-Leu-Trp-His-Ade pulsing 3AT (DO) plates with X-Gal to detect the transcription of reporter genes (HIS, LEU, TRP, and ADE). Colonies growing at 30 °C and having turned into blue in 8 h were selected as positive clones. Plasmid DNA from the single positive clones was extracted and sequenced with the primer provided with the kit. The clone was identified by DNA sequence and compared with GenBank. To further exclude the false positives, plasmid was transformed into yeast strain AH109 to rule out its self-activation.

In order to further confirm the positive clones in yeast system, experiments were performed in AH109 yeast strain to detect the transcription of LacZ reporter gene according to the protocols. Colony-lift filter assay was used to check the activity of β -galactosidase. Briefly, fresh colonies growing to about 1-3 mm in diameter were transferred completely to a sterile filter and submerged in liquid nitrogen for 10 s and thawed at room temperature, then put on a pre-soaked filter with Z buffer ($\text{Na}_2\text{HPO}_4 \cdot 7\text{H}_2\text{O}$ 16.1 g/L, $\text{NaH}_2\text{PO}_4 \cdot \text{H}_2\text{O}$ 5.50 g/L, KCl 0.75 g/L, and $\text{MgSO}_4 \cdot \text{H}_2\text{O}$ 0.246 g/L, pH 7.0) containing 0.27 mL β -mercaptoethanol and 1.67 mL X-Gal stock solution (20 mg/mL) in 100 mL volume. The filters were incubated at 30 °C and the colors of colonies were checked periodically.

Co-immunoprecipitation

When COS-7 cells reached 50-70% confluence on the dish, the plasmids expressing NS and interacted protein of NS were cotransfected into COS-7 cells with DEAE-dextran as described^[12], and total plasmid DNA was 8 $\mu\text{g}/100 \text{ mm}/\text{dish}$. After 48 h, the cells were washed with PBS, then scraped and collected by spinning down. The cell pellet was lysed in 0.5 mL HEDL buffer (50 mmol/L HEPES pH 8.0, 150 mmol/L NaCl, 2 mmol/L EDTA, 1% Triton X-100, 10 mmol/L MgCl_2 , 1 mmol/L Na_3VO_4 , 25 mmol/L NaF, 1 mmol/L PMSF) and shaken for 2 h at 4 °C, centrifuged at 12 000 *g* for 15 min at 4 °C. The resulting supernatants were immunoprecipitated with various antibodies (mouse anti-c-myc, mouse anti-nucleostemin and mouse non-specific antibodies) respectively as described^[12]. SDS-PAGE and Western blot were performed with suitable antibodies and the signal was detected with ECL (Pulilai Co.).

RESULTS

Plasmids construction

The constructed plasmid pGBKT7-NS was identified by

restriction endonucleases *Bam*HI/*Xho*I and DNA sequence analysis. As shown in Figure 1A, there was an expected DNA band about 1.7 kb released from the digested plasmid pGBKT7-NS and the DNA sequence was completely identical with NS in GenBank. Western blot showed that the NS protein fused with yeast Gal4 DNA-binding domain was expressed in yeast (Figure 1B). The recombinant plasmids PPP2R5A/pCDNA3-myc and pCDNA3-NS were identified by restriction endonucleases *Bam*HI/*Xho*I and DNA sequencing, respectively (Figure 2). As shown in Figure 3, there was an expected band about 2.3 or 1.7 kb released from the digested plasmid and the DNA sequence was completely identical with PPP2R5A or NS in GenBank.

Figure 1 Identification of the recombinant clone of NS and its expression in yeast cell. **A:** Analysis of pGBKT7-NS with restriction enzyme digestion. M: DNA markers; lane 1: undigested pGBKT7-NS; lane 2: digestion of pGBKT7-NS with *Bam*HI/*Xho*I and 1 680-bp fragment was released; **B:** Western blotting analysis of NS expression by pGBKT7-NS in yeast. Total protein from yeast AH109 transfected with pGBKT7-NS was subjected to Western blot and the NS mAb was used to detect the NS protein. Lane 1: total proteins from pGBKT7-NS transfected AH109; lane 2: total proteins from pGBKT7 transfected AH109.

Figure 2 Restriction enzyme analysis of recombinant pcDNA3-NS and pcDNA3-myc-PPP2R5A. M: DNA markers; lane 1: undigested pcDNA3-NS; lane 2: digestion of pcDNA3-NS by *Bam*HI/*Xho*I and 1 680-bp fragment was released; lane 3: undigested pcDNA3-myc-PPP2R5A; lane 4: digestion of pcDNA3-myc-PPP2R5A with *Bam*HI/*Xho*I and 2 300 bp fragment was released.

Figure 3 Co-immunoprecipitation of protein NS and PPP2R5A. Total proteins from cells co-transfected with plasmids pcDNA3-NS and pcDNA3-myc-PPP2R5A were used for immunoprecipitation with antibody against NS or c-myc and antibody against c-myc or NS was used in Western blot. Mouse IgG was used in immunoprecipitation as negative control.

Screening of clones interacted with NS

To rule out the transcription activity of NS, the bait plasmid pGBKT7-NS was transformed into yeast AH109 and the transcription initiation of HIS and MEL1 reporter genes was tested. The results showed that the self-activation of NS was negative.

Amplification of human placenta cDNA library was pre-performed and transformed into the AH109 yeast strain containing pGBKT7-NS plasmids using modified lithium acetate. The transformants of pGBKT7 and pCL1 were used as negative and positive control respectively in the experiment. There were two positive clones, which were subjected to DNA sequence analysis. The results showed that one clone was identical to gene PPP2R5A (GenBank, GI: 30795205), the other was a novel gene being highly homologous to the gene associated with spondylo paralysis. To identify the specificity of the protein interaction, PPP2R5A/pACT2 was co-transformed into yeast cells with plasmids pGBKT7-NS or pGBKT7. The results showed that PPP2R5A/pACT2 interacted with pGBKT7-NS, but not with pGBKT7.

Co-immunoprecipitation

To further testify the two protein interaction in mammalian cells, eukaryotic plasmids expressing NS or PPP2R5A were cotransfected into COS-7 cells and the total protein was extracted and used for immunoprecipitation and Western blot sequentially. The proteins precipitated with NS antibody could be recognized by c-myc tag antibody, and vice versa, indicating the interaction between NS and PPP2R5A in mammalian cell.

DISCUSSION

Yeast two-hybrid assay is an effective method to isolate interacted proteins^[8], and can screen all protein-protein interactions *in vivo*. The proteins obtained by yeast two-hybrid assay are more likely in their native conformations^[12]. However, the yeast two-hybrid assay also has its limitations, and false positive clones may occur. In this study, more sensitive and credible yeast strain AH109 was used, which has three reporter genes regulated by different promoters, such as GAL1-HIS3, GAL2-ADE2, and MEL1-LacZ. By using this system, a novel binding protein PPP2R5A of NS was obtained from human placenta cDNA library and its interaction with NS and PPP2R5A was further characterized in mammalian cells using co-immunoprecipitation.

P53 plays an important role in the physiological or pathological processes, including cell growth regulation and cell cycle progress. It was reported that the p53 protein can bind to NS protein by GST pull-down and co-immunoprecipitation, respectively^[7]. In our study, a novel NS binding protein was identified as an alpha isoform of human protein phosphatase 2 regulatory subunit B (B56) (PPP2R5A). PPP2R5A belongs to the phosphatase 2A regulatory subunit B family. Phosphatase 2A is one of the four major Ser/Thr phosphatases, and plays an important role in negative control of cell growth and division as well as cell cycle progress^[13]. According to Gene Database,

PPP2R5A is located in cytoplasm^[14-18]. It was found in our study that NS was expressed in cytoplasm and nucleoli (data not shown). NS expression in gastric cancer tissue is higher than that in other gastric tissues (data not shown), suggesting that NS may play a role in the carcinogenesis of gastric cancer. In conclusion, the results of our study help to investigate the functions of NS.

Abstract

AIM: To investigate whether continuous veno-venous hemofiltration (CVVH) in different filtration rate to eliminate cytokines would result in different efficiency in acute pancreatitis, whether the saturation time of filter membrane was related to different filtration rate, and whether the onset time of CVVH could influence the survival of acute pancreatitis.

METHODS: Thirty-seven patients were classified into four groups randomly. Group 1 underwent low-volume CVVH within 48 h of the onset of abdominal pain (early CVVH, $n = 9$). Group 2 received low-volume CVVH after 96 h of the onset of abdominal pain (late CVVH, $n = 10$). Group 3 underwent high-volume CVVH within 48 h of the onset of abdominal pain (early CVVH, $n = 9$). Group 4 received high-volume CVVH after 96 h of the onset of abdominal pain (late CVVH, $n = 9$). CVVH was sustained for at least 72 h. Blood was taken before hemofiltration, and ultrafiltrate was collected at the start of CVVH and every 12 h during CVVH period for the purpose of measuring the concentrations of TNF- α , IL-1 β and IL-6. The concentrations of TNF- α , IL-1 β and IL-6 were measured by swine-specific ELISA. The Solartron 1 255 B frequency response analyzer (British) was used to observe the resistance of filter membrane.

RESULTS: The survival rate had a significant difference (94.44% vs 68.42%, $P < 0.01$) high-volume and low-volume CVVH patients. The survival rate had also a significant difference (88.89% vs 73.68%, $P < 0.05$) between early and late CVVH patients. The hemodynamic deterioration (MAP, HR, CVP) was less severe in groups 4 and 1 than that in group 2, and in group 3 than in group 4. The adsorptive saturation time of filters membranes was 120-180 min if the filtration rate was 1 000-4 000 mL/h. After the first, second and third new hemofilters were changed, serum TNF- α concentrations had a negative correlation

with resistance (r : -0.91, -0.89, and -0.86, respectively in group 1; -0.89, -0.85, and -0.76, respectively in group 2; -0.88, -0.92, and -0.82, respectively in group 3; -0.84, -0.87, and -0.79, respectively in group 4). The decreasing extent of TNF- α , IL-1 β and IL-6 was significantly different between group 3 and group 1 (TNF- α $P < 0.05$, IL-1 β $P < 0.05$, IL-6 $P < 0.01$), between group 4 and group 2 (TNF- α $P < 0.05$, IL-1 β $P < 0.05$, IL-6 $P < 0.01$), between group 1 and group 2 (TNF- α $P < 0.05$, IL-1 β $P < 0.05$, IL-6 $P < 0.05$), and between group 3 and group 4 (TNF- α $P < 0.01$, IL-1 β $P < 0.01$, IL-6 $P < 0.05$), respectively during CVVH period. The decreasing extent of TNF- α and IL-1 β was also significantly different between survival patients and dead patients (TNF- α $P < 0.05$, IL-1 β $P < 0.05$). In survival patients, serum concentration of TNF- α and IL-1 β decreased more significantly than that in dead patients.

CONCLUSION: High-volume and early CVVH improve hemodynamic deterioration and survival in acute pancreatitis patients. High-volume CVVH can eliminate cytokines more efficiently than low-volume CVVH. The survival rate is related to the decrease extent of TNF- α and IL-1 β . The adsorptive saturation time of filter membranes are different under different filtration rate condition. The filter should be changed timely once filter membrane adsorption is saturated.

INTRODUCTION

Excessive activation of inflammatory mediator cascade during severe acute pancreatitis is a major cause of multiple organ dysfunction associated with a high mortality^[1]. Non-selective elimination of pancreatitis-related mediators is a preventive measure against the systemic complications of the disease. Continuous veno-venous hemofiltration (CVVH) has been shown to have considerable benefit for the treatment of multiple organ dysfunction secondary to sepsis^[2,3]. Clinical and experimental studies indicate that CVVH is able to eliminate small and medium-sized inflammatory mediators such as cytokines^[4-6]. These data suggest that the mechanisms of

mediator elimination are convective filtration through the filters and adsorption of mediators to the filter membrane. Whether different filtration rate can induce different efficiency in removing inflammatory mediators is controversial^[7,8]. If filter membrane adsorption reaches saturation, the filter should be changed timely. However, little is known about the saturation time of filter membrane. Whether the filtrate rate can change membrane saturation time is unclear. The present study therefore investigated whether low-volume and high-volume CVVH could eliminate cytokines in acute pancreatitis, and whether the onset time of CVVH could affect the survival of acute pancreatitis patients. By measuring electrical resistance of filter membranes with the impedance method, we studied the adsorptive saturation time of filter membranes. Furthermore, we investigated whether the saturation time of filter membrane was related to different filtration rates.

MATERIALS AND METHODS

Patients

Thirty-seven patients (21 males, 16 females, averaging 51.4 ± 11.6 years in age with a range of 36-70 years) with acute pancreatitis were studied. Prior to the study, all patients or their relatives were informed in detail, and consent was obtained. The diagnosis was based on typical abdominal pain associated with an increase in serum amylase and lipase concentration. All the patients studied also had morphologic abnormalities compatible with acute pancreatitis demonstrated by contrast-enhanced computed tomography and/or ultrasonography. Pancreatitis was biliary origin in 31 patients, alcoholic origin in 4 patients, and unknown origin in 2 patients.

Diagnostic criteria for severe acute pancreatitis (SAP) standardized by the British Society of Gastroenterology Working Party on the management of acute pancreatitis in 1995^[9] and diagnostic criteria for multiple organ dysfunction syndrome (MODS) standardized by American College of Chest Physicians (ACCP) and Society of Critical Care Medicine (SCCM) were applied^[10]. The frequencies of various complications observed in patients with severe pancreatitis are reported in Table 1. All patients initially received standard conservative treatment. Two patients with severe pancreatitis underwent surgery for infection of pancreatic necrosis. Mean arterial blood pressure (MAP), central venous pressure (CVP), and heart rate (HR) were monitored continuously. The primary end point was mortality on d 14.

Table 1 Complications in 37 patients with acute pancreatitis

Complication	Patients (n)
Pancreatic necrosis	20
Pulmonary involvement (pleural effusion, atelectasis)	16
Pancreatic fluid collection	12
Renal failure	6
Pseudocyst	5
Infection	4
Multi-organ failure	4

Patients were classified into four groups randomly by the onset of acute pancreatitis and the intensity of CVVH.

Group 1: Nine cases underwent low-volume CVVH within 48 h of the onset of abdominal pain (early CVVH);

Group 2: Ten cases underwent low-volume CVVH after 96 h of the onset of abdominal pain (late CVVH);

Group 3: Nine cases received high-volume CVVH within 48 h of the onset of abdominal pain (early CVVH);

Group 4: Nine cases received high-volume CVVH after 96 h of the onset of abdominal pain (late CVVH).

Procedures of CVVH

A double lumen catheter was inserted into the internal jugular vein of 23 patients and into the femoral vein of 14 patients to establish vascular access. The blood flow rate ranged 250-300 mL/min. CVVH was sustained for at least 72 h. The substitution fluid was infused at a rate of 1 000 mL/h in low-CVVH group and at a rate of 4 000 mL/h in high-CVVH group^[11] in a pre-diluted manner (before hemofiltration). The substitution fluid rate was equal to the ultrafiltrate rate. An AN69 hemofilter (HOSPAL, Industrie-69 330 Meyzieu, France, 1.2 m²) was used and changed every 24 h. To prevent clotting, low molecular weight heparin (Fraxi, 0.4 mL) was given at the start of CVVH. Then Fraxi was infused into the blood circuit before filtration every four hours, and ceased when the patient displayed hemorrhagic tendencies, such as hematemesis, hemafecia and emorrhagia nasalis.

Application of frequency response analyzer

The Solartron 1 255 B frequency response analyzer (UK) was used to observe the resistance of filter membrane. Filters were holed near the inlet and outlet of dialysate. Two ends of pyrogen-free electrode (alloy of nickel chromium thread coated with pvc. diameter: 0.5 mm) of the Solartron 1 255 B frequency response analyzer were fixed to the periphery of filter membranes through the holes. Then the holes were sealed up by pyrogen-free gel bar gun. The resistance of filter membrane was constantly observed and recorded every 10 min.

Cytokine measurement

Blood was taken before hemofiltration, the ultrafiltrate was collected at the start of CVVH and every 12 h during CVVH for the purpose of measuring the concentration of TNF- α , IL-1 β , and IL-6. To analyze the correlation of serum inflammatory mediators with resistance of filter membrane, blood samples for measuring TNF- α were collected every 10-min when a new filter was used until the resistance of filter membrane reached the plateau. The concentrations of TNF- α , IL-1 β , and IL-6 were measured by swine-specific ELISA (Sigma, USA).

Statistical analysis

Student's *t*-test was used to compare the data between groups. The data were expressed as mean \pm SD. The survival time was calculated by the Kaplan-Meier analysis and compared by the log-rank test. Hemodynamic parameters were evaluated by one-way analysis of variance (ANOVA). The change of hemodynamic parameters, cytokines, and electrical resistance of filter membrane was evaluated and by ANOVA. The correlation between serum TNF- α and the resistance of filter membrane was determined by Pearson correlation analysis. $P < 0.05$ was considered statistically significant.

RESULTS

Survival

Among the 19 patients in groups 1 and 2 who underwent low-volume CVVH, 13 patients were still alive at the end of the observation period. In groups 3 and 4, among the 18 patients who underwent high-volume CVVH, 17 patients were still alive at the end of the observation period (Figure 1A). The survival rate was significantly different between the patients undergone high-volume and low-volume CVVH (94.44% *vs* 68.42%, $P<0.01$). The data showed that the survival could be improved significantly by high-volume CVVH.

In groups 1 and 3, among the 18 patients who underwent early CVVH, 16 patients were still alive at the end of the observation period. In groups 2 and 4, among the 19 patients who received late CVVH, 14 patients were still alive at the end of the observation period (Figure 1B). The survival rate was significantly different between the patients who had undergone early and late CVVH (88.89% *vs* 73.68%, $P<0.05$). The results suggested that early CVVH could improve survival of acute pancreatitis patients.

Hemodynamic parameters

Seventy-two hours after CVVH, MAP and CVP had no significant difference between group 1 and group 3 ($P>0.05$). MAP and CVP significantly decreased in group 2 compared to group 4 ($P<0.05$, Table 2). The hemodynamic diversity (MAP, HR, CVP) was different between group 2 and group 4 ($P<0.05$). The hemodynamic deterioration (MAP, HR, CVP) was less severe in group 4 than in group 2 ($P<0.05$). The data demonstrated that high-volume CVVH significantly improved hemodynamic deterioration compared to low-volume CVVH.

MAP and CVP had a significant difference in groups 2 and 4 compared to groups 1 and 3 ($P<0.01$), 72 h after

CVVH (Table 2). The hemodynamic diversity (MAP, HR, CVP) was different between groups 1 and 2 ($P<0.05$) and between groups 3 and 4 ($P<0.01$). The hemodynamic deterioration (MAP, HR, CVP) was less severe in groups 1 and 3 than in groups 2 and 4 ($P<0.05$). These data showed that CVVH could improve hemodynamic parameters in pancreatitis, and that early CVVH significantly improved hemodynamic deterioration than compared to late CVVH.

Resistance of filter membrane in different filtration flow rate

The filter membrane is an insulator before it contacts with blood or substitution fluid. In our study, when pyrogen-free saline passed through the blood compartment of filter, the resistance of filter membranes did not change at different time points. Electrical resistance tended to change in all treatment groups ($P<0.05$, Table 3). The highest resistance of filter membrane demonstrated at 120 min in groups 1 and 2, and at 180 min in groups 3 and 4. It also showed that the adsorptive saturation time of filter membranes was at 120 and 180 min in 1 000 mL/h filtration rate and in 4 000 mL/h filtration rate, respectively. The resistance at the same time point was significantly different ($P<0.01$) between groups 4 and 2, and groups 3 and 1. The data demonstrated that the adsorptive saturation time of filter membranes was different under different filtration rate conditions. The adsorptive saturation time of filter membranes was 120-180 min if the filtration rate was 1 000-4 000 mL/h.

Serum TNF- α levels and relationship between TNF- α and resistance

Serum TNF- α levels decreased significantly ($P<0.01$) until the resistance reached the plateau (120 min in group 2 and 180 min in group 4) after a new filter was exchanged (Table 4). Then, TNF- α concentrations decreased slowly in groups 1

Table 2 Clinical outcome parameters of acute pancreatitis (mean \pm SD)

Parameter	Group	Pre-CVVH	12 h	24 h	36 h	48 h	60 h	72 h

^b $P<0.01$ vs group 2 1st.

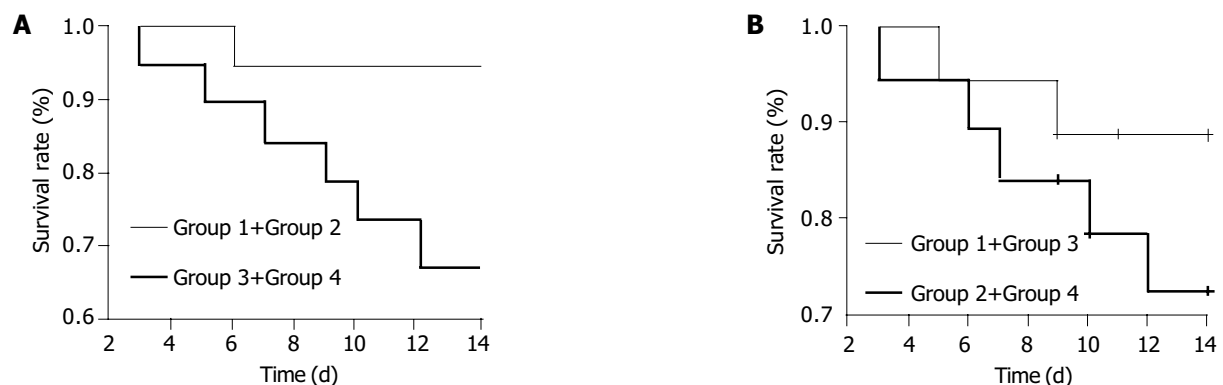

and 3 compared to groups 2 and 4 ($P<0.05$). When the first filter was used, TNF- α concentration decreased significantly in groups 4 and 3 compared to groups 2 and 1 ($P<0.05$). The data suggested that there was a correlation between resistance and serum TNF- α concentration. When the resistance increased, serum TNF- α concentration decreased significantly in the same group after a new filter was installed. After the first, second, and third new hemofilters were exchanged, serum TNF- α concentration was negatively correlated with the resistance (r : -0.91, -0.89, and -0.86 in group 1; -0.89, -0.85, and -0.76 in group 2; -0.88, -0.92, and -0.82 in group 3; -0.84, -0.87, and -0.79 in group 4). The data showed that the time point at which the resistance reached plateau was the membrane adsorptive saturation time, and the resistance could reflect the mass of inflammatory mediators for membrane adsorption.

Cytokine levels in different groups

Before CVVH, serum concentrations of TNF- α , IL-1 β ,

and IL-6 had no significant difference between groups 3 and 1, and between groups 4 and 2 ($P>0.05$). Serum concentrations of TNF- α , IL-1 β and IL-6 tended to decrease in all treatment groups during CVVH. The decreasing extent of TNF- α , IL-1 β and IL-6 was different between groups 3 and 1 (TNF- α $P<0.05$, IL-1 β $P<0.05$, IL-6 $P<0.01$), between groups 4 and 2 (TNF- α $P<0.05$, IL-1 β $P<0.05$, IL-6 $P<0.01$), (Figure 2A-C). The data demonstrated that the diversity of TNF- α , IL-1 β and IL-6 levels increased 72 h after CVVH. The results showed that high-volume CVVH could eliminate cytokines more effectively than low-volume CVVH.

The decreasing extent of TNF- α , IL-1 β and IL-6 was different between groups 1 and 2 (TNF- α $P<0.05$, IL-1 β $P<0.05$, IL-6 $P<0.05$), between groups 3 and 4 (TNF- α $P<0.01$, IL-1 β $P<0.01$, IL-6 $P<0.05$) during CVVH (Figure 2A-C). Serum concentrations of TNF- α , IL-1 β , and IL-6 decreased more significantly in groups 1 and 3

**Figure 1** Survival rate of different intensifying CVVH (A) and different start time of CVVH (B).**Figure 2** Serum level of TNF α (A), IL-1 β (B), and IL-6 (C) in different groups of acute pancreatitis patients.

than in groups 2 and 4 ($\text{TNF-}\alpha$ $P < 0.05$, $\text{IL-1}\beta$ $P < 0.05$, IL-6 $P < 0.01$). Early CVVH decreased serum concentrations of $\text{TNF-}\alpha$, $\text{IL-1}\beta$ and IL-6 more efficiently than late CVVH. The data showed that early CVVH could decrease the excessive activation of inflammatory mediator cascade by reducing $\text{TNF-}\alpha$, $\text{IL-1}\beta$ and IL-6 .

The decreased extent of $\text{TNF-}\alpha$ and $\text{IL-1}\beta$ had no significant difference ($P > 0.05$), but was significantly different between IL-6 and $\text{TNF-}\alpha$, and between IL-6 and $\text{IL-1}\beta$ ($P < 0.01$, Figure 3) in group 4. The data showed that IL-6 decreased more significantly during high-volume CVVH. $\text{TNF-}\alpha$, $\text{IL-1}\beta$ and IL-6 were detectable in the ultrafiltrate.

Figure 3 Different cytokine levels in group 4 of acute pancreatitis patients.

Relationship between survival rate and cytokine levels

Before CVVH, serum concentrations of $\text{TNF-}\alpha$ and $\text{IL-1}\beta$ had a difference between survival and dead patients ($\text{TNF-}\alpha$ $P < 0.05$, $\text{IL-1}\beta$ $P < 0.05$, Figure 4). $\text{TNF-}\alpha$ and $\text{IL-1}\beta$ levels were higher in dead patients. Serum concentrations of $\text{TNF-}\alpha$ and $\text{IL-1}\beta$ decreased in both survival and dead patients during CVVH. The decreasing extent of $\text{TNF-}\alpha$ and $\text{IL-1}\beta$ was different between survival and dead patients ($\text{TNF-}\alpha$ $P < 0.05$, $\text{IL-1}\beta$ $P < 0.05$). In survival patients, serum concentrations of $\text{TNF-}\alpha$ and $\text{IL-1}\beta$ decreased more significantly than that in dead patients (Figure 4). The data demonstrated that survival patients had lower serum levels of $\text{TNF-}\alpha$ and $\text{IL-1}\beta$. Survival rate might be related to the decreasing extent of $\text{TNF-}\alpha$ and $\text{IL-1}\beta$.

Figure 4 Cytokine levels in survival and dead patients of acute pancreatitis.

DISCUSSION

There is evidence that secondary multiple organ failure resulting from septic complications, is the main cause of mortality in severe pancreatitis. The final pathway of pancreatitis-induced sepsis shares many characteristics with other septic diseases, including systemic histopathological abnormalities, excessive release of pro-and anti-inflammatory cytokines. It has been suggested that patients with severe pancreatitis at the risk to develop septic complications might benefit from early application of CVVH irrespective of the presence of acute renal failure (ARF)^[12,13].

Clinical studies have shown that cumulative ultrafiltrate volume is directly correlated with survival rate in patients with sepsis-associated acute renal failure and acute pancreatitis^[13,14]. In our study, high-volume CVVH could significantly improve the survival compared to low-volume CVVH. Joannes-Boyau *et al.*^[15], evaluated the effect of high volume CVVH on hemodynamic and outcome in patients with septic shock, and found that the mortality in the hemofiltration group decreases significantly. Yekebas *et al.*^[16], examined the impact of CVVH on the course of experimental pancreatitis in pigs, and found that the survival time is significantly prolonged by high-volume CVVH. Most likely, this is due to a more effective removal of sepsis mediators. Furthermore, our data show that early CVVH improves survival significantly compared to late CVVH. In a non-randomized trial, it has been hypothesized that early CVVH prior to overt ARF might result in considerable reduction of morbidity in patients with necrotizing pancreatitis^[12]. Xie *et al.*^[17], studied whether initial time of CVVH could influence survival in acute pancreatitis, and found that the average interval is significantly longer in the mortality group than in the survival group from the onset of acute pancreatitis to CVVH. Yekebas *et al.*^[18], reported that animals receiving prophylactic CVVH have a longer survival period, than those receiving CVVH after clinical impairment, suggesting that the improved survival is also due to the fact that early CVVH improves hemodynamic deterioration better than late CVVH. Improved hemodynamic parameters may be due to the application of high-volume CVVH as it was shown in our study. The results are similar to those reported by other studies^[15,19]. As Ronco *et al.*^[20], argued that it is the time to move from the simple goal of achieving adequate renal support, the proper goal of CVVH in ICU should be multi-organ support therapy.

The resistance of filter membrane was constantly measured by means of the electrical impedance technique during CVVH in the present study. The resistance level reached the plateau at 120 min in 1 000 mL/h filtration rate and at 180 min in 4 000 mL/h filtration rate, respectively. The results demonstrate that the adsorptive saturation time of filter membranes is different in different filtration rate. The adsorptive saturation time of filter membranes is 120 -180 min, if the filtration rate is 1 000-4 000 mL/h. De Vriese *et al.*^[21], calculated the cytokine mass balance during hemofiltration in septic patients with acute renal failure, and demonstrated that the adsorption is most prominent immediately after the installation of a new hemofilter (at $t = 1$ and $t = 13$) with a steady decrease thereafter. The

adsorption and the convective elimination increased in a higher blood flow rate and filtration rate. Kellum *et al.*^[22], performed CVVH in patients with severe systemic inflammatory response syndrome, and deduced that the adsorptive saturation time of filter membranes is at 6 h after exchanging a new hemofilter by measuring the decreasing extent of serum cytokines. By delivering a large amount of blood per a unit of time or higher transmembrane pressure to push the molecules deeper into the membrane, the adsorptive surface area increases. The higher convection driving force may increase the surface area accessible to adsorption, by pushing the molecules deeper into the hydrogel. In this respect, only minimal adsorption occurs when the ultrafiltrate line is clamped^[23]. Therefore, increasing filtration rate can increase the adsorption mass and prolong adsorptive saturation time of filter membranes. Our results showed that serum TNF α concentration decreased significantly in the same group after new filters were installed. After the first, second and third new hemofilters were exchanged, serum TNF- α concentration was negatively correlated with the resistance, demonstrating that the time point at which the resistance reached plateau was the membrane adsorptive saturation time. The resistance could reflect the mass of membrane adsorption of inflammatory mediators. To eliminate more inflammatory mediators, the filter should be changed timely when the filter membrane adsorption is saturated. Compared to that reported by De Vriese *et al.*^[21], the method we used to measure the adsorptive saturation time of filter membranes by electrical impedance technique is convenient. The impedance technique has also been used by Rapoza *et al.*^[25], to evaluate the permeability of dentin. Several studies have shown that proteins are denatured and desorbed with increasing treatment time^[21,24]. Clark *et al.*^[26], demonstrated that the desorption of denatured proteins into the blood may be deleterious, indicating that it is very important to change filter timely once filter membrane adsorption is saturated.

In our study, we particularly focused on whether the removal of cytokines, such as TNF- α , IL-1 β and, IL-6 was related to different filtration rate and the onset of CVVH. The impact of CVVH on serum cytokine levels is controversial^[18,19]. Some investigators have not detected significant decreases of inflammatory mediators in the bloodstream, although relevant concentrations are measured in ultrafiltrate^[27,28]. This may be due to the fact that CVVH was performed with low filtration rates. In contrast, De Vriese *et al.*^[21], reported that in septic patients with ARF, plasma cytokine levels decrease significantly after hemofiltration and found that there is a close relationship between the filtration rate and the efficiency of CVVH in removing cytokines. Other studies have confirmed the benefits of increasing the filtration rate in terms of improved survival or accelerated recovery from ARF^[14,29]. In our study, the filtration rate was 4 000 mL/h which is recommended by Uchino *et al.*^[11], as high-volume CVVH. Our data show that high-volume CVVH could eliminate more cytokines than low-volume CVVH. The results are similar to those of some previous clinical studies^[17,30]. Watanabe *et al.*^[31], found that extremely high interleukin-6 blood levels and bad outcome in critically ill patients are associated with tumor necrosis factor- α and interleukin-1, suggesting that activation of

inflammatory mediator is a kind of excessive cascade effect during acute pancreatitis. In the present study, early CVVH decreased serum concentrations of TNF- α , IL-1 β , and IL-6 more efficiently than late CVVH, demonstrating that early CVVH can decrease the excessive activation of inflammatory mediator cascade through reduced TNF- α , IL-1 β , and IL-6, especially in high CVVH patients. We found that IL-6 decreased more significantly than TNF- α and IL-1 β during high-volume CVVH. This may be due to the fact that pro-inflammatory cytokines, such as TNF- α and IL-1 β , are removed efficiently by high-volume CVVH and the causative factors increasing the serum IL-6 level are reduced. Gomez-Cambronero *et al.*^[1], reported that serum levels of pro-inflammatory cytokines, such as TNF-alpha and IL-1beta, increase during acute pancreatitis and appear to be the driving force for the initiation and propagation of the systemic response. The excessive inflammatory response could be down regulated by removing cytokines and other mediators as Lonneman *et al.*^[32], reported. Early CVVH could prevent inflammatory mediators from increasing.

SAP mortality is associated with organ failure. In the early course, organ failure results from inflammatory mediators released by systemic inflammatory response syndrome even in the absence of infection. In the septic phase, since organ failure occurs because of sepsis, it is common in SAP. Inflammatory cytokines play an important role in the progress of acute pancreatitis. In our study, serum concentration of TNF- α and IL-1 β decreased more significantly in survival patients than in dead patients 72 h after CVVH, and similar studies in MODS field are available^[2,3,5], suggesting that the survival rate is related to the decreasing extent of TNF- α and IL-1 β in acute pancreatitis. IL-1 β and its mRNA do not exist in the normal pancreas, but are released immediately after pancreatitis is induced. Blockage of the IL-1 receptor significantly decreases intrinsic pancreatic damage and mortality^[1,33]. Elevated levels of TNF α may contribute to the pathophysiological sequelae of the disease, and pretreatment with anti-TNF α antibody before induction of the disease can prevent release of TNF α ^[34], lessen disease severity and increase survival time^[35]. Blocking the network of cytokines and eliminating cytokines can improve the prognosis and survival rate of pancreatitis.

In summary, CVVH, especially high-volume CVVH, offers several therapeutic options for patients with acute pancreatitis experiencing multiple organ dysfunction. It can improve the hemodynamic parameters and survival rate of pancreatitis patients by removing inflammatory mediators. CVVH can be performed at the early stage of acute pancreatitis. The adsorptive saturation time of filter membranes is different in different filtration rate. The filter should be changed timely once filter membrane adsorption is saturated.

Abstract

AIM: To investigate the effects of leptin administration on liver fibrosis induced by thioacetamide (TAA).

METHODS: Twenty-four male C57BL/6 mice were randomly allocated into four groups, which were intra-peritoneally given saline (2 mL/kg), leptin (1 mg/kg), TAA (200 mg/kg), TAA (200 mg/kg) plus leptin (1 mg/kg) respectively, thrice a week. All mice were killed after 4 wk. The changes in biochemical markers, such as the levels of alanine aminotransferase (ALT) and aspartate aminotransferase (AST) in serum and superoxide dismutase (SOD), malondialdehyde (MDA) in liver were determined. For histological analysis, liver tissues were fixed with 10% buffered formalin, embedded with paraffin. Hematoxylin-eosin (HE) staining and picric acid-Sirius red dyeing were performed. The level of $\alpha 1(I)$ procollagen mRNA in liver tissues was analyzed by RT-PCR.

RESULTS: Apparent liver fibrosis was found in TAA group and TAA plus leptin group. Compared to saline group, the levels of ALT and AST in serum and MDA in liver increased in TAA group (205.67 ± 27.69 U/L vs 50.67 ± 10.46 U/L, 177.50 ± 23.65 U/L vs 76.33 ± 12.27 U/L, 2.60 ± 0.18 nmol/mg pro vs 1.91 ± 0.14 nmol/mg pro, $P < 0.01$) and in TAA plus leptin group (256.17 ± 22.50 U/L vs 50.67 ± 10.46 U/L, 234.17 ± 27.37 U/L vs 76.33 ± 12.27 U/L, 2.97 ± 0.19 nmol/mg pro vs 1.91 ± 0.14 nmol/mg pro, $P < 0.01$). The level of SOD in livers decreased (51.80 ± 8.36 U/mg pro vs 81.52 ± 11.40 U/mg pro, 35.78 ± 6.11 U/mg pro vs 81.52 ± 11.40 U/mg pro, $P < 0.01$) and the level of $\alpha 1(I)$ procollagen mRNA in liver tissues also increased (0.28 ± 0.04 vs 0.11 ± 0.02 , 0.54 ± 0.07 vs 0.11 ± 0.02 , $P < 0.01$). But no significant changes were found in leptin group and saline group. Compared to TAA group, ALT, AST, MDA, and $\alpha 1(I)$ procollagen mRNA and grade of liver fibrosis in TAA plus leptin group increased (256.17 ± 22.50 U/L vs 205.67 ± 27.69 U/L, $P < 0.05$; 234.17 ± 27.37 U/L vs 177.50 ± 23.65 U/L, $P < 0.05$; 2.97 ± 0.19 nmol/mg pro vs 2.60 ± 0.18 nmol/mg

pro, $P < 0.05$; 0.54 ± 0.07 vs 0.28 ± 0.04 , $P < 0.01$; 3.17 vs 2.00 , $P < 0.05$), and the level of SOD in liver decreased (35.78 ± 6.11 U/mg pro vs 51.80 ± 8.36 U/mg pro, $P < 0.05$). There were similar changes in the degree of type I collagen deposition confirmed by picric acid-Sirius red dyeing.

CONCLUSION: Leptin can exacerbate the degree of TAA-induced liver fibrosis in mice. Leptin may be an important factor in the development of liver fibrosis.

INTRODUCTION

Leptin, an obese gene product, is a 16-ku peptide hormone expressed and secreted predominantly by adipose tissue^[1], and plays an essential role in the regulation of body weight mainly by reducing food intake and increasing energy expenditure^[2]. In addition to the effect of controlling body fat mass, leptin has a variety of other biological functions, such as wound healing, angiogenesis, immune response, etc.^[3-6], thus exerting its effects on many tissues or organs, including the liver. Potter *et al.*^[7] found that isolated hepatic stellate cells (HSCs) also produce leptin during the *in vitro* transactivation process in 1998. Since then researchers have paid more attention to the correlation between leptin and liver diseases. Recently, it was reported that the serum leptin levels are elevated in patients with chronic viral hepatitis, alcohol-induced cirrhosis, or non-alcoholic steatohepatitis (NASH)^[8-11]. These observations suggest that leptin may be involved in the progression of liver fibrosis. Accordingly, in the present study we investigated the effect of leptin administration on liver fibrosis caused by thioacetamide (TAA).

MATERIALS AND METHODS

Animals and treatment

Twenty-four, 6-wk-old male C57BL/6 mice, weighing 18.4-24.2 g, were obtained from Institute of Transplantation, Tongji Medical College, Huazhong University of Science and Technology. All mice were housed in a temperature-humidity-controlled environment in a 12 h light-dark cycle

with free access to food and water. The mice were randomly divided into four groups with six mice in each, which were given an intra-peritoneal injection of saline (2 mL/kg), recombinant murine leptin (1 mg/kg, R&D Systems Inc., USA), TAA (200 mg/kg), TAA (200 mg/kg) plus leptin (1 mg/kg) thrice a week. All mice were killed after 4 wk. Blood and livers were collected for further examination.

Histological examination

Liver tissues were fixed with 10% buffered formalin, embedded with paraffin, and then hematoxylin-eosin (HE) staining and picric acid-Sirius red dyeing were performed. Liver fibrosis was evaluated by a semi-quantitative method to assess the degree of histological injury using the following criteria: grade 0: normal liver; grade 1: few collagen fibrils extended from the central vein to the portal tract; grade 2: apparent collagen fibril extension without encompassing the whole lobule; grade 3: collagen fibrils extended into and encompassed the whole lobule; grade 4: diffuse extension of collagen fibrils and formation of pseudo-lobule.

Estimation of liver function

Blood was obtained at the time of killing. The serum aspartate aminotransferase (AST) and alanine aminotransferase (ALT) levels were measured by the Olympus AU-1000 biochemical autoanalyzer, as markers of hepatic damage.

Level of malondialdehyde and superoxide dismutase

Malondialdehyde (MDA) and superoxide dismutase (SOD) contents in liver tissue were assayed by assay kits (Jiancheng Biotech Ltd, Nanjing, China).

RNA extraction and RT-PCR assay

Expression of $\alpha 1$ (I) procollagen mRNA was evaluated with RT-PCR. Total RNA was isolated from liver specimens with RNAex reagent (Watson Biotechnologies, Inc., Shanghai, China) according to the manufacturer's descriptions. Total RNA was quantified spectrometrically at 260 nm, and the quality of isolated RNA was analyzed on agarose gels under standard conditions. Two-step RT-PCR was performed as recommended by the suppliers. Primer sequences were $\alpha 1$ (I) procollagen: forward 5'-CCT GGA CGC CAT CAA GGT CTA C-3' and reverse 5'-CCA AGT TCC GGT GTG ACT CG-3', fragment length 419 bp; β -actin: forward 5'-ACC ACA GCT GAG AGG GAA ATC G-3' and reverse 5'-AGA GGT CTT TAC GGA TGT CAA CG-3', fragment length 277 bp. Amplification conditions were as follows: pre-denaturation at 95 °C for 2 min, then in a thermal controller for 35 cycles (denaturation at 95 °C for 45 s,

annealing at 56 °C for 45 s and extension at 72 °C for 1 min), and a final extension at 72 °C for 7 min after the last cycle. Ten milliliters of the PCR products was analyzed on 2% agarose gel containing ethidium bromide with TAE buffer at 80 V for 30 min and photographed under UV illumination. The band intensities were quantified by densitometry. $\alpha 1$ (I) procollagen/ β -actin quotient indicated the relative expression of $\alpha 1$ (I) procollagen.

Statistical analysis

The results were expressed as mean \pm SD. One-way analysis of variance (ANOVA) with LSD post hoc comparison was used to test for differences in means of variables between groups. $P < 0.05$ was considered statistically significant. All data were analyzed by SPSS 11.0 software.

RESULTS

Animal model and liver histology

Compared to saline group and leptin group, the mice in TAA group and TAA plus leptin group were thin and less haired. The surface of liver was rough and formation of small nodules was observed, indicating that liver fibrosis developed as expected. The degree of type I collagen deposition was confirmed by liver histology stained with picric acid-Sirius red. As anticipated, liver tissue specimens from both the saline group and leptin group showed no significant picric acid-Sirius red staining, indicating a lack of type I collagen deposition outside of central and portal blood vessels. Apparent hepatocyte degeneration, necrosis, infiltration of inflammatory cells, expanded portal tracts and collagen deposition were found in TAA group and TAA plus leptin group. The degree of liver fibrosis in these two groups significantly increased compared to that in saline group or leptin group ($P < 0.01$). But compared to TAA group, the deposition of type I collagen in TAA plus leptin group was more apparent and the degree of liver fibrosis also increased ($P < 0.05$). The details about the degree of liver fibrosis in each group are shown in Table 1. Type I collagen deposition in each group is shown in Figure 1.

Serum ALT and AST level

At the end of the study, there was no difference in serum ALT and AST levels between saline group and leptin group. But serum ALT and AST levels in TAA group and TAA plus leptin group significantly increased compared to those in saline group and leptin group ($P < 0.01$). Furthermore, treatment with TAA plus leptin increased the ALT and AST levels compared to treatment with TAA ($P < 0.05$, Table 2).

Table 1 Degree of liver fibrosis in each group of mice

Changes of MDA and SOD in liver tissue

The amount of MDA and SOD did not obviously change in leptin group, compared to that in the saline group. The amount of MDA in TAA group and TAA plus leptin group was significantly higher than that in saline group ($P<0.01$), while SOD in the two groups was significantly lower than that in saline group ($P<0.01$). But MDA was higher in TAA plus leptin group than in TAA group ($P<0.05$), while SOD was lower in TAA plus leptin group than in TAA group ($P<0.05$, Table 3).

for $\alpha 1(I)$ procollagen were assessed. RNA extracts from livers were analyzed by reverse transcription PCR. Furthermore, the band intensity ratio of $\alpha 1(I)$ procollagen to β -actin was evaluated and presented as percentage of β -actin. As shown in Table 4 and Figure 2, the expression of $\alpha 1(I)$ procollagen in leptin group did not obviously change, compared to that in the saline group, but significantly increased in TAA group and TAA plus leptin group ($P<0.01$). The expression of $\alpha 1(I)$ procollagen in TAA plus leptin group was much higher than that in TAA group ($P<0.01$, Table 4 and Figure 2).

DISCUSSION

In the present study, chronic administration of TAA or TAA plus leptin caused liver fibrosis as indicated by the changes of serum markers, histopathological changes, and molecular biological changes. But more overt liver fibrosis was observed, when leptin was used in combination with TAA. Our results are in line with other findings that leptin-deficient *ob/ob* mice do not develop fibrosis during steatohepatitis or in response to chronic toxic liver injury^[12,13], indicating that leptin can exacerbate the degree of fibrosis in mouse liver induced by TAA, and may be an important

Figure 2 Expression of $\alpha 1(I)$ procollagen mRNA. M: 100-bp DNA marker; lane 1: saline group; lane 2: leptin group; lane 3: TAA group; and lane 4: TAA plus leptin group.

factor in the development of liver fibrosis.

The activities of serum fibrosis-associated enzymes, namely ALT and AST, significantly increased along with the increased expression of $\alpha 1(I)$ procollagen mRNA in TAA group and TAA plus leptin group. But leptin could augment TAA-induced inflammatory response and increase the expression of $\alpha 1(I)$ procollagen mRNA. The histological examination also found that leptin increased the TAA-induced deposition of type I collagen. Specific increase in procollagen mRNAs in liver fibrosis parallels increase in tissue collagen content. Since increased synthesis of procollagen contributes to the increase of collagen content in fibrotic liver, the expression of $\alpha 1(I)$ procollagen mRNA can reflect the degree of hepatic fibrosis^[14,15]. Activation of HSCs is the essential event in hepatic fibrogenesis, because HSCs transactivate to myofibroblast-like cells that produce a large, excess amount of matrix proteins (e.g., fibrillar collagen, fibronectin, laminin, and proteoglycans) in injured liver^[16]. It was reported that HSCs express short forms of the leptin receptor (Ob-Ra), but not the functional long form of the leptin receptor Ob-Rb. Since the sinusoidal endothelial cells and Kupffer cells in the liver express the long form of the leptin receptor Ob-Rb^[17,18], leptin may exert an indirect effect on the activation of HSCs mediated by TGF- β_1 . As Ob-Rb leptin can increase TGF- β_1 expression in the sinusoidal endothelial cells and Kupffer cells, TGF- β_1 activates type I collagen promoters, and upregulates the extracellular matrix such as collagen and fibronectin from HSCs^[19]. Recently, it was reported that leptin also can activate HSCs directly^[20]. However, the role of leptin in the activation of HSCs needs to be further analyzed.

TAA is a typical hepatotoxin and causes centrilobular necrosis by generation of ROS. ROS triggers lipid peroxidation chain reaction. MDA is the production of lipid peroxidation, the amount of MDA can express the degree of lipid peroxidation. SOD is a ubiquitous chain breaking anti-oxidant found in all aerobic organisms. It is a metalloprotein widely distributed in all cells and protects cells against ROS-induced oxidative damage. Oxidative stress contributes to the pathogenesis of hepatic fibrosis induced by alcohol and virus infection^[21,22]. Furthermore, oxidative stress is involved in activation of HSCs and promotion of their proliferation, collagen synthesis, and migration^[23]. The activation of

quiescent HSCs plays an important role in the process of liver fibrosis^[16,24]. In our experiment, MDA was higher in TAA plus leptin group than in TAA group ($P < 0.05$), while SOD was lower in TAA plus leptin group than in TAA group. The results suggest leptin can augment TAA-induced lipid peroxidation by lowering the level of enzymic antioxidant. But leptin administration alone has no apparent effect on lipid peroxidation. Whether leptin is just a co-factor needs to be further studied. On the other hand, leptin can regulate macrophage function^[25] and augment endotoxin-stimulated TNF production by macrophages^[3]. Hematopoietic cells including macrophages and lymphocytes contain a functional leptin receptor^[26], through which leptin regulates proliferation and maturation of immune cells^[27,28] and elicits release of pro-inflammatory cytokines from macrophages^[3]. These pro-inflammatory cytokines and immune responses play a critical role in the development of liver fibrosis. The above findings may explain, at least in part, why leptin increases the degree of liver fibrosis in mice induced by TAA.

It has been reported that hepatic cirrhosis is six fold more prevalent in obese individuals than in the general population^[29,30], and obesity is an independent risk factor for the development of chronic liver diseases caused by alcohol, chronic hepatitis C, and NASH^[31-34]. These observations indicate that there could be a pathogenic link between obesity and liver fibrosis. But the reason why obesity accelerates the development of hepatic fibrosis has not been elucidated. Circulating levels of leptin correlate well with body fat mass^[35]. Obese people have remarkably high serum leptin levels. Increased serum leptin presumably enhances pro-inflammatory and pro-fibrogenic responses in the liver, and generate oxidative stress. Leptin may be a determinant of hepatic inflammation and fibrosis in obese individuals, especially in those with NASH. Our findings support the hypothesis that leptin is involved in the progression of liver fibrosis. However, additional studies are needed to elucidate the role of leptin in the progression of chronic liver fibrosis in obese patients.

Abstract

AIM: To investigate the response of astrocytes and neurons in rat lumbo-sacral spinal cord and medulla oblongata induced by chronic colonic inflammation, and the relationship between them.

METHODS: Thirty-three male Sprague-Dawley rats were randomly divided into two groups: experimental group ($n = 17$), colonic inflammation was induced by intra-luminal administration of trinitrobenzenesulfonic acid (TNBS); control group ($n = 16$), saline was administered intra-luminally. After 3, 7, 14, and 28 d of administration, the lumbo-sacral spinal cord and medulla oblongata were removed and processed for anti-glial fibrillary acidic protein (GFAP), Fos and GFAP/Fos immunohistochemistry.

RESULTS: Activated astrocytes positive for GFAP were mainly distributed in the superficial laminae (laminae I-II) of dorsal horn, intermediolateral nucleus (laminae V), posterior commissural nucleus (laminae X) and anterolateral nucleus (laminae IX). Fos-IR (Fos-immunoreactive) neurons were mainly distributed in the deeper laminae of the spinal cord (laminae III-IV, V-VI). In the medulla oblongata, both GFAP-IR astrocytes and Fos-IR neurons were mainly distributed in the medullary visceral zone (MVZ). The density of GFAP in the spinal cord of experimental rats was significantly higher after 3, 7, and 14 d of TNBS administration compared with the controls (50.4 ± 16.8 , 29.2 ± 6.5 , 24.1 ± 5.6 , $P < 0.05$). The density of GFAP in MVZ was significantly higher after 3 d of TNBS administration (34.3 ± 2.5 , $P < 0.05$). After 28 d of TNBS administration, the density of GFAP in the spinal cord and MVZ decreased and became comparable to that of the controls (18.0 ± 4.9 , 14.6 ± 6.4 , $P > 0.05$).

CONCLUSION: Astrocytes in spinal cord and medulla oblongata can be activated by colonic inflammation. The activated astrocytes are closely related to Fos-IR neurons. With the recovery of colonic inflammation, the activity of

astrocytes in the spinal cord and medulla oblongata is reduced.

INTRODUCTION

Recent studies have shown that astrocytes, being in intimate contact with neurons, may respond to various kinds of stimulation. Both peripheral inflammation and nerve injuries are able to induce astrocytic activation in the spinal cord and brain stem. Moreover, astrocytic activation was shown to be involved in central nervous system (CNS) responses leading to hypersensitivity and persistent pain states^[1-3]. Glial fibrillary acidic protein (GFAP) is an intermediate filament component in astrocytes of nervous tissue. The expression of GFAP may increase with astrocytic activation^[4]. By using GFAP and Fos immunoreactivity (IR) as markers, we aimed to determine the response of astrocytes and neurons in rat lumbo-sacral spinal cord and medulla oblongata induced by chronic colonic inflammation, and the relationship between them.

MATERIALS AND METHODS

Animals

Thirty-three adult male Sprague-Dawley rats (The Fourth Military Medical University) weighing 220-250 g were used in this study. The animals were housed in a quiet room with a constant ambient temperature of 20 °C, and free access to rat chow and water. They were divided randomly into experimental group ($n = 17$) and control group ($n = 16$).

Experimental protocol

After 24 h fast, trinitrobenzenesulfonic acid (TNBS, 100 mg/kg in 300 mL/L ethanol) was administered intra-luminally through a silicone rubber catheter introduced 7 cm into the anus with light diethyl-ether anesthesia, as previously described^[5]. To keep TNBS in the colon for a longer time and to avoid leakage, the tubing was slowly

withdrawn and the tail of the rat was kept elevated for 8-10 min. After intra-luminal administration of TNBS, rats in the experimental group were allowed to live 3 ($n = 4$), 7 ($n = 4$), 14 ($n = 4$) and 28 ($n = 5$) d, respectively.

After intra-luminal administration of 0.5 mL saline, rats in the control group were allowed to live 3 ($n = 4$), 7 ($n = 4$), 14 ($n = 4$) and 28 ($n = 4$) d, respectively.

Immunohistochemistry

The animals were deeply anesthetized with pentobarbital Na (80 mg/kg, intraperitoneal) and perfused intracardially with 100 mL saline followed by 500 mL fixative of 4% paraformaldehyde in 0.1 mol/L phosphate buffer (pH 7.4). L₃-S₂ segments of the spinal cord and medulla oblongata were removed post-fixed in the same fixative at 4 °C for 2-4 h and then cryoprotected in 20% sucrose overnight. Serial frozen sections of 40 µm thick were cut on a Leitz cryocut. Sections were collected in 0.01 mol/L PBS for immunohistochemistry.

The spinal cord and medulla oblongata sections from each rat were randomly divided into three sets. Two sets were processed for anti-GFAP and anti-Fos immunohistochemical staining by using avidin-biotin-peroxidase complex (ABC) method. Briefly, free-floating tissue sections were treated in 800 mL/L methanol containing 0.3% H₂O₂ to block endogenous peroxidase activity for 30 min at room temperature. They were treated with 0.01 mol/L PBS containing 0.1% Triton X100 for 20 min at room temperature. The sections were then incubated with a polyclonal rabbit anti-Fos antibody (1:3 000, Santa Cruz) or rabbit anti-GFAP antibody (1:3 000 Dako) for 48 h at 4 °C. After that, the sections were incubated with biotinylated goat anti-rabbit IgG (1:500, Sigma), and subsequently with the ABC complex (1:500, Sigma) at room temperature for 2 h each. The antigen-antibody reaction sites were visualized by incubation with glucose oxidase-DAB-nickel method for 15-30 min at room temperature. The sections were rinsed in 0.01 mol/L PBS for 3 min×10 min during the transition of these steps. The other set group of sections was stained for GFAP and Fos by using double immunohistochemical labeled method. Finally, the sections were mounted onto gelatin-coated slides, dried, dehydrated, cleared and coverslipped.

Histopathological analysis

Colon specimens that were 1 cm long and 7 cm proximal to the anus were taken for histological assessment. They were rapidly immersed in cold 100 mL/L neutral buffered formalin, fixed overnight. Then they were processed routinely and embedded in paraffin blocks, and 3-5 µm-thick cross sections were stained with H&E and examined by light microscope.

Measurement of the density of GFAP staining and Fos immunoreactive neuronal counts

The density of GFAP staining and the numbers of neuronal nuclear profiles expressing Fos were analyzed with computer assisted QUIC Menu System. The ratio of the area of stained GFAP to the area of outlined regions was presented as the density of GFAP. Fos counting was done by outlining specific regions and then, particles (stained nuclei) were counted in

the outlined regions.

For each animal, the average for density measurements and number counts in the spinal cord was obtained unilaterally from five randomly selected sections. In the medulla oblongata, four sections were selected from above the obex, obex, the area postrema, and pyramidal decussation levels respectively. The average for density measurements and number counts was obtained unilaterally in the nucleus of the solitary tract (NTS), ventrolateral medulla (VLM) and intermediate reticular zone (IRt) from those four section levels.

Statistical analysis

Pictures were taken under BX-60 microscope with the support of IM50 software. All results are expressed as mean±SD. An unpaired *t*-test was used to compare GFAP density and Fos-IR cell count data between the groups. A difference was accepted as significant, if the probability was less than 5% ($P < 0.05$).

RESULTS

Histopathological changes in the inflamed colon

After 3, 7, and 14 d of TNBS administration, macroscopic and histological examination of the rat colon showed that TNBS-induced colitis was uniform, with submucosal and mucosal infiltration with numerous inflammatory cells, signs of extensive ulceration, and dilated blood vessels (Figures 1A and 1B). The colon appeared macroscopically normal in rats that received TNBS for 28 d (Figure 1C). The presence of inflammatory cells was minimal in the colon of the control rats treated with saline (Figure 1D).

GFAP and Fos protein expression in the spinal cord

In the experimental animals, colonic inflammation induced robust astrocytic activation responses after 3, 7, and 14 d of TNBS administration. The activated glial cells were characterized by decreased ramification, hypertrophy and proliferation. Most activated astrocytes positive for GFAP were distributed bilaterally in the superficial laminae (laminae I-II) of dorsal horn, intermediolateral nucleus (laminae V), posterior commissural nucleus (laminae X) and anterolateral nucleus (laminae IX, Figure 2A). Mild GFAP-IR astrocytes exhibited in the spinal cord of the rats treated with saline (Figure 2B). The density of GFAP in the spinal cord of experimental rats was significantly higher after 3, 7, and 14 d of TNBS administration compared with that of the controls ($P < 0.05$). After 28 d of TNBS administration, the density of GFAP in the spinal cord decreased and was comparable to that of the control group ($P > 0.05$, Table 1).

The majority of Fos-IR neurons were distributed bilaterally in L₅, L₆, and S₁ segments of lumbo-sacral spinal cord after TNBS administration. At various post-inflammatory days, Fos-IR cells were mainly localized in deeper laminae III-IV and laminae V-VI in the spinal dorsal horn (Figure 2C). Only a few Fos-IR neurons were sparsely distributed in the dorsal horn of the rats treated with saline (Figure 2D). After 3 d following TNBS administration, the number of Fos-IR neurons in the dorsal horn did not increase significantly

Figure 1 Histopathological changes of the colon. **A:** After 3 d of TNBS administration, the structure of the colon was destroyed ($\times 10$); **B:** Numerous inflammatory cells were infiltrated in the submucosa and mucosa of the colon

($\times 40$); **C:** After 28 d of TNBS administration, only a few inflammatory cells were infiltrated in submucosa and mucosa of the colon ($\times 40$); **D:** The inflammatory cells were minimal in the colon of the rats after 3 d of saline administration ($\times 40$).

($P > 0.05$). With the aggravation of colonic inflammation, the number of Fos-IR cells in the dorsal horn increased after 7 and 14 d following TNBS injection, a significant difference compared with that of the control group ($P < 0.05$). It was noted that Fos expression in the spinal cord displayed two patterns after 28 d of TNBS administration. Few Fos-IR neurons exhibited in the spinal dorsal horn in two rats (12.0 and 13.3, 12.7 ± 0.9), without significant difference from the control ($P > 0.05$). However, many Fos-IR neurons presented in the spinal dorsal horn in three rats (56.7, 69.0 and 36.7, 54.1 ± 16.3), with a significant difference compared with that in control rats ($P < 0.05$, Table 2).

Table 1 Density of GFAP in the spinal cord and MVZ at various post-inflammatory days (%)

	Spinal cord		MVZ	
	Experimental	Control	Experimental	Control
3 d	50.4 ± 16.8^a	17.7 ± 0.4	34.3 ± 2.5^a	15.9 ± 3.9
7 d	29.2 ± 6.5^a	15.5 ± 0.6	15.6 ± 1.8	13.0 ± 1.6
14 d	24.1 ± 5.6^a	14.9 ± 1.1	16.3 ± 1.6	13.5 ± 2.9
28 d	18.0 ± 4.9	15.9 ± 1.3	14.6 ± 6.4	12.8 ± 1.8

^a $P < 0.05$ vs the control.

GFAP and Fos protein expression in the medulla oblongata

In the control animals, only few GFAP-IR astrocytes exhibited in the medulla oblongata. After TNBS administration, GFAP-IR astrocytes increased and were primarily localized in MVZ, which was composed of NTS, VLM, and IRt, from the level of pyramidal decussation to the level rostral to the obex (Figure 2E). The density of GFAP in MVZ was

significantly increased after 3 d of TNBS administration compared with that of the control group ($P < 0.05$). After 7, 14, and 28 d of TNBS administration, the density of GFAP in MVZ decreased gradually and became comparable to the control group ($P > 0.05$, Table 1).

Similarly, Fos-IR neurons were primarily localized in MVZ in the experimental animals. Fos-IR neurons in MVZ did not increase significantly after 3 d of TNBS administration ($P > 0.05$). After 7 and 14 d of TNBS administration, Fos-IR neurons in MVZ increased significantly compared with those in control animals ($P < 0.05$). Fos-IR cells in MVZ decreased significantly and were comparable to those in the control group after 28 days of TNBS administration (41.2 ± 31.4 , $P > 0.05$, Table 2).

In the medulla oblongata, activated astrocytes positive for GFAP enveloped activated neurons stained for Fos (Figure 2F).

Table 2 Number of Fos-IR neurons in the spinal cord and MVZ at various post-inflammatory days

	Spinal cord		MVZ	
	Experimental	Control	Experimental	Control

DISCUSSION

It is well known that gut afferent signals reach conscious

Figure 2 GFAP and Fos expression in the spinal cord and NTS. **A:** After 3 d of TNBS administration, most activated astrocytes positive for GFAP were distributed in the superficial laminae (laminae I-II) of dorsal horn ($\times 20$); **B:** Mild GFAP-IR astrocytes exhibited in the spinal cord of rats after 3 d of saline administration ($\times 20$); **C:** After 14 d of TNBS administration, Fos-IR cells were mainly localized in deeper laminae III-IV and laminae V-VI in the spinal dorsal

horn ($\times 10$); **D:** Only a few Fos-IR neurons were sparsely distributed in the dorsal horn after 7 d of saline administration ($\times 10$); **E:** After 3 d of TNBS administration, GFAP-IR glial cells increased and were primarily localized in NTS ($\times 10$); **F:** After 3 d of TNBS administration, activated astrocytes positive for GFAP enveloped activated neurons stained for Fos in the medulla oblongata ($\times 40$).

perception through a three-neuron chain. The second-order neuron, whose cell body is in the dorsal horn of the spinal cord, converge visceral and somatic afferents^[6]. In the rat, the descending colon is innervated by sensory afferent fibers in the pelvic nerve projecting to the lumbar-sacral (L₆-S₂) spinal cord^[7]. MVZ is an arch zone extending from the dorsomedial area across reticular formation to VLM. It is situated in the middle-caudal segment of the medulla oblongata, from the level of the pyramidal decussation to the level, rostral to the obex. MVZ is a relay station predominantly transmitting visceral sensory information, and takes part in perception of noxious stimulation^[8]. Because of the importance of the lumbo-sacral spinal cord segments and MVZ in transmitting visceral signals, we studied the responses of astrocytes and neurons induced by colonic inflammation in these tissues.

Studies have shown that astrocytes may respond to a number of stimulations, such as somatic and visceral inflammation^[3,9], nerve injuries^[10] and bone cancer^[11]. Activated astrocytes may involve in mediating hyperalgesia

and chronic pain. The activated astrocytes are characterized by decreased ramification, hypertrophy, proliferation, and the up-regulation of immunoregulatory molecules^[12]. GFAP are distributed in the cytoplasm of many types of glial cells. GFAP expression is low in the intact adult CNS, but increases after astrocytic activation^[13]. Sweitzer *et al.*, reported that acute peripheral inflammation induced by subcutaneous injection of formalin and zymosan resulted in increased expression of GFAP in astrocytes. Astrocytic activation has been implicated in regenerative processes and synaptic remodeling that may be detrimental when aberrant processing ensues, leading to chronic pain states^[1].

In our experiment, colonic inflammation induced robust astrocytic activation responses after 3, 7, and 14 d of TNBS administration. Most activated astrocytes positive for GFAP were distributed bilaterally in the superficial laminae (laminae I-II) of dorsal horn. These results are consistent with other studies. In a rat model of bone cancer, significant enhancement of GFAP staining was described in the superficial laminae of the ipsilateral spinal cord^[11]. Watkins

et al., have shown that astrocytes were able to release nerve growth factor (NGF), which exerts its pain modulatory actions on primary afferents. Furthermore, primary afferents expressing high affinity NGF receptors terminate exclusively in laminae I and the outer region of laminae II. Astrocytes in the intermediolateral nucleus (laminae V), posterior commissural nucleus (laminae X) and anterolateral nucleus (laminae IX) were also activated after 3, 7, and 14 d of TNBS administration. In the lumbo-sacral spinal cord, cell bodies of parasympathetic nerve are located in intermediolateral nucleus i.e., is parasympathetic sacral nucleus. Somatic and visceral afferents converge at posterior commissural nucleus. Therefore, astrocytic responses in these nuclei were directly activated by colonic inflammation. Astrocytic activation in anterolateral nucleus might be related to diarrhea induced by TNBS administration.

The timing of the changes of GFAP is relevant to the mode by which astrocytes are activated. A rapid increase in GFAP-IR has been reported to occur between 30 min and 3 h and then a secondary increase which follows approximately 3 d later. GFAP-IR in the trigeminal ganglion in response to dental injury reported by Stephenson *et al.*, appeared by 3 d and was most intense by 7 d^[4]. Astrocytic activation in the spinal cord segments increased 42 d after lumbar root injury^[14]. Chudler *et al.*, proposed that the persistence of GFAP-IR 59 d after nerve injury suggested GFAP was involved in the long-term recovery of injured neurons^[15]. In the experimental rats, the density of GFAP in lumbo-sacral spinal cord and MVZ was most intense by 3 d and decreased gradually after TNBS administration. After 7 and 14 d of TNBS administration, the density of GFAP in the spinal cord was still significantly higher compared with that of the controls ($P < 0.05$). However, the density of GFAP in MVZ became comparable to that of the control group ($P > 0.05$). This result suggested that astrocytic activation in the spinal cord lasted much longer than that in MVZ. The response of astrocytes in both the spinal cord and MVZ decreased significantly with the recovery of colonic inflammation.

The evoked expression of the immediate-early-gene-encoded protein, Fos, serves as a quantifiable marker to identify neuronal populations activated by noxious somatic and visceral stimulation^[16]. Fos protein is thought to be a nuclear third messenger coupling short-term extracellular signals with long-term alterations in cell function^[17]. Thus, Fos protein expression can be used to study long-term changes in stimulus-induced neuronal activity^[18]. We found that Fos-IR cells were mainly localized in deeper laminae III-IV and laminae V-VI in the spinal dorsal horn over time in experimental groups. Only a few Fos-IR neurons were sparsely distributed in the superficial laminae I-II in the dorsal horn. This suggested that persistent noxious visceral stimulation induced Fos expression to a greater extent in deeper laminae than in the superficial ones in the spinal dorsal horn. These results are in line with the spatial distribution of Fos protein in the lumbar spinal dorsal horn in rats following chronic adjuvant-induced arthritis^[19] and chronic constriction injury to the sciatic nerve^[20]. The study of Imbe *et al.*, showed that Fos-IR cells might spread from the superficial laminae to deeper ones in the dorsal horn

when deep tissue inflammation persisted^[18].

The timing changes of Fos expression differed from that of GFAP. After 3 d following TNBS administration, the number of Fos-IR neurons in the spinal dorsal horn and MVZ did not increase significantly. With intensification of colonic inflammation, the number of Fos-IR cells both in the dorsal horn and in MVZ increased significantly after 7 and 14 d following TNBS administration. After 28 d of TNBS administration when colonic inflammation recovered, Fos-IR cells in MVZ decreased significantly and were comparable to those in the control group. However, a lot of Fos-IR neurons still presented in the spinal dorsal horn in three experimental rats. Although it is not known exactly whether increased central hyperexcitability contributes to greater Fos protein expression following inflammation. The study of Zimmerman and Herdegen suggested that the increase in Fos may be a necessary pre-requisite for the development of chronic pain and allodynia, because increased expression of the gene product renders the neurons susceptible to subsequent stimuli^[21]. The development of neuronal activation in the lumbo-sacral dorsal horn may play a role in visceral hypersensitivity.

Astrocytes display an intimate structural relationship with the neurons that they envelope in the CNS. Gap junctions between astrocytes have been demonstrated using the freeze-fracture technique and adherents junctions between neurons and astrocytes have been observed in many species^[4]. In addition to the morphological associations between neurons and astrocytes, there appears to be a wide range of functional interactions between these cells. Duan *et al.*, reported that the number of connexin32/connexin43 gap junction (HGJ) between neurons and astrocytes in rat supraoptic nuclei was significantly increased following hyperosmotic stimuli. They proposed HGJ may be a rapid adaptive signal structure between neurons and astrocytes in response to stimulation. Apart from playing roles in synaptic remodeling and providing neurotrophic support for regenerating neurons, astrocytes which are known to express both voltage gated sodium channels and glutamate receptors could serve as sensors for neuronal activity or injury^[22]. The present study has shown that GFAP-IR astrocytes and Fos-IR neurons distributed similarly in deeper laminae of the spinal dorsal horn and MVZ, especially in the commissural subnucleus inside NTS. This suggested that colonic inflammation could not only induce neuronal activation in visceral transmitting chain, but also induce astrocytic responses via signal interactions between neurons and astrocytes.

Abstract

AIM: To investigate the frequency and distribution of *N*-acetyltransferase 2 (*NAT2*) and uridine 5'-diphosphate (UDP)-glucuronosyltransferase 1A7 (*UGT1A7*) genes in patients with ulcerative colitis (UC) and Crohn's disease (CD).

METHODS: Frequencies and distributions of *NAT2* and *UGT1A7* SNPs as well as their haplotypes were investigated in 95 patients with UC, 60 patients with CD, and 200 gender-matched, unrelated, healthy, control volunteers by PCR-restriction fragment length polymorphism (RFLP), PCR-denaturing high-performance liquid chromatography (DHPLC), and direct DNA sequencing.

RESULTS: Multiple logistic regression analysis revealed that the frequency of haplotype, *NAT2**7B, significantly increased in CD patients, compared to that in controls ($P = 0.0130$, OR = 2.802, 95%CI = 1.243-6.316). However, there was no association between *NAT2* haplotypes and UC, or between any *UGT1A7* haplotypes and inflammatory bowel disease (IBD).

CONCLUSION: It is likely that the *NAT2* gene is one of

the determinants for CD in Japanese. Alternatively, a new CD determinant may exist in the 8p22 region, where *NAT2* is located.

INTRODUCTION

Chronic inflammatory bowel disease (IBD) is a multi-factorial disorder characterized by non-specific inflammation of the gastrointestinal tract with an increase in the permeability to xenobiotics in the intestinal mucosa, finally resulting in intestinal malabsorption and immune defense abnormalities^[1,2]. Ulcerative colitis (UC) and Crohn's disease (CD) are the major forms of IBD. Although the precise etiology of IBD remains unknown, not only several environmental factors, such as dietary components and microorganisms, but also genetic factors may contribute to the occurrence of this disorder^[3,4]. Recently, extensive molecular genetic studies have been launched to identify genes underlying the etiology^[5]. One of them is the caspase activating recruitment domain 15/nucleotide oligomerization domain 2 gene (*CARD15/NOD2*) located at 16q12. Although mutations in *NOD2* are observed frequently in Caucasian patients with CD, but not with UC^[6,7], they have rarely been found in Japanese CD patients^[8,9], suggesting that *NOD2* is not a major determinant for CD in Japanese.

We have particularly focused on genes for *N*-acetyltransferase 2 (*NAT2*) and uridine 5'-diphosphate (UDP)-glucuronosyltransferase 1A7 (*UGT1A7*) as candidates susceptible to IBD, because they are expressed in the gastrointestinal tract and play a role in biochemical barriers against internal and external xenobiotics^[10-12]. Diminution or disturbance of these barriers might result in increased permeability to xenobiotics in the gastrointestinal tract, and subsequently their accumulation in the body, probably leading to the development of IBD. *N*-acetyltransferases (NATs)

are the enzymes catalyzing *N*-acetylation (deactivation) of a variety of carbocyclic and heterocyclic arylamines by means of transferring acetyl-CoA to the amino or hydroxyl side chain of arylamines in metabolism of the phase II reaction^[10]. NATs are encoded by two genes, *NAT1* and *NAT2*, both are located at 8p22. *NAT1* is ubiquitously expressed, while the expression of *NAT2* is confined to the gastrointestinal tract and liver^[10]. The UDP-glucuronosyl-transferase 1 family genes located at 2q37 consist of nine functional genes, *UGT1A1*, *UGT1A3-10*, which catalyze the glucuronidation of small lipophilic agents by means of conversion of hydrophobic substrates to inactive hydrophilic UDP-glucuronides, and are expressed in a tissue-specific fashion in the gastrointestinal tract and liver. In particular, *UGT1A7* is expressed exclusively in the gastrointestinal tract and lung, but not in the liver^[13-15]. The degree of metabolism with regard to both *NAT2* and *UGT1A7* varies among individuals, suggesting the presence of genetic variations contributing to the metabolic activation capacity. Current studies have shown an association between *NAT2* or *UGT1A7* polymorphisms and various diseases, i.e., systemic sclerosis and systemic lupus erythematosus^[16], drug toxicity^[17,18], orolaryngeal cancer^[19], esophageal cancer^[20], colorectal cancer^[21,22], pancreas cancer^[23], hepatocellular carcinoma^[15,24], or bladder cancer^[25].

Here we report the results of studies on association between *NAT2* or *UGT1A7* and IBD in Japanese using six and three polymorphic haplotypes in the two genes, respectively.

MATERIALS AND METHODS

Subjects

The subjects studied comprised 95 patients with UC, 60 patients with CD, and 200 gender-matched, unrelated, healthy volunteers, and were further characterized as listed in Table 1. All participants were Japanese, who were randomly recruited from eight general health clinics in the Nagasaki area in Japan. The study protocol was approved by the Committee for the Ethical Issue on Human Genome and Gene Analysis in Nagasaki University, and written informed consent was obtained from each participant. Diagnosis of IBD was made according to endoscopic, radiological, histological, and clinical criteria provided by both the Council for International Organizations of Medical Sciences in WHO and the International Organization for the Study of Inflammatory Bowel Disease^[26-28]. Patients with indeterminate colitis, multiple sclerosis, systemic lupus erythematosus, or other recognized autoimmune diseases were excluded from the subjects studied.

Table 1 Clinical characteristics of study subjects

Characteristic	Disease		Control
	UC	CD	
Number of subjects	95	60	200
Age range (yr)	14-83	17-75	20-60
Age (mean±SD)	44.4±16.4 ^b	35.0±12.6	32.5±11.1
Male/female (%)	53 (55.8)/42 (44.2)	35 (58.3)/25 (41.7)	125 (62.5)/75 (37.5)

Determination of *NAT2* polymorphisms

Genomic DNA was extracted from peripheral whole blood of each individual using the DNA Extractor WB-rapid Kit (Wako, Osaka, Japan) according to the manufacturer's protocol. Single nucleotide polymorphisms (SNPs) of *NAT2* deposited in SNP-database^[29] were determined with the PCR-restriction fragment length polymorphism (RFLP) method using primer pairs and protocol described by Leff *et al.*^[30]. The PCR-RFLP method was modified in order to distinguish among all known *NAT2* SNPs^[29]. In brief, polymorphic region in *NAT2* was amplified by PCR with a GeneAmp PCR system 9700 thermal cycler (Applied Biosystems, Foster City, CA, USA) using 250 ng of genomic DNA in a 50-μL reaction containing 10 mmol/L Tris-HCl, pH 8.3, 50 mmol/L KCl, 1.5 mmol/L MgCl₂, 0.2 mmol/L each dNTP, 500 ng of forward primer: 5'-GGCTATAA-GAACTCTAGGAAC-3', 500 ng of reverse primer: 5'-AAGGGTTTATTTTGTTTCCTTATTCTAAAT-3', and 2.0 U *Taq* DNA polymerase. The amplification protocol comprised initial denaturation at 94 °C for 5 min; 35 cycles of denaturation at 94 °C for 30 s, annealing at 55 °C for 30 s, and extension at 72 °C for 30 s; and a final extension at 72 °C for 5 min. PCR product of 896 bp was digested by restriction enzymes (TaKaRa Biomedical, Shiga, Japan). Three SNPs, C190T, G191A, and A434C, were detected by digestion with *MspI*. Likewise, C282T, C481T, or G857A was detected by digestion with *FokI*, *KpnI*, or *BamHI*, respectively. T111C, G590A, and C759T were detected by digestion with *TaqI*. These fragments were subjected to electrophoresis on 2% agarose or 5% polyacrylamide gel, and visualized with UV transilluminator (Alpha Innotech, CA, USA) after ethidium bromide staining. Moreover, T341C, A803G, and A845C were detected by further nested PCR. Amplified *NAT2* product (1 μL) was used as a template in a 25-μL reaction containing 10 mmol/L Tris-HCl, pH 8.3, 50 mmol/L KCl, 1.5 mmol/L MgCl₂, 0.2 mmol/L each dNTP, 250 ng of forward primer: 5'-CACCTTCT-CCTGCAGGTGACCG-3' and reverse primer: 5'-TGTC AAGCAGAAAATGCAAGGC-3' for T341C and A803G, or 250 ng of forward primer: 5'-TGAGGAA-GAGGTTGAAGAAGTGCT-3' and reverse primer: 5'-AAGGGTTTATTTTGTTTCCTTATTCTAAAT-3' for A845C, and 0.5 U *Taq* DNA polymerase. The amplification protocol comprised initial denaturation at 94 °C for 5 min; 35 cycles of denaturation at 94 °C for 30 s, annealing at 62 °C for 30 s, and extension at 72 °C for 30 s; and a final extension at 72 °C for 5 min. The former nested PCR products were digested with *AclI* and *DdeI* (New England BioLabs Inc., MA, USA) to detect T341C and A803G, respectively. The latter products were digested with *DraIII* (New England BioLabs Inc.) to detect A845C. All these products were subjected to electrophoresis on 6% polyacrylamide gel, and visualized as described above.

Determination of *UGT1A7* polymorphisms

Four SNPs have been known within *UGT1A7*-exon 1^[15]. A SNP at codon 11 is a silent mutation. SNPs at codons 129 and 131 lying in a linkage disequilibrium (LD) block were detected by PCR-denaturing high-performance liquid chromatography (DHPLC) with an automated HPLC

instrument (WAVE™, Transgenomic, CA, USA), and by direct DNA sequencing with ABI 310 (Applied Biosystems, Foster City, USA). A DNA fragment containing codons 129 and 131 was amplified by PCR using 125 ng of genomic DNA in a 25-μL reaction containing 10 mmol/L Tris-HCl, pH 8.3, 50 mmol/L KCl, 1.5 mmol/L MgCl₂, 0.2 mmol/L each dNTP, 500 ng of forward primer: 5'-CCGGGAGTTCATGGTTT-3', 250 ng of reverse primer: 5'-CACAGAGGGGAGGGAGAAAT-3', and 1.0 U *Taq* DNA polymerase, generating a 260-bp fragment. Amplification protocol comprised initial denaturation at 94 °C for 5 min; 35 cycles of denaturation at 94 °C for 30 s, annealing at 55 °C for 30 s, and extension at 72 °C for 30 s; and a final extension at 72 °C for 5 min. PCR products were used for DHPLC analysis. The temperature required for successful resolution of heteroduplex molecules was determined to be 56.8 °C according to the manufacturer's protocol. Another SNP at codon 208 was detected by PCR-RFLP using primer pair of 5'-GCATGAGGTGGTCGTCGTCA-3'/5'-CATCACGGGTTTGGGATACT-3', as in the *NAT2* SNP-detection. After digestion of PCR products by *RsaI* (Promega, WI, USA), the fragments were subjected to electrophoresis on 2% agarose gel, and visualized as described above.

Statistical analysis

Gender and age value among the subjects were evaluated by χ^2 test and unpaired Student's *t* test, respectively. Allele frequencies were estimated by the gene-counting method, and χ^2 test was used to identify significant departures from the Hardy-Weinberg equilibrium. Subsequently, the odds ratio (OR) with 95% confidence interval (95%CI) was calculated by multiple logistic regression analysis using the JMP program package (version 5, SAS Institute, Cary, NC, USA) and the StatView program package (version 5, SAS Institute). Haplotype and genotype frequencies were compared between individuals with and without haplotype or genotype, using χ^2 test. A *P* value of 0.05 or less was considered statistically significant.

RESULTS

Haplotype frequencies of *NAT2*

We identified six haplotypes composed of six SNPs among the subjects examined (Table 2). The haplotype "*NAT2*4*" comprising 69.5% of controls was wild-type, while five other haplotypes were variants. Distributions of the haplotypes in our study population were well corresponded to the Hardy-Weinberg equilibrium (Table 2). The results implied that the population we studied had a homogeneous genetic background, being consistent with the previous observations^[31-33]. However, since the frequencies of three haplotypes, *NAT2*5B*, *NAT2*11*, and *NAT2*13*, were very low, they were not considered for subsequent multiple logistic regression analysis.

The frequency of haplotype "*NAT2*7B*" composed of two SNPs (C282T and G857A) significantly increased in patients with CD, compared to that in controls (*P* = 0.0130, OR = 2.802, 95%CI: 1.243-6.316, Table 3). In contrast, there was no difference in frequency of *NAT2*7B* between

patients with UC and controls (*P* = 0.3338, OR = 1.436, 95%CI: 0.689-2.992). Of the 60 CD patients, 17 (28.3%) had *NAT2*7B*, the incidence being significantly higher than that (32/200, 16.0%) in controls (*P* = 0.032, OR = 2.076, Table 4). These results indicated that the haplotype *NAT2*7B* was associated with the susceptibility to CD, but not to UC.

Cascorbi *et al.*^[34], and Gross *et al.*^[35], have shown a relationship between genotypes of *NAT2* polymorphism and phenotypes. The haplotypes *NAT2*4*, *NAT2*11*, and *NAT2*13*, code for the rapid acetylator phenotype, while *NAT2*5B*, *NAT2*6A*, and *NAT2*7B*, code for the slow acetylators. According to their reports, we divided the subjects in to two groups: the rapid acetylators comprised homozygous and heterozygous carriers of the haplotypes *NAT2*4*, *NAT2*11*, or *NAT2*13* and the slow acetylators comprised all homozygous carriers of the other haplotypes. The frequency and distribution were compared between these groups, but there were no significant differences in frequencies of these estimated phenotypes among patients with UC, CD, and controls (data not shown).

Table 2 Distributions of six *NAT2*-haplotypes in patients with UC/CD and controls

Haplotype	SNP	Number (%) of subjects with haplotype		
		UC (allele = 190)	CD (allele = 120)	Control (allele = 400)
<i>NAT2*4</i>	None	122 (64.2)	77 (64.2)	278 (69.5)
<i>NAT2*5B</i>	T341C, C481T, A803G	3 (1.6)	1 (0.8)	2 (0.5)
<i>NAT2*6A</i>	C282T, G590A	43 (22.6)	21 (17.5)	79 (19.75)
<i>NAT2*7B</i>	C282T, G857A	20 (10.5)	18 (15.0)	35 (8.75)
<i>NAT2*11</i>	C481T	0 (0)	1 (0.8)	1 (0.25)
<i>NAT2*13</i>	C282T	2 (1.1)	2 (1.7)	5 (1.25)

Table 3 Comparisons of frequencies of *NAT2*-haplotypes among study subjects by multiple logistic regression analysis

Haplotype	<i>P</i>	Odds ratio	95% confidence interval
UC patients vs controls			
<i>NAT2*4</i>	0.6823	0.809	0.293-2.232
<i>NAT2*6A</i>	0.5621	1.183	0.671-2.084
<i>NAT2*7B</i>	0.3338	1.436	0.689-2.992
CD patients vs controls			
<i>NAT2*4</i>	0.2616	2.162	0.563-8.304
<i>NAT2*6A</i>	0.3898	1.349	0.682-2.670
<i>NAT2*7B</i>	0.0130	2.802	1.243-6.316

Table 4 Number of subjects with or without haplotype *NAT2*7B*

<i>NAT2*7B</i>	UC (n = 95, %)	CD (n = 60, %)	Control (n = 200, %)
Presence	19 (20.0)	17 (28.3)	32 (16.0)
Absence	76 (80.0)	43 (71.7)	168 (84.0)

CD patients vs controls: *P* = 0.032, OR = 2.076.

Haplotype frequencies of *UGT1A7*

We detected two SNPs at codons 129 and 131 of *UGT1A7* by DHPLC with 100% accuracy, as confirmed by direct

DNA sequencing. Subsequently, on the basis of the results by PCR-DHPLC and PCR-RFLP, three haplotypes, *UGT1A7*1*, *UGT1A7*2*, and *UGT1A7*3*, were determined in the Japanese population studied (Table 5). The *UGT1A7*1* haplotype was wild-type, *UGT1A7*2* and *UGT1A7*3* were identified as variants, while another haplotype, *UGT1A*4*, was not observed, indicating that it was very rare in Japanese. There were no significant differences in frequencies of haplotypes and genotypes among patients UC, CD, and controls (data not shown).

Table 5 Distributions of three *UGT1A7* haplotypes among study subjects

Haplotype	SNP	Number (%) of subjects with haplotype		
		UC (allele = 190)	CD (allele = 120)	Control (allele = 400)
<i>UGT1A7*1</i>	None	120 (63.2)	69 (57.5)	242 (60.5)
<i>UGT1A7*2</i>	T387G, C391A, G392A	29 (15.3)	24 (20.0)	55 (13.8)
<i>UGT1A7*3</i>	T387G, C391A, G392A, T622C	41 (21.6)	27 (22.5)	103 (25.7)
<i>UGT1A7*4</i>	T622C	0 (0)	0 (0)	0 (0)

DISCUSSION

We have shown that a *NAT2* haplotype, *NAT2*7B*, is associated with CD, and thus, *NAT2* could be one of the genetic factors for the predisposition to the onset and/or development of CD, although its contribution to this disease appears relatively small. In contrast, we could not find any association between *UGT1A7* polymorphism and IBD, suggesting that *UGT1A7* never confers to these diseases. Although there are previous reports demonstrating an association between certain *NAT2* variants and diseases, they deal with phenotypical variations, such as rapid, intermediate, and slow acetylators in different conditions such as systemic sclerosis, systemic lupus erythematosus, and drug-induced agranulocytosis^[16,17]. Therefore, the present study is the first report documenting an association between *NAT2* genetic variation and CD.

Three *NAT2* haplotypes, *NAT2*5B*, *NAT2*6A*, and *NAT2*7B*, are estimated to show slow acetylator phenotypes^[34,35]. The present study showed that slow acetylator carrying these haplotypes was not associated, with CD (data not shown). Although a role of the *NAT2*7B* haplotype in the susceptibility to CD is unknown, Fretland *et al.*, demonstrated, that this haplotype is functionally related to low activity of *N*-acetylation^[36]. It is likely, that low activity of *N*-acetylation due to *NAT2*7B* might fail to metabolite xenobiotics in the state of increased permeability in the gastrointestinal tract and subsequently accumulates them in the body since *NAT2* functions as a biochemical barrier against xenobiotics including dietary intake, intestinal bacteria, and toxins^[10-12,15]. Our hypothesis may be partly supported by clinical evidence that total parenteral nutrition and elemental diet placing the gastrointestinal tract "at rest" can successfully improve CD, and refeeding by oral conventional diet aggravates the activity of CD^[37].

Recent genome-wide linkage analyses and candidate gene-based association studies have shown possible IBD

susceptibility regions at 16q12 (IBD1), 12p13 (IBD2), 6p21 (IBD3), 14q11 (IBD4), 19p13 (IBD5), 5q31-q33 (IBD6), 1p36 (IBD7), and at 16p (IBD8)^[5,38,39]. Our results indicate the existence of a new CD determinant at an LD region of 8p22, even if it is not *NAT2* itself. It remains to be confirmed whether the association is reproducible in larger Japanese samples as well as in other populations.

ACKNOWLEDGMENTS

We are grateful to physicians, patients, and volunteers for participating in this study. We thank Miss Naoko Sakemi, Dr. Hiroshi Soda, and Professor Norio Niikawa for their support.

Abstract

AIM: To demonstrate the prevalence of sonographic fatty liver, overweight and ischemic heart disease (IHD) among the male workers in Taiwan, and to investigate the possible association of these three factors.

METHODS: From July to September 2003, a total of 2 088 male aircraft-maintenance workers aged from 22 to 65 years (mean 40.5) underwent an annual health examination, including anthropometrical evaluation, blood pressure measurement, personal medical history assessment, biochemical blood analysis, abdominal ultrasonographic examination and digital electrocardiography (ECG). The Student's *t*-test, χ^2 test and multivariate logistic regression analysis were utilized to evaluate the relationship between IHD and salient risk factors.

RESULTS: The all-over prevalence of overweight was 41.4%, and that of fatty liver was 29.5% (mild, moderate and severe fatty liver being 14.5%, 11.3%, and 3.7%, respectively); while the prevalence of ischemic changes on ECG was 17.1% in this study. The abnormal rates for conventional IHD risk factors including hypertension, dyslipidemia, hyperglycemia and overweight increased in accordance with the severity of fatty liver. Overweight and severity of fatty liver were independently associated with increased risks for developing IHD. Overweight subjects had a 1.32-fold (95%CI: 1.01-1.73) increased IHD risk. Participants with mild, moderate, and severe fatty liver had a 1.88-fold (95%CI: 1.37-2.6), 2.37-fold (95%CI: 1.66-3.37) and 2.76-fold (95%CI: 1.62-4.72) increased risk for developing IHD. The prevalence of ischemic ECG for the fatty liver-affected subjects with or without overweight was 30.1% and 19.1%, while that of overweight subjects free from fatty liver was 14.4%. Compared to the subjects without fatty liver nor overweight, IHD risk for the three subgroups above was as follows: OR: 2.95 (95%CI: 2.31-4.09), OR: 1.60 (95%CI: 1.07-2.39) and OR: 1.11 (95%CI: 0.78-1.56), respectively.

CONCLUSION: The presence of fatty liver and its severity should be carefully considered as independent risk factors for IHD. Results of the study suggest the synergistic effect between fatty liver and overweight for developing IHD. Abdominal sonographic examination may provide valuable information for IHD risk assessment in addition to limited report about liver status, especially for overweight males.

INTRODUCTION

Fatty change in the liver is closely associated with overweight status and metabolic impairments such as hyperglycemia, and dyslipidemia^[1-3] which are also regarded as factors for atherosclerosis^[1,4,5] and ischemic heart disease (IHD)^[6-9]. However, the association between fatty liver and IHD is waiting for epidemiological investigation.

Since resting electrocardiogram (ECG) and abdominal sonographic examination are two routine, non-invasive health examinations used in medical check-ups in Taiwan^[10-15], we had the opportunity to examine the association between fatty liver and ischemic ECG changes, the hallmark of IHD and strong predictor for cardiac events^[16-18].

The purpose of this study was to evaluate the relationships between fatty liver and IHD utilizing epidemic data. Data analyses were controlled for conventional risk factors, especially overweight.

MATERIALS AND METHODS

Subjects

Records from a total of 2 088 male aircraft maintenance workers who underwent a periodic health examination from July to September 2003.

Methods

The health examinations included anthropometrical evaluation, measurement of weight and height, systolic and diastolic blood pressure. Definition of overweight was BMI ≥ 25 kg/m², based on WHO criteria^[19]. A questionnaire about personal medical history, including alcohol (usage more than once a week: yes *vs* no) and tobacco (current usage: yes *vs* no) consumption was filled by the examinees.

Biochemical blood tests were conducted by Hitachi autoanalyzer model 7150 (Hitachi Corp, Tokyo, Japan), including fasting plasma glucose, levels of triglyceride, and total, low, and high-density lipoprotein (LDL, HDL) cholesterol. The definition of hypertension was systolic blood pressure ≥ 18.7 kPa or diastolic blood pressure ≥ 12 kPa. The cut points of hyperglycemia, hypocholesterolemia, hypercholesterolemia, and hypertriglyceridemia were fasting sugar ≥ 6.1 mmol/L, HDL < 1.0 mmol/L, total cholesterol ≥ 5.2 mmol/L and triglyceride ≥ 17.0 mmol/L.

Abdominal ultrasonographic examinations were performed using convex-type real-time electronic scanners (Toshiba SSA-340 with 3.75 MHz convex-type transducer) by three gastrointestinal specialists who were blind to the medical history and blood test results of the examinees. The definition of ultrasonic fatty liver was based on a comparative assessment of image brightness relative to the kidneys, in line with previously reported diagnostic criteria^[10,20-23]. Severity of fatty liver was classified according to the following modified scoring system^[10,13,15,22,23]: brightness compared to kidneys (0-3), blurring of gall bladder wall (0-3), blurring of hepatic veins (0-3), blurring of portal vein (0-3), far gain attenuation (0-3). Severity was defined as mild (total scores of 2-6), moderate (7-10), and severe (11-15) fatty liver.

A digital electrocardiograph recorder (Kenz Cardico 1207; Suzuken Co., Ltd 8, Higashi Kataha-machi, Higashi-ku Nagoya 461-8701, Japan.) was used for IHD assessment. IHD was defined based on evidence of resting ECG ischemic abnormalities, as expressed in computerized Minnesota code (1.1. \times -1.3. \times , 4.1. \times -4.4. \times , 5.1. \times -5.3. \times)^[12,16-18].

The Student's *t* and χ^2 tests were used for analyzing continuous variables and categorical variables, respectively. Multivariate logistic regression was utilized to evaluate the relationship between IHD and salient risk factors. SAS software was used for statistical analysis (Version 8.0; SAS Institute, Cary, NC, USA).

RESULTS

After 63 cases whose data were incomplete (e.g., biochemical blood test, questionnaire) were excluded, a total of 2 025

subjects were enrolled in the final analysis. The excluded subjects had a similar distribution of anthropometric measurement and biochemical data as subjects in final analysis.

As shown in Table 1, the age for this sample population ranged from 22 to 63 years (mean, 40.5), the mean value of BMI was 24.6 kg/m². The over-all prevalence of overweight was 41.4%, while that of fatty liver was 29.5%. The prevalence of ischemic changes in the resting ECG was 17.1%. The means and standard deviations for serum blood sugar and atherogenic lipid profile were 5.7 \pm 1.1 mmol/L of fasting sugar, 5.1 \pm 0.9 mmol/L of total cholesterol, 1.3 \pm 0.3 mmol/L of HDL cholesterol, 3.3 \pm 0.8 mmol/L of LDL cholesterol, and 17.1 \pm 13.9 mmol/L of triglyceride.

Table 1 Baseline characteristics of middle-aged male workers in Taiwan from a periodic health examination (mean \pm SD, *n* = 2 025)

Risk factor	Value	Range
Age (yr)	40.5 \pm 9.9	22.0-63.0
Height (cm)	169.6 \pm 6.3	150.1-191.1
Body weight (kg)	70.9 \pm 10.6	42.8-121.9
BMI (body mass index) (kg/m ²)	24.6 \pm 3.3	15.6-40.6
Systolic blood pressure (kPa)	17.1 \pm 2.2	11.7-27.5
Diastolic blood pressure (kPa)	10.6 \pm 1.6	6.7-17.3
Fasting sugar (mmol/L)	5.7 \pm 1.1	3.0-24.5
Cholesterol total (mmol/L)	5.1 \pm 0.9	2.6-9.3
Cholesterol HDL (mmol/L)	1.3 \pm 0.3	0.2-4.0
Cholesterol LDL (mmol/L)	3.3 \pm 0.8	1.2-7.1
Triglyceride (mmol/L)	17.1 \pm 13.9	3.1-171.1
ECG with ischemic changes (<i>n</i> , %)	347	(17.1)
Fatty liver (<i>n</i> , %)	597	(29.5)
Overweight (<i>n</i> , %)	839	(41.4)
Smoking (<i>n</i> , %)	702	(34.7)
Alcohol use (<i>n</i> , %)	444	(21.9)

Risk-factor distribution among subgroups stratified according to the severity of fatty liver, is presented in Table 2. The prevalence of mild, moderate and severe fatty liver was 14.5%, 11.3%, and 3.7%, respectively. The abnormal rates for conventional IHD risk factor including hypertension, dyslipidemia, hyperglycemia and overweight increased in accordance with the severity of fatty liver (Figure 1).

Table 2 Assessment of risk factors stratified according to severity of fatty liver (FL)

Risk factors	<i>n</i> = 2 025			
	Non FL 1 428 (70.5%)	Mild FL 294 (14.5%)	Moderate FL 228 (11.3%)	Severe FL 75 (3.7%)
Age (yr)	39.8 \pm 9.9	41.8 \pm 9.9 ^a	42.7 \pm 9.4 ^c	42.6 \pm 9.5 ^e
BMI (body mass index) (kg/m ²)	23.9 \pm 3.1	25.0 \pm 2.6 ^a	26.9 \pm 2.7 ^c	29.0 \pm 3.1 ^e
Systolic blood pressure (kPa)	16.9 \pm 2.2	17.2 \pm 2.1 ^a	17.5 \pm 2.2 ^c	18.3 \pm 2.6 ^e

Figure 1 Abnormal rates of IHD risk factors for middle-aged male workers in Taiwan.

Multivariable analysis and odds ratios for IHD are summarized in Table 3. Results showed that overweight, increased systolic blood pressure and fatty liver severity were independently associated with IHD risk. Overweight subjects had a 1.32-fold (95%CI: 1.01-1.73) increased IHD risk. Participants with mild, moderate, and severe fatty liver experienced a 1.88-fold (95%CI: 1.37-2.60), 2.37-fold (95%CI: 1.66-3.37), and 2.76-fold (95%CI: 1.62-4.72) increased risk for developing IHD.

The prevalence of ischemic ECG and odds ratios (OR) for IHD of the middle-aged male workers in Taiwan, stratified according to overweight and fatty liver status, are presented in Table 4. The prevalence of ischemic ECG and the risk for IHD of the fatty liver-affected subjects with or without overweight and the overweight subjects free from fatty liver was 30.1%, OR: 2.95 (95% CI: 2.31-4.09), 19.1%, OR: 1.60 (95% CI: 1.07-2.39) and 14.4%, OR: 1.11 (95% CI: 0.78-1.56), respectively, compared to the subjects without fatty liver nor overweight. Result of test for interaction between fatty liver and overweight was significant ($P < 0.05$).

DISCUSSION

Stress test or even coronary catheterization examination naturally has better specificity in IHD diagnosis, and biopsy of liver is the gold standard for hepatosteatosis. However, in the viewpoints of safety, ethic and screening purpose, resting ECG and abdominal sonographic examination have acceptable reliability and are practical tools of epidemiological survey^[10,16-18,21].

Our study indicates that adult male workers with fatty liver are more likely to develop IHD compared to subjects

Table 3 Multivariate logistic regression analysis for the risk factors for IHD

Risk factors	Odds ratio	95% CI
Age (yr)	0.99	0.97-1.00
Systolic blood pressure	1.01 ^a	1.003-1.03
Diastolic blood pressure	0.99	0.97-1.01
Fasting sugar	1.00	1.00-1.006
Cholesterol total	0.99	0.98-1.007
Cholesterol HDL	1.01	1.00-1.03
Cholesterol LDL	1.01	0.99-1.02
Triglyceride	1.00	1.00-1.003
Overweight	1.32 ^a	1.01-1.73
Fatty liver ^b		
Mild fatty liver	1.88 ^a	1.37-2.60
Moderate fatty liver	2.37 ^a	1.66-3.37
Severe fatty liver	2.76 ^d	1.62-4.72
Smoking	0.85	0.65-1.10
Alcohol consumption	1.054	0.79-1.41

without fatty liver. This finding is compatible to previous studies demonstrating that fatty liver, as a developer of oxidative stress plays a cardinal role in cardiac dysfunction^[24,25]. Of particular significance is the fact that non-overweight subjects with fatty liver experience a significantly increased IHD risk (OR: 1.6). As Park *et al.*^[26], concluded, for non-obese men with fatty liver, systemic inflammatory response increases, and systemic inflammatory response is the integral part of the atherosclerotic process^[27,28]. IHD prevention for non-overweight subjects having fatty liver should be emphasized in clinical practice.

Findings of this study show a synergistic interaction between fatty liver and overweight, this combination makes middle-aged males have significantly highest IHD risk (OR: 2.95) in the four entities (Table 4). Similar findings have been shown in studies about insulin resistance^[7,10,26,29-31], these studies manifested that both overweight and fatty liver are closely correlated with insulin resistance, which aggravates the atherogenic metabolic process^[32,33], accelerating the development of atherosclerosis^[34] and IHD^[35]. For overweight middle-aged male workers with fatty liver, a comprehensive management for IHD risk reduction is needed.

Serum sugar and lipids had insignificant effects on developing IHD in this study, these findings are similar to our previous study based on Eastern population^[36]. Genetic differences^[37] and differences in diet components^[38] may have affected these findings.

Smoking and drinking did not show significant effects on developing IHD in this study, the partial explanation

Table 4 Odds ratio for IHD stratified according to fatty liver (FL) and overweight status

	Non-overweight (n = 1 186)		Overweight (n = 839)	
	Non-FL (n = 970)	FL (n = 216)	Non-FL (n = 458)	FL (n = 381)

¹ OR (95%CI)	1.0 ^a (-)	1.60 ^c (1.07-2.39)	1.11 (0.78-1.56)	2.95 ^b (2.31-4.09)

^a $P < 0.05$ vs overweight and fatty, adjusted for age, blood pressure, blood sugar and lipid profile; ^b $P < 0.001$ vs non-overweight and non-FL group; ^c $P < 0.05$ vs non-overweight and non-FL group; ¹OR: adjusted odds ratio; CI: confidence interval.

might be that binary questionnaire could provide only limited information about the dose-effect, which is important in the development of IHD, and then leads to the unsteady results^[36,39].

The findings of this study demonstrate that fatty liver is an independent risk factor for IHD. Abdominal sonographic examination may not only provide limited report about the liver status, but also can provide valuable information for IHD risk assessment, especially for those who are overweight.

Abstract

AIM: To evaluate the value of CT-guided core-needle biopsy in diagnosis and classification of malignant lymphomas.

METHODS: From January 1999 to October 2004, CT-guided core-needle biopsies were performed in 80 patients with suspected malignant lymphoma. Biopsies were performed with an 18-20 G biopsy-cut (CR Bard, Inc., Covington, GA, USA) needle driven by a spring-loaded Bard biopsy gun.

