At the initial assessment, the medical history, past history, life-style (smoking, drinking, coffee consumption) and baseline demographic data, hematologic and serum biochemistry were recorded. A physical examination will be by performed.

### Treatment medications

**Drug information:** Topaal<sup>®</sup> contains 200 mg alginic acid, 30 mg colloidal aluminum hydroxide and 40 mg magnesium hydrocarbonate per tablet. Nacid<sup>®</sup> contains 500 mg Mg<sub>6</sub>Al<sub>2</sub>(OH)<sub>16</sub>CO<sub>3</sub> 4H<sub>2</sub>O per tablet.

Topaal<sup>®</sup> is an alginate-based raft-forming formulation<sup>[16]</sup>

**Table 2** The change in the VAS of heartburn (ITT population)

Unit: cm	Topaal Mean (SE)	Nacid Mean (SE)	Difference	P
Visit 1/baseline				
Observed data	7.52 (0.42)	7.43 (0.45)	0.09	0.8774
Visit 3/week 7				
Observed data	1.15 (0.30)	3.06 (0.34)	-1.91	<0.0001
Change from baseline	-6.39 (0.28)	-4.44 (0.31)	-1.95	<0.0001

ANCOVA model: Dependent variable = (baseline value) + treatment.

comprising alginic acid and antacid. In the presence of gastric acid, alginates precipitate and form a gel<sup>[16]</sup>. The bicarbonate inside is converted to carbon dioxide, which is then entrapped within the gel precipitate, converting it into foams floating on the surface of the gastric contents, much like a raft on water. The “raft” can act as a physical barrier to reduce reflux episodes.

### Statistical analysis

Comparisons of frequency employed the  $\chi^2$  test of Fisher's exact test, the test of linear trend for the ordered variables, Student's *t*-test of non-parametric Wilcoxon test, and variance analysis for the repeated VAS, all adjusted to the initial values. Two-sample *t* test was used to compare the continuous data such as height, weight, age, the number of heartburn, the number of sleeping disturbance etc., and the 95%CI for the difference were calculated. Statistical significance was assessed at the 5% level. The principle analysis was carried out on an ITT basis.

A listing of patients with withdrawal as well as those with premature termination of study drugs, along with the date and reasons for the termination was provided.

## RESULTS

### Disposition of patients

The trial was conducted from June 10, 2003 (first patient screened) to December 24, 2004 (last patient completed). Figure 1 gives an overview of the disposition of the patient population for the treatment phases. A total of 134 patients were randomized to the treatment phase; 69 patients were randomized to Topaal<sup>®</sup> and 65 were randomized to Nacid<sup>®</sup>. Of the 134 randomized patients, a total of 112 patients completed the study.

The safety population included 134 patients (69 in the Topaal<sup>®</sup> group, 65 in the Nacid<sup>®</sup> group) who received at least one dose of study medication after randomization. The ITT population consisted of all randomized subjects who received at least one dose of study treatment and who had a baseline and at least one post-baseline efficacy assessment. Three of the sixty-five patients in Nacid<sup>®</sup> group dropped out for safety/efficacy reason; six in Nacid<sup>®</sup> group and four in the Topaal<sup>®</sup> group dropped out for administrative reasons (e.g., lost to follow-up, moved out of the area, etc.). Therefore, 65 patients in the Topaal<sup>®</sup> group and 56 patients in the Nacid<sup>®</sup> group were included in the efficacy population.

### Demographics and baseline characteristics

Demographic characteristics of randomized subjects in each treatment group are summarized in Table 1. The mean age of the patients in both treatment groups was about 42 years. There were more female than male patients participating in the study in both groups. Although there were significant differences in gender ratio between groups (36.23% male in the Topaal<sup>®</sup> group *vs* 16.92% male in the Nacid<sup>®</sup> group), no evidence showed that the gender difference would have an effect on the pharmacokinetics or efficacy of study medications. The body mass index (BMI), pulse rate and diastolic blood pressure were all comparable between treatment groups. Although the patients in the Topaal<sup>®</sup> group seem to have higher systolic blood pressure than the patients in the Nacid<sup>®</sup> group (119.7  $\pm$  14.2 mmHg in the Topaal<sup>®</sup> group *vs* 114.1  $\pm$  13.5 mmHg in the Nacid<sup>®</sup> group), those values were all clinically considered to be within normal limits.

Table 1 also summarizes patients' baseline symptom analysis that included VAS, the reflux symptoms from doctor's point of view, and quality of life from doctor's point of view. More than 56% of the patients in each group had suffered from the reflux symptom of heartburn for at least 6-12 mo. No significant difference in other characteristics including life-style was noted. The baseline characteristics of all randomized subjects were compatible between the two treatment groups, and no statistically significant difference between treatment groups was detected, except for the mean VAS of epigastric pain ( $P = 0.0218$ ).

### EFFICACY EVALUATION

The change in the severity of the heartburn as evaluated using a VAS at 6 wk, using LOCF data from ITT population, was the primary efficacy endpoint of this trial. At

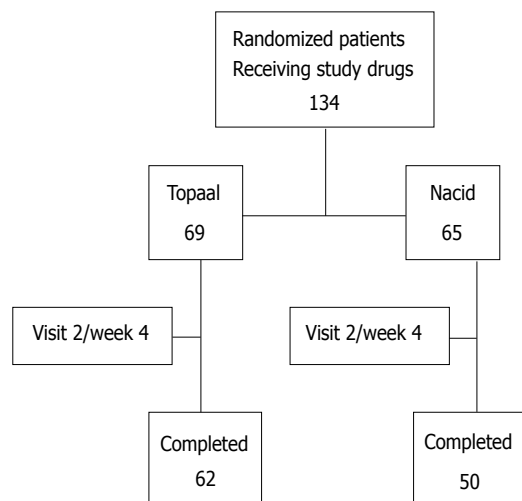

baseline, the mean VAS of heartburn was 7.52 cm in the Topaal<sup>®</sup> group and 7.43 cm in the Nacid<sup>®</sup> group. At the end of the 6-week treatment period, the mean VAS of heartburn was 1.20 cm in the Topaal<sup>®</sup> group and 3.36 cm in the Nacid<sup>®</sup> group. Overall, the mean change from baseline in VAS of heartburn over the 6-weeks treatment was -6.29 cm (-6.85 to -5.74 cm) in the Topaal<sup>®</sup> group, and -4.11 cm in the Nacid<sup>®</sup> group (-4.71 to -3.51 cm). The mean difference between the two treatment groups was -2.19 cm (-3.01 to -1.37 cm) and the difference was statistically significant ( $P < 0.0001$ ) as detailed in Table 2.

The first secondary endpoint was to compare the change of VAS at 3 wk (Table 3). There were significant differences in the mean change of VAS for heartburn ( $P = 0.0016$ ), regurgitation ( $P = 0.0006$ ), vomiting ( $P = 0.0373$ ) and belching ( $P < 0.0001$ ). No significant differences were found in the mean change of VAS for nausea, epigastric pain, and dysphagia. The results suggested that Topaal<sup>®</sup> is superior to Nacid<sup>®</sup> for the improvement of the predominant symptoms of ENRD such as heartburn and regurgitation.

The second secondary endpoint was to compare the frequency of heartburn, regurgitation, pain, and sleep disturbance according to patient's diary every week during treatment period (Figure 2). Patients taking Topaal<sup>®</sup> showed consistently and significantly lower frequency of heartburn than those who were taking Nacid<sup>®</sup> throughout the entire 6-week period ( $P = 0.0015$ ). Patients taking Topaal<sup>®</sup> also had fewer episodes of pain than those who were taking Nacid<sup>®</sup> from the 4<sup>th</sup> week to the end of the study. Both Topaal<sup>®</sup> and Nacid<sup>®</sup> decreased the frequency of regurgitation during the study period compared to baseline, but the difference between treatments was not significant. No difference was observed for the change in the frequency of sleeping disturbance.

The third and fourth secondary endpoints were to

**Figure 1** Disposition of patients in the treatment phase.

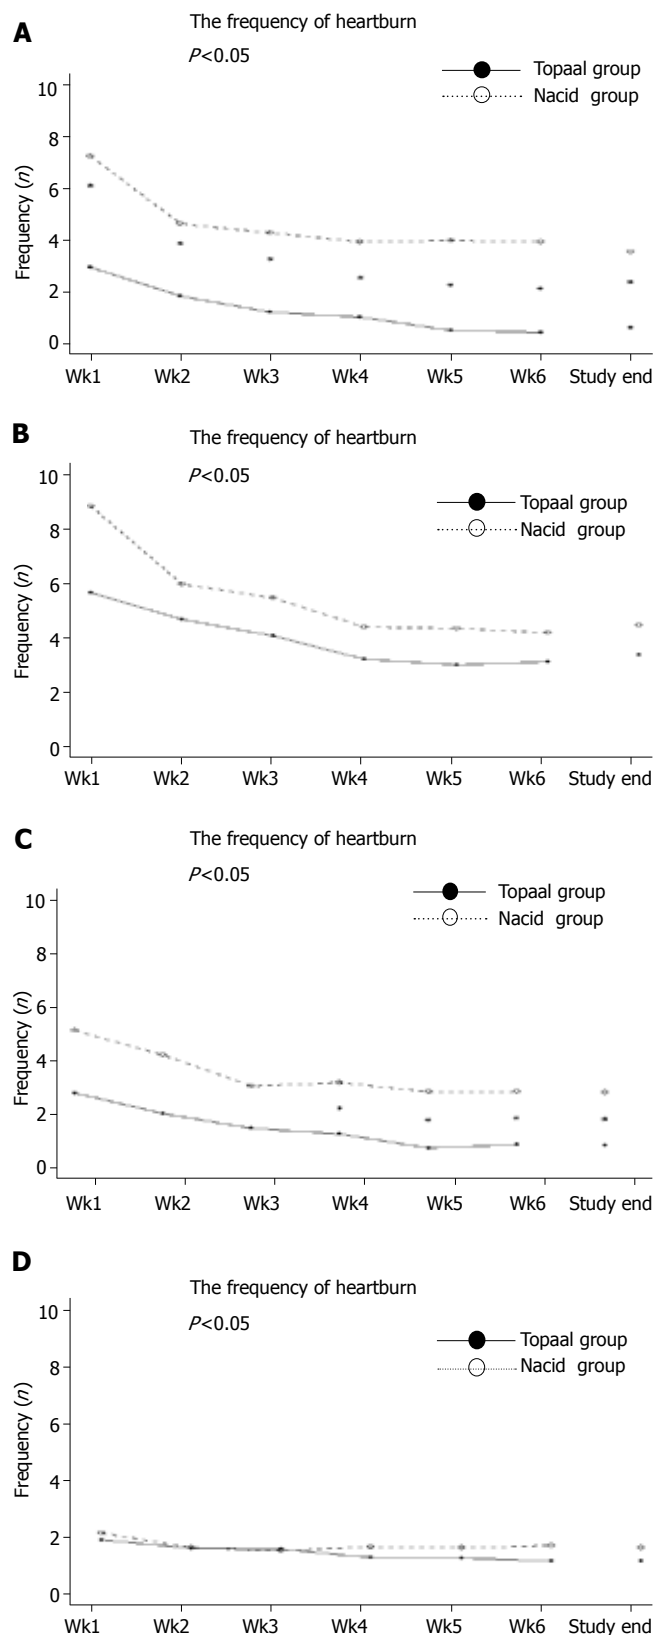

compare the change in the severity of the reflux symptoms (Table 4) and the quality of life from doctor's point of view (Table 5). There were no significant differences in the severity of the reflux symptoms and the quality of life from doctor's point of view at baseline. At the end of the 6-week treatment period, patients who took Topaal® showed better improvement in the severity of heartburn ( $P=0.0020$ ), regurgitation ( $P=0.0081$ ), vomiting ( $P=0.0182$ ), and belching ( $P=0.0018$ ) than those who took Nacid®. There were no significant differences in the improvement of dysphagia ( $P=0.7551$ ), epigastric pain ( $P=0.2648$ ), and nausea ( $P=0.0577$ ).

For the quality of life from doctor's point of view, there were no significant differences at baseline. About 50% of the patients in each group suffered from moderate reflux symptoms interfering with the quality of life before the treatment. At the end of treatment period, patients who took Topaal® had greater alleviations of symptoms ( $P<0.0001$ ) and greater reduction of symptom score from baseline ( $P<0.0001$ ) than those who took Nacid®. The results suggested that Topaal is more efficient than Nacid for improving the quality of life of ENRD patients.

### SAFETY EVALUATION

The ADRs of Topaal® and Nacid® were the safety end-points of this trial. In this analysis, data from the Topaal® group were compared with data from Nacid® group.

Adverse events which occurred during the course of the study were recorded. Seven patients had at least one adverse event after entering the study, three (4.35%) patients in the Topaal® group and four (6.15%) patients in the Nacid® group. The most commonly adverse events reported by Topaal®-treated patients were constipation (2 patients, 2.90%). For Nacid® group, two patients (3.08%) experienced diarrhea and two patients (3.08%) reported constipation. No statistical significant difference was found between the two groups in the incidence of adverse event. All of these adverse events were resolved and graded as mild or moderate in severity. None of them was considered by the investigators to be definitely related to treatment. No dosage modification of medication was

**Figure 2** The frequency of heartburn, regurgitation, pain and sleep disturbance.

applied for the three adverse events in Topaal®-treated patients, whereas two of the four adverse events in Nacid®-treated patients led to dose reduction of medication. No serious adverse event was reported during the entire study period. The results suggest that Topaal® had a similar safety profile as Nacid®.

## DISCUSSION

The design of this study is based on symptomatic analysis. This is an original, though not blind, trial that compares the therapeutic effects of an alginate to an antacid on ENRD patients. For the best interest of the patients, a placebo-controlled study was not considered in our design. The investigators' and the patients' assessments of efficacy over the study period are similar and in favor of the alginate. After 6-week treatment, Topaal<sup>®</sup> was found to be more effective than Nacid<sup>®</sup> in reducing VAS of five symptoms including heartburn, regurgitation, vomiting,

and belching in patients with ERND. Patients in Topaal<sup>®</sup> group had fewer episodes of heartburn and epigastric pain at the end of treatment. Also, from doctor's point of view, Topaal<sup>®</sup> is more effective than Nacid<sup>®</sup> in reducing symptoms of reflux and in improving the quality of life in patients with ERND. Our result is consistent with that of other trials that compared the effects of alginate-based formulation with antacids on patients with reflux esophagitis<sup>[17]</sup> and volunteers<sup>[18]</sup>, though their patient groups were more heterogeneous.

According to our data, the symptom-relieving effect in the Topaal<sup>®</sup> group was faster than that of Nacid<sup>®</sup>. Patients

<sup>1</sup>Mantel-Henszel  $\chi^2$  test.

taking Topaal<sup>®</sup> had major reduction in VAS scores of heartburn and regurgitation from the 1<sup>st</sup> week of study, and patients taking Nacid<sup>®</sup> did not feel the difference in symptoms until the 2<sup>nd</sup> week of study. Alginic acid is different from antacids in the mechanism of efficacy. The alginic acid is converted to sodium alginate by the small amount of antacid contained in the formulation. This salt floats atop of the esophagogastric junction and provides a barrier when reflux occurs<sup>[16]</sup>. The physical property of Topaal<sup>®</sup> might explain why it worked faster and better than Nacid<sup>®</sup> in relieving the symptoms of reflux. On the other hand, our results did not show differences in improving the sleep disturbance in patients of both groups. We did not assess the incidence of night refluxer or asthma in the enrolled patients who might have greater disturbance in sleeping. We deduced that the incidence of night refluxer maybe low because both study groups had low VAS score of sleep disturbance at the baseline. Though alginate products have been shown to be effective in relieving symptoms of reflux, it has not been proved that the alginates promote healing of erosive esophagitis. In this way, alginate-based formulation is a reasonable option for patients with ENRD.

Goves *et al*<sup>[19]</sup> compared the effectiveness of PPI, with alginates for heartburn relief in dyspeptic patients. This design showed that PPI was superior to alginates in relieving the heartburn of patients at 4 weeks of treatment. This is not surprising for they included patients with severe esophagitis, and omeprazole had the dramatic antisecretory actions. However, considering ENRD is a protracted disease, alginate is a better option for long-term and on-demand use in these patients for cost-effectiveness. For adverse events, Topaal<sup>®</sup> group had a compatible safety profile as Nacid<sup>®</sup> group. Alginates have been shown to be safe when used in pregnant women<sup>[20]</sup> and children<sup>[21]</sup>. In our patients treated with Topaal<sup>®</sup>, the most commonly

reported adverse events were constipation (2.90%).

In conclusion, Topaal<sup>®</sup> is more effective than Nacid<sup>®</sup> in symptomatic control of patient with ENRD. For the safety measures, the results supported that Topaal<sup>®</sup> group had a compatible safety profile as Nacid<sup>®</sup> group.

## Abstract

**AIM:** To summarize our experience with the application of self-expanding metallic stent (SEMS) in the management of acute left-sided colorectal malignant obstruction.

**METHODS:** A retrospective chart review of all patients undergoing placement of SEMS between April 2000 and January 2004 was performed.

**RESULTS:** Insertion of SEMS was attempted in 26 patients under fluoroscopic guidance with occasional endoscopic assistance. The sites of lesions were located in splenic flexure of two patients, left colon of seven patients, sigmoid colon of eight patients and rectum of nine patients. The intended uses of SEMS were for palliation in 7 patients and as a bridge to elective surgery in 19 patients. In the latter group, placement of SEMS allowed for preoperative systemic and bowel preparation and the following one-stage anastomosis. Successful stent placement was achieved in 22 (85%) of the 26 patients. The clinical bowel obstruction resolved 24 hours after successful stent placement in 21 (95%) patients. Three SEMS-related minor complications occurred, two stents migrated and one caused anal pain.

**CONCLUSION:** SEMS represents an effective and safe tool in the management of acute malignant colorectal obstruction. As a bridge to surgery, SEMS can provide time for systematic support and bowel preparation and obviate the need for fecal diversion or on-table lavage. As a palliative measure, SEMS can eliminate the need for emergent colostomy.

## INTRODUCTION

Acute left-sided colorectal malignant obstruction represents a frequent surgical emergency. It is the first symptom in approximately 15-20% of colorectal cancers<sup>[1-2]</sup>. Single-stage surgery (subtotal colectomy with primary anastomosis or partial colectomy with intraoperative lavage) appears to be gaining acceptance as a good therapeutic option in such cases. However, this treatment option is not feasible in all patients, and it is often necessary to use a two-stage procedure (Hartmann's procedure) or to perform permanent colostomy in advanced stages of the disease<sup>[3]</sup>. Smothers *et al.*<sup>[4]</sup> found that the overall surgical morbidity and mortality are significantly higher in patients with colon cancer undergoing emergency surgery than in those undergoing selective surgery. Some other factors such as advanced age as well as stage and volume of the disease are closely correlated with emergency surgery, and emergency surgery has a strong independent negative influence on immediate surgical morbidity and mortality. If emergency surgery could be transferred to elective surgery after a simple effective therapy, complications would be significantly decreased in patients with acute left-sided colorectal malignant obstruction.

SEMS<sup>[5-7]</sup> has been used to relieve obstruction in different situations. Application of metallic stents in the treatment of acute malignant colonic obstruction was first reported by Dohmoto<sup>[8]</sup> in 1991 and has become a promising treatment option, though the number of reported cases is only about 600 in the world<sup>[9,10]</sup>. Placement of SEMS across the obstructing lesion can relieve obstructive symptoms and avoid emergency surgery. In most cases, a radical colectomy with primary

**Figure 1** Endoscopic view of partially expanded stent immediately after the stent placement.

anastomosis can be subsequently performed in 6-9 days. Colostomy is the only surgical option, and implantation of stent is the best final palliative treatment in some cases with advanced stages of the disease<sup>[11-23]</sup>. This report describes the experience with the application of SEMS in the management of acute malignant left-sided colorectal obstruction.

## MATERIALS AND METHODS

### Patients

All patients had clinical symptoms and signs of acute bowel obstruction. From April 2000 to January 2004, a total of 26 patients (16 men, 10 women; mean age: 63.23 years; range: 38-85 years) were selected to receive decompressive therapy by implanting SEMS. Patient selection criteria included the site of obstruction from the middle rectum to the descending colon and absence of bowel necrosis and perforation. Patients with more proximal obstructions were excluded on the basis of poor site accessibility and low emergency surgery risk. Age, general condition, and tumor stage were not used as exclusion criteria.

All patients received plain radiography of the abdomen and emergency contrast-enhanced computed tomography. The sites of obstruction were located in rectum of nine patients, sigmoid colon of eight patients, descending colon of seven patients and splenic flexure of two patients. Informed consent was obtained from all patients or from their relatives after the risks and benefits of treatment were fully explained.

### Procedure

All procedures were performed at the interventional radiology by endoscopy (Figure 1) and fluoroscopy (Figure 2). Neither analgesia nor sedation was administered during the procedure. There was no routine administration of antibiotics.

Once the guide wire passed through the lesion, the catheter was advanced to the most proximal point, and contrast medium was injected to evaluate tumor length and exclude the possibility of perforation. The superstiff 0.038-inch guide wire was then inserted, and a stent was placed using the delivery system under fluoroscopic control (Figure 2).

Several silver clips were clipped around the lesion during colonoscopy. Then the guide wire inserted through the lesion under direct vision was confirmed to arrive at the splenic flexure under fluoroscopic monitor.

The stent used in all patients was esophageal endoprosthesis (Nanjing Microinvasive Corporation, China), 20 or 25 mm in diameter and 70-100 mm in length. After the placement of the stent, a catheter was inserted over the superstiff guide wire until the tip projected a few centimeters beyond the stent. Contrast medium was injected to ensure that the stent was placed properly across the tumor and to assess the stent patency.

When one stent was not long enough to span the lesion, a second stent was inserted to overlap the first. Balloon dilation was not performed in any of the patients either before or after the implantation of the stent.

Patients were transferred to the surgical ward for observation after the procedure. Abdominal plain radiography was performed to assess the stent expansion and patency as well as possible complications in 24 h. Once symptoms of obstruction remitted, further tumor staging and clinical evaluation were carried out to determine which patients should receive selective surgical therapy and which patients should undergo stent implantation as the definitive palliative treatment.

## RESULTS

Successful stent placement was achieved in 22 (85%) of the 26 patients. The procedure could not be completed in four patients. The sites of lesions were located in splenic flexure of one patient, descending colon of two patients and sigmoid colon of one patient. The successful rate was 50% in splenic flexure (1/2), 71% in the descending colon (5/7), 89% in sigmoid colon (7/8), 100% in rectum (9/9), respectively. The obstruction could not be relieved in three patients even though the guide wire and catheter were advanced successfully to the edge of the lesion. Though the guide wire was successfully advanced proximally, the stent could not be implanted in the remaining patient because of the tortuosity of the rectosigmoid region. Emergency laparotomy was performed in these four patients, and colostomy or Hartmann's procedure was completed.

A total of 25 self-expanding metallic stents were implanted. One stent was placed in 19 patients and two stents in 3 patients. The mean fluoroscopy time of the procedure was 46 min (range: 15-120 min).

The clinical bowel obstruction resolved in 21 patients (21/22, 95%) within 24 h after successful stent placement, with expansion and patency observable in all radiographic films. Clinical failure occurred in one patient and symptom of incomplete obstruction persisted for 24 h following the successful placement of SEMS. Emergency laparotomy revealed vegetable residues proximal to the lesion and Hartmann's procedure was performed. Complications of SEMS placement occurred in three patients. Stent migration occurred in two patients after obstruction disappeared but no re-obstruction was found after stent migration. Mild anal pain persisted for one month in the remaining one because the stent was close to the anus. The

**Figure 2** Good patency of the second stent coaxially placed covering the entire malignant stricture (A), a patent and nearly full in the upper rectum (B), SEMS with a waist shape in descending colon cancer (C), SEMS bridging the descending colon (D), a patent stent after SEMS placement in the rectum (E) and a bent stent in sigmoid cancer (F).

pain resolved after analgesic was administered (Table 1).

### Surgery

Patients with operable colorectal carcinoma were considered as candidates for selective surgery. The mean time between stent placement and surgery was  $8 \pm 3$  days (range: 5-11 days). These patients underwent adequate bowel preparation and adjuvant systematic therapy. The stent did not interfere with or prolong the surgery in any of these patients. The stents were fully expanded as well as in good position and afforded sufficient tumoral coverage (except for two patients with stent migration) and adequate cleaning of the colon in all patients during surgical exploration. Left colectomy, sigmoidectomy, and (low) anterior resection were performed in five patients, respectively.

### Palliation

Stent placement was considered as the definitive palliative treatment of colonic obstruction in seven patients. Lesions were located at the sigmoid of three patients and rectum of four patients. Two patients suffered from gastric carcinoma with sigmoid or rectal seeding and three patients had primary sigmoid or rectal carcinomas with inoperable liver metastases. One patient with sigmoid carcinoma failed in stenting and underwent Hartmann's procedure. The other six patients received adjuvant chemotherapy, or radiation therapy, or both.

## DISCUSSION

Usually, it is not difficult to detect acute left-sided colorectal obstruction by abdominal radiography. CT can help find the site and etiology of colon stenosis and the nature of acute colonic occlusion. Barium enema for the diagnosis and treatment of colonic obstruction is not recommended when doctors plan to implant SEMS<sup>[12]</sup>.

SEMS for colorectal obstruction was performed in the past either under radiological or endoscopic control. We introduced the guide wire under radiological and

endoscopic guidance in most patients. The guide wire could be inserted under direct vision, radiation exposure could be reduced, and biopsies for histology could be taken during the procedure.

Endoscopic placement of SEMS is advantageous over radiological placement because the accessibility to colorectal tumor sites is greater and stents can directly pass through the working channel of the endoscope<sup>[13]</sup>. These advantages are especially obvious when the obstruction is proximal to the rectosigmoid. De Gregorio *et al.*<sup>[14]</sup> have reported that the guide wire cannot be progressed under fluoroscopic guidance but reaches the neoplastic stricture under endoscopic guidance. Interventional radiologists are much more experienced in passing the guide wires through obstructive lesions and deploying SEMS<sup>[12,13]</sup>. In our study, fluoroscopy in combination with endoscopy improved SEMS deployment. Even then, stent was still rather difficult to implant in the descending colon and splenic flexure compared with that in the rectum and sigmoid (6/9, 67%; 16/17, 94%;  $P < 0.05$ ).

We treated 26 patients with acute malignant colorectal obstruction with SEMS placement with a successful rate of 85% (22/26). Only one patient (5%, 1/22) failed to relieve obstruction due to vegetable residues. If we had used colonoscopy to detect and get out the vegetable residues, the patient could have the obstruction relieved and emergency colostomy could not have been performed (Hartmann's procedure). After successful stent placement and proper bowel preparation, 15 patients achieved elective radical colorectal surgery and anastomosis without severe complication. Six patients with inoperable malignancy obviated emergency colostomy after successful stent placement. Although 85% of successful stent placement was a little lower than 90-95% of some foreign reports, we believe that success rate of SEMS placement would be further increased with more refined Chinese instruments and improved manipulation skill.

It was reported that SEMS placement can be used as a palliative treatment for colonic obstruction. In Cristina's study, in 17 (of 43) patients with Dukes D tumor (40%),

Table 1 Details of patients with colorectal obstruction after SEMS placement

Patient No. (gender/ age yr)	Diagnosis	Site of obstruction	Nature of treatment	Stent insertion	Stent number	Subsequent treatment	Complication
1 (F/45)	Primary Ca descending	Splenic flexure	Temporizing	Failed	-	Colostomy	No
2 (F/48)	Primary Ca rectum, ascites, liver metastasis	Middle rectum	Palliative	Successful	2	Chemo- therapy	No

16 (M/40)	Primary Ca rectum	Upper rectum	Temporizing	Successful	1	LAR	No
17 (M/72)	Primary Ca descending	Descending	Temporizing	Successful	1	Hartmann	Food residue obstruction
18 (F/79)	Primary Ca rectum Liver metastasis	Middle rectum	Palliative	Successful	1	Chemotherapy	No
19 (M/45)	Primary Ca descending	Descending	Temporizing	Successful	1	Left colectomy	No
20 (M/85)	Primary Ca descending	Descending	Temporizing	Successful	1	Left colectomy	No
21 (M/41)	Gastric Ca rectum seeding	Rectum	Palliative	Successful	1	Chemo- therapy	No
22 (M/69)	Primary Ca descending	Descending	Temporizing	Failed	-	Hartmann	No
23 (M/74)	Primary Ca sigmoid	Sigmoid	Temporizing	Successful	1	Sigmoidectomy	No
24 (M/85)	Primary Ca sigmoid	Sigmoid	Temporizing	Successful	1	Sigmoidectomy	No
25 (M/75)	Primary Ca sigmoid	Sigmoid	Temporizing	Successful	1	Sigmoidectomy	No
26 (F/67)	Primary Ca sigmoid	Sigmoid	Temporizing	Successful	1	Sigmoidectomy	No

the stent was considered as a definitive palliative treatment. In only one case the abdominal computed tomography scan failed to detect peritoneal implants of tumor, and the metastatic disease was identified at the time of laparotomy. As a result, 17 (94%) out of 18 unnecessary operations were avoided<sup>[24]</sup>.

It was also reported that patients who were not operated have a shorter hospital stay and lower incidence of stoma after SEMS placement<sup>[25]</sup>.

Binkert *et al.*<sup>[26]</sup> showed that SEMS placement can

reduce the cost due to a shorter hospital stay and a lower complication rate. Morino *et al.*<sup>[27]</sup> have proposed a new minimally invasive therapeutic strategy for the management of acute malignant colonic obstructions: emergency endoscopic stenting followed by elective laparoscopic one-stage resection. They reported that four patients with malignant colonic obstruction had an immediate restored bowel functions after SEMS deployment within a period that varied from 4 to 5 days, then underwent a one-stage laparoscopic resection and were discharged 5-7 days later

without any complications.

Preoperative stent insertion for obstructive colorectal cancer can result in satisfactory postoperative outcome with good prognoses<sup>[28]</sup>. Perforation is the most severe complication of SEMS placement. Neoplastic strictures of the colon are generally soft. Acute neoplastic occlusion may be caused by neoplastic edema or stool residue or both. If the guide wire can be passed through neoplastic strictures, stent placement without balloon dilation should be easy for experienced physicians. The incidence of perforation was 2% (12/493) in the non-balloon dilatation group and 10% (10/105) in the dilatation group, suggesting that balloon dilation should not be recommended<sup>[9]</sup>.

Some minor SEMS-placement-related complications including stent migration, mild bleeding, pain, and reobstruction may occur. Stent migration occurred in two patients of our group possibly due to abated edema and/or inadequate stent. Because of the limited cases and short survival time, we did not find reobstruction.

In conclusion, colorectal stenting procedure is effective and safe and can be used for acute left-sided colorectal malignant obstruction both as a temporary relief before selective resection and as a definitive treatment in palliative cases.

## Abstract

**AIM:** To objectively evaluate the effect of TJ-68 on colonic spasms during colonoscopy.

**METHODS:** One hundred and one patients subjected to screening colonoscopy were randomly assigned to two groups: TJ-68 in 51 subjects and saline as the control in 50. The endoscope was inserted into the sigmoid colon, then a spastic region was identified and the tip of the colonoscope was positioned at a distance of about 10 mm from the spastic region. The endoscopic view was recorded before and after direct spraying of the TJ-68 solution or warm saline. The intraluminal area of the spastic region was serially measured using a computer image analyzer and expressed as pixel counts. The area under the curve (AUC) was calculated from the pixel curve. Statistical significance was assessed by Wilcoxon's test and Mann-Whitney *U* test.

**RESULTS:** The mean AUC of the spastic region before and after TJ-68 spraying was 29 128 and 121 943 pixels, respectively, while with saline, it was 31 635 pixels and 48 617 pixels, respectively. Thus, the AUC significantly increased after TJ-68 spraying compared with the spraying of saline ( $P < 0.001$ ).

**CONCLUSION:** Direct spraying of TJ-68 on the colonic mucosa suppressed colonic spasm and it may be useful during colonoscopy when anticholinergic agents are contraindicated.

## INTRODUCTION

In colonoscopy, it is often difficult to insert the endoscope and observation tends to be hampered because of colonic spasms. In patients with colonic spasm sometimes excess air is used to get a good view of the colonic mucosa causing discomfort and pain in the patient, and resulting in an unsuccessful colonoscopy.

Hyoscine *n*-butyl bromide (Hyoscine) is usually and widely used as an antispasmodic agent in colonoscopy and it is administered by intramuscular or intravenous injection. However, systemic use of Hyoscine sometimes causes many adverse reactions; namely palpitation, dry mouth, urinary retention, orthostatic hypotension, anaphylactic reactions, and temporary visual impairment. Hyoscine, in addition, often causes serious complications in patients with heart disease and it is contraindicated in such cases. For this reason, a safer means to obtain the necessary antispasmodic effect is required for colonoscopy. In this regard, peppermint oil and warm water have been investigated by directly spraying them onto the colonic wall, however, there are some limitations for their clinical use<sup>[1,2]</sup>.

Shakuyaku-kanzo-to (TJ-68), a Chinese herbal medicine, is traditionally used in China and Japan, to treat patients with convulsions, spasms, a pain in the limb, etc. Recently, the analgesic and sedative effects of TJ-68 as a premedication have been reported in endoscopy<sup>[3]</sup>. Although the antispasmodic effects of TJ-68 during barium enema examination was studied, the usefulness of TJ-68 as an antispasmodic agent in colonoscopy has not been examined<sup>[4]</sup>.

The aim of this study was to objectively evaluate

**Table 1** Background characteristics of the patients

the antispasmodic effect of TJ-68 by direct intraluminal spraying of TJ-68 solution during colonoscopy.

## MATERIALS AND METHODS

### Patients

A total of 531 patients were registered for endoscopy between July 2002 and March 2004. Exclusion criteria were as follows: suspected intestinal bleeding, severe abdominal pain accompanied by acute colitis and inflammatory bowel disease, history of abdominal surgery, and habitual user of drugs which may affect bowel motility. Of these, 110 patients who fulfilled the eligibility criteria were allocated at random to either the TJ-68 group or the control (saline) group. Of them, 9 patients - 5 in the TJ-68 group and 4 in the control group - were excluded from this study: due to loss of sight of the endoscopic view because of influx of residual irrigation solution from the oral side. The background characteristics of all the subjects are shown in Table 1. There was no significant difference in gender, mean age, or the reason for colonoscopy between the two groups.

### Methods

This study was a prospective, randomized trial performed from July 2002 to March 2004 to compare the effects of TJ-68 solution (Tsumura Co., Tokyo, Japan) with those of saline, administered by intraluminal spraying on a colonic spastic area during colonoscopy. Colonoscopy was performed by one endoscopist (MA) using a standard colonoscope (CF-Q240I; Olympus Optical Co., Ltd, Tokyo). All patients were given a routine bowel preparation including 59 g of magnesium citrate in 250 mL (Magcorol P, Horii Pharmaceutical Ind., Ltd, Osaka, Japan) on the day before the procedure and ingestion of 2 L of a balanced solution of electrolytes with 137.155 g of polyethyleneglycol (Niflec, Ajinomoto Pharma Co., Ltd, Tokyo) before the procedure. The TJ-68 solution contained; 0.5 g of TSUMURA Shakuyaku-kanzo-to

**Figure 1** Illustration of the procedure (A) and actual endoscopic image (B). A distance of about 10 mm was kept between the spastic region (arrow head) and the tip of the colonoscope. The distance was objectively measured using a wire (arrow) which was inserted through the working channel.

Extract Granules for Ethical Use dissolved in 50 mL saline ( $10^{-2}$  g/mL) at 36 °C. Normal saline was also prepared at 36 °C. In our experimental observations, we found that this concentration of TJ-68 solution significantly relaxed guinea pig colonic smooth muscle (unpublished), therefore we used TJ-68 at this concentration in the present study. During the procedure, we did not use any sedative agents.

With the patient in the left decubitus position, the endoscope was advanced to about 20-25 cm from the anal canal into the sigmoid colon and then, a spastic region was identified. With the tip of the colonoscope positioned at about 10 mm from the surface of the spastic area, endoscopic views were recorded for 6 min on digital videotape before and after spraying TJ-68 solution or saline through a working channel. During the examination, no air was used. Distance between the region and the tip of the endoscope was confirmed regularly using a measured guide-wire (Figure 1).

Informed consent was obtained from all the patients and the protocol was reviewed and approved by the Institutional Review Board of our hospital.

### Measurement of the intraluminal spastic area

On the personal computer (VAIO PCG-GR5F, Sony), 12 spot images (3.0, 2.5, 2.0, 1.5, 1.0, and 0.5 min before and after spraying the solution) were captured every 30 s to assess luminal changes using a computer software (DVgate Still, Sony) from the recorded digital videotapes. The intraluminal spastic area was measured using a computer image analyzer (Adobe Photoshop 7.0, Adobe Systems Co., San Jose, CA, USA) and expressed as pixel counts (Figure 2). Then the mean pixel counts were used to construct a pixel curve in each group. The mean area under the curve (AUC) was calculated from the pixel curve obtained before and after spraying the TJ-68 solution or saline in each group.

### Statistical analysis

Normally distributed continuous data are presented as the mean plus standard deviation and differences between the

**Figure 2** The white broken line demarcates the intraluminal spastic region and the area of the region was measured using a computer image analyzer (\*).

**Table 2** Comparison of the mean AUC between the TJ-68 and control groups before and after spraying of TJ-68 or saline

	Mean AUC (pixels × min)	
	Before	After
TJ-68	29 127 <sup>1</sup>	121 942 <sup>b,d</sup>
Control	31 635	4 8617 <sup>2</sup>

<sup>1</sup>NS vs control (Mann-Whitney U test), <sup>b</sup> $P < 0.001$  vs before (Wilcoxon's test),

<sup>d</sup> $P < 0.001$  vs control after (Mann-Whitney U test), <sup>2</sup>NS vs before (Wilcoxon's test).

**Figure 3** Endoscopic view in the TJ-68 group. Serial endoscopic views of the spastic region at the sigmoid colon before and after spraying of the TJ-68 solution are shown (A-F). The white broken line demarcates the area of the spastic region. The spastic region started to relax 0.5 min after spraying of the TJ-68 solution and remained open for 3 min.

groups were evaluated by Student's *t* test. Categorical data were compared with the  $\chi^2$  test and Fisher's exact test.

Wilcoxon's test was used to compare the AUCs before and after spraying the TJ-68 solution or saline in each group. Mann-Whitney *U* test was used to compare the AUCs before or after spraying, A *P* value of  $< 0.01$  was considered statistically significant. Data were analyzed using a statistical software package (Stat Mate III, ATMS Co., Ltd, Tokyo).

## RESULTS

Representative endoscopic photographs of the spastic area in the sigmoid colon taken from one patient in each group before and after spraying of TJ-68 solution and normal saline are shown in Figures 3 and 4.

### Antispasmodic effects of the TJ-68 solution

The mean changes of intraluminal spastic area before and after spraying of the agents are shown in Figure 5. In the TJ-68 group, the intraluminal area varied from 8 954 to 13 181 pixels at each point during 3 min before spraying, showing no difference, but after spraying, an obvious increase was observed. The intraluminal area rapidly increased 1 min after spraying and the mean area 3 min after it was 56 063 pixels. The mean AUC before and after TJ-68 spraying was 29 127 and 121 942 pixels/min,

respectively, showing significant difference ( $P < 0.001$ ).

The mean intraluminal spastic area in the control group varied from 10 696 to 15 246 pixels at each point during 3 min before spraying, showing no difference. Spraying of saline did not significantly affect the mean intraluminal spastic area, and there was no significant increase of the mean AUC after spraying: 31 635 and 48 617 pixels/min, respectively. Thus, the AUC significantly increased after TJ-68 spraying compared with the spraying of saline ( $P < 0.001$ , Table 2).

No complication was encountered in this study.

## DISCUSSION

The TJ-68 solution caused the relaxation of the spastic colonic region as early as 0.5 min after spraying, and the relaxation was maintained for 3 min, or more. This phenomenon was sought to be as the local effects of the TJ-68 on the colonic wall. While in the control, the spastic area did not increase significantly after spraying of saline. Judging from the increase in the number of pixels in the control, this increase seemed to be simply attributable to a volume load. While the increase in the TJ-68 group was attributable to the active relaxing effect of TJ-68, and relaxation of the spastic area was observed within 0.5 min after spraying. We think there is a close correlation between the intraluminal movement of a spastic region

**Figure 4** Endoscopic view in the normal saline group. Serial endoscopic views of the spastic region at the sigmoid colon before and after spraying of normal saline are shown (A-F). The white broken line demarcates the area of the spastic region. The region showed only little relaxation and did not open significantly during the study.

**Figure 5** Pixel curve and area under the curve (AUC) before and after the administration of the TJ-68 solution and normal saline. The graph shows the mean AUC of the two groups before and after spraying of TJ-68 (\*) and normal saline (\*\*): the mean AUC in the TJ-68 group increased significantly from 29 127 to 121 942 pixels, but the control group did not show a significant increase.

and the intraluminal pressure. Actually, Asao *et al.* reported that the changes of the endoscopic findings by the intraluminal administration of the peppermint oil solution is correlated well with the intraluminal pressure measured by the Barostat<sup>[1]</sup>. Based on this phenomenon, we assume that TJ-68 will permeate and be absorbed through the colonic wall, and directly act on the myenteric plexus.

Since TJ-68 solution has a light brown color, blinding of the study is thought to be difficult in the strict sense. But selection of the patients or assignment of the agents to each group was performed in a strictly blind fashion. Furthermore, as relaxation of spasms was evaluated objectively, we believe that discernment of the agent after spraying had only a little influence on the outcome.

TJ-68 is an extract powder composed of Shakuyaku (*Paeoniae radix*) and Kanzo (*Glycyrrhizae radix*) combined at a ratio (g) of 1:1. TJ-68 inhibits acetylcholine-induced contraction and the contractile machinery of the smooth

muscle by Kanzo and that of neurogenic contraction by Shakuyaku in guinea pig ileum<sup>[5,6]</sup>. Furthermore, the two components of TJ-68 exert synergistic effects<sup>[5]</sup>.

Peppermint oil and warm water were examined in a way, analogous to our study, for their relaxing effect on the colonic wall after direct spraying<sup>[1,2]</sup>. Peppermint oil was reported to have a direct relaxing effect on the colonic smooth muscle when used in endoscopy or barium enema examination<sup>[1,7,8]</sup>. We also studied the antispasmodic effect of peppermint oil on the colonic wall using our method of evaluation and compared it to that of TJ-68. As a result, TJ-68 was found to have an antispasmodic effect similar or stronger than that of peppermint oil (data not shown). Peppermint oil is not sold via a regular medical distribution system. Furthermore, it is sometimes difficult to get and prepare the peppermint oil solution<sup>[1]</sup>. On the other hand, TJ-68 is available in any medical facility in Japan, because it is a regular medical prescription sold via a regular medical distribution system. In addition, the preparation of TJ-68 solution is easy and simple: only mixing TJ-68 with saline.

Church reported that warm water irrigation significantly reduced discomfort related to colonoscopy, but there was no difference regarding insertion time, total duration of colonoscopy, dose of midazolam administered, or frequency of severe spasm. Decrease of the patient's discomfort was the parameter of effectiveness of warm water in their study. But their study had some limitations because they used a sedation drug (midazolam) as premedication<sup>[2]</sup>. Moreover, warm water has basically no direct antispasmodic effect on the colonic wall.

Colonic relaxation by antispasmodic drugs has been evaluated using various parameters: pain score, colonic spasm score, difficulty of the procedure scored by an endoscopist, and dose of drugs used for sedation<sup>[1,2,9-14]</sup>. However, these parameters were considered to be subjective, moreover, most studies were performed under sedation<sup>[2,9-14]</sup>. In the present study, we evaluated colonic relaxation quantitatively. In addition, we did not use any drugs to induce sedation. But the clinical relevance of TJ-68 in colonoscopy should be investigated in subsequent studies, although our preliminary study showed significant

differences between the TJ-68 group and the control group in total colonoscopy time and patient's pain score (data not shown).

Contrary to the ordinary use of antispasmodic agents, we sprayed TJ-68 directly on the colonic wall. Antispasmodic agents are generally administered intramuscularly or intravenously, but systemic administration sometimes prevents the insertion of the endoscope because the muscle tone of the colon is excessively reduced<sup>[13]</sup>. Colonoscopy is difficult to carry out at the spastic region but not every spasm affects the examination. Ideally, the examiner expects to obtain effective relaxation in only some of them. In this respect, direct spraying of the antispasmodic agent TJ-68 is one of the meaningful ways of administration. But administration of this agent by spraying differed from the common oral administration. Since this was the first attempt to spray this agent directly onto the colonic wall, we had essentially no idea about the adverse effects. But the total amount of TJ-68 used in this study was no more than 2.5 g, that is to say one third of the oral dose: 7.5 g. In fact, no complication was experienced in this study.

In this study, we set the concentration of the TJ-68 solution at  $10^{-2}$  mg/dL. Significant relaxation of the guinea pig distal colon was obtained with this concentration of TJ-68 in our preliminary experimental study; thus this concentration was thought to be effective enough to depress colonic spasm during colonoscopy.

In conclusion, we objectively demonstrated that intraluminal direct spraying of TJ-68 solution on the colonic mucosa could lower the colonic spasm. Additional studies are needed to determine the time required for colonoscopy or to assess patient's compliance before TJ-68 can be definitively recommended as a useful antispasmodic agent for use in colonoscopy.

## Abstract

**AIM:** To investigate the surgical treatment of patients with intermediate-terminal pancreatic cancer.

**METHODS:** A retrospective analysis was made of the clinical data of 163 patients with intermediate-terminal pancreatic cancer who were surgically treated between August 1994 and August 2003.

**RESULTS:** A total of 149 patients underwent palliative surgery. The mortality rate of those who underwent cholecystojejunostomy alone was 14.2%, the icterus or cholangitis recurrence rate was 61.9% with an average survival period of 7.1 mo. The mortality rate for those who received hepatic duct-jejunostomy (HDJS) was 5.7%, the icterus or cholangitis recurrence rate was 6.8% with an average survival period of 7.1 mo. But 31.8% of the patients developed duodenum obstruction within 6 mo after the surgery, six of seven patients with severe pain were given peri-abdominal aorta injection with absolute alcohol and their pain was alleviated. The other patients underwent percutaneous transhepatic cholangial drainage (PTCD) and their icterus index returned to normal level within 40 d with an average survival period of 7.5 mo.

**CONCLUSION:** Roux-en-y HDJS combined with prophylactic gastrojejunostomy is recommended for patients with intermediate-terminal pancreatic cancer, and biliary prosthesis can partly relieve biliary obstruction in a short term.

## INTRODUCTION

Generally speaking, not until the patient has developed terminal pancreatic cancer can a diagnosis be made. The non-clinical survival time is not more than half a year and the post-operative survival rate is still lower than 20%<sup>[1]</sup>. At present, surgical treatment is the most common method for patients with intermediate-terminal pancreatic cancer. The hospital received 163 patients with intermediate-terminal pancreatic cancer between August 1994 and August 2003.

## MATERIALS AND METHODS

### Basic data

A total of 107 male and 56 female patients aged 28-79 years with an average age of 43.2 years were included in the study.

### Clinical symptoms

The most common symptoms were upper-abdominal spasm and gastric bulge without any motivation. One hundred and twelve patients (68.7%) suffered from anorexia and only 51 patients (31.2%) developed icterus. Among these 163 patients, 124 were not in the hospital until they had icterus. All the 163 patients were diagnosed as intermediate-terminal pancreatic cancer by B-ultrasound, CT, MR and explorative operation.

### Operation procedures

One hundred and forty-nine patients underwent palliative surgery. Among them, 28 patients received cholecystojejunostomy (CJS), 53 hepatic duct-jejunostomy (HDJS) and 61 biliary enteric anastomosis plus gastrojejunostomy, 7 terminal peri-abdominal aorta injection with absolute alcohol. The other 14 patients did not undergo surgery but biliary prosthesis placement for PTCD.

## RESULTS

Among the 149 patients who received palliative surgical treatment, 10 died 30 days after the surgery. The estimated

mortality rate of those who underwent CJS, HDJS, and biliary enteric anastomosis plus gastrojejunostomy was 14.2% (4/28), 5.7% (3/53), and 4.9% (3/61), respectively. Among the 21 patients who underwent CJS, 13 developed icterus or cholangitis, the recurrence rate was 61.9% with an average survival period of 7.1 mo. Among the 44 patients who underwent hepaticocholedochojejunostomy, only 3 developed icterus or cholangitis, the recurrence rate was 6.8% with an average survival period of 10.3 mo. Likewise, the recurrence rate of icterus or cholangitis among the 51 patients who underwent biliary enteric anastomosis plus gastrojejunostomy was 5.9% (3/51), but the average survival period was 13.9 mo.

Fourteen out of the forty-four patients who were followed up after HDJS developed duodenal obstruction, the rate was 31.8%. Among them, 11 patients who received an additional gastrojejunostomy did not survive for more than 3 mo. Fifty-one patients who received biliary enteric anastomosis in combination with gastrojejunostomy needed no additional surgical treatment for duodenal obstruction.

The icterus index of 14 patients became normal within 40 days after biliary prosthesis placement, 11 followed-up cases had an average survival period of 7.5 mo. Seven patients were given absolute alcohol injection and their pain was relieved with an average survival period of 3.4 mo.

## DISCUSSION

### ***Surgical treatment of patients with intermediate-terminal pancreatic cancer***

Most patients have already developed terminal pancreatic cancer when a confirmed diagnosis was made. Palliative surgical treatment is the first choice of treatment for these patients. The purposes of the treatment are to relieve biliary tract and duodenal obstruction, to control and alleviate the symptoms in order to prolong the post-operative survival time<sup>[2]</sup>.

Common treatment approaches for intermediate-terminal pancreatic cancer include biliary enteric anastomosis, biliary prosthesis, and Roux-Y loop, etc. Biliary enteric anastomosis including cholecystojejunostomy (CJS) and HDJS is the most commonly used approach today.

CJS is easy to perform and does not incur severe trauma, but has certain disadvantages. For example, 10% of the patients have the opening of the cystic duct on the lower part of the common bile duct, thus the patients are liable to develop duodenal obstruction due to tumors and metastatic lymph nodes. Since it is difficult to make sure whether the bile duct is blocked during surgery, cholangiography is needed, thus the surgery is time-consuming. Such a surgery is inappropriate in the presence of cholecystitis, gallstones or ill-function. Post-operative icterus and cholangitis are more likely to occur. Rosemurgy *et al*<sup>[4]</sup> demonstrated that the success rate of CJS and HDJS to relieve icterus is 89% and 97%, respectively, and the incidence rate of icterus and cholangitis is 20% and 8%, respectively. In our patients, the recurrence rate of icterus or cholangitis was 61.9%, much higher than that after HDJS (6.8%). The average survival period (7.1 mo) was far lower than that after HDJS (10.3 mo), suggesting that HDJS is a

better therapeutic approach than CJS.

It was reported that Roux-en-Capital Y anastomosis can be performed for patients with pancreatic cancer, because the suturing position of HDJS is relatively higher and less liable to be assaulted by tumors and suturing point is larger<sup>[4]</sup>. On the other hand, Roux-en-y anastomosis can significantly reduce the incidence of reflux cholangitis and hepatitis<sup>[6]</sup>. In addition, HDJS incurs direct hepatobiliary drainage, thus effectively reducing the incidence of icterus as well as the recurrence rate of icterus or cholangitis<sup>[6]</sup>. We believe that it is suitable for patients whose potential survival period is relatively longer. However, the common bile duct in the superior border of the duodenum should be cut off leaving the distal end blocked, and the proximal end should be anastomosed to the duodenum to avoid tumor-incurred icterus. The common bile duct should be sutured with only one layer of stitches and the passage above the stitches should be unobstructed.

Biliary tract drainage or percutaneous transhepatic biliary drainage (PTBD) can effectively reduce icterus. But loss of bile seriously unbalances the electrolytes.

### ***Pre-emptive application of gastrojejunostomy and pancreaticojejunostomy***

One of the most important problems in the treatment of pancreatic cancer is whether the surgeon can resolve the duodenal obstruction during the biliary enteric looping process. It was reported that apart from direct tumor assaults, gastrointestinal dysfunction caused by visceral nerves is also a reason for duodenal obstruction<sup>[7]</sup>. When duodenal obstruction occurs, GJS cannot improve the gastric drainage<sup>[8]</sup>. Therefore pre-emptive GJS is not recommended. But 13-34% of the patients undergoing biliary enteric anastomosis suffer from duodenal obstruction<sup>[6]</sup>. An additional GJS can prolong the survival period significantly but does not increase the mortality rate. Gastrointestinal conduction can assist the treatment by providing nutrition. The data in this series also showed that compared to biliary enteric anastomosis only, biliary enteric anastomosis combined with GJS resulted in a sharp increase of mortality rate but prolonged the post-operative survival time. Besides, biliary enteric anastomosis alone tended to cause duodenal obstruction, while the combination reduced its occurrence, suggesting that GJS should be normally accepted as an approach for unresectable patients. This is because terminal pancreatic cancer patients are more liable to develop duodenal obstruction, the mortality rate is high and the survival time is short when GJS is performed after the diagnosis of duodenal obstruction. Biliary enteric anastomosis in combination with GJS does not increase the risk of operative deaths, while prolongs the post-operative survival time.

It was reported that biliary enteric anastomosis combined with pancreatoenterostomy can prevent duodenal or pancreatic obstruction, relieve the accompanying pain caused by dilation and indigestion, and reduce the mortality rate<sup>[10]</sup>. We believe that patients with apparent indigestive symptoms and pancreatic dilation confirmed by ultrasonic and CT examinations can undergo pancreatoenterostomy, since three anastomoses can be made in one surgery and there is no need for subsequent surgeries.

### Application of biliary prosthesis

Biliary prosthesis is an advanced technique and the trauma caused by it is small, thus, patients can recover quickly. In our study, 14 patients with terminal pancreatic cancer underwent PTCD and their icterus index returned to normal level within 40 d, suggesting that this operation is applicable to terminal pancreatic cancer patients or very old patients in bad physical conditions. But this new technique leads to some complications, such as a relatively high failure rate and no long-term effect on reducing icterus. It is suggested that surgical treatment can reduce icterus in patients and prolong post-surgery survival<sup>[2]</sup>.

### Treatment of persistent pain

Persistent pain is one of the major symptoms of intermediate-terminal pancreatic cancer patients, 30-40% of the patients suffer from abdominal and back pain due to cancer-afflicting post-peritoneum nerve plexus or chronic pancreatitis. In addition, high pressure of biliary tract, cholangitis or incomplete duodenal obstruction can also be a factor. Pain can be relieved or partly relieved by biliary or gastrointestinal by-pass surgery for some patients. But they have no effect on pain caused by post-peritoneum nerve plexus affliction. Some scholars have proposed that using a dose of 20 mL alcohol (50%) or lidocaine (1%) as a blockage injection to post-peritoneum nerve plexus near the tumor can alleviate or prevent late pancreatic cancer-related pain.

### Abstract

**AIM:** To study the changes of portal blood flow in congestive heart failure.

**METHODS:** We studied the congestion index (CI) and portal vein pulsatility index (PI) in patients with varied degrees of congestive heart failure using ultrasonic Doppler. Ten patients with mean right atrial pressure (RA)  $< 10$  mmHg were classified as group 1 and the remaining 10 patients with RA  $\geq 10$  mmHg as group 2.