RESULTS: A definite diagnosis and accurate histological subtype were obtained in 61 patients with a success rate of 76.25% (61/80). Surgical sampling was performed in 19 patients (23.75%) with non-diagnostic core-needle biopsies. The success rate of CT-guided core-needle biopsy varied with the histopathologic subtypes in our group. The relatively high success rates of core-needle biopsy were noted in diffuse large B-cell non-Hodgkin's lymphoma (NHL, 88.89%) and peripheral T-cell NHL (90%). However, the success rates were relatively low in anaplastic large cell (T/null cell) lymphoma (ALCL, 44.44%) and Hodgkin's disease (HD, 28.57%) in our group.

CONCLUSION: CT-guided core-needle biopsy is a reliable means of diagnosing and classifying malignant lymphomas, and can be widely applied in the management of patients with suspected malignant lymphoma.

INTRODUCTION

CT-guided percutaneous needle biopsy has become an important diagnostic tool and can minimize the need for open biopsy^[1,2]. However, satisfactory sampling is essential for the diagnosis and classification of malignant lymphoma^[3-5]. Percutaneous core-needle biopsy under the guidance of CT or ultrasound in evaluation of malignant lymphomas has a limited value^[6-8]. The advantage of CT guidance is that the whole mediastinum or abdomen is visualized, allowing accurate planning of biopsy for deep and small lesions and avoiding damage to important organs and greater vessels^[9,10]. In recent years, with the advance in new needle biopsy systems and technology of needle biopsy^[11,12], CT-guided core-needle biopsy is widely used in the diagnosis and classification of malignant lymphoma^[13,14]. Since 1999, CT-guided core-needle biopsy has been used as one of the routine sampling techniques for malignant lymphomas in our hospital. This study aimed to retrospectively evaluate the reliability of CT-guided core-needle biopsy for the diagnosis and classification of malignant lymphoma using an automated biopsy gun.

MATERIALS AND METHODS

Patients

From January 1999 to October 2004, 80 patients (51 men, 29 women) with suspected malignant lymphomas underwent CT-guided core-needle biopsy. They aged from 2.8 to 72 years (mean age, 48.5 years). In our series, six patients (7.5%) had a history of malignant lymphoma including two diffuse large B-cell non-Hodgkin's lymphoma (NHLs), one peripheral T-cell NHL, one anaplastic large cell (T/null cell) NHL, one follicular B-cell NHL and one nodular sclerosis Hodgkin's disease (HD). The sites of core-needle biopsy are shown in Table 1. Repeated core-needle biopsies were performed in five patients (6.25%). Nineteen patients (23.75%) with non-diagnostic core-needle biopsy underwent surgery depending on the sites, dimensions, and clinical diagnosis (Table 2). The histological classification in our group was according to 2001 World Health Organization classification of malignant lymphoma^[15].

CT scanning

CT scanning was performed for all patients with incremental

Table 1 Sites of CT-guided core-needle biopsy in patients with lymphoma

	Number of patients	%
Mediastinum	42	52.5

scanning in cranial-to-caudal direction with 2.7-5 mm collimation on a CT twin flash scanner (Philips Co.). Before biopsies, all patients were subjected to enhanced CT to determine the exact tumor location, its degree of vascularity and the presence of necrosis. The optimal approach of needle was decided for deep or small lesions and lesions with extensive necrotic areas, avoiding damage to the important organs and relatively large vessels near the tumor (Figures 1A-C).

Biopsies

Biopsies were performed during the scanning with an 18-20 G biopsy-cut (CR Bard, Inc., Covington, GA, USA) needle driven by the spring-loaded Bard biopsy gun. The Bard biopsy gun consists of a hand-held device that triggers rapid firing of an 18 (20)-G cutting needle. When the gun is fired, an inner trocar with its 1.7 cm sample notch thrusts forward, followed by its outer cannula which shears a core of tissue with minimum crushing of the specimen^[11,16]. For a satisfactory sampling, an average of three specimens was obtained during each CT-guided core-needle biopsy.

CT scanning was performed immediately after the biopsies to evaluate the possible complications such as bleeding or pneumothorax. Patients were kept under observation for 2 h and discharged, if there were no significant complications, and encouraged to contact their

Exploratory laparotomy	6	31.58
Total	19	100.00

%; percentage of total biopsies.

physicians if any evidence of complications developed subsequently.

Histologic analysis

All the samples were fixed in 40 g/L formaldehyde and embedded in paraffin and stained with hematoxylin and eosin. Routine immunohistochemical studies were performed using antibodies to leukocyte common antigen, cytokeratin, and vimentin. Histological subtyping of NHL was made using antibodies (CD3, CD8, CD15, CD30, CD43, CD79a, L26, UCHL-1, ALK, EMA).

A biopsy was considered successful, if the definite diagnosis and accurate classification of malignant lymphoma could be established and sufficient information was provided for a therapeutic decision.

RESULTS

No serious complications were noted in all the 80 patients who underwent CT-guided core-needle biopsy. A definite diagnosis and an accurate histological subtype were made in 61 patients with a success rate of 76.25%, including 80.82% (59/73) in NHL and 28.57% (2/7) in HD (Table 3). Nineteen patients (23.75%) with non-diagnostic core-needle biopsies were subjected to surgical interventions including mediastinoscopy, mediastinotomy, lymphadenectomy, and exploratory laparotomy. The main reasons for unsuccessful biopsy were extensive necrosis and unsatisfactory sampling.

The final histopathologic subtypes in 80 patients are listed in Table 4, including 63 NHLs and 7 HDs. In the diagnostic patient group, the majority of NHL subtypes were diffuse large B-cell NHL ($n = 32$) and peripheral T-cell NHL ($n = 9$). The remaining subtypes included one

**Figure 1** CT-guided core-needle biopsy for paratracheal mass (A), large anterior

mediastinal mass (B), and retroperitoneal mass (C).

lymphocyte-predominant HD, one lymphocytic depletion HD, six marginal zone B-cell NHLs, two diffuse small lymphocytic NHLs, three mantle B-cell NHLs, one follicular B-cell NHL, two angioimmunoblastic T-cell NHLs, and four anaplastic large cell (T/null cell) NHLs (ALCL).

The non-diagnostic patient group included two lymphocyte-predominant HDs, three nodular sclerosis HDs, four diffuse large B-cell NHLs, one mantle B-cell NHL, one follicular B-cell NHL, one Burkitt's NHL, one peripheral T-cell NHL, one angioimmunoblastic T-cell NHL, and five anaplastic large cell NHLs (ALCL, Table 4).

In our group, the success rates varied with the histopathologic subtypes. A relatively high success rate was obtained in diffuse large B-cell NHL (88.89%) and peripheral T-cell NHL (90%). However, the success rate was relatively low in anaplastic large cell lymphoma (ALCL, 44.44%) and HD (28.57%) in our group.

HD: Hodgkin's disease; NHL: non-Hodgkin's lymphoma.

DISCUSSION

A satisfactory sampling for histological examination is fundamental to the diagnosis and management of malignant lymphomas^[5,17]. Fine-needle aspiration (FNA) biopsies in the diagnosis of malignant lymphomas have been reported^[18–20]. Core-needle biopsies were superior to FNA since histology is more reliable than cytology^[21–23]. The use of CT guidance and improved histological diagnostic techniques have promoted the development of non-surgical sampling of tumor masses in almost any location^[4,9]. Silverman *et al.*^[24],

reported that image-guided biopsy of abdominal lymphoma provided an adequate tissue sample that enables treatment in 72% of patients. Pappa *et al.*^[14], have achieved a diagnostic rate of 83% lymphomas, and suggested that image-guided core-needle biopsy should become the procedure of choice for histological sampling in the absence of peripheral lymphadenopathy. de Kerviler *et al.*^[25], have reported, a relatively high success rate of 88%. Recently, Agid *et al.*^[4], reported, that CT-guided core-needle biopsies are sufficient to establish a diagnosis of 82.5% patients with lympho-proliferative disorders and suggested that it should be used as the first step in diagnosis of lymphomas. In our group, 61 of 80 (76.25%) patients had a definite diagnosis and histological classification, and subsequent treatment was performed on the basis of the results of core-needle biopsy. CT-guided core-needle biopsy is therefore widely regarded as a quick, safe, and efficient alternative to excisional biopsy in patients without enlarged superficial lymph nodes^[10,14].

The core-needle can acquire a relatively large specimen, which allows a better immunohistochemical staining^[26,27]. CT-guided core-needle biopsy obviates the need for surgical biopsy in the majority of cases^[4,9,25]. Automated biopsy systems such as Bard biopsy gun (CR, Inc., Covington, GA, USA) are rapid, simple, and highly efficient in sampling^[11] and have been used as the commonest tool for percutaneous CT-guided biopsy in our hospital. Guided by CT, an 18–20 G needle is driven forward by the spring-loaded gun, and a biopsy specimen with a size of about 1.5-cm in length is rapidly cut, which is sufficient for imm-ohistochemistry staining for complete subtyping^[14,16]. The reliability of CT-guided core-needle biopsy in diagnosis and classification of malignant lymphomas has largely been confirmed, and the opportunity of open biopsy or exploratory operation is greatly reduced^[9,26].

In our study, 76.25% (61/80) of patients with malignant lymphoma underwent CT-guided core-needle biopsies and treated on the basis of biopsy results alone. However, the definite diagnosis and explicit histological classifications were not obtained by core-needle biopsy alone in 19 patients with malignant lymphomas. The most common reason for the failure of core-needle biopsy diagnosis is that satisfactory sampling is not obtained due to the extensive necrosis of the lesions^[1,10]. In diagnosis of follicular lymphoma, very large follicular structures might potentially be missed by core-needle biopsy. However, this theoretical drawback is rarely encountered^[16,28]. Also, primary diagnosis of uncommon lymphomas may be compromised by small samples obtained by needle biopsy, and as with biopsies negative for lymphoma, surgical intervention may be required^[16,29]. Indeed, some subtypes of malignant lymphoma might not be definitely diagnosed and categorized by CT-guided core-needle biopsy alone^[29,30]. Ben-Yehuda *et al.*^[31], suggested that the most problematic category is mixed small- and large-cell NHL, because of the difficulty in making a reliable assessment of the relative number of large cells present and distinguishing diffuse from nodular patterns in these cases.

Due to its morphologic variations, anaplastic large cell (T/null cell) lymphoma (ALCL) might be mistaken for

other lymphoid or non-lymphoid malignancies^[32]. In general, ALCL is of T-cell phenotype and characterized by the classic “anaplastic” morphology and a peculiar CD30 expression. Its diagnosis relies on recognition of distinctive morphologic clues, such as the presence of occasional “hallmark” cells, especially around small vessels, as well as immunopositivity for CD30 and occasionally ALK protein. Therefore, a definitive diagnosis of ALCL is possibly based on careful interpretation of immunohistochemical features^[32,33]. If the explicit diagnosis of ALCL cannot be made on the basis of a small size of samples obtained by core-needle biopsy, the relatively larger specimen obtained by open biopsy may be needed for definite diagnosis.

A common subtype of lymphomas such as diffuse large B cell lymphoma often yields a predominant population of large lymphoid cells with a high mitotic activity and a relatively high rate of diagnosis^[13,32]. The success rate was as high as 88.89% (32/36) in our group. However, there were nine patients (11.25%) with ALCL in our group, and a definite diagnosis by core-needle biopsy alone was made in only four (44.44%). The main reason for this failure is due to the small size of samples obtained by core-needle biopsy.

Zinzani *et al.*^[13], and Pappa *et al.*^[14], have reported, relatively high success rates in diagnosis of HD using core-needle biopsy. However, there were a relatively small number of patients with HD in our group (8.75%), and only 28.57% (2/7) of patients with HD were definitely diagnosed by core-needle biopsy. Except for unsatisfactory sampling^[25], our low success rate may largely be due to lack of experience of pathological diagnosis of HD on the basis of core-needle biopsy in our hospital.

In conclusion, CT-guided core-needle biopsy is a reliable diagnostic procedure for malignant lymphoma, and can be widely used in patients with suspected malignant lymphoma in absence of palpable, enlarged superficial lymph nodes.

Abstract

AIM: To determine the relative potency and contribution of intestinal nutrients to net gastric accommodative relaxation and conscious perception.

METHODS: In 12 healthy subjects, we randomly tested duodenal loads of lipids and carbohydrates (12 mL administered in 4 min) at various caloric concentrations (0.0125-0.8 kcal/mL) separated by 12-24 min wash-out periods of saline infusion. Maximal gastric relaxation was induced at the end of each experiment by i.v glucagon (5 µg/kg), as reference. The reflex gastric response was measured by a barostat, and symptom perception by a 0-6 score questionnaire.

RESULTS: Lipids induced a dose-response gastric relaxation with a steep and early rise. Maximal effect (179±42 mL relaxation) reached at a relatively low concentration (0.2 kcal/mL), maximal lipid-induced relaxation was 61±6% of the glucagon effect. By contrast, duodenal infusion of carbohydrates induced weaker relaxation that became significant only at the high end of the physiological concentration range (65±14 mL with 0.8 kcal/mL). Intestinal nutrient loads, either of lipid or carbohydrates, did not induce significant changes in perception (0.6±0.4 and 0.1±0.4 score increase for the highest concentrations, respectively).

CONCLUSION: Chyme entering the small bowel induces nutrient-specific gastric relaxatory reflexes by a physiologically saturable mechanism. Normally, neither the intestinal nutrient load nor the gastric accommodative response is perceived.

INTRODUCTION

The intestine exerts a feedback control on gastric emptying, and thereby regulates the rate of nutrient delivery into the intestine. The duodenum, in particular, plays a key role in this process, by modulating the level of gastric tone via entero-gastric reflexes. The mechanisms that control the gastric relaxatory response to intestinal nutrients have been extensively studied in experimental animal models^[1]. Human data are relatively scarce. Although it has been shown that duodenal nutrients induce a gastric relaxation, and that this effect depends on the type of nutrient^[2-4], comparative dose-related responses to various nutrients are not available. Our aim was to compare the relative potency of duodeno-gastric relaxatory reflexes induced physiologically by different types of nutrients, namely, lipids *vs* carbohydrates in healthy humans employing a combination of enteric nutrient infusion and measurement of gastric tone responses by the barostat.

MATERIALS AND METHODS

Participants

Twelve healthy subjects without gastrointestinal symptoms (seven women, five men; 20-26 years of age) participated in the study after giving written informed consent. The protocol for the study was previously approved by the Institutional Review Board of the University Hospital Vall d'Hebron.

Duodenal nutrient infusion

Using an intra-luminal polyvinyl tube (2 mm outer diameter) located into the duodenum, either saline solution, carbohydrates (Maxijul®; Scientific Hospital Supplies, Barcelona, Spain) or lipids (Intralipid®, Pharmacia and Upjohn, St Cugat del Valles, Spain) were continuously infused at 2 mL/min rate using a perfusion pump (Asid Bonz PP50-300; Lubratronics, Unterschleissheim, Germany). Nutrients were diluted in saline to various caloric concentrations. All perfusates were adjusted to 300 mOsm/L and pH 7.

Gastric tone measurement

Gastric tone was continuously measured using a barostat connected by a double lumen tube (127 Argyle; Sherwood Medical, St. Louis, MO, USA) to an intra-gastric bag (1 L capacity, 36 cm maximal diameter, made of ultrathin

polyethylene). Tone was measured as changes in intra-gastric volume at a constant pressure level, 2 mmHg above the intra-abdominal pressure. The intra-abdominal pressure was determined at the beginning of each study as the minimal distending pressure that detected respiratory variations, by increasing intrabag pressure in 1 mmHg steps every minute^[5]. Detailed description of the barostat has been previously published^[5,6].

Perception measurements

Subjective perception was measured using a graded questionnaire to measure the intensity and the type of sensations perceived^[7]. The graded questionnaire included four graphic rating scales graded from 0 (no perception) to 6 (pain), specifically for scoring the following abdominal sensations: (1) pressure; (2) fullness; (3) nausea; and (4) other type of sensation (to be specified), respectively.

Procedure and experimental design

Participants were orally intubated after 6 h fast. The intestinal infusion tube was positioned under fluoroscopic control in the duodenum, 10 cm distal to the pylorus, and the bag of the barostat was introduced into the stomach. The studies were conducted in a quiet, isolated room with participants sitting on an ergonomic chair with the trunk erect.

The barostat was connected to the intra-gastric bag, and gastric tone was continuously recorded on a paper polygraph (model 6006; Letica, Barcelona, Spain). The duodenal tube was connected to the perfusion pump, and saline solution was infused. Nutrient tests were started after 10 min basal recording. In each subject the following nutrient solutions (12 mL administered as 4 mL bolus plus 4 min infusion at 2 mL/min) were tested in random order: (1) lipids at 0.0125, 0.05, 0.2, and 0.8 kcal/mL; and (2) carbohydrates at 0.2 and 0.8 kcal/mL. After each nutrient perfusion, the saline perfusion was restored. In preliminary studies, the duration of the effects of duodenal nutrients on gastric tone depended on the type of nutrient and the caloric load. Hence, to assure the lack of carry-over effects, we adjusted the duration of the saline wash-out periods between nutrients tests, allowing 24 min after the 0.8 kcal/mL lipid dose, 16 min after the 0.2 kcal lipid dose, and 12 min after the rest. At the end of each nutrient perfusion, subjects were asked to fill in the perception questionnaire. After the nutrient tests were completed, glucagon (Glucagon Novo, Laboratorios Novo, Madrid, Spain) was administered as a 5 µg/kg iv bolus, and gastric tone was recorded for another 20 min.

Data analysis

The response of gastric tone to duodenal nutrients was measured as the difference of mean intra-gastric volume recorded by the barostat during the 2 min before and during the last 2 min of each nutrient perfusion. Perception was measured by the highest score (rather than by the mean or cumulative scores) marked on the scales.

Statistical analysis

Mean±SE of the parameters measured for each nutrient concentration tested was calculated. Comparison of normally

distributed data was performed by the paired Student's *t* test.

RESULTS

Lipids induced a dose-related gastric relaxation with a steep and early rise (Figure 1). The lowest lipid load (0.0125 kcal/mL) did not modify gastric tone. However, the 0.05 kcal/mL load produced a significant relaxation ($P<0.05$ vs 0.0125 kcal/mL), exceeding half of the relaxation induced by the maximal lipid concentration (0.8 kcal/mL). A full effect was achieved with a relatively low concentration (0.2 kcal/mL), and no further gastric relaxation was produced by the highest load (0.8 kcal/mL). The maximal effect achieved by lipids was $61\pm6\%$ of the pharmacological effect of glucagon. The gastric relaxatory response developed rapidly after the lipid administration was started, so that a plateau effect was reached 2 min later (Figure 2). Conversely, during the washout period after the lipid infusion, the relaxation faded and gastric tone reverted to the previous baseline.

Duodenal carbohydrate infusion produced a significantly weaker relaxation than lipids (Figure 1). The 0.2 kcal/mL carbohydrate concentration did not modify gastric tone, though the equicaloric lipid load produced a maximal effect ($P<0.05$ vs lipids). The highest carbohydrate concentration (0.8 kcal/mL) produced a significant ($P<0.05$ kcal/mL vs 0.2 kcal/mL) but modest gastric relaxation of only about one-third than that induced by the equicaloric lipid load ($P<0.05$ vs lipids). The maximal effect achieved by carbohydrates reached only 19% of the glucagon effect.

Figure 1 Gastric relaxatory response to duodenal nutrients. Values are mean±SE. Note the saturable dose-related gastric relaxation with lipids, and a significantly weaker response with carbohydrates. ^a $P<0.05$ vs carbohydrates.

Figure 2 Example of gastric relaxation induced by duodenal lipid infusion (0.2 kcal/mL). Gastric relaxation was measured as intra-gastric volume increment at constant pressure by a barostat. Note rapid relaxation and complete recovery after the infusion.

None of the nutrient loads tested or their reflex effects on gastric tone induced significant conscious perception (Figure 3).

Figure 3 Perception of duodenal nutrient loads. All nutrient loads were unperceived, despite the prominent gastric accommodative response associate to some of them.

DISCUSSION

In our study, chyme entering the small bowel induced nutrient-specific gastric relaxatory reflexes by a physiologically saturable mechanism. In healthy subjects, neither the intestinal nutrient load nor the gastric accommodative response was perceived.

As previously shown, lipids in the duodenum induce a gastric relaxatory reflex^[2-4]. We have further shown that this effect is concentration-related. Indeed low lipid concentration induced marked effects. Full effect was achieved with a very low concentration, and one fourth of this concentration induced a gastric relaxation which was half of the full effect. This mechanism seems saturable, because a four-fold increase of the full-effect concentration did not increase the magnitude of gastric relaxation. Furthermore, we administered at the end of the study, a pharmacological dose of glucagon to produce a maximal gastric relaxation^[8,9], evidenced that the full effect produced by even a very small lipid concentration was about two thirds of the glucagon effect.

By contrast to lipids, intra-duodenal carbohydrates had minor gastric relaxatory effects. Equicaloric amounts of carbohydrates induced significantly smaller gastric relaxation. The same concentration of carbohydrates as that of lipids producing full effect was ineffective, and the maximal concentration tested, achieved only one fifth of the glucagon effect.

The effect of nutrients on gastric tone has been studied on an experimental dog model with isolated intestinal loops^[10]. These studies indicate that nutrient specificity depends on the region of intestine stimulated. When infused into the proximal small bowel, lipids are significantly more potent than carbohydrates, which is consistent with that observed in the present study, but in the distal small bowel, carbohydrates elicit a much stronger response. At variance with humans, in this canine model, carbohydrates into the proximal intestine failed to induce a gastric relaxation, but this could be related to the different regions that were exposed. However, in the present study, nutrients were infused directly into the duodenum and a more distal loop was

isolated in dogs.

Additional experimental studies in animals have further characterized this nutrient-dependent entero-gastric reflex. In a model of isolated vagus, it was that reflex gastric relaxation is mediated by non-adrenergic, non-cholinergic, vagal fibers^[11]. It has also been shown that CCK may be involved in lipid-induced reflexes^[12]. However, CCK is only released by long chain fatty acids, but not by the short-medium length acids^[13,14]. Furthermore, the rapid onset and reversible response, without appreciable carry-over effects, all point toward a neural rather than a humoral type of response. Hence, the different effects of lipids and carbohydrates seem related to the specific reflex pathways activated.

Detection of the reflex relaxation in the present experiments was possible by an artificial manipulation of intra-gastric conditions. During basal conditions, the stomach is empty and contracted. The barostat applies a small, constant intra-gastric pressure insufficient to expand the gastric walls. However, when the stomach relaxes in response to experimental administration of nutrients directly into the intestine, the intra-gastric volume expands and the barostat makes this relaxation visible by the intra-gastric volume increment. Interestingly, this isobaric expansion does not induce conscious sensations.

It has been shown that intra-gastric volumes are perceived via activation of tension receptors^[9], and the present data confirm that expansion and wall elongation do not elicit perception. Nutrients, particularly lipids, have been shown to sensitize mechanoreceptors and heighten perception of gastric distension^[2-4], but in the present experimental conditions, nutrients did not modify perception, conceivably because tension receptors were not activated. The gastric expansion measured by the barostat mimics the normal accommodation process, during which gastric filling by food is associated to an accommodative relaxation^[1,15]. Indeed, this type of nutrient-mediated reflexes, by modulating the level of contraction/relaxation of the gastric wall, plays a dual role, contributing, both, to the unperceived accommodation of the stomach to the meal, and to the control of the gastric emptying rate. In the present study, even high lipid concentration produced only a partial relaxation, as evidenced by the comparison to the effect of glucagon, suggesting that the stomach still exerts some degree of contraction. This residual contraction, similar to that produced during meal accommodation, is enough to gently force intra-gastric content distally and initiate gastric emptying. Subsequently, the emptying profile is controlled by a net of reflexes depending on the nutrient composition of chyme along the small intestine, to adapt the gastric delivery of nutrients to the intestinal processing capability^[1].

The characterization of the nutrient-induced reflexes described in this paper may contribute to a better understanding of the pathophysiology of accommodation-related symptomatic disorders, such as functional dyspepsia. Indeed, it has been shown that dyspeptic patients have impaired entero-gastric reflexes^[16,17] that result in impaired gastric accommodation and post-prandial symptoms^[18,19], but the specific effects of individual nutrients have not been characterized. Hence, evaluation of the full dose-response to different nutrient elements may help to clarify the reflex

dysfunction in functional dyspepsia.

Abstract

AIM: To investigate whether S100A4 played an important role in the development or progression of colorectal cancer.

METHODS: A total of 124 colorectal adenocarcinoma tissue specimens were analyzed by immunohistochemistry for the expression of S100A4 protein and subsequently investigated for the gene mutations in the coding region of *S100A4* gene. The specimens were collected over a 3-year period in the laboratories at our large teaching hospital in Seoul, Republic of Korea.

RESULTS: Normal colonic epithelium either failed to express or showed focal weak expression of S100A4. Moderate to strong cytoplasmic expression of S100A4 was seen in 69 (55.6%) of the 124 colorectal carcinoma tissue specimens. S100A4 expression was detected in 43 (69.4%) of 62 specimens with lymph node metastasis. Statistically, overexpression of S100A4 was significantly associated with Dukes' stage and lymph node metastasis. Nuclear staining was also observed in 24 (19.4%) of 124 samples and closely associated with Dukes' stage. However, there was no significant correlation between overexpression of S100A4 and other investigated clinico-pathologic parameters, including tumor localization, tumor size, and survival period. In mutational analysis, no gene mutation was found in the analyzed genomic area of colorectal cancer.

CONCLUSION: Overexpression of S100A4 may be closely related with the aggressiveness of colorectal carcinoma.

INTRODUCTION

Colorectal cancer remains one of the most frequent malignant neoplasms worldwide. In Korea, it accounts for an estimated 9.9% of all malignancies, with 9.7% in the male population and 10.2% in the female population^[1]. The major cause of death is the metastatic spread of the disease from the primary tumor to distant sites, especially to the liver^[2]. Research into colorectal cancer has highlighted the prognostic significance of TNM tumor staging including depth of tumor invasion, involvement of regional lymph nodes, and infiltration to distant organs. Although there are a lot of reports showing the significance of many other prognostic parameters such as histological grade, serum carcino-embryonic antigen levels and flow cytometric DNA analysis, none of them has been widely used in the clinic^[3-5].

The concept of multi-stage carcinogenesis has been widely accepted as a consequence of multiple genetic alterations accumulated in cancer cells^[6]. Interestingly, stepwise accumulation of genetic alterations during progression has been observed in several tumor types, particularly in tumors of epithelial origin like colorectal cancer. It is also well known that highly metastatic cells often acquire more genetic alterations than non-metastatic cells. Therefore, it is indispensable to identify the genes, whose alterations accumulate during cancer progression as well as the genes, whose expression is responsible for the acquisition of invasive and/or metastatic potential in cancer cells.

The S100 family of calcium binding proteins has been shown to be involved in a variety of physiological functions, such as cell proliferation, extracellular signal transduction, intercellular adhesion, and motility as well as cancer metastasis^[7-9]. Of these, S100A4 (mts1, p9Ka, calvasculin) has been identified as a cytoplasmic protein in normal cells, which is associated with the actin/myosin cytoskeleton in fixed cells^[10]. Interestingly, elevated levels of S100A4 are closely associated with the process of metastasis in several human solid cancers including gastric cancer^[11,12], colorectal adenocarcinoma^[13-15], and breast cancer^[16]. Recently,

Flatmark *et al.*^[15], reported, that nuclear localization of S100A4 is correlated with tumor stage in colorectal cancer. Furthermore, S100A4 secreted from tumor cells can increase endothelial cell motility and hence induce angiogenesis^[17]. All these findings suggest that S100A4 may exert its effect on metastasis formation not only by stimulating the motility of tumor cells but also by affecting their invasive properties through deregulation of the extracellular matrix^[18]. In the present study, to investigate whether S100A4 played an important role in the development and/or progression of Korean colorectal cancers, the expression patterns of S100A4 in 124 colorectal adenocarcinoma tissues were examined. We also performed mutational analysis of the *S100A4* gene, one of the possible overexpression mechanisms of oncogenic proteins.

MATERIALS AND METHODS

Tissue samples

One hundred and twenty-four colorectal cancer patients between 2001 and 2002 were enrolled in this study and their tissue samples were formalin-fixed and paraffin-embedded. No patient had a family history of colorectal cancer. Tumor stage was classified according to Dukes' criteria. Thirteen patients were classified as Dukes' A, 47 as Dukes' B, 56 as Dukes' C and 8 as Dukes' D. The observation time was 14-38 mo for the survivors. Among the 113 patients who were followed up, 15 patients showed relapse of cancer and 11 patients died of cancer during this time. Two pathologists screened histological sections and selected areas of the representative tumor cells. Three tissue cores (0.6 mm in diameter) were taken from each tumor sample and placed in a new recipient paraffin block using a commercially available microarray instrument (Beecher Instruments, Micro-Array Technologies, Silver Spring, MD, USA), according to the established methods^[19]. One cylinder of normal colonic mucosa adjacent to each tumor was also transferred to the recipient block.

Microdissection

The histological section were stained with hematoxylin and eosin (H and E) and reviewed. Malignant cells were selectively procured from H and E stained slides without normal cell contamination using a laser micro-dissection device (ION LMD, Jungwoo International Co, Seoul, South Korea). Corresponding normal cells were obtained from non-metastatic lymph nodes. DNA was extracted by a modified single-step DNA extraction method, as described previously^[20].

Single strand conformation polymorphism (SSCP) analysis

Genomic DNAs from tumor cells and corresponding normal cells were amplified with 2 primer pairs covering exons 2 and 3, the coding region of *S100A4*. The primer sequences were as follows: 5'-CCAGATCCTGACTGCTGTC-3' and 5'-GACTCACTCAGGCACCTACCC-3' for exon 2, and 5'-GGGCTTCTGTTTTCTATC TGT-3' and 5'-CCAACCACA TCAGAG GAG-3' for exon 3. Each PCR was performed under standard conditions in a 10 μ L reaction mixture containing 1 μ L of template DNA, 0.5 μ mol/L

of each primer, 0.2 μ mol/L of each deoxynucleotide triphosphate, 1.5 mmol/L MgCl₂, 0.4 unit of Ampli Taq gold polymerase (Perkin-Elmer, Foster City, CA, USA), 0.5 μ Ci of [³²P]dCTP (Amersham, Buckinghamshire, UK), and 1 μ L of 10X buffer. The reaction mixture was denatured for 1 min at 94 °C and amplified for 35 cycles (denaturing for 40 s at 94 °C, annealing for 40 s at 56 °C, and extending for 40 s at 72 °C). Final extension was continued for 5 min at 72 °C. After amplification, PCR products were denatured for 5 min at 95 °C at a 1:1 dilution of sample buffer containing 98% formamide/5 mmol/L NaOH and loaded onto a SSCP gel (FMC mutation detection enhancement system; Intermountain Scientific, Kaysville, UT, USA) with 10% glycerol. After electrophoresis, the gels were transferred to 3-mm Whatman paper and dried, and autoradiography was performed with Kodak X-OMAT film (Eastman Kodak, Rochester, NY, USA). We repeated the experiment thrice, including tissue micro-dissection, PCR, SSCP, and sequencing, and found that the data were consistent.

Immunohistochemistry for S100A4

The primary polyclonal rabbit anti-S100A4 antibody (DAKO, Carpinteria, CA, USA, dilution 1/200) was used. Immunostaining was performed on microarray tissue sections with a tyramide signal amplification kit (NEN Life Science, Boston, MA, USA) for signal intensification. Antigen retrieval was performed by microwave heating in a citrate buffer (pH 6.0). Other procedures were performed as previously described^[21]. The reaction products were developed with diaminobenzidine (Sigma, St Louis, MO, USA) and counterstained with hematoxylin. As a negative control, we used non-immune rabbit serum instead of the S100A4 antibody. Three pathologists independently reviewed the results. For statistical analysis, the stained sections were scored microscopically. The number of tumor cells stained in the cytoplasm was semi-quantitatively estimated and classified into negative and positive: negative $0 \leq 30\%$ and positive $\geq 30\%$ labeling in tumor cells.

RESULTS

Mutational analysis

We analyzed mutations of the *S100A4* gene in 124 colorectal carcinoma tissue specimens. There was no aberrant SSCP pattern in DNAs extracted from cancer cells, suggesting that there were no somatic mutations in the coding regions of the *S100A4* gene in colorectal carcinoma. We found a single nucleotide polymorphism, which was an A to G transition at nucleotide number 99 in both corresponding normal and tumor DNAs of cases No. 10 and No. 67 (data not shown). The variation was an identical single nucleotide polymorphism found in our previous report^[11] and showed no amino acid change at codon 33 (Glu→Glu, GAA→GAG). The data were consistent with triplicate experiments.

Expression of S100A4

One hundred and twenty-four colorectal carcinoma tissue specimens were screened for S100A4 protein expression. The expression was mainly faint or negative in normal colonic

mucosa, but moderate to strong in lymphocytes and smooth muscle cells, concordant with previous report^[14]. In the present study, overexpression of S100A4 was found in 69 (55.6%) of the 124 colorectal carcinoma tissue specimens, in which immunostaining was predominantly marked on the cytoplasm of tumor cells (Figure 1). Cytoplasmic staining was seen in 30.8% (4 of 13) stage A cases, 44.6% (21 of 47) stage B cases, 66.1% (37 of 56) stage C cases, and 87.5% (7 of 8) stage D cases, respectively (Table 1).

Statistically, overexpression of S100A4 was closely associated with Dukes' stage ($P<0.01$) and lymph node metastasis ($P<0.01$). However, there was no significant correlation between over-expression of S100A4 and other investigated clinico-pathologic parameters, including tumor localization, tumor size, and survival period (Table 1). Interestingly, 12 of 15 patients with recurrence of cancer demonstrated cytoplasmic staining at diagnosis. Nine of them died of cancer and 2 died of cardio-vascular disease.

Figure 1 Expression of S100A4 in colonic mucosa (A), tubular adenocarcinoma (B, C), and nuclear staining of S100A4 (D). (Original magnifications: A-C,

×200; D, ×400).

Nuclear staining was also observed in 24 (19.4%) of 124 samples and the percentage of S100A4 positive cases was closely associated with Dukes' stage ($P < 0.05$, Table 1). However, there was no correlation between nuclear staining of S100A4 and pathologic parameters, including lymph node metastasis, tumor localization, tumor size, and survival period (Table 1). Additionally, nuclear staining was found in 4 of 15 patients with relapse and 3 of them died of cancer.

DISCUSSION

Oncogene amplification usually occurs late in tumor progression and correlates well with clinical aggressiveness of tumors^[21]. Over-expression of S100A4 has been reported in several human cancers, including gastric^[11,12], colorectal^[13-15], and breast cancers^[16]. Recently, it has been suggested that nuclear localization of S100A4 is related to tumor stage of colorectal cancer, and S100A4 may be involved in gene regulatory pathways related to the metastatic phenotype of cancer cells^[15].

In the present study, cytoplasmic over-expression of S100A4 was found in 69 (55.6%) of the 124 colorectal adenocarcinoma tissue specimens. Interestingly, the cytoplasmic expression of S100A4 was statistically associated with Dukes' stage and lymph node metastasis (Table 1). Additionally, 12 of 15 patients with recurrence of cancer demonstrated cytoplasmic staining and 9 of them died of cancer. It was reported that over-expression of S100A4 is closely correlated with a number of factors for tumor aggressiveness, such as lymph node metastasis, depth of invasion, and peritoneal dissemination^[11]. Overexpression of S100A4 is more frequently found in cancer cells than in normal colonic mucosa, as well as more in liver metastasis than in primary tumors^[14,15]. Furthermore, S100A4 expression has been proved to be a highly significant and independent prognostic marker in colorectal cancer^[22]. These data further support the significant correlation between over-expression of S100A4 and progression of colorectal cancer, and the putative role of S100A4 in tumor cell aggressiveness^[3,6,15].

In this study, nuclear staining of S100A4 was seen in 24 (19.4%) of 124 samples (Figure 1) and showed a significant association with higher Dukes' stage (Table 1). Previously, Flatmark *et al.*^[15], examined the nuclear expression of S100A4 in colorectal cancer and reported that nuclear location of S100A4 is associated with tumor stage. Our results also suggest that nuclear translocation of S100A4 protein might be involved in the process of invasion and metastasis of colorectal cancer. It is possible that S100A4 regulates transcription of other genes either through direct DNA binding to or through interaction with other DNA-binding proteins. Further large-scale and functional studies are necessary to elucidate the effect of nuclear translocation of S100A4 on the progression of human cancers, including colorectal cancer.

Generally, activation of a proto-oncogene results from mutation, rearrangement or manifold amplification of the DNA sequences, like *N-myc* in neuroblastoma and *c-erb B2* in breast cancer^[23-25]. Since there was no detectable somatic mutation of *S100A4* gene in the primary tumors in this

study, we considered that the S100A4 over-expression might not result from genetic mutation in colorectal carcinogenesis. However, we cannot completely rule out the possibility of a genetic alteration in other regions, such as the promoter, non-coding exon, and splice sites. Another possibility is the amplification or hypo-methylation of the *S100A4* gene in colorectal cancer, as in pancreatic ductal adenocarcinoma^[26]. In addition, our results may underestimate the prevalence of *S100A4* somatic mutations in colorectal cancer, as the sensitivity rate of SSCP analysis for the detection of single base substitutions is about 80%^[27].

In conclusion, S100A4 is overexpressed in colorectal cancer, cytoplasmic and nuclear expression is closely associated with a number of factors for tumor aggressiveness, such as tumor stage and lymph node metastasis.

Abstract

AIM: To determine the prevalence of hepatitis B in Nahavand and evaluate the HBsAg positive prevalence in families with a member who was confirmed to have HBV infection.

METHODS: This study was performed in two phases. In the first phase, 1 824 subjects in Nahavand city were selected. The interviewers visited the houses of chosen families to fill the questionnaire and take the blood samples. All subjects signed an informed consent before interviews and blood sampling. The samples were evaluated for HBV virologic markers. In the second phase, 115 HBsAg-positive cases were enrolled and evaluated for HBV virologic markers.

RESULTS: The prevalence of positive HBsAg in Nahavand was 2.3%. The most frequent relatives of index cases were sons and daughters (32.2% and 23.5% respectively). Twelve (11%) of all family members were HBsAg positive. Fifty (56.2%) were isolated HBsAb positive and only one person (2.5%) was isolated HBcAb positive. The higher rates of HBsAg marker were detected in the brothers (1-25%) and fathers (1-12.5%). The infection rate in husbands and wives of index cases was 10%. Only two (16.7%) of all HBsAg-positive participants reported previous HBV vaccination.

CONCLUSION: The prevalence of intra-familial HBV infection is lower in Nahavand of Iran compared to other studies. More attention should be paid to HBV vaccination and risk-lowering activities.

INTRODUCTION

Middle East countries including Iran have an intermediate prevalence of hepatitis B. In Iran, hepatitis B prevalence is low as 1.07% in Shiraz and as high as 8.96% in Toiserkan^[1]. There are three main routes of HBV transmission including blood, sexual contacts, and horizontal. In endemic regions of the world such as Africa, Greece, and Hong Kong, vertical transmission from mother to newborn infant and horizontal transmission among children play an important role in intra-familial transmission of HBV. In North America and Western Europe, however, the main route of transmission is intimate sexual contacts^[2-4].

A study of general population in Hamadan of Iran^[5] reported that HBV infection is low in unmarried men and women (18.26%) and high in widows and divorcees (51.59%), suggesting that horizontal transmission is likely to be the primary mode of acquisition of HBV infection in children and young adults. Also, infection is partly transmitted before or soon after birth to babies of HBsAg-carrier mothers. Socio-economic and demographic variables have a greater impact on the prevalence of HBV infection than blood or medical care variables in this population.

In a study in Spain, 848 of family members of 285 HBsAg-positive patients were evaluated and reported that 33.5% of them were positive for at least one HBV virologic marker^[6]. In the other study in Australia, family members of 145 HBV patients were studied and the results showed that 16% of them were HBsAg positive, and that HBV transmission within families is greater, if the index case has a HBsAg and HBeAg-positive mother rather than a HBeAg-negative one^[7].

The city of Nahavand in Hamedan Province (in west of Iran) has always been considered to have high prevalence of hepatitis B without any definitive study. This study aimed to determine the prevalence of hepatitis B in Nahavand and evaluate the HBsAg positive prevalence in families with a member who was confirmed to have HBV infection.

MATERIALS AND METHODS

This cross-sectional study was conducted during a 2-mo period (February-March 2003) in people aged 6 years and over in the city of Nahavand, located in the western part of Iran with a population of 72 000. In Nahavand there are 5 health care centers and 1 health site, and 304 participations were randomly selected from each of them.

This research was carried out in two phases. First, we studied the prevalence of hepatitis B in population of Nahavand (2002) and after identifying the HBsAg-positive cases, all of their families were enrolled into the second phase. The population less than 5 years old was not included in our study because blood sampling was difficult.

A questionnaire including demographic data, marital status and history of vaccination was developed. After taking the approval of health authorities of the city and city council, the educational sessions for data collection teams and directors of health care centers were held to train them on the details of interviewing, questionnaire filling, and blood sampling. Demographic data on eligible families were obtained from 1999 health registry.

The selected families were contacted at their residence. The family members older than 5 years were interviewed and informed consent was obtained. For those under 15 the parents also signed the consent forms. The questionnaires were filled by interviewers, who also took blood samples. The blood samples were sent to the laboratory of research center for gastro-enterology and liver disease, Shaheed Beheshti University of Medical Sciences at the end of each day. The virologic markers of hepatitis B were assessed.

After revealing HBsAg-positive cases, we collected demographic data of their families. The selected families were contacted at their residence and given description of the second phase by the interviewers. After signing the consent forms by the family members, the interviewers took blood samples and sent them to the laboratory (as above mentioned). All the virologic markers of hepatitis B were assessed.

It should be explained that HBsAg detection was carried out by Diasorin kit with lot no. 0370790/1A through sandwiched

ELISA. HBsAb and HBcAb levels were measured by Diasorin kit with lot no. 9230320/A through sandwiched non-competitive ELISA and Diasorin kit with lot no. 8540480/1B through competitive ELISA, respectively. All data were fed into an access data bank. SPSS version 11 was used for the analysis of data.

RESULTS

Of all subjects, 85 (4.6%) did not participate in study, 1 005 (55.1%) were married. The mean family population was 4.8 ± 1.9 , the smallest family had 1 member while biggest family had 13 members. The prevalence of HBsAg-positive cases in Nahavand was 2.3%. The hepatitis B serologic markers in the study subjects are shown in Table 1.

One hundred and fifteen family members including 8 (7%) mothers, 8 (7%) fathers, 11 (9.6%) sisters, 4 (3.5%) brothers, 27 (23.5%) daughters, and 37 (32.2%) sons, 10 (8.7%) husbands, and 10 (8.7%) wives were enrolled. Seventy-one (61.7%) of them were married.

In the participants, 23 (20.2%) had the education of literacy, 19 (16.7%) diploma and 15 (13.2%) higher than diploma, 33 (28.9%) were students and 26 (22.8%) were housekeepers. Twelve (11%) of all family members were HBsAg positive. Fifty (56.2%) were isolated HBsAb positive and only one person (2.5%) was isolated HBcAb positive.

Table 2 shows the relevance of HBV virologic markers to the index case. Higher rates of HBsAg marker were detected in the brothers (1-25%) and fathers (1-12.5%). The prevalence of HBsAg-positive cases in sons and daughters was identical (1.1%). The infection rate in husbands and wives was 10%.

The most frequent relatives with HBsAb positive were husbands and wives (5-71.4%) and then daughters (17-70.8%). There was no positive HBsAb in fathers. Only one person (son) was HBcAb positive.

It should be mentioned that the HBsAg-positive family members were evaluated for HBeAg and HBeAb and all of them were HBeAg negative and HBeAb positive. Also

Table 1 Frequency distribution of hepatitis B serologic markers in participants

	HBsAg positive	Isolated HBcAb positive	Isolated HBsAb positive	HBcAb and HBsAb positive
Number (%)	42 (2.3)	143 (7.84)	212 (11.62)	217 (11.9)
Sex (male%)	54.8	44.1	41.5	53.9
Age (mean \pm SD)	40.2 \pm 18	55.2 \pm 16	37.3 \pm 22	52.8 \pm 17
Marriage (%)	66.7	71.3	51.4	80.2

Table 2 Frequency distribution of hepatitis B virologic markers in family members of index cases, *n* (%)

	HBsAg positive	Isolated HBsAb positive	Isolated HBcAb positive
Mother	0 (0)	2/8 (25)	0 (0)
Father	1/8 (12.5)	0 (0)	0 (0)
Sister	1/8 (10)	5/8 (62.5)	0 (0)
Brother	1/4 (25)	1/4 (25)	0 (0)
Daughter	3/27 (1.1)	17/27 (63)	0 (0)
Son	4/37 (1.1)	15/37 (40.5)	1/37 (2.7)
Husband	1/10 (10)	5/10 (50)	0 (0)
Wife	1/10 (10)	5/10 (50)	0 (0)

they had normal liver function test.

Only 2 (16.7%) of the HBsAg-positive participants reported previous HBV vaccination, while 23 (46.9%) of the subjects with isolated HBsAb had previous HBV vaccination.

DISCUSSION

Among the 115 family members studied, sons and daughters were the most frequent relatives. We had some limitations in categorizing the data for discussion, because the number of positive HBsAg cases in children was low (three daughters and four sons). Sex proportion was identical in HBsAg-positive cases and others. Single participants were about twice of married ones. The most frequent level of education of family members was illiteracy and the most frequent occupations were students and housekeepers. The population less than 5 years old was not included in our study because blood sampling was difficult. This can underestimate the true frequency of hepatitis B in our population.

The mean age of HBsAg-positive cases was 40.2 ± 18 years. The phenomenon of e-seroconversion in this age group may responsible for the low transmission rate of HBV in our study in comparison to some other regions because marriage age during recent years has increased in Iran. There is no population-based study about genotypes of HBV in Iran. In a limited study, genotype D is found to be the most common genotype in patients with chronic hepatitis B^[8].

In overall, 11% of family members were HBsAg positive. There are different studies about HBV intra-familial transmission in the world that in the strongest ones, phylogenetic sequence analysis and amino-acid variation of the HBV core gene were performed. It is obvious that this way is the only way to confirm HBV intra-familial transmission, but due to lack of sufficient resources in present study, this procedure was not possible^[8-10].

In a study in 2002 in Italy^[9], 49 individuals from 13 families with sibling clusters of positive HBsAg carriers are investigated, HBV isolates are genotyped following amplification of the surface gene region of the viral genome, thus providing convincing evidence that viral isolates within a family originate from the same source. It was reported that the prevalence of HBsAg is significantly higher in family members than in the control group ($P < 0.001$)^[10]. A study in South Korea also reported that among 71 non-vaccinated HBsAg carriers, 10 are positive for HBsAg (14.1%), but none of the controls is positive for HBsAg^[11]. In a study in Spain, among 330 relatives of 145 HBsAg carriers observed over a mean period of 20.1 mo, 284 were positive for at least one HBV marker^[6]. It was reported that relatives of 26 positive HBsAg cases present an intra-familial prevalence of HBV infection of 28.8%^[12]. In other countries, variable results have been reported^[13-18].

In this study, the highest prevalence of HBsAg was in the fathers and sons, and infection rate in the husbands and wives was identical. A Turkey study showed that the husbands had a higher rate of HBsAg than wives (70.0% *vs* 21.9%, $P < 0.01$)^[10]. The high prevalence of HBsAg infection among spouses may be due to sexual transmission in menstrual period in other countries. In Iran, because of cultural and

religious aspects, this way of intra-familial transmission has a low prevalence. HBV transmission within families is greater, if they have a HBsAg positive mother rather than a HBsAg positive father^[6]. The current results show that most of the family members are not vaccinated for HBV infection, so the necessity of HBV vaccination in HBsAg-positive family members must be considered. It has been shown that only half of the isolated HBsAb-positive persons have a history of HBV vaccination. Some people might have insufficient information about vaccines. Coexistence of HBsAg and hepatitis B surface antibody (anti-HBs) has been reported in approximately 24% of HBsAg-positive individuals^[19] and low level of HBsAg in some of our people with isolated positive HBsAb may describe the above finding. We think that repeat testing for HBcAb in people with isolated positive HBsAb during a long time of follow-up may be helpful.

In conclusion, the prevalence of intra-familial HBV infection is low in Nahavand of Iran. More attention should be paid to HBV vaccination and risk-lowering activities.

Abstract

AIM: To clarify clinical features of the NSAID-induced small bowel lesions using a new method of endoscopy.

METHODS: This is a retrospective study and we analyzed seven patients with small bowel lesions while taking NSAIDs among 61 patients who had undergone double-balloon endoscopy because of gastro-intestinal bleeding or anemia between September 2000 and March 2004, at Jichi Medical School Hospital in Japan. Neither conventional EGD nor colonoscopy revealed any lesions of potential bleeding sources including ulcerations. Double-balloon endoscopy was carried out from oral approach in three patients, from anal approach in three patients, and from both approaches in one patient.

RESULTS: Ulcers or erosions were observed in the ileum in six patients and in the jejunum in one patient, respectively. The ulcers were multiple in all the patients with different features from tiny punched out ulcers to deep ulcerations with oozing hemorrhage or scar. All the patients recovered uneventfully and had full resolution of symptoms after suspension of the drug.

CONCLUSION: NSAIDs can induce injuries in the small bowel even in patients without any lesions in both the stomach and colon.

INTRODUCTION

Adverse effects of non-steroidal anti-inflammatory drugs (NSAIDs) in the upper and lower gastro-intestinal tract are well known^[1]. In addition, NSAIDs can induce and exacerbate damage in the small bowel^[2,3]. There is a study showing that 8.4% of patients taking NSAIDs developed small bowel ulcerations^[4]. Evidence that those lesions may also cause perforation, strictures or hemorrhage stems from a case-control study and several case reports^[5-14]. Despite the necessity, endoscopic observation of the small intestine was technically difficult because of its long length and multiple complex looped configurations. Recently, a video capsule endoscopy, which enables observation of the entire small bowel, was developed and this novel technology provided an outstanding progress for the diagnosis of small bowel diseases^[15-19]. In addition, we have developed a new method of endoscopy using a double-balloon technique (Fujinon EN-450P5/20, Fujinon Corp., Saitama, Japan), which also allows observations of small bowel under controlled movement even from a retrograde approach^[20-23]. The aim of this study was to delineate clinical features of the NSAID-induced small bowel mucosal injuries using the double-balloon endoscopy.

MATERIALS AND METHODS

The records of all the patients who underwent double-balloon endoscopy at Jichi Medical School Hospital, Japan between September 2000 and March 2004 were reviewed. Patients were identified from endoscopy case logs and cross-referenced with pathology database. Charts were also reviewed for NSAID prescription in those patients. Necessary telephone interview was also carried out. Patients with pre-existing or concomitant risk factors for possible small bowel complications, including Crohn's disease and mesenteric vascular disease, were excluded and all the patients with evidence of other small bowel pathology were also excluded. Reasons for exclusion on review of pathology included inflammatory bowel disease, small bowel lymphoma, primary or metastatic carcinoma, small bowel gastro-intestinal stromal

tumor, small bowel granuloma, small bowel diverticulum, angiodysplasia, and post-operative lesions. Two patients who have been on NSAIDs, were excluded and seven patients, in whom small bowel injuries were found while still on NSAIDs, were selected among 61 patients with obscure gastro-intestinal bleeding. These seven patients, two men and five women, with ages ranging 65-89 years (73.7 years on an average), were enrolled and subjected to the analysis.

RESULTS

Of these seven patients, six had melena and one had undetermined anemia with positive fecal occult blood tests during NSAID medications. Underlining disease of these patients included knee joint pain, back pain, headache, and rheumatoid arthritis. Neither conventional EGD nor colonoscopy revealed any lesions of possible cause of bleeding including ulcerations except for one patient (patient 1) in whom gastric ulcer scar was observed. Drug usage by these patients consisted of diclofenac in four patients (57%), and either ampiroxicam, aspirin, or loxoprofen in each of the remaining three patients, respectively (Table 1). Duration of the medication was different for patients, ranging from 7 d to 10 years. More than five units of packed red blood cell was required on an average for blood transfusion before diagnosis.

Double-balloon endoscopy was carried out from oral approach alone in three patients and from anal approach alone in three patients. The approach route was chosen, based on the clinical information including color of the stool. The depth of insertion estimated from the number of pleating procedures and the fluoroscopic images of the small intestine and endoscope in these patients was difficult but approximately 1/2-2/3 of the entire length of the small intestine with rough estimation, although we have succeeded in examining the entire small intestine from oral approach alone in one patient. In addition, another patient underwent total enteroscopy by both approaches. Patient's demographics are delineated in Table 1. Whether the lesions were located in the jejunum or ileum was determined radiographically based on a distance from either pylorus ring or ileocecal valve in each case. Ulcers or erosions were observed in the ileum in six patients (86%) and in the jejunum in one patient (14%). The ulcers were multiple in all the patients with different features from tiny punched out ulcers (Figure 1) to deep ulcerations with oozing hemorrhage (Figure 2A) or scar. Edematous villi around the ulcers were prominent features

by the endoscopic observation. Oozing hemorrhage from the ulcer, observed in one patient, was treated endoscopically using coagulator (ERBE, German, Figure 2B). Of interest, both circular ulcers (Figure 3A) and circular scars (Figure 3B) were observed in a different part of the small bowel in the same patient. Biopsies, taken from the edge of the ulcer in two patients, revealed non-specific inflammation. All the patients recovered uneventfully and had full resolution of the symptoms in accordance with their hemoglobin levels after suspension of the drug.

Figure 1 Endoscopic view of the punched-out ulcer in the ileum in a 65-year-old woman (patient 3). Edematous villi were observed around the ulcer.

DISCUSSION

This is a report to delineate NSAID-induced small bowel injuries using double-balloon endoscopy. NSAID-induced injuries were identified in seven out of 61 patients with obscure gastro-intestinal bleeding (11.5%). Despite limitation of this study due to the lack of observation of the entire small bowel in most patients, NSAID-induced ulcers were observed more frequently in the ileum than in the jejunum in consistent with a previous report by Kessler *et al.*^[13]. Further prospective study intended for evaluation of the entire small bowel, if substantiated, will clarify the exact distribution of NSAIDs-induced lesions. NSAIDs-induced lesions, identified by endoscopy, were multiple with different features from tiny ulcers to hemorrhagic ulcers or circular ulcers. These different features of ulcers, even observed in different parts of the small intestine in the same patient, may represent different stages of ulcers. The ulcers may be healing, because NSAIDs were suspended on the day of

Table 1 Clinical Features of the patients with nonsteroidal anti-inflammatory drug-induced small bowel lesions

Patient	Age/sex	Approach	Partial/total	Findings	Location	Dose (mg/d)	NSAIDs	Duration	Serum albumin (g/dL)	Blood transfusion (unit ¹)
1 ²	89/M	Oral	Partial, -middle ileum	Ulcers and erosions	Ileum	27	Ampiroxicam	10 yr	2.1	10
2	69/F	Oral	Total	Ulcers	Ileum	25	Diclofenac	7 yr	3.1	12
3	65/M	Anal	Partial, -upper jejunum	Ulcers and erosions	Ileum	75	Diclofenac	1 wk	3.9	0

¹1 unit = Packed blood cells separated from 450 mL of whole blood. ²Gastric ulcer scar was observed in this patient.

Figure 2 Endoscopic view of the ulcer with oozing hemorrhage in the ileum in a 74-year-old woman (patient 4). **A:** Before coagulation therapy; **B:** After

coagulation therapy.

Figure 3 Endoscopic view of the (A) circular ulcer and (B) circular ulcer scar

in the ileum in a 67-year-old woman (patient 7).

admission in all patients. Alternatively, either the dose of NSAIDs or the length that NSAIDs that was given, could attribute to the difference in size and shape of the ulcers, although such tendency was not observed in our study. Of interest, we could observe circular ulcers and even circular scars in the same patients. This observation may reinforce the association between ulcers and severe strictures in the small bowel after NSAID therapy. Further study describing the feature of circular ulcers is warranted for better understanding of these relationships.

In conclusion, NSAID-induced injuries in the small bowel were endoscopically observed and described using double-balloon endoscopy. NSAIDs-induced ulcers were found in the small bowel even in patients without any ulcers and erosions in the stomach as well as colon. Although this was a preliminary study, double-balloon endoscopy was useful for the direct observation and description of each lesion in detail by antegrade as well as retrograde approach.

Abstract

AIM: To determine the effect of oral erythromycin on gastric and small bowel transit time of capsule endoscopy.

METHODS: Consecutive patients who underwent capsule endoscopy during the 16-mo study period were either given 250 mg oral erythromycin, 1 h prior to swallowing the capsule endoscope or nothing. The gastric and small bowel transit time, and the small bowel image quality were compared.

RESULTS: Twenty-four patients received oral erythromycin whereas 14 patients were not given any prokinetic agent. Patients who received erythromycin had a significantly lower gastric transit time than control (16 min vs 70 min, $P = 0.005$), whereas the small bowel transit time was comparable between the two groups (227 min vs 183 min, $P = 0.18$). Incomplete small bowel examination was found in three patients of the control group and in one patient of the erythromycin group. There was no significant difference in the overall quality of small bowel images between the two groups. A marked reduction in gastric transit time was noted in two patients who had repeat capsule endoscopy after oral erythromycin.

CONCLUSION: Use of oral erythromycin significantly reduces the gastric transit time of capsule endoscopy.

INTRODUCTION

The introduction of wireless capsule endoscopy, which

has made direct visualization of the small bowel possible, has opened up a new chapter on small bowel imaging. Initial comparative studies showed that wireless capsule endoscopy is superior to push enteroscopy^[1-4] or conventional radiological imaging^[5]. The wireless capsule endoscopy is approved by the Food and Drug Administration of USA and is particularly useful for the diagnosis of obscure gastrointestinal bleeding.

With the limited battery life, the current capsule endoscope could take images for up to 8 h. Any delay in gastric transit may inadvertently result in incomplete small bowel examination. Whilst the capsule endoscope is passively propelled by peristalsis down the intestinal lumen, it is impossible to predict the time required for the capsule endoscope to navigate through the stomach. Although the use of prokinetic agents may potentially speed up the gastric emptying time, the effect of prokinetic agents on the outcome of wireless capsule endoscopy remains undetermined. Among various prokinetic agents, erythromycin, a motilin agonist, has been used to speed up gastric emptying in patients with gastroparesis^[6-8]. Moreover, the use of intravenous erythromycin has been shown to improve the quality of upper gastro-intestinal endoscopy in patients with upper gastro-intestinal bleeding, possibly via emptying of the blood contents within the stomach^[9]. Here, we determined the effects of oral erythromycin on the gastric and small bowel transit time of the capsule endoscope as well as the quality of small bowel images in patients undergoing capsule endoscopy.

MATERIALS AND METHODS

Patients

Consecutive patients who underwent capsule endoscopy in the Prince of Wales Hospital of Hong Kong between December 2002 and March 2004 were included. The use of prokinetic agents in these patients was based on the date of the procedure. All patients who had this examination after October 2003 received oral erythromycin (250 mg) 1 h prior to swallowing the capsule endoscope. In contrast, patients who had capsule endoscopy before October 2003 did not receive any prokinetic agent and were used as controls. Exclusion criteria included patients with swallowing difficulties, previous gastric or small bowel surgery, allergic to erythromycin, use of other prokinetic agents, and known or suspected bowel obstruction. All patients gave informed consent for undergoing the procedure.

A total of 38 patients had capsule endoscopy during the 16-mo study period. There were 17 males and 21 females with a mean age of 60.3 (SD 18.1) years. Twenty-four

(63%) patients were given oral erythromycin (250 mg) prior to swallowing the capsule endoscope (erythromycin group) whereas 14 (37%) patients did not receive any prokinetic agent (control group). None of the patients in the erythromycin group experienced any abdominal discomfort or gastrointestinal upset.

The indications of capsule endoscopy were as follows: unexplained iron deficiency anemia in 11, obscure gastro-intestinal bleeding in 20, recurrent abdominal pain in 6, and Crohn's disease in 1. Ten patients had diabetes mellitus and none of them was taking medications that would alter the gastric or intestinal motility. There was no significant difference in the demographic data, body build, history of diabetes or thyroid disease, and indications of capsule endoscopy between the two groups of patients (Table 1).

Table 1 Baseline characteristics of patients

	Erythromycin (n = 24)	Control (n = 14)
Mean age \pm SD (yr)	62.7 \pm 17.8	56.3 \pm 18.6
Male (%)	9 (37.5)	8 (57.1)
Mean body mass index (\pm SD)	22.9 \pm 3.8	22.3 \pm 3.2
Diabetes mellitus (%)	7 (29.2)	3 (21.4)
Indication		
Iron deficiency anemia (%)	6 (25)	5 (36)
Obscure gastro-intestinal bleeding (%)	12 (50)	8 (57)
Recurrent abdominal pain (%)	5 (21)	1 (7)
Crohn's disease (%)	1 (4)	0 (0)

Capsule endoscopy

Capsule endoscopy was performed after 12 h of fasting. Eight aeriels, which were connected to a battery-powered portable data recorder, were attached to the chest and abdominal wall of the patients prior to the procedure. Patients were asked to swallow the M2A[®] capsule endoscope (Given Imaging, Yoqneam, Israel) with plenty of water mixed with simethicone to eliminate small bubbles in the gastrointestinal tract. No bowel cleansing agent was used. Patients were allowed to resume clear fluid diet, 4 h after swallowing the capsule endoscope. The sensor array and recorder were removed from the patients after 8 h of recording. The recorded images were then downloaded to the workstation and viewed by the RAPID software (Given Imaging). Patients were monitored for any abdominal discomfort and pain during and after the examination. The time of spontaneous passage of the capsule endoscope was recorded. Patients who were uncertain of the natural passage of the capsule endoscope were called back for abdominal x-ray to check for possible retention of the capsule endoscope.

Gastric and small bowel transit time

All capsule images were independently viewed by two endoscopists who were unaware of the use of prokinetic agents. Gastric transit time was defined as the time taken from the first gastric image to the first duodenal image. Due to the potential difficulty in accurately identifying the

ileo-cecal valve, small bowel transit time was defined as the time taken between the first duodenal image and the first cecal image. Cases having capsules passed to the cecum were considered to be complete small bowel examination. The overall quality of small bowel images was graded as satisfactory or unsatisfactory by the viewers according to the percentage of good and clear images that were not obscured by food particles or bile. Satisfactory image was defined when more than 90% of the images were optimal and clear. All discrepant findings between the two viewers were resolved on discussion.

Statistical analysis

Categorical data were analyzed by Pearson χ^2 test whereas numerical data were analyzed by Student's *t*-test. All statistical analyses were made by the statistical software SPSS version 11.5 (SPSS Inc., Chicago, IL, USA). A two-sided *P* value of less than 0.05 was considered statistically significant.

RESULTS

Effects of erythromycin on gastric transit time

There was no retention of the capsule endoscope in these 38 examinations. The mean gastric and small intestinal transit time in all patients was 35.9 and 218 min respectively. Notably, the gastric transit time was significantly lower in the erythromycin group. The mean gastric transit was 15.8 min (range <1-60 min) in the erythromycin group and 70.2 min (range 1-298 min) in the control group (*P* = 0.005). While the longest gastric transit time in the erythromycin group was 60 min, five (36%) patients in the control group had gastric transit time of more than 1 h. On the other hand, there was no significant difference in the gastric transit time between diabetic and non-diabetic patients (mean 34.2 *vs* 36.4 min, *P* = 0.92). There was also no significant association between gastric transit time and age (*P* = 0.88), gender (*P* = 0.73), or body mass index (*P* = 0.22) of the patients.

Effects of erythromycin on small bowel examination

One (4%) patient in the erythromycin group had incomplete small bowel examination due to the prolonged small bowel transit time of more than 7 h. In contrast, 3 (21%) patients in the control group had incomplete small bowel examination (*P* = 0.13 *vs* erythromycin group). The reasons were the prolonged gastric and small bowel transit time in two and technical failure in one. For those who had complete small bowel examination, the small bowel transit time was comparable in the erythromycin (mean 227 min, range 85-446 min) and control groups (183 min, range 117-401 min; *P* = 0.18, Table 2). Unsatisfactory images were obtained in 46% patients of the erythromycin group and in 36% of patients of the control group (*P* = 0.74).

Effects of erythromycin on repeat capsule endoscopy

Four patients had repeat capsule endoscopy due to incomplete or sub-optimal examination. The minimal interval between the two examinations was 4 d. Two patients received erythromycin only on the second examination while the other two patients received erythromycin in both

examinations. As shown in Figure 1, there was a marked reduction in gastric transit time of the two patients who were given erythromycin in the second examination. In contrast, there was no apparent change in gastric transit time of the two patients who were given erythromycin in both examinations. The gastric transit time was less than 50 min in all examinations pre-treated with oral erythromycin.

Figure 1 Changes in gastric transit time in patients undergoing repeated capsule endoscopy. Four patients had repeat capsule endoscopy examinations. Two patients (CSK and LMZ), as shown by the black lines, received only erythromycin on the second examination and there was a marked reduction in gastric transit time in the second examination after the use of oral erythromycin. The other patients (WT and MPH), as illustrated by the dotted lines, received erythromycin in both examinations and the gastric emptying time was less than 50 min in both examinations.

Table 2 Gastric and small bowel transit of capsule endoscopy in two groups of patients (mean±SD)

	Erythromycin (n = 24)	Control (n = 14)	P
Gastric transit time (min)	15.8±16.8	70.3±88.1	0.005
Small bowel transit time (min)	226.5±84.0	183.0±91.2	0.18
Incomplete small bowel examination (%)	1 (4)	3 (21)	0.13
Image quality (%)			
Satisfactory	13 (54)	9 (64)	0.74
Unsatisfactory	11 (46)	5 (36)	

DISCUSSION

As gastric and small bowel transit time shows considerable inter-individual variations and the prime interest of the capsule endoscopy is to examine the small bowel only, ways to enhance gastric transit time without compromising small bowel examination would potentially improve the outcome of this investigation. However, the effect of prokinetic agent on this relatively new examination remains elusive. In this study, we specifically addressed the effect of oral erythromycin on gastric and small bowel transit time in patients undergoing capsule endoscopy.

Erythromycin promotes gastric emptying by binding to motilin receptors and acts as a motilin agonist. The use of low dose intravenous erythromycin has been shown to improve gastric emptying in patients with diabetic gastroparesis^[7]. Moreover, erythromycin infusion prior to endoscopy in patients with recent hematemesis has been shown to make endoscopy easier, and reduces the need for a repeat procedure by enhancing the emptying of blood

within the stomach^[9]. Results from this study showed that the use of low dose oral erythromycin could enhance gastric transit time of the wireless capsule endoscopy. The gastric transit time in the 24 patients who received erythromycin was all within 60 min. In contrast, 5 (36%) patients in the control group had gastric transit time of more than 1 h. In a previous volunteer study, it was noted that the mean gastric transit time of capsule endoscopy is 63 min (range 10-319 min)^[10]. This result is comparable to the findings in our control group. To further support our findings, there was a marked reduction in gastric transit time in the two patients who used oral erythromycin on the second examination only.

Other than speeding up the gastric transit time, the use of erythromycin was not associated with any significant changes in small bowel transit time. On the other hand, patients receiving erythromycin tended to have a higher rate of complete small bowel examination. This is probably due to the shortened gastric transit time instead of alterations in small bowel passage by the use of erythromycin. More importantly, the use of erythromycin did not appear to alter the overall quality of small bowel images. The percentage of “unsatisfactory” small bowel images reported in this study was relatively high, which may be related to the use of very stringent criteria for satisfactory images, i.e., >90% clear and optimal images. Moreover, we did not use any bowel cleansing agent in this study, which may further improve the quality of small bowel images^[11]. It was shown in a small uncontrolled study that the use of polyethylene glycol may also shorten the transit time of the capsule endoscopy through the stomach and small bowel^[12]. It remains to be determined whether the combined use of prokinetic agents and bowel cleansing agent has synergistic effect on small bowel transit time.

Erythromycin is a safe and cheap antibiotic, which can be conveniently given via oral route. It is also relatively free of adverse reactions including drug sensitivity. Although most published data used an intravenous preparation of erythromycin, we found that the use of oral dosage was also effective for this purpose. Apart from erythromycin, there are several other prokinetic agents that may be used in reducing gastric transit time during capsule endoscopy. Cisapride, which was previously used as a gastric prokinetic agent, is associated with fatal arrhythmia in susceptible individuals^[13,14] and has been withdrawn by the Food and Drug Administration in 1999^[15]. Domperidone and metoclopramide are also used in treating symptomatic patients with gastroparesis. However, the latter is not infrequently associated with extra-pyramidal side effects. Recently, the 5-HT₄ receptor partial agonist, tegaserod, is found to accelerate gastric emptying and gastro-intestinal transit time in healthy male subjects^[16]. Whether these drugs can also be used as prokinetic agents for capsule endoscopy remains to be determined and it is interesting to compare the effects of different prokinetic agents in future studies.

Although this was a non-randomized study, most of the potential confounding factors were comparable in the two groups. All demographic and clinical details of the two groups were matched. Moreover, all viewers were blinded to the clinical information of the patients. With the shortened

gastric transit time, it is not difficult to anticipate that the time spent by the examiners on reviewing the images would be reduced accordingly. This may be another advantage of using prokinetic agents in this rather time-consuming examination.

In summary, erythromycin given orally prior to swallowing capsule endoscope significantly reduces the gastric emptying time without compromising small bowel transit time and image quality. Further randomized study is necessary to evaluate the role of various prokinetic agents in the performance of capsule endoscopy.

Abstract

AIM: The role of the appendix has been highlighted in the pathogenesis of ulcerative colitis (UC). The aims of this study were to elucidate the immuno-imbances in the appendix of UC patients, and to clarify the role of the appendix in the development of UC.

METHODS: Colonoscopic biopsy specimens of the appendix, transverse colon, and rectum were obtained from 86 patients with UC: active pancolitis (A-Pan; $n = 15$), active left-sided colitis (A-Lt; $n = 25$), A-Lt with appendiceal involvement (A-Lt/Ap; $n = 10$), inactive pancolitis (I-Pan; $n = 14$), and inactive left-sided colitis (I-Lt; $n = 22$), and from controls. In the isolated mucosal T cells, the CD4/CD8 ratio and proportion of activated CD4+ T cells were investigated, and compared with controls.

RESULTS: In the appendix, the CD4/CD8 ratio significantly increased in A-Lt and A-Lt/Ap. The ratio in the appendix also tended to increase in A-Pan. In the rectum, the ratio significantly increased in all UC groups. In the appendix, the proportion of CD4+CD69+ (early activation antigen) T cells significantly increased in all UC groups. In the rectum, the proportion of CD4+CD69+ T cells significantly increased only in A-Pan. The proportion of CD4+HLA-DR+ (mature activation antigen) T cells significantly increased only in the rectum of A-Pan, but not in the other

areas of any groups.

CONCLUSION: The increased CD4/CD8 ratio and predominant infiltration of CD4+CD69+ T cells in the appendix suggest that the appendix is a priming site in the development of UC.

INTRODUCTION

Although the triggering factor for ulcerative colitis (UC) is still unknown, cytokine imbalance and the production of inflammatory mediators by activated CD4+ T cells play an important role in the pathogenesis of UC. T helper type 2 cells and their cytokines, particularly interleukin (IL)-4, have been suggested to enhance the development of UC^[1]. Recently, regulatory T cells, characterized by the expression of cell surface markers CD4 and CD25, have been shown to actively suppress immune responses, and lack of regulatory T cells leads to organ-specific autoimmunity^[2]. On the other hand, a sub-population of CD8+ T cells also suppresses the response of activated CD4+ T cells and B cells through an interaction that depends on expression of the major histocompatibility complex class Ib molecule Qa-1, the mouse homolog of human leukocyte antigen (HLA)-E^[3]. However, the precise role of these regulatory T cells in UC remains unclear.

Although human appendix is considered as a vestigial remnant^[4], recent observations have focused attention on the role of the appendix in the pathogenesis of UC. Many case-control studies suggest that previous appendectomy is rare in UC patients^[5-7], raising the possibility that appendectomy protects against the subsequent development of UC^[8-11]. Patients with previous appendectomy also have a delayed onset of UC^[8,9], a reduced need for immunosuppression therapy and proctocolectomy^[8,10], and a reduced relapse rate and extent of UC^[11]. Appendectomy in T-cell receptor (TCR)- α deficient mice suppresses the development of experimental colitis^[12]. Moreover, we first reported a patient with improvement of left-sided UC after appendectomy^[13]. Although these findings support that the appendix may be

related to the pathogenesis of UC, the immunological role of human appendix is unknown.

Extensive infiltration of lymphocytes, especially CD4+ T cells^[14], has been observed in the inflamed mucosa of UC patients^[15]. Activated CD4+ T cells exhibit increased cytotoxic activity^[16] and secrete cytokines that enhance the inflammatory state resulting in tissue injury^[17,18]. Several studies concerning T-cell subsets in the resected appendix have been performed previously^[19], but very few have focused on the activation status of the immune cells in the appendix as well as in the uninfamed mucosa. In this study, we investigated the CD4/CD8 ratio and proportion of activated CD4+ T cells in the inflamed and uninfamed colonic mucosa, especially in the appendiceal mucosa, of UC patients in order to clarify the role of the appendix in the development of UC.

MATERIALS AND METHODS

Subjects

UC patients with toxic megacolon, coexistence of known cancer, complication of extra-intestinal disease, past colectomy, poor general condition, and no consent to participate in the study were excluded. A total of 86 patients with UC and 27 control subjects were subsequently enrolled in the study. Informed consent to participate in this study was obtained from each patient. The diagnosis of UC was based on the established clinical, endoscopic, histological, and/or radiological criteria^[20]. Patients with no malignant or inflammatory colonic disorders, including adenomatous polyps ($n = 8$), diverticular disease ($n = 6$), non-specific abdominal pain ($n = 5$), family history of colorectal cancer ($n = 4$), and chronic constipation ($n = 4$) served as the control subjects. Patients receiving non-steroidal anti-inflammatory drugs or immuno-regulatory drugs, such as corticosteroids and azathioprine were excluded from controls. There was no history of appendectomy both in the patients and controls.

Scoring system of disease activity

The disease activity was evaluated based on the endoscopic findings according to the scoring system as reported previously^[21]: grade 0, normal vascular pattern; grade 1, erythema with loss of vascular pattern; grade 2, grade 1 plus contact bleeding; grade 3, grade 1 plus spontaneous bleeding; and grade 4, grade 1 plus obvious ulceration. We defined the grades 0 and 1 as inactive disease, and the other grades as active disease. The disease extent was also classified endoscopically into three subgroups: pancolitis and left-sided colitis (involvement up to the splenic flexure) with and without appendiceal involvement (skipped erosions in the appendiceal orifice).

Disease activity and patients

A total of 86 patients with UC were divided into six groups according to the activity and extent of the disease: active pancolitis (A-Pan; $n = 15$), active left-sided colitis without appendiceal involvement (A-Lt; $n = 25$), active left-sided colitis with appendiceal involvement (A-Lt/Ap; $n = 10$), inactive pancolitis (I-Pan; $n = 14$), inactive left-sided colitis

without appendiceal involvement (I-Lt; $n = 22$), and inactive left-sided colitis with appendiceal involvement (I-Lt/Ap; $n = 0$). Because the inflamed mucosa in the appendiceal orifice may be restructured by the normal mucosa after treatment, there were no patients with I-Lt/Ap. The characteristics of each group are summarized in Table 1. There was no significant difference in sex (the χ^2 test or Fisher's exact test) and age (Student's t -test) among groups.

At the time of the study, 27 patients with active UC and 3 patients with inactive UC had received no medications. Twenty-five patients were treated with salazosulfapyridine (SASP) (1 000-6 000 mg/d) only, 12 were treated with mesalazine (5-ASA) (1 000-2 250 mg/d) only, 2 were treated with prednisolone (PDN) (10 mg/d) only, 12 were treated with PDN (5-20 mg/d) plus SASP (1 500-4 500 mg/d), and 5 were treated with PDN (5-20 mg/d) plus 5-ASA (1 000-2 250 mg/d).

Cell isolation

We obtained colonic mucosal samples from UC patients and control subjects. At diagnostic or follow-up total colonoscopy when the activity and extent of the disease were evaluated, biopsy specimens from the appendix near the appendiceal orifice, transverse colon, and rectum (four specimens in each area) were obtained. We isolated mucosal mononuclear cells from biopsy specimens, as previously described^[22]. The initial viability of the cellular suspensions exceeded 95% in all instances when estimated by the trypan blue dye exclusion test. The viability was maintained at >80% during the entire assay period.

Flow cytometric analysis

Mucosal mononuclear cells were analyzed by two-color or three-color flow cytometry with the following mAbs: anti-CD4-PE/anti-CD8-FITC (Coulter Immunology, Tokyo, Japan), anti-CD45 (leukocyte common antigen)-PE-Cy5 (Immunotech, Cedex, France), anti-CD4-PE (Nichirei, Tokyo, Japan), anti-CD69 (early activation antigen)-FITC (Becton-Dickinson, Tokyo, Japan), and anti-HLA-DR (mature activation antigen)-FITC (Immunotech). The isolated cells were incubated with antibodies at 4 °C for 30 min, and washed thrice in FACS buffer (PBS, sodium azide 0.01%, and bovine serum albumin 0.1%, Sigma, St. Louis, USA), and applied for flow cytometry (EPICS XL system II, Coulter Company).

We first analyzed the phenotyped cells by two-color flow cytometry. After the cell suspensions were initially visualized in the forward scatter/side scatter profile, lymphocyte populations were gated to exclude monocytes. The proportion of CD4+ and CD8+ T cells in the total lymphocyte populations was expressed as CD4/CD8 ratio.

By three-color flow cytometry, we also analyzed the activated CD4+ T cells. In the process of T cell activation, CD69, CD25, CD71, and HLA-DR antigens are serially expressed on the surface of T cells. To identify this process, we investigated the expressions of CD69 (early activation antigen) and HLA-DR (mature activation antigen). After the cell suspensions were visualized, lymphocyte populations were gated as defined by CD45 (leukocyte common antigen) expression. The proportion of CD4+CD69+ and CD4+HLA-

DR+ T cells in the total lymphocyte populations was calculated.

Prior to the present study, we performed a pilot study with immuno-flow cytometric analysis in UC patients (A-Pan: *n* = 7 and A-Lt/Ap: *n* = 3), ascending colon cancer patients (*n* = 5), and ascending colon diverticulitis patients (*n* = 5). The population of T cells, expressing CD4, CD8, CD69, and HLA-DR antigens, in pre-operative biopsy samples of the appendix near the appendiceal orifice and in mucosal samples of resected appendix, was similar in each patient. The results of the pilot study suggested that the analysis of biopsy samples of the appendix near the appendiceal orifice represented those of the appendix.

Statistical analysis

All values were expressed as mean±SD. The Student's *t*-test for comparisons among groups was used for statistical analysis. *P*<0.05 (two-tailed) was considered statistically significant.

RESULTS

CD4/CD8 ratio in appendix

In the appendix, the CD4/CD8 ratio both in A-Lt (*P* = 0.0166) and A-Lt/Ap (*P* = 0.0445) significantly increased compared with that in controls (Table 2). Moreover, the CD4/CD8 ratio significantly increased both in A-Lt (*P* = 0.0452) and A-Lt/Ap (*P* = 0.0445) compared with that in I-Lt. The ratio in A-Pan tended to increase compared with that in controls (*P* = 0.1654) and in I-Pan (*P* = 0.6890). The ratio tended to increase in A-Lt/Ap compared with that in A-Lt (*P* = 0.7370). Interestingly, as the CD4/CD8 ratio in the appendix increased, the ratio in the rectum tended to increase, suggesting that some relations might be present in the immune responses between the appendix and the rectum.

CD4/CD8 ratio in transverse colon

In the normal appearance transverse colon of A-Lt/Ap, the CD4/CD8 ratio significantly increased compared with that in controls (*P* = 0.0374, Table 2). The ratio tended to increase in A-Lt/Ap compared with that in I-Lt (*P* = 0.3051). The ratio significantly increased in A-Lt/Ap compared with that in A-Lt (*P* = 0.0064), and in A-Pan compared with that in I-Pan (*P* = 0.0442).

CD4/CD8 ratio in rectum

In the rectum, the CD4/CD8 ratio significantly increased in all UC groups (A-Pan; *P* = 0.0102, A-Lt; *P*<0.0001, and A-Lt/Ap; *P*<0.0001), even in I-Pan (*P* = 0.0109) and I-Lt (*P* = 0.0046), compared with that in controls (Table 2). The ratio also significantly increased both in A-Lt (*P* = 0.0343) and A-Lt/Ap (*P* = 0.0236) compared with that in I-Lt. The ratio tended to increase in A-Lt/Ap compared with that in A-Lt (*P* = 0.1436), and in A-Pan compared with that in I-Pan (*P* = 0.4682). These findings suggested that the CD4/CD8 ratio might represent the inflammation degree in the mucosa.

Early activated T cells

In the appendix, the proportion of CD4+CD69+ (early activation antigen) T cells significantly increased in all UC groups (A-Pan; *P* = 0.0013, A-Lt; *P* = 0.0042, and A-Lt/Ap; *P* = 0.0245), even in I-Pan (*P*<0.0001) and I-Lt (*P* = 0.0357), compared with that in controls (Table 3), but there were no significant differences among UC groups. In the transverse colon, the proportion did not significantly increase in any UC groups compared with that in controls. In the rectum, the proportion significantly increased only in A-Pan (*P* = 0.0497), but not in the other groups, compared with that in controls.

Table 3 Activated T cells in the colon (mean±SD, %)

^a $P<0.05$, ^b $P<0.01$ vs controls. A-Pan, active pancolitis; A-Lt, active left-sided colitis; A-Lt/Ap, active left-sided colitis with appendiceal involvement; I-Pan, inactive pancolitis; I-Lt, inactive left-sided colitis.

Late activated T cells

The proportion of CD4+HLA-DR+ (mature activation antigen) T cells in the rectum significantly increased only in A-Pan compared with that in controls ($P = 0.0299$), while the proportion of CD4+HLA-DR+ T cells in the appendix did not significantly increase in any UC groups, compared with that in controls (Table 3). The proportion in the transverse colon also did not significantly increase in any UC groups compared with that in controls.

Effects of drugs on CD4/CD8 ratio and activated T cells

To identify the effects of drug treatment on the profiles of T cells, we analyzed the CD4/CD8 ratio and proportions of CD4+CD69+ and CD4+HLA-DR+ T cells in active UC patients with medication (A-Pan; $n = 8$, and A-Lt; $n = 14$) and those without medication (A-Pan; $n = 7$, and A-Lt; $n = 11$). Although the CD4/CD8 ratio in the transverse colon of A-Pan significantly increased in the patients without medication compared with those with medication ($P = 0.0306$), the other ratios and proportions were not significant between the patients with medication and those without medication. Our results were therefore not so influenced with medical therapy.

DISCUSSION

Although the pathogenesis of UC has not been determined, an abnormal mucosal immune response plays a major role in the development and pathophysiology of UC^[23,24]. There are few studies investigating the immune-regulatory cells in the appendix of patients with UC, especially with left-sided UC. Most studies have used cells isolated from colectomy specimens involving the disease to detect local immune abnormality^[23,24]. Because colectomy is usually performed in severe and refractory cases, mostly in pancolitis cases, but not in other active or inactive cases after a period of medical therapy, these studies may not cover the whole spectrum of disease activity^[25]. We therefore used cells isolated from colonoscopic biopsy specimens of UC patients with a wide range of disease activity, but the appendiceal mucosa is usually hard to obtain by biopsy. In this study, biopsy specimens of the appendix near the appendiceal orifice were used, instead of specimens of the appendix itself, because our prior pilot study showed that the analysis of biopsy samples of the appendix near the appendiceal orifice represented those of the appendix.

Although CD4+ and CD8+ T cells contain counterpart functions, such immuno-activation as helper/inducer T cells and immuno-suppression as regulatory T cells, the CD4/CD8 ratio is one of the most reflective markers for immune activation^[14,26]. In the present study, the CD4/CD8 ratio in the appendix significantly increased both in A-Lt and A-Lt/Ap compared with that in controls (Table 2). The ratio in the appendix also tended to increase in A-Pan compared with that in controls. Interestingly, as the CD4/CD8 ratio in the appendix increased, the ratio in the rectum tended to increase, suggesting that some relationships might be present in the immune responses between the appendix and the rectum.

In the normal appearance transverse colon of A-Lt/Ap, the CD4/CD8 ratio significantly increased compared with that in controls (Table 2). In the entire colon, the CD4/CD8 ratio tended to increase in A-Lt/Ap compared with that in A-Lt, but it was significant only in the transverse colon. Matsumoto *et al.*^[27] also reported that the histological inflammation grade in the entire colon was higher in A-Lt/Ap than that in A-Lt. The grade was significant both in the inflamed appendiceal orifice ($P<0.001$) and in the uninflamed ascending colon ($P<0.05$). The CD4/CD8 ratio therefore may represent the inflammation degree in the mucosa.

Even in the inactive UC groups, the CD4/CD8 ratio significantly increased in the rectum compared with that in controls. Most patients with inactive UC have low-grade inflammation, and it is possible that symptomatic relapse occurs only when the inflammatory process reaches a critical intensity^[28]. Also, because inflammation is a continuous process, direct assessment of the level of inflammatory activity may provide a quantitative pre-symptomatic measure of imminent clinical relapse of the disease^[28]. In our study, the increased CD4/CD8 ratio suggested that the significant immuno-imbalance was persistent in the inactive rectum. Because patients with inactive UC even receiving maintenance therapy are easy to relapse^[29], we suspect that the disease can relapse when the immuno-imbalance is persistent in the rectum.

Recent investigations including TCR- α deficient mice colitis models suggest that non-pathogenic enteric bacterial flora may be involved in the induction of colitis^[12,30]. However, it is unclear which part of the colon is involved in priming luminal antigens as the inductive site. To identify the priming site, we compared early- and late-activated CD4+ T cells with CD69 as an early activation antigen and HLA-DR as a late activation antigen, respectively. In the

appendix, the proportion of CD4+CD69+ T cells significantly increased in all UC groups, even in the inactive UC groups, compared with that in controls (Table 3). In the transverse colon, the proportion did not significantly increase in any UC groups compared with that in controls. In the rectum, the proportion significantly increased only in A-Pan, but not in the other groups, compared with that in controls. The proportion of CD4+HLA-DR+ T cells significantly increased only in the rectum of A-Pan, but not in the other areas of any groups compared with that in controls (Table 3). These findings suggest that the appendix may be a priming site in the development of UC. In A-Pan, the CD4/CD8 ratio tended to increase in all areas compared with that in controls, but it was significant only in the rectum (Table 2), where the proportions of CD4+CD69+ and CD4+HLA-DR+ T cells significantly increased compared with those in controls (Table 3). The findings suggest that the appendix may not play a major role in extended colitis.

In TCR- α -deficient mice, the pathological T cells are initially concentrated in the appendix^[31]. Mucosal TCR- $\alpha\beta$ + T cells, including CD4+ T cells, in IL-2-deficient mice appear in the colon prior to the manifestation of colitis^[16]. An increase of identical T cell clones involved in the development of inflammation is detectable in the uninfamed appendix and the inflamed colon of UC patients as well as in TCR- α -deficient mice^[32,33]. Therefore, the increased CD4+CD69+ T cells indicate that CD4+ T cells may be initially activated in the appendix, and may re-circulate to the entire colon and rectum (increased CD4/CD8) prior to the manifestation of UC, and inflammation originating from the rectum extends to the entire colon. The reason why the inflammation begins in the rectum is unknown.

We first reported the improvement of UC (A-Lt/Ap) without medication during the 3 years after appendectomy in a young patient (21-year-old), and proposed that appendectomy may have a place as a therapeutic strategy in UC patients^[13]. Ja'rrnerot *et al.*^[34], also performed laparoscopic appendectomy in six patients with refractory UC (two A-Pan and four A-Lt), and found that one young patient (26-years old) was in remission with continued maintenance treatment, but five patients (mean age: 50.8 years, range: 44-56 years) had relapse of the disease. Histological analysis of the resected appendix showed mucosal erosions and moderate infiltrations of CD4+ T cells in our patient^[13], but did not show any inflammation in all patients as reported by Ja'rrnerot *et al.*^[34]. They concluded that appendectomy does not influence the course of established UC in a consistent way, which supports our results in this study. Eri *et al.*^[35], also reported the clinical course of six patients (mean age: 30.5 years) with refractory UC (five A-Lt and one A-Lt/Ap) after laparoscopic appendectomy, and found that five patients were in complete clinical remission, and one patient had improved. Histological analysis of the resected appendix showed colitis-type inflammation (ulcerative appendicitis), containing a highly activated lymphocyte population, in the five patients. Recently, Jo *et al.*^[19], reported the clinical course of nine patients (mean age; 32.5 years, range; 13-48 years) with mildly activated UC (four A-Pan and five A-Lt) after appendectomy, and found that two A-Lt patients with ulcerative appendicitis had improved, but

the disease remained active in the other patients (three A-Lt without ulcerative appendicitis and four A-Pan). Hallas *et al.*^[36], reported the nationwide study with complete follow-up of 202 patients (mean age; 43.3 years) with UC who underwent appendectomy after their onset of UC, and concluded that appendectomy has no beneficial effect on admission rates in UC patients. Although appendectomy is associated with a low risk for subsequent UC only in young patients^[13,19,34,35], especially before the age of 20 years^[7], no stratification of data for any age had been performed^[36]. Later, Hallas *et al.*^[37], supported that appendectomy would be useful against UC in young subjects by analyzing those who underwent appendectomy before the age of 30 years. These findings and our results indicate that appendectomy may be performed in young UC patients with ulcerative appendicitis.

In conclusion, our study suggests that the CD4/CD8 ratio represents the inflammation degree in the mucosa. Appendectomy may be a benefit therapy in young UC patients with ulcerative appendicitis. Apart from the rectum, the appendix is a priming site in the development of UC, and should no longer be considered as an evolutionary redundancy. Further studies including analysis of CD4+ and CD8+ T cells are necessary to clarify the role of the appendix in the pathogenesis of UC.

Abstract

AIM: To investigate the ability of ursodeoxycholic acid (UDCA) to scavenge superoxide anion (O_2^-).

METHODS: We assessed the ability of UDCA to scavenge (O_2^-) generated by xanthine-xanthine oxidase (X-XO) in a cell-free system and its effect on the rate of O_2^- -induced ascorbic acid (AA) oxidation in hepatic post-mitochondrial supernatants.

RESULTS: UDCA at a concentration as high as 1 mmol/L did not impair the ability of the X-XO system to generate O_2^- , but could scavenge O_2^- at concentrations of 0.5 and 1 mmol/L, and decrease the rate of AA oxidation at a concentration of 100 μ mol/L.

CONCLUSION: UDCA can scavenge O_2^- , an action that may be beneficial to patients with primary biliary cirrhosis.

INTRODUCTION

Ursodeoxycholic acid (UDCA) is a naturally occurring tertiary dihydroxy hydrophilic bile acid used with considerable success in the treatment of primary biliary cirrhosis (PBC)^[1-5]. Traditional mechanisms whereby UDCA is beneficial to the diseased liver center on its ability to block the deleterious actions and encourage the choleresis of toxic bile acids^[6]. We have reported that UDCA has antioxidant properties. This finding is based on our observation that 100 μ mol/L

UDCA could prevent oxidative activation of cultured macrophages by the pro-oxidant hydrophobic bile acid, deoxycholic acid^[7]. In a follow-up *in vivo* study, we demonstrated that the therapeutic dose of 15 mg/kg UDCA administered for 24 d, suppresses the augmented extent of lipid peroxidation in the diseased liver of bile duct-ligated (BDL) rats, a widely used animal model of cholestatic liver disease^[8]. Accordingly, we proposed the antioxidant action of UDCA could contribute to its beneficial effect in patients with PBC^[7,8]. This proposal was recently confirmed by Serviddio and his colleagues who reported UDCA administered for 28 d minimized oxidative damage in the diseased liver of BDL rats^[9]. Other studies have established that UDCA can augment the biosynthesis of glutathione (GSH) and thiol-containing proteins in hepatocytes^[10,11] and could scavenge the hydroxyl radical (OH) in a cell-free system^[12]. Collectively, these findings have contributed to our current awareness that UDCA is a binary antioxidant possessing direct and indirect antioxidant properties.

Superoxide anion (O_2^-) is a reactive oxygen species (ROS) generated in microsomal and mitochondrial electron transport systems when oxygen is reduced by a single electron. It can also be generated by numerous oxidative enzymes including cytosolic xanthine oxidase (XO) during oxidation of xanthine (X) to uric acid. The generation of O_2^- is important, because its biotransformation can lead to formation of hydrogen peroxide through the activity of superoxide dismutase, generation of OH[•] radical in the presence of transition metals such as Fe²⁺ or formation of the reactive peroxynitrite radical by interacting with nitric oxide. Any intervention reducing or preventing excessive generation of O_2^- would result in decreased production of reactive oxygen and nitroxy species thereby lowering the extent of oxidative stress.

Mitsuyoshi *et al.*^[10], reported that UDCA increases hepatocyte levels of GSH and thiol-containing proteins. In this experiment, they spectrophotometrically measured the rate of oxidation of ascorbic acid (AA) by O_2^- and reported that the difference of absorbance before and after the addition of XO was lower in UDCA-treated hepatocytes than in controls. Since bile acids are enzyme inhibitors^[13,14], the difference in absorbance may be due to UDCA inhibiting the ability of the X-XO system to generate O_2^- . Because Mitsuyoshi *et al.*, did not assess the effect of UDCA on the generation of O_2^- by X-XO system in their investigation, we evaluated the ability of UDCA to scavenge O_2^- generated in the X-XO system and its effect on the activity of XO.

MATERIALS AND METHODS

Chemicals and reagents

All chemicals and reagents of the highest purity were

purchased from the Sigma Chemical Co. (St. Louis, MO, USA), except for UDCA that was purchased as its sodium salt from Megapharm Ltd, the Israeli agent of Calbiochem-Novabiochem Corporation.

Preparation of hepatic post-mitochondrial supernatants

The livers were harvested from healthy rats used as “healthy untreated controls” in institute-approved animal-based investigations. The harvested livers were washed in normal ice-cold saline, weighed and then cut into small pieces using scissors before their homogenization in 100 mmol/L ice-cold phosphate buffer, pH 7.4 at 4 °C with a Potter-Elvehjem glass homogenizer. The crude liver homogenates were centrifuged (1 000 r/min×10 min) at 4 °C. The resultant supernatants were then centrifuged at 10 000 g×10 min at 4 °C to pellet mitochondria and the supernatant was collected. The protein content in the supernatants was determined by the method of Lowry *et al.*^[15].

Analytical procedures

Ability of UDCA to scavenge superoxide anion Using the xanthine-xanthine oxidase (X-XO) reaction to generate $O_2^{\cdot-}$ ^[16], we evaluated the ability of 0.01-1 mmol/L UDCA to scavenge $O_2^{\cdot-}$ by the nitroblue tetrazolium (NBT) reduction assay^[17]. The reaction mixture contained 100 μ mol/L Na_2EDTA , 40 μ mol/L X, and 40 μ mol/L NBT in 10 mmol/L phosphate buffer pH 7.4. The reaction was started by adding 10 mU/mL XO and its rate was continuously monitored spectrophotometrically at A_{560} nm for 15 min at 25 °C in the absence and presence of different concentrations of UDCA. The specificity of the reaction was confirmed by 300 mU/mL superoxide dismutase. The ability of UDCA to scavenge $O_2^{\cdot-}$, as expressed as percentage of inhibition of NBT reduction in UDCA-present samples compared to NBT reduction in UDCA-absent samples. The experiment was repeated between 9 and 11 times at each UDCA concentration.

Effect of UDCA on activity of xanthine oxidase

Compounds interacting with XO could affect the kinetics of reaction of oxidation of xanthine to uric acid^[18]. Accordingly, we assessed the effect of 0.01-1 mmol/L UDCA on XO activity by spectrophotometrically monitoring the rate of uric acid formation at A_{295} nm for 3 min at 25 °C in the absence and presence of UDCA^[19]. The rate of uric acid formation was compared in the absence and presence of UDCA. The specificity of the reaction was confirmed by 100 μ g/mL allopurinol. The experiment was repeated nine times at each UDCA concentration.

Effect of UDCA on hepatic antioxidant capacity

The effect of 100 μ mol/L UDCA on hepatic antioxidant capacity was determined by monitoring the rate of oxidation of AA by the $O_2^{\cdot-}$ generated by the X-XO according to the original method of Nishikimi^[20] with modifications described by Mitsuyoshi *et al.*^[10]. Liver supernatants were incubated for 120 min at 37 °C in shaking water bath in the absence and presence of 100 μ mol/L UDCA. Upon completion of the incubation, the change in the rate of oxidation of AA was monitored in a quartz cuvette containing 1 mL reaction

mixture. The post-mitochondrial liver supernatant contained 100 μ mol/L X, 100 μ mol/L EDTA, 22 μ g/mL catalase, 100 μ mol/L AA and 0.1 mol/L phosphate buffer pH 7.4. The assay reaction was commenced by adding 10 mU/mL XO. The reaction was monitored spectrophotometrically at A_{250} nm for 10 min at 25 °C. The differences in absorbance between UDCA-absent and UDCA-added samples were compared. The results were expressed as the reaction rate of AA oxidation (Δ absorbance/mg protein). The experiment was repeated thrice.

Experimental design and statistical analysis

The data were analyzed using a two-tailed *t*-test. The sample size for each experiment was determined by power analysis arbitrarily set between 80-90% in order to detect the effect at the 5% significance level using Statmate™ version 1 (GraphPad Software Inc., San Diego, CA, USA). All figures were prepared using Prism™ version 3.02 (GraphPad Software Inc., San Diego, CA, USA). All data were expressed as mean \pm SD.

RESULTS

Ability of UDCA to scavenge $O_2^{\cdot-}$ and effect of UDCA on activity of xanthine oxidase

Figure 1A summarizes the experiments to establish whether UDCA could scavenge $O_2^{\cdot-}$ using the NBT reduction assay. UDCA (10 μ mol/L and 100 μ mol/L) had no effect on NBT reduction (Figures 1 A1 and A2). Higher concentrations of UDCA (500 μ mol/L and 1 mmol/L) slowed the rate of NBT reduction by 11% and 16% respectively (Figure 1A3 and A4). In order to eliminate the possibility that UDCA suppressed the rate of conversion of X to uric acid to account for this $O_2^{\cdot-}$ scavenging ability, we also measured the effects of the identical concentrations of UDCA on XO activity. None of the UDCA concentrations affected the rate of formation of uric acid (Figure 1B). Overall, these experiments demonstrated UDCA could scavenge $O_2^{\cdot-}$ without affecting the activity of XO.

Effect of UDCA on rate of oxidation of ascorbic acid

UDCA (100 μ mol/L) significantly ($P<0.002$) decreased the rate of AA oxidation (Figure 2).

DISCUSSION

The aim of the present study was to assess the ability of UDCA to scavenge $O_2^{\cdot-}$ and its effects on the activity of XO in a cell-free system and post-mitochondrial supernatants prepared from rat livers. In the cell-free experiments, we used UDCA concentrations not greater than 1 mmol/L in order to avoid the problems when extrapolating data to cell-containing systems in which millimolar concentrations of bile acids solubilize membranes to form micellar poly-aggregates (critical micellar concentration)^[21-23]. On the other hand, we used 100 μ mol/L UDCA in the experiments conducted in post-mitochondrial supernatants because this is the concentration used by Mitsuyoshi *et al.*^[10], and that found in the plasma of patients treated with UDCA^[24]. Using NBT reduction in the cell-free X-XO system to evaluate the ability of UDCA to scavenge $O_2^{\cdot-}$, we found UDCA

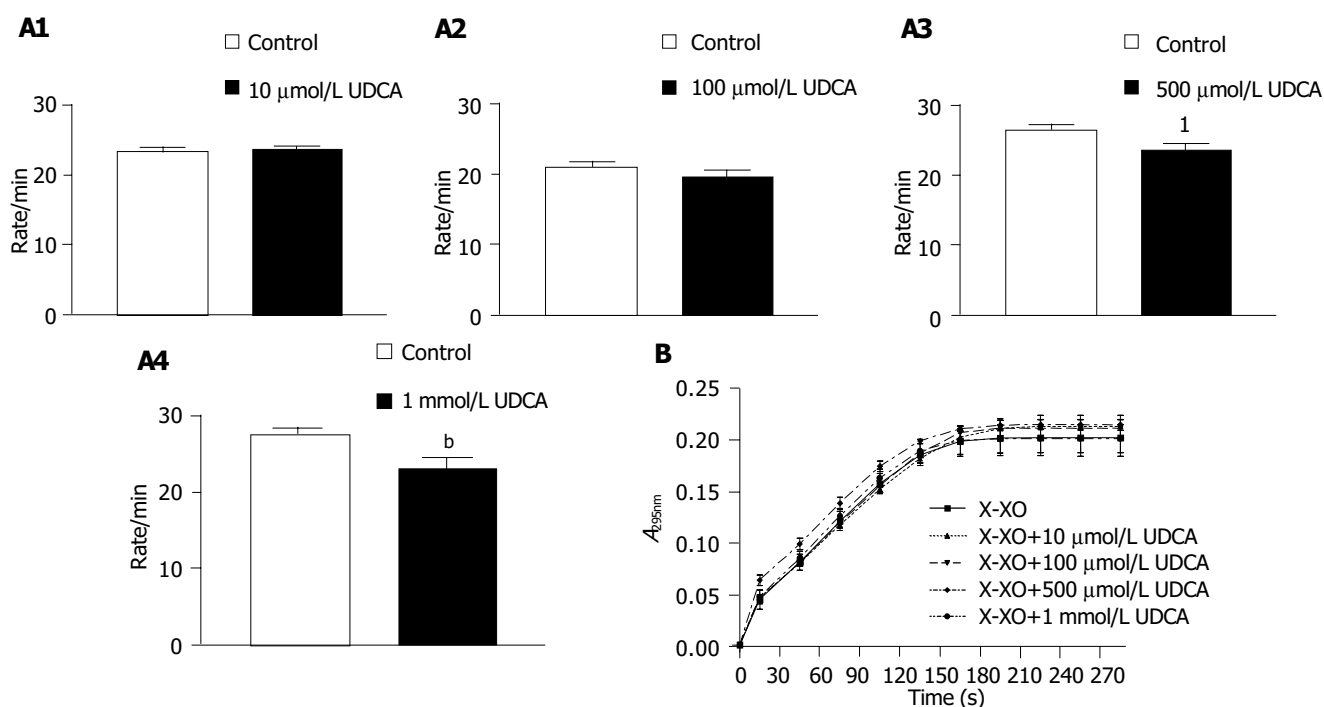

Figure 1 Ability of UDCA to scavenge O_2^- (A) and effect of UDCA on activity

of xanthine oxidase (B) in a cell-free system. ¹ $P < 0.02$, ^b $P < 0.01$ vs control.

Figure 2 Effect of 100 $\mu\text{mol/L}$ UDCA on rate of oxidation of AA by O_2^- generated by X-XO in post-mitochondrial hepatic supernatants. ¹ $P < 0.002$ vs control.

could scavenge O_2^- at concentrations of 0.5 and 1 mmol/L, respectively. Given the knowledge that bile acids can inhibit enzyme activity^[13,14], we checked the possibility that suppression of the activity of XO accounted for ability of UDCA to scavenge O_2^- . We found that UDCA at concentrations as high as 1 mmol/L did not inhibit the rate of conversion of X to uric acid. After establishing that UDCA could not impair the ability of the X-XO system to generate O_2^- , we then evaluated the effect of 100 $\mu\text{mol/L}$ UDCA on the rate of O_2^- -induced AA oxidation in hepatic post-mitochondrial supernatants. We found that UDCA decreased the rate of AA oxidation. This result agrees with that of Mitsuyoshi *et al.*^[10].

Is the scavenging of O_2^- by UDCA therapeutically relevant? Free-radical-induced peroxidation of phospholipids has been implicated in the pathogenesis of the formation of cholesterol gallstones^[25-27]. In addition, Liu and Hu demonstrated that O_2^- can attack the bilirubin molecule to

generate cytotoxic bilirubin radicals. ROS can also be generated in bile because hydrophobic bile acids are pro-oxidants^[28,29]. It was reported that the concentration of UDCA in bile may reach as high as 29 mmol/L in individuals given 750 mg UDCA daily for 2-3 wk^[30]. In our experiments, UDCA scavenged O_2^- at the concentrations of 0.5 and 1 mmol/L suggesting that the ability of UDCA to scavenge O_2^- may be beneficial in bile.

Lapenna *et al.*^[12], reported that UDCA is an efficient OH^\cdot scavenger. We have confirmed their finding and established the second order rate constant (k_2) for the reaction of UDCA with OH^\cdot in the D-ribose oxidation assay exceeded the rate constants of other OH^\cdot radical scavengers, such as mannitol or dimethylsulfoxide (Ljubuncic, Abu-Salach and Bomzon, *unpublished results*). In conclusion, UDCA is a direct scavenger of superoxide anion and hydroxyl radicals.

Abstract

AIM: To evaluate the seroprevalence of hepatitis B surface antigen (HBsAg) in 13 581 women at reproductive age and the hepatitis B e antigen (HBeAg)/anti-HBe status as well as serum hepatitis B virus (HBV)-DNA levels in a subgroup of HBsAg(+) pregnant women at labor in Greece.

METHODS: Serological markers were detected using enzyme immunoassays. Serum HBV-DNA was determined by a sensitive quantitative PCR assay. Statistical analysis of data was based on parametric methodology.

RESULTS: Overall, 1.156% of women were HBsAg(+) and the majority of them (71.3%) were Albanian. The prevalence of HBsAg was 5.1% in Albanian women, 4.2% in Asian women and 1.14% in women from Eastern European countries. The prevalence of HBsAg in African (0.36%) and Greek women (0.29%) was very low. Only 4.45% of HBsAg(+) women were also HBeAg(+) whereas the vast majority of them were HBeAg(-)/anti-HBe(+). Undetectable levels of viremia (<200 copies/mL) were observed in 32.26% of pregnant women at labor and 29.03% exhibited extremely low levels of viral replication (<400 copies/mL). Only two pregnant women exhibited extremely high serum HBV-DNA levels (>10 000 000 copies/mL), whereas 32.26% exhibited HBV-DNA levels between 1 500 and 40 000 copies/mL.

CONCLUSION: The overall prevalence of HBsAg is relatively low among women at reproductive age in Greece but is higher enough among specific populations. The HBeAg(-)/anti-HBe(+) serological status and the extremely low or even undetectable viral replicative status in the majority of HBsAg(+) women of our study population, suggest

INTRODUCTION

Worldwide, about 350 million people are chronically infected with hepatitis B virus (HBV)^[1]. Vertical transmission of the infection occurs usually in peri-natal period and is the major cause of HBV transmission in endemic countries of the world. Mother to infant transmission represents a basic factor in maintaining chronic HBV infection and usually depends on the degree of maternal infectivity, especially in peri-natal period^[2]. Vertical transmission of the infection is mainly seen in infants born from hepatitis B e antigen (HBeAg)(+) mothers with very high levels of viremia and maternal serum HBV-DNA levels are positively associated with immunoprophylaxis failure^[2,3].

Hepatitis B has long been a serious public health problem in Greece. Historically, Greece has had the highest burden of HBV infection in the European Union and unfortunately a hepatitis B prevention program aimed at high-risk groups in 1982, had little impact on disease incidence or prevalence^[4]. In recent years, HBV vaccination programs, demographic and socio-economic changes, medical precautions and screening of blood donors have resulted in a significant decline in chronic HBV infection in our country^[4,5]. However, the entrance of a great number of refugees, especially from endemic countries of HBV infection in the last decade, has possibly led to alteration of the epidemiological data, so these data have to be re-evaluated.

In our study we examined the seroprevalence of hepatitis B surface antigen (HBsAg) in a large multinational group of women at reproductive age and evaluated the presence

of HBeAg, antibody to HBeAg (anti-HBeAg) as well as antibody to hepatitis C virus (anti-HCV) in HBsAg(+) individuals. Moreover we measured the serum HBV-DNA levels in a subgroup of HBsAg(+)/anti-HCV(-) pregnant women at labor, in order to gain information about maternal viral load at this important period, a factor positively correlated with vertical transmission of the infection.

MATERIALS AND METHODS

Between August 2003 and August 2004, a total of 13 581 women at reproductive age (range 16-45 years) were prospectively evaluated at the Department of Obstetrics and Gynecology of the Maternal Hospital 'Helena Venizelou' of Athens, Greece. HBsAg, HBeAg, anti-HBeAg, and antibody to hepatitis B core antigen (anti-HBcAg) as well as anti-HCV were detected by routine commercially available enzyme immunoassays (Abbott Laboratories, Abbott Park, IL, USA). All women of the study were screened for HBsAg whereas the rest of the serological markers were evaluated only in HBsAg(+) ones. Antibody to hepatitis D virus (anti-HDV) and antibody to HIV (anti-HIV) were not detected. Serum HBV-DNA was determined by a sensitive, commercially available quantitative PCR assay (COBAS-Amplificor HBV Monitor, Version 2, Roche, Basel, Switzerland), with a lower limit of quantification of 200 copies/mL in a subgroup of HBsAg(+)/anti-HCV(-) pregnant women of the study population, with available serum samples, at labor.

Statistical analysis of data was based on parametric methodology. Student's *t*-test and χ^2 test were used. $P < 0.05$ was statistically significant. The study was reviewed and approved by the local ethics committee. The study protocol conforms to the ethical guidelines of the Declaration of Helsinki.

RESULTS

The majority of the study population came from Greece (70.31%) whereas 15.96% came from Albania, 7.06% from Eastern European countries (Russia, Romania, and Bulgaria), 4.09% from African countries, 0.69% from Asian countries, 0.99% from countries of Northwestern Europe, 0.46% from Australia and 0.43% from North American countries. Overall, 157 of 13 581 females (1.156%) were HBsAg(+) and the vast majority of them (112/157, 71.3%) were Albanian. The participation of each national group in HBsAg(+) cases of the study population is presented in Figure 1. None of the females from countries of North America, Northwestern Europe, and Australia (countries of low prevalence of HBV infection) was HBsAg(+).

The seroprevalence of HBsAg was 5.1% in women from Albania, representing the higher seroprevalence rate among the national groups of the study population, followed by 4.2% in Asian women and 1.14% in women from Eastern European countries. The seroprevalence of HBsAg in African (0.36%) and Greek women (0.29%) was very low, compared to the mean seroprevalence rate of the study population ($P < 0.05$). Overall, only 4.45% of HBsAg(+) women were also HBeAg(+) whereas the vast majority of them were HBeAg(-)/anti-HBeAg(+). HBeAg(+) cases represented 10.7% and 3.6% of Greek and Albanian HBsAg

Figure 1 Participation of each national group in HBsAg (+) cases of the study population.

(+) women respectively, whereas 92.9% of Greek and Albanian HBsAg(+) women, 90.9% of Eastern European countries HBsAg(+) women and all Asian/African HBsAg(+) women were HBeAg(-)/anti-HBeAg(+). Only 3 of 157 women (1.91%) with chronic HBV infection were HBV/HCV coinfect.

Serum HBV-DNA was quantified in 31 HBsAg(+)/anti-HCV(-) pregnant women of our study population with available serum samples at labor. Only one of them was HBeAg(+) whereas the vast majority of them were HBeAg(-)/anti-HBeAg(+), as it was the majority of HBsAg(+) cases of the study population. Twenty-two of them were Albanian (22/31, 70.96%), six of them (6/31, 19.35%) were Greek and the rest three were from an Eastern European, an Asian and an African country, respectively. Undetectable levels of serum HBV-DNA (< 200 copies/mL) were observed in 10 of 31 (32.26%) pregnant women at labor and 9 of 31 (29.03%) pregnant women exhibited extremely low levels of viral replication (lower than 400 copies/mL) during this important period. Only two, one HBeAg(-) and one HBeAg(+), of 31 pregnant women (6.45%) evaluated for HBV viral load, exhibited extremely high serum HBV-DNA levels (19 800 000 and 85 500 000 copies/mL, respectively) whereas the rest of the 10 women evaluated (32.26%) exhibited HBV-DNA levels between 1 500 and 40 000 copies/mL. Serum HBV-DNA levels in this subgroup of our study population are presented in Figure 2. As we can see from this figure, the majority (61.29%) of chronic HBV-infected pregnant women evaluated for serum HBV-DNA levels at labor by a very sensitive PCR assay, exhibited undetectable (< 200 copies/mL) or extremely low (< 400 copies/mL) levels.

DISCUSSION

Epidemiological data on the prevalence of serological markers of HBV infection in women at reproductive age in Greece are limited. It is estimated from previous studies that in Greece, the HBsAg carrier rate in pregnant women is 2.8-3.0%^[6]. In our study we found that the mean prevalence of HBsAg in 13 581 women at reproductive age from multinational origin, was relatively low (1.156%) and the vast majority of HBsAg-positive women (71.3%) came from Albania, representing the 5.1% of the Albanian women of the study population.

Figure 2 Serum HBV-DNA levels in 31 HBsAg(+)/anti-HCV(-) pregnant women at labor.

Although the seroprevalence rate of HBsAg in Albanian (5.1%) and Asian (4.2%) women was significantly higher than in Greek women (0.29%, $P < 0.001$), which was significantly lower than the mean rate of the study population (1.156%, $P < 0.05$), suggesting that there is a significant decline in seroprevalence of HBsAg in the refugees living in Greece in the last decade. In 1995 Malamitsi-Puchner *et al.*^[7], reported that 13.4% of 500 Albanian pregnant women evaluated in a Greek Maternal Hospital are HBsAg(+) and 7.5% of them are also HBeAg(+), representing an endemic and highly infective group of HBV infection. Significant socio-economic changes, specific precautions due to the knowledge of the modes of transmission of the infection and HBV vaccination programs may have possibly led to this decline observed nowadays in these specific populations.

Maternal HBeAg-positivity in peri-natal period is of great importance for the vertical transmission of HBV infection resulting in extremely higher rates of mother to infant transmission compared to infant born from HBeAg(-) mothers^[2,3,8]. In our study, the vast majority (>90%) of HBsAg(+) women were HBeAg(-)/anti-HBeAg(+), resulting possibly in the low rates of peri-natal transmission of HBV infection and passive/active immunoprophylaxis failure observed in our country, a finding that needs further investigation. Moreover, maternal serum HBV-DNA at labor was undetectable or extremely low in the majority of pregnant women of the study population evaluated, by a sensitive PCR assay. The predominance of HBeAg(-)/anti-HBeAg(+) serological status in combination with the low levels of viremia observed in the majority of chronic HBV-infected women of our study population, suggests that chronic HBV-infected women at reproductive age in Greece represent a group of low infectivity, resulting possibly in low vertical transmission and passive/active immunoprophylaxis failure rates.

Intra-uterine/transplacental transmission of HBV infection in infants born from HBsAg(+) mothers observed in endemic countries is positively correlated to HBeAg(+) maternal serological status and high levels of maternal serum HBV-DNA. It is believed that transplacental transmission of HBV infection is a major cause of immunoprophylaxis failure and this mode of transmission can be effectively

reduced by administration of hepatitis B immune globulin (HBIG) or lamivudine in the third trimester of HBsAg(+) pregnant women^[9]. It seems that this problem is not of clinical significance in our country, because of the relatively low seroprevalence rates of HBsAg observed in our study population, and the serological and virological data of chronic HBV-infected women at reproductive age in Greece, as previously noted.

In Greece, both active (HBV vaccine) and passive (HBIG) immunoprophylaxis are the current clinical practice in newborns from HBsAg(+) mothers, irrespective of maternal serological (HBeAg(+) or HBeAg(-)) and/or virological status. Studies from hyper-endemic countries of HBV infection suggest that there is no clear benefit of passive-active *vs* active immunization alone for chronic HBV infection in infants born from HBsAg(+)/HBeAg(-) mothers^[10]. The estimated efficacy of HBV vaccination alone without HBIG is 84% in infants born from HBeAg(+) mothers and 100% in those born from HBeAg(-) ones, according to a study from endemic Vietnam^[11]. The high cost of HBIG and the serological and virological data of women at reproductive age in our study, may suggest that passive-active immunoprophylaxis of infants born from chronic HBV-infected mothers in our country, possibly represents an over-protection strategy, at least in a significant proportion of them, especially from HBeAg(-)/anti-HBeAg(+) mothers with HBV-DNA <400 copies/mL at labor. This possibility needs further investigation in large-scale clinical trials. Moreover, more than one third (38.7%) of HBsAg(+)/anti-HBeAg(+) women of our study population exhibited active viral replication at labor and some of them exhibited extremely high viral load levels, representing possibly an infection with a mutant HBV variant (precore mutant), a finding that needs further investigation.

In conclusion, the overall seroprevalence rate of HBsAg is relatively low in women at reproductive age in Greece but is rather higher in specific populations (Albanian, Asian) who need screening, vaccination, and immunoprophylaxis programs in order to decline further the rates of peri-natally acquired HBV infection. The HBeAg(-)/anti-HBeAg(+) serological status and the extremely low or even undetectable viral replicative status in the majority of HBsAg(+) women suggest that only a small proportion of HBsAg(+) women in Greece exhibit an extremely high risk for vertical transmission of the infection.

Abstract

AIM: α -Lipoic acid (ALA) has been used as an antioxidant. The aim of this study was to investigate the effect of α -lipoic acid on cholecystokinin (CCK)-octapeptide induced acute pancreatitis in rats.

METHODS: ALA at 1 mg/kg was intra-peritoneally injected, followed by 75 μ g/kg CCK-octapeptide injected thrice subcutaneously after 1, 3, and 5 h. This whole procedure was repeated for 5 d. We checked the pancreatic weight/body weight ratio, the secretion of pro-inflammatory cytokines and the levels of lipase, amylase of serum. Repeated CCK octapeptide treatment resulted in typical laboratory and morphological changes of experimentally induced pancreatitis.

RESULTS: ALA significantly decreased the pancreatic weight/body weight ratio and serum amylase and lipase in CCK octapeptide-induced acute pancreatitis. However, the secretion of IL-1 β , IL-6, and TNF- α were comparable in CCK octapeptide-induced acute pancreatitis.

CONCLUSION: ALA may have a protective effect against CCK octapeptide-induced acute pancreatitis.

INTRODUCTION

Acute pancreatitis (AP) is a clinical entity that is believed to have intracellular activation of digestive enzymes and autodigestion of the pancreas as its central patho-physiologic cause. This non-infectious destruction of pancreatic parenchyma quickly induces an inflammatory reaction at the site of injury. AP usually occurs as a result of alcohol abuse. Histologically, acute pancreatitis is characterized by interstitial edema, vacuolization, inflammation and acinar cell necrosis^[1,2]. The diagnosis of acute pancreatitis is usually based on pancreatic edema index (pancreatic weight/ body weight), pancreatic serum enzymes (e.g. pancreatic amylase, lipase, immunoreactive trypsin or elastase) at animal models^[3,4].

Cytokines are important immunoregulatory mediators. Their contribution to the pathogenesis of acute and chronic gastroenterological disorders is obvious. Increased expression of interleukin-1 (IL-1), interleukin-6 (IL-6), tumor necrosis factor (TNF)- α can be detected in AP. These cytokines are involved in the pathogenesis of pancreatitis-associated multiple organ dysfunction.

Among the neurohormonal regulators, Cholecystokinin (CCK) is well known gastrointestinal hormone and neural agonist for inducing the release of pancreatic digestive enzymes. At supra-maximal doses (dose greater than those that cause maximal secretion of digestion enzyme by the pancreatic acinar cell) CCK are able to cause the pancreatic responses^[5,6].

Oxidative stress has been shown to be involved in the pathophysiology of AP^[7,8]. α -Lipoic acid (ALA) is a thiol antioxidant compound with demonstrated direct free-radical scavenging properties^[9,10]. However, the effects of ALA on AP have not yet been investigated. Therefore, in this study, we investigated whether ALA can ameliorate the severity of AP using CCK-octapeptide induced AP system.

MATERIALS AND METHODS

Animals

Male Wistar rats weighing 240-260 g were used. The animals were kept at a constant room temperature of 25 °C with a 12 h light-dark cycle, and allowed free access to water and standard laboratory chow. The rats were fasted for 16 h before the induction of AP. In each experimental group five rats were used.

Reagents

Avidin-peroxidase and 2'-AZINO-bis (3-ethylbenzothiazoline 6-sulfonic acid) tablet substrate were purchased from Sigma (St. Louis, MO, USA). Anti-rat TNF- α , IL-1 β and IL-6 antibodies

was purchased from R&D Systems (Minneapolis, MN, USA).

CCK-induced acute pancreatitis

ALA at 1 mg/kg was intraperitoneally injected, followed by CCK injected subcutaneously at 75 µg/kg thrice after 1, 3, and 5 h. This whole procedure was repeated for 5 d ($n = 5$). Other rodents ($n = 5$) received saline as control. The animals were killed by exanguinations through the abdominal aorta 12 h, after the last CCK injection. The pancreas was quickly removed, cleaned from fat and lymph nodes, weighed, and frozen at -70 °C until use. Rats were treated in accordance with the current law and NIH Guide for Care and Use of Laboratory Animals.

Pancreatic weight/body weight ratio

This ratio (pancreatic weight g/body weight g $\times 1\ 000$) was utilized to evaluate the degree of pancreatic edema.

Enzyme-linked immunosorbent assay (ELISA)

ELISA for IL-6 and TNF- α was carried out in duplicate in 96-well plates (Nunc, Denmark) coated with each of 100 µL aliquots of anti-rat IL-6, IL-1 β and TNF- α mAb at 1.0 µg/mL in PBS at pH 7.4 and was incubated overnight at 4 °C. The plates were washed in PBS containing 0.05% Tween-20 (Sigma, St. Louis, MO, USA) and blocked with PBS containing 1% BSA, 5% sucrose and 0.05% NaN₃ for 1 h. After additional washes, standards were added and incubated at 37 °C for 2 h. After 2 h incubation at 37 °C, the wells were washed and then each of 0.2 µg/mL of biotinylated anti-rat IL-6, IL-1 β , and TNF- α were added and again incubated at 37 °C for 2 h. After the wells were washed, avidin-peroxidase was added and plates were incubated for 20 min at 37 °C. Wells were again washed and ABTS substrate was added. Color development was measured at 405 nm using an automated microplate ELISA reader. A standard curve was run on each assay plate using recombinant IL-6, IL-1 β and TNF- α in serial dilutions.

Measures of serum amylase and lipase

Serum amylase was measured by using an ADIVA 1650 (BAYER, USA). Serum lipase was measured by using a Cobas-mira (Roche, USA).

Statistical analysis

Results are expressed as mean \pm SE. The significance of changes was evaluated using Student's *t*-test. Differences between the experimental groups were evaluated by using analysis of variance. Values of $P < 0.05$ were accepted as significant.

RESULTS

Effect of ALA on pancreatic weight/body weight ratio

To assess the effect of ALA on the pancreatic weight/body weight ratio, pancreatic weight was divided by the body weight of the rats. As shown in Figure 1, in ALA treated group, pancreatic weight/body weight ratio (3.676 ± 0.63) was significantly decreased compared to the DMSO treated group (6.46 ± 0.66 , $P < 0.05$, Figure 1).

Figure 1 Effect of ALA on the pancreatic weight/body weight ratio (pw/bw) in CCK-induced AP. Groups were treated as indicated in the Materials and method. mean \pm SE for 5 animals are shown. Significant difference ($P < 0.05$) vs the saline treated group.

Effect of ALA on IL-6, IL-1 β , and TNF- α secretion in CCK-induced AP

Secretion of pro-inflammatory cytokines to serum were increased during CCK-induced AP. Then, we investigated whether ALA reduces the serum levels of pro-inflammatory cytokines such as TNF- α , IL-1 β , and IL-6. ALA pre-treatment did not change the level of IL-1 β , IL-6 and TNF- α production during CCK-induced AP (Table 1).

Table 1 Effects of ALA on IL-1 β , IL-6, and TNF- α secretion in CCK-induced AP (mean \pm SE)

Treatment		IL-1 β	IL-6	TNF- α
CCK	ALA	(pg/mL)		
-	-	165.0 \pm 26	61 \pm 3	140 \pm 51
+	-	334.7 \pm 15	85 \pm 4	289 \pm 9
+	+	334.7 \pm 14	83 \pm 5	238 \pm 25

Effect of ALA on serum amylase and lipase activity in CCK-induced AP

The levels of serum amylase and lipase are commonly used as a marker of AP. Pre-treatment of ALA significantly decreased the serum amylase and lipase activity CCK - induced AP (Figure 2).

Figure 2 ALA inhibits hyperlipasemia on CCK-induced pancreatitis in rats. **A** and **B**: serum amylase and lipase levels in control rats and with pancreatitis induced by CCK. CCK was applied as described in the Materials and method. Values are mean \pm SE from at least five animals for each group. In lipase measurement, values for animals with AP receiving ALA were significantly lower than for those without ALA $P < 0.05$.

DISCUSSION

Our findings showed that ALA reduced CCK-induced AP. Furthermore, we showed that pancreatic weight/body

weight ratio and serum amylase and lipase were not correlated with the level of cytokines in the rat model. Many previous reports have suggested that ROS may play an important role in the initiation and development of pancreatitis^[11,12]. Anti-oxidant, N-acetyl cysteine (NAC) reduced the severity of AP^[13,14]. ALA is also a potent anti-oxidant and has anti-inflammatory effect^[9,10]. Therefore, in this study, we investigated the effects of ALA on CCK-induced AP. ALA decreased pancreatic weight/body weight ratio in CCK-induced AP. The levels of amylase and lipase usually rise after the onset of symptoms of acute pancreatitis. Compared with serum amylase, serum lipase rises slightly later and remains elevated longer^[15]. We found ALA decreased serum level of amylase, lipase in CCK-induced AP (Figure 2). Furthermore, we also examined several kinds of cytokines. IL-1 β , IL-6, and TNF- α levels are not attenuated by ALA after CCK treatment (Table 1). Recent study suggest that COX (Cyclooxygenase)-2 inhibition by selective inhibitor (SC-58125), induced alteration of serum amylase and lipase level but not IL-6 and IL-1 production on Caerulein (CAE) induced AP^[16]. In the previous report, ALA markedly inhibited radiation or H₂O₂-induced COX-2 upregulation^[17]. On the basis of this report, ALA maybe ameliorates AP via COX-2 inhibition. However, it is needed to investigate its mechanism whether inhibition of COX-2 is involve in the ALA-mediated decrease of AP. Despite of previous studies which link between IL-6 levels and increased severity of AP, recent studies suggest that IL-6 may have an anti-inflammatory role during pancreatitis^[18]. IL-6 KO mice exhibited a more severe pancreatitis after CAE injections than wild type mice^[18]. Our results indicate that pro-inflammatory cytokine levels are elevated in mice treated with or without ALA despite attenuated pancreatitis. This finding suggests that the stimulus for pro-inflammatory cytokines secretion remains intact; however, it is still unclear whether pro-inflammatory cytokines are mechanistically linked to the amelioration of pancreatitis.

In conclusion, this study showed that ALA pr-treatment ameliorated the severity of CCK induced pancreatitis in rats.

Abstract

AIM: To determine whether there was an association between inter-cellular adhesion molecule-1 (ICAM-1) gene polymorphism and biliary atresia (BA), and to investigate the relationship between serum soluble ICAM-1 (sICAM-1) and clinical outcome in BA patients after surgical treatment.

METHODS: Eighty-three BA patients and 115 normal controls were genotyped. K469E ICAM-1 polymorphism was analyzed using PCR assay. Serum sICAM-1 was determined using ELISA method from 72 BA patients. In order to evaluate the association between these variables and their clinical outcome, the patients were categorized into two groups: patients without jaundice and those with persistent jaundice.

RESULTS: There were no significant differences between BA patients and controls in terms of gender, K469E ICAM-1 genotypes, and alleles. The proportion of patients having serum sICAM-1 ≥ 3 500 ng/mL in persistent jaundice group was significantly higher than that in the other group. In addition, there was no association between K469E ICAM-1 polymorphism and the status of jaundice in BA patients after Kasai operation.

CONCLUSION: ICAM-1 possibly plays an important and active role in the disease progression. However, the process is not associated with genetic variation of K469E ICAM-1 polymorphism.

INTRODUCTION

Biliary atresia (BA), the obliteration of extra- and intra-hepatic biliary system, remains one of the most intractable liver diseases in children. When patients with BA are left untreated, the majority of them will die of complications of biliary cirrhosis^[1,2]. At present, it is accepted that hepatic porto-enterostomy or Kasai operation is the first choice of treatment. Surgical correction at an early age is therefore the key to a successful management of infants with BA^[3], especially in countries where liver transplantation program is not widely available. So far, liver transplantation is preserved for BA patients who have gross cirrhosis at diagnosis or who failed Kasai operation^[1]. Since BA is a serious liver disease with poor long-term outcome, extensive research for its exact cause in order to understand the disease has been carried out^[4]. Nevertheless, its etiology is still unclear. A number of hypotheses have been proposed to explain the origin of the disease including peri-natal infection^[5], immune-mediated disorders^[2], and defect of morphogenesis^[6]. It has also been suggested by some research groups that susceptibility to BA is influenced by genetic factors via pro-inflammatory cytokines^[7-9].

Inter-cellular adhesion molecule-1 (ICAM-1) is a transmembrane glycoprotein involved in cell adhesion and acts as a cell surface ligand for members of the leukocyte integrin family. The interaction of leukocyte integrins with endothelial ICAM-1 leads to leukocyte adherence, transendothelial migration and cell activation, which are fundamental to the recruitment of leukocytes to the tissue leading to inflammatory process^[10]. A soluble form of ICAM-1 (sICAM-1) can release into the circulation during the course of an inflammatory reaction^[11,12]. Recently, it has been shown that the elevated serum sICAM-1 is associated with primary biliary cirrhosis. The levels correlate with the disease activity and the degree of cholestasis^[13].

ICAM-1 gene is located on chromosome 19p13. The gene encoding ICAM-1 is affected by a common, functionally important, genetic polymorphism^[14]. The K469E polymorphism of the ICAM-1 gene has already been described^[15,16]. This polymorphism occurs in exon 6 of the ICAM-1 gene and results in a change from lysine to glutamic acid in Ig-like

domain 5. The ICAM-1 gene polymorphism can affect the interaction between ICAM-1 and its receptor, namely leukocyte function-associated antigen-1, and influence B-cell activation^[17]. ICAM-1 plays a pivotal role in the migration of leukocytes to inflammatory sites. Therefore, it may be involved in various inflammatory diseases.

As far as we are concerned, there is no investigation regarding ICAM-1 gene polymorphism in BA. Since progressive inflammatory process within the liver is an important feature of BA^[18,19], there may be some links between the pathophysiology of BA and ICAM-1 gene polymorphism. Therefore, the study aimed to evaluate the ICAM-1 gene polymorphism in BA patients and to investigate whether there was an association between serum sICAM-1 and clinical outcome in BA patients after surgical treatment.

MATERIALS AND METHODS

This study was approved by the Ethical Committee of the Faculty of Medicine, Chulalongkorn University, Thailand. All parents of the children with BA and healthy controls had been informed of the purpose of the study. The written informed consents were obtained.

Study of ICAM-1 gene polymorphism in biliary atresia

BA patients were recruited into the study during annual follow-ups between January 2002 and July 2003. All patients were diagnosed as BA by exploratory laparotomy with intra-operative cholangiography during early infancy period. The control group, whose ethnicity is similar to the BA patients (Thai), comprised healthy teenagers among those who participated in an evaluation of hepatitis B vaccination during the same period. Eighty-three BA patients participated in the study. Six out of eighty-three patients received liver transplantation. The healthy control group comprised 115 teenagers.

ICAM-1 DNA detection

Peripheral whole blood from BA patients and controls was collected in tubes containing EDTA. Genomic DNA was extracted from samples according to the manufacturer's protocol. Single base polymorphism at codon 469 (K469E) in exon 6 of ICAM-1 was determined using a method based on polymerase chain reaction-restriction fragment length polymorphism for the detection of K469E ICAM-1 gene, as previously described^[14,17]. The ICAM-1 F 5'CCCCGAC-TGGACGAGAGG3' is a sense primer and ICAM-1 R 5'GGGGCTGTGGGGAGGATA3' is an anti-sense primer. We combined 2 mL of DNA sample with a reaction mixture containing 20 mL of 2.5X Eppendorf MasterMix (Hamburg, Germany), 1 mmol/L P1, 1 mmol/L P2, and sterile water, in a final volume of 25 mL. PCR was performed under the following conditions: after an initial 4 min denaturation step at 95 °C, 37 cycles of amplification were performed, each including 30 s denaturation at 95 °C, 30 s annealing at 60 °C and 30 s extension at 72 °C, followed by a final 4 min extension at 72 °C. Each amplified DNA sample (10 mL) was added to loading buffer and run on a 2% agarose gel (FMC Bioproducts, Rockland, ME, USA) at 100 V for 60 min. The 331-bp product stained with ethidium bromide on preparation was visualized on a UV transilluminator.

PCR-RFLP analysis

PCR products were subjected to RFLP analysis, using restriction endonuclease *Bst*UI1 (New England Biolabs, Beverly, MA, USA) to determine the ICAM-1 polymorphism. Briefly, 10 mL of PCR product was mixed with 1.5 mL of 10× buffer, 3 mL of sterile water and 0.5 mL (5 U) of *Bst*UI1 incubated at 60 °C for 4 h. After incubation, the samples were run on a composite gel containing 2% NuSieve agarose (FMC BioProducts, Rockland, ME, USA) and 1% standard agarose. The clusters of PCR products were visible under UV light, as a result of prior ethidium bromide staining.

Study of serum sICAM-1 in biliary atresia

Seventy-two serum samples of BA patients were available for the study of sICAM-1. All patients underwent hepatic porto-jejunostomy with Roux-en-Y (original Kasai operation) during infancy period. Patients who received liver transplantation were excluded from the study to avoid confounding effects of different therapeutic modalities. Briefly, peripheral venous whole blood was drawn with a sterile syringe, transferred to a centrifuge tube, allowed to clot and then centrifuged at 4 °C. The sera were stored at -70 °C until they could be assayed. Serum sICAM-1 levels were determined by a commercially available ELISA kit (Quantikine, R&D Systems, USA). This assay employs the quantitative sandwich enzyme immunoassay technique. The serum sICAM-1 levels were expressed as nanogram per milliliter. In addition, liver function tests including serum albumin, total bilirubin (TB), direct bilirubin (DB), alkaline phosphatase (AP), aspartate aminotransferase (AST), alanine aminotransferase (ALT), and γ -glutamyl transpeptidase (GGT) were performed using an automated chemical analyzer (Hitachi 911) at the central laboratory of the hospital.

Out of 72 BA patients, none in this study exhibited symptoms and signs of fever or ascending cholangitis at the time of blood sampling. None received liver transplantation. In order to compare the outcome among the BA patients, they were subsequently divided into two groups according to the status of jaundice and levels of TB: patients with no jaundice (TB < 2.0 mg%) and patients with persistent jaundice (TB \geq 2.0 mg%). In addition, subgroup analysis between BA patients as per the presence of jaundice and ICAM-1 gene polymorphism was carried out.

Statistical analyses

Demographic data between groups were compared by Fisher's exact and unpaired *t*-tests. Genotype and allele frequencies were compared by χ^2 test. Significant differences were established at *P* < 0.05. Odds ratios were also calculated. For all statistical analyses, either GraphPad Prism version 3.02 (GraphPad Software Inc., CA, USA) or SPSS software version 10.0 (SPSS Inc., Chicago, IL, USA) was used. Data were expressed as mean \pm SD.

RESULTS

Study of ICAM-1 gene polymorphism in biliary atresia

The distribution of ICAM-1 genotypes and alleles in 83 BA patients and 115 controls is shown in Table 1. There

Table 1 ICAM-1 genotypic and allele distribution in BA patients and controls

	BA patients, <i>n</i> (%) <i>n</i> = 83	Controls, <i>n</i> (%) <i>n</i> = 115	Odds ratio (95% CI)	<i>P</i>
Age (yr)	6.09±4.67	13.07±2.13		<0.0005
Male	37:46	57:58		0.49
Genotype				
E/E	28 (33.74)	41 (35.65)	0.92 (0.51–1.66)	0.78
E/K	7 (8.43)	11 (9.57)	0.87 (0.32–2.35)	0.78
K/K	48 (57.83)	63 (54.78)	1.13 (0.64–2.00)	0.67
Alleles				
E	63 (37.95)	93 (40.43)	0.90 (0.60–1.36)	0.62
K	103 (62.05)	137 (59.57)	1.11 (0.74–1.67)	
E/K ratio	0.61	0.68		

were no significant differences between two groups in terms of gender, K469E ICAM-1 genotypes, and K469E ICAM-1 alleles.

Study of serum sICAM-1 in biliary atresia

Serum sICAM-1 levels in 72 BA patients were determined. The demographic data between patients with no jaundice and patients with persistent jaundice are shown in Table 2. There was no difference in age and gender between the two groups. Patients with persistent jaundice had lower levels of albumin and higher levels of AST, ALT, AP, and GGT compared to patients without jaundice.

We also found that 24 out of 72 patients had sICAM-1 levels above the upper limit detected by the ELISA kit (3 500 ng/mL), therefore, the cut point of 3 500 ng/mL was selected to subdivide the patients. By using χ^2 test, the proportion of patients having serum sICAM-1 levels ≥ 3 500 ng/mL in persistent jaundice group was significantly higher than that of patients having serum sICAM-1 levels

≥ 3 500 ng/mL in the other group ($P < 0.0005$), as shown in Table 2.

Association between K469E ICAM-1 gene polymorphism and status of jaundice

After excluding the BA patients who had undergone liver transplantation, 63 out of 83 BA patients had both data of genotype and total bilirubin levels. Therefore, an analysis of the association between ICAM-1 gene polymorphism and the status of jaundice after Kasai operation was conducted in 63 patients. The analysis showed that there was no difference in terms of age, gender, K469E ICAM-1 genotypes, and alleles between patients with no jaundice and with persistent jaundice (Table 3).

DISCUSSION

BA remains one of the major hepatic causes of death in early childhood. Although a number of hypotheses have

Table 2 Demographic data, liver function test, and serum sICAM-1 levels between BA patients without jaundice and with persistent jaundice (mean±SD)

BA patients	No jaundice (<i>n</i> = 41)	Persistent jaundice (<i>n</i> = 31)	<i>P</i>
Age (yr)	6.41±4.05	6.00±5.91	0.73

been proposed to account for the disease, its etio-pathogenesis is poorly understood. One possibility is that BA is an immune-mediated disease, which occurs following either a toxic or an infectious insult on a genetically susceptible host^[20]. Therefore, a number of studies have investigated whether bile duct epithelial cells are susceptible to immune or inflammatory attack because of abnormal expression of human leukocyte antigens (HLA) or ICAM-1 on their cell surface^[18]. It has been demonstrated that the expression of ICAM-1 and HLA-DR antigen in BA patients increases compared to that in controls^[21]. In addition to immune-mediated theory, a role of inflammation in the pathophysiology of BA has long been proposed. Histopathologic studies of the hepatic bile duct demonstrate various stages of inflammation causing progressive destruction of biliary system^[3]. This process might be caused by an overexpression of ICAM-1^[22]. The ICAM-1 gene is located on chromosome 19p13 and two non-synonymous single nucleotide polymorphisms are known as 12959G>A (G241R) and 13848A>G (K469E)^[23].

Several investigators have demonstrated the genetic association between ICAM-1 gene polymorphism and chronic inflammation diseases including inflammatory bowel disease^[14], multiple sclerosis^[16], Behcet's disease^[24], and endometriosis^[25]. Although there is a lot of information supporting the role of ICAM-1 gene polymorphism as a risk factor for diseases characterized by inflammatory process, the study of genetic susceptibility to BA, however, receives little attention. Donaldson *et al.*^[8], suggested that BA is not a HLA-associated disease, and that IL-1 and IL-10 gene polymorphisms are not risk factors for BA. Since inflammatory process and obliterative cholangiopathy within the liver are important features of BA, together with the fact that ICAM-1 molecule plays a major role in initiating inflammation, it is of our interest to evaluate whether ICAM-1 gene polymorphism is associated with BA. According to our knowledge, such a study has not been carried out.

The present study revealed that there was no association between K469E ICAM-1 gene polymorphism and BA in Thai population. Our results suggest that K469E ICAM-1 gene polymorphism is not a risk factor for both the etiopathogenesis and the prediction of success after Kasai operation. However, another study of serum sICAM-1 in BA patients showed that high levels of serum sICAM-1 are associated with the presence of jaundice and poor liver function, as illustrated by lower levels of serum albumin as well as higher levels of serum ALT, AST, and GGT^[26]. Our findings support the results from other research groups. Kobayashi *et al.*^[27], demonstrated that serum sICAM-1 levels can be used as a marker of end-stage liver disease in BA. Serum sICAM-1 also increases in BA patients but does not correlate with liver function^[28]. Davenport *et al.*^[2], reported, that a reduction in ICAM-1 expression on infiltrating cells in the biliary remnants is associated with a better post-operative prognosis. It might be possible that elevated sICAM-1 levels in BA patients with persistent jaundice found in this study reflect the impaired clearance of ICAM-1 from significant liver damage or, alternatively that the elevated sICAM-1 levels are caused by the increased ICAM-1 expression or by either mechanisms. Thus, the regulatory mechanisms of serum sICAM-1 seem to be complex. It is not easy to explain

the mechanisms of our observation from the study of serum sICAM-1 levels alone. At least, however, our findings show that the association between serum sICAM-1 and liver function in BA patients is significant enough to bring about a serious consideration.

According to our findings that high serum sICAM-1 levels are associated with poor outcome in BA patients following Kasai operation and the fact that ICAM-1 signaling is responsible for the initiation of inflammation, sICAM-1 levels in BA patients might have a prognostic role. In the study of serum sICAM-1, we recruited only patients who did not receive liver transplantation, in order to avoid the confounding effects from different therapeutic modalities.

It has been demonstrated that serum sICAM-1 levels in normal controls are low (less than 500 ng/mL)^[27,28]. Although there was no normal control group in our study, at least we found that the proportion of BA patients having serum sICAM-1 ≥ 3 500 ng/mL was significantly higher than that of patients without jaundice. Together with evidence supporting the role of ICAM-1 signaling pathway in inflammation, the manipulation of ICAM-1 expression might benefit BA patients. Therefore, apart from the prognostic role of serum sICAM-1 levels in BA, the therapeutic potential for BA using the immunomodulation of BA deserves attention. However, the specific mechanism requires further investigation.

In conclusion, the absence of association between K469E polymorphism of ICAM-1 and BA in Thai population has been demonstrated. BA patients with persistent jaundice following Kasai operation have higher serum sICAM-1 levels than those without jaundice. These findings suggest that ICAM-1 signaling is involved in the immunopathology of BA. Although ICAM-1 plays an important and active role in the disease progression, the process is not influenced by genetic susceptibility of K469E ICAM-1 gene polymorphism.

ACKNOWLEDGMENTS

We are grateful to the Thailand Research Fund and Center of Excellence of Thailand for generous support. Also we would like to express our gratitude to the entire staff of the Viral Hepatitis Research Unit, Chulalongkorn University and Hospital for their efforts in the present study. We would like to thank Rachadaphisek Somphot Endowment, Chulalongkorn University for supporting the research work. Lastly, we thank Venerable Dr. Mettanando Bhikkhu for reviewing the manuscript.

Abstract

AIM: The Lewis b (Le^b) antigen has been implicated as a possible binding site for attachment of *Helicobacter pylori* (*H pylori*) to gastric mucosa. However, studies both supporting and denying this association have been reported in the literature. Differences in secretor (Se) genotype have been suggested as a possible reason for previous discrepancies. Therefore, we investigated the relationship between Le and Se genotypes and *H pylori* infection rates in people with peptic ulcer or gastric cancer.

METHODS: Peripheral blood samples were obtained from 347 patients with endoscopic evidence of peptic ulcer disease (235 cases of duodenal ulcer, 62 of gastric ulcer, and 50 of combined duodenal ulcer/ gastric ulcer) and 51 patients with gastric cancer on endoscopy. Peripheral blood specimens from 101 unrelated normal volunteers were used as controls. Lewis phenotype was determined using an antibody method, whereas Le and Se genotypes were determined by DNA amplification and restriction enzyme analysis. Gastric or duodenal biopsies taken from patients with endoscopic evidence of peptic ulcer or gastric cancer were cultured for *H pylori*. Isolates were identified as *H pylori* by morphology and production of urease and catalase. The *H pylori* infection status was also evaluated by rapid urease test (CLO test), and urea breath test (¹³C-UBT). Results of studies were analyzed by chi-square test (taken as significant).

RESULTS: *H pylori* was isolated from 83.7% (303/347) of patients with peptic ulcer disease. Statistical analysis did not show any significant difference in Lewis phenotype or genotype between patients with and without *H pylori* infection. No significant association was found between Lewis genotype and peptic ulcer or gastric cancer.

INTRODUCTION

The Lewis blood group determinants are structurally related to the antigens of the ABO and H/h blood group systems. They are made by sequential addition of specific monosaccharides onto terminal saccharide precursor chains on glycolipids or glycoproteins. The glycolipids on which they reside on the erythrocyte surface are not synthesized in erythroid tissues, but are acquired by erythrocyte membranes from other tissues through circulating soluble forms that are bound to lipoproteins^[1].

The synthesis of the epitopes is dependent on the interaction of two different fucosyltransferases: alpha(1,2) fucosyltransferase encoded by the *FUT2* or secretor (Se) locus of the H/h blood group system, and alpha(1,3;1,4) fucosyltransferase (*FUT3*) encoded by the *FUT3* locus. Fucosylation by *FUT3* gives rise to the Le^a epitope, whereas the action of both enzymes results in Le^b.

If *FUT3* is not expressed, the phenotype is Le^{a-b-} regardless of whether *FUT2* (Se) is expressed or not. If *FUT3* and *FUT2* are both expressed, the phenotype is Le^{a-b+}. If *FUT3*, but not *FUT2* is expressed, the phenotype is Le^{a+b-}. A Le^{a+b+} phenotype may occur, if there is reduced expression of *FUT2*.

The Le^b glycan has been reported to mediate the attachment of *Helicobacter pylori* (*H pylori*) to human gastric mucosa^[2,3]. However, the clinical significance of this reported association remains a topic of debate. It has also been reported that people who do not secrete soluble Lewis b antigen are more susceptible to *H pylori* infection than people with secretor phenotypes^[4].

This study aimed to explore the association among Lewis antigen phenotypes and genotypes, infection with *H pylori*,

and consequent development of peptic ulcer or gastric cancer.

MATERIALS AND METHODS

Peripheral blood samples were collected as previously described^[4] from 347 patients with endoscopic evidence of peptic ulcer disease (235 cases of duodenal ulcer, 62 cases of gastric ulcer, 50 cases of duodenal ulcer and gastric ulcer) and 51 patients diagnosed with gastric cancer on endoscopy. Peripheral blood specimens from 101 unrelated healthy volunteers were used as normal controls. Subjects were enrolled from the Division of Gastroenterology, Department of Internal Medicine, Taipei Municipal Jen-Ai Hospital from August 1998 to December 2002.

The erythrocyte Lewis phenotype was determined by a tube method using monoclonal antibody (Gamma-CloneR, anti-Le^a, anti-Le^b Gamma Biologicals, Inc. Houston, TX, USA) at Taipei Municipal Jen-Ai Hospital.

Total genomic DNA was isolated from peripheral blood leukocytes as described previously^[5], and Le and Se genotypes were determined by DNA amplification (polymerase chain reaction, PCR) and restriction enzyme analysis^[6,7]. Oligonucleotide primer design and restriction enzyme analysis were carried out as previously described^[5]. The primer sequences and restriction enzymes used in this study are shown in Table 1. The amplified products were digested with appropriate restriction enzymes, followed by electrophoresis on 1.5-4% agarose gels. Direct sequencing of the PCR products in selected cases provided a check on the validity of the procedure.

Gastric or duodenal biopsies were taken from all patients with endoscopic evidence of peptic ulcer or gastric cancer and cultured for *H pylori*. Bacterial isolates were identified as *H pylori* by morphology and production of urease and

catalase^[8]. The *H pylori* infection status was also evaluated by rapid urease test (CLO test), and urea breath test (¹³C-UBT). *H pylori* infection was defined as positive results by culture or two positive test results on histology, rapid urease test, and ¹³C-urea breath test^[9].

Results were analyzed by the chi-square test, $P < 0.05$ was considered statistically significant.

RESULTS

H pylori was isolated from 83.7% (303/347) of patients with peptic ulcer disease. Statistical analysis did not show a significant difference in Lewis phenotype (Table 2) or Lewis genotype (Table 3) between peptic ulcer patients with *H pylori* infection and those without infection. Among the 51 gastric cancer patients, *H pylori* infection prevalence in the different Lewis phenotypes was Le^{a-b+}, 30/33 (90.9%); Le^{a-b-}, 7/8 (87.5%); Le^{a+b-}, 3/3 (100%); and Le^{a+b+}, 6/7 (85.7%).

H pylori was detected in 109/124 (87.9%) of peptic ulcer patients with Se/Se genotype, 148/174 (85%) of those with Se/se genotype, and 53/58 (91.3%) of those with se/se genotype. The difference in proportion of infected patients was not significant ($P = 0.436$).

Similarly, no significant difference ($P = 0.440$) was found for presence of *H pylori* infection in peptic ulcer patients with Le/Le (86/97, 88.6%), Le/le (182/215, 84.6%) or le/le (31/34, 91.3%) genotypes.

No significant association was found between Lewis genotype and presence of peptic ulcer disease or gastric cancer (Table 4). Again, an analysis by Se genotype showed no significant difference between patients with peptic ulcer disease and normal controls ($P = 0.915$) or between patients with gastric cancer and normal controls ($P = 0.741$), whereas analysis by Le genotype gave similar, non-significant results

(P = 0.067 and P = 0.344 respectively).

Finally, no significant correlation was obtained between ABO blood group type and *H pylori* infection (Table 5).

DISCUSSION

H pylori is the main causative agent of gastric and duodenal ulcers^[10] and gastric adenocarcinoma^[11]. Attachment is a pre-requisite for microbial colonization of epithelial surfaces and is mediated through interaction of adhesins on the bacterial surface and proteins or glycoconjugates on the surface of the epithelial cells^[12,13]. Borén *et al.*^[2], reported that the attachment of *H pylori* to gastric mucosa is mediated by the Lewis^b (Le^b) antigen and that the availability of receptors might therefore be reduced in individuals of blood groups A and B compared to people with blood group O.

Carneiro *et al.*^[14], found that there is a significant relationship between ABO blood group in combination with Lewis phenotype on the one hand and *H pylori* infection on the other. *H pylori* is present in 100% of those with Le^{b+}/O phenotype but in only 57% of Le^{b-}/A or B phenotype. However, infection is also present in 92% of Le^{b-}/O individuals and 86% of Le^{b+}/A or B individuals. Nonetheless, the Carneiro

group challenged the finding of Niv *et al.*^[15], that positivity for *H pylori* is not associated with blood group O and their conclusion that their observations do not support the contention that the receptor for *H pylori* in the gastric mucosa is the Le^b antigen.

However, Clyne and Drumm^[16] found that adherence of *H pylori* to isolated human gastric cells is not dependent on Lewis antigen expression on the cells, and Umlauf *et al.*^[17], could not demonstrate any *in vivo* correlation between *H pylori* infection or disease and Le^b antigen. Taylor *et al.*^[18], also found that there is no correlation between Lewis antigen expression by *H pylori* and gastric epithelial cells in infected patients.

More recently, Keller *et al.*^[19], found that there is no significant association between secretor status or specific ABO blood group and *H pylori* infection or occurrence of gastro-duodenal ulcer. Aguiar^[20] also found that there is no significant association between the presence of *H pylori* and ABO, Lewis or secretor phenotype, while Nogueira *et al.*^[21], actually found that Le^b expression is nearly twice as common among children without *H pylori* (15/23, 65%) as in those with *H pylori* (16/47, 34%).

However, Yang *et al.*^[22], found that there are significant

Table 5 ABO blood types and susceptibility to *H pylori* infection (n = 230)

Blood types	A (n = 44)	B (n = 54)	O (n = 122)	AB (n = 10)	P
<i>H pylori</i> status					0.255
Positive	34	49	106	8	
Negative	10	5	16	2	
Prevalence %	77.2	90.7	86.8	80	

relationships between Lewis phenotype and *H. pylori* infection. Expression of Le^a antigen (whether Le^{a+b-} or Le^{a+b+}) is associated with a higher infection rate but a lower bacterial density, a lower severity of chronic inflammation, and a lower frequency of lymphoid follicles in the gastric cardia. To complicate things even further, *H. pylori*-infected patients expressing the Le^b antigen have a lower rate of gastro-duodenal ulcers but a higher bacterial density and inflammation severity in the gastric cardia. It is difficult to know how to interpret these results.

In vitro studies by Lindén *et al.*^[23], and Van de Bovenkamp *et al.*^[24], showed that binding of *H. pylori* to human gastric MUC5AC mucin is blood group antigen-binding adhesin dependent and mediated by the Le^b structure in the mucin. However, it has also been shown that *H. pylori* bacteria that do not express Lewis antigens but do express other complex carbohydrates that may still have the ability to form long-term colonies in the stomach^[25,26].

It may be that differences in reported results are due to strain differences in *H. pylori*. Hennig *et al.*^[27], found that there is considerable heterogeneity among *H. pylori* isolates in expression of the BabA adhesion, which is thought to bind to Le^b antigen present on the surface of gastric epithelial cells. Sheu *et al.*^[28], in a study of 188 dyspeptic patients with *H. pylori* infection in Taiwan, found that all isolates have a positive babA2 genotype and that, among 139 patients with Le^b expression, *H. pylori* density increases with Le^b intensity. In the 49 patients without gastric Le^b expression, *H. pylori* density is positively correlated with Le^x and Le^a expression.

In conclusion, Lewis blood genotype or phenotype may not play a role in the pathogenesis of *H. pylori* infection. However, bacterial strain differences and the presence of more than one attachment mechanism may limit the contribution of epidemiological studies toward elucidating this matter.

INTRODUCTION

Colorectal cancer (CRC) is one of the most common malignancies worldwide, accounting for a significant percentage of cancer mortality. The incidence in both developing and developed countries has been increasing over the past few decades. Concurrent chemo-radiation therapy (CCRT) plays an important role in controlling CRC and palliating symptoms. This is particularly true when aiming for anal preservation in locally advanced disease, and it therefore offers an attractive alternative to surgery, the current mainstay of treatment^[1].

Radiation therapy (RT), either as a definitive treatment along with chemotherapy for unresectable disease or as a post-operative adjuvant for resectable disease, plays an important role in the management of CRC^[2,3]. However, large portions of the colorectum, small intestine, and urinary bladder are inevitably included within the radiation field in order to treat the areas of pelvic lymphatic drainage. Therefore, radiation-induced toxicity limits the use of RT in treating this malignancy, either alone or as part of a CCRT protocol. Moreover, some tumor clones are resistant to RT or chemotherapy. Currently, CCRT using a 5-fluorouracil (5-FU)-based regimen is the mainstay of CRC therapy. 5-FU is known to be a radiosensitizer, but some cancer cell clones are resistant to it^[4,5]. Given these limitations, it is desirable to look for radiosensitizers that augment the efficacy of RT, thus allowing a lower RT dose, and have acceptably low toxicity.

Etoposide (VP-16) is a semi-synthetic derivative of the naturally occurring antibiotic podophyllotoxin, which poisons type II topoisomerase without binding to DNA^[6]. Etoposide has been widely used in the treatment of lung and ovarian cancer, given either intravenously or orally^[7-9]. The combination of etoposide and cisplatin given concurrently with RT for lung cancer has yielded promising results^[10]. Etoposide-based CCRT also appears to be effective in newly diagnosed malignant glioma^[11]. Chemotherapy with etoposide as a single agent, however, is not very successful in a phase II trial for colorectal cancer^[12], which may explain why there

Abstract

AIM: To investigate the combined effect of etoposide and radiation on CT26 colorectal adenocarcinoma implanted into BALB/c mice.

METHODS: We evaluated the radiosensitizing effect of etoposide on CT26 colorectal adenocarcinoma in a syngeneic animal model. BALB/c mice were subcutaneously implanted with CT26 cells and divided into four groups: control (intra-peritoneal saline×2) group, etoposide (5 mg/kg intra-peritoneally×2) group, radiation therapy (RT 5 Gy×2 fractions) group, and combination therapy with etoposide (5 mg/kg intra-peritoneally 1 h before radiation) group.

RESULTS: Tumor growth was significantly inhibited by RT and combination therapy. The effect of combination therapy was better than that of RT. No significant changes were noted in body weight, plasma alanine aminotransferase, or creatinine in any group. The leukocyte count significantly but transiently decreased in the RT and combination therapy groups, but not in the etoposide and control groups. There was no skin change or hair loss in the RT and combination therapy groups.

CONCLUSION: Etoposide can sensitize CT26 colorectal adenocarcinoma in BALB/c mice to RT without significant toxicity.

is little interest in this drug for this disease. However, Shigematsu *et al.*^[13], reported, that a combination of low dose etoposide and radiation, arrests V79 (Chinese hamster fibroblasts) and T24 (human bladder cancer) cells in the G₂/M phase of the cell cycle, decreasing their survival. Since G₂/M is a radiosensitive phase of cell cycle, it is possible that etoposide functions as a radiosensitizer rather than a cytotoxic agent.

In this study, we investigated the combined effect of etoposide and radiation on CT26 colorectal adenocarcinoma implanted into BALB/c mice. Both the therapeutic effect and safety profile were evaluated.

MATERIALS AND METHODS

Cell culture and mice

CT26 cells, N-nitroso-N-methyl urethane-induced mouse colon carcinoma cells of BALB/c origin^[14], were purchased from the American Type Culture Collection (ATCC, Manassas, VA, USA). Cells were cultured in RPMI1640 medium (GIBCO, Grand Island, NY, USA) supplemented with 10% heat-inactivated fetal calf serum (Hyclone, Logan, UT, USA) at 37 °C in a humidified 50 mL/L CO₂ incubator. The cell cultures were passaged every 2-3 d with TEG solution (0.25% trypsin, 0.1% EDTA and 0.05% glucose in Hanks' balanced salt solution) and maintained in exponential growth. Male BALB/c mice, aged from 6 to 8 wk, were obtained from the National Laboratory Animal Center (Taipei, Taiwan) and housed in a rodent facility at 22±1 °C in a 12-h light-dark cycle. Four groups of animals of 9-11 mice each were implanted with CT26 cells (2×10⁵ cells) by subcutaneous injection into the right gluteal region. Treatment was started when the tumors grew to 0.5 cm in diameter. All experiments were performed in accordance with the regulations of the NIH *Guide for the Care and Use of Laboratory Animals* (DHHS publication no. NIH 85-23, revised 1996).

Drug preparation

Etoposide was purchased from Sigma-Aldrich Co. (St. Louis, MO, USA). It was dissolved in dimethyl sulfoxide (DMSO) at 10 mmol/L as a stock solution and stored at -20 °C. For experimental use, the stock solution was diluted to the appropriate concentration with growth medium, with a final DMSO concentration of less than 0.1%. This concentration of DMSO has been previously proven to be nontoxic to cells.

Drug administration and radiation delivery

There were four groups of mice in our study. The first group received intra-peritoneal (i.p.) saline for 2 consecutive days, and served as controls. The second group received daily i.p. injections of etoposide, 5 mg/kg for 2 consecutive days. The third group received RT, 5 Gy daily for 2 consecutive days. The fourth group received a combination of etoposide, followed by RT 1 h later. The doses of etoposide and RT were the same as used in the previous two groups. The mice were anesthetized with pentobarbital (50 mg/kg i.p.) before RT. The gluteal region, including both femurs and tumor, was irradiated with a total of 10 Gy in two daily fractions (6 MV photon beam at source-to-axis

distance of 100 cm, dose rate 2.4 Gy/min) by an accelerator (Clinac® 1800, Varian Associates Inc., CA, USA, dose rate 2.4 Gy/min). Two tissue-equivalent polystyrene plates (1.3 cm thick upward and 5.0 cm thick downward) were used to provide adequate build-up. Dosimetry was measured using a N30001 ionization chamber (PTW-FREIBURG, Germany) prior to radiation.

Evaluation of tumor volume, liver and renal function, leukocyte count, and skin changes

The total body weight of each mouse and size of implanted tumors were determined every other day by a single observer. Calipers were used to measure the largest (*a*) and smallest (*b*) diameter, and the tumor volume was estimated according to the formula $0.5ab^2$ ^[19]. The leukocyte count was estimated by retro-orbital blood sampling every other day after treatment. Animals were killed when the first mouse expired after treatment. The plasma levels of alanine aminotransferase (ALT) and creatinine were measured with a SYNCHRON LX20 spectrophotometer (Beckman Coulter, San Diego, CA, USA) by heart blood sampling after being killed. Skin changes and hair loss in the mice were evaluated by a single observer after RT every other day.

Statistical analysis

Data were expressed as mean±SE or percentage. Analysis of variance was used to compare tumor size, body weight, ALT, and creatinine, and leukocyte count among the groups and controls. We used Sigma Stat software (version 2.03, SPSS Inc., Chicago, IL, USA) to perform the statistical analysis. *P*<0.05 was considered statistically significant.

RESULTS

Tumor growth

As shown in Figure 1, low-dose etoposide alone had no significant effect on tumor growth compared to the control group. However, RT alone and the combination therapy resulted in significant decrease in tumor size compared to controls (*P*<0.05). Combination therapy yielded the best results among the four groups. The tumor size at the end of the study in the combination therapy group was only 54% that of the RT group (1.27 cm³ *vs* 2.35 cm³).

Figure 1 Tumor size in BALB/c mice implanted with CT26 colorectal adenocarcinoma cells. (●) control group, saline only; (○) etoposide group, 5 mg/kg×2; (▼) RT group, 5 Gy×2; (▽) combination therapy group (etoposide plus RT).

Figure 2 Changes in body weight of BALB/c mice implanted with CT26 colorectal adenocarcinoma cells. (●) control group, saline only; (○) etoposide group, 5 mg/kg×2; (▼) RT group, 5 Gy×2; (△) combination therapy group (etoposide plus RT).

Changes in body weight, liver, renal function, and skin

There were no significant changes in body weight in any of the four groups (Figure 2). Similarly, there were no significant differences in the plasma ALT and creatinine levels among the four groups (Figure 3). There was no obvious skin change or hair loss in any of the mice after RT or combination therapy except for tumor-related destruction.

Changes in leukocyte count

The leukocyte count decreased significantly but transiently after treatment with RT or combination therapy ($P < 0.05$). As shown in Figure 4, the nadir of the leukocyte count occurred 8 d after treatment. In contrast, the leukocyte counts in the control and etoposide groups had no evident change.

Figure 4 Serial changes in leukocyte counts of BALB/c mice implanted with CT26 colorectal adenocarcinoma cells. (●) control group, saline only; (○) etoposide group, 5 mg/kg×2; (▼) RT group, 5 Gy×2; (△) combination therapy group (etoposide plus RT).

DISCUSSION

Our findings indicate that etoposide is a potent radiosensitizer in murine CT-26 colorectal adenocarcinoma cells without evident toxicity *in vivo*. This supports the contention that the role of etoposide in CRC treatment is as a radiosensitizer rather than as a cytotoxic agent.

Body weight and plasma ALT and creatinine were unaffected by any of the treatment modalities. The fact that transient leukopenia was found in both the RT and combination therapy groups but not in the etoposide group

Figure 3 Plasma ALT and creatinine levels after killing of BALB/c mice implanted with CT26 colorectal adenocarcinoma cells. From left to right are: control group, etoposide group, RT group, and combination therapy group.

suggests that the bone marrow suppression may be caused by the radiation alone. The RT regimen used in this study may therefore needs to be adjusted to avoid myelosuppression. O'Dwyer *et al.*^[16] reported, that etoposide-related leukopenia is dose-dependent. The low dose we used was apparently successful in avoiding bone marrow suppression. Low-dose etoposide therefore may have little toxicity *per se*, but in our study, even this low dose appeared to have significant radiosensitizing activity.

One advantage of etoposide is that it comes in an oral form. Long term oral administration of etoposide improves the prognosis of ovarian cancer in patients who tolerate it well^[8,17]. This suggests that oral etoposide might be a good candidate for a daily radiosensitizer. One study has shown that there is no significant difference between intravenous and oral administration of etoposide in terms of median response duration, time to progression, and survival when used to treat small cell lung cancer^[18]. Shigematsu *et al.*^[13] also reported that the killing effect of low dose etoposide *in vitro*, seems to depend on the duration of exposure rather than the concentration. This duration-dependent rather than concentration-dependent also supports the use of lower dose etoposide as a radiosensitizer, as we found in our study.

Newer chemotherapeutic and biological agents, such as irinotecan (CPT-11)^[19], oxaliplatin^[20], and cyclooxygenase-2 inhibitors (e.g. celecoxib)^[21] have been studied for their radiosensitizing potential in rectal cancer. These agents are particularly attractive because they have a favorable safety profile^[22]. According to our results, low dose etoposide also appears to be safe and effective in the mouse model. It would therefore be worth conducting a clinical trial of etoposide-based CCRT for 5-FU resistant rectal cancer.

Although CCRT for CRC has promising clinical results, the mechanism of conventional radiosensitizers such as 5-FU remains unclear^[23]. This is true for etoposide as well. Shigematsu *et al.*^[13] have reported a significant increase in cells in the G₂/M phase after exposure to low-dose etoposide *in vitro*. This phenomenon is similar to our preliminary results (data not shown). Since cells in the G₂/M phase are radiosensitive, etoposide may act to arrest CT26 cells in that phase, thus sensitizing them to RT. Another possibility is that the drug upregulates p53 and Bcl-2 expression, as has been reported in CT26 cells *in vivo*^[24], an effect that

may induce apoptosis. Apoptosis may play an important role in the mechanism of radiosensitization. In the future, we are planning to assess apoptosis in tumors by annexin V/propidium iodide or the TUNEL test.

In conclusion, the results of this study indicate that low-dose etoposide can sensitize CT26 cells to RT *in vivo* without evident toxicity. Further studies to identify the mechanism of etoposide-related radiosensitization are needed.

ACKNOWLEDGMENT

The authors wish to thank Dr. Mary Jeanne Buttrey for critical reading and correction of the manuscript.

INTRODUCTION

Bacterial superantigen *Staphylococcal enterotoxin A* (SEA) is an efficient activator of cytotoxic T cells when presented on MHCII antigens and shows a potential ability in cancer immunotherapy^[1-3]. But SEA also has cytotoxicity against the normal cells when used to kill carcinoma cells and has no effect on MHCII⁻ carcinoma cells. The monoclonal antibody (mAb) preparation technique has brought about a new method for cancer therapy known as tumor-targeting therapy. Which therapy can solve the two problems mentioned above? The mAb B3 is a murine antibody directed against a carbohydrate antigen in the Le^x family, that is found on the surface of many mucinous carcinomas of the colon, stomach, ovaries, breast, and lung as well as some epidermal carcinomas. Because mAbB3 reacts with a limited number of normal tissues, it is an ideal candidate for the treatment and diagnosis of cancer^[4]. Immunotoxins made from mAb B3 are cytotoxic to various human cancer cell lines that express B3 antigen on their surface, and some of them have been evaluated in clinical or preclinical trials^[5].

Antibodies penetrate tumors slowly and take several days to mix completely within a tumor because of their large size^[6]. Fv fragments of antibodies are heterodimers of the heavy chain variable domain (VH) and the light chain variable domain (VL), and the smallest functional modules of antibodies required for high affinity antigen binding. The polypeptide chains of whole IgG or Fab fragments are joined by a disulfide bond, but Fv fragments have no such inter-chain disulfide bridge and are therefore unstable^[7]. Stable Fv fragments can be produced by making recombinant molecules in which the VH and VL domains are connected by a peptide linker (ScFv) or a disulfide bond (DsFv), so that the antigen binding site is regenerated in a single protein. However, many single-chain Fvs are unstable. When they are fused to toxins, the resulting recombinant immunotoxins are also unstable, presumably owing to aggregation during the transient separation of VH from VL by the peptide linker. DsFv is more stable than ScFv, but the low yield after renaturation limits its application^[8]. A new type of engineered antibody, known as scdsFv has a linker and a disulfide bond between VH and VL, and is more stable than dsFv^[8].

Abstract

AIM: To construct the expression vector of B3 (scdsFv)-SEA (D227A) and to identify its binding and cytotoxic ability to B3 antigen positive carcinoma cell lines.

METHODS: This fusion protein was produced by a bacterial expression system in this study. It was expressed mainly in the inclusion body. The gene product was solubilized by guanidine hydrochloride, refolded by conventional dilution method, and purified using SP-sepharose cation chromatography.

RESULTS: The expression vector B3 (scdsFv)-SEA-PET was constructed, the expression product existed mainly in the inclusion body, the refolding product retained the binding ability of the single-chain antibody and had cytotoxic effect on HT-29 colon carcinoma cells. The stability assay showed that the resulting protein was stable at 37 °C.

CONCLUSION: This genetically engineered B3 (scdsFv)-SEA fusion protein has bifunction of tumor targeting and tumor cell killing and shows its promises as an effective reagent for tumor-targeted immunotherapy.

Wang JL, Zheng YL, Ma R, Wang BL, Guo AG, Jiang YQ. Disulfide-stabilized single-chain antibody-targeted superantigen: Construction of a prokaryotic expression

In this study, scdsFv of B3mAb (B3scdsFv) was fused to the SEA (D227A) by genetic engineering method and expressed in *E. coli*. The refolding protein has been proved to be stable at 37 °C. It can bind to tumor surface antigen and is cytotoxic to HT-29 colon cells, thus SEA can be used in tumor targeting therapy.

MATERIALS AND METHODS

Plasmids and cell lines

Template plasmids B3scFv-pET32a and SEA (D227A)-pET32a were constructed by our laboratory. Expression plasmid pET22b, *E. coli* TOP10, human colon carcinoma cell line HT-29, human hepatoma cell line SMMC-7721, human breast carcinoma cell line MCF-7 were all kept in our laboratory.

Reagents

LATaqDNA polymerase and restricted enzymes were purchased from Takara Biotechnology Co., Ltd (Dalian, China). T4 DNA ligase and non-radioactive cell proliferation assay kit were obtained from Promega (USA). AKTA FPLC and Hitrap-SP sepharose column were products of Amersham Biosciences (Switzerland). Primer synthesizing and DNA sequencing were completed by Bioasia Co., Ltd (Shanghai, China).

Construction of plasmid B3scdsFv-pET22b

Mutated disulfide bond sites in B3VH (Cys⁴⁴) and B3VL (Cys¹⁰⁵) were designed as previously described^[9,10]. A mutation in the linker between VH and VL was found in the template plasmid B3scdsFv-pET32a after DNA sequencing. Since the 6th base in GGGGSGGGGSGGGGS (linker) was mutated from G to S, we corrected the mutation by overlap PCR and ligated B3VH and B3VL at the same time. Four primers were designed according to the gene sequence in GenBank and the linker sequence (Table 1). Part of the linker sequence was involved in P₂ and P₃. Primers 1 and 2 were used for amplification of B3VH and primers 3 and 4 for B3VL. The purified B3VH and B3VL products were mixed at the ratio of 1:1 and then applied as the template for the amplification of B3scdsFv with primers 1 and 4. Then the purified B3scdsFv fragment was cloned into the DNA sequencing vector pMD-18T. The full length B3scdsFv was excised from pMD-18T-vector containing correct insert with *Nde*I and *Bam*HI and subcloned into a similarly digested pET22b vector to produce the recombinant plasmid B3scdsFv-pET22b.

Construction of expression plasmid B3scdsFv-SEA-pET22b

The SEA gene was amplified by PCR using primer pair P₅ and P₆ and template SEA (D227A)-pET32a. The PCR products were purified and directly cloned into pMD-18T-vector and further cloned into pET22b (Figure 1).

Figure 1 Schematic representation of B3scdsFv-SEA-pET22b expression plasmid. L: polypeptide linker; L1: (GlyGlyGlyGlySer)₃; L2: (GlyGlyGlySer-GlyGlySer).

Expression of B3scdsFv-SEA

The bacterial strain BL21 (DE₃) pLysS was used to express the fusion protein. Briefly, one positive clone was grown in LB medium containing 100 µg/mL ampicillin and induction was started by addition of IPTG (final concentration, 1 mmol/L) when the culture reached $A_{600} = 0.5$. After the culture was induced for 3 h at 37 °C, the cells were harvested. The bacterial pellet was resuspended in 50 mmol/L Tris-HCl, 5 mmol/L EDTA, pH 8.5, 0.8% NaCl, and sonicated, then centrifuged at 12 000 g for 15 min at 4 °C to separate the supernatant and the inclusion body, and analyzed on 15% SDS-PAGE.

Western blotting analysis

Western blotting was performed to confirm B3scdsFv-SEA identity. Protein samples were dissolved by 15% SDS-PAGE under reducing conditions and using duplicate gels. One gel was Coomassie stained while the other was used for semi-dry electrophoretic transfer (Jim-X Biotechnology Co., Ltd, Dalian, China) of the proteins onto nitrocellulose membrane. The membrane was then blocked with 0.05 mol/L Tris-HCl, pH 7.4, 0.5 mol/L NaCl, 3% BSA and incubated with the rabbit polyclonal antibody against SEA for 1 h and followed by the incubation of HRP-coupled goat anti-rabbit IgG as secondary antibody. Finally, the recombinant B3scdsFv-SEA was visualized with Fast DAB peroxidase substrate. In this part, the B3scdsFv-SEA-pET22b before induction (total protein) was used as a negative control.

Refolding and purification of B3scdsFv-SEA

The inclusion body was washed twice in 0.05 mol/L Tris-HCl, pH 8.0, 20 mmol/L EDTA, 2% Triton X-100, 0.5 mol/L NaCl, then dissolved in 6 mol/L guanidine hydrochloride, 2 mmol/L EDTA, 0.05 mol/L Tris-HCl, pH 8.5, 10 mmol/L DTT and incubated for 3 h at room temperature. The denatured products were centrifuged for 10 min at 12 000 g at 4 °C. The supernatant was slowly

diluted into the refolding solution containing 0.1 mol/L Tris-HCl, pH 8.0, 0.5 mol/L L-Arg, 2 mmol/L EDTA, 0.9 mmol/L oxidized glutathione at the ratio 1:30, refolded for 48 h at 10 °C.

The refolding solution was concentrated by hollow fiber cartridges, and buffer exchange was carried out at the same time. The denatured protein in 5 mmol/L phosphate buffer, pH 5.8 (buffer A) was loaded into a 5 mL sp-sepharose column pre-equilibrated by buffer A. The protein was eluted with a linear gradient from 0 to 0.5 mol/L NaCl in 0.04 mol/L phosphate buffer, pH 7.4 (buffer B). The eluted protein was analyzed on 15% SDS-PAGE.

Binding assay

Analysis for the binding of B3scdsFv-SEA to B3 positive tumor cells (including human colon carcinoma cell line HT-29, human hepatoma cell line SMMC-7721, human breast carcinoma cell line MCF-7) was performed as described previously^[11]. Briefly, the prepared tumor cells were seeded in a 96-well plate containing 5×10^3 cells per well. Cells were cultured for 48 h at 37 °C and the plate was washed thrice with PBS. After fixation with pre-cooled fixing solution (methanol/acetone solution, v/v = 1:1) for 30 min, the reaction was ended by addition of PBS containing 1% H₂O₂. Blocking was performed with 1% bovine serum albumin in PBS with 0.05% Tween-20. After blocking, the purified B3scdsFv-SEA was added to each well. PBS served as the negative control. The plate was incubated at 37 °C for 1 h. After being washed with PBST, the rabbit polyclonal antibody against SEA (1:1 000 diluted by PBST) was added and incubated at 37 °C for 1 h followed by incubation with HRP-coupled goat anti-rabbit IgG for 30 min. At last, the substrate TMB was applied for 3 min and the absorbance at 450 nm was measured when the reaction was stopped by the addition of 2 mol/L H₂SO₄.

Tumor cell growth inhibition assay

Growth inhibition assay was performed in 96-well plates as described previously^[11]. Briefly, 5×10^3 HT-29 cells were added to each well, followed by B3scdsFv-SEA dilutions and 4×10^4 effector cells (human peripheral blood T lymphocytes) in a total volume of 200 μ L. Cells were cultured for 5 d at 37 °C in a humidified atmosphere containing 50 mL/L CO₂. After the culture, the number of remaining tumor cells was determined using a non-radioactive cell proliferation assay kit (Promega, USA) and the A_{490} was measured using a SPECTRA max Plus spectrophotometer (Molecular Device Corp., USA). Data were expressed as percentage of tumor growth inhibition, which was calculated as $(1 - A_{\text{test}}/A_{\text{C}}) \times 100\%$, where A_{test} indicates the absorbance of tumor cells grown in the presence of effector cells and B3scdsFv-SEA dilutions, A_{C} indicates the absorbance of tumor cells grown in medium with the effector cells.

Stability assay

The stability of recombinant toxin was determined by incubating for different periods at 37 °C in PBS, and the remaining activity was determined by testing the binding to the HT-29 cell line.

RESULTS

Expression of B3scdsFv-SEA in *E. coli*

The expression products in bacterial strain BL21 (DE3) pLysS was mainly found in the inclusion body as shown in Figure 2A. The relative mass of targeted protein was approximately 50 ku, and its expression level was approximately 30% of the total cellular protein as determined by TotalLab 2.01 software analysis. Western blotting was performed to test the identity of B3scdsFv-SEA. The rabbit polyclonal antibody could recognize the B3scdsFv-SEA protein at around 50 ku, but the same reaction was not observed at lane 2 (the negative control) (Figure 2B).

Figure 2 The SDS-PAGE analysis of expression products (A) and Western blot of inclusion body (B). A: Lane 1: B3scdsFv-SEA- pET22b before induction; lane 2: total protein after induction; lane 3: ultrasonic supernatant of B3scdsFv-SEA-pET22b induced by 1 mmol/L IPTG; lane 4: ultrasonic deposit after induction; lane M: low molecular weight protein marker; B: Lane 1: Western blot of B3scdsFv-SEA; lane 2: negative control (total protein before induction); lane M: low molecular weight protein marker.

Refolding and purification of B3scdsFv-SEA

In order to generate protein with a native conformation, we solubilized and reduced the inclusion body in guanidine hydrochloride and DTT, and refolded the protein by dilution in a buffer containing arginine at 10 °C. The refolded product was purified through SP-sepharose column after concentration and buffer exchange.

The fraction of B3scdsFv-SEA molecules could be determined by SDS-PAGE. Figure 3 shows, that the gel mobility of B3scdsFv-SEA was more rapid under non-reducing condition than under reducing condition, indicating that the disulfide bond might be formed during the refolding process.

Binding assay

The binding affinity of B3scdsFv-SEA was measured on B3 antigen expressing cell lines HT-29, MCF-7, and SMMC-

7721. Figure 4 shows, that the binding affinity increased with the protein concentration, and had a better binding ability on MCF-7 cells because the expression level of B3 antigen on MCF-7 was higher than that of the other two cell lines^[12].

Figure 3 Gel mobility of B3scdsFv-SEA under reducing (lane 1) and non-reducing condition (lane 2).

Figure 4 Binding assay of B3scdsFv-SEA to B3 antigen positive carcinoma cell lines.

Stability assay

B3scdsFv-SEA was very stable at 37 °C in PBS. The binding activity of B3scdsFv-SEA at different time points was determined by ELISA. The recombinant toxin retained 85% of its activity after 16 h incubation at 37 °C (Figure 5).

Figure 5 Stability of B3scdsFv-SEA.

Cytotoxic effect on tumor cells of B3scdsFv-SEA

The toxicity of B3scdsFv-SEA to human colon carcinoma

cell line HT-29 was determined by the MTT assay. The results of a representative experiment are shown in Figure 6. The maximum killing effect could achieve 95% when the protein concentration was 1 μg/mL. But the cytotoxic potency was a bit lower than native SEA. No killing effect on tumor cells was observed when the effector cells were added alone (data not shown).

Figure 6 Cytotoxic effects of B3scdsFv-SEA on HT-29 cell line.

DISCUSSION

The Fv fragment of an antibody can penetrate tumors more quickly than the intact antibody because of its small size^[13]. Because of this advantage, different types of Fv fragments such as ScFv and dsFv have been extensively applied in tumor targeting therapy. But the instability of the ScFv and the low yield of dsFv become the obstacles in their clinical application. It was reported that the ScdsFv which has a peptide linker and a disulfide bond between VH and VL is stable at least after 1 wk exposure to human plasma at 37 °C, even under denaturing urea (6 mol/L) conditions, and it has a higher yield after renaturation than dsFv^[8].

In this study, the ScdsFv of B3 mAb was fused to SEA (D227A). The fusion protein was expressed as inclusion body in *E. coli*. Small-scale preparations were performed in order to determine the optimal denaturing conditions, and we found that the maximum protein activity could be achieved in the presence of 0.5 mol/L L-Arg and 0.9 mmol/L GSSG in the refolding solution and the optimal denaturing temperature was 10 °C. The refolded products were purified to get rid of the renaturation agents, the purified B3scdsFv-SEA (D227A) had excellent binding affinity when incubated with B3 antigen positive tumor cell lines. The cytotoxic results indicate that the B3scdsFv-targeted superantigen suppresses the tumor cell growth successfully by activating the T lymphocytes. Moreover, the resulting protein is stable when incubated at 37 °C. All the SEA show that the binding and cytotoxic ability is not affected by the presence of both a linker and a disulfide bond between B3VH and B3VL.

In conclusion, B3scdsFv-targeted superantigen can be constructed in a bacterial system and this fusion protein shows its promise as a good reagent for cancer immunotherapy.

Abstract

AIM: To investigate the microsatellite instability (MSI) in cancer and pre-cancerous lesions of the stomach and its mechanisms underlying the development of gastric cancer.

METHODS: Thirty-six gastric cancer samples were obtained from patients undergoing surgery. Forty-one gastric mucosa samples with dysplasia and 51 with intestinal metaplasia (IM) were obtained from patients with chronic gastritis undergoing gastro-endoscopy. Genomic DNA was extracted from the samples. Silver staining single strand conformation polymorphis-polymerize chain reaction (SSCP-PCR) was used to screen MSI markers at 5 loci (Bat-25, Bat-26, D5S346, D17S250, and D2S123) in fresh tissues and formalin-fixed, paraffin-embedded samples and their corresponding normal gastric mucosa.

RESULTS: The abnormal shifting of the single-strand DNA (MSI) was identified in 21 out of 36 (58.3%) gastric cancers. Seven cases showed high-level MSI (two or more loci altered) and 14 showed low-level MSI (one locus altered). Gastric cancer with MSI had a tendency to be located in the distal stomach. MSI was also detected in 11 out of 41 (26.8%) dysplasia samples and in 9 of 51 (17.6%) IM samples respectively. Three cases of dysplasia and one case of IM showed high-level MSI. Eight cases of dysplasia and 8 cases of IM displayed low-level MSI. MIS in IM was found only in moderate or severe-grade IM. No association was detected between MSI and dysplasia grade.

CONCLUSION: Accumulation of MSI in dysplasia and intestinal metaplasia of gastric mucosa may be an early molecular event during gastric carcinogenesis and may contribute to the acquisition of transformed cell phenotype and the development of gastric cancer.

INTRODUCTION

There is evidence that gastric carcinogenesis is a long-term, multistep process associated with abnormal alterations in cellular oncogenes, tumor suppressor genes and other genes or factors necessary for cell malignant transformation^[1-4]. Genetic instability is strongly involved in neoplastic transformation and progression^[5-9]. Microsatellite instability (MSI), an important form of genetic instability associated with defective DNA mismatch repair in tumors, was first described in hereditary non-polyposis colorectal cancer (HNPCC) in 1993^[6]. Since then, the presence of MSI has been reported in a variety of sporadic cancers including gastric cancer^[5,10-14], suggesting that MSI may play an important role in the development of gastric cancer^[15]. Intestinal metaplasia and dysplasia predisposed in gastric mucosa have been regarded as pre-cancerous lesions of the stomach and are closely related to the gastric carcinogenesis^[16-19]. However, there are few reports concerning the changeable patterns of MSI in the two pre-cancerous lesions. In this study, we investigated MSI alterations by use of SSCP-PCR technique in gastric mucosa with intestinal metaplasia and dysplasia, and gastric cancer samples to explore the potential role of MSI in gastric carcinogenesis.

MATERIALS AND METHODS

Stomach specimens

Thirty-six gastric cancer samples were obtained from patients undergoing surgery. Forty-one gastric mucosa samples with dysplasia and 51 with intestinal metaplasia were obtained from patients with chronic gastritis undergoing gastro-endoscopy in Jiangsu Provincial Hospital, Nanjing, China. The tumors were graded as well, moderately and poorly differentiated. Lesions of intestinal metaplasia and dysplasia were graded as mild, moderate and severe according to the WHO criteria. Tissues from non-tumor or non-inflammatory gastric mucosa were used as a control in analysis of MSI.

Tissue DNA extraction

Serial 5- μ m-thick sections were obtained from formalin-fixed and paraffin-embedded tissue blocks. After tissue deparaffinization, genomic DNA was isolated by standard proteinase-K digestion and phenol-chloroform extraction protocol as previously described^[20].

PCR-SSCP analysis

All samples were analyzed using five markers (Bat-25, Bat-26, D5S346, D17S250, and D2S123) recommended by America National Cancer Institute (NCI) workshop on MSI^[21]. Oligonucleotides of five pair primers were synthesized by Sangon Technologies, Shanghai, China. The primer sequences are listed in Table 1.

Polymerase chain reaction (PCR) was performed as described by Fleisher *et al.*^[11] with some modifications. In brief, 25 μ L reaction mixture containing 200 ng of DNA, 2.5 μ L 10 \times PCR buffer, 1 μ mol/L primer, 1.5–2.0 mmol/L MgCl₂, 200 μ mol/L dNTPs, and 0.5 Utaq DNA polymerase (Takara, Japan), was amplified for one cycle at 95 $^{\circ}$ C for 5 min followed by 35 cycles at 94 $^{\circ}$ C for 30 s, at

55–58 $^{\circ}$ C for 30 s, at 72 $^{\circ}$ C for 15 s, and 72 $^{\circ}$ C for 1 min.

Single strand conformation polymorphism (SSCP) was carried out. In brief, 12 μ L of each PCR product was mixed with 12 μ L denaturing buffer, denatured at 97 $^{\circ}$ C for 7 min, loaded onto a non-denaturing 7% polyacrylamide gel and electrophoresed for 3 h at 20 $^{\circ}$ C. The bands were visualized by silver staining.

Existence of MSI was defined as an band mobility shift from either alleles or as appearance of a new band with a different size in the testing sample compared to the control one. The analysis was performed once more in samples displaying MSI for confirmation of the results. High-level MSI (MSI-H) was recognized, when more than 30% of the markers showed instability and low-level MSI (MSI-L) was recognized, if less than 30% of the markers displayed instability. None of the markers showing MSI indicated microsatellite stability (MSS)^[21].

Statistical analysis

Statistical analysis was performed using the *t* test or Fisher's exact test. *P* < 0.05 was considered statistically significant.

RESULTS

MSI in gastric cancer

None of the 36 gastric cancer patients had a family history of gastric cancer. MSI was observed in 21 out of 36 (58.3%) gastric cancers. Among the 21 MSI⁺ cases, 7 showed MSI-H and 14 showed MSI-L. Figure 1 displays a representative MSI band compared to control counterpart. No association was observed between MSI status and age, gender, tumor grade, tumor location or lymph node spread. Gastric cancer with MSI had a tendency to be located in the distal stomach compared to gastric cancer with MSS (Table 2).

Table 2 Characteristics of 36 gastric cancer patients

Characteristic	MSS (n = 15)	MSI-L (n = 14)	MSI-H (n = 7)
Average age	58	62	58
Sex			
Male	10	11	4
Female	5	3	3
Differentiation grade			
well-moderate	7	9	6
poor	8	5	1
Tumor location			
Distal	8	8	5
Proximal	7	6	2
Lymph node spread			
Absent	9	7	4
Present	6	8	3

MSI in dysplasia

MSI was detected in 11 out of 41 (26.8%) dysplasia samples. Among the 11 MSI⁺ samples, three showed MSI-H and 8 displayed MSI-L. The frequency of MSI in moderate to severe dysplasia was higher (33.3%) than that in mild dysplasia (20%), but the difference was not significant. Notably, four out of five severe dysplasia samples presented MSI, suggesting MSI tended to develop frequently in mucosa with severe dysplasia (Table 3).

Table 3 Characteristics of 41 patients with dysplasia

Characteristic	MSS (n = 30)	MSI-L (n = 8)	MSI-H (n = 3)
Histological grade			
Mild	16	3	1
Moderate	13	2	1
Poor	1	3	1

MSI in intestinal metaplasia

MSI was detected in 9 of 51 (17.6%) intestinal metaplasia samples. Among the nine samples, one showed MSI-H and the other eight showed MSI-L. Notably, MSI was found only in moderate or severe-grade IM (9/14) other than in mild-grade IM (0/28, $Z = 3.630$, $P = 0.001$). Moreover, IM samples from female patients had a higher frequency of MSI compared to IM tissues from males (29.2% *vs* 7.4%), but the P value was more than 0.05 (Table 4).

DISCUSSION

The mechanisms of carcinogenesis in gastric mucosa remain

Table 4 Characteristics of 51 patients with intestinal metaplasia

Characteristic	MSS (n = 42)	MSI-L (n = 8)	MSI-H (n = 1)
Sex			
Male	25	2	0
Female	17	6	1
Histological grade			
Mild	28	0	0
Moderate	13	7	0
Poor	1	0	1

unclear, and may involve multiple genetic and epigenetic changes in susceptible cells of the stomach. Genetic instability including chromosomal instability and microsatellite instability is an important factor for the accumulation of these genetic changes.

Microsatellites are ubiquitous, short, repetitive DNA sequences widely and randomly distributed throughout the human genome, with unknown function. MSI is a form of genetic instability characterized by expansions and contractions of simple sequence repeats in DNA. It represents an important form of genomic instability associated with defective DNA mismatch repair in tumors. MSI can be identified in tumors when alleles of novel sizes are detected in microsatellite sequences derived from cancer DNA that are not present in normal tissues of the same individual. MSI has been observed in a subset of gastric carcinoma ranging from 13% to 44%, even more than 70% in some individual reports^[10-14]. The discrepancy in different researches is probably due to different types and numbers of microsatellite markers used in different studies.

In the present study, we have screened three groups of patients with the reference set of five markers (two mono- and three di-nucleotide repeats) recommended by America National Cancer Institute (NCI) and the criteria for identification of MSI. In our study, the incidence of MSI in gastric cancer was 58.3%. Leung *et al.*^[12], reported, that MSI in gastric cancer is 76.7%, while Halling *et al.*^[14], reported, that MSI in gastric cancer is 19% with 32 makers, and Wang *et al.*^[13], reported, that MSI is 33.9% with 42 markers in Chinese. We therefore postulate that different MSI rates in gastric cancer may be associated with the markers used in study, the criteria chosen for definition of MSI, the number of samples, race and different geographic regions.

The association between MSI and clinicopathologic characteristics of gastric cancer remains unknown. Wu *et al.*^[22], reported, that MSI-H gastric tumors are statistically associated with location of the tumor (distal area of the stomach), fewer lymph node metastases and better prognosis. Wirtz *et al.*^[23], reported, that no association is observed between MSI and gender, tumor invasion, pathological grade, lymph node metastases, Lauren's classification and prognosis, which is similar to our results.

IM and dysplasia are considered as early phenotypic changes in cascade of events leading to gastric cancer. Development of some gastric cancer may be the result of an accumulation of abnormal gene change in these pre-cancerous lesions^[12, 16-19]. In our study, the MSI incidence of IM was 17.6%, lower than that previously reported (30-44.5%)^[15,19]. The discrepancy might be due to the IM samples

collected from the patients with chronic gastritis, other than gastric cancer and the histological grade of IM. Different markers used in different studies may be another explanation for the discrepancy. MSI is connected with moderate-grade, which is of importance in grading of IM. We detected MSI in 26.8% samples with dysplasia in the present study. Lee *et al.*^[24], reported, that there is no significant association between MSI and histological grade of dysplasia.

Investigating the occurrence of MSI in gastric cancer and pre-cancerous lesions may help us to explore the mechanisms of gastric carcinogenesis. Being detected in gastric cancer, IM and dysplastic mucosa, MSI might play a role in the multistep process of carcinogenesis of the stomach. It was reported that a well-differentiated adenocarcinoma develops 3 years later at the IM mucosa displaying MSI^[25]. In conclusion, early involvement and continuous accumulation of MSI in susceptible cells of the stomach may trigger the multi-step carcinogenesis pathway. Detection of MSI in pre-cancerous lesions may help us to investigate the stomach carcinogenesis and to identify patients at risk of developing gastric malignancies.

Abstract

AIM: To investigate the expression of cyclooxygenase-2 (COX-2) in gastric cancer and its relation with the liver metastasis and prognosis.

METHODS: Expression of COX-2 mRNA and protein was examined in gastric cancer and its paired substantial normal tissue by semi-quantitative reverse transcription-polymerase chain reaction and immunohistochemistry. The relation between COX-2 expression and prognosis was investigated in 195 cases.

RESULTS: The expression of COX-2 mRNA in gastric cancer tissue was significantly higher than that in normal tissue in 47 cases ($w = 792$, $P < 0.01$). The COX-2 mRNA in pT3-4 tissue expressed higher than that in pT1-2 tissue ($w = 204$, $P < 0.05$). The positive expression rate of COX-2 protein was 57.9% (113/195). The COX-2 expression was significantly related to histological type, lymphnode metastasis, venous invasion and liver metastasis ($P < 0.05$). No relation was found between COX-2 expression and invasion depth, peritoneal metastasis and International Union against Cancer TNM stage. The multiple regression analysis showed that the COX-2 expression and venous invasion were obviously associated with liver metastasis ($P < 0.05$). However, there was no significant correlation between COX-2 immunoreactivity and prognosis.

CONCLUSION: COX-2 may play an important role in the development of gastric cancer, and the over-expression of COX-2 protein may be a high risk factor for liver metastasis.

Key words: Gastric cancer; Cyclooxygenase-2; Neoplasm metastasis; Long-term prognosis

INTRODUCTION

Gastric cancer is one of the most common malignancies worldwide, and yet little is known about its molecular process of development and progression. Epidemiological studies showed that non-steroidal anti-inflammatory drugs (NSAID) can reduce the incidence of cancer of digestive tract^[1-4]. Although the mechanism of NSAID remains unclear, it may inhibit COX^[5]. COX, a key enzyme in conversion of arachidonic acid to prostaglandin, has two isoforms, namely COX-1 and cyclooxygenase-2 (COX-2). COX-1 is constitutively expressed in various tissues and involved in various physiological processes, whereas COX-2 is induced by pathological stimuli, such as inflammation, growth factors and cytokines produced by tumor cells^[6,7]. Abnormal expression of COX-2 has been supposed to be related to the pathogenesis of human cancers^[6,8,9].

We attempted to determine the expression of COX-2 in gastric cancer, and the relation between COX-2 and the pathological features of gastric cancer. In addition, the role of COX-2 in liver metastasis of gastric cancer and its prognostic value were explored.

MATERIALS AND METHODS

Patients and tissue samples for RT-PCR

Tissue specimens were taken from 47 gastric cancer patients who underwent resection (15 women and 32 men, aged 29-82 years). Paired samples of cancer tissue and normal gastric mucosa were obtained from each patient during surgery. Resected specimens were snap frozen in liquid nitrogen and stored at -80 °C. All patients were treated at Department of General Surgery, First Affiliated Hospital, Medical College of Zhejiang University, in 2001-2002. According to the criteria of International Union against Cancer (UICC), the depth of invasion was divided into pT1, pT2, pT3, and pT4.

Patients and tissue samples for immunohistochemistry

One hundred and ninety-five patients undergoing resection

for primary gastric cancer were examined at Department of Gastrointestinal Surgery, First Affiliated Hospital, Medical School, Zhejiang University in 1993-1997 (57 women and 138 men, aged 27-85 years). Resected specimens were fixed in 40 g/L formaldehyde and embedded in paraffin. The cancers were reviewed according to the rules of clinical and pathological studies on gastric cancer for histological type, depth of invasion, lymphatic invasion, and venous invasion. Liver metastasis was found in 25 cases (12.8%). Peritoneal metastasis was found in 35 cases (17.9%).

Reverse transcription-PCR analysis for COX-2

Total RNA was isolated using TRIzol reagent (Life Technologies, Inc., Gaithersburg, MD, USA) according to standard acid-guanidium-phenol-chloroform method. About 2 µg of RNA from each sample was reverse transcribed at 42 °C for 60 min in a 20 µL reaction volume using RevertAid™ M-MuLV reverse transcriptase (MBI Fermentas). cDNA was incubated at 95 °C for 5 min to inactivate the reverse transcriptase, and served as template DNA for 32 cycles of amplification using the GeneAmp PCR System 2400 (Perkin-Elmer Applied Biosystems, CA, USA). PCR was performed in a standard 25 µL reaction mixture containing 1.5 µL of 25 mmol/L magnesium chloride, 1 µL 10 mmol/L dNTP, 25 µmol/L of each sense and antisense primer and 1.5 U of Taq DNA polymerase (Promega). Amplification was performed (at 94 °C for 1 min, at 57 °C for 1 min and at 72 °C for 1.5 min) after heat-start for 5 min. Finally, an additional extension step was carried out for 10 min. As a negative control, the DNA template was omitted in the reaction. The primer sequences and PCR product sizes were as follows. COX-2: forward primer, 5'-TGA AAC CCA CTC CAA ACA CAG-3'; reverse primer, 5'-TCA TCA GGC ACA GGG AGG AAG-3', 232 bp; β -actin: forward primer, 5'-TCG TGA TGG ACT CCG GTG AC-3'; reverse primer, 5'-TCG TGG ATG CCA CAG GAC TC-3', 370 bp. The amplified products were evaluated in 2% agarose gel and visualized by ethidium bromide staining under UV light. The stained bands were analyzed with a digital gel documentation system and associated densitometry software (EDAS 290 and 1D software; Kodak Digital Science, Rochester, NY, USA). To estimate COX-2 expression levels, the expression ratio was designated as a band density ratio of COX-2 to β -actin.

Immunohistochemistry

The EnVision™ method was used for immunohistochemical staining. Five micrometer-thick sections were deparaffinized with xylene and progressively dehydrated in decreasing concentrations of alcohol. Endogenous peroxidase activity was blocked by hydrogen peroxidase (3%) in Tris-buffered saline (TBS) for 30 min. Sections were boiled (pressure-cooking) in citrate buffer, pH 6.0, for 3 min for antigen retrieval. Non-specific binding was blocked with 5% goat serum in TBS for 15 min, and the tissues were incubated with monoclonal antibody to COX-2 (1:200; Cayman Chemical, Ann Arbor, MI, USA; catalog no. 160112) in TBS containing 2% rabbit serum and 1% bovine serum albumin for 1 h. The sections were washed with TBS, and incubated with EnVision (goat anti-mouse/HRP) for 60 min.

The color was developed in diaminobenzidine solution (Sigma Chemical Co., St. Louis, MO, USA) and counterstained with Mayer's hematoxylin. Tissues were incubated with TBS containing 2% rabbit serum and 1% bovine serum albumin without the primary antibody as control. Furthermore, each run included a positive control side, which was shown previously to be strongly positive for COX-2. The scientists who performed the immunohistochemical analysis were blinded to pathological features. Tissues stained more than 10% were classified as COX-2 protein-positive^[11].

Statistical analysis

Statistical analysis was performed by use of Wilcoxon signed-ranks, χ^2 test and Kaplan-Meier test. The risk factors for liver metastasis were evaluated by a multivariate logistic regression analysis, variables with a *P*-value less than 0.1 in univariate analysis were included. *P*<0.05 was considered statistically significant.

RESULTS

RT-PCR analysis

The expression of COX-2 mRNA in gastric cancer was apparently elevated in comparison to the normal gastric mucosa (1.08 ± 0.65 vs 0.33 ± 0.21 , *P*<0.01). In addition, the COX-2 mRNA in pT3, pT4 tissues was significantly higher than that in pT1, pT2 (0.75 ± 0.43 vs 1.14 ± 0.67 , *P*<0.05) (Figure 1).

Figure 1 Expression of COX-2 mRNA in gastric cancer. M: pUC19 DNA/*MspI* marker; lanes 1 and 2: gastric cancer tissues; lanes 3 and 4: matched normal gastric mucosal tissue.

Relation between COX-2 expression and clinicopathological features

As shown in Figure 2, the COX-2 protein was expressed intensely, mainly in cytoplasm and nuclear membrane of cancer cells. In the 195 specimens, 113 (58%) tumor tissue specimens showed positive immunoreactivity for the mAb COX-2. The COX-2 protein was expressed more frequently and intensely in differentiated adenocarcinoma than in diffuse-type carcinoma. The samples with lymph node metastasis, venous invasion and liver metastasis were significantly stained by COX-2, compared to those without lymph node metastasis. No statistical correlation was revealed between COX-2 immunoreactivity and depth of invasion, peritoneal metastasis and UICC TNM stage (Table 1).

Figure 2 Immunostaining of COX-2 in gastric cancer.

Table 1 Correlation between clinicopathologic features of gastric cancer and COX-2 expression

Variable	n	COX-2 positive cases (%)	P(χ^2)
Histologic type			
Differentiated	84	59 (70.2)	0.002 (9.15)
Diffuse	111	54 (48.6)	
Depth of invasion			
T2	84	47 (60.0)	0.483 (1.46)
T3	88	50 (56.8)	
T4	23	16 (69.6)	
UICC stage			
I	14	6 (42.8)	0.410 (2.88)
II	23	11 (47.8)	
III	61	38 (62.3)	
IV	97	58 (59.8)	
Venous invasion			
Negative	80	39 (48.8)	0.030 (4.71)
Positive	115	74 (64.3)	
Lymph node metastasis			
Negative	20	7 (35.0)	0.028 (4.82)
Positive	175	106 (60.6)	
Liver metastasis			
Negative	170	93 (54.7)	0.017 (5.72)
Positive	25	20 (80.0)	
Peritoneal metastasis			
Negative	160	95 (59.4)	0.388 (0.74)
Positive	35	18 (51.4)	

Risk factors for liver metastasis of gastric cancer

Based on the results of the univariate analysis, histological type ($P = 0.066$), depth of invasion ($P = 0.601$), venous invasion ($P = 0.011$), lymph node metastasis ($P = 0.810$), COX-2 immunoreactivity ($P = 0.008$), and venous invasion were included as covariables in the multivariate regression analysis. The result revealed that COX-2 immunoreactivity and venous invasion were the significant risk factors for liver metastasis (Table 2).

Table 2 Multivariate logistic regression analysis of independent risk factors for liver metastasis in 195 gastric cancer patients

Independent risk factor	Relative risk	95%CI	P
Venous invasion			
Negative	1		0.031
Positive	2.698	1.093-6.660	
COX-2 immunoreactivity			
Negative	1		0.023
Positive	2.857	1.159-7.041	

Expression of COX-2 and prognosis

According to the expression of COX-2, the Kaplan-Meier survival curves showed no significant correlation between COX-2 immunoreactivity and prognosis of gastric cancer (Figure 3).

Figure 3 Overall survival curves of patients with gastric cancer.

DISCUSSION

In the current study, we demonstrated that both COX-2 mRNA and protein were expressed in gastric cancer tissue. The COX-2 mRNA level was associated with the depth of tumor invasion. Ristimäki *et al.*^[8], initially reported, that COX-2 mRNA level is elevated in gastric cancer. Uefuji *et al.*^[11], found that the level of COX-2 protein is higher in gastric cancer than in paired normal gastric mucosa by Western blot analysis. Furthermore, Ohno *et al.*^[12], revealed, that COX-2 mRNA level increases gradually with the depth of gastric cancer invasion. But the exact mechanism is still unknown. The COX-2 specific antibody identified that COX-2 protein is located in cytoplasm and nuclear membrane of gastric cancer cells, but not in stroma surrounding cancerous tissues, the COX-2 protein is also observed in smooth muscle cells, fibroblasts, and inflammatory mononuclear cells^[12-14]. Additionally, epithelial cells showing intestinal metaplasia and adenoma are also strongly immunoreactive to anti-COX-2 Ab. The above data demonstrate that COX-2 is upregulated in gastric cancer, and high COX-2 expression may be an early event in the carcinogenesis of stomach.

In our study, the COX-2 protein was expressed higher in differentiated adenocarcinoma than in diffuse-type carcinoma. Yamagata *et al.*^[15], reported, that COX-2 expression increases in early intestinal-type gastric cancer, and is significantly higher than that in diffuse-type carcinoma. However, no correlation is found between the histologic type of gastric cancer and COX-2 protein in other reports^[12].

Recent studies have shown that COX-2 expression is correlated with lymph node metastasis and lymphatic invasion in gastric carcinoma. Murata *et al.*^[17], showed that COX-2 overexpression is associated significantly with tumor invasion of gastric wall lymphatic vessels and lymph node metastasis. The same results are also disclosed in other reports^[13,17]. Taken together, these results suggest that COX-2 may influence lymphatic involvement and promote tumor invasion.