**RESULTS:** There were no difference on cardiac index (HI,  $P=0.28$ ), aortic pressure (AO,  $P=0.78$ ), left ventricular end-diastolic pressure (LVED,  $P=0.06$ ), maximum portal blood velocity ( $V_{\max}$ ,  $P=0.17$ ), mean portal blood velocity ( $V_{\text{mean}}$ ,  $P=0.15$ ) and portal blood flow volume (PBF,  $P=0.95$ ) between the two groups. Group 2 patients had higher pulmonary wedge pressure (PW,  $29.9 \pm 9.3$  mmHg vs  $14.6 \pm 7.3$  mmHg,  $P=0.002$ ), pulmonary arterial pressure (PA,  $46.3 \pm 13.2$  mmHg vs  $25.0 \pm 8.2$  mmHg,  $P=0.004$ ), RA ( $17.5 \pm 5.7$  mmHg vs  $4.7 \pm 2.4$  mmHg,  $P<0.001$ ), right ventricular end-diastolic pressure (RVED,  $18.3 \pm 5.6$  mmHg vs  $6.4 \pm 2.7$  mmHg,  $P<0.001$ ), CI ( $8.7 \pm 2.4$  vs  $5.8 \pm 1.2$ ,  $P=0.03$ ), and PI ( $87.8 \pm 32.3\%$  vs  $27.0 \pm 7.4\%$ ,  $P<0.001$ ) than Group 1. CI was correlated with PI ( $P<0.001$ ), PW ( $P<0.001$ ), PA ( $P<0.001$ ), RA ( $P=0.043$ ), RVED ( $P=0.005$ ), HI ( $P<0.001$ ), AO ( $P<0.001$ ), CO ( $P<0.001$ ), LVED ( $P<0.001$ ),  $V_{\max}$  ( $P<0.001$ ),  $V_{\text{mean}}$  ( $P<0.001$ ), cross-sectional area of the main portal vein ( $P<0.001$ ) and PBF ( $P<0.001$ ). CI could be as high as 8.3 in patients with RA  $< 10$  mmHg and as low as 5.9 in those with RA  $\geq 10$  mmHg.

### INTRODUCTION

Congestive heart failure increases the pressure in the inferior vena cava and hepatic veins<sup>[1-3]</sup>. Ultrasonic Doppler is a safe and non-invasive method in the clinical evaluation of portal blood flow and portal hypertension<sup>[4-9]</sup>. Portal vein pulsatility index (PI) is calculated by the percentage of peak-to-peak maximum portal vein velocities<sup>[10,11]</sup>. In our earlier study<sup>[10]</sup>, patients with right heart failure developed transient reduced, stagnant, or hepatofugal portal blood flow with increased PI. However, the change of portal flow pattern and PI did not correlate with left heart function.

The congestion index (CI) has been used to assess the pathophysiological hemodynamics of portal venous system in different forms of liver diseases<sup>[12-14]</sup>. The correlation between CI and PI and the role of CI on right heart function remain uncertain. Therefore, we have studied the changes of portal blood flow in patients with different degrees of heart failure using non-invasive ultrasonic Doppler<sup>[15,16]</sup>.

### MATERIALS AND METHODS

We studied the portal hemodynamic profiles in 20 patients (9 males, 11 females, mean age:  $49 \pm 13$  years) who received cardiac and Swan-Ganz catheterizations for cardiovascular disorders (16 rheumatic heart disease, 4 atherosclerotic heart disease) to compare with 20 healthy volunteers. All

RA, right atrial pressure; HI, cardiac index; LVED, left ventricular end-diastolic pressure; AO, mean aortic pressure; PW, pulmonary wedge pressure; PA, mean pulmonary arterial pressure; RA, mean right atrial pressure; RVED, right ventricular end-diastolic pressure.

patients had medications affecting the hemodynamics such as isosorbide dinitrate and furosemide, and their systemic blood pressure and body weight were measured to be constant for more than 48 h prior to the study. Patients with fever, infection, and shock were excluded. All patients had no history of liver disease, alcoholism or other metabolic disorders. None of the patients received transfusion, inotropic agents or dopamine. All patients had an abdominal sonography to exclude chronic liver disease or splenomegaly. Patients with severe orthopnea were excluded if they were not able to remain in the supine position for the study of ultrasonic Doppler.

Cardiac profiles including cardiac index (HI), left ventricular end-diastolic pressure (LVED), mean aortic pressure (AO), pulmonary wedge pressure (PW), mean pulmonary arterial pressure (PA), mean right atrial pressure (RA), right ventricular end-diastolic pressure (RVED) were recorded during the cardiac and Swan-Ganz catheterizations. Ten patients with RA < 10 mmHg (range: 1-7 mmHg) and without right heart failure were classified as Group 1. The remaining 10 patients with right heart failure and RA  $\geq$  10 mmHg (range: 10-28 mmHg) were classified as Group 2.

The portal profiles were assessed using an ultrasonic Doppler composed of a real-time mechanical sector scanner and a 3.5 MHz pulsed Doppler flowmetry (Aloka Echo Camera, Model SSD-1700, Tokyo) within 12 h of cardiac catheterization. After more than 8 h of fasting, portal pro-

files were measured in the supine position for more than 30 min. Portal blood flow was measured from the main portal vein at a site just entering or immediately after entering the liver with the patient in expiratory apnea. The flow angle formed by the directions of ultrasonic beam and the portal blood flow below 55 degree was corrected to minimize the variation caused by the angle of insonation. The Doppler signal could be viewed on the screen and heard through a build-in speaker. Portal blood flow was measured by the same physician (SY) to avoid interobserver variation<sup>[17]</sup>.

For each measurement, at least three reproducible spectral patterns were recorded for calculating the mean maximum portal blood velocity ( $V_{\max}$ ) over a period of 3-4 s to ensure accuracy. Mean portal blood velocity ( $V_{\text{mean}}$ ) was calculated by the equation " $V_{\text{mean}}=0.57 \times V_{\max}$ " as described by Moriyasu *et al.*<sup>[18]</sup>. Cross-sectional area (area, cm<sup>2</sup>) was also recorded at the site of main portal vein where portal blood velocity was measured. The direction of portal blood velocity, antegrade or retrograde, was also measured. Positive velocity indicates the blood flow towards the transducer and vice versa. Portal blood flow volume (PBF, mL/min) was obtained by the equation " $\text{PBF}=\text{area} \times V_{\text{mean}} \times 60$ "<sup>[17,18]</sup>. PI was calculated by the equation " $\text{PI}=(\text{maximum}-\text{minimum})/\text{maximum frequency shift}$ "<sup>[6,15,17]</sup>. The waveforms were classified as continuous (PI  $\leq$  40%), decreased (PI 41-99%), stagnant (PI = 100%), or retrograde (PI > 100%)<sup>[10,19]</sup>. CI was calculated by the equation " $\text{CI}=(\text{area}/V_{\text{mean}}) \times 100$ "<sup>[12]</sup>.

The study protocol was reviewed and approved by the Institutional Review Committee under the guidelines of the 1975 Declaration of Helsinki. Statistical analysis was performed using Student's *t*-test and simple linear regression as appropriate.

## RESULTS

The biochemical data of the 20 patients (Table 1) showed total protein 7.0  $\pm$  0.8 g/dL, albumin 3.8  $\pm$  0.5 g/dL, total bilirubin 1.3  $\pm$  0.6 mg/dL, AST 49.5  $\pm$  23.4 IU/L, ALT 28.7  $\pm$  10.4 IU/L, and prolonged prothrombin time 1.2  $\pm$  0.9 s (normal < 3 s). All controls had normal blood chemistries. Gender ( $P=0.11$ ), age ( $P=0.61$ ), total protein ( $P=0.85$ ), albumin ( $P=0.62$ ), total bilirubin ( $P=0.83$ ), ALT ( $P=0.15$ ) and prolonged prothrombin time ( $P=0.19$ ) were not different between those with RA < 10 mmHg and  $\geq$  10 mmHg. Patients with RA  $\geq$  10 mmHg had higher serum AST activities ( $P=0.009$ ), which were related to ischemic hepatitis.

HI (3.0  $\pm$  0.9 L/min/m<sup>2</sup>; range: 1.6-5.3 L/min/m<sup>2</sup> vs 2.4  $\pm$  0.4 L/min/m<sup>2</sup>; range: 1.7-2.9 L/min/m<sup>2</sup>;  $P=0.28$ ), AO (89.0  $\pm$  9.6 mmHg; range: 85-100 mmHg vs 87.3  $\pm$  12.8 mmHg; range: 65-115 mmHg;  $P=0.78$ ), and LVED (12.2  $\pm$  6.7; range: 4-34 mmHg vs 22.1  $\pm$  10.9 mmHg; range: 10-40 mmHg;  $P=0.06$ ) were not statistically different between Groups 1 and 2 (Table 2).

For all Group 1 patients, the values of PW (mean: 14.6  $\pm$  5.6 mmHg; range: 5-28 mmHg), PA (mean: 25.0  $\pm$  6.8 mmHg; range: 16-38 mmHg), RA (mean: 4.7  $\pm$  2.1 mmHg; range: 1-7 mmHg), and RVED (mean: 6.4  $\pm$  2.1 mmHg; range: 2-11 mmHg) were within the nor-

**Figure 1** Portal vein pulsatility index of patients with right atrial pressure < 10 mmHg (Group 1) and ≥ 10 mmHg (Group 2).

$V_{\max}$ (cm/s)	20.1 ± 3.1	24.5 ± 3.9	21.1 ± 4.8
$V_{\text{mean}}$ (cm/s)	11.2 ± 1.9	14.0 ± 2.3	12.0 ± 2.7
Area (cm <sup>2</sup> )	1.01 ± 0.20	0.80 ± 0.13	0.96 ± 0.13
PBF (mL/min)	685 ± 136	678 ± 172	672 ± 162
PI (%)	23.3 ± 6.3	27.0 ± 7.4	87.8 ± 32.3 <sup>b</sup>
Congestion index	5.3 ± 1.2	5.8 ± 1.2	8.7 ± 2.4 <sup>1</sup>

RA, right atrial pressure;  $V_{\max}$ , maximum portal velocity;  $V_{\text{mean}}$ , mean portal velocity; PBF, portal blood flow; PI, portal vein pulsatility index. <sup>b</sup> $P < 0.001$ , <sup>1</sup> $P = 0.03$  vs controls and RA ≤ 10 mmHg.

mal limits.

All Group 2 patients had higher PW (mean:  $29.1 \pm 7.7$  mmHg; range: 13-40 mmHg;  $P = 0.002$ ), PA (mean:  $42.4 \pm 12.0$  mmHg; range: 25-65 mmHg;  $P = 0.004$ ), RA (mean:  $16.8 \pm 4.9$  mmHg; range: 10-28 mmHg;  $P < 0.001$ ), and RVED (mean:  $17.8 \pm 4.4$  mmHg; range: 9-26 mmHg;  $P < 0.001$ ) than Group 1 patients.

The healthy controls had  $V_{\max}$   $20.1 \pm 3.1$  cm/s,  $V_{\text{mean}}$   $11.2 \pm 1.9$  cm/s, area  $1.01 \pm 0.20$  cm<sup>2</sup>, PBF  $685 \pm 136$  mL/min, PI  $23.3 \pm 6.3\%$ , and CI  $5.3 \pm 1.2$ . The mean values of  $V_{\max}$  ( $24.5 \pm 3.9$  cm/s; range 17-33 cm/s vs  $21.1 \pm 4.8$  cm/s; range 14-33 cm/s;  $P = 0.17$ ),  $V_{\text{mean}}$  ( $14.0 \pm 2.3$  cm/s; range: 9.7-18.8 cm/s vs  $12.0 \pm 2.7$  cm/s; range: 8.6-18.8 mmHg;  $P = 0.15$ ) and PBF ( $678 \pm 172$  mL/min; range: 373-1 120 mL/min vs  $672 \pm 162$  mL/min; range: 432-922 mL/min;  $P = 0.95$ ) between Groups 1 and 2 did not show any statistical difference (Table 3). Group 2 patients had a larger area of portal vein than that of Group 1 ( $0.80 \pm 0.13$  cm<sup>2</sup>; range: 0.64-1.13 cm<sup>2</sup> vs  $0.96 \pm 0.13$  cm<sup>2</sup>; range: 0.79-1.33 cm<sup>2</sup>;  $P = 0.04$ ).

All the 10 patients in Group 1 had a continuous antegrade portal flow with a mean PI  $27.0 \pm 7.4\%$  (range: 17-40%) (Figure 1). The mean PI of the 10 patients in Group 2 was  $87.8 \pm 32.2\%$  (range: 43-194%). In Group 2, all the patients had a PI > 40%. Six of them had transient reduced portal blood flow, one had stagnant flow, and

three had hepatofugal flow.

Group 2 patients (mean:  $8.7 \pm 2.4$ , range: 5.9-16.7) had a higher CI than that of Group 1 patients (mean:  $5.8 \pm 1.2$ , range: 3.9-8.3;  $P = 0.03$ ). Although Group 2 had a higher mean CI than Group 1, the CI could be as low as 5.9 in Group 2 and as high as 8.3 in Group 1 (Figure 2).

Using linear regression, CI showed a good correlation with PI ( $P < 0.001$ ), PW ( $P < 0.001$ ), PA ( $P < 0.001$ ), RA ( $P = 0.043$ ), RVED ( $P = 0.005$ ), HI ( $P < 0.001$ ), AO ( $P < 0.001$ ), CO ( $P < 0.001$ ), LVED ( $P < 0.001$ ),  $V_{\max}$  ( $P < 0.001$ ),  $V_{\text{mean}}$  ( $P < 0.001$ ), area ( $P < 0.001$ ) and PBF ( $P < 0.001$ ).

## DISCUSSION

It is well known that the passive “backward” congested liver develops into hepatomegaly, synchronous pulsation, engorged and dilated terminal hepatic veins, atrophy of hepatocytes and eventually cardiac cirrhosis. The high hepatic vein pressure can transmit through the liver to cause post-sinusoidal portal hypertension, cardiac ascites and change of portal vein flow patterns<sup>[12,13]</sup>. Therefore, the changes of portal flow may help the assessment of heart function.

Prolonged right heart failure may result in atrophy of hepatocytes and eventually cardiac cirrhosis<sup>[3]</sup>. In the present study, we have strived to exclude those patients with chronic liver disease. The abdominal sonographies showed no splenomegaly or coarse liver echogenicity and the peripheral blood showed no abnormal reduction of leukocyte, hemoglobin or platelet account, which were common in cirrhosis. Furthermore, the portal flow pattern did not show reduced fluctuation, which was common in cirrhosis with portal hypertension<sup>[4]</sup>. Our patients were not likely to develop obvious cardiac cirrhosis.

In the present study, all patients with RA ≥ 10 mmHg had a PI > 40% and all patients with RA < 10 had a PI < 40% or less. The findings were consistent with our prior study<sup>[10]</sup> that PI showed a good correlation with PW, PA, RA, and RVED. The waveform changes of portal blood flow correlate well with right heart function, and the measurement of PI change is a simple and non-

invasive method to identify right heart failure<sup>[10]</sup>. Our data also demonstrated that PI had no any correlation with HI, AO, CO, LVED,  $V_{\max}$ ,  $V_{\text{mean}}$  and PBF. Furthermore, the waveform changes of portal blood flow correlated well with right heart function; and the PI is helpful for the diagnosis of stagnant or hepatofugal portal blood flow but not by the CI<sup>[10]</sup>. Therefore, CI is better than PI in the assessment of left heart function.

In addition to the assessment of left heart function, the CI correlated with all PBF,  $V_{\max}$ ,  $V_{\text{mean}}$ , area, PI, HI, PW, PA, RA, AO, CO, LVED, and RVED. These results suggest that CI also correlates well with right heart profiles. Our findings were consistent with earlier studies<sup>[12,20,21]</sup>. However, the CI values could be as high as 8.3 in patients with RA < 10 mmHg and as low as 5.9 in those with RA ≥ 10 mmHg. If the CI value is between 5.9 and 8.3, it is difficult to predict whether or not the RA values ≥ 10 mmHg. Therefore, RI is a more significant indicator than CI in the clinical evaluation of high RA ≥ 10 mmHg.

The occurrence of congestive liver is not uncommon in patients with congestive heart failure. In addition to the occurrence of congestive hepatomegaly and dilatation of inferior vena cava and hepatic veins during abdominal sonography, the measurement of both CI and PI is helpful for the indirect non-invasive evaluation of cardiac function.

## Abstract

**AIM:** Since 1987, laparoscopic cholecystectomy (LC) has been widely used as the favored treatment for gallbladder lesions. Cholecystoenteric fistula (CF) is an uncommon complication of the gallbladder disease, which has been one of the reasons for the conversion from LC to open cholecystectomy. Here, we have reported four cases of CF managed successfully by laparoscopic approach without conversion to open cholecystectomy.

**METHODS:** During the 4-year period from 2000 to 2004, the medical records of the four patients with CF treated successfully with laparoscopic management at the Chang Gung Memorial Hospital-Taipei were retrospectively reviewed.

**RESULTS:** The study comprised two male and two female patients with ages ranging from 36 to 74 years (median: 53.5 years). All the four patients had right upper quadrant pain. Two of the four patients were detected with pneumobilia by abdominal ultrasonography. One patient was diagnosed with cholecystocolic fistula preoperatively correctly by endoscopic retrograde cholangiopancreatography and the other one was diagnosed as cholecystoduodenal fistula by magnetic resonance cholangiopancreatography. Correct preoperative diagnosis of CF was made in two of the four patients with 50% preoperative diagnostic rate. All the four patients underwent LC and closure of the fistula was carried out by using Endo-GIA successfully with uneventful postoperative courses. The hospital stay of the four patients ranged from 7 to 10 d (median, 8 d).

**CONCLUSION:** CF is a known complication of chronic gallbladder disease that is traditionally considered as a contraindication to LC. Correct preoperative diagnosis of CF demands high index of suspicion and determines the success of laparoscopic management for the subset

of patients. The difficult laparoscopic repair is safe and effective in the experienced hands of laparoscopic surgeons.

## INTRODUCTION

Since 1987, laparoscopic cholecystectomy (LC) has been the favored treatment for gallbladder lesions<sup>[1]</sup>. With experience gained from laparoscopic surgery, LC has successfully been attempted in every kind of gallbladder disease.

Cholecystoenteric fistula (CF) is an uncommon disease affecting both biliary and the gastrointestinal tracts, with reported incidences ranging from 0.15% to 5% of biliary disease<sup>[2]</sup>. Chronic cholecystitis with gallstones is the primary etiology in as many as 75% of CF patients. Cholecystoduodenal type accounts for as many as 80% of CF<sup>[3]</sup>. CF is generally considered to be a relative contraindication to LC because of the difficulties involved in its management intraoperatively<sup>[4]</sup>. Laparoscopic stapling techniques have been reported as feasible and safe methods for treating such fistula<sup>[2,3,5-7]</sup>; however, these procedures are not always performed successfully. We have reported four cases of CF managed successfully by laparoscopic approach due to the correct preoperative diagnosis and experienced laparoscopic techniques.

## MATERIALS AND METHODS

From January 2000 to December 2003, 4131 patients underwent LC for gallbladder lesions at the Department of General Surgery, Chang Gung Memorial Hospital (Taipei, Taiwan), 4 (0.1%) of them were identified as having CF. CF was defined as an abnormal communication between gallbladder and the neighboring organ. This study retrospectively reviewed the medical records of these four patients. All the patients' history was recorded and under-

**Figure 1** Procedures showing management of cholecystoenteric fistula. **A:** Identification of cholecystocolic fistula; **B:** fistula is clearly exposed; **C:** fistula tract communicating with the transverse colon is resected using an Endo-GIA device; **D:** fistula is disconnected.

went physical examination, ultrasonography (USG), or endoscopic retrograde cholangiopancreatography (ERCP), or computed tomography (CT), or magnetic resonance cholangiopancreatogram (MRCP) to establish a preoperative diagnosis. Preoperative ERCP was done routinely in patients with a history of jaundice, cholangitis or pancreatitis, patients with dilated common bile duct (CBD) displayed on abdominal USG, and patients with abnormal liver function tests. Patients with CBD stones had the stones removed endoscopically before LC. Moreover, endoscopic papillotomy (EPT) with stone retrieval and/or endonasobiliary drainage (ENBD) was performed to relieve fever, jaundice, and/or CBD stone retrieval. Data were collected on patients' age, sex, preoperative diagnoses, operative findings, operative methods, morbidity, and management.

Surgery was performed under general anesthesia using the standard four-cannula technique. The cystic artery generally was first controlled using metallic clips and divided. Moreover, the fistula was cleaned until the anatomy was clear and adequate space existed to apply an Endo-GIA (US Surgical Corp., Norwalk, CT, USA). Endo-GIA was applied via the epigastric port and then was applied to the adjacent organ end of the fistula using an applicator (Ethicon Endo-surgery). One of the blades of the Endo-GIA with the locking mechanism at its end must be seen clearly behind the fistula tract and the locking mechanism should be free of the intervening tissue to facilitate and ensure Endo-GIA locking. The gallbladder end of the fistula was ligated and simultaneously the fistula was divided (Figures 1A-1D). The gallbladder was dissected from the liver using electrocautery and removed via the umbilical or epigastric wound with an endo-bag. The postoperative course and complications were recorded. Patients were followed up in the outpatient clinic one month after the surgery and at three-monthly intervals for one year. Patients who operated more than one year before were interviewed by telephone to identify any unrecorded complications before the conclusion of the study (2004, June).

**Table 1** Demographic and laboratory data of patients with cholecystoenteric fistula

Patients	1	2	3	4
Age (yr)	63	74	36	44

## RESULTS

### Age and sex

The study comprised two male and two female patients with ages ranging from 36 to 74 years (median: 53.5 years, Table 1). All the four patients exhibited right upper quadrant pain. Table 1 summarizes the laboratory data of these four patients. All the four patients revealed anemia and leukocytosis. Only one patient revealed elevated bilirubin level due to common bile duct stone and cholangitis.

### Preoperative investigations, diagnoses, managements, and operative outcomes

Table 2 displays the preoperative investigations, diagnoses, managements, and operative outcomes. Two of the four patients were detected as gallbladder stone with pneumobilia by abdominal USG. One patient had gallbladder stone and a cholecystocolic fistula displayed by ERCP (patient 1,

Figure 2A). ERCP revealed opacification of the gallbladder and abnormal fistula communication with colon demonstrated by haustration. The other one had pneumobilia revealed by ERCP (patient 2, Figure 2B). MRCP diagnosed cholecystoduodenal fistula in one patient as demonstrated by air-fluid level and abnormal communication between gallbladder and duodenum in T2-weighted image (patient 4, Figures 2C and 2D). Correct preoperative diagnosis of CF was made in two of the four patients with 50% preoperative diagnostic rate. Operative findings revealed two cholecystoduodenal fistula (patients 2 and 4), one cholecystocolic fistula (patient 1), and one cholecystocholedochal fistula (Mirizzi syndrome type II, patient 3). All the four patients underwent LC and closure of the fistula by Endo-GIA (after successful identification of the fistula). None of the patients needed to be converted to open cholecystectomy and all the four patients had uneventful postoperative course. None of the CF was caused by malignancy. The hospital stay of the four patients ranged from 7 to 10 d (median, 8 d). Length of follow-up ranged from 8 to 48 mo (median, 36.5 mo).

## DISCUSSION

As we know, the development of a fistulous tract from the gallbladder is associated with gallstones in 90% of cases. Our study demonstrated CF was associated with gallstones in 100% cases. As seen in this study, patients with a biliary-enteric fistula are commonly presented with signs and symptoms similar to those of chronic cholecystitis. These lack specific symptoms that suggest the presence or development of a biliary-intestinal fistula. Right upper quadrant pain was present in all the CF patients, irrespective of the level of the fistula. Yamashita *et al*<sup>[8]</sup> reviewed 33 (1.3%) of 1 929 consecutive patients who had been treated for biliary tract diseases during a 12-year period had biliary fistulas. In this study, we found that the incidence of CF was only

0.1%, showing a decreased incidence these years in Asia corresponding to Western observations. CF is generally considered to be a relative contraindication to LC because of the difficulties involved in its management intraoperatively, and CF is therefore usually managed by laparotomy. This may partly explain the reason of lower incidence in this series.

Preoperative findings can be suggestive of internal biliary fistula. Pneumobilia with an atrophic gallbladder adherent to neighboring organs seen on CT scanning or USG is highly suggestive of the presence of cholecystoenteric fistula, as seen in patients 1 and 4<sup>[4]</sup>. However, the reliability of a diagnosis based on the presence or absence of pneumobilia has been questioned. Similar to the report by Yamashita *et al*<sup>[8]</sup>, ERCP was the most valuable diagnostic method for revealing the presence of biliary-enteric fistula. As seen in the patient 1, ERCP could be used to diagnose the cholecystocolic fistula by demonstration of the haustration of the colon. In this study, we were able to diagnose biliary-enteric fistula preoperatively by USG, ERCP, or MRCP, and could therefore decide on a treatment strategy preoperatively. Besides, MRCP provides another reliable diagnostic tool to clearly demonstrate the abnormal communication, especially in T2-weighted image. However, only 50% of CF was diagnosed preoperatively in our series.

Treatment advocated for CF is cholecystectomy and closure of the fistula communication. Making a knot either intracorporeally or extracorporeally is time-consuming and cannot secure this difficult fistula closure. An alternative is applying laparoscopic intracorporeal suturing interruptedly or continuously with absorbable or non-absorbable material to close the inflammatory fistula, as performed in the open procedure. However, this method is technically demanding and time-consuming<sup>[5]</sup>. Ligation of the fistula with an endoloop offers a solution to the problem. The technique for the application of an endoloop consists

**Figure 2** Detection of cholecystoenteric fistula radiologically. **A:** ERCP showing appearance of pneumobilia with common bile duct stone and a fistula between collapsed gallbladder and transverse colon; **B:** ERCP showing common bile duct stone and pneumobilia; **C:** MRCP T2-weighted image showing pneumobilia and air-fluid level within the gallbladder; **D:** MRCP T2-weighted image revealing fistula between collapsed gallbladder and duodenum.

of dividing the fistula and then applying the endoloop. This becomes more difficult if, after the fistula is divided, loss of traction on the communicating organ results in retraction of the divided fistula stump outside of the laparoscopic field of view. Although endoloop is cheaper than Endo-GIA, some new devices are needed to apply to avoid this difficulty<sup>[9]</sup>. Endo-GIA is easy to use and effective. However, the following important safety points must be noted. First, the fistula must be cleaned until the anatomy of the abnormal communication is clear and adequate space exists to apply an Endo-GIA. Second, one of the blades of the Endo-GIA with the locking mechanism at its end must be seen clearly behind the communicating organ and the locking mechanism should be free of the intervening tissue to ensure successful Endo-GIA locking. The above ensures safe closure of the fistula tract with the communicating organ. Especially, when resecting the fistula laparoscopically, it is important to ensure that part of the colonic wall is included in the excised specimen. Two reasons explain the maneuver, including that histological examination is essential to rule out colonic carcinoma at the site of fistula and unhealthy fistula or gallbladder tissue, if left on the wall of the colon, can become ischemic at a later date, thereby subsequently leading to the perforation of the wall<sup>[6]</sup>. However, no malignancy was seen in the colonic wall of the cholecystocolonic fistula in this study.

In conclusion, this report shows that with increasing experience and confidence, contraindications to laparoscopic cholecystectomy are diminishing. Laparoscopic management of CF with Endo-GIA is feasible and safe, if

CF is diagnosed correctly preoperatively and managed by experienced laparoscopic surgeons.

## Abstract

**AIM:** To examine the effect of interleukin-1-beta (IL-1 $\beta$ ) promoter region C-511T and IL-1 receptor antagonist (IL-1RN) polymorphism among the patients with chronic hepatitis B virus (HBV) infection (HCC and non-HCC).

**METHODS:** Genomic DNA from 136 Thai patients with chronic HBV infection (HCC = 46 and non-HCC = 90) and 152 healthy individuals was genotyped for IL-1 $\beta$  gene polymorphism (-511) using polymerase chain reaction with sequence specific primers (PCR-SSP). The variable number of tandem repeats (VNTR) of IL-1RN gene was assessed by a PCR-based assay. The association between these genes and status of the disease was evaluated by  $\chi^2$  test.

**RESULTS:** IL-1B-511 genotype C/C was found to be significantly different in patients with HCC when compared with healthy individuals ( $P = 0.036$ , OR = 2.29, 95%CI = 1.05-4.97) and patients without HCC ( $P = 0.036$ , OR = 2.52, 95%CI = 1.05-6.04). Analysis of allele frequencies of IL-1B-511 showed that IL-1B-511 C allele was also significantly increased in patients with HCC, compared to that in healthy control ( $P = 0.033$ , OR = 1.72, 95%CI = 1.04-2.84). However, no significant association in IL-1RN gene was found between the two groups.

**CONCLUSION:** IL-1B-511C allele, which may be associated with high IL-1B production in the liver, is a genetic marker for the development of HCC in chronic

## INTRODUCTION

Hepatitis B virus (HBV) is the most common cause of acute and chronic liver disease worldwide, especially in Asia and Africa. It has been estimated that more than 350 million people worldwide, representing more than 5% of world population are carriers of HBV infection<sup>[1,2]</sup>. Approximately 250 000 deaths occur each year resulting from fulminant hepatic failure, cirrhosis, and hepatocellular carcinoma (HCC)<sup>[3]</sup>. Family studies in China provide some evidence that the host genetic factors influence viral persistence, as a higher concordance rate has been found for HBeAg persistence in identical twins compared with non-identical twins<sup>[4]</sup>. Thus, it is conceivable that genetic difference may affect the different outcomes of patients with HBV infection. Several genetic studies on the hosts have reported that human leukocyte antigen (HLA) genes<sup>[5-7]</sup> and various cytokine genes (TNF- $\alpha$ , IFN- $\gamma$ , IL-12, IL-18, TGF- $\beta$ , IL-10, IL-4) are associated with HBV susceptibility and/or HBV persistence or disease severity<sup>[8-11]</sup>.

Interleukin-1 (IL-1) is a proinflammatory cytokine with multiple biological effects<sup>[12]</sup>. The IL-1 gene family (including IL-1A, IL-1B, and IL-1RN) on chromosome 2q13-21 encodes three proteins, which comprise the agonists IL-1 $\alpha$ , IL-1 $\beta$ , and their naturally occurring inhibitor, IL-1 receptor antagonist (IL-1RN)<sup>[12,13]</sup>. Recently, allele 2 of IL-1RN intron 2 has been reported as a resistant marker of HBV infection, suggesting the role of IL-1 polymorphisms in the pathogenesis of developing chronic hepatitis B<sup>[14]</sup>. This allele is associated with enhanced IL-1 $\beta$  production *in vitro*<sup>[15]</sup> and *in vivo*<sup>[16]</sup>. Therefore, Zhang *et al*<sup>[14]</sup> hypothesized that high production of IL-1 $\beta$  may help

increase the production of other cytokines such as IL-2, IL-6, and TNF- $\alpha$  and trigger the complex immunological processes to eliminate the virus. Interestingly, besides its major role as a proinflammatory cytokine, IL-1 $\beta$  has been implicated as an important factor for tumor growth<sup>[17-19]</sup>. Several independent lines of evidence have also suggested that genetic polymorphisms within IL-1 $\beta$  gene are associated with gastric cancer and HCC in HCV infection<sup>[20-22]</sup>.

The aim of the present study was to determine the genotype and allele frequencies of IL-1B-511 and IL-1RN VNTR polymorphisms among the Thai patients with chronic HBV infection (HCC and non-HCC) and healthy individuals to assess whether these genes are involved in chronic HBV susceptibility and/or HCC development.

## MATERIALS AND METHODS

### Subjects

One hundred and thirty-six Thai patients with chronic HBV infection were recruited into this study from Chulalongkorn Memorial Hospital. The diagnosis of chronic hepatitis B was established by seropositivity for HBsAg over a 6-month period and did not have any other type of liver diseases such as chronic hepatitis C or alcoholic liver disease. In addition, all the patients had elevated serum ALT and AST levels. Patients with chronic HBV infection were further divided into two groups: without ( $n=90$ ) and with HCC ( $n=46$ ) according to the absence or presence of concurrent HCC. Diagnosis of HCC was based on histopathology and/or a combination of mass lesion in the liver from hepatic imaging and serum alpha fetoprotein level  $>400$  ng/mL. Moreover, 152 ethnically and geographically matched controls from healthy blood donors of the Thai Red Cross Society were recruited.

### Genotyping for SNPs of IL-1B and IL-1RN genes

Molecular genetic analysis was performed on genomic DNA obtained from peripheral blood leukocytes using standard salting-out method as previously described<sup>[23]</sup>. SNP at position -511 of IL-1B was genotyped by polymerase chain reaction (PCR) with sequence specific primer (PCR-SSP) (F-5' CTCATCTGGCATTGATCTGG-3' and R-5' GGTGCTGTTCTCTGCCTCGA-3')<sup>[24]</sup>. The PCR conditions were established as previously described<sup>[25]</sup>.

The VNTR of IL-1RN gene was assessed by a PCR-based assay. Oligonucleotides F-5' CTCAGCAACACTCCTAT-3' and R-5' TCCTGGTCTGCAGGTAA-3' flanking this region were used as primers<sup>[24]</sup>. The PCR conditions were an initial denaturation at 94 °C for 2 min, followed by 35 cycles at 94 °C for 20, at 59 °C for 50 s, at 72 °C for 20 s, and a final extension at 72 °C for 7 min. Each allele was identified according to its size<sup>[24]</sup>.

### Statistical analysis

The association between these genes and disease status was evaluated by the statcalc from Epi info version 6 program<sup>[26]</sup> to calculate the odds ratio (OR) and 95% confidence interval (CI), Yates' corrected  $\chi^2$  and associated

$P$  values.  $P<0.05$  was considered statistically significant. The groups were tested for conformity to the Hardy-Weinberg equilibrium by  $2 \times 2 \chi^2$  test comparing observed and expected numbers.

## RESULTS

The genotype and allele frequencies of IL-1B and IL-1RN in healthy control subjects and patients with chronic hepatitis B, including patients with and without HCC are shown in Table 1. All the three groups were in Hardy-Weinberg equilibrium with no significant  $\chi^2$  values compared to the observed and expected genotype frequencies of each of the tested polymorphisms. The heterozygous C/T of IL-1B was the most common genotype in all the three groups (51.97% in healthy controls, 45.65% in patients with HCC and 56.67% in patients without HCC). The homozygous T/T was the second most common genotype in healthy controls (27.63%) and patients without HCC (24.44%), followed by the C/C genotype that was found in 20.39% of healthy controls and in 18.89% of patients without HCC, respectively. In contrast to these two groups, the C/C was the second most common genotype in patients with HCC (36.96%), followed by the T/T genotype (17.39%). Comparison of IL-1B-511 genotype revealed that IL-1B-511 C/C genotype was significantly increased in patients with HCC compared to that in healthy controls ( $P=0.036$ , OR = 2.29, 95%CI = 1.05-4.97) and patients without HCC ( $P=0.036$ , OR = 2.52, 95%CI = 1.05-6.04). Analysis of allele frequencies of IL-1B-511 showed

that IL-1B-511 C allele was also significantly increased in patients with HCC, compared to that in the healthy controls ( $P=0.033$ , OR = 1.72, 95%CI = 1.04-2.84). The effect of IL-1B-511 C allele was similar to autosomal recessive mode of inheritance. The presence of two C alleles (CC) was required to increase the likelihood of HCC development.

Four genotypes of IL-1RN (1/1, 1/2, 2/2, 1/4) were found in this study. The IL-1RN 1/1 genotype was the most common genotype in all the three groups (79.61% in healthy controls, 82.61% in patients with HCC and 82.22% in patients without HCC), followed by 1/2 genotype that was 19.08% in healthy controls, 17.39% in patients with HCC and 16.67% in patients without HCC, respectively. The 2/2 genotype was 0.66% in healthy control and 1.11% in patients without HCC, whereas the 1/4 genotype was 0.66% in healthy controls. There were no significant differences in genotype or allele frequencies of IL-1RN between patients with chronic hepatitis B and healthy controls.

## DISCUSSION

The association between the development of chronic hepatitis B and the polymorphisms of IL-1B gene (-511C/T) and IL-1RN gene (VNTR at intron 2) was not observed in this study. However, the -511C allele of IL-1B gene was identified as a genetic marker for the development of HCC in patients with chronic HBV infection. The hypothesis regarding IL-1 genetic polymorphism and hepatocarcinogenesis is based on the assumption that carriers of these genotypes are associated with increased levels of IL-1B in the liver in response to HBV infection and hepatocyte damage that may finally lead to the development of HCC. This hypothesis is supported by the observation that IL-1B level is increased in the liver tissue surrounding the tumor tissue<sup>[27]</sup>. IL-1B is a proinflammatory cytokine as well as a tumor growth factor. There are several lines of evidence that support its role in tumor growth development. First, IL-1B can increase the production of prostaglandin E2 and hepatocyte growth factor<sup>[17]</sup>. Second, IL-1B can induce angiogenesis which is an important step in promoting tumor growth by either upregulating COX-2 or inducing nitric oxide<sup>[19]</sup> and vascular endothelial growth factor (VEGF)<sup>[28]</sup>. Third, IL-1B can also attenuate interferon-induced antiviral activity and STAT1 activation in the liver<sup>[29]</sup>.

However, the IL-1B polymorphism in the promoter area in association with cancer remains controversial. Briefly, a number of studies mostly in the Caucasian population support that -511T in linkage disequilibrium with -31C is a risk haplotype for the development of gastric cancer<sup>[30-34]</sup>. There are more conflicting data regarding the effect of IL-1B-511/-31 haplotype on the risk of gastric cancer and HCV-related HCC in Asian population, while some studies support the result from the Caucasian group<sup>[16,21,35]</sup> and a number of studies reported that -511C/-31T is a risk haplotype for the development of cancer<sup>[22,36-40]</sup>. Interestingly, functional studies of IL-1B genotype seem to support that -511C/-31T haplotype is associated with high-production of IL-1B. First, the IL-

1B -31 polymorphism involves a TATA sequence in the promoter and the -31T allele is associated with a five-fold elevated binding activity with the transcription initiation factor<sup>[30,31]</sup>. Second, mucosal IL-1B level is higher than IL-1B-31T level in *H. pylori*-infected gastric cancer patients<sup>[40]</sup>. Although IL-1B -511T/-31C is associated with high level of IL-1B in the plasma<sup>[41]</sup>, it is likely that gene expression in each organ is differently regulated and the assessment of IL-1B level in targeted organ is more reliable. The functional study in liver tissue is also required for the better understanding of the role of IL-1B genotype in chronic hepatitis and HCC development.

In conclusion, IL-1B-511C allele which may be associated with the high IL-1B production in the liver is a genetic marker for the development of HCC in chronic hepatitis B patients in Thai population.

## ACKNOWLEDGMENTS

The authors greatly appreciate the participants and all the staff members who participated in chronic HBV study at King Chulalongkorn Memorial Hospital. Also, we would like to thank the National Blood Center for the recruitment of healthy controls and collection of research materials.

### Abstract

**AIM:** To investigate the ultra-structural changes and heat shock protein 70 (HSP70) expression in the pancreas of rats with endotoxic shock and to detect their possible relationship.

**METHODS:** A total of 33 Wistar rats were randomly divided into three groups: control group (given normal saline), small dose lipopolysaccharide (LPS) group (given LPS 5 mg/kg) and large dose LPS group (given LPS 10 mg/kg). Pancreas was explanted to detect the ultra-structural changes by TEM and the HSP70 expression by immunohistochemistry and Western blot.

**RESULTS:** Rats given small doses of LPS showed swelling and loss of mitochondrial cristae of acinar cells and increased number of autophagic vacuoles in the cytoplasm of acinar cells. Rats given large doses of LPS showed swelling, vacuolization, and obvious myeloid changes of mitochondrial cristae of acinar cells, increased number of autophagic vacuoles in the cytoplasm of acinar cells. HSP70 expression was increased compared to the control group ( $P < 0.05$ ).

**CONCLUSION:** Small doses of LPS may induce stronger expression of HSP70, promote autophagocytosis and ameliorate ultra-structural injuries.

### INTRODUCTION

Septic shock is a clinical syndrome resulting from the systemic response of the body to infection. Septic shock is characterized by hypoperfusion of major organs, leading to multiple organ failure and finally to death. Though advances have been achieved in supportive and anti-microbial treatment, septic shock continues to be a common cause of intensive care with the mortality rate being approximately 40%<sup>[1]</sup>. Sepsis is associated with secondary pancreatic dysfunction<sup>[2]</sup>.

Heat shock proteins (HSPs) are highly conserved molecules present in both prokaryotic and eukaryotic cells and play an important role in cellular function and stress conditions. HSPs function as molecular chaperones and are categorized into HSP90, HSP70, HSP60, HSP20, and HSP8.5 on the basis of their molecular weight. HSP70 proteins constitute the central part of the chaperone system. In mammals, two isoforms of HSP70 exist in cytoplasm: a 73-ku constitutively expressed form (HSC70) and a 72-ku stress-inducible form (HSP70). HSPs are usually constitutively present at low concentrations in cells, but are actively synthesized to reach much higher concentrations as cells react to aggressive situations<sup>[3]</sup>.

This study was to investigate the effect of different doses of LPS on the expression of HSP70 in a model of LPS-induced septic shock.

### MATERIALS AND METHODS

#### Experimental animals

A total of 33 Wistar rats weighing  $250 \pm 10$  g were supplied by China Medical University Animal Department. All animals received humane care.

#### Induction of sepsis

A total of 33 Wistar rats were randomly divided into three groups. Small dose LPS group ( $n = 12$ ) was given a single dose of 5 mg/kg LPS, large dose LPS group ( $n = 12$ ) was

**Table 1** Expression of HSP70 in the pancreas of the three groups

Groups	<i>n</i>	–	+	++	+++
LPS5 mg/kg	12	2	0	3	7
LPS10 mg/kg	12	4	1	3	4
Control group	9	2	6	1	0

given 10 mg/kg LPS, control group ( $n=9$ ) was given the same volume of 0.9% normal saline. All rats were anesthetized with sodium pentobarbital (36 mg/kg). LPS (SIGMA, O127B8) was given via the femoral vein. A catheter was connected to the femoral artery to measure the mean arterial pressure. Death occurred after 3.5 h. The rats that survived were killed at 6 h. Pancreas were removed immediately and stored at  $-70^{\circ}\text{C}$  for later use.

### Immunohistochemistry

Pancreatic samples were fixed in neutral buffered formalin, embedded in paraffin, sectioned, and mounted on slides. After being deparaffinized, endogenous peroxidase activity was quenched with 10%  $\text{H}_2\text{O}_2$  for 10 min. After being blocked with goat serum, the sections were incubated with anti-mouse IgG polyclonal HSP70 antibody at  $37^{\circ}\text{C}$  for 90 min, followed by incubation with S-A/HRP at  $37^{\circ}\text{C}$  for 20 min. The Ag-Ab complex was visualized using diaminobenzidine method. Slides were then counterstained with hematoxylin for 1 min. After dehydration, the slides were coverslipped. To ensure specificity of the immunoreactions, control sections were subjected to the same immunohistochemical method with the exception that the primary Ab antibody was replaced with PBS.

### Electromicroscopic study

Pancreatic tissue was cut into  $1\text{ mm} \times 1\text{ mm} \times 1\text{ mm}$  pieces and placed in a freshly prepared fixative buffer (2.5% glutaraldehyde) at  $4^{\circ}\text{C}$  for 2 h. After being fixed in 1% osmium tetroxide at  $4^{\circ}\text{C}$  for 1 h, the tissue was exposed twice to an increased concentration of ethanol (30%, 50%, 70%, and 99.5%) at 5-min intervals for partial dehydration. Tissue was embedded with resin in gelatin capsules and incubated at  $55\text{--}60^{\circ}\text{C}$  for 24 h. Ultra-thin (70 nm) sections were cut and transferred to 300-mesh nickel grids. After being stained with tannic acid, saturated uranyl acetate in 50% alcohol and 0.01% lead citrate, the samples were examined under transmission electron microscope (JEM-1200EX, Tokyo, Japan).

### Western blot

Tissues were sonicated on ice for approximately 10 min until the tissues were completely homogenized in a solution containing 2 mmol/L EDTA, 2 mmol/L EGTA, 0.2 mmol/L NaCl, 20 mmol/L Tris-HCl, 1% Triton, 1 mmol/L DTT, and 1 mmol/L aprotinin. The homogenate was then centrifuged at  $12000\text{ g}$  for 60 min at  $4^{\circ}\text{C}$  and the resulting supernatant fraction was transferred to a fresh tube.

An equal amount (30  $\mu\text{g}$ ) of protein extracts was loaded and separated by 8% SDS-polyacrylamide gel electropho-

**Figure 1** HSP70 expression in three groups.

resis (PAGE). After electrophoresis, the proteins on the gel were transferred to polyvinylidene difluoride (PVDF) membrane. After being blocked with 5% nonfat dry milk at  $4^{\circ}\text{C}$  overnight, the PVDF membranes were incubated with anti-rabbit polyclonal antibody of HSP70 diluted 1:200 with TPBS at  $37^{\circ}\text{C}$  for 2 h. Then the blots were reacted with goat anti-rabbit antibody at room temperature for 2 h. Pre-stained molecular mass was used to estimate the positions of various proteins on the gel. Blots were stripped and incubated with a monoclonal Ab against  $\beta$ -actin (Sigma) to confirm that an equal protein was loaded. The target was then detected by enhanced chemiluminescence and exposed to X-ray film for appropriate time. The pictures were analyzed by GIS TANON.

### Statistical analysis

All data were expressed as mean  $\pm$  SD.  $P < 0.05$  was considered statistically significant.

## RESULTS

### TEM changes

No obvious ultra-structural damage was found in the control group. Swelling and loss of mitochondrial cristae of acinar cells and increased number of autophagic vacuoles in the cytoplasm of acinar cells were found in small dose LPS group. Swelling, vacuolization, and obvious myeloid changes of mitochondrial cristae of acinar cells and increased number of autophagic vacuoles in the cytoplasm of acinar cells were found in large dose LPS group (figure 2).

### Immunohistochemistry changes

HSP70 was expressed at a low level in pancreatic acinar cells of the control group. After injection of LPS, HSP70 was highly expressed in the cytoplasm and nuclei of acinar cells and endothelia of blood vessels. Immunohistochemical examination showed overexpression

**Figure 2** Ultra-structural changes of the pancreas in control (A), small dose LPS (B) and large dose LPS (C) groups.

**Figure 3** HSP70 expression in the pancreatic tissue of control (A), small dose LPS (B) and large dose LPS (C) groups.

of HSP70 in the vascular endothelial cells and cytoplasm of pancreatic tissue of the small dose LPS group. There were no significant differences between the two groups (Table 1).

#### Western blots

HSP70 expression in the control group was  $112 \pm 18.9$  ( $0.62 \pm 0.04$ ). HSP70 expression in the large dose LPS group was  $169 \pm 13.4$  ( $0.974 \pm 0.04$ ). HSP70 expression in the small dose LPS group was  $211 \pm 11.5$  ( $1.34 \pm 0.17$ ) (Figure 1 and 3).  $\beta$ -Actin expression was constant, indicating the equal protein loading on the blots. HSP70 expression increased compared to the control group ( $P < 0.05$ ).

## DISCUSSION

This study showed that LPS could induce HSP70 expression in the pancreas of rats with endotoxic shock and the upregulation of HSP70 was associated with the doses of LPS and the extent of pancreatic ultra-structural injury. Endotoxin caused mitochondrial changes in the acinar cells of the pancreas and large doses of endotoxin led to myeloid changes of mitochondria. Small doses of LPS induced obvious overexpression of HSP70 and autophagocytosis, suggesting that high level of HSP70 promotes degradation of damaged proteins and ameliorates ultra-structural damages.

HSPs can protect cells from injury induced by environmental challenges, such as hypoxia, ischemia, high temperature, endotoxin, infection, and fever<sup>[4]</sup>. The protective effects of HSPs have been confirmed in various animal models of sepsis<sup>[5]</sup>. Several studies have demonstrated that

a preceding HSP reaction reduces both mortality and organ dysfunction in experimentally induced severe sepsis<sup>[6]</sup>. Induction of HSPs in response to stress correlates with increased resistance to subsequent cellular damage. HSP70 is believed to act in a chaperone-like manner aiding in the passage of proteins across membrane barriers, preventing misfolding of newly synthesized proteins, facilitating elimination of improperly assembled, misfolded or aggregated proteins<sup>[7]</sup>. HSP70 contributes to the delivery of dysfunctional proteins to lysosomes for proteolytic degradation<sup>[8]</sup>. HSP70 is also known to facilitate antigen presentation in cells such as macrophages and dendrites<sup>[9]</sup>. Elevations in intracellular HSP levels have been shown to improve cell tolerance to inflammatory cytokines, such as TNF- $\alpha$  and IL-1 $\beta$ <sup>[10]</sup>. TNF- $\alpha$  and IL-1 $\beta$  are thought to be the main mediators in the pathogenesis of septic shock<sup>[11]</sup>. HSP70 expression protects the lung against ventilator-induced lung injury by decreasing cytokine transcription<sup>[12]</sup>.

Mitochondrial oxidative phosphorylation is responsible for over 90% of total body oxygen consumption and ATP generation. HSP70 upregulation protects mitochondrial function after ischemia-reperfusion injury<sup>[13]</sup>. Increased levels of HSP70 through gene transfection lead to a greater protection of mitochondrial function after ischemia-reperfusion in a donor heart preservation protocol<sup>[13]</sup>. This may be one mechanism by which HSP70 overexpression leads to a better protection. Overexpression of HSP70 in the whole pancreas can protect mitochondrial integrity<sup>[14]</sup>. It was reported that structural deformity and decrease of respiratory chain enzyme activity in mitochondria and decline of ATP content are highly correlated with the deterioration of cardiac function during sepsis<sup>[15]</sup>. Heat shock

pretreatment prevents cardiac mitochondrial dysfunction during sepsis<sup>[16]</sup>, thus achieving a protective goal.

HSP70 protection against LPS is most probably mediated through the modulation of iNOS activation and the subsequent decreased synthesis of nitric oxide (NO)<sup>[17]</sup>. NO plays an important role in the pathogenesis of septic shock<sup>[18]</sup>. A key role of HSP70 in the natural resistance of human beta cells against NO-induced injury is by preserving mitochondrial function<sup>[19]</sup>. Constitutive expression of HSP70 in human beta cells is essential for the natural resistance against NO-induced injury<sup>[19]</sup>. HSP70 prevents secretagogue-induced cell injury in the pancreas<sup>[20]</sup>. Hyperthermia protects against arginine-induced pancreatitis and induces HSP70 in the pancreas<sup>[21]</sup>.

After entering blood, endotoxin combines with CD14<sup>[22]</sup>. Both CD14 and TLR2 are receptors of LPS<sup>[22]</sup>. TLR-4 and CD14 are involved in HSP70-mediated proinflammatory responses<sup>[23]</sup> and in HSP70-mediated activation of innate immunity<sup>[24]</sup>. Further investigation is necessary to elucidate the mechanism underlying the induction of endotoxin by HSP70.

wk after the end of treatment, was remarkably high by 84.4%, (146/173) by an intention-to-treat analysis. A significant difference in SVR was found between patients with and without the discontinuation of ribavirin (46.9% vs 92.9%), but no difference was found between those with and without a dose reduction of ribavirin. A significant difference in SVR was also found between patients with less than 16 wk and patients with 16 or more weeks of ribavirin treatment (34.8% vs 92.0%).

**CONCLUSION:** The 24-wk interferon and ribavirin treatment is highly effective for Japanese patients with HCV genotype 2. The significant predictor of SVR is continuation of the ribavirin treatment for up to 16 weeks.

### Abstract

**AIM:** To determine the efficacy of an interferon alpha and ribavirin combination treatment for Japanese patients infected with hepatitis C virus (HCV) of genotype 2, a multi-center study was retrospectively analyzed.

**METHODS:** In total, 173 patients with HCV genotype 2 started to receive interferon-alpha subcutaneously thrice a week and 600–800 mg of ribavirin daily for 24 wk.

**RESULTS:** The overall sustained virological response (SVR), defined as undetectable HCV RNA in serum, 24

### INTRODUCTION

The heterogeneity of the hepatitis C virus (HCV) genome has warranted the classification of the virus into different genotypes, with six major genotypes and more than 50 subtypes of HCV having been described till date<sup>[1-3]</sup>. The different genotypes may be important to the pathogenesis of the disease<sup>[4]</sup>, response to antiviral therapy<sup>[5]</sup>, and the diagnosis<sup>[6]</sup>, as shown by molecular epidemiological studies and research on vaccine development.

A currently popular treatment regimen for the treat-

ment of chronic HCV infection in the world is pegylated interferon (IFN) alpha in combination with ribavirin. However, there was no data of response to such combination treatment for Japanese patients, because the treatment was just approved by the Japanese Minister of Health, Labour and Welfare in December 2004. Treatment with these drugs has resulted in a high rate of sustained virological response (SVR), over 50%<sup>[7,8]</sup>; however, the treatment duration is long, 48 wk and it causes various side effects, which are sometimes serious. Such a combination treatment is also expensive; a 24-wk treatment course costs approximately \$20 000<sup>[9]</sup>. The efficacy and economic aspects need to be analyzed. Quite recently, a very short duration treatment for acute hepatitis C was shown to be highly effective<sup>[10]</sup>.

The HCV genotype has been reported to be the most important predictor of IFN treatment response<sup>[7-13]</sup>. Patients infected with genotypes 2 and 3 have achieved about 65% SVR in a trial of 24-wk IFN alpha in combination with ribavirin, in contrast to patients with genotype 1 who had under 30% SVR<sup>[14,15]</sup>. Recently, multicenter studies in Europe and North America showed that patients with genotypes 2 and 3 were able to achieve a high SVR in a trial of 14-16 wk of pegylated IFN alpha in combination with ribavirin<sup>[16,17]</sup>. However, their analysis included very few genotype 2 patients: one included 23 genotype 2 patients and the other had 43 patients.

The distribution of HCV genotypes in Japan includes about 70% genotype 1b, with the remaining 30% genotypes 2a and 2b<sup>[18]</sup>. The SVRs to treatment of even shorter duration have not yet been reported for Japanese patients. Data are needed to define whether or not the duration of treatment with IFN alpha in combination with ribavirin can be reduced from 24 wk without compromising antiviral efficacy in patients chronically infected with HCV of genotype 2. This investigation has assessed the efficacy of a 24-wk combination treatment of IFN alpha and ribavirin for Japanese patients with HCV genotype 2 infection and focussed on the issue of the relationship between the duration of treatment and the efficacy.

## MATERIALS AND METHODS

### Patients

A retrospective study was done on Japanese patients treated between December 2000 and March 2004 that included 173 patients, 20 years or older, who satisfied the following criteria: (1) chronically infected with HCV genotype 2a or 2b; and (2) a history of an increased alanine aminotransferase (ALT) level for over 6 months. Criteria for exclusion were: (1) clinical or biochemical evidence of hepatic decompensation; (2) hemoglobin level less than 115 g/L, white blood cell count less than  $3 \times 10^9$ /L, and platelet count less than  $50 \times 10^9$ /L; (3) concomitant liver disease other than hepatitis C (hepatitis B surface antigen or human immunodeficiency virus-positive); (4) alcohol or drug abuse; (5) suspected hepatocellular carcinoma; (6) severe psychiatric disease; and (7) treatment with antiviral or immunosuppressive agents prior to enrolment. Patients who fulfilled the above criteria were recruited at Kyushu University Hospital and 32 affiliated hospitals in the

northern Kyushu area of Japan.

Informed consent was obtained from all the patients before enrollment in this study. The study was approved by the institutional Ethics Committees of the hospitals involved and conducted in accordance with the ethical guidelines of the Declaration of Helsinki and the International Conference on Harmonization of guidelines for good clinical practice.

### Study design

All patients were treated with 6-10 MU of IFN alpha-2b (Intron A; Schering-Plough, Osaka, Japan) subcutaneously daily for the first 2 wk, then thrice a week for 22 wk. Ribavirin (Rebetol; Schering-Plough) was administered orally for 24 wk at a daily dose of 600-800 mg based on the body weight (600 mg for patients weighing less than 60 kg and 800 mg for those weighing 60 kg or more). The above duration and dose were approved by the Japanese Minister of Health, Labour and Welfare. The 48-wk combination treatment and the ribavirin dosage of 1 000-1 200 mg recommended by the international guidelines were not permitted under the rules of the Japanese national health insurance system during the period of this study. The dose of ribavirin was reduced by 200 mg if the hemoglobin level fell to 100 g/L. Patients were considered to have ribavirin-induced anemia if the hemoglobin level decreased to less than 100 g/L. In such cases, a reduction in the dose of ribavirin was required. Both IFN alpha-2b and ribavirin were discontinued if the hemoglobin level, white blood cell count, or platelet count fell below 85 g/L,  $1 \times 10^9$ /L, and  $2.5 \times 10^9$ /L, respectively. The treatment was also discontinued if severe malaise developed, the continuation of treatment was judged not to be possible by the attending physician, or the patient desired to discontinue treatment.

### Grouping by continuation or discontinuation of treatment

Patients were divided into the following four categories: Group A, patients who well tolerated the 24-wk combination treatment with IFN and ribavirin without a reduction in the dose of either drug; Group B, patients who received the full 24-wk combination treatment but who needed a reduction of the dose of IFN or ribavirin, or both; Group C, patients who discontinued the ribavirin treatment but continued the 24-wk IFN treatment; and Group D, patients who did not complete the 24 wk of treatment, because of adverse effects or who dropped out.

### Determination of HCV RNA and HCV genotype and serotype

The serum HCV RNA level was examined with an Amplicor HCV monitor assay (version 2.0) (Roche, Tokyo, Japan), with a lower limit of quantitation of 500 IU (135 copies/mL) and an outer limit of quantitation of 850 000 IU/mL. Samples with HCV RNA over the limit of 850 000 IU/L were not diluted to determine the levels between 850 000-5 000 000 IU/mL. HCV RNA was also examined with the qualitative Amplicor HCV assay (Roche). HCV genotype was determined by type-specific primer from the core region of the HCV genome. The protocol for genotyping was carried out as described earlier<sup>[11,12]</sup>.

**Figure 1** The sustained virological response (SVR) rate and undetectable hepatitis C virus (HCV) RNA rates during the treatment of 173 patients, classified by continuation and discontinuation of interferon and ribavirin combination treatment. Group A patients ( $n=93$ ) who well tolerated the 24-week treatment with IFN and ribavirin in combination without any reduction in the dose of either drug; Group B patients ( $n=48$ ) received the 24-week combination treatment, but needed a dose reduction of IFN or ribavirin, or both; Group C patients ( $n=11$ ) discontinued the ribavirin treatment, but continued the full 24 weeks of IFN treatment; Group D patients ( $n=21$ ) did not complete the 24 weeks of treatment because of adverse effects ( $n=17$ ) or dropped out ( $n=4$ ). <sup>1</sup> $P=0.0001$ ; <sup>2</sup> $P<0.0001$ ; <sup>3</sup> $P=0.0031$ ; <sup>4</sup> $P=0.0003$ ; <sup>5</sup> $P=0.0001$ ; <sup>6</sup> $P=0.0002$ ; <sup>7</sup> $P=0.0003$ ; <sup>8</sup> $P=0.0002$ ; <sup>9</sup> $P=0.124$ ; <sup>10</sup> $P=0.0182$ .

### Histological examination

Liver biopsy was done for 117 patients infected with genotype 2 within the 6 months before the start of the treatment. For each specimen, a stage of fibrosis and a grade of activity were established according to the following criteria. Fibrosis was staged on a scale of 0-4: F0=no fibrosis, F1=portal fibrosis without septa, F2=few septa, F3=numerous septa without cirrhosis, F4=cirrhosis. The grading of activity, including the intensity of the necroinflammation, was scored as follows: A0=no histological activity, A1=mild activity, A2=moderate activity, A3=severe activity. Liver biopsy was not available from 56 patients who declined to have a biopsy.

### Efficacy of treatment

The SVR was defined as undetectable HCV RNA by the qualitative Amplicor HCV assay (Roche) and a normal ALT level (under 40 IU/L) at 6 months after the end or stoppage of the treatment. Patients not achieving a SVR were considered as non-SVR. Patients who had undetectable HCV RNA within 4 wk of the start of treatment were considered to have had an early virological response (EVR).

### Statistical analysis

The analysis of SVR was done on an intention-to-treatment basis, including dropouts, who were counted as non-sustained virological responders, and patients who stopped treatment. The  $\chi^2$  test or Fisher's exact test was used to examine the association between baseline characteristics and SVR. The Mann-Whitney  $U$  test was also used to compare responders and non-responders with regard to various characteristics, when appropriate. Independent factors associated with SVR were studied using forward

stepwise logistic regression analysis of the variables. Forward stepwise logistic regression analysis was done using a commercially available software package (BMDP Statistical Software Inc., Los Angeles, CA, USA) for the IBM 3090 system computer. A  $P$ -value of less than 0.05 was considered significant. All  $P$ -values were two tailed.

## RESULTS

### Patient characteristics, dose reduction and discontinuation of treatment regimen

The distribution of Groups A, B, C, and D patients was 93 (53.8%), 48 (27.7%), 11 (6.4%), and 21 (12.1%), respectively. Completing the 24-week ribavirin treatment were 141 patients in Groups A and B. Thirty-two patients of Groups C and D discontinued the ribavirin treatment.

The pretreatment characteristics of these four groups of patients are summarized in Table 1 and 2. The median age was significantly younger in Group A (51 years) than in Groups B (56 years) and C (59 years). Significantly more men were in Group A (71.0%) than in Group B (33.3%). The median creatinine clearance was significantly higher in Group A (110 mL/min) than Groups B (92 mL/min) and C (85 mL/min). The median hemoglobin level was significantly higher in Group A (150 g/L) than Groups B (136 g/L), C (134 g/L), and D (134 g/L). The median platelet count was significantly higher in Group A ( $168 \times 10^9/L$ ) than in Group C ( $127 \times 10^9/L$ ). No notable differences between the groups were found in body weight, ribavirin dose, HCV RNA level, genotype, or histology.

### Virological response

SVR was achieved by 146 (84.4%) of 173 patients. The SVR did not differ between patients with genotypes 2a and 2b (83.1% *vs* 84.6%). The SVRs were 82.4% (14 of 17) (under 100 kIU/mL), 84.2% (16 of 19) (100-199 kIU/mL), 85.7% (24 of 28) (200-299 kIU/mL), 83.3% (15 of 18) (300-399 kIU/mL), 100% (12 of 12) (400-499 kIU/mL), 76.9% (10 of 13) (500-599 kIU/mL), 77.8% (7 of 9) (600-699 kIU/mL), 90.9% (10 of 11) (700-799 kIU/mL), and 82.6% (38 of 46) (800 and over kIU/mL). The SVRs were 76.9-100%. The SVRs of the HCV genotype 2 patients with any level of viremia level did not significantly differ.

Figure 1 shows the SVR and undetectable HCV viremia rate during the treatment of 173 patients, classified by continuation and discontinuation of combination treatment. The SVRs were significantly higher in Groups A (94.6%) and B (89.6%) than in Groups C (45.5%) and D (47.6%). A significant difference of SVR was found between patients with and without discontinuation of ribavirin (46.9%, 15 of 32 of Groups C and D patients *vs* 92.9%, 131 of 141 of Groups A and B patients,  $P<0.0001$ ). During the treatment period, except for at week 4, the rates of undetectable HCV RNA were also significantly higher in Groups A and B than in Groups C and D.

Figure 2 shows the relationship between SVR and the ribavirin treatment period in all the patients. A significant difference was found between patients with less than 16 wk of treatment period and patients with longer periods

<sup>6</sup>*P* = 0.0003; <sup>7</sup>*P* = 0.0063; <sup>8</sup>*P* = 0.0225; <sup>9</sup>*P* = 0.0120

(34.8%, 8 of 23 *vs* 92.0%, 138 of 150, *P* < 0.0001), showing that 16 wk of ribavirin treatment significantly contributed to a SVR. Of the 173 studied patients, 104 (60.1%) had an EVR, defined as undetectable HCV RNA within 4 wk of the start of treatment. The SVR was 94 (90.4%) of these 104 patients with EVR, which was significantly higher than the non-EVR patients (52 of 69, 75.4%) (*P* = 0.0142). No significant differences were found between patients with and without undetectable HCV RNA at 8 or 12 wk of the start of treatment. Moreover, we analyzed the relationship between SVR and the length of ribavirin treatment in the 104 patients with EVR. A significant difference was found between patients with less than 16 wk of ribavirin treatment and those with a longer treatment period (46.2%, 6 of 13 *vs* 96.7%, 88 of 91, *P* < 0.0001). These findings

showed that 16 wk of ribavirin treatment significantly contributed to a SVR, even in patients with EVR.

### Factors contributing to SVR

To assess the independent role of the IFN and ribavirin combination treatment on SVR, an adjustment by forward stepwise logistic regression analysis for all other independent risk factors identified was done. The continuation of ribavirin treatment (*P* < 0.0001) was significantly associated with SVR in analysis of all the patients. A higher SVR (odds ratio = 13.15) was found for patients who continued to receive ribavirin treatment than for those who discontinued it. Other factors such as sex, age, HCV genotype, pretreatment-HCV RNA level, histological findings, pretreatment platelet count and creatinine clearance, history

**Figure 2** Relationship between the sustained virological response rates and the length of ribavirin treatment period of the 173 studied patients.

of prior IFN, and dose reduction of IFN or ribavirin were not significantly, independently associated with a SVR.

## DISCUSSION

The large number of Japanese HCV genotype 2 patients enrolled in this study was sufficient to provide for meaningful statistical analysis, even though it was retrospective. This study demonstrated that a 24-wk IFN and ribavirin combination treatment was highly effective and resulted in a remarkably high SVR (84.4%) in genotype 2 patients, as expected. Importantly, we also showed that dose reductions of ribavirin were not associated with a poor outcome in these patients, only ribavirin discontinuation, and that the addition of ribavirin for up to 16 wk contributed to the high SVR.

In December 2004, pegylated IFN plus ribavirin combination treatment received the official approval in Japan. The combination treatment was not yet approved for clinical use for patients with chronic HCV viremia by the Japanese Ministry of Health, Labour and Welfare at the time of the present study. So far, our most effective and available treatment is the 6-month IFN-alpha plus ribavirin combination.

Remarkably high SVRs were observed for our patients with genotype 2 who took the IFN and ribavirin combination treatment. IFN monotherapy does not result in a satisfactory outcome for patients with chronic hepatitis C, particularly those with genotype 1, which is known to be IFN-resistant, whereas genotype 2 is IFN-sensitive<sup>[11-13]</sup>. The addition of ribavirin, a synthetic purine nucleoside analog, to IFN enhances the virological response<sup>[8,9,13-17]</sup>. Our research group, KULDS, also analyzed the data of patients with genotype 1 who were treated with this 24-wk combination treatment: SVR was achieved by 21% of 528 patients with genotype 1 by intention-to-treat analysis

(data not published). Differences between genotype 1 and 2 patients still existed following the ribavirin combination treatment. Moreover, a striking finding in our study was that there were no differences among the patients with genotype 2 of any HCV RNA level (76.9-100%). The precise mechanism is unclear, although it possibly originates in different nucleotide sequence of their genome. Further study is needed to clarify the reasons for the differences in antiviral effect, by the use of novel and new tools for the quantification of the HCV replication system<sup>[19,20]</sup>.

How long the ribavirin needs to be administrated to achieve the best efficacy with IFN alpha-treated patients of genotype 2 is unclear. In the present study, SVR after 16 or more weeks of treatment ranged from 83.3% to 100% and was not dependent on the dose reduction of ribavirin treatment but on the discontinuation of IFN or ribavirin treatment. A pilot study from Norway showed that patients with genotype 2 and an EVR obtained a high SVR after 14 weeks of pegylated IFN and ribavirin combination treatment<sup>[21]</sup>. The Zeuzem group also demonstrated a very high SVR in a 24-week pegylated IFN and ribavirin treatment for genotype 2 patients, and 16-week treatment duration was observed to be a significant independent predictor<sup>[17]</sup>. In view of the adverse effects, high cost of ribavirin, and the above mentioned findings along with our results, a 16-week ribavirin addition to IFN treatment would seem to produce a high rate of SVR for patients with genotype 2, especially for those with EVR, defined as undetectable HCV RNA within 4 wk of the start of the treatment.

The Davis group attempted to confirm that an EVR in patients with chronic hepatitis C undergoing initial treatment with a combination therapy of pegylated IFN alpha and ribavirin was predictive of SVR<sup>[22]</sup>. Retrospective analysis of data from other trials<sup>[23]</sup> has also suggested that patients who do not attain EVR have a nominal chance of SVR with additional weeks of treatment. While the primary goal, or "holy grail", of treatment of chronic hepatitis C is SVR, it must be acknowledged there are other secondary goals that compel physicians to continue treatment without EVR. In fact, patients who do not achieve EVR or SVR may have histological benefit<sup>[24]</sup>, leading to a decreased risk of hepatocellular carcinoma<sup>[19]</sup>. Thus, it remains to be determined whether or not early discontinuation of treatment would reduce economic costs if a long-term perspective is taken.

Several adverse reactions are associated with ribavirin. One of the most significant reactions is hemolytic problems, especially anemia<sup>[15]</sup>. Most of our patients who had to have a dose reduction or who discontinued ribavirin were observed to have anemia. It is important to reduce the dose of ribavirin at as early a stage as possible to allow the safe continuation of the combination treatment. The Nomura group pointed out that careful administration is necessary in patients over 60 years, in female patients, and in patients receiving a ribavirin dose by body weight of 12 mg/kg or more<sup>[21]</sup>. Our forward stepwise logistic regression analysis showed that the continuation of ribavirin treatment was significantly associated with SVR. This combination treatment, which could depend on hemolytic adverse reaction, has a high efficacy, if physicians are able to continue the ribavirin treatment for as short a period as

16 wk, even when taking into account of the dose reductions necessary for patients with a dangerous decrease of hemoglobin caused by ribavirin, as often seen in genotype 2 patients with a low hemoglobin level at pretreatment.

In conclusion, the 24-week IFN and ribavirin combination treatment was highly effective and resulted in a remarkably high SVR in Japanese HCV patients with genotype 2 from the retrospective study of ours. The most significant predictor was continuation of the ribavirin treatment for up to 16 wk. These findings are not pertinent to the other different genotypes.

### Abstract

**AIM:** To evaluate the omeprazole maintenance therapy in patients with recurrent ulcer bleeding after surgery for duodenal ulcer.

**METHODS:** We studied 15 consecutive patients with recurrent ulcer bleeding after surgery for duodenal ulcer. Omeprazole (20 mg/d) maintenance therapy was given after ulcer healing. In addition to clinical follow-up, ambulatory 24-h gastric pH assay was performed before and during omeprazole therapy in those patients and controls with previous duodenal ulcer surgery but no ulcer recurrence.

**RESULTS:** All the 15 ulcers were healed after being treated with omeprazole (40 mg/d) for 2 mo. Eleven patients with two (1-9) episodes of recurrent ulcer bleeding completed the follow-up (43, 12-72 mo). None of them had a bleeding episode while on omeprazole. One patient discontinued the therapy and had recurrent bleeding. The median 24-h fraction time of gastric pH <4 in patients was 80, 46-95%, and was reduced to 32, 13-70% by omeprazole ( $P=0.002$ ).

**CONCLUSION:** Long-term maintenance therapy with omeprazole (20 mg/day) is effective in preventing recurrent ulcer bleeding.

### INTRODUCTION

*H. pylori* eradication therapy and the use of potent proton pump inhibitors (PPIs) have dramatically reduced the need for surgical therapy of peptic ulcer disease. Still, about 10% of duodenal ulcer patients undergo emergency surgical therapy for acute ulcer bleeding<sup>[1]</sup>. However, recurrent ulcer is not uncommon as it occurs in 10-15% of patients after vagotomy and drainage and in 2-5% of patients after gastric resection<sup>[2]</sup>. This may be complicated by life threatening acute recurrent ulcer bleeding in certain patients, requiring hospitalization.

Several studies have investigated the rate of ulcer recurrence after duodenal ulcer surgery<sup>[2,3]</sup> and the completeness of vagotomy<sup>[4,5]</sup>, but only a few studies have evaluated the anastomotic ulcer healing rates after being treated with H<sub>2</sub> receptor antagonists (H<sub>2</sub>RA)<sup>[6,7]</sup> or PPI<sup>[8]</sup> therapy. Studies have shown that *H. pylori* infection of the gastric mucosa is not related to ulcer recurrence after gastric surgery<sup>[4,9,10]</sup>. Furthermore, it has been shown that 28% of anastomotic ulcers recur within 6 wk after discontinuing cimetidine therapy<sup>[7]</sup>, and 33% relapse within a year while on cimetidine maintenance therapy<sup>[6]</sup>.

These patients are often treated with a second operation<sup>[1]</sup>. However, to the best of our knowledge, there are no studies investigating the long-term outcome of patients with recurrent post-surgical ulcer and whether maintenance acid suppression therapy with PPIs may prevent recurrent ulceration and/or re-bleeding. Therefore, the present prospective open label study was conducted to investigate gastric pH profile and the effect of omeprazole maintenance therapy in patients presented with recurrent ulcer bleeding after duodenal ulcer surgical therapy.

### MATERIALS AND METHODS

Over a 7-year period, this prospective open label study included 15 consecutive male patients admitted to our department due to recurrent acute ulcer bleeding. All patients underwent gastric surgery for duodenal ulcer disease at least 2 years ago.

### Clinical study

In each case, emergency endoscopy was performed to confirm recurrent ulcer bleeding. The finding of an ulcer was considered as the bleeding cause if active bleeding or stigmata of recent hemorrhage were noted in the absence of other lesions. The recurrent ulcers were peristomal or duodenal in location. At the same time, detailed history was obtained about the indication and time of past gastric operation and the number of hospital admissions with hematemesis or melena after gastric surgery. History specifically included questions about the use of H<sub>2</sub>RA, PPIs or non-steroidal anti-inflammatory drugs (NSAIDs)<sup>[11]</sup>, smoking and alcohol abuse. In all the patients fasting serum gastrin and salicylate concentrations were determined to exclude Zollinger–Ellison syndrome and recent consumption of non-steroidal anti-inflammatory drugs. Patients who were on non-steroidal anti-inflammatory drugs were excluded. During endoscopy, multiple gastric mucosal biopsies were obtained to investigate *H pylori* infection.

All patients were initially treated with intravenous omeprazole (20 mg every 12 h) and then orally after discharge from the hospital. *H pylori* eradication therapy was not used to prevent ulcer recurrence<sup>[10,12]</sup>, but *H pylori* was eradicated in two patients because of severe *H pylori* gastritis. Follow-up endoscopy was scheduled at 2 mo, while on oral omeprazole (40 mg/d) to confirm ulcer healing. Thereafter, the patients were instructed to receive oral omeprazole (20 mg/d) maintenance therapy, to avoid the use of any non-steroidal anti-inflammatory drugs and to have follow-up every 6 mo as outpatients.

### Twenty-four-hour gastric pH studies

Twenty-four-hour gastric pH studies were performed in the following groups on omeprazole therapy (20 mg/d) but not on antisecretory therapy: patients with first or second degree reflux esophagitis (Los Angeles classification) (“normal” controls); patients with duodenal ulcer; controls who underwent vagotomy and pyloroplasty or gastrojejunostomy for duodenal ulcer but had no ulcer recurrence; controls who had Billroth II partial gastrectomy and patients who had recurrent anastomotic ulcer bleeding after gastric surgery for duodenal ulcer. In the latter group of patients (test group), 24-h gastric pH studies were performed while on omeprazole (40 mg/d, 20 mg/d). Omeprazole was then discontinued and the patients were treated with ranitidine 150 mg twice daily for 2 d, followed by a 2-d washout period before the pH study in patients not on antisecretory therapy. The duodenal ulcer group included patients admitted to our department for acute ulcer bleeding and volunteered to have 24-h pH studies. The vagotomy and gastrectomy control groups included patients who attended the outpatient clinic for various epigastric symptoms and volunteered to participate in the study after having a negative gastroscopy.

Gastric ambulatory pH monitoring was performed using a monocrystalline antimony pH catheter. The electrode was passed transnasally into the stomach, 10-15 cm below the detectable esophagogastric junction by endoscopy. The catheter was connected to a portable pH-recording device

(Digitrapper Mk III, Synectics Medical AB, Stockholm, Sweden). Recorded data were uploaded into the “EsopHogram Analysis Software” for analysis and review. During the 24-h pH studies, patients were encouraged to keep up their usual activities and diet in order to maximize the diagnostic yield of the test. The 24-h fraction (%) time when the gastric pH was below 4 was calculated.

All patients and volunteers gave oral consent after being informed of the purpose of the study by the investigator. The study protocol was approved by the Ethics Committee on Human Studies, Department of Internal Medicine, Medical School of the Athens University. The trial was conducted according to the declarations of Helsinki.

### Statistical analysis

We used non-parametric statistics [“Statgraphics-Plus” version 4 for Windows (Manugistics Inc., Rockville, USA)], because of the small number of observations included in each group. Results were presented as median with ranges. We used the non-parametric Mann-Whitney (Wilcoxon) two-sided *U*-test and the Kruskal-Wallis *t*-test for two and multiple-sample comparison analysis, respectively<sup>[13]</sup>. *P* < 0.05 was considered statistically significant.

## RESULTS

### Clinical data and follow-up

Over a 7-year period, 15 consecutive male patients with recurrent ulcer bleeding after surgery for duodenal ulcer were admitted to our department because of acute bleeding episode. Serum gastrin was normal and salicylates were not detected in the serum in any of the 15 patients during their hospitalization. In addition, all patients denied the use of non-aspirin, non-steroidal anti-inflammatory drugs after thorough interrogation.

Ulcer in all the 15 patients was healed after treatment with omeprazole (40 mg/d) for 2 mo. However, four of them did not consent to gastric pH studies and were lost to clinical follow-up within the first year from entering the study. Therefore, data were presented for 11 patients (Table 1).

Two out of the eleven patients had a history of two gastric operations because of recurrent ulcer bleeding. The time of recurrent ulcer bleeding after gastric surgery was 6 years, averaged 2-18 years. The number of hospital admissions because of post surgical ulcer bleeding was 2, averaged 1-9. At study entry, 3/11 patients were smokers and 5/11 were *H pylori*-positive. *H pylori* was successfully eradicated in two of these five patients upon admission to the study. One of the *H pylori*-negative patients had successful triple eradication therapy at another hospital a year ago.

No recurrent ulcer or re-bleeding occurred during the maintenance therapy (omeprazole 20 mg/d) over the follow-up period (43 mo, averaged 12-72 mo). One patient discontinued treatment and had recurrent bleeding 8 mo after stopping omeprazole. Currently, he was symptom-free on omeprazole maintenance therapy. There were no significant adverse events related to treatment.

**Table 1** Background information of patients who had recurrent ulcer bleeding after surgery for peptic ulcer disease

Case	Age (yr)	Smoking status	<i>H. pylori</i> status	Type of operation	Years since operation	Bleeding episodes after surgery	Follow-up (mo)
1	62	Never	Positive <sup>1</sup>	TV+D <sup>2</sup>	5, 2 <sup>3</sup>	3	72
2	60	Ex-smoker	Positive	TV+D	6	8	62

11	48	Ex-smoker	Negative	TV+P	13	9	12

<sup>1</sup>Successful *H. pylori* eradication therapy upon entering the study. <sup>2</sup>Final operation. <sup>3</sup>Years elapsed since the first and second gastric operation, upon entering the study. TV+D: truncal vagotomy and gastrojejunostomy. TV+P: truncal vagotomy and pyloroplasty. BII: Billroth II partial gastrectomy.

### Twenty-four-hour gastric pH studies

Results of the 24-h intragastric pH monitoring studies are shown in Table 2. The "normal" control group included 10 patients with first or second degree reflux esophagitis, who were matched for age, sex and *H. pylori* status with the recurrent post-surgical ulcer patients. They were selected from a pool of patients with reflux esophagitis on 24-h esophageal-gastric pH monitoring. The duodenal ulcer control group included seven patients hospitalized because of duodenal ulcer bleeding. The vagotomy control group included seven patients who had truncal vagotomy and drainage for duodenal ulcer. The gastrectomy control group included seven patients who had partial gastrectomy (Billroth II) for duodenal ulcer. Volunteers of the vagotomy and gastrectomy control groups studied at least 2 years postoperatively had no postoperative ulcer recurrence. The test group included ten of the eleven patients who had truncal vagotomy ( $n=5$ ) or Billroth II gastrectomy ( $n=5$ ) and recurrent anastomotic ulcer bleeding. Intolerance to nasogastric pH probe was not studied in another patient who had vagotomy and drainage. There were three failures out of 30 24-h gastric pH recordings in the test group, as shown by missing values in Figure 1. One of the vagotomy controls refused to have the 24-h pH study on omeprazole.

### Treatment-free (baseline) 24-hour gastric pH studies

The 24-h gastric pH measurements of the groups studied during treatment-free period are shown in Table 2. There was a statistically significant difference in the 24-h fraction time of gastric pH <4 among the six groups ( $T=29.10$ ,  $P<0.001$ ), with the lowest values recorded in the Billroth II gastrectomy control group. Patients who had vagotomy and recurrent ulcer bleeding had a significantly different (higher) 24-h fraction time of gastric pH <4 as compared to vagotomy controls ( $U=32$ ,  $P=0.023$ ). This difference was also significant when bleeding patients after gastrectomy were compared to those of the gastrectomy

**Figure 1** Individual data points of the 24-h intra gastric pH monitoring studies while on no treatment (baseline), and during therapy with 20 or 40 mg/d omeprazole (OME) in patients with recurrent post-surgical ulcer bleeding.

control group ( $U=35$ ,  $P=0.006$ ).

### Twenty-four hour gastric pH studies (omeprazole 20 mg/day)

Gastric pH studies were performed in the control and patient (test) groups on omeprazole (20 mg/d). Billroth II gastrectomy control group did not undergo this study because of the low fraction time of gastric pH <4 recorded during treatment-free gastric pH monitoring. Omeprazole therapy (20 mg/d) significantly reduced the 24-h fraction time of gastric pH <4 in both control and patient groups (Table 2).

### Twenty-four hour gastric pH studies in patient group

Eight out of the ten patients underwent all (baseline 20 mg/day and 40 mg/day omeprazole) 24-h gastric pH studies. One additional patient underwent only baseline, and another patient both baseline and omeprazole (20 mg/day) 24-h gastric pH studies. Individual data are shown in Figure 1. The 24-h fraction time of gastric pH <4 (80, 46-95%) was significantly reduced by omeprazole (20 mg/d) to 32, 13-70% ( $U=6$ ,  $P=0.002$ ) and by omeprazole (40 mg/d) to 11, 1-40% (omeprazole 20 mg/day *vs* 40 mg/day,  $U=9$ ,  $P=0.01$ ).

## DISCUSSION

The data of the present study showed that recurrent ulcers after gastric surgery for duodenal ulcer can heal after 2 months of 40 mg/day omeprazole therapy. Even more important, none of our patients had a re-bleeding episode while on omeprazole maintenance therapy over a 3.5-year follow-up period.

A large review is available on the complications associated with ulcer recurrence following gastric surgery including 130 studies published on this topic over a

**Table 2** Demographic data of patients and control groups and results (median, range) of the 24-h fraction (%) time of gastric pH <4 before (basal) and while on 20 mg/d omeprazole.

Groups studied	Number of patients	Age (yr)	<i>H pylori</i> (+)	Treatment-free (baseline)	Omeprazole 20 mg/d	<i>P</i> value

<sup>1</sup>ND, not done. <sup>2</sup>Truncal vagotomy and gastrojejunostomy (*n*=5), truncal vagotomy and pyloroplasty (*n*=2).

30-year period<sup>[14]</sup>. The authors estimated that vagotomy plus drainage is associated with a 9% recurrence rate and a risk of hemorrhage of 1.7%. Partial gastrectomy has a lower recurrence rate (<1%) but a similar risk of hemorrhage (1.3%). Such patients with recurrent ulcer bleeding are often submitted to a second gastric operation to cure recurrent ulcer. Similarly, most of our patients had a history of two or more hospital admissions for recurrent ulcer bleeding after surgery and two of them had a second gastric operation that failed to cure recurrent ulcer.

Cimetidine has been used in a few clinical trials including a small number of patients with recurrent ulcer bleeding following surgery for peptic ulcer disease<sup>[6,7,15–17]</sup>. Cimetidine heals about 85% of ulcers within 8 weeks<sup>[17]</sup>, but about 30% of ulcers relapse within 6 months after discontinuing therapy<sup>[7,17]</sup>. Furthermore, 33% of ulcers recur 1 year after surgery while on cimetidine maintenance therapy<sup>[6]</sup>, probably because of tolerance to H<sub>2</sub>RA, which is more significant after 4 wk of therapy<sup>[18]</sup>. Finally, there is only one clinical trial using omeprazole therapy for 12 patients with recurrent ulcer after vagotomy or gastrectomy and all ulcers are healed after 8 weeks of omeprazole therapy<sup>[8]</sup>, suggesting that maintenance therapy with PPIs is the only alternative for surgical intervention. Since as many as one-third of patients with anastomotic ulcer have recurrent ulcer within a year after discontinuing acid reduction therapy<sup>[6,15]</sup>, an open trial of PPI maintenance treatment should be considered ethically justifiable.

The role of *H pylori* in recurrent peptic ulcer disease after gastric surgery has been investigated in several clinical studies<sup>[9,10,12,19]</sup>, showing that *H pylori* does not play an important role in post surgical ulcer recurrence. Less than half of our patients with recurrent ulcer bleeding were *H pylori*-positive upon admission to the study. Furthermore, one of our patients who had successful *H pylori* eradication therapy during a previous hospitalization was admitted to our department for a new episode of anastomotic ulcer bleeding. Another patient had two gastric operations for recurrent ulcer bleeding. Upon study entry, he had successful *H pylori* eradication therapy, followed by omeprazole (20 mg/d) maintenance therapy. He was healthy for 2 years and then lost his follow-up. He was readmitted to another hospital for recurrent ulcer bleeding 8 mo after discontinuing PPI maintenance therapy, though he was *H pylori*-negative.

With regard to the underlying mechanism of ulcer recurrence, our study showed that patients with recurrent ulcer bleeding after truncal vagotomy or partial gastrectomy had a higher treatment-free 24-h intragastric acidity than controls with no ulcer recurrence after the same operation, suggesting that vagotomy may be incomplete due to a retained antrum<sup>[20,21]</sup>. Our data showed that ulcer healing therapy with omeprazole (40 mg/d) could strongly inhibit gastric acid secretion. The intragastric acidity could also be significantly reduced with oral omeprazole maintenance treatment (20 mg/d).

Other factors that may be implicated in ulcer recurrence after surgical treatment for duodenal ulcer include a decreased resistance to acid in the jejunal mucosa, the site of pyloroplasty and anastomosis, possibly due to local ischemia and scarring. Hirschowitz and Lanos<sup>[11]</sup> also showed that aspirin abusers develop intractable recurrent ulceration following gastric surgery for peptic ulcer disease. However, our patients refused to use non-steroidal anti-inflammatory drugs and their serum salicylates were negative. Zollinger-Ellison syndrome was also excluded by normal fasting serum gastrin.

In conclusion, omeprazole (20 mg/d) maintenance therapy should be the treatment of choice for patients with recurrent ulcer after gastric surgery for duodenal ulcer disease.

## Abstract

**AIM:** Interstitial cells of Cajal (ICCs) are the pacemaker cells that generate slow waves in the gastrointestinal (GI) tract. We have aimed to investigate the involvement of mitochondrial  $\text{Na}^+-\text{Ca}^{2+}$  exchange in intestinal pacemaking activity in cultured interstitial cells of Cajal.

**METHODS:** Enzymatic digestions were used to dissociate ICCs from the small intestine of a mouse. The whole-cell patch-clamp configuration was used to record membrane currents (voltage clamp) and potentials (current clamp) from cultured ICCs.

**RESULTS:** Clonazepam and CGP37157 inhibited the pacemaking activity of ICCs in a dose-dependent manner. Clonazepam from 20 to 60  $\mu\text{mol/L}$  and CGP37157 from 10 to 30  $\mu\text{mol/L}$  effectively inhibited  $\text{Ca}^{2+}$  efflux from mitochondria in pacemaking activity of ICCs. The  $\text{IC}_{50}$ s of clonazepam and CGP37157 were 37.1 and 18.2  $\mu\text{mol/L}$ , respectively. The addition of 20  $\mu\text{mol/L}$   $\text{NiCl}_2$  to the internal solution caused a "wax and wane" phenomenon of pacemaking activity of ICCs.

**CONCLUSION:** These results suggest that mitochondrial  $\text{Na}^+-\text{Ca}^{2+}$  exchange has an important role in intestinal pacemaking activity.

## INTRODUCTION

The interstitial cells of Cajal (ICCs) produce spontaneous rhythmic inward currents that are critical for the generation of slow waves in intestinal smooth muscle<sup>[1-3]</sup>. Pacemaker currents in ICCs result from the activation of a voltage-independent, non-selective cation conductance<sup>[4,5]</sup>. Pacemaking activity in ICCs is dependent upon metabolic activity<sup>[6]</sup> and  $\text{Ca}^{2+}$  release from intracellular stores<sup>[7]</sup>. Recent findings suggested that the pacemaker conductance in ICC is regulated by intracellular  $\text{Ca}^{2+}$  modulation<sup>[8]</sup>. The close association between  $\text{IP}_3$  receptor-dependent  $\text{Ca}^{2+}$  stores, mitochondria, and ion channels in the plasma membrane creates a basic cellular structure<sup>[9,10]</sup>. Release of  $\text{Ca}^{2+}$  from  $\text{IP}_3$  receptors does not directly initiate pacemaker currents in ICC, but rather, initiates  $\text{Ca}^{2+}$  uptake into the mitochondria. It was found that mitochondria in ICCs experience  $\text{Ca}^{2+}$  oscillations at the same frequency as pacemaker currents and that a rise in mitochondrial  $\text{Ca}^{2+}$  slightly precedes the activation of pacemaker currents<sup>[8]</sup>. This implies that pacemaker channels in the plasma membrane are activated by the falling phase of localized  $\text{Ca}^{2+}$  transients.

In isolated mitochondria,  $\text{Ca}^{2+}$  influx occurs via a  $\text{Ca}^{2+}$  uniporter driven by the membrane potential<sup>[11]</sup>.  $\text{Ca}^{2+}$  efflux occurs via  $\text{Na}^+-\text{Ca}^{2+}$  exchange and can be inhibited by diltiazem, clonazepam, CGP37157, and by high external  $\text{Ca}^{2+}$ <sup>[11-14]</sup>. However, the effect of inhibiting mitochondrial efflux, by using inhibitors of the  $\text{Na}^+-\text{Ca}^{2+}$  exchange, on pacemaking activity of ICCs has not yet been investigated. Therefore, we undertook to investigate the involvement of mitochondrial  $\text{Na}^+-\text{Ca}^{2+}$  exchange in pacemaking activity of ICCs.

## MATERIALS AND METHODS

### Preparation of cells and cell cultures

Balb/c mice (8-13 days old) of either sex were anesthetized with ether and killed by cervical dislocation. The small intestines from 1 cm below the pyloric ring to the cecum were removed and opened along the mesenteric border. Luminal contents were removed by washing with Krebs-Ringer bicarbonate solution. The tissues were pinned to

**A****B**

**Figure 1** The effect of clonazepam on the pacemaking activity of ICCs. Clonazepam was applied to examine its effect on the pacemaking activity of ICCs. A: Under a voltage clamp at a holding potential of  $-60$  mV,  $50$   $\mu\text{mol/L}$  clonazepam inhibited the pacemaking currents of ICCs ( $n=4$ ). B: Clonazepam from  $20$  to  $60$   $\mu\text{mol/L}$  effectively inhibited  $\text{Ca}^{2+}$  efflux from mitochondria in the pacemaking activity of ICCs. The  $\text{IC}_{50}$  of clonazepam was  $37.1$   $\mu\text{mol/L}$ .

the base of a Sylgard dish and the mucosa removed by sharp dissection. Small tissue strips of the intestine muscle (consisting of both circular and longitudinal muscles) were equilibrated in  $\text{Ca}^{2+}$ -free Hanks solution (containing in mmol/L: KCl  $5.36$ , NaCl  $125$ , NaOH  $0.34$ ,  $\text{NaHCO}_3$   $0.44$ , glucose  $10$ , sucrose  $2.9$ , and HEPES  $11$ ) for  $30$  min. Then, the cells were dispersed using an enzyme solution containing collagenase (Worthington Biochemical Co., Lakewood, NJ, USA)  $1.3$  mg/mL, bovine serum albumin (Sigma Chemical Co., St. Louis, MO, USA)  $2$  mg/mL, trypsin inhibitor (Sigma)  $2$  mg/mL and ATP  $0.27$  mg/mL. Cells were plated onto sterile glass coverslips coated with murine collagen ( $2.5$   $\mu\text{g/mL}$ , Falcon/BD, Franklin Lakes, NJ, USA) in a  $35$ -mm culture dish and then cultured at  $37^\circ\text{C}$  in a  $95\%$   $\text{O}_2$ ,  $50$  mL/L  $\text{CO}_2$  incubator in a smooth muscle growth medium (Clonetics Corp., San Diego, CA, USA) supplemented with  $2\%$  antibiotics/antimycotics (Gibco, Grand Island, NY, USA) and murine stem cell factor (SCF,  $5$  ng/mL, Sigma). ICCs were identified immunologically with anti-c-kit antibody (phycoerythrin-conjugated rat anti-mouse c-kit monoclonal antibody; eBioscience, San Diego, CA, USA) at a dilution of  $1:50$  for  $20$  min<sup>[15]</sup>. ICCs were morphologically distinct from other cell types in the culture and thus it was possible to identify the cells by phase contrast microscopy once they had been verified with anti-c-kit antibody.

#### Patch-clamp experiments

The whole-cell patch-clamp configuration was used to record membrane currents (voltage clamp) and potentials (current clamp) from cultured ICCs. An axopatch ID (Axon Instruments, Foster, CA, USA) was used to amplify membrane currents and potentials. The command pulse was applied using an IBM-compatible personal computer and pClamp software (version  $6.1$ ; Axon Instruments). Data

obtained were filtered at  $5$  kHz and displayed on an oscilloscope, a computer monitor, and using a pen recorder (Gould 2200, Gould, Valley View, OH, USA).

Results were analyzed using pClamp and Origin (version  $6.0$ ) software. All experiments were performed at  $30$ – $32^\circ\text{C}$ .

#### Solutions and drugs

The physiological salt solution used to bathe cells (Na<sup>+</sup>-Tyrode) contained (mmol/L): KCl  $5$ , NaCl  $135$ ,  $\text{CaCl}_2$   $2$ , glucose  $10$ ,  $\text{MgCl}_2$   $1.2$  and HEPES  $10$ , adjusted to pH  $7.4$  with NaOH. The pipette solution contained (mmol/L): KCl  $140$ ,  $\text{MgCl}_2$   $5$ ,  $\text{K}_2\text{ATP}$   $2.7$ , NaGTP  $0.1$ , creatine phosphate disodium  $2.5$ , HEPES  $5$  and EGTA  $0.1$ , adjusted to pH  $7.2$  with KOH.

Before the development of CGP37157, several benzodiazepines (except clonazepam) were used as mitochondrial Na<sup>+</sup>-Ca<sup>2+</sup> exchange inhibitors<sup>[12]</sup>. Clonazepam and CGP37157 were dissolved in dimethyl sulfoxide (DMSO) for  $100$  and  $50$  mmol/L stock solution, respectively and added ( $1$  000 times dilution) to the bathing solution at the day of the experiment. The final concentration of DMSO in the bath solution was always  $<0.1\%$ , and we confirmed that this concentration of DMSO did not affect the results that were recorded. Nickel chloride was directly added to the pipette solutions at the day of the experiment. CGP37157 was purchased from Tocris Cookson (Ellisville, MO, USA). The rest of the drugs were obtained from Sigma (Sigma Chemical Co., USA), unless otherwise stated. Diltiazem was not used because of its known effects on the cell membrane Ca<sup>2+</sup> channels.

## RESULTS

**Effect of clonazepam on the pacemaking activity of ICCs**  
Under a voltage clamp at a holding potential of  $-60$  mV, clonazepam  $50$   $\mu\text{mol/L}$  inhibited the pacemaking currents of ICCs ( $n=4$ , Figure 1A). Clonazepam from  $20$  to  $60$   $\mu\text{mol/L}$  effectively inhibited  $\text{Ca}^{2+}$  efflux from mitochondria on the pacemaking activity of ICCs. Concentrations of clonazepam of  $>100$   $\mu\text{mol/L}$  produced no further inhibition. The  $\text{IC}_{50}$  of clonazepam was  $37.1$   $\mu\text{mol/L}$  (Figure 1B).

#### Effect of CGP37157 on the pacemaking activity of ICCs

The benzodiazepine CGP37157 has been shown to be a more potent inhibitor than either clonazepam or diltiazem in terms of  $\text{Ca}^{2+}$  efflux measured in isolated mitochondria<sup>[12]</sup>. Thus, CGP37157 was applied to examine its effect on the pacemaking activity of ICCs. Under a current clamp ( $I=0$ ), CGP37157 was found to inhibit pacemaking potentials in a dose-dependent manner ( $n=15$ , Figures 2A–2C). CGP37157 from  $10$  to  $30$   $\mu\text{mol/L}$  effectively inhibited  $\text{Ca}^{2+}$  efflux from mitochondria on the pacemaking activity of ICCs. Concentrations of CGP37157 of  $>50$   $\mu\text{mol/L}$  produced no further inhibition. The  $\text{IC}_{50}$  of CGP37157 was  $18.2$   $\mu\text{mol/L}$  (Figure 2D).

#### Effect of internal $\text{Ni}^{2+}$ on the pacemaking activity of ICCs

$\text{Ni}^{2+}$  is a competitive inhibitor of the  $\text{Ca}^{2+}$  carrier, but it is not transported into the mitochondria<sup>[16]</sup>. Micromolar concentrations of nickel ( $\text{Ni}^{2+}$ ) chloride have been reported

**Figure 2** The effect of CGP37157 in the pacemaking activity of the ICCs. CGP37157 was applied to examine its effect on the pacemaking activity of ICCs. **A, B, and C:** Under a current clamp ( $I=0$ ), CGP37157 inhibited the pacemaking potentials in a dose-dependent manner ( $n=15$ ). **D:** CGP37157 from 10 to 30  $\mu\text{mol/L}$  effectively inhibited  $\text{Ca}^{2+}$  efflux from mitochondria in the pacemaking activity of ICCs. The  $\text{IC}_{50}$  of CGP37157 was 18.2  $\mu\text{mol/L}$ .

to inhibit  $\text{Na}^{+}\text{-Ca}^{2+}$  exchange in both vascular and non-vascular cells<sup>[17]</sup>. In order to investigate the effect of  $\text{NiCl}_2$  on the pacemaking activity of ICCs, we added 20  $\mu\text{mol/L}$   $\text{NiCl}_2$  to the internal solution. Under a voltage clamp mode at a holding potential of -60 mV, the pacemaking activity of ICCs showed a "wax and wane" phenomenon ( $n=6$ , Figure 3A). Also in current clamp mode ( $I=0$ ), the same phenomenon was shown ( $n=3$ , Figure 3B). In case of 100  $\mu\text{mol/L}$   $\text{NiCl}_2$ , the pacemaking activity of ICCs stopped (data not shown).

## DISCUSSION

Intracellular  $\text{Ca}^{2+}$  plays an important role in the regulation of various cellular functions including exocytosis, metabolic activity, contractile activity, and gene expression in excitable cells. In these cells, the intracellular  $\text{Ca}^{2+}$  concentration ( $[\text{Ca}^{2+}]_i$ ) is lowered by various mechanisms such as  $\text{Ca}^{2+}$  extrusion due to the actions of  $\text{Na}^{+}\text{-Ca}^{2+}$  exchangers and  $\text{Ca}^{2+}$  pumps in the plasma membrane,  $\text{Ca}^{2+}$  uptake by  $\text{Ca}^{2+}$  pumps in the endoplasmic reticulum, and by  $\text{Ca}^{2+}$  uniporters in the mitochondria<sup>[17]</sup>. Sequestered  $\text{Ca}^{2+}$  in mitochondria is, in turn, released to the cytoplasm via various mechanisms<sup>[11]</sup>.  $\text{Na}^{+}\text{-Ca}^{2+}$  exchangers and/or permeability transition pores are proposed to be involved in  $\text{Ca}^{2+}$  efflux from the mitochondria<sup>[11]</sup>.

In case of ICCs, pacemaking activity is associated with mitochondrial  $\text{Ca}^{2+}$  transients. Pacemaker currents and rhythmic mitochondrial  $\text{Ca}^{2+}$  uptake by ICCs are blocked by inhibitors of  $\text{IP}_3$ -dependent  $\text{Ca}^{2+}$  release from the endoplasmic reticulum and by inhibitors of endoplasmic reticulum  $\text{Ca}^{2+}$  reuptake. Therefore, integrated  $\text{Ca}^{2+}$  management by endoplasmic reticulum and mitochondria is a prerequisite of electrical pacemaking in the gastrointestinal tract<sup>[8]</sup>.

CGP37157 is a benzodiazepine derivative that inhibits

**Figure 3** Effect of internal  $\text{Ni}^{2+}$  on the pacemaking activity of ICCs. In order to investigate the effect of  $\text{NiCl}_2$  on the pacemaking activity of ICCs, we added 20  $\mu\text{mol/L}$  of  $\text{NiCl}_2$  to the internal solution. **A:** Under a voltage clamp at a holding potential of -60 mV, the pacemaking activity of ICCs showed a "wax and wane" phenomenon ( $n=6$ ). **B:** Current clamp mode ( $I=0$ ) showed the same phenomenon ( $n=3$ ).

electroneutral mitochondrial  $\text{Na}^{+}\text{-Ca}^{2+}$  exchanger with sub-micromolar potency. In the heart, for example, this transporter is inhibited by CGP37157 at 400 nmol/L<sup>[12,14]</sup>. Before the development of CGP37157, several related benzodiazepines (e.g., clonazepam and diltiazem) were used as mitochondrial  $\text{Na}^{+}\text{-Ca}^{2+}$  exchange inhibitors<sup>[14]</sup>. In general, few have reported that these compounds inhibit the cardiac plasmalemmal  $\text{Na}^{+}\text{-Ca}^{2+}$  exchanger<sup>[18,19]</sup>. Mitochondrial  $\text{Na}^{+}\text{-Ca}^{2+}$  exchanger protein participates in  $\text{Ca}^{2+}$  efflux and operates in opposition to a  $\text{Ca}^{2+}$  uniporter within the inner mitochondrial membrane. Thus, the inhibition of mitochondrial  $\text{Na}^{+}\text{-Ca}^{2+}$  exchanger leads to an increase in  $\text{Ca}^{2+}$  levels within the mitochondria<sup>[14]</sup>. Calcium within the mitochondria serves as an important regulator of several key enzymes involved in energy metabolism. For example, the upregulation of the steady-state level of mitochondrial  $[\text{Ca}^{2+}]$  ( $[\text{Ca}^{2+}]_m$ ) result increases NADH production and stimulates oxidative phosphorylation<sup>[14]</sup>.

The benzodiazepine CGP37157 has been shown to be a more potent inhibitor than either clonazepam or diltiazem on  $\text{Ca}^{2+}$  efflux, as measured in isolated mitochondria<sup>[12]</sup>. In ICCs, the  $\text{IC}_{50}$ s of clonazepam and CGP37157 were found to be 37.1 and 18.2  $\mu\text{mol/L}$ , respectively. Thus, CGP37157 was about twofold more potent than clonazepam.

$\text{Ni}^{2+}$  is a potent inhibitor of mitochondrial  $\text{Ca}^{2+}$  transport<sup>[20]</sup> and a competitive inhibitor of  $\text{Ca}^{2+}$  carrier<sup>[16]</sup>. Also micromolar concentrations of nickel ( $\text{Ni}^{2+}$ ) chloride were found to inhibit  $\text{Na}^{+}\text{-Ca}^{2+}$  exchanger in both vascular and non-vascular cells<sup>[21]</sup>. Therefore, we have investigated the effect of  $\text{NiCl}_2$  added to the internal solution. At 20  $\mu\text{mol/L}$ , we observed a "wax and wane" phenomenon and at 100  $\mu\text{mol/L}$ , the pacemaking activity of ICCs stopped.

Our data indicate that both clonazepam and CGP37157 inhibit the pacemaking activity of ICCs in a dose-dependent manner. The  $\text{IC}_{50}$ s of clonazepam and CGP37157 were 37.1 and 18.2  $\mu\text{mol/L}$ , respectively. When 20  $\mu\text{mol/L}$   $\text{NiCl}_2$  was added to the internal solution, the pacemaking activity of ICCs showed a "wax and wane" phenomenon.

We conclude that mitochondrial  $\text{Na}^{+}\text{-Ca}^{2+}$  exchange has an important role in intestinal pacemaking activity.

### Abstract

Desmoplastic small round cell tumor (DSRCT) is a rare, highly aggressive malignancy with distinctive histological features: a nesting pattern of cellular growth within dense desmoplastic stroma, occurring in young population with male predominance. The mean survival period is only about 1.5-2.5 years. The tumor has co-expressed epithelial, muscle, and neural markers in immunohistochemical studies. This work reports a 27-year-old man presenting with hematemesis and chronic constipation. Serial studies including endoscopy, upper gastrointestinal series, abdominal computed tomography and barium enema study showed disseminated involvement of visceral organs. The patient underwent aggressive surgery and received postoperative adjuvant chemotherapy consisting of 5-fluorouracil, cyclophosphamide, etoposide, doxorubicin, and cisplatin. He survived without any disease for 20 mo after the surgery. No standard treatment protocol has been established. Aggressive surgery combined with postoperative multi-agent adjuvant chemotherapy is justified not only to relieve symptoms but also to try to improve the outcome in this advanced DSRCT young patient.

### INTRODUCTION

Desmoplastic small round cell tumor (DSRCT) is a rare malignancy with highly aggressive behavior spreading widely along the serosal surface. Gerald and Rosai<sup>[1]</sup> first described the disease in 1989 in terms of distinctive pathologic findings: a nesting pattern of cellular growth within dense desmoplastic stroma, and immunohistochemical co-expression of epithelial, muscle and neural markers<sup>[1-3]</sup>. A specific chromosome abnormality, t (11;22) (p13;q11 or q12) was identified<sup>[4]</sup>, and DSRCT is believed to be the result of involvement of both Wilms' tumor suppressor gene and Ewing's sarcoma gene located on Chromosome 11 and 22, respectively<sup>[5]</sup>. The tumors usually present in young male individual, as a single mass or multiple masses in the abdominal-pelvic cavity with metastases common to peritoneum, liver and lymphoid tissue<sup>[6]</sup>. Some cases had presentation sites in the scrotum<sup>[6,7]</sup>, pleural space<sup>[6,8,9]</sup> and mediastinum<sup>[6,10]</sup>. Complete resection is generally difficult to obtain due to multiple foci and dissemination. The standard treatment protocol has not been well established. Chemotherapy currently seems to be the best potential treatment. This work reports on a case of DSRCT with no disease for 20 months following complete resection of tumors and postoperative multi-agent adjuvant chemotherapy consisting of 5-fluorouracil (5-FU) and PAVEP (cyclophosphamide, etoposide, doxorubicin and cisplatin).

### CASE REPORT

The 27-year-old man had intermittent epigastralgia, abdominal fullness, and chronic constipation for 3 months. He presented sudden onset of hematemesis (500 mL) outside our hospital on September 15, 2003. Physical examination revealed only mild epigastric tenderness. The hemoglobin level was normal. Endoscopy showed esophageal and cardiac ulcers without complete study owing to poor compliance of the patient. Upper gastrointestinal (GI) series demonstrated a mass with external compression at the gastric antrum (Figure 1). Abdominal computed tomography (CT) indicated a 5 cm heterogeneous mass located among the gastric antrum, duodenum loop and pancreatic head (Figure 2). Barium enema study showed external compression of the middle transverse colon, ileocecal valve and ascending colon (Figure 3). Laparoscopic biopsy was performed because multiple intra-abdominal organs were involved. A histo-

**Figure 1** Upper gastrointestinal series shows that the gastric antrum (arrows) is deformed due to external compression.

**Figure 2** Abdominal computed tomography shows a 5 cm heterogeneous mass (arrows) located between the gastric antrum, duodenal loop, and pancreatic head.

pathologic exam of the specimen revealed poorly differentiated carcinoma. The patient was then referred to our hospital for further treatment.

No significant medical or pertinent family history was found. Additionally, no history of exposure to carcinogens such as radiation, tobacco or asbestos was identified. Hematogram showed hemoglobin, 110 g/L and white blood cells (WBC),  $11 \times 10^9$ /L. Biochemistry studies yielded normal results. Tumor markers such as carcinoembryonic antigen and carbohydrate antigen 19-9 were within the normal range. Laparotomy was performed on October 3, 2003 to relieve the patient's symptoms. During the operation, the gastric antrum, pancreas, terminal ileum and cecum, sigmoid colon, rectovesicular region and omentum were all involved by tumors. Right hydroureter was also identified due to external compression by the tumor. Subtotal gastrectomy, partial pancreatic resection, total omentectomy, proctocolectomy and J-pouch ileo-anal anastomosis were performed for complete resection of tumors. A double-J stenting was inserted through the ureterostomy by a urologist.

A histopathologic exam of the surgical specimens demonstrated invasive nests of poorly differentiated carcinoma, mainly involving omentum, pancreatic, and gastric, colonic and ileal muscular walls with focal mucosa extension. Large and small foci of tumor cells were observed in fibrous interstitium (Figure 4A). The tumor cells

**Figure 3** Barium enema study demonstrates a mass compressing the middle transverse colon with tethering appearance, suggesting gastrocolic ligament invasion (black arrows). Long segmental encasement of cecum, proximal ascending colon (white arrows), and ileocecal valve (arrows head) is also evident.

had a small spherical or spheroid nucleus, which was rich in chromatin (Figure 4B). One of 20 peri-colic lymph nodes was positive for metastasis. The section margins were free of tumor. The immunohistochemical tests were positive for desmin (Figure 4C), epithelium membrane antigen and neuron-specific enolase, and focal positive for vimentin, indicating DSRCT.

J-pouch ileo-anal anastomosis leakage with intra-abdominal abscess occurred on postoperative day 7. The patient recovered after treatment by antibiotics and CT-guidance drainage. Postoperative adjuvant chemotherapy with high dose 5-FU ( $2600 \text{ mg/m}^2$ , day 1) was initiated on 24<sup>th</sup> October, 2003. The patient received altogether eight courses of chemotherapy of 5-FU thereafter. Another chemotherapeutic regimen consisting of PAVEP (cyclophosphamide  $300 \text{ mg/m}^2$ , d 1-3; etoposide  $75 \text{ mg/m}^2$ , day 1-3; doxorubicin  $40 \text{ mg/m}^2$ , day 1; cisplatin  $100 \text{ mg/m}^2$ , day 4) was administered on February 17, 2004. Neutropenic (WBC,  $2 \times 10^9$ /L) fever developed one week later even though prophylactic granulocyte colony-stimulating factor (G-CSF) was given the day following chemotherapy. The patient received broad-spectrum antibiotics treatment, and his fever was gradually controlled. He was discharged 12 d later when his WBC returned to normal. Another four chemotherapy courses with PAVEP regimens were completed on May 24, 2004. He survived without any disease 20 mo after the surgery.