Our study showed that COX-2 expression was associated with venous invasion and liver metastasis of gastric cancer. The multivariate analysis revealed that the COX-2 immunoreactivity was an independent risk factor for liver metastasis of gastric carcinoma. COX-2 can enhance the adhesive ability of endothelial cells in colonic carcinoma cells, and fortify liver metastatic potential via secretion of sialyl Lewis antigens^[18,19]. Nagatsuka *et al.*^[16], also discovered that the selective COX-2 inhibitor (JTE 522) has inhibitory effects on liver metastasis of colon cancer. On the contrary, some reports showed that COX-2 does not play a major role in the process of distant metastasis of gastric cancer^[11,12,17]. The reason why there is such a discrepancy is not clear, but the differences in methods (antibody, results evaluation) might be an important reason.

It was reported that COX-2 protein overexpression is significantly associated with the UICC TNM stage and the prognosis of gastric cancer patients^[16,17]. Ristimaki *et al.*^[20], have connected COX-2 overexpression to an unfavorable distant disease-free survival in breast cancer patients ($n = 1\,576$). However, no significant correlation was found between COX-2 immunoreactivity and peritoneal metastasis, UICC TNM stage and prognosis in our study. Joo *et al.*^[21], also have not found any significant correlation between them. A large group and long term follow-up are necessary to assess the prognostic value of COX-2 in gastric cancer.

Our results suggest that COX-2 is overexpressed in gastric cancer, and COX-2 may play an important role in liver and lymphatic metastasis of gastric cancer. Inhibiting the activity of COX-2 may provide therapeutic benefit to gastric cancer.

Abstract

AIM: To investigate the anti-inflammatory mechanism of oxymatrine in dextran sulfate sodium (DSS)-induced colitis of rats.

METHODS: Acute colitis was induced by giving 2% DSS orally in drinking water for 8 d. Twenty-six male rats were randomized into oxymatrine-treated group (group A, 10 rats), DSS control (group B, 10 rats) and normal control (group C, 6 rats). The rats in group A were injected muscularly with oxymatrine at the dosage of 63 mg/(kg·d) from d 1 to 11 and drank 2% DSS solution from d 4 to 11. The rats in group B were treated with 0.9% saline in an equal volume as group A and drank 2% DSS solution from d 4 to 11. The rats in group C were treated with 0.9% saline as group B from d 1 to 11 and drank water normally. Diarrhea and bloody stool as well as colonic histology were observed. The levels of serum tumor necrosis factor- α (TNF- α) and interleukin-6 (IL-6) were determined by ELISA, and nuclear factor- κ B (NF- κ B) activity and the expression of inter-cellular adhesion molecule-1 (ICAM-1) in colonic mucosa were detected by immunohistochemistry method.

RESULTS: Compared with DSS control group, the inflammatory symptoms and histological damages of colonic mucosa in oxymatrine-treated group were significantly improved, the serum levels of TNF- α , IL-6, and the expression of NF- κ B, ICAM-1 in colonic mucosa were significantly reduced.

CONCLUSION: The fact that oxymatrine can reduce the serum levels of TNF- α , IL-6, and the expression of NF- κ B and ICAM-1 in colonic mucosa in DSS-induced colitis of rats indicates that oxymatrine may ameliorate the colonic inflammation and thus alleviate diarrhea and bloody stool.

Key words: Oxymatrine; Colitis; Colonic mucosa

<http://www.wjgnet.com/1007-9327/11/4912.asp>

INTRODUCTION

The symptoms and colonic histopathology of rodent colitis model induced by dextran sulfate sodium salt (DSS) resemble more the human ulcerative colitis (UC) than other chemically induced colitis, which has become a research tool for the pathogenesis of UC and the development of new drugs in our country and abroad. *Sophora flavescens* Ait has distinct anti-inflammatory effect and, several mixture formulas with *Sophora flavescens* Ait are effectively used to treat UC in the clinic^[1]. Oxymatrine, as the main efficacy component of light yellow sophora root, has been reported to be effective in the treatment of viral hepatitis and bronchial asthma. Our previous experiments suggested that oxymatrine might significantly improve the colonic inflamed damage in rat colitis induced by DSS, but its exact mechanism is unclear^[2]. The present experiment aimed to elicit the anti-inflammatory mechanism of oxymatrine in terms of the regulation of nuclear factor- κ B (NF- κ B) to tumor necrosis factor- α (TNF- α), interleukin-6 (IL-6), and inter-cellular adhesion molecule-1 (ICAM-1)^[3-5]. The inflamed damage of DSS colitis in rats appears early, so many researches reported to administer studied drugs along with or ahead of DSS administration to obtain predicated efficacy^[6-10]. As diarrhea and bloody stool alleviate rapidly after the withdrawal of DSS, which may affect the observation of drug effect, the present study administered oxymatrine 3 d earlier than DSS and terminated oxymatrine and DSS at the same time according to the literature mentioned above and preliminary experiments.

MATERIALS AND METHODS

Materials

Healthy male SD rats ($n = 26$, 4-5 wk) were obtained from Shanghai Experiment Center of Chinese Academy of Science, Shanghai, China. DSS (Sigma) was prepared as 2% solution with distilled water. Injection oxymatrine (kurorinone) was obtained from Ningxia Pharmaceutical Factory, Ningxia, China, with purity of more than 98%. TNF- α and IL-6 ELISA kits were purchased from R&D Corporation (Cat. R6000 and RTA00). NF- κ Bp65 (F-6) monoclonal antibody

was from Santa Cruz Co., Ltd (Cat. Sc-8008). Mouse CD54 monoclonal antibody was from Cedarlane Laboratory Co., Ltd (Cat. 01010603). Pepsin (Cat. DIG3009) and SP immunohistological staining hypersensitive kit (Cat. 9702) were obtained from Fuzhou Maixin Biotechnological Co., Ltd, Fujian, China.

Methods

Experimental design Rats ($n = 26$) were randomized into three groups: oxymatrine treatment group (group A, $n = 10$), DSS control (group B, $n = 10$) and normal control (group C, $n = 6$). In group A, oxymatrine was injected intramuscularly at the dose of 63 mg/(kg·d) on d 1-11 and 2% DSS solution was given from d 4-11; in group B, equal volume of 0.9% saline was used to take oxymatrine and other procedures referred to group A; in group C, only an equal volume of 0.9% saline was given intramuscularly on d 1-11 and drinking water was obtainable freely. Drinking volume of DSS in group A was controlled to near group B. The symptoms of rats were assessed by disease activity index (DAI) based on stool consistency and incidence of stool hemorrhage^[11]. After blood sampling from inferior vena cava to obtain serum stored in -20°C for detection on d 12, all rats were killed and the intact colons were taken and excised longitudinally to be fixed in 40 g/L formaldehyde. On d 13, colonic segments (8 cm) up from the anus were removed, embedded in paraffin and placed on lysine slices^[2]. Sections were stained with hematoxylin and eosin for assessment of histological changes and scoring^[6].

Detection of serum TNF- α and IL-6 ABC-ELISA assay of double antibodies sandwich were adopted.

Immunohistochemical detection of ICAM-1 SP immunohistological staining hypersensitive kit was used. The sections were deparaffinized and hydrated as routine and digested with pepsin for 15 min at 37°C . A solution (50 μL) was added and kept for 15 min at room temperature followed by a B solution (50 μL) for 30 min at room temperature; 50 μL of the primary antibody (diluted in 1:75) was added and kept at 37°C for 1 h, then placed at room temperature for 15 min and kept at 4°C overnight (no primary antibody added samples were used for negative control); C solution (50 μL) was added, and kept for 1.5 h at room temperature followed by a D solution (50 μL) for another 1 h. Finally, the sections were processed with DAB, stained with hematoxylin followed by routine dehydration and slice-sealing.

Assessment criteria of the results: positive cells presented as buffy, located on cell membrane. Positive vessel was defined as one more positive vascular endothelial cells that were observed in the vessels of mucosa and submucosa. Then the positive vessels of distal colon (about 4 cm up from the anus) and the number of positive vessels of single colonic segment were counted (positive vessels/cm).

Immunohistochemical detection of NF- κB activity After digestion with pepsin, the sections were rinsed thrice with 0.1% PBS Triton X-100 for 5 min respectively, primary antibody diluted in 1:100.

Assessment criteria of the results: positive cells presented as buffy, located on nuclei and cytoplasm. The counting method of positive endothelial cells refers to procedures

above. The counting criteria of positive epithelia cells are as follows: 50 crypts were randomly observed in the distal colon (about 4 cm up from anus) and the percent of positive cells per crypt was counted, then the scores were counted according to the standards: 0 score for $\leq 5\%$; 1 score for 6-25%, presented as +; 2 scores for 26-50%, presented as ++; 3 scores for 51-75%, presented as +++; 4 scores for 76-100%, presented as ++++. Finally, the mean score of each rat was obtained.

Statistical analysis

Statistical analysis was performed according to one factor analysis of variance and Wilcoxon rank sum test. $P < 0.05$ was considered to be statistically significant.

RESULTS

Comparison of DAI and histological scores

Eight days after drinking 2% DSS, SD rats appeared to have diarrhea, bloody stool; erosion and superficial ulcer of colonic mucosa; epithelial damage; inflammatory cell infiltration and proliferation of lymph follicles in mucosa and submucosa; dilatation and proliferation of capillaries and small vessels, which resembled human UC^[11]. Each colon existed with mucosal damage that was located in distal colon. Compared with B group, both DAI and histological scores in group A decreased significantly ($P < 0.05$, Table 1).

Table 1 Scores of DAI and mucosal damage in group A and B ($n = 10$) (mean \pm SD)

Group	DAI	Scores of mucosal damage
A	6.0 \pm 1.2 ^a	5.9 \pm 1.1 ^a
B	7.3 \pm 1.1	7.1 \pm 0.7

Comparison of serum levels of TNF- α and IL-6

The serum levels of TNF- α and IL-6 in rat DSS-colitis increased distinctly than normal rats and declined obviously after treatment with oxymatrine. The serum levels of TNF- α and IL-6 in groups A-C were as follows: (9.49 \pm 1.01) and (55.50 \pm 12.13) ng/L, (13.70 \pm 1.33) and (77.80 \pm 14.03) ng/L, (8.32 \pm 1.15) and (40.57 \pm 4.79) ng/L. Compared with B group, the levels of serum TNF- α and IL-6 in group A were significantly reduced ($P < 0.01$, $P < 0.05$, Table 2).

Table 2 Serum levels of TNF- α and IL-6 in three groups (ng/L) (mean \pm SD)

Group	TNF- α	IL-6
A ($n = 10$)	9.49 \pm 1.01 ^b	55.50 \pm 12.13 ^a
B ($n = 10$)	13.70 \pm 1.33 ^d	77.80 \pm 14.03 ^f
C ($n = 6$)	8.32 \pm 1.15	40.57 \pm 4.79

^a $P < 0.05$ vs group C; ^b $P < 0.01$ vs group B; ^c $P < 0.01$, ^d $P < 0.01$ vs group C.

Expression of colonic ICAM-1

In rat DSS-colitis, ICAM-1 expressed on vascular endothelial

cells and macrophages and its expressions in capillaries and venules were higher than arterioles and most frequently appeared in mucosa and submucosa. The positive rates were high in sites and nearby of colonic erosion and superficial ulcer, and became more and more low following the alleviation of inflammatory damage up from 3 cm distance to the anus. Both the stainings of crypt epithelia in mucosa and lymphocytes were negative.

After administration of oxymatrine, the amount of positive vessels in rat DSS-colitis reduced obviously; only small amount of positive vessels were observed in colons of group C. The mean amount of positive cells in groups A-C were as follows: (82.75 ± 19.46) , (137.27 ± 23.31) , $(12.97 \pm 1.53)/\text{cm}$ with significant differences by comparison between any two groups ($P < 0.01$). The amount in group A decreased obviously compared to group B.

Expression or activation of NF- κ B

In rat DSS-colitis, NF- κ B expressed on vascular endothelial cells and mucosal epithelial cells located in nuclei and/or cytoplasm. Its expressions in capillaries and venules were higher than arterioles, and most frequently appeared in mucosa and submucosa. The positive rates were high in sites and nearby of colonic erosion and superficial ulcer, and became more and more low following the alleviation of inflammatory damage from 3 cm distance to the anus.

After administration of oxymatrine, the amount of positive vessels and positive rates of epithelial cells in rat DSS-colitis reduced obviously; the mean amount of positive cells of endothelial and epithelial cells in distal distant colon were (24.09 ± 4.39) and $(0.86 \pm 0.17)/\text{cm}$ in group A, (30.49 ± 6.07) and $(1.19 \pm 0.36)/\text{cm}$ in group B. The amount in group A decreased obviously compared to group B. None or only little amount of positive cells were observed in colons of group C with amount of $(3.83 \pm 1.00)/\text{cm}$ of positive endothelial cells. The amount of positive cells of vessels in distal colon in group A decreased obviously compared to group B ($P < 0.05$).

DISCUSSION

The present experiment indicates that the serum levels of TNF- α and IL-6 in rat DSS colitis increased distinctly than normal rats and declined obviously after treatment with oxymatrine, which suggests that oxymatrine may inhibit the expression of the above pro-inflammatory cytokines and therefore ameliorate the colonic damage related to them. TNF- α can recruit leukocytes in the inflammatory sites, stimulate monocytes, and vascular endothelial cells to express cytokines, induce the cascade effects for other cytokines and finally result in inflamed lesion of tissues. So it is necessary to inhibit the expression of TNF- α in the early stage of DSS colitis, prevent and alleviate the development of colitis^[12,13]. IL-6 is capable of promoting lymphocyte proliferation and leading to the production of acute phase proteins in liver^[9], also plays an important role in the development of colonic inflammation. The anti-inflammatory effect of oxymatrine may be associated with its inhibitory role to the expression of TNF- α and IL-6^[14,15].

The experiment also demonstrated that expression of

ICAM-1 by vascular endothelial cells and macrophages were enhanced greatly than normal in DSS-induced colonic sites; prophylactic treatment with oxymatrine reduced the inflamed, infiltration and ICAM-1 expression in rat colons, which indicates that oxymatrine may ameliorate DSS colitis by inhibiting ICAM-1 production. Bendjelloul *et al.*^[16], reported that expression of ICAM-1 in ICAM-1 defected mice appears as negative or mild positive, its interaction with leukocytes and inflammatory activity were alleviated. ICAM-1 plays a key role in the trans-endothelial migration and immunological cell activation of leukocytes and prophylactic administration of ICAM-1 mAb could lighten the inflamed damage^[7,17].

The present study also showed that no expression of NF- κ B was observed in non-inflammatory colonic epithelial cells in rat and only mild positive was observed among vascular endothelial cells. However, NF- κ B activation presented in both colonic epithelial cells and vascular endothelial cells; prophylactic treatment with oxymatrine reduced the colonic inflammation and NF- κ B activation, which indicates that oxymatrine may ameliorate DSS colitis by downregulating NF- κ B activation. Marrero *et al.*^[18], also reported, that DSS colitis was related to the high activation of NF- κ B. Inducers of NF- κ B include TNF- α , oxidative stress and so on; NF- κ B is capable of activating many genes such as adhesion molecule ICAM-1 and cytokine TNF- α , IL-1, IL-6, etc.^[3-5,19,20] and therefore it is possible to block the key initial step of inflammation and its secondary effect by inhibiting NF- κ B activity^[21].

Abstract

AIM: To investigate the effects of anti-sense oligonucleotides (ASODNs) on mRNA expression of heparanase in human esophageal cancer EC9706 cells.

METHODS: One non-sense oligonucleotide (N-ODN) and five ASODNs against different heparanase mRNA sites were transfected into EC9706 cells, then the expression of heparanase mRNA in EC9706 cells was studied by *in situ* hybridization.

RESULTS: The expression of heparanase mRNA could be inhibited by ASODNs. There was no significant difference among five ASODNs ($P>0.05$), but there was a significant difference between ASODNs and N-ODN or non-transfected group (ASODN1: 2.25 ± 0.25 , ASODN2: 2.21 ± 0.23 , ASODN3: 2.23 ± 0.23 , ASODN4: 2.25 ± 0.24 vs N-ODN: 3.47 ± 2.80 or non-transfected group: 3.51 ± 2.93 respectively, $P<0.05$).

CONCLUSION: The expression of heparanase mRNA in EC9706 cells can be inhibited by ASODNs *in vivo*, and heparanase ASODNs can inhibit metastasis of esophageal squamous cell carcinoma or other tumors by inhibiting the expression of heparanase.

INTRODUCTION

Heparanase (HPA) is closely associated with cell proliferation, differentiation, adhesion and exudation, and may play a crucial role not only in tumor development and progression but also in tumor invasion and metastasis^[1]. Studies indicate that HPA is expressed in tumor tissues, such as liver carcinoma, ovarian adenocarcinoma, cervical squamous carcinoma, colonic adenocarcinoma, lymphoma, fibrosarcoma and melanoma^[1,2]. We detected the expression of HPA mRNA in anti-sense oligonucleotide (ASODN) transfected by *in situ* hybridization, so as to provide the basic theory for esophageal carcinoma target therapy by heparanase ASODN technique.

MATERIALS AND METHODS

Materials

Human esophageal carcinoma EC9706 cell line was provided by Chinese Academy of Medical Sciences Heparanase ASODNs1-4, N-ODN and biotin-labeled HPA cDNA probe were synthesized by DaLian Bao Bio Co., Ltd. SA-Bio-AP and BCIP/NBT were purchased from Promega Company, USA RPMI-1640 was obtained from Gibco Company, USA.

Cell culture

Human esophageal carcinoma EC9706 cells (a adherent cell line) were cultured in RPMI-1640 and divided into six groups until formation of monolayer on the bottle wall. Groups 1 to 4 were treated with 20 $\mu\text{mol/L}$ ASDON1, ASDON2, ASDON3, ASDON4, respectively. Control group 1 was treated with N-ODN at the same concentration. Neither ASDON nor N-ODN was added to control group 2. All groups were cultured for another 48 h, and then the cells were harvested after trypsinization. The cells were adjusted to a concentration of $10^6/\text{mL}$ and added to the prepared slides for hybridization.

In situ hybridization

The samples were fixed in 40 g/L paraformaldehyde for 30 min. After being washed in distilled water, samples were pre-treated with fresh 0.5% H_2O_2 /formaldehyde to block endogenous peroxidases for 30 min at room temperature. The samples were treated with 30 g/L proteinase k diluted freshly by citric acid for 10 min at 37 °C, pre-hybridized in pre-hybridized solution without probe for 4 h, and then for an additional 12 h at 42 °C. The final concentration of the labeled heparanase probe was 1 $\mu\text{g/L}$. After hybridization, excess probes were removed through rinsing in 0.1 \times SSC at 42 °C, and samples were treated with SA-Bio-AP for 10 min

at 37 °C, and rinsed again. Color reaction was performed with new BCIP/NBT in dark for 2-4 h. The samples without probe were used as negative control.

Result assessment

Ten fields of each section were observed under oil microscope and 100 cells of each field were counted. Scores were obtained according to the staining intensity and count degree of *in situ* hybridization [3].

Statistical analysis

The SPSS 10.0 statistical package was used for all analyses. Data were expressed as mean±SD, and analyzed by ANOVA $P<0.05$ was considered statistically significant.

RESULTS

Expression of heparanase mRNA in EC9706 cells

Heparanase mRNA (blue-purple granule) was located in cytoplasm. There was no positive signal in the cell sample without probe (Figure 1).

Figure 1 Expression of heparanase mRNA in human esophageal cancer EC9706 cells. **A:** non- transfected group; **B:** ASODNs-transfected group; **C:** control group without probe.

Influence of ASODN on expression of heparanase mRNA in EC9706 cells

The level of heparanase mRNA expression in ASODNs1-4-transfected EC9706 cells was 2.25 ± 0.25 , 2.21 ± 0.23 , 2.23 ± 0.23 , 2.25 ± 0.24 , respectively. There was a significant difference between experimental group and control group 1 (3.47 ± 2.80 , $P<0.05$). But there was no significant difference between control groups 1 and 2 (3.51 ± 2.93). There was no significant difference in different ASODNs.

DISCUSSION

Heparanase is a kind of endoglycosidase. It can degrade heparan sulfate glycoprotein, damage the basement membrane and

promote invasion and metastasis of tumors. It expresses in tissues of spleen, lymph nodes, peripheral blood, bone marrow and infant liver, but not in tissues of heart, encephalon, lung, liver, kidney and pancreas of normal adults^[1,4]. Studies indicate that the level of heparanase expression in liver carcinoma, ovarian adenocarcinoma, colonic adenocarcinoma and melanoma is high^[4,5]. Its activity correlates with the metastatic potential of mouse lymphoma, fibrosarcoma and melanoma cells. The level of heparanase expression in tumor cells with high metastatic potential is higher than that in tumor cells with little or no metastatic potential^[6-9], suggesting that heparanase gene expression is closely associated with metastasis of tumors.

To explore new methods of inhibiting the metastasis of tumor we transfected human esophageal carcinoma EC9706 cells with four heparanase anti-sense oligodeoxynucleotides (ASODNs1-4) and observed the effect of ASODN on the expression of HPA gene in EC9706 cells. The results indicate that heparanase can express in human esophageal carcinoma EC9706 cell line and the expression of heparanase mRNA in EC9706 cells were effectively depressed by transfected ASODNs1-4 suggesting that ASODNs may inhibit the invasion and expression of heparanase gene. These results may provide the basic theory for preventing the invasion and metastasis of esophageal carcinoma.

Abstract

AIM: To study the expression of cyclooxygenase-2 (COX-2) in human gastric cancer tissues and their paired adjacent mucosa, as well as mucosa from gastric antrum and corpus of the first-degree relatives of the recruited cancer patients.

METHODS: The expression of COX-2 mRNA in 38 patients with gastric cancer and their 29 first-degree relatives and 18 healthy controls was assessed by the real time RT-PCR. The expression of COX-2 protein was determined by Western blot.

RESULTS: A marked increase in COX-2 mRNA expression was found in 20 of 37 (54%) cancerous tissues compared to their respective paired normal mucosa ($P < 0.001$). Interestingly, increased COX-2 mRNA expression was also found in mucosa of the corpus (6/29) and antrum (13/29) of their first-degree relatives. Increased COX-2 mRNA expression was more frequently observed in the antrum biopsies from cancer patients than in the antrum biopsies from healthy controls ($P < 0.05$). In addition, 3 of 23 (13%) patients with atrophic mucosa and 6 of 35 (17%) patients with intestinal metaplasia showed increased COX-2 mRNA expression. Furthermore, COX-2 expression increased in *H pylori*-positive tissues, especially in antrum mucosa.

CONCLUSION: Increased COX-2 expression is involved in gastric carcinogenesis, and may be necessary for maintenance of the malignant phenotype and contribute to *Helicobacter pylori*-associated malignant transformation.

<http://www.wjgnet.com/1007-9327/11/4918.asp>

INTRODUCTION

Gastric cancer is one of the most common malignancies in China and the most frequent cause of cancer-related death^[1]. Although its incidence is increasing, it is still the second most commonly diagnosed fatal cancer worldwide^[2]. Unfortunately, gastric tumors are usually diagnosed at their advanced stage and the current 5-year survival rate is only 17%. Development of gastric cancer, like many other malignancies, is a multi-step process involving the accumulation of genetic alterations. However, much remains to be learned about the molecular pathogenesis of gastric cancer progression and new molecular targets are needed for the prevention and treatment of gastric cancer, especially in its early stage.

Previous studies showed that about 10% of gastric cancer patients exhibit familial clustering^[3,4], and a high prevalence of intestinal metaplasia has been found to be in the first-degree relatives of patients with gastric cancer in contrast to age-matched controls. Thus, the first-degree relatives are considered to be in pre-malignant state^[5]. Therefore, identification of genes predisposing to familial cancer is an essential step towards understanding the molecular events underlying tumorigenesis and is critical for the clinical management of affected families.

Prostaglandins play an important role in the protection of the upper gastrointestinal tract mucosa against injurious agents. Prostaglandin production in the gastro-duodenal mucosa is due to a single isoform of cyclooxygenase (COX)^[6]. Two COX isoforms, COX-1 and -2, have been identified^[7]. COX-1 is a housekeeping gene that is constantly expressed in a number of cell types, whereas COX-2 is an early responsive gene that is rapidly induced by growth factors, tumor promoters, oncogenes, and carcinogens^[8]. COX-2 products have also been shown to be mutagenic^[9] and tumorigenic^[10]. Multiple lines of evidence suggest that COX-2 plays an important role in the malignant transformation of cells^[11] including various cancer cells^[12]. In contrast, levels of COX-1 are relatively constant. Recently, the importance of COX-2 in gastro-intestinal carcinogenesis has been recognized. In humans, COX-2 is frequently detected in the majority of colon tumor samples and is involved in early events of colon carcinogenesis^[13,14]. Indeed, increased COX-2 expression has been observed in gastric carcinoma

with no alteration in the levels of COX-1^[15]. Whether COX-2 is associated with early gastric carcinogenesis in humans, especially in gastric mucosa of the first-degree relatives of gastric cancer patients, remains unclear. In this study, we aimed to detect the expression level of COX-2 in gastric cancer and non-cancerous tissues to look for a possible relationship between the development of gastric cancer and COX-2 expression.

MATERIALS AND METHODS

Subjects

Fifty patients with gastric cancer (mean age 66 years, range 50-87 years), 29 of their first-degree relatives (mean age 50 years, range 27-74 years) and 18 healthy subjects without gastric cancer family history (mean age 58 years, range 24-86 years) were recruited in this study. Tissues were collected from tumor area and their adjacent non-tumor corpus and antrum of cancer patients, their first-degree relatives and healthy subjects. Two or three biopsies were snap-frozen in liquid nitrogen for mRNA and protein analysis, and two additional specimens were fixed in 10% buffered formalin for routine histology. Written informed consent was obtained from all participants before commencement of the study.

Histology

Formalin fixed tissues were processed and stained with hematoxylin and eosin, for routine histological evaluation. *Helicobacter pylori* (*H. pylori*) was detected by Warthin-Starry staining^[16]. Histological classification of gastric cancer type was based upon Lauren system which divides gastric cancer into intestinal or diffuse type. The severity of gastritis and *H. pylori* colonization status of the non-tumorous gastric mucosa were determined by updated Sydney System^[17]. All histological sections were reviewed by an experienced gastrointestinal pathologist.

RNA and protein isolation

Gastric tissue specimens were homogenized with an ultrasonographic homogenizer. Total RNA and proteins were sequentially extracted using TRIzol reagents (CINNA/MRC, Cincinnati, OH, USA), according to the manufacturer's instructions.

RT-PCR

One microgram of total RNA was reverse transcribed using dNTPs (1 mol/L), 5× reverse transcription (RT) buffer (500 mol/L Tris-HCl, pH 8.3, 250 mol/L KCl, 50 mol/L MgCl₂ and 50 mol/L DTT), 16 units RNasin, and 2.5 units of AMV reverse transcriptase (Gibco-BRL, Life Technologies). mRNA expression of COX-2 was first determined by conventional RT-PCR. One microliter of reverse-transcription product (cDNA) was amplified by PCR using 1 U of Ampli-Taq DNA polymerase (Gibco-BRL), and 6 pmoL each of COX-2 forward and reverse primers, with 6 pmoL each of forward and reverse β -actin primers included in the same multiplex PCR reaction, as an internal control for efficiency of RT and amount of RNA. Each PCR cycle consisted of a denaturation at 94 °C for 28 s, an annealing at 60 °C for 48 s and an elongation at 72 °C for 1 min. A

total of 30 cycles were performed with an additional extension at 72 °C for 5 min. The primer sequences and PCR product sizes were as follows: cox-2, sense 5'-AGATCATCTCTGCCTGAGTATCTT-3', anti-sense 5'-TTCAAATGAGATTGTGGGAAAAT-3', with a 305-bp amplification; β -actin, sense, 5'-TGACGGGGTCACCC-ACACTGTGCCCATCTA-3', anti-sense, 5'-CTAGAAGC-ATTTGCGGTGGACGATGGAGGG-3' with a 654-bp amplification. PCR products were separated on 1.5% agarose gels with 0.5 μ g/mL of ethidium bromide, and stained bands were visualized under UV light, photographed, and digitized with a scanner.

Real-time quantitative PCR was then performed on ABI PRISM 7000 sequence detection system using Sybrgreen, PCR mastermix (Perkin Elmer, Branchburg, NJ, USA) and primers. Primer sequences were designed from the GenBank as follows: COX-2, (forward) 5'-GCCCTTCC-TCTGTGCC-3', (reverse) 5'-AATCAGGAAGCTGC-TTTTAC-3'; and β -actin, (forward), 5'-CTAATGGGCA-CCCAGCACAATG-3', (reverse) 5'-GCCGATCCACA-CGGAGTACT-3'. A 24- μ L reaction mix was aliquot with 1 μ L/replicate of cDNA. A DNA-free template control (containing water) was included and each sample was added in duplicate. Reaction tubes were sealed with optical caps, and the PCR reaction was run at 50 °C for 2 min, at 95 °C for 10 min, followed by 40 cycles at 96 °C for 45 s, at 60 °C for 45 s and at 72 °C for 1 min. Specificity of PCR products was characterized by melting curve analysis and followed by gel electrophoresis. Quantification was determined by the threshold cycle. Actin was used as a housekeeping gene to normalize mRNA levels and compared to mRNA expression levels in normal control stomach.

Western blotting

Total protein concentration was determined by the method of Bradford (DC protein assay, Bio-Rad, Hercules, CA, USA). Fifteen micrograms of protein was separated by 12% sodium dodecyl sulfate-polyacrylamide gel electrophoresis and then transferred onto equilibrated polyvinylidene difluoride membrane (Amersham Biosciences, Buckinghamshire, UK) by electroblotting. Membranes were blocked using 5% skim milk, and then incubated with primary antibodies (Santa Cruz Biotechnology, Santa Cruz, CA, USA) against COX-2 (1:1 000) or β -actin (1:1 000) overnight at 4 °C. After incubation with secondary antibody, proteins were detected by enhanced chemiluminescence (ECL, Amersham Corporation), and bands were quantified by scanning densitometry using the SCAN Control (Scanco~1.lnk) imaging system.

Statistical analysis

Statistical association between COX-2 expression and various clinicopathological factors was determined using the χ^2 test. An exact comparison densitometric analysis of COX-2 PCR products was performed by Student's *t*-test. *P*<0.05 was considered statistically significant.

RESULTS

COX-2 expression in gastric cancer

Increased COX-2 mRNA expression was detected in 37 of

50 (74%) gastric cancer tissues, COX-2 mRNA expression was found to be at very low levels in adjacent gastric mucosa, with 6 of 34 (18%) corpus tissues and 2 of 35 (6%) antrum tissues showing positive COX-2 expression (Table 1 and Figure 1). Quantitative analysis showed that tumor tissues expressed significantly higher levels of COX-2 mRNA compared to the adjacent antrum or corpus samples (Figure 2). COX-2 mRNA was expressed in both intestinal and diffuse types of gastric cancer and did not show any significant difference. By Western blot, COX-2 protein expression was found in 15 of 24 (62.5%) cancers and 4 of 24 (16.7%) adjacent non-tumor specimens (Figure 3). There was a significant correlation between COX-2 mRNA and COX-2 protein expression in gastric tumor samples ($r = 0.522$; $P = 0.001$).

Figure 1 RT-PCR analysis of COX-2 mRNA in gastric tissues. Lanes 1-4: gastric cancer; lanes 5 and 6: first-degree relatives; lanes 7 and 8: healthy control; lane 9: negative control; lane 10: 100-bp DNA ladder. T: Tumor; NT: adjacent non-tumor; C: corpus, and A: antrum.

Figure 2 Quantitative RT-PCR analysis of COX-2 mRNA in gastric tissues. GC: gastric cancer; FDR: first degree relatives.

Figure 3 COX-2 protein expression in gastric tissues. T: Tumor; NT: adjacent non-tumor; C: corpus, and A: antrum.

Expression of COX-2 in gastric mucosa of first degree relatives

We also studied the COX-2 expression in 29 first-degree relatives of gastric cancer patients, and in 18 normal subjects without family history of gastric cancer. Increased COX-2 mRNA expression was observed in 6 of 29 (20.1%) corpus tissues and in 13 of 29 (44.8%) antrum tissues of

first-degree relatives (Figure 1). In contrast, only 1 of 18 normal controls exhibited very low COX-2 mRNA expression in both corpus and antrum tissues. Quantitative analysis showed that expression of COX-2 mRNA increased in corpus and antrum tissues of first-degree relatives compared to healthy controls ($P < 0.01$, Figure 2). Weakly positive COX-2 protein was detected in the mucosa of first degree relatives (Figure 3), whereas it was undetectable in normal controls.

We then proceeded to investigate the COX-2 expression in two pre-cancerous conditions: atrophic mucosa and mucosa with intestinal metaplasia, to determine whether upregulation of this gene occurred at an earlier stage in malignant transformation. COX-2 mRNA was upregulated in 3 of 23 (13%) cases of mucosal atrophy and 6 of 35 (17%) cases of intestinal metaplasia.

Table 1 COX-2 mRNA expression in gastric tissues

Tissues	COX-2 mRNA expression		%
	+	-	
Gastric cancer	20	17	54
Paired adjacent corpus	6	28	18
Paired adjacent antrum	2	33	6
Corpus of first-degree relatives	6	23	21
Antrum of first-degree relatives	13	16	45
Corpus of healthy control	1	17	6
Antrum of healthy control	1	17	6

Correlation of COX-2 expression with *H pylori* infection

We compared the COX-2 mRNA expression in *H pylori* infected and *H pylori*-negative tissues (Table 2). RT-PCR analysis of the gastric tissues showed that the expression of COX-2 was significantly upregulated in *H pylori* infected tissues compared to *H pylori*-negative tissues ($P < 0.05$). Because *H pylori* is most commonly colonized in gastric antrum^[18], we also compared the levels of COX-2 expression in *H pylori* infected antrum and corpus tissues, and found that the expression of COX-2 mRNA was significantly higher in the antrum ($P < 0.05$).

Table 2 Correlation between COX-2 mRNA expression and *H pylori* infection

<i>H pylori</i>	COX-2 mRNA expression					
	Antrum	%	Corpus	%	Total	%
Positive	12/34	35	8/36	22	20/70	29
Negative	4/44	9	4/39	10	8/83	10
<i>P</i>	<0.005		>0.05		<0.005	

DISCUSSION

Gastric cancer is one of the most commonly encountered malignancies worldwide. Several of its pre-cancerous conditions, such as atrophic gastritis and intestinal metaplasia, have been well recognized. The concern with these gastric cancer precursor conditions or lesions is related to the attempt to prevent carcinoma or to detect it at an early

stage. Atrophic gastritis is defined as the loss of gastric glands, which can occur either in antrum or in corpus. Increased prevalence of this type of gastritis has been found in subjects who are at high risk for gastric cancer^[19]. Intestinal metaplasia is defined as the replacement of gastric mucosa by glands that have the characteristics of the small intestine^[20], and this condition has been strongly associated with development of gastric cancer. Atrophic gastritis and intestinal metaplasia have been accepted as pre-cancerous conditions for some years. Generalized genetic instability has been shown to occur early in this process^[21,22]. In contrast, the relative contributions of inherited susceptibility and environmental effects to familial gastric cancer are poorly understood, because little is known about the genetic events that predispose to gastric cancer. The first-degree relatives of gastric cancer patients have a three-fold risk for developing gastric carcinoma^[3,9]. Therefore, the identification of genes predisposing to familial cancer is an essential step towards understanding the molecular events underlying tumorigenesis and critical for the clinical management of affected families.

In our study, COX-2 gene expression was undetectable in normal control gastric mucosa. In the majority of gastric carcinomas studied, COX-2 expression was clearly upregulated compared to the levels of expression in accompanying antrum and corpus mucosa devoid of cancer cells. A similar pattern of COX-2 mRNA expression has previously been found in human gastric carcinoma^[23]. More importantly in this study, upregulation of COX-2 mRNA and protein was found in first-degree relatives. Furthermore, we detected COX-2 expression in atrophic mucosa and in intestinal metaplasia. These results suggest that COX-2 overexpression constitutes an early event in the gastric neoplastic transformation process which occurs at the pre-cancerous stage. Similarly, expression of COX-2 is found in some non-malignant hyperplastic gastric glands that may represent pre-malignant lesions stained for the COX-2 protein^[23]. Expression of COX-2 is also found in rat epidermis during hyperplastic transformation^[24]. In addition, colonic epithelium expresses only low levels of COX-2 mRNA and elevated levels are found in more than 40% of pre-malignant colonic adenomas. COX-2 expression is detected in hyperplastic bronchial epithelium and atypical alveolar epithelium in lung specimens^[25]. COX-2 is involved in Barrett's-associated metaplastic and dysplastic specimens^[17]. All these findings strongly suggest that COX-2 may play a role in early carcinogenesis.

H. pylori has been epidemiologically linked to gastric cancer and classified as a class I carcinogen by the World Health Organization^[26]. In the present study, expression of COX-2 mRNA was upregulated in gastric mucosa from *H. pylori*-positive tissues compared to *H. pylori*-negative tissues, suggesting that induction of COX-2 may be a specific response to *H. pylori* infection. COX-2 mRNA expression was significantly correlated with *H. pylori* infected antrum tissues, but not with *H. pylori* infected corpus tissues. A more important factor may be the consistent finding that *H. pylori* infection density is greater in gastric antrum than in corpus^[27,28]. Therefore, the overexpression of COX-2 may be a direct effect of *H. pylori*.

In conclusion, gastric cancer and pre-cancerous lesions

express COX-2. COX-2 mRNA is detectable in gastric mucosa of first-degree relatives of cancer patients. COX-2 may contribute to *H. pylori* associated neoplastic transformation. Further investigation is necessary to determine the putative role of this gene in gastric carcinogenesis.

Abstract

In view of the poor prognosis of patients with cholangiocarcinoma (CCC), there is a need for new therapeutic strategies. Inter-disciplinary therapy seems to be most promising. Radiotherapy is an effective alternative to surgery for hilar CCC (Klatskin tumors) if an adequate radiation dose can be delivered to the liver hilus. Here, we describe a patient for whom we used a stereotactic radiotherapy technique in the context of an inter-disciplinary treatment concept. We report a 45-year-old patient with a locally advanced Klatskin tumor. Explorative laparotomy showed that the tumor was not resectable. A metallic stent was implanted and the patient was treated by stereotactic radiotherapy using a body frame. A total dose of 48 Gy (3×4 Gy/wk) was administered. Therapy was well tolerated. After 32 mo, local tumor recurrence and a chest wall metastasis developed and were controlled by radio-chemotherapy. After more than 56 mo with a good quality of life, the patient died of advanced neoplastic disease. Stereotactic radiotherapy led to a long-term survival of this patient with a locally advanced Klatskin tumor. In the context of inter-disciplinary treatment concepts, this radiotherapy technique is a promising choice of treatment for patients with hilar CCC.

Becker G, Momm F, Schwacha H, Hodapp N, Usadel H, Geißler M, Barke A, Schmitt-Gräff A, Henne K, Blum HE. Klatskin tumor treated by inter-disciplinary therapies including stereotactic radiotherapy: A case report. *World J*

INTRODUCTION

Cholangiocarcinoma (CCC) is the second most common primary liver cancer after hepatocellular carcinoma^[1]. Its prognosis is poor. The 5-year survival after surgical treatment with curative intention is 10-30%^[2], but at the time of diagnosis less than one-third of tumors are resectable^[3,4]. Single agent or combination chemotherapy and conventional radiation therapy are so far not effective, neither as primary treatment nor as adjuvant treatment after resection^[1,5]. The majority of patients survive less than 12 mo after diagnosis^[5,6]. Thus, there is a strong need for new therapeutic strategies. Here we report a 45-year-old patient with inoperable hilar CCC, who was treated using an inter-disciplinary concept including stereotactic radiotherapy. This highly precise technique also known as *extracranial stereotactic radiotherapy*^[7], was first developed for the treatment of brain tumors. Using a body frame, it is applicable to the whole body. By this technique, an adequate radiation dose can be delivered to the tumor, while sparing normal structures in the liver hilus and the upper abdomen that are highly radiosensitive. A total dose of 48 Gy (3×4 Gy/wk) could be given and therapy is well tolerated. Although the tumor is locally advanced at the time of diagnosis and prognosis was extremely poor, an unusual long survival of more than 4 years with a good quality of life could be achieved. Stereotactic radiotherapy seems to be a promising choice of treatment for hilar CCC.

CASE REPORT

In December 1998, a 45-year-old male patient was admitted to our hospital. The only pathologic finding at clinical examination was a generalized, painless jaundice. The patient reported itching, but no abdominal pain, no fever, and no weight loss. Laboratory tests showed elevated levels of alkaline phosphatase (591 U/L; normal 35-104 U/L), γ -glutamyltransferase (75 U/L; normal <39 U/L) and bilirubin (22.8 mg/dL; normal <1.2 mg/dL). C-reactive protein increased slightly (15 mg/L; normal <5 mg/L). The tumor antigen CA 19-9 was elevated (405 U/L; normal <37 U/L). All other routine biochemical tests were normal. Abdominal ultrasound examination showed dilation of intra-hepatic and extra-hepatic bile ducts. Computer

tomography (CT) and magnetic resonance imaging (MRI) revealed a 6 cm×7 cm tumor in hepatic duct bifurcation and cholestasis predominantly in the atrophic left lobe of the liver. Several enlarged lymph nodes were detected in the hepato-duodenal ligament and one retro-pancreatic lymph node in contact to the inferior vena cava. Endoscopic retrograde cholangiopancreatography (ERCP) showed a stenosis of the hepatic duct bifurcation. A biopsy was taken and using percutaneous transhepatic cholangial drainage (PTCD), an external-internal Yamakawa drainage was placed. Histological examination revealed a highly differentiated CCC. Chest X-ray showed no evidence for metastases. Explorative laparotomy showed a non-resectable tumor. The tumor was classified as American Joint Committee on Cancer stage III according to the staging system for CCC^[8] and as type IV according to modified Bismuth-Corlette classification for hilar CCC^[9,10]. The biliary drain was internalized post-operatively by implanting a metallic Memotherm stent (60 mm/10 mm, Fa. Bard-Angiomed, Karlsruhe, Germany). Subsequently a stereotactic radiotherapy with 48 Gy was performed for over 4 wk (3×4 Gy/wk) using the technique of Lax *et al.*^[7,11], with slight modifications. After careful fixation of the patient in a body frame, treatment planning was performed in series of 45 axial CT slices with a distance and thickness of 5 mm. The planning target volume^[12,13], including the clinical target volume (tumor and involved structures/lymphatic nodes) at a distance between 3 and 5 mm to compensate for organ motion and repositioning errors, was 370 cm³. To check the repositioning accuracy in the body frame, a second CT series was performed few days after the first. The maximum positioning deviation in the region of the target volume was less than 3 mm. An optimal dose distribution could be achieved with seven coplanar conformal photon beams from a 6 MV linear accelerator (Figure 1). Using this technique, the mean dose values to liver, right kidney, spleen, and duodenum could be kept at 20.2, 3.2, 8.7, and 22.2 Gy, respectively. The patient developed cholangitis 2 mo after radiotherapy. An ERCP showed a stenosis close to the papilla Vateri. A biopsy was not conclusive and could not determine whether the stenosis was caused by tumor or radiation. The patient was treated with antibiotics. An internal plastic stent (10F/7 cm, Endo-Flex GmbH, Voerde, Germany) was placed to relieve the distal biliary obstruction. Jaundice and associated symptoms resolved. The patient was followed up at 3-mo intervals. Because transhepatic biliary stents have a 1-year patency rate of only 50%^[14,15], the stent was replaced endoscopically every 3 mo between May 1999 and July 2003. MRI, in November 1999, showed no contrast medium enhancement in the tumor region and stable size of the lymph nodes. MRI, one year later (October 2000), showed constant size of the tumor, but a slightly contrast medium enhancement and enlargement of one retro-pancreatic lymph node consistent with a slowly growing residual tumor. In addition, a metastasis was detected in the right lobe of the liver. The patient refused chemotherapy. MRI, in April 2001, showed stable disease. In July 2001, the patient reported a weight loss of 18 kg in 2 mo and pain in the right chest. MRI revealed tumor progression and a metastasis in the right chest wall. Therefore, a combined palliative

radiochemotherapy was initiated in September 2001. The chest wall metastasis was irradiated with a photon beam of a 6 MV linear accelerator with a total dose of 24 Gy (3×4 Gy/wk). Chemotherapy with gemcitabine 1 000 mg/m² was initiated. MRI, after three cycles of chemotherapy in December 2001, showed partial remission with regression of all lesions. Therefore, chemotherapy was continued. Because of thrombocytopenia and anemia, only two additional cycles of gemcitabine at a reduced dose could be given and chemotherapy had to be stopped in March 2002. After tumor progression, the patient received four cycles of 5-fluorouracil/leucovorin/oxaliplatin FOLFOX^[7] and two cycles of 5-fluorouracil/leucovorin/irinotecan FOLFIRI. In July 2003, MRI showed significant progression of the tumor. Though the tumor had such a final progression, the patient had a good quality of life for more than 4 years. Four years and six months after diagnosis he died of liver failure. The treatment course of the patient is shown in Figure 2.

Figure 1 CT slice of radiotherapy treatment plan in the drainage area (planning system: TMS Helax). 1-7: Coplanar beams. Isodoses: green: 100% = 48.0 Gy; light blue 1: 90% = 43.2 Gy; light blue 2: 80% = 38.4 Gy; light blue 3: 70% = 33.6 Gy; dark blue: 50% = 24.0 Gy. A: PTV (planning target volume): outer red line includes a safety rim. B: Body frame (low density materials to avoid shielding) with positioning marks. C: Vacuum cushion for reproducible fixation of the patient (low density materials to avoid shielding: not visible in CT scan). D: Drainage. E: Radio-opaque fiducials for the coordinate read out in longitudinal direction.

Figure 2 Patient's treatment course from 12/1998 to 08/2003.

DISCUSSION

Patients with CCC have an extremely poor prognosis. Because of the high recurrence rate of CCC, there is no indication for liver transplantation^[14,16,17]. Thus, surgical resection remains the only potentially curative treatment with a 5-year survival rate of 0-22% (mean 14%) for hilar CCC and 0-39% (mean 25%) for distal CCC^[18]. At the time of diagnosis, however, resection is possible in less than a third of the patients^[3]. If the tumor is unresectable, therapeutic interventions are directed toward the relief of biliary obstruction and its associated symptoms. Palliative options include ERC, PTCD, or a bilio-digestive anastomosis. Endoscopic biliary drainage with self-expandable metal stents has become the favored palliative drainage procedure and can be successfully performed on most patients with hilar CCC^[5]. Metallic wall stents are preferred over plastic stents because of their longer patency^[19-21]. In a small number of patients with unresectable CCC and failed endoscopic stents, photodynamic therapy (PDT) has been used. This technique involves the intravenous application of a photosensitizer followed by intra-luminal cholangioscopic photoactivation and generation of oxygen free radicals that harm cancer cells preferentially. Therapy decreases bilirubin levels and leads to a slightly better survival rate^[22,23]. It was reported that biliary stenting with and without PDT shows a survival benefit for patients receiving PDT^[24]. However, a puzzling aspect of the study is the failure to relieve bile duct obstruction with stenting alone. Therefore the observed survival benefit is probably caused by relief of cholestasis rather than by a reduction of tumor and it remains unclear, if PDT prolongs survival in patients responding to conventional biliary stenting procedures. Although this new technique appears promising, further studies are needed. Chemotherapy has not been shown to have a significant impact on survival^[25]. The majority of reports use 5-FU alone or in combination with leucovorin, methotrexate, cisplatin, mitomycin C, or interferon alpha^[5]. In some phase II studies, a response rate of about 20% is reported for gemcitabine^[26,27]. The majority of reports concerning chemotherapy in patients with CCC are retrospective and include only few patients. In intra-hepatic CCC, transarterial chemoperfusion in combination with temporary embolization of the feeding artery can be performed. But randomized controlled trials demonstrating an impact on survival are lacking. Few studies have reported benefits of primary or adjuvant standard radiation therapy^[28,29]. There are no randomized controlled trials demonstrating a therapeutic effect of brachytherapy or external beam radiotherapy^[5]. The main problem of radiation therapy of the upper abdomen is to deliver an adequate dose to the tumor without serious side effects. Using a conforming, stereotactic radiation technique, a steep dose gradient can be obtained^[30]. This means that a high radiation dose reaches the tumor while the normal tissue around the target volume is irradiated with comparatively low doses. Such a highly precise dose distribution is a need in radiotherapy of the liver hilus. Apart from the dose distribution the repositioning accuracy of the target volume is central to a successful radiation therapy. The high repositioning accuracy by a body frame^[7,11] can explain the differences between our patient and published

series with respect to side effects and tumor regression. Thus, stereotactic radiotherapy using a body frame is a valuable option for non-invasive treatment of inoperable tumors in critical regions as the liver hilus. Further technical developments as image guided radiotherapy or breath-triggered radiotherapy should further increase the repositioning accuracy and may make this technique available for routine use.

In conclusion, considering the generally poor prognosis of patients with Klatskin tumor, the long-term survival of our patient treated by stereotactic radiotherapy should encourage a systematic evaluation of this therapeutic strategy by prospective and randomized protocols.

Abstract

We herein report a gossypiboma resulting from a retained surgical swab, which had been left in peritoneum for 20 years after appendectomy. CT revealed a cystic mass with a calcified reticulate rind. Subsequent surgery and pathological examination showed a gossypiboma. A simple experiment, using a barium-soaked surgical swab demonstrating similar CT appearance, supported our postulation that calcium deposition on the reticulated fibers of a surgical swab could generate such a characteristic “calcified reticulate rind” sign. We believe that identification of this CT sign facilitates the diagnosis of gossypibomas.

INTRODUCTIONS

Gossypiboma (also called textiloma), an infrequent complication of surgery, is a mass lesion owing to a retained surgical swab surrounded by foreign-body reaction. Because the symptoms of gossypiboma usually are non-specific and may appear years after surgery, awareness of a gossypiboma usually comes from imaging studies^[1,2]. The most specific imaging finding of a gossypiboma is a radiopaque marker on plain radiography, followed by entrapment of air bubbles in a spongiform pattern on CT^[1,2]. However, it is difficult to diagnose some long-lasting gossypibomas with these two

imaging findings because the surgical swabs used long time ago may not contain radiopaque markers, surrounding calcifications increased with time may mask radiopaque markers, and gas bubbles within a gossypiboma do not last for years. Herein, we describe a long-lasting gossypiboma with the “calcified reticulate rind” on CT which may ascribe to long-standing deposition of calcifications along the network architecture of a surgical swab. Identification of this novel CT feature may help doctors to diagnose some long-lasting gossypibomas.

CASE REPORT

A 43-year-old man sought medical attention due to progressive abdominal fullness and right flank pain for 2 mo. He denied fever, chill, nausea, vomiting, constipation, dysuria, gross hematuria, or body weight loss. Physical examination revealed a soft mass at the right lower quadrante of his abdomen. The blood cell count, blood chemistries, and urinalysis were all within the normal range. He received appendectomy at another hospital 20 years ago and also underwent bilateral vasectomy for contraception at our hospital 4 mo prior to this admission.

Abdominal radiograph revealed a round pelvic mass with a calcified rim (Figure 1). Intravenous urogram revealed right moderate hydronephrosis due to distal ureteral compression by the pelvic mass. Pre-enhanced CT scan demonstrated a 10-cm cystic lesion, with a thick calcified rind, which exhibited a reticulate pattern (Figures 2 and 3). Enhanced CT showed no abnormal contrast enhancement. During laparotomy, a 10 cm×10 cm cystic lesion with a well-defined fibrotic wall was disclosed in the pelvic cavity. Adhesion of the lesion to the right lower ureter was also noted. On gross examination, a piece of gauze of about 10 cm×4 cm×0.2 cm containing necrotic debris was removed from the thick-wall cystic lesion. Microscopic examination revealed suture granuloma, cholesterol clefts, fibrinoid necrosis, fibrosis, and calcification on the capsule. The final diagnosis was gossypiboma, plausibly resulted from the retained gauze during the appendectomy performed 20 years ago.

We postulated that the “calcified reticulate rind” in this gossypiboma might result from a gradual calcium deposition along the fiber network of the surgical swab. A simple experiment was performed for correlation. We soaked a piece of surgical swab with radiopaque marker in diluted barium. After drying the swab and wrapping it into a mass, we scanned it with CT. CT revealed a reticulate rind pattern (Figures 2 and 3), similar to that of the “calcified reticulate rind” of the gossypiboma noted in our case.

Figure 1 A round mass in pelvis with rim calcification on the abdominal plain radiograph.

Figure 2 A cystic lesion in pelvic cavity with a thick “calcified reticulate rind” demonstrated by pre-enhanced CT scan.

Figure 3 “Calcified reticulate rind” on another level (2 cm below Figure 2) demonstrated by pre-enhanced CT scan.

DISCUSSION

The term gossypiboma is derived from the Latin word gossypium, meaning cotton, and Kiswahili word boma, meaning place of concealment. This is an uncommon surgical complication with an estimated incidence of 1/1 500^[3]. Gossypibomas are most frequently discovered in the abdomen. However, their occurrences in the thorax^[4], extremity^[5], central nervous system^[6], and breast^[7] have also been reported. Pathologically, there are two types of foreign body reactions in gossypibomas. One is an aseptic fibrous response resulting in adhesion, encapsulation, and

granuloma, and the other is an exudative reaction leading to cyst or abscess formation^[8].

The most impressive imaging finding of gossypibomas is the curved or banded radiopaque lines on plain radiograph or CT, which represent the radiopaque markers of the surgical swabs. However, calcification depositions over the surgical gauze may mask the characteristic radiopaque markers, and some surgical swabs used long time ago may not have radiopaque markers. Hence, such radiographic finding may not be seen in every gossypiboma. On CT, a gossypiboma may manifest as a cystic lesion with internal spongiform appearance with mottled gas bubbles, hyperdense capsule, concentric layering, or mottled mural calcifications^[4,9-12]. In a series of 13 cases of gossypiboma found 3 mo to 8 years after surgery, Lars Kopka *et al.*^[2] suggested that the spongiform pattern with entrapped gas bubbles is the most specific CT finding for gossypibomas with an incidence of 54%. They also found that gas bubbles within a gossypiboma decrease slowly with time in an experiment. On MRI, gossypibomas may appear as a low-signal-intensity lesion on T2-weighted images with wavy, striped or spotted appearances^[13-15].

In our case, the gossypiboma might be due to the retention of the gauze during appendectomy 20 years ago. We could not find the conventional characteristic imaging findings of gossypibomas, such as the radiopaque markers and the spongiform pattern with entrapped air bubbles. The plausible explanations are that most surgical swabs at that moment usually contain no radiopaque markers while the air bubbles are completely absorbed after such a long duration of 20 years. Instead, this unique case demonstrated a novel imaging feature of gossypiboma, so-called the “calcified reticulate rind” sign which is probably formed by gradual deposition of calcifications along the fiber network of the surgical gauze. To our knowledge, this CT feature of gossypiboma has not been previously reported.

In summary, this report documents a unique case of gossypiboma that exhibits a “calcified reticulate rind”, a characteristic feature of gossypiboma.

INTRODUCTION

A number of conditions characterized by chronic liver damage are associated with the development of liver fibrosis, ultimately leading to cirrhosis and functional alterations^[1]. Although fibrotic progression represents the final outcome of the liver 'wound healing' response in several conditions of chronic injury, different types of fibrosis show relatively unique features. Biliary fibroses, such as the one observed in conditions of chronic obstruction of the biliary tree, are characterized by the accumulation of extracellular matrix at portal tracts, surrounding newly formed bile ducts emerging during the course of the so-called 'typical' ductular reaction and originated from proliferation of pre-existing bile duct epithelial cells^[2,3]. If the obstruction persists, fibrosis bridging different portal tracts develops, ultimately leading to biliary cirrhosis. Common bile duct ligation (BDL) and scission in rats represents a classical experimental model for the analysis of the events leading the initial injury of the bile ducts to the organization of a fibrotic reaction, which involves different matrix-producing cells of mesenchymal origin, including α -smooth muscle actin (SMA)-positive portal myofibroblasts and activated hepatic stellate cells (HSC)^[2,4-6]. This model has been widely used to investigate the molecular and cellular mechanisms of liver fibrosis and to assess potential treatments for this disorder. In addition, due to the close anatomical and functional contacts between cholangiocytes and matrix-producing cells, the BDL model represents an optimal tool for the study of epithelial-mesenchymal interactions.

Peroxisome proliferator-activated receptors (PPARs) belong to the nuclear hormone receptor superfamily^[7]. All these molecules share the ability to function as transcription factors by binding to target DNA elements, and change their transcriptional activity after binding to specific ligands. Three different PPAR isoforms have been cloned and

Abstract

AIM: To investigate the effects of troglitazone (TGZ), an anti-diabetic drug which activates peroxisome proliferator-activated receptor- γ (PPAR- γ), for liver tissue repair, and the development of ductular reaction, following common bile duct ligation (BDL) in rats.

METHODS: Rats were supplemented with TGZ (0.2% w/w in the pelleted food) for 1 wk before BDL or sham operation. Animals were killed at 1, 2, or 4 wk after surgery.

RESULTS: The development of liver fibrosis was reduced in rats receiving TGZ, as indicated by significant decreases of procollagen type I gene expression and liver hydroxyproline levels. Accumulation of α -smooth-muscle actin (SMA)-expressing cells surrounding newly formed bile ducts following BDL, as well as total hepatic levels of SMA were partially inhibited by TGZ treatment, indicating the presence of a reduced number and/or activation of hepatic stellate cells (HSC) and myofibroblasts. Development of the ductular reaction was inhibited by TGZ, as indicated by histochemical evaluation and hepatic activity of γ -glutamyl-transferase (GGT).

CONCLUSION: Treatment with thiazolidinedione reduces ductular proliferation and fibrosis in a model of chronic cholestasis, and suggests that limiting cholangiocyte proliferation may contribute to the lower development of scarring in this system.

characterized. PPAR- α binds to fatty acids and fibrates and is known to induce transcription of genes involved in ω - and β -oxidation of fatty acids^[7]. PPAR- β (or - δ) is expressed ubiquitously, and could be involved in fatty acid and lipid metabolism^[8]. Finally, the ligands for PPAR- γ include anti-diabetic drugs of the thiazolidinedione group and arachidonic acid metabolites, such as prostaglandins of the D series and its derivatives such as 15deoxy- $\Delta^{12,14}$ PGJ₂. PPAR- γ is expressed at high levels in the adipose tissue, where it regulates lipid storage and modulates the action of insulin^[9-11].

Agonists of PPAR- γ have been shown to regulate multiple and critical functions in diverse pathophysiologic conditions, including type 2 diabetes and the metabolic syndrome, cancer, and inflammation^[12]. In the liver, considerable attention has been directed to the modulation of the development of fibrosis through actions on HSC and liver myofibroblasts^[13-15]. In this study, we investigated the effects of treatment with troglitazone (TGZ), the first thiazolidinedione introduced in clinical practice, on the development of ductular reaction and fibrosis in the BDL model. The results indicate that TGZ not only limits extracellular matrix deposition and HSC activation, but also inhibits the formation of newly formed bile ducts, thus acting on both epithelial and mesenchymal cells involved in the response to this type of chronic liver injury.

MATERIALS AND METHODS

In vivo model

Male Wistar rats (Harlan-Nossan, Correnzana, Italy), weighing 180-200 g, were used according to the national and local ethical guidelines. For experimental purposes, animals were divided into two experimental groups and fed for 2 wk either with a standard pelleted diet (rat diet No. 48, Piccioni, Gessate Milanese, Italy) and water *ad libitum* (control diet) or with the same pelleted diet containing 0.2% (w/w) troglitazone (TGZ diet), according to previously described procedures^[16,17]. In the animals from both experimental groups, permanent extrahepatic cholestasis was induced by common BDL and scission under light ether anesthesia as previously described^[18,19]. Animals receiving sham operation were subjected only to the manipulation of the common bile duct, and served as controls. After BDL or sham operation, the animals continued to receive the same diet according to the following experimental groups: (1) Sham (control, receiving normal diet), (2) TGZ (sham, receiving TGZ-supplemented diet), (3) BDL (operated, receiving normal diet), and (4) BDL/TGZ (operated, receiving TGZ-supplemented diet). The amount of consumed food in each experimental group was recorded throughout the study. The animals were then killed after 1, 2, and 4 wk of surgery ($n = 6-8$ animals for each experimental group at any time point). The liver was promptly removed, and portions of the organ were either immediately used or frozen in liquid nitrogen and stored at -80 °C for further determinations or processed for histological and histochemical examination. Blood samples were also collected from individual animals before they were killed.

Serum and liver biochemistry

Serum activities of glutamic oxalacetic transaminase (GOT) and alkaline phosphatase (AP) were determined using a commercial kit (Sigma Diagnostics, Sigma, Milan, Italy). L-Hydroxyproline concentration in liver samples was determined according to standard procedures^[20]. γ -Glutamyltransferase (GGT) activity was evaluated on diluted liver homogenate samples using a modified standard procedure^[21] as previously described^[22].

RNase protection assay

Total RNA was isolated from frozen liver tissues using Nucleospin columns (Mackerey-Nagel, Dürer, Germany). Integrity of RNA was checked by agarose electrophoresis. ³²P-labeled cRNA probes were transcribed from templates encoding for rat α_1 (I) procollagen (kindly provided by Dr. Jackie J. Maher, University of California at San Francisco) and housekeeping gene 36B4. After hybridization, protected fragments were separated on a sequencing gel and autoradiographed. All procedures for probe labeling, hybridization, and digestion have been described in detail elsewhere^[23].

Western blotting

Liver tissue was homogenized in an Ultra-Turrax homogenizer in RIPA buffer containing 1% Nonidet P40 and protease inhibitors. Insoluble proteins were discarded by high-speed centrifugation at 4 °C. The protein concentration in the supernatant was measured using a commercially available kit (Pierce, Rockford, IL, USA). Fifty micrograms of protein was separated by 10% SDS-PAGE, and electroblotted on a PVDF membrane. After transfer, the membrane was stained with a Ponceau red solution (Sigma) to ensure an equal protein loading. The staining was then removed by washing in PBS-Tween and the membrane was blocked with 3% BSA in PBS-Tween overnight. After an additional washing, the blots were sequentially incubated with monoclonal anti- α -SMA antibodies and anti-mouse horseradish peroxidase-conjugated antibodies. Detection was performed by chemiluminescence, according to the manufacturer's protocol (Amersham, Arlington Heights, IL, USA).

Immunohistochemistry

Experiments were conducted on frozen sections as described in detail elsewhere^[24]. Dried sections were sequentially incubated with the primary antibody followed by affinity-purified rabbit anti-mouse antibodies after washing. At the end of incubation, sections were washed twice in TBS, incubated with APAAP and developed. Negative controls were treated with omission of the primary antibody or its substitution with non-immune rabbit immunoglobulins.

Histology and histochemistry

Frozen liver specimens or specimens fixed in 4% formaldehyde in phosphate buffer (pH 7.2) and embedded in paraffin were used for morphological analysis. Standard liver sections (4-6- μ m thick) embedded in paraffin were stained with hematoxylin and eosin. Biliary epithelial cells of the newly formed ductular structures were identified by histochemical staining for GGT activity as previously described^[18].

RESULTS

In vivo administration of TGZ-supplemented diet to control animals (TGZ group) did not significantly affect either the liver morphology or the serum chemistry (Table 1 and

Figures 1A and B). Following BDL, an increase in serum transaminase and AP was observed in all animals (BDL group, Table 1).

Comparison of the BDL and BDL/TG groups showed

Figure 1 Effects of oral supplementation with TGZ on liver pathology in control rats (A and B) and bile duct-ligated rats (C-J). Animals received sham operation

(A and B) or were subjected to BDL for 2 wk (C-F) or for 4 wk (G-J).

no significant differences in serum enzyme levels or in liver weight, while body weight was significantly lower in BDL animals (Table 1). No difference in food consumption was found between the two groups undergoing BDL. Histological examination of rats undergoing BDL revealed bile duct proliferation in the portal tract (Figure 1), already evident after 1 wk and progressively worsening thereafter. This 'typical' ductular reaction was associated with progressive deposition of extracellular matrix surrounding the newly formed bile ducts. After 4 wk, alteration of liver structure was evident, with bridging fibrosis encircling most of the newly formed bile ducts. These histological alterations were considerably less evident in the group of BDL/TGZ rats (Figure 1). Thus, at 2 wk, only moderate fibrosis was present, and the area occupied by proliferating bile ducts was more limited than in rats not undergoing TGZ supplementation (Figures 1C-F). Similarly, after 4 wk, less fibrosis and a more limited disarray of liver structure were observed in BDL/TGZ animals (Figures 1G-J).

^a*P*<0.05 vs BDL, ^b*P*<0.01 vs Sham.

To establish whether these morphologic changes were associated with reduced fibrogenesis, gene expression levels of procollagen I were measured at different time points. In all animals undergoing BDL, a marked increase in procollagen I gene expression was observed, as indicated by RNase protection assay (Figure 2). In BDL/TGZ rats, the increase in procollagen expression was less marked at 1st and 2nd wk after surgery (Figure 2). Interestingly, the inhibitory effects on procollagen type I expression were no longer evident 4 wk after BDL. We next evaluated whether reduced fibrosis and procollagen expression were associated with modified collagen levels, by measuring hepatic hydroxyproline levels. As expected, a progressive increase in hepatic hydroxyproline was evident in animals undergoing BDL, with a peak at 4 wk, when mean values were approximately five times higher than in controls (Figure 3). Administration of TGZ resulted in a marked inhibition of hydroxyproline accumulation after BDL. At 4 wk, hepatic hydroxyproline levels were inhibited more than 50% in BDL/TGZ rats, being comparable to those measured after 2 wk in BDL animals not receiving the drug. These data indicate that TGZ could effectively reduce hepatic fibrosis caused by BDL.

In vitro studies indicated that thiazolidinediones could inhibit HSC activation and related phenotypic responses,

including proliferation and migration. We analyzed the expression of SMA as an index of the number and activation state of HSC and other fibrogenic mesenchymal cells in the different groups of animals.

Immunohistochemical analysis showed that there was a progressive accumulation of SMA-expressing cells around the expanded portal tracts, in close proximity to bile duct epithelial cells of the ductular reaction. At 4 wk after BDL, SMA-positive cells occupied a significant portion of the hepatic lobule, being a part of the porto-portal septae (Figure 4). This picture was clearly modified in BDL/TGZ rats, where a less marked abundance of cells expressing SMA was present. To substantiate and quantify the inhibitory effect of TGZ on activated matrix-producing cells, SMA expression in the whole liver was analyzed by Western blotting. The progressive increase in SMA expression observed in the BDL group (up to fivefold at 4 wk) was markedly reduced by TGZ treatment (Figure 5). Taken together, these data indicate that TGZ treatment was associated with a reduction in the number of matrix-producing cells accumulated in close contact with cells of the ductular reaction.

Figure 2 Effects of TGZ on type I procollagen expression in bile duct-ligated rats.

Figure 3 TGZ inhibits collagen accumulation in bile duct-ligated rats in different experimental groups. ^a*P*<0.05 vs Sham, ^c*P*<0.05 vs BDL.

Morphological analysis of tissue samples from BDL/TGZ animals suggested a reduction of the extent of the ductular reaction in this group. We estimated the number of bile duct epithelial cells in the different groups of animals by performing a histochemical staining for GGT, which allowed to identify this cell type (Figure 6). In BDL rats, a progressive accumulation of newly formed bile ducts was

Figure 4 TGZ reduces accumulation of SMA-positive cells after BDL in different

experimental groups. **A:** Sham; **B:** TGZ; **C:** BDL; **D:** BDL/TGZ.

evident, reaching a maximum after 4 wk. At all time points after BDL, TGZ treatment reduced the number of GGT-expressing cells, indicating a marked inhibition on the development of the ductular reaction (Figure 6). To quantify this effect, the enzymatic GGT activity was measured in total liver tissue lysates obtained from control and BDL rats (Figure 7). We observed a progressive increase in GGT activity in the BDL group, which was in parallel to the accumulation of newly formed bile ducts. A significant reduction of GGT activity was present in rats treated with TGZ at 2nd and 4th wk after BDL, confirming the inhibitory action shown by histochemical analysis. Thus, treatment with TGZ was also associated with a reduction in the severity of the ductular reaction caused by BDL.

DISCUSSION

Biliary fibrosis is a reproducible and reliable model for the study of experimental liver fibrogenesis^[25]. Long-standing cholestasis leads to an ordered bile duct proliferation, or

typical ductular reaction^[3], associated with progressive accumulation of extracellular matrix, starting from the portal tracts and extending to the other areas of the lobule. This model is characterized by low-grade inflammation, activation of HSC and other mesenchymal cells, including portal myofibroblasts participating in the deposition of extracellular matrix components and contributing to the development of fibrosis^[5,6,26]. In this study, we have provided evidence that TGZ, which activates the nuclear hormone receptor PPAR- γ , reduces the development of fibrosis and the extent of bile duct proliferation following BDL in rats. In the past 3 years, the potential role of PPAR- γ agonists as negative modulators of liver fibrosis has received considerable attention. We and others have shown that thiazolidinediones and 15deoxy- $\Delta^{12,14}$ PGJ₂ inhibit HSC activation and downregulate several biologic actions of activated HSC, which are important for liver wound healing and fibrogenesis, including cell proliferation, migration, extracellular matrix synthesis, and expression of chemokines^[13-15]. 15deoxy- $\Delta^{12,14}$ PGJ₂ also induces apoptosis and reduces matrix

expression in cultured liver myofibroblasts, which contribute to extracellular matrix production during injury, although this effect seems to be mediated by PPAR- γ -independent mechanisms^[27]. These mechanisms highlighted in *in vitro* studies are likely to contribute to the observed inhibition of the development of liver fibrosis in this *in vivo* model. Moreover, data from the present study are in agreement with recently reported findings, demonstrating that other thiazolidinediones inhibit collagen deposition in several models of chronic liver damage, including chronic intoxication with carbon tetrachloride or dimethylnitrosamine, or BDL^[28,29]. In our study, collagen accumulation was evaluated using liver hydroxyproline content, which is considered as the 'gold standard' for measuring matrix deposition. We used TGZ, the prototype of thiazolidinediones, as a PPAR- γ agonist. Although TGZ has been withdrawn from the market because of its severe hepatotoxicity^[30], it is still currently used in animal models or in cell culture systems, to establish a 'proof of concept' that may be expanded to other drugs

of the same class, such as rosiglitazone or pioglitazone^[31,32]. Thiazolidinediones also exert a protective role in other conditions of liver injury, as indicated by the recent findings, showing amelioration of ethanol- or diet-induced liver injury by pioglitazone^[33-35].

The most novel and relevant finding of the present work is the observation that treatment with TGZ inhibits bile duct proliferation or typical ductular reaction in this model and in some cases of chronic cholestasis in humans. At the level of portal tract, newly formed bile ducts progressively invade the other parts of the lobule and are surrounded by fibrous tissue. TGZ reduces formation of bile ducts as indicated by histochemical analysis of GGT that is known to be selectively expressed by bile duct cells^[36]. In addition, analysis of the enzymatic activity of GGT in total tissue homogenates has confirmed that this observation is not due to focal changes, but is the result of a general inhibitory action exerted by thiazolidinedione. The reported inhibitory effect on bile duct proliferation is indirectly in agreement with the report of Han *et al.*^[37]. Although these data may not be directly extrapolated to normal cells, they are consistent with the involvement of the PPAR- γ system in growth control of cholangiocytes. Further studies are needed to establish if the molecular mechanisms mediating the effects of TGZ on cholangiocarcinoma cells, such as elevated expression of p53, also operate in non-transformed cholangiocytes.

The intriguing findings on bile duct proliferation provide further insight on the mechanisms of reduced fibrogenesis and epithelial-mesenchymal interactions in this model. Bile duct epithelial cells express soluble mediators affecting the biology of matrix-producing cells. We have previously reported that in the BDL model, cholangiocytes express platelet-derived growth factor (PDGF)^[19], which may contribute to local accumulation of matrix-producing cells

in proximity to newly formed bile ducts, as the result of chemotaxis and proliferation^[26,38-40]. There is evidence that PDGF stimulates the conversion of peri-biliary cells to matrix-producing myofibroblasts, and that an inhibitor of PDGF receptor's tyrosine kinase activity reduces fibrosis in BDL rats^[6]. In addition, bile duct segments isolated from cholestatic rats exert a potent chemotactic action on HSC^[38]. Along these lines, secretion of endothelin-1 by cholangiocytes may induce proliferation and contraction of HSC, and inhibition of endothelin's activity is associated with reversal of fibrosis following BDL^[41-43]. Chemokines produced by cholangiocytes, such as monocyte chemoattractant protein-1 and interleukin-8^[44] are responsible for the recruitment of inflammatory cells that may amplify the fibrogenic stimulus through secretion of additional mediators. Moreover, monocyte chemoattractant protein-1 is chemotactic for activated HSC, providing an additional mechanism leading to local accumulation of fibrogenic cells^[45]. On the other hand, it is also possible that the inhibitory effects of TGZ on HSC and myofibroblasts lead to reduced secretion of mitogenic factors for cholangiocytes. Indeed, liver pro-fibrogenic cells have been shown to secrete cytokines such as interleukin-6 and hepatocyte growth factor modulating cholangiocyte survival and growth^[46,47]. Thus, a bi-directional modulation of the biology of epithelial and mesenchymal cells by soluble factors is likely to occur in this model system.

In conclusion, TGZ can affect not only the development of fibrosis through direct action on matrix-producing cells, but also may modulate the epithelial-mesenchymal interactions characterizing chronic obstructive cholestasis.

Abstract

AIM: To investigate the expressions of MUC1 and MUC5AC in intrahepatic cholangiocarcinoma (ICC). Association of expressions of mucins MUC1 and MUC5AC with clinical findings, metastasis, and survival of the liver fluke-associated ICC patients was determined.

METHODS: The expressions of MUC1 and MUC5AC mucins were examined by immunohistochemical staining in 87 cases of histologically-proven ICC. The expressions of mucins in relationship between clinicopathological significance and prognosis of the patients were evaluated.

RESULTS: Fifty-two patients (60%) exhibited both MUC1 and MUC5AC expressions, whereas 31% expressed either MUC1 or MUC5AC, and 9% expressed neither. High MUC1 immunoreactivity displayed a significant correlation with tumor progression as reflected by vascular invasion ($P < 0.001$), whereas high expression of MUC5AC significantly correlated with neural invasion ($P = 0.022$) and advanced ICC stage ($P = 0.008$). Patients with high expression of MUC1 had a significantly shorter survival ($P = 0.0002$). According to multivariate analyses, MUC1 reactivity ($P = 0.026$), histological grading and stage of tumor represented the least probability of survival.

CONCLUSION: MUC1 is overexpressed in liver fluke-associated cholangiocarcinoma and relates to vascular invasion and poor prognosis, whereas MUC5AC mucin is neoexpressed and relates to neural invasion and advanced ICC stage. High MUC1 expression in tumor may be useful for predicting the poor outcome of ICC patients.

INTRODUCTION

Cholangiocarcinoma (CC), malignancy of bile duct epithelia, is a relatively rare cancer in Western countries, but it is found frequently in Southeast Asia, especially in Northeast Thailand. The cancer is still a challenging public health problem in the region.

Risk factors for CC in Asia are obviously different from those in the Western countries, according to epidemiological and experimental studies. In Western countries, primary sclerosing cholangitis is the most strong predisposing factor, with a relative risk of 10-30% to develop CC as compared to the general population^[1,2]. In Asia, the animal studies^[3-5] and epidemiological evidence^[6] support the association of liver fluke infection with the development of cancer in this region. The different risk factors and etiology of CC among different geographic regions may lead to different carcinogenesis and pathogenesis of CC in these regions.

Liver fluke (*Opisthorchis viverrini*) infection is a major risk in Thai, Laos, and Malaysia, while *Clonorchis sinensis* infection is prominent in Japanese, Korean and Vietnamese^[7-9]. Liver flukes chronically inhabit in the biliary tree, leading to chronic inflammation, bile duct proliferation, dysplasia, and eventually, development of CC. Liver fluke *per se*, however, is not a sufficient cause to develop cancer^[3]. Potent carcinogens such as nitrosamine compounds enhance the carcinogenic effect of flukes^[10]. These compounds can be obtained from both exogenous and endogenous sources^[11,12]. The former is mostly from diet, while the latter is the byproduct of endogenous nitrosation of nitrogenous compounds, such as nitric oxides and derivatives.

CC is a slowly-growing tumor and frequently diagnosed, when the tumor is big enough to obstruct the biliary tract and produce signs and symptoms. Most of the patients are thus diagnosed at the late stage of tumor and their survival is poor, due to the original as well as disseminated tumors. At present, there is no effective tool or specific biomarkers that can indicate the early stage and status of

CC. A specific marker for either early detection or monitoring of the tumor may significantly improve the prognosis and therapeutic management of such patients.

Mucins are heavily O-glycosylated proteins, mainly expressed by ductal and glandular epithelial tissues. To date, 19 human mucin genes have been identified and designated, according to their distinct structures and functions as transmembrane mucins or secreted gel-forming mucins. Mucin genes are expressed in a cell- and tissue-specific manner, for instances, MUC2 and MUC3 in bowel^[13], MUC5AC and MUC6 in gastric tissue^[14].

Vast production of mucus is frequently found in various carcinomas. The alterations in quantity and quality of mucins have been demonstrated in cancer tissues, including CC^[15-18]. Neoexpressed and overexpressed mucins are of clinical values as a maker for supportive diagnosis, prognosis or monitoring therapy^[19-21]. In this study, we investigated the expressions of two aberrant apomucins, namely MUC1 and MUC5AC in CC tissues obtained from 87 intrahepatic cholangiocarcinoma (ICC) patients who had an active or past history of *O. viverrini* infection. The correlation between mucin expressions and their malignant potential, clinicopathological findings, and patient survival was analyzed.

MATERIALS AND METHODS

Tissue samples

Between January 1998 and December 2000, 87 surgically resected specimens of ICC were selected from the files of the Liver Fluke and Cholangiocarcinoma Research Center, Khon Kaen University, Thailand. Informed consent was obtained from each subject before surgery and the Human Research Ethics Committee, Khon Kaen University approved the research protocol (#HE43210).

Of the 87 ICC patients, 67% had a high titer of antibody against *O. viverrini*, of which 30% had active infection of *O. viverrini* as determined by the presence of parasite eggs in the bile, the others had a past history of liver fluke infection. The age, gender, tumor location, histological grading, and pTNM stage^[22] were evaluated by reviewing the medical charts and pathologic records. Tumor size was evaluated using the greatest perpendicular diameter of each liver lesion. Survival of each CC patient was recorded from the date of surgery to the date of death or to December 31, 2000. Twenty-three patients were (26.4%) lost to follow-up.

Immunohistochemistry

All specimens were fixed in 10% neutral formalin buffer, embedded in paraffin, and cut into 4- μ m-thick sections. Immunohistochemical staining was performed by an immunoperoxidase method using a mAb MUC-1-Core (Clone Ma695, Novocastra Laboratories, Newcastle-Upon-Tyne, UK) or a polyclonal anti-serum MAN-5ACI^[23].

Each section was deparaffinized and the endogenous peroxidase was blocked with 0.3% hydrogen peroxide. The sections were incubated with 1:100 MUC-1-core protein antibody, followed by 1:300 biotin-conjugated goat anti-mouse immunoglobulin (Zymed, San Francisco, CA, USA), or with 1:1 000 MUC-5ACI antisera followed by 1:300 biotin-conjugated goat anti-rabbit immunoglobulin (Zymed, San Francisco, CA, USA). The sections were then incubated

with 1:300 peroxidase-conjugated streptavidin. After being washed, the sections were reacted with 0.05% 3,3'-diaminobenzidine tetrahydrochloride (DAB, Sigma Chemical Co., St. Louis, MO, USA) and 0.1% H₂O₂ in 50 mol/L Tris-HCl pH 7.8. The positive staining was counteracted, when PBS was applied instead of the primary antibody.

The intensity of mucin expression was semi-quantitatively classified into four groups, on the basis of the percentage of positive tumor cells: 0, negative; +1, 1-25%; +2, 26-50%; and +3 >50%. For statistical analysis, the 0 and +1 were categorized as low expression, +2 and +3 as high expression.

Tumor invasion of lymphatic, vascular, or nerve tissues was identified in both tumorous and non-tumorous liver tissues. Lymphatic and vascular invasion was so accounted by the presence of infiltrating cancer cells within the lymphatic or blood vessels, respectively. Neural invasion was presented as positive cancer cells in the perineurium and/or neural fascicle.

Real-time PCR

ICC tissues with either none, low or high expressions of MUC1 or MUC5AC mucin were analyzed by real-time PCR. Total RNA was extracted from the CC tissues, using the standard acid guanidinium thiocyanate-phenol-chloroform protocol. RT-PCR was done using TaqMan[®] Gold RT-PCR Kit in a two-step reaction. The reverse transcription step was performed in 50 μ L reaction for 1 μ g total RNA. The reaction mixture was composed of 5.5 mmol/L MgCl₂, 500 μ mol/L of each dNTP, 2.5 μ mol/L random hexamers, 20 U RNase inhibitor and 62.5 U of MultiScribe[®] reverse transcriptase in regular strength TaqMan RT Buffer[®]. Incubation was at 25 $^{\circ}$ C for 10 min, at 48 $^{\circ}$ C for 30 min and at 95 $^{\circ}$ C for 5 min. The cDNA was stored in solution at -20 $^{\circ}$ C until use.

Primers and probes were originally designed by Primer Express[®] software. The DNA and cDNA sequences were obtained from the GenBank database. The sequence of the primers and TaqMan[®] probes for MUC1 and MUC5AC are presented in Table 1. The real-time PCR step was done using an ABI7700 machine (Applied Biosystems) in a 25 μ L reaction using the TaqMan[®] Gold RT-PCR Kit (GAPDH was used as the internal control). Each reaction mixture was composed of 25 ng cDNA, 5.5 mmol/L MgCl₂, 200 μ mol/L of dGTP, dATP, dCTP, and 400 μ mol/L dUTP, 100 nmol/L of the TaqMan[®] probe, 200 nmol/L of each primer, 0.25 U of AmpErase[®] enzyme and 0.625 U of AmpliTaq Gold DNA polymerase[®] enzyme in regular strength TaqMan Buffer A[®]. The reaction mixture was incubated at 50 $^{\circ}$ C for 2 min and at 95 $^{\circ}$ C for 10 min before the PCR step. The PCR cycle was performed at 95 $^{\circ}$ C for 15 s at 60 $^{\circ}$ C for 15 s and at 72 $^{\circ}$ C for 30 s. The total number of cycles for GAPDH and MUC1 mucin was 40 and 50 for MUC5AC. The comparative temperature was determined by the PCR machine and Sequence Detector 1.7[®] program.

Statistical analysis

Statistical analyses for comparisons between clinicopathologic findings, survival and MUC1 or MUC5AC expression were performed using SPSS software (Chicago, IL, USA). Association among a variety of variables, including age,

MUC5AC expression	Low (0, 1+)	41	47.1
	High (2+, 3+)	46	52.8

gender, tumor histology, tumor stage, tumor size, and invasion, was evaluated using the χ^2 test for heterogeneity or the Fisher's exact test. Multivariate analyses for variables influenced by the presence of MUC1 and MUC5AC mucins in the bile duct epithelium were carried out using a logistic regression model.

Patient survival was calculated from the time of resection to either death or the last follow-up. The Kaplan-Meier analysis was used to assess the relation of disease-free survival to the expression of mucins using the log-rank test. Several prognostic factors were evaluated for their association with the overall and disease-free survival in a multivariate analysis using Cox's regression model. $P < 0.05$ was considered statistically significant.

RESULTS

Patient characteristics

Of the 87 ICC patients explored, 59 were male and 28 were female with male to female ratio = 2:1. The mean age was 56.7 ± 8.6 years (range, 36-73 years). Most of the patients

were at advance ICC stage, with 73% lymphatic, 65% vascular, and 47% neural invasion. Thirty percent of the tumors had well-differentiated histopathological grading and 10 specimens (11%) could not be classified. The majority of patients (70%) possessed a tumor size >5 cm (Table 2).

Real-time PCR and immunohistochemistry of MUC1 and MUC5AC expressions

Alteration in glycosylation of mucin epitopes is frequent in carcinomas and this alters the assessment of mucins by a particular antibody^[24,25]. Therefore, immunohistochemical studies using different antibodies against a particular mucin have produced conflicting and inconclusive results^[26,27]. To exclude ambiguity, a semi-quantitative analysis of MUC1 and MUC5AC mucins using antibodies in the immunohistochemical staining study was checked first for their reliabilities with the mRNA transcripts obtained by real-time PCR.

The semi-quantitative immunohistochemistry of ICC tissues with none, low or high expressions of MUC1 or MUC5AC mucin using the antibodies selected in this study corresponded to the quantitative analyses of MUC1 and

MUC5AC mucin transcripts by real-time PCR. MUC1 and MUC5AC transcripts were not detectable in the tumor tissues with negative immunohistochemistry for either MUC1 or MUC5AC mucin. The levels of MUC1 and MUC5AC transcripts matched well with those of immunohistochemistry.

The immunohistochemistry demonstrated that MUC1 and MUC5AC mucins were frequently expressed in ICC (Table 2). Fifty-two patients (60%) exhibited both MUC1 and MUC5AC expressions, whereas 31% expressed either MUC1 or MUC5AC, and only 9% expressed neither. The frequency of MUC1 and MUC5AC expressions in ICC was not significantly different.

Expression of MUC1 and clinicopathological findings

MUC1 was expressed on the luminal surface, cell membrane and cytoplasm of cholangiocarcinoma cells (Figure 1A). Expression of MUC1 was observed in 77% (67/87) of ICC patients, 39.1% (34/87) of the patients had high expression. Increased expression of MUC1 did not show a preference to any histological subtypes of tumor, tumor size, or tumor stage (Table 3). However, statistical analysis showed that high expression of MUC1 significantly correlated with poor prognosis. There was a positive correlation between MUC1 expression and vascular invasion ($P < 0.001$, Figure 1B).

Expression of MUC5AC and clinicopathological findings

The site of MUC5AC expression was mainly in the cytoplasm and luminal mucin (Figure 1C). MUC5AC mucin was frequently detected in 73% (64/87) ICC tissues, 52.8% (46/87) of which were highly expressed.

Increased expression of MUC5AC showed a preference to advanced stage of the tumor ($P = 0.008$) but not to histological grading, tumor size, or tumor stage (Table 3). Tumor invasion of neighboring vascular, lymphatic and

neural tissues was common in ICC patients with MUC5AC expression. However, only neural invasion significantly correlated with high MUC5AC expression ($P = 0.022$, Figure 1D).

Expressions of MUC1 and MUC5AC mucins and cumulative survival

The median length of survival for patients with low MUC1 expression was 294 d (95%CI, 214-507 d) whereas it was 151 d (95%CI, 90-202 d) for patients with high MUC1 expression. The survival rate of patients with high MUC1 expression was significantly lower than that of patients with low MUC1 expression ($P = 0.0002$, log-rank test, Figure 2A).

The median length of survival for patients with low MUC5AC expression was 256 d (95%CI, 169-430 d) whereas it was 195 d (95%CI, 138-285 d) for patients with high MUC5AC expression. The ICC patients with high MUC5AC expression had a shorter survival than those with low MUC5AC expression, but without statistical significance (Figure 2B). There was no significant difference in survival between ICC patients with either MUC1 expression or MUC5AC expression and those with expressions of both MUC1 and MUC5AC.

The multivariate Cox's regression model showed that MUC1 (but not MUC5AC) expression ($P = 0.026$), histological grading ($P < 0.05$), and tumor stage ($P < 0.05$) statistically correlated with patient survival independent of age and gender (Table 4).

DISCUSSION

Alterations of epithelial mucin expression have been described in different malignant localizations. Varying degrees of glycosylation of MUC1 mucin between normal

and tumor cells are documented in various cancers. The carbohydrate side chains of MUC1 from breast adenocarcinomas are shorter and less densely distributed than those produced by normal breast cells^[28-30], whereas those of advanced stage or metastatic colorectal carcinomas had a high level of fully glycosylated mucin^[31]. Since different

antibodies may require different carbohydrates for their actions, the discrepancies in the immunoreactivity may be obtained, when different mucin antibodies are used^[28,29]. In our study, we have shown that the immunoreactivity obtained using MUC1 (Ma695) and MUC5AC (MAN-5AC1) antibodies corresponds to the levels of the mucin transcripts obtained

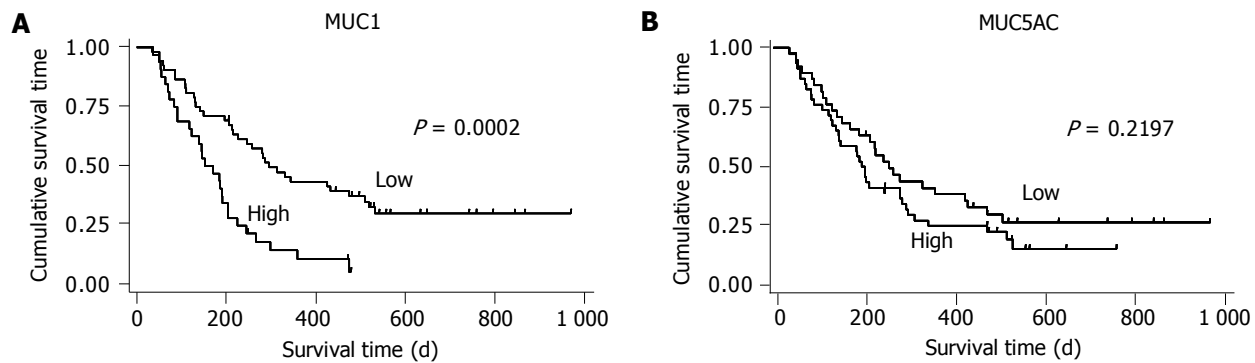

Figure 2 Survival curves using Kaplan-Meier method. **A:** Significant unfavorable prognosis of tumors with high expression of MUC1 compared to low-expression carcinoma ($P = 0.0002$); **B:** Poor survival of patients with tumors having a high

expression of MUC5AC as opposed to patients having a low-expression carcinoma.

by real-time PCR, suggesting that these antibodies are appropriate for semi-quantitative analysis of MUC1 and MUC5AC expressions in the study of immunohistochemistry.

MUC1 is a transmembrane glycoprotein found frequently in the developing intrahepatic bile ducts in fetal liver^[32] but not in the normal adult intrahepatic biliary tree^[33,34]. Overexpression of MUC1 has been reported continuously in various cancers including CC^[35,36]. Therefore, MUC1 apomucin is proposed as an oncofetal antigen in the intrahepatic biliary tree^[32]. In contrast, MUC5AC, a gel-forming phenotype of secretory mucin, is rarely expressed in the intrahepatic biliary tree^[32,35,37], and only aberrantly in CC tissues^[38,39].

In the current study, MUC1 and MUC5AC were significantly expressed in ICC patients. These ectopically expressing mucins showed a significant correlation with poor prognosis. High MUC1 immunoreactivity was associated with vascular invasion, whereas high MUC5AC expression was related to neural invasion. The results suggest that the expression of these two mucins may be influenced by different modulators and may acquire different biological pathways and different clinical courses of ICC.

Association between mucin expression and prognosis of patient outcome has been repeatedly reported in several cancers^[17,40,41] including CC. Expressions of mucin MUC4 is a statistically significant risk factor, affecting the survival of patients with ICC^[42]. Extensive expression of MUC1 apomucin is an independent risk factor for poor outcome of patients with ICC^[35,36,42] and extrahepatic CC^[43]. Our study on MUC1 expression in ICC agrees well with the previous reports. However, the association between high expression of MUC5AC mucin in tumor tissue and unfavorable survival observed here is not statistically significant. The result disagrees with our previous finding that the detection of MUC5AC mucin in the serum of CC patients^[44] correlates with shorter survival outcomes^[39]. This discrepancy may be due to the small number of samples used in the present study.

The link between MUC1 expression and malignant progression is significant in three ways. First, MUC1 is negatively charged and cells expressing high levels may repel each other^[45,46]. Cell repulsion is a pivotal event in metastasis. Decreased carbohydrate epitope on MUC1 mucin and other surface molecules markedly increases tumor cells to tumor cell adhesion and hence reduces the ability of these tumor

cells to adhere to the surrounding endothelium.

Vascular invasion involves the binding to a ligand (E-selectin) of endothelial cells and epitopes (sialyl Lewis^{x/a}) on tumor cells^[47,48]. The association between high MUC1 expression and vascular invasion found in our study may indicate the role of MUC1 in tumor adhesion to endothelial cells. This suggestion is supported by the fact that sialyl Lewis^a, a carbohydrate epitope which is present at high level in tumor and serum of CC patients, has been identified as an epitope on MUC1^[49]. In addition, our previous study indicates that CC patients with positive sialyl Lewis^a expression in tumor tissue have a significantly poorer prognosis and the expression of sialyl Lewis^a is associated with vascular invasion^[50].

Overexpression of MUC1 on the membrane of tumor cells can suppress the immunity of patients. Tumor cells with high expression of MUC1 could inhibit the interaction between cytotoxic lymphocytes and tumor cells^[51], and high levels of MUC1 correlate with immunosuppression in adenocarcinoma patients^[52]. At present, MUC1 mucin is known to serve as a target molecule for killing particular cancer cells by cytotoxic T-lymphocytes and as an antigen for cancer vaccine^[53,54]. Attempts to eliminate or control metastasis of tumor cells via anti-MUC1 and phase I/II trials of cancer vaccines using antigen MUC1 are now underway^[53].

Perineural invasion is one of the most crucial factors, which tend to yield the poor outcome after resection for biliary tract cancer, because cancer cells in the perineural space often remain on the surgical margin of the tumor after an assumed curative resection^[55,56]. In our study, MUC5AC was aberrantly expressed in ICC patients, correlated with neural invasion and advanced stage of tumor, suggesting that MUC5AC mucin plays a role in the late stage carcinogenesis and the poor prognosis of ICC patients is due to neural metastasis.

Even the presently available evidence for the association between MUC5AC mucin expression and neural invasion is limited; however, we can postulate the possible role of MUC5AC mucous layer surrounding the cancer cells in the invasion of cancer cells in several ways. First, the MUC5AC mucin layer may shield the tumor cells from immune recognition by the cellular arm of the immune system, thus favoring metastasis. Second, a number of tumor cells may

cluster as tumor emboli within the mucin layer, which may result in tumor dissemination to distant organ sites. Finally, specific epitopes of carbohydrate ligand on MUC5AC may manipulate specific adherence of tumor cells via some adhesion molecules, e.g., NCAM^[57]. Further investigation, including expression of NCAM in ICC patients with positive MUC5AC mucin expression and neural invasion is needed.

In summary, high expressions of MUC1 mucin significantly correlate with poor survival of ICC patients according to the Kaplan-Meier method. Expression of MUC1 and MUC5AC mucins is associated with metastasis, and is thus considered to be a useful prognostic marker for a poor outcome in ICC patients. We suggest that MUC1 and MUC5AC mucin immunohistochemistry may augment the classic histochemistry for diagnosis and prognosis of ICC as well as prediction of the patient outcome.

Abstract

AIM: In this study, a hepatocyte-specific targeting technology was developed by modifying cationic liposomes with soybean sterylglucoside (SG) and polyethylene glycol (PEG) (C/SG/PEG-liposomes).

METHODS: The liposomal transfection efficiencies in HepG₂ 2.2.15 cells were estimated with the use of fluorescein sodium (FS) as a model drug, by flow cytometry. The antisense activity of C/SG/PEG-liposomes entrapped antisense oligonucleotides (ODN) was determined as HBsAg and HBeAg in HepG₂ 2.2.15 cells by ELISA. The liposome uptake by liver and liver cells in mice was carried out after intravenous injection of ³H-labeled liposomes.

RESULTS: C/SG-liposomes entrapped FS were effectively transfected into HepG₂ 2.2.15 cells *in vitro*. C/SG/PEG-liposomes entrapped ODN, reduced the secretion of both HBsAg and HBeAg in HepG₂ 2.2.15 cells when compared to free ODN. After *in vivo* injection of ³H-labeled C/SG/PEG-liposomes, higher radiation accumulation was observed in the hepatocytes than non-parenchymal cells of the liver.

CONCLUSION: C/SG/PEG-liposomes mediated gene transfer to the liver is an effective gene-delivery method for hepatocytes-specific targeting, which appears to have a potential for gene therapy of HBV infections.

INTRODUCTION

Cationic liposomes have been accepted as effective non-viral vectors for gene delivery with a lower immunogenicity than the viral ones. However, the lack of organ or cell specificity sometimes hampers their applications. In the case of cationic liposomes, the highest gene expression is observed in the lung after intravenous injection of their plasmid DNA complexes in most cases, because the lung capillaries are the first traps to be encountered^[1,2]. Development of cell-specific targeting technology for cationic liposomes attracts great interest in gene therapy.

Since the liver is one of most important target organs in the body, and Kupffer cells in the liver are a part of the reticular endothelial system (RES), relatively high accumulation of administered liposomes is observed in the liver, mostly in non-parenchymal cells^[3]. However, preferential incorporation of liposomes into liver hepatocytes is required for therapeutic situations. Thus, reducing the Kupffer cell uptake and enhancing hepatocyte uptake, are challenges of research in liposome-targeting.

For cell specific delivery, the receptor-mediated endocytosis systems endowed to various cell types would be useful and a number of gene delivery systems have been developed to introduce gene into specific cells with receptor-mediated endocytosis. Ligands currently being investigated include galactose^[4,5], lactose^[6], transferrin^[7], etc. Among these receptors, asialoglycoprotein receptor (ASGP-R) is the most promising for gene targeting, since it exhibits high affinity and a rapid internalization rate^[8].

It was reported that liposomes with soybean sterylglucoside (SG) gets accumulated in the liver, especially in hepatocytes^[9,10]. Doxorubicin (DXR) entrapped in liposomes contained SG (SG-liposomes) showed a high therapeutic effect for its selective delivery of drugs to hepatocytes in animals with liver cancer^[11]. SG-liposomes have glucose residue on the surface of liposomes^[12], which is essential for selective accumulation in liver cells.

Hepatitis B is a disease of global importance with more than 300 million carriers of the hepatitis B virus (HBV) worldwide^[13]. Unfortunately, treatment of chronic HBV infection is far from satisfactory. The most successful therapeutic agent so far available is interferon-alpha, which shows a 40% response rate for patients after completion of the therapy^[14,15]. Since several viruses have become successful targets of the ODN approach, this strategy may be promising in targeting chronic HBV infection, and several studies have now shown that ODN are capable of suppressing HBV *in vitro*^[16,17] and *in vivo*^[18,19]. ODN are synthetic single chain DNA molecules that can inhibit gene expression within cells

by their capability to bind a complementary mRNA sequence, and prevent translation of mRNA, thus providing potentially powerful therapeutic tools against viral diseases and cancer^[20]. For an ODN delivery system towards HBV infection, the SG may be useful for targeting hepatocytes of the liver.

This study describes a specific targeting approach which results in increased hepatocytes uptake. A cationic liposome carrier modified with SG and encapsulated 15-mer ODN for the HBV therapy *in vitro* was constructed. The influence of SG on facilitating the uptake of liposomes by hepatocytes was investigated *in vivo*. The value of the surface modified cationic liposomes as a delivery vehicle, mainly for hepatocytes targeting antisense agent *in vitro* and *in vivo* was assessed.

MATERIALS AND METHODS

Synthesis of ODN

ODN with phosphorothioate backbone encoding the cap site of SP II promoter transcribed mRNA (cap site/SP II) sequences were synthesized using standard phosphoramidite chemistry by Aoke (Beijing, China) and purified by SDS-PAGE. The complementary ODN sequences were: 5' GAT GAC TGT CTC TTA 3'.

Animals and cell line

Male KM mice (18-23 g) were obtained from the Institute of Zoology, Chinese Academy of Sciences (Beijing, China). All animals received good care. A human hepatoblastoma cell line, HepG₂ 2.2.15 was provided by the Institute of Hepatology of the People's Hospital, Peking University (Beijing, China).

Materials

N, N-dimethylethylenediamine (99%) and cholesteryl chloroformate (97%) were obtained from ACROS (USA); dipalmitoylphosphatidylcholine (DPPC) and polyethylene glycol-distearoylphosphatidylethanolamine (PEG-DSPE) were purchased from NOF (Tokyo, Japan); SG was generously supplied by Ryukakusan Co. Ltd. (Tokyo, Japan); cholesterol (Ch) was purchased from Wako Pure Chemical Industries (Tokyo, Japan); ³H-Ch and ¹²⁵I-ODN was provided by China Institute of Atomic Energy (Beijing, China). FS was obtained from the Third Chemical Reagent Factory of Shanghai (Shanghai, China); DMEM medium and fetal bovine serum (FBS) was purchased from Life Technologies (NY, USA). 2, 5-Diphenyloxazole (PPO) and 1, 4-bis (5-phenyl-2-oxazolyl)-benzene (POPOP) were provided by Fluka (Buchs, Switzerland). Collagenase (II) was purchased from Sigma (St. Louis, MO, USA). All other chemicals were of reagent grade.

Synthesis of DC-chol

DC-chol was synthesized according to the method described by Gao^[21]. The production was confirmed by thin-layer chromatogram (TLC), melting point, ¹H nuclear magnetic resonance (NMR) (500 MHz, CDCl₃), mass spectrum (MS), etc.

Preparation of liposomes

The FS or ODN encapsulated liposomes used in the present

study were prepared according to the compositions in Table 1, respectively. A mixture of lipids in chloroform was dried under a stream of nitrogen and additionally dried under vacuum for 3 h to remove all chloroform. The dry lipid film was resuspended with FS or ODN solution (solution in 50 g/L glucose) by vortexing and sonicating, and then **extruded through 0.2 μm pore size polycarbonate filters** to generate the FS and ODN encapsulated liposomes, respectively. The concentration of lipids was 20 μmol/L. To prepare lipid-radioactive labeled liposomes, ³H-Ch was added to the lipid mixture at the beginning of the liposomes preparation and the dry lipid film was resuspended with 5% glucose. The ³H-labeled C-liposomes and C/SG/PEG-liposomes were prepared. The radioactivity of liposomes was 4 μCi/200 μL.

Determination of encapsulation efficacy of liposomes

Free ODN was separated from ODN encapsulated liposomes by equilibrium dialysis, in a dialysis tubing (SpectraPor 12 000 to 14 000 MWCO) at 4 °C for 12 h in 10 mL of 5% glucose solution. The incubation liquid was taken and the concentration of ODN was detected by UV spectro-photometer at 260 nm. Free FS was separated from encapsulated FS by passing through a Sephadex G-50 column (1 cm×20 cm). The concentration of FS was determined by measuring the fluorescence intensity of FS with excitation and emission wavelengths at 490 and 512 nm, respectively. According to the amount of ODN or FS entrapped in the liposomes, the encapsulation efficiency was calculated.

Morphology and size analysis

The size of liposomes was determined by dynamic light scattering using a Zetasizer 3 000HS (Malvern Instruments, Ltd., UK). The morphologies of these liposomes were also observed by the transmission electron microscope.

Cell culture and transfection efficiency measurement

HepG₂ 2.2.15 was maintained in DMEM medium supplemented with 100 mL/L FBS at 37 °C with 50 mL/L CO₂. The cells were scraped by 0.25% trypsin and planted in 96-well tissue culture plates (5×10³/well) for 2 d before the experiment, until the percentage of adherent cells reached approximately 70% confluence. The upper medium was removed and fresh DMEM medium was added with 100 mL/L FS encapsulated liposome. When the liposomes were incubated with cells for 3, 6, and 24 h, respectively, the cells were detached with 0.25% trypsin and washed thrice with 10 mmol/L PBS. The transfection efficiency was determined by counting the amount of cells transferred by FS with flow cytometry (BD, USA). The transfection efficiency was calculated according to the following equation: amount of FS transferred cells/amount of total cells×100%. The means of transfection efficiency were calculated from two independent experiments.

Antisense activity of ODN encapsulated in liposomes

For lipofection, HepG₂ 2.2.15 cells were seeded at an initial concentration of 1×10⁴ per well for 96-well plates. The cells were allowed to grow for about 24 h, until the percentage

of adherent cells reached approximately 80% confluence. Then the cells were washed extensively to remove the previously secreted HBsAg and HBeAg in the medium. After washing, 100 μ L free ODN or C/SG/PEG-liposomes entrapped ODN with an ODN concentration at 1.25, 2.5 or 5.0 μ mol/L, together with 100 μ L DMEM containing 10% serum, were added. The secretion of HBsAg and HBeAg into the culture supernatants was measured daily for 3 d, using ELISA immunoassay kits. The means of HBsAg and HBeAg immunoassay measurements were calculated from two independent experiments.

Liver uptake in vivo and scintillation counting

Liposomes labeled with 3 H-Ch (C-liposomes and C/SG/PEG-liposomes) were injected into the tail vein of three male mice with a dose of 200 μ L/20 g. At 0.5 and 4 h after injection, the mice were killed. The liver tissue was collected and washed with saline. About 100 mg of liver samples were decolorized in a solution, containing 200 μ L HClO₄ and 300 μ L 60% H₂O₂. Radiation scintillation fluid was added and mixed thoroughly. The radioactivity (dpm) of samples was counted on a scintillation counter (Pharmacia WALAC 1410, Turku, Finland).

Isolation of liver cells

Mice were injected intravenously by tail vein with 3 H-labeled C-liposomes and C/SG/PEG-liposomes, respectively. At 0.5 and 4 h after administration, the mice were anesthetized, and the liver was perfused via the portal vein with isotonic saline to remove the blood. Then the liver was excised, minced and digested in 0.5 g/L collagenase for 30 min at 37 °C. The suspended cells were filtered through cotton mesh sieves, followed by centrifugation at 500 r/min for 3 min. The pellets containing hepatocytes were washed thrice with saline solution by centrifugation at 500 r/min for 3 min. The supernatant containing non-parenchymal cells were similarly centrifuged and washed thrice at 1 500 r/min for 15 min. The radioactivity (dpm) of hepatocytes and non-parenchymal samples was counted on a scintillation counter, as described previously.

RESULTS

Characteristics of liposomes

The entrapment efficiencies, size, polydispersity index of all kinds of FS or ODN encapsulated liposomes are shown in Table 1. The results indicated that FS could hardly be

entrapped in the N-liposomes, with an entrapment efficiency only at 0.64%. By adding DC-chol to the N-liposomes, the entrapment efficiencies of FS and ODN were increased to more than 83%, when the charge ratio of anionic FS or ODN/cationic lipid was 1:1. The C-liposomes, C/SG-liposomes and C/SG/PEG-liposomes had small size (155.0, 117.8, and 96.2 nm for FS entrapped in liposomes, 71.0, 75.4, and 183.0 nm for ODN entrapped in liposomes, respectively). The polydispersity index indicated the uniformity in size distribution. Transmission electron micrographs of these liposomes showed spherical vesicles (data not shown).

Transfection efficiency of liposome in HepG₂ 2.2.15 cells

Figure 1 showed the transfection of FS entrapped in N-liposomes, C-liposomes and C/SG-liposomes when they were incubated for 3, 6, and 24 h with HepG₂ 2.2.15 cells at 37 °C, respectively. FS served as a fluorescent marker because the cell uptake of free FS was almost negligible. As shown in Figure 1A, the transfection of C-liposomes entrapped FS was significantly higher than that of N-liposomes, and the transfection of C/SG-liposomes entrapped FS was the highest. The enhancement of transfection efficiency was about 7.7-fold for the C/SG-liposomes than that of C-liposomes when incubated with cells for 6 h. When different types of liposomes were incubated with HepG₂ 2.2.15 cells at 37 °C for 24 h, the C/SG-liposomes showed the highest transfection efficiencies, while the C-liposomes and C/PEG-liposomes did not show significant differences (Figure 1B).

Effect of cationic liposomes entrapped ODN on HepG₂ 2.2.15 expression

Figure 2 showed the effect of cellular treatment with free ODN and C/SG/PEG-liposomes entrapped ODN on the expression level of HBsAg and HBeAg protein in HepG₂ 2.2.15 cells. The antisense effect (percent of inhibition on HBsAg and HBeAg secretion) of free ODN and C/SG/PEG-liposomes entrapped ODN was affected by the concentration of ODN and the cultured times. When the concentration of ODN that was added increased from 1.25 to 5.0 μ mol/L, the inhibition percentage of HBsAg by C/SG/PEG-liposomes entrapped ODN increased from 59.15% to 90.37% at 72 h, meanwhile, the inhibition of HBeAg increased from 42.9% to 73.43%. The inhibition effects of free ODN on HBsAg and HBeAg were decreased

Table 1 Entrapment efficiencies (EE), mean intensity diameter (D) of vesicle and polydispersity index (PI) of FS entrapped in liposomes and ODN entrapped in liposomes

Sample	Liposome compositions (molar ratio)	Entrapment of FS			Entrapment of ODN

and the inhibition effects of C/SG/PEG-liposomes entrapped ODN were increased when incubation time was increased from 24 to 72 h. The inhibition on HBeAg secretion brought by free ODN and C/SG/PEG-liposomes entrapped ODN showed lower tendency compared to the HBsAg. The cells remained viable throughout the experiments and no morphological abnormalities were observed.

Distribution in liver and intrahepatic cells in vivo

³H-Ch labeled C-liposomes and C/SG/PEG-liposomes were injected in mice at a dose of 4 μCi/20 g. At 0.5 and 4 h after injection, the radioactivity in 100 mg of liver tissue is shown in Figure 3. The distribution amount in liver tissue

(total hepatocyte and non-parenchymal cells) was not significantly different for C-liposomes and C/PEG/SG-liposomes. The uptake amounts of liposomes at 0.5 and 4 h in hepatocytes and non-parenchymal cells are also shown in Figure 3. After separating liver cells into hepatocytes and non-parenchymal cells, it was found that the uptake of C/SG/PEG-liposomes was higher than that of C-liposomes by hepatocytes at 0.5 h (*P*<0.01) and the uptake of C/SG/PEG-liposomes was lower than that of C-liposomes by non-parenchymal cells at 0.5 and 4 h (*P*<0.01). These results indicated that the C/SG/PEG-liposomes have more appetency to hepatocytes than non-parenchymal cells in the liver.

represents C-liposomes and the filled bar represents C/PEG/SG-liposomes. Data represent mean±SD, *n* = 3. The statistical significance of differences was analyzed by Student's *t*-test. ^a*P*<0.01 vs C/PEG/SG-liposomes.

DISCUSSION

Among various types of non-viral vector systems, cationic liposomes seem to be promising, because of their high gene expression efficiency. When using simple cationic liposomes by both intravenous and intraportal administration^[19,22], it is difficult to transfect into hepatocytes because liposomes prefer targeting the lung and RES. A great challenge faces the investigator who wishes to target liposomes to hepatocytes, for some disorders such as hepatitis B or metabolic diseases which require that the liposomes be steered away from their natural targets. In this study, the characteristics of SG modified liposomes and its inhibition on HBsAg and HBeAg secretion was investigated. In addition, the liver uptake and intrahepatic distribution of a labeled cationic liposome and SG modified cationic liposome were also evaluated.

To investigate the effect of DC-chol, SG and PEG-DSPE on the entrapment and transfection efficiency, FS was used as a marker. DC-chol (positively charged) can bind with FS or ODN (both negatively charged) by electrostatic interaction. Typical cationic liposomes that carry excess positive charge will interact with plasma proteins, and would be rapidly taken up into the mononuclear phagocytic system. In order to decrease the adsorption of plasma proteins and interaction with non-target cells, 6% PEG-DSPE was added into the cationic liposomes.

Entrapment of FS and ODN to cationic liposomes was very efficient, even when containing a relatively high amount of SG and PEG-DSPE (6%, Table 1). Evidently, SG and PEG coating seldom shields the positively charged liposome surface from interaction with FS and ODN.

Receptors for carbohydrates such as the ASGP-R on hepatocytes and the mannose receptor on macrophages and liver endothelial cells produce opportunities for cell-specific gene delivery with liposomal carriers. The presence of a glucoside on the surface of electrically neutral FS entrapped in C/SG-liposomes, resulted in more than a 2-fold increased transfection efficiency of HepG₂ cells, which is a human hepatoblastoma cell line that is known to express ASGP-R, when compared to C-liposomes encapsulated FS (Figure 1). It was surmised that such glucoside in SG could be identified by ASGP-R present on the surface of the HepG₂ cells, leading to liposome entry into cells through endocytosis.

The major HBsAg, and in some cases, the HBeAg, is detectable in the serum of individuals with chronically infected HBV. Serological detection of HBeAg usually correlates well with the presence of circulating virions and is commonly used clinically as an indicator of active HBV replication. Elimination of HBsAg and HBeAg from the supernatant is associated with resolution of infection with a wild-type strain of HBV. Synthetic ODN (15-mers), complementary to the cap site of SP II promoter transcribed mRNA, showed a sequence-specific, dose-dependent inhibitory effect on HBV gene expression from a concentration of 1.25–5.0 $\mu\text{mol/L}$. A previous study showed that, such ODN could inhibit the expression of HBsAg without a significant effect on total synthesized protein in the cells^[23]. According to the results of this study, it is found that the initial concentration of ODN and incubation time appeared to be important factors in obtaining a desired inhibition effect. As the ODN concentration and incubation time increased, the inhibition

efficiency of C/SG/PEG-liposomes entrapped ODN also increased (Figure 2). However, it is demonstrated that larger amounts of ODN and cationic lipid would lead to a higher toxicity to the cells; therefore, concentration of liposome-ODN complexes should be restricted at a certain level^[24]. As for the present ODN encapsulated C/SG/PEG-liposomes, a concentration of DC-chol lower than 10 $\mu\text{g/mL}$ with a cationic lipid/ODN at 1:1 of charge ratio was regarded suitable.

In the study of liver uptake of ³H labeled cationic liposomes, no significant difference was found between C-liposomes and C/SG/PEG-liposomes. These results indicated that the PEG chain and glucose residue in SG did not necessarily improve the *in vivo* behavior of cationic liposomes. Kirby *et al.*, showed that when the cationic liposomes contain only 5% of charged lipid with small zeta potential, the behavior of the cationic liposomes are not different from that of neutral liposomes^[22,25]. Our results agree with these findings. These results could be attributed to the special hepatocytes targeting behavior of SG. A previous study showed that the glucose residue on the surface of liposomes could selectively recognize the ASGP-R of hepatocytes cells^[9]. The result also demonstrated that the liver targeting effect of SG is not diminished by the PEG chain on the surface of liposomes.

In conclusion, this study established a highly efficient receptor-mediated delivery system for ODN to hepatocytes by using SG and PEG modified cationic liposomes. By utilizing this delivery system, an ODN targeting the encapsidation site of the HBV pregenome causes a strong inhibition of HBV replication *in vitro*. Therefore, SG modified liposomes may be effective vehicles to improve the delivery of ODN to the liver for the therapy of hepatotropic viruses.

Abstract

AIM: To investigate the effects of Danshao Huaxian (DSHX) capsules, a preparation of traditional Chinese medicine, on the expression of matrix metalloproteinase-1 (MMP-1), and tissue inhibitor of metalloproteinase-1 (TIMP-1) in the fibrous livers of rats.

METHODS: Eighty male Wistar rats were randomly divided into normal control group (group A), CCl₄-induced hepatic fibrosis group (group B), non-DSHX-treated group (group C), low dose-treated group (group D), and high dose-treated group (group E). Fibrous liver models in rats were induced by subcutaneous injection of CCl₄, oral administration of alcohol and high-lipid/low-protein diet for 8 wk. After the models were established, the rats in groups D and E were orally given a low dose (0.5 g/kg) and a high dose (1.0 g/kg) of DSHX daily for 8 wk, respectively. Then, the liver indexes, serum hyaluronic acid (HA) and alanine aminotransferase (ALT) were examined. The degree of hepatic fibrosis was evaluated by optical microscopy. Hydroxyproline (Hyp) in the urine was determined, and the expression of MMP-1 and TIMP-1 was detected by immunohistochemical techniques.

RESULTS: In groups D and E, the liver indexes, levels of serum HA and ALT reduced and development of hepatic fibrosis weakened significantly. The urinary Hyp and expression of MMP-1 in the liver tissues elevated, but the expression of TIMP-1 decreased obviously, as compared to groups B and C.

INTRODUCTION

Hepatic fibrosis is a common result of any chronic injury to the liver. It is characterized by excessive deposition of extracellular matrix (ECM), especially collagens I and III^[1-4]. Matrix metalloproteinase (MMP), is a member of zinc-dependent endopeptidase family, that degrades various components of ECM. In liver tissues, 8 members of MMP have been discovered^[5]. One of them is matrix metalloproteinase-1 (MMP-1) with its specific inhibitor, tissue inhibitor of metalloproteinase-1 (TIMP-1) closely correlated with liver fibrosis due to the accumulation and degradation balance of collagens I and III^[6-8]. In this study, we examined the therapeutic effect of Danshao Huaxian (DSHX) capsule on CCl₄-induced hepatic fibrosis in rats and explored its mechanism.

MATERIALS AND METHODS

Experimental animals

Eighty male Wistar rats weighing 180-220 g were provided by the Experimental Animal Center of Guiyang Medical College. The rats were randomly divided into five groups: normal control group (group A), CCl₄-induced hepatic fibrosis group (group B), non-DSHX-treated group (group C), low dose DSHX-treated group (group D), and high dose DSHX-treated group (group E). Each group consisted of 16 rats.

Chemicals and reagents

DSHX capsule containing five Chinese herbal medicines (Tetrandrine, *Radix Salviae Miltiorrhizae*, *Radix Paeoniae Rubra*,

Astragalus Membranaceus and Ginkgo leaf) was supplied by Guiyang Pharmaceutical Company. Carbon tetrachloride (CCl₄) was obtained from Chongqing Inorganic Chemistry Factory and cholesterol was from Beijing Chemical Reagent Company. Immunohistochemical kits for MMP-1 and TIMP-1, hyaluronic acid (HA) and hydroxyproline (Hyp) kits were purchased from Wuhan Boster Biological Engineering Ltd Co., Beijing Northern Biological Technical Research Institute and Nanjing Jiancheng Biological Engineering Research Institute, respectively.

Instruments

Automatic biochemical analytic instrument (Hitachi 7170A) and Olympus BX41 Microimage Collecting System were employed in the study.

CCl₄-induced liver fibrosis and sample collection

Liver fibrosis was induced in four groups by a complex method^[9]. The rats in groups B, C, D, and E received subcutaneous injections of 40% CCl₄ solution (a mixture of pure CCl₄ and peanut oil) and 0.3 mL/100 g, twice a week for 8 wk (the first dose was pure CCl₄ 0.5 mL/100 g). Meanwhile, they were fed with high-lipid/low-protein diet (79.5% corn farina, 20% fat, and 0.5% cholesterol) daily, and orally supplemented with 30% alcohol every other day. Rats in group A were fed only with normal diet. After liver fibrosis was produced, the rats in group B (by this time, only 12 rats survived) were killed and their blood and livers were collected. The wet livers were weighed and liver samples were fixed in 40 g/L formaldehyde. The serum was centrifuged at 1 500 r/min for 5 min and stored at -80 °C. DSHX capsules were then given to the rats in group D (0.5 g/kg, p.o., daily) and group E (1.0 g/kg, p.o., daily) for 8 wk. The rats in group C were given normal saline instead of DSHX. At the end of the experiment (by this time, the rat survivors in group A and groups C-E were 16, 10, 10, and 10, respectively), all the rats were killed, the liver and serum samples were handled in the same way as mentioned above.

Liver index calculation

Liver index was calculated according to the formula (liver weight/body weight)×100%.

Measurements of serum HA and ALT

Concentrations of serum HA and alanine aminotransferase (ALT) were measured by radioimmunoassay or automatic biochemical analytic instrument (Hitachi 7170A).

Histopathological examination

An equal portion of liver from each rat (1 cm×1 cm×0.5 cm) was fixed in 40 g/L formaldehyde for 48 h, embedded in paraffin, and sectioned with a microtome. The 5-μm-thick sections were stained with hematoxylin and eosin for general histopathology examination. Van-Gieson staining was performed for evaluating the severity of liver fibrosis. Liver fibrosis was classified as previously described^[10].

Urinary Hyp determination

The 24 h urine of the rats in each experimental group was collected for determination of urinary Hyp in the 8th wk

and at the end of the experiment, respectively.

Expression of MMP-1 and TIMP-1

The expressions of MMP-1 and TIMP-1 were detected by the streptavidin-biotin complex (SABC) immunohistochemical technique strictly following the directions offered. PBS was used as the negative control to produce MMP-1 and TIMP-1 polyclonal rabbit IgG. Finally, the number of positive cells per field of vision at 400× magnification was counted.

Statistical analysis

Quantitative data were expressed as mean±SD and subjected to one-way analysis of variance, followed by *t* test for multiple comparisons. Ordinal data were analyzed by Radit analysis. *P*<0.05 was considered statistically significant.

RESULTS

Effect of DSHX on liver index, concentration of serum HA and ALT in rats

As shown in Table 1, compared to group A, the liver index and concentrations of serum HA and ALT of rats in group B and group C increased greatly (*P*<0.05). After 8 wk of treatment with DSHX, the liver index and concentration of serum HA and ALT in groups D and E, reduced obviously compared to those in groups B and C (*P*<0.05).

Table 1 Liver index, serum HA, and ALT in rats of each group (mean±SD)

Group	<i>n</i>	Liver index (relative liver weight)	HA (ng/mL)	ALT (U/L)
A	16	0.0249±0.0027	192.52±41.97	32.40±2.30
B	12	0.0423±0.0044 ^b	316.17±78.48 ^a	174.50±6.02 ^b
C	10	0.0295±0.0019 ^{b,d}	300.86±72.73 ^a	104.75±6.54 ^{b,d}
D	10	0.0268±0.0028 ^{d,e}	224.92±36.62 ^{c,e}	96.13±4.94 ^{d,e}
E	10	0.0267±0.0017 ^{d,f}	200.78±31.71 ^{c,e}	93.13±5.79 ^{d,f}

^a*P*<0.05, ^b*P*<0.01 vs normal control group; ^c*P*<0.05, ^d*P*<0.01 vs hepatic fibrosis group; ^e*P*<0.05, ^f*P*<0.01 vs non-DSHX-treated group.

Effect of DSHX on degree of hepatic fibrosis

After HE and V-G staining, hepatocytes of the normal control rats were arrayed radially along the central vein and there were no collagen fibers. The lobular structure of the liver was destroyed and the hepatic cords were disordered in the rats of group B. Also, the fibrous connective tissues containing numerous inflammatory cells regenerated in the portal area. Meanwhile, collagen fibers expanded into the hepatic parenchyma and there appeared fibrous septa surrounding and separating the normal lobules. The degree of hepatic fibrosis in this group was significantly serious compared to that in group A (*P*<0.01). The hepatic fibrosis in group C was alleviated and the fibrous septa were thinner than those in group B. Except for the obvious expansion of collagen fibers, pseudo lobules were also found in some severe samples from group C. The lobular structure in groups D and E was ameliorated significantly, and regeneration of fibrous connective tissues and septa reduced as compared to that in groups B and C. The degree of the hepatic fibrosis in each group is shown in Table 2.

Table 2 Degree of hepatic fibrosis in rats of each group

Group	n	Degree of hepatic fibrosis						Average
		0	I	II	III	IV	V	
A	16	16	0	0	0	0	0	0
B	12	0	0	0	1	7	4	4.25 ^d
C	10	0	1	4	3	2	0	2.60 ^{df}
D	10	1	3	5	1	0	0	1.60 ^{af}
E	10	1	6	2	1	0	0	1.30 ^{bf}

^a*P*<0.05 and ^b*P*<0.01 *vs* non-DSHX-treated group; ^d*P*<0.01 *vs* normal control group; ^f*P*<0.01 *vs* hepatic fibrosis group.

Effect of DSHX on urinary excretion of Hyp

Urinary Hyp is an useful index to evaluate the degradation of hepatic collagen. Compared to group A, the Hyp excretion increased in groups B and C. After being treated with DSHX, Hyp in the urine of groups D and E was more than that in groups B and C, suggesting that DSHX capsule could facilitate degradation of collagen (Table 3).

Table 3 Urinary excretion of Hyp (μg/24 h) in rats of each group (mean±SD)

Group	n	Urinary excretion of Hyp
A	16	47.80±5.76
B	12	62.00±6.40 ^b
C	10	182.44±30.83 ^b
D	10	242.76±49.76 ^d
E	10	541.09±73.39 ^{df}

^b*P*<0.01 *vs* normal control group; ^d*P*<0.01 *vs* hepatic fibrosis group; ^f*P*<0.01 *vs* non-DSHX-treated group.

Effect of DSHX on expression of MMP-1 and TIMP-1

Immunohistochemical (SABC) study showed that there were only a small number of cells with positive light yellow staining of MMP-1 and TIMP-1 in the normal livers. MMP-1 was observed only in some hepatocytes and stromal cells, whereas TIMP-1 was mainly distributed in vascular endothelial cells and some fibroblasts in the portal area. In the livers of groups B, C, D, and E, the cells with MMP-1 and TIMP-1 positive staining were detected in the fibrous septa and stained dark yellow. The expression of MMP-1 and TIMP-1 in group B was higher than that in group A (*P*<0.01). Compared to groups B and C, the expression of MMP-1 in groups D and E increased significantly, whereas that of TIMP-1 decreased sharply. The results are shown in Table 4.

Table 4 Percentage of expression of MMP-1 and TIMP-1 in each group (mean±SD)

Group	n	MMP-1 (%)	TIMP-1 (%)
A	16	0.595±0.87	1.08±0.68
B	12	5.956±1.85 ^f	9.04±1.60 ^f
C	10	5.104±2.20 ^f	6.46±1.77 ^{bf}

DISCUSSION

DSHX capsule is a mixed preparation, composed of five traditional Chinese herbal medicines. We previously reported that DSHX is effective in prevention of hepatic fibrosis^[11]. In this study, we found that after DSHX treatment of rats with liver fibrosis for 8 wk, the relative liver weight and concentration of serum HA and ALT significantly reduced and liver fibrosis was alleviated, suggesting that DSHX possesses a therapeutic effect on CCl₄-induced hepatic fibrosis in rats by attenuating liver inflammation, preventing necrosis of hepatocytes and promoting their generation.

Hepatic fibrosis is a common consequence of enhanced ECM synthesis and weakened breakdown of proteins in the connective tissue, which lead to increased deposition of ECM in the extracellular matrix. The main component of ECM in normal liver is collagen, which is divided into types I, III-VI. Except for these collagen fibers, there are many other non-collagen components, including fibronectin, laminin, tenascin, and entactin^[12]. In fibrous liver, overaccumulated ECM is mainly interstitial collagens (types I and III). Activated hepatic stellate cells (HSCs) are the main source of ECM^[13-17] during liver fibrosis. HSCs in the space of Disse are in a quiescent form without fibrogenic activity, in part because they are in contact with a complex ECM composed of collagen type IV, laminin, and proteoglycans^[18]. When separated from these factors, they are activated into a pro-fibrogenic myofibroblastic phenotype. The expression of MMP-2 increases obviously after liver injury, which may result in excess degradation of type IV collagen and disorder of the microenvironment of the space of Disse, and then HSCs become activated. Meanwhile, Kupffer cells generate cytokines in response to liver injury, in which HSCs are activated and ECM is overexpressed. Normally, deposition of matrix components in liver is well controlled through constant remodeling by matrix-degrading enzymes. MMP is the most important among ECM-degrading enzymes. MMP, a zinc-dependent endopeptidase, can degrade specific components of ECM and its biological activity can be suppressed by TIMPs^[19]. MMPs are released by a variety of cells (macrophages, neutrophils, endothelial cells, etc.) and participate in such physiological and pathological processes as ECM degradation, tissue remodeling, angiogenesis, and tumor invasion^[20-22].

Till now, 26 members of the family of MMPs have been identified^[22] and with the following characteristics^[23-25]. (1) Structurally, there is a zinc atom at the active site; (2) they are often in an inactivated form, when produced; (3) their primary structures contain two highly conserved sequences, a N-terminal peptide domain and a catalytic domain; and (4) they can be inhibited by specific inhibitors known as TIMPs. The activities of MMPs are regulated at the transcriptional level, through zymogen activation and suppression by a family of inhibitory proteins, TIMPs. Four members of the TIMP family have been identified so far, including TIMPs 1-4, which are named in the order of their discovery. Their sequences possess a highly conserved secondary structure interacting with proteins via six conserved disulfide bonds. It seems that there are two domains in the TIMP molecule, a N-terminal domain that is endowed with inhibition of metalloproteinase and a C-terminal domain

that may be important in protein location or combination with progelatinases^[26]. TIMPs act widely and their most important action is to inhibit the activity of MMPs. TIMPs can interact with MMPs to inhibit their activities at 1:1 stoichiometry^[27-29]. MMP-1, a member of the MMP family that specifically degrades native collagen types III and I, plays an important role in the accumulation and degradation balance of ECM. The level of MMP-1 increases transiently in the early stage of liver fibrosis, but becomes undetectable in the stage of cirrhosis^[30]. In contrast, the level of TIMP-1, a specific tissue inhibitor of MMP-1, elevates consistently in the fibrosis process and reaches its peak in the stage of cirrhosis. Upregulation of TIMP-1 and downregulation of MMP-1 result in the inhibition of degradation of collagen types I and III, which leads to overexpression and deposition of ECM in the extracellular matrix.

In addition to inhibiting the degradation of matrix, TIMP-1 plays a significant role in regulation of the apoptosis of such cells such as B lymphocytes, breast epithelial cells and HSCs. TIMP-1 inhibits the apoptosis of HSCs, indicating another possible mechanism whereby it is implicated in the pathogenesis of liver fibrosis. In this study, we found that MMP-1 in the two groups treated with DSHX was overexpressed, whereas the expression of TIMP-1 reduced significantly. We conclude that DSHX can reverse the process of liver fibrosis by upregulating the gene expression and generation of MMP-1 and downregulating the TIMP-1 expression. These results may provide a therapeutic strategy to combat hepatic fibrosis by targeting MMP-1 and TIMP-1.

Abstract

AIM: To evaluate the effects of dietary supplementation with vitamin E and selenium on proliferation and apoptosis of hepatic stellate cells (HSCs), in acute liver injury induced by CCl₄, and to explore their role in the recovery from hepatic fibrosis phase.

METHODS: An acute liver damage model of rats was established by intraperitoneal injection of carbon tetrachloride (0.3 mL/100 g body weight) twice a week, then the rats were killed at 6, 24, 48, and 72 h after the first and third injection, respectively. A liver fibrosis model was established by the same injection for 8 wk. Then three rats were killed at 3, 7, 14, and 28 d after the last injection, respectively. The rats from the intervention group were fed with chow supplemented with vitamin E (250 mg/kg) and selenium (0.2 mg/kg), and the rats in the normal control group and pathological group were given standard chow. Livers were harvested and stained with hematoxylin and eosin, Sirius red. Activated HSCs were determined by α -smooth muscle actin immunohistochemistry staining. Apoptotic HSCs were determined by dual staining with the terminal deoxynucleotidyl transferase UTP nick end labeling (TUNEL) and α -smooth muscle actin immunohistochemistry. Serum alanine aminotransferase and aspartate aminotransferase were also analyzed.

RESULTS: In the acute liver damage model, the degree of liver injury was more serious in the pathological group than in the intervention group. At each time point, the number of activated HSCs was less in the intervention group than in the pathological group, while the number of apoptotic HSCs was more in the intervention group than in the pathological group. In the liver fibrosis model, the degree of liver fibrosis was more serious in the

pathological group than in the intervention group. At each time point, the number of activated HSCs was less in the intervention group than in the pathological group, and the number of apoptotic HSCs was more in the intervention group than in the pathological group.

CONCLUSION: Vitamin E and selenium supplementation at the given level can inhibit CCl₄-induced activation and proliferation of HSCs and promote the apoptosis of activated HSCs in acute damage phase. Vitamin E and selenium can also effectively decrease the degree of hepatic fibrosis and promote the recovery process.

INTRODUCTION

Liver fibrosis is characterized by increased deposition of extracellular matrix, and its mechanism is extremely complex. The common understanding about liver fibrosis is that the activation and proliferation of HSCs, a major source of extracellular matrix, play a key role in liver fibrogenesis^[1,2]. Activated HSCs express α -SMA and are the major source of collagens and other matrix proteins which result in fibrosis. Resolution of liver fibrosis is associated with a net loss of activated HSCs mediated by apoptosis. Therefore, promoting HSC apoptosis may be a viable method to facilitate matrix degradation in fibrotic liver^[3,4].

Studies have shown that oxidative stress is one of the mechanisms in the development of liver fibrosis^[5-8], it is worth investigating the therapeutic role of antioxidative nutrients in hepatic fibrosis. A wealth of evidence indicates that antioxidative nutrients such as vitamin E and selenium can prevent liver fibrosis induced by carbon tetrachloride (CCl₄)^[9,10]. The major mechanism by which CCl₄ induces rat liver fibrosis is that CCl₃• results in a series of lipid peroxidation reactions. The activation of HSCs is enhanced with the increasing CCl₄ concentration^[11]. The results from our previous study confirmed, that dietary supplementation with vitamin E and selenium can protect hepatocytes and prevent liver fibrosis induced by CCl₄ in rat model^[12]. However, the mechanism of the effects is still not clear.

Therefore, rat acute liver injury and hepatic fibrosis models were established by intraperitoneal injection of CCl₄. Dietary supplementation with proper doses of vitamin E and selenium was given to rats in order to determine whether the antioxidative nutrients had an effect on the proliferation and apoptosis of activated HSCs during liver injury or recovery from liver fibrosis *in vivo*.

MATERIALS AND METHODS

Animal model of acute liver damage and liver fibrosis

One hundred and fifty-six male Sprague Dawley rats (Shanghai Xipuer-bikai Company) weighing 250-300 g were randomly divided into normal control group, pathological group, and intervention group, 52 rats each group. The rats were fed with chow supplemented with vitamin E (250 mg/kg) and selenium (0.2 mg/kg diet) in the intervention group, and the rats in the other two groups were given standard chow. After 2 wk, the rats were injected with saline in the normal control group, and those in the other two groups were intraperitoneally injected with 0.3 mL/100 g body weight sterile CCl₄ at 1:1 with olive oil twice a week. In the acute liver damage model, five rats were killed at 6, 24, 48, and 72 h after the first and third injection. In the liver fibrosis model, the same dose of CCl₄ was given to rats for 6 wk, then the dose of CCl₄ was reduced to 0.15 mL/100 g body weight for another 2 wk. Starting from the 8th wk, three rats were killed at 3, 7, 14, and 28 d after the last injection. Livers and serum were collected, one lobe from each liver was fixed in buffered formalin for histological observation. Serum alanine aminotransferase and aspartate aminotransferase were analyzed.

Pathological observation of liver

Liver sections were stained with hematoxylin and eosin, Sirius red. Pathological changes of the liver were observed. Five low power fields (×4) of each slide were randomly selected. The IMS color image integrate system was used to get the total area with Sirius red positive changes of these 5 views. The mean of area was calculated at each time point.

Measurement of serum alanine aminotransferase and aspartate aminotransferase during acute liver damage phase

Serum was collected at each time point in the model of acute liver damage. Alanine aminotransferase and aspartate aminotransferase were tested by Beckman automatic clinic biochemistry system.

Quantification of activated HSCs during acute liver damage and recovery from fibrosis

Activation of HSCs was associated with expression of

α-smooth muscle actin (α-SMA). Immunostaining for α-SMA was used to detect and quantify activated HSCs in each specimen of the liver. The liver section of each rat at each time point was immunostained with horseradish peroxidase-conjugated secondary antibody (monoclonal anti α-SMA, Envision™, DAKO Company) for its expression of α-SMA, and identified by DAB(brown). The number of α-SMA positive cells of each liver slide was counted in 30 randomly selected high power fields (×40) by two observers, one of whom was blinded. If the difference in results between the two observers was higher than 10%, the slides were recounted.

Determination of activated HSCs undergoing apoptosis by double stain with TUNEL and α-SMA

The liver section of each rat was treated with 0.3% H₂O₂, 180 μg/mL proteinase K, then fragmented DNA in apoptotic cells was detected by TUNEL technique. The Boehringer TUNEL staining kit(German) was used following the manufacturer's instructions. TUNEL positive nuclei were identified by NBT/BCIP (violet) and immunostaining for α-SMA with horseradish peroxidase-conjugated secondary antibody (brown). Cells expressed both in TUNEL (with violet nuclei) and in immunostaining for α-SMA (with brown cell plasma) were considered as apoptotic HSCs. Each slide was then analyzed by two researchers as described above.

Statistical analysis

The data were expressed as mean±SD and analyzed by ANOVA. *P*<0.05 was considered statistically significant. All analyses were conducted by SPSS 10.0 statistical package. All the charts were drawn by excel 2000.

RESULTS

Histology of acute liver damage

After injection of CCl₄, livers of the rats were damaged and swollen and became yellow, perivenular ballooning degeneration was present, the pathological changes increased with the increase of time. At each time point, the lesion was more serious in the pathological group than in the intervention group.

Serum alanine aminotransferase and aspartate aminotransferase levels during acute liver damage

Because there was no significant difference at different time points after the first or third injection of CCl₄, the data were regrouped into one group for statistical analysis. The lesion in the pathological group was more serious than that in the intervention group, and became worse with the increase of time (Table 1).

Table 1 Comparison between ALT and AST (mean±SD)

	ALT (IU/L)		AST (IU/L)	
	After the first injection	After the third injection	After the first injection	After the third injection
Intervention group (<i>n</i> = 20)	289.6±80.7 ^{a,b}	446.4±136.5 ^b	63±16.9 ^{a,b}	219.9±98.2 ^a
Pathological group (<i>n</i> = 20)	396.5±134.4 ^b	781.6±295.7	85.3±57.9 ^b	362.5±129.6
Normal control group (<i>n</i> = 20)	256.4±71.6	194.1±69.7	53.9±20.1	58.5±25.0

^a*P*<0.05 vs pathological group; ^b*P*<0.01 vs third injection.

Histology of liver fibrosis recovery

Three days after the last injection of CCl₄, the livers of rats were swollen, yellow, hard and had hepatocyte fatty degeneration with many fibrotic septae. The changes were more serious in the pathological group than in the intervention group. After 28 d of the last injection, the degree and areas of hepatocyte fatty degeneration decreased, compared to those in the normal control group.

Quantification of collagen fiber during acute liver damage (Sirius red staining)

Also, because there was no significant difference at different time points after the first or third injection of CCl₄, the data were regrouped into one group for statistical analysis. Collagen fibers in the intervention group were significantly more than those in the pathological group after the first and third injection of CCl₄, but no significant difference was observed between the first and the third injection (Table 2).

Table 2 Quantitative analysis of collagen fibers during acute liver damage (Sirius red staining, mean±SD)

	After the first injection (pixel)	After the third injection (pixel)
Pathological group (n = 20)	2 686.3±1 109.4 ^b	1 843.5±706.7 ^a
Intervention group (n = 20)	6 351.3±524.2	5 992.0±2 637.2
Normal control group (n = 20)	2 785.5±294.1	2 978.5±214.8

^aP<0.05 vs intervention group; ^bP<0.01 vs intervention group.

Quantification analysis of collagen fibers during liver fibrosis recovery (Sirius red staining)

In the liver fibrosis recovery model, the amount of collagen

fibers 3, and 7 d after the last injection of CCl₄ was much more than that in the model of acute liver injury. The amount of collagen fibers decreased with the changes of time, but was still more than that in the normal control group on d 28. At each time point, the amount of collagen fibers in the pathological group was more than that in the intervention group (Table 2, Figure 1).

Figure 1 Area of collagen fiber at each time point during recovery of liver fibrosis.

Change of activated HSCs during acute liver damage

Twenty-four hours after the first injection of CCl₄, the number of activated HSCs in the pathological and intervention groups began to increase, and reached the peak after 72 h. The number of activated HSCs began to decrease, 6 h after the third injection. The number of activated HSCs in the intervention group was less than that in the pathological group and more than that in the normal control group (Figures 2A, B).

Change of activated HSCs during liver fibrosis recovery

In the pathological and intervention groups, the activated

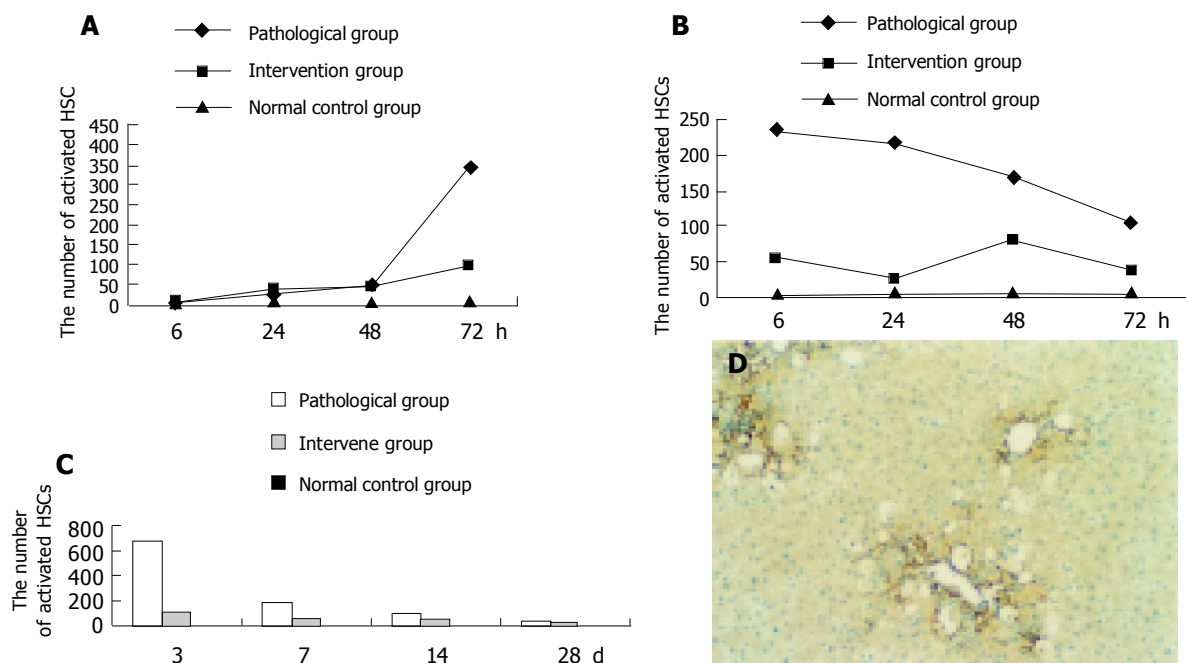

Figure 2 Change of activated HSCs after the first (A) and third (B) injection, during liver fibrosis recovery (C) and positive for α-SMA Immunohistochemistry

staining (D).

HSCs were clustered around the fibrotic septae. The number of activated HSCs decreased gradually 7 d after injection of CCl₄, and was still more than that in the normal control group 28 d after injection of CCl₄. At each time point, the number of activated HSCs in the intervention group was less than that in the pathological group (Figures 2C and D).

Apoptosis of activated HSCs during acute liver damage

Twenty-four hours after the first injection of CCl₄, the apoptotic HSCs began to increase gradually, and the number of apoptotic HSCs in the intervention group was more than that in the pathological group. As expected, 6, 24, 48 h after the first injection, the number of apoptotic HSCs in the intervention and pathological groups was less than that in the normal control group (Figure 3).

Figure 3 Apoptosis of activated HSCs after the first injection (A) and apoptotic HSCs positive for both TUNEL staining (violet) and α -SMA immunohistochemistry staining (brown) (B).

Apoptosis of activated HSCs during liver fibrosis recovery

The apoptotic HSCs decreased gradually in the pathological and intervention groups after injection of CCl₄, but was still more than that in the normal control group, 28 d after injection of CCl₄. The number of apoptotic HSCs in the intervention group was more than that in the pathological group at each time point during liver fibrosis recovery, and was much more in the intervention and pathological groups than in the normal control group (Figure 4).

DISCUSSION

Experiment design

The dosage of CCl₄, vitamin E, and selenium used in the study was selected as previously described^[12-14]. Tests were carried out at different time points during acute damage

and recovery, because it was reported that this is the best way to observe the continual changes of HSCs *in vivo*^[15].

Vitamin E and selenium protect hepatocytes and promote recovery from liver fibrosis

The results from histology and serum ALT and AST showed that vitamin E and selenium reduced liver damage during acute liver injury and had the effect of decreasing collagen fibers, thus preventing liver fibrosis. Hepatocyte damage or liver fibrosis as shown by many variables at each time point was different.

In the model of acute liver injury, although α -SMA immunostaining showed that the number of HSCs in the intervention group was less than that in the pathological group at each time point, Sirius red staining showed that the number of collagen fibers in the intervention group was more than that in the pathological and normal control groups, suggesting that vitamin E and selenium may promote the synthesis of collagen fibers. Since the synthesis of collagen also is a positive repairing response to hepatocyte injury, vitamin E and selenium can prevent liver damage during acute liver injury, not only by affecting HSCs but also by other ways. This needs to be confirmed by further studies.

Effect of vitamin E and selenium on proliferation and apoptosis of HSCs during acute liver damage

The number of activated HSCs in the intervention group was less than that in the pathological group and more than that in the normal control group during acute damage phase. Meanwhile, the number of apoptotic activated HSCs in the intervention group was more than that in the pathological group and less than that in the normal control group, suggesting that CCl₄ breaks the normal balance between activation and apoptosis of HSCs, resulting in more activation and lesser apoptosis. When the injury continues, more and more activated HSCs are generated thus producing more and more collagen fibers and leads to fibrosis. Vitamin E and selenium can inhibit the activation of HSCs and promote their apoptosis during acute damage phase, which helps to rebuild the balance between activation and apoptosis of HSCs, thus preventing liver fibrosis.

Effect of vitamin E and selenium on proliferation and apoptosis of HSCs during recovery from liver fibrosis

As expected, the number of apoptotic HSCs was more and that of activated HSCs was less than in the pathological

Figure 4 Number of apoptotic HSCs during recovery from liver fibrosis.

group, suggesting that vitamin E and selenium can promote apoptosis of HSCs during recovery from liver fibrosis. During this stage, both activated and apoptotic HSCs in the pathological and intervention groups were more than those in the normal control group.

Iredale *et al.*^[15], have examined an experimental model of fibrosis during progressive and recovery phase to determine whether activated HSCs underwent apoptosis during spontaneous resolution of fibrosis *in vivo*, which is consistent with our results in the pathological group, suggesting that HSCs play a central role in the development and resolution of liver fibrosis.

Furthermore, the data in our study demonstrate that it needs more than 28 d for the rats to recover from hepatic fibrosis.

Activation and proliferation of HSC are the key to the formation of hepatic fibrosis, and apoptosis of HSCs is the crux of the recovery of fibrosis. Therefore, the disease can be intervened by inhibiting the activation of HSCs and inducing apoptosis. Our data show that vitamin E and selenium supplementation may be one of the mechanisms underlying the recovery of fibrosis^[12]. Meanwhile, vitamin E and selenium may be an effective anti-fibrotic approach.

Abstract

AIM: To study the protective effect of acupuncturing Tsusanli (S_T36) on cold stress ulcer, and the expression of nitric oxide synthase (NOS) in hypothalamus and adrenal gland.

METHODS: Ulcer index in rats and RT-PCR were used to study the protective effect of acupuncture on cold stress ulcer, and the expression of NOS in hypothalamus and adrenal gland. Images were analyzed with semi-quantitative method.

RESULTS: The ulcer index significantly decreased in rats with stress ulcer. Plasma cortisol concentration was up regulated during cold stress, which could be depressed by pre-acupuncture. The expression of NOS1 in hypothalamus increased after acupuncture. The increased expression of NOS2 was related with stress ulcer, which could be decreased by acupuncture. The expression of NOS3 in hypothalamus was similar to NOS2, but the effect of acupuncture was limited. The expression of NOS2 and NOS3 in adrenal gland increased after cold stress, only the expression of NOS1 could be repressed with acupuncture. There was no NOS2 expression in adrenal gland in rats with stress ulcer.

CONCLUSION: The protective effect of acupuncturing Tsusanli (S_T36) on the expression of NOS in hypothalamus and adrenal gland can be achieved.

INTRODUCTION

Hypothalamus is a higher vegetative nerve center, which can accommodate not only the viscera activation, but also some important physiological functions, such as body temperature regulation, endocrine regulation and emotional response. Damage to this region would lead to acute gastric mucosal lesion.

Glands play an important role in the processes of stress. Psychological and physical stress may result in acute gastric mucosal lesions. It was reported that stress relates to nitric oxide (NO) catalyzed by nitric oxide synthase (NOS)^[1,2]. Studies have demonstrated that NO also plays an important role in the healing process of both gastric and duodenal ulcers^[3].

In this study, we focused on the protective effect of acupuncturing Tsusanli (S_T36) on cold stress ulcer and the expression of NOS in hypothalamus and adrenal gland.

MATERIALS AND METHODS

Animals

Twenty-two adult male Sprague-Dawley (SD) rats weighting 250±25 g were provided by Experimental Animal Center of PLA General Hospital.

The rats were divided into three groups randomly, 6 in control group, 8 in cold stress group (stress group), and 8 in pre-acupuncture group (pre-acupuncture group). Cold stress was induced in rats of stress group, pre-acupuncture group received pre-acupuncture treatment for 1 wk, before cold stress was induced. Control group received no treatment. Rats were housed at controlled temperature and humidity in 12 h light/dark cycle. The animals had free access to food and water.

Cold stress ulcer rat model

SD rats were fasted for 24 h and water was deprived for 1 h before the experiments. The rats were fixed on board after being anesthetized with ether and then they were put into the cold room for 3 h.

The cold stress ulcer rat model was successfully established. There were point and line hemorrhage or superficial ulcer (1-2 mm in diameter).

Electro-acupuncture treatment

The rats were placed into tailor-made mouse cages, and their bilateral legs were sufficiently exposed. Acupuncture at Tsusanli (S_T36) was performed.

The rats were acupuncture with electrical needles (WQ1002K, electro-acupuncture equipment company, China) at 9-10 am, 30 min each time for 7 d. The frequency was 2-20 Hz. The original intensity was 2 V, and increased by 1 V every 10 min. No stimulation was given to the control group.

Rats were killed, hypothalamus and adrenal gland were preserved in liquid nitrogen for expression of NOS by reverse transcriptase-polymerase chain reaction (RT-PCR). Plasma cortisol levels were measured by specific radioimmunoassay (RIA). Biopsy mucosal samples were taken for the measurement of ulcer size, preserved and fixed in 40 mg/L formaldehyde solution for HE staining and then photographed under microscope.

Ulcer index (UI)

The ulcer index calculation was expressed as^[4] 1 score, if there was blotch erosion, 2 scores, when the erosion length was less than 1 mm, 3 scores, when the erosion length was 1-2 mm, 4 scores, when the erosion length was 2-3 mm, and 5 scores, when the erosion length was greater than 4 mm.

Total RNA extraction from hypothalamus and adrenal gland

Total RNA was extracted using TRIzol one-step extraction method. Ultraviolet spectrophotometer was used to determine its concentration and purity.

RT-PCR protocol

All laboratory chemicals were obtained from Sigma Chemical Company.

cDNA was reverse transcribed using 20 µg total RNA, including Oligo dT (1.5 µL), dNTPs [25 mmol/(L µL), 2 µL] and DEPC water (26 µL). In PCR procedure, 30 µL of the reaction system was used including 10× buffer (3 µL), dNTPs [2.5 mmol/(L µL), 1.8 µL], sense primer [10 pmol/(L µL), 1.2 µL], anti-sense primer [10 pmol/(L µL), 1.2 µL], cDNA (1.2 µL/per tube) and MilliQ H₂O (20.3 µL). Thirty-two cycles of RT-PCR were amplified at 94 °C for 30 s, at 58 °C for 30 s, and at 72 °C for 1 min.

The following primer sequences were used (Beijing SBS Company, China): rNOS1-sense: 5' > CGC AGA ACA CAT CAC AGG <3'; rNOS1-antisense: 5' > AGA ACG GGG AGA AAT TCG <3' (450-bp product);

rNOS2-sense: 5' > TGT TCC ATG CAG ACA ACC <3'; rNOS2-antisense: 5' > TTC AGA AGC AGA ATG TGA CC <3' (407-bp product);

rNOS3-sense: 5' > CCT TTG ATC TCA ATG TCG <3'; rNOS3-antisense: 5' > TAC GAA GAA TGG AAG TGG <3' (374-bp product);

β-actin was used as control, its primer sequences: 5' > AAC CCT AAG GCC AAC CTG GAA AAG <3', and 5' > TCG TGA GGT AGT CTG TCA GGT <3' (241-bp product).

After completion of the PCR amplifications, 10 µL of each PCR reaction was added to each lane of 2% agarose gel. The gel was then stained with 1 µg/mL ethidium

bromide, viewed with a transilluminator, and photographed using UVP-GDS7600 gel image system to perform semi-quantitative analysis.

Statistical analysis

SPSS was used to perform statistical analysis and mapping. The data in experiments for ulcer index and plasma cortisol were presented as mean±SE, and analyzed by Student's *t*-test for unpaired samples. Data for RT-PCR were analyzed by one-way analysis of variance (ANOVA) followed by a post hoc Duncan's test. *P*<0.05 was considered statistically significant.

RESULTS

Plasma cortisol concentration (nmol/L)

Plasma cortisol concentration was 104.38±8.31 in stress group, 66.83±12.25 in pre-acupuncture group, and 79.1±11.07 in control group. Difference was statistically significant in three groups (*P*<0.01 or *P*<0.05, Figure 1).

Figure 1 Effects of acupuncture at Tsusanli (S_T36) on plasma cortisol concentration in rats with stress ulcer.

Result of UI

UI was 26.25±4.40 in stress group, 9.75±1.91 in pre-acupuncture group and 0 in control group (*P*<0.01).

Data for NOS mRNA expression in hypothalamus (Figure 2)

Expression of NOS1 mRNA The ratio of NOS1 mRNA to β-actin mRNA was 0.69±0.05 in control group, 0.77±0.09 in stress group, and 1.87±0.15 in pre-acupuncture group. There was a significant difference compared between acupuncture group and control group (*P*<0.01), but no significant difference was found between stress group and control group.

Expression of NOS2 mRNA The ratio of NOS2 mRNA to β-actin mRNA was 0.06±0.02 in control group, 0.24±0.05 in stress group, and 0.12±0.06 in pre-acupuncture group. There was a significant difference between pre-acupuncture group and stress group (*P*<0.01), as well as between stress group and control group (*P*<0.01).

Expression of NOS3 mRNA The ratio of NOS3 mRNA to β-actin mRNA was 0.30±0.08 in control group, 0.63±0.14 in stress group, and 0.45±0.14 in pre-acupuncture group. There was a significant difference between pre-acupuncture group and stress group (*P*<0.05), as well as between pre-acupuncture group and control group, stress group, and control group (*P*<0.05).

Figure 2 Effects of acupuncture at Tsusanli (S₃₆) on expression of NOS1 (A), NOS2 (B), and NOS3 (C) in rats with stress ulcer. M: marker; lanes 1-4: pre-acupuncture group; lanes 5-8: stress group; lanes 9-11: control group.

Data for NOS mRNA expression in adrenal gland (Figure 3)

Expression of NOS1 mRNA The ratio of NOS1 mRNA to β -actin mRNA was 0.43 ± 0.09 in control group, 0.98 ± 0.23 in stress group, and 0.77 ± 0.22 in pre-acupuncture group. There was a significant difference between pre-acupuncture group and stress group ($P < 0.05$), as well as between stress group and control group ($P < 0.01$), pre-acupuncture group and control group ($P < 0.01$).

Expression of NOS2 mRNA There was no expression of NOS2 mRNA.

Figure 3 Effects of acupuncture at Tsusanli (S₃₆) on expression of NOS1 (A) and NOS3 (B) in rats with stress ulcer. M: marker; lanes 1-4: pre-acupuncture group; lanes 5-8: stress group; lanes 9-11: control group.

Expression of NOS3 mRNA The ratio of NOS3 mRNA to β -actin mRNA was 0.71 ± 0.25 in control group, 2.54 ± 1.15 in stress group, and 1.70 ± 0.86 in pre-acupuncture group. There was a significant difference between stress group and control group ($P < 0.01$), but no significance difference was found between pre-acupuncture group and stress group and between pre-acupuncture group and control group ($P < 0.05$).

Demonstration of gastric mucosa with HE Staining (Figure 4)

Interruption of continuity in gastric mucosa and submucosa, as well as damage in muscular layer were found in stress group. The continuity in gastric mucosa was slightly damaged, and its tissue morphology was relatively normal in pre-acupuncture group.

Figure 4 Effects of acupuncture at Tsusanli (S₃₆) on gastric mucosa of stress group (A), pre-acupuncture group (B) and control group (C).

DISCUSSION

Studies have shown that the imbalance between NO and ET, decreases the gastric mucosal blood flow (GBF) and accelerates the gastric lesions^[5,6]. NO has both protective and deleterious effects on gastric mucosa by different physiological and pathological mechanisms in various diseases. This double effect depends on the type of NOS involved in these pathological conditions^[7].

It was reported that NO, as a neurotransmitter and a sensory neuropeptide, takes part in the physiological and pathological hyperemia reaction in gastric mucosa, increases gastric mucosal blood flow, thus protecting gastric mucosa^[8,9]. Endogenous NO plays an important role in maintaining vascular integrity and promoting the ulcer healing^[10]. NO catalyzed by NOS, can function both as a second messenger and as a neurotransmitter, and also performs numerous physiological functions as an effective

molecule. In pathological status, superfluous NO can increase vascular permeability, neuron decrease, neurotransmitter release and transitive obstacle, thus affecting organic physiological functions^[11,12]. The damage of NO to gastric mucosa indicates, that higher concentrations of NO exhibit toxic effects through nitrosative and oxidative stress. The mechanism responsible for water immersion stress-induced gastric lesions in aged is related with the activity decrease of NOS in gastric mucosa^[13].

Three types of NOS including neuronal NOS (NOS1), inducible NOS (NOS2) and endothelial NOS (NOS3) have been identified^[14,15].

NOS1 is primarily expressed in neural cells and relates to many physiological functions of the central nervous system, such as synapse plasticity, neural regeneration, nerve conduction, neural development, and neuroendocrine regulation^[16,17]. NOS2, also known as inducible NOS is typically expressed only after induction by pro-inflammatory cytokines and /or lipopolysaccharide (LPS). In a wide variety of pathological conditions, there is a notable biosynthesis of large quantities of NO, due to the increased expression of NOS2^[18-20]. Both NOS2 and COX2 result in stress of rats^[21]. NOS3 is primarily expressed in endothelial cells.

Both NOS1 and NOS3, also named as constitutive NOS (cNOS), are expressed in physiological status. NO catalyzed by NOS, mainly functions as a second messenger and a neurotransmitter. cNOS are related with gastric mucosa protection and the process of ulcer healing. In contrast, NOS2 affects the ulceration^[22-24].

Stress could cause mucosal damage and increase vascular permeability. NOS inhibitor can aggravate these kinds of changes. L-arginine or endotoxin lipopolysaccharide can restrain the increase of vascular permeability^[25,26]. In contrast, some studies reported that L-NAME (a nonspecific inhibitor of NOS) can delay mucosal lesions^[27] by depressing bile acid secretion and ulcer index in stomach^[28].

Results from the present studies, show that cold stress can differently affect NOS in hypothalamus. Acupuncture regulation for NOS is also different.

There was no significant difference in NOS1 in hypothalamus between stress group and control group, suggesting that NOS1 does not take part in stress reaction.

NOS1 expression in pre-acupuncture group was higher than that in control and stress groups, suggesting that puncturing Tsusanli (S₇36) can upregulate the expression of NOS1, leading to synthesizing more NO, and protecting gastric mucosa against the damage induced by cold stress.

Different from NOS1, cold stress caused high expression of NOS3 compared to control group. Moreover, acupuncture Tsusanli (S₇36) could inhibit high expression of NOS3, suggesting that the mechanism of acupuncture in inhibiting NOS3 is different from NOS1. Acupuncture Tsusanli (S₇36) can, in part, downregulate the expression of NOS3, instead of those previously completely inhibiting its injurious expression. The above results are different from reported. Whether the peripheral reaction of NOS3 is different from that in central reaction needs to be confirmed.

The results of this study also showed that NOS in adrenal gland did not play a role as in hypothalamus. NOS3 takes part in the pathological process of cold stress ulcer,

both in adrenal gland and in hypothalamus. Acupuncture can decrease the expression of NOS3. Although it can only be decreased in part, there is no statistical difference. The difference is that NOS1 takes part in the pathological stress process in adrenal gland. Acupuncture can down-regulate the pathological reaction.

The present experimental results display that NOS2 is highly expressed in hypothalamus, which is induced by cold stress. High expression of NOS2 leads to pathological changes in gastric mucosa^[29,30]. Acupuncturing Tsusanli (S₇36) can depress the overexpression of NOS2, thus leading to the protection of the body against injury. Studies have demonstrated that the expression of NOS2 is markedly upregulated after ulceration.

In the present study, we have confirmed that NOS2 participates in the pathological stress reaction, whereas NOS1 does not. NOS3 also participates in the pathological stress reaction, which is different from the previous reports^[31,32]. It was reported that NOS1, NOS2, and NOS3 affect the healing of gastric ulcer^[3].

In conclusion, NOS2 and NOS3 in hypothalamus participate in the pathological process of cold stress ulcer. Acupuncturing Tsusanli (S₇36) can modulate the expression of NOS1 upward and depress the expression of NOS2 and NOS3, thus playing a role in protecting gastric mucous.

Abstract

AIM: To detect the effects of DNA vaccines in combination with duck IFN- γ gene on the protection of ducks against duck hepatitis B virus (DHBV) infection.

METHODS: DuIFN- γ cDNA was cloned and expressed in COS-7 cells, and the antiviral activity of DuIFN- γ was detected and neutralized by specific antibodies. Ducks were vaccinated with DHBpreS/S DNA alone or co-immunized with plasmid expressing DuIFN- γ . DuIFN- γ mRNA in peripheral blood mononuclear cells (PBMCs) from immunized ducks was detected by semi-quantitative competitive RT-PCR. Anti-DHBpreS was titrated by enzyme-linked immunosorbent assay (ELISA). DHBV DNA in sera and liver was detected by Southern blot hybridization, after ducks were challenged with high doses of DHBV.

RESULTS: DuIFN- γ expressed by COS-7 was able to protect duck fibroblasts against vesicular stomatitis virus (VSV) infection in a dose-dependent fashion, and anti-DuIFN- γ antibodies neutralized the antiviral effects. DuIFN- γ in the supernatant also inhibited the release of DHBV DNA from LMH-D2 cells. When ducks were co-immunized with DNA vaccine expressing DHBpreS/S and DuIFN- γ gene as an adjuvant, the level of DuIFN- γ mRNA in PBMCs was higher than that in ducks vaccinated with DHBpreS/S DNA alone. However, the titer of anti-DHBpreS elicited by DHBpreS/S DNA alone was higher than that co-immunized with DuIFN- γ gene and DHBpreS/S DNA. After being challenged with DHBV at high doses, the load of DHBV in sera dropped faster, and the amount of total DNA and cccDNA in the liver decreased more significantly in the group of ducks co-immunized with DuIFN- γ gene and

INTRODUCTION

An estimated 350 million people are chronically infected with hepatitis B virus (HBV). Cytotoxic T lymphocytes (CTLs) play a critical role in the clearance of HBV from patients by lysis of virus-infected hepatocytes^[1]. However, IFN- γ and TNF- α have been shown to inhibit HBV replication in HBV transgenic mice, without lysing infected hepatocytes^[2,3]. An *in vitro* model in which lymphocytes from HBsAg positive patients are co-cultured with HBV replicating hepatocytes, shows that the secretion of IFN- γ from lymphocytes inhibits HBV replication^[4]. Consequently, in addition to enhancing the cytotoxicity of CTLs, IFN- γ also mediates the non-cytolytic inhibition of HBV replication, and shows its significance in the host defense against HBV infection and recovery from virus infection.

Recombinant woodchuck IFN- γ up-regulates MHC class I molecule transcription, but hardly inhibits or clears woodchuck hepatitis virus replicating intermediates and RNAs in persistently infected woodchuck primary hepatocytes^[5]. However, treatment of primary duck hepatocytes with recombinant duck IFN- γ can inhibit DHBV replication in a dose-dependent manner^[6]. The role of IFN- γ in hepadnavirus infection is still controversial.

DHBV and HBV share common genomic and structural features, with an envelope surrounding a spherical nucleocapsid that contains a similar viral DNA genome in terms of size, structure, and organization. This is why DHBV-infected ducks have become a useful animal model to explore the molecular mechanism of host defense against HBV infection^[7-9]. Animals immunized with antigen and IFN- γ gene develop Th1-biased immune responses, and it has been reported that IFN- γ , as a genetic adjuvant has

stronger effects on the nature of immune response in neonates than in adults^[10]. To date, whether IFN- γ inhibits DHBV replication *in vivo* has not been reported. Whether DNA vaccine protects ducks against DHBV infection is still controversial^[11-14]. To test the function of IFN- γ as an immune adjuvant and to validate the efficacy of DHBV vaccines, ducks were immunized with the mixture of plasmid expressing DHBV preS/S protein and IFN- γ . The results support the view that DuIFN- γ inhibits DHBV replication and increases the protective efficacy of DNA vaccines expressing DHBV preS/S protein.

MATERIALS AND METHODS

Animals and cells

Cherry valley ducks (*Anas platyrhynchos*) were supplied by Breeding Center of Shanghai Institute of Veterinary Medical Sciences, China. Duck embryo fibroblasts were prepared as previously described^[15], and maintained in Dulbecco's Modified Eagle's Medium (DMEM) containing 2 mmol/L glutamine, 100 U/mL penicillin and streptomycin, supplemented with 2% duck sera (prepared from DHBV-free ducks and filtered through a 0.22 μ m membrane) and 8% fetal calf sera (FCS). COS-7 cells were cultured in DMEM containing 10% FCS. LMH-D2, a chicken hepatoma cell line and a gift from Dr. William S. Mason (Fox Chase Cancer Center), was incubated in DMEM/F12 medium supplemented with 2% chicken sera and 8% FCS.

Separation of duck PBMCs and amplification of DuIFN- γ mRNA by RT-PCR

Blood was taken from adult ducks and diluted by an equal volume of heparinized PBS. PBMCs were separated with Ficoll as described previously^[16], 5×10^6 PBMCs in 1 mL of RPMI 1 640 supplemented with 10% FCS were transferred into 24-well plates and stimulated with PHA at 10 mg/mL for 24 h. Total RNA was extracted from PBMCs with TRIzol reagent (Gibco BRL, USA) and 4 μ g of total RNA was reverse transcribed into cDNA by Superscript IITM and hexamer random primer (Gibco BRL). The sequences of sense and anti-sense primers are 5-CGCCGGATCCAT-GACTTGCCAGACCTACTGCTT-3 and 5-CGCCG-ATATCTCATTAACATCTGCATCTCTTTGG-3. cDNA of DuIFN- γ was amplified for 30 cycles at 94 $^{\circ}$ C for 5 min, 94 $^{\circ}$ C for 1 min, 54 $^{\circ}$ C for 1 min, and at 72 $^{\circ}$ C for 2 min.

Expression of recombinant DuIFN- γ in COS-7 cells

For expression of recombinant DuIFN- γ , the amplified DuIFN- γ DNA fragment was cloned into eukaryotic expression vector pcDNA3.1 (Invitrogen) at the *EcoRV*/*Bam*HI sites. Transfection was performed by the method of calcium phosphate precipitation. At 72 h post-transfection, the culture supernatant were harvested and centrifuged to remove the cell debris.

Titration of recombinant DuIFN- γ

Duck embryo fibroblasts were seeded into 96-well plates and incubated in the presence of serial four-fold dilution of DuIFN- γ in the supernatant. After 12 h incubation, the cells were challenged with VSV at 100 TCID₅₀ for 36 h.

Under microscope, the cytopathic effects (CPE) were observed and MTT was added for another 8 h. MTT could be degraded by mitochondrial enzymes and developed blue color. Consequently, the optical density could indicate the course of virus infection and cellular pathogenesis^[17]. DuIFN- γ titers were expressed as reciprocals of the dilutions that resulted in 50% protection against virus-induced cell CPE. The role of DuIFN- γ in protecting cells against virus infection also was confirmed by specific IgG of anti-DuIFN- γ provided by Dr. C.J. Burrell (University of Adelaide, Australia).

Treatment of LMH-D2 cells with DuIFN- γ

LMH-D2 cells were seeded at 1×10^6 cells/flask at 37 $^{\circ}$ C in 50 mL/L CO₂, and incubated with 10% of recombinant DuIFN- γ supernatant (titrated as 4^7 - 4^8) or the same volume of supernatant derived from transfected pcDNA3.1 vector. After the culture supernatant was collected, fresh DMEM/F12 was refilled everyday or every other day, the collected culture supernatant was centrifuged at 5 000 r/min \times 10 min, and 5 μ L of the supernatant was spotted onto positively charged nylon membranes and the DHBV DNA was detected by dot hybridization.

Subcloning of DHBV-preS/S gene into eukaryotic expression vector and detection of gene expression in COS-7 cells

The full length of DHBV genome clone (pCMV-DHBV9) was also a gift from Dr. William S. Mason. DHBV preS/S gene was subcloned into pcDNA3.1 with *A*f/II/*E*coRI restriction sites introduced by PCR primers. The sequences of sense and antisense primers are 5-CGCCTTAAGA-TGGGGCAACATCCAGCAAAATC-3 and 5-CGCG-AATTCAGTTTATTTCTTATTCCTAACTCTT-3, respectively. The subcloned DHBV preS/S gene was transfected into COS-7 cells by calcium phosphate precipitation. The expressed protein was detected by indirect immunofluorescence (IMF) staining with mAb against DHBV-preS/S protein as previously described^[11]. A reporter gene secreting alkaline phosphatase (SEAP)^[18] was transfected into COS-7 cells simultaneously for detection of the efficacy.

Vaccination protocol

Three-day-old ducks were vaccinated intramuscularly in the quadriceps anterior muscle. DHBpreS/S DNA and DuIFN- γ DNA were extracted with a kit (QIAGEN Mega DNA extracted kit) following the manufacturer's instructions. All ducks were grouped. Group 1 was vaccinated with plasmid pcDNA3.1-DHBpreS/S at 200 μ g/duck, group 2 with DHBpreS/S DNA at 200 μ g and plasmid pcDNA3.1-DuIFN- γ at 200 μ g/duck, group 3 was injected with an equal volume of PBS. The same procedure for DNA vaccination was repeated after 4 wk.

Detection of mRNA of DuIFN- γ in PBMCs after being stimulated with DHBsAg by competitive RT-PCR

Competitive RT-PCR method has been described^[19]. Briefly, β -actin gene functioned as a housekeeping gene. Competitive internal control (IC) was constructed by deleting the partial segment of DuIFN- γ cDNA using a pair of specific PCR

primers. The sequences of sense and anti-sense primers are 5-GGATGTAGCTGATGGCAATCC-3' and 5-TCATTAACATCTGCATCTCTTTGGGACAGTTCC-ACGAGGTC-3', respectively. The sequence of anti-sense primer for amplification of the target segment of DuIFN- γ cDNA is 5-TCATTAACATCTGCATCTCTTTGGG-3' (partial sequences of anti-sense primer for IC), and the sequence of sense primer is the same as the one used for constructing IC. After peripheral blood was separated using Ficoll, PBMCs were transferred into 24-well plates at 5×10^6 cells/well, and then stimulated with purified DHBsAg at 1 $\mu\text{g/mL}$ for 24 h. IC (1.25×10^{-5} $\mu\text{g/mL}$) was used to quantify the samples. The conditions of amplification were at 94 °C for 4 min, 94 °C for 1 min, 60 °C for 45 s, at 72 °C for 1 min. In the next five cycles, the temperature for annealing was decreased at 1 °C per cycles and another 25 cycles were performed at 94 °C for 1 min, 55 °C for 45 s, 72 °C for 1 min, at 72 °C for 10 min.

Serological assay

DHBV preS protein was expressed in *E. coli* and 100 μL of purified protein (1 $\mu\text{g/mL}$) was coated on 96-well microdilution plates at 4 °C overnight. Non-specific sites were blocked with 200 μL skim milk (Shanghai Guangming Milk Co., Ltd) in PBS-0.05% Tween 20. The plates were incubated with 2-fold serially diluted serum sample and then with 100 μL of HRP-goat anti-duck immunoglobulin Y at 1/1 000 dilution (KPL). The color was developed by substrate of TMB system in darkness for 15 min and terminated by 50 μL 2 N H_2SO_4 . The optical density at 450 nm (A_{450}) was read on an automatic ELISA reader. The antibody titer in each serum sample was defined as the highest serum dilution that resulted in $S/N > 3$ (S for A_{450} of serum sample, N for A_{450} of control normal duck serum sample at the same dilution).

Viral challenge and DHBV DNA assay

All vaccinated ducks were boosted again at wk 7, vaccinated ducks were challenged with DHBV at a high-titer dosage (1.0×10^{10} DHBV DNA genomes/mL) at wk 13. The volume for injection was adjusted according to the body weight of ducks: volume (mL) = weight (g) $\times 7\% \times 10\%$. The ducks were cannulated via the jugular vein. Blood samples were collected before virus challenge and at 1, 5, 15, 30, 45, 60, 90, 120 min post-challenge. After being challenged

with virus for 5 d, the ducks were killed and livers were taken out for extraction of DHBV DNA. DHBV DNA in sera and liver was detected by Southern blot as previously described^[20]. The whole DHBV genome from pCMV-DHBV9 was used as DNA template for producing specific probes labeled by [α - ^{32}P] dCTP with a random primer.

RESULTS

Expression of recombinant DuIFN- γ in vitro and biological assay

Monolayer of duck embryo skin fibroblast cells was incubated with the supernatant from recombinant plasmid pcDNA3.1-DuIFN- γ transfected COS-7 cells, and then infected with VSV at 100 TCID₅₀. The results indicated that the supernatant from pcDNA3.1-DuIFN- γ transfected cell culture could protect the duck embryo fibroblast cells against VSV infection, while the supernatant from pcDNA3.1 transfected cells showed no antiviral effect (Figure 1A). The protective effect was dose-dependent. The antiviral effect of DuIFN- γ in the supernatant was titrated in a series of four-fold dilution, and titer was expressed as 4^7 - 4^8 (Figure 2 and Table 1). The antiviral activity of the supernatant from pcDNA3.1-DuIFN- γ transfected cells could be neutralized by anti-DuIFN- γ (Figure 1B), indicating that recombinant DuIFN- γ played a role in the control of viral infection.

Inhibition of the DHBV replication by DuIFN- γ

For investigation of anti-DHBV effect of recombinant DuIFN- γ , LMH-D2 cells continuously producing DHBV, were incubated with the supernatant from pcDNA3.1-DuIFN- γ transfected cells, culture fluid was collected everyday or every other day. DHBV in the supernatant was spotted on the nylon membrane and detected by hybridization with a DHBV DNA probe. The results showed that the amount of DHBV DNA decreased dramatically 1 d after treatment with DuIFN- γ and the anti-DHBV effect lasted for 4 d, while no anti-DHBV effect of recombinant DuIFN- γ on the supernatant from pcDNA3.1 transfected cell culture was observed. After treatment for 4 d, no apparent difference was observed between cells treated with the recombinant DuIFN- γ and the control supernatant (Figure 3). The results demonstrated that the recombinant DuIFN- γ temporally inhibited the DHBV replication in LMH-D2 cells.

Table 1 CPE inhibition assay to quantify recombinant DuIFN- γ

IFN- γ (Diluted by log4)	CPE (Four wells)	Average of CPE	Inhibition of CPE	Accumulation of inhibitory CPE	Accumulation of CPE	Inhibition of CPE	Inhibition of CPE (%)

Effects of DuIFN- γ as adjuvant of DNA vaccine on DuIFN- γ mRNA transcription in duck PBMCs

Three-day-old ducks were immunized with plasmids expressing DHBV-preS/S gene alone (group 1) or expressing DHBV-preS/S gene and DuIFN- γ DNA (group 2), or PBS alone (group 3), and boosted at wk 4 and 7 after the first immunization. The blood was taken and separated PBMCs were incubated with purified DHBsAg at 1 $\mu\text{g/mL}$ for 24 h. The cellular total RNA was extracted and DuIFN- γ mRNA was quantified by competitive RT-PCR. The ducks co-vaccinated with plasmids expressing DHBV-preS/S and DuIFN- γ showed a higher ratio of DuIFN- γ T/IC (1.56 \pm 0.08) than those immunized with plasmid expressing DHBV-preS/S alone (the ratio is 1.29 \pm 0.09), or normal ducks (0.92 \pm 0.06) 3 wk after immunization (P <0.05).

(Table 2 and Figure 4). The effects were more significant at wk 5 and 7 post-immunization (P <0.01), the ratios of DuIFN- γ T/IC were 2.51 \pm 0.11 and 1.81 \pm 0.10 in group 2, 1.96 \pm 0.17 and 1.26 \pm 0.11 in group 1, 1.33 \pm 0.11 and 0.94 \pm 0.04 in group 3 at wk 5 and 7, respectively. These results suggested that DuIFN- γ mRNA transcription of duck PBMCs was enhanced by DuIFN- γ as an immuno-adjuvant co-immunized with DNA vaccines.

Table 2 Detection of DuIFN- γ mRNA of PBMCs from ducks after immunization (mean \pm SD)

Immunized groups	Ratio of DuIFN- γ /IC (weeks after first vaccination)			
	1 wk	3 wk	5 wk	7 wk

Effects of DuIFN- γ as an adjuvant of DNA vaccine on anti-DHBpreS antibody responses in ducks

Anti-DHBpreS antibody responses in immunized ducks were detected by ELISA after the first vaccination (Figure 5), the titers of anti-DHBpreS antibody increased gradually after boost at wk 4 and 7. The titer of anti-DHBpreS in ducks vaccinated with DHBV preS/S DNA alone, gradually increased to 2^{7.4}-2^{10.6} from wk 4 to wk 13, and was higher than that in ducks co-immunized with plasmid expressing

Figure 4 Detection of DuIFN- γ mRNA of PBMCs from ducks after immunization.

Figure 5 Anti-DHBpreS antibody responses following DNA immunization of DHBV-free ducks.

DuIFN- γ and DHBV preS/S DNA, whose titer of anti-DHBpreS was $2^{5.6-2^{8.8}}$ from wk 4 to wk 13. The results showed that DHBV vaccine expressing DHBV preS/S induced antibody responses, but DuIFN- γ DNA down-regulated the elicitation of IgY against DHBV preS.

Clearance of viremia in vaccinated-ducks after being challenged with DHBV

To investigate the role of DuIFN- γ as an adjuvant of DNA

vaccines in protecting ducks against DHBV infection, 6 wk after the second boost, the vaccinated ducks were challenged with a high dose of DHBV according to their body weight (7.0×10^{10} /kg). The peripheral blood was collected from ducks at different time points after being challenged to detect DHBV DNA. The results showed that ducks co-vaccinated with plasmids expressing DuIFN- γ and DHBV preS/S had a stronger competence to remove DHBV from bloodstream than ducks immunized with DHBV preS/S DNA alone (Figure 6). After DHBV challenge, more than 50% of DHBV DNA in the blood of co-vaccinated ducks was removed in 5 min, whereas DHBV DNA in the ducks immunized with DHBV preS/S DNA alone decreased only a little in 45 min, and DHBV in both groups was undetectable at the last observation time point (120 min after virus challenge). As a viral infection control, the ducks immunized with PBS did not show significant viremia clearance in 120 min. We further detected the DHBV in liver 5 d after the challenge. Although total and ccc DHBV DNA could be detected in the liver, DHBV DNA was much lower in the ducks co-immunized with DuIFN- γ DNA than that in ducks injected only with DHBV preS/S DNA or PBS. The results indicated that DNA vaccine expressing DHBV preS/S protein enhanced the ability of ducks to exclude the DHBV

from bloodstream and remove the DHBV from liver. The capability of ducks was much more significantly upregulated by co-immunization with DuIFN- γ DNA than simple immunization with DHBV preS/S DNA (Figure 7).

DISCUSSION

IFN- γ plays a critical role in the host defense against virus infection. It was reported that IFN- γ regulates immune responses and induces strong Th1 biased responses, which are weak in persistent infection and immune tolerance^[21-23]. Transfer of specific CTLs to HBV transgenic mice could inhibit HBV replication in a non-cytolytic way and the CTL capacity of inhibiting HBV infection contributes to IFN- γ and TNF- α ^[2,3]. The efficacy of IFN- γ in inhibiting HBV replication is also observed by Suri *et al.*^[4]. Lu *et al.*^[5] showed that woodchuck IFN- γ *in vitro* upregulates the expression of MHC class I molecules, but does not inhibit the formation of WHV intermediates. Schultz and Chisari^[6], reported that duck IFN- γ inhibits DHBV replication in a dose-dependent fashion. In the present study, we found that recombinant duck IFN- γ could inhibit the release of DHBV from LMH-D2 cells, suggesting that duck IFN- γ can inhibit DHBV replication.

It has been reported that cytokines function as an efficient immuno-adjuvant, when animals are immunized with DNA vaccines^[24-26], but it is unknown whether DuIFN- γ gene also enhances the activity of DNA vaccine in protecting ducks against DHBV infection. Whether DNA vaccine expressing DHBV preS/S protein elicits neutralizing antibodies is still

controversial. Triyatni *et al.*^[11], reported that, DNA vaccine expressing DHBV preS/S induces high titer anti-DHBV preS/S, but shows less protection against virus infection than plasmid pCI/Amp expressing DHBV S protein. Plasmids expressing DHBV preS/S elicits high neutralizing antibodies and the protection could be transferred to offsprings through specific IgY^[12-14]. We have also proved the protective efficacy of DNA vaccine expressing DHBV preS/S, and showed that it could promote DuIFN- γ mRNA transcription of duck PBMCs and quicken the removal of virus from bloodstream and inhibit virus replication in liver, after being challenged with high titer viruses, when the plasmid expressing DuIFN- γ functioned as an immuno-adjuvant.

Little is known about the specific mechanism of DuIFN- γ enhancing the protective capacity of DNA vaccine. Since the titer of anti-DHBpreS elicited by DHBV preS/S DNA vaccine was down-regulated by DuIFN- γ in the present study, the affinity of antibody against antigen may be enhanced and more Th1 cytokines are induced to take effects synergistically. Furthermore, the number and killing capacity of specific cytotoxic lymphocytes could also increase. Further studies are necessary to clarify these important issues.

Thermet *et al.*^[27], have shown that DHBV preS/S DNA vaccine has some protective activity and early administration of anti-DHBV drugs such as lamivudine, significantly increases the protection and clears virus from chronic infection patient. However, it was not the case in our experiments and no significant differences were observed in virus-carriers between non-vaccinated and vaccinated ducks, including the ducks co-administered with plasmid expressing DuIFN- γ (data not shown). Many factors may affect the efficacy of vaccines, such as pathway of vaccination, DNA dosage and protocol. It is possible that the antigens in different pathways of vaccination recruit different antigen presenting cells. If the co-stimulatory signals are lost, immune tolerance but not viral clearance occurs^[28-30]. When animals are vaccinated at different growth phases, their ability to respond to antigens is significantly different. Also the distribution of the same antigen may affect the pathway of antigen presentation, which might be the reason, why viral antigen in circulating bloodstream cannot be cleared by host itself but DNA vaccines expressing antigen induces the efficacy of immune protection and exclude the viruses, when host is re-infected. Consequently, there is a long way to go for defining the molecular mechanism of DNA immunization and developing efficient vaccines.

Abstract

AIM: To measure the time-dependent (viscoelastic) behavior in the change of the small intestinal opening angle and to test how well the behavior could be described by the Kelvin model for a standard linear solid.

METHODS: Segments from the duodenum, jejunum, and ileum were harvested from 10 female Wistar rats and the luminal diameter, wall thickness, and opening angle over time ($\alpha(t)$) were measured from rings cut from these segments.

RESULTS: Morphometric variations were found along the small intestine with an increase in luminal area and a decrease in wall thickness from the duodenum to the ileum. The opening angle obtained after 60 min was highest in the duodenum ($220.8 \pm 12.9^\circ$) and decreased along the length of the intestine to $143.9 \pm 8.9^\circ$ in the jejunum and $151.4 \pm 9.4^\circ$ in the ileum. The change of opening angle as a function of time, fitted well to the Kelvin model using the equation $\theta(t)/\theta_0 = [1 - \eta \exp(-\lambda t)]$ after the ring was cut. The computed creep rate λ did not differ between the segments. Compared to constant calculated from pig aorta and coronary artery, it showed that α agreed well (within 5%), η was three times larger than that for vascular tissue, and λ ranged $\pm 40\%$ from the value of the pig coronary artery and was a third of the value of pig aorta.

CONCLUSION: The change of opening angle over time for all the small intestine segments fits well to the standard linear spring-dashpot model. This viscoelastic constant of the rat small intestine is fairly homogenous along its length. The data obtained from this study add to a base set of biomechanical data on the small intestine and provide a reference state for comparison to other tissues,

INTRODUCTION

The small intestine, like other hollow organs such as heart, blood vessels, bladder and urethra, is functionally subjected to dimensional changes depending on active and passive biomechanical properties. Hence, the biomechanical properties of the small intestine are of particular functional importance.

Most of the data relating to the mechanical aspects of the gastrointestinal (GI) tract deal with motility patterns, flow rates, peristaltic reflexes, and tone in sphincter regions^[1-7]. Data in the literature pertaining to the passive mechanical properties of small intestine are concerned with the length-tension relationship in circular and longitudinal tissue strips *in vitro*^[8-11], the compliance^[12], and the stress-strain relationship of the intact wall^[13,14]. These studies have provided valuable information on some mechanical properties of small intestinal tissue and the distensibility of the intact intestinal wall. However, we still lack a complete database of mechanical parameters to fulfill detailed biomechanical analysis of small intestinal physiology.

In biomechanical analysis, it is important to determine the stress-free state as the reference for the strain analysis. Residual stress and strain are the internal stress and strain that reside in the organ when external forces are removed (the no-load state). Residual strain has been demonstrated in the small intestine^[15-18]. Residual stress reduces transmural stress and strain variations at physiological loads in biological tissues and hence may optimize the mechanical function. The opening angle is commonly used to characterize residual stresses in hollow organs, such as the cardiovascular system and the GI tract. When a hollow organ is cut into rings perpendicular to the central axis, and the rings are then cut radially, the rings will open over a period of time into sectors. When the opening angle has reached a final, static angle, the tissue is considered to have attained a "zero-stress state". Since zero-stress configuration serves as the reference state for computing stress and strain under physiological or

pathophysiological conditions, knowing it is essential in any mechanical analysis. It was reported that the opening angle of rat small intestine reached steady state opening angles after 30–60 min^[15–18].

Viscoelastic properties have been described for the normal and diseased human rectum using pressure data^[19,20]. The viscoelastic behavior of the intestinal wall during diabetes has been investigated by Zhao *et al.*^[21]. However, information is lacking in the time-dependent course of the opening angle. The gradual increase of opening angle over time, until reaching steady state is defined as creep and reflects the viscoelastic properties of the organ wall. The aims of the current study were: (1) to provide the data on the morphometry of the small intestine in rats, (2) to study the time-dependent changes of the opening angle (creep) along the length of the intestine and (3) to model this relationship based on the assumption that the small intestine behaves like a standard linear solid and derives viscoelastic constants to allow for comparison with other tissue types in the literature.

MATERIALS AND METHODS

Sample preparation

Ten female Wistar rats weighing 220–240 g were included in this study. The rats were anesthetized with pentobarbital sodium (50 mg/kg ip). Following laparotomy, the calcium antagonist, papaverine (60 mg/kg) was injected into the lower thoracic aorta through an iv cannula (22 G/25 mm), in order to abolish contractile activity in the GI tract. Once muscular relaxation was achieved, three 6 cm long segments were harvested from the duodenum, jejunum and ileum. The duodenum was taken from the descending part starting 1 cm from the pylorus, the jejunum from 5 cm distal to the ligament of Treitz, and the ileum from 5 cm proximal to the ileo-cecal valve. The residual contents in the lumens were gently cleared using saline and the segments were then placed immediately into cold Krebs solution containing 6% dextran and 10⁻² mol/L MgCl and aerated with a gas mixture (95% O₂ and 50 mL/L CO₂, pH 7.4) for 30 min.

From the proximal end of each segment, rings of 1–2 mm in length were cut for the morphometric measurement and zero-stress state experiment. Each ring was placed into a separate Petri dish filled with cold Krebs solution as mentioned above. The rings were placed into the dishes with a portion of the ring running between two metal pins planted into the surface of the dish in order to assist in keeping the rings upright after opening. Three successive rings from each of the three intestinal segments were arranged in series and the rings were cut radially opposite to the mesentery (at 90° relative to the horizontal plane) with a pair of microsurgery scissors, while in the solution. Successive rings were cut open, each after 5 min. Each series of rings was filmed using a video camera (SONY CCD Camera, Japan) and a videocassette recorder for later analysis.

Data analysis

The morphometric data were obtained from digitized images captured from videocassette at 10, 20, 30, 40, 50 s, 1, 2, 3, 4, 10 min, and every 5 min afterwards until 60 min after

the initial cut (Optimas 5.2 image capture software, Optimas Corp., USA). Measurements of inner diameter (d), wall thickness (w), and opening angle (θ) were made using dedicated software (Sigmascan 4.1, Jandel Scientific). The opening angle θ was defined as the angle subtended by two radii drawn from the midpoint of the inner wall to the inner tips of two ends of the specimen (Figure 1). The measured data were used to model the change of opening angle as a function of time, primarily by fitting the observed data to the Kelvin model for a standard linear solid (Figure 2). Thus, the data were fitted to the exponential function^[22]

$$\theta(t) = \theta_0 [1 - \eta e^{-\lambda t}] \quad (1)$$

where θ_0 = asymptotic steady state value of the opening angle, λ = the creep rate (s⁻¹), t = time after the initial cut (s), η = the creep fraction (nondimensional).

This equation relates to the Kelvin body as follows. In the model, μ_1 and μ_2 are spring constants and η_1 is a coefficient of viscosity. By letting

$$\tau_\varepsilon = \frac{\eta_1}{\mu_1}, \tau_\sigma = \frac{\eta_1}{\mu_0} \left(1 + \frac{\mu_0}{\mu_1}\right), E_R = \mu_0, \quad (2)$$

where τ_ε = relaxation time for constant strain, τ_σ = relaxation time for constant stress, E_R = relaxed elastic modulus.

We obtained the equation describing this model:

$$C(t) = \frac{1}{E_R} \left[1 - \left(1 - \frac{\tau_\varepsilon}{\tau_\sigma} \right) e^{-\frac{t}{\tau_\sigma}} \right]. \quad (3)$$

We defined

$$\alpha = \frac{1}{E_R}; \eta = 1 - \frac{\tau_\varepsilon}{\tau_\sigma}; \lambda = \frac{1}{\tau_\sigma}. \quad (4)$$

The empirical constants η and λ could then be used to plot predicted creep curves and for comparison with other tissues.

For most rings, the opening angle reached 90% of its maximum value in 45 min. Subsequently, the opening angle data were normalized by the angle at 45 min before fitting the data to the exponential function. In order to take this normalization into account, the equation modeling a standard linear solid was modified as follows. Taking Equation (1) and letting $\theta(45 \text{ min}) = \alpha\theta_0$, we have

$$\frac{\theta(t)}{\theta(45 \text{ min})} = \frac{1}{\alpha} [1 - \eta e^{-\lambda t}]. \quad (5)$$

Figure 1 Schematic diagram of wall thickness (w), inner diameter (d), and opening angle (θ) for a ring radially cut into a sector.

The empirical constants α , η , and λ were calculated for the data obtained in this study and are presented in Table 2.

Figure 2 Kelvin body, a mechanical model for a standard linear solid viscoelastic material. μ_1 and μ_0 are spring constants; η_1 is a coefficient of viscosity; u is the displacement including u_1 for dashpot and u_2 for spring; F is the sum of the force.

Statistical analysis

The data were representative of a normal distribution and results were subsequently expressed as mean \pm SE. Analysis of variance (ANOVA) was used to test for the differences in the viscoelastic constants (α , η , and λ) for the various intestinal segments (Sigmaplot 2.0TM). In case of significance, data were evaluated in pairs by a multiple comparison procedure (Student-Newman-Keuls method). If the normality test or the equal variance test failed, Kruskal-Wallis one-way analysis of variance on ranks was used. $P<0.05$ was considered statistically significant.

RESULTS

Morphometry data

Seventy-eight intestinal rings, and 30 duodenal, 18 jejunal, and 30 ileal rings were obtained from 10 rats. There were fewer jejunal rings because the jejunum was implemented in the study after the fourth rat was completed. This was done in order to obtain a more complete dataset. The highest wall thickness of 0.88 ± 0.03 mm was found in the duodenum. The wall thickness decreased to 0.72 ± 0.06 mm in jejunum and 0.66 ± 0.02 mm in ileum (Table 1, $P<0.05$). The biggest inner diameter was in the ileal rings and the smallest in the jejunal rings (Table 1, $P<0.05$). The maximum opening angle was achieved within 60 min, and it was highest in the duodenum ($220.8\pm12.9^\circ$) and decreased along the length of small intestine (Table 1, $P<0.01$).

Table 1 Average opening angle at 45 and 60 min and maximal luminal area and wall thickness for rings cut from rat duodenum, jejunum, and ileum from rat intestine (mean \pm SE)

	Duodenum	Jejunum	Ileum
Angle (45 min)	211.1 \pm 17.2	128.5 \pm 10.1 ^b	145.9 \pm 9.2 ^b
Angle (60 min)	220.8 \pm 12.9	143.9 \pm 8.9 ^b	151.4 \pm 9.3 ^b
Lumen diameter (mm)	0.86 \pm 0.03	0.73 \pm 0.04 ^a	0.89 \pm 0.03
Wall thickness (mm)	0.88 \pm 0.03	0.72 \pm 0.06 ^a	0.66 \pm 0.02 ^b

^a $P<0.05$, ^b $P<0.01$ vs duodenum.

Creep of opening angle

The changes of opening angle and normalized opening

angle as function of time (creep) are shown in Figure 3. The opening angles became bigger as function of time. The opening angle was significantly bigger in the duodenal rings than in the other two segmental rings at all time points (Figure 3 top, $P<0.01$). However, the opening angles did not differ between the jejunal and ileal rings (Figure 3 top, $P>0.05$). After the opening angle data were normalized by the angle at 45 min, the normalized opening angles as function of time did not differ between the duodenal, jejunal and ileal rings (Figure 3 bottom, $P>0.05$).

The empirical constants α , η , and λ from a standard linear model analysis did not differ between the different segments (Table 2, $P>0.05$). Experimental data and predicted data are shown in Figure 4. The solid points represent experimental data of $\theta(t)/\theta(45\text{ min})$, and the hollow points represent calculated values of $\theta(t)/\theta_0$ using the empirical constants α , η , and λ . It showed that the predicted creep curves agreed well with data obtained from this study.

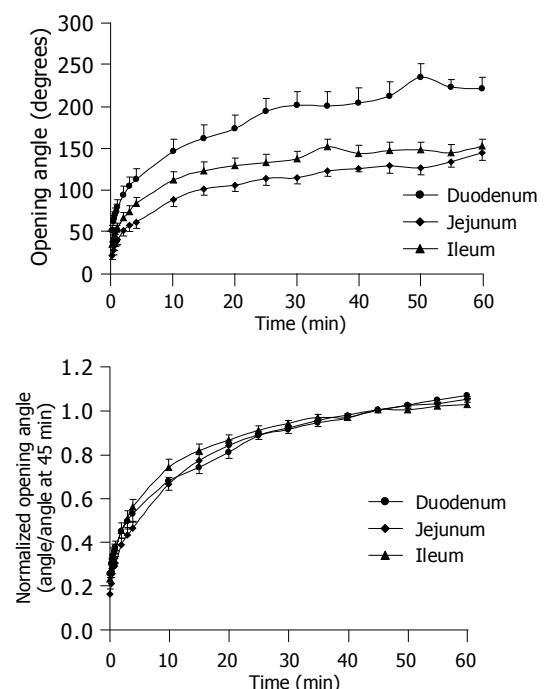

Figure 3 Changes of opening angle and normalized opening angle as function of time.

Figure 4 Experimental data and predicted data in rat 10.

Table 2 Standard linear solid coefficients determined for duodenum, jejunum, and ileum of rat small intestine (mean±SE)

	α	η	λ (s ⁻¹)	R ²
Duodenum	0.954±0.023	0.710±0.013	1.04×10 ⁻³ ±1.09 ⁻⁰⁴	0.989
Jejunum	0.978±0.017	0.779±0.012	1.29×10 ⁻³ ±1.05 ⁻⁰⁴	0.992
Ileum	1.005±0.013	0.720±0.012	1.63×10 ⁻³ ±1.33 ⁻⁰⁴	0.992

DISCUSSION

The time-dependent change of the intestinal opening angle reflects viscoelastic properties (creep). The major finding in this study is that the opening angles at all time points are bigger in the duodenum than in the jejunum and ileum in the normal rats. The change of opening angle for all the small intestine segments showed a slow creep phase and the behavior fitted well to the standard linear spring-dashpot model. The empirical constants α , η , and λ calculated from the standard linear solid model did not differ among the three intestinal segments. Furthermore, we have confirmed previous data that both opening angle and the wall thickness decrease from the duodenum to the ileum, whereas the lumen area increases.

Axial variations of morphometric parameters of small intestine

Our results and previous study^[15] has demonstrated substantial axial variations of the morphometric parameters. A decrease in wall thickness is in line with findings in prior studies^[24]. Several zero-stress state studies have been done in the GI tract^[15-18]. All GI studies done so far showed that the rings open into sectors when cut radially. When radial cuts are made, the duodenal rings are more likely to turn inside out producing large opening angles and therefore indicate a larger residual strain than the jejunal and ileal rings^[15]. From a mechanical point of view, a large residual strain may be a natural way of efficiently resisting luminal pressures. Thus, it is likely that the compressed duodenal mucosa may be better protected against injury from pressure changes produced by frequent contractions and the luminal contents ejected at intervals from stomach. In contrast, the less compressed ileal mucosa represents a region under a relatively lower and stable pressure.

Creep of opening angle of intestinal segments

Creep occurs when the material is suddenly stressed and the stress is maintained constant. Hence, the material continues to deform^[25]. Creep is a feature of viscoelasticity that is found in most materials including those in the GI tract. Mechanical models, such as the Maxwell model, the Voigt model, and the Kelvin model (also called the standard linear solid)^[25,26] are often used to describe the visco-elastic behavior of materials. We assumed that the intestine was a standard linear solid and described the change of opening angles of intestine as function of time using this model. A slow creep phase was found and the behavior fitted well to the standard linear spring-dashpot model. Bharucha *et al.*^[27], developed a technique to assess quasi-static colonic P-V curves in the human descending colon and demonstrated that colonic P-V curves approximate to a power exponential function and are reproducible within subjects. In the present

study, the experimental data also fit to the exponential function^[22]. The predicted creep curves were plotted using the empirical constants α , η , and λ calculated for standard linear solid model. The constants were relatively similar for all three intestinal segments, indicating that the viscoelastic properties of the rat small intestine are fairly homogenous. This is consistent with the relaxation data of normal small intestine reported by Zhao *et al.*^[21], (unpublished data). Using these constants, it was also found that $\theta(t)/\theta_0$ reached 95% of the full amplitude after 35 min for the duodenum and jejunum and after 30 min for the ileum. The data obtained from this study add to a base set of morphometric and biomechanical data on the small intestine. These data also provide a reference state for comparison to other tissues, diseased intestine or intestine exposed to drugs or chemicals.

Comparison to other studies

The research by Han and Fung^[22] on the pig aorta showed that the opening angle reaches 95-98% of the steady-state value after 10-15 min. The constants α , η , and λ obtained in the present study were compared to those calculated from work done by Han and Fung^[22] and Frobert *et al.*^[23], for pig aorta and coronary artery (Table 3). The results for α agreed very well, η was three times larger than that for vascular tissue and λ ranged $\pm 40\%$ of the value found by Frobert *et al.*^[23], for the pig coronary artery and was a third of the value that was found by Han and Fung^[22] for the pig aorta. It is likely that the differences are caused by structural differences between tissues^[25]. Studies using enzymatic digestion of structural components have been carried out on the zero-stress state analysis of the cardiovascular system^[28]. Similar studies may shed more light on the viscoelastic properties of different tissue components in the intestine.

In conclusion, the geometric parameters and biomechanical properties of the different segments of small intestine are different. The results obtained from this study add to a base set of morphometric and biomechanical data on the small intestine. The data obtained in this study provide a reference state for future comparison to other tissues, diseased intestinal tissue or intestinal tissue exposed to drugs or chemicals.

Table 3 Comparison of standard linear solid coefficients obtained in this study and from the literature

	Rat duodenum	Rat jejunum	Rat ileum	Pig aorta ^[22]	Pig coronary artery ^[23]
α	0.954	0.978	1.005	0.981	0.971
η	0.710	0.779	0.720	0.263 ^b	0.274 ^b
λ (s ⁻¹)	1.04×10 ⁻³	1.29×10 ⁻³	1.63×10 ⁻³	3.31×10 ^{-3b}	1.17×10 ⁻³

^b $P < 0.01$ vs rat intestine.

Abstract

AIM: To investigate the role of CXCL16 in the pathogenesis of immunological liver injury and to explore the possible mechanism of T lymphocyte infiltration regulated by CXCL16.

METHODS: Immunological liver injury in murine model was induced by Bacille Calmette-Guerin and lipopolysaccharide. Expression pattern and distribution of CXCL16 were examined by real-time quantitative RT-PCR and immunohistochemical analysis. Anti-CXCL16 antibody was administered *in vivo* to investigate its effect on T-cell recruitment and acute hepatic necrosis. The survival of murine model was also evaluated.

RESULTS: The murine immunological liver injury model was successfully established. CXCL16 expression increased and predominantly distributed in periportal areas and vascular endothelia in injured liver tissues. Administration of anti-CXCL16 Ab protected the mice from death and acute liver damage. Approximately 70% of the mice survived for 72 h in the anti-CXCL16 Ab treatment group, whereas 80% died within 72 h in control Ab group. The number of liver-infiltrating T lymphocytes was significantly reduced from 1.01×10^7 to 3.52×10^6 /liver, compared with control Ab treatment.

CONCLUSION: CXCL16 is involved in immunological liver injury by regulating T lymphocyte infiltration in liver tissue.

INTRODUCTION

Immunological liver injury is a key pathological change in liver disease, with a high mortality rate and histopathologically characterized by diffuse intrahepatic infiltration of inflammatory cells with massive multilobular necrosis. The details of the mechanisms involved in immunological liver injury remain to be elucidated. It was reported that injection of a small dose of lipopolysaccharide (LPS) into mice primed with Bacille Calmette-Guerin (BCG) causes lethal acute hepatic necrosis^[1], mimicking fulminant hepatic failure. There is evidence that activated macrophages and T lymphocytes are essential for the induction of liver damage^[2-5].

The current paradigm of T lymphocytes recruited to the inflamed liver is a multiple-step model, which describes the sequence of tethering/rolling, firm adhesion, and diapedesis/extravasation^[6,7]. The chemokine family is a small secreted protein, that directs migration of various types of leukocytes and is involved in inflammatory and immunological processes including lymphocyte homing, angiogenesis and enhancement of cytotoxic T lymphocyte (CTL) responses^[8,9]. Chemokines have been classified into four subfamilies, C, CC, CXC and CX₃C, based on the motif formed by the conserved cysteine residues in the N-terminal region. The selective interaction of chemokines and their receptors in part contributes to the specificity by which leukocyte subsets might be preferentially determined^[10,11].

CXCL16, with its structure similar to that of FKN^[12], containing both membrane-anchored and soluble forms, is a ligand for CXC chemokine receptor 6 (CXCR6), which is expressed on natural killer T (NKT) cells, and type 1-polarized, activated CD4⁺ and CD8⁺ T cells. CXCL16 is markedly expressed in lung, small intestine and kidney, and weakly expressed in liver^[13-18]. Because the pathological characteristics of immunological liver injury are associated with T-lymphocyte infiltration, and CXCL16 is chemotactic for T-lymphocyte migration to the liver tissue damage^[4,5,19-21], we could reason that CXCL16 might play a crucial role in the pathogenesis of immunological liver injury. In the present study, we investigated the expression pattern and distribution of CXCL16, and studied the role of CXCL16 in liver T-cell infiltration, and the effect of anti-CXCL16 antibody on the pathogenesis of immunological liver injury.

MATERIALS AND METHODS

Mice

Specific pathogen-free BALB/c mice (6-7 wk old) obtained from Shanghai Animal Center of Chinese Academy of Sciences (Shanghai, China) were bred in pathogen-free conditions and allowed free access to food and water.

Reagents

LPS (*Escherichia coli* 055:B5) was purchased from Sigma (St. Louis, MO). BCG was from Institute of Biological Product (Shanghai, China). Rat immunoglobulin (goat IgG) was gifted by Dr. XL Wang. Rat anti-mouse CXCL16 mAb (clone 142417, rat IgG2a) was obtained from R&D systems. PE-labeled anti-CD4 mAb and FITC-conjugated anti-CD8 mAb were obtained from PharMingen (San Diego, CA, USA). TRIzol RNA extraction kit was purchased from Gibco. All other chemicals used were of analytical grade.