## DISCUSSION

DSRCT has a strong male predominance, and the majority arises below the diaphragm with serosal spreading and easily metastasizing to lung, liver, and lymphoid tissues<sup>[2,6,11]</sup>. The most common site was the pelvis (62%), followed by spreading widely on the peritoneal surface (42%)<sup>[12]</sup>. Symptoms such as abdominal pain (52.1%), increased abdominal girth (8.4%), and abdominal mass (5.6%) have been reported<sup>[14]</sup>. Patients also presented with GI or genitourinary obstruction. GI bleeding does not appear to have been reported in the literature. This patient was the first case with DSRCT presented with GI bleeding. The bleeding was associated with tumors directly invading to the gastric mucosa.

The prognosis of DSRCT is dismal with a mean survival of 1.5-2.5 years since the wide spread of the tumor makes radical resection difficult to achieve, and

**Figure 4A:** Photomicrography depicts nests or clusters of small tumor cells outlined by characteristic desmoplastic stroma bands (hematoxylin and eosin staining, 100 $\times$ ). **B:** Photomicrography demonstrates the monomorphic, small round tumor cell population with a small spherical or spheroid nucleus, rich in chromatin (hematoxylin and eosin staining, 400 $\times$ ). **C:** The immunohistochemical staining of tumor cells is positive for desmin.

chemotherapeutic agents are only temporarily effective in treating this disease<sup>[6,12-15]</sup>. Farhat *et al*<sup>[13]</sup> recommended that PAVEP should be the first-line drug for treating DSRCT after reviewing 8 cases with complete remission from the treated 60 cases. However, grade four neutropenia occurred in 69% cycles while administering PAVEP regimens despite prophylactic use of G-CSF in 90% of cases in his report<sup>[15]</sup>. Considering the severe and life-threatening side effects and uncertainty of therapeutic results of PAVEP regimens, other safer and effective chemotherapeutic agents should be considered prior to PAVEP.

5-FU is well-known as a chemotherapeutic agent and a radioactive sensitizer broadly used for GI tract cancers and

disseminated intra-abdominal metastatic adenocarcinoma. Gerald *et al*<sup>[2]</sup> reported a successful application of 5-FU in treating intra-abdominal DSRCT. Kretschmar *et al*<sup>[6]</sup> also reported 60% responsive rate to this tumor. Since DSRCT is a highly aggressive and progressive malignancy, post-operative adjuvant chemotherapy should be initiated as soon as possible. Post-operative anastomotic leakage and right urinary tract obstruction arose in our case. Therefore, 5-FU was applied instead of PAVEP regimen as the first-line drug to treat DSRCT considering the infection problems and the adverse effects of PAVEP regimens such as myelo-suppression and renal toxicity.

DSRCT is a disease so rare that no consistent response to chemotherapy was seen in the literature review<sup>[12]</sup>. Kurre *et al*<sup>[16]</sup> presented another alkylator-based chemotherapy protocol named P6 (cyclophosphamide, doxorubicin, vincristine, ifosfamide, and etoposide), which only improved the progression-free survival without significant survival benefit. Gil *et al*<sup>[12]</sup> recommended performing perioperative intraperitoneal chemotherapy when treating DSRCT patients, but no evidence of prolonged survival was observed.

The effect of complete resection of disseminated tumors on survival is still unknown because of the rarity of achieving complete resection at operation. Gil *et al*<sup>[12]</sup> reported that the median survival was 20 mo in 4 patients with complete resection of tumors compared with 11 mo in 3 cases without complete resection. Significantly, long-term survivors, including one patient who survived for 101 mo, have been reported when utilizing combined modality treatment comprising surgery and multi-agent chemotherapy. The influence of other salvage therapies, such as immunotherapy or bone marrow ablation, is still undetermined. In this work, the patient underwent complete resection of tumors and received postoperative adjuvant chemotherapy surviving without any disease and without gastrointestinal symptoms 20 mo after surgery, similar to that in Gil's report<sup>[12]</sup>.

In conclusion, the optimal treatment for DSRCT remains to be determined, indicating the rarity and virulent behavior of the disease. In this advanced DSRCT patient, aggressive surgery combined with postoperative systemic multi-agent adjuvant chemotherapy was justified not only to relieve his symptoms but also to try to improve his outcome. The effectiveness and safety of chemotherapeutic regimens still need to be improved to treat this disease as early as possible postoperatively, especially when patients cannot tolerate the toxicity of alkylator agents after such an aggressive surgery.

chloride, arsenic, thorotrast and irradiation are associated with an increased risk for the development of AS of the liver and are considered as etiologic cofactors<sup>[3-5]</sup>. Clinical diagnosis is usually hampered by the unspecific clinical signs and symptoms. Patients reported have been found with pain, loss of energy, and weight, hemorrhage and extrusion<sup>[6,7,8]</sup>. The therapeutical options described are oncological liver resection and chemotherapy<sup>[6,7,9]</sup>. Liver transplantation has not been reported to be significantly beneficial in this subgroup of sarcoma patients so far<sup>[10]</sup>. The clinical course of AS, even after curative surgery and chemotherapy is aggressive with a poor prognosis has been reported<sup>[7,11,12]</sup>.

Here, we report about the rare case of a patient with acute bleeding to the abdominal cavity by a spontaneously ruptured AS of the liver.

### CASE REPORT

A 76-year-old man was referred to the hospital with acute abdominal pain. With the onset of pain the patient collapsed. The subsequent consultation lead to emergency admission to the department of surgery. Apart from a slowly progressive local prostate cancer which was already resected transurethrally thrice (5 years ago, 1 year ago and palliatively 1 month before the admission), no significant disease was reported. The patient neither reported any kind of abdominal trauma nor prior abdominal surgery. Medication comprised antihypertensive drugs, iodine and androgene blockers since 1999. Besides that the patient had controlled his diabetes with an insulin pump.

At physical examination of the conscious patient, the abdomen was distended and showed a diffuse pain at deep palpation without clinical signs for peritonitis. Vital signs showed a slightly elevated blood pressure (140/70 mmHg) and a tachycardia (120 heart beats/min). Emergency blood test including hemoglobin, white blood count, electrolytes and hemostasis parameters revealed a reduced hemoglobin with 6.9 g/dL. Besides that, infection parameters were elevated with leukocytes of 16.0/nL and a C-reactive protein of 75.4 mg/L. Cholinesterase and albumin were also lowered significantly. Hemostasis parameters were normal.

The ultrasound examination of the abdomen, performed as the primary diagnostic modality, showed free abdominal fluid and a pathological finding in the left lobe of the liver, diagnosed as a ruptured liver lesion, at that time suspicious of a liver cell adenoma due to a 5-year

### Abstract

Angiosarcoma is a rare primary malignant neoplasm of the liver with a poor prognosis. Here, we report a case of a patient with a ruptured hepatic angiosarcoma which was treated by emergency catheter-directed embolization, followed by left-sided hemihepatectomy.

### INTRODUCTION

Angiosarcoma (AS) is a rare tumor entity which comprises less than 1% of all sarcomas<sup>[1]</sup>. Although rarely observed, it is the third most common primary malignant tumor of the liver. The occurrence of AS in the liver shows a predelection for elderly males<sup>[2]</sup>. The exposures to vinyl

**Figure 1** CT scan before embolization.

period of regular intake of androgene blockers. In order to identify the location of the active bleeding within the liver, an additive contrast enhanced computed tomography (CT) of the abdomen was carried out. The CT images confirmed a ruptured lesion of the left liver lobe with an ongoing active arterial bleeding located centrally within segments 2 and 3. In addition, a considerable amount of intra-abdominal blood (1-2 L) was diagnosed (Figure 1). The patient received blood transfusions (2 erythrocyte concentrates) and stayed hemodynamically stable. The interdisciplinary decision between radiologists and surgeons was made for therapeutic radiological intervention.

Subsequently, the patient was transferred to the radiological catheter room. The intervention was carried out by puncture of the right femoral artery and selective catheterization of the left hepatic artery. After cannulation of the left liver artery, the left lobe of the liver was completely and successfully embolized with 2 mL of embosphere 500-700 and 2 mL of embosphere 900-1 200. After intervention, there were no more signs for active bleeding, and blood pressure and heart rate stayed regular (Figure 2A, before embolization and Figure 2B after embolization). The patient was treated post-interventionally for 2 d at the intensive care unit before he was referred in a completely stable condition to the regular ward. Consecutively, elective surgery was scheduled to treat the abdominal hematoma and the ruptured lesion of the left lobe of the liver.

Preoperatively performed endoscopy of the upper GI tract and colonoscopy showed no substantial pathological findings (small axial hiatus hernia and a diverticulosis of the sigma without signs for inflammation).

### **Intraoperative findings**

Surgery was performed 7 d after embolization. Explorative laparotomy revealed approximately 3 L of intra-abdominal hematoma without signs for active liver bleeding. Exploration of the left lobe of the liver revealed a ruptured hepatic tumor to the peritoneal cavity with a diameter of 12.5 cm which showed macroscopic characteristics of a hepatic adenoma. In order to treat the ruptured left lobe and to remove the liver tumor,

**Figure 2** Angiography A: before embolization B: after embolization.

a left sided hemihepatectomy was carried out. After resection, intraoperative sonography of the remaining liver parenchyma showed no pathological findings. Intraoperatively and during the early post-operative course, the patient received five erythrocyte-concentrates and two units of fresh frozen plasma. The post-operative course was uneventful and the patient could be discharged from hospital 19 d after the surgery.

### **Histopathologic findings**

Histopathological examination of the specimen revealed a ruptured hematous hepatic malignancy of 12.5 cm diameter without sharp demarcation. The histopathological examination and the immunostaining diagnosed a tumor with endothelial proliferates along the liver sinusoids, large necroses and cell atypias consisting of solid and papillary tumor parts. Immunohistochemical staining for CD31, CD34, MIB-1 confirmed the diagnosis of a hemangiosarcoma. The final diagnosis was a ruptured AS of the left lobe of the liver with tumor-free resection margins at microscopic evaluation.

### **Postoperative course**

Four weeks after primary surgery, the patient was readmitted to the hospital with the suspicion of recurrent acute intra-abdominal bleeding. A CT-scan showed free intra-abdominal fluid collection. An angiography showed small contracted vessels of the liver without proof of

**Figures 3** A and B Intraoperative pictures of peritoneal sarcomatosis.

active bleeding. The patient showed signs of hemorrhagic shock and received four erythrocyte concentrates and six units of fresh frozen plasma. Duplex-sonography showed reduced perfusion of the liver. Liver transaminases were elevated and the patient suffered simultaneously from a non-STEMI myocardial infarction without indication for acute catheter intervention.

In the following course the patient's abdomen became more and more distended with an aggravated pulmonary situation and progredient amounts of free intra-abdominal fluid. At this point, indication for explorative laparotomy was stated. Intraoperatively, multiple bleeding AS were found in the liver with massive peritoneal sarcomatosis (Figures 3A and 3B). Hemorrhage control of the diffuse bleeding could not be obtained surgically. The abdomen was closed and the patient was taken to the intensive care unit at basal infusion and kept on sedation and mechanical

respiration. Few hours after the explorative laparotomy the patient died from persistent intra-abdominal bleeding from the angiosarcomatosis lesions.

## DISCUSSION

Among malignant vascular tumors, AS is one of the most common subtypes diagnosed in patients undergoing surgery<sup>[13]</sup>. AS has a predilection for cutaneous sites, mostly in the head and neck region of elderly male patients<sup>[14]</sup>. AS also affects gastrointestinal organs<sup>[9,15-18]</sup> and hepatic AS is the second most common primary malignant neoplasm of the liver<sup>[19]</sup>. However, there have only been a few case reports available in the literature concerning primary hepatic AS over the past 10 years (Table 1).

The clinical course of AS is aggressive and prognosis is poor. In a study of 67 patients with AS, an overall 5-year survival of 35% has been reported<sup>[20]</sup>. Morgan *et al*<sup>[21]</sup> investigated 47 patients with cutaneous AS, outlining the

restricted prognosis and demonstrating a 5-year survival of 34%. Another analysis showed a median overall survival of 28.4 months in a cohort of 88 patients with AS of the scalp<sup>[14]</sup>. We observed a lethality of 65% in 43 patients who underwent surgery for AS with a median follow-up of 56 months<sup>[13]</sup>.

AS presents with various unspecific clinical symptoms and a multilocular occurrence. Different sites of occurrence go along with a wide range of non-specific symptoms such as pain, swelling, extrusion, hemorrhage, or bowel obstruction<sup>[22]</sup>. Tumors of the skin and of superficial or deep soft tissue are usually biopsied preoperatively and thus, therapeutic decisions are made before surgery<sup>[13]</sup>. However, as also reported here, organotropic AS may be diagnosed consecutive to emergency treatment<sup>[23-26]</sup> or after the surgery for assumed benign disease. Thus, AS is often diagnosed unexpectedly after surgical procedures which do not meet oncological treatment standards.

To our knowledge, there are only two cases of hepatic AS reported to date, which have been treated by emergency catheter-directed embolization with consecutive liver resection (Table 1)<sup>[24,25]</sup>. Catheter-directed intervention is a useful method to cease acute arterial bleeding from the liver. The most common indication is traumatic laceration of the liver parenchyma<sup>[27]</sup>. Spontaneous bleeding and the formation of hematoma impede the clinical differentiation of the cause of the hemorrhage. In benign lesions (adenoma), a subsequent surgical resection of the affected parenchyma is curative. The catheter-directed embolization allows to perform a planned and well structured operation without the need of emergency liver surgery with high morbidity and lethality. In emergency cases with spontaneous bleeding, a differentiation of malignant or benign disease is impossible. Therefore, the final diagnosis is usually made by the histopathological evaluation of the resected specimen. At the time of the histopathological diagnosis, the prognosis of the disease becomes clear. In ruptured AS of the liver, the prognosis is devastating. Rupture in these cases leads to tumor cell spillage and consecutive diffuse angiosarcomatosis in the peritoneum. The angiosarcomatous lesions consecutively induce diffuse hemorrhage with subsequent loss of large amounts of blood. The acute bleeding from diffuse peritoneal angiosarcomatosis cannot be cured by surgical intervention and thus seems to be the leading cause for death in this rare subset of patients with AS. In an own observational series of 22 AS, 6 primary hepatic AS were found. Three of these patients died within 4 months and one patient 29 months after the diagnosis in spite of surgical intervention. The preliminary cause of death in the latter patients was peritoneal sarcomatosis with diffuse intra-abdominal bleeding<sup>[13]</sup>.

The clinical course of the patient reported here shows that there is no effective treatment available till date either for cure or palliation of ruptured AS of the liver. The value of chemotherapy applied to the peritoneal cavity or systemically has not been clarified nor the value of experimental antitumoral strategies such as molecular therapies (e.g., with VEGF-antagonists) or hyperthermia. This clinical situation underlines the need for new therapy

modalities and broader based clinical studies in patients with ruptured AS of the liver. An effort needs to be undertaken to include patients with ruptured AS of the liver after surgery into prospective trials. The opportunity to establish an international study group may, furthermore, allow a collection of tumor samples from AS in a reasonable number. Consecutive molecular analysis could help to establish targeted antitumoral therapies for these rare and extremely lethal malignancies.

### Abstract

Hereditary non-polyposis colorectal carcinoma (HNPCC) is an autosomal dominant disorder associated with colorectal and endometrial cancer and a range of other tumor types. Germline mutations in the DNA mismatch repair (MMR) genes, particularly *MLH1*, *MSH2*, and *MSH6*, underlie this disorder. The vast majority of these HNPCC-associated mutations have been proven, or assumed, given the family history of cancer, to be transmitted through several generations. To the best of our knowledge, only a single case of a *de novo* germline MMR gene mutation (in *MSH2*) has been reported till now. Here, we report a patient with a *de novo* mutation in *MLH1*. We identified a *MLH1* Q701X truncating mutation in the blood lymphocytes of a male who had been diagnosed with rectal cancer at the age of 35. His family history of cancer was negative for the first- and second-degree relatives. The mutation could not be detected in the patient's parents and sibling and paternity was confirmed with a set of highly polymorphic markers. Non-penetrance and small family size is the common explanation of verified negative family histories of cancer in patients with a germline MMR gene mutation. However, in addition to some cases explained by non-paternity, *de novo* germline mutations should be considered as a possible explanation as well. As guidelines that stress not to restrict MMR gene mutation testing to patients with a positive family history are more widely introduced, more cases of *de novo* MMR gene germline mutations may be revealed.

### INTRODUCTION

Hereditary non-polyposis colorectal carcinoma (HNPCC) is a genetic disorder caused by germline mutations in DNA mismatch repair (MMR) genes, especially *MLH1*, *MSH2* and *MSH6*. HNPCC is characterized clinically by the early-onset colorectal and endometrial cancer as well as a range of other tumor types. In contrast to familial adenomatous polyposis (FAP), HNPCC lacks an easily recognizable clinical phenotype in individual patients. The original and revised Amsterdam criteria (AC and AC II) introduced to clinically define HNPCC therefore include specific characteristics of the family history that should be met<sup>[1,2]</sup>. However, it has become clear that HNPCC patients may have a negative family history. Small family sizes and less than 100% penetrance of the germline mutations involved are its most common explanation. Here, we report the rare phenomenon of a *de novo* germline MMR gene mutation as the cause of a negative family history in a patient with hereditary non-polyposis colorectal carcinoma.

### CASE REPORT

A 35-year-old male had been referred to our department for genetic testing and counseling because he had very recently been diagnosed with a T<sub>4</sub>N<sub>0</sub>M<sub>0</sub> rectal adenocarcinoma. Family history of cancer was negative for the first- and second-degree relatives of the patient. The patient's mother, father, and sibling (aged 60, 61, and 38 years, respectively) were healthy.

As part of an ongoing study on the genetics of colorectal cancer, testing for tumor microsatellite instability (MSI), tumor immunohistochemistry for the *MLH1*, *MSH2* and *MSH6* proteins as well as mutation analysis of *MLH1*, *MSH2* and *MSH6* are offered to all the patients with colorectal cancer diagnosed before the age of 50 who are referred to our department for genetic testing and counseling.

DNA was extracted from formalin-fixed and paraffin-embedded tumor and non-tumor tissues as described previously<sup>[3]</sup>. Subsequent MSI analysis was performed using criteria and primers as described in the Bethesda

**Figure 1** Denaturing gradient gel electrophoresis (DGGE) analysis of exon 18 of *MLH1* gene. Lanes 1 and 2: Father and mother, respectively; lane 3: index patient.

**Figure 2** DNA sequence analysis of exon 18 of *MLH1* gene. (a) A control sample without mutation, (b) the index patient showing a C to T substitution of base 2101 leading to Gln701Stop.

**Figure 3** Paternity test using six highly informative microsatellites. a: The index patient; b: his father; c: his mother.

guidelines<sup>[4]</sup>. PCR products were analyzed on 60 g/L denaturing polyacrylamide gels with an LKB ALF DNA sequencer. For data analysis, the DNA fragment analyzer (Pharmacia) was used.

Immunohistochemistry for MLH1, MSH2, and MSH6 protein expression was carried out as described previously<sup>[5]</sup>. Protein expression in normal tissue surrounding the cancer served as internal control.

Mutation analysis of the *MLH1* and *MSH2* genes in DNA obtained from peripheral blood lymphocytes was carried out using denaturing gradient gel electrophoresis (DGGE), followed in case of aberrant patterns by direct sequencing of independently amplified PCR products as previously described<sup>[6,7]</sup>. To investigate paternity, a panel of six highly polymorphic markers was analyzed with PCR using markers D1S162, D2S202, D4S174, D11S875, D17S250, and IL2-RB in the patient and his parents. PCR products were analyzed on 60 g/L denaturing polyacrylamide gels with an LKB ALF DNA sequencer. For data analysis, the DNA fragment analyzer (Pharmacia) was used.

The tumor of the patient revealed microsatellite instability (MSI-H), as well as loss of immunohistochemical staining for the MLH1 protein with a positive internal control. Mutation analysis revealed a C to T substitution at nucleotide 2101 in exon 18 of the *MLH1* gene, leading to an early stop codon (Gln701Stop). Neither the father nor the mother carried the mutation identified in their son (Figures 1 and 2). All six tested markers were in concordance with paternity (likelihood: >99.9%) (Figure 3)

## DISCUSSION

Although the Q701X *MLH1* mutation has not been

reported before in either the Human Gene Mutation Database (HGMD) and the ICG-HNPCC database, we have no reason to doubt its pathogenicity given its truncating nature and the findings of MSI-H and loss of staining for the MLH1 protein in the patient's tumor<sup>[8,9]</sup>.

*De novo* germline mutations of the MMR genes in HNPCC are rare. To the best of our knowledge, only one single case, involving *MSH2*, has been reported so far<sup>[10]</sup>. We have identified a *de novo* germline mutation in the *MLH1* gene. The classification "germline" mutation is generally used in oncogenetics to distinguish mutations that can be transmitted to the offspring from the somatic mutations occurring locally in tissues and which may lead to local tumor development. For practical purposes, we therefore used the "germline" label. Strictly speaking, mutations classified as *de novo* germline mutations should refer to a single mutation occurring in a single germcell. Clinically, these often cannot be distinguished from an early postzygotic mutational event in the patient, or from germline mosaicism or somatic mosaicism extending to extra-gonadal tissues in the parents. We did not have the opportunity to test multiple tissues in our patient or his parents for the mutation. The patient's single sibling was offered mutation analysis and was shown to carry the wild-type *MLH1* alleles. Therefore, we lack proof of the germline nature of the *de novo* mutation reported by us and the same is true for the *MSH2* case published earlier by Kraus *et al*<sup>[10]</sup>. In clinical practice, this lack of proof does not lead to any obvious problems. One will simply discuss with the patient the fact that his or her siblings have a, probably small, risk to carry the mutation as well and one will offer to test them for it.

Non-penetrance and small family size is the common explanation of verified negative family histories of cancer

in patients with a germline MMR gene mutation. However, in addition to some cases due to non-paternity, *de novo* “germline” mutations should be considered as a possible explanation as well. The percentage of these mutations in HNPCC remains to be established. As guidelines (e.g., the Bethesda guidelines)<sup>[4]</sup> that stress not to limit MMR gene mutation testing to patients with a positive family history are more widely introduced, more cases of *de novo* “germline” MMR mutations are yet to be revealed.

## CASE REPORT

A 35-year-old female was hospitalized for abdominal pain, bloating, and vomiting. Plain X-ray pictures exhibited bowel obstruction for which she underwent emergency surgery. On the second postoperative day, she started to complain about dull right upper quadrant abdominal pain and bloating. Abdominal CT scans revealed very large cystic lesion with an inhomogeneous fluid content. The cyst occupied the whole right lobe of the liver compressing the surrounding organs and dislocating the left lobe of the liver towards the left hypochondrium (Figure 1). Additionally, several more cysts of various sizes were seen in the whole abdomen. This radio-morphology raised the possibility of a hydatid disease (caused by ruptured hydatid cyst) confirmed through positive echinococcus IgG serology (ELISA). Interestingly, no hypereosinophilia could be detected through repeated blood tests.

Mebendazole (200 mg/d for 3 d) was administered in order to prevent anaphylactic reactions and the dissemination of the disease. After obtaining written consent from the patient, the site of the puncture was defined to the X–XI intercostal space. The procedure was performed under ultrasound guidance (Diasonics Master

Series VST) and the patient was closely monitored for any sign of anaphylaxis. The cyst that was punctured on its free surface with an 18 gauge needle contained a dense whitish fluid. Samples were taken for parasitological examinations. Because of the huge size of the cyst, an 8F pigtail catheter (polyurethane drainage catheter, COOK) with 32 side holes was introduced into the cyst. After aspiration of 6 200 mL of the cystic fluid (Figure 2), 150 mL of 15% hypertonic saline was injected into the cyst cavity. Twenty minutes later, the catheter was attached to a vacuum tube and left for suction drainage. This cycle (hypertonic 15% saline injection and 20 min later reaspiration) was repeated daily with 40 mL 15% sterile saline. The initial procedure lasted for 30 min. At the end of the flushing series, absolute alcohol of 30 mL was injected and removed after 20 min during the last 5 days. During the procedure the patient remained symptomless and no anaphylactic reaction could be observed. Ultrasonographically, the cyst decreased in size gradually with only a 7.6 mm subcapsular fluid collection remaining under the right diaphragm. The total time of percutaneous drainage took 43 d.

Under light microscopy, the aspirated cystic fluid showed clear evidence of hydatid scolices verifying the presumed diagnosis of echinococcosis. After 6 weeks of percutaneous drainage the catheter was removed. Abdominal CT scans exhibited total disappearance of the cyst. Subsequently, the patient was discharged and reported no symptom relapses on the follow-up period of 1 year.

## DISCUSSION

*Echinococcus granulosus* is a small, 5-mm-long tapeworm being responsible for unilocular hydatid cyst disease. Human infection by *E. granulosus* occurs most commonly in sheep- and cattle-raising areas where dogs assist in herding; the infection is more frequent in Eastern Europe, the Mediterranean, Australia, New Zealand, Chile, Argentina, and Africa. Human beings are usually infected as intermediate hosts when they ingest egg-contaminated food or water. Over 50% of all human *E. granulosus* infections involve the liver<sup>[1]</sup>. Additional common sites for hydatid cysts are the lungs, spleen, kidneys, heart, bones, and brain<sup>[2]</sup>.

Since hydatid cysts grow at a rate of about 1–5 cm/year, a long latent period is typical. The symptoms of hydatid disease are related primarily to the mass effect of the slowly enlarging cyst: right upper quadrant pain from the stretching hepatic capsule, jaundice from compression

**Figure 1** Abdominal CT scan. **A:** Axial CT scan shows the large inhomogeneous cystic fluid collection occupying the whole right lobe of the liver; **B:** CT scan of the cystic lesion on the level of spleen; **C:** the largest cystic lesion compresses the left lobe of the liver dislocating the nearby organs; **D:** cystic collection was seen also in the pararenal spaces and extended into the small pelvis.

**Figure 2** **A:** The aspirated fluid (6200 mL); **B:** drainage catheter with sucking bottle.

of the bile duct, or portal hypertension from portal vein obstruction. Following a presumably long latency, our patient presented with symptoms related to bowel obstruction caused by the space-occupying effect of the giant hydatid cyst. CT scans and ultrasonography are very useful for revealing well-defined cysts with thick or thin walls which correspond to our case as well<sup>[2]</sup>. The 6.2-L large cyst of our case is the largest hydatid cyst published in the literature. The visualization of daughter cysts within the larger cyst and the mural calcification helps to distinguish *E. granulosus* infection from carcinomas, bacterial or amebic liver abscesses, or hemangiomas<sup>[3]</sup>. Either spontaneously or as a result of a complication to surgery, free peritoneal rupture of the cyst can lead to fatal anaphylaxis. On the long term, leakage of the cyst may cause an intense antigenic response, resulting in eosinophilia, bronchial spasm, or anaphylactic shock.

Open surgical drainage of the hydatid cysts has been the preferred method of therapy. Several surgical techniques have been applied for the treatment of hydatid disease: simple-closure tube drainage, marsupialization, cystectomy, total pericystectomy, hepatic resection, and cavity management (omentoplasty, internal drainage)<sup>[4]</sup>. Among them, total pericystectomy was found to be the most effective method at reducing recurrence and improving resolution of the hepatic defect. The mortality rate after surgery ranges from 0% to 6.3%, while the rate of postoperative complications varies between 12.5% and 80%<sup>[4]</sup>. Jabbour *et al.*<sup>[5]</sup> suggested that surgery should be the treatment of choice for large, multiple, complicated, and recurrent hydatid cysts of the liver.

The percutaneous treatment has been used in many hospitals as the alternative method to surgery<sup>[6]</sup>. A prospective randomized trial of 50 patients found that

percutaneous drainage and hypertonic saline irrigation of the cysts combined with albendazole is as effective as surgical drainage, with fewer complications and shorter durations of hospitalization<sup>[7]</sup>. A long-term follow-up study has also confirmed the effectiveness of percutaneous drainage with mortality and morbidity rates more favorably than those of conventional surgical approaches<sup>[8]</sup>. The generally accepted and safe technique for percutaneous drainage is called PAIR that stands for puncture, aspiration of cyst, injection of hypertonic saline and absolute alcohol, and reaspiration<sup>[9]</sup>. Hypertonic saline exerts a scolical effect and prevents the formation of daughter cysts through the irrigation of the germinative layer<sup>[10]</sup>. Absolute alcohol is the agent of sclerotherapy against the wall of the hydatid cyst. Formerly, the percutaneous drainage of the hydatid cyst was deemed to be a hazardous procedure due to the potential risk of anaphylaxis and dissemination<sup>[11]</sup>. Filice and Brunetti<sup>[12]</sup>, however, observed no anaphylactic reaction or peritoneal dissemination having applied the PAIR technique for 231 cysts in 163 patients. In agreement with this report, Haddad *et al*<sup>[13]</sup> experienced only minor complications including pain, mild fever, pleural effusion, and transient hypernatremia in their series. In a 6-9 year follow-up involving ultrasonography, CT scans, and serology tests, no local recurrence or spread of the disease were found<sup>[13]</sup>. Peláez *et al*<sup>[14]</sup> successfully treated 55 hydatid cysts in the liver in 34 patients with the combination of PAIR technique and albendazole prophylaxis. They reported only urticaria and subcapsular hematoma as minor complications and the mean hospitalization duration was 1.82 d. Akhan *et al*<sup>[4,8]</sup> reported good accuracy rate and low complication rate in the percutaneous treatment of hydatid disease. Using the percutaneous drainage treatment combined with mebendazole prophylaxis in our patient, we could successfully manage the largest hydatid cyst ever reported. The applied drainage method seems to be useful for the treatment of huge hydatid cysts and has also been recommended as an effective and safe therapeutic choice.

In summary, this patient has demonstrated that percutaneous drainage is the appropriate and feasible alternative to surgery in treating hydatid cysts even of this

giant size with a low risk of severe complications.

### Abstract

The term gastrointestinal stromal tumors (GISTs) is defined diagnostically as the main group of mesenchymal tumors with spindle or epithelioid cells arising from the wall of the gastrointestinal tract with immunohistochemical reactivity for CD117 antibody. Previous studies revealed that cells in GISTs express a growth factor receptor with tyrosine kinase activity (termed c-kit), which is the product of the c-kit proto-oncogene. The most specific and practical diagnostic criteria for GISTs are: immunohistochemically determined c-kit (CD117) expression; mitotic score; and tumor size. A small GIST concomitant with early gastric cancer is rarely encountered clinically. Herein we have reported a case of a 1.1-cm GIST detected by esophagogastroduodenoscopy concomitant with a IIc type of early gastric cancer (signet ring cell type). It was detected during a routine physical health examination. To our knowledge, this is the first report of a small GIST concomitant with a signet ring cell type of early gastric cancer.

### INTRODUCTION

Gastrointestinal stromal tumors (GISTs) are malignant or potentially malignant tumors and are considered to have a specific molecular pathogenesis. They are

distinguished from other mesenchymal tumors by optimal immunostaining for CD117 and a prognostic classification is based on tumor size, mitotic score, and MIB-1 grade<sup>[1]</sup>. Gain-of-function mutations of the *c-kit* gene and immunoreactivity of the c-kit protein (CD117) in many GISTs support the idea that GISTs are a biologically distinct entity. We have reported a case of a small GIST concomitant with a IIc type of early gastric cancer (signet ring cell type) and provided a literature review.

### CASE REPORT

A 70-year-old yellow race female came to our hospital for a physical health examination in November 2003. She had no past history of epigastralgia or peptic ulcer. Esophagogastroduodenoscopy (EGD) showed one approximately 0.4-cm sessile polyp with a smooth surface at the right upper posterior wall of the gastric fundus (Figure 1A). Biopsy was taken and three specimens were acquired. Histologically, one of the three specimens showed whorling bundles of spindle cells with mitosis. Only chronic gastritis was found in the other two specimens. A GIST was suspected. EGD simultaneously detected one approximately 1.7 cm × 1.4 cm, depressed, flat white-red based lesion with oozing hemorrhages at the gastric angle. The lesion looked like a IIc type of early gastric cancer (Figure 1B). Biopsy was carried out and 13 specimens were obtained. Pathological sections demonstrated an ill-defined tumor with signet ring cells within the gastric mucosa. A poorly differentiated adenocarcinoma was diagnosed and *Helicobacter* microorganisms were found. An imaging study with abdominal computed tomography demonstrated no remarkable mass lesion at the posterior wall of the gastric fundus and gastric angle. There was no fluid collection, and no mass lesion or lymph node was found in the intraperitoneal cavity, liver, kidneys, and other organs. Owing to its malignant nature, surgical intervention was performed one week later. Grossly, we observed a 1.1 cm × 0.8 cm × 0.7 cm fundal mass protruding from the inner muscularis propria to the mucosa (Figures 2A and 2B). Histologically, the gastric fundal tumor demonstrated whorling sheets of spindle cells which stained positively for CD117, CD34, NSE, S-100 protein, and actin-851 antibodies after immunohistochemical (IHC) staining (Figures 2C and 2D). GIST, with combined smooth muscle-neural differentiation, was diagnosed. The gastric angular tumor showed a residual adenocarcinoma of the signet ring cell type within the mucosa (Figures 2E and 2F). The postoperative period of the patient was uneventful, and

**Figure 1** Esophagogastroduodenoscopic examination. **A:** A 0.4-cm sessile polyp with a smooth surface is seen at the right upper posterior wall of the gastric fundus. **B:** An approximately 1.7 cm × 1.4 cm, depressed, flat white-red based lesion with oozing hemorrhages is present at the gastric angle.

she was discharged one week later. No evidence of tumor recurrence was found after 14-months of follow-up.

## DISCUSSION

GIST concomitant with early gastric cancer has rarely been reported. To the best of our knowledge, a small GIST concomitant with a signet ring cell type of early gastric cancer has never been reported. Although Japanese investigators reported some cases of gastric leiomyoblastoma associated with gastric cancer between 1971 and 2000, CD-117 immunohistochemical staining was not confirmed in those cases. Our 1.1-cm GIST detected by EGD was a small one. The origin of a GIST concomitant with an early gastric adenocarcinoma is unclear. This small GIST showed a positive microscopic finding of *H. pylori* microorganisms and a positive CLO test (biopsy urease test) for *H. pylori* infections. *H. pylori* was implicated as a carcinogen of the stomach by the World Health Organization in 1994. We had previously detected two gastric GIST cases in 2003; both of those had a positive finding of *H. pylori* microorganisms and a positive CLO test for *H. pylori* infections. However, this finding is more likely an incidental finding rather than a causal association.

GISTs are considered to be a group of mesenchymal neoplasms, and are also the subject of much debate and controversy regarding their nomenclature, histogenesis, criteria for diagnosis, prognostic manifestations, and classification<sup>[1,2]</sup>. Studies have revealed that some of these tumors may have tumor markers and features of neural, muscular or vascular endothelial differentiation. The term GIST has been adopted and defined as tumors arising from the stroma with no definite cell line of origin and varying patterns of differentiation<sup>[3]</sup>. Our GIST showed a mixed type of smooth muscle-neural origin. Some investigators emphasize the CD117 and CD34 expression in GISTs<sup>[1,4-6]</sup>. GISTs are now preferentially defined as tumors with c-kit (CD117) positive mesenchymal spindle cells or epithelioid neoplasms primarily in the gastrointestinal tract, omentum, and mesentery<sup>[4]</sup>.

Statistically, GISTs are most common in the stomach (60-84.8%), followed by small intestine (10.5-30%), colon and rectum (3.5-5%), and esophagus (1.2-5%)<sup>[1,4]</sup>. The most important manifestation of stromal tumors is their

**Figure 2** **A** The excised 1.1-cm fundal tumor showing gray fleshy and nodular cut surface; **B** and **C:** Its histologic picture demonstrating whorling bundles of spindle cells with a mitosis (arrow, H&E, ×200); **D:** staining of spindle cells for CD117 (IHC, ×200); **E:** subtotal gastrectomized specimen showing a 1.7 cm × 1.4 cm ulcerative mass at the angularis of the lesser curvature side; **F:** tumor showing signet ring cells within the lamina propria histologically (H&E, ×200); **G:** tumor stained for PAS-diesterase (×200); **H:** tumors stained for cytokeratin (IHC, ×200).

indolent, slow growing nature. The tumors are generally found within the deeper stroma and the submucosa, and are often incidentally found during imaging studies. Our small GIST protruded about half of its mass into the upper posterior wall of the gastric fundus and only a 0.4 cm polypoid mass could be found in the endoscopic field.

GISTs often present with non-specific symptoms, such as nausea, vomiting, abdominal pain, gastrointestinal bleeding, and metastatic diseases. Bleeding is considered as the most common presentation of the clinical course<sup>[2]</sup>. Symptoms depend on tumor size and location. In our case, the GIST was totally asymptomatic. Ulcerations seem relevant to the size of GISTs. The size and mitotic score are considered as important diagnostic criteria and prognostic predictive indicators<sup>[1,2]</sup>. This GIST was diagnosed as a potential malignancy with a very low risk according to the pathological findings of mitosis (2 per 50 HPF) with combined smooth muscle-neural differentiation and positive stains for CD117 and CD34<sup>[1,2,5-7]</sup>.

Generally, the preoperative rate of diagnosis of submucosal tumors by an endoscopic biopsy or an imaging

study without skillful examination with an endoscopic ultrasonographic system and angiography is very low. Once a submucosal tumor is suspected, more careful endoscopic procedures, and repeat deep biopsy of the same area to reach the target tumor may have a higher diagnostic rate of histological findings, as our experience attests.

Patients with advanced GISTs which progress rapidly and result in organ destruction have poor prognosis. Therapeutic options for GISTs include surgery and treatment with STI-571 (Gleevec). STI-571 is a small molecule competitive inhibitor of the ATP binding site and demonstrates a high degree of specificity for inhibiting the activity of a small number of related tyrosine kinases: c-Ab1, Bcr-Ab1 (the molecular cause of chronic myeloid leukemia), platelet-derived growth factor receptors<sup>[8-10]</sup>, and wild-type and mutant c-kit (stem cell factor receptor)<sup>[8,11,13]</sup>. This selective activity of STI-571 suggests that it has a relatively narrow target spectrum of anticancer activity. This highly selective molecule has a different therapeutic effect. Most malignant GISTs have mutant c-kit and some studies show that c-kit may be activated by mutation in three domains: extracellular, juxtamembrane and kinase portions (exon 9 or 11 or 13)<sup>[5,6,11,12]</sup>. STI-571 has the ability to inhibit signal transduction via c-kit and it is predictable that it should inhibit hematopoietic stem cells, resulting in neutropenia, anemia, thrombocytopenia, GI bleeding or intratumor hemorrhage<sup>[7]</sup>.

Surgery is still the mainstay treatment for GISTs. Subtotal gastrectomy for the early gastric cancer with local resection for the small GIST was performed simultaneously for our patient with a small GIST concomitant with a IIc type of early gastric cancer.

In conclusion, we have reported a rare case of a small GIST combined with an early gastric cancer. It showed positive microscopic findings of *H pylori* microorganisms, a positive CLO test, and stainings for CD117 and CD34. More GIST cases are required for evaluating the relationship between *H pylori* infections and the etiologies of GIST concomitant with an early gastric cancer. Long-term observation for all GIST cases is greatly needed.

## ACKNOWLEDGMENTS

We greatly appreciate the financial and technical support of Dalin Tzu Chi General Hospital, Dr. Takahira Ikeda and

## Abstract

The congenital dyserythropoietic anemias comprise a group of rare hereditary disorders of erythropoiesis, characterized by ineffective erythropoiesis as the predominant mechanism of anemia and by characteristic morphological aberrations of the majority of erythroblasts in the bone marrow. Congenital dyserythropoietic anemia type II is the most frequent type. All types of congenital dyserythropoietic anemias distinctly share a high incidence of iron loading. Iron accumulation occurs even in untransfused patients and can result in heart failure and liver cirrhosis. We have reported about a patient who presented with liver cirrhosis and intractable ascites caused by congenital dyserythropoietic anemia type II. Her clinical course was further complicated by the development of autoimmune hemolytic anemia. Splenectomy was eventually performed which achieved complete resolution of ascites, increase of hemoglobin concentration and abrogation of transfusion requirements.

## INTRODUCTION

All types of congenital dyserythropoietic anemias (CDAs) distinctly share a high incidence of iron loading<sup>[1]</sup>. As in other forms of anemia with ineffective erythropoiesis, this is due to the upregulation of iron resorption<sup>[2]</sup>. Iron accumulation occurs even in untransfused patients and can result in diabetes mellitus, hypogonadotropic hypogonadism and more importantly, heart failure and liver cirrhosis<sup>[3-5]</sup>.

We have reported about a patient who presented with liver cirrhosis and intractable ascites caused by CDA II. Her clinical course was further complicated by the development of autoimmune hemolytic anemia. Splenectomy was eventually performed, which achieved complete resolution of ascites, increase of hemoglobin concentration and abrogation of transfusion requirements.

## CASE REPORT

A 58-year-old female presented to our department because of progressive abdominal distention. She had a history of CDA II that was diagnosed 15 years ago, and received blood transfusion only at the time of diagnosis and never again.

Physical examination revealed mild jaundice and abdominal distention. The edge of the liver extended 3 cm below the right costal margin and marked splenomegaly

**Figure 1** Peripheral blood smear showing binucleated normoblasts.

was also found. Percussion of the abdomen revealed the presence of flank dullness and “shifting”.

The results of laboratory tests were: WBC 7700/ $\mu$ L, Hb 9.8 g/dL, MCV 91.7  $\mu$ m<sup>3</sup>, MCH 32.1 pg, PLT 223 000/ $\mu$ L, PT 13.9, INR 1.07, PTT 28.0, glucose 120 mg/dL, urea 53 mg/dL, creatinine 0.9 mg/dL, AST 81 U/L, ALT 117 U/L, LDH 176 U/L, protein 7.0 g/dL, albumin 4.3 g/dL, total bilirubin 1.76 mg/dL, unconjugated bilirubin 1.44 mg/dL, ferritin 2 200 ng/mL. Folic acid was 7.4 ng/mL (normal range, >5.38 ng/mL) and vitamin B12 was 352 pg/mL (normal range, 211-911 pg/mL), thus ruling out megaloblastic anemia. Hemoglobin electrophoresis showed normal findings.

Analysis of the ascitic fluid obtained after abdominal paracentesis yielded the following results: absolute polymorphonuclear leukocyte count 100/mm<sup>3</sup>, albumin 1.0 g/dL (serum-ascites albumin gradient 3.3 g/dL), glucose 128 mg/dL, LDH 43 U/L.

Peripheral blood smear showed anisopoikilocytosis, basophilic stippling and binucleated normoblasts (Figure 1). The Ham's test was negative, possibly because of a small amount of normal sera used. Polyacrylamide gel electrophoresis in the presence of sodium dodecyl sulfate (SDS-PAGE) of erythrocyte membrane proteins showed that band 3 was narrower and had an accelerated migration rate. Bone marrow examination revealed marked erythroid hyperplasia, while approximately 30% of the mature erythroblasts were binucleate.

A liver biopsy documented cirrhosis with marked siderosis of hepatocytes as well as Kupffer cells and portal macrophages (Figure 2). Genetic testing for mutations of the HFE gene revealed heterozygosity for the H63D mutation, whereas the patient was negative for the C282Y mutation. Other causes of cirrhosis were thoroughly excluded, based on the medical history of the patient, negative virology for hepatitis B and C, normal immunologic tests (including testing for the presence of antinuclear antibodies, anti-smooth muscle cell antibodies and anti-mitochondrial antibodies) and liver biopsy findings.

Upper endoscopy revealed the presence of esophageal varices. An abdominal ultrasonographic study showed cholelithiasis. A cardiac ultrasonographic examination showed concentric hypertrophy and impaired diastolic function of the left ventricle, left atrium dilatation, mitral

**Figure 2** Liver biopsy showing marked siderosis of hepatocytes (curved arrows), Kupffer cells (arrowheads with ball) and portal macrophages (arrows) (Perl's stain,  $\times 200$ ).

valve regurgitation and right ventricle dilatation with tricuspid valve regurgitation and pulmonary hypertension (right ventricular systolic pressure: 5332 Pa). Magnetic resonance imaging was performed in order to determine heart and liver iron concentration using a unit (Magnetom Impact; Siemens, Germany) operating at a field strength of 1.0 Tesla. We used an electrocardiogram-triggered gradient-recalled-echo sequence for the evaluation of both myocardial and liver iron. Iron content measurement was based on a modification of the method of Bonkovsky, calculating the natural logarithm of the ratio of the mean signal intensity of the liver or heart respectively by that of the standard deviation of the mean of the signal intensity of the overlying air [ $\ln$  signal intensity ratio,  $\ln$  (SIR); normal values for both heart and liver, > 3.2]<sup>[6]</sup>. The  $\ln$  (SIR) values obtained for the heart and liver were 2.66 and 1.26 respectively.

Since the patient persistently refused to undergo iron chelation therapy with desferrioxamine, deferiprone (75 mg/kg per day in three divided doses) was initiated, spironolactone (200 mg once daily) and furosemide (80 mg once daily) were also prescribed but dose escalation was not possible because of deterioration in renal function. Since the patient also did not decrease her salt intake, large volume of paracentesis (approximately 8-10 L of ascitic fluid) had to be performed approximately every 10 d due to the development of refractory ascites.

Soon after her presentation, the patient began to require frequent blood transfusions. Direct antiglobulin test was positive due to the presence of IgG autoantibodies. Extensive investigation, including repeated immunologic tests to rule out autoimmune diseases and imaging studies to rule out occult malignancy, excluded secondary causes of autoimmune hemolytic anemia (AIHA). The patient was treated with prednisone and subsequently with intravenous immunoglobulin, both failed to produce a significant response. Therefore, we performed splenectomy in order to control both CDA and AIHA as well as proximal splenorenal shunt in order to relieve portal hypertension and ascites. Surgery and recovery were uneventful, but a Doppler examination performed immediately after the operation showed complete shunt occlusion.

During the 10-mo post-operative follow-up period, the

patient was transfusion-independent and ascites did not relapse although diuretics were discontinued. Hemoglobin concentration was persistently above 12.0 g/dL and unconjugated bilirubin was normalized. Nevertheless, the concentration of ferritin remained elevated at 1 800 ng/mL. A new cardiac ultrasonographic examination disclosed regression of the right ventricle dilatation and no signs of pulmonary hypertension (right ventricular systolic pressure: 1 999.5 Pa). Follow-up magnetic resonance imaging of the heart and liver showed heart siderosis within normal limits but no change in liver siderosis with her In (SIR) values being 4.04 and 1.38, respectively.

## DISCUSSION

The evolution of CDA II is doomed by iron overloading, which is also seen in patients with no need for transfusion and is mainly due to increased iron resorption. Lethal organ damage of the liver and myocardium is observed in untreated patients<sup>[7]</sup>. The rate of iron accumulation seems not to be affected by *HFE* gene polymorphism<sup>[8,9]</sup>. Our patient was heterozygous for the H63D mutation, which may contribute to increased hepatic iron levels but does not result in iron overload in the absence of the main mutation responsible for hereditary hemosiderosis (C282Y)<sup>[10-12]</sup>.

Hemosiderosis in CDA type II is treated with desferrioxamine which is usually introduced as soon as ferritin reaches the concentration of 1 000 ng/mL<sup>[13,14]</sup>. Normal ferritin concentrations were reached in all the patients with satisfactory compliance<sup>[4]</sup> a full-stop. Nevertheless, desferrioxamine must be given 5 to 7 d per week by a prolonged subcutaneous infusion<sup>[15]</sup>. On the other hand, deferiprone is an alternative chelator that is orally active and more effective than desferrioxamine in the removal of myocardial iron<sup>[16]</sup>. Indeed, heart siderosis returned to normal levels in our patient, even though the reduction in ferritin levels and liver iron overload was not so pronounced.

In CDA II, splenectomy leads to a moderate and sustained increase in hemoglobin concentration and decrease of hemolysis<sup>[4,8]</sup>. Though splenectomy has these benefits, recommendation for the operation is not uniform among the hematologists<sup>[8]</sup>. Furthermore, splenectomy does not prevent further iron loading, even in those patients with their hemoglobin concentrations becoming nearly normal as observed in our patient<sup>[4]</sup>.

The concurrence of CDA II and AIHA has been described only once, thus suggesting chance occurrence<sup>[17]</sup>. In AIHA, splenectomy has the distinct advantage over other therapeutic options in that it has the potential for complete and long-term remission. Available data suggest that it triggers remission in more than 50% of patients<sup>[18]</sup>. Excellent responses or improvements are maintained during a mean follow-up period of 33 or 73 mo, respectively<sup>[19]</sup>. Accordingly, splenectomy should be considered in patients who do not respond adequately to corticosteroids<sup>[20]</sup>.

In patients with refractory ascites, both transjugular intrahepatic portosystemic shunt (TIPS) and surgical portal systemic shunt have been used<sup>[21]</sup>. TIPS is a widely accepted

percutaneous interventional procedure for treating complications of portal hypertension. An experienced skillful team, however, is necessary to ensure the technical success of TIPS and to avoid its potential procedural complications<sup>[22]</sup>. Shunt dysfunction is also a major problem, since over 50% of TIPS develop stenosis within 1 year and therefore, close shunt surveillance and frequent re-treatment are required with ensuing high costs<sup>[23-25]</sup>. Furthermore, hepatic encephalopathy is another important complication of cirrhotic patients with refractory ascites treated with TIPS, more than 40% of these patients develop encephalopathy<sup>[26,27]</sup>. Nevertheless, calibrated prosthesis can partly prevent TIPS complications<sup>[28]</sup>.

The role of surgery in the treatment of portal hypertension remains a complex and highly controversial issue. Several factors must be considered when surgical options are to be entertained, including origin and extent of liver disease, response to prior medical treatment, and possibility of future liver transplantation<sup>[29]</sup>. Splenectomy was mandatory in our patient in order to control CDA and particularly AIHA. However, splenectomy alone is inappropriate for the treatment of portal hypertension and does not relieve ascites<sup>[30,31]</sup>. In contrast, portosystemic shunting is efficient in clearing ascites, but is associated with a high rate of encephalopathy and liver failure<sup>[29,32,33]</sup>. The indications for portosystemic shunting are therefore limited for the treatment of intractable ascites and portosystemic shunting should be performed only in patients with good liver function or when all other treatments fail<sup>[29,32]</sup>. Since our patient had preserved hepatic synthetic capacity, we chose to combine splenectomy with portosystemic shunting in order to relieve ascites and thus performed proximal splenorenal shunt. Compared to selective shunts, the central or proximal splenorenal shunt does not differ in operative mortality rates, 5-year survival rates, development of individual episodes of post-operative encephalopathy, or chronic post-operative encephalopathy<sup>[34]</sup>. Unfortunately, shunt occlusion may occur immediately after the operation. It is thus difficult to explain the complete remission of ascites and we can only postulate that a reduction in the blood flow into the portal system from the greatly enlarged spleen may result in a decrease in portal pressure. This reduction in portal pressure may also contribute to the amelioration of pulmonary hypertension as observed in our patient.

In conclusion, even in transfusion-independent patients with CDA II, iron overload can result in dramatic manifestations, posing major therapeutic difficulties. Therefore, ferritin levels should be controlled in all the patients with CDA II, because iron overload may approach risk levels at any age<sup>[1]</sup>. Iron depletion has to be started at the latest when ferritin approaches a level of 1 000 ng/mL to avoid the devastating complications of excessive iron accumulation<sup>[4]</sup>.

### Abstract

We report a rare case of a patient who survived for 5 years after undergoing a medial pancreatectomy for invasive ductal carcinoma originating from the body of the pancreas. A 63-year-old woman was diagnosed as a small cancer of the pancreatic body, and surgery was performed. Even though the tumor was a carcinoma, its small size prompted us to perform a medial pancreatectomy with regional lymph nodes dissection. Additional chemoradiation was performed and, five years after surgery, the patient is well with no signs of recurrence. Medial pancreatectomy for invasive ductal carcinoma has not ever been reported. Furthermore, long-term survival after a lumpectomy for invasive ductal carcinoma has never been reported in the literatures. The current case suggests that long-term survival in patients with invasive ductal carcinoma of the pancreas may be associated with the pathological or biological features of pancreatic carcinoma.

### INTRODUCTION

Invasive ductal carcinomas that originate from the body

or tail of the pancreas are often unresectable because of unfortunate delays in tumor diagnosis. Most institutions continue to report resection rates for standard surgical procedures and 3-year or 5-year survival rates of no more than 20%<sup>[1]</sup>. Medial pancreatectomy is a segmental pancreatectomy for the treatment of benign lesions in the neck and body of the pancreas<sup>[2]</sup>. We report the extremely rare case of a patient who survived for 5 years after undergoing a medial pancreatectomy for invasive ductal carcinoma originating from the body of the pancreas.

### CASE REPORT

A 63-year-old woman was admitted to our hospital for an evaluation of a dilatation in her main pancreatic duct. She had been diagnosed as having diabetes mellitus at the age of 53 years. Blood sugar control prompted her previous doctor to perform an abdominal computed tomography examination, which showed an apparent dilatation of the main pancreatic duct in the body and tail of the pancreas. Neither contrast-enhanced computed tomography, magnetic resonance imaging nor endoscopic ultrasonography revealed the cause of the dilatation, however, magnetic resonance cholangiopancreatography showed that the main pancreatic duct with beaded dilatation suddenly became occluded in the body of the pancreas. A clinical diagnosis of non-detectable, small cancer of the pancreatic body was made, and surgery was performed. An intraoperative ultrasonography examination depicted a round hypoechoic mass, measuring 1.0 cm in diameter, in the body of the pancreas. No infiltration to the vessels or metastatic lesions was detected. Even though the tumor was a carcinoma, its small size prompted us not to perform a Whipple procedure or a left pancreatectomy. Instead, a medial pancreatectomy, 4 cm along the long pancreatic axis, and an independent dissection of the lymph nodes around the common hepatic artery and proximal splenic artery were performed. The tail of the pancreas was anastomosed using a Roux loop. The tumor was histologically diagnosed as a well-differentiated adenocarcinoma, with a maximum diameter of 1.0 cm (Figure 1); one peripancreatic lymph node containing a metastasis was observed (Figure 2). When examined under low magnification, lymphocyte aggregation around the cancer stroma was observed, immunohistochemically, the tissue stained positive for both CD4 and CD8. The patient's postoperative course was uneventful; adjuvant chemoradiation was performed for 4 wk. The external-beam radiation doses were delivered using conventional

**Figure 1** Under high magnification, the tumor is histologically diagnosed as a well-differentiated adenocarcinoma and is surrounded by lymphocyte aggregation.

fractionation: 2 Gy, 5 fractions a week. Concomitant chemotherapy was also performed on the first and fifth days of every week (10mg CDDP, 1KE OK432). In addition, she received a 120-h continuous infusion of 625 mg of 5-fluorouracil per week during the radiotherapy. The patient is well with no signs of recurrence five years after surgery.

## DISCUSSION

Many surgeons perform extended radical surgeries, including an extended lymphadenectomy and retroperitoneal soft-tissue clearance, for various stages of pancreatic cancer; however, a survival benefit has not been demonstrated<sup>[3]</sup>. Even after a curative Whipple resection is performed, adjuvant treatments like radiotherapy and 5-FU treatment are often performed in the USA. So, Jeekel stated that a Whipple procedure was inadequate for pancreatic head cancer and regarded this procedure to be a lumpectomy rather than a curative procedure<sup>[4]</sup>. A medial pancreatectomy for invasive ductal carcinoma should also be regarded as a lumpectomy.