Induction of liver injury by BCG and LPS

BCG was suspended in pyrogen-free physiological saline. To induce liver injury, mice were primed with intravenous injection of BCG (5×10^7 viable bacilli) via tail veins. After 12 d, they were given an intravenous injection of LPS (7.5 µg/mouse) suspended in pyrogen-free phosphate-buffered saline (PBS). To examine the effect of anti-CXCL16 antibodies on BCG-LPS-induced liver injury, monoclonal anti-CXCL16 antibody (0.2 mg/mouse) or nonimmune rat isotype IgG (0.2 mg/mouse) was administered intravenously 1-2 h before LPS challenge. Mice were killed to collect sera and liver specimens, and stored at -70 °C until use. Survival rate was determined 72 h after the LPS challenge.

Determination of serum alanine transferase (ALT)

Serum was collected for the measurement of ALT levels at various time points after LPS challenge.

Histology

Liver specimens were fixed in 10% neutrally buffered formalin and embedded in paraffin. Deparaffinized thin sections from each paraffin block were stained with hematoxylin and eosin for histologic examination and analyzed by light microscopy.

Analysis of specific gene expression in liver tissue by real-time quantitative RT-PCR

Total RNA was isolated from liver specimens using TRIzol, according to the manufacturer's instructions. The specific mRNA level was quantified by real-time quantitative PCR using a LightCycler instrument (Roche Molecular Biochemicals, Germany) with the DNA binding dye SYBR Green I as described with minor modifications^[22]. The sense primer for CXCL16 was 5'-AAC CAG GGC AGT GTC GC-3', and the antisense primer was 5'-AGG CAA ATG TTT TTG GTG G-3' (position: 79-342). The sense primer for β-actin was 5'-GCT ACA GCT TCA CCA CCA CAG-3', and the antisense primer was 5'-GGT CTT TAC GGA TGT CAA CGT C-3' (position: 590-877). Expression of mRNA was normalized by β-actin. In brief, external standards were

plasmids containing CXCL16 gene fragment (and β-actin). Plasmid DNA was purified and quantified photometrically and serially diluted. One microgram total RNA was reverse transcribed to cDNA. One microliter cDNA or external standard was added to capillary to a final reaction volume of 20 µL. The primer final concentration was adjusted to 0.5 µmol/L. The amplification conditions were initial denaturation at 95 °C for 30 s, 45 cycles at 95 °C for 0 s, at 60 °C for 3 s, at 72 °C for 12 s. Melting curve analysis was performed at the end of amplification. The acquisition temperature for the fluorescence signal was adjusted to 84 °C. PCR products were electrophoresed on 2% agarose gels and photos were taken under ultraviolet light to identify their specificity and sensitivity.

Immunohistochemistry

Experiments were conducted on frozen sections as described in detail elsewhere^[23]. Sections were incubated with primary antibody, and then with HRP-conjugated anti-rat IgG antibodies. After being visualized using DAB containing 0.01% hydrogen peroxide and counterstained with hematoxylin, sections were microscopically examined. Control sections were treated with omission of the primary antibody.

Preparation of intrahepatic infiltrating leukocytes and FACS analysis

Liver-infiltrating leukocytes were prepared as previously described^[24]. In brief, livers were taken from mice, pressed through the nylon mesh, and suspended in 2% fetal calf serum (FCS). The cell suspension was treated with Percoll density (1.09) gradient centrifugation. Mononuclear cells (MNCs) were isolated from parenchymal hepatocytes by centrifugation at 2 500 r/min for 30 min. The pellet was washed thrice in DMEM and resuspended in 10% FCS-DMEM. Flow cytometric immunofluorescence analysis of liver-infiltrating cells was performed with FACS calibur (BD Corp.). In brief, 4×10^5 cells were incubated with a PE-labeled anti-CD4 Ab and FITC-conjugated anti-CD8 Ab or FITC-conjugated anti-CD3 Ab at 4 °C for 30 min after washing twice with PBS solution.

Statistical analysis

All statistical calculations were performed using GraphPad PRISM™ (Graphpad Software Inc.). The survival rates were analyzed using the log-rank test. Student's *t* test was used to test for significance. $P < 0.05$ was considered statistically significant.

RESULTS

Establishment of immunological liver injury model in mice

BCG treatment alone induced MNC infiltration into hepatic lobes and formed granuloma (Figure 1B). Subsequent LPS challenge in BCG-primed mice induced diffuse infiltration of MNCs and multilobular hepatocellular necrosis in liver tissue (Figure 1C). The ALT level dramatically increased in BCG-primed mice after LPS challenge (Figure 2) compared to BCG treatment alone ($P < 0.05$). All these data confirmed that the murine immunological liver injury model was successfully conducted.

Figure 1 Pathological examination showing granuloma formation with BCG administration and hepatocellular necrosis followed by LPS injection. H&E staining

of cross-sections of normal liver (A), 12 d after BCG injection (B) and BCG-primed mice sequentially challenged with LPS (C). Bars = 20 μ m.

Figure 2 Levels of serum ALT in mice. The serum ALT levels of mice ($n = 5$ at each group) were measured as described in Materials and methods. Data represent mean \pm SD. ^a $P < 0.05$ vs BCG-primed mice.

Figure 3 Detection of CXCL16 mRNA in the injured liver by real-time quantitative RT-PCR analysis. Total RNA was isolated from the liver tissues at the different group as indicated and then reverse transcribed with reverse transcriptase and amplified by real-time quantitative PCR specific for CXCL16. Amplification of β -actin by same approach was used as control. The results represent three independent experiments. ^a $P < 0.05$ vs normal mice, ^c $P < 0.05$ vs BCG-primed mice.

Expression pattern and distribution of CXCL16 in murine injured liver model

Total RNA were isolated from liver tissue of normal, BCG-treated and BCG-primed mice after LPS challenge. CXCL16 mRNA was quantified by real-time quantitative PCR. CXCL16 was expressed in BCG-primed mice and strongly upregulated after LPS challenge, compared to that in normal liver tissue (Figure 3). These results suggested that upregulation of CXCL16 expression might be associated with liver injury.

Immunohistochemical analysis further showed that expression of CXCL16 in the liver significantly increased after LPS challenge in BCG-primed mice, compared to that in normal mice (Figure 4). CXCL16 was predominantly distributed in periportal area, hepatic sinusoids and vascular endothelia (Figure 4).

Infiltration of T lymphocytes in injured liver tissue

To investigate the characteristics of circulating T lymphocyte recruitment and infiltration in immunological liver injury,

cell surface expressions of CD3, CD4 and CD8 in the infiltrated MNCs were analyzed using a flow cytometer. The results revealed that the CD4⁺ T lymphocyte population increased from 0.92% to 2.93%, and further increased to 11.2% in BCG-primed mice after LPS challenge. CD8⁺ T lymphocyte population also increased from 0.16% to 1.56%, and reached 2.35% after LPS challenge (Figure 5A). The total absolute number of T lymphocytes increased from 0.399×10^6 to 3.179×10^6 /liver and reached 1.01×10^7 /liver in BCG-primed mice injected with LPS (Figure 5B). These findings demonstrated that T lymphocytes might be involved in the pathogenesis of immunological liver injury.

Anti-CXCL16 antibody increased survival of mice with immunological liver injury

Neutralizing anti-CXCL16 antibody could protect mice

Figure 4 Immunohistochemical examination of CXCL16 expression in liver tissue. Sections of livers were obtained from normal mice without any treatment (A) and BCG-primed mice sequentially injected with LPS (B). CXCL16-positive

(brown) cells are shown in the liver tissue with hematoxylin counterstaining. Bars = 20 μ m.

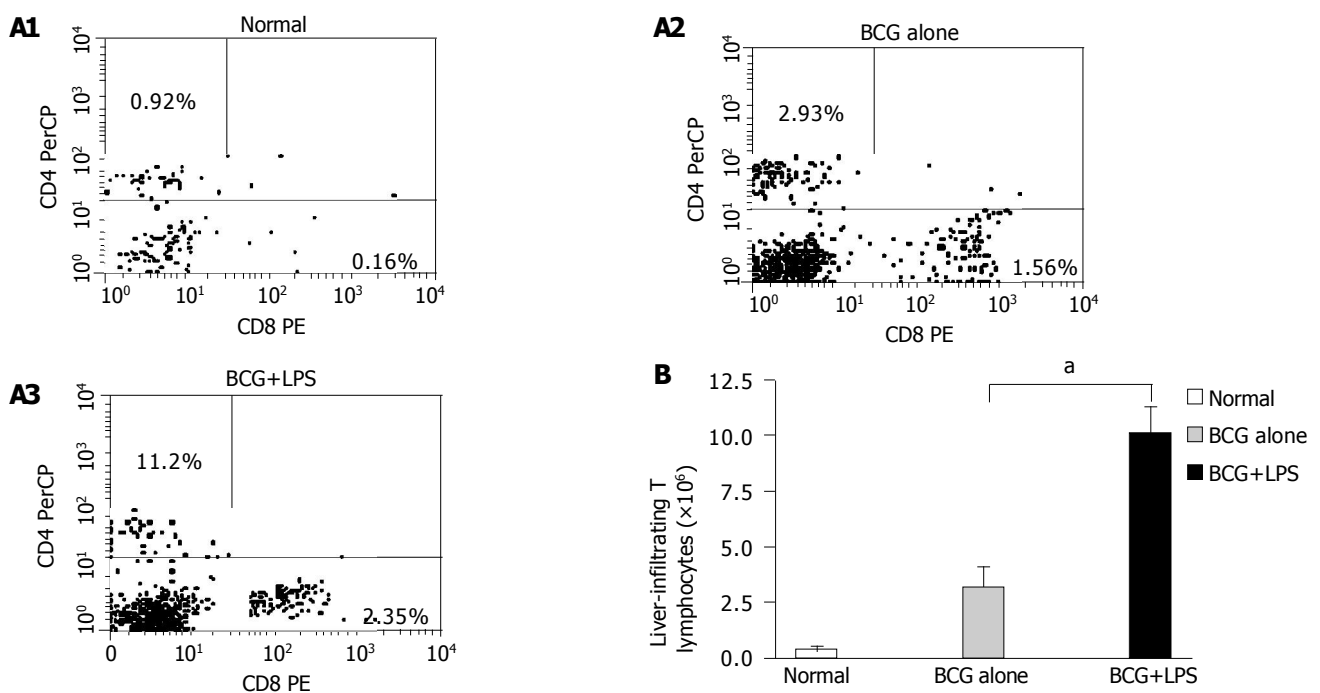

Figure 5 Analysis of liver-infiltrating CD4⁺ and CD8⁺ T lymphocytes population in liver injury induced by BCG and LPS. Mice were primed with BCG and sequentially challenged by LPS, 12 d after priming. MNCs derived from normal (without any treatment, open bars); BCG-primed (horizontal bars) and BCG-primed plus LPS challenged mice (hatched bars) were harvested for FACS

analysis. A₁-A₃: The CD4⁺ and CD8⁺ T lymphocytes population were analyzed with FACS; B: the absolute number of T lymphocytes was determined by multiplying the total MNC number by the fraction of CD4⁺, CD8⁺ T-lymphocytes population. **P* < 0.05 vs BCG-primed mice.

against lethal liver failure induced by BCG and LPS. Approximately 70% of the mice (*n* = 10) survived for 72 h, whereas most (80%) of the mice treated with control Ab died within 72 h (Figure 6).

Anti-CXCL16 antibody reduced infiltration of T lymphocytes in liver injury

Infiltrated MNCs in the liver were observed and granuloma formed after BCG treatment. The diffuse infiltration of MNCs resulted in multilobular necrosis after LPS challenge. To investigate the effects of anti-CXCL16 antibody on intrahepatic infiltrating T lymphocytes, liver MNCs were isolated and T lymphocytes were analyzed. The results revealed that anti-CXCL16 antibody *in vivo* significantly decreased the number of T-infiltrating lymphocytes from

Figure 6 Protective effect of anti-CXCL16 antibody on survival rate for murine lethal hepatic failure. Immunological liver injury was induced by BCG and LPS treatment and anti-CXCL16 Ab (solid line, *n* = 10) or control Ab (dashed line, *n* = 10) was injected as indicated in Materials and methods. The anti-CXCL16 antibody significantly protected the mice from lethality (**P* < 0.01 vs control Ab).

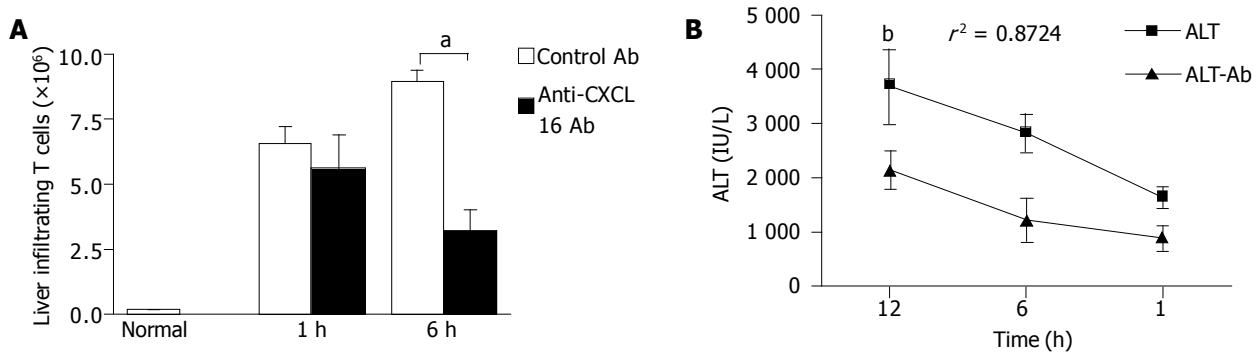

Figure 7 Effects of anti-CXCL16 antibody on intrahepatic infiltration of T lymphocytes and serum ALT level in the mice. Mice were primed with BCG and sequentially challenged by LPS 12 d after priming. Anti-CXCL16 antibody and isotype antibody were administrated into the mice, respectively. **A:** T lymphocytes derived from the mice treated with either anti-CXCL16 antibody (closed bars) or isotype antibody (hatched bars) was harvested for FACS

analysis. The absolute number of T lymphocytes was determined by multiplying the total MNC number by the fraction of CD3⁺T lymphocytes population. ^a $P < 0.05$ vs control Ab treatment. **B:** Anti-CXCL16 antibody significantly suppressed the elevation of serum ALT. ^b $P < 0.01$ vs control Ab group. Results were obtained from three independent experiments.

Figure 8 Effect of anti-CXCL16 antibody on the formation of hepatic lesion in liver injury induced by BCG and LPS. Sections of livers were obtained as follows: **A:** The liver tissue without any treatment; **B:** The liver tissue of mice primed with BCG was treated with the anti-CXCL16 Ab followed by LPS

challenge; **C:** The liver tissue of mice primed with BCG was treated with nonimmune rat IgG followed by LPS challenge. An arrow shows a necrotic lesion. Tissues were stained with H&E and examined histologically. Bars = 20 μ m.

1.01×10^7 to 3.52×10^6 /liver in BCG-primed mice after LPS challenge (Figure 7A, $P < 0.05$).

Change in serum ALT levels was characteristic of the immunological liver injury model in mice. The serum ALT level significantly decreased, when anti-CXCL16 antibody was applied *in vivo* compared to that after treatment with control Ab. The correlation coefficient of specific Ab and control Ab was 0.8724 ($P < 0.01$, Figure 7B). These data indicated that T cells might play a key role in the BCG and LPS-induced immunological liver injury.

Anti-CXCL16 antibody protected mice against multilobular necrosis in liver injury

MNCs infiltrated into liver lobes and formed granuloma in

liver 12 d after BCG treatment, compared to the normal mice (Figure 8A). Massive necrosis with diffuse infiltration of MNCs was observed in the livers of BCG-primed mice after LPS challenge (Figure 8C). In contrast, liver necrosis was significantly reduced by anti-CXCL16 Ab administration, and the specific Ab blocked the infiltration of MNCs infiltration in liver lobes and portal areas (Figure 8B).

DISCUSSION

In the present study, accumulation of T lymphocytes and massive hepatic necrosis were found and CXCL16 was strongly upregulated in the injured liver tissue in murine model. Upregulation of CXCL16 might be associated with

necrosis and liver injury. Administration of anti-CXCL16 antibody markedly inhibited the intrahepatic infiltration of T lymphocytes, and prevented lethal hepatic failure. These findings demonstrate that CXCL16 may play an important role in T lymphocyte infiltration and hepatic necrosis in immunological liver injury.

Serum ALT level is an important characteristic of hepatitis accompanied with pathologic changes of liver. Our results demonstrate that intravenous administration of anti-CXCL16 Ab can significantly decrease serum ALT level and hepatic necrosis, suggesting that CXCL16 plays a role in liver injury through some mechanisms. CXCL16 is predominantly expressed on APCs, existing in both secretory and transmembrane forms, and selectively chemoattracts CXCR6+T lymphocytes, which are potential cytotoxic effector cells, such as CD4+Th1, activated CD8+T cells and NKT cells^[13,14]. It was reported that these effector cells are closely associated with massive liver injury^[25-28]. These effector T lymphocytes, perhaps accompanying other leukocytes, might be recruited and involved in the pathogenesis of acute liver injury.

Activated CD4+T, CD8+T and NKT cells express TNF- α and FasL molecules associated with liver injury^[3,15,21,29-31]. Therefore, infiltrated T lymphocytes may mediate cytotoxicity to Fas-expressing hepatocytes and cause liver damage. Injection of LPS activates lymphocytes and triggers the release various soluble factors such as TNF- α , IFN- γ and IL-1, resulting in hepatocyte apoptosis and severe liver injury^[12,31,32]. All these and sequential cytokine production are the key factors in the pathogenesis of acute hepatic failure. Anti-CXCL16 antibody can decrease the number of intrahepatic infiltrating T lymphocytes, especially CD4+ and CD8+T-lymphocyte population. These might explain in part the reason, why specific antibody can rescue mice from death. Some leukocytes, such as neutrophils, are involved in liver injury. However, available evidence suggests that a small dose of LPS, that does not cause overt organ injury, can effectively inhibit extravascular recruitment of neutrophils^[33,34].

It is well known that many chemokines contribute to chemoattraction to trafficking leukocytes during liver inflammation^[8,35,36]. However, anti-CXCL16 antibody could significantly reduce the number of intrahepatic T lymphocytes and liver necrosis, indicating that CXCL16 might play other roles besides chemotactic function. There is evidence that supports these functions^[17,37]. Our experiments have confirmed that macrophages infected with *Mycobacterium tuberculosis* significantly increase the expression of CXCL16 and release chemokines and cytokines (data not shown). CXCL16 function in macrophages needs to be further studied.

Anti-CXCL16 Ab could not completely protect mice against death, suggesting that other chemokines or cytokines can also induce liver injury. Recently, it was reported that chemokines such as migration inhibitory factor, macrophage inflammatory protein-2 and thymus and activation-regulated chemokine are involved in the pathogenesis of liver injury^[1,38,39]. Although these facts can explain in part the possible reason why anti-CXCL16 Ab can protect mice from death, the precise mechanism needs to be elucidated further.

Abstract

AIM: To study the protective effect of *Astragalus membranaceus* on intestinal mucosa reperfusion injury and its mechanism after hemorrhagic shock in rats.

METHODS: A total of 32 SD rats were randomly divided into four groups ($n = 8$, each group): normal group, model group, low dosage group (treated with 10 g/kg *Astragalus membranaceus*) and high dosage group (treated with 20 g/kg *Astragalus membranaceus*). The model of hemorrhagic shock for 60 min and reperfusion for 90 min was established. Therapeutic solution (3 mL) was administrated before reperfusion. At the end of the study, the observed intestinal pathology was analyzed. The blood concentrations of lactic acid (LD), nitric oxide (NO), endothelin-1 (ET-1), malondialdehyde (MDA) and the activity of superoxide dismutase (SOD), glutathione peroxidase (GSH-PX) in intestinal mucosa were determined.

RESULTS: The intestinal mucosa pathology showed severe damage in model group and low dosage group, slight damage in high dosage group and no obvious damage in normal group. The Chiu's score in low dose group and high dose group was significantly lower than that in model group. The content of MDA in model group was higher than that in low and high dose groups, while that in high dose group was almost the same as in normal group. The activity of SOD and GSH-PX was the lowest in model group and significantly higher in high dose group than in normal and low dose groups. The concentrations of LD and ET-1 in model group were the highest. The concentrations of NO in model group and low dose group were significantly lower than those in high dose group and normal group.

CONCLUSION: High dose *Astragalus membranaceus* has

much better protective effect on hemorrhagic shock-reperfusion injury of intestinal mucosa than low dose *Astragalus membranaceus*. The mechanism may be that *Astragalus membranaceus* can improve antioxidative effect and regulate NO/ET level during hemorrhagic reperfusion.

INTRODUCTION

Under normal conditions, the integrity of intestinal mucosa as a barrier, can prevent bacterial translocation^[1,2]. Bacterial and endotoxin can enter into blood across the barrier when the intestinal mucosal barrier is demolished due to anoxia, ischemic and reperfusion injury. It is possible to induce systemic inflammatory response syndrome (SIRS) or multiple organ dysfunction syndrome (MODS), leading to the hemorrhagic shock^[3-6].

Free oxygen radical is one of the major activating factors in ischemia/reperfusion injury of intestinal mucosa^[7]. The maladjustment of NO/ET can not only aggravate oxidative damage, but also lead to dysfunction of the microcirculation of intestinal mucosa^[8-11]. Many drugs have been tried to palliate the ischemia-reperfusion injury of intestinal mucosa after hemorrhagic shock^[8,12,13]. However the results are still controversial and unsatisfactory.

Astragalus membranaceus is a traditional Chinese medicine which can improve microcirculation and has good curative effect. The main purpose of our study was to investigate whether *Astragalus membranaceus* could protect intestinal mucosa against ischemia-reperfusion injury after hemorrhagic shock, and to observe the effect of *Astragalus membranaceus* on intestinal oxidative damage, NO and ET levels.

MATERIALS AND METHODS

Animal experimental protocol

Approved by the University Animal Study Committee, 32 healthy male Sprague-Dawley rats (200-300 g, provided by

Animal Center of Sun Yat-Sen University) were randomly divided into four groups: normal group ($n = 8$, sham-operation, no shock and reperfusion), model group ($n = 8$, with hemorrhagic shock and treated only with 3 mL normal saline intravenously prior to reperfusion), low dose group ($n = 8$, with hemorrhagic shock and treated with 10 mg/kg *Astragalus membranaceus* which was five times of the human clinical dose) and high dose group ($n = 8$, with hemorrhagic shock and treated with 20 mg/kg of *Astragalus membranaceus* which was 10 times of the human clinical dose). The latter three groups were experimental groups.

Astragalus membranaceus (provided by Dioujiuhong Pharmaceutical Co., Ltd, Chengdu, China) was diluted in 3 mL normal saline and infused intravenously for 3 min prior to reperfusion.

Experimental model of hemorrhagic shock and resuscitation

Laboratory temperature was kept at 25–27 °C. The rats were anesthetized by intraperitoneal injection of urethane (5.0 mL, 20%) after they were fasted for 24 h. Tracheotomy was performed for ventilation. The right cervical vein was cannulated for monitoring central venous pressure and fluid infusion and drugs. The left carotid artery and femoral artery were catheterized for monitoring arterial pressure. The femoral artery was used to withdraw blood samples and to create hemorrhagic shock model.

Preparation of hemorrhagic shock model

Hemorrhagic shock model was established by withdrawing blood by femoral artery until mean arterial blood pressure (MABP) reached about 5.3 kPa (40 mmHg) and maintained for 60 min.

Rat resuscitation

Rats were administrated with 3 mL solution/drugs. Then their blood was reinfused for approximately 5 min and observed for 90 min. The segment samples of small intestinal mucosa were taken. The rats were killed at the end of the experiment.

The parameters included room temperature, rat weight and blood loss.

Mean arterial pressure and pulse rate were recorded every 10 min during the hemorrhagic shock and resuscitation period.

Preparation of specimens and measurements

After successful establishment of experimental model, the rats were killed and paunched rapidly. A segment of 0.5–1.0 cm intestine was cut from 5 cm to terminal ileum, fixed in 4% formaldehyde polymerisatum and embedded in paraffin for section. Another segment of small intestine was washed with frozen saline. The intestinal mucosa was scraped off, dried with suction paper and preserved at -70 °C.

The segment of small intestine was stained with hematoxylin-eosin. The damages of intestinal mucosa were evaluated by criteria of modified Chius method. Criteria of modified Chiu grading system were divided into 10 subdivisions according to the changes of villus and gland of intestinal mucosa: 0, normal villus and gland; 1, changes

in top of villus and initial formation of subepidermal Gruenhagen's antrum; 2, formation of subepidermal Gruenhagen's antrum and slightly injured gland; 3, enlargement of subepidermal gap and engorgement of capillary vessel; 4, epidermis moderately isolated with lamina propria and injured gland; 5, top villus shedding; 6, obvious villus shedding and capillary vessel dilating; 7, lamina propria villus shedding, and distinct injured gland; 8, initially decomposed lamina propria; 9, hemorrhage and ulcer.

Detection of lactic acid content in intestinal mucosa

Intestinal mucosal tissues were weighed and made into 10% homogenate. The lactic acid content in tissues was determined by the method of minim quick measurement (Jiancheng Bioengineering Ltd, Nanjing, China) and the concentration of protein was determined by Coomassie brilliant blue. The results were expressed as mmol/gpro.

Detection of content of MDA (malondisIdehyde) in intestinal mucosa

Intestinal mucosal tissues (100 mg) were homogenized with normal saline. MDA content was determined by TBA method (Jiancheng Bioengineering Ltd, Nanjing, China). Homogenate (0.1 mL) was taken to detect MDA content. Briefly, 0.1 mL 8.1% SDS, 0.8 mL acetic acid buffer, 0.8 mL 0.8% TBA and 0.2 mL distilled water were added into the sample tubes and one standard tube (containing 0.1 mL tetraethoxypropane). Then all the tubes were incubated at 100 °C for 1 h. After cooled at -20 °C for 5 min, 2 mL n-butyl alcohol was added into the sample, which was then vibrated for 1 min and centrifuged for 10 min at 3 000 r/min. The supernatant of the samples was taken to detect absorbance at 533 nm with spectrophotometer (content of MDA (nmol/100 mg) = absorbance of each sample/absorbance of standard \times dilution times).

Detection of activity of superoxide dismutase (SOD) in intestinal mucosa

Intestinal mucosal tissues (100 mg) were weighed and made into 10% homogenate with 0.9 mL normal saline, frozen in refrigerator at -20 °C for 5 min and centrifuged for 15 min at 4 000 r/min. Supernatants were transferred into fresh tubes for the evaluation of SOD activity. SOD activity was evaluated with SOD detection kit according to the manufacturer's instructions (Kits were provided by Jiancheng Bioengineering Ltd, Nanjing, China). SOD activity (μ /mL) = $(A_0 - A_1) / A_0 \times 360 \times V$ (A_0 : absorbance of self-oxidation rate per minute; A_1 : absorbance of each sample per minute; V : volume of extracted tissues).

Detection of activity of glutathione peroxidase (GSH-PX) in intestinal mucoa

Intestinal mucosal tissues (100 mg) were weighed and made into 10% homogenate with 0.9 mL normal saline. The activity of GSH-PX was detected according to the manufacturer's instructions (reagents were purchased from Jiancheng Bioengineering Ltd, Nanjing, China). Protein of homogenates was detected with Coomassie brilliant blue. The calculated results were expressed by U/100 mg protein.

Detection of content of NO in intestinal mucosa

Intestinal mucosal tissues (100 mg) were weighed and made into 10% homogenate with 0.9 mL normal saline. After being centrifuged for 10 min at 10 000 *g*, the supernatants were placed in boiling water for 3 min and then centrifuged for 5 min at 10 000 *g*. Supernatant (0.1 mL) was taken for detection, 0.2 mL 35% sulfosalicylic acid was added into the sample to make protein deposits. The sample was homogenized and centrifuged at 10 000 *g* for 10 min. The supernatants were taken again and preserved at -20 °C in refrigerator. One hundred μ L supernatant was detected by indirect nitric acid deoxidized enzyme method (Kits were provided by Jingmei Bioengineering Ltd). After 100 μ L nitrate reductase was homogenized gently, the sample was placed in water at 37 °C for 1 h with KNO₂ standard succi homogenized. After being placed in ambient temperature for 10 min and with zero setting with blank tube at 530 nm wavelength and 0.5 cm colorimetric cylinder, *A* value of detection tube and standard tube was read respectively.

Detection of ET-1 concentration in intestinal mucosa

Intestinal mucosal tissues (100 mg) were weighed and made into 10% homogenate with 0.9 mL normal saline. Homogenate ET-1 levels were measured by radioimmunoassay (Kits were obtained from Beijing East Asian Radioimmunoassay Technology Institute, Beijing, China).

Statistical analysis

Data were expressed as mean \pm SD and analysis of variance was performed using SPSS10.0 software. One-way analysis of variance was used for multiple comparisons and least significant difference test (LSD-*t*) was used for intra-group comparison. *P*<0.05 was considered statistically significant.

RESULTS

Basic status of each group

There was no difference in the four groups (*P*>0.05). The amount of withdrawn blood in three groups was similar, except in normal group (Table 1).

Table 1 Status of animals in each group (mean \pm SD)

Group	<i>n</i>	Weight (g)	Ambient temperature (°C)	Bloodletting volume (mL)
Normal	8	265 \pm 18	26.38 \pm 1.06	-----

^b*P*<0.01 vs pre-shock, ^d*P*<0.01 vs pre-shock.

Changes of animals' vital signs

There was no difference in MAP and HR in four groups before the experiment (*P*>0.05). The MAP in experimental groups was maintained at 5.33 kPa (40 mmHg), but the HR decreased during hemorrhage shock period. There was no significant difference after resuscitation in experimental group (*P*>0.05, Table 2).

Changes of intestinal mucosa under light microscope

The villus and glands were normal and no inflammatory cell infiltration was observed in mucosal epithelial layer in normal group. Severe edema of mucosa villus and infiltration of necrotic epithelial and inflammatory cells were found, indicating that damage was severe in model group. Light edema of mucosa villus and infiltration of few necrotic epithelial inflammatory cells were found in mucosa epithelial layer in low dosage group. No significant edema and necrotic mucosa villus were observed, but infiltration of a few inflammatory cells in mucosal epithelial layer was found in high dosage group, which was also the same as those in normal intestinal mucosa (Figures 1-4).

Figure 1 Normal villus and glands in normal group.

Chiu's score of small intestinal structure

The Chiu's score was the lowest in normal group and the highest in model group. Compared to model group, the Chiu's score was significantly lower in high dose group (*P*<0.05, Table 3).

Changes of MDA in small intestinal mucosa

The content of MDA in intestinal mucosa was the highest in model group, compared to that in normal, high and low dose groups. However there was no difference in Chiu's

Figure 2 Severe edema of mucosa villus and infiltration of necrotic epithelial cells and inflammatory cells in model group.

Figure 4 No significant edema and necrotic mucosa villus and infiltration of a few inflammatory cells in high dose group.

Figure 3 Light edema of mucosa villus and few necrotic epithelial cells and infiltration of few inflammatory cells in low dose group.

score among normal, low and high dose groups ($P>0.05$, Table 3).

Changes of activity of SOD

The activity of SOD in intestinal mucosa was the highest in high dose group ($P<0.05$ or 0.01), and the lowest in model group ($P<0.05$, Table 3).

Change of activity of GSH-PX in intestinal mucosa

The activity of GSH-PX was the lowest in model group ($P<0.05$) compared to that in the other three groups. There was no difference between normal group and low dose group ($P>0.05$, Table 3).

Lactic acid content in intestinal mucosa

The content of lactic acid in model group and low dose group was significantly higher than that in normal and high dose groups ($P<0.05$). There was no significant difference

among model group, low and high dose groups ($P>0.05$, Table 3).

Change of NO content in small intestinal mucosa

The content of NO in small intestinal mucosa in model group and low dosage group was significantly lower than that in normal group and high dosage group ($P<0.05$ or 0.01). There was no significant difference between model group and low dosage group ($P>0.05$) and between normal group and high dosage group ($P>0.05$, Table 3).

Changes of ET-1 content in intestinal mucosa

The content of ET-1 in intestinal mucosa was significantly higher in three experimental groups ($P<0.01$). The content of ET-1 in model group was higher than that in low and high dose groups ($P<0.05$ or 0.01 , Table 3).

DISCUSSION

Blood supply of small intestine from celiac branch of superior mesenteric artery accounts for 20% of total body blood volume. The blood flow in mucous layer is about 70-80% of total intestine blood flow, while the blood flow in muscular layer and serosa is about 15-25% of intestine blood flow. The blood flow in submucous layer is less than 5% of intestine blood flow. But 60% of blood flow in mucous layer is concentrated on the top of mucosa which provides enough hemoperfusion of endotheliocytes and villus^[14]. When shock occurs, the blood flow in intestinal mucosa decreases sharply. That is why the small intestinal mucosa is most easily subjected to ischemia and reperfusion injury^[15,16].

Studies have proved that ischemia reperfusion injury of intestinal mucosa plays an important role in inducing

^a $P<0.05$, ^b $P<0.01$ vs normal group, ^c $P<0.05$, ^d $P<0.01$ vs low dose group and high dose group, ^e $P<0.05$ vs low dose group.

multiple organ dysfunction syndrome (MODS)^[3-6]. Therefore prevention of intestinal mucosal barrier from hemorrhagic shock is very important. The results of our study showed that small intestinal mucosa was severely injured after simple hemorrhagic shock. However, the injury of small intestinal villus was alleviated after *Astragalus membranaceus* was administrated. The best result was obtained with high dose *Astragalus membranaceus* treatment, indicating that *Astragalus membranaceus* can protect intestinal mucosa against reperfusion injury, after hemorrhagic shock in a dose-dependant manner.

NO and ET-1 are active substances released by vascular endothelial cells (especially in lung) and the most important endogenous regulatory factors. It is most important to keep the dynamic balance between NO and ET in order to maintain tissue and organ hemoperfusion. Some studies^[9,17,18] reported that NO and ET-1 increase in plasma sharply during hemorrhagic shock and after resuscitation. At the same time, the intestinal barrier is also damaged.

NO/ET imbalance and endothelial disorder can induce intestinal mucosal hypoperfusion or ischemic injury, when hemorrhagic shock occurs.

Our study showed lactic acid content in intestinal mucosa in model group increased markedly, suggesting that anaerobic metabolism of intestinal mucosa occurs. NO level decreased and ET level increased sharply, suggesting that microcirculation of the intestinal mucosa is destroyed during and after hemorrhagic shock /reperfusion injury.

Bauer *et al.*^[19,20], found that intestinal damage can be relieved by drugs, when endogenous NO release is evoked. Oktar *et al.*^[21], and Anadol *et al.*^[22], used ET receptor antagonists to suppress endogenous ET activity, and found that they can relieve the damage due to intestine ischemic reperfusion, demonstrating that ET receptor antagonists can relieve ischemia reperfusion injury of intestine by modulating NO/ET level.

We found that *Astragalus membranaceus* could increase endogenous NO level and decrease endogenous ET level in intestinal mucosa, suggesting that *Astragalus membranaceus* can relieve endothelial dysfunction and ameliorate microcirculation via regulating NO/ET level during hemorrhagic-reperfusion.

Oxygen free radical is another major factor in inducing ischemia reperfusion injury. It could damage the structure of cell membrane and mitochondrial membrane through lipid peroxidation and result in cellular structure destroy and cell dysfunction^[7,8]. MDA is the direct products of lipid peroxidation^[7,8]. The extent of lipid peroxidation could be accessed by measuring MDA level in tissues. Our study also showed that the content of MDA in intestinal mucosa in model group was significantly higher than that in other groups, suggesting that significant lipid peroxidation occurs in small intestinal mucosa during hemorrhagic shock and reperfusion period. Some previous studies found^[23,24] that peroxide dismutase significantly relieves small intestine mucosal injury after 3 h ischemia, demonstrating that oxygen free radical plays an important role in ischemic injury of small intestinal mucosa.

SOD and GSH-PX are the major enzymes for scavenging oxygen free radical, whose activity could reflect its functional

status^[25-27]. The activity of SOD and GSH-PX in *Astragalus membranaceus*-treated groups was markedly higher than that in normal group and model group, which would be beneficial to scavenging oxygen free radical.

The content of MDA in intestinal mucosa in *Astragalus membranaceus*-treated groups was obviously lower than that in model group, demonstrating that *Astragalus membranaceus* has powerful antioxidative effects and protects small intestinal mucosa against hemorrhagic- reperfusion injury.

In conclusion, *Astragalus membranaceus* protects intestinal mucosa against hemorrhagic-reperfusion injury in a dose-dependant manner by regulating NO/ET level of intestinal mucosa after ischemia-reperfusion.

ACKNOWLEDGMENTS

The authors thank Professor Wei-Kan Wu for his good advice and Hui-Lan Sun for assistance to the experiments.

Abstract

AIM: To observe the biologic behavior of pancreatic cancer cells *in vitro* and *in vivo*, and to explore the potential value of angiostatin gene therapy for pancreatic cancer.

METHODS: The recombinant vector pcDNA3.1(+)-angiostatin was transfected into human pancreatic cancer cells PC-3 with Lipofectamine 2000, and paralleled with the vector and mock control. Angiostatin transcription and protein expression were determined by immunofluorescence and Western blot. The stable cell line was selected by G418. The supernatant was collected to treat endothelial cells. Cell proliferation and growth *in vitro* were observed under microscope. Cell growth curves were plotted. The transfected or untransfected cells overexpressing angiostatin vector were implanted subcutaneously into nude mice. The size of tumors was measured, and microvessel density count (MVD) in tumor tissues was assessed by immunohistochemistry with primary anti-CD34 antibody.

RESULTS: After transfected into PC-3 with Lipofectamine 2000 and selected by G418, macroscopic resistant cell clones were formed in the experimental group transfected with pcDNA 3.1(+)-angiostatin and vector control. But untreated cells died in the mock control. Angiostatin protein expression was detected in the experimental group by immunofluorescence and Western-blot. Cell proliferation and growth *in vitro* in the three groups were observed respectively under microscope. After treatment with supernatant, significant differences were observed in endothelial cell (ECV-304) growth *in vitro*. The cell proliferation and growth were inhibited. In nude mice model, markedly inhibited tumorigenesis and slowed tumor expansion were observed in the experimental group as compared to controls, which was parallel to the decreased

microvessel density in and around tumor tissue.

CONCLUSION: Angiostatin does not directly inhibit human pancreatic cancer cell proliferation and growth *in vitro*, but it inhibits endothelial cell growth *in vitro*. It exerts the anti-tumor functions through antiangiogenesis in a paracrine way *in vivo*.

INTRODUCTION

Angiogenesis means the formation of new blood vessels and is indispensable to various physiological processes including reproduction, development, wound repair, and tissue regeneration. There is evidence that tumor growth and metastasis are accompanied with the growth of new blood vessels, which proves the rationality and feasibility of anti-angiogenic therapy for tumor^[1,2].

Pancreatic cancer is the second most common cause of death from any type of gastrointestinal diseases in the United States^[3]. The common treatment of pancreatic cancer is suboptimal and the prognosis of patients is poor^[4].

Although pancreatic cancer is not a grossly vascular tumor, this malignancy often exhibits enhanced foci of endothelial cell proliferation. But several^[5-7] studies have reported a positive correlation between blood vessel density. Angiogenesis may play an important role in this disease. Angiostatin plays a key role in regulating endothelial cell proliferation and migration during the process of angiogenesis^[8,9] and inhibits the growth of a variety of murine and human tumors^[10].

We transfected eukaryotic vector encoding mouse angiostatin into human pancreatic cancer cells to observe the anti-tumor function of angiostatin and to explore the potential activity in gene therapy for pancreatic cancer.

MATERIALS AND METHODS

Cell lines and reagents

Recombinant vector pcDNA3.1(+)-angiostatin was

identified by restriction endonuclease digestion and sequencing. The human pancreatic cancer cell line PC-3 and endothelial cell line ECV-304 were purchased from China Center for Type Culture Collection. *Pvu*II was purchased from Bioson Corporation. Lipofectamine™ 2000 and G418 were purchased from Gibco Company; Rabbit anti-HA tag monoclonal antibody was presented by Jicheng Zhang doctor; FITC was purchased from Boster Biological Technology Co. CD-34 was purchased from Beijing Zhongshan Golden Bridge Biotechnology Co.

Cell culture

Pancreatic cancer cells and endothelial cells were cultured in RPMI1640 (Gibco) supplemented with 10% fetal bovine serum (FBS) (Sijiqing, Hangzhou, China), penicillin (100 U/mL) and streptomycin (100 mg/mL) in a humidified atmosphere of 50 mL/L CO₂ at 37 °C.

Transfection

Pancreatic cancer cells (PC-3) in logarithmic growth phase were implanted in 24-well plates at 2×10^5 cells/well, and approximately 80% confluence was obtained, after overnight incubation. pcDNA3.1(+)-angiostatin was digested by *Pvu* I according to the protocol of the manufacturer, and the recombinant was linearized. DNA/Lipofectamine 2000 complexes were prepared and transfected according to the protocol of the manufacturer. The experimental group and the vector control was designed with pcDNA3.1(+) and the mock control with Lipofectamine 2000. After 12 h of transfection, the selective medium containing G418 (50 mg/L) was used to culture cells for 14 d. Then the isolated resistant cell clones were selected and amplified.

Analysis of angiostatin by immunofluorescence cytochemistry and Western blot

PC-3 with pcDNA3.1(+) angiostatin in logarithmic growth phase was implanted in 6-well plates. After 24 h, the glass flake was taken out and immunofluorescence cytochemistry was carried out according to manufacturer's instructions, and the expression was detected under fluorescent microscope.

The cells were cultured in a conditioned media for 5 d. Cell supernatant was mixed with lysine-sepharose and incubated at 4 °C overnight. Detection was performed by the enhanced chemiluminescence (ECL) Western blotting analysis system according to the manufacturer's instructions.

Inhibitory on vascular endothelial cells

In logarithmic growth phase, the supernatant was collected. Endothelial cells ECV-304 were treated with supernatant separately for 7 d (supernatant/medium = 1/9), and counted under microscope.

Viable cell number counting and growth curve

Pancreatic cancer cells (PC-3) and endothelial cells (ECV-304) were plated on 24-well plates at 1×10^4 cells/well and cultured for 7 d. Viable cells was counted under microscope and growth curves were plotted.

Tumormodels

Balb/c nude mice were randomly divided into three groups,

5 in each group. The experimental group with pcDNA3.1(+)-angio/PC-3, the vector control with pcDNA3.1(+)/PC-3 and the mock control with untransfected PC-3 were separately injected subcutaneously with pancreatic cancer cells PC-3 at 1.0×10^6 cells each mouse. After 56 d, the mice were killed to measure the size of tumor formed and to calculate the percentage of inhibition on tumorigenesis *in vivo*.

Quantitative analysis for microvessel densities (MVD)

Tumor tissues were fixed and embedded in paraffin. MVD was detected by immunohistochemistry SP method, and counted in four fields under light microscope (200× selected randomly).

Statistical analysis

To determine statistical significance, data were analyzed by statistical software of SPSS 10.0, Student's *t* test and χ^2 test.

RESULTS

Vector-mediated expression and secretion of angiostatin *in vitro*

Pancreatic cancer cells (PC-3) transfected with the corresponding vectors were selected by G418 for 14 d. The experimental and vector control groups formed macroscopic cell clones, but the mock group of cells was dead completely after 8 d of selection. Immunofluorescence showed signals of angiostatin in the experimental group of cell clones genetically engineered, but not in the controls (Figure 1A). Western blot analysis of cell supernatants (Figure 1B) revealed the detected protein with the size (5 800 kb) being consistent with angiostatin in the experimental group, whereas no specific band was observed in the controls.

Figure 1 Angiostatin protein expression by immunofluorescence (A) Western blot analysis (B). M: Marker; lane 1: PBS control; lane 2: PC-3; lane 3: PC-3/pcDNA3.1(+); lane 4: PC-3/pcDNA3.1(+).

Biological activity of angiostatin protein expression *in vitro*

To detect biological activity of the encoded angiostatin *in vitro*, tumor cells transduced with and without the corresponding vectors were cultured for 7 d to make cell growth curve (Figure 2A). Under microscope, no obvious difference was observed in the cell morphology among the three groups of cells. Cell growth curves indicated no change in cell growth speed and doubling time among the three groups. These results indicated that upregulated angiostatin expression could neither directly inhibit cell growth and proliferation, nor affect cell cycle *in vitro*. But biological activity of the cell treated with supernatant of PC-3/pcDNA3.1(+)-angiostatin, the growth was obviously inhibited. The growth of the vector and mock control groups was similar to that of normal (Figure 2B). These results indicated that angiostatin expression could directly inhibit endothelial cell growth and proliferation *in vitro*.

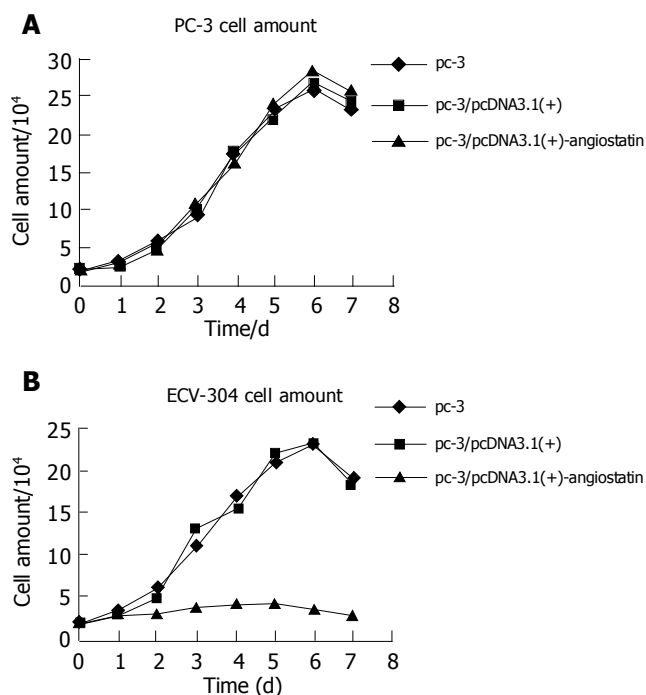

Figure 2 Cell growth curves of PC-3 (A) and ECV-304 (B).

Biological activity of angiostatin protein expression *in vivo*

Macroscopic tumors were observed on d 10, after injection

of angiostatin developed fast in the vector and mock control groups of nude mice. However, no macroscopic tumors were observed until 14 d, after injection of angiostatin in the experimental group and tumors developed slowly. After 56 d of injection of angiostatin, no mice died in the three groups and the tumors were resected and measured. Small pale tumor nodules were observed in the angiostatin-transfected tumors, whereas red and hypervascularized large tumors were present in the vector-transfected control and mock control tumor cells. The average size of tumors in the experimental group was $6.2 \times 10^{-2} \text{ cm}^3$, much less than the average size of the vector control $1.4 \times 10^{-2} \text{ cm}^3$ and the mock control (Figure 3). The inhibition of angiostatin overexpression reached 77%.

Tumor tissue in the experimental group was more vascularized than in the control groups. Greater microvascular density were found by immunohistochemical staining in tumors in the experimental group than in the vector or mock control groups respectively ($P < 0.01$, Figure 4). The results indicated that overexpression of angiostatin could decrease tumorigenesis by inhibiting neovascularization in tumors *in vivo*. Angiostatin might have inhibitory actions on surrounding tumor tissues and indirectly inhibit tumorigenesis.

DISCUSSION

Angiogenesis is critical for normal and pathologic processes in new blood vessel formation and plays an important role in the growth and spread of cancer. New blood vessels “feed” cancer cells with oxygen and nutrients, allow these

Figure 4 MVD in immunochemistry staining. A: PC-3/pcDNA-angiostatin; B:

PC-3/pcDNA3.1; C: PC-3. SP×200.

cells to grow, invade nearby tissue, spread to other parts of the body, and form new colonies of cancer cells. At the prevascular stage, tumor is unable to grow to a size beyond 2-3 mm³ and remains in its dormant state. However, once the angiogenic phenotype of the tumor is switched on, tumor growth rate changes from linear to exponential^[11-14].

Angiogenesis begins, when a fibrin clot forms on the adventitial surface of an existing blood vessel^[15], followed by sprouting of new capillaries. The initial phase begins with increased vascular permeability and local degradation of the vessel wall. Endothelial cells enter the tumor stroma and proliferate. At this time, the cells may be most vulnerable to agents that interfere with their proliferation, since they lack protection from other cell types^[16]. The next step in vessel formation is recruitment of pericytes, followed by smooth muscle cells.

Angiogenesis is a process controlled by certain chemicals produced in the body. These chemicals stimulate cells to repair damaged blood vessels or form new ones such as vascular endothelial growth factor (VEGF)^[17], basic fibroblast growth factor (bFGF)^[18], acidic fibroblast growth factor (aFGF), Interleukin-8, angiogenin, placental growth factor (PGF)^[19], transforming growth factor-TGF α , β ^[20], other chemicals are inhibitors such as angiostatin^[21], thrombospondin-1^[22], 16-kd prolactin fragment^[23], Interferon- α , β ^[24], Endostatin^[25]. Because cancer cannot grow or spread without the formation of new blood vessels^[26], scientists are trying to find ways to stop angiogenesis.

Tumor angiogenesis is often the consequence of an angiogenic imbalance in which pro-angiogenic factors predominate over anti-angiogenic factors^[27]. Furthermore, angiogenesis is essential for growth and metastasis of most solid cancers. Pancreatic cancer is not a grossly vascular tumor, but is related to angiogenesis^[28]. Anti-angiogenic treatment may be necessary and has potential for treatment of pancreatic cancer.

Angiostatin was first isolated as a circulating angiogenesis inhibitor. The structure of angiostatin includes the first four-kringle domains of plasminogen. Amino acid sequence analysis of kringle domains of human angiostatin has shown that K1, K2, K3, and K4 display considerable similarity (about 50% identity). Among these individual kringles, K1 has been identified as the most potent inhibitor of endothelial cell growth. K3 has higher inhibitory potency than K2. Surprisingly, K4 is virtually inactive in suppression of endothelial cell growth. Indeed, a short version of angiostatin only containing the first three kringle domains without K4 (K1-3) seems to be more active than K1-4 in inhibition of endothelial cell growth^[29]. Angiostatin inhibits proliferation of endothelial lineages in a dose-dependant manner, but not in the proliferation of normal and neoplastic nonendothelial cell lines^[30]. Human angiostatin inhibits the growth of transplanted human breast carcinoma, colon carcinoma and prostate carcinoma in mice, without obvious weight loss or other toxicity observed. It causes human primary carcinomas to regress to a dormant state by a net balance of tumor cell proliferation and apoptosis^[31]. Although angiostatin is a potent inhibitor of angiogenesis and tumor growth, the need of high dosages, repeated injections and long-term administration of this protein has made it less attractive for clinical trials.

In our study, mouse angiostatin cDNA was transfected into human pancreatic cancer cells PC-3, and stable cell lines expressing the secreted angiostatin were proved by immunofluorescence and Western-blot. Although angiostatin has no direct effect on pancreatic cancer cell PC-3 growth *in vitro*, the supernatant of stable cells inhibited the growth of endothelial cells ECV-304. The stable cell clones were implanted in the back of nude mice and the tumor growth inhibition rate of primary tumor growth was 77%, tumor growth inhibition is related to vascularization. According to the observation, angiostatin exerted its anti-tumor effect through anti-angiogenesis. These results are consistent with previous reports^[31]. By transfecting angiostatin into pancreatic cancer cells PC-3, we have gotten the protein. Thus angiostatin gene therapy is for pancreatic cancer. However, long-term, high-level, and sustained expression of angiostatin, are necessary to prevent dormant tumors from becoming active again. To achieve this objective, Xu *et al.*^[32], engineered a recombinant adeno-associated virus (AAV) vector encoding mouse angiostatin, and found that it suppresses metastatic liver cancer in mice. In our study, we used Lipofectamine-2000 for transfection and got the similar result. These results support that angiostatin-gene therapy is a potential strategy in the treatment of pancreatic cancer.

In conclusion, angiostatin inhibits pancreatic cancer cell proliferation and growth, and may provide a new way for its treatment.

Abstract

AIM: To analyze the hepatic and intestinal microcirculation in an animal model of liver cirrhosis and inflammatory bowel disease (IBD) and to characterize the anti-inflammatory action of antithrombin III (ATIII) on leukocyte kinetics and liver damage.

METHODS: Hepatic and intestinal microcirculation was investigated by intravital videomicroscopy. Standardized models of experimental chronic liver cirrhosis and bowel inflammation were employed. Animals were divided into four groups ($n = 6/\text{group}$): controls, animals with cirrhosis, animals with cirrhosis and IBD, animals with cirrhosis and IBD treated with ATIII.

RESULTS: Cirrhosis facilitated leukocyte rolling and sticking in hepatic sinusoids (1.91 ± 0.28 sticker/ μm vs 0.5 ± 0.5 sticker/ μm in controls, $P < 0.05$). The effect enhanced in animals with cirrhosis and IBD (5.4 ± 1.65 sticker/ μm), but reversed after ATIII application (3.97 ± 1.04 sticker/ μm , $P < 0.05$). Mucosal blood flow showed no differences in cirrhotic animals and controls (5.3 ± 0.31 nL/min vs 5.4 ± 0.25 nL/min) and was attenuated in animals with cirrhosis and IBD significantly (3.49 ± 0.6 nL/min). This effect was normalized in the treatment group (5.13 ± 0.4 nL/min, $P < 0.05$). Enzyme values rose during development of cirrhosis and bowel inflammation, and reduced after ATIII application ($P < 0.05$).

CONCLUSION: Liver cirrhosis in the presence of IBD leads to a significant reduction in mucosal blood flow and an increase in hepatic leukocyte adherence with consecutive liver injury, which can be prevented by administration of ATIII.

INTRODUCTION

Liver cirrhosis is a well-known immunocompromised state, with a high susceptibility to infection and organ dysfunction^[1]. Cirrhotic patients are prone to develop a progressive impairment in local and systemic hemodynamics, leading to renal and hepatic failure. The gut mucosa plays an important role in the pathogenesis of complications of cirrhosis. However, little is known about the exact mechanisms promoting severe septic complications and liver failure in cirrhotic patients. Among other pathophysiological mechanisms, hypoperfusion of the gut mucosa has been implicated as an important mechanism contributing to mucosal injury^[2]. Likewise changes in the intestinal flora and in the intestinal barrier as well as leukocyte dysfunction are presumed to be responsible for infective complications of cirrhosis^[3].

Any inflammatory process is characterized by tissue infiltration of leukocytes mediated by cytokines and cell adhesion molecules expressed on the endothelial surface^[4]. By intravital videomicroscopy, leukocyte-endothelial interaction can be visualized and quantitated. Furthermore, the effects of therapeutic agents can be investigated in the same setting.

Patients with progressive liver disease are known to have low plasma concentrations of antithrombin III (ATIII)^[5,6]. ATIII is synthesized in liver parenchymal cells and plays a central role in regulating hemostasis^[7]. In addition, ATIII has been reported to have some influence on the inflammatory process, which is independent of its effects on coagulation. This effect is thought to be indirect via enhanced prostacyclin release from endothelial cells^[8]. We have previously shown that hepatic reperfusion injury could be attenuated by administration of ATIII in an animal model of warm hepatic ischemia and reperfusion^[9].

The aim of this study was to analyze the intestinal and hepatic microcirculation in cirrhotic animals with inflammatory bowel disease (IBD) and to evaluate the effects of ATIII application during the onset of bowel

inflammation on microcirculation, leukocyte-endothelium interaction and liver function.

Data of control and cirrhotic animals without bowel inflammation published recently by our group were considered for statistical comparison in the present study.

MATERIALS AND METHODS

All experiments were performed in accordance with the Governmental Animal Protection Committee.

Experimental protocol

Twenty-four male Wistar rats weighing 200-220 g were eligible for analysis in this study. Two rats died during induction of liver cirrhosis. Animals were divided into four groups, six animals each: controls, animals with cirrhosis, animals with cirrhosis and IBD, and animals with cirrhosis and IBD treated with ATIII.

Induction of liver cirrhosis

Chronic progressive liver cirrhosis was induced by gavage with carbon tetrachloride (CCl₄) as previously described^[10]. In brief, animals had free access to tap water containing barbitural sodium (100 mg/dL) 2 wk before the first CCl₄ dose. The CCl₄ doses were calibrated weekly from an initial dose of 0.04 mL, to a maximum dose of 0.4 mL after 10 wk.

Induction of bowel inflammation

Bowel inflammation was induced by the protocol of Yamada, described in detail elsewhere^[11]. Indomethacin at a dose of 7.5 mg/kg body weight (Sigma, Germany) was injected subcutaneously in the lower abdomen. Drug application was repeated after 24 h, and intravital videomicroscopy was performed 7 d, after induction of bowel inflammation.

Antithrombin III application

A group of six animals received intravenously 250 IU/kg body weight ATIII (Kybernin HS 1000, Centeon Pharma, Germany) 24 h, after the last indomethacin application.

Monitoring

Mean arterial blood pressure and heart rate were recorded continuously via an arterial catheter placed in the left carotid artery. In addition, arterial blood samples were obtained to perform blood-gas analysis (ABL 5, Radiometer GmbH, Willich, Germany) and venous samples to measure liver enzymes (AST, ALT, GGT, and alkaline phosphatase) and clotting (ATIII levels and prothrombin time) using commercial assays.

Intravital videomicroscopy

Animals were fasted overnight, but received water *ad libitum*. Experiments were performed under general anesthesia with ketamine/pentobarbital (Ketanest, Park-Davis, Germany and Narcoren, Merial, Germany), administered via a catheter (B. Braun, Melsungen, Germany) placed in the left jugular vein. A midline incision was made and intravital fluorescence microscopy was performed using a Leitz orthoplan microscope (Leitz, Wetzlar, Germany). With different excitation filters

(wavelengths 450-490 and 530-560 nm), selective visualization of FITC-labeled erythrocytes and rhodamine 6G stained leukocytes was possible. For contrast enhancement, FITC-labeled albumin was administered intravenously.

Liver microcirculation

The left liver lobe was exteriorized onto a specially designed stage and videomicroscopy was performed according to the technique described by Menger *et al.*^[12]. Ten liver lobules were observed for 30-60 s. Vessels with a diameter between 20 and 40 μ m were eligible for analysis.

Small intestine microcirculation

In the same animal, the terminal ileum was exteriorized and placed on a glass slide. Videomicroscopy of mean mesenteric vessels was performed. Then the bowel was opened along the anti-mesenteric border and fixed at the incision margins. Continuous superfusion with buffered Ringer's solution was provided. Mesenteric microcirculation was investigated in 10 fields of ileal arteries and corresponding veins following the technique described in detail elsewhere^[13]. Mucosal microcirculation was measured in the main arteriole of five single villi. Each vessel was observed for 30 s.

Data analysis

Microcirculatory parameters were quantified by off-line analysis of video-recorded microscopic images using the computer-assisted image analysis system Capimage (Capimage, Zeintl, Heidelberg, Germany)^[14]. Vessel diameter and erythrocyte velocity were evaluated. Leukocyte-endothelium interaction (LEI) was characterized by leukocyte adherence measurements as the number of leukocytes that remained stationary or temporary on the vessel wall. Leukocytes that adhered for at least 30 s were considered as stickers, whereas leukocyte rolling was based on endothelial lining that was less than 66% of the erythrocyte velocity. Microvascular blood flow was derived from erythrocyte velocity (V_e) and vessel diameter (D) using the following equation^[15]: $V_b = V_e \times \pi \times (D/2)^2$.

Histology

After microscopy, animals were killed. One part of the liver and one part of the small intestine were obtained for histopathological investigations. Specimens were fixed in buffered formalin (4%), embedded in paraffin and stained with hematoxylin and eosin.

Statistical analysis

All data were expressed as mean \pm SD. Inter-group comparisons were made using the Mann-Whitney *U* test. $P < 0.05$ was considered statistically significant.

RESULTS

Hemodynamics and laboratory data

There were no significant differences in hemodynamic variables between the groups. Signs of sepsis were not observed in any of the animals (Table 1). Analysis of laboratory data demonstrated significant differences in all groups (Table 4). In summary, transaminase values rose

during development of cirrhosis and bowel inflammation. This effect was withdrawn after ATIII treatment. Prothrombin time showed comparable characteristics.

Table 1 Cardiorespiratory parameters at the beginning of intravital videomicroscopy (mean±SD)

	Cirrhosis	Cirrhosis and IBD	ATIII treatment group (cirrhosis and IBD)	Controls
Mean arterial blood pressure (mmHg)	107±8.4	102±8.7	106±7.8	112±7.3
Heart rate (bpm)	310±9.2	318±7.4	312±8.2	304±8.4
paO ₂ (mmHg)	89.1±5.3	86.4±4.3	88.6±5.4	92.3±4.8

Microcirculation

Table 2 compares the vessel diameter, RBC velocity and blood flow of the liver, mesentery, and ileal mucosa. Blood flow analysis showed significant differences between the groups. Liver cirrhosis was associated with a reduction of volumetric blood flow in mesenteric vessels, compared to control animals (135.1±3.56 nL/min *vs* 156.5±4.3 nL/min). However, an inverse effect was observed in the presence of bowel inflammation: mesentery blood flow increased significantly (149.8±2.41 nL/min) and rose further in the ATIII treatment group (243.1±3.71 nL/min). Mucosal blood flow in central arterioles showed no differences in cirrhotic animals and controls (5.3±0.31 nL/min *vs* 5.4±0.25 nL/min), but was significantly attenuated in the inflammation group (3.49±0.6 nL/min). This effect was normalized in the treatment group (5.13±0.4 nL/min). Hepatic blood flow increased in the IBD group and remained stable under ATIII substitution.

Table 2 Microcirculatory parameters of the liver, mesentery and ileal mucosa (mean±SD)

	Cirrhosis	Cirrhosis and IBD	ATIII treatment group (cirrhosis and IBD)	Controls
Vessel diameter (μm)				
Liver	27.86±2.03 ^a	28.15±1.72	28.08±1.27	23.03±0.62
Mesentery	32.06±8.91	33.51±5.16	42.51±7.04 ^c	33.46±11.66
Mucosa	7.51±0.30	6.32±0.41	7.21±0.52	7.20±0.23

Leukocyte-endothelium interaction

Analysis of leukocyte kinetics showed marked differences

in hepatic leukocyte adherence. Cirrhosis facilitated leukocyte rolling and sticking in hepatic sinusoids (1.91±0.28 sticker/100 μm *vs* 0.5±0.5 sticker/100 μm in control, *P*<0.05). The effect was enhanced in bowel inflammation (5.4±1.65 sticker/100 μm), but reversed in the ATIII group (3.97±1.04 sticker/100 μm, *P*<0.05). LEI in mesenteric vessels was characterized by a significant increase of adherent leukocytes during bowel inflammation (5.24±1.23 sticker/100 μm *vs* 2.54±1.19 sticker/100 μm, *P*<0.05) with no substantial difference in the ATIII treatment group (Table 3).

Table 3 Results of intravital videomicroscopy: LEI in the liver and mesentery (mean±SD)

	Cirrhosis	Cirrhosis and IBD	ATIII treatment group (cirrhosis and IBD)	Controls
Adherent leukocytes (n/100 μm)				
Liver	1.91±0.28 ^a	5.40±1.65 ^c	3.97±1.04 ^e	0.5±0.5

Histology

At the time of videomicroscopy, all animals had evidence of ascites. Light microscopy examination showed that features of cirrhosis were evident in the liver of all rats. The overall impression of the liver was nodular with extensive deposits of fibrous tissue. Sections of ileum revealed macroscopic inflammation. Necrotic areas were not assessed in any group and network of lymphatic vessels was extended in cirrhotic animals and influenced markedly by ATIII treatment.

DISCUSSION

Portal hypertension caused by cirrhosis is characterized by multiple complications, including development of ascites, disturbance of the mucosal barrier, thrombotic, and intestinal derangements^[16,17]. Microcirculation is of

heterogeneous nature in cirrhosis^[18,19]. As portal hypertension develops, local production of vasodilators, mainly nitric oxide, increases, leading to splanchnic arterial vasodilatation^[20]. Clinical observations revealed that there was a close relationship between circulatory dysfunction in portal hemodynamic and the impairment in hepatic function. The results of our study indicate that liver cirrhosis is associated with a significant increase of liver enzymes and hepatic vessel diameter, but has no influence on hepatic blood flow. There was a marked decrease in mesenteric blood flow and this effect was significantly reversed by bowel inflammation. This observation has led to the hypothesis that increased portal pressure may in part depend upon an increased splanchnic inflow and may be related to the overactivity of the endogenous vasoconstrictor systems^[21]. Mucosal blood flow on the other hand, showed a significant decrease in animals with cirrhosis and bowel inflammation. Our data are consistent with the hypothesis that mucosal inflammation may induce shunting in the villus microcirculation, with a depression in capillary perfusion, though the levels of central arteriolar blood flow are normal^[22]. However, the magnitude of mucosal hemodynamic alterations in rats treated with ATIII was not as pronounced as in cirrhotic rats with IBD without this treatment.

LEI and microvascular perfusion changes are known to play a crucial role in the development of organ dysfunction and failure. Leukocyte-endothelial cell adhesion is modulated by a variety of adhesion glycoproteins expressed on the surface of leukocytes and endothelial cells^[23,24]. It has been shown that both leukocyte and endothelial cell adhesion molecules contribute to the granulocyte accumulation in a chronic model of intestinal inflammation^[25]. As venous drainage of the intestine occurs via the portal vein in the liver, intestinal inflammation may lead to an upregulation of the liver LEI and contribute to liver injury. This phenomenon is also described for gut ischemia and reperfusion^[26].

In addition, endothelium plays a key role in the pathogenesis of inflammation and coagulation disorders in infectious diseases^[27]. Though the exact mechanism is not known, there is evidence that intervention in the coagulation pathway may have some beneficial influence on the course of infections^[28]. It has been shown that small intestine injury and LEI are significantly reduced in endotoxemic rats after application of ATIII^[29]. Our group has previously described the same effect in an animal model of hepatic ischemia-reperfusion injury^[9], which is in agreement with the observation of the present study, indicating that application of ATIII reduces both intestinal and hepatic microcirculation failure in bowel inflammation with coexisting liver cirrhosis. The extent of leukocyte adherence to the endothelium and the course of liver enzymes can significantly improve.

In conclusion, though vessel morphology is changed during liver cirrhosis, systemic effects of bowel inflammation in cirrhosis can be attenuated by substitution of dropped ATIII levels subsequently to the onset of inflammation. Maintenance of gut perfusion seems to prevent enhancement of LEI and hepatic damage.

Abstract

AIM: To identify the misperceptions among CHB patients, as well as to determine the factors associated with better knowledge.

METHODS: A telephone interview was conducted on 192 adult CHB patients, who earlier responded to an advertisement for free screening. The questionnaire included items about socio-demographic factors and a 14-item quiz on knowledge of general aspects, transmission, and management of HBV infection.

RESULTS: The mean knowledge score on HBV was 10.4/14. Common misperceptions included availability of treatment for HBV infection and early liver cancer, as well as on transmission. Having completed tertiary education was the only independent factor associated with a high knowledge score, after controlling other demographic factors.

CONCLUSION: More educational efforts should be focused on patients' misperceptions and target the less educated HBV carriers.

INTRODUCTION

HBV infection remains an important global health problem.

There are approximately 350 million people chronically infected with HBV worldwide. During the course of chronic HBV infection, an estimated 15-40% of HBV carriers would develop complications such as exacerbations of hepatitis, cirrhosis, liver failure, and hepatocellular carcinoma (HCC)^[1,2].

Singapore is a small, multi-racial nation in Southeast Asia with a population of four million, and racial distribution of 76% Chinese, 14% Malay, 8% Indian, and 2% others. HBV infection is an important disease in Singapore, where 4.1% of the general population are carriers of HBV^[3]. In Singapore, liver cirrhosis and its complications are the 10th commonest cause of death, and HCC is the 4th commonest cancer among Singaporean males^[4].

Only patients with chronic hepatitis B (CHB), elevated liver enzymes and high hepatitis B viral load are candidates for anti-viral treatment^[1,2,5]. As liver enzymes and viral replication may fluctuate during the prolonged course of CHB, regular measurement of liver panel and viral load is needed to identify suitable patients for antiviral therapy^[1,2,5]. In addition, regular surveillance for HCC may allow diagnosis of early lesions, which are potentially curable by resection or liver transplantation^[6,7]. To sum up, for the regular surveillance with liver panel and alpha-fetoprotein level, ultrasonography is important in the follow-up of patients with CHB to select suitable candidates for anti-viral therapy, and to diagnose complications early, for better treatment^[1,2,8-10]. However, compliance of surveillance among patients with CHB has not been evaluated. Our recent pilot study showed that about two-thirds of HBV carriers in Singapore are not on regular follow-up, and the reasons are unclear^[11].

Many hepatitis B carriers are not aware of the implications of their disease, and have numerous misperceptions. In one study among 320 Cambodian American women, the median score on their knowledge is only 4.8 out of a maximum of 12^[12]. In another similar study among 147 Chinese Canadian women, respondents correctly answered only 6.9 of the 12 questions^[13]. At multivariate analysis, fluency in spoken English and duration of education are independently associated with the level of knowledge about HBV of patients.

We hypothesize that the low compliance with follow-up among HBV carriers could be due to their lack of knowledge about HBV infection. Hence, in this study, our first objective was to identify the misperceptions among HBV carriers attending a free screening program in Singapore, as well as any particular group with poor knowledge of HBV, and our second objective was to correlate their knowledge of HBV with regular follow-up.

MATERIALS AND METHODS

Patients

A free screening program for adult HBV carriers was advertised in local newspapers in Chinese and English over a 4-wk period. Known HBV carriers were invited to come forward for a free screening. HBV carrier status of all subjects was confirmed by repeat testing of the hepatitis B surface antigen. The study subjects came from the community and included those not screened previously, or defaulted screening.

Six hundred and nineteen subjects responded and came forward for the free screening program. These subjects were then contacted and invited to take part in this study. All subjects gave informed consent to the study. Three hundred and ninety-eight subjects could not be contacted due to incorrect contact information. Two hundred and twenty-one subjects were contacted, 29 of them refused to take part in the study. Hence, 192 (86.9%) subjects of those who could be contacted were interviewed for the current study. A waiver for application was obtained from the Institutional Review Board of the National University Hospital but, all study subjects gave informed consent before taking part in the study.

Survey instrument

All subjects were interviewed through telephone, using a standard questionnaire by a team of bilingual (English and Chinese), hepatology-trained research nurses. The questionnaire contained questions on basic socio-demographic factors, and a 14-item quiz on general knowledge of HBV infection adapted from a previously validated questionnaire^[12,13] (Table 1). The survey was carried out in either Mandarin or English. Each interview lasted for about 20 min. Carriers of HBV who were seen by any doctor for monitoring of their liver status and surveillance of complications of CHB over the last 12 mo were considered to be on regular follow-up.

Data analysis

Data were expressed as mean \pm SE unless otherwise stated, and analyzed by SPSS v. 10.0 (SPSS Inc., Chicago, IL, USA). The main outcome variables were level of knowledge about HBV. Each question was answered as "Yes", "No", or "Do not know". A correct answer scored one point. An incorrect or "Do not know" answer scored zero point. A summary score of knowledge was computed by summing correct responses to the 14-item quiz. Hence, the maximum score for each subject was 14 and the minimum 0.

Total knowledge score was first analyzed as a continuous variable. Factors associated with total knowledge score, namely gender, age, ethnicity, education level, income level, family history of HCC, and hepatitis B, were analyzed by multiple linear regression to evaluate the independent factors associated with knowledge score.

In addition, the knowledge score was arbitrarily dichotomized as "high" (10 or higher) and "low" (9 or less), and analyzed as a categorical variable. Factors related to high knowledge scores were first analyzed by univariate analysis, where categorical and continuous variables were analyzed by Fisher's exact test or Mann-Whitney *U* test as

appropriate. Factors with $P < 0.10$ from univariate analysis were further analyzed by multivariate analysis using backward logistic regression to evaluate the significant independent factors associated with high knowledge scores.

Knowledge score between those with or without regular follow-up was compared by Kruskal-Wallis test. A two-tailed test with $P < 0.05$ was considered statistically significant.

RESULTS

Patient characteristics

One hundred and ninety-two HBV carriers, aged 43 ± 1 years, 148 (77%) male, and 184 (96%) Chinese, completed the survey. One hundred and thirty-five (70%) earned S \$ 2 000 (US \$ 1 100) or more monthly, and 64 (33%) had monthly income of S \$ 4 000 (US \$ 2 200) or more. One hundred and nine subjects (57%) completed tertiary (college) education, 76 (40%) secondary (up to Grade 12) education, and 7 (4%) primary (up to Grade 6) education. Sixty-seven subjects (35%) had a known family history of CHB and 35 (18%) had a known family history of HCC. One hundred and seven subjects (57%) were on regular follow-up for their CHB over the last 12 mo. None of the subjects consumed more than three drinks of alcohol per week.

Hepatitis B knowledge

Overall mean knowledge score was 10.4 ± 0.1 , out of a maximum of 14. More than 80% of study subjects were aware of that HBV was infectious and could cause long-term complications such as liver cirrhosis or HCC, and that they should not consume alcohol regularly (Table 1). More than 80% of subjects were also aware of the main modes of transmission such as childbirth, sexual activity, and sharing of needles.

However, many misperceptions existed. Only about one-third of them, knew that early liver cancer did not cause any symptom and treatment was available for CHB. Besides, half of the subjects were unaware of that HBV infection was not transmitted by sharing food, and 37% of the subjects thought that hepatitis B could be transmitted by taking seafood.

Table 1 Responses to hepatitis B knowledge questions ($n = 192$)

Statements (correct response)	Correct response (%)
General aspects of hepatitis B	
Hepatitis B is infectious? (Yes)	165 (86)
Hepatitis B causes liver cancer in the long run (Yes)	173 (90)
Hepatitis B causes liver cirrhosis in the long run (Yes)	168 (88)
Hepatitis B carriers can be recognized easily from their appearance (No)	143 (75)
Hepatitis B carriers can drink alcohol as much as non-carriers (No)	180 (94)
Management of hepatitis B	
Treatment is available for hepatitis B (Yes)	65 (34)
Early liver cancer causes symptoms (No)	62 (32)
Early liver cancer is curable (Yes)	133 (69)
My family members should be screened for hepatitis B (Yes)	185 (96)
Transmission of hepatitis B	
Hepatitis B transmits through sexual intercourse (Yes)	171 (89)
Hepatitis B transmits through sharing of needles (Yes)	179 (93)
Hepatitis B transmits through sharing of food (No)	96 (50)
Hepatitis B transmits through taking seafood (No)	120 (63)
Hepatitis B transmits through childbirth (Yes)	165 (86)

Factors associated with better knowledge

Knowledge score was first analyzed as a continuous variable. Multiple linear regression showed that having completed tertiary education was the only statistically significant factor associated with knowledge score ($P < 0.001$), after controlling for other potential confounding demographic factors.

Knowledge score was then analyzed as a categorical variable as “high” and “low” knowledge score. Overall, 139 (73%) subjects had high knowledge scores of 10 points or more. Univariate analysis revealed that subjects with high knowledge scores were significantly younger, and more likely to have received tertiary (college) education. Association of high knowledge with higher income reached borderline significance (Table 2). When these three factors were analyzed by logistic regression, having completed tertiary (college) education was the only independent factor associated with high knowledge scores. Those with tertiary (college) education were 3.3 times more likely (OR 3.30, 95%CI 1.4-7.6, $P = 0.005$) to have high knowledge score than those without tertiary (college) education.

Correlation between regular follow-up and knowledge score

No statistically significant difference in knowledge score was seen between those with and without regular follow-up (10.7 ± 0.2 vs 10.2 ± 0.4 , $P = 0.23$). Neither was there any difference in gender, age, income level, or educational level between the two groups.

DISCUSSION

One important finding of this study is that the mean knowledge score was reasonably good at 10.3 out of a maximum of 14. We also found that 139 (73%) of the subjects scored 10 or more, i.e., having a high knowledge score. Although it is difficult to compare the knowledge score in our population with the scores from prior studies, this may suggest that public health education in Singapore in the past has been generally successful.

However, we also identified many misperceptions among HBV carriers. To begin with, many HBV carriers were not aware of the benefits of regular surveillance for complications of HBV, as evidenced by the findings that many were not aware that treatment of HBV infection was available and were not aware of that early liver cancer was asymptomatic, but potentially curable. Secondly, although many HBV carriers were aware of the common modes of HBV transmission, and believed that HBV infection could

also be transmitted by sharing food or consuming seafood. Our findings are consistent with those by Taylor *et al.*^[12], and Thompson *et al.*^[13], where only 23.5% and 41% of their respondents thought that HBV infection can be spread by food. This highlights the need to improve the current public education program on hepatitis B.

Another important finding of our study is that patients with tertiary (college) education were more likely to have a high knowledge score. This is not surprising as patients with better education are more likely to have read or heard about HBV infection in schools or in the mass media. Besides, subjects with better education were more likely to understand the complexity of various aspects of HBV infection. Our study highlights the importance of targeting further public and patient education on those with less or no education.

One last important finding is that we found no difference in knowledge score between those with and without regular follow-up. This highlights the complexity of the issue of regular follow-up among patients with chronic illnesses^[14,15], and that factors other than knowledge influenced patient compliance with follow-up. Perhaps efforts from community, healthcare organizations, and patients are needed in improving the long-term compliance rate. Further studies are needed to identify factor(s) associated with better compliance in patients with chronic illnesses.

There are limitations in our study. Firstly, it is unclear to what extent our conclusions could be extended to HBV carriers in other geographical locations, where cultural backgrounds and educational level vary. Secondly, as we interviewed only those who responded initially to our advertisement for free HBV screening, it is possible that we could have selected a more health-conscious group of HBV carriers, who might have better knowledge of HBV. However, it should be noted that any new screening program would have a low uptake in the beginning. The strength of this study is that we were able to identify the educational needs of individuals who participated in our screening program and this has helped us achieve two objectives. Firstly, it provided us with a better understanding of the level of awareness and misperceptions among individuals, who were sufficiently motivated to participate in our screening program in the first place. This information would help us identify strategies to improve their compliance with regular screening. Secondly, this study has prepared us better for the next phase of our study, that is, to assess the level of knowledge and misperceptions among HBV carriers in the general population, which may be lower than the

Table 2 Factors associated with high and low scores on HBV knowledge

Factors	Low scores (≤ 9) $n = 53$	High scores (≥ 10) $n = 139$	Univariate analysis P	Multivariate analysis ¹ P
Age (yr)	46 \pm 1	41 \pm 1	0.002	0.066
Male (%)	39 (74)	109 (78)	0.57	
Chinese (%)	52 (98)	132 (97)	1.00	
Monthly income \geq S\$4 000 (%)	8 (15)	37 (27)	0.057	0.199
Family history of HBV (%)	19 (36)	48 (35)	0.87	
Family history of HCC (%)	11 (21)	24 (17)	0.68	
On regular follow-up (%)	61 (44)	78 (56)	0.91	
Tertiary educated (%)	17 (32)	92 (66)	<0.001	0.005

¹Multivariate analysis using multiple regression analysis.

participants in our present study. Notwithstanding the above limitations, we believe our study provides important findings for public health officials, as well as hepatologists, to improve their patient education programs particularly for individuals who have been motivated to participate in screening, to ensure that they would not default follow-up after their first screening appointments.

In conclusion, many misperceptions exist among HBV carriers who participated in a screening program in Singapore and HBV carriers with better education are more likely to know HBV better. Future patient and public health education efforts should focus on dispelling misperceptions and target HBV carriers with less education.

Abstract

AIM: To investigate clinical significance of Pin1 and β -catenin expression in colorectal cancers and to demonstrate the relationship of their expression.

METHODS: The role of Pin1 and β -catenin protein in colorectal tumorigenesis and their clinicopathologic significance were analyzed by immunohistochemistry, and the correlation between Pin1 and β -catenin protein expressions was also studied in 124 patients with colorectal cancer who were surgically treated.

RESULTS: Normal colonic epithelium either failed to express or showed focal and weak expression of Pin1 and β -catenin. Overexpression of Pin1 and β -catenin protein was found in 23 (18.54%) and 50 (40.3%) of 124 colorectal cancers, respectively. Overexpression of both proteins was not related to the lymph node metastasis, tumor stage and survival period after excision. Survival analysis results indicated that tumor stage was a valuable predictor of survival. Interestingly, a significant correlation was found between Pin1 and β -catenin protein expression.

CONCLUSION: Overexpression of Pin1 and β -catenin may be closely related with the development and/or progression of colorectal carcinoma and further supports that Pin1 overexpression might contribute to the upregulation of β -catenin.

INTRODUCTION

β -catenin is a multifunctional protein that plays an important role in the transduction of Wnt signals and in the intercellular adhesion by linking the cytoplasmic domain of cadherin^[1]. In general, the cytoplasmic level of β -catenin is kept low through interaction with a protein complex, comprised of adenomatous polyposis coli (APC), Axin, protein phosphatase 2A, and glycogen synthase kinase 3 β (GSK3 β). It is believed that this complex phosphorylates the β -catenin, thereby inducing ubiquitination-dependent proteolysis of β -catenin. Therefore, alterations of these genes cause accumulation of cytoplasmic β -catenin and nuclear translocation of β -catenin. After its translocation into the nucleus, β -catenin binds to members of the Tcf/Lef family thereby activating target genes, such as cyclin D1 and myc. In cancer cells, only one of these genes is mutated in a given tumor sample reflecting their role in a common pathway^[2]. For instance, colon tumor with mutations in APC has α wild-type β -catenin gene, and vice versa, any tumor with mutations in β -catenin is wild-type for APC.

Recently, it has been shown that Pin1 is overexpressed in some human malignancies and that its expression closely correlates with the level of cyclin D1 in human cancer^[3]. Pin1 is a peptidyl-prolyl cis-trans isomerase that isomerizes only phosphorylated serine/threonine residues preceding proline peptide bonds to regulate various cellular processes including cell division and transcription^[4-7]. Interestingly, Pin1 contributes to the upregulation of β -catenin in tumors such as breast cancer by inhibiting interaction between APC and β -catenin^[8]. Thus, this study aimed to elucidate, whether Pin1 and β -catenin expressions were involved in colorectal carcinogenesis and whether Pin1 expression contributed to aberrant β -catenin overexpression.

MATERIALS AND METHODS

Patients and specimens

One hundred and twenty-four patients with colorectal cancers from January 2001 to December 2002, were enrolled in this study. No patient had a family history of colorectal cancer and was treated with chemotherapy before tumor removal.

Tumor stage was classified according to Dukes' criteria. Thirteen patients were classified as Dukes' A, 47 as Dukes' B, 56 as Dukes' C and 8 as Dukes' D. The range of observation was 14-36 mo for the survivors. Of these, 15 patients showed relapse of cancer and 11 patients died of cancer during this time. Specimens collected from these patients were fixed by formalin and embedded in paraffin. Two pathologists screened histological sections and selected areas of the representative tumor cells. Three tissue cores (0.6 mm in diameter) were taken from each tumor sample and placed in a new recipient paraffin block using a commercially available microarray instrument (Beecher Instruments, Micro-Array Technologies, Silver Spring, MD, USA) according to established methods^[9]. One cylinder of normal colonic mucosa adjacent to each tumor was also transferred to the recipient block.

Immunohistochemistry for Pin1 and β -catenin

Primary polyclonal rabbit anti-Pin1 antibody (Oncogene Research Products, San Diego, CA, USA, dilution 1/100) and anti- β -catenin (Transduction Laboratories, Lexington, KY, USA) were used. Immunostaining was performed on microarray tissue sections with a tyramide signal amplification kit (NEN Life Science, Boston, MA, USA) for signal intensification. Antigen retrieval was performed by microwave heating in a citrate buffer (pH 6.0). Other procedures were performed as previously described^[10]. The reaction products were developed with diaminobenzidine (Sigma, St. Louis, MO, USA) and counterstained with hematoxylin. A negative control, using non-immune rabbit serum instead of the primary antisera, did not produce any staining (data not shown). Three pathologists independently reviewed the results. Immunoreactivities of both Pin1 and β -catenin were categorized into four groups: (1) negative, 0-5%; (2) low, 5-30%; (3) moderate, 30-50%; (4) high, $\geq 50\%$. Since both

Pin1 and β -catenin expressions were negative or low in normal colonic mucosa, we considered moderate and high immunoreactivities as overexpression.

Statistical analysis

We used χ^2 test to analyze the correlation between clinicopathologic parameters of colorectal cancer and expressions of Pin1 and β -catenin, and the association between Pin1 and β -catenin expressions. $P < 0.05$ was considered statistically significant. The predictive value of clinical parameters for survival was evaluated using the Kaplan-Meier analysis.

RESULTS

Pin1 protein expression in colorectal cancer

One hundred and twenty-four colorectal carcinomas were screened for Pin1 protein expression. The expression was mainly negative or low in normal colonic mucosa. In the present study, overexpression of Pin1 was found in 23 (18.5%) of the 124 colorectal carcinomas, in which immunostaining was predominant in either the cytoplasm or the nuclei of tumor cells (Figure 1). Of these 23 colorectal carcinomas, 3 had high expression of Pin1 and 20 had moderate expression of Pin1. Positive staining was seen in 23.1% (3 of 13 cases) of stage A patients, 23.4% (11 of 47) of stage B patients, 12.5% (7 of 56) of stage C patients, and 25.0% (2 of 8) of stage D patients, respectively (Table 1). There was no significant correlation between overexpression of Pin1 and Dukes' stage. In addition, Pin1 expression was detected in 8 (13.6%) of 59 cases with lymph node metastasis and showed no significant correlation with lymph node metastasis. Univariate analysis showed that the expression of Pin1 in colorectal cancer was not related with survival period after excision, indicating that the presence of Pin1 staining was not a valuable predictor of survival.

Expression of β -catenin protein

Expression of β -catenin protein was found on cell membrane in the normal colonic mucosa. The cancer cells demonstrated abnormal nuclear and cytoplasmic staining of β -catenin, whereas the membrane staining was negative or low in tumors (Figure 1). Overexpression was observed in 50 (40.3%) of 124 specimens. There was no significant correlation between β -catenin expression and clinicopathologic parameters, including lymph node metastasis, tumor stage and survival period after surgical resection (Table 1). Overall, only tumor stage was a significant predictor of survival, and lower stage patients had a longer survival as shown in log rank test ($P < 0.05$).

Correlation between Pin1 and β -catenin

Overexpression of Pin1 protein was detected in 19 of 50 colorectal cancers with aberrant expression of β -catenin protein. There was a significant positive correlation between the expressions of Pin1 and β -catenin ($P < 0.01$, Table 1).

DISCUSSION

Phosphorylation of proteins on serine/threonine residues preceding proline is a major regulatory mechanism in cell proliferation and transformation^[11,12]. The prolyl isomerase Pin1, catalyzes conformational changes in certain key proline-directed phosphorylation sites and functions as a pivotal catalyst for oncogenesis^[13]. Pin1 is overexpressed in many human tumors such as breast and prostate cancer^[14-16], and increases the transcriptional activity of c-Jun towards the cyclin D1 promoter^[3]. In the present study, we found that Pin1 protein levels in colorectal cancer cells were not positively correlated with any commonly used clinicopathologic parameters, such as tumor stage and lymph node metastasis. Additionally, univariate analysis demonstrated that there was no association between Pin1 expression and survival, suggesting that the Pin1 level might not a valuable prognostic marker for predicting the overall survival of colorectal cancer patients.

β -catenin is a multifunctional protein, and plays an

essential role in the transduction of Wnt signals. Cytosolic β -catenin is eliminated by APC-dependent proteasomal degradation pathways regulated by GSK3 β or p53-inducible Siah-1. Conditional degradation of β -catenin represents a central event of Wnt signaling pathway controlling cell fate and proliferation^[2]. Dysregulation of β -catenin turnover caused by genetic alterations of Wnt signaling pathway-related genes is implicated in cancers^[17]. Alterations of β -catenin expression have been documented in many malignancies, including breast cancer, gastric cancer, colonic and hepatocellular carcinomas^[18-21]. Additionally, overexpression of Pin1 can upregulate β -catenin in tumors, by inhibiting interaction between APC and β -catenin^[8]. We also found that β -catenin was abnormally expressed in 50 (40.3%) of 124 colorectal cancers. The expression was not related to clinical parameters and survival period after surgical excision. By comparing survival and clinicopathologic features, we found that only tumor stage was positively correlated with survival in log rank test ($P < 0.05$).

Interestingly, statistical analysis revealed a significant correlation between Pin1 overexpression and β -catenin expression, suggesting that Pin1 overexpression is significantly correlated with β -catenin expression in colorectal cancer and further supports, that aberrant Pin1 expression may be important for the upregulation of β -catenin expression.

Abstract

AIM: To compare the effects of neurolytic celiac plexus block (NCPB) and videothoroscopic splanchnicectomy (VSPL) on pain and quality of life of chronic pancreatitis (CP) patients.

METHODS: Forty-eight small duct CP patients were treated invasively with NCPB ($n = 30$) or VSPL ($n = 18$) in two non-randomized, prospective, case-controlled protocols due to chronic pain syndrome, and compared to a control group who were treated conservatively ($n = 32$). Visual analog scales were used to assess pain and opioid consumption rate was evaluated. In addition, the quality of life was measured using QLQ C-30 for NCPB and FACIT for VSPL. Although both questionnaires covered similar problems, they could not be compared directly one with another. Therefore, the studies were compared by meta-analysis methodology.

RESULTS: Both procedures resulted in a significant positive effect on pain of CP patients. Opioids were withdrawn totally in 47.0% of NCPB and 36.4% of VSPL patients, and reduced in 53.0% and 45.4% of the respective patient groups. No reduction in opioid usage was observed in the control group. In addition, fatigue and emotional well-being showed improvements. Finally, NCPB demonstrated stronger positive effects on social support, which might possibly be attributed to earlier presentation of patients treated with NCPB.

CONCLUSION: Both invasive pain treatment methods are effective in CP patients with chronic pain.

INTRODUCTION

Pain is the most significant, frequent and difficult to treat symptom of chronic pancreatitis (CP). The pain is severe, persistent, excruciating and unbearable^[1-4]. It is often localized in the epigastrium, radiates to the left or more frequently to the right side, or to the lower part of the thoracic vertebral column or to the right scapula^[2-5]. The pain is often accompanied with nausea and vomiting. The underlying pathophysiological mechanisms of pain are still unknown.

Typical CP pain is associated with increased pancreatic duct pressure and caused by stimulation of specific nociceptors or sensing receptors^[3]. Currently, the most significant reason of pain in CP is considered to be the pressure of pancreatic fluid increased intraductally and within the pancreatic tissue. This may result in impaired outflow of pancreatic fluid and may also present as pancreatic pseudocysts (in cases of pancreatic duct rupture)^[1]. It can also be influenced by self-digestion of pancreatic ducts due to progressing inflammation and by inflammation of nerves involved in transfer of stimuli from the pancreas (pancreatitis associated neuritis)^[6].

Afferent fibers from the celiac region may enter the spinal cord at a different level from which the respective efferent fibers originate. Fibers of these bunches enter the gray matter and terminate within layers I and IV^[9]. There is no morphological or functional evidence for the existence of an indirect celiac projection in the layer II, contrary to the somatic projection found extensively in layers I and II^[7-9]. Thus, the distribution of celiac and somatic stimuli within the spinal cord is different. Nevertheless, the fact that visceral pain is sometimes associated with somatic structures and convergence of the stimuli from organs and somatic structures into sensory neurons may further initiate a sensation of somatic pain^[10].

It is generally acknowledged that the quality of life of CP patients significantly decreases due to severe and constant pain^[1,4]. Various methods, including invasive techniques, have been proposed to treat pain^[11]. The aim of the present study

was to compare the effect of two most frequently applied methods of treatment, NCPB and videothoracoscopic splanchnicectomy (VSPL) on pain, opioid consumption rate and quality of life of CP patients.

MATERIALS AND METHODS

Patients

Two groups of small-duct CP patients were treated in two separate prospective, case-controlled studies with NCPB ($n = 30$) or VSPL ($n = 18$). In addition, a control group ($n = 32$) consisting of CP patients with chronic pain syndrome managed conservatively took part in this study.

The patients chose the procedure according to their needs (consumer approach – orientation towards the needs of patients).

All the procedures were performed by surgeons experienced in videoscopic surgery.

The demographic data of the three groups are presented in Table 1. No patient had structural lesions: pancreatic duct stricture, pseudocyst, or distal common bile duct stricture amenable to either endoscopic or surgical treatment. The inclusion criteria were a CP diagnosed by CT scan and endoscopic retrograde cholangiopancreatography, persistent pain for at least 3 mo, scoring at least 66.7% on the pain visual analog scale. Patients with pancreatic inflammatory tumors or pseudocysts were excluded from the study.

Measurement

Pain was measured using visual analog scales and quality of life of CP patients was assessed by well-validated EORTC, quality of life questionnaire QLQ C-30 and functional assessment of chronic illness therapy (FACIT). The control group completed both health-related quality of life measurements. The patients were assessed 2 d before the treatment, then followed up and reassessed after 2nd and 8th wk.

NCPB

The patients were fixed in the prone position with a slight bending forward. The lower margin of the 12th rib was marked on both sides of the body. After the superficial anesthesia with 1% lignocaine, the 20-G needle (10–12 cm) pierced into the point located 5–7 cm laterally from the midline on both sides just under the lower margin of the 12th rib, at the angle of 30–45 towards the trunk of L₁ and Th₁₂ vertebrae or the space between L₁ and Th₁₂ vertebrae. The canal of the needle was then additionally anesthetized with further 6–10 mL of 1% lignocaine. The needle was pierced into until the resistance of the bone was met. If this resistance was met at the level of 3–5 cm under the skin, it was assumed that the needle reached the vertebra and the needle was withdrawn and re-introduced in order to bypass above or below the vertebra towards its lateral surface.

The surface was achieved at the depth of 6–8 cm. Then, the needle was rotated 90 towards the vertebra and re-introduced with a continuous decrease of the angle of the introduction, aiming to slide on the lateral surface of the vertebra. When the needle bypassed the vertebra by 1–2 cm, and after reassuring that it was not located in the aorta or other major vessel, 20–30 mL of 50% ethanol with 5 mL of 1% lignocaine was injected into both sides.

VSPL

Because unilateral (preferably left-sided) splanchnicectomy was reported to be adequate in control of the intractable pancreatic pain^[12], all patients were given a left-sided intervention. General anesthesia was administered with single-bronchus intubation in every case. The patient was placed in the right lateral decubitus position with the left arm elevated at a 90° angle, and fixed with support-arms and bandages, and the table was then tilted 30° anteriorly in the longitudinal axis (thus, after induction of a pneumothorax, the lung would “fall away” from the costovertebral gutter). After desufflation of the lung, two trocars were inserted into the thorax: one (a 5-mm trocar) was placed in the fifth intercostal space in a medial axillary line for the camera, and the second (a 5-mm trocar) was placed in the seventh intercostal space in an anterior axillary line for the instruments. After identification of the splanchnic nerve, situated above the aorta on the left or above the azygos vein on the right, the parietal pleura was incised and the nerve together with its minor connecting branches, was prepared to a distance of 5–8 cm and then excised. After insufflation of the lung, the trocars were removed, a single chest tube was placed, and the wounds were closed according to surgical standards.

Statistical analysis

This study consisted of two separate, prospective, non-randomized, case-controlled experiments (NCPB *vs* control and VSPL *vs* control). By consequence, the statistical techniques applied in meta-analysis were employed, fixed-effects and effect sizes were calculated as the difference between the outcome means of the groups divided by the pooled standard deviations. An overall weighed effect size was obtained and presented with 95% confidence interval (95%CI). Results were tested for homogeneity using the Breslow-Day tests.

Parametric data were tested with *t* test, ANOVA, and non-parametric estimations were conducted with *U* Mann-Whitney and χ^2 tests. All analyses were performed using Statistica 6.0 software licensed to Medical University of Gdansk.

RESULTS

The raw data and univariate statistics for both protocols are shown in Figure 1.

Table 1 Socio-demographic data and initial medical information of all groups included in protocols 1 and 2 (mean±SD)

	Protocol 1 NCPB ($n = 30$)	Protocol 2 VSPL ($n = 18$)	Control ($n = 32$)
Age (yr)	49.9±7.8	47.3±5.0	52.3±6.6
Sex (M:F ratio)	3.01	3.51	3.34
Etiology (alcohol <i>vs</i> other ratio)	6.5	8.0	7.0
Period from the symptomatic onset of the disease	6.2±2.2	11.5±4.3	7.1±3.0

Figure 1 Results of pain and quality of life assessment in CP patients and controls. **A:** VAS-Pain; **B:** Physical well-being; **C:** Emotional well-being; **D:** Social support; **E:** Fatigue; **F:** Ailments characteristic for the illness. ^a $P < 0.05$

t-test vs NCPB or VSPL group and corresponding control; ^c $P < 0.05$ vs paired ANOVA. Results are shown as mean \pm SD.

In both groups of CP patients, the therapeutic intervention was beneficial (Table 2).

The effects were significant and very strong, especially concerning pain, as indicated on VAS scale. In order to control for possible regression to the mean effect, the mean effect sizes were calculated by comparison of the results after 2nd and 8th wk, not only to the pre-treatment baseline, but also to the results of the control group treated conservatively and evaluated at the corresponding periods of follow-up.

Opioids were administered to 17 patients (56.7%) in the NCPB group and to 11 patients (61.1%) in the VSPL group. In the control group, 18 patients (56.2%) were treated with opioids and this number was not altered during the follow-up. The initial frequency of opioid treatment did not differ between the groups. The opioids were withdrawn totally after invasive treatment in 8 (47%) NCPB patients, and in 4 (36.4%) VSPL patients, and the dosage was reduced in another 9 (53%) and 5 (45.4%) patients, respectively (no statistically significant difference). No changes were observed throughout the whole period of follow-up. In two remaining opioid-using patients (18.2%) after VSPL, no long-term opioid reduction could be achieved (Figure 2).

There was no mortality and no major morbidity. Orthostatic

hypotension was observed for 3 d in nine patients (30%) from NCPB group and in one patient (5.5%) from VSPL group. Diarrhea was resolved after symptomatic treatment for 14 d in four patients (13.3%) from the NCPB group. Intermittent intercostal pain was treated with paracetamol for 2 wk in four patients (22.2%) from VSPL group. In one of them (5.5%), intercostal nerve block had to be instituted. In one case, classic thoracotomy had to be performed due to massive adhesions (who was excluded from the study).

DISCUSSION

In the presented study, the effects of NCPB and VSPL on CP patients and controls were compared. As the methods for assessment of life quality differed in two protocols, the comparison was performed by meta-analytic approach. The reduction of pain was stronger in VSPL group than in NCPB group, but the effects in both groups were very potent.

The influence on physical well-being was slightly better in NCPB group, but did not differ statistically from the VSPL group. No improvement concerning ailments typical for the disease was noticed. This finding can be explained by the fact that the analgesic treatment cannot obviously affect the cause of the disease.

Table 2 Comparison of mean effects of both therapeutic interventions in CP patients

Therapy	Group size	Parameter	Mean effect	95% CI (min-max)
VSPL	18	Pain ^a	15.82	(14.68-16.96)
NCPL	30		8.89	(8.30-9.48)
VSPL	18	Physical well-being ^a	1.81	(1.57-2.06)
NCPL	30		2.19	(1.96-2.42)
VSPL	18	Emotional well-being ^a	1.12	(0.91-1.34)
NCPL	30		4.40	(4.07-4.73)
VSPL	18	Social support ^a	0.08	(-0.11-0.29)
NCPL	30		3.55	(3.27-3.84)
VSPL	18	Fatigue	2.52	(2.25-2.79)
NCPL	30		6.87	(6.39-7.34)
VSPL	18	Ailments typical for the illness ^a	0.05	(-0.14-0.26)
NCPL	30		0.64	(0.45-0.83)

The effects presented are mean effects of intervention after 2nd and 8th wk compared to the value measured before the therapy and after 2nd and 8th wk of follow-up compared to the control group ($n = 32$) treated conservatively and evaluated at the corresponding periods of time. ^a $P < 0.05$ vs others.

**Figure 2** Effect of VSPL and NCPB on pain of CP patients and controls. Bars show mean effect from two measurements.

Interestingly, the effect on social support and emotional well-being was significantly stronger in NCPB group than in VSPL group. Moreover, the effect of VSPL on social support was weak, while it was very strong after neurolysis. This may be explained by the fact, that this procedure is the first available treatment for the patients in the NCPB group, whereas the VSPL patients have already tried some other treatments, thus having longer history of chronic pain syndrome. Therefore, the decision to receive an invasive treatment is more intensely approved by the NCPB group and the improvement resulting from this treatment is very likely more appreciated emotionally by the patients.

Since conservative treatment of CP chronic pain syndrome is not always effective and may be associated with significant morbidity of iatrogenic opioid addiction, both at physical (suppression of immune function, chronic constipation, drowsiness, and fatigue^[13,14]) and psychological level (decrease in social support, depression, addiction behavior)^[14], an attention has been paid to more invasive methods for pain control.

In the present study, the reduction of opioid consumption was significant in both groups, which gives an optimistic perspective for minimizing the adverse effects of this group of drugs, especially in the chronic treatment. Nevertheless, in two patients treated with opioids for more than a year, VSPL did not result in decrease of the opioid consumption or withdrawal. As early as 3 d after the procedure, the patients

complained about persistent pain localized on the opposite side of the abdomen. The pain could only be alleviated by pethidine. As to date, no diagnostic or treatment guidelines for suspected iatrogenic opioid addiction are available, opioid analgesics were administered. It should be highlighted that administering opioids ought to be considered as the last resort and should only be applied, if any other method has failed. Since the life expectancy of CP patients is 10-20 years shorter than that of general population^[15], the adverse effects of iatrogenic opioid addiction are very likely to occur in these patients. In contrast, the life expectancy of pancreatic cancer rarely exceeds 12 mo^[16].

The pathogenesis of pain in CP still remains a mystery. The factors postulated in its genesis include the release of excessive oxygen-derived free radicals, tissue hypoxia and acidosis, inflammatory infiltration with influx of pain-transmitting substances into damaged nerve ends, and the development of pancreatic ductal and tissue fluid hypertension due to morphological changes of the pancreas^[1-5]. Di Sebastiano *et al.*^[6], reported that the possible additional relevant pancreatic pain pathology factors are ischemia as well as inflammatory and autoimmune reactions. Toma *et al.*^[17], described that expression of the neurotrophin nerve growth factor increased during the course of experimental acute pancreatitis in rats. In human CP, neurotrophin gene expression correlates with the intensity of pain^[18], so that pathogenesis could be speculated in acute phases of CP. Keith *et al.*^[19], proposed that neural and perineural alterations may be important in pain pathogenesis of CP, and concluded that pain severity correlates with duration of alcohol consumption, pancreatic calcification, and percentage of eosinophils in perineural inflammatory cell infiltrates, but not with duct dilatation.

Bockman *et al.*^[20], have provided evidence for an increase in both the number and diameter of pancreatic nerve fibers during the course of CP. In tissue specimens from patients suffering from CP, foci of chronic inflammatory cells are often found surrounding pancreatic nerves exhibiting a damaged perineurium and invasion by lymphocytes. These abnormalities might allow free access of inflammatory mediators or active pancreatic enzymes into nerves, generating and sustaining pain.

The pro-inflammatory cytokine, IL-8 is a well-known chemokine involved in leukocyte recruitment, and activation

of IL-8 release generates hyperalgesia by stimulation of post-ganglionic sympathetic neurones. A significant increase in IL-8 mRNA has been reported in CP tissue samples^[21]. Major sources of IL-8 are inflammatory cells present around enlarged nerves in the inflammatory foci. Thus, induction of IL-8 in immune cells might contribute to amplification of the inflammatory process in CP. The release of IL-8 from the remaining exocrine pancreatic parenchyma may indicate the intrinsic maintenance of the inflammatory response after the first damage to the pancreatic gland, thus sustaining progression and evolution of the disease^[6].

It has been recently suggested that differential epidural anesthesia might be beneficial for differentiating cases susceptible to further sympathetic pain treatment from those who are resistant to it^[22]. Moreover, we would add that the use of NCPB as a therapeutic and diagnostic procedure might be crucial for selecting patients for further VSPL treatment in case of the ailment recurrence. Thus, NCPB should be suggested as the first step of invasive analgetic therapy, as soon as the opioid treatment is needed. Vranken *et al.*^[23], have demonstrated that the efficacy of the second NCPB in CP is significantly lower than that of the first, and that the pain-free period is usually shorter. Therefore, when all the non-opioid methods of analgesia are exhausted, the second step would be left-sided VSPL. Due to rare but fairly significant complications following bilateral splanchnicectomy^[24,25], we would favor unilateral or bilateral non-simultaneous VSPL in CP patients. Only after both-sided VSPLs have been performed and additional NCPB is also attempted, use of opioids is justified in CP patients.

It should also be stressed that the present analysis covers a relatively short period of follow-up. Moreover, the use of two different quality of life measurements may be perceived as another drawback of the present study. Therefore, future studies should include randomization, uniform outcome assessment, and longer follow-up assessment.

INTRODUCTION

Alpha-fetoprotein (AFP) is one of the earliest recognized oncofetal markers^[1]. It is produced in large amount by the fetal liver, but its expression reduces sharply at birth. AFP is synthesized by most hepatoblastomas and approximately half of hepatocellular carcinomas (HCC), and widely used in differential diagnosis and follow-up of patients with liver tumors, but so far no correlation has been found between the clinical behavior and AFP production in HCC.

DNA microarray analysis may result in the discovery of new tumor markers and can re-evaluate the known tumor parameters. Two independent teams studied the gene expression profile of human HCC cell lines and divided the cell lines into two groups, based on their gene expression pattern. AFP expression is highly correlated with the molecular subtypes of HCC^[2,3]. This observation led us to study the AFP expression in HCC samples and to compare it with other immunophenotypic and clinical features of the tumor.

MATERIALS AND METHODS

Thirty-seven recently diagnosed HCC cases were collected. Formalin-fixed and paraffin-embedded tumor samples (19 needle biopsies and 18 resected tumors) were immunohistochemically stained. The primary antibodies used were: AFP: DAKO (A 0008), MLH-1: Bio PharMingen (554072), MSH-2: Bio PharMingen (556349), β -catenin: Sigma (C2206), CD44: R&D (BBA10), HNF-4: Santa Cruz (SC 6556), p53: DAKO (M 3566). The reaction was visualized using Vector Laboratories' Elite kit (Burlingame, CA, USA), DAB was used as a chromogen. Since AFP expression was frequently focal, all tumors were taken as positive when any reliable staining was detected. In case of p53 and β -catenin, tumors with at least 20% nuclear staining were deemed as positive. CD44 staining resulted in a more or less diffuse stromal reaction in positive cases. Tumor grade and histological subtype were evaluated on H&E-stained sections. Grading was done as previously described by Edmondson and Steiner^[4]. The tumors were classified histologically into pseudoglandular, trabecular, sheet-like, and mixed pattern groups. The clinical parameters studied were age and gender of the patients, the presence of cirrhosis and etiological factors (HCV, HBV, alcoholism, etc.).

Abstract

AIM: To characterize the alpha-fetoprotein (AFP) positive and negative hepatocellular carcinoma (HCC) samples.

METHODS: Thirty-seven paraffin-embedded human HCC samples were analyzed by immunohistochemistry for the following antigens: AFP, β -catenin, p53, CD44, MSH-2, MLH-1, and HNF-4. The tumors were divided into two groups based on the AFP expression. The immunophenotypic data and important clinical parameters were studied between the two groups.

RESULTS: Twenty-one of the thirty-seven examined HCCs were AFP positive. Seven with nuclear p53 staining were AFP positive, while seven tumors with nuclear β -catenin staining were AFP negative. CD44 staining and high histological tumor grade were more frequent among the AFP-positive HCCs. The other immunophenotypic and clinical parameters did not show statistically significant difference in their distribution between the AFP positive and negative samples.

CONCLUSION: AFP expression in HCC correlates with unfavorable prognostic factors, while nuclear β -catenin positivity is more common among the AFP-negative liver tumors. This observation supports the microarray data on *in vivo* human tumors.

Unfortunately, no serum AFP value was available for half of the patients; therefore, it was not included in our study. Since the majority of the cases were diagnosed in the last 2 years, their survival was not analyzed. Statistical analysis was done by χ^2 and Student's *t*-test.

The study protocol conformed to the ethical guidelines of the 1975 Declaration of Helsinki as reflected in *a priori* approval by the institution's guidelines (permission number: TUKEB 156/2003).

RESULTS

The tumors were divided into two groups, based on the AFP staining and other parameters. Twenty-one of the thirty-seven examined HCCs were AFP positive (Figure 1A), which was comparable to previous data in the literature. No correlation was found between the AFP staining and age/gender of the patients, etiological factors, presence or absence of cirrhosis, histological subtype of the tumor, MLH-1, MSH-2, HNF-4 staining (data not shown). However, four of the parameters showed statistically significant ($P<0.05$) difference between the AFP positive and negative HCCs (Tables 1 and 2). Seven p53-positive tumors (Figure 1B) were positive for AFP, while seven nuclear β -catenin-positive tumors (Figure 1C) AFP negative. Nineteen of the twenty-one AFP-positive tumors were positive for CD44 (Figure 1D), while only 3 of the 17 AFP-negative tumors were positive for this adhesion molecule. Statistical comparison resulted in a significant difference between the tumor grades ($P<0.05$). The AFP-positive tumors had a higher statistical value.

DISCUSSION

We compared the distribution of several parameters between AFP positive and negative HCCs and found that some of

them were significantly different between the two groups. All the p53-positive tumors were stained with AFP antibody and the CD44 positivity was also more common in this group.

β -catenin nuclear staining occurred exclusively in the AFP-negative tumors and the tumor grade was significantly lower in this group, which is in agreement with the reports of Kawai *et al.*^[2], and Lee and Thorgerirsson^[3]. There are some sporadic observations that AFP is more frequently expressed in poorly differentiated HCCs^[5-8].

We found that three unfavorable prognostic markers were correlated with positive AFP. Tumor grade is not as

¹Positivity indicates more than 20% nuclear staining. ²Positivity indicates diffuse stromal staining.

meaningful in HCCs as in other tumors (e.g., prostate carcinoma), but shorter survival has been described in poorly differentiated tumors^[9]. Nuclear p53 staining indicates increased protein half-life, which is usually the consequence of point mutation. Therefore, we can assume that tumors with p53 nuclear staining carry p53 mutation. It is well documented that p53 mutation or nuclear accumulation is a valuable marker for predicting the poor prognosis of HCC patients^[10,11]. CD44, a widely distributed integral membrane protein, has been implicated in tumor invasion and development of metastasis. It was reported that upregulation of CD44 in liver tumors is associated with a shorter survival and p53 overexpression^[12,13].

β -catenin nuclear staining is observed in AFP-negative liver carcinomas. Nuclear accumulation of this protein indicates the increased activity of Wnt signal pathway^[14]. In cases of HCC, this is most frequently caused by β -catenin mutation^[15,16]. The significance of nuclear β -catenin positivity in HCC is controversial. Suzuki *et al.*^[17], have described nuclear expression in poorly differentiated tumors. Van Nhieu *et al.*^[18], reported that the higher proliferative index and poor outcome correlate with nuclear β -catenin-stained HCCs, but others could not confirm the role of β -catenin in the progression of HCC^[19]. In fact, Hsu *et al.*^[20], and Mao *et al.*^[21], have found that the nuclear expression of β -catenin is present in a subgroup of HCCs with a favorable prognosis. Laurent-Puig *et al.*^[22], demonstrated that nuclear β -catenin staining occurs in HCC with a low AFP serum level, but there is high chromosomal instability, frequent p53 mutations, and high AFP level in tumors without β -catenin mutation. A similar conclusion can be found in studies by Calvisi *et al.*^[23,24]. They suggested the existence of two major genetic pathways of neoplastic development in the liver. The first was characterized by disruption of

Wnt signaling, including β -catenin mutation and a low rate of loss of heterozygosity. The Wnt signaling is intact in the second group of tumors, but they could detect chromosomal instability in them. AFP expression was more common in the second group. Mao *et al.*^[21], also described that nuclear β -catenin expression is less frequently associated with serum AFP elevation. Unfortunately, the serum AFP values were not available in all the cases in our study, but our results had a close correlation with immunohistochemical staining.

Among the parameters we studied, only CD44 was detected in microarray experiments as differentially expressed between the AFP positive and negative HCC cell lines^[2]. This is not surprising, since the difference in p53 and β -catenin is not transcriptionally regulated.

In brief, the three clearly unfavorable prognostic markers of p53 nuclear staining, CD44 expression, and high grade are more common in AFP-producing HCCs, while one potentially favorable parameter, nuclear β -catenin staining occurs in AFP-negative tumors, indicating that AFP can be used as a prognostic marker in patients with liver tumors.

Abstract

AIM: To explore the expression and replication of hepatitis B virus (HBV) DNA in primary duck hepatocytes (PDHs).

METHODS: Complete HBV genome was transfected into PDHs by electroporation (transfected group, 1.19×10^{12} copies of linear HBV DNA/ 1×10^7 PDHs). After 1-5 d of transfection, HBsAg and HBeAg in the supernatant and lysate of PDHs were measured with the IMX System. Meanwhile, replicative intermediates of HBV DNA were analyzed by Southern blotting and Dot blotting. PDHs electroporated were used as control group.

RESULTS: HBsAg in the hepatocyte lysates of transfected group was 15.24 (1 d), 14.55 (3 d) and 5.13 (5 d; P/N values, positive ≥ 2.1) respectively. HBeAg was negative (< 2.1). Both HBsAg and HBeAg were negative in the supernatant of transfected group. Dot blotting revealed that HBV DNA was strongly positive in the transfected group and negative in the control group. Southern blot analysis of intracellular total DNA indicated that there were relaxed circular (rc DNA), covalently closed circular (ccc DNA), and single-stranded (ss DNA) HBV DNA replicative intermediates in the transfected group, there was no integrated HBV DNA in the cellular genome. These parameters were negative in control group.

CONCLUSION: Expression and replication of HBV genes can occur in hepatocytes from non-mammalian species. HBV replication has no critical species-specificity, and yet hepatic-specific regulating factors in hepatocytes may be essential for viral replication.

INTRODUCTION

Hepatitis B is one of the fatal diseases all over the world, and its pathogenesis is still unclear and its therapy appears difficult too. In recent years, reports have revealed that hepatocytes were not only the target cells infected with hepatitis B virus (HBV) and destructed by activated cytotoxic T lymphocytes, but also the immune modulating cells activated by effector cells, and even take part in the process of HBV non-cytolytic clearance^[1,2]. In order to study interactions between HBV and hepatocytes, we established an *in vitro* model of primary culture hepatocytes from heterologous species transfected with linear HBV DNA. Since whether naked HBV DNA can replicate or express protein in non-human hepatocytes, and whether its replication process is similar to that in normal specific host are not reported, we transfected linear HBV DNA into primary duck hepatocytes (PDHs) to investigate the host-specific regulating role in the replication of HBV in hepatocytes from non-mammalian species.

MATERIALS AND METHODS

Isolation and culture of primary duck hepatocytes

Duck hepatitis B virus (DHBV) DNA and DHBsAg in duck serum were negative tested by Dot blot analysis and ELISA respectively. Hepatocytes were harvested from Chongqing ducks using an *in situ* collagenase perfusion technique^[3]. The ducks were injected into the peritoneal cavity pentobarbital sodium (30 mg/kg body weight) and heparin (100 IU/kg body weight), the abdomen of the animals was opened and the portal vein was exposed and cannulated. Then the liver was *in situ* perfused at 37 °C with calcium-free, Hanks' balanced salt solution (HBSS) for

10 min, then with 0.2 g/L collagenase type I in calcium-presenting HBSS for 15 min. The liver was removed and the cells were combed gently in tissue culture medium. Hepatocytes were centrifugated, washed, and separated from non-parenchymal cells by differential centrifugation at 50 g. Viability of hepatocytes detected by trypan blue exclusion (TBE) was about 90%, and the cells were counted.

Freshly isolated hepatocytes were transfected with linear HBV DNA, and then inoculated at a density of 3×10^6 cells per 25 cm² culture flask. Culture medium was composed of RPMI 1640 with insulin (100 IU/L), penicillin, streptomycin and 100 mL/L fetal bovine serum. Cultures were incubated at 37 °C in a humidified atmosphere containing 50 mL/L CO₂ and media were renewed every two days.

Extraction of linear HBV DNA

Plasmid pEcob 6 containing two *Eco*RI copies of HBV genome in a head-to-tail arrangement was used to extract the linear HBV DNA. Extraction was carried out as previously described^[4]. Briefly, pEcob 6 was digested by *Eco*RI at 37 °C for 2 h, then fractionated by electrophoresis on 1% agarose gel. The complete HBV DNA 3.2 kb fragment was extracted and quantified for transfection.

Transfection procedures

Transfection was performed as previously described^[5], electroporation conditions were optimized by Yao *et al.* In briefly, 4 µg linear HBV DNA was added to 1×10^7 hepatocytes and electroporated for about 29 ms at 220 V and 950 µF of capacitance. After gene transfer, the cells were inoculated and cultured for 5 d. The electroporated hepatocytes were used as control.

Test for HBV-specific proteins

After 1-5 d of transfection, HBsAg and HBeAg in the supernatant and lysate of hepatocytes were identified using radioimmunoassay kits (Abbott Laboratories) according to the manufacturer's instructions. The HBsAg signal/noise (P/N ratio) >2.1 was considered positive.

DNA extraction from hepatocytes and HBV DNA replication analysis

Intracellular total DNA was extracted 2 d after transfection. Southern blotting was used to analyze replicative intermediates of HBV DNA. Dot blotting was used to test the total HBV DNA in hepatocytes from d 1 to 5 after transfection. All procedures were performed as previously described^[4].

RESULTS

Viral antigen production in transfected duck hepatocytes

Production of HBsAg and HBeAg was measured in culture supernatant and cell lysate was collected daily from transfected hepatocytes group. HBsAg in the lysate of transfected hepatocytes increased during the first 3 d following transfection, with HBsAg P/N value being around 15 (Table 1). HBsAg was negative in all culture supernatants of transfected hepatocytes. Both lysate and supernatant were negative for HBeAg. Both HBsAg and HBeAg in control group were negative.

Table 1 HBsAg values (P/N) in primary duck hepatocyte lysates

Time after transfection	1 d	3 d	5 d
Transfected group	15.24	14.55	5.13
Control group	1.01	0.93	1.38

DNA analysis of intracellular total DNA

Dot blotting revealed that total amount of HBV DNA in transfected hepatocytes was strongly positive from d 1 to 5 following transfection (Figure 1). Southern blot analysis of intracellular total DNA indicated that, there were relaxed circular (rc DNA), covalently closed circular (ccc DNA) and single-stranded (ss DNA) HBV DNA replicative intermediates in the transfected hepatocytes (Figure 2). There was no integrated viral DNA in the cellular genome.

DISCUSSION

DHBV *in vivo* and *in vitro* models have been used for the study of HBV infection and the evaluation of new anti-HBV strategies^[6-10]. However, until now, there is no report on the process of viral infection, the level of DNA replication and protein expression and the mechanisms of hepatitis B virus in hepatocytes from heterologous species. Whether naked HBV DNA can replicate or express protein in nonhuman hepatocytes, and whether its replication process is similar to that in normal specific host are still unclear. We transfected linear HBV DNA into non-mammalian hepatocytes, PDH to investigate the host-specific regulating role in the replication of HBV.

Our results indicate that naked DNA of HBV can effectively replicate in PDHs and its replicative intermediates include relaxed circular DNA, covalently closed circular DNA, single-stranded DNA, and non integrated viral DNA

in the cellular genome. The pattern of DNA replication of HBV is similar to that in normal permissive human cells and in liver of chimpanzee acutely infected with HBV^[11], which is the same as that of DHBV replication in liver of chronically infected duck^[12], and is further supported by the results of PDHs acutely or chronically infected with DHBV^[3,13]. Thus complete HBV genome effectively transfected into primary hepatocytes can efficiently replicate.

Our results also show that HBV can effectively express proteins in primary duck hepatocytes, such as HBsAg, with its P/N value peak being around 15.0 1-5 d after transfection. In our study, HBsAg was found only in the lysate of duck hepatocytes, but not in the supernatant of cultured hepatocytes, which can be explained that HBsAg is insufficient to excrete in outer media of hepatocytes, and unbalance between large, mediate and small proteins of HBsAg might also affect its secretion. Furthermore, it needs further study. No HBeAg was measured in the lysate or supernatant of duck hepatocytes, which might be related to two reasons. The first, is that in duck hepatocytes there is no sufficient translation activators essential for effective activation of HBV core gene promoter. Yu and Mertz^[14,15], found that HBV pre-C RNAs and pre-genome RNAs are separately regulated by two activators. The other reason is that shortly after expression, HBeAg is digested by lysozymes in duck hepatocyte plasma. The real causes need further study.

In conclusion, expression and replication of HBV genes can occur in hepatocytes from non-mammalian species, which strongly supports the idea that replication of HBV has no critical species-specificity, and hepatic-specific regulating factors in hepatocytes are essential for viral replication. Further more, the differences in inner environments of hepatocytes from different species affect and even determine the expressions of HBV genes and proteins.

Abstract

AIM: To observe the expressions of early growth response factor-1 (Egr-1) and tissue factor (TF) in rats with cerulein-induced acute pancreatitis and to explore its significance.

METHODS: A large dose of cerulein was used to create the experimental acute pancreatitis model in rats. The changes of Egr-1 mRNA and protein in rats were observed during 30 min to 4 h after the treatment and immunohistochemical method was used to observe the localized expression of Egr-1 in tissues. In addition to the mRNA expression of Egr-1 target gene, TF was also observed. A blank control group, and a bombesin-administered group were used for comparison.

RESULTS: After the stimulation of a large dose of cerulein, the rats showed typical inflammatory changes of acute pancreatitis. Thirty minutes after the stimulation, the mRNA expression of Egr-1 in the pancreatic tissue reached its peak and then declined, while the expression of Egr-1 protein reached its peak 2 h after the stimulation. Histologically, 2 h after the stimulation, almost all pancreatic acinar cells had the expression of Egr-1 protein, which was focused in the nuclei. The mRNA expression of TF occurred 1 h after the stimulation and gradually increased within 4 h. However, a large dose of bombesin only stimulated the pancreatic tissue to produce a little mRNA expression of Egr-1 and no mRNA expression of Egr-1 protein and TF.

CONCLUSION: Egr-1 as a pro-inflammatory transcription factor may play an important role in the pathogenesis of acute pancreatitis by modulating the expression of TF.

INTRODUCTION

Acute pancreatitis is a common disease with its severe case having a mortality of up to 25-40%, while its pathogenesis still remains unclear^[1,2]. The activation of pancreatic enzyme in acinar cells and its digestion of pancreatic tissues have been generally regarded as its trigger so far. However, recent studies on transcription factor, nuclear factor- κ B (NF κ B) and other cytokines showed that inflammatory cytokines play an important role in the pathogenesis of acute pancreatitis due to their inflammation-inducing properties^[3-7]. Early growth response factor-1 (Egr-1), also known as nerve growth factor-induced protein A, Krox-24 or Zif268, is a transcription factor -NF κ B^[8]. A recent study showed that Egr-1 may be an initial factor of inflammation^[9]. In our experiment, we studied the expression of Egr-1 in rats with cerulein-induced acute pancreatitis to understand its role in the pathogenesis of acute pancreatitis.

MATERIALS AND METHODS

Animal models

Following the procedures for construction of animal models^[3,6], cerulein was dissolved in normal saline. Then cerulein solution [20 μ g/(kg h)] was injected into abdominal cavity of male Wistar rats. After 4 h of the stimulation, a large dose of sodium pentobarbital was injected into the abdominal cavity of the rats, followed by incision of the thorax cavity to collect blood by a syringe needle; besides, a little lung tissue was harvested. Subsequently, an incision was made to open the abdominal cavity to expose the pancreatic tissue and a piece of pancreatic tissue was harvested and put into the pre-cooled neutral PBS (pH 7.4) with its fat removed. Pancreatic tissue was fixed in neutral 10% paraformaldehyde and cooled in liquid nitrogen and preserved at -70 °C. The blood was centrifuged for blood serum, which was then preserved at -70 °C.

Test for acute pancreatitis index

The acute pancreatitis indexes included serum amylase, tissue

myeloperoxidase (MPO) and percentage water content. The test procedures are described in our previous study^[6].

Western blotting

According to the method described in our previous study^[6], the cooled pancreatic tissue was homogenized and centrifuged with its supernatant for protein quantification. About 25 µg protein was added into each hole for PAGE-SDS gel electrophoresis, the product of which was then transferred to PVDF film for incubation with an antibody at -4 °C overnight. The immunoblotting protein band was detected using emission chemiluminescence kit. The film was scanned and saved as a digital image (Figure 1). The antibody used in our study was from Santa Cruz Company.

Quantitative polymerase chain reaction

The fresh pancreatic tissue was put into TRIzol (Invitrogen) for homogenate and then chloroform and isopropanol were added, followed by centrifugation of supernatant to obtain DNA by ethanol precipitation. The obtained DNA was then digested with DNA enzyme I and purified by RNA purification (Qiagen). Through qualification of RNA, RT kit (Promega) was used for transcription to obtain cDNA, which was then amplified by routine PCR. SYBR (Bio-Rad) dye was added and 27-32 cycles were amplified, the relative production was detected with quantitative PCR system. The result was shown in a ratio of the production to APRO. The primers used were Egr-1 (GenBank NM_012551) of sense: 5'CCCGTATGCTTGCCCTGTTGAGTC3' and antisense: 5'CCCGTTGAGGTGCTGAAGGAGTTG3' with PCR product of 548 bp and tissue factor (TF, GenBank U07619) of sense: 5'TGTTTCAGATAAGCGATAGA3' and antisense: 5'GTGCGAAGAAGCAGTAG3' with a PCR product of 482 bp as control, rat acidic ribosomal phosphoprotein (GenBank X15096) of sense: 5'CCGC-GGGAAGGCTGTGGTG3' and antisense: 5'AGGGC-CTGCTCTGTGATGTC3' with a PCR product of 492 bp as control.

Histology and immunohistochemistry

The tissue was processed routinely, dehydrated and paraffin-embedded, cut into 5-µm-thick sections and stained with hematoxylin and eosin. Then, the histological and morphological changes were observed under an optical microscope. During immunohistochemistry, the tissue

sections were routinely dewaxed and liquefied and rabbit Egr-1 antibody was added. Then, Egr-1 was detected.

Statistical analysis

The data were expressed as mean±SD and analyzed with SPSS 1.0 software package.

RESULTS

Large dose of cerulein-induced obvious acute pancreatitis and the pancreatic tissue had the manifestations of acute abscess, widened tissue interspace and obvious, swollen pancreatic acinar cells (Figure 1). The indexes for diagnosis of acute pancreatitis, including blood serum amylase, tissue MPO, and percentage of water content, significantly increased (Figure 2). Similar to the previous report^[10], bombesin failed to induce typical experimental acute pancreatitis. Large dose of bombesin induced only tissue edema, which was relatively milder than that induced by cerulein, amylase, and MPO increased with no statistical significance (Figure 2).

The expression of Egr-1 mRNA reached its peak 30 min after the injection of cerulein, which was 60 times higher than that in the control (Figure 3B). However, it significantly declined after 4 h. Correspondingly, the expression of Egr-1 protein occurred 2 h after injection and obviously declined after 4 h. Egr-1 protein expression occurred 2 h after the stimulation, and almost all acinar cells had the expression of Egr-1 protein, while the expression was locally stronger and the expression of Egr-1 was found in nuclei. The expression of TF was later than that of Egr-1. Obvious expression of TF mRNA was seen 1 h after the stimulation and peaked in 2-4 h (Figure 3A).

control (B). Con: control; Bom: bombesin control.

DISCUSSION

Recent studies have shown that Egr-1, as one of the transcription factors during the early stage of inflammation, can regulate the expression of multiple inflammatory factors, such as tumor necrosis factor, interleukin-2, transforming growth factor- β 1, intracellular adhesion molecule-1 (ICAM-1), and TF, and eradication of Egr-1 can protect lungs from injuries induced by ischemia and decrease the expression of tissue IL-1 β , IL-6, ICAM-1, MCP-1, TF, and PAI^[9]. However, the expression and function of Egr-1 in acute pancreatitis remain unclear.

In our study, during the early stage of acute pancreatitis induced by cerulein, Egr-1 demonstrated high expression in mRNA and protein. Its protein expression occurred 1 h after stimulation, peaked at 2 h, and lasted for at least 4 h. Egr-1 was found in nuclei 2 h after stimulation in our experiment, indicating that Egr-1 may play an important regulatory role during the early stage of acute pancreatitis. We also found that the expression of Egr-1 in acinar cells was locally distinct, which may be related to the property of Egr-1 that it is extremely easy to attenuate. Being different from cerulein, bombesin could not induce typical acute pancreatitis^[10] and did not increase blood serum amylase and tissue MPO level although bombesin could also induce mild edema of pancreatic tissue. Correspondingly, bombesin induced only trace expression of Egr-1 mRNA, but expression of protein could not be detected. The result further indicates, that the expression of Egr-1 plays a role in the pathogenesis of acute pancreatitis.

Previous studies have shown that during the initial and developmental process of acute pancreatitis, ischemia-reperfusion plays an important role^[11] and TF is an initial factor for coagulation, which can result in decrease of the tissue blood flow and ischemia^[8,9]. It was reported that TF is an important targeting factor of Egr-1, whose expression is modulated by Egr-1^[9]. Our study indicated that during the early stage of acute pancreatitis, TF also had high expression. However, compared to Egr-1, its expression was 1-2 h later. Therefore, we believe that during acute pancreatitis, Egr-1 may regulate the expression of TF and

trigger coagulation to induce ischemia of pancreatic tissue, thus aggravating the disease. Nevertheless, the detailed mechanism of TF during acute pancreatitis needs further studies.

In conclusion, Egr-1, as a pro-inflammatory transcription factor that may play an important role in the pathogenesis of acute pancreatitis.

Abstract

AIM: To investigate the relation between hepatotoxicity of halothane and sevoflurane and altered hepatic calcium homeostasis in enzyme-induced hypoxic rats.

METHODS: Forty-eight rats were pretreated with phenobarbital and randomly divided into six groups (eight in each group) and exposed to O₂/N₂/1.2 MAC anesthetics for 1 h: normal control (NC), 21% O₂/79% N₂; hypoxic control (HC), 14% O₂/86% N₂; normal sevoflurane (NS), 21% O₂/N₂/1.2MAC sevoflurane; hypoxic sevoflurane (HS), 14% O₂/N₂/1.2MAC sevoflurane; normal halothane (NH) 21% O₂/79% N₂/1.2MAC halothane; hypoxic halothane (HH), 14% O₂/N₂/1.2MAC halothane. Liver specimens and blood were taken 24 h after exposure to calcium and determined by EDX microanalysis.

RESULTS: The liver of all rats given halothane (14% O₂) had extensive centrilobular necrosis and denaturation. Morphologic damage was accompanied with an increase in serum glutamic pyruvic transaminase. In groups NH and HH, more calcium was precipitated in cytoplasm and mitochondria.

CONCLUSION: These results suggest that halothane increases cytosolic Ca²⁺ concentration in hepatocytes. Elevation in Ca²⁺ concentration is implicated in the mechanism of halothane-induced hepatotoxicity. sevoflurane is less effective in affecting hepatic calcium homeostasis than halothane.

INTRODUCTION

It is now recognized that two types of halothane-induced hepatic dysfunction exist^[1,2]. A mild sub-clinical form manifested by abnormal biochemical indices of hepatic function can be caused by toxic products of halothane metabolism, possibly determined by genetic factors, or by hepatic hypoxia, resulting from an imbalance between hepatic oxygen supply and demand. A much rarer, fulminant form may occur with severe necrosis, which may prove fatal^[3]. It is probable that this form results from an immune reaction: an oxidative metabolite binds covalently to liver proteins, producing a haptan, which in turn provokes immune reaction and formation of circulating antibody.

A major question being addressed in hepato-cellular injury is whether a unifying mechanism exists involving a loss of regulation of cellular Ca²⁺ levels. In this regard, alteration of Ca²⁺ homeostasis plays a major role in cell injury induced by a diversity of situations such as chemical intoxication and abnormal physiological states such as ischemia^[4,5].

Animal studies have provided evidence supporting a role for altered calcium fluxes in the mechanism of halothane-induced liver injury. In guinea pigs, hepatic calcium content increases significantly 24 h after exposure to halothane. Subsequent changes in liver calcium are proportional to the severity of liver necrosis, as determined morphologically^[6]. More recently it was shown that halothane, enflurane, and isoflurane stimulated dose-dependent release of radiolabeled calcium from internal calcium stores in isolated rat hepatocytes^[7]. Further evidence in support of the carcinogenic hypothesis of cell injury is offered by studies, in which the administration of a calcium channel blocker reduces hepatic necrosis in animals exposed to hepatotoxic agents, including halothane^[8]. For a better understanding of the mechanism of liver injury, attributing to halothane and sevoflurane hepatotoxicity, we used cytochemical methods to evaluate the changes of intracellular calcium and corresponding hepatic histopathological changes in enzyme-induced hypoxic rats.

MATERIALS AND METHODS

Animal model

The protocol was approved by the institutional Animal Care

and Use committee. Adult male Sprague-Dawley rats weighing 150-160 g were obtained from the Animal Center of the Second Military Medical University and maintained in a 12 h dark-light cycle. The animals had free access to water and diet of Wayne rodent food. To induce the hepatic microsomal drug-metabolizing enzymes, 48 animals were given phenobarbital (1 mg/mL) in their drinking water for 10 d prior to any experiment^[9].

For exposure to halothane and sevoflurane, animals were placed into 35 L plexiglass cages (g per cage). These animals were randomly divided into six groups and anesthetized for 1 h with O₂/N₂/1.2MAC anesthetic agents according to the following schedule: NC group was given 21% O₂/79% N₂; HC group 14% O₂/86% N₂; NNS group 21% O₂/79% N₂/1.2MAC sevoflurane; HS group 14% O₂/86% N₂/1.2MAC sevoflurane; NH group 21% O₂/79% N₂/1.2MAC halothane; HH group 14% O₂/86% N₂/1.2MAC halothane. Nitrogen and oxygen were delivered to the chamber by Dräger anesthetic machine at a flow rate of 4 L/min. The concentrations of O₂/CO₂, halothane, and sevoflurane in the chamber were monitored with a calibrated Capnomac Ultima.

After anesthesia or appropriate exposure, the animals were sent back into their metal cages and killed by decapitation, 24 h after anesthesia. Blood from the trunks was collected into dried beakers, and livers were rapidly removed and placed in chilled petridishes. Serum was separated from clotted blood, and assayed for ALT by automated methods in the Department of Clinical Chemistry. For histological examination, liver samples were collected into 10% PBS, fixed and mounted on paraffin blocks. Tissue sections were stained with hematoxylin and eosin, Gomori trichrome and a reticulin stain. Coded liver sections were examined without knowledge of the experimental details. The necrosis and denaturation of the slides of each section were quantitatively estimated as previously described^[10].

Calcium cytochemistry

A portion of the right anterior lobe was cut into 0.5 mm blocks. The specimens were treated in cold fixative consisting of 25% glutaraldehyde in 0.9 mol/L potassium oxalate adjusted to pH 7.4 with 1 mol/L potassium hydroxide. Sucrose was added to 1.4% final concentration. Fixation was done for 4 h at 4 °C. The specimens were subsequently kept in a cold mixture of 1% osmium tetroxide and 2% potassium pyroantimonate for 2 h, followed by osmium tetroxide and 1% potassium ferrocyanide for 1 h. Then, the specimens were rinsed for 15 min with distilled water adjusted to pH 10 with 1 mol/L potassium hydroxide, dehydrated in cold ethanol series, and routinely embedded in Epon-812 or Spur.

EDX microanalysis

The 100 nm thick sections for calcium cytochemistry, were left unstained and coated with carbon films in a vacuum evaporator. EDX microanalysis was performed under an analytical electron microscope (Hitachi-800) equipped with an energy-dispersive X-ray detecting system (EDAX, type 9 100/60). The acceleration voltage was 100 KV and the probe current was for 100 s and evaluation of the energy-

dispersive X-ray spectra was performed by a computer program^[11].

Statistical analysis

Data were expressed as mean±SE and analyzed by analysis of variance. Means were compared with Fisher's least significant difference test. *P*<0.05 was considered statistically significant.

RESULTS

Hepatotoxicity

Under conditions of hypoxia and induction of the microsomal enzymes, halothane anesthesia produced extensive hepatic injury. Within 24 h after exposure to halothane at 14% O₂, all the rats had many areas of hepatic necrosis radiating from the central veins. The necrosis and denaturation in HH group increased significantly as compared to the clusters of lymphocytes, histocytes and neutrophils, and often encircled by a layer of swollen hepatocytes containing single large vacuoles, strands of degenerating cytoplasm, and eccentric, intact pyknotic nuclei. Morphologic damage was accompanied with an increase in serum glutamic pyruvic transaminase (*P*<0.01, Table 1). No statistically significant histologic change was found in the following variables: normal control, hypoxic control, halothane anesthesia at 21% O₂, sevoflurane exposure at 21% O₂ (Figure 1).

Table 1 Serum ALT levels, and hepatic damage in enzyme-induced hypoxic rats (mean±SE)

Group	<i>n</i>	ALT (IU/L)	Hepatic damage
NC	8	56.12±20.88	0.145±0.043
HC	8	79.88±46.08	0.533±0.426
NS	8	58.31±23.12	0.576±0.106
HS	8	147.75±72.89	0.576±0.106
NH	8	142.15±78.19	0.614±0.433
HH	8	646.13±412.90 ^b	2.740±0.714 ^b

^b*P*<0.01 vs normal control.

Calcium cytochemistry

In NC and NS groups, calcium precipitation was located in nuclei with mitochondria and cytoplasm as fine particles. In HC and HS groups, intracellular calcium increased slightly. But after exposure to 21% O₂/ N₂/1.2MAC halothane or 14% O₂/ N₂/1.2MAC halothane, more and more calcium was precipitated in calcified cytoplasm and mitochondria. In HH group, a large amount of calcium deposition was found in cytoplasm and mitochondria (Figure 2).

EDX microanalysis

Qualitative analyses were performed in nuclei, mitochondria and cytoplasm. The characteristic emission of calcium (Kα) was observed. Neither sodium nor potassium was present. Semi-quantitative analyses were performed in mitochondria and cytoplasm. The calcium emission analyses are shown in Table 2. The amount of cellular calcium increased in HH group (*P*<0.01) and there was a positive linear correlation between the calcium in mitochondria and cytoplasm.

Figure 1 Morphological change in HH group (A) and NC group (B). ($\times 20\,000$). A: The liver of rats anesthetized with 14% $O_2/86\%$ $N_2/1.2MAC$ Halothane had extensive centrilobular necrosis and denaturation; B: There was

a increase in serum glutamic pyruvic transaminase accompanying the morphologic damage, but no marked change was found in liver morphology inhaled with 21% $O_2/79\%$ N_2 .

Figure 2 Hepatic Ca^{2+} cytochemical changes in HH group (A) and NC group (B). A: The liver of rats anesthetized with 14% $O_2/86\%$ $N_2/1.2MAC$. Halothane had a large amount of calcium deposition as shown in cytoplasm and

mitochondria; B: The liver of rats inhaled with 21% $O_2/79\%$ N_2 , calcium precipitation was mainly located in nucleus, in mitochondria and cytoplasm as fine particles.

DISCUSSION

The principle of calcium cytochemical technique is to use potassium pyroantimonate to deposit intracellular cations and can contribute to the understanding of cellular cation redistribution resulting from physiologic and pathologic stimuli. Because the precipitation by potassium pyroantimonate of cations is nonspecific, careful choice of reaction conditions for calcium cytochemistry is very important, and it must be done in conjunction with analytical techniques such as X-ray analysis to ascertain whether other cations are deposited^[12]. When tissue is first fixed with glutaraldehyde and potassium pyroantimonate at low temperature (4 °C), better results can be acquired. Thus, the precipitation of calcium with cytochemical methods in combination with EDX microanalysis is valuable in investigating the mechanisms of hepatocellular injuries. Stereological methods provide

the means of efficiently producing quantitative data on the internal structure of organs, tissues, and cells. These methods can easily be applied to cytological work at the light or electron microscopy level of resolution^[13]. Although particular caution is indicated in avoiding systematic errors which may result from inadequate preparation, section thickness, etc, the results are generally very reliable.

Cytosolic Ca^{2+} concentration in hepatocytes may increase under hypoxic condition, which might be due to the changes of membrane functions, such as Ca^{2+} -ATPase activity, Na^+ - Ca^{2+} exchange system^[14]. But cellular and mitochondrial calcium did not significantly increase in HC group. The causes are follows. (1) The degree of hypoxia (14% O_2) is not severe; (2) Hypoxia differs from ischemia, and the substances synthesizing ATP do not exhaust; (3) Ca^{2+} -ATPase activity may partly recover 24 h after hypoxic exposure for 1 h.

It has been proposed that hepatic damage occurs secondary to the disruption of mechanism, which maintains cellular calcium homeostasis. A retrospective study showed that there is evidence that halothane can elevate cytosolic free Ca^{2+} by releasing calcium from internal calcium stores and uptaking calcium from extracellular medium^[15]. Recent work^[16] has demonstrated that loss of sarcoplasmic reticulum's Ca^{2+} -ATPase activity by oxidizing agents, results direct oxidation of thiol groups on ATPase, but not lipid peroxidation. Halothane is also an oxidizing agent, but its mechanism underlying the increase of cytosolic Ca^{2+} is not

clear. Sevoflurane, an inhalation anesthetic agent, undergoes considerable less metabolism and less disturbed Ca^{2+} homeostasis than halothane, which may be relevant to its lesser hepatotoxicity^[17].

Cell injury due to loss of Ca^{2+} homeostasis correlates with blebbing of plasma membranes involving cytoskeletal proteins, Ca^{2+} ions and Ca^{2+} dependent proteases^[18]. The cytoskeletal protein is therefore expected to be a target for cytoplasmic calcium ions that promote changes in cell shape. Most of the known cytoskeletal receptors for calcium are associated with the actin filament system and these may be important in regulating many types of cell motility, including locomotion, phagocytosis, and secretion. Cytosolic free Ca^{2+} plays an increasingly important and fundamental role in the control of membrane permeability and cellular response to stimulation. Channel of discrete unitary conductance and selectivity activated by increased cytosolic free Ca^{2+} are responsible for K^+ efflux transfer and Na^+ influx, respectively. The elevation of mitochondrial Ca^{2+} influences mitochondrial respiration by changing activities of three matrix enzymes, pyruvate dehydrogenase, 2-oxoglutarate dehydrogenase and isocitrate dehydrogenase. Ca^{2+} activates proteases and endonucleases. Ca^{2+} enhances formation of active oxygen species, etc.

Sugimura *et al.*^[19], found that calcium channel blocking agent inhibits the production of radical intermediates during metabolism of halothane. These results suggest that calcium can activate the metabolism of halothane. Thus, we consider that the viscous circle of peroxidation activated by radical intermediates and elevation of cytosolic calcium may be the basis of halothane-induced hepatotoxicity under hypoxic internal environment.

Abstract

AIM: To investigate the level of nitric oxide (NO) and nitrous oxide synthase (NOS) enzyme and its effect on gastric mucosal pathologic change in patients infected with *Helicobacter pylori* (*H pylori*), and to study the pathogenic mechanism of *H pylori*.

METHODS: The mucosal tissues of gastric antrum were taken by endoscopy, then their pathology, *H pylori* and anti-CagA-IgG were determined. Fifty *H pylori* positive cases and 35 *H pylori* negative cases were randomly chosen. Serum level of NO and NOS was detected.

RESULTS: One hundred and seven cases (71.33%) were anti-CagA-IgG positive in 150 *H pylori* positive cases. The positive rate was higher especially in those with pre-neoplastic diseases, such as atrophy, intestinal metaplasia and dysplasia. The level of NO and NOS in positive group was higher than that in negative group, and apparently lower in active gastritis than in pre-neoplastic diseases such as atrophy, intestinal metaplasia and dysplasia.

CONCLUSION: *H pylori* is closely related with chronic gastric diseases, and type I *H pylori* may be the real factor for *H pylori*-related gastric diseases. Infection with *H pylori* can induce elevation of NOS, which produces NO.

INTRODUCTION

There is evidence that *Helicobacter pylori* (*H pylori*) is closely related with gastric carcinoma, and is considered as the first grade oncogene of gastric carcinoma by World Health Organization (WHO). *H pylori* infection correlates closely with gastric mucous pathology^[1-4].

NO is a medium produced in vessel endothelial cells or smooth muscle cells by NOS^[5,6]. As an inflammatory medium, NO plays an important role in the physical function and pathological process. Changes of NO in serum and tissue are related with damage to gastric mucosa and *H pylori* infection^[7-11].

This study aimed to investigate the changes of NO, NOS and the pathological transformation of gastric mucosa in patients infected with *H pylori*.

MATERIALS AND METHODS

Patients

Two hundred and eighty-two patients with chronic gastric disease were enrolled in this study. *H pylori* was detected by both rapid urease test and real-time fluorescent quantitative PCR in these patients. Anti-CagA-IgG was detected in the *H pylori* positive patients, the serum samples were collected from 50 *H pylori* positive patients and 35 *H pylori* negative patients for detection of NO and NOS.

Real-time fluorescent quantitative PCR

Real-time fluorescent quantitative PCR was performed with PCR kit (Da'an Gene Diagnosis Center, Guangzhou). Fluorescence was detected with a type DA620 fluorescent detector.

CagA *H pylori*-IgG

CagA *H pylori* IgG was detected according to the manufacturer's instructions (Shanghai Jingying Biology Corporation).

Measurement of NO and NOS

Because NO could be converted into NO₂⁻ and NO₃⁻ *in vivo*, nitrate reductase was used to deoxidize NO₃⁻ into NO₂⁻, and to determinate its concentration. NO and NOS were tested with the kits, (Nanjing Jiancheng Biology Corporation).

Statistical analysis

Data were presented as mean±SD and analyzed with SPSS software. Statistical analysis was performed using two-tailed Student's *t* test and χ^2 test. *P*<0.05 was considered statistically significant.

RESULTS

Relationship between *H pylori* infection and pathology

Among the 282 cases, *H pylori* was found in 150 cases, (53.19%), including 38.54% (37/96) in chronic superficial gastritis group, 51.26% (61/119) in atrophic gastritis group, 73.17% (30/41) in intestinal metaplasia group, and 84.62% (22/26) in dysplasia group. The *H pylori* positive rate in atrophic gastritis group was higher than that in chronic superficial gastritis group ($P<0.05$), and significantly higher in intestinal metaplasia group and dysplasia group than that in chronic superficial gastritis group ($P<0.01$, Table 1).

Table 1 *H pylori* positive rate in chronic gastric disease (%)

Group	<i>n</i>	<i>H pylori</i> positive	<i>H pylori</i> negative
CSG	96	37 (38.54)	59 (61.46)
CAG	119	61 (51.26) ^a	58 (48.74)
IM	41	30 (73.17) ^b	11 (26.83)
Dysplasia	26	22 (84.62) ^b	4 (15.38)
Total	282	150 (53.19)	132 (46.81)

^a $P<0.05$, ^b $P<0.01$ vs CSG.

Relationship between anti-CagA-IgG and pathology

The anti-CagA-IgG positive rate was 71.33% (107/150) in 150 *H pylori* positive patients, including 40.54% (15/37) in chronic superficial gastritis group, 75.41% (46/61) in atrophic gastritis group, 86.67% (26/30) in intestinal metaplasia group and 90.91% (20/22) in dysplasia group. The anti-CagA-IgG positive rate in chronic superficial gastritis group was significantly lower than that in the other three groups (Table 2).

Table 2 Positive rate of anti-CagA in 150 *H pylori* positive patients (%)

Group	CSG	CAG	IM	Dysplasia
<i>n</i>	37	61	30	22
Anti-CagA Positive (%)	15 (40.54) ^b	46 (75.41)	26 (86.67)	20 (90.91)

^b $P<0.01$ vs Cag, IM, dysplasia.

Relationship between NO, NOS, and *H pylori* infection

The serum concentration of NO and NOS was 87.6 ± 16.1 $\mu\text{mol/L}$ and 51.4 ± 13.3 $\mu\text{mol/L}$ respectively in *H pylori* positive group, and 69.8 ± 19.4 $\mu\text{mol/L}$ and 35.2 ± 13.3 $\mu\text{mol/L}$ respectively in *H pylori* negative group (Table 3).

Table 3 Serum concentration of NO and NOS (mean \pm SD)

Group	<i>n</i>	NO($\mu\text{mol/L}$)	NOS($\mu\text{mol/L}$)
<i>H pylori</i> positive	50	87.6 ± 16.1^b	51.4 ± 13.3^b
<i>H pylori</i> negative	35	69.8 ± 19.4	35.2 ± 13.3

^b $P<0.01$ vs *H pylori* negative group.

Relationship between NO, NOS, and pathology

The serum concentration of NO in chronic superficial

gastritis group was significantly lower than that in atrophic gastritis group, intestinal metaplasia group and dysplasia group ($P<0.05$, Table 4).

Table 4 Serum concentration of NO in different pathological groups ($\mu\text{mol/L}$, mean \pm SD)

Group	<i>H pylori</i> positive		<i>H pylori</i> negative	
	<i>n</i>	Concentration	<i>n</i>	Concentration
CSG	16	80.0 ± 14.6^a	11	62.2 ± 16.9^a
CAG	25	95.4 ± 8.4	21	74.6 ± 19.2
IM	12	91.2 ± 13.9	4	75.5 ± 27.7
Dysplasia	9	95.3 ± 10.3	3	71.5 ± 19.6

^a $P<0.05$ vs atrophic gastritis group, intestinal metaplasia group, and dysplasia group.

The serum concentration of NOS in chronic superficial gastritis group was significantly lower than that in atrophic gastritis group, intestinal metaplasia group and dysplasia group ($P<0.05$), but there was no significant difference among the four groups (Table 5).

Table 5 Serum concentration of NOS in different pathological groups ($\mu\text{mol/L}$, mean \pm SD)

Group	<i>H pylori</i> positive		<i>H pylori</i> negative	
	<i>n</i>	Concentration	<i>n</i>	Concentration
CSG	16	38.0 ± 12.4^a	11	31.7 ± 9.4
CAG	25	57.6 ± 8.3	21	35.4 ± 13.0
IM	12	54.8 ± 8.3	4	26.1 ± 4.4
Dysplasia	9	59.6 ± 9.4	3	46.1 ± 22.9

^a $P<0.05$ vs atrophic gastritis group, intestinal metaplasia group, and dysplasia group.

DISCUSSION

H pylori infection plays a leading role in the pathogenesis of chronic gastritis. Furthermore, *H pylori* infection is also a high risk factor for the development of gastric cancer [12]. *H pylori* can destroy gastric mucosa, leading to inflammation of gastric mucosa and digestive symptoms.

Our study showed that the *H pylori* positive rate in chronic superficial gastritis group was 38.54%, suggesting that *H pylori* is related to inflammation of gastric mucosa. Other factors may be involved in inflammation of gastric mucosa, such as pH value, mucus, glycoprotein. But in atrophic gastritis group, intestinal metaplasia group, and dysplasia group, the *H pylori* positive rate was 51.26%, 73.17% and 84.62%, respectively, indicating that *H pylori* infection has a close relationship with gastric pre-neoplastic diseases, such as atrophy, intestinal metaplasia, and dysplasia.

It was reported that *H pylori* has two types. Type I *H pylori* possesses high virulence energy producing cytotoxin-associated protein A and vacuole toxin, which are responsible for inflammatory response of gastric epithelial cells, and promotes cell proliferation and apoptosis [13,14]. Therefore, type I *H pylori* has a close relationship with development of gastric pre-neoplastic diseases [15-18]. Our study showed that

the pathological change of gastric mucosa was parallel with the anti-CagA-IgG positive rate. These observations support the hypothesis that type I *H. pylori* infection is a high risk factor for the development of gastric pre-neoplastic diseases.

It has been proved that there are lots of NOS in smooth muscle cells and myenteric nerve plexus of stomach^[19], which are induced to produce endogenous NO by cytotoxins of *H. pylori*. Moreover, a high pH value is beneficial for anaerobes to colonize in the stomach, and can degrade nitrate of food into nitrite. NO is regarded as an important inflammatory medium, related with acute and chronic inflammatory responses^[20-22]. But NO seems to have both beneficial and harmful effects on different stages of inflammation. In earlier period, NO can relieve mucosal inflammation and prevents cellular damage. However, it can prevent cellular apoptosis, induce mutation and contribute to the development of gastric pre-neoplastic diseases in later period^[23].

In this study, the levels of NO and NOS in chronic superficial gastritis group were significantly lower than those in pre-neoplastic diseases groups, such as atrophic gastritis group, intestinal metaplasia group, and dysplasia group in *H. pylori* positive patients, but the condition existed not only in *H. pylori* positive group, but also in *H. pylori* negative group, suggesting that the serum level of NO induced by *H. pylori* may be related with pre-neoplastic diseases. In *H. pylori* negative patients, the levels of NOS had no difference in every pathological group, but the levels of NO were significantly higher in gastric pre-neoplastic disease groups, showing that other ways may stimulate the producing of NO besides *H. pylori* in pre-neoplastic diseases. However, we believe that NO plays an important role in the development of pre-neoplastic diseases.

Abstract

AIM: To explore the expression and correlation of CD44v6, vascular endothelial growth factor (VEGF), matrix metalloproteinase (MMP)-2 and matrix metalloproteinase (MMP)-9 in Krukenberg and primary epithelial ovarian carcinoma.

METHODS: The expressions of CD44v6, VEGF, MMP-2 and MMP-9 were detected by immunohistochemical method in 20 cases of normal ovarian tissues, 38 cases of Krukenberg tumor and 45 cases of primary epithelial ovarian carcinoma.

RESULTS: The expression of CD44v6 (primary epithelial ovarian carcinoma tissue *vs* normal ovarian tissue: $\chi^2 = 4.516$, $P = 0.034$; Krukenberg tumor tissue *vs* normal ovarian tissue: $\chi^2 = 19.537$, $P = 0.001$) and VEGF (primary epithelial ovarian carcinoma tissue *vs* normal ovarian tissue: $P = 0.026$; Krukenberg tumor tissue *vs* normal ovarian tissue: $\chi^2 = 22.895$, $P = 0.001$) was significantly higher in primary epithelial ovarian carcinoma tissue and Krukenberg tumor tissue than in normal ovarian tissue. The positive expression rate of MMP-2 and MMP-9 was 0% in the normal ovarian tissue. The positive expression rate of CD44v6 ($\chi^2 = 10.398$, $P = 0.001$), VEGF ($\chi^2 = 13.149$, $P = 0.001$), MMP-2 ($\chi^2 = 33.668$, $P = 0.001$) and MMP-9 ($\chi^2 = 38.839$, $P = 0.001$) was remarkably higher in Krukenberg tumor than in primary epithelial ovarian carcinoma. The correlation of CD44v6, VEGF, MMP-2, and MMP-9 was observed in primary epithelial ovarian carcinoma and Krukenberg tumor.

CONCLUSION: CD44v6, VEGF, MMP-2, and MMP-9 are involved in ovarian carcinoma, gastric cancer and Krukenberg tumor. Detection of CD44v6, VEGF, MMP-2 and MMP-9 may contribute to the diagnosis of ovarian

INTRODUCTION

Gastric cancer is one of the common malignancies in gastrointestinal tract^[1-3]. Its metastasis rate is 64.2% in China^[4]. Krukenberg tumor is an ovary metastatic cancer from gastrointestinal cancer. Krukenberg tumor is highly malignant with a poor prognosis and its mechanism is not clear.

Invasion and metastasis are the leading biological characteristics of malignant tumor, and have a close relation with factors such as movement of tumor cells, apoptosis and metastasis-associated genes. VEGF is an important angiogenic factor, which may induce angiogenesis in tumor, and has a higher expression in tumor tissues, which is closely related with invasion and metastasis of tumor^[5-7]. CD44v6 is one of the numerous adhesive molecules and a transmembrane glycoprotein located on cell surface. It induces homing of lymphocytes and participates in adhesion between cells, influencing invasion and metastasis of tumor^[8-10]. MMP is one of the proteolytic enzymes and plays an important role in occurrence and development of tumor^[11-13].

MATERIALS AND METHODS

Patients and specimens

Patients were selected from Tumor Hospital of Harbin Medical University from 1992 to 2001. All patients were informed of the purpose of the study and gave their informed consent. Forty-five cases of primary epithelial ovarian carcinoma (15 cases of serious adenocarcinoma, 16 cases of mucous adenocarcinoma, and 14 cases of others pathologic types) and 35 cases of Krukenberg tumor were included in the study. All ovarian cancers had metastasis to other organs and all Krukenberg tumors came from gastric cancer. The age of the patients was 20-75 years, averaged

41 years. All cases were diagnosed by histology or cytology, and received no chemotherapy and radiotherapy before operation. Specimens were embedded in paraffin.

Reagents and method

Monoclonal antibody was purchased from Bossed Company of Wuhan. Immunohistochemical method was used to detect the expression of CD44v6, VEGF, and MMPs. Staining was performed following the manufacturer's instructions. The first antigen of negative control was replaced by PBS.

Determination criteria

The cells with unambiguous brown and yellow particles present in cytoplasm of tumor cells under optical microscope were defined as positive cells. Positive intensity was divided into three grades: weak positive (counting score was 1), strong positive (counting score was 3) and moderately positive (counting score was 2). At the same time, the number of positive cells was calculated. Zero to four grades represented the number of positive cells less than 5%, 5-25%, 26-50%, 51-75% and more than 75%, respectively. The last counting scores were intensity scores. If the product had one or more scores, it was positive. Otherwise, it was negative.

Statistical analysis

Analysis of variance was used to analyze the difference between groups. Data were analyzed by χ^2 test or Fisher's exact test. Correlation among variables was tested by Pearson of bivariate.

RESULTS

Expression of CD44v6, VEGF, MMP-2, and MMP-9 in ovarian carcinoma, Krukenberg tumor, and gastric carcinoma

Positively staining particles of Cd44v6 were mainly distributed in plasmalemma of tumor, some of which were expressed in cytoplasm (Figure 1A). Significant difference in positive expression was observed between normal ovarian tissue and primary epithelial ovarian carcinoma, Krukenberg tumor, and gastric carcinoma ($P<0.05$). The positive expression of CD44v6 had no significant difference in ovarian carcinoma, ovarian mucous carcinoma and other carcinomas. No significant difference was found in moderately- and poorly-differentiated Krukenberg tumor.

Positive-staining particles of VEGF were mainly

distributed in cytoplasm (Figure 1B). The positive expression rate was higher in primary epithelial ovarian carcinoma, Krukenberg tumor, and gastric carcinoma than in normal ovarian tissue ($P<0.05$). The positive expression rates of VEGF were 31.1% and 71.1% respectively for primary epithelial ovarian carcinoma and Krukenberg tumor ($P<0.05$). No significant difference was found in ovarian carcinoma. No significant difference in positive expression rate was observed in moderately- and poorly-differentiated Krukenberg tumor.

Positive-staining particles of MMP-2 and MMP-9 were distributed in cytoplasm (Figures 1C and D). Positive expression rate of MMP-2 and MMP-9 was 0% in normal ovarian carcinoma (0/20). The positive expression rate of MMP-2 and MMP-9 was significantly higher in Krukenberg tumor, than in primary epithelial ovarian carcinoma ($P<0.05$ for all of them). There was no relation between positive expression rate of MMPs and pathological types of primary epithelial ovarian carcinoma and between positive expression rate of MMPs and differentiation degree of Krukenberg tumor.

There was no significant difference in positive expression rate of VEGF, CD44v6, and MMP-2 between gastric carcinoma and Krukenberg tumor. The positive expression rate of MMP-9 was remarkably higher in Krukenberg tumor than in gastric carcinoma ($P<0.05$). Obvious difference of positive expression rate of MMP-2 and MMP-9 was found in different differentiation degrees of gastric carcinoma. The positive expression rate was significantly higher in poorly-differentiated gastric carcinoma than in well- and moderately-differentiated gastric carcinoma ($P<0.05$, Table 1).

Relation among expressions of CD44v6, VEGF, MMP-2, and MMP-9

Positive expression was graded by rank correlation method. The results indicated that there was a remarkable relation between positive expressions of VEGF and CD44v6, CD44v6 and MMP-2 and MMP-9, MMP-2, and MMP-9 (Table 2).

In primary epithelial ovarian carcinoma, there was a significant relation between expressions of CD44v6, VEGF, MMP-2, and MMP-9 (Table 3). VEGF *vs* MMP-9, and CD44v6 *vs* MMP-9.

The relation between variables was significant in gastric carcinoma (Table 4).

DISCUSSION

CD44v6 is highly expressed in serum and tissues of ovarian carcinoma and correlates with development of ovarian carcinoma^[14,15]. In the present study, the expression of CD44v6 was significantly higher in primary epithelial ovarian carcinoma and Krukenberg tumor than in normal ovarian tissue ($P<0.05$), suggesting that expression of CD44v6 is related with malignant behaviors of ovarian carcinoma. The high expression of CD44v6 correlates with formation, development and transfer of ovarian carcinoma.

CD44 plays an important role in regulation of progress and metastasis of primary gastric carcinoma. Our study found that there was a significant difference in positive expression rate of CD44 between primary epithelial ovarian

carcinoma and Krukenberg tumor ($P<0.05$). The positive expression rate of CD44v6 was higher in primary gastric carcinoma (78.9%), indicating that higher expression of CD44v6 has a close correlation with metastasis of gastric carcinoma. It was reported that the positive expression rate of CD44v6 is 64-77% in gastric carcinoma tissue^[16-18]. Studies indicate that superfluous expression of CD44v6 correlates closely with occurrence, development, infiltration and metastasis of cancers.

VEGF is one of the agents accelerating the formation of blood vessels^[19-21], and has multiple functions after it binds to specific receptors of endothelial cell surface, indicating that the development, infiltration and metastasis of cancer is related with higher expression of CD44v6 in cancer^[5-7,22].

VEGF is highly expressed in serum and tissues of ovarian carcinoma^[23-28]. In the present study, the expression of VEGF was significantly higher in primary epithelial ovarian carcinoma and Krukenberg tumor than in normal ovarian tissue ($P<0.05$), indicating that the occurrence, development and metastasis of ovarian carcinoma is closely related with high expression of VEGF.

It has been identified that tumor metastasis is accelerated by VEGF, which is highly expressed in gastric carcinoma. VEGF may be used as an index for poor prognosis of gastric carcinoma^[29-34]. The positive expression is significantly different between primary epithelial ovarian carcinoma and Krukenberg tumor ($P<0.05$). There is no significant difference between mucous and mixed epithelial tumor and differentiation of Krukenberg tumor ($P>0.05$). The expression of VEGF is higher in primary gastric cancer, suggesting that cancer metastasis may be accelerated by VEGF. It was reported that the expression of VEGF is higher in carcinoma of colon with metastasis, than in carcinoma of colon without metastasis^[35-38], suggesting that metastasis of colonic carcinoma is closely related with positive expression of VEGF.

MMPs play an important role among enzymes breaking the extracellular matrix. MMP-2 and MMP-9 are closely related with metastasis of tumor^[39-41]. Collagenase has enzymolysis not only for matrix component of cells, but also for main component of membrana basalis. The expression of collagenase increases obviously in tumor tissues, metastasis and serum^[42-44].

In this study, MMP-2 and MMP-9 were not expressed in ovarian normal tissue. The expression was low in primary epithelial ovarian carcinoma, the reasons might be that the samples were stored for a long time and the staining was not ideal. Expression of MMP-2 and MMP-9 was higher in malignant tumor tissues than in normal tissues. There was a significant difference in expression of MMP-2 and MMP-9 between Krukenberg tumor and normal tissue, and primary epithelial ovarian carcinoma and normal tissue ($P < 0.05$). The expression rate was higher in primary gastric cancer. The results indicate that invasion and metastasis of tumor are accelerated by MMP-2 and MMP-9, and MMP-2 and MMP-9 play an important role in the metastasis of gastric carcinoma. It was reported that invasion and metastasis of tumors are related to the expression of MMP-2 and MMP-9^[43,46]. High expression of MMP-2 and MMP-9 may be the molecular basis of invasion and metastasis of tumor cells. Invasion and metastasis are present, if there is overexpression of MMP-2 and MMP-9 in tumor tissue.

There was not a significant difference in MMP-2 expression between moderately- and poorly-differentiated Krukenberg tumor ($P > 0.05$), indicating that expression of MMP-2 is not related with tumor differentiation.

Tumor metastasis involves a series of complex processes. Many gene products take part in the process and play an important role in forming metastasis. The significant correlations were obtained between variables in primary epithelial ovarian carcinoma and Krukenberg tumor, but not in CD44v6 and MMP-9 in our study, indicating that the above-mentioned factors participate in tumor invasion and metastasis.

INTRODUCTION

A new contagious disease occurred in 2003^[1-3], which lasted for at least 6 mo and swept over 29 countries in the world, causing numerous deaths and triggering public panic^[4]. However, it took less than 2 mo to successfully identify the causative agent-a novel coronavirus^[3,5]. Meanwhile, investigation of the unique pathogenic mechanism of this disease is still challenging and intriguing. Clinical data suggest that it is an abnormal pathological reaction to pulmonary viral infection characterized by acute lung injury^[1,2,4,6] that determines the process of the symptoms. Acute lung injury is a multi-factorial, pathophysiological process involving cytokines and adhesion molecules, as well as inflammatory and immune cells^[6-8]. Many pro- and anti-inflammatory cytokines such as IL-1, TNF- α , IL-8, IL-4, and IL-10 have been demonstrated to play a pivotal role in the pathogenesis of acute lung injury and severe systemic inflammation^[6,8-11]. To determine the role of cytokines in the pathogenesis of SARS, immunological techniques such as RIA, ELISPOT, and ELISA have been employed to measure cytokine alterations in blood samples from SARS patients^[12-14]. Jones *et al.*^[12], reported that the number of IFN- γ , IL-2, IL-4, IL-10, and IL-12 secreting cells induced by T-cell activators is below normal in many or most patients, while the number of cells which are induced to produce IL-6 and TNF- α by T-cell or monocyte activators is higher than normal in many early SARS patients, and increases in some SARS patients during and after treatment. Wong *et al.*^[13], found that Th1 cytokine, inflammatory cytokines such as IL-1, IL-6, and IL-12 and chemokines such as IL-8, MCP-1, and IP-10 are increased. Furthermore, Zhang *et al.*^[14], revealed that there is a difference in relationship between IL6, IL-8, TGF- β concentration, and SARS severity (positive for IL-6, but negative for IL-8 and TGF- β). Although these studies have shown the evidence of activated Th1 cell-mediated immunity and the hyper-innate inflammatory response, the role of these cytokines in the pathogenesis of the severe systemic inflammation and the mechanisms underlying the pathogenesis of SARS need to be further studied.

Abstract

AIM: To investigate the role of inflammatory and anti-viral genes in the pathogenesis of SARS.

METHODS: cDNA microarrays were used to screen the gene expression profiles of peripheral blood mononuclear cells (PBMCs) in two SARS patients (one in the acute severe phase and the other in the convalescent phase) and a healthy donor. In addition, real-time qualitative PCR was also performed to verify the reproducibility of the microarray results. The data were further analyzed.

RESULTS: Many inflammatory and anti-viral genes were differentially expressed in SARS patients. Compared to the healthy control or the convalescent case, plenty of pro-inflammatory cytokines such as IL-1, TNF- α , IL-8, and MAPK signaling pathway were significantly upregulated in the acute severe case. However, anti-inflammatory agents such as IL-4 receptor, IL-13 receptor, IL-1Ra, and TNF- α -induced proteins 3 and 6 also increased dramatically in the acute severe case. On the contrary, a lot of IFN-stimulated genes like PKR, GBP-1 and 2, CXCL-10 and 11, and JAK/STAT signal pathway were downregulated in the acute severe case compared to the convalescent case.

CONCLUSION: Gene expression in SARS patients mirrors a host state of inflammation and anti-viral immunity at the transcription level, and understanding of gene expression profiles may make contribution to further studies of the SARS pathogenesis.

Development of microarray technology has provided a powerful tool for study of the complicated biological process in cells and tissues. cDNA microarray is used to analyze the virus-host cell interactions, and improvements have been achieved in the diagnosis, treatment, and prevention of infectious diseases^[15]. Therefore, in this study, we used cDNA microarray to analyze the global gene expression profiles of peripheral blood mononuclear cells (PBMCs) from two SARS patients, one in the acute severe phase and the other in the convalescent phase. The results may make contribution to studies of the SARS pathogenesis.

MATERIALS AND METHODS

Patients

Shanghai Municipal Hospital for Infectious Diseases was the appointed hospital for SARS patients during the SARS outbreak in Shanghai area. A total of seven patients with SARS were accepted for treatment in this hospital from 2nd May to 20th August 2003. In this study, two SARS patients in different clinical courses were enrolled, one in the acute severe phase (1 wk after admission to hospital and died 1 d after blood samples were taken) and the other in the convalescent phase (about 1 mo after admission). After admission to the hospital, both patients received the standard treatment. Additional clinical information is summarized in Table 1.

Table 1 Clinical characteristics of two SARS patients

	P1	P2
Age (yr)	57	40
Gender	Male	Female
Body temperature (°C)	39.2	36.8
White cell count ($\times 10^9/L$)	13.30	4.67
Neutrophil ($\times 10^9/L$)	12.80	3.25

Blood samples and RNA isolation from peripheral blood mononuclear cells

Blood samples (5 mL each) were collected from two patients and a healthy donor with anticoagulant at bedside. PBMCs

in lymphocyte separation medium (Sigma, USA) were isolated. Total RNA was isolated using the TRIzol reagent (Invitrogen, USA) according to the manufacturer's instructions. After TRIzol purification, RNA was repurified by phenol-chloroform extraction and ethanol precipitation, and quantified by spectrophotometry. In addition, RNA samples were electrophoresed on 2.2 mol/L 0.7% agarose-formaldehyde gel and visualized by ethidium bromide staining to ensure that there was not overt RNA degradation.

Microarray hybridization and data analysis

Microarray hybridization was performed by Shanghai Genentech Company according to the standard Affymetrix protocol. In brief, RNA from two patients and a healthy control was converted to cDNA with SuperscriptTM II RT (Invitrogen, USA) and then to biotin-labeled cRNA with RNA transcript labeling kit (Affymetrix, USA). cRNA was cleaned up and qualified and then fragmented for hybridization. After hybridization to the human HG-U113A GeneChip containing approximately 13 000 unique genes or expression-signature tags (Affymetrix), the gene chips were automatically washed and stained with streptavidin-phycoerythrin by a fluidics system. After the chips were scanned with a GeneArray scanner (Hewlett-Packard, USA), gene transcript values were determined using algorithms in the Microarray Analysis Suite Software (5.0 version, Affymetrix). Each chip was scaled to an overall intensity of 1 500 to correct for minor differences in the overall chip hybridization intensity and to allow comparison between chips. Data were normalized to the average of the healthy control. The gene lists of two patients containing genes with $P < 0.05$ were put out in the style of Excel files.

Real-time quantitative PCR

Real-time quantitative PCR of cDNA samples from two patients and a healthy control was carried out in triplicate with the indicated primers (Table 2), at a volume of 20 μL using FastStart DNA Master SYBR Green I Mixture Kit[®] (Roche Diagnostics, USA) in a LightCycle[®] system (Roche Diagnostics, USA). Initial denaturing for 10 min at 95 °C was followed by 45 cycles at 95 °C for 10 s, at 55 °C for 15 s, and at 72 °C for 20 s. Detection of the fluorescent products was set at the last step of each cycle. To determine the specificity of amplification, melting curve analysis was applied to all final PCR products, after the cycling protocol. In addition, template-free negative controls were run with each gene specific primer. PCR for RNA products of three samples was performed in order to exclude genomic DNA contamination. The standard curve was prepared with a serial of dilutions of genomic cDNA from a GAPDH-containing plasmid. Results were representative of three independent experiments.

Table 2 Primer sequence used in real-time quantitative PCR analysis

Accession number	Description	Forward primer (5'→3')	Reverse primer (5'→3')
NM_000634	IL-8R α	GGAACGTGGTGTCTTCAGGG	CATCTAATGTCAGATTCCGGG
NM_003855	IL-18R1	GGGTATTACTCTGCGTGCA	CCATTTTCITCCCCGAACATCC
BC025925	GAPDH	GGTATCGTGGAAGGACTCATGAC	ATGCCAGTGAGCTTCCCGTTCAGC

RESULTS

Validation of microarray results

To verify the reproducibility of the microarray results, 2 genes (IL-8 receptor- α and IL-18 receptor-1) were selected and tested by real-time quantitative PCR. GAPDH was used as internal control to normalize the total RNA. The ratios of the signal intensity of specific genes to GAPDH, as well as their comparison to microarray results, are listed in Table 3. As shown in Table 3, the results of RT-PCR analysis were aligned with those from the microarray analysis, suggesting the creditability of our microarray results.

	Real-time qPCR	48.55 \pm 0.36	0.38 \pm 0.27

Global characteristics of gene expression in PBMCs of SARS patients

We uploaded the genes altered over 2.0-fold (at <http://www.mvlab-fudan.cn/part9.htm>) to Affymetrix online data analysis system (https://www.affymetrix.com/analysis/netaffx/batch_query.affx), and then got an illustration of hierarchical structure according to their biological process. The number of genes changed over 2.0-fold in two SARS patients is summarized in Table 4. Results showed that many genes including those for cell communication, cellular physiological process, death, metabolism, organismal physiological process, and response to stimulus changed significantly in both SARS patients. The number of genes changed in the acute severe case, was much higher than that in the convalescent case.

Table 4 Functional categories of over 2.0-fold-regulated genes in two SARS patients

Classification	P1	P2
Cell communication	802 (518 \uparrow 284 \downarrow)	288 (116 \uparrow 172 \downarrow)
Cell differentiation	65 (33 \uparrow 32 \downarrow)	24 (6 \uparrow 12 \downarrow)

Differentially expressed genes involved in inflammation and immune response in SARS patients

In the light of a pivotal role in the pathogenesis of SARS, the genes involved in inflammation, immune response or anti-viral effect are categorized in Tables 5-7.

As shown in Table 5, the pro- and anti-inflammatory cytokine genes were differentially expressed in two patients. Compared to healthy control, the genes encoding IL-1, IL-8, TNF- α , and ICAM-1 increased by 3.73, 8.00, 17.15 and 17.15 folds respectively in the acute severe case. Type I IL-1 receptor, TNFRSF1A, IL-8 receptor, IL-18 receptor 1 also increased by 18.38, 4.00, 73.52/51.98, and 42.22 folds respectively in the acute severe case. However, all of them did not change in the convalescent case. In addition, many anti-inflammatory agents were also remarkably upregulated in the acute severe case. Inhibitors of IL-1 and TNF- α signal pathway such as type II IL-1 receptor, soluble type II IL-1 receptor, IL-1Ra, IRAK3, soluble IL-1 receptor accessory protein, TNFRSF10C, TNF- α -induced proteins 3 and 6 were upregulated by more than 10-folds in the acute severe case, but did not change or were expressed at low level in the convalescent case.

As shown in Table 6, in 21 IFN-related molecules, most of the IFN-related molecules except for IFNGRs and IFNAR1 were not upregulated in the severe case, but they were upregulated more than two-fold in the convalescent case. For the 12 chemokine-related genes detected in this microarray, RANTES (a marker of activated T cells) and CX3CR1 were strikingly downregulated in the acute severe case. Two viral RNA-recognized TLRs (TLR-3 and -7), especially TLR-7, were significantly downregulated in the acute severe case. The above results indicated that there was dysfunction of the innate immune responses in the acute severe case.

The altered genes which could play a vital role in the process of stress, inflammation, and immune response are summarized in Table 7. In comparison to the convalescent case, the JAK/STATs were suppressed in the acute severe case. The expression of STATs 1, 2, and 4 were not upregulated, while MAPKs were upregulated in the acute severe case as compared to the healthy control. Six out of seven components of MAPK signal cascade were upregulated.

DISCUSSION

As an emerging disease, attention has been paid to the high infectivity and virulence of SARS. In the course of the disease, the important observation is lymphopenia and the depletion of T-lymphocyte subsets in most SARS cases, indicating the immunity dysfunction in this readily-transmissible disease, particularly during its early phase^[7]. Another characteristic of the disease is acute lung injury accompanied with signs of the systemic inflammation, the duration and intensity of which are closely associated with the severity and prognosis of the disease^[1,24].

A typical feature of all inflammatory disorders is the excessive recruitment of leukocytes to the inflammation site, which is a well-orchestrated process involving several protein families, including pro-inflammatory cytokines, chemotactic cytokines, and adhesion molecules^[9,10]. This

and etc.) were highly expressed in the acute severe case and lowly expressed in the convalescent case. Real-time quantitative PCR of empirically selected genes also showed that pro-inflammatory cytokines were highly expressed. These findings, as expected, are consistent with the clinical stage^[2,6,8], though individual variation and sensitivity of examination exist. In addition, anti-inflammatory agents (IL-4, 10, and 13 receptors) and agonists of IL-1 and TNF (type II IL-1 receptor, soluble IL-1 receptor, IL-1Ra, and TNF- α decoy receptor) increased dramatically in the acute severe case, which could constitute a negative feedback to robust inflammation or manifestations of systemic inflammation^[16,17]. But whether the alteration is associated with virus replication or interaction between the viral and cellular proteins is to be further elucidated.

Chemokines are also important cytokines involved in inflammation, dendritic cell maturation, neutrophil degranulation,

antibody class switching and T-cell activation^[18-20]. Furthermore, recent *in vitro* and *in vivo* findings support some members of chemokine system like CXCL9, CXCL10, and CXCL11 contribute to the resolution of viral infections^[19,20]. Unfortunately, transcripts of IFN-induced chemokines^[18,19] (RANTES, CXCL10, and CXCL11) were downregulated in the acute severe case, while inflammatory chemokines such as GRO-1, G-CSF3R, IL-8 and its receptors increased significantly. The expression profiles of chemokines as well as neutrophil predominance in white cells reflect rampant inflammation in the acute severe case^[8,9].

Although the acute severe case is treated with IFN- α , poor expression of IFN-stimulated genes^[21], TLR3, 7 and immune cell activation markers (CD antigens and MHC molecules, data not shown) may mirror the defect of host anti-viral immunity. Furthermore, some studies indicate that the activation of some pro-inflammatory cytokines such as IL-1, IL-6 or IL-8 signaling pathways interferes with the IFN signaling^[22-25], let alone the action of IL-4, IL-10 or IL-13^[9]. Outbreak of pro- and anti-inflammatory agents might interfere with the IFN signaling pathway, but direct interaction between coronavirus and IFN system cannot be excluded.

It is intriguing to find that, although the important genes involved in NF- κ B signaling pathway were not detected in our microarrays, JAK/STAT signaling pathway was suppressed, another important signaling pathway associated with production of inflammatory cytokines, the MAPK signaling pathway^[20,26,27], was upregulated in the acute severe case compared to the healthy control or convalescent case. It was reported that there are expression alterations in the MAPK pathway in different leukocytes from patients with SARS and virus infection and viral proteins exert effects on the MAPK signaling pathway in cell culture models^[27-29]. But the relationship between changes of three signaling pathways and the SARS process needs to be further studied.

In conclusion, our results may partially reveal the different expression patterns of inflammatory and immune genes and related signal pathways at different phases of SARS pathological process. The overexpressed pro- and anti-inflammatory cytokines may contribute to acute lung injury and imbalance of homeostasis especially in acute severe phase. Thus our results may hopefully make a contribution to further studies of the SARS pathogenesis.

Abstract

AIM: To investigate the anti-neoplastic effect of inositol hexaphosphate (InsP₆ or phytic acid) on dimethylhydrazine (DMH)-induced colon tumor in rats and its effect on blood natural killer (NK) cell activity.

METHODS: Healthy Wistar rats, 4 wk old, were divided into control group (fed with common food) and InsP₆ group (fed with common food+2% sodium inositol hexaphosphate in the drinking water), 15 rats in each group. Both groups were injected with 1,2-dimethylhydrazine subcutaneously (20 mg/kg body weight) once a week for 20 wk. Rats were killed after 21 wk. The whole large intestine was isolated to determine the general condition of tumors and to test blood NK cell activity by lactate-dehydrogenase-release assay.

RESULTS: Administration of InsP₆ significantly increased blood NK cell activity in DMH-induced colorectal tumor in rats. InsP₆ group had a smaller tumor size on average and a smaller number of tumors than the control group. Its mortality was also higher than that in control. However, the variables of body weight and tumor incidence were not significantly different between the two groups.

CONCLUSION: InsP₆ can increase blood NK cell activity in DMH-induced colon tumor in rats and inhibit tumor growth and metastasis in rats.

Zhang Z, Song Y, Wang XL. Inositol hexaphosphate-induced enhancement of natural killer cell activity correlates with

INTRODUCTION

Inositol hexaphosphate (InsP₆) is a naturally occurring compound that has various chemical properties and biological activities^[1]. It is rich in matured plant seeds, particularly in cereals and legumes, and exists in nature as a salt with monovalent and divalent cations (Ca²⁺, Mg²⁺, and K⁺). It has the ability to chelate minerals such as iron, copper, zinc, cobalt, and manganese, most efficiently at neutral pH^[2-4].

InsP₆ has anti-neoplastic activity on a variety of experimental models of carcinogenesis, decreases serum cholesterol level, inhibits renal stone formation, and may find use in controlling myocardial damage following ischemia. Among these biological activities, anti-neoplastic activity is one of the most intriguing properties of InsP₆^[5,6].

The above facts need clinical trials in human colorectal cancer. It has been reported that intestinal lipodystrophy can be prevented by InsP₆ treatment^[7]. Recent studies demonstrate that InsP₆ inhibits experimental colon carcinogenesis in rats^[8-10]. There is a correlation between neoplastic diseases and depressed natural killer (NK) activity^[11]. There is evidence that NK cells are involved in the destruction and growth inhibition of tumor cells *in vivo*. This study aimed to study the effect of InsP₆ on blood NK cell activity in dimethylhydrazine (DMH)-induced colon tumor in rats.

MATERIALS AND METHODS

Animals and chemicals

Thirty-four-weeks old male Wistar rats (70-110 g) were purchased from Animal Center of Henan Medical University. After acclimatization for 1 wk, the experimental animals were randomly divided into control group and InsP₆ group (15 rats/group). Animals in the control group were fed with the basal diet and had regular access to drinking water. Rats in InsP₆ group were fed with the basal diet and had access to 2% sodium inositol hexaphosphate (purchased from Guangdong Qingyun Chemical Factory) solution. Basal diet was made by American Institute of Nutrition method.

Animals in both groups were given subcutaneous injections of DMH (from Sigma) dissolved in normal saline solution (20 mg/kg body wt) once a week for 20 wk. Body weight was measured and food consumption was recorded once a week. All surviving animals were killed under 4.3% trichloraldehyde hydrate anesthesia after 21 wk.

Tissue processing

All animals (including rats that died before the end of experiment) were autopsied. The colons were removed, flushed with saline, opened along the longitudinal median axis. Macroscopically, the number of tumors in each colon was counted. Tumor width and length were measured with clippers. Simultaneously, peripheral blood was obtained from the abdominal aorta for testing NK cell activity.

Test of NK cell activity

Peripheral blood mononuclear cells (PBMCs) were separated by Ficoll-Hypaque density centrifugation from the collected blood. Lactate-dehydrogenase (LDH)-release assay was used to measure the NK cell activity. PBMCs were washed and suspended in complete RPMI-1640 medium, counted and diluted to $1.0 \times 10^6/\text{mL}$. The amount of LDH released from the lysed target cells was determined for NK cell activity measurement. The NK-sensitive cell line K₅₆₂ (human erythroleukemia cell line, Shandong Medical Science Institute, Shandong, China) was used as the target cell. K₅₆₂ cells were washed with complete RPMI-1640 medium, counted and finally diluted to $1.0 \times 10^5/\text{mL}$ with the medium. An equal volume of K₅₆₂ cells and PBMCs was added to the wells of 96-round-bottomed microwell plates (the cell ratio of effector-to-target was 10:1). Each test was repeated in three wells. To ensure contact between cells, the plate was centrifuged at a low speed for 2 min. After 2-h incubation at 37 °C in a humidified atmosphere with 50 mL/L CO₂, the plate was centrifuged at 1 000 r/min for 5 min. The supernatant from each well (100 μL) was transferred into the corresponding wells of a 96-flat-bottomed microwell plate. Then 100 μL of lactic acid hydrogenase substrate mixture was added to each well. After 3 min, reactions were stopped by adding 50 μL of cold medium. Finally, a microtiter plate reader (Bio-Rad, MODE-550) was used for evaluation of changes in the absorbance at a wavelength of 490 nm. The release of LDH from K₅₆₂ cells was expressed as absorbance. The percentage of NK cell activity was calculated by the formula: $\text{NK cell activity} = (E-S)/(M-S) \times 100\%$, where *E* represents the experimental release of LDH activity from target cells incubated in the presence of PBMCs, *M* represents the maximum release of the LDH activity determined by lysing the target cells with 1% of NP40, and *S* is the spontaneous release of the LDH activity from target cells incubated in the absence of PBMCs.

Statistical analysis

Results were expressed as mean \pm SD. Statistical analyses were performed with SPSS 9.0. The significance of differences in the average values between the two groups was analyzed using *t*-test. $P < 0.05$ was considered statistically significant.

RESULTS

During the initial period of the experiment, body weight of animals increased steadily in the first 20 wk. Then both groups began to lose their body weight. In addition, the animals consumed a less amount of food. The change in two groups had no difference (Figure 1).

Figure 1 Body weight change of rats during feeding.

After DMH was injected for 10 wk, death occurred in rats of control group. By the end of the experiment, six rats died in the control group. Only one rat died in InsP₆ group. The difference in mortality was significant ($P < 0.01$, Table 1).

Table 1 Effect of InsP₆ on mortality of rats

Groups	Survival	Death	Mortality (%)
Control	9	6	40.0
InsP ₆	14	1	7.1 ^b

^b $P < 0.01$ vs control group.

Twelve rats had colon tumor in control group treated with DMH but not InsP₆. Tumors were found in 11 rats of InsP₆ group. The difference in tumor incidence was not significant ($P > 0.05$). But the number of tumors and their size were significantly less in InsP₆ group than in control group ($P < 0.05$, Table 2).

Table 2 Effect of InsP₆ on total large intestinal carcinomas (mean \pm SD)

Groups	<i>n</i>	Incidence of tumor (%)	Average tumor number	Average size of tumor (mm ³)
Control	15	80	4.1 \pm 1.2	1 080.3 \pm 463.4
InsP ₆	15	73	0.9 \pm 0.2 ^b	123.6 \pm 29.6 ^a

^a $P < 0.05$, ^b $P < 0.01$ vs control group.

Blood NK cell activity was reduced in the two groups after DMH treatment. But the blood NK cell activity was significantly higher in InsP₆ group than in control group ($P < 0.01$, Table 3).

Table 3 Effect of InsP₆ on blood NK cell activity (NK-A) (mean \pm SD)

Group	<i>n</i>	NK-A (%)
Control	9	15.7 \pm 1.2
InsP ₆	14	42.2 \pm 1.1 ^b

^b $P < 0.01$ vs control group.

DISCUSSION

Diet composition is an important etiologic factor in colon

carcinogenesis and has a significant impact on colon cancer occurrence. InsP₆ is a dietary phytochemical present in cereals, soy, legumes, and fiber-rich foods^[12,13]. Epidemiological studies have shown that InsP₆ can inhibit the metastasis of tumor^[14-16]. But the anti-tumor mechanism of InsP₆ awaits further investigation.

Our study demonstrated that InsP₆ could significantly increase blood NK cell activity in DMH-induced colorectal cancer in rats ($P < 0.01$). The number and size of tumors were smaller in InsP₆ group than in control group ($P < 0.05$), indicating that InsP₆ can also inhibit tumor growth and metastasis in DMH-induced colorectal cancer in rats.

InsP₆ is degraded into lower polyphosphorylated forms of inositol (including InsP₁-InsP₅) by the enzyme meso-inositol hexaphosphate phosphohydrolase, and dephosphorylated by acid, acid phosphatase and intestinal alkaline phosphatase. When InsP₆ was administered to rats as a soluble form in drinking water, it is rapidly absorbed through the upper gastrointestinal tract and quickly distributed in various organs, most notably in liver, kidneys, and skeletal muscle^[17,18]. Among the lower polyphosphorylated forms of inositol, InsP₃ appears to act as a second messenger and promotes intracellular free calcium (Ca²⁺) release, which can induce proliferation of NK cells^[19] as well as the release of NK cell cytotoxicity factor (NKCF). NKCF can bind to target cells (tumor cells) which are subsequently lysed^[20]. Close contact between the plasma membrane of the two types of cells, affects the cytotoxic reaction. InsP₃ can also affect the membrane phosphatidyl inositol proteins, which may be important in attachment and subsequent fusion with the target cells, suggesting that InsP₆ mediates its chemopreventive and probably chemotherapeutic effect via InsP₃^[21,22].

Our data indicate that DMH depresses the NK cell activity, while InsP₆ significantly increases the NK cell activity and inhibits tumor growth, suggesting that changes in NK cell activity are related to progressive cancer growth^[23]. Since InsP₆ enhances the NK cell activity *in vivo*, it may have potential application in therapy of cancer and other diseases associated with depressed NK cytotoxicity.

Abstract

AIM: To explore the relationship between the level of proinsulin with cardiovascular risk factors and sleep snoring.

METHODS: Based on the random stratified sampling principle, 1 193 Chinese residents in Pizhou City, Jiangsu Province (530 males and 663 females, aged 35-59 years with an average age of 46.69 years) were recruited. Their sleep snoring habits were investigated. Biotin-avidin based double mAbs ELISA was used to detect specific insulin and proinsulin, and a risk factor score was established to evaluate the individuals according to the number of their risk factors.

RESULTS: The results of Spearman correlation analysis and covariate ANOVA analysis after age and sex were controlled, indicated that not only the level of proinsulin ($r = 0.156$, $P = 0.000$, $F = 5.980$ $P = 0.000$), but also cardiovascular risk factors score ($r = 0.194$, $P = 0.000$, $F = 11.135$, $P = 0.000$) significantly associated with the frequency of sleep snoring, and the significant relationship between true insulin and frequency of sleep snoring was only shown in the covariate ANOVA analysis ($F = 2.868$, $P = 0.022$). The result of multivariate stepwise logistic regression after age, sex, body mass index, waist circumference and true insulin were controlled showed that proinsulin (division by interval of quartile) was an independent risk factor for sleep snoring (OR = 1.220, 95%CI: 1.085-1.373, $P = 0.001$).

CONCLUSION: The interaction of cardiovascular risk factors clustering, high proinsulin level and sleep breathing disorder may be a syndrome, which has not been recognized in human beings so far.

INTRODUCTION

Dyslipidemia, hypertension, hyperinsulinemia and obesity (special central obesity) have been recognized as potent risk factors for coronary heart disease in adults, the clustering of the above cardiovascular risk factors often occurs in adults, and the condition has been termed as syndrome X^[1], and insulin resistance emerges as a common pathogenetic denominator underlying the above risk factor clustering^[2]. Obstructive sleep apnea syndrome is associated with the increased cardiovascular and cerebrovascular morbidity. It is also recognized that many people with obstructive sleep apnea syndrome have features of the insulin resistance syndrome, and it is suggested that insulin resistance syndrome may actually include sleep apnea syndrome and could be better considered as syndrome Z^[3]. The level of circulating proinsulin (PI) has been recognized as a sensitive marker for the dysfunction of islet beta cells^[4], and several groups reported that proinsulin was more strongly associated with cardiovascular disease than true insulin^[5]. So far, few epidemiological studies have been focused on the relationship between true insulin vs proinsulin and cardiovascular risk factors clustering, and sleep breathing disorder. Although polysomnography is the definitive method for diagnosing sleep apnea syndrome, the costs of this method in combination with the high demand for accurate screening limits its utility in clinical practice and epidemiological studies. It has been proposed that snoring is a precursor to the development of obstructive sleep apnea syndrome. This theory is supported by retrospective studies in which patients reported snoring more loudly over the years, before they developed nocturnal respiratory pauses, which later became increasingly frequent^[6]. To explore the relationship between PI vs true insulin and

cardiovascular risk factors and sleep snoring, a population-based epidemiological investigation was conducted in Pizhou city, located in the mideastern part of China.

MATERIALS AND METHODS

Study subjects

From April 2001 to May 2001, a large cross-sectional, community-based epidemiological study was conducted. The subjects for the survey were adults aged between 35 and 59 years. A two-stage cluster-sampling scheme based on existing census divisions was used to randomly select four areas, each with a population from 300 to 350 subjects, and sample was stratified by sex and age group (5 years) to ensure representation of each part of the population. Among the 1 351 individuals investigated, the response rate was 88.5%, and the random sample and random-sample responder populations closely reflected the actual distribution of age group and sex in Pizhou area. Among 1 193 rural residents, there were 530 males (44.57%) and 663 females (55.43%), and their average age was 46.69 years. Signed informed consent was obtained from all participants and the study was approved by the Nanjing Medical University Ethics Review Committee.

Questionnaires and investigators

A standard questionnaire was adopted, and the investigators were students from Nanjing Medical University, who had received special training. The questionnaire included questions about occupation, height, weight, sleep habits, sleep quality, and frequency of disruptive snoring. The question concerning snoring was "How often do you snore loudly and disturbingly?" with the following response alternatives: 1 = never, 2 = seldom, 3 = sometimes, 4 = often, 5 = very often, and those who answered 2-5 were regarded as snorers.

Anthropometric measurements

Anthropometric measurements were performed after the participants had removed their shoes and upper garments and donned an examining gown. Each measurement was performed twice and the average was used in the analysis. Height was measured to the nearest 0.1 cm using a wall-mounted stadiometer. Weight was measured to the nearest 0.1 kg using a hospital balance beam scale. Body mass index (BMI) was calculated as weight (kg) divided by the square of height (m^2). The waist circumference was measured to the nearest 0.5 cm at the point of narrowing between the umbilicus and xiphoid process (as viewed from behind) and the waist circumference was used as a judgment of upper-body adiposity. Blood pressure was measured in the right arm with the participant seated and the arm bared. Three readings were recorded for each individual, and the average of the three readings was defined as the subject's blood pressure.

Laboratory measurement

The 12-h fasting blood samples were drawn in the morning and the sera were stored at $-70\text{ }^{\circ}\text{C}$ immediately after centrifugation until being assayed. All laboratory measurements were conducted at the Central Clinical Laboratory in the

First Affiliated Hospital of Nanjing Medical University. Fasting blood glucose (FBG), fasting total cholesterol (TCH), fasting triglyceride (TG) and fasting high-density lipoprotein cholesterol (HDL-c) were determined by enzymatic procedures on an automated autoanalyzer (AU 2700 Olympus, 1st Chemical Ltd., Japan), and the source of reagents for the autoanalyzer was from 1st Chemical Ltd., Japan. The laboratory was monitored for precision and accuracy of glucose and lipid measurements by the agency's surveillance program. Measurements of agency-assigned quality control samples showed no consistent bias over time within or between surveys. Low-density lipoprotein cholesterol (LDL-c) was assessed by the Friedwald method^[7], and the concentration of LDL-c was calculated for each subject according to the following formula: $C_{LDL-c} = C_{PLASMA} - C_{HDL} - TG/5$.

Measurement of intact insulin and proinsulin

The intact insulin level was measured using a highly sensitive two-site sandwich ELISA^[8]. This assay method for insulin is based on the enzyme immunoassay principle and it is constructed as a sandwich immunoassay. Two monoclonal murine antibodies specific for insulin were employed. One of the antibodies (HUI-018), which binds to an epitope on one side of the insulin-molecule, was used for coating on the ELISA plate wells. The other antibody (OXI-005), which binds to another epitope on the other side of the insulin-molecule, was covalently bound to biotin. The biotin-antibody reagent and sample or calibrator were added to the precoated-wells followed by incubation. During incubation, a complex between plastic-surface, coated-antibody, insulin and the biotinylated-antibody was formed. This complex would not be removed by the washing procedure, which followed the incubation. After the wash, avidin-peroxidase was added. It bound to the biotin of the biotinylated-antibody and extended the complex with the enzyme peroxidase. The amount of enzyme was visualized by addition of the substrate peroxide and 3',3',5',5'-tetramethylbenzidine (TMB), which was converted to a soluble colored product. The developed color was proportional to the amount of insulin in the sample. The color-development progressed with time and it was interrupted after a fixed time by the addition of phosphoric acid. The color was stable and absorbance was measured in an ELISA-plate photometer. A calibrator curve was constructed based on the absorbance values and the insulin concentration in the serum samples could be found. The detection limit was 5.0 pmol/L. The specificity of the assay excluded intact, split (32-33) and des (31, 32) PI. There was some cross-reactivity with the less abundant split (65-66) PI (30%) and des (64, 65) PI (63%).

The PI level was measured in a similar manner using another sensitive two-site sandwich ELISA^[9]. The analysis for human PI is an enzyme immunoassay constructed as a sandwich immunoassay. Two monoclonal mouse antibodies were used: one with specificity for human C-peptide (PEP-001) was used for coating, the other antibody (HUI-001) with specificity for insulin was biotin labeled and acted as detecting antibody. The plasma samples were diluted 1:2 during analysis to eliminate the plasma effect. In the first reaction, after the samples were applied to the coated wells, PI in the samples would bind to the coating antibody. In the

second reaction, the bound PI was detected by the use of another mAb directed against human insulin and biotin labeled. In a third reaction, the amount of bound detecting antibody in the coating antibody-PI-detection antibody complex was visualized by the use of streptavidin-peroxidase that bound to the biotin label. Between each step, the plate was washed four times in a washing buffer in order to measure only the bound material. Finally, a substrate for the peroxidase (tetramethylbenzidine and H_2O_2) was applied to the wells resulting in color development proportional to the amount of peroxidase, i.e., PI present. The enzymatic reaction resulted in development of a blue color, which changed into yellow, when the reaction was stopped with H_3PO_4 . The plate was read in an ELISA reader at 450 nm and the absorbance at 620 nm was subtracted. The detection limit in human serum was 0.25 pmol/L. There was no cross-reactivity with human insulin and human C-peptide. However, the four major PI conversion intermediates reacted at various proportions of 65-99%.

The between- and within-assay coefficients of variation were 6.8, 7.8% for true insulin respectively and 6.7, 7.8% for PI respectively. All measurements were performed in duplicate. The four mAbs including OXI-005, HUI-018, PEP-001 and HUI-001 were kind gifts from Novo Nordisk, Bagsvaerd, Denmark, and the standard samples of true insulin and PI were supplied by the Mercodia Company, Sweden. The ELISA-plate photometer (Bio-tek EL900, USA) and ELISA plate (NUNC company, Denmark) were employed in the assay.

Definition of risk factors

To investigate the relationship between the level of PI and cardiovascular risk factors clustering, we created a risk factor score to rank individuals according to the number of the risk factors at the time of the survey. The following risk factors and cut-off points were used to build up the risk factor scores: (1) hypertension was defined when systolic blood pressure (SBP) was ≥ 140 mmHg and/or diastolic blood pressure (DBP) ≥ 90 mmHg or taking anti-hypertensive drugs because of previous hypertension according to the 1999 WHO/ISH criteria^[10]; (2) hyperglycemia was diagnosed based on the FBG serum glucose ≥ 6.1 mmol/L according to the American Diabetes Association (ADA) criteria^[11] or having a history of diabetes mellitus; (3) hypercholesterolemia was defined as fasting TCH ≥ 5.20 mmol/L; (4) high LDL-c was defined as LDL-c ≥ 3.38 mmol/L; (5) low HDL-c was defined as HDL-c ≤ 1.04 mmol/L; (6) hypertriglyceridemia was defined as fasting TG ≥ 1.70 mmol/L^[12]; (7) overall overweight was considered as BMI ≥ 25.0 kg/m² according

to the WHO guideline^[13]; (8) visceral obesity was defined as waist circumference ≥ 85 cm in male and ≥ 80 cm in female^[14]. The final risk factor score varied from 0 to 5, with 0 meaning no exposure to these risk factors; one exposure to any one risk factor; 2-4 exposure to any combination of 2-4 risk factors respectively; five exposure to any combination of five or more than five risk factors simultaneously.

Statistical analysis

All data analyses were performed using statistical package for social science (SPSS for Windows, version 10.0, 1999, SPSS Inc, Chicago, IL, USA). Data of BMI, waist circumference, age and blood pressure were normally distributed parameters and presented as mean \pm SD, whereas skewed data including FBG, fasting lipid, fasting true insulin, and PI were logarithmically transformed before analysis and were expressed as median (quartile range).

RESULTS

Sex and age distribution of sleep snoring subjects

Tables 1 and 2 show sex and age distribution of sleep snoring in the population-based epidemiological study. The results indicated that the frequency of sleep snoring in males was significantly higher than in females ($\chi^2 = 68.227$, $P < 0.001$), and the frequency of sleep snoring significantly increased with the elevation of age ($\chi^2 = 44.465$, $P < 0.001$).

Table 1 Sex distribution of sleep snoring subjects

Snoring	Male	Female	Total
Never	265	481	746
Seldom	34	29	63
Sometimes	83	68	151
Often	59	39	98
Very often	89	46	135
Total	530	663	1 193
Statistical parameter	$\chi^2 = 68.227$		$P < 0.001$

Spearman correlation analysis of sleep snoring with tested parameters

The results of Spearman correlation analysis (Table 3) indicated that the frequency of sleep snoring was significantly correlated with such parameters as BMI, waist circumference, SBP, DBP, fasting TCH, fasting TG, fasting LDL-c, PI, and risk factors score ($P < 0.01$). However, the significant correlation was not found between the frequency of sleep snoring and FBG, true insulin, and fasting HDL-c ($P > 0.05$).

Table 2 Age distribution of sleep snoring subjects

Snoring	35~	40~	45~	50~	55~	Total

Table 3 Spearman correlation analysis of sleep snoring with tested parameters

Parameters	BMI	WC	SBP	DBP	FBG	CH
Correlation coefficient	0.177 ^b	0.268 ^b	0.211 ^b	0.191 ^b	0.027	0.126 ^b
Parameters	TG	HDL	LDL	TI	PI	RFS
Correlation coefficient	0.132 ^b	-0.043	0.108 ^b	0.050	0.156 ^b	0.194 ^b

^bP<0.01 *vs* others. Abbreviations: BMI, body mass index; WC, waist circumference; SBP, systolic blood pressure; DBP, diastolic blood pressure; FBG, fasting blood glucose; CH, fasting total cholesterol; TG, fasting triglycerides; HDL, fasting high-density lipoprotein cholesterol; LDL, fasting low-density lipoprotein cholesterol; TI, true insulin; PI, proinsulin; RFS, risk factors score.

Analysis of covariate variance of sleep snoring with tested parameters

Table 4 summarizes the results of analysis of covariate variance of sleep snoring and its relevant parameters. In the analysis, age and sex were controlling variables; the frequency of sleep snoring was factor variable, and the parameters including BMI, waist circumference, SBP, DBP, FBG (logarithmically transformed value), TCH (logarithmically transformed value), TG (logarithmically transformed value), HDL (logarithmically transformed value), LDL (logarithmically transformed value), true insulin (logarithmically transformed value), PI (logarithmically transformed value), and risk factors score were employed as dependent variables, respectively. The results indicated that a significant difference in parameters including BMI, waist circumference, SBP, DBP, TCH, TG, true insulin, PI, and risk factors score was found among various sleep snoring groups respectively after controlling for age and sex, and significant difference was not found in FBG, HDL-c, LDL-c between different frequencies of sleep snoring groups.

Analysis of multivariate logistic regression with sleep snoring as an independent variable

The results of multivariate logistic regression analysis are shown in Table 5, in which the dependent variable was the frequency of sleep snoring (the never snoring was coded as 0, and the seldom, sometimes, often, and very often snoring was considered as sleep snoring and was coded as 1), and age stratum (age stratification was performed with 5-year age strata), sex (male was coded as 1, female as 0), BMI (group division by an interval of quartile), waist circumference (group division by an interval of quartile), true insulin (group division by an interval of quartile), and PI (group division by an interval of quartile) were employed as independent variables. In the analysis of multivariate logistic regression, the variables including sex, age, PI, and waist circumference were accepted by the final model, and BMI and true insulin were refused by the regression model. The final model suggested that male, age, PI, and waist circumference were risk factors for sleep snoring, and the OR (95%CI) for sex, age, PI, and waist circumference was 0.401 (0.311-0.518)

DISCUSSION

Snoring is the main symptom of obstructive sleep apnea syndrome, which is one of the most frequent sleep disorders affecting 2-4% of middle-aged white^[15] and Asian populations^[16]. A predominantly Chinese population-based epidemiological study was conducted in Singapore, in which, 220 people aged 30-60 years, were interviewed for their snoring habits, and 87.5% of loud habitual snorers had significant obstructive apneas on the polysomnogram and 72% of these apneics complained of excessive daytime sleepiness (EDS)^[17]. The results from a population-based study investigating the long-term outcome in men with snoring over a 10-year period suggest, that snoring is the preceding form of obstructive sleep apnea syndrome^[18]. PI is a multi-peptide with 86 amino acids and its molecular weight is 9 390. It is synthesized in the β -cells of the islets of Langerhans and is subsequently processed through enzymatic cleavage to form C-peptide and insulin^[19]. The biological activity of PI is very low (approximately 10% of insulin), and it is the major storage form of insulin. Under physiological conditions, only small amounts of intact and split PI (less than 3% of insulin) are co-secreted with insulin from the pancreatic β -cells^[4]. In the earlier studies, insulin concentration was measured with radioimmunoassay using polyclonal antibodies, which cross-reacted with largely inactive insulin precursor molecules such as PI and des-31, 32 PI, hence it was called immunoreactive insulin (IRI). These PI molecules can be distinguished from more biologically active true insulin molecules by using highly sensitive and specific, two site immunoassays based on monoclonal antibodies. Since it is rather common that sleep breathing disorder is accompanied with insulin resistance, it has been clinically considered that both of them are closely correlated and even syndrome Z was named for coexisting sleep breathing disorder and insulin resistance. So far the associated pathogenesis between sleep breathing disorder and insulin resistance has not been elucidated clearly. To explore the relationship between sleep snoring and true insulin vs PI, a population-based epidemiological investigation was conducted in Pizhou city located in the mideastern part of China.