The main problem associated with performing a medial pancreatectomy is the need for careful patient selection<sup>[2]</sup>. In the present case, a very small tumor was visualized in the neck or right margin of the body of the pancreas. Preoperatively, evidence suggesting an invasive ductal carcinoma was minimal. The involvement of the main pancreatic duct enabled us to avoid enucleation. In conventional pancreatectomies, a pancreaticoduodenectomy or a near-total left pancreatectomy may be required. To avoid postoperative or late complications from a major pancreatic resection, we performed a medial pancreatectomy and independent lymph-node dissection in the present case. Medial pancreatectomy for invasive ductal carcinoma has not ever been reported. Furthermore, long-term survival after a lumpectomy for invasive ductal carcinoma has never been reported in the literatures, to the best our knowledge.

Large multivariate analyses of resected pancreatic adenocarcinoma have proven that lymph node metastasis serve as prognostic features, however, Fortner *et al*<sup>[5]</sup> reported that the presence of lymph node metastasis did not significantly influence survival after regional pancreatectomies for various stages of pancreatic cancer. In tumor

**Figure 2** Cancer metastasis in a lymph node close to the pancreatic body.

biology, the existence of carcinoma cells in a lymph node is regarded as indicating metastatic invasion through the lymphatic ducts out of primary organ. In the present case, the peripancreatic lymph-node metastasis did not preclude long-term survival. Thus, long-term survival may not be precluded by the presence of lymph node metastasis, otherwise, extended radical surgery can not contribute to the treatment of metastatic invasion through the lymphatic ducts. The prognosis of patients with invasive ductal carcinoma of the pancreas who have survived for 5 years may be the same, regardless of whether an extended radical surgery or a lumpectomy is performed.

Many patients with even stage I diseases have recurrences after resection. Fortner *et al*<sup>[5]</sup> reported in 1996 that the 5-year survival rate after a regional pancreatectomy was 33% in 12 patients with ductal adenocarcinoma of the pancreatic head, in whom the tumor measured 2.5 cm or less in diameter. Some patients with advanced diseases, however, have survived longer than 5 years after their initial treatment. The pathological and biological features of the 5-year survivors varied.<sup>[6]</sup> In the present case, peritumoral lymphocyte aggregation was observed, and CD4+ and CD8+ T cells were noted using immunohistochemistry. Fukunaga *et al*<sup>[7]</sup> reported that the presence of CD4+ and CD8+ T cells in pancreatic adenocarcinoma serves as a good indicator of a favorable outcome after surgical treatment.

In summary, we report a patient with invasive ductal carcinoma from the body of the pancreas that survived for more than five years after undergoing a medial pancreatectomy. The current case suggests that complete surgical extirpation of early-stage carcinomas of the pancreas accompanied with adjuvant therapy can be long-term survival may be associated with the pathological or biological features of pancreatic carcinoma.

### Abstract

This report describes an extremely rare adult case of an omphalomesenteric cyst resected by laparoscopic-assisted surgery. A 29-years-old Japanese man was referred and admitted to Kyushu University Hospital because of an abdominal mass and an elevated serum CEA (carcinoembryonic antigen) level (21.3 ng/mL) in August 2001. Abdominal CT and US demonstrated a cystic mass with septum and calcification. Laparoscopy showed a large mass to be attached to his abdominal wall, measuring 110 mm x 70 mm x 50 mm and filled with mucus. The mass was resected by laparoscopic-assisted surgery. The histological findings of its wall showed fibromuscular tissue, adipose tissue, calcification, and an intestinal structure. It was finally diagnosed to be an omphalomesenteric cyst.

### INTRODUCTION

The omphalomesenteric duct remnant is one of the rare congenital anomalies associated with the primitive yolk stalk. Most omphalomesenteric duct remnants tend to be Meckel's diverticulum, however, the occurrence of an omphalomesenteric cyst is very rare. An omphalomesenteric duct remnant induces several symptoms, such as intestinal obstruction, abdominal pain, melena, and umbilical hernia. These symptoms tend to occur most frequently during the childhood years. In this report, we have described an extremely rare adult case of omphalomesenteric cyst resected by laparoscopic-assisted surgery.

### CASE REPORT

A 29-year-old male patient visited Aso Iizuka Hospital with the complaint of an abdominal mass of one month duration in July 2001. The laboratory data revealed an elevated CEA level (21.3 ng/mL). Abdominal CT showed a cystic mass, suspected of being a mesenteric cyst. In August 2001, he was referred and admitted to Kyushu University Hospital for further management. Physical examinations showed no abnormalities except for a fist-sized, elastic soft mass in his umbilical region. The laboratory data demonstrated elevations in the ALT (32I U/L), CEA (7.9 ng/mL, normal range <3.2 ng/mL), and CA19-9 (62.6 U/mL, normal range <37.0 U/mL) levels. However, the serum CA125 and alpha fetoprotein (AFP) levels were both within the normal limits. Abdominal US and CT showed a cystic mass with septum and calcification, measuring 100 mm x 80 mm x 50 mm in size (Figure 1). MRI (T2-WI) showed a cystic mass with septum, which was suspected to be a mesenteric cyst (Figure 2). A barium small-bowel enema showed no abnormality except for extraductal oppression. Angiography showed an avascular area in the mass. Our preoperative diagnosis was mesenteric cyst.

Laparoscopic-assisted surgery was performed for the purpose of making a precise diagnosis and resection, because the possibility of a CEA-producing malignant tumor first had to be ruled out. A laparoscope was inserted through a 1 cm-trocar site at the median upper abdomen. Laparoscopy showed the mass to be attached to his abdominal wall at the median hypogastrium (Figure 3), and two ligaments, considered to be remnants of the umbilical arteries, at its attached portion. The mass had no communication with his small bowel. There was no evidence

**Figure 1** Abdominal CT demonstrating a cystic mass (arrow), measuring 100 mm x 80 mm x 50 mm in size, with septum (arrow head) and calcification in the umbilical region.

**Figure 2** MRI (T2-WI) showing a cystic mass with septum.

**Figure 3** Laparoscopy showing the mass to be attached to abdominal wall.

of a persistent urachus. Next, an additional two ports were made with one at the right upper abdomen and another at the right lateral abdomen. The mass was then resected from his abdominal wall using laparoscopic scissors and electrocautery. The mass was removed through a 5-cm median incision made at his lower abdomen. The mass measured 110 mm x 70 mm x 50 mm in size (Figure 4), and weighed 160 g. This cystic mass was filled with mucus (Figure 5). The histological findings demonstrated the cystic wall to be composed of fibromuscular tissue, adipose tissue, focal calcification and an intestinal type mucosa with goblet cells, accompanied by ulceration with a regenerative

**Figure 4** Mass measuring 110 mm x 70 mm x 50 mm in size.

**Figure 5** Cystic mass filled with mucus.

**Figure 6** Histological features showing cystic wall to be composed of fibromuscular tissue, adipose tissue, focal calcification, and an intestinal structure, lined by an intestinal type mucosa with goblet cells, accompanied by ulceration with a regenerative epithelium.

epithelium (Figure 6). The histological findings showed no evidence of malignancy. It was finally diagnosed to be an omphalomesenteric cyst. Six months after the operation, the serum CEA and CA19-9 levels both became normal (0.7 ng/mL and 12.46 U/mL, respectively).

## DISCUSSION

Omphalomesenteric duct remnants (vitelline duct anomalies) have been reported to be congenital anomalies associated with the primitive yolk stalk. The omphalomesenteric duct is the embryonic structure connecting the primary yolk sac to the embryonic midgut that normally closes off spontaneously at about 5-9 wk of gestation<sup>[1]</sup>. The failure of such closure may result in various lesions occurring in the omphalomesenteric duct remnants, such as Meckel's diverticulum, complete umbilical enteric fistula, incomplete umbilical sinus, omphalomesenteric cyst, or umbilical mucosal polyp<sup>[2]</sup>. Most of omphalomesenteric duct remnants (67%) tend to develop into Meckel's diverticulum, however,

omphalomesenteric cyst is also rarely observed<sup>[3]</sup>. Vane *et al*<sup>[1]</sup> reported only three cases of omphalomesenteric cyst in 217 children with omphalomesenteric duct remnants. The etiology of omphalomesenteric cyst is a persistent lesion of the intermediate duct with closure at both ends, leaving a cyst which can attach itself to the umbilicus, bowel, or both<sup>[4]</sup>.

Omphalomesenteric duct remnants may persist in approximately 2% of infants<sup>[4,5]</sup>. Vane *et al*<sup>[1]</sup> reported the male-female ratio in a 217 remnant series to be 2:1. Yamada *et al*<sup>[6]</sup> reported the male-female ratio to be 2.8:1 in a Japanese series of 65 cases. The male-female ratio of omphalomesenteric cyst was reported to be 4:1 which correlates with the previously reported male predominance in other omphalomesenteric duct anomalies<sup>[7]</sup>.

Common symptoms of omphalomesenteric duct remnants include abdominal pain, rectal bleeding, intestinal obstruction, umbilical drainage, and umbilical hernia<sup>[3]</sup>, and all these symptoms appear to be age-dependent. In addition, most of the symptoms usually appear before the age of 4 years<sup>[1]</sup>. Eighty-five percent of infants younger than 1 month and 77% of children aged 1 month to 2 years had a symptomatic presentation<sup>[1]</sup>. It was also reported that 40% of the children with this anomaly had symptomatic lesions, while this anomaly is usually asymptomatic in adults<sup>[1]</sup>. Adult cases of omphalomesenteric cyst are extremely rare. A surgical resection is necessary for symptomatic omphalomesenteric duct remnants, but not necessary for asymptomatic omphalomesenteric duct remnants<sup>[8,9]</sup>. In our case, although asymptomatic omphalomesenteric cyst was incidentally found, it was removed because the possibility of a CEA-producing malignant tumor and small-bowel

obstruction had to be ruled out<sup>[1]</sup>. The elevated tumor markers (CEA, CA19-9) all returned to normal levels after the resection. However, its histological findings showed no evidence of malignancy. The etiology of such elevated tumor markers remains to be elucidated.

In our case, the omphalomesenteric cyst was resected safely by laparoscopic-assisted surgery. Recent advances in diagnostic modalities have resulted in an increased incidental discovery of asymptomatic congenital anomalies. In such cases, the use of laparoscopic surgery is considered to be an effective, safe and less invasive treatment.

### TO THE EDITOR

Hepatocellular carcinoma (HCC) is one of the leading causes of cancer death in Japan, ranked 3<sup>rd</sup> in males and 5<sup>th</sup> in females. Thanks to recent progress, there are several definitive treatment modalities available for HCC, including surgery (liver resection and transplantation), ablation therapy, and transarterial chemoembolization (TACE). It is fortunate for both patients and doctors to have multiple treatment options, however, there have been very few

evidence-based guidelines for decision-making<sup>[1]</sup>. Supported by the Japanese Ministry of Health, Labour and Welfare, we have compiled the “Clinical practice guidelines for hepatocellular carcinoma”<sup>[2]</sup>. This set of guidelines covers 6 fields for HCC, including prevention, diagnosis and surveillance, surgery, chemotherapy, TACE, and ablation therapy. We have surveyed 7192 publications on HCC extracted mainly from MEDLINE (1966-2002), and selected 334 articles to form 58 pairs of research questions and recommendations. For convenience in practical use, we have also created algorithms for the surveillance and treatment of HCC.

The algorithm for the treatment of HCC was based on the evidence from the selected articles above and modified according to the current status in Japan, where liver resection for HCC is safe with less than 1% mortality, and cadaveric donors for liver transplantation are extremely difficult to obtain (Figure 1). This algorithm was devised on the basis of three factors, namely, degree of liver damage<sup>[3]</sup>, number of tumors, and diameter of the tumors. In patients with the severity of the liver damage categorized into class A or B: (1) If there is only one tumor, liver resection is recommended, irrespective of the diameter of the tumor. Ablation therapy may also be selected if the severity of liver damage is class B and the diameter of the tumor is not more than 2 cm; (2) From 2 to 3 tumors of no more than 3 cm in diameter, liver resection or ablation therapy is recommended; (3) From 2 to 3 tumors with a diameter of 3 cm or more, liver resection or TACE is recommended; (4) For 4 or more tumors, TACE or he-

**Figure 1** Treatment algorithm for hepatocellular carcinoma (cited from Ref.2 with permission). <sup>a</sup>Presence of vascular invasion or extrahepatic metastasis to be indicated separately. <sup>b</sup>Selected when the severity of liver damage is class B and tumor diameter is no greater than 2 cm. <sup>c</sup>Tumor diameter should be no greater than 5 cm when there is only one tumor.

patric arterial infusion chemotherapy is recommended. For patients with class C liver damage: (1) If the tumor condition is within the so-called Milan criteria<sup>[4]</sup>, liver transplantation is recommended; (2) If the number of tumors is 4 or more, palliative treatment is recommended. For patients with class A liver damage accompanied by vascular invasion, liver resection may be selected, and for patients with extra-hepatic metastasis, chemotherapy may be selected.

English translation for this guideline will be released on the website of The Japan Society of Hepatology (<http://www.jsh.or.jp/>) soon.

## TO THE EDITOR

We read with a great interest the recent work of Deli and colleagues<sup>[1]</sup> in the *World Journal of Gastroenterology* reporting vascular endothelial growth factor (VEGF) expression in hepatocellular carcinoma (HCC) and cirrhotic liver tissues. This well-documented work shows that VEGF was significantly higher in surrounding cirrhotic liver tissues than in HCC. Authors assessed VEGF expression using immunohistochemistry. The immunohistochemical staining is an efficient tool to assess the percentage of cells stained positively for VEGF but is not really efficient to estimate their true VEGF content. Evaluation of the VEGF protein by an enzyme-linked immunosorbent assay (ELISA) has been reported, by us and others<sup>[2-5]</sup>, to be an efficient tool in order to assess tissue VEGF expression. We have, thus, tested whether the ELISA method might be an efficient tool in order to confirm data reporting higher amounts of VEGF in surrounding cirrhotic liver tissues than in HCC. Deli and colleagues<sup>[1]</sup> also correctly pointed out that basic fibroblast growth factor (bFGF) has been reported to act cooperatively on VEGF expression<sup>[6]</sup>. We have, thus, also assessed bFGF tissue levels in order to

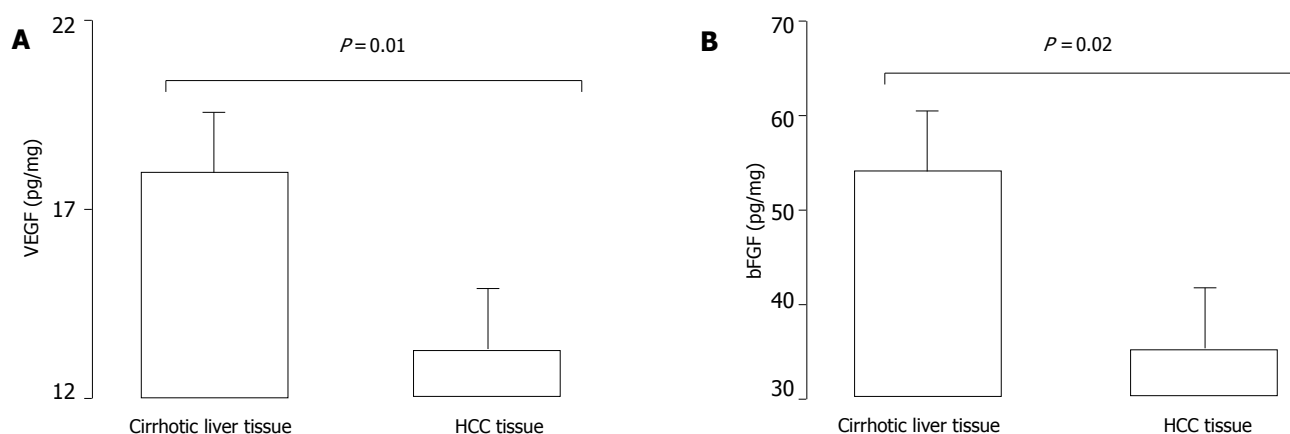

search for a putative link between VEGF and bFGF levels in cirrhotic tissues.

The procedure of the present study followed the rules edited by the French National Ethics. Between January 1999 and December 2004, 12 consecutive (10 males and 2 females, mean age  $67 \pm 4$  years, range 36-83 years) patients with an HCC developed in a cirrhosis underwent resection in the Department of Surgery of Limoges' CHU. Specimens for the HCC tissue and the surrounding cirrhotic liver tissue were obtained during the surgical procedure and frozen at  $-80^{\circ}\text{C}$  until used. Cirrhosis was present in all cases with the cause being alcoholism or hepatitis C. Histologically, there was 5 well-differentiated HCC, 4 moderately differentiated HCC, and 3 poorly differentiated HCC. Tissue samples were homogenized in potassium phosphate buffer and VEGF and bFGF dosages were performed by specific ELISA assays (DuoSet®, R&D Systems Europe) according to the manufacturer's recommendations. Results in pg per mg of wet weight are reported as means  $\pm$  SEM of 12 patients. Differences in mean content of VEGF and bFGF among tumour and the surrounding cirrhotic tissue were analysed by the Student's *t*-test for paired data. A  $P < 0.05$  was considered statistically significant. Correlations between bFGF and VEGF values were assessed using linear regression analysis. A  $P < 0.05$  and  $r > 0.5$  were considered statistically significant.

As shown in Figure 1A, VEGF contents were significantly elevated ( $P = 0.01$ ) in the surrounding cirrhotic liver tissues ( $18.9 \pm 2.1$  pg/mg, range 2-33 pg/mg) than in HCC tissues ( $13.6 \pm 1.9$ , range 2-25 pg/mg). As shown in Figure 1B, bFGF contents were significantly elevated ( $P = 0.02$ ) in the surrounding cirrhotic liver tissues ( $55.4 \pm 6.0$  pg/mg, range 15-94 pg/mg) than in HCC tissues ( $35.2 \pm 8.5$ , range 4-63 pg/mg). While bFGF and VEGF levels were not correlated in HCC ( $r = 0.02$ ,  $P = 0.66$ ), bFGF and VEGF were strongly correlated in cirrhotic liver tissues ( $r = 0.85$ ,  $P = 0.0005$ ).

VEGF and bFGF amounts are elevated in cirrhotic liver tissue as compared with HCC ones. VEGF results obtained with the ELISA method corroborate those of Deli and colleagues<sup>[1]</sup> concerning VEGF expression using immunohistochemistry. Immunohistochemistry and ELISA are, thus, two complementary methods that can be used in concert and bring concordant results. However, in our opinion, the main advantage of the ELISA method is the possibility to test several factors into the same tissue extract in order to highlight potential links between factors such as those found between VEGF and bFGF in the cirrhotic tissues (but not in HCC ones). As suggested by Deli

**Figure 1** VEGF and bFGF in HCC and surrounding cirrhotic liver tissues. Specimens of HCC and surrounding cirrhotic tissues were obtained during the surgical procedure. VEGF (**A**) and bFGF (**B**) amounts were determined by ELISA. Results are reported as means $\pm$ SEM of 12 patients. Statistical analysis was performed using the Student's *t* test for paired samples.

and colleagues, VEGF (but also bFGF) may play an important role in the angiogenesis of liver cirrhosis. The higher expression of VEGF and bFGF suggested a possible role of angiogenesis in HCC carcinogenesis. Anti-angiogenic therapy potentially targeting VEGF and bFGF pathways could promise new strategies for the treatment of HCC.

## Instructions to authors

### GENERAL INFORMATION

*World Journal of Gastroenterology* (WJG, *World J Gastroenterol* ISSN 1007-9327 CN 14-1219/R) is a weekly journal of more than 48 000 circulation, published on the 7<sup>th</sup>, 14<sup>th</sup>, 21<sup>st</sup> and 28<sup>th</sup> of every month.

Original Research, Clinical Trials, Reviews, Comments, and Case Reports in esophageal cancer, gastric cancer, colon cancer, liver cancer, viral liver diseases, *etc.*, from all over the world are welcome on the condition that they have not been published previously and have not been submitted simultaneously elsewhere.

**Published by**  
The WJG Press

### SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed double-spaced on A4 (297mm×210 mm) white paper with outer margins of 2.5 cm. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, acknowledgements, References, Tables, Figures and Figure Legends. Neither the editors nor the Publisher is responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press, and may not be reproduced by any means, in whole or in part without the written permission of both the authors and the Publisher. We reserve the right to put onto our website and copy-edit accepted manuscripts. Authors should also follow the guidelines for the care and use of laboratory animals of their institution or national animal welfare committee.

Authors should retain one copy of the text, tables, photographs and illustrations, as rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for the loss or damage to photographs and illustrations in mailing process.

#### Online submission

Online submission is strongly advised. Manuscripts should be submitted through the Online Submission System at: <http://www.wjgnet.com/index.jsp>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (<http://www.wjgnet.com/wjg/help/instructions.jsp>) before attempting to submit online. Authors encountering problems with the Online Submission System may send an email you describing the problem to [wjg@wjgnet.com](mailto:wjg@wjgnet.com) for assistance. If you submit your manuscript online, do not make a postal contribution. A repeated online submission for the same manuscript is strictly prohibited.

#### Postal submission

Send 3 duplicate hard copies of the full-text manuscript typed double-spaced on A4(297 mm×210 mm) white paper together with any original photographs or illustrations and a 3.5 inch computer diskette or CD-ROM containing an electronic copy of the manuscript including all the figures, graphs and tables in native Microsoft Word format or \*.rtf format to:

#### Editorial Office

**World Journal of Gastroenterology**  
Editorial Department: Apartment 1066, Yishou Garden,  
58 North Langxinzhuang Road,  
PO Box 2345, Beijing 100023, China  
E-mail: [wjg@wjgnet.com](mailto:wjg@wjgnet.com)  
<http://www.wjgnet.com>

### MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using a word-processing software. All submissions must be typed in 1.5 line spacing and in word size 12 with ample margins. The letter font is Tahoma. For authors from China, one copy of the Chinese translation of the manuscript is also required (excluding references). Style should conform to our house format. Required information for each of the manuscript sections is as follows:

#### Title page

Full manuscript title, running title, all author(s) name(s), affiliations, institution(s) and/or department(s) where the work was accomplished, disclosure of any financial support for the research, and the name, full

address, telephone and fax numbers and email address of the corresponding author should be included. Titles should be concise and informative (removing all unnecessary words), emphasize what is new, and avoid abbreviations. A short running title of less than 40 letters should be provided. List the author(s)' name(s) as follows: initial and/or first name, middle name or initial(s) and full family name.

#### Abstract

An informative, structured abstract of no more than 250 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections: AIM: Only the purpose should be included. METHODS: The materials, techniques, instruments and equipments, and the experimental procedures should be included. RESULTS: The observatory and experimental results, including data, effects, outcome, *etc.* should be included. Authors should present *P* value where necessary, and the significant data should accompany. CONCLUSION: Accurate view and the value of the results should be included.

The format of structured abstracts is at: <http://www.wjgnet.com/wjg/help/11.doc>

#### Key words

Please list 3-10 key words that could reflect content of the study mainly from *Index Medicus*.

#### Text

For most article types, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include in appropriate Figures and Tables. Data should be presented in the body text or in Figures and Tables, but not in both.

#### Illustrations

Figures should be numbered as 1, 2, 3 and so on, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. No detailed legend should be involved under the figures. This part should be added into the text where the figures are applicable. Digital images: black and white photographs should be scanned and saved in TIFF format at a resolution of 300 dpi; color images should be saved as CMYK (print files) but not as RGB (screen-viewing files). Place each photograph in a separate file. Print images: supply images of size no smaller than 126 mm×76 mm printed on smooth surface paper; label the image by writing the Figure number and orientation using an arrow. Photomicrographs: indicate the original magnification and stain in the legend. Digital Drawings: supply files in EPS if created by freehand and illustrator, or TIFF from photoshops. EPS files must be accompanied by a version in native file format for editing purposes. Existing line drawings should be scanned at a resolution of 1200 dpi and as close as possible to the size where they will appear when printed. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes of atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ...

#### Tables

Three-line tables should be numbered as 1, 2, 3 and so on, and mentioned clearly in the main text. Provide a brief title for each table. No detailed legend should be included under the tables. This part should be added into the text where the tables are applicable. The information should complement but not duplicate that contained in the text. Use one horizontal line under the title, a second under the column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

#### Notes in tables and illustrations

Data that are not statistically significant should not be noted. <sup>a</sup>*P*<0.05, <sup>b</sup>*P*<0.01 should be noted (*P*>0.05 should not be noted). If there are other series of *P* values, <sup>c</sup>*P*<0.05 and <sup>d</sup>*P*<0.01 are used. Third series of *P* values can be expressed as <sup>e</sup>*P*<0.05 and <sup>f</sup>*P*<0.01. Other notes in tables or under illustrations should be expressed as <sup>1</sup>*F*, <sup>2</sup>*F*, <sup>3</sup>*F*; or some other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.* in a certain sequence.

#### Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscripts and who endorse the data and conclusions are included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

## REFERENCES

### Coding system

The author should code the references according the citation order in text in Arabic numerals, put references codes in square brackets, superscript it at the end of citation content or the author name of the citation. For those citation content as the narrate part, the coding number and square brackets should be typeset normally. For example, Crohn's disease (CD) is associated with increased intestinal permeability<sup>[1,2]</sup>. If references are directly cited in the text, they would be put together with the text, for example, from references [19,22-24], we know that...

When the authors code the references, please ensure that the order in text is the same as in reference part and also insure the spelling accuracy of the first author's name. Do not code the same citation twice.

### PMID requirement

PMID roots in the abstract serial number indexed by PubMed (<http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=PubMed>). The author should supply the PMID for journal citation. For those references that have not been indexed by PubMed, a printed copy of the first page of the full reference should be submitted.

The accuracy of the information of the journal citations is very important. Through reference testing system (<http://www.aushome.cn/cgi-bin/index.pl>), the authors and editor could check the authors name, title, journal title, publication date, volume number, start page, and end page. We will interlink all references with PubMed in ASP file so that the readers can read the abstract of the citations online immediately.

### Style for journal references

Authors: the first author should be typed in bold-faced letter. The surname of all authors should be typed with the initial letter capitalized and followed by their name in abbreviation (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). Title of the cited article and italicized journal title (Journal title should be in its abbreviation form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634]

Note: The author should test the references through reference testing system (<http://www.aushome.cn/cgi-bin/index.pl>)

### Style for book references

Authors: the first author should be typed in bold-faced letter. The surname of all authors should be typed with the initial letter capitalized and followed by their name in abbreviation (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

### Format

Standard journal article (list all authors and include the PubMed ID [PMID] where applicable)

- 1 **Das KM**, Farag SA. Current medical therapy of inflammatory bowel disease. *World J Gastroenterol* 2000; 6: 483-489 [PMID: 11819634]
- 2 **Pan BR**, Hodgson HJF, Kalsi J. Hyperglobulinemia in chronic liver disease: Relationships between *in vitro* immunoglobulin synthesis, short lived suppressor cell activity and serum immunoglobulin levels. *Clin Exp Immunol* 1984; 55: 546-551 [PMID: 6231144]
- 3 **Lin GZ**, Wang XZ, Wang P, Lin J, Yang FD. Immunologic effect of Jianpi Yishen decoction in treatment of Pixu-diarrhoea. *Shijie Huaren Xiaobua Zazhi* 1999; 7: 285-287

Books and other monographs (list all authors)

- 4 **Sherlock S**, Dooley J. Diseases of the liver and biliary system. 9th ed. Oxford: Blackwell Sci Pub, 1993: 258-296

Chapter in a book (list all authors)

- 5 **Lam SK**. Academic investigator's perspectives of medical treatment for peptic ulcer. In: Swabb EA, Azabo S. Ulcer disease: investigation and basis for therapy. New York: Marcel Dekker, 1991: 431-450

Electronic journal (list all authors)

- 6 **Morse SS**. Factors in the emergence of infectious diseases. Emerg Infect Dis serial online, 1995-01-03, cited 1996-06-05; 1(1):24 screens. Available from: URL: <http://www.cdc.gov/ncidod/EID/eid.htm>

### Inappropriate references

Authors should always cite references that are relevant to their article, and avoid any inappropriate references. Inappropriate references include those that are linked with a hyphen and the difference between the two numbers at two sides of the hyphen is more than 5. For example, [1-6], [2-14] and [1, 3, 4-10, 22] are all considered as inappropriate references. Authors should not cite their own unrelated published articles.

### Statistical data

Present as mean  $\pm$  SD and mean  $\pm$  SE.

### Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as  $\chi^2$  (in Greek), related coefficient as *r* (in italics), degree of freedom as  $\gamma$  (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

### Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose) 6.4  $\pm$  2.1 mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6 24.5  $\mu$ g/L; CO<sub>2</sub> volume fraction, 50 mL/L CO<sub>2</sub> not 5% CO<sub>2</sub>; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format about how to accurately write common units and quantum is at: <http://www.wjgnet.com/wjg/help/15.doc>

### Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further mention.

### Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindII*, *BamHI*, *Kho I*, *Kpn I*, etc.

Biology: *Helicobacter pylori*, *H pylori*, *E coli*, etc.

## SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. Author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, the final check list for authors, and responses to reviewers by a courier (such as EMS) (submission of revised manuscript by e-mail or on the *WJG* Editorial Office Online System is NOT available at present).

### Language evaluation

The language of a manuscript will be graded before sending for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing; (4) Grade D: rejected. The revised articles should be in grade B or grade A.

### Copyright assignment form

It is the policy of *WJG* to acquire copyright in all contributions. Papers accepted for publication become the copyright of *WJG* and authors will be asked to sign a transfer of copyright form. All authors must read and agree to the conditions outlined in the Copyright Assignment Form (which can be downloaded from <http://www.wjgnet.com/wjg/help/9.doc>).

### Final check list for authors

The format is at: <http://www.wjgnet.com/wjg/help/13.doc>

### Responses to reviewers

Please revise your article according to the comments/suggestions of reviewers. The format for responses to the reviewers' comments is at: <http://www.wjgnet.com/wjg/help/10.doc>

### Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

### Publication fee

Authors of accepted articles must pay publication fee.

EDITORIAL and LETTERS TO THE EDITOR are free of charge.

## World Journal of Gastroenterology standard of quantities and units

Number	Nonstandard	Standard	Notice
1	4 days	4 d	In figures, tables and numerical narration
2	4 days	four days	In text narration
3	day	d	After Arabic numerals
4	Four d	Four days	At the beginning of a sentence
5	2 hours	2 h	After Arabic numerals
6	2 hs	2 h	After Arabic numerals
7	hr, hrs,	h	After Arabic numerals
8	10 seconds	10 s	After Arabic numerals
9	10 year	10 years	In text narration
10	Ten yr	Ten years	At the beginning of a sentence
11	0,1,2 years	0,1,2 yr	In figures and tables
12	0,1,2 year	0,1,2 yr	In figures and tables
13	4 weeks	4 wk	
14	Four wk	Four weeks	At the beginning of a sentence
15	2 months	2 mo	In figures and tables
16	Two mo	Two months	At the beginning of a sentence
17	10 minutes	10 min	
18	Ten min	Ten minutes	At the beginning of a sentence
19	50% (V/V)	500 mL/L	
20	50% (m/V)	500 g/L	
21	1 M	1 mol/L	
22	10 μM	10 μmol/L	
23	1N HCl	1 mol/L HCl	
24	1N H <sub>2</sub> SO <sub>4</sub>	0.5 mol/L H <sub>2</sub> SO <sub>4</sub>	
25	4rd edition	4 <sup>th</sup> edition	
26	15 year experience	15- year experience	
27	18.5 kDa	18.5 ku, 18 500u or M:18 500	
28	25 g.kg <sup>-1</sup> /d <sup>-1</sup>	25 g/(kg·d) or 25 g/kg per day	
29	6900	6 900	
30	1000 rpm	1 000 r/min	
31	sec	s	After Arabic numerals
32	1 pg L <sup>-1</sup>	1 pg/L	
33	10 kilograms	10 kg	
34	13 000 rpm	13 000 g	High speed; g should be in italic and suitable conversion.
35	1000 g	1 000 r/min	Low speed. g cannot be used.
36	Gene bank	GenBank	International classified genetic materials collection bank
37	Ten L	Ten liters	At the beginning of a sentence
38	Ten mL	Ten milliliters	At the beginning of a sentence
39	umol	μmol	
40	30 sec	30 s	
41	1 g/dl	10 g/L	10-fold conversion
42	OD <sub>260</sub>	A <sub>260</sub>	"OD" has been abandoned.
43	One g/L	One microgram per liter	At the beginning of a sentence
44	A260 nm <sup>b</sup> P<0.05	A <sub>260</sub> nm <sup>a</sup> P<0.05	A should be in italic. In Table, no note is needed if there is no significance instatistics: <sup>a</sup> P<0.05, <sup>b</sup> P<0.01 (no note if P>0.05). If ther is a second set of P value in the same table, <sup>c</sup> P<0.05 and <sup>d</sup> P<0.01 are used for a third set: <sup>a</sup> P<0.05, <sup>b</sup> P<0.01.
45	<sup>*</sup> F=9.87, <sup>§</sup> F=25.9, <sup>#</sup> F=67.4	<sup>1</sup> F=9.87, <sup>2</sup> F=25.9, <sup>3</sup> F=67.4	Notices in or under a table
46	KM	km	kilometer
47	CM	cm	centimeter
48	MM	mm	millimeter
49	Kg, KG	kg	kilogram
50	Gm, gr	g	gram
51	nt	N	newton
52	l	L	liter
53	db	dB	decibel
54	rpm	r/min	rotation per minute
55	bq	Bq	becquerel, a unit symbol
56	amp	A	ampere
57	coul	C	coulomb
58	HZ	Hz	
59	w	W	watt
60	KPa	kPa	kilo-pascal
61	p	Pa	pascal
62	ev	EV	volt (electronic unit)
63	Jonle	J	joule
64	J/mm <sup>3</sup>	kJ/mol	kilojoule per mole
65	10×10×10cm <sup>3</sup>	10 cm×10 cm×10 cm	
66	N·km	KN·m	moment
67	x±s	mean±SD	In figures, tables or text narration
68	Mean±SEM	mean±SE	In figures, tables or text narration
69	im	im	intramuscular injection
70	iv	iv	intravenous injection
71	Wang et al	Wang <i>et al.</i>	
72	EcoRI	EcoRI	<i>Eco</i> in italic and RI in positive. Restriction endonuclease has its prescript form of writing.
73	Ecoli	<i>E.coli</i>	Bacteria and other biologic terms have their specific expression.
74	Hp	<i>H pylori</i>	
75	Iga	<i>Iga</i>	writing form of genes
76	igA	IgA	writing form of proteins
77	~70 kDa	~70 ku

## Contents

### EDITORIAL

- 837 Cardiac and vascular changes in cirrhosis: Pathogenic mechanisms  
*Liu H, Gaskari SA, Lee SS*
- 843 Cutaneous manifestations in celiac disease  
*Abenavoli L, Proietti I, Leggio L, Ferrulli A, Vonghia L, Capizzi R, Rotoli M, Amerio PL, Gasbarrini G, Addolorato G*
- 853 Probiotics and the gastrointestinal tract: Where are we in 2005?  
*Chermesh I, Eliakim R*

### LIVER CANCER

- 858 Macrophage inflammatory protein-2 contributes to liver resection-induced acceleration of hepatic metastatic tumor growth  
*Kollmar O, Menger MD, Schilling MK*
- 868 Relationship between therapeutic efficacy of arterial infusion chemotherapy and expression of P-glycoprotein and p53 protein in advanced hepatocellular carcinoma  
*Akimoto M, Yoshikawa M, Ebara M, Sato T, Fukuda H, Kondo F, Saisho H*
- 874 Anti-hepatoma activity and mechanism of ursolic acid and its derivatives isolated from *Aralia decaisneana*  
*Tian Z, Lin G, Zheng RX, Huang F, Yang MS, Xiao PG*
- 880 Role of CD80 in stimulating T lymphocyte activation  
*Li DC, Zhu XG, Zhang Y, Fu JX*

### BASIC RESEARCH

- 885 Characterization of H<sup>+</sup> and HCO<sub>3</sub><sup>-</sup> transporters in CFPAC-1 human pancreatic duct cells  
*Rakonczay Z Jr, Fearn A, Hegyi P, Boros I, Gray MA, Argent BE*
- 896 Inhibitory effects of interferons on pancreatic stellate cell activation  
*Baumert JT, Sparmann G, Emmrich J, Liebe S, Jaster R*
- 902 Characterization of human gene encoding SLA/LP autoantigen and its conserved homologs in mouse, fish, fly, and worm  
*Wang CX, Teufel A, Cheruti U, Grötzinger J, Galle PR, Lohse AW, Herkel J*
- 908 Trimetazidine: Is it a promising drug for use in steatotic grafts?  
*Ben Mosbah I, Casillas-Ramírez A, Xaus C, Serafin A, Roselló-Catafau J, Peralta C*
- 915 Epidural anaesthesia restores pancreatic microcirculation and decreases the severity of acute pancreatitis  
*Demirag A, Pastor CM, Morel P, Jean-Christophe C, Sielenkämper AW, Güvener N, Mai G, Berney T, Frossard JL, Bühler LH*
- 921 Expression, purification and characterization of enterovirus-71 virus-like particles  
*Chung YC, Huang JH, Lai CW, Sheng HC, Shih SR, Ho MS, Hu YC*

### CLINICAL RESEARCH

- 928 Cyclooxygenase-2 and epithelial growth factor receptor up-regulation during progression of Barrett's esophagus to adenocarcinoma  
*Li Y, Wo JM, Ray MB, Jones W, Su RR, Ellis S, Martin RCG*

Contents		World Journal of Gastroenterology Volume 12 Number 6 February 14, 2006
	935	Low central venous pressure reduces blood loss in hepatectomy <i>Wang WD, Liang LJ, Huang XQ, Yin XY</i>
<b>RAPID COMMUNICATION</b>	940	Removal selectivity of Prometheus: A new extracorporeal liver support device <i>Rifai K, Ernst T, Kretschmer U, Haller H, Manns MP, Fliser D</i>
	945	Randomized controlled trial of consensus interferon with or without zinc for chronic hepatitis C patients with genotype 2 <i>Suzuki H, Sato K, Takagi H, Kanda D, Sohara N, Kakizaki S, Nakajima H, Otsuka T, Nagamine T, Mori M</i>
	951	Absence of <i>MutY</i> homologue mutation in patients with multiple sporadic adenomatous polyps in Korea <i>Kim H, Kim HJ, Chi SG, Lee SK, Joo GR, Dong SH, Kim BH, Chang YW, Lee JI, Chang R</i>
	956	Risk factors of acute cholecystitis after endoscopic common bile duct stone removal <i>Lee JK, Ryu JK, Park JK, Yoon WJ, Lee SH, Lee KH, Kim YT, Yoon YB</i>
	961	Effect of interferon alpha and ribavirin treatment on serum levels of transforming growth factor- $\beta$ 1, vascular endothelial growth factor, and basic fibroblast growth factor in patients with chronic hepatitis C <i>Janczewska-Kazek E, Marek B, Kajdaniuk D, Borgiel-Marek H</i>
	966	Conversion of cadherin isoforms in cultured human gastric carcinoma cells <i>Wang BJ, Zhang ZQ, Ke Y</i>
<b>CASE REPORTS</b>	971	A case of an intussuscepted neuroendocrine carcinoma of the appendix <i>Thomas RE, Maude K, Rotimi O</i>
	974	Subfulminant hepatitis B after infliximab in Crohn's disease: Need for HBV-screening? <i>Millonig G, Kern M, Ludwiczek O, Nachbaur K, Vogel W</i>
	977	A case of Crohn's disease involving the gallbladder <i>Andoh A, Endo Y, Kushima R, Hata K, Tsujikawa T, Sasaki M, Mekata E, Tani T, Fujiyama Y</i>
	979	Intestinal Behcet's disease with pyoderma gangrenosum: A case report <i>Nakamura T, Yagi H, Kurachi K, Suzuki S, Konno H</i>
	982	Spontaneous rupture of a type IV <sub>A</sub> choledochal cyst in a young adult during radiological imaging <i>Stipsanelli E, Valsamaki P, Tsiouris S, Arka A, Papathanasiou G, Ptohis N, Lahanis S, Papantoniou V, Zerva C</i>
	987	Ultrastructure of Kupffer cells and hepatocytes in the Dubin-Johnson syndrome: A case report <i>Sobaniec-Lotowska ME, Lebensztejn DM</i>
	990	Pyogenic liver abscess associated with large colonic tubulovillous adenoma <i>Lai HC, Chan CY, Peng CY, Chen CB, Huang WH</i>
	993	Delayed ischemic gangrene change of distal limb despite optimal decompressed colostomy constructed in obstructed sigmoid colon cancer: A case report <i>Huang WS, Liu KW, Lin PY, Hsieh CC, Wang JY</i>
<b>ACKNOWLEDGMENTS</b>	996	Acknowledgments to Reviewers of <i>World Journal of Gastroenterology</i>
<b>APPENDIX</b>	997	Meetings
	998	Instructions to authors

## Abstract

Cardiovascular abnormalities accompany both portal hypertension and cirrhosis. These consist of hyperdynamic circulation, defined as reduced mean arterial pressure and systemic vascular resistance, and increased cardiac output. Despite the baseline increased cardiac output, ventricular inotropic and chronotropic responses to stimuli are blunted, a condition known as cirrhotic cardiomyopathy. Both conditions may play an initiating or aggravating pathogenic role in many of the complications of liver failure or portal hypertension including ascites, variceal bleeding, hepatorenal syndrome and increased postoperative mortality after major surgery or liver transplantation. This review briefly examines the major mechanisms that may underlie these cardiovascular abnormalities, concentrating on nitric oxide, endogenous cannabinoids, central neural activation and adrenergic receptor changes. Future work should address the complex interrelationships between these systems.

## INTRODUCTION

The cardiovascular system in patients with cirrhosis or

portal hypertension is abnormal. The circulation becomes hyperdynamic, characterized by increased cardiac output and decreased peripheral vascular resistance and arterial pressure. Moreover, despite the increased cardiac output at rest, with stressful stimuli such as hemorrhage, surgery or vasoactive drug administration, the ventricular response is blunted, a condition known as cirrhotic cardiomyopathy. These cardiovascular abnormalities have been suggested to induce or aggravate several complications of cirrhosis such as renal salt and water retention, variceal bleeding, hepatopulmonary syndrome, and increased cardiovascular fragility under stress. Recent reviews have detailed the clinical aspects of hyperdynamic circulation<sup>[1,2]</sup> and cirrhotic cardiomyopathy<sup>[3-5]</sup>. This review will summarize the recent work on pathogenic mechanisms underlying these two conditions.

## HYPERDYNAMIC CIRCULATION

Peripheral vasodilatation is central to hyperdynamic circulation and portal hypertension in cirrhosis. However, the factors directly initiating vasodilatation remain obscure. A hypothesis that has received much attention over the past three decades is the "humoral factor" theory. In cirrhosis, increased intrahepatic resistance induces portosystemic collateral formation, allowing gut-derived humoral substances to directly enter the systemic circulation without detoxification by the liver. The following gut-derived or locally-produced humoral factors have been implicated as possible mediators of peripheral vasodilatation in cirrhosis or portal hypertension.

### Endocannabinoids

Endocannabinoids are lipid-like substances that act on two inhibitory G protein-coupled receptors, CB1 and CB2. The vasodilatory effect of endogenous cannabinoids in cirrhosis was first reported in 2001<sup>[6]</sup>. Anandamide, an endogenous cannabinoid or endocannabinoid, is increased in monocytes of cirrhotic rats<sup>[6,7]</sup>, and its receptor CB1 is also upregulated in the vascular endothelium of patients with cirrhosis<sup>[6]</sup>. Infusing monocytes isolated from cirrhotic rats into normal rats decreases the mean arterial pressure in the recipients. Furthermore, administering a CB1 receptor antagonist SR141716A to cirrhotic rats increases the total peripheral resistance<sup>[6,7]</sup>, both studies demonstrated that SR141716A significantly increases the reduced arterial pressure in cirrhosis, and blocks the hypotension induced by the infusion of isolated cirrhotic monocytes into normal rats<sup>[6,7]</sup>. Batkai and colleagues also

found that SR141716A decreases mesenteric blood flow and portal venous pressure in cirrhotic rats<sup>[6]</sup>. All of these data indicate that the vascular tone in cirrhosis is regulated by CB1 receptors in both the splanchnic and systemic circulations.

Besides vasodilatation, anandamide rapidly and dose-dependently induces apoptosis in primary culture-activated and *in vivo*-activated hepatic stellate cells, with over 70% cell death after 4 h at 25  $\mu\text{mol/L}$ <sup>[8]</sup>. This effect could alter the hepatic sinusoidal microcirculation and enhance the development of portal hypertension that leads to hyperdynamic circulation.

How does cirrhosis leads to increased endocannabinoids? Varga and co-workers found that bacterial endotoxin stimulates endocannabinoid production in cirrhosis<sup>[9]</sup>. The upregulation of CB1 receptors in cirrhotic vascular endothelium and thus increased end-organ sensitivity may also enhance endocannabinoid vasodilator tone<sup>[6]</sup>.

### Nitric oxide

NO has been extensively studied. It is now clear that in cirrhosis, changes in NO activity affect different vascular beds in variable ways. In the liver microcirculation, endothelial-constitutive NO synthase (eNOS or NOS3) expression is decreased in a cirrhotic rat model<sup>[10]</sup>. Simvastatin enhances hepatic nitric oxide production and decreases the hepatic vascular tone in patients with cirrhosis<sup>[11]</sup>. An NO donor<sup>[12]</sup> or NOS3 gene transfection<sup>[10]</sup>, which compensates for the decreased hepatic NOS3 expression, significantly lowers the increased portal pressure in cirrhosis.

In contrast, systemic NO production is increased in cirrhotic patients and animal models<sup>[13-15]</sup>. Moreover, normalization of NO production in cirrhotic rats, by achieving normal concentrations of aortic cGMP with small doses of the NOS inhibitor L-NAME, normalizes the decreased peripheral vascular resistance and the increased cardiac output<sup>[16]</sup>. *In vitro*, an NO inhibitor reverses the hyporeactivity of blood vessels from cirrhotic rats to vasoconstrictors<sup>[17]</sup>.

All these results strongly support the hypothesis that increased NO production is a major factor in the peripheral arterial vasodilation of cirrhosis. Agents promoting nitric oxide production include inflammatory cytokines and endotoxin. In that regard, selective intestinal decontamination with norfloxacin partially reverses the hyperdynamic circulatory state in cirrhotic patients, suggesting a role for the endotoxin-NO pathway<sup>[18]</sup>. Where does this endotoxin come from in cirrhosis? First, alcohol is a major cause of cirrhosis in Western countries, and alcoholic gastrointestinal mucosal damage<sup>[19]</sup>, could potentially facilitate transfer of bacteria into the circulation. Second, portosystemic shunting allows gut-derived bacterial endotoxins passage to the systemic circulation. Third, cirrhotic patients with portal hypertension show intestinal structural abnormalities characterized by vascular congestion and edema, which leads to increased intestinal permeability to bacterial toxins<sup>[20]</sup>. Fourth, intestinal bacterial overgrowth and bacterial translocation are increased in cirrhosis<sup>[21]</sup>. Besides endotoxins, the other possible factors stimulating NO production include

cytokines such as TNF- $\alpha$ , IL-1, IL-6, and IFN- $\gamma$ <sup>[22-24]</sup>. Among these, TNF- $\alpha$  has been studied the most. Lopez-Talavera *et al* found that anti-TNF- $\alpha$  antibody increases mean arterial pressure and systemic vascular resistance, and decreases cardiac index and portal pressure<sup>[25]</sup>. In our 4-week BDL rats, in parallel with increased serum TNF- $\alpha$ , aortic NOS3 expression and serum nitrate/nitrite concentrations were increased<sup>[26]</sup>.

Although the evidence is strong that the increased NOS activity in cirrhosis plays an important role in hyperdynamic circulation in cirrhosis, it remains obscure which NOS isoform is involved. The majority of previous studies have used a nonspecific NOS inhibitor to diminish NO production. However, a recent study used aminoguanidine, a preferential inhibitor of NOS2 (inducible NOS), and showed that *in vivo*, the hyperdynamic circulation in portal hypertensive rats is reversed<sup>[27]</sup>. But in another study aminoguanidine had no *in vitro* effect on the hyporeactivity of aortic rings from cirrhotic rats<sup>[28]</sup>. We have recently evaluated the activity of the L-arginine-NO pathway at different levels<sup>[26]</sup>. Although NOS2 mRNA was detectable in the cirrhotic aorta, no NOS2 protein was observed in our Western blots. It is unclear why the mRNA was not expressed as a protein. It might have been degraded or not been transcribed. It is also possible that our method of Western blotting did not allow the detection of small amounts of NOS2 protein.

A consistent augmentation in the expression of NOS3 mRNA and protein levels is observed in cirrhotic rats. Because NOS3 can be upregulated by stimuli such as shear stress and mechanical deformation, some have suggested that hyperdynamic circulation is the cause rather than the consequence of the activation of the NO pathway<sup>[14,29,30]</sup>. In addition, there may be other reasons for the increased NOS3. Cirrhosis is associated with increased levels of estrogens<sup>[31,32]</sup>, and these compounds have been shown to upregulate NOS3 activity<sup>[33]</sup>. Other factors which may stimulate NOS3 expression need further investigation.

What is the role of another isoform of NOS, neuronal NOS (nNOS or NOS1)? Xu and his colleagues have demonstrated that nNOS expression is significantly increased in rat cirrhotic aortae<sup>[34]</sup>. Furthermore, an nNOS-specific inhibitor, 7-nitroindazole (7-NI), significantly decreased the sodium and water retention and normalized the hyperdynamic indices such as cardiac index, mean arterial pressure, and systemic vascular resistance in these rats<sup>[34]</sup>. Biecker *et al* also showed that nNOS partially compensates for the absence of eNOS in producing hyperdynamic circulation in eNOS-gene knockout mice<sup>[35]</sup>. These data indicate that the nNOS isoform plays a major pathogenic role in hyperdynamic circulation, and perhaps even in renal salt and water retention in cirrhosis.

It seems that endocannabinoids and nitric oxide may both play an important role in hyperdynamic circulation, but what is the relationship between them? The literature remains inconclusive. In a kidney study, Deutsch *et al* found that the vasodilatation of anandamide is NO dependent, because the NOS inhibitor L-NAME completely blocked the vasodilatory effect of anandamide, similar to a CB1 antagonist<sup>[36]</sup>. However, another study showed no effect

of L-NAME infusion on the hypotensive effects of anandamide<sup>[7]</sup>.

Some studies suggest the possible involvement of other humoral vasodilators, but a definitive pathogenic role for any of these substances remains elusive. This list includes: glucagons<sup>[37]</sup>, prostaglandins<sup>[38]</sup>, GABA<sup>[39]</sup>, VIP<sup>[40]</sup>, bile acids<sup>[41]</sup>, endotoxin, histamine<sup>[42]</sup> and adenosine<sup>[43]</sup>.

### Central neural mechanisms

Although most research has focused on the humoral mediators, in recent years we and others have shown an important mechanistic role of central nervous system (CNS) activation. A decade ago, our laboratory demonstrated that primary afferent denervation by capsaicin reversed the hyperdynamic circulation in rats with cirrhosis or portal hypertension due to portal vein stenosis (PVS)<sup>[44]</sup>. What is the relationship between the CNS and hyperdynamic circulation in portal hypertension? Using *c-fos*, an immediate-early gene (whose protein product can be detected by immunohistochemistry as Fos), as a marker of central neuronal activation, we have showed that the brainstem and hypothalamic cardiovascular-regulatory nuclei are activated at the first day after PVS, whereas the hyperdynamic circulation does not start up until 3-5 days after PVS. This time sequence suggests that central neural activation is the initiating signal in the pathogenesis of hyperdynamic circulation.

Subsequently, in portal hypertensive rats, we microinjected *c-fos* antisense oligonucleotide into one of the major cardiovascular-regulatory brainstem nuclei, the nucleus tractus solitarius (NTS), to block local Fos expression. This treatment completely blocked the development of the hyperdynamic circulation, i.e., abnormalities in cardiac output, mean arterial pressure and systemic vascular resistance were completely eliminated<sup>[45]</sup>. In normal control rats, *c-fos* antisense oligonucleotides had no effect<sup>[45]</sup>. These results indicate that central neural activation is a *sine qua non* for the development of the hyperdynamic circulation in portal hypertension.

The CNS, as the controller of the circulation, presumably would not arbitrarily activate the cardiovascular system without reason. This raises the question of what the initiating signal is? Likely, it is somehow related to the portal hypertension *per se*. Moreover, the exact route of signaling from the periphery to the CNS remains unclear. The aforementioned capsaicin study suggests that primary afferent nerves may be the signaling pathway from the periphery to the CNS<sup>[44]</sup>. Our subsequent study showed that capsaicin-treated BDL rats improve the renal function and do not develop ascites<sup>[46]</sup>. Moreover, both BDL-cirrhotic and portal hypertensive rats show diminished Fos expression in NTS after capsaicin-induced denervation of the afferent nerves as neonates<sup>[46]</sup>. These observations indicate that intact primary afferent innervation is necessary for the central neuronal activation and development or maintenance of hyperdynamic circulation. Additionally, sodium retention and ascites formation is also dependent on either the presence of hyperdynamic circulation or intact afferent innervation, or both. The complex relationship between CNS activation, local or neurohormonal humoral factor stimulation,

and cardiovascular disturbances in cirrhosis/portal hypertension continues to be studied in several labs.

## CIRRHOTIC CARDIOMYOPATHY

This syndrome was first described in the late 1960s, although for many years, it was mistakenly attributed to latent or subclinical alcoholic cardiomyopathy<sup>[47-49]</sup>. However, studies in human and animal models with nonalcoholic cirrhosis, dating from the mid-1980s showed a similar pattern of increased baseline cardiac output with blunted response to stress<sup>[4]</sup>. The clinical features of cirrhotic cardiomyopathy include blunted systolic and diastolic contractile responses to stress, in conjunction with evidence of ventricular hypertrophy or chamber dilatation and electrophysiological abnormalities including prolonged QT interval. Recent studies suggest the presence of cirrhotic cardiomyopathy may contribute to the pathogenesis of hepatorenal syndrome precipitated by spontaneous bacterial peritonitis<sup>[50]</sup>, acute heart failure after insertion of transjugular intrahepatic portosystemic shunts (TIPS)<sup>[51,52]</sup>, and increased cardiovascular morbidity and mortality after liver transplantation<sup>[53]</sup>. Therefore this syndrome is more than an academic curiosity, but rather an important clinical entity. We herein review possible pathogenic mechanisms reported by our laboratory and others.

### Endocannabinoids

Endocannabinoids are known to have a negative inotropic effect on cardiac contractility in both human<sup>[54]</sup> and rats<sup>[55]</sup>. The plasma level of an endogenous cannabinoid, anandamide, is known to be increased in cirrhosis<sup>[6]</sup>. We recently demonstrated a major role for increased local cardiac production of endocannabinoids in cirrhotic cardiomyopathy<sup>[56]</sup>. This conclusion is based on the restoration of blunted contractile response of isolated left ventricular papillary muscles from BDL-cirrhotic rats after preincubation with a CB1 antagonist, AM251. Additionally, endocannabinoid reuptake blockers (VDM11 and AM404) enhance the relaxant response of cirrhotic papillary muscle to higher frequencies of contraction in an AM251-sensitive fashion, suggesting an increase in the local production of endocannabinoids acting through CB1 receptors. Other *in vitro* evidence suggest a main neuronal source for the increase in local production of endocannabinoids, as these effects were mostly abolished by pretreatment with the neurotoxin tetrodotoxin<sup>[56]</sup>.

### $\beta$ -adrenergic signaling

Cardiac-adrenergic signaling is one of the main regulators of cardiac contractility. Adrenergic receptors increase adenylyl cyclase activity through stimulatory G proteins. Increased production of cAMP in turn results in an increase in calcium influx and contractile force mainly through activation of protein kinase A (PKA). We have previously shown that expression and responsiveness of  $\beta$ -adrenergic receptors<sup>[57]</sup> as well as its post receptor signaling pathway is blunted in cardiac tissue of cirrhotic rats. Post receptor impairment was found at different levels including content and function of stimulatory Gs-proteins<sup>[58]</sup>, uncoupling of the  $\beta$ -adrenoceptor-ligand

complex from G protein<sup>[59]</sup>, and responsiveness of adenylyl cyclase to stimuli<sup>[58,60]</sup>.

### Membrane fluidity

Biochemical and biophysical properties of the cell membrane determines the mobility of membrane-bound protein moieties. This mobility is known as membrane fluidity<sup>[61]</sup>, which is shown to be an important factor in the function of a number of membrane-bound receptors including  $\beta$ -adrenergic receptors<sup>[62]</sup>. We have shown that membrane fluidity in cardiomyocytes from bile duct-ligated rats is decreased in association with an increase in membrane cholesterol content and cholesterol/phospholipid ratio<sup>[58]</sup>. Restoration of these abnormalities *in vitro* results in normalization of blunted response of  $\beta$ -adrenergic receptors<sup>[58]</sup>. Alterations in membrane fluidity may also play a role in abnormal function of other membrane-bound components in cirrhotic cardiomyocytes including ion channels. The significant decrease in  $K^+$  currents through  $Ca^{2+}$ -independent transient outward  $K^+$  channel and the delayed rectifier current reported by Ward *et al* is an example that requires further investigation<sup>[63]</sup>.

### Nitric oxide

Nitric oxide is known to negatively regulate cardiac contractile function. It has been shown to be involved in some types of cardiac dysfunction including ischemic heart disease<sup>[64]</sup>. Balligand *et al* have reported that non-selective blockade of NOS augments the contractile response of rat ventricular myocytes to the  $\beta$ -agonist isoproterenol without affecting the baseline contractility<sup>[65]</sup>. Whether this effect is mediated by the inhibition of adenylyl cyclase activity by NO<sup>[66]</sup> or through the second messenger, cyclic guanosine monophosphate (cGMP), remains to be elucidated. Possible effects of NO on cardiac function in physiological and some pathophysiological states were extensively reviewed previously<sup>[67,68]</sup>.

As noted previously, cirrhosis is known to be associated with NO overproduction<sup>[29]</sup>. Involvement of NO overproduction in the development of cirrhotic cardiomyopathy was first reported in 1996 by Van Obbergh *et al* in the BDL rat. They showed that a nonselective NOS inhibitor, L-NMMA, restored the blunted contractile function of isolated heart from cirrhotic rats while it had no significant effect in control animals<sup>[69]</sup>. We have reported a similar effect in isolated left ventricular papillary muscles of cirrhotic rats. Furthermore, we observed that iNOS and not eNOS mRNA and protein expression were significantly increased in the heart of a cirrhotic rat<sup>[22]</sup>. Increased levels of cGMP in cirrhotic ventricles and elevated serum and cardiac levels of cytokines like TNF- $\alpha$  suggest a cytokine/iNOS/cGMP pathway for this effect<sup>[22]</sup>.

### Carbon monoxide

Carbon monoxide (CO) is mainly produced in the body through the action of heme oxygenases. These enzymes are responsible for converting heme to biliverdin and CO. Like NO, CO activates soluble guanylate cyclase resulting in increased levels of cGMP<sup>[70,71]</sup>. Expression of inducible heme oxygenase (HO-1) mRNA was increased in the right ventricle in a canine model of congestive heart

failure<sup>[72]</sup>. We previously reported an increase in mRNA and protein expression of HO-1 in left ventricle of bile duct-ligated rats, which was associated with an increase in left ventricular cGMP levels<sup>[73]</sup>. Furthermore, treatment of cirrhotic heart with an HO inhibitor, zinc protoporphyrin IX, restored the elevated cGMP levels<sup>[73]</sup>. These findings suggest the involvement of an HO-CO-cGMP pathway in the development of cirrhotic cardiomyopathy.

## CONCLUSION

Cardiovascular abnormalities consisting of hyperdynamic circulation and cardiomyopathy are frequent complications in cirrhotic patients and may contribute to significant morbidity and mortality, especially under stressful conditions. Underlying mechanisms of cardiac dysfunction and vascular abnormalities in cirrhosis have been separately explored in recent years, but a number of vasoactive mediator systems may be common to the genesis of both conditions. We believe that central neural activation plays an important initiating role in the genesis of hyperdynamic circulation, eventually leading to an imbalance between the tonic vasodilator vs vasoconstrictor tone, with a predominance of the former. Predominant among these peripheral vasodilator pathways are NO and endocannabinoids. The mechanisms of cirrhotic cardiomyopathy include altered cardiomyocyte plasma membrane physicochemical properties, impairment of  $\beta$ -adrenergic receptor signaling pathways, and overactivity of NO, carbon monoxide and endocannabinoid systems. Considering the undeniable interrelation of these systems, further studies are required to elucidate the complex interactions between these mechanisms.

### Abstract

Celiac disease (CD) is an autoimmune gluten-dependent enteropathy characterized by atrophy of intestinal villi that improves after gluten-free diet (GFD). CD is often associated with extra-intestinal manifestations; among them, several skin diseases are described in CD patients. The present review reports all CD-associated skin manifestations described in the literature and tries to analyze the possible mechanisms involved in this association. The opportunity to evaluate the possible presence of CD in patients affected by skin disorders is discussed.

### INTRODUCTION

Celiac disease (CD) can be defined as a chronic immune-mediated gluten-dependent enteropathy, resulting from an inappropriate T-cell-mediated immune response, against ingested gluten in genetically predisposed people<sup>[1]</sup>. Epidemiological studies have shown that CD is very common and affects about 1 in 250 people<sup>[2]</sup>. CD is a multigenic disorder associated with HLA-DQ2 (DQA1\*/DQB1\*2) expressed in more than 90% of patients, or HLA-DQ8 (DQA1\*0301/DQB1\*0302)<sup>[3]</sup>. The expression of these molecules is necessary, but not sufficient, to develop the disease<sup>[4]</sup>. The immune response to gluten

takes place in two compartments: the lamina propria and the epithelium. While lamina propria CD4 T cells have a recognized role in the pathogenesis of CD, the role of CD8 T cells in the intestinal epithelium is controversial<sup>[5]</sup>.

CD is characterized by intestinal malabsorption and subtotal or total atrophy of intestinal villi which improves after gluten-free diet (GFD)<sup>[6]</sup>. The classic form of CD presents several symptoms such as diarrhea, abdominal pain, weight loss and nutritional deficiencies, particularly of iron, folate, calcium, and vitamin D<sup>[7]</sup>. However, there is a large variety of clinical presentations characterized by the presence of extra-intestinal manifestations, including anemia<sup>[8]</sup>, persistent hypertransaminasemia<sup>[9]</sup>, osteopenia<sup>[10]</sup>, neurological<sup>[11]</sup>, psychiatric and affective disorders<sup>[12-14]</sup>, features of hyposplenism (Howell-Jolly bodies and thrombocytosis)<sup>[15]</sup> and autoimmune diseases<sup>[6]</sup>. In the last years, growing evidence has documented the involvement of skin diseases among the extra-intestinal manifestations of CD<sup>[17]</sup>. The aim of this review is to report all CD associated skin manifestations described in the English literature and to analyze the possible mechanisms involved in this association.

### Dermatitis herpetiformis

Dermatitis herpetiformis (DH) is a well-described entity, presenting as an itchy, chronic, papulovesicular eruption which may leave pigmentation and scarring<sup>[18]</sup>. Classically, skin lesions are characterized by a symmetrical eruption on the extensor surfaces of the body such as the knees, elbows, buttocks, and back. DH tends to occur more in the adult male (M/F ratio 2:1) who may also present with the involvement of oral and genital membranes. However this pattern is reversed in children who may simply have purpura over the palmar surfaces. The age of onset varies with geographical location and the incidence is highest in Ireland and Sweden and rare in Asia<sup>[19]</sup>. Histology of lesional skin shows micro abscesses consisting of neutrophils and eosinophils within the dermal papillae. Sub-epidermal vesicles and bullae are produced within the lamina lucida as a result of collagen degradation. Furthermore there is an increased number of activated T cells. Direct immunofluorescence of the normal skin shows the pathogenomic granular IgA deposits in the papillary dermis but the exact target antigen is still unknown<sup>[19-21]</sup>. These deposits are often associated with C3 to support the suggestion that the complement is activated via the alternative pathway and C5<sup>[22,23]</sup>. The activated fraction, C5a, is highly chemotactic for neutrophils and may contribute to the inflammatory change at the papillary tip.

HLA studies in patients, who have DH based on

clinical and immunological criteria, have shown that 85-90% are HLA B8-positive and that there is an even stronger association with HLA DW3 and DRW3. Interestingly, patients with a GSE without DH show a similar high incidence of these antigens<sup>[24]</sup>. Specific B cell/macrophage antigens have been noted in patients with DH and the gluten-sensitive enteropathy<sup>[25]</sup>. Family studies have shown that these B cell antigens segregated independently of HLA antigens<sup>[26]</sup>. One hypothesis is that both HLA and non-HLA disease genes are necessary for the development of lymphoid cell surface receptors that recognize gluten.

Antigluten, antiendomysium, antigliadin and tissue transglutaminase antibodies have been detected in patients with DH<sup>[27-29]</sup>. These gluten-specific cells migrate to the gut mucosa where they mediate cytotoxic reactions involving the epithelial cells<sup>[30]</sup>. There is an immunogenetic association with HLA DR3 DQW2 (HLA class II alleles DQAI 0501 and DQBI 0201), which is very much more common in Caucasians than in Orientals and may be important for the different incidences of DH in different ethnic populations. Gluten must be present in the diet for the development of DH; however, a genetic susceptibility to gluten has been proposed as an etiological mechanism. This observation could explain why DH is very common in some Asian populations, which have a low daily gluten intake (e.g., 7-8 g/d in Korea) compared with Western populations which have higher daily gluten intake (e.g., 15-20 g/d in Scandinavia)<sup>[19]</sup>.

As CD and DH may seem to be vastly different, they both share a unique intestinal sensitivity to gluten, with the rash of DH thought to be an external marker of the underlying intestinal sensitivity that is likely to be the result of molecular mimicry between the auto antigen tissue transglutaminase resident in the gut and the skin derived epidermal transglutaminase.

Although patients with DH are unlikely to have gastrointestinal symptoms or features of malabsorption, they have small intestinal histopathologic changes, with either a classical atrophic appearance with complete villous atrophy, or more commonly a more subtle infiltrative pattern with partial or no villous atrophy. When there is a suspicion of DH with a negative skin biopsy but serologic evidence of CD, a skin biopsy should be repeated given the patchy nature of the lesions, and referral to a gastroenterologist for small bowel biopsy should be pursued. Interestingly, topical skin application of gluten-containing products does not produce the rash of DH in susceptible patients; however, oral or rectal introduction of gluten has been found to result in the classic DH rash<sup>[31,32]</sup>.

The DH rash is often treated with dapsone in conjunction with the gluten withdrawal. In addition to improving the histological changes of the small intestine, the gluten-free diet may also allow a reduction of suppressive medication<sup>[32]</sup>. Just as patients with CD are at a higher risk of malignancies such as lymphomas, so are those patients with DH not compliant with GFD, which should motivate patients with DH to follow the diet regardless of the absence of other symptoms<sup>[31]</sup>.

### **Linear IgA bullous dermatosis**

Linear IgA bullous dermatosis (LABD) is a rare disease

characterized by erythematous papules or groups of small vesicles. The onset may be acute or gradual and the predominant symptom is usually pruritus. Immunoelectron microscopic studies have shown a linear deposition of IgA along the lamina lucida or in the sub-basal lamina area of stratified squamous epithelium<sup>[32]</sup>. At the moment, it is considered as a distinct entity from DH and Bullous pemphigoid<sup>[32,33]</sup>. The incidence of gluten sensitivity enteropathy (GSE) in LABD has been described in the literature to range from 0% to 24%<sup>[33-36]</sup>. The HLA haplotype (A1, B8, DR3) of LABD patients is often that found in classic DH which is in >85% of CD patients<sup>[37,38]</sup>. Although the prevalence of CD is low in LABD, some authors have suggested a diagnosis of GSE in these patients<sup>[34-36,39]</sup>.

### **Urticaria**

Urticaria is an eruption of transient erythematous or edematous swellings of the dermis or sub-cutaneous tissue and is due to a local increase of permeability of capillaries and small venules. Hautekeete *et al*<sup>[40]</sup> first described the association between CD and chronic urticaria, although this association is still debated<sup>[41]</sup>. Adults with CD also often have an increase of atopic or immunologic disorders<sup>[42,43]</sup>. Scala *et al* reported that a GFD eliminated both skin and intestinal symptoms in patients with concomitant CD and chronic urticaria<sup>[44]</sup>. The passage of antigens and immune-complex formation may be facilitated by an increased mucosal permeability. Theoretically, this mechanism might cause urticarial lesions and so, by restoring the integrity of the mucosa, a gluten-free diet might resolve skin symptomatology.

### **Hereditary angioneurotic edema**

Hereditary angioneurotic edema (HANE) is characterized by recurrent edematous attacks in the sub-cutis and sub-mucous due to C1-esterase inhibitor (C1-INH) deficiency<sup>[45]</sup>. Brickman *et al*<sup>[46,47]</sup> described HANE in association with inflammatory bowel diseases (IBD). In 2002, Farkas *et al*<sup>[48]</sup> first described the simultaneous occurrence of HANE and CD. The classic activation pathway of the complement system plays a potential role in the immune regulation of both disorders: it is deficient in HANE and gluten is a potent activator of the alternative pathway in CD<sup>[49]</sup>. There might also be a genetically determined etiology of both diseases<sup>[50]</sup>. Complement testing is justified whenever the GI symptoms of CD persist despite restoration of damaged mucous. Conversely HANE unresponsive to adequate prophylaxis should prompt for complete GI group tests<sup>[48]</sup>.

### **Cutaneous vasculitis**

CD may give rise to many skin manifestations but vasculitic skin lesions have rarely been encountered<sup>[51,52]</sup>. Leucocytoclastic vasculitis is characterized by the involvement of postcapillary venules. The skin is the most common organ involved with the usual clinical appearance of a palpable purpura. In most cases, leucocytoclastic vasculitis is mediated by immunocomplex deposition and the antigen being either exogenous or endogenous<sup>[53]</sup>. The coexistence of cutaneous vasculitis and CD might be related to in-

creased intestinal permeability<sup>[54]</sup>, and immune complexes, originating from exogenous or endogenous antigens, might circulate because of the impaired phagocytic function of reticular endothelium system and be deposited in the skin<sup>[55]</sup>. As in inflammatory bowel disease (IBD), exogenous antigens may permeate the damaged CD mucous in larger quantities than normal<sup>[54,56]</sup>. This is reflected by significant serum milk and gluten fraction antibody titers<sup>[57,58]</sup>. Alternatively, an autoimmune sensitization may result because of the release of endogenous antigens from damaged small bowel mucosa<sup>[59]</sup>. Meyers *et al*<sup>[60]</sup> described a case of cutaneous vasculitis complicating CD and the remission of skin lesions after the treatment with a strict GFD. Treatment of leucocytoclastic vasculitis has generally been difficult, but corticosteroids and a gluten-free diet may improve the dermatosis in cases associated with CD<sup>[52]</sup>.

### **Erythema nodosum**

Erythema nodosum (EN) is a chronic panniculitis characterized by inflammation of the fat septa and its etiology seems to involve an allergic or immune complex-mediated reaction to many antigens. Triggers include infections, sarcoidosis, adverse drug reaction, IBD, and lymphomas<sup>[61]</sup>. EN generally resolves in 5-8 weeks but if antigenic stimulus persists, the disease may last for a long period<sup>[62]</sup>. In 1991, Durand *et al* first observed a causal linkage between CD and EN<sup>[63]</sup>. CD can be a triggering factor of EN because an altered intestinal permeability to endogenous or exogenous antigens may provoke the immunologic response. EN is also a common finding in sarcoidosis which frequently coincides with CD<sup>[62-65]</sup>. When EN skin lesions are chronically recurrent or persistent, it is advisable to search for an underlying CD even if it is difficult to estimate the true incidence of the coexistence of both diseases.

### **Erythema elevatum diutinum**

Erythema elevatum diutinum (EED) is a rare variation of cutaneous leucocytoclastic vasculitis, originally described in 1894<sup>[66]</sup>. Its lesions appear as soft erythematous papule-plaques and become hard nodules mainly symmetrically affecting the backs of the hands and other extensor surfaces overlying the joints<sup>[67]</sup>. Ulceration, arthralgia and pain can be other features of this disease<sup>[67,68]</sup>. Even if it is presumed to be an immune reaction by bacterial antigens, the etiology of EED is unknown<sup>[69]</sup>. EED has been described in association with several other immunological diseases, especially paraproteinemias (i.e., monoclonal IgA gammopathy)<sup>[70]</sup>. Tasanen *et al*<sup>[70]</sup> detected dermo-epidermal IgA and complement deposits in lesional skin of a patient affected by CD; the histopathology was suggestive of EED<sup>[71]</sup>. The EED skin lesions appear to result from an immune complex reaction, as suggested by the association of various infections or autoimmune diseases. Joint pains are often present in patients affected by autoimmune disease such as EED but are also often found in association with CD<sup>[72]</sup>. Some authors have therefore suggested that it is important to warrant consideration of underlying CD in at least some patients with EED<sup>[71-73]</sup>.

### **Necrolytic migratory erythema**

The features of necrolytic migratory erythema (NME) have been reviewed by several authors. Becker *et al*<sup>[74]</sup> first described a cutaneous reaction pattern with specific histopathologic features in association with a pancreatic islet cell carcinoma. NME is a term used by Wilkinson<sup>[75]</sup> to describe the characteristic skin disease related with glucagonoma. Typically lesions start with figurate areas of erythema followed by erosions mainly over the trunk, perineum, lower extremities and perioral area. Eventual shedding is caused by superficial necrosis<sup>[76]</sup>. Most patients have angular cheilitis, stomatitis, glossitis, diffuse alopecia and brittle nails. Gastrointestinal symptoms such as weight loss and diarrhea are common<sup>[77]</sup>. Most cases of NME were part of the glucagonoma syndrome<sup>[76-77]</sup>. NME occasionally occurs with chronic liver disease or malabsorption with villous atrophy<sup>[78,79]</sup>. Kelly *et al*<sup>[80]</sup>, Goodenberg *et al*<sup>[79]</sup> and Thorisdottir *et al*<sup>[81]</sup> described the association between CD and NME. The etiology of NME is uncertain, although deficiencies of zinc, amino acids, or essentially fatty acids could play an important role<sup>[77,78,82,83]</sup>. It must be stressed that in CD patients with NME, this latter disorder seems to have an excellent response to GFD<sup>[79,81]</sup>.

### **Psoriasis**

Psoriasis is a chronic, relapsing dermatosis characterized by scaling, erythema, and less commonly pustulation<sup>[84]</sup>. It has been demonstrated that psoriasis is an immunological disease with hyperproliferation of T-cell mediated keratocytes<sup>[85]</sup>. Recent data indicate that HLA-Cw\*0602 may play an important pathogenetic role in the majority of psoriasis patients<sup>[86]</sup>. Immune mechanisms have an important role in the pathogenesis of this disease. In particular, an overexpression of T helper cell type 1 (Th1) cytokines and a relative under-expression of Th 2 cytokines have been shown in psoriatic patients<sup>[87]</sup>. The treatment is often difficult; all currently available effective remedies are retinoids or immunosuppressant drugs such as steroids or cyclosporin<sup>[84]</sup>, other than topical treatment<sup>[88]</sup>, photochemotherapy (PUVA)<sup>[89]</sup> and biological treatment such as infliximab or etanercept<sup>[90]</sup>. Recent studies have showed an association between CD and psoriasis<sup>[91,92,93]</sup> and an improvement of skin lesions after 3-6 mo of GFD, without other pharmacological approaches, was described<sup>[91]</sup>. However at present the relationship between CD and psoriasis remains controversial since there are few data on this topic and other authors sustain that this association seems to be coincidental<sup>[94]</sup>.

In one study, 10 out of 32 (31%) subjects affected by different clinical forms of psoriasis had positive antireticulin antibodies with a variability of titers, related to the extent of the disease<sup>[95]</sup>. Subsequently, in a first screening study conducted by Michaelsson *et al*<sup>[96]</sup> 16% of 302 subjects with psoriasis had IgA and/or IgG AGA. Only in 1 of 11 IgA AGA-positive patients from this group screened for antibodies to reticulin/EMA was this positive. An increase of EG2-positive eosinophils in duodenal mucosa associated with elevated serum levels of eosinophil cation protein (ECP) has been documented in psoriatic subjects with AGA, but no tendency to higher

ECP values has been detected in those with AGA<sup>[97]</sup>. The same authors reported that the increase in the number of eosinophils in the gastrointestinal tract is explained as being part of some unknown process that may be related to the development of skin psoriatic lesions. Cardinali and co-workers<sup>[92]</sup> performed a study to verify whether gluten intolerance is more frequent in Mediterranean subjects with psoriasis than in healthy controls. The sera of 39 psoriatic patients and 39 controls were screened for AGA, EMA, antibodies anti-transglutaminase (TgA), ECP, serum total IgE levels and number of eosinophils. The results showed positivity for IgG AGA in two psoriatic patients, one borderline for TgA, and none was positive for EMA or IgA AGA. In these subjects the authors found high serum levels of ECP and IgE, but a normal number of eosinophils; on the contrary eosinophil count and serum IgE levels were within the normal range in the controls. Michaelsson *et al*<sup>[91]</sup> evaluated the effect of GFD in 33 AGA positive patients and six AGA negative patients with psoriasis in an open study. Of the 33 AGA-positive patients, 2 had IgA EMA, and at the duodenal biopsy 15 showed an increased number of lymphocytes in the epithelium, but in some this increase was only slight. GFD was for 3 mo. Thirty out of thirty-three patients strictly complied with GFD, after which they showed a significant decrease of psoriatic lesions. This included a significant decrease in the 16 AGA positive patients with normal routine histology in duodenal biopsy. The AGA negative patients did not improve. There was also a significant decrease in the serum of eosinophil cation protein in patients with elevated AGA. In conclusion, the positive effects of GFD were observed not only in patients with an increased number of lymphocytes in the duodenal epithelium, but also in some patients with seemingly normal epithelium<sup>[91,98]</sup>.

Our group recently reported a case of severe psoriasis in a CD patient, not responding to specific therapies for psoriasis and in whom the regression of skin lesions after GFD was very rapid<sup>[99,100]</sup>. The association between psoriasis and CD was subsequently confirmed by Ojetti *et al*<sup>[101]</sup>. The authors evaluated the prevalence of CD in patients affected by psoriasis, showing a high frequency of CD (4.34%) in psoriatic patients.

At present the mechanisms implicated in the possible association between CD and psoriasis, and the effect of GFD on psoriatic skin lesions are not known. There are some hypotheses:

Hypothesis 1: Abnormal small intestinal permeability, frequently present both in psoriasis<sup>[102]</sup> and in CD patients<sup>[103]</sup>, could be a triggering factor between CD and psoriasis.

Hypothesis 2: T cells play an important role in the pathogenesis of both psoriasis and CD. An increased number of T cells in the blood, in the dermis and in the epidermis of psoriatic patients has been documented<sup>[87]</sup>. In CD patients, gliadin induces a sensitization of T cells<sup>[104]</sup> and this may play a role in the pathogenesis of psoriatic skin lesions<sup>[99]</sup>.

Hypothesis 3: Psoriatic lesions in CD patients could be related to vitamin D deficiency, which is present both in CD<sup>[105]</sup> and in psoriasis<sup>[106-107]</sup>.

### Vitiligo disease

Vitiligo is a specific, common, often heritable acquired disorder characterized by well-circumscribed milky white cutaneous macules devoid of identifiable melanocytes<sup>[108]</sup>. This disease appears to be more commonly observed in parts of the body exposed to the sun and in darker skin types and may develop at any age. The etiology is complex: there appears to be a certain genetic predisposition and a number of potential precipitating causes (i.e. crisis, illness, physical injury, etc.). Numerous attempts to identify HLA markers have revealed certain ethnic-specific markers: HLA-DR4 (blacks), B13 (Jews) and BW-35 (Yemenites). Theiligore<sup>[108]</sup> has proposed three prevailing theories to explain vitiligo: the neural hypothesis, the self-destruct hypothesis and the immune hypothesis. It carries a risk for ocular abnormalities, particularly iritis, and a significant risk for thyroid disease, diabetes mellitus, Addison's disease and pernicious anemia.

The relationship between CD and vitiligo is controversial. Although some authors have described some cases of vitiligo in patients affected by CD<sup>[94,109]</sup>, a serological screening study for CD in patients with vitiligo did not show any correlation between these two immunological disorders<sup>[110]</sup>. This implies that the sporadic associated cases must be considered as coincidental.

### Behçet's disease

A history of oral ulceration has been described in 25% of patients with CD and about 2-4% of patients with recurrent oral ulceration also have CD<sup>[111]</sup>. Behçet's disease (BD) is characterized by recurrent ulceration of the mouth and genitalia associated with iritis. Males are affected 5-10 times more frequently than females and the onset is usually between the ages of 10 and 30. The oral ulcers usually show only non-specific inflammatory changes, although there may be infiltration of the grossly thickened walls of thrombosed arterioles. Some authors have suggested that BD may be caused by a virus<sup>[112]</sup> and antibodies against mucous membrane were demonstrated in 17 of 40 patients<sup>[113]</sup> but their significance has not yet been evaluated. Triolo and co-workers<sup>[114]</sup> described 3 cases of coexistence of BD and symptomless CD in 11 patients with BD (defined according to International Study Group-ISG criteria). IgA and IgG class AGA and EMA were found in one patient, another two had IgG AGA alone. There is suggestive but as yet inconclusive evidence of a probable association between CD and autoimmune diseases such as BD. It could be supposed that both diseases are likely the result of molecular mimicry between two undefined auto antigens or virus trigger action. In patients affected by BD, it may therefore be important to search for underlying undiagnosed CD, but future studies are needed to shed light on this point.

### Oral lichen planus

The associations between CD and recurrent oral ulceration, glossitis, angular cheilitis and burning mouth are common<sup>[111]</sup>. Three to six percent of patients with these oral manifestations may have underlying undiagnosed CD<sup>[111,115]</sup>. Fortune *et al*<sup>[116]</sup> described the erosive type

of oral lichen planus (OLP) in a patient with gluten enteropathy. OLP is not rare and frequently involves the buccal mucosa, gingiva and tongue. In both the diseases, the lesions had a mucosal T-cell infiltrate and the relief from eating a gluten-free diet was surprising. It is not clear whether the oral lesions are a direct manifestation of CD or due to the effect of malabsorption on the rapidly dividing mucosal cells already predisposed to soreness by a pre-existing disease; because palliative medication of chronic ulcerative stomatitis is often ineffective, it is important to detect the underlying nutritional deficiencies for the patient's general well-being also.

### **Dermatomyositis**

Dermatomyositis is a disorder mainly of the skin, muscle and blood vessels in which characteristic erythematous and edematous changes in the skin are associated with muscle weakness and inflammation. An underlying carcinoma is commonly described in adults. Juvenile dermatomyositis (JDM) has a more favorable prognosis for life but functional disability is usually severe. Its pathogenesis is probably due to cell-mediated immunity to muscle antigens, humoral immunity and immune complex deposition<sup>[117]</sup>.

Some authors have described an association with CD<sup>[118-121]</sup>. Both diseases have a strong association with DQA1 0501 heterodimer because a linkage disequilibrium with HLA-DR3 haplotype or alternatively DR5/DR7 heterozygosity in CD<sup>[122,123]</sup> DQA1 0501 may lead to the activation of CD4-positive T cells by presentation of a still unidentified peptide that may induce CD or JDM. Evron *et al.*<sup>[124]</sup> and Marie *et al.*<sup>[120]</sup> have also described the association between dermatomyositis (DM) and polymyositis (PM) and CD in adults. For these authors CD may be included within the spectrum of gastrointestinal manifestations of DM/PM and they showed that GFD may resolve clinical and laboratory abnormalities.

### **Porphyria**

Mustajoki *et al.*<sup>[125]</sup> and subsequently Twaddle *et al.*<sup>[126]</sup> reported the coincidental diagnosis of CD in porphyrics. Patients with CD and porphyria present particular problems in terms of management<sup>[127]</sup>. The porphyrias are a group of rare diseases affecting the enzymes of the heme biosynthetic pathway with subsequent accumulation of porphyrins in the tissues. These substances are photosensitizers and their accumulation in the skin can cause bullae, erosions, increased fragility, scarring, hirsutism and pigmentation on photo-exposed areas. CD is often associated with DH which has some features in common with skin lesions of porphyrias. In one type of porphyria, variegate porphyria (VP), accumulation of porphobilinogen and 5-aminolevulinic acid is associated with gastrointestinal symptoms and an acute neuropsychiatric syndrome. Some drugs such as dapsone are precipitants of these acute attacks<sup>[127]</sup>. It is essential that patients with bullous skin lesions are adequately investigated to distinguish VP from DH because the administration of dapsone could have a potentially fatal outcome. Furthermore, symptomatic control of CD (e.g.,

malabsorption, anorexia, calorie restriction) can prevent precipitation of acute attacks of VP and because gluten sensitivity itself may be associated with neurological and psychiatric disorders<sup>[12,15]</sup>, neuropsychiatric porphyria could be one of the differential diagnoses<sup>[128]</sup>.

### **Alopecia areata**

Alopecia areata (AA) is a chronic autoimmune disease characterized by non-scarring alopecia. Histologically it is possible to find perifollicular lymphocyte infiltration, pointing to an immunologic etiology such as CD. In both the diseases there is the presence of organ-specific autoantibodies<sup>[109,129-131]</sup>, T-lymphocyte infiltration at the site of lesion<sup>[132,133]</sup>, association with HLA genes<sup>[134,135]</sup> and possible etiologic importance of viral co-factors<sup>[136,137]</sup>.

In the general population the prevalence of CD is 1 in 305<sup>[138]</sup> and of AA is 1 in 819<sup>[139]</sup>. Corazza and co-workers<sup>[140]</sup> found that the prevalence of CD in patients with AA was 1 in 85. Although remission and recurrence may be observed during the clinical course of AA<sup>[141]</sup>, many patients on gluten-free diet showed complete regrowth of scalp and other body hair and no further recurrence of AA at follow-up<sup>[140,142]</sup>. The positive effects of gluten-free diet on the pattern of autoimmune conditions, such as AA, associated with CD have been attributed to a normalization of the immune response. This study suggests that AA patients constitute a novel risk group of CD. Because AA may be the only clinical manifestation of CD, some authors suggest GSE serological screening tests in alopecia universalis<sup>[140]</sup>.

### **Acquired hypertrichosis lanuginosa**

Acquired hypertrichosis lanuginosa (AHL) is a rare disease and there are less than 40 cases in the literature<sup>[143,144]</sup>. This type of hypertrichosis is characterized in its extreme by the rapid growth of fine, down-like hair all over the body, occasionally associated with glossitis and loss of taste. A lesser degree of hypertrichosis in which lanugo hair occurs only on the face is more common. It is three times more common in females than in males and most commonly associated with malignancy<sup>[145]</sup>. Lymphomas, carcinoid tumors, and the Zollinger-Ellison syndrome have also been associated with this pathology<sup>[145,146]</sup>.

In 1988, Corazza *et al.*<sup>[147]</sup> described the only case reported in the literature of acquired hypertrichosis lanuginosa associated with CD. This case report confirms the paraneoplastic features of AHL. CD is often reported as being associated with tumors and can precede clinical presentation of the tumors<sup>[148]</sup>.

### **Pyoderma gangrenosum**

The pyoderma gangrenosum (PG) is a neutrophilic dermatosis, with destructive, necrotizing and non infectious ulcers, involving face and inferior limbs. The association between PG and CD has been described in some case reports and the importance of GFD in the resolution of PG has been suggested<sup>[149]</sup>.

### **Ichthyosiform dermatoses**

The ichthyosiform dermatoses consist of a heterogeneous

group of hereditary disorders, all of which are characterized by the accumulation of large amounts of scale on the cutaneous surface. The earliest reports of ichthyosis have been traced to the Indian and Chinese literatures several hundred years B.C. and a dermatology text by William first discussed the problem. Kinetic studies of the epidermis in the major forms of ichthyosis have shown increased germinative cell hyperplasia and increased transit rate through the epidermis in lamellar ichthyosis<sup>[150]</sup>. Menni *et al*<sup>[151]</sup> first reported a case of ichthyosis revealing CD but the reason for this association is still unknown.

### Pellagra

Pellagra is a disease characterized by lesions of the skin usually preceded by prodromal symptoms, especially of digestive and nervous systems. The dermatosis begins as erythema and edema on the back of the hands, with pruritus and burnings, determined especially by exposure to the sun and by localized pressure. In some patients, several days after the onset of erythema, blisters appear; these run together to form bullae and then break. In the second stage, the dermatosis becomes hard and brittle. The skin may look like a goose. The usual sites are the face, neck, dorsal surfaces of the hands, arms, and feet. The cause of pellagra is still not entirely clear. It may arise from a diet deficient in niacin or tryptophan, or more commonly both, and amino acid imbalance may also play a part<sup>[152]</sup>. In 1999, Schattner<sup>[152]</sup> described a case of a man with a pellagra-like syndrome due to CD.

### Generalized acquired cutis laxa

Cutis laxa (CL) is a heterogeneous group of inherited and acquired (generalized or localized) diseases characterized by looseness of the skin with the development of inelastic folds that gives the affected person a prematurely senile appearance<sup>[153-155]</sup>. CL presents a destructive phenomenon of previously apparently normal elastic fibers, with cephalocaudal progression<sup>[156]</sup>. It occurs mainly in adults and the etiology is unknown. Immunological abnormality has been postulated to explain the destruction of elastic tissue<sup>[157]</sup>. Generalized acquired cutis laxa (GACL) has been reported in association with infectious disorders, drugs and autoimmune diseases<sup>[153,157,159-163]</sup>. Many authors have described a dermal deposit of immunoglobulins (IgA) in various diseases, suggesting that destruction of elastic tissue may be immunologically mediated<sup>[159]</sup>. Cases of association between GACL and CD have been reported<sup>[159,164]</sup>. Bodvarsson *et al*<sup>[164]</sup> proposed that dietary intake of glutenin may induce the production of antibodies to elastin and mediate adherence of neutrophils<sup>[165,166]</sup>. A cross-reaction is possible between gluten and some components of elastic fibers, since glutenin presents a 22.3% amino acid sequence similar to elastin<sup>[164,167]</sup>. Garcia-Patos and co-workers<sup>[163]</sup> described a case of GACL associated with CD, evidence of IgA deposits on the dermal elastic fibers and moderate improvement of eruption after treatment with GFD.

### Atypical mole syndrome and congenital giant naevus

Montalto *et al*<sup>[168]</sup> first described the association between CD, atypical mole syndrome and congenital giant naevus.

Table 1 Skin disorders in celiac disease

Dermatitis herpetiformis	Seah <i>et al</i> <sup>[20]</sup> Mann <i>et al</i> <sup>[25]</sup> Katz <i>et al</i> <sup>[22]</sup> Porter <i>et al</i> <sup>[28]</sup>

Dermatomyositis	Buderus <i>et al</i> <sup>[119]</sup> Falcini <i>et al</i> <sup>[120]</sup> Marie <i>et al</i> <sup>[121]</sup> Iannone and Lapadula <sup>[122]</sup>
Porphyria	Mustajoki <i>et al</i> <sup>[126]</sup> Twaddle <i>et al</i> <sup>[127]</sup>
Alopecia areata	Corazza <i>et al</i> <sup>[141]</sup> Naveh <i>et al</i> <sup>[143]</sup>
Acquired hypertrichosis lanuginosa	Corazza <i>et al</i> <sup>[148]</sup>
Ichthyosiform dermatoses	Menni <i>et al</i> <sup>[152]</sup>
Pellagra	Schattner <sup>[153]</sup>
Generalized acquired cutis laxa	Lewis <i>et al</i> <sup>[160]</sup> Garcia-Patos <i>et al</i> <sup>[165]</sup>
Atypical mole syndrome and congenital giant nevus	Montalto <i>et al</i> <sup>[170]</sup>
Pyoderma gangrenosum	Gasbarrini and Corazza <sup>[150]</sup>

They reported a case of a patient affected by a rare multiple disorder of the cutaneous pigmentary system, which increased the risk of melanoma, and by CD which is frequently associated with some neoplasms<sup>[169-172]</sup>. Some authors have therefore suggested a more careful objective examination in all the patients with CD<sup>[168]</sup>.

## CONCLUSION

CD is an enteropathy associated with various extra-intestinal manifestations, including several skin diseases. Several hypotheses have been proposed regarding the possible mechanisms involved in this association. In particular, an abnormal small intestinal permeability appears to be implicated, which may allow the crossing of endogenous or exogenous antigens and may provoke the immunological response, common immune mechanisms, vascular alterations and, lastly, vitamin and amino acid deficiency secondary to malabsorption in patients with CD. However at present the data are not homogeneous and most of the evidence for the association between CD

and skin disorders is based on "case-reports", making it difficult to draw definitive conclusions on this topic; future controlled studies are consequently needed to verify the real involvement of the cutaneous district in CD (Table 1). Nevertheless, despite these limitations, the opportunity to investigate the possible presence of CD in some dermatological patients seems at present justified.

## ACKNOWLEDGMENTS

We express our gratitude to Dr Cristina D'Angelo, Dr Antonio Mirijello, Dr Silvia Cardone, Dr Veruscka Leso (*Università Cattolica del Sacro Cuore*, Rome, Italy) for their cooperation in this paper. The study was partially supported by grants from the "Associazione Ricerca in Medicina", Bologna-Rome, Italy.

### Abstract

Probiotic agents are live microbes or components of microbes that have a positive effect on the host. They exert their action through interplay with the immune system of the host. Some of this effect is local and some is systemic. The full story is yet to be discovered. Probiotics have a definite positive effect on rotavirus diarrhea, post antibiotic diarrhea and pouchitis. Their exact role in inflammatory bowel disease, irritable bowel syndrome, other forms of infectious diarrhea, and prevention of cancer is yet to be determined. This review summarizes the data about probiotics in these conditions.

### INTRODUCTION

The modern term 'probiotic' was first used by Fuller<sup>[1]</sup>, describing a live microbial feed supplement which beneficially affects the host animal by improving its microbial balance. Later it was demonstrated that heat-inactivated bacteria or fragments of bacterial DNA have positive effects as well. Marteau *et al*<sup>[2]</sup> in 2002 defined probiotics as 'microbial cell preparations or components of microbial cells that have a beneficial effect on the health and well-

being'. The mechanisms by which probiotics beneficially affect the host are multiple. Probiotics can prevent or ameliorate diarrhea and inflammation through their local effects and/or their effect on the immune system. In the gut, probiotic bacteria are thought to occupy binding sites on the gut mucosa, preventing pathogenic bacteria from adhering to the mucosa<sup>[3,4]</sup>. Lactobacilli produce proteinaceous compounds, namely bacteriocins, that act as local antibiotics against more pathogenic organisms<sup>[5,6]</sup> and decrease production of pro-inflammatory cytokines such as IFN- $\gamma$ , TNF- $\alpha$  and IL-12<sup>[7-9]</sup>. Probiotics stimulate IgA production<sup>[10]</sup>. Lactobacilli produce acetic and lactic acid and inhibit the growth of bacterial pathogens<sup>[3]</sup>. It has been postulated that probiotics compete with pathogens for nutrients and modify toxins produced by pathogens or toxin receptors found in the gut wall. Rachmilewitz *et al*<sup>[11]</sup> have shown that specific DNA repeats isolated from probiotics (VSL #3) can attenuate experimental colitis in various animal models. This is true even with inactivated bacteria. By using toll-like receptor 9 (TLR-9) deficient mice, they have proved that TLR9 signaling is essential in mediating the anti-inflammatory effect of probiotics<sup>[12]</sup>.

Prerequisites for probiotics are to be effective and safe. The characteristics of an effective probiotic as defined by Saavedra<sup>[11]</sup> are resistance to digestion by enteric or pancreatic enzymes, gastric acid and bile, ability to prevent the adherence, establishment and/or replication of pathogens in the gastrointestinal tract.

Examples of probiotic bacteria are members of the Lactobacilli family such as *Lactobacillus rhamnosus* GG, bifidobacteria and the yeast *saccharomyces boulardii*. There are many candidate bacteria which can be qualified as probiotics, but different bacteria have different actions in different disease states, taking into account that some disease states are better treated with a combination of bacteria and that there is an issue of dosing and viable vs. non viable components of the bacteria. Treatment with probiotics is relatively safe, but not risk free. Probiotics are potentially pathogenic<sup>[13]</sup>. A recent report describes 3 patients with fungemia in whom the probiotic origin was proven by DNA fingerprinting<sup>[14]</sup>. Reports of infections of probiotic origin emphasize the fact that these patients are usually immunosuppressed with multiple ports of entry, such as venous and urinary catheter.

This article reviews the use of various probiotics in the treatment of infectious diarrhea, inflammatory bowel disease and lactose intolerance.

## PROBIOTICS AND DIARRHEAL DISEASE

Probiotics have been proved to be beneficial to four types of diarrhea: rotavirus diarrhea, antibiotic-associated diarrhea, clostridium difficile diarrhea, and traveler's diarrhea.

Trials of probiotics for other infectious diarrhea diseases have not been consistent in terms of efficacy so far. Paton *et al*<sup>[15]</sup> have produced toxin binding probiotics in a breakthrough study using a toxin-binding recombinant probiotic for the treatment and prevention of enterotoxigenic *Escherichia coli* diarrhea. If these probiotics can be proved effective, it might open a whole new era in the treatment of different kinds of diarrhea.

## ACUTE VIRAL DIARRHEA

One of the established benefits of probiotics is that they are effective in the treatment of children with acute viral enteritis<sup>[16,17]</sup>. *Lactobacillus reuteri* can shorten the course of acute diarrhea in infants from 2.5 days to 1.5 days<sup>[18]</sup>. *Lactobacillus casei* GG is effective in treating acute diarrhea as well<sup>[19]</sup>. Different strains of probiotics exhibit different efficacy. Kaila *et al*<sup>[20]</sup> studied different lactic acid bacteria for their effect on the immune response to rotavirus in children with acute rotavirus gastroenteritis and found that *Lactobacillus casei* subsp. *casei* strain GG (LGG) is most effective on disease duration and produces the highest titers of IgA antibodies. It has been postulated that IgA specific Ab confers immunity against future infectious diarrhea, a higher level of such Ab is desired. Allan *et al*<sup>[21]</sup> systematically reviewed 23 papers concerning probiotic treatment of infectious diarrhea and concluded that probiotics appear to be a useful adjunct to rehydration therapy in treating acute infectious diarrhea in adults and children.

## ANTIBIOTIC-ASSOCIATED DIARRHEA AND PSEUDOMEMBRANOUS COLITIS

Antibiotic-associated diarrhea (AAD) is seen in up to 39% of hospitalized patients treated with antibiotics<sup>[22]</sup> and varies from uncomplicated diarrhea to colitis and pseudomembranous colitis. The pathogenic factors include any one or all the followings: use of antibiotics causing changes in the normal gut flora, pathogenic bacteria taking advantage of the situation and causing inflammation and diarrhea, change in bacterial flora causing changes in carbohydrate metabolism and changes in short chain fatty acid metabolism and absorption. The latter is interfered and osmotic diarrhea ensues. The well-known syndrome of pseudomembranous colitis characterized by high levels of toxin forming *Clostridium difficile* may take a fulminate course with a high recurrence and mortality rate. AAD can be prevented or treated with probiotics. A meta-analysis summing the results of nine controlled trials indicates that both *Lactobacilli* and *S. boulardii* are effective in preventing AAD<sup>[23]</sup>. Various probiotics have been used to prevent and treat *Clostridium difficile*-associated pseudomembranous colitis, including *S. boulardii*, *Lactobacillus* GG, *B. longum* and *B. longum* with *L. acidophilus*. *S. boulardii* and fecal

transplantation can be used through a naso-enteric tube or as an enema<sup>[24]</sup>. *S. boulardii* seems to be a choice in prevention and treatment of recurrent *Clostridium difficile* pseudomembranous colitis<sup>[24]</sup>.

## INFLAMMATORY BOWEL DISEASE

Inflammatory bowel disease (IBD) has a complex etiology. Environmental as well as genetic factors play a role. It has been established that microbes play a crucial role in IBD though search for an infectious agent has been futile so far. It was reported that *Lactobacillus* and *bifidobacteria* counts are significantly reduced in feces of patients with Crohn's disease compared to those with ulcerative colitis and controls and continuous interplay exists between the immune system and intestinal flora, suggesting that normalization of gut flora is a logical means of treatment<sup>[25,26]</sup>. Venturi *et al*<sup>[25]</sup> treated 20 ulcerative colitis patients with VSL#3 and it is able to change the gut microflora because the faecal concentrations of *Streptococcus salivarius* ssp. *thermophilus*, *Lactobacilli* and *bifidobacteria* were significantly increased in all patients, compared to their basal level which remained stable throughout study. As mentioned before, probiotics have local and systemic effects. *Lactobacillus casei* strain GG given to pediatric Crohn's patients results in increased serum titers of IgA<sup>[27]</sup>. It was also reported that murine colitis was successfully treated with *Lactococcus lactis* secreting interleukin-10<sup>[28]</sup>.

Probiotics can achieve and maintain remission, prevent post surgical recurrence of Crohn's disease and pouchitis, and treat pouchitis, but an established role of probiotics exists only in the latter two indications. Gosselink *et al*<sup>[29]</sup> treated 39 patients with *L. rhamnosus* GG and proved that it had a better effect on these patients than on those not treated with it. Gionchetti *et al*<sup>[30,32]</sup> demonstrated that pouchitis episode was reduced by 30% using VSL#3 in a double blind placebo-controlled study. Mirura *et al*<sup>[31]</sup> and Kuusima *et al*<sup>[33]</sup> showed that remission of chronic pouchitis can be achieved with antibiotics. *S. boulardii* has no efficacy on ulcerative colitis<sup>[34]</sup>.

Treatment of active ulcerative colitis has been extensively investigated in clinical trials<sup>[34-37]</sup>. All the studies proved that probiotics are effective at least on one of the followings: clinical and endoscopic improvement or decrease in proinflammatory cytokine expression. One additional report described six active refractory patients treated with human probiotic infusions and symptoms were abolished in all within four months<sup>[38]</sup>. These data support using probiotics in mild to moderate active disease. Three trials showed probiotics can be used as a maintenance treatment of UC<sup>[39-41]</sup>.

Clinical trials have also been conducted in Crohn's disease patients<sup>[42-45]</sup>. Campieri *et al*<sup>[45]</sup> compared mesalazine with VSL#3 in 40 patients and found that endoscopic recurrence was significantly reduced noted in probiotic-treated patients, but *Lactobacillus* GG and *L. Jonhsonii* effect cannot prevent post surgical recurrence of Crohn's disease. Treatment of active Crohn's disease has been assessed in some studies<sup>[46,47]</sup>, no definite conclusion could be reached due to methodological drawbacks.

## LACTOSE MALABSORPTION

Lactase deficiency is a frequent condition causing intolerance to lactose due to maldigestion. Kolars *et al*<sup>[48]</sup> and Savaiano *et al*<sup>[49]</sup> in 1984 showed that absorption of lactose from yogurt is improved compared with milk, presumably due to digestion of lactose by lactase released from the yogurt microorganisms<sup>[50]</sup>. Shermak *et al*<sup>[51]</sup> examined the effect of yogurt or milk on symptoms and hydrogen breath concentration in children with lactose intolerance and found that symptoms as well as exhaled hydrogen concentration were lower in children challenged with yogurt.

## IRRITABLE BOWEL SYNDROME

Evidence for benefit of probiotic treatment in irritable bowel syndrome (IBS) has not been consistent. Nobaek *et al*<sup>[52]</sup> conducted a double-blind, randomized placebo-controlled study in 60 unselected patients with IBS, and found that probiotic treatment resulted in improvement of flatulence only. Recently, O'Mahony *et al*<sup>[53]</sup> reported patients taking *B. infantis* had improvement in their symptoms, but no difference was observed between patients treated with *L. salivarius* and those treated with placebo. An interesting finding was that the basal ratio of IL-10/IL-12 was lower in IBS patients than in matched healthy controls. Treatment with *B. infantis* but not *L. salivarius* or placebo led to normalization of the ratio, suggesting that inflammation plays a role in the pathogenesis of IBS.

## PROBIOTICS AND CANCER

It is assumed that cancer is the outcome of genetic and environmental conditions. In each individual the interplay between the two is different. Cancer is the endpoint of a series of events. Various studies have shown the effect of probiotics on some of the enzymatic pathways and intermediates assumed to precede cancer<sup>[54-56]</sup>. Brady *et al*<sup>[54]</sup> have summarized the data concerning the use of probiotics in the prevention of cancer in their review. Other studies reported that the use of probiotics is inversely related with aberrant crypts or tumor development<sup>[55, 56]</sup>.

## POTENTIAL BENEFIT OF PROBIOTICS

Treatment of constipation with probiotics has yielded confusing results<sup>[57, 58]</sup>. Probiotic *E. coli* strain has been found to be effective on collagenous colitis<sup>[59]</sup>.

## CONCLUSION

Probiotics are a large group of microbes. Different microbes have different actions in different situations. Probiotics play a definite role in a number of clinical situations, namely rotavirus diarrhea, post antibiotic diarrhea and pouchitis. Their role in other clinical situations is yet to be defined.

## Abstract

**AIM:** To study the role of macrophage inflammatory protein (MIP)-2 in liver resection-induced acceleration of tumor growth in a mouse model of hepatic metastasis.

**METHODS:** After a 50% hepatectomy,  $1 \times 10^5$  CT26.WT cells were implanted into the left liver lobe of syngeneic balb/c mice (PHx). Additional animals were treated with a monoclonal antibody (MAB452) neutralizing MIP-2 (PHx+mAB). Non-resected and non-mAB-treated mice (Con) served as controls. After 7 d, tumor angiogenesis and microcirculation as well as cell proliferation, tumor growth, and CXCR-2 expression were analyzed using intravital fluorescence microscopy, histology, immunohistochemistry, and flow cytometry.

**RESULTS:** Partial hepatectomy increased ( $P < 0.05$ ) the expression of the MIP-2 receptor CXCR-2 on tumor cells when compared with non-resected controls, and markedly accelerated ( $P < 0.05$ ) angiogenesis and metastatic tumor growth. Neutralization of MIP-2 by MAB452 treatment significantly ( $P < 0.05$ ) depressed CXCR-2 expression. Further, the blockade of MIP-2 reduced the angiogenic response ( $P < 0.05$ ) and inhibited tumor growth ( $P < 0.05$ ). Of interest, liver resection-induced hepatocyte proliferation was not effected by anti-MIP-2 treatment.

**CONCLUSION:** MIP-2 significantly contributes to liver resection-induced acceleration of colorectal CT26.WT hepatic metastasis growth.

## INTRODUCTION

Major liver resection initiates rapid regeneration and growth of the remaining liver to restore the functional hepatic capacity<sup>[1]</sup>. The cellular changes which provoke liver regeneration are orchestrated by a complex network of different growth factors, cytokines<sup>[1-3]</sup> and chemokines<sup>[4-6]</sup>. The latter include macrophage inflammatory protein (MIP)-2, ENA-78, and IL-8, which all may act through the CXCR-2 receptor. The role of this receptor has been shown in that blockade with antibodies or deletion in gene-targeted animals significantly reduced the regeneration after hepatectomy<sup>[4,6]</sup>. The role of the individual chemokines in regeneration after hepatectomy, however, may be redundant. The murine CXC chemokine MIP-2 is a functional analog of human IL-8<sup>[7]</sup>. Similar to IL-8, it acts as a potent neutrophil chemoattractant, contributing to wound healing<sup>[8]</sup> and inflammation<sup>[9]</sup>. While blockade of the chemokine receptor CXCR-2 decreases regeneration of the residual liver, neutralization of MIP-2 through the use of anti-MIP-2 antibodies did not affect the process of regeneration as indicated by the unchanged liver weight to body weight (BW) ratios<sup>[4]</sup>. These findings indicate that other chemokines may replace or act via the CXCR-2 receptor in case of MIP-2 deletion for liver regeneration<sup>[4,6]</sup>.

Besides parenchymal regeneration, hepatectomy also accelerates tumor growth in the remaining liver<sup>[10-14]</sup> as well as in remote organ sites<sup>[15]</sup>. Slooter and co-workers showed that a 70% liver resection provokes excessive growth of liver metastases when compared to non-resected controls. Of interest, the intravenous application of TNF- $\alpha$  was effective to significantly reduce these outgrowths of tumor masses<sup>[11]</sup>. In fact, the acceleration of tumor growth seems to be proportional to the volume of the resected

liver tissue<sup>[10,11,13]</sup>. The cause of enhanced tumor growth in the liver after hepatectomy is likely to be multifactorial. It has been suggested that, besides mechanisms of liver regeneration, residual “dormant” micrometastases or tumor cells in the remnant liver are stimulated through distinct pro-tumorigenic factors<sup>[13,14]</sup>. In addition, a depression of local defense mechanisms due to a decrease of Kupffer cell tumoricidal activity and systemic immune paralysis may also contribute to the enhancement of tumor growth<sup>[16]</sup>. The role of chemokines, such as MIP-2, in the hepatectomy-induced acceleration of tumor growth, however, has not been elucidated yet.

By use of a murine colorectal hepatic metastasis model, we studied whether the accelerated metastatic growth after hepatectomy is mediated by the CXC chemokine MIP-2, and whether the inhibition of tumor growth by blockade of MIP-2 is associated with a downregulation of angiogenesis and tumor blood vessel formation.

## MATERIALS AND METHODS

Experiments were performed after approval by the local governmental ethic committee, and were in accordance with the UKCCCR Guidelines for the Welfare of Animals in Experimental Neoplasia (*Br J Cancer* 1998; 77: 1-10) and the Interdisciplinary Principles and Guidelines for the Use of Animals in Research (New York Academy of Sciences Ad Hoc Committee on Animal Research, NY, USA).

### **Tumor cell line and culture conditions**

The CT26 cell line is an *N*-nitroso-*N*-methylurethane-induced undifferentiated adenocarcinoma of the colon, syngeneic with the BALB/c mouse. For our studies, the CT26.WT cell line (ATCC CRL-2638<sup>®</sup>, LGC Promochem GmbH, Wesel, Germany) was grown in cell culture as monolayers in RPMI-1640 medium with 2 mmol/L L-glutamine (Sigma Aldrich Chemie GmbH, Taufkirchen, Germany) supplemented with 10% fetal calf serum (FCS Gold, PAA Laboratories GmbH, Cölbe, Germany), 100 U/mL penicillin and 100 µg/mL streptomycin (PAA Laboratories GmbH). The cells were incubated at 37°C in a humidified atmosphere containing 50 mL/L CO<sub>2</sub> in air. Only cells of the first two serial passages after cryo-storage were used. At the day of implantation, CT26.WT cells were harvested from sub-confluent cultures (70%-85%) by trypsinization (0.5 g/L trypsin and 0.2 g/L EDTA, PAA Laboratories GmbH), and washed twice in phosphate-buffered saline solution (PBS, PAA Laboratories GmbH) before being resuspended in PBS at 1×10<sup>7</sup> cells/L.