The results from this study showed that the frequency of sleep snoring in males was significantly higher than those in females, and the frequency of sleep snoring significantly increased with age. Furthermore, the results of Spearman correlation analysis indicate that the frequency of sleep snoring was significantly correlated with the concentration of PI and risk factors score. Moreover, the results of analysis of covariate variance in which age and sex were controlling variables suggest that the frequency of sleep snoring was positively and significantly associated with the risk factors score, and this finding is in agreement with several previous studies^[3-5].

In the present study, the level of circulating PI was positively and significantly associated with the frequency of sleep

snoring in the analysis including Spearman correlation, covariate variance in which age and sex were controlling variables, and multivariate stepwise logistic regression in which age, sex, BMI, and true insulin were adjustment variables. To our knowledge, this finding is the first, from a Chinese population-based epidemiological study. Obesity is the accumulation of excessive fat in the body and plays a role in metabolic disorders and the mortality and morbidity of cardiovascular diseases. Obesity, especially the local obesity represented by increased waist circumference and neck circumference, is related to the narrowness of upper respiratory tract and can lead to sleep apnea and hypopnea, as well as hypoxia and hypercapnia^[20]. This study demonstrated that in the multivariate stepwise logistic regression analysis, when the obesity represented as BMI and local obesity represented by waist circumference entered in the final regression model, the waist circumference rather than BMI was accepted by the model. Thus, it could be concluded that visceral obesity rather than general obesity was the independent risk factor for sleep snoring. To date, the mechanism underlying the consistent and significant association between PI and sleep snoring is unknown. In insulin resistance atherosclerosis study (IRAS), it demonstrated that the visceral fat accumulation could result in the elevation of circulating PI level^[21], and the concentration of PI was independently correlated with fibrinogen, and plasminogen activator inhibitor type 1 (PAI-1)^[22]. The elevation of the activity of fibrinogen, and PAI-1 following the increase of PI level can lead to the disorder of homeostasis and finally result in the clustering of cardiovascular risk factors. The above finding may be one of the mechanisms for the association between PI, sleep snoring and cardiovascular risk factors clustering.

Our conclusions are that the frequency of sleep snoring which is the main symptom of obstructive sleep apnea syndrome is independently associated with the level of PI, and is associated with the clustering of cardiovascular risk factors. This might be the first study demonstrating a relationship between sleep breathing disorder, circulating PI level, and clustering of cardiovascular risk factors in healthy middle-aged subjects from the general Chinese population.

Abstract

AIM: To explore the relationship between changes of intestinal environment and pathogenesis of non-alcoholic steatohepatitis (NASH).

METHODS: Forty-two Sprague-Dawley rats were randomly divided into model group ($n = 24$), treatment group ($n = 12$), and control group ($n = 6$). The rats of model and treatment groups were given high-fat diet, and those of the control group were given normal diet. Furthermore, the rats of treatment group were given lactulose after 8 wk of high-fat diet. Twelve rats of the model group were killed at 8 wk of high-fat diet. At the 16 wk the rats of treatment group, control group, and the rest of the model group were killed. The serum levels of aminotransferase were measured and the histology of livers was observed by H&E staining.

RESULTS: The livers of rats presented the pathological features of steatohepatitis with higher serum levels of alanine aminotransferase (ALT) and aspartate aminotransferase (AST) in the model group after 16 wk. Compared to the model group, the serum levels of ALT and AST in treatment group decreased significantly and were close to the normal group, and the hepatic inflammation scores also decreased markedly than those in the model group after 16 wk (5.83 ± 2.02 vs 3.63 ± 0.64 , $P < 0.05$), but were still higher than those in the model group after 8 wk (3.63 ± 0.64 vs 1.98 ± 0.90 , $P < 0.05$). However, the degree of hepatic steatosis had no changes in treatment group compared to the model group after 16 wk.

CONCLUSION: Lactulose could ameliorate the hepatic inflammation of rats with steatohepatitis induced by fat-rich diet, but could not completely prevent the development of steatohepatitis. It is suggested that intestinal environmental changes such as intestinal bacteria overgrowth, are one of the important factors in the pathogenesis of NASH.

INTRODUCTION

The pathogenesis of non-alcoholic steatohepatitis (NASH) remains unclear^[1-5]. Several studies have suggested that small intestine bacterial overgrowth might play a role in NASH^[6-9]. NASH is a common complication of jejuno-ileal bypass for morbid obesity^[10-12]. NASH has also been described in adults during total parenteral nutrition (TPN) and in multiple jejunal diverticulae with bacterial overgrowth in small intestine^[13,14]. However, evidence is insufficient to indicate that intestinal flora has much to do with the usually insidious process of NASH^[15-18]. Recently, it was reported that the prevalence of small intestine bacterial overgrowth is high in obese patients with NASH, as assessed by the 14C-D-xylose-lactulose breath test^[15], suggesting that intestinal environmental changes such as small intestine bacterial overgrowth and gut original endotoxemia may play an important role in the development of NASH. To further study the relationship between the change of intestinal environment and pathogenesis of NASH, we investigated the effect of lactulose on the establishment of a rat NASH model.

MATERIALS AND METHODS

Animals

Male Sprague-Dawley rats ($n = 42$) weighing 140-160 g were purchased from the Shanghai Experimental Animal Center (Shanghai, China), and housed in cages under standard conditions with free access to water. After being fed with standard rat chow for 1 wk, the animals were randomly divided into control, model, and treatment groups. The control group ($n = 6$) received normal diet, the model group ($n = 24$) and treatment group ($n = 12$) received fat-rich diet (normal diet plus 2% cholesterol and 10% lard). Eight weeks later, the treatment group was administered a solution of lactulose syrup (Solvay Pharma, China) instead of water. In general, the dose of lactulose syrup for adults was 45 mL/d. If the average weight of adults was 59 kg, the dose of lactulose liquid was 0.9 mL/(kg·d). According to the dose of adults, rats might be given a 10-fold higher dose (3.7 mL/d). Livers and blood samples were collected from 12 rats of model group at the wk 8. At wk 16, samples were collected from other rats in three groups. In brief: after fasting and water deprivation for more than 12 h, the rats were weighed and

anesthetized with 1% pentobarbital by intraperitoneal injection. Then the blood samples were collected through abdominal aorta, the liver tissues were weighed and fixed in 40 g/L formaldehyde, embedded in paraffin.

Biochemical measurement

The serum levels of alanine aminotransferase (ALT), aspartate aminotransferase (AST), triglycerides (TG), and total cholesterol (TC) were measured using an automatic biochemical analytical system.

Serum endotoxin level

Serum endotoxin level was measured by chromogenic limulus amoebocyte lysate test in Shanghai Clinical Test Center, and the tubes without pyrogen were supplied by the center.

Hepatic histology

The liver tissue sections were stained with hematoxylin and eosin. Each section was assessed under 10×20 light microscopic fields and scored for the severity of steatosis and inflammation according to the following criteria: Steatosis was scored as: grade 0: no fat; grade 1: fatty hepatocytes occupying less than 33% of the hepatic parenchyma; grade 2: fatty hepatocytes occupying 34-66% of the hepatic parenchyma; and grade 3: fatty hepatocytes occupying more than 66% of the hepatic parenchyma. The diagnosis of fatty liver could be confirmed, when fatty hepatocytes occupying more than 33% of the hepatic parenchyma. Portal inflammation (P), intralobular inflammation (L), piecemeal necrosis (PN), and bridging hepatic necrosis (BN) had a score from 1 to 4 according to the pathologic severity. PN and BN had a greater correlation with the prognosis, the score was two times higher than P and L. The inflammation score was P+L+2PN+2BN.

Statistical analysis

All results were expressed as mean±SD. Statistical differences between means were determined by Student's *t* test. Rank sum test was used in enumeration of data. *P*<0.05 was considered statistically significant.

RESULTS

During the experiment, no rat died in three groups. In the treatment group, there were no marked increase in the volume of feces. The feces were soft. No significant difference was found in the body weights between model group and control group. But the ratio of the liver wet weight with the body weight in the model group increased significantly than that in the control group. In the treatment group, the body weights were lower than those in the model group at wk 16, and the ratio of the liver wet weight with the body weight (liver exponent, %) significantly decreased compared to that in the model group at wk 8 and 16 (Table 1).

Serum lipid

In model group, the serum level of TC was markedly higher than that in control group, but the serum level of TG was similar to that in control group. No significant difference in serum levels of TC between the model group and the treatment group, but the serum level of TG in the treatment group decreased markedly (Table 2).

Serum aminotransferase

The serum levels of ALT and AST in the model group had an increasing tendency at wk 8, but no significant difference was found between the model group and control group until wk 16. The serum levels of ALT and AST in treatment group decreased significantly, and almost became normal (Table 3).

Serum endotoxin level

The serum endotoxin level in portal vein was higher than that in abdominal aorta, both in model group and control group (*P*<0.05), but there was no significant difference in serum endotoxin level both in portal vein and in abdominal aorta between the two groups. Therefore, we did not measure the serum endotoxin level in treatment group (Table 4).

Hepatic histology

The livers of control group had normal morphology, while

the livers of model group and treatment group became yellow, dull, enlarged, fragile, and full. Microscopically, the livers of control group had no marked abnormality. At wk 8, the livers of model group were engorged with microvesicular and macrovesicular fat. Fatty liver could be diagnosed in 11 of 12 rats. Four out of twelve rats had mild intralobular inflammation. At wk 16, hepatic steatosis was much severe, and intralobular areas were infiltrated by mixed inflammatory cells in model group. These lesions were located mainly in zone 3 areas. Intralobular inflammation was more severe than portal inflammation. Some livers had several large areas of necrosis melted by focal intralobular inflammation. Two rats had hepatic piecemeal necrosis and three had bridging necrosis. In treatment group, the degree of hepatic steatosis slightly decreased, while the score of hepatic inflammation activity significantly decreased compared to those in model group. No hepatic piecemeal necrosis and bridging necrosis were found in treatment group (Tables 5 and 6).

DISCUSSION

The histological characteristics of NASH resemble those

of alcoholic steatohepatitis, suggesting that both diseases may have a similar pathogenesis and can benefit from similar therapies^[15-18]. Studies in alcohol-fed rodents have shown that intestinal bacteria, bacterial endotoxin, and endotoxin-inducible cytokine can modulate alcohol-induced liver damages including hepatic necrosis and fibrosis^[19,20]. Treatment with antibiotics and lactobacillus that inhibit production of endotoxin by the intestinal flora can significantly inhibit the development of steatohepatitis in alcohol-fed animals^[21,22].

Although the intestinal flora is known to play a critical role in the pathogenesis of alcohol-related liver disease, its role in NASH has been poorly understood. Surgical procedures (such as jejunio-ileal bypass) and TPN cause intestinal stasis and secondary bacterial overgrowth, accelerate the progression of fatty liver disease in obesity patients, suggesting that increased exposure to intestinal bacterial products may contribute to the pathogenesis of NASH^[1-3]. It has been reported that the prevalence of small intestinal bacterial overgrowth is high in patients with NASH^[13].

Lactulose could be fermented by colonic bacteria and turn into lactic acid and acetic acid, which can lower colonic

pH, diminish ammonia production and normalize intestinal transit; therefore, lactulose syrup can be used in treatment of hepatic encephalopathy. Lactulose promotes the growth of acidophilous lactobacilli, bifidobacteria, and Gram-positive bacteria, while inhibits Gram-negative bacteria and prevents gut-derived endotoxemia^[23]. In order to explore the relationship between the change of intestinal environmental and pathogenesis of NASH, we observed the effect of lactulose on NASH rats.

The treatment group was given lactulose after 8 wk of high-fat diet, when simple fatty liver developed in rats. The model group developed NASH after 16 wk, while treatment with lactulose for 8 wk improved both serum aminotransferase and hepatic inflammation. These results suggest that intestinal environmental changes, such as small intestinal bacterial overgrowth, increased intestinal permeability and subsequent gut-derived endotoxemia may play an important role in the development of NASH. Although the treatment group received lactulose for 8 wk, the hepatic inflammation scores were still higher than those in model group, indicating that lactulose can ameliorate hepatic inflammation, but cannot prevent NASH. Lactulose could not improve hepatic steatosis in treatment group, suggesting that the change of intestinal environment is not closely related to hepatic steatosis.

In our serial researches, we found that the serum endotoxin level in NASH rats were significantly elevated, when hepatic fibrosis occurred after 24 wk of high-fat diet. The serum endotoxin level in portal vein and peripheral vessels had no significant difference between model group and control group, but the serum endotoxin level in portal vein was markedly higher than that in peripheral vessels in both groups. These results suggest that SD rats might have mild endotoxemia. We also found that the expression of endotoxin receptors-CD14 and toll-like receptor 4 was upregulated in model group, suggesting that Kupffer cell sensitivity to endotoxin increases and low doses of endotoxin might injure liver. Oral administration of lactulose may improve hepatic inflammation of NASH rats by reducing serum endotoxin level in portal vein.

Furthermore, other bacterial products such as peptidoglycan-polysaccharide polymers rather than endotoxin, could stimulate Kupffer cells and injure liver, because bacterial species rather than aerobic Gram-negative bacteria such as *Escherichia coli* may play a role in the pathogenesis of small intestinal bacterial overgrowth^[23,24].

Abstract

AIM: To investigate the effects of p57^{kip2}, cyclinE protein and proliferating cell nuclear antigen (PCNA) on occurrence and progression of human pancreatic cancer.

METHODS: The expression of p57^{kip2}, cyclinE protein and PCNA in tumor tissues and adjacent tissues from 32 patients with pancreatic cancer was detected by SP immunohistochemical technique.

RESULTS: The positive expression rate of p57^{kip2} protein in tumor tissues was 46.9%, which was lower than that in adjacent pancreatic tissues ($\chi^2 = 5.317$, $P < 0.05$). p57^{kip2} protein positive expression remarkably correlated with tumor cell differentiation ($P < 0.05$), but not with lymph node metastasis ($P > 0.05$). The positive expression rate of cyclinE protein in tumor tissues was 68.8%, which was higher than that in adjacent pancreatic tissues ($\chi^2 = 4.063$, $P < 0.05$). CyclinE protein positive expression significantly correlated with tumor cell differentiation and lymph node metastasis ($P < 0.05$). The positive expression rate of PCNA in the tumor tissues was 71.9%, which was higher than that in adjacent pancreatic tissues ($\chi^2 = 5.189$, $P < 0.05$). PCNA positive expression remarkably correlated with tumor cell differentiation and lymph node metastasis ($P < 0.05$).

CONCLUSION: The decreased expression of p57^{kip2} and/or overexpression of cyclinE protein and PCNA may contribute to the occurrence and progression of pancreatic cancer. p57^{kip2}, cyclinE protein, and PCNA play an important role in occurrence and progression of pancreatic cancer.

INTRODUCTION

Abnormality in mammalian cell cycle regulation is an important cause of cell proliferation and oncogenesis^[1]. Orderly progression of the cell cycle is controlled by a family of cyclins and cyclin-dependent kinases (CDKs), which are restrictively counterbalanced by CDK inhibitors (CDKIs)^[2]. Two distinct families of CDKIs, INK4, and CIP/KIP families, which regulate the activity of cyclin-CDK complexes, have been described^[3]. The CIP/KIP family, including p21, p27, and p57 proteins, harbors homologous CDK-binding domains or functions of cyclin-CDK complexes and causes the cell cycle to arrest in G₁ phase. CyclinE protein is a positive regulator of cell cycle, which promotes the transfer from G₁ to S phase. The expression of PCNA remarkably correlates with status of cell proliferation. There are few reports about the relationship between p57^{kip2} protein as negative factor of cell cycle regulation and pancreatic cancer. In this study, the expression of p57^{kip2}, cyclinE protein, and PCNA in pancreatic cancer tissues and adjacent tissues was detected by immunohistochemical technique to investigate the effects of p57^{kip2}, cyclinE protein, and PCNA on occurrence and progression of human pancreatic cancer.

MATERIALS AND METHODS

Patients and tumor samples

Thirty-two specimens of primary human pancreatic cancer were collected from pancreatic resection performed in the Department of General Surgery, General Hospital of Shenyang Military Command. There were 20 male and 12 female patients, with a mean age of 59.5 years (26-72 years). Nineteen patients had well-differentiated pancreatic cancer, 13 had moderately or poorly-differentiated pancreatic cancer, and 12 had lymph node metastasis. All patients were confirmed by clinicopathological diagnosis. These specimens were fixed in 10% buffered formalin and embedded in paraffin. All sections stained with hematoxylin and eosin were reviewed and kept for further studies.

Immunohistochemical study

Four-micrometer-thick sections from the tissues were cut for

immunohistochemical study. The expression of p57^{kip2}, cyclinE protein, and PCNA was assessed by SP immunohistochemical method using anti-human p57^{kip2} mAb (57P06), anti-human cyclinE protein mAb (13A3), anti-human PCNA mAb (PC10), and the UltraSensitive™ SP kit (kit-9720). Immunohistochemical staining for these proteins was then performed according to the UltraSensitive™ SP kit manual. All reagents were supplied by Maixin-Bio Co., Fuzhou, China. The cells with brown-yellow granules in the nuclei or cytoplasm were taken as positive. Five hundred cells on each slide were counted. The slides were classified as negative (-), positive (+), strong positive (++), and strongest positive (+++) according to the count of positive cells for p57^{kip2} and cyclinE proteins less than 10%, 10-25%, 25-50%, and more than 50%, respectively. The slides was distinguished as negative (-), and positive (+) when the count of positive cells were less than 50% and over 50% for PCNA respectively.

Statistical analysis

The χ^2 test and Fisher's exact test were used in the analysis by SAS system statistical software (release 6.12). $P < 0.05$ was considered statistically significant.

RESULTS

Expression of p57^{kip2} protein

The p57^{kip2} protein was located in the nuclei or cytoplasm of normal pancreatic cells and positive pancreatic cancer cells with brown-yellow granules (Figure 1A). The positive expression rate of p57^{kip2} protein in tumor tissues was 46.9%, which was lower than that in adjacent pancreatic tissues ($\chi^2 = 5.317$, $P < 0.05$). The positive expression rate of p57^{kip2} protein in the moderately or poorly differentiated tumor

tissues was 23.1%, which was lower than that in well-differentiated tumor tissues ($\chi^2 = 4.979$, $P < 0.05$). The positive expression rate of p57^{kip2} protein in lymph node metastasis group was 25.0%, which was lower than that in non-lymph node metastasis group ($P > 0.05$, Table 1).

Table 1 Expression of p57^{kip2} protein in pancreatic cancer tissues

Characteristics	p57 ^{kip2} protein expression				Rate (%)
	-	+	++	+++	
Tumor tissue	17	11	3	1	46.9 ^a
Well-differentiated	7	9	2	1	63.2 ^c
Moderately or poorly-differentiated	10	2	1	0	23.1 ^c

Adjacent tissue	8	13	6	5	75.0 ^a

^a $P < 0.05$, ^c $P < 0.05$, ^e $P > 0.05$ vs others.

Expression of cyclinE protein

CyclinE protein was located in the nuclei or cytoplasm of normal pancreatic cells and positive pancreatic cancer cells with brown-yellow granules (Figure 1B). The positive expression rate of cyclinE protein in tumor tissues was 68.8%, which was higher than that in adjacent pancreatic tissues ($\chi^2 = 4.063$, $P < 0.05$). The positive expression rate of cyclinE protein in moderately or poorly differentiated tumor tissues was 84.6%, which was higher than that in well-differentiated tumor tissues ($\chi^2 = 5.128$, $P < 0.05$). The cyclinE protein positive expression rate in lymph node metastasis group was 91.7%, which was higher than that in non-lymph node metastasis group ($\chi^2 = 4.693$, $P < 0.05$, Table 2).

Figure 1 P57^{kip2} protein in well-differentiated pancreatic adenocarcinoma (A), cyclin E protein in poorly-differentiated pancreatic adenocarcinoma (B), and

PCNA protein in moderately-differentiated pancreatic adenocarcinoma (C).

Table 2 Expression of cyclinE protein in pancreatic cancer tissues

Characteristics	CyclinE protein expression				Rate (%)
	-	+	++	+++

Relationship between expression of p57^{kip2} and cyclinE proteins

The cyclinE protein positive expression rate in tumor tissues of the p57^{kip2} protein positive expression group and the p57^{kip2} protein negative expression was 60.0% and 76.5% respectively. There was no significant correlation between the two groups (*r* = -0.11211, *P*>0.05, Table 4).

Table 4 Relationship between expression of p57^{kip2} and cyclinE proteins

p57 ^{kip2}	CyclinE protein expression				Rate (%)
	-	+	++	+++	
-	4	4	6	3	76.5
+	4	3	2	2	
++	2	0	0	1	60.0
+++	0	0	1	0	

DISCUSSION

Studies in recent years have shown that G₁ phase regulation is a complex procedure^[4-7]. p57^{kip2} gene is located in chromosome 11p15.5, and p57^{kip2} protein is a cell cycle inhibitor with molecular weight of 57 ku, which is included in the CIP/KIP family and similar to p21 and p27 proteins in functions^[8,9]. Lee *et al.*^[10], suggested that the tumor suppressor mechanism of p57^{kip2} protein may be integrated with cyclin-CDK complexes and makes cell cycle to arrest in the G₁ phase. Kondo *et al.*^[11], considered that paternal alleles of p57^{kip2} are imprinted, maternal alleles of p57^{kip2} are expressed in the normal status, loss of imprinting and imprinting mistakes of p57^{kip2} lead to a decrease at level of gene expression in tumors. Matsumoto *et al.*^[12], reported that p57^{kip2} protein positive expression rate is 43.3±3.2% in patients with esophageal squamous cell carcinoma. From then on, studies about p57^{kip2} protein expression in human colorectal carcinoma^[13], hepatocellular carcinoma^[14,15], prostate tumor^[16], neoplastic thyroid tissues^[17], epithelial ovarian tumor^[18], extrahepatic bile duct carcinoma and intrahepatic cholangiocellular carcinoma have been reported^[19,20], but few reports on the relationship between p57^{kip2} protein expression and pancreatic cancer are available^[21]. In this study, we found that the positive expression rate of p57^{kip2} protein in pancreatic cancer tissues was significantly lower than that in adjacent pancreatic tissues. The worse the cancer cell differentiation, the lower was the p57^{kip2} protein expression, and there was no correlation between the reduced expression of p57^{kip2} protein and lymph node metastasis. The results suggest that reduced expression of p57^{kip2} protein correlates with the occurrence and malignant degree of pancreatic cancer. CyclinE protein is a positive regulating factor in the cell cycle and promotes the genesis and progression of tumors^[22-24]. Our results suggest that overexpression of cyclinE is associated with the genesis and malignant degree, as well as lymph node metastasis of pancreatic cancer. PCNA is a δ -assistant factor of DNA synthetase, takes part in DNA biological synthesis and regulates cell cycle and cell proliferation by tetramer with cyclin, CDK and p21. Overexpression of PCNA is associated with a variety of tumors of digestive system including human colorectal cancer^[25], gastric cancer^[26], hepatocellular carcinoma^[27], pancreas tumor^[28,29]. The results in the present study suggest that overexpression of PCNA is associated with the occurrence and progression of pancreatic cancer, and malignant proliferation status of pancreatic cancer determined by expression of PCNA is of practical value. Our results suggest that cell proliferative activity is high for the negative or reduced expression of p57^{kip2} protein. Furthermore, p57^{kip2} protein plays a role in suppressing cell proliferation. Our findings are in accordance with the results of previous studies^[5].

In summary, decreased expression of p57^{kip2} and/or overexpression of cyclinE protein and PCNA might contribute to the occurrence and progression of pancreatic cancer. The p57^{kip2}, cyclinE protein, and PCNA might play an important role in occurrence and progression of pancreatic cancer.

Abstract

Pneumoserotum is uncommon and also rarely reported as a complication associated with colonic perforation. A case of colonic perforation in delayed fashion associated with EMR, revealed by pneumoserotum, is reported and the associated literatures are reviewed. A 52-year-old male received piecemeal EMR for a laterally spreading tumor 35 mm in size in our hospital. He complained of enlargement of the scrotum and revisited our hospital the day after the procedure. A diagnosis of pneumoserotum was made, and as most such cases have been reported to be associated with pneumoperitoneum, colonic perforation was suspected. Free air but no fluid collection was found by abdominal computed tomography, and delayed colonic perforation was diagnosed. However, as there were no clinical signs of peritoneal irritation, conservative treatment was administered and the patient recovered uneventfully. Pneumoserotum could be a sign of colonic perforation after EMR, and treatment should be carefully chosen.

INTRODUCTION

Endoscopic mucosal resection (EMR) is a well-established and non-invasive therapeutic procedure for colorectal neoplasm in the early stage. Although rare, various complications including hemorrhage and perforation have been reported. On the other hand, pneumoserotum is uncommon and it is generally a term used for the expression of the presence of gas within the scrotum^[1]. Although most cases are associated with pneumoperitoneum, there have only been two reported cases after colonoscopy. We report herein, a delayed colonic perforation revealed by a rare manifestation of pneumoserotum after EMR of a laterally spreading tumor in the descending colon.

CASE REPORT

A 52-year-old man underwent total colonoscopy because of a positive fecal occult blood test in our hospital. The colonoscopy showed a laterally spreading tumor with uneven nodules in the descending colon, of which the superficial margin was clear after chromoendoscopy using indigo-carmin dye spraying. (Figure 1A) Magnifying colonoscopy after indigo-carmin dye and crystal violet staining disclosed type IIIIL and type IV pit patterns, therefore, this lesion was endoscopically diagnosed as an intra-mucosal carcinoma in an adenoma^[2]. Endoscopic mucosal resection (EMR) was attempted with a curative intent. Subsequently, for better elevation and identification of the submucosal layer, 20 mL of 10% glycerin (GLYCEOL[®]) containing a small amount of 0.4% indigo-carmin was injected into the submucosal layer^[3]. The lesion was well-elevated, and was resected with five fragments. After the EMR, magnifying observation revealed a small amount of residual tumor at the periphery, and argon plasma coagulation (APC) was performed for ablation. (Figure 1B) The argon plasma coagulator was used with setting at 2.0 L/min gas flow and with power of 50 W. To reduce the risk of perforation, APC was only applied to coagulate the edge of the EMR site and the duration of application was as short as 5 s. The patient did not complain of abdominal pain or fullness during or immediately after the therapeutic procedure, and no complication such as bleeding or perforation was identified during colonoscopy. The patient's education included no alcohol and no exercise for 1 wk after EMR. He was discharged 1 h after the procedure, uneventfully. However, he revisited our center the next day because of mild inguinal pain and an enlarged scrotum. Before admission, he had taken two meals including a dinner and a breakfast as usual. On admission, his vital

Figure 1 A: Colonoscopy after indigo-carmin dye spraying showed a laterally spreading tumor 35 mm in diameter in the descending colon; B: The ulcer after piecemeal EMR and APC revealed no active bleeding or perforation.

Figure 2 Upright abdominal X-p film showed free air in the sub-diaphragmatic space.

signs were within normal limits excluding mild fever, and physical examination disclosed only an enlarged but light scrotum, and no abdominal tenderness or muscular defense was found. Upright abdominal X-ray film showed free air in the left sub-diaphragm. (Figure 2) Computed tomography (CT) of the chest and abdomen revealed pneumopericardium, pneumoperitoneum and bilateral pneumoscrotum. (Figure 3) The laboratory data showed that WBC count was 12 000 and C-reactive protein was 58 mg/dL, respectively. Other data were within normal limitation. A diagnosis of colonic perforation in delayed fashion was made. After consultation with the surgeons, the patient was first treated medically under NPO; administration of antibiotics (cefmetazole sodium, 4 g/d) and subsequent hyperalimentation were carried out for 2 d. The fever and inguinal pain were relieved within 24 h. The pneumoscrotum resolved within 2 d, the resolution of the pneumoscrotum was judged by CT and physical examination and the symptoms of the patient. C-reactive protein levels decreased from 5.8 to 0.6 mg/dL in 4 d. The permission of oral intake was based on the clinical course, physical examination, laboratory data, and the patient's symptoms. Oral intake was started on the third day at hospital, and he was discharged uneventfully after five days of hospitalization. The removed specimen was histologically diagnosed as a tubular adenoma, with focal carcinoma limited to within the mucosal layer. No muscle layer was identified in the resected specimens.

Figure 3 Abdominal computed tomography disclosed free air in the scrotum.

DISCUSSION

Colonic perforation associated with therapeutic colonoscopy is uncommon, and the reported incidence ranges from 0.073% to 2.14%^[4-6]. It could occur immediately or in a delayed fashion. Most of the signs of colonic perforation are abdominal symptoms including peritonitis. However, our case presented pneumoscrotum as a sign of a colonic perforation after EMR in delayed fashion. Pneumoscrotum is a term, which implies the presence of air within the scrotum^[1]. Although pneumoscrotum associated with pneumomediastinum and subcutaneous emphysema, secondary to pneumothorax is a well-described entity, there have only been two reported cases following colonoscopy and both cases occurred immediately after the procedures^[7-11]. Our patient developed pneumoscrotum in a delayed fashion, which is different from the previous reports. The reason, why we diagnosed the perforation developed in delayed fashion is as follows, first, our patient did not complain of any symptoms related to colonic perforation during EMR or in the recovery room before discharge. Second, repeated review of the recorded video tape of the procedure also revealed no definite perforation. Therefore, the perforation was suggested to have developed in a delayed fashion to firstly create pneumoperitoneum, and the air then reached the scrotum and created pneumoscrotum, which presented as the first symptom and sign of colonic perforation.

Colonic perforation may be intraperitoneal or retroperitoneal, or both^[11]. Our case presented pneumoscrotum, pneumopericardium and pneumoperitoneum, which suggested that the perforation developed in the retroperitoneal space. That our case developed in a delayed fashion also supported that the perforation was retroperitoneal, as, compared to intraperitoneal perforation, retroperitoneal perforation is reported to be relatively painless and to become clear, some hours after the procedure. Furthermore, most cases presenting pneumoscrotum are associated with pneumoperitoneum, like ours^[12-14].

Our case was treated successfully without laparotomy, however, the choice of conservative or surgical treatment for iatrogenic colonic perforation remains controversial^[15-18]. The finding of air in the scrotal sac may be an early sign of a life-threatening condition, or may represent an incidental finding associated with more common benign conditions^[1]. It depends on the local air production or movement of air

from the peritoneal space. Local air production suggests gas gangrene or scrotal trauma, which is infectious and may be fatal, unless treated appropriately. On the other hand, movement of air from the peritoneal space is usually non-infectious and can be treated conservatively. The reported case of pneumoscotum secondary to colonic perforation in the retroperitoneal space following colonoscopy were successfully treated non-operatively^[10,11]. In this case, the choice of non-surgical treatment was based on the following: first, the patient's vital signs were stable; second, the abdominal pain was mild and localized; and third, the pneumoscotum was painless and the air was not locally produced but originated from the pneumoperitoneum. Additionally, and perhaps most important, no unexplained peritoneal fluid was found in the abdominal CT, which suggested no severe peritonitis. Therefore, in this case the pneumoscotum and pneumoperitoneum was finally judged to be non-infectious.

In conclusion, we report a case of colonic perforation occurring in delayed fashion after EMR, which was revealed by pneumoscotum. Although rare, colonoscopists should keep in mind that pneumoscotum could present as a sign of colonic perforation, and the choice of treatment should be chosen carefully.

Abstract

The transjugular intrahepatic portosystemic stent-shunt (TIPS) has successfully been used in the management of refractory variceal bleeding and ascites in patients with portal hypertension. Major drawbacks are the induction of hepatic encephalopathy and shunt dysfunction. We present a 59-year-old woman with alcoholic liver cirrhosis who received a TIPS because of recurrent bleeding from esophageal varices. Stent occlusion occurred 4 mo after placement of the TIPS. Laboratory testing revealed resistance to activated protein C (APC). Combination therapy with low-dose enoxaparin and clopidogrel could not prevent her recurrent stent occlusion. Finally, therapy with high-dose enoxaparin was sufficient to prevent further shunt complications up to now (follow-up period of 1 year). In conclusion, early occlusion of a TIPS warrants testing for thrombophilia. If risk factors are confirmed, anticoagulation should be intensified. There are currently no evidence-based recommendations regarding the best available anticoagulant therapy and surveillance protocol for patients with TIPS.

INTRODUCTION

Cirrhosis, the common end stage of various chronic liver diseases, results from the necrosis of liver cells and increased

connective tissue production (fibrosis) with nodule formation. The distorted liver architecture interferes with liver function and blood flow, thereby producing the clinical features of impaired liver cell function and portal hypertension. When the portal vein pressure, which normally is around 7 mmHg, rises above 14 mmHg, splenomegaly, ascites and collaterals develop between the portal and systemic circulation^[1]. Ascites can be treated by diuretics and paracentesis, and esophago-gastric varices by β -blockers, vasoactive drugs (octreotide, terlipressin) and endoscopic procedures (variceal band ligation, sclerotherapy) respectively^[1]. Alternatively, a transjugular intrahepatic portosystemic stent-shunt (TIPS) which leads to portal decompression can be inserted by creation of a communication between a central hepatic vein and an intrahepatic branch of the portal vein. The idea of creating an intrahepatic shunt was first introduced more than 30 years ago^[2]. The use of an expandable metal stent was further developed in the 1980s. The relative ease with which the stent can be placed has led to the widespread use of TIPS for the treatment of many complications of portal hypertension (acute variceal hemorrhage, prevention of re-bleeding from varices, control of ascites, hepato-renal failure, hepato-pulmonary syndrome and hepatic hydrothorax^[3-7]), acute and chronic Budd-Chiari syndrome^[8] or portal vein thrombosis^[9-11]. We report a 59-year-old woman with alcoholic liver cirrhosis, who had recurrent TIPS occlusion after having received a TIPS because of variceal bleeding. Thrombophilia results from resistance to activated protein C (APC) and demands intensification of anticoagulant therapy, which prevents further stent dysfunction.

CASE REPORT

History and examination

Alcoholic liver cirrhosis (Child-Pugh class A) in a 59-year-old woman was complicated by recurrent hemorrhages from esophago-gastric varices. Finally, she was referred to our clinic with the request that a TIPS should be inserted. The past medical history was uneventful, except for an appendectomy at age 12, a hysterectomy because of intramural uterine fibroids and surgery for varicose veins. There was no history of venous thrombosis or embolism, but an episode of transient ischemic attack seemed to have occurred because the patient reported a brief episode of aphasia and weakness in her right arm, 3 years ago. She admitted alcohol dependence for a period of approximately 5 years.

Examination revealed that she was in slightly reduced general health condition and nutritional status with a

BMI of 20.8 kg/m² (58 kg, 1.67 m). There was neither lymphadenopathy nor jaundice nor edema. Some facial telangiectasia and spider naevi on the upper chest could be found, but no palmar erythema or other skin liver signs. Blood pressure was 115/60 mmHg, heart beats were regular at 74/min. Examination of the cardiovascular, respiratory, and abdominal systems was normal.

Blood tests and investigations

Routine laboratory testing revealed the following pathological parameters (normal range): hemoglobin 82 g/L (120-160 g/L), MCV 98 fL (<93 fL), platelets 104 000 G/L (150 000-350 000 G/L), aPTT (activated partial thromboplastin time) 46 s (28-45 s), INR 1.1 and Quick 75% (70-100%), CRP 25 mg/L (<5 mg/L), total protein 54 g/L (66-83 g/L), albumin 28 g/L (34-48 g/L), γ -globulins 22% (14-19%), total bilirubin 1.2 mg/dL (<1.1 mg/dL), γ -GT 120 U/L (<19 U/L), alkaline phosphatase 206 U/L (<180 U/L), pseudocholinesterase 2 127 U/L (>3 500 U/L). Serologically, there was no evidence for current or previous hepatitis A, B, or C.

On abdominal ultrasound, liver size was reduced to 9.6 cm in the right mid-clavicular line, the surface was irregular, the echogenicity enhanced. The spleen was enlarged to 15 cm×5 cm with no ascites. Color Doppler sonography demonstrated orthograde flow in the portal vein, but velocity was reduced to 4 cm/s on duplex sonography. Gastroscopy confirmed the fourth grade esophageal varices with scarring due to previous sclerotherapy, fundal gastric varices, and hypertensive gastropathy.

Treatment and follow-up

A TIPS (expandable metal Wallstent, Boston Scientific/Ratingen Germany, 10 mm in diameter) was inserted without any short-term complications. Post-interventionally, 75 mg of clopidogrel, an inhibitor of platelet aggregation, was taken orally once daily, and the patient was discharged from the hospital. The portocaval pressure gradient decreased from 24 to 7 mmHg. On an outpatient-visit 4 mo later, the patient was in good general health and asymptomatic, but color Doppler sonography and duplex sonography revealed thrombotic occlusion of the TIPS. Therefore, she was re-admitted to our hospital. Gastroscopy again found the fourth grade esophageal varices (Figure 1A). Shunt angiography verified TIPS occlusion (Figure 2A), and shunt revision was successfully performed (Figure 2B). Control gastroscopy confirmed excellent size reduction of the varices (Figure 1B). Additionally, screening laboratory testing for thrombophilia was initiated, and heterozygous factor V-Leiden resulting in resistance to APC was identified by PCR. Therefore, clopidogrel medication was supplemented with daily subcutaneous self-injections of 40 mg enoxaparin, a low molecular weight heparin. Intensified anticoagulation could not prevent the recurrent stent occlusion 2 mo after revision of the shunt, which became obvious on routine color Doppler examination after an additional 2 mo. Once again, TIPS revision was successfully performed. Due to repeated thrombosis, anticoagulant therapy was further intensified. In addition to clopidogrel, high-dose enoxaparin (60 mg twice daily s.c.) was initiated, which was sufficient to

prevent further shunt complications up to now, i.e. a follow-up period of 1 year.

Figure 1 Esophageal varices before (A) and after (B) TIPS revision.

Figure 2 Shunt angiography before (A) and after (B) TIPS revision.

DISCUSSION

Though TIPS placement is used as a treatment modality for the complications of portal hypertension, only in the case of refractory ascites (four randomized controlled trials) and recurrent variceal hemorrhage, as in the patient presented here (12 randomized controlled trials), TIPS has been compared to other forms of therapy. The superiority of TIPS with regard to symptom control could be demonstrated, whereas insertion of a TIPS could not improve survival. TIPS is widely accepted as the main second-line treatment option for acute variceal hemorrhage not responding to other treatment options^[3-7,12,13].

On the one hand, TIPS is an elegant therapeutic procedure with a low (1-2%) procedure-related mortality^[4,5,7] thus offering the chance of taking a diagnostic transjugular liver biopsy in patients with advanced liver cirrhosis. Moreover, TIPS does not hamper or exclude future liver transplantation because normal anatomy of the extrahepatic vessels is preserved. Indeed, it can serve as a valuable bridging procedure to liver transplantation. On the other hand, placement of a TIPS can be complicated by substantial acute and chronic morbidity^[3,4,14] (Table 1). The major long-term drawback of TIPS besides the induction or worsening of hepatic encephalopathy^[15,16] is stent dysfunction due to occlusion or stenosis. Meta-analysis indicates that within 2 years of TIPS creation, re-intervention to re-establish or maintain the patency of the shunt is required in 70-90% of patients, and total occlusion occurs in 20-40% of patients.

Nevertheless the secondary or assisted patency rate during a 2- to 5-year follow-up period is between 72% and 91%^[3,16-20].

Stent occlusion during the first month after TIPS placement is mainly a consequence of shunt thrombosis, thereafter, shunt stenosis in most cases is the result of pseudointimal hyperplasia^[3-5,20]. We described a patient with repeated shunt thrombosis for a longer time period due to resistance to APC. Hence, in patients with recurrent thrombotic TIPS occlusion, hypercoagulopathy as a risk factor for shunt complications should be ruled out. APC resistance (or Factor V-Leiden) as a cause of familial thrombophilia was first described in 1993^[21]. A point mutation in the gene encoding factor V (G1691A) leads to a conformational change at the site, where factor Va is cleaved by APC and thereby inactivated. Prolonged activation of factor V results in hypercoagulopathy. Heterozygous factor V mutation carriers have a 5-10-fold increased risk of thromboembolic events, and in patients with homozygous factor V mutation, the risk shoots up further^[22,23]. Prevalence of the mutation is about 5% in the normal population, and inheritance follows an autosomal dominant manner. Other major causes of inherited and acquired thrombophilia which have to be excluded are listed in Table 2.

In the patient described here, escalation of anticoagulation combining the usually given inhibitors of platelet aggregation with low molecular weight heparin in therapeutic dosage was sufficient to prevent further shunt occlusions. However, no data are currently available on the optimal anticoagulant therapy to prevent shunt occlusion. When a TIPS is placed for the prevention of variceal re-bleeding, peri-interventional anticoagulation with heparin is recommended to reduce early shunt occlusion^[17]. Additional therapy with the inhibitors of platelet aggregation, ticlopidine and trapidil for 6 mo after initial intravenous heparin for 24 h significantly reduces the rate of TIPS stenosis^[24]. In a recent review article, the use of subcutaneous low-dose low molecular weight heparin for 4 wk, together with trapidil and ticlopidine for 12 mo^[3] is suggested. Higher dosage of heparin seems to be necessary in patients with thrombophilia, but in a controlled trial, phenprocoumon does not reduce the risk of early stent occlusion or later stent stenosis in patients without hypercoagulopathy^[25]. Moreover, since the risk of bleeding is significant in patients with cirrhosis, the use of oral anticoagulants with long half-lives is problematic. Alternatively, coated stents or drug-eluting stents can probably protect against shunt thrombosis, and preliminary results indicate that the rates of stent thrombosis and occlusion can be reduced^[26-30]. However, patients must be selected more carefully, because covered stents have a higher risk of hepatic encephalopathy^[31].

The high rates of shunt dysfunction with the resulting risk of re-bleeding ask for a surveillance program of TIPS patients. Unfortunately, follow-up protocols differ significantly between centers because the optimal regime is unknown. Duplex ultrasonography at intervals of 3-6 mo has been practiced in most studies exhibiting a sensitivity of 53-100% and a specificity of 62-98% in detecting shunt insufficiency^[3,4,17], although a recent study has reported a poorer sensitivity of only 35%^[32]. However, the finding of shunt dysfunction does not always make shunt revision

mandatory. When duplex sonography confirms TIPS occlusion or when the technique does not yield a clear result, an endoscopic re-evaluation is followed. Only when significant varices can be demonstrated, shunt angiography with measurement of the portal-venous pressure gradient is necessary and clearly discriminates whether radiological shunt revision is indicated or not.

In conclusion, TIPS is an elegant procedure which simultaneously serves as a diagnostic and therapeutic tool in patients with complications of portal hypertension. Shunt dysfunction by thrombosis or neointimal proliferation, the major complication besides worsening of hepatic encephalopathy, may be reduced temporarily by using inhibitors of thrombocyte aggregation and (low molecular weight) heparin. Repeated thrombotic TIPS occlusion is mostly due to thrombophilia, which requires more extensive laboratory testing to detect the underlying inherited or acquired coagulation disorder(s).

Table 1 Complications of TIPS

Acute complications	Chronic complications
Transcapsular puncture	Deterioration of liver function
Intrahepatic hematoma	New or worsened hepatic encephalopathy
Intraperitoneal bleed	TIPS dysfunction (thrombosis, stenosis)
Fistulae:	Hyperdynamic circulation and cardiac failure
Hemobilia	
Arterio-portal fistulae	
Malpuncture of other organs	
Portal vein thrombosis	
TIPS dislocation	
Infections and sepsis	
Hemolysis	
Contrast media-related complications:	
Allergic reactions	
Acute renal failure	
Cardiac arrhythmias/myocardial infarction	

Table 2 Causes of thrombophilia

Hereditary causes	Acquired causes
Resistance to APC = Factor V-Leiden (Factor V gene mutation G1691A)	Antiphospholipid syndrome
Prothrombin gene mutation (G20210A)	Lupus anticoagulant
Antithrombin III deficiency	Malignancy and myeloproliferative disorders
Hyperhomocysteinemia (MTHFR mutation)	Hyperviscosity (multiple myeloma)
Protein C deficiency	Cardiac failure and any type of shock
Protein S deficiency	
Dysfibrinogenemia	Nephrotic syndrome
Increased factor VIII and PAI-1	Liver cirrhosis
Plasminogen deficiency	Protein-losing enteropathy
tPA deficiency	Chronic inflammatory bowel disease
	Hemolytic uremic syndrome
	Thrombotic thrombocytopenic purpura
	Post-surgery, post-traumatic, immobilization
	Oral contraceptives and smoking
	Obesity
	Pregnancy
	Geriatric patients

Abstract

Among the various congenital anomalies of the biliary system, an ectopic opening of the common bile duct (CBD) in the duodenal bulb is extremely rare. ERCP is essential for diagnosing the anomaly. A 55-year-old male was admitted to hospital for severe right upper quadrant abdominal pain, followed by fever, chills, elevated body temperature and mild icterus. The diagnosis of ectopic opening of CBD in the duodenal bulb was established on endoscopic ultrasonography (EUS), which clearly demonstrated dilated CBD, with multiple stones and air in the lumen, draining into the bulb. A normal pancreatic duct, which did not drain into the bulb, was also observed. This finding was confirmed on ERCP and surgery. As far as we know, this is the first case of this anomaly diagnosed by EUS. Ectopic opening of the CBD in the duodenal bulb is not an incidental finding, but a pathologic condition which can be associated with clinical entities such as recurrent or intractable duodenal ulcer, recurrent biliary pain, choledocholithiasis or acute cholangitis. Endoscopic ultrasonography features allow preoperative diagnosis of this anomaly and can replace ERCP as a first diagnostic tool in such clinical circumstances. Embryology of the anomalies of the extrahepatic biliary tree has been also reviewed.

INTRODUCTION

Among the various congenital anomalies of the biliary

system, an ectopic opening of the common bile duct (CBD) in the duodenal bulb is extremely rare. Until recently, there were only a few sporadic case reports of this anomaly in the literature worldwide^[1-3]. In 2003, Lee *et al.*, presented the largest study consisting of 18 Patients with this anomaly^[4]. In that study, as well as in case reports published elsewhere, the diagnosis of an ectopic opening of the CBD in the duodenal bulb was established on ERCP when: (1) an orifice was observed in the bulb by duodenoscopy or upper endoscopy, and the bile duct and/or the pancreatic duct were directly visualized radiographically, when contrast was injected via this opening; (2) there was direct drainage of the CBD into the duodenum on cholangiography; and (3) there was no evidence of a papilla-like structure in the second or third portion on duodenoscopic examination^[1-4]. However, ERCP is an invasive endoscopic procedure which is associated with significantly greater morbidity and mortality, when compared with either upper endoscopy or endoscopic ultrasonography (EUS)^[5]. Septic complications of ERCP can be life-threatening^[6]. Mortality rates for post-ERCP cholangitis vary from 10 to 16%^[7]. On the other hand, diagnostic EUS is a non-invasive endoscopic procedure with negligible rate of complications. We present, for the first time, a patient with ectopic opening of the CBD in duodenal bulb, diagnosed by EUS.

CASE REPORT

A 55-year-old male presented at the University Clinic for Gastroenterology on March 27, 2002, with severe right upper quadrant abdominal pain, followed by fever, chills, elevated body temperature (39.5 °C) and mild icterus. His history revealed two identical attacks in the previous 4 mo, which subsided with parenteral antibiotics at a local hospital. His body weight loss in the previous 6 mo was more than 10 kg. In 1998, he was operated on due to malignant melanoma and had a history of non-insulin dependent diabetes mellitus for the previous 4 years. On admission, physical examination revealed only mild tenderness in the upper abdomen followed by obscure jaundice. Routine biochemistry revealed cholestatic pattern: elevated alkaline phosphatase 149 U/L ($n < 70$ U/L), gamma glutamyl transpeptidase 404 U/L ($n < 35$ U/L), conjugated bilirubin 35 μ mol/L ($n < 11$ μ mol/L) and ALT 88 U/L ($n < 23$ U/L). Abdominal ultrasonography performed at our hospital disclosed gall bladder with few small gallstones, dilatation of the common bile duct of more than 20 mm, with suspicious stones in the lumen, and a pseudotumor in the projection of the duodenal bulb. The computed tomography finding was unremarkable revealing

only discreet intrahepatic biliary dilatation in left liver lobe. Endoscopic examination of the duodenum disclosed bulbar deformity without ulcers and erosions, as well as a slit-like opening on the posterior bulbar wall from which bile flowed intermittently, especially when suction was applied with the endoscope (Figure 1). At that particular moment, our idea was that a spontaneous fistula, secondary to choledocholithiasis or ulcer disease had occurred in this patient. Endoscopic ultrasonography examination of the upper GI tract and biliary system (using radial 7.5/12 MHz switchable probe-Olympus device) was carried on. EUS exploration from the duodenal bulb with the 7.5 MHz radial probe clearly demonstrated dilated common bile duct with multiple stones and air in the lumen, draining in the duodenal bulb (Figures 2A and B). There were no EUS signs of fistula. The mild lobulation and inhomogeneity of pancreatic parenchyma was also documented, since the main pancreatic duct appeared non-dilated and unchanged and was not draining into the duodenal bulb (Figure 2C).

Figure 1 Endoscopic image: deformed duodenal bulb with slit-like opening (black arrow).

Figure 2 EUS image **A**: EUS image: dilated common bile duct (thick arrow) with stones and air (thin arrows) draining in the bulb; **B**: EUS image: dilated common

The final diagnosis of an ectopic opening of the CBD in the duodenal bulb was confirmed on ERCP, where markedly dilated biliary tree with stones was directly visualized radiographically on injection of contrast via the orifice observed previously in the bulb. Technically, it was especially demanding to cannulate the opening in the duodenal bulb blindly with duodenoscope placed horizontally in the stomach body (Figure 3A). At the end of this procedure, cannulation of the major duodenal papilla, which appeared regularly in the descending duodenum, disclosed the unchanged main pancreatic duct, making a loop in the head of pancreas (Figure 3B).

The patient underwent surgery including open cholecystectomy, bile duct exploration with subsequent extraction of biliary stones, and choledochenterostomy (Figure 4). On the 7th d after the operation, the patient was discharged from the hospital. Two years after the operation, he has been doing well and denied any symptoms.

DISCUSSION

The embryonic development of the liver and biliary tree begins late in the 3rd wk of intrauterine development, when a small hepatic diverticulum arises from the thickened area of endoderm (epithelium), at the junction of the foregut and the midgut^[8]. The cells of hepatic diverticulum penetrate the mesenchyma of the ventral mesogastrium, dividing into a ventral and a dorsal bud. The ventral bud (*pars cystica*) stays close to the free edge of the mesogastrium, and, after developing a lumen, forms the primitive gall bladder. The dorsal bud (*pars hepatica*) divides in turn to the left and right liver lobe primordia. As the liver and biliary tree develop inseparably, these primordia multiply to form an epithelial spongework or cords which come in close relation

bile duct with stones (black arrow) in the lumen; **C**: EUS image: unchanged main pancreatic duct (black arrow) with parenchymal irregularity (white arrows).

to vitelline and umbilical veins. The stem of the hepatic primordium becomes the bile duct, its connection to the ventral bud forms the cystic duct, and the divisions of the dorsal bud become left and right hepatic ducts. Initially, the gall bladder is a hollow organ, but, as a result of proliferation of its epithelial lining, it becomes temporarily solid. The definite lumen develops by recanalization of the epithelium. The intra- and extrahepatic ducts also go through a solid and recanalization stage in their development. If their lumen fails to reopen, the ducts will appear as narrow, fibrous cords. Occasionally, such an atresia is limited to a small portion of the bile duct only. Another important feature of the bile duct development is rotation of the primitive duodenum 90° on its longer axis, which brings the bile duct dorsal to the upper limb of duodenum.

The development of duodenum, pancreas, and bile ducts has been wittily described as embryological “traffic jam”^[9]. In a case report of a complete absence of bile and pancreatic ducts in a newborn^[10], it has been postulated that there may be a genetic factor related to defects in the liver and pancreas. Like those genes themselves, their products are largely unknown, as are the interactions of the few products that have been identified^[8].

Variations in the extrahepatic duct topography, which extend from the complete absence of the CBD^[11], anomalous opening of the biliary tree^[12], through accessory hepatic ducts to duplications of the gall bladder or the bile duct, are thought to arise from the difference in extension and projection of the analage derived from the caudal hepatic bud.

The description of the development of liver, pancreas and connected duct systems provides no evidence that two extrahepatic ducts with separate openings into the gastrointestinal tract are stages in normal organogenesis^[13], so that the development of double common bile duct can be ascribed to disturbances in recanalization of the hepatic primordium. The accessory bile duct can open into various parts of the digestive tube-stomach^[14], all four portions of the duodenum, pancreatic duct, or can be only presented by a septum in the common bile duct^[15].

According to the above-mentioned criteria for diagnosing ectopic opening of CBD in the duodenal bulb^[4], in such cases there should be no evidence of a papilla-like structure in the lower duodenum. This is in contradiction to a previous report^[16], which permits the possibility of the pancreatic duct opening elsewhere in the duodenum, apart from the ectopic CBD. In our case, we clearly demonstrated an ectopic opening of CBD in the duodenal bulb, and, apart from it, the existence of a normal pancreatic duct opening through the papilla in the descending duodenum. Therefore, we hypothesize that the primary embryological event was the duplication of the common bile duct (double CBD). One of those ducts had an anomalous opening in the duodenal bulb, while the other took a normal course to join the pancreatic duct. The latter duct probably underwent atresia, which left the whole biliary drainage through the ectopically positioned duct. This is in accordance with the fact, that the pancreatic duct has been visualized in only 1/8 and 7/18 cases in the previous studies on ectopic opening of CBD into the duodenal bulb^[1,6,4]. Therefore, we suggest that the 3rd criterion concerning the papilla-like structure in the descending duodenum should be discarded.

An ectopic opening of the common bile duct in the duodenal bulb is extremely rare. The percentage of asymptomatic individuals is unknown, since there was no consistent autopsy study^[4]. Until recently there were only a few sporadic case reports of symptomatic anomaly^[1-3]. However, true incidence could be much higher than presently appreciated, as Lee *et al.* stressed recently^[4]. They concluded that ectopic opening of the CBD in the duodenal bulb is not an incidental finding, but a pathologic condition which can be associated with clinical entities such as recurrent or intractable duodenal ulcer, recurrent biliary pain, choledocholithiasis or acute cholangitis. Our patient had two episodes of acute cholangitis in regional hospitals before establishing correct diagnosis.

The same scenario took place in other studies, whereas anomaly was not diagnosed in any patient before referral to tertiary institutions, where the patients were evaluated^[16].

The diagnostic tools for such entities ranged from plain upper GI barium X-ray^[17], operative cholangiography^[1] to CT^[16], but ERCP is the “golden standard”. However, ERCP is an invasive endoscopic procedure, which is associated with a variety of possible complications^[18]. Some of them, like sepsis can be life-threatening^[6]. Mortality rate for post-ERCP cholangitis is very high, reaches even 16%^[7]. On the other hand, diagnostic EUS is a non-invasive endoscopic procedure with negligible rate of complications.

For the first time, we presented clear EUS features of this anomaly, which undoubtedly excluded other possibilities in differential diagnosis: fistula secondary to ulcer disease or choledocholithiasis or spontaneous biliodigestive fistula. Endoscopic ultrasonography features allow preoperative diagnosis of this anomaly and can replace ERCP as a first diagnostic tool in such clinical circumstances.

Abstract

Gastrointestinal duplication is an uncommon congenital abnormality in two-thirds of cases manifesting before the age of 2 years. Ileal duplication is common while colonic duplication, either cystic or tubular, is a rather unusual clinical entity that remains asymptomatic and undiagnosed in most cases. Mostly occurring in pediatric patients, colonic duplication is encountered in adults only in a few cases. This study reports two cases of colonic duplication in adults. Both cases presented with rectal bleeding on admission. The study was focused on clinical, imaging, histological, and therapeutical aspects of the presenting cases. Gastrografen enema established the diagnosis in both cases. The cystic structure and the adjacent part of the colon were excised en-block. The study implies that colonic duplication, though uncommon, should be included in the differential diagnosis of rectal bleeding.

INTRODUCTION

Gastrointestinal duplication is an uncommon congenital abnormality^[1]. More than 80% of cases present before the age of 2 years as an acute abdomen or bowel obstruction and can occur anywhere throughout the alimentary tract^[1,2]. Ileum is the most common site for duplication, accounting for over 60% of cases^[4]. On the other hand, duplication of

the colon is a rare abnormality, accounting for 4-18% of all gastrointestinal duplications, often located in the cecum^[3,4]. A thorough review of the international literature since 1950, has revealed 83 cases of colonic duplications reported up-to-date.

Although intestinal duplications are considered to be benign lesions, mostly asymptomatic, they may result in significant morbidity and mortality, if left untreated^[5]. Indications for surgical intervention often arise in an acute setting, in the form of a complication. Specifically, patients with previously undetected duplications may present in the setting of bowel obstruction or severe gastrointestinal hemorrhage (i.e., ulcerating gastric mucosa within a duplication cyst)^[3]. If encountered incidentally, these lesions should be surgically addressed to avoid any future complication, including the possibility of malignant degeneration within the duplication cyst^[3,5].

The cases mentioned in the present article refer to patients manifesting bleeding of the lower gastrointestinal tract, which was finally proved as originating from the mucosa of a colonic duplication.

CASE REPORTS

Case 1

A 53-year-old male was admitted to our department with rectal bleeding. He claimed of stool mixed with blood, without pain or changes in bowel habits, 5 d prior to admission. The patient had a medical history of constipation, being treated with diet for more than 20 years. On admission, he was in a stable clinical condition, with normal vital signs and blood tests were within normal ranges. Rectal examination confirmed the presence of blood in the stools. Plain X-rays of the abdomen showed no particular findings.

Colonoscopy was performed showing only two small diverticula in the sigmoid colon, but could not reveal the site of bleeding. It was not possible for the right colon to be examined thoroughly, due to imperfect bowel cleansing. As a second step of the diagnostic procedure, radiographic colon imaging after gastrografen enema was performed. It showed a fistula in the middle of the ascending colon, communicating with a cystic formation approximately 2 cm×1 cm in dimension. Furthermore, a computerized tomography of the abdomen was performed, which confirmed the findings and a possible diagnosis of colonic duplication of ascending colon was concluded. A second colonoscopy detected the mucosa of the colonic duplication to be the origin of bleeding.

Excision of the cystic lesion was decided (Figure 1). It was resected en-block to the section of the ascending colon

and an end-to-end anastomosis of the colon was performed. Pathological examination of the resected lesion revealed a duplication cyst in the mesenteric border of the ascending colon, with normal intestinal mucosa lining its wall (Figure 2). Within the mucosa of the duplication, a site of angiodysplasia was detected as the origin of bleeding.

The patient had an uneventful postoperative course and was discharged on the 6th post-operative day. He remained asymptomatic ever since.

Figure 1 Surgical specimen including the ascending colon together with a duplication cyst attached to the mesenteric border of the colon.

Figure 2 Normal intestinal mucosa of the cyst in the first case (HE ×125).

Case 2

A 45-year-old male was referred to our department claiming of fatigue and a 5-d history of bloody stools. Physical examination as well as blood investigations were entirely unremarkable. The patient was submitted to rectal examination as well as colonoscopy, which did not reveal any source of bleeding. The radiological imaging control using gastrografin enema showed a cystic formation of 0.5 cm×5 cm in size, located in the mesenteric border of the descending colon. This finding was confirmed by a second colonoscopy, which established the diagnosis of a colonic duplication.

A surgical intervention was decided in order to detect the site of bleeding, as well as to prevent any further complication of the cyst. The cystic lesion was resected en-block to the adjacent part of the colon (Figure 3) and an end-to-end anastomosis was performed. The cyst was confirmed to be a colonic duplication of normal colonic mucosa according to the pathologic study. Indeed, there

was a mucosal ulceration in the cystic cavity, probably representing the origin of bleeding. There was no immediate or delayed post-operative complication.

Figure 3 Surgical specimen in the second case including the descending colon with a duplication cyst adjacent to the colon.

DISCUSSION

Intestinal duplication is a congenital malformation, that occurs mostly in pediatric patients^[2,6]. It could be encountered anywhere throughout the gastrointestinal tract, from the mouth to the anus. Current nomenclature relies on the anatomic location of the duplication in relation to the normal intestinal tract and not on the histological features of the mucosal lining^[2]. Intestinal duplications are located in, or attached (share a common wall) to the wall of an adjacent part of the gastrointestinal tract and possess at least one exterior layer of smooth muscle and are lined with various types of gastrointestinal mucosa^[1]. Further characterization defines these abnormalities as either spherical or tubular. Rarely, complete duplication of the colon may be encountered^[7].

Approximately 75% of duplications have been reported to be located within the abdominal cavity. Jejunal and ileal lesions are the most commonly encountered (53%), while colonic lesions are found in 13% of cases. These lesions may be cystic (75%) or tubular (25%) in appearance and characteristically arise from the mesenteric border of the bowel^[5,6]. They may or may not have one or more direct communications with the adjacent part of the bowel across the common septum^[3]. Non-communicating duplications typically contain clear alkaline fluid, except in cases in which gastric mucosa is present (25%) and acidic fluid is observed. In addition, non-activated pancreatic enzymes may also be observed in cases of ectopic pancreatic tissue within the duplication lesion^[3]. In adults, either cystic or tubular duplication of the colon is a rare entity^[8].

Most colonic duplication cysts are asymptomatic and remain undiagnosed for years^[9]. If symptomatic, they manifest with obstruction^[10,11], bleeding^[10-13] or constipation^[8]. Cystic duplications have been reported to cause obstruction of the colon as a result of direct compression, volvulus, or intussusception, whereas tubular duplications of the rectum have been described as having direct communication with the perineum^[3,13]. Although many duplications are diagnosed incidentally, most patients present with a combination of

pain and/or obstructive symptoms^[14,15]. These symptoms may be the direct effects of distension of the duplication or caused by compression of adjacent organs (including their associated blood supplies). In addition, abrupt hemorrhage with hemodynamic instability can be encountered in the case of a cyst, lined with mucosa that ulcerates and eventually erodes into adjacent organs and/or vessels^[3,13]. There are scattered reports of intestinal carcinomas found within duplication cysts^[14,16]. No significant difference in clinical presentation has been detected between communicating and non-communicating cysts^[3].

Histological analysis typically reveals at least one outer muscular layer with an inner gastrointestinal mucosal lining. The mucosal lining does not necessarily correspond to that of the adjacent normal intestine and may be comprised several different types of gastrointestinal mucosa^[2]. Because of the relative scarcity of such abnormalities, current literature consists mainly of small populations and case reports rather than any large single or multi-institutional series^[8-10,13].

The first patient reported in this study, presented with bleeding in the stools and constipation as his major complaints on admission, while the other one claimed of rectal bleeding. Abdominal X-rays in both cases showed no abnormal findings. The use of contrast material in the imaging control was necessary to discover the cysts. Ultrasonography could help in the diagnostic procedure^[17,18]. Colonoscopy and CT imaging could establish the diagnosis. Colonoscopic examination revealed a cystic formation, lined by normal intestinal mucosa, communicating with the colon. CT imaging showed a cystic mass attached to the colon.

Preoperative diagnosis of colonic duplication is often difficult. Symptoms usually include abdominal pain, often confusing colonic duplication with other more common diagnoses. Plain X-rays of the chest and abdomen should be routinely performed; however, because of the non-specificity of their results, it is difficult to make a pre-operative diagnosis on the basis of radiographic findings. Computerized tomography of the chest or abdomen is useful in establishing a diagnosis of alimentary tract duplication during the pre-operative workup and may be used to evaluate the synchronous lesions, once a single duplication is identified^[2,3]. Ultrasonography is also helpful in establishing a pre-operative diagnosis^[17,18].

Treatment is reserved for symptomatic cases and usually includes resection of the cyst and the neighboring part of the intestine^[11,13,19]. Complications related to surgical intervention are typically nonspecific and include post-operative bleeding, infection, and bowel obstruction^[3]. However, in patients with large tubular duplications, injury to the normal intestine with resultant short bowel syndrome must be considered^[3].

In most instances, cystic duplications can be completely excised. Resection of normal intestine must often accompany removal of the lesion, because of the intimate attachment of the common wall or because isolated resection of

the cyst would compromise blood flow to the adjacent intestinal segment^[3,11,13,19]. An alternative approach involving marsupialization of the cystic structure consists of a partial cystectomy combined with mucosal stripping of the remaining cyst wall to preserve normal anatomy^[3]. Although current literature does not specifically address the prognosis and outcome related to the diagnosis of alimentary tract duplications, the overall outcome is generally favorable^[2,3].

Abstract

Chronic pancreatitis is a relatively common disease. We encountered two different cases of belatedly demonstrated pancreatic carcinoma featuring underlying chronic pancreatitis. The first case was one that was highly suspected as that of a malignancy based upon imaging study, but unfortunately, it could not be confirmed by intra-operative cytology at that time. Following this, the surgeon elected to perform only conservative bypass surgery for obstructive biliary complication. Peritoneal carcinomatosis was later noted and the patient finally died. The second case, a malignant mucinous neoplasm, was falsely diagnosed as a pseudocyst, based upon the lesion's sonographic appearance and associated elevated serum amylase levels. After suffering repeated hemoptysis, the patient was found to exhibit lung metastasis and peritoneal seeding. We reviewed some of the literature, including those studies discussing chronic pancreatitis predisposing to a malignant change. These two case analyses illustrate clearly that the diagnosis for such conditions, which is simply based upon imagery or pathological considerations may end up being one of a mistaken malignancy. Some of our suggestions for the treatment of such malignancies as revealed herein include, total pancreatectomy for univocal mass lesion, and needle aspiration of lesion-contained tissue for amylase, CA199 and CEA levels for a suspicious cystic pancreatic mass.

INTRODUCTION

We herein report on two cases of pancreatic malignancy, an adenocarcinoma and a mucinous cystadenocarcinoma, both of which featured an underlying chronic pancreatitis. The first case was incorrectly diagnosed initially, even though such diagnosis followed multiple-modality imagery studies and intra-operative frozen-section pathology. The second case was, initially, falsely diagnosed as a case of a pseudocyst that had missed the 'golden period' of opportunity for surgical treatment for this relatively non-aggressive malignant tumor. The true diagnosis for this case was made subsequent to the discovery of the widespread distribution of mucinous tumor cells to the lungs and peritoneum. In an attempt to improve our image-interpretation skills, and to provide some more-effective suggestions for clinicians as regards to the appropriate diagnostic procedures for future cases of a similar nature, we have discussed these cases and reviewed some of the related literature.

CASE REPORTS

Case 1

A 60-year-old female patient presented at our hospital, suffering from diabetes mellitus and chronic pancreatitis, and revealed a smoking habit of greater than 30 years. On one previous occasion, this patient was admitted to a local hospital on a complaint of chronic inflammation complicating post-inflammatory obstructive jaundice. Two years subsequent to this event, this patient suffered a relapse; she complained of abdominal fullness and poor appetite. Tea-colored urine and yellowish-colored skin were both noted, the patient was diagnosed with biliary obstruction, and her condition failed to improve following admission. The patient was then referred to our OPD for further evaluation, at which time her condition had progressed to one of general malaise and notable body-weight loss. Serum amylase, CA-199 and CEA levels were, respectively, 58 IU/L (normal <100), 1 387 U/mL (normal <37) and 5.75 ng/mL (normal <4.6). Endoscopic retrograde cholangiopancreatography (ERCP) was performed, but obviously not sufficiently and effectively, it only revealed pancreatic-duct dilatation and failed to provide appropriate visualization of the common bile duct (CBD). Subsequent enhanced CT and MRCP studies revealed dilatation of the CBD, IHD, and MPD, and an ill-defined, heterogeneous enhanced mass located in the uncinate process of the pancreatic head (Figure 1A). Our impression at that time was malignant pancreatic lesion complicating CBD obstruction. Surgical intervention was then conducted, it revealed the presence of a large, stony hard mass, measuring

Figure 1 Enhanced CT scan shows extensive heterogenous mass (arrow) occupying at para-pancreatic region to be involved with adjacent gastric wall and para-ampullary region. Pancreatic duct dilatation is suggested and superior mesenteric vein thrombosis cannot be ruled out (A). multiple heterogenous hepatic lesions are demonstrated (B).

5-6 cm in diameter, located at the pancreatic head and being tightly adherent to the portal vein and the common hepatic artery. Further, we noted a 1.5 cm-diameter lymph node located along the superior mesenteric artery. A gall-bladder stone was also noted. Intra-operative frozen-sectioning of a needle biopsy from the pancreatic head and body revealed fibrosis and chronic inflammation with lymphocytic infiltration into the fibrotic stroma. Intralobular and perilobular fibrosis with atrophy of acini admixed with disorderly arranged islets were also seen, but no evidence of malignancy was apparent, a result that contrasted our initial impression. The patient then underwent a bypass surgery including cholecystectomy, choledochojejunostomy with Roux-en-Y and gastrojejunostomy. Two months later, this patient again presented at our hospital with similar symptoms to those detected at her previous admission, computed tomography (CT) revealing multiple heterogenous ill-defined hepatic tumors (Figure 1B). At this time, we strongly suspected metastatic lesions according to our past impressions of her condition, the past history of this patient, and the updated CT findings. Sonographically guided biopsy was conducted, but the subsequent histopathological report concluded that the lesion was a liver abscess. The patient was administered antibiotics and other supportive treatment. Her condition improved and remained stable for about 2 mo, following which, her condition deteriorated, and she was admitted again to our institution due to progressive abdominal distension, poor appetite and further body-weight loss. The patient's serum CA-199 level had elevated to 4 000 U/mL (normal <37). An abdominal CT scan was performed; it revealed a progressively enlarging heterogenous enhanced mass, located at the pancreatic body and tail

section. This pancreatic mass had also invaded the lesser sac of the stomach, there being direct invasion into the stomach. The pancreatic mass had also resulted in celiac-trunk encasement and the encirclement of the superior mesenteric vessels, with ascites being massive. A condition of pancreatitis superimposed onto malignant change and metastatic peritoneal seeding into the transverse mesocolon and sigmoid mesocolon was diagnosed. Pathological review finally confirmed intraperitoneal carcinomatosis due to the presence of an advanced pancreatic carcinoma, the patient expired about 5 mo later.

Case 2

This 62-year-old male patient featured chronic alcoholism over a period of more than 30 years. Chronic pancreatitis and liver cirrhosis were diagnosed for this patient and he was recommended regular OPD follow up. Slightly elevated serum amylase levels were recorded for this patient, and for approximately 3 mo, he suffered from intermittent abdominal fullness; diffuse dull pain and a general sensation of nausea. Sonographic evaluation revealed multiple pancreatic cystic lesions, ascites, splenomegaly and portal hypertension, with no evidence of tumor septation, loculation, no cystic-wall calcification, and no evidence of the presence of any soft-tissue masses. The initial diagnosis for this patient was chronic pancreatitis with associated pseudocyst formation, based upon the combined results of laboratory and sonographic investigations. Three months later, this patient's condition had, by-and-large, persisted, and upon presentation at our hospital for further evaluation, he was found to be suffering from hemoptysis. This patient's serum amylase, CA199 and CEA levels were reported as, respectively, 150 IU/L (normal <100), 3 841 U/mL (normal <37) and 9.79 ng/mL (normal <4.6). A chest X ray revealed hazy bilateral shadows over the lower lung fields. The patient underwent CT investigation, which revealed multiple cystic pancreatic masses (Figure 2A) confluent with contrast-enhanced soft-tissue components, the largest two masses measuring greater than 7.7 and 3.7 cm in diameter, these lesions arising from the pancreatic body and tail. Fluid distribution within the intraperitoneal and pelvic cavities was described, respectively, as extensive and moderate. CT investigation also revealed multiple foci of alveolar patches (Figure 2B) with a mean density of 10-15 HU. PET scanning was then performed, the results demonstrating multiple areas of FDG uptake including the posterior and bilateral aspects of the lower lungs, the middle-upper abdomen (pancreatic body featured irregular shapes) and the middle-lower abdomen. CT guided fine needle aspiration of the para-pancreatic cystic fluid [f] revealed normal level of amylase, but enormous elevation of CA-199 (32 000 001 U/mL) and CEA (43 000 ng/mL). CT guide biopsy for the lung patch also revealed mucinous adenocarcinoma metastasis. Combined with the results of images and the histopathological investigations, the presence of pancreatic mucinous adenocarcinoma complicated by lung and peritoneal seedings was confirmed.

DISCUSSION

Chronic pancreatitis may eventuate as a consequence of recurrent acute inflammation in the pancreas, such a condition

Figure 2 Enhanced CT scan shows multiple, non-enhanced, pancreatic cystic mass (straight and curved arrows) with soft tissue part (A). multiple, hypodense, alveolar patches at bilateral basal lung parenchyma (straight and curved arrows) (B).

often affecting neighboring structures and their functions. Typical image manifestations of chronic pancreatitis include pancreatic calcification on KUB, atrophic changes and/or the presence of coexistent focal hypertrophy, pseudocyst formation and a dilated pancreatic duct as detected by sonographic or CT investigation. ERCP may be used to demonstrate abnormalities of the main pancreatic duct as also secondary branches. Other possible imagery findings for chronic pancreatitis include fatty replacement, fibrotic changes complicating duodenal stenosis with outflow obstruction and long tapered stenoses of the distal common bile duct with biliary obstruction, aneurysms or pseudoaneurysms of the splanchnic arteries and splenic-vein thrombosis. The predisposing factors for pancreatic adenocarcinoma include chronic pancreatitis, diabetes mellitus, smoking and a potential underlying genetic risk^[1]. The pathophysiological and molecular events underlying chronic pancreatitis have been reported to predispose to the development of, or potentiate the growth of, pancreatic adenocarcinomas^[2]. Mutation of the codon 12 K-ras gene, tumor angiogenesis and microvascular proliferation are, reportedly, genetically-linked aberrations^[2] commonly associated with the development of pancreatic adenocarcinoma.

Discrimination between a well-differentiated pancreatic carcinoma^[3] and chronic fibrotizing pancreatitis is a challenge not only to the radiologist^[4], but also to the pathologist^[5,6]. As mentioned above, pancreatic adenocarcinoma and chronic pancreatitis may coexist, and a malignant tumor can develop as a complication of long-standing chronic pancreatitis. On the other hand, pancreatic carcinoma is frequently accompanied by chronic inflammation. The majority of adenocarcinomas induce a striking desmoplastic

stromal reaction within the pancreas, which may effectively mimic the macroscopic view of vigorous fibroblast proliferation. Microscopically, pancreatitis can be mistaken for pancreatic carcinoma, because the actively growing connective tissue associated with pancreatitis, tends to irregularly separate the existing pancreatic ducts. This continuous regenerative activity may lead to regressive atypia **that resembles malignancy**^[5]. A retrospective study of 5 837 previously histopathologically confirmed pancreatic carcinoma patients, reported little more than 0.5% false-positive results^[7]. In our opinion, for the first case described above, only total pancreatectomy with tissue sent for a precise histopathological examination, instead of frozen-section biopsy, could have increased the likelihood of arriving at a correct diagnosis.

Pseudocyst formation is present for about 30% of chronic pancreatitis cases, such lesions being a collection of pancreatic “juice” enclosed by a wall of fibrous or granulation tissue. Pseudocyst lesions of the pancreas tend to populate the majority of pancreatic cystic lesions. For our second case, however, the diagnostic challenge was to differentiate correctly between a cystic neoplasm and pseudocysts for the patient featuring underlying chronic pancreatitis. Patients who are afflicted with pseudocysts often reveal a history of acute or chronic pancreatitis, whilst most of those featuring cystic tumors lack such antecedent factors. The typical findings of a pseudocyst upon a CT scan, include the presence of a well-defined, non-epithelial, fibrous wall around the cyst lesion. Pseudocysts are typically round or ovoid in configuration and, apart from the assessment of pseudocysts by CT, pseudocysts can generally be identified by hypovascularity upon angiography; and the detection of a communication between the cyst and the pancreatic ductal system upon ERCP. On the other hand, MRI has its advantages over CT in the evaluation of pancreatic pseudocysts. T1W MRI with gadolinium could be more sensitive to demonstrate internal structure of cyst-like lesion, such as very thin septa, which may not be detected by enhanced CT scan. MRCP could help for ruling out of pseudocysts by determining whether they communicate with the pancreatic duct. Cystic neoplasm of the pancreas would appear to be rare, it constituting less than 4% of all pancreatic neoplasms^[8]. The features of a cystic neoplasm, as compared to a pseudocyst, include, for the former, the presence of septa, loculation, solid components and/or cystic-wall calcification. It would appear that sonography is not sufficiently reliable to unequivocally distinguish between pseudocysts and other cystic neoplasms of the pancreas. In our opinion, the early scheduling of abdominal CT subsequent to sonography having been completed for our second case, probably would have hastened the correct diagnosis for this patient. Moreover, analysis of cyst-contained fluid^[9,10], can also aid in the evaluation of cystic neoplasms, in that elevated fluid amylase levels are characteristic of over 95% of pseudocysts, and a normal serum amylase level can be used to exclude the presence of a pseudocyst. Fluid CEA levels can become elevated for a variety of cystic lesions including mucinous cystic neoplasm^[11], intra-ductal papillary mucinous tumors and some pseudocysts, but such levels are always low or normal for cases of serious cystadenoma. A summary of

the laboratory-elicited features of cystic fluid for the purposes of distinguishing between pancreatic cysts and the most-common type of cystic tumors is presented in Table 1.

Table 1 Laboratory features of cystic fluid in different cystic tumors of pancreas

	Pseudocyst	Serous cystadenoma	Mucinous cystadenoma	Mucinous cystadenocarcinoma
Amylase (normal <100 IU/L)	High	Low	Low	Low
CA 199 (normal <37 U/mL)	Low	Low	Intermediate	High
CEA (normal <4.6 ng/mL)	Low	Low	High	High

In conclusion, if an accurate diagnosis of suspicious pancreatic lesions for patients suffering from chronic pancreatitis is not able to be reached based upon appropriate imagery studies, we suggest fine-needle aspiration biopsy^[9] of cystic neoplasms for subsequent laboratory investigation, or, alternatively, wide resection of the pancreatic mass for a precise histopathological evaluation, rather than simple observation^[12].

Abstract

Schwannomas are rare tumors derived from the cells of Schwann that form the neural sheath. When located in the gastrointestinal tract, they constitute together with leiomyoma, leiomyoblastoma, and leiomyosarcoma, the gastrointestinal stromal tumors (GIST). Peripheral nerve sheath tumors represent 2-6% GIST with most common location, the stomach and the small intestine. Schwannomas of the colon and rectum are extremely rare and radical excision with wide margins is mandatory, due to their tendency to recur locally and become malignant, if left untreated. In the present study, we report a rare case of a sigmoid schwannoma, which was successfully treated in our department and reviewed the literature.

INTRODUCTION

Gastrointestinal stromal tumors (GIST) include a variety of primary mesenchymal tumors of the gastrointestinal tract such as leiomyoma, leiomyosarcoma, leiomyoblastoma, and schwannoma^[1]. They have recently been distinguished from each other on the basis of the tumor cell differentiation revealed by immunohistochemical studies^[2,3]. Besides the above-mentioned pathologies, the term GIST has been recently applied to mesenchymal tumors that represent neither typical leiomyoma nor schwannoma^[2,4].

It is well established that schwannomas appear more frequently in the stomach and the small intestine, while location in the colon or in the rectum is uncommon^[5,6].

Most of them are benign and asymptomatic; nevertheless, the possibility of malignant degeneration does exist and is directly related to the tumor dimensions. Radical surgical treatment is the gold standard in all cases, since the results of both chemotherapy and radiotherapy remain uncertain^[7].

CASE REPORT

A 55-year-old male patient was admitted to our department, with a chief complaint of intermittent rectal bleeding and diarrhea that had started 2 mo before admission. Physical findings and digital examination were undiagnostic, but laboratory tests disclosed red blood cell count: $3.2 \times 10^5/\text{mm}^3$, hemoglobin: 74 g/L, and hematocrit: 26.4%. Colonoscopy revealed a wide-based mass protruding from the posterior wall of sigmoid and multiple biopsies were taken from different parts of the tumor. Abdominal x-rays were negative for bowel obstruction, while CT scans proved no metastatic disease. Additionally, the serum levels of tumor markers including carcinoembryonic antigen and Ca 19-9 were within normal ranges. The diagnosis of schwannoma Antoni B type was set preoperatively based on the endoscopic biopsies and intraoperatively, segmental resection of the tumor with wide margins was performed (Figures 1A and B). Permanent sections with H&E confirmed the preoperative diagnosis (Figure 2). The patient recovered uneventfully and at 5 years following surgery, he was free of disease without receiving adjuvant therapy.

DISCUSSION

Schwannomas are mainly benign tumors derived from the cells of Schwann that form the neural sheath, which may become malignant, if left untreated^[8-10]. They can be located everywhere, but the most common type of benign schwannoma is the acoustic neuroma (VIII cranial nerve)^[11].

Malignant schwannomas usually come under the heading of soft tissue sarcomas and the gastrointestinal tract is one of the sites that such tumors can be found^[12]. In these cases they constitute together with leiomyoma, leiomyosarcoma, leiomyoblastoma, and another type with mixed characteristics between leiomyoma and schwannoma, the GIST^[13]. All of these primary mesenchymal tumors show a wide range of common histological and immunohistochemical characteristics^[2,14].

Peripheral nerve sheath tumors represent 2-6% of stromal tumors of the gastrointestinal tract^[3,4] but reports of solitary schwannomas of the rectum and colon are even more rare^[15]. They have almost the same incidence in men and women and a median age of presentation, 65 years of age^[4]. Their size may vary; a case of a rectal schwannoma with a diameter of 8 cm which was primarily misdiagnosed as a myogenic sarcoma has been reported^[2,5].

Figure 1 Macroscopic view of the sigmoid colon showed a well-circumscribed submucosal tumor (A). The cut surface of this tumor consisted of fibrotic and myxoid parts and was gray-yellowish in color (B).

Figure 2 Microscopic view of a benign schwannoma (H&E×40). Compact spindle cells arranged in short bundles are seen.

Although, they usually grow very slowly and are asymptomatic, sometimes they may cause rectal bleeding, colonic obstruction, defecation disorders, and pain^[3,4]. It is very important to emphasize that rectal pain can also be the only symptom of intraspinal schwannomas which they often mislead the diagnosis to proctalgia fugax or rectal neuralgia^[15].

Two histologic types of schwannomas have been described; Antoni type A with densely packed spindle cells (Verocay bodies) and Antoni type B with loosely organized spindle cells (absence of Verocay bodies) in myxoid stroma^[3,4]. Immunology plays a central role to the diagnosis of schwannoma as in many other types of cancer^[16]. Strongly positive S-100 protein, low affinity, nerve growth factor receptor (P75), collagen IV, GFAP, CD34, and negative CD117, neurofilament protein, smooth muscle actin, and desmin, turn out to be supportive to the diagnosis of the benign tumor as a

schwannoma^[2,3,12]. Schwannomas may also appear in patients with Von Recklinghausen disease (NF I), although there is no evident connection between colorectal schwannomas and NF I^[17].

Radical excision with margins free of disease is the treatment of choice, since their response to both chemotherapy and radiotherapy remain uncertain^[4,18]. Nevertheless, despite aggressive surgical management, these tumors appear with a high rate of local recurrence and malignant degeneration. In such case's the treatment options are few and the prognosis is poor^[3,7,8].

The surgical approach depends on the tumor size and histologic features that mainly determine the prognosis. Preoperative imaging tests including abdominal x-rays, transanal 3D-ECHO, MRI, and CT scans can be very useful in the selection of patients for surgical treatment^[19]. Besides the commonly used surgical techniques, minimally invasive modalities can be performed too. In the transanal endoscopic microsurgery (TEM), the local excision is accomplished through a rectal expander^[20,21] with or without the use of an ultrasonically activated scalpel^[22]. Alternatively, in cases of the benign schwannomas located on the distal parts of the rectum, a transanal resection can be performed followed by recto-anal anastomosis^[21].

In conclusion, rectal schwannoma is a very rare tumor, whose diagnostic approach and treatment present certain gray areas. Nevertheless, it has become obvious that the preoperative histological identification of the tumor followed by a radical surgical resection is the cornerstone, which will determine the overall outcome.

Abstract

Choledochal cysts are congenital anomalies of the biliary ducts, characterized by cystic dilatation of the ducts. Prenatal diagnosis of this anomaly using ultrasonography (US) has been well documented. Magnetic resonance imaging (MRI) has recently become an important complement to US in prenatal diagnosis of fetal anomalies. We herein report a patient in whom at 24 wk' gestation US suggested a right upper quadrant abdominal cyst and in whom at 26 wk' gestation MRI more clearly delineated the cyst and its surrounding structures and suggested a choledochal cyst, which was confirmed at postnatal surgery and histopathology.

INTRODUCTION

Choledochal cyst is characterized by a balloon-like dilatation of the extrahepatic duct, occasionally associated with dilatation of the intrahepatic ducts. Ultrasonography (US) remains the primary imaging modality for the evaluation of the fetus and can suggest the diagnosis of choledochal cyst, when a tubular structure is identified at the right upper quadrant abdomen^[1-4]. Magnetic resonance imaging (MRI) has evolved and has become an important complement to US, for more accurate and precise delineation and characterization of fetal anomalies. With recently developed ultrafast MR sequences such as half-Fourier, single-shot, turbo spin-echo

(HASTE), a single slice can be obtained in less than 400 ms^[5]. Many studies have shown the usefulness of these ultrafast MR scans in evaluating the fetus^[6-8]. Here, we report a case of choledochal cyst prenatally diagnosed by using US and MRI and confirmed by postnatal surgery and histopathology.

CASE REPORT

A 29-year-old woman, gravida 2, para 1, presented at our hospital at 24th wk' gestation for prenatal US surveillance. Fetal US showed an ovoid cystic lesion measuring 2.1 cm × 1.1 cm × 1.2 cm at the right upper quadrant abdomen. A choledochal cyst or an enteric cyst was impressed.

Two weeks later, a fetal MRI (Philips 1.5 T Intera; Erlangen, Germany) was performed to further evaluate the cyst using HASTE sequence (TR 10 ms; TE 100 ms; time of acquisition 12 s; flip angle 90°; field of view 280 mm × 250 mm; matrix 256 × 256). MRI showed a 1.3 cm × 1.2 cm × 2.7 cm, ellipsoid, homogeneous cystic lesion extending from the liver hilum posteriorly and inferomedially to the mid-abdomen (Figure 1). This lesion showed hypointensity on T1-weighted and hyperintensity on T2-weighted images. A more detailed anatomical relationship of the cyst to the gall bladder and the biliary tracts was shown. Type 1 choledochal cyst was tentatively diagnosed.

A female infant weighing 3 890 g was delivered at 39 wk with APGAR scores of 8 and 10 at 1 and 5 min, respectively. Postnatal US at 3 d of age showed further enlargement of the cyst. At 13 d of age, the cyst was excised and a Roux-en-Y hepatico-jejunostomy was performed. Histopathological examination confirmed the diagnosis of a choledochal cyst. The infant was discharged a week later with no jaundice noted thereafter.

Figure 1 MRI performed at 26 wk' gestation using HASTE sequence. **A:** Coronal T2-weighted image showed the choledochal cyst, its tapered ends (arrows), its connection to the cystic duct (arrowhead), and its relationship to the gall bladder (G) and the liver (L); **B:** Sagittal T2-weighted image showed the posterior-inferior orientation of the choledochal cyst and its connection to the common hepatic duct (arrow).

DISCUSSION

Choledochal cysts are rare anomalies, characterized by cystic or fusiform dilatation of the intrahepatic and/or extrahepatic biliary tracts. These cysts have been classified into five major types^[9]. Cystic dilatation of the common bile duct (type 1 choledochal cyst) comprises 80-90% of the cysts. In affected newborns, about 70% had jaundice but only 25% had a palpable abdominal mass^[4]. Potential complications in untreated patients include recurrent cholangitis, pancreatitis, liver cirrhosis, portal hypertension, and malignant transformation^[10-12].

Ultrasonography is the primary imaging modality for evaluating the fetus due to its real-time display and non-invasiveness. In cases of choledochal cyst, tubular structures can be identified entering or leaving a right upper quadrant cyst^[1,2,4]. However, the choledochal cyst could be missed, if confused with the gall bladder and the umbilical vein. Other common cystic lesions, including hydronephrosis, duodenal duplication, intestinal atresia, mesenteric cyst, and ovarian cyst, may appear similar to a choledochal cyst.

Recent development of ultrafast MR imaging techniques has allowed MRI to become an important complement to US in fetal imaging^[5-8]. MRI offers superior soft tissue contrast, larger field of view, and is relatively operator independent. In our case, while the prenatal US showed a subhepatic cyst, the MRI showed additional findings of tapered ends of the cyst, its proximity to the liver hilum, its inferomedial orientation, and characteristic fluid-intensity of the cyst. Also, the relationship between the choledochal cyst, the cystic duct and the dilated gall bladder was clearly depicted. Concerning the differential diagnoses of a right upper quadrant cyst, an umbilical vein may be excluded by the lack of vascular flow void on MRI. Other common cystic lesions, including hydronephrosis, intestinal atresia, mesenteric cyst, and ovarian cyst have locations different from that of a choledochal cyst. Duodenal duplication may not be easily excluded, but it would be less likely to have tapered ends as a choledochal cyst^[13]. To our best knowledge, we found two reports of prenatal MRI investigation of choledochal cysts^[14,15]. However, the finding of tapered ends of the choledochal cyst, which may be specific to a biliary tract anomaly, was not emphasized in their reports.

In conclusion, owing to its excellent anatomical and contrast resolutions, MRI can clearly delineate a choledochal cyst and may be helpful in differential diagnosis of right upper quadrant cystic lesions. The additional information provided by prenatal MRI, which is complementary to US,

may be valuable for family counseling, and may help clinicians manage pregnancy and plan post-natal treatment earlier.

Abstract

We herein describe the case of a 27-year-old female, who presented with a large mass of the upper left abdominal cavity discovered incidentally, through an annual health examination. Preoperative studies including abdominal ultrasonography and magnetic resonance imaging were performed, but they could not accurately determine the nature of the tumor. At laparotomy, a large cystic tumor of the small bowel mesentery was found. Histopathologic examination diagnosed the tumor as a cystic lymphangioma. Although lymphangiomas are rare, especially in the abdomen of adults, they may sometimes present as acute abdomen, causing complications that require emergent surgery.

<http://www.wjgnet.com/1007-9327/11/5084.asp>

INTRODUCTION

Lymphangiomas are rare benign tumors. They are preferentially located in the head, neck, and axilla in children. However, lymphangiomas in the peritoneal cavity are extremely rare, particularly in adults. This report describes a case of an adult with a large lymphangioma of the jejunal mesentery.

CASE REPORT

A 27-year-old female was referred to us on April 10, 2003 due to an intra-abdominal mass lesion found incidentally, during her annual health examination. Recently, she had begun to experience epigastralgia and abdominal fullness

especially after having meals. Her family and medical history were unremarkable. She had no history of previous abdominal surgery. On physical examination, a soft, non-tender mass was palpated in the upper left abdomen. Auscultation of the abdomen revealed normal bowel sounds. Laboratory data including tumor markers were within normal limits. A plain film of the abdomen showed several loops of small intestine without dilatation or air-fluid level. Abdominal ultrasonography revealed a large, multilocular, cystic mass with an obscure margin. MRI of the abdomen showed a large homogeneous mass measuring 16 cm×7 cm×5 cm in size with multiple enhancement septa by contrast medium. This lesion was located at the anterior aspect of the left kidney and descending colon, causing compression and stretching of the small bowel (Figure 1). A cystic neoplasm of the mesentery was considered.

At laparotomy, a yellowish cystic tumor with soft consistency was found in the mesentery of the jejunum, about 30 cm distal to Treitz's ligament. The tumor was not adhered to the wall of the intestine or adjacent organs. No ascites was seen in the peritoneal cavity, nor was there any dilatation or inflammatory change of the intestines or mesentery. With careful dissection of the mesenteric arteries, the tumor was resected completely without resection of the intestine. The specimen consisted of one piece of cystic tumor in the mesentery measuring 15 cm×8 cm×6 cm. Macroscopically, it was yellowish in color and soft in consistency (Figure 2). Microscopically, the sections showed numerous dilated lymphatic channels of varying sizes within loose fibroconnective tissue and a few disorganized bundles of smooth muscle present in the wall of the larger channels. Immunohistochemical stains were positive for Factor VIII and actin. The same cells did not react to cytokeratin. These findings were consistent with a cystic lymphangioma (Figure 3). The patient had an uneventful postoperative course, and no evidence of recurrence, 18 mo after the operation.

Figure 1 MRI of the abdomen showing a 16 cm×7 cm×5 cm homogenous multilocular tumor with enhancement by contrast medium (A and B).

Figure 2 Surgical findings (A-C). A large cystic tumor was located in the mesentery of the jejunum, causing compression and stretching of the small

bowel. The tumor was not adhered to the small intestine.

Figure 3 Histopathological results revealed that the mesenteric tumor contained numerous dilated lymphatic lumen of varying sizes lined by attenuated endothelial cells (H&E, $\times 100$).

DISCUSSION

Lymphangiomas are uncommon and occur mainly in children; approximately 80-90% are diagnosed within the first few years of life and adult cases are rare^[1]. They are commonly found in the head, neck, and axillary region. However, isolated occurrence in the mesentery of the small intestine is encountered even less frequently, comprising less than 1% of all lymphangiomas^[2]. The most common location of such intraperitoneal lymphatic tumor appears to be the mesentery of the small bowel, accounting for 70% of all such tumors^[3,4].

The etiology of lymphangiomas is probably a congenital abnormality of the lymphatic system, causing sequestrations of lymphatic tissue during embryologic development^[2]. This theory would explain why lymphangiomas occur primarily in children. However, it is suggested that abdominal trauma, lymphatic obstruction, inflammatory process, surgery, or radiation therapy may lead to the secondary formation of such a tumor^[4,5]. Traditionally, lymphangiomas are classified as simple, cavernous, or cystic. The simple type is usually situated superficially in the skin and composed of small thin-walled lymphatic vessels. The cavernous type is composed of dilated lymphatic vessels and lymphoid stroma, and has a connection with spaces of various normal adjacent lymphatics. Lastly, the cystic type consists of lymphatic spaces of various sizes that contains fascicles of smooth muscle and collagen bundles, but has no connection with

adjacent normal lymphatics. However, cystic lymphangioma is not always clearly differentiated from cavernous type because the cystic type may also contain cavernous areas^[6].

Mesenteric lymphangiomas are usually asymptomatic until they enlarge. Abdominal pain and distention seem to be the most common symptoms, but the clinical presentation of mesenteric lymphangiomas varies^[7]. Although benign in nature, mesenteric lymphangiomas may cause significant morbidity or mortality due to their large size and critical location, when they compress the adjacent structures. In addition, complications such as secondary infection, rupture with hemorrhage, volvulus, or intestinal obstruction have all been reported^[8-11]. The ultrasonographic presentation of a mesenteric lymphangioma is described as a cystic lesion with multiple thin septa. On CT imaging, mesenteric lymphangiomas appear as a uni- or multilocular mass with enhancement of the wall and septum by contrast medium^[12]. These studies help to determine, if the tumor is cystic as well as its size and location, but they are insufficient to establish an accurate diagnosis preoperatively. One report suggested that fine needle aspiration of a milky fluid containing lymphoid cells could confirm a preoperative diagnosis of lymphangioma^[13].

Mesenteric lymphangiomas may behave in an aggressively invasive manner and grow to an enormous size. The optimal treatment is radical excision, even when asymptomatic. However, mesenteric lymphangiomas may cause complications such as infiltration of the intestine, or involvement of the main branch of mesenteric arteries or adjacent organs that necessitate segmental resection of the intestine. Sometimes radical resection might be technically impossible^[14]. Mesenteric lymphangiomas are very rare, but they can cause acute abdomen that requires an emergent surgery. Therefore, they should be included in the differential diagnosis of acute abdomen.

Abstract

Angiolipoma, a common benign tumor mostly seen in the subcutaneous tissue, is a rare pathological condition in the gastrointestinal tract that is usually diagnosed postoperatively. In this case report, an angiolipoma was diagnosed preoperatively by imaging (including CT scans, abdominal echo, barium enema, and colonoscopy). This pathology was confirmed postoperatively. Computed tomography scan, abdominal echo, and barium enema images were presented.

INTRODUCTION

Angiolipoma is a benign tumor, commonly occurring in the subcutaneous tissue and other locations, but is rarely found in the gastrointestinal tract. Histologically, it is comprised of adipose tissue and proliferative blood vessels. There have been three cases of colonic angiolipoma reported in the literature, which were all diagnosed postoperatively. This report presents the first preoperative diagnosis of colonic angiolipoma using a combination of colonoscopy, barium enema, abdominal echo, and CT scans. The diagnosis was confirmed postoperatively.

CASE REPORT

A 70-year-old male presented to Changhua Christian Hospital with a history of passing bloody stool once a day for 3 d. Additionally, the patient experienced abdominal distension and cramping pain for the past 7 d. Physical examination revealed mild anemia, abdominal obesity, no palpable mass,

and hyperactive bowel sounds. Full blood count showed Hb of 10.7 and Hct of 31.5, but otherwise normal results. Colonoscopy found a submucosal tumor with ulceration of 5 cm located in the transverse colon obstructing the lumen almost completely. Contrast barium enema also revealed a 5-cm submucosal tumor located at the transverse colon with nearly complete obstruction of the lumen (Figure 1). Abdominal echo showed a centrally hyperechoic dense tumor surrounded by hypoechoic density (Figure 2). Pre-contrast enhancement CT scan showed a mixed low density and isodensity tumor (Figure 3). Post-contrast enhancement scans showed a high-density tumor with a fat component (Figure 4).

Based on the combined findings, it was diagnosed as an angiolipoma and surgical segmental resection was carried out. The resected tumor was encapsulated by a thin layer of connective tissue arising from the submucosa. Histology showed that the tumor was comprised of mature adipose tissue and proliferative blood vessels (Figure 5). After 2 years of follow-up, the patient did not have any abnormalities.

Figure 1 Submucosal tumor with nearly complete obstruction shown in barium enema.

Figure 2 Centrally hyperechoic dense tumor surrounded by hypoechoic density shown by abdominal echo.

Figure 3 Mixed low and isodensity tumor shown by pre-contrast CT scan.

Figure 4 High-density tumor with a fat component shown by post-contrast CT.

Figure 5 Photomicrograph of resection specimen.

DISCUSSION

Angioliipoma was first described in 1912 by Bowen. In 1960, Howard and Helwig described its clinical pathological characteristics, which are different from those of lipoma^[1]. Since then, angioliipoma has been regarded as a new entity. Angioliipoma is an encapsulated, subcutaneous tumor commonly occurring in young adults. It usually occurs in multiple locations on both the arms and trunk^[2,3]. Angioliipoma is usually painful. Histologically it is comprised of mature adipose tissue and proliferative vascular tissues. It can be classified as predominantly lipomatous- or angiomatous-type, based on the ratio of adipose tissue and vascular tissue composition.

A search of the current literature revealed only seven cases of angioliipoma in the gastrointestinal tract. Of these,

three cases had angioliipoma in the stomach^[4-6]. One angioliipoma was in the small intestine^[7] and three were reported to be in the colon^[8-10]. Two of the colonic angioliipomas were located at the ileocecal valve. One case had intussusception originally thought to be due to malignant tumor. Thus, the author emphasizes using histological pathology to diagnose this condition^[8]. In another case, the patient had right lower quadrant abdomen. Laparoscopy-assisted ileocecostomy is selected to remove the tumor^[9]. In the third case, the patient was asymptomatic, but had positive occult blood on routine medical examination. Double-contrast barium enema showed angioliipoma in the sigmoid colon, which was resected by colonoscopic polypectomy. The patient in this case report had lower gastrointestinal tract bleeding. Preoperative imaging allowed the diagnosis of angioliipoma, which was removed by segmentectomy.

None of the seven patients with gastrointestinal tract angioliipoma had preoperative abdominal echogram. Because the composition of angioliipoma can range from predominantly lipomatous to angiomatous type, echogram can vary from hyperechoic to hypoechoic density. In 1998, Mintz and Mengoni^[11] used sonography to diagnose breast angioliipoma, which showed homogeneously hyperechoic density under echogram. In this case report, the tumor was between the two types of angioliipoma, showing hyperechoic density centrally and hypoechoic density peripherally.

Computed tomography scan pattern depends on the composition of fat in the tumor. It can vary from a lipomatous type of tumor comprised totally of fat without post-contrast enhancement, which was thought to be lipoma preoperatively^[12], to a low-fat containing tumor, showing numerous small round density enhancements^[13,14]. In this case, diffuse high-density enhancement post-contrast was observed around the adipose tissue, which is consistent with the histological pattern.

In our case, contrast barium enema confirmed the submucosal tumor. Sonography showed hyperechoic density surrounded by hypoechoic density, and CT showed post-contrast fat containing mass, surrounded by high-density enhancement. The combination of these results allowed the tumor to be differentiated from lipoma, thus it could be diagnosed as an angioliipoma preoperatively.

Although management of colonic lipoma or angioliipoma is still controversial, endoscopic resection should not be used on sessile or broad-based lesions because of increased risk of bleeding or perforation. Urgent treatment should be given to those with intussusception, obstruction, or bleeding, as in this case. The tumor should then be removed, while the patient is still in the hospital. However, both lipoma and angioliipoma are benign tumors, thus colonic resection should be kept to a minimum when the tumor is removed^[9,10]. In this case, a small segmental resection was performed.