### **Flow cytometric analysis of CT26.WT cells**

FACScan (Becton Dickinson, Mountain View, CA, USA) analysis was performed to assess the expression of the chemokine receptor CXCR-2 of the CT26.WT cells. After trypsinization, the cells were fixed in 1 mL Cytofix/Cytoperm (BD Biosciences, Heidelberg, Germany) for 20 min at 4°C, washed twice with Perm Wash (BD Biosciences) and incubated at room temperature for 40 min with a polyclonal rabbit anti-mouse CXCR-2 antibody (Santa Cruz, Heidelberg, Germany) or an

isotype-matched control antibody (Dianova, Hamburg, Germany). A goat anti-rabbit Cy3-conjugated antibody (1:25; Dianova) was used for fluorescence labeling. To remove excess of antibody, cells were washed again and were then maintained in 10 g/L paraformaldehyde in PBS. Flow cytometry was performed within the next 3 h. The FACScan flow cytometer was calibrated with fluorescent standard microbeads (CaliBRITE Beads, BD Biosciences) for accurate instrument setting. Tumor cells were selectively analyzed for their fluorescence properties using the CellQuest data handling program (BD Biosciences) with the assessment of 5 000 events per sample.

### **Hepatectomy and tumor cell implantation**

Eight to twelve weeks old female BALB/c mice with a BW of 18-20 g, kept in a temperature and humidity controlled 12-h light/dark cycle environment, were used. The animals were anesthetized by intraperitoneal injection of 25 mg/kg BW xylazin hydrochloride (Rompun<sup>®</sup>, Bayer, Leverkusen, Germany) and 125 mg/kg BW ketamine hydrochloride (Ketavet<sup>®</sup>, Pharmacia GmbH, Erlangen, Germany). The anesthetized animals were placed in supine position. After laparotomy through a midline incision, a 50% hepatectomy was performed. After ligation of the supplying and draining blood vessels with PDS 5-0 (Ethicon, Johnson & Johnson Company, Norderstedt, Germany), the right lateral lobes (ventral and dorsal), the right medial lobe and a part of the left medial lobe were resected. The weight of the resected tissue was 0.35 ± 0.01 g. The procedure of intrahepatic implantation of CT26.WT tumor cells was performed as described previously<sup>[17]</sup>. The left liver lobe was gently mobilized and 1×10<sup>5</sup> tumor cells in 10 µL PBS were implanted under the capsule of the lower surface using a 25-µL syringe with a 32-G needle (Gastight<sup>®</sup> #1702, Hamilton Bonaduz AG, Bonaduz, Switzerland). The puncture site was sealed with acrylic glue (Histoacryl<sup>®</sup>, B. Braun, Aesculap AG, Tuttlingen, Germany), and the left liver lobe was repositioned anatomically into the peritoneal cavity. The abdominal wall was closed by a one layer technique with a polypropylene suture (Prolene<sup>®</sup> 5-0).

### **Intravital fluorescence microscopy**

At d 7 after tumor cell implantation, the animals were again anesthetized and laparotomized. The left liver lobe with the tumor was exteriorized and placed on an adjustable stage, so that the lower surface of the lobe was positioned horizontally to the microscope. This guaranteed adequate focus levels for the *in vivo* fluorescence microscopy procedure. The surface of the lobe was covered with a cover slip to avoid drying of the tissue and influences of the ambient oxygen<sup>[17]</sup>. *In vivo* fluorescence microscopy was performed by epi-illumination technique using a modified Zeiss Axiotech microscope (Zeiss, Oberkochen, Germany)<sup>[18]</sup>. Microscopic images were monitored by a charge-coupled device video camera (FK 6990, Prospective Measurements Inc., San Diego, CA, USA) and were transferred to a video system (VO-5800 PS, Sony, München, Germany) for subsequent off-line analysis. Angioarchitecture and microvascular perfusion were analyzed after intravenous contrast enhancement with sodium fluorescein (2 µmol/kg; Merck, Darmstadt,

Germany) using blue light epi-illumination (450 to 490 nm > 520 nm, excitation and emission wavelengths).

### Microcirculation analysis

Assessment of hepatic microcirculatory parameters was performed off-line by frame-to-frame analysis of the videotaped images using a computer-assisted image analysis system (CapImage; Zeintl, Heidelberg, Germany). Sinusoidal, capillary and venular diameters ( $\mu\text{m}$ ) were measured perpendicularly to the vessel path. Sinusoidal density within the liver and capillary density within the tumors ( $\text{cm}/\text{cm}^2$ ) were determined by measuring the length of red cell perfused capillary per area of observation. The number of venules draining the blood flow from the tumor was counted and was given per tumor margin. The angiogenic front neighboring the tumor margin, characterized by newly developed, chaotically arranged capillaries, was measured in  $\text{mm}^2$  surface area.

### Morphological examinations

At the end of the experiment, the left liver lobe was harvested and cut into slices with a diameter of 1 mm using a Tissue Slicer (McIlwain Tissue Shopper, Saur Laborbedarf, Reutlingen, Germany). Slices were documented with the use of a stereo-microscope (Leica M651, Leica Microsystems AG, Heerbrugg, Switzerland) and a video system, and the size of the tumor was measured with CapImage according to: tumor volume ( $\text{mm}^3$ ) =  $4/3\pi \times a/2 \times b/2 \times c/2$  ( $a$ ,  $b$ , and  $c$  represent the three perpendicularly orientated diameters of the tumor).

### Histochemistry and immunohistochemistry

For light microscopy, formalin-fixed biopsies were embedded in paraffin. Five micrometer thick sections were cut and stained with hematoxylin and eosin for routine histology according to standard procedures.

Proliferating cell nuclear antigen (PCNA) staining was performed using indirect immunoperoxidase techniques. Therefore, deparaffinized sections were incubated with 30 mL/L  $\text{H}_2\text{O}_2$  to block endogenous peroxidases and with 20 mL/L goat normal serum for blocking unspecific binding sites. A monoclonal mouse anti-pan PCNA antibody (PC10, 1:50; DakoCytomation, Hamburg, Germany) was used as primary antibody. A biotinylated goat anti-mouse rabbit IgG antibody was used as secondary antibody for streptavidin-biotin-complex peroxidase staining (1:200, LSAB 2 System HRP, DakoCytomation). 3,3'-Diaminobenzidine (DakoCytomation) was used as a chromogen. Sections were counterstained with hemalaun according to Mayer and examined by light microscopy.

For CXCR-2 immunohistochemistry tumor slices were embedded in Tissue Freezing Medium (Jung; Leica Microsystems, Nussloch, Germany), snap-frozen in liquid nitrogen and stored at  $-80^\circ\text{C}$ . Five micrometer thick cryostat sections were cut, fixed in  $4^\circ\text{C}$  cold acetone for 5 s followed by fixation in 16 g/L formaldehyde for 10 min and blocked with 2% normal donkey serum. Tissue sections were then incubated with the polyclonal rabbit anti-mouse CXCR-2 antibody (1:100; Santa Cruz, CA, USA). A donkey anti-rabbit IgG HRP conjugated antibody (1:500; Amersham, Freiburg, Germany) was used

as secondary antibody. 3,3'-Diaminobenzidine was used as chromogen. Sections were counterstained with hemalaun according to Mayer and examined by light microscopy. As a negative control, additional slices from each specimen were exposed to appropriate IgG isotype-matched antibody (Sigma Aldrich Chemie GmbH) in place of primary antibody under the same conditions to determine the specificity of antibody binding. All of the control stainings were found negative.

### Experimental protocol

A total of 21 animals received tumor cell implantation and were assigned to three different groups. Animals without liver resection and without further treatment received tumor cell implantation in the left liver lobe and served as controls (Con;  $n=7$ ). In the additional two groups ( $n=7$  each), a 50% hepatectomy was performed before the tumor cells were implanted into the left liver lobe. One group of animals (PHx+mAB) received 1 mg/kg BW of the monoclonal rat anti-mouse MIP-2 antibody (MAB452, R&D Systems, Wiesbaden, Germany) at the day of operation and every second day thereafter. Untreated animals with 50% liver resection served as hepatectomy controls (PHx). Seven days after tumor cell implantation and treatment, all animals underwent intravital microscopic examination and the liver and tumor tissue were harvested for histology and immunohistochemistry.

### Statistical analysis

All values were expressed as mean  $\pm$  SE. After proving the assumption of normality and homogeneity of variance across groups, differences between groups were calculated by a one-way analysis of variance (ANOVA) followed by a *post hoc* Student-Newman-Keuls test, including correction of the alpha error to compensate for multiple comparisons. Overall statistical significance was set at  $P<0.05$ . Statistical analysis was performed with the use of the software package SigmaStat (SPSS Inc., Chicago, IL, USA).

## RESULTS

### Tumor growth

Tumor cell implantation, hepatectomy and treatment with the anti-mouse MIP-2 antibody did not affect the general conditions of the animals. All animals had an uneventful postoperative recovery, and, regardless of the group, animals did not show significant changes of BW during the 7-d experimental period. Intravital fluorescence microscopy at d 7 after tumor cell implantation showed that hepatectomy (PHx) provoked a significant ( $P<0.05$ ) acceleration of tumor growth, as indicated by an increased tumor area at the surface of the liver when compared with that of controls (Figure 1). Analysis of the tumor volume confirmed the significantly ( $P<0.05$ ) increased tumor growth, demonstrating a tumor mass which was 18-fold greater than that of controls (Figure 1). Treatment with the MIP-2 antibody (PHx+mAB) was capable of significantly ( $P<0.05$ ) reducing the hepatectomy-induced acceleration of tumor growth, resulting in a tumor volume which was only 6-fold of that of non-resected controls (Figure 1).

**Figure 1** Intravital fluorescence microscopy at d 7 after tumor cell implantation. **A:** Displays the normal liver microvasculature; **B:** shows the microvasculature of the tumor of a non-resected control animal (Con); **C:** displays a 7-day tumor and its microvasculature of an animal which underwent hepatectomy (PHx); **D:** shows the tumor microvasculature after additional anti-MIP-2 treatment (PHx+mAB). Quantitative analysis of tumor area (**E**) and tumor volume (**F**) showed that hepatectomy (PHx) markedly accelerated tumor growth when compared with controls (Con), and that additional anti-MIP-2 treatment (PHx+mAB) was capable of significantly reducing this liver resection-induced tumor growth. Mean  $\pm$  SE; <sup>a</sup> $P < 0.05$  vs Con; <sup>c</sup> $P < 0.05$  vs PHx. Magnifications (**A-D**)  $\times 16$ .

### Angiogenesis and microangioarchitecture

Intravital fluorescence microscopy revealed that normal liver presents with a regularly arranged architecture of sinusoids and homogeneous staining of parenchymal cell nuclei (Figure 1A). In contrast, the center of the tumor showed a density of capillaries which was markedly lower than that of the sinusoids in the normal liver (Figure 1 and 2). The margin of the tumor showed an angiogenic front with newly developed, chaotically arranged capillaries (Figure 2) and large draining venules (Figure 3). In control animals, the implantation of CT26.WT cells induced an area of the tumor surrounding angiogenic front of 0.33 mm<sup>2</sup> at day 7 (Figure 2). Hepatectomy (PHx) significantly increased the area of the angiogenic front by 3-fold ( $P < 0.05$ ) when compared with that of controls. Blockade of MIP-2 (PHx+mAB) was capable of inhibiting angiogenesis, as indicated by a significantly ( $P < 0.05$ ) reduced area at the tumor margin which showed new blood vessel development (Figure 2D).

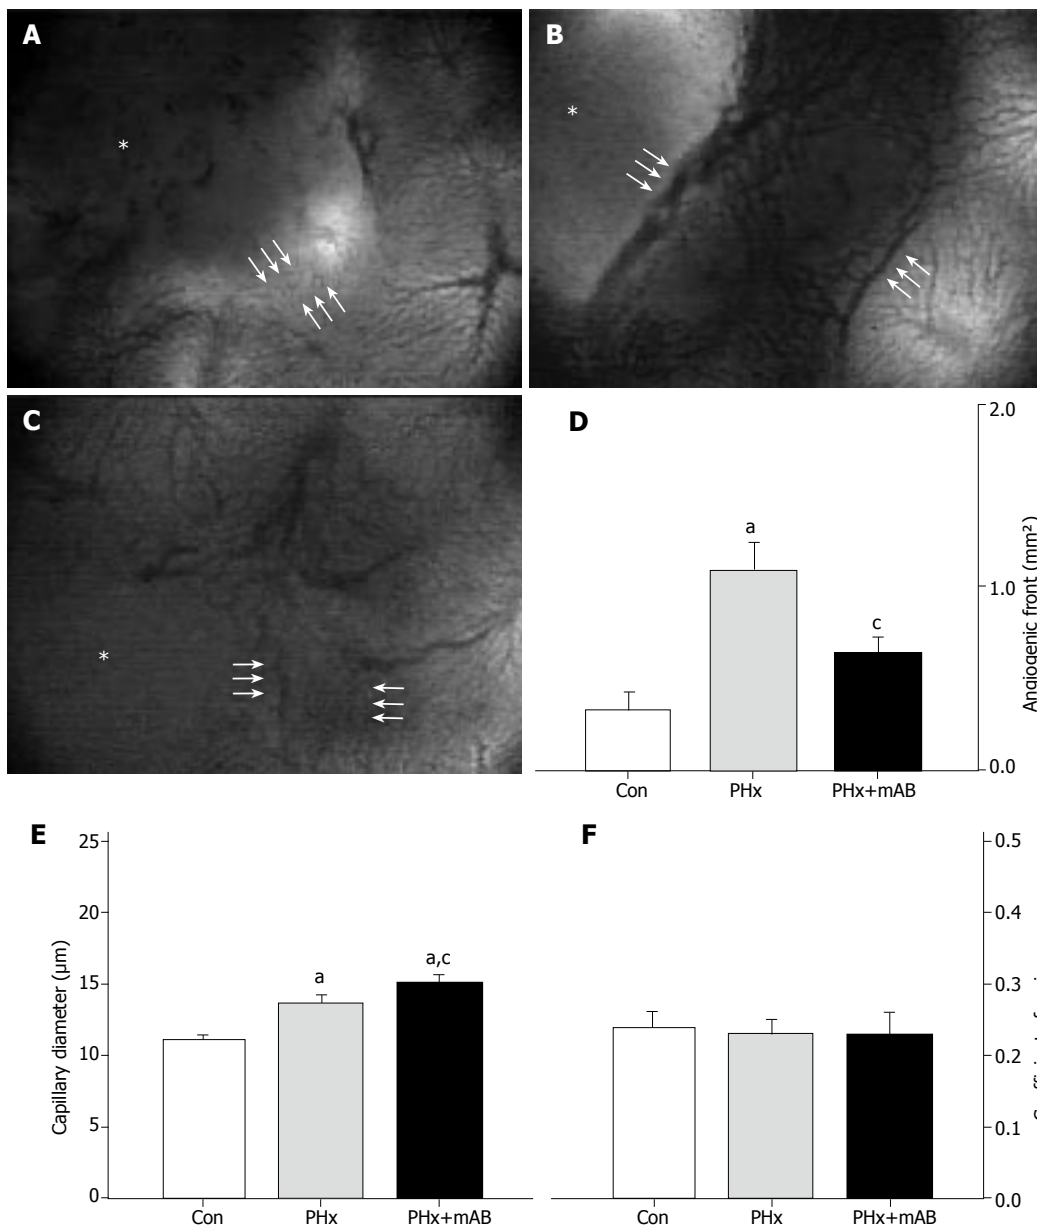

Because angiogenesis is regularly associated with vasodilation, we analyzed the capillary diameters within the angiogenic front. Within the tumor margin, hepatectomy (PHx) induced a significant dilation of the newly formed capillaries ( $P < 0.05$ ) when compared with that of controls.

Additional anti-MIP-2 treatment (PHx+mAB) further pronounced ( $P < 0.05$ ) this dilatory effect (Figure 2E). Of interest, the enlargement of the newly formed capillaries within the angiogenic front after hepatectomy and MIP-2 treatment was a homogeneous response, as indicated by the fact that the coefficient of variance of capillary diameters did not differ when compared with untreated controls (Figure 2F). Further, hepatectomy (PHx) also significantly ( $P < 0.05$ ) increased the density of venules draining the tumor, as indicated by a 6.5-fold increase of the number of venules within the tumor margin when compared to controls (Figure 3). These venules were also found enlarged in diameter (Figure 3E), however, without increased heterogeneity when compared with controls (Figure 3F). Interestingly, blockade of MIP-2 significantly ( $P < 0.05$ ) reduced the number of draining tumor venules when compared with animals undergoing only hepatectomy (Figure 3D).

### Tumor morphology

Hematoxylin-eosin-stained sections revealed solid growth of the colorectal CT26.WT hepatic metastasis in all the animals (Figure 4). Satellite metastases were not observed in the left liver lobe. In the control group, tumors were

**Figure 2** Analysis of the size of the angiogenic front (area between the triple arrows) at the margin of tumors (asterisks) in control mice (A, Con), after hepatectomy (B, PHx) and after hepatectomy and additional anti-MIP-2 treatment (C, PHx+mAB). Quantitative analysis of the area of the angiogenic front (D) indicated a significant increase after hepatectomy (PHx) when compared with that of controls (Con). Additional anti-MIP-2 treatment (PHx+mAB) was capable of reducing the angiogenic process. Further, hepatectomy (PHx) significantly increased capillary dilation within the angiogenic front (E) compared to controls (Con), which was even more pronounced after additional anti-MIP-2 treatment (PHx+mAB). The heterogeneity of capillary diameters, as given by the coefficient of variance, was not affected in either of the treatment groups (F). Mean  $\pm$  SE; <sup>a</sup> $P < 0.05$  vs Con; <sup>c</sup> $P < 0.05$  vs PHx. Magnifications (A-C)  $\times 40$ .

round in nature with a homogeneous appearance, however, with aggressive growth characteristics (Figures 4A and B). Hepatectomy (PHx) accelerated tumor growth, resulting in enlarged tumors with a dense arrangement of tumor cells in the center (Figures 4C and D). In two of the seven animals, lung metastases could be detected macroscopically, although no additional metastases could be found in the abdominal cavity. In contrast, tumors of animals, which additionally were treated with anti-MIP-2 showed central cell death via either necrotic or apoptotic pathways (Figures 4E and F). In this group tumor growth at distant sites was not observed.

*In vitro* FACS analysis and CXCR-2 expression *in vivo*

FACS analysis showed that 98.8% of the CT26.WT cells were CXCR-2 receptor positive *in vitro* (Figure 5). *In vivo*, CXCR-2 immunohistochemistry revealed that ~40% of the tumor cells were receptor-positive. The majority of these CXCR-2 expressing cells were located within the tumor margin (Figure 6). Quantitative analysis of CXCR-2 expression indicated that hepatectomy (PHx)

significantly increased ( $P < 0.05$ ) CXCR-2 expression to ~60% of tumor cells (Figure 6). Blockade of MIP-2 (PHx+mAB) not only abolished the hepatectomy-induced increase of CXCR-2 expression, but further reduced ( $P < 0.05$ ) CXCR-2 expression on tumor cells to only ~10% (Figure 6).

#### Proliferation of tumor cells and normal liver

PCNA as an indicator of cell proliferation showed that >90% of tumor cells displayed strong PCNA staining (Figure 7). By this, the tumor sharply demarcated from the surrounding liver tissue. Notably, neutralization of MIP-2 (PHx+mAB) decreased the rate of PCNA-positive cells to ~60% (Figures 7C and D), indicating a reduction of proliferation by deletion of MIP-2 function. Normal liver tissue only occasionally showed single PCNA-positive cells (Figure 8). Hepatectomy (PHx) resulted in a significant ( $P < 0.05$ ) increase of the number of PCNA-stained cells when compared with that of non-resected controls (Figure 8). Of interest, additional blockade of MIP-2 induced

**Figure 3** Analysis of the number of venules within the margin of tumors (A-C, asterisk) of control mice (A, Con), after hepatectomy (B, PHx) and after hepatectomy and additional anti-MIP-2 treatment (C, PHx+mAB). Quantitative analysis showed that hepatectomy significantly increases the number of venules (D), and causes a marked dilation of the draining venules within the margin of the tumors (E). Additional anti-MIP-2 treatment was capable of significantly reducing the liver resection-induced increase of the number of tumor venules (D). The heterogeneity of venular diameters, as given by the coefficient of variance, was not affected in either of the treatment groups (F). Mean ± SE; <sup>a</sup> $P < 0.05$  vs Con; <sup>c</sup> $P < 0.05$  vs PHx. Magnifications (A-C) ×40.

a further increase ( $P < 0.05$ ) of the fraction of PCNA-positive cells in the normal liver (Figure 8).

## DISCUSSION

The major findings of the present study are that (1) MIP-2 significantly promotes liver resection-induced expression of the chemokine receptor CXCR-2, and (2) blockade of MIP-2 blunts the augmentation of angiogenesis and metastatic tumor growth after hepatectomy. This indicates for the first time a significant role of this chemokine in the acceleration of tumor growth after hepatectomy. The rodent liver fully regenerates within 8 d after resection<sup>[19,20]</sup>. The setpoint for growth regulation is the ratio between liver mass and body mass rather than liver mass *per se*<sup>[1]</sup>. Using a 70% liver resection model in mice, Drixler *et al.* demonstrated that liver regeneration is accompanied by intrahepatic angiogenesis<sup>[20]</sup>. Liver resection has also been shown to affect the immune system in the early phase of liver regeneration<sup>[3]</sup>. The MIP-2-CXCR-2 system is thought

to be involved in the hepatic regenerative processes after extended resection<sup>[4,6]</sup>. While blockade of the chemokine receptor CXCR-2 decreases regeneration of the residual liver, selective neutralization of MIP-2 through the use of anti-MIP-2 antibodies is not affecting the liver-to-BW ratio<sup>[4]</sup>. Of interest, CXCR-2 seems to be pivotal, because other chemokines may replace or act via the CXCR-2 receptor in case of MIP-2 deletion for liver regeneration<sup>[4,6]</sup>.

After resection of colorectal liver metastases, diseases recur in over two-thirds of the patients<sup>[21]</sup>. This observation indicates that undetected residual microscopic tumors remain in the majority of patients undergoing curative hepatectomy<sup>[22]</sup>. The locally released factors which trigger the process of regeneration after hepatectomy may even augment the outgrowth of these residual microtumors, thus, additionally contributing to the high rate of recurrences. This view is supported by experimental studies, demonstrating that liver resection enhances tumor growth during regeneration<sup>[11,13,14,16]</sup>. Using different rat hepatectomy models, these authors suggested

**Figure 4** Hematoxylin-eosin-staining of tumors of a control mouse (A and B), a mouse which underwent hepatectomy (PHx) (C and D), and a mouse which additionally received anti-MIP-2 treatment (E and F). Sections revealed solid growth of the colorectal CT26.WT hepatic metastasis in all the animals. Tumors were round in nature, however, showed aggressive growth characteristics. Anti-MIP-2 treatment provoked an area of necrosis within the tumor center (E and F). Magnifications (A, C and E)  $\times 18$ , (B, D and F)  $\times 88$ .

**Figure 5** FACSscan analysis of CT26.WT cells, demonstrating positive staining and thus expression of the chemokine receptor CXCR-2 by almost all of the tumors cells studied.

that immunoparalysis with lack of Kupffer cell function and TNF- $\alpha$  response as well as overproduction of growth factors, such as TGF- $\alpha$ , TGF- $\beta$  and bFGF, contribute to the acceleration of tumor growth.

For the first time, we have herein demonstrated that MIP-2 is involved in hepatectomy-induced metastatic tumor growth. So far, little is known about the role of MIP-2 in tumorigenesis. A recent study indicated that the reduction of fibrosarcoma growth by inhibiting lymphotoxin- $\beta$  receptor can be reconstituted through co-transfection with MIP-2<sup>[23]</sup>. The mechanism how MIP-2 is involved in the herein observed liver resection-induced acceleration of tumor growth seems to be the

pro-proliferative action of this chemokine, because neutralization of MIP-2 significantly reduced PCNA expression on the tumor cells. Of interest, regeneration of the normal liver was not affected by the anti-MIP-2 treatment, inasmuch as hepatocyte PCNA expression after resection was found even increased when compared with that of untreated hepatectomized controls. This is in line with other experimental studies, which demonstrate that blockade of MIP-2 alone did not affect the process of regeneration<sup>[4]</sup>.

In the present study, we have shown that *in vitro* almost all CT26.WT cells expressed the CXC receptor CXCR-2. *In vivo*, approximately 40% of the cells of non-treated CT26 tumors showed positive CXCR-2 staining 7 days after tumor cell implantation. The reduction of the number of CXCR-2 positive cells is probably due to the fact that solid tumors *in vivo* consist besides the CT26.WT clone of a variety of other cells, including endothelia, fibroblasts and stromal cells, which do not necessarily express CXCR-2. Furthermore, we have demonstrated for the first time that over a 7-d period partial hepatectomy increased the expression of CXCR-2 to ~60%. Because receptor expression seems to be required for the proliferative action of chemokines on tumors<sup>[24]</sup>, the increased *in vivo* expression of CXCR-2 may represent the mechanism of action of the MIP-2-associated acceleration of tumor growth after hepatectomy. The neutralization of MIP-2 by MAB452 significantly reduced CXCR-2 expression within the tumor. Although we cannot exclude that neutralization of MIP-2 directly alters the CXCR-2 expression of tumor cells, the histological findings may additionally suggest a relative increase of CXCR-2-negative stromal cells.

The progressive growth of a malignant solid tumor depends on the development of new blood vessels. The

**Figure 6** CXCR-2 immunohistochemistry and quantitative analysis of the number of receptor-positive cells (given in percent of all cells) revealed that within tumors of control animals (Con) ~40% of the cells express CXCR-2 (A and D). Hepatectomy (PHx) significantly increased CXCR-2 expression to ~60% (B and D). Of interest, additional blockade of MIP-2 (PHx+mAB) significantly reduced tumor cell CXCR-2 expression and inhibits significantly the liver resection-induced increase of CXCR-2 expression (C and D). Mean  $\pm$  SE; <sup>a</sup> $P$  < 0.05 vs Con; <sup>c</sup> $P$  < 0.05 vs PHx. Magnifications (A-C)  $\times$  175.

**Figure 7** PCNA immunohistochemistry and quantitative analysis of the number of PCNA-positive cells (given in percent of all cells) in liver tumors of control mice (A, Con), after hepatectomy (B, PHx), and after hepatectomy and additional anti-MIP-2 treatment (C, PHx+mAB). Tumor cells display massive PCNA staining, in particular to those located within the tumor margin. By this, these positive cells sharply demarcate the tumor from the surrounding liver tissue (A, B, and C). Quantitative analysis revealed that neutralization of MIP-2 significantly reduces the number of PCNA-positive tumor cells (D). Mean  $\pm$  SE; <sup>a</sup> $P$  < 0.05 vs Con. Magnifications (A-C)  $\times$  175.

tumor vasculature is chaotically organized and does not follow a hierarchical branching pattern of normal vascular networks<sup>[25]</sup>. As a result of this abnormal organization, the diameters of those tumor vessels are irregular, the blood flow is heterogeneous, and the endothelial lining is leaky<sup>[25]</sup>. In the present study, the tumor microvasculature presented with a marked heterogeneity, as indicated by a relatively

high coefficient of variance of capillary and venular diameter within the angiogenic front. This is in line with the results of previous reports, which also demonstrated markedly irregular vessel diameters of tumors grown from other colon cancer cell lines at ectopic sites different from that of the liver<sup>[26]</sup>.

CXC chemokines with the three amino acids Glu-

**Figure 8** PCNA immunohistochemistry of normal liver tissue of control mice (A, Con), after hepatectomy (B, PHx), and after hepatectomy and additional anti-MIP-2 treatment (C, PHx+mAB). Quantitative analysis revealed that hepatectomy increases the number of PCNA-positive stained cells when compared to controls (D). Additional neutralization of MIP-2 further enhanced the number of PCNA-positive cells (D). Mean  $\pm$  SE; <sup>a</sup> $P < 0.05$  vs Con; <sup>c</sup> $P < 0.05$  vs PHx. Magnifications (A-C)  $\times 175$ .

Leu-Arg immediately amino-terminal to the CXC motif (ELR+) are thought to be angiogenic, while CXC (ELR-) chemokines are angiostatic<sup>[27]</sup>. There is no information, however, on whether the CXC (ELR+) chemokine MIP-2 is involved in angiogenesis of tumors. In inflammation, Scapini *et al*<sup>[28]</sup> demonstrated that MIP-2 induces angiogenesis *in vivo* and that this is mediated by the neutrophil-derived vascular endothelial growth factor-A. In addition, Keane *et al*<sup>[29]</sup> showed that neutralization of MIP-2 by monoclonal antibodies inhibits the bleomycin-induced angiogenic activity in lung specimens. The present study provides evidence that MIP-2 is also involved in tumor angiogenesis, because the inhibition of the chemokine blunted the liver resection-induced acceleration of new blood vessel formation.

The mechanisms of inhibition of angiogenesis by blockade of MIP-2 are not clarified yet. Our intravital microscopic studies demonstrate that the hepatectomy-mediated increase in angiogenesis is associated with pronounced dilation of the newly formed microvessels. Although we have not studied the mechanism of this dilatory response, it may be speculated that it is caused by the action of VEGF, which is capable of inducing distinct vasodilation, in particular in ischemic tissue<sup>[30]</sup>. VEGF is known as the predominant inducer of tumor angiogenesis and its promoter is preferentially activated within the angiogenic front of the tumor margin<sup>[31]</sup>. This effect, however, cannot be attributed to the action of MIP-2, because anti-MIP-2 treatment could not abolish the liver-resection-induced dilation of the newly formed microvessels.

In the present study we found that inhibition of MIP-2 induced central cell death within the tumors. Previous studies on inflammation have demonstrated

that apoptotic cells are capable of enhancing secretion of MIP-2 by macrophages, triggering an inflammatory response to remove cell debris<sup>[32,33]</sup>. Accordingly, the functional inhibition of MIP-2 in our experiments may have prevented the recruitment of inflammatory cells, and, thus avoided the removal of the cell debris from the center of the tumors.

In conclusion, we have demonstrated that MIP-2 significantly promotes liver resection-induced acceleration of angiogenesis and metastatic tumor growth. Our results therefore indicate that the neutralization of MIP-2 may be a potential strategy for additional anti-tumor therapy in patients undergoing liver resection.

### Abstract

**AIM:** To investigate the relationship between the chemotherapeutic drug efficacy and the expression of P-glycoprotein (PGP) and p53 protein in advanced hepatocellular carcinoma (HCC).

**METHODS:** The study was conducted on 41 patients with advanced HCC who were treated by repeated arterial infusion chemotherapy. Biopsy specimens from the tumor were collected before the start of treatment in all the patients, and the specimens were stored frozen until immunohistochemical staining, which was performed after the start of treatment, to detect PGP and p53 protein expressions. Twenty of the forty-one patients were treated with an anthracycline drug (epirubicin hydrochloride; anthracycline group), and the remaining 21 were treated with a non-anthracycline drug (mitoxantrone hydrochloride in 11 patients and carboplatin in 10 patients; non-anthracycline group). The relationship between the chemotherapeutic efficacy and the results of immunostaining were compared between the two groups.

**RESULTS:** Before the start of the treatment, PGP-positive rate was 90.2% (strongly-positive, 36.6%) and p53 protein-positive rate was 34.1% (strongly-positive, 19.5%). In the anthracycline group, the response rate was 40.0%. The number of patients showing poor response to the treatment was significantly larger in the patients with strongly positive PGP expression ( $P=0.005$ ), and their prognoses were poor ( $P=0.001$ ). In the non-anthracycline group, the response rate was 42.9%,

and there was no significant relationship between the chemotherapeutic drug efficacy and the PGP or p53 protein expression. When only the data from the 11 patients treated with anthraquinone drug, mitoxantrone, were analyzed, however, the number of patients who showed poor response to treatment was significantly higher among the p53-positive patients ( $P=0.012$ ), irrespective of the survival outcome.

**CONCLUSION:** The chemotherapeutic efficacy with an anthracycline drug for advanced HCC can be predicted by immunohistochemical analysis of PGP expression. Similarly, immunostaining to evaluate p53 protein may be useful to predict the response in patients treated with an anthraquinone drug.

### INTRODUCTION

Transcatheter hepatic arterial embolization (TAE) is widely employed for the treatment of inoperable advanced hepatocellular carcinoma (HCC). However, TAE is unsuitable for the cases with a tumor embolus in the main trunk or the first branch of the portal vein, or for those with severe hepatic injury. For these cases, repeated arterial infusion chemotherapy (RAIC) with a reservoir may be useful, although it is still difficult, at present, to assert that RAIC would provide satisfactory therapeutic results.

Drug resistance is a serious problem in the treatment of HCC, and is mediated by various mechanisms, including those mediated by P-glycoprotein (PGP) and p53 protein expressions. PGP is known to act as an ATP-dependent pump that facilitates transport of substances,

including anticancer drugs, from within to outside the cells, facilitating the development of multidrug resistance, including that to anthracyclines<sup>[1]</sup>. Moreover, resistance to apoptosis conferred by p53 protein expression is also thought to be a potential factor in the development of multidrug resistance in cancer cells<sup>[2]</sup>. It has been reported that a mutant-type p53 protein may emerge in various types of cancers due to gene deletion, recombination, or point mutations. This mutant type of p53 protein has been reported to have a considerably longer half life as compared with its wild-type counterpart<sup>[3]</sup>, and it is thought to act as a dominant-negative inhibitor against the wild-type protein, influencing the anti-tumor effects of anticancer drugs<sup>[4]</sup>.

While PGP and p53 protein expressions have been reported in HCC, mainly from the examination of surgically resected specimens, only a few reports have discussed the relationship between the efficacy of chemotherapeutic agents and the expression of PGP in cases of HCC<sup>[5,6]</sup>; the relationship between the outcome of arterial infusion chemotherapy and the expression of PGP and p53 protein remains particularly obscure. In this study, immunohistochemical analysis was conducted on frozen biopsy specimens obtained from patients with advanced HCC before the treatment to evaluate PGP and p53 protein expressions, and the therapeutic outcomes of RAIC in relation to the expression of these proteins were compared by the type of drugs that were administered.

## MATERIALS AND METHODS

### Patients

One hundred and thirty patients were diagnosed to have an unresectable advanced HCC and treated by RAIC at the Department of Medicine and Clinical Oncology, School of Medicine, Chiba University, and its affiliated institutes between April 1995 and June 1997. We could obtain tumor biopsy specimens before the initiation of RAIC from 41 of these patients, and stored these specimens at -80°C until the assay. Immunohistochemical staining for PGP and p53 expressions was performed on these specimens and the results were analyzed in relation to the therapeutic outcome in the patients.

### Immunohistochemical staining for PGP and p53 protein

Immediately before the start of RAIC, two or three biopsy specimens were obtained percutaneously using a 21G biopsy needle under ultrasound guidance from 41 patients. The tissue specimens were embedded in OCT compound and immediately stored at -80°C.

For the immunohistochemical staining, frozen sections (5 µm thick) were prepared and fixed with acetone for 5 min. After pretreatment to prevent non-specific staining, the sections were allowed to react overnight at 4°C with mdr (Ab-1, diluted 1:250) (Oncogene Research Products, Cambridge, MA, USA) as the primary antibody for PGP. For p53 protein staining, the sections were allowed to react at room temperature for 1 h with DO-7 (diluted 1:40, DAKO, Denmark). The sections were then successively treated with the secondary antibody, and then stained by the avidin-biotinylated peroxidase complex method for

PGP, and the streptavidin-biotin method for p53 protein. Color development was conducted by DAB staining, and nuclear staining was conducted with Mayer's hematoxylin for PGP and methyl green for the p53 protein.

Light-microscopic examinations of the stained sections were conducted to detect positive staining for PGP on the cytoplasmic membranes or for p53 protein within the nuclei of the cells in the cancerous areas. At least 300 cells were examined, and the staining intensity was classified based on the percentage of positively stained cells as follows: negative (0-5%); weakly positive (6%-30%); and strongly positive (31% or more).

### Arterial infusion chemotherapy

A 6F indwelling catheter (Anthon PU®; Toray, Tokyo) was introduced percutaneously through the left subaxillary artery (16 patients) or right femoral artery (25 patients) up to the level of the proper hepatic artery or common hepatic artery. The catheter was connected at the other end to a subcutaneously implanted reservoir (Port-A-Cath®, Pharmacia Deltec, St. Paul, MN, USA; or Cersite®, Toray, Tokyo)<sup>[7,8]</sup>.

An anticancer drug was administered over a period of 15 min once in every 4 wk at the outpatient clinic, after first confirming the patency of the catheter by fluoroscopy. Twenty, eleven, and ten of the forty-one patients received epirubicin hydrochloride, mitoxantrone hydrochloride, and carboplatin, respectively. The doses for each administration were set as follows: 70 mg/body surface area for epirubicin hydrochloride, 12 mg/body surface area for mitoxantrone hydrochloride, and 300 mg/body surface area for carboplatin. No other therapy was administered concomitantly in any of the patients. All the patients had underlying liver cirrhosis, and the diagnosis of HCC was confirmed histopathologically in all of them. Fifteen of the forty-one patients had received TAE prior to the RAIC with epirubicin hydrochloride at 40-70 mg/body surface area, while in the remaining 26 patients, RAIC was administered as the initial therapy. Informed consent was obtained from all the patients prior to tissue biopsy and RAIC. In this study, these patients were divided into anthracycline group (20 patients) treated with the anthracycline drugs, epirubicin hydrochloride and non-anthracycline group (remaining 21 patients) treated with the other drugs. No significant differences in the background characteristics were observed between the anthracycline group and the non-anthracycline group (Table 1). The therapeutic efficacies of the drugs were evaluated according to WHO guidelines. The anticancer drug administration was discontinued in the event of detection of any serious side effects, such as leucopenia, thrombocytopenia, or hepatic dysfunction. Observation of the patients was continued until September 30, 2003, by which date, all of the patients died.

### Statistical analysis

The data were statistically analyzed using  $\chi^2$  test or Mann-Whitney's *U*-test. Differences at a *P* value of 5% or lower were considered to be statistically significant. The survival rate from the start of the RAIC was calculated by the Kaplan-Meier method and analyzed using the log rank test.

**Figure 1** Immunohistochemical staining of PGP and p53 protein ( $\times 100$ ). **A:** Strongly positive staining for PGP; **B:** Strongly positive staining for p53.

## RESULTS

### Immunohistochemical analysis for PGP and p53 protein expressions

Strongly-positive, weakly-positive, and negative PGP expressions were observed in 15 (36.6%), 22 (53.7%), and 4 patients (9.8%), respectively. Strongly-positive, weakly-positive, and negative p53 protein expressions were observed in 8 (19.5%), 6 (14.6%), and 27 patients (65.9%), respectively. Sections showing strong positivity for PGP and p53 protein expressions on immunohistochemical staining are shown in Figures 1A and B, respectively.

Of the 15 patients who had received TAE with anthracycline, 9 (60%) and 6 (40%) were found to be strongly and weakly positive for PGP, respectively, and none of the cases showed negative staining for PGP. Of the 26 patients who had not undergone TAE prior to the RAIC, 6 (23.1%), 16 (61.5%), and 4 (15.4%) patients were found to have strongly positive, weakly positive, and negative PGP expressions, respectively. Thus, the number of cases showing strong positivity for PGP expression was significantly higher among those who had a previous history of treatment with an anthracycline drug than those without such history ( $P=0.036$ ). The percentage of cases showing p53 protein expression did not differ significantly among the patients with or without a history of treatment with an anthracycline drug.

No significant relationship was observed between the expression of PGP and that of the p53 protein (Table 2).

### Relationship between therapeutic outcomes and immunohistochemical findings

Of the 41 patients, the 20 belonging to the anthracycline

	Poorly	5	4

Not significant (Mann-Whitney U-test). <sup>1</sup>Number of patients. <sup>2</sup>According to the criteria for tumor stage according to TNM classification (UICC). <sup>3</sup>Chemoembolization with epirubicin hydrochloride.

**Table 2** Correlation between positivity of PGP and that of p53 protein

Positivity	PGP positivity		
	Strongly-positive	Weakly-positive	Negative
p53 strongly-positive	5	2	1
p53 weakly-positive	2	4	0
p53 negative	8	16	3
Not significant ( $\chi^2$ )			

group received average arterial infusions of  $11.4 \pm 8.1$  (range, 3-34) times during a mean follow-up period of 14.5 (range, 3-43) mo; 95%CI = 0.00-30.3. Of these 20 patients, 2, 6, 7, and 5 patients showed CR, PR, NC, and PD, respectively, yielding a response rate of 40.0% (95%CI = 18.5-61.5). In the 21 patients belonging to the non-anthracycline group, the mean number of arterial infusions and the mean duration of follow-up were  $13.3 \pm 9.5$  (range, 3-38) times and 18.7 (range, 3-78) mo; 95%CI = 8.1-29.4, respectively. In this group, 3, 6, 8, and 4 patients showed CR, PR, NC, and PD, respectively, yielding a response rate of 42.9% (95%CI = 21.7-64.0).

The expression rate of PGP and p53 protein did not differ significantly between the anthracycline group and the non-anthracycline group (Table 3). Since the positive rate of PGP expression was very high in cases of HCC, the patients were further divided into those showing strongly positive expression (positive group) and those showing weakly positive or negative expression (non-positive group); a similar classification of the patients was conducted for p53 protein expression, into those showing strongly or weakly positive expression (positive group) and

**Table 3 Correlation between PGP or p53 protein positivity and therapeutic efficacy by anticancer drugs**

Positivity	Anthracycline group (n = 20)				Response rate (%) (95%CI)	Non-anthracycline group (n = 21)				Response rate (%) (95%CI)

P53						
Non-positive	15	80.0	46.7	33.3	18.7	5.7-31.8
Positive	6	50.0	33.3	16.7	9.3	0.0-25.2

<sup>b</sup>P<0.01 vs positive group (log rank test).

those showing negative expression (non-positive group). As for the relationship of the therapeutic outcome to PGP expression in the anthracycline group, the number of non-responders was significantly higher in the positive group ( $P=0.005$ ); on the other hand, no such difference regarding PGP expression was found in the non-anthracycline group. In regard to the correlation of the therapeutic outcome with the expression of p53 protein, no significant differences between the positive and non-positive patients were found in either the anthracycline group or in the non-anthracycline group. But when only the data of the 11 mitoxantrone-treated patients of the non-anthracycline group were analyzed, 2 and 4 patients in the non-p53-positive group showed CR and PR, respectively, while 4 and 1 patients in the p53-positive group showed NC and PD, respectively, demonstrating the significant correlation between therapeutic outcome and the expression status of the p53 protein ( $P=0.012$ ). On the other hand, in the remaining 10 carboplatin-treated patients in this group, 1, 2, 4, and 2 patients in the non-p53-positive group showed CR, PR, NC, and PD, respectively, and the remaining one p53-positive patient showed PD, revealing the absence of any significant correlation between the therapeutic outcome and the p53

protein expression status.

The relationships between the positive rates for PGP or p53 protein and the survival rate are shown in Table 4. With regard to the PGP expression status in the anthracycline group, the survival rate was significantly lower in the positive group compared to non-positive group ( $P=0.001$ ); on the other hand, in the non-anthracycline group, no significant difference was observed between patients in the positive and non-positive group. As for the p53 protein expression status, no significant correlation was observed between the expression and the survival rate in either the anthracycline or the non-anthracycline group, including the 11 mitoxantrone-treated patients.

## DISCUSSION

In conventional studies, the PGP-positive rate has been determined, mainly based on the examination of surgically resected specimens, to range from 52% to 92%<sup>[5,9]</sup>. It has also been suggested that the expression of PGP decreases with decreasing degree of differentiation<sup>[10]</sup>. In the present study, our patients had a relatively high PGP-positive rate of 90.2%, when weakly positive cases were

also included. It has been suggested that PGP expression might be induced by previously administered anthracycline chemotherapy in some cases<sup>[11]</sup>, and that following therapy, only the PGP-positive cells survived, resulting in the high overall positivity rate. However, further studies are required because the study population was small and we could not perform biopsies of the tumors for the duration of chemotherapy or after chemotherapy. On the other hand, the p53-positivity rate in patients with HCC has been reported to range from 12.5% to 51.2%<sup>[6,10]</sup>. Consistent with these reports, the p53-positivity rate in our present study was 34.1%.

As to the relationship between the p53 tumor suppressor gene expression and the MDR1 gene expression, while some reported that the wild-type p53 protein represses the MDR1 promoter and the mutant-type p53 protein stimulates it, other investigators have suggested that the wild-type p53 stimulates the expression of this promoter<sup>[12,13]</sup>. In our patients, no significant correlation was observed between the expression of PGP and that of the mutant-type p53 protein, suggesting that mutation of p53 may not regulate the expression of PGP, consistent with recently reported studies<sup>[6,9,10]</sup>. In the present study, p53 protein was examined only by immunostaining using DO-7 which indicates the expressions of p53 protein variants. Therefore, a relationship between wild-type p53 protein and expressions of PGP could not be identified.

A relationship between PGP expression and the therapeutic efficacy of chemotherapeutic agents has been reported in cases of osteosarcoma and neuroblastoma<sup>[14,15]</sup>. On the other hand, while no significant correlation was observed between the therapeutic outcome and the expression of PGP in 13 patients with HCC treated with hepatic arterial infusion of doxorubicin<sup>[5]</sup>, a significant correlation between the two was observed in 25 patients with advanced HCC treated by oral or intravenous administration of VP-16 or doxorubicin<sup>[6]</sup>. In the present study on RAIC, the expression of PGP was significantly correlated with the therapeutic outcome and prognosis of the patients with advanced HCC, but only in the group treated with an anthracycline drug. These results, obtained from actually treated clinical cases of HCC, provide important evidence supporting the involvement of PGP in anthracycline resistance which was demonstrated in basic scientific studies<sup>[1]</sup>. In addition, resistance mediated by alteration of nuclear topoisomerase, rather than PGP, has also been reported in patients receiving anthracycline drugs<sup>[16]</sup>, necessitating further studies on this issue. No significant correlation was found in this study between the expression of PGP and the therapeutic outcome or prognosis in patients treated with non-anthracycline drugs, such as an anthraquinone or a platinum-based drug. It is speculated that canalicular multispecific organic anion transporter (cMOAT) is involved in the excretion of cisplatin, and over-expression of cMOAT has been observed in an HCC cell line<sup>[17]</sup>.

As for the p53 protein, expression of a mutant-type of p53 protein has been reported to be associated with a poor prognosis<sup>[10,18]</sup>, and it has been suggested that apoptosis induced by anti-cancer drugs, such as doxorubicin, mitoxantrone, cisplatin and bleomycin, is

mediated, at least in part, by p53-dependent stimulation of the CD95 receptor/ligand system<sup>[19,20]</sup>. However, no relationship between the chemotherapeutic drug efficacy and expression of the p53 protein has been reported until now in patients with HCC. In our present study, expression of p53 protein was not correlated with the chemotherapeutic drug efficacy or prognosis in patients treated with the anthracycline drug, suggesting a lesser importance of the expression of a mutant-type p53 protein, as compared with that of PGP, in the evaluation of the sensitivity of advanced HCC to anthracyclines. As for the anthraquinones among the non-anthracycline drugs, a fundamental study in a mitoxantrone-resistant cell line revealed that the expression of wild-type p53 protein induced cellular apoptosis<sup>[21]</sup>; on the other hand, in relation to platinum-based drugs, expression of an abnormal type of p53 protein was reported to be associated with resistance to chemotherapy in cases of lung cancer<sup>[22]</sup>. In our patients, treated with an anthraquinone, a significant correlation was observed between the expression of the p53 protein and the chemotherapeutic drug efficacy, but not the prognosis of patients with advanced HCC. On the other hand, no such correlation of the p53 expression was observed with either the chemotherapeutic drug efficacy or the prognosis in HCC patients treated with the platinum-based drug, carboplatin. Although further studies are required, these results indicate the possibility that evaluation of the expression of a mutant-type p53 protein may be useful for predicting the sensitivity of HCC to anthraquinone drugs.

In conclusion, our study demonstrates the existence of a correlation between the outcome of arterial infusion chemotherapy and the expression of PGP and p53 protein in patients with advanced HCC. Therefore, it is suggested that immunostaining for PGP may be useful for predicting the effectiveness of RAIC in cases treated with an anthracycline drug, and that p53 protein expression may be useful for predicting the outcome in cases treated with an anthraquinone drug.

### Abstract

**AIM:** To investigate the anti-tumor activity of ursolic acid (UA) and its derivatives isolated from *Aralia decaisneana* on hepatocellular carcinoma both *in vitro* and *in vivo*.

**METHODS:** *In vivo* cytotoxicity was first screened by 3-[4,5-dimethylthiazol-2-yl]-2, 5-diphenyltetrazolium bromide (MTT) assay. Morphological observation, DNA ladder, flow cytometry analysis, Western blot and real time PCR were employed to elucidate the cytotoxic mechanism of UA. Implanted mouse hepatoma H<sub>22</sub> was used to evaluate the growth inhibitory effect of UA *in vivo*.

**RESULTS:** UA could significantly inhibit the proliferation of HepG2 and its drug-resistance strain, R-HepG2 cells, but had no inhibitory effect on primarily cultured normal mouse hepatocytes whereas all the six derivatives of UA could not inhibit the growth of all tested cell lines. Further study on mechanism demonstrated that apoptosis and G<sub>0</sub>/G<sub>1</sub> arrest were involved in the cytotoxicity and cleavage of poly-(ADP-ribose)-polymerase (PARP). Downregulation of cyclooxygenase-2 (COX-2) protein and upregulation of heat shock protein (HSP) 105 mRNA correlated to the apoptosis of HepG2 cells treated with UA. In addition, UA also could inhibit the growth of H<sub>22</sub> hepatoma *in vivo*.

**CONCLUSION:** UA is a promising anti-tumor agent, but further work needs to be done to improve its solubility.

**Key words:** *Aralia decaisneana*; Ursolic acid; Hepatoma

### INTRODUCTION

Hepatocellular carcinoma is one of the most common malignant neoplasms worldwide and one of the leading causes of malignancy-related death in China<sup>[1,2]</sup>. Its therapy in clinic is still a big challenge.

Ursolic acid (UA) is a versatile compound, which possesses anti-cancer<sup>[3,4]</sup>, anti-inflammatory<sup>[5,6]</sup>, anti-HIV<sup>[7]</sup> and immunomodulatory effects<sup>[8]</sup>. There is a growing interest in the anti-tumor activities of UA. UA could act on almost all steps in the whole cancer process: initiation, promotion, progression, and metastasis. Multiple lines of evidence indicate that UA is a promising chemo-preventive agent both *in vivo* and *in vitro*. UA could inhibit Epstein-Barr virus activation induced by 12-*O*-tetradecanoylphorbol-13-acetate in Raji cells and two-stage mouse skin tumor promotion<sup>[9,10]</sup>. The mechanism involved might associate with the inhibition of AP-1-mediated induction of COX-2 by disrupting PKC signal transduction pathway<sup>[11]</sup>. UA could inhibit the proliferation of various cancerous cell lines by inhibiting DNA polymerase and topoisomerase<sup>[12]</sup>, inducing apoptosis through proteolytic activation of caspase-3 and/or other similar caspases<sup>[3]</sup>. It was also reported that UA has anti-invasion and anti-metastasis activity by inhibiting nuclear factor-kappa B (NF- $\kappa$ B) activation, down-regulating COX-2 and matrix metalloproteinase 9<sup>[13]</sup>.

Besides its cytotoxicity to hepatoma, it was reported that UA can exert its hepatoprotective action in mice and rats<sup>[14-16]</sup>. The reason for the phenomenon is worth studying. Moreover, the growth inhibitory activity of UA on hepatocellular carcinoma *in vivo* is still unknown.

In the present study, UA and its six derivatives isolated from the bark of *Aralia decaisneana* were used to treat rheumatism, lumbago, hepatitis, nephritis, and diabetes mellitus in Chinese folk medicine. The cytotoxicity of these UA compounds to HepG2, its drug-resistance strain R-HepG2 and primarily cultured normal mouse and rat hepatocytes were examined in order to find their anti-hepatoma efficiency on both parental and drug-resistant hepatocellular carcinoma as well as their low toxicity.

3. UA-3-O-[[β-D-xylopyranosyl-(1→2)]]β-D-glucopyranosyl-(1→3)]-α-L-arabinopyranoside,
4. UA-3-O-β-D-glucopyranosyl-(1→3)-α-L-arabinopyranosyl-28-O-β-D-glucopyranoside,
5. UA-3-O-[[β-D-glucopyranosyl-(1→2)]]β-D-xylopyranosyl-(1→3)]-α-L-arabinopyranosyl-28-O-β-D-glucopyranoside,
6. UA-3-O-β-D-glucopyranosyl-(1→3)-α-L-arabinopyranosyl-28-O-β-D-glucopyranosyl-(1→6)-O-β-D-glucopyranoside,
7. UA-3-O-[[β-D-glucopyranosyl-(1→2)]]β-D-xylopyranosyl-(1→3)]-β-D-xylopyranosyl-28-O-β-D-glucopyranoside.

Morphological observation, DNA ladder, cell cycle analysis, Western blot and real time PCR were performed to elucidate the cytotoxic mechanism of UA on HepG2 cells. Mice bearing murine hepatoma H<sub>22</sub> were used to investigate the growth inhibitory effect of UA *in vivo*.

## MATERIALS AND METHODS

### Tissue culture and drug treatment

HepG2 (ATCC) cells were maintained in RPMI 1640 (Gibco) containing 10% FBS (Gibco), 2 mg/mL sodium bicarbonate, 100 µg/mL penicillin sodium salt and 100 µg/mL streptomycin sulfate. R-HepG2 (City University of Hong Kong) was maintained in the presence of 1.2 µmol/L doxorubicin (Sigma). Hepatocytes were isolated from normal Kunming mice (Experimental Animal Centre of Zhongshan Medical University) and SD rats (Experimental Animal Centre of Zoology, Chinese Academy of Sciences) with enzymatic perfusion technique as previously described<sup>[17]</sup>. Logarithmically growing cells were used for all the experiments.

UA and its derivatives (Figure 1) were isolated from the bark of *Aralia decaisneana* by silica gel column chromatography and their structures were identified by spectral analysis<sup>[18]</sup>. UA was dissolved in DMSO at the

concentration of 100 and 10 mmol/L in cellular and *in vivo* experiments, respectively and diluted in tissue culture medium and saline before use. Six UA derivatives were directly dissolved in tissue culture medium.

### Cytotoxicity assay

HepG2 and R-HepG2 cells ( $1.5 \times 10^4$ ) as well as mouse and rat hepatocytes ( $8 \times 10^3$ ) were seeded in 96-well plates and treated with the compounds at various concentrations (3.125–100 µmol/L). Then the cells were incubated at 37 °C in an atmosphere containing 50 mL/L CO<sub>2</sub> for 48 h followed by MTT assay. IC<sub>50</sub> of the tested compounds on different cell lines were obtained from the concentration–effect curves.

### Morphology observation

HepG2 cells were cultured in 3.5-cm dishes. UA was added to the medium at 20 µmol/L for 6, 12, and 24 h. A harringtonin-(20 µmol/L, 24 h) and vehicle-(0.1% DMSO) treated sample was regarded as a positive and negative control, respectively. After the treatment, all the cultures were incubated at 37 °C in an atmosphere containing 50 mL/L CO<sub>2</sub> for the indicated time. Photographs were taken under an inverted Leica fluorescence 40×10 microscope after acridine orange (AO)/ethidium bromide (EB) staining.

### DNA ladder analysis

HepG2 cells were grown to 70–80% confluence and exposed to 20 µmol/L UA or harringtonin. Then the cultures were incubated at 37 °C in an atmosphere containing 50 mL/L CO<sub>2</sub> and collected at 0, 6, 12, and 24 h. Their genomic DNA was extracted and analyzed by gel electrophoresis<sup>[19]</sup>.

### Flow cytometry analysis

Flow cytometry analysis was used to evaluate cell cycle distribution of HepG2 cells. HepG2 cells were treated with 20 µmol/L UA for 0, 6, 12, and 24 h, respectively, collected and fixed in 70% cold ethanol (–20 °C) overnight. After being washed twice with PBS, the cells were resuspended in PBS. RNA in the fixed cells was digested using RNase A (0.5 mg/mL) at 37 °C for 1 h. Finally, the cells were stained with 2.5 µg/mL propidium iodide (PI). The DNA content of the cells was then analyzed with an FACSCalibur instrument (Becton-Dickinson) at excitation 488/emission 600 nm. Data were analyzed by cell cycle distribution software (ModFit LT version 2.0, Verity Software House, USA).

### Western blotting

After the treatment, cells were washed thrice with ice-cold PBS and collected with lysis buffer. Protein determination, SDS-PAGE and transfer were performed as previously described<sup>[17]</sup>. Nitrocellulose membranes were then incubated with a monoclonal anti-PARP or polyclonal anti-COX-2 antiserum. Secondary antibody to IgG conjugated to horseradish peroxidase was used. The blots were probed with the ECL Western blot detection system according to the manufacturer's instructions.

Figure 2 Cytotoxicity of UA to a panel of hepatocytes.

### RT-PCR and real time PCR analysis

Total RNA was isolated from HepG2 cells using Trizol reagent according to the standard protocol and used to generate cDNA in each sample using the SuperScript II reverse transcriptase with oligo (dT) primers. Aliquots of total cDNA were diluted and added into each PCR reaction mixture together with 0.5 μmol/L of forward and reverse primers of HSP 105 (F: CAGGATCCAGTTGTACGTGCTC; R: TGATGTGGAGGTTTCAGCACC, 197 bp) and glyceraldehyde-3-phosphate dehydrogenase (GAPDH, F: ATCAGCAATGCCTCCTGCA; R: CCTGCTTCACCACCTTCTTGA, 355 bp) (Shanghai Biotech Engineering Service Limited Company). PCR amplification was performed on a GeneAmp 9700 PCR System (ABI). After denaturation of cDNA at 94 °C for 3 min, the cycling conditions were as follows: 32 cycles consisting of denaturation at 94 °C for 30 s, annealing at 59 °C for 30 s, and extension at 72 °C for 1 min. The PCR products were analyzed by agarose gel electrophoresis and Bio-Rad Chemi Doc. The mRNA expression levels were normalized to the expression of a housekeeping gene GAPDH. SYBR-Green-I fluorescence labeling method was used in real-time quantitative RT-PCR amplification on an ABI Prism 7000 SDS and analyzed with its software according to the standard protocol and manufacturer's instructions<sup>[20]</sup>. The  $2^{-\Delta\Delta CT}$  method was used in data analysis based on similar (<10%) amplification efficiency of the target and reference genes, which was achieved by the determination of  $\Delta CT$  variations with template dilution<sup>[21]</sup>. GAPDH was used as a reference gene for internal control.

### Anti-tumor evaluation on implanted mouse H22

Male CD-1 (ICR) mice (Beijing Vital Laboratory Animal Technology Company) weighing 20–22 g were used for the implantation of hepatoma H22 (s.c.) which was maintained by weekly i.p. passages in CD-1 (ICR) mice, 0.2 mL ascites of 1:6 dilution from tumor-bearing mice 7 days after the tumor inoculation was implanted (s.c.) into the armpit region of the mice. Eight mice were treated i.p. with either UA or vehicle (1% DMSO in saline) once a day for 10 days 24 h after the tumor inoculation. Cyclophosphamide (10 mg/kg b.w.) was used as positive control. Tumor inhibition rate (TIR) was derived from  $(1-T/C) \times 100$ , where  $T$  is the mean tumor weight of the UA-treated group and  $C$  is the mean tumor weight of the negative control group.

Figure 3 Morphological changes of HepG2 cells in response to harringtonin and UA. Cells were stained with AO/EB and observed under an inverted Leica fluorescence 40×10 microscope. A: Normal HepG2 cells; B: harringtonin (20 μmol/L) for 24 h; C-E: UA (20 μmol/L) for 6, 12, and 24 h, respectively.

### Statistical analysis

Student's *t*-test was used in all the experiments.  $P < 0.05$  was considered statistically significant.

## RESULTS

### Selective cytotoxicity

Cytotoxicity of UA and its derivatives was determined by MTT assay. UA was demonstrated to have similar anti-proliferation activity on HepG2 and R-HepG2 cells in a concentration-dependent manner (Figure 2) with its  $IC_{50}$  value being 18 and 15 μmol/L, respectively, whereas it exhibited less growth inhibitory activity on primarily cultured normal mouse and rat hepatocytes and the  $IC_{50}$  value could not be detected at the tested concentration. On the contrary, six UA derivatives did not show any cytotoxicity to all the tested cells, while they possessed better solubility in water than UA.

### Morphological changes of HepG2 cells

HepG2 cells treated with harringtonin and 20 μmol/L UA showed similar and significant changes (Figure 3). Chromatin aggregation, nuclear, and cytoplasmic condensation only could be seen in a few cells after being treated with UA for 6 and 12 h. Partition of cytoplasm and nuclei into the membrane bound-vesicles (apoptotic bodies) was observed in the cells treated with harringtonin and UA for 24 h. At the same time, apoptotic cells were found at this time point.

### DNA ladder analysis of HepG2 cells

DNA ladder was used to prove the apoptosis of HepG2 cells induced by UA. After treatment with 20 μmol/L

**Figure 4** Induction of time-dependent fragmentation of nuclear DNA by harringtonin and UA. Genomic DNA of the treated cells was collected at different time points during the incubation. Lane 1: DNA marker (DL-2000); lane 3: harringtonin (20 μmol/L) for 24 h; lanes 2, 4–6: UA (20 μmol/L) for 0, 6, 12, and 24 h, respectively.

**Figure 5** Cell cycle analysis of HepG2 cells treated with UA (20 μmol/L) for 0 (A), 6 (B), 12 (C), and 24 h (D), respectively. Cells were stained with PI and analyzed by flow cytometry.

**Figure 6** Cleavage of PARP and downregulation of COX-2 protein expression in HepG2 cells treated with UA. Cellular lysate protein (23 μg/lane) was loaded for 10% SDS-polyacrylamide gel electrophoresis, and subsequently transferred onto nitrocellulose. Immunoblots were probed with antibody specific for PARP and COX-2 protein. Lysates were from HepG2 cells treated with 20 μmol/L UA for indicated times.

UA for different time points, evident DNA ladder was detected at 24 h on HepG2 cells treated with UA and

**Figure 7** RT-PCR and real time PCR analysis of up-regulated HSP 105 gene in HepG2 cells in response to treatment with UA. HepG2 cells were treated with 20 μmol/L UA for 0, 3, 6, and 9 h. Total RNA was isolated and subjected to semi-quantitative and quantitative RT-PCR analysis. GAPDH was used as a control. For quantitative analysis, data shown are mean±SD. <sup>a</sup>*P*<0.001 vs control, *n*=3.

harringtonin (Figure 4), indicating the apoptosis observed in morphological inspection.

#### Cell cycle distributions in HepG2 cells

After being exposed to 20 μmol/L UA for 0, 6, 12, and 24 h, respectively, the cell cycle progression of HepG2 cells showed evident changes (Figure 5). UA caused significant G<sub>0</sub>/G<sub>1</sub> arrest with a concomitant decrease of cell population in S and G<sub>2</sub>/M phases. The distribution of cell cycle in G<sub>0</sub>/G<sub>1</sub>, S and G<sub>2</sub>/M phases was 57.80%, 27.24%, and 14.96% at 0 h; 67.78%, 22.92%, and 9.3% at 6 h; 73.73%, 19.59%, and 6.69% at 12 h; 74.31%, 15.69%, and 10.0% at 24 h, respectively. When treated with UA for 12 and 24 h, higher percentage of cell cycle distribution in G<sub>0</sub>/G<sub>1</sub> phase was detected than that at 6 h.

#### Cleavage of PARP protein and downregulation of COX-2

Exposure to 20 μmol/L UA for 0, 12, 24, and 48 h, respectively, PARP was cleaved into 89- and 24-kDa fragments, indicating that the apoptosis of HepG2 cells induced by UA was involved in caspase activation. After HepG2 cells were treated with UA for 0, 3, 6, and 9 h, respectively, COX-2 expression was significantly inhibited (Figure 6).

#### Upregulation of HSP 105 mRNA expression

HSP 105 belongs to HSP 70 super family and is closely related with apoptosis. The amplification efficiency of target and reference genes HSP 105 and GAPDH was quite similar (data not shown). The  $2^{-\Delta\Delta C_t}$  method was used in data analysis. After being treated with 20 μmol/L UA for 3, 6, and 9 h, respectively, HSP 105 mRNA expression was upregulated in a time-dependent manner both in RT-PCR and real time PCR (Figure 7).

**Table 1 Tumor growth inhibition effect of UA in mice bearing H<sub>22</sub> (mean±SD, n = 8)**

Samples	Dosage (mg/kg)	Tumor weight (g)	Growth inhibition (%)
Control		2.8±1.22	
C.P.	10	1.07±0.55 <sup>b</sup>	61.1
UA	30	1.27±0.90 <sup>a</sup>	54.6
UA	15	1.55±0.91 <sup>a</sup>	44.6

<sup>a</sup>P<0.05, <sup>b</sup>P<0.01 vs control.

### Tumor growth inhibitory effect

Twenty-four hours after tumor implantation, administration of UA (30 and 15 mg/kg b.w.) and cyclophosphamide (10 mg/kg b.w.) once a day for 10 days, could significantly suppress the growth of H<sub>22</sub> (Table 1). Significant body weight loss was observed in cyclophosphamide-treated group compared to the control group, whereas only slight body weight loss was observed in UA-treated group, suggesting that UA might possess anti-hepatoma effect *in vivo* with low toxicity.

## DISCUSSION

In terms of cancer treatment, chemotherapy has serious limitations, namely the lack of selectivity of active ingredients and resistance of cancer cells to these chemicals<sup>[22]</sup>. Thus, it is urgent to find new compounds that can kill both parental cancer cells and drug resistant cells and differentiate between normal and cancer cells in order to selectively kill cancerous cells with reduced toxicity. UA possesses good cytotoxicity on HepG2 and R-HepG2 cells, but no cytotoxicity to primarily cultured normal mouse and rat hepatocytes has been detected at corresponding concentrations. These results indicate that UA is a promising anti-tumor agent to parental and drug resistant HepG2 cells with low toxicity and could partially explain why UA inhibits the proliferation of hepatoma while possesses hepatoprotective activity. In addition, UA can lead to apoptosis, DNA ladder and PARP protein cleavage as well as G<sub>0</sub>/G<sub>1</sub> cell-cycle arrest.

However, the cytotoxic mechanisms of HepG2 cells induced by UA are not completely understood. PARP is a substrate of apoptosis specific protease from the ICE-family (caspases). The 113 ku PARP is cleaved during apoptosis into 89- and 24-ku fragments which could serve as an early hallmark of apoptosis. In our study, cleaved PARP protein not only further proved apoptosis, but also it was implied that activation of caspases was involved in apoptosis of HepG2 cells treated with UA. COX-2 is an early-response gene that is highly inducible by mitogenic and inflammatory stimuli<sup>[23-25]</sup>. Multiple lines of evidence suggest that COX-2 is important in carcinogenesis and overexpressed in cancer cells<sup>[26,27]</sup>. NS-398, a representative of non-selective COX inhibitors can induce G<sub>0</sub>/G<sub>1</sub> cell cycle arrest through inhibition of CDK2 and induction of p21 and p27<sup>[28,29]</sup>. Upregulation of p21 could further stimulate mRNA transcription of cytochrome C and caspase 3 which induces apoptosis in the end<sup>[30]</sup>. In the light of our study, UA could significantly inhibit COX-2 protein expression, suggesting that inhibition of

**Figure 8** Summary of current understanding of cytotoxicity of UA to hepatoma cells. Functions with reference number represent known mechanism and bold words without reference number represent the mechanism revealed in our study.

COX-2 may correlate with increased p21 expression and subsequent activation of cytochrome C and caspase-3 in HepG2 cells treated with UA<sup>[31]</sup>.

HSP 105 belonging to heat shock protein (HSP) 70 super family acts as a chaperone and plays a role in control of cell proliferation and cellular aging. It was reported that overexpression of HSP105α could enhance stress-induced apoptosis, but not necrosis in mouse embryonal F9 cells<sup>[32,33]</sup>. Some HSPs purified from murine tumors and used as vaccine are prophylactically and therapeutically effective in cancer immunotherapy models<sup>[34]</sup>. Further more, MKT-077, a cationic rhodacyanine dye analog exerts its selective toxicity to cancer cells by binding to the HSP 70 family protein mot-2 and reactivating p53 function, thus resulting in increased p53 downstream gene p21 expression<sup>[35]</sup>. Upregulation of HSP 105 and increase of p21 expression<sup>[31]</sup> may contribute to apoptosis and G<sub>0</sub>/G<sub>1</sub> cell-cycle arrest induced by UA, which are at least partially responsible for the selectivity of UA for cancer cells.

Tumor growth inhibitory effect in mice bearing hepatoma could predict the activity of corresponding tumors in human beings. Accordingly, the anti-neoplasm action of UA on mouse hepatoma H<sub>22</sub> indicates that it can be used to treat human hepatoma. However, few researches have been done on the pharmacokinetics of UA. We also did not monitor the concentration of UA in the blood of mice. Therefore, more attention should be paid to the active plasma concentration of UA in future.

In conclusion, UA is a potential anti-hepatoma agent with reduced toxicity both *in vitro* and *in vivo*. Summary of current understanding of anti-tumor activity of UA on hepatoma is shown in Figure 8. However, poor water solubility of UA has confined its use. Although its derivatives have good water solubility, these derivatives possess no anti-neoplasm activity. More work should be done to solve this problem.

## Abstract

**AIM:** To observe biological characteristics of hepatocarcinoma cells before and after CD80 transfection and to compare the effect of CD80-transfected hepatocarcinoma cells on T lymphocyte activation.

**METHODS:** Retro virus vector carrying CD80 gene was transfected into HepG2 cells to establish CD80-transfected hepatocarcinoma cells (HepG2/hCD80). Flow cytometry (FCM) was performed to detect CD80 expression in the transfected cells. RT-PCR was used to evaluate CD80 expression at mRNA level. In the presence of anti-CD3 mAb, the proliferation of T lymphocyte was observed by MTT. Meanwhile, the expression of activated molecule marker CD25 was analyzed through FCM.

**RESULTS:** A stable cell line HepG2/hCD80 expressing the human CD80 was established. Growth curve showed that the molecule CD80 could obviously decrease the growth of tumor cells. HepG2/hCD80 was evidenced to have a potency to enhance T cell proliferation and up-regulate CD25 expression.

**CONCLUSION:** CD80 transfection can lower malignant phenotype of hepatocarcinoma cells. CD80 transfection has a down-regulatory effect to activated T cells *in vitro*.

## INTRODUCTION

It has been widely accepted that T cell activation in the

course of anti-tumor immunity requires two distinct signals for T helper precursor cell expansion<sup>[1,2]</sup>. Optimal activation of antigen-specific T cells requires not only the engagement of T-cell receptor (TCR) with Ag/major histocompatibility complex (MHC), but also co-stimulatory signals provided by antigen-presenting cells<sup>[3,4]</sup>. Among the interactions of these co-stimulatory molecules, ligation of CD28/CTLA-4 and CD86 or CD80 is regarded as a major signal transduction pathway<sup>[5]</sup>. As the first identified B7 family member, CD80 is widely expressed in a broad spectrum of tissues, even on some malignant tumor cells, thereby suggesting the potential mechanism of immune evasion of tumor cells<sup>[6]</sup>. Cancer of the liver is regarded as a tumor of low immunogenicity. Although there is a high level of HLA I expression on the surface of hepatocarcinoma cells, it still has a low immunogenicity due to the absence or low expression of CD80<sup>[7]</sup>. In this study, we established a CD80-transfected hepatocarcinoma cell line to observe the characteristic of HepG2/hCD80 and make further investigation on the role it plays in T cell activation.

## MATERIALS AND METHODS

### Materials

Retro virus vector pLNShB7 carrying hCD80 was presented by Professor Lu Daru of Fudan University. Package cell (singlephilic GP+E86, doublephilic GP+envAm12) and fibroblast cell NIH3T3 were kept by Jiangsu Hematological Research Institute and cultured in DMEM supplemented with 150 mL/L new born calf serum (NCS), and incubated at 37 °C in a humidified atmosphere containing 50 mL/L CO<sub>2</sub> in air. Hepatocarcinoma cell line HepG2 was purchased from Shanghai Zhongshang Hospital, cultured in RPMI 1640 medium supplemented with 150 mL/L NCS, and incubated at 37 °C in a humidified atmosphere containing 50 mL/L CO<sub>2</sub> in air. ELISA kit was purchased from Shanghai Senxiong Biological Co., Ltd. Mouse IgG-PE or IgG-FITC was purchased from Immunotech Company. MTT kit was purchased from Sigma Company. The mouse anti-human CD80 mAb was kindly gifted by Dr. Qiu Yuhua, Immunology Research Institute of Suzhou University.

### Vector transduction and production of envAm12/CD80

Plasmid pLNShCD80 was transfected into *E. coli* JM109 and was confirmed by *Eco*RI. Purified vector DNA was transfected into GP+E86 cells using Lipofectamine. Singlephilic GP+E86/CD80 cells were selected by G418

(0.6 g/L) and then Ping-pong transfection strategy was adopted to produce doublephilic GP+envAm12/CD80. Supernatant of GP+envAm12/CD80 was collected and stored at  $-80^{\circ}\text{C}$ .

#### **CD80 virus transduction into HepG2 cells**

HepG2 cells were incubated in Petri dish until they grew to 60% confluence. Then, the culture medium was replaced with 1:1 mixed virus supernatant and culture medium containing Polybrene at the final concentration of 4 mg/L. Such transduction process was repeated after a 3-h incubation at  $37^{\circ}\text{C}$ . After 24 h, the cells were digested and adjusted to proper concentration for selective culture in medium with G418 (0.6 g/L). The empty vector-transfected HepG2 (HepG2/mock) cells were prepared as a negative control in the following experiment.

#### **Integration of CD80 gene**

PCR was adopted to integrate NeoR gene in target cells and hCD80 gene. Primers for NeoR gene: 5'-CGTTG TCACT GAAGC GGGAA GG-3'. Primers for hCD80: 5'-ATTTT CTTCT CCTTT TGCCA GTAG-3'. Samples were initially denatured for 5 min at  $95^{\circ}\text{C}$ . Gene amplification was conducted for 32 cycles, each cycle consisted of denaturation at  $94^{\circ}\text{C}$  for 45 s, annealing at  $58^{\circ}\text{C}$  for 45 s, and polymerization at  $72^{\circ}\text{C}$  for 2 min, followed by an extra incubation at  $72^{\circ}\text{C}$  for 7 min to ensure full extension of the products. Products of amplification were analyzed on 12 g/L agarose gels in Tris-borate-EDTA, and stained with ethidium bromide.

#### **Detection of CD80 expression by FCM**

CD80-transfected HepG2 cells were cultured with anti-CD80 mAb (2 mg/L) at  $4^{\circ}\text{C}$  for 30 min. After being washed twice, the FITC-goat anti-mouse IgG as secondary antibody was added, followed by incubation at  $4^{\circ}\text{C}$  for 30 min. Then flow cytometry (FCM) was performed to detect the expression of CD80 after washes.

#### **CD80 expression analysis by RT-PCR**

Total RNA was isolated from  $10^6$  transfected cells with TRIzol reagents (Takara, Dalian, China) following the manufacturer's instructions. Using the total RNA as template, the first-strand cDNA of CD80 was obtained with oligo (dT) as a reverse primer following the manufacturer's protocol. Then the PCR amplification was carried out under the similar PCR conditions with the primers mentioned above.

#### **Proliferation analysis of HepG2 and HepG2/hCD80 cells**

The HepG2/hCD80 or HepG2/mock cells were seeded onto a 24-well plate with  $1 \times 10^3$ /well. During the 8-day culture, cells' status was detected every day for an average value. According to the results, curves of cell growth were drawn and multiple proliferation time was calculated by the following formula: times of growth=maximum living cell number/living cell number of inoculation; multiple proliferation time=time from inoculation to the maximum cell number/time of growth.

#### **Isolation of T lymphocytes**

Two milliliters fresh peripheral blood was diluted with Hanks' balanced salt solution at a ratio of 1:3 and subjected to separation by 10 mL Ficoll density-gradient centrifugation at 2 000 r/min for 20 min. Then turbid fluid containing T cells was collected and subjected to another 10 mL Ficoll. After being washed twice with Hanks' balanced salt solution and separated by density-gradient centrifugation at 1 500 r/min for 15 min, the isolated T cells were cultured in RPMI 1640 at  $37^{\circ}\text{C}$  in a humidified atmosphere containing 50 mL/L  $\text{CO}_2$  in air. Through the detection by FCM with PE-labeled anti-CD3 mAb, the T cell purification was about 70%.

#### **Preparation of tumor vaccine**

About  $1 \times 10^6$  HepG2/CD80 or HepG2/mock cells were collected separately for Co-60 radiation (100 Gy) and then cultured in RPMI 1640 at  $37^{\circ}\text{C}$  in a humidified atmosphere containing 50 mL/L  $\text{CO}_2$  in air for further usage.

#### **Detection of proliferation index (PI)**

HepG2/CD80 or HepG2/mock cells were seeded onto 96-well plates with 200  $\mu\text{L}$ /well. Each was divided into two groups, and three double wells were set for each group. Lymphocytes were added into each well according to E:T ratio of 1:10. The mixture of lymphocytes and tumor cells was cultured in RPMI 1640 at  $37^{\circ}\text{C}$  in a humidified atmosphere containing 50 mL/L  $\text{CO}_2$  in air. After a 3-day culture, MTT solution was added to each well to the final concentration of 10 g/L and the cells were further incubated for 5 h. Then 100  $\mu\text{L}$  of isopropylalcohol was added to dissolve the crystal after the supernatant was removed by centrifugation at 3 000 r/min for 5 min and the wells were washed thrice with PBS. Then the absorbance of solution of each well was measured at 570 nm by a microplate reader (Bio-Rad). All the measurements were separately performed in triplicate. PI was calculated using the formula:  $\text{PI} = (A_{570 \text{ nm of HepG2/hCD80}} - A_{570 \text{ nm of HepG2/mock well}}) / A_{570 \text{ nm of lymphocytes in each well}}$ .

#### **Analysis of surface antigen expression**

HepG2/CD80 or HepG2/mock cells were seeded onto 24-well plates. Lymphocytes were added into each well according to E:T ratio of 1:10. The mixture of lymphocytes and tumor cells was cultured in RPMI 1640 at  $37^{\circ}\text{C}$  in a humidified atmosphere containing 50 mL/L  $\text{CO}_2$  in air. After 2-, 5- and 7-day co-cultures, the lymphocytes, respectively, were stained with FITC-CD4 mAb, FITC-CD8 mAb, and FITC-CD25 mAb and incubated for 30 min, washed again with PBS. FCM was performed to detect the expressions of CD4, CD8, and CD25 on the surface of T cells.

#### **Statistical analysis**

The data was statistically analyzed by two-sided *t*-test, and  $P \leq 0.01$  was considered statistically significant. Values were expressed as mean  $\pm$  SD.

**Figure 1** Flow cytometric analysis of CD80 expression in cells of different groups. A: HepG2/mock; B: negative control; C: HepG2/hCD80; D: positive control.

**Figure 2** RT-PCR analysis of CD80 mRNA expression in different group cells. M: DL1000 molecule marker; lane 1:  $\beta$ -action; lane 2: positive control; lane 3: HepG2/mock; lane 4: HepG2/hCD80 cells.

## RESULTS

### Stable expression of CD80 in HepG2 cells

Retro virus vector pLNShB7 was transfected into HepG2 cells with the help of GP+envAm12 package cell. Drug resistant strains were selected by G418 to obtain doublephilic GP+envAm12/CD80 clones. FCM analysis showed that the expression of CD80 reached a rather high level (Figure 1). RT-PCR result further confirmed the expression of CD80 in the transfected cells at mRNA level (Figure 2).

### Curve of cell growth and time of multiple proliferations

During 8 d of culture, the cells were counted each day for an average value. Curve of cell growth was drawn according to the results (Figure 3), which showed that the curve of HepG2/hCD80 cells was rising up very slowly, indicating that the growth ratio of HepG2/hCD80 cells was obviously lower compared to HepG2/mock cells. Multiple proliferation time of HepG2 cells was 13.86 h,

**Figure 3** Curve of cell growth and time of multiple proliferation.

**Figure 4** CD25 expression on T cells stimulated by HepG2/mock cells or HepG2/hCD80 cells. A: T cells stimulated by HepG2/hCD80 cells; B: T cells stimulated by HepG2/mock cells. Shaded histograms show reactivity with the isotype control. Each figure is representative of at least three experiments.

while that of HepG2/hCD80 was 25.09 h.

### Surface molecular expression of T cells stimulated by HepG2/hCD80

After Co-60 radiation, HepG2/mock or HepG2/hCD80 cells were mixed with lymphocytes and cultured together. FCM was used to detect surface molecular expression in T cells on days 2, 5, and 7. The results showed that CD4,

CD8, and CD25 expressions were obviously higher in HepG2/hCD80 group than in HepG2/mock group on day 5 (Figure 4).

#### **T cell proliferation stimulated by HepG2/hCD80**

HepG2/CD80 or HepG2/mock cells were mixed with lymphocytes and cultured together as described above. After a 3-day co-culture, lymphocyte proliferation was examined by MTT. The results showed that PI of HepG2/hCD80 group ( $1.25 \pm 0.12$ ) was obviously higher than that of HepG2 group ( $0.43 \pm 0.07$ ,  $P < 0.01$ ).

## **DISCUSSION**

Immune response of solid tumor is mainly cell immunity whose major effector cells are T lymphocytes. An optimal initiation of antigen-specific lymphocytes requires a combination of signals 1 and 2 (co-stimulatory signals). Hepatocarcinoma was regarded as a tumor of absent or low immunogenicity. Through testing different hepatocarcinoma cell lines, Tatsumi *et al.*<sup>[8]</sup> discovered that only high level MHC-II molecules were expressed on the surface of hepatocarcinoma cells, while the expression levels of CD80 and CD86 turned to be very low. Although mRNA of both CD80 and CD86 was detected, the concentration was very low. Using FCM, we also examined CD80 expression level on the surface of HepG2 cells, which showed that only a few HepG2 cells expressed CD80 molecule with a percentage of only 3.66%. Obvious differentiation was found compared with positive control group. RT-PCR showed that human CD80 mRNA was about 605-bp in length (Figure 2), which was consistent with that of FCM results. Taken together the present and previous studies, we speculated that absence of CD80 expression contributed to the low immunogenicity of HepG2 cells.

CD80, a glycoprotein of 44/45 ku, is mainly expressed on activated B lymphocytes, macrophages and dendritic cells as well as tissues of chronic infection and tumor cells<sup>[9]</sup>. Our experiment demonstrated that only a low level of CD80 expression was detected on the surface of HepG2 cells. Researches showed that some cytokines could upregulate CD80 expression on many kinds of cells. For example, IL-2 and IL-4 are able to enhance CD80 expression on B lymphocytes<sup>[12]</sup>. But, generally speaking CD80 expression, even under above stimulation, is yet relatively low and unable to stimulate effective anti-tumor immune response. Therefore, by means of highly effective CD80 gene transfection to enhance B7 molecule expression at gene level, signal 2 was regained so as to effectively trigger anti-tumor immune response.

To effectively transfect CD80 gene, a vector of high efficiency and fewer side effects is necessary. Retro virus vector, at present, is a vector most widely used in the study of gene therapy. With this kind of vector, IL-2, p53 and other therapeutic genes could be transferred with high efficiency into hepatocarcinoma cells<sup>[10]</sup>. So, we adopted retro virus as a carrier of CD80 gene. After selection by G418, FCM analysis showed that the positive ratio of HepG2/hCD80 group was about 92.2%, 28 times higher than the control group. Thus, a clone stably expressing

CD80 molecule was established, host cell HepG2 regained the ability of transducing the second signal, which is necessary to trigger T cell immune response.

By CD80 transfection, we not only established positive clones highly expressing CD80 molecules but also found that the growth curve of HepG2/hCD80 cells was rising up very slowly with the growth ratio obviously lower than that of HepG2 cells. Multiple proliferation time of HepG2/hCD80 was markedly longer than that of HepG2 ( $P < 0.01$ ). So, CD80 transfection might change the status of tumor cells, while there is still a long way to go before clarifying its underlying molecular mechanisms.

T cell activation is crucial to immune response. After activation, a series of biochemical reactions occur, including signal transduction, gene activation and transcription, new molecule expression on cell surface, cytokine secretion and cells entering proliferation cycles<sup>[11]</sup>. Following activation, interaction between IL-2 and IL-2R plays an important role in T cell proliferation<sup>[12]</sup>. Absence of co-stimulatory signals might lead to T cell anergy, which could be explained by IL-2 decrease or no-response on IL-2 stimulation. On the surface of T cells, there are two IL-2 receptors, one is p55 (CD25) the other is p75 which has a relatively higher affinity, both have low affinity to IL-2<sup>[13]</sup>. Resting T cells just express p75 and not p55, so it could only be activated by highly concentrated IL-2<sup>[14]</sup>. A study showed that by the positive-feedback regulation of IL-2, CD25 could rapidly express and form complex with p75 to enhance the affinity of IL-2 and T cells<sup>[15]</sup>. In this way, biological effects could be fully exerted with low level of IL-2 stimulation. After CD80 transfection, our experiment showed that CD25 expression on T cell surface was greatly improved and was obviously higher compared to control group, which may be explained by cascade effects of immune system<sup>[16]</sup>.

Enhancement of CD4 and CD8 expressions on T cell surface means the improvement of combined ability between TCR and MHC-I or MHC-II molecules<sup>[17]</sup>. Compared with HepG2 group, HepG2/hCD80 group showed markedly increased CD4 and CD8 molecules and actively proliferated T cells, suggesting that the malignant status of hepatocarcinoma cells might be changed and enhancement of co-stimulatory signal could effectively stimulate T cell activation so as to exert strong anti-tumor effects.

The basolateral AE had a much higher activity than that in the apical membrane, whereas there was no such difference with the NHE under resting conditions. Also, 10 μmol/L forskolin did not significantly influence Cl<sup>-</sup>/HCO<sub>3</sub><sup>-</sup> exchange on the apical and basolateral membranes. The administration of 250 μmol/L H<sub>2</sub>-DIDS significantly inhibited the basolateral AE. Amiloride (300 μmol/L) completely inhibited NHEs on both membranes of the cells. RT-PCR revealed the expression of pNBC1, AE2, and NHE1 mRNA.

**CONCLUSION:** These data suggest that apart from the lack of CFTR and apical Cl<sup>-</sup>/HCO<sub>3</sub><sup>-</sup> exchanger activity, CFPAC-1 cells express similar H<sup>+</sup> and HCO<sub>3</sub><sup>-</sup> transporters to those observed in native animal tissue.

### Abstract

**AIM:** To characterize H<sup>+</sup> and HCO<sub>3</sub><sup>-</sup> transporters in polarized CFPAC-1 human pancreatic duct cells, which were derived from a cystic fibrosis patient with the ΔF508 CFTR mutation.

**METHODS:** CFPAC-1 cells were seeded at high density onto permeable supports and grown to confluence. The cells were loaded with the pH-sensitive fluorescent dye BCECF, and mounted into a perfusion chamber, which allowed the simultaneous perfusion of the basolateral and apical membranes. Transmembrane base flux was calculated from the changes in intracellular pH and the buffering capacity of the cells.

**RESULTS:** Our results showed differential permeability to HCO<sub>3</sub><sup>-</sup>/CO<sub>2</sub> at the apical and basolateral membranes of CFPAC-1 cells. Na<sup>+</sup>/HCO<sub>3</sub><sup>-</sup> co-transporters (NBCs) and Cl<sup>-</sup>/HCO<sub>3</sub><sup>-</sup> exchangers (AEs) were present on the basolateral membrane, and Na<sup>+</sup>/H<sup>+</sup> exchangers (NHEs) on both the apical and basolateral membranes of the cells. Basolateral HCO<sub>3</sub><sup>-</sup> uptake was sensitive to variations of extracellular K<sup>+</sup> concentration, the membrane permeable carbonic anhydrase (CA) inhibitors acetazolamide (100 μmol/L) and ethoxzolamide (100 μmol/L), and was partially inhibited by H<sub>2</sub>-DIDS (600 μmol/L). The membrane-impermeable CA inhibitor 1-*N*-(4-sulfamoylphenylethyl)-2,4,6-trimethylpyridine perchlorate did not have any effect on HCO<sub>3</sub><sup>-</sup> uptake.

### INTRODUCTION

There are two HCO<sub>3</sub><sup>-</sup> transport processes in the pancreatic ductal epithelium. The first is the secretion, mainly by the smaller ducts, of HCO<sub>3</sub><sup>-</sup> rich isotonic fluid that serves to flush digestive enzymes down the ductal tree and to neutralize gastric acid entering the duodenum<sup>[1,2]</sup>. The second HCO<sub>3</sub><sup>-</sup> transport process is the flow-dependent exchange of luminal HCO<sub>3</sub><sup>-</sup> for blood Cl<sup>-</sup> that is generally considered to occur in the larger ducts, including the main duct<sup>[1,2]</sup>. The physiological function of ductal HCO<sub>3</sub><sup>-</sup> absorption (or salvage) may be protective as it will lower luminal HCO<sub>3</sub><sup>-</sup> (and therefore luminal pH) during interdigestive periods when the flow is low or absent. A fall in luminal pH would reduce the activity of digestive enzymes within the static column of fluid in the ductal tree, thereby preventing damage to the ductal epithelium.

The initial step of HCO<sub>3</sub><sup>-</sup> secretion is the accumulation of HCO<sub>3</sub><sup>-</sup> within the duct cell<sup>[1,2]</sup>. This can occur by two

mechanisms: (1) the forward transport of  $\text{HCO}_3^-$  by the  $\text{Na}^+/\text{HCO}_3^-$  co-transporter (NBC); and (2) diffusion of  $\text{CO}_2$  into the duct cell which is then hydrated to carbonic acid by carbonic anhydrase (CA), followed by the backward transport of protons via the  $\text{Na}^+/\text{H}^+$  exchangers and  $\text{H}^+$ -pumps. The  $\text{HCO}_3^-$  ions are then secreted across the apical membrane via  $\text{Cl}^-/\text{HCO}_3^-$  exchangers (SLC26A3, DRA and SLC26A6, PAT1)<sup>[3]</sup> and/or cystic fibrosis transmembrane conductance regulator (CFTR)  $\text{Cl}^-$  channels, which exhibit a finite permeability to  $\text{HCO}_3^-$ <sup>[4,5]</sup>. The exact mechanism how the SLC26 exchangers and apical  $\text{Cl}^-$  channels produce a high  $\text{HCO}_3^-$  secretion is controversial<sup>[1,2]</sup>. Nevertheless, the key role of CFTR in  $\text{HCO}_3^-$  secretion is emphasized by the fact that the severity of the pancreatic phenotype in cystic fibrosis correlates best with the ability of mutant CFTRs to activate SLC26 exchangers, rather than their ability to conduct  $\text{Cl}^-$  ions<sup>[6]</sup>.

Rather less is known about the secondary, flow- and  $\text{Cl}^-$ -dependent absorption of  $\text{HCO}_3^-$  that occurs in the larger ducts. A luminal  $\text{Na}^+/\text{H}^+$  exchanger (NHE3) and an electroneutral NBC (SLC4A7, NBCn1, NBC3) have been identified in the main duct of the mouse pancreas and probably explain  $\text{HCO}_3^-$  absorption across the apical membrane<sup>[7-9]</sup>. There is a clear evidence that activity of these luminal  $\text{HCO}_3^-$  salvage transporters is downregulated following stimulation of  $\text{HCO}_3^-$  secretion by a rise in intracellular cyclic AMP<sup>[7-9]</sup>. How the absorbed  $\text{HCO}_3^-$  exits the duct cell at the basolateral membrane is uncertain, but a candidate pathway is the basolateral  $\text{Cl}^-/\text{HCO}_3^-$  exchanger (possibly AE2)<sup>[10]</sup>. The AE2 must be switched off during stimulation as the prevailing ion gradients would favor  $\text{Cl}^-$  uptake and  $\text{HCO}_3^-$  efflux across the basolateral membrane.

Our current understanding of pancreatic ductal  $\text{HCO}_3^-$  secretion/salvage is mainly based on the experiments performed in animal tissues<sup>[1]</sup>. Studies in human tissue have been largely confined to adenocarcinoma duct cell lines; however, with the exception of CAPAN-1, human duct cell lines do not express CFTR to any significant degree<sup>[11]</sup>. An alternative approach is to use CFPAC-1 cells, which were derived from a 26-year-old cystic fibrosis (CF) patient with the  $\Delta\text{F508}$  mutation<sup>[12]</sup>. The utility of CFPAC-1 cells is that they allow us to examine  $\text{HCO}_3^-$  transport not only in the diseased state, but also in the corrected state by transfecting the cells with wild-type CFTR. A number of previous studies have shown that wild-type CFPAC-1 cells express some of the key transporters involved in  $\text{HCO}_3^-$  secretion; e.g. the basolateral NBC<sup>[13]</sup>, anion exchanger-2 and the apical  $\text{Cl}^-/\text{HCO}_3^-$  exchangers DRA and PAT-1<sup>[14]</sup>. Moreover, the expression of apical  $\text{Cl}^-/\text{HCO}_3^-$  exchangers was significantly increased in CFPAC-1 cells expressing functional CFTR, as was the stimulatory effect of ATP on luminal  $\text{Cl}^-/\text{HCO}_3^-$  exchange<sup>[15]</sup>. CFPAC-1 cells can also be reconstituted as polarized monolayers on permeable supports and the effects of various agents, such as angiotensin II<sup>[16,17]</sup> and PKC<sup>[18]</sup>, have been studied using the short circuit current technique. Finally, in one study a stimulatory effect of ATP on  $\text{HCO}_3^-$  secretion from CFPAC cells was demonstrated by measuring the extracellular pH at the apical cell surface<sup>[19]</sup>.

A number of issues regarding the mechanism of pancreatic ductal  $\text{HCO}_3^-$  secretion remain controversial.

For instance, how much of the secreted  $\text{HCO}_3^-$  enters the lumen via CFTR and how much via SLC26 anion exchangers? How is coordinate regulation of apical and basolateral acid base transporters achieved during secretion and salvage? How do luminal signals regulate apical  $\text{HCO}_3^-$  and  $\text{H}^+$  transporters? What is the molecular explanation for the strong outward rectification of  $\text{HCO}_3^-$  permeability exhibited by the apical membrane of the duct cell? A human pancreatic duct cell line, which reconstituted as a polarized monolayer allowing easy access to the luminal membrane, would be a very useful resource for answering these questions. An added bonus would be a model system that facilitates investigation of how CFTR expression affects duct cell transporters. Therefore, in this study, we aimed to establish whether polarized CFPAC-1 cells grown on permeable supports could fulfill these requirements. To do this, we investigated the  $\text{HCO}_3^-$  permeability characteristics of the basolateral and apical membranes of CFPAC-1 cells, and the spatial distribution of acid/base transporters.

## MATERIALS AND METHODS

### Materials and solutions

All laboratory chemicals were purchased from Sigma (Poole, Dorset, UK). 2',7'-Bis-(2-carboxyethyl)-5(6)-carboxyfluorescein-acetoxymethyl ester (BCECF-AM) and dihydro-4,4'-diisothiocyanostilbene-2,2'-disulfonic acid ( $\text{H}_2$ -DIDS) were from Molecular Probes Inc. (Eugene, OR, USA); 1-N-(4-sulfamoylphenylethyl)-2,4,6-trimethylpyridine perchlorate (STP) was kindly provided by Prof. C Supuran. Stock solutions of BCECF (2 mmol/L), acetazolamide (0.4 mol/L), ethoxzolamide (0.4 mol/L), amiloride (0.8 mol/L) and STP (10 mmol/L) were prepared in dimethyl sulfoxide (DMSO). Nigericin (10 mmol/L) and forskolin (50 mmol/L) were dissolved in ethanol and stored at  $-20^\circ\text{C}$ . Polyester Transwells were supplied by Corning-Costar (Buckinghamshire, UK). The standard HEPES-buffered solution contained 130 mmol/L NaCl, 5 mmol/L KCl, 1 mmol/L  $\text{MgCl}_2$ , 1 mmol/L  $\text{CaCl}_2$ , 10 mmol/L Na-HEPES, and 10 mmol/L D-glucose (pH 7.4 with HCl). In the  $\text{Na}^+$ -free HEPES solution, NaCl was replaced by 140 mmol/L N-methyl-D-glucamine (NMDG)-Cl and the Na-HEPES was replaced by equimolar HEPES-acid. The  $\text{Cl}^-$ -free HEPES solution contained 140 mmol/L Na-gluconate, 2.5 mmol/L  $\text{K}_2\text{SO}_4$ , 6 mmol/L Ca-gluconate, 1 mmol/L Mg-gluconate, 10 mmol/L HEPES-acid, 10 mmol/L D-glucose (pH 7.4 with NaOH). The  $\text{Na}^+/\text{Cl}^-$ -free HEPES solution contained 130 mmol/L NMDG-gluconate, 2.5 mmol/L  $\text{K}_2\text{SO}_4$ , 1 mmol/L  $\text{MgSO}_4$ , 1 mmol/L  $\text{CaSO}_4$ , 10 mmol/L HEPES-acid, 10 mmol/L D-glucose (pH 7.4 with gluconate). The standard  $\text{HCO}_3^-$  solution contained 115 mmol/L NaCl, 5 mmol/L KCl, 1 mmol/L  $\text{MgCl}_2$ , 1 mmol/L  $\text{CaCl}_2$ , 25 mmol/L Na- $\text{HCO}_3$ , 10 mmol/L D-glucose. In the  $\text{K}^+$ -free  $\text{HCO}_3^-$  solution, KCl was replaced with equimolar NaCl. The high  $\text{K}^+$   $\text{HCO}_3^-$  solution contained the same ingredients as the standard  $\text{HCO}_3^-$  solution but the KCl and NaCl concentrations were 115 and 5 mmol/L, respectively. The  $\text{Na}^+$ -free  $\text{HCO}_3^-$  solution contained NMDG-Cl instead of NaCl and choline  $\text{HCO}_3^-$  in place of  $\text{NaHCO}_3$ .  $\text{Cl}^-$ -free

$\text{HCO}_3^-$  solution contained 115 mmol/L sodium gluconate, 2.5 mmol/L  $\text{K}_2\text{SO}_4$ , 6 mmol/L Ca-gluconate, 1 mmol/L Mg-gluconate, 25 mmol/L Na- $\text{HCO}_3$ , 10 mmol/L D-glucose. The  $\text{Na}^+/\text{Cl}^-$ -free  $\text{HCO}_3^-$  solution contained 115 mmol/L NMDG-gluconate, 2.5 mmol/L  $\text{K}_2\text{SO}_4$ , 1 mmol/L  $\text{MgSO}_4$ , 1 mmol/L  $\text{CaSO}_4$ , 25 mmol/L choline- $\text{HCO}_3$ , 10 mmol/L D-glucose (pH 7.4 with gluconate). 10  $\mu\text{mol/L}$  atropine was added to the solutions containing choline to prevent the possible activation of muscarinic receptors. In solutions containing  $\text{NH}_4^+$ , the concentration of  $\text{Na}^+$  or NMDG was replaced to maintain osmolality. All the solutions containing  $\text{HCO}_3^-$  were continuously equilibrated with 5%  $\text{CO}_2$ -95%  $\text{O}_2$  to maintain pH at 7.4.

### Culture of CFPAC-1 cells

CFPAC-1 cells (passage number 27-60) were obtained from Prof. RA Frizzell (University of Pittsburgh, Pittsburgh, PA, USA) and were grown in Iscove's modified Dulbecco's medium supplemented with 100 mL/L fetal calf serum, 2 mmol/L glutamine, 100 units/mL penicillin and 0.1 mg/mL streptomycin and were cultured as described previously<sup>[12]</sup>. The media was changed every 1-2 d. Cells were maintained at 37 °C in a humidified atmosphere containing 5%  $\text{CO}_2$ . Cell monolayers were prepared by seeding at high density (300-350 cells/ $\text{cm}^2$ ) onto polyester permeable supports (12 mm diameter, 0.4  $\mu\text{m}$  pore size Transwells). Cell confluence was checked by microscopy and determination of transepithelial electrical resistance using an EVOM-G volt ohmmeter (World Precision Instruments, Sarasota, FL, USA). Experiments were performed 4-6 d after seeding.

### Measurement of intracellular pH

Intracellular  $\text{pH}_i$  was estimated with the pH-sensitive dye BCECF<sup>[20,21]</sup>. CFPAC-1 cells were loaded with 2  $\mu\text{mol/L}$  BCECF-AM in both the apical and basal chambers in standard HEPES for 30-45 min at 37 °C. After loading, the Transwells were transferred to a perfusion chamber mounted on an inverted Nikon Diaphot microscope (Nikon UK, Kingston upon Thames, UK). Apical and basal bath volumes were 0.5 and 1 mL and the perfusion rates were 3 and 6 mL/min, respectively. All the experiments started and ended with standard HEPES solution perfusing both sides of the cells. Experiments were performed at 37 °C.  $\text{pH}_i$  was measured using a Life Sciences Microfluorimeter System (Life Sciences Resources, Cambridge, UK). About 10-15 cells were alternately excited with wavelengths of 440 and 490 nm, and the 490/440 fluorescence emission ratio was recorded at 535 nm over a sampling period of 256 ms. The resting  $\text{pH}_i$  of CFPAC-1 cells in standard HEPES solution was determined using the method described by Hegyi *et al.*<sup>[21]</sup>. Calibration of 490/440 ratio to  $\text{pH}_i$  was obtained using the high- $\text{K}^+$ /nigericin method. Extracellular pH was stepped between 5.94 and 8.46.

### Determination of buffering capacity

The intrinsic buffering capacity ( $\beta_i$ ) of CFPAC-1 cells was estimated according to the  $\text{NH}_4^+$  prepulse technique<sup>[22]</sup>. Briefly, the cells were exposed to varying concentrations of  $\text{NH}_4\text{Cl}$  (0-30 mmol/L) while  $\text{Na}^+$  and  $\text{HCO}_3^-$  were omitted

**Figure 1** Buffering capacity of CFPAC-1 human pancreatic duct cells at different  $\text{pH}_i$  values. Polarized CFPAC-1 cells were exposed to varying concentrations of  $\text{NH}_4\text{Cl}$  (0-30 mmol/L), while  $\text{Na}^+$  and  $\text{HCO}_3^-$  were omitted from the bath solution to block the  $\text{Na}^+$  and  $\text{HCO}_3^-$ -dependent pH regulatory mechanisms.  $\beta_i$  was estimated by the Henderson-Hasselbalch equation ( $n=50$ ). The total buffering capacity ( $\beta_{\text{total}}$ ) was calculated as  $\beta_{\text{total}} = \beta_i + \beta_{\text{HCO}_3^-}$ , where  $\beta_{\text{HCO}_3^-}$  is the buffering capacity of the  $\text{HCO}_3^-/\text{CO}_2$  system.  $\beta_{\text{HCO}_3^-} = 2.3 \times [\text{HCO}_3^-]_i$ .  $[\text{HCO}_3^-]_i$  is the intracellular concentration of  $\text{HCO}_3^-$ .

from the bath solution to block the  $\text{Na}^+$ - and  $\text{HCO}_3^-$ -dependent pH regulatory mechanisms.  $\beta_i$  was estimated by the Henderson-Hasselbalch equation. The total buffering capacity ( $\beta_{\text{total}}$ ) was calculated as  $\beta_{\text{total}} = \beta_i + \beta_{\text{HCO}_3^-}$ , where  $\beta_{\text{HCO}_3^-}$  is the buffering capacity of the  $\text{HCO}_3^-/\text{CO}_2$  system.  $\beta_{\text{HCO}_3^-} = 2.3 \times [\text{HCO}_3^-]_i$ .  $[\text{HCO}_3^-]_i$  is the intracellular concentration of  $\text{HCO}_3^-$ .

### Overall $\Delta\text{pH}_i$ , base flux

The overall  $\Delta\text{pH}_i$  was measured by determining the  $\text{pH}_i$  immediately before and at the peak level during the administration of solutions containing  $\text{HCO}_3^-/\text{CO}_2$  by averaging the values of 80 data points. The initial rates of  $\Delta\text{pH}_i$  (over 30 s) were used to calculate transmembrane base flux  $J(B)$  using the equation  $J(B) = \Delta\text{pH}_i / \Delta t \cdot \beta_i$ . The  $\beta_i$  value used in the calculation of  $J(B)$ s was obtained from Figure 1 by using the average  $\text{pH}_i$  value over a 30-s period immediately before the administration of  $\text{HCO}_3^-/\text{CO}_2$  (virtually no  $\text{HCO}_3^-$  in the cells). Therefore, we were most likely underestimating  $J(B)$  because of the increase in buffering capacity as  $\text{HCO}_3^-$  fluxes into the cell during the administration of the basolateral  $\text{HCO}_3^-/\text{CO}_2$  solution. The only time we used  $\beta_{\text{total}}$  to calculate  $J(B)$  was when we administered basolateral standard  $\text{HCO}_3^-/\text{CO}_2$  solution during perfusion with apical standard  $\text{HCO}_3^-/\text{CO}_2$ . We denote base influx as  $J(B)$  and base efflux as  $-J(B)$ .

### RT-PCR

Total RNA was extracted from CFPAC-1 cells grown in tissue culture flasks using RNAzol solution (Gibco-BRL) according to the manufacturer's instructions. For reverse transcriptase (RT)-PCR, 2  $\mu\text{g}$  of RNA was reverse transcribed with 50 ng of random hexamer primers (GIBCO-BRL) in a final volume

**Figure 2** Functional polarities of CFPAC-1 cells. CFPAC-1 cells were grown to confluence on permeable supports, loaded with the pH-sensitive fluorescent dye BCECF-AM (2  $\mu\text{mol/L}$ ) and mounted into a perfusion chamber, which allowed the simultaneous perfusion of different solutions to the basolateral and apical membranes. The figure shows representative  $\text{pH}_i$  traces demonstrating cell polarity. The administration of standard  $\text{HCO}_3^-/\text{CO}_2$  solution to the apical and the basolateral sides of the cells showed a marked difference in response ( $n=12-20$ ).

of 20  $\mu\text{L}$  using 50 U of Moloney murine leukemia virus RT (Fermentas) at 37  $^\circ\text{C}$  for 1 h, following the manufacturer's instructions. The primers used for PCR amplification were previously described<sup>[23-25]</sup>. NHE1: 5'-CCAGCTCATTGCCTTCTACC-3' (sense) and 5'-TGTGTCTGTTGTAGGACCGC-3' (antisense) (length of amplified region 245 residues); AE2: 5'-GAAGATTCCTGAGAATGCCG-3' (sense) and 5'-GTCCATGTTGGCACTACTCG-3' (antisense) (length of amplified region 181 residues); pancreatic NBC1 (pNBC): 5'-ATGTGTGTGATGAAGAAGAAGTAGAAG-3' (sense) and 5'-GACCGAAGGTGGATTCTTG-3' (antisense) (length of amplified region 621 residues); glyceraldehyde-3-phosphate dehydrogenase (GAPDH): 5'-ATGGCACCGTCAAGGCTGAGA-3' (sense) and 5'-GCATGGACTGTGGTCATGAG-3' (antisense) (length of amplified region 371 residues). The PCR reaction was started with a 3-min 94  $^\circ\text{C}$  step and was followed by standard step-cycling conditions with 30 cycles of amplification utilizing *Taq* DNA polymerase (Fermentas); the reaction was ended by a 10-min 72  $^\circ\text{C}$  step. The cycling conditions for NHE1, AE2, and GAPDH were 94  $^\circ\text{C}$  for 30 s, 58  $^\circ\text{C}$  for 30 s and 72  $^\circ\text{C}$  for 30 s; and for pNBC1 were 94  $^\circ\text{C}$  for 30 s, 58  $^\circ\text{C}$  for 30 s and 68  $^\circ\text{C}$  for 3 min. RT-PCR products were separated by electrophoresis on a 20 g/L agarose gel containing ethidium bromide (0.5  $\mu\text{g/mL}$ ) and were visualized under ultraviolet light.

### Statistical analyses

In agreement with Zsembery *et al*<sup>[26]</sup>, we noticed a variation in the rate and magnitude of  $\text{HCO}_3^-$  uptake between the different set of monolayers that we could not attribute to the passage number or time after seeding. To avoid errors arising from this fact, we (1) performed a particular experimental protocol on the same day using one set of cell cultures, (2) randomized the order in which monolayers in the same group were exposed to experimental maneuvers (i.e., exposure to inhibitors), and (3) always included internal controls where possible. Summary data in the figures are expressed as percent change from control and statistical analyses were performed using either Student's paired or unpaired *t* test or the analysis of variance as appropriate. *P* values <0.05 were considered statistically significant.

## RESULTS

### Transepithelial electrical resistance, resting $\text{pH}_i$ and buffering capacity

The CFPAC-1 cells grown on polyester Transwells became confluent in 2-3 d as judged by visual observation. The net transepithelial resistance increased steadily over 4-5 d after seeding when it reached a plateau of  $100 \pm 4 \Omega/\text{cm}^2$  ( $n=88$ ). The resting  $\text{pH}_i$  of the cells in standard HEPES solution was  $7.11 \pm 0.08$  ( $n=6$ ).

### Apical administration of $\text{HCO}_3^-/\text{CO}_2$

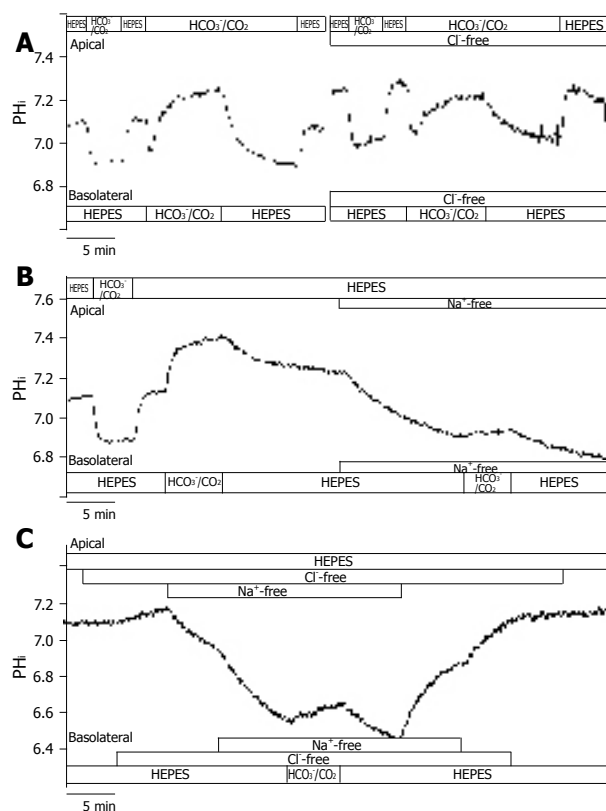

After perfusing both the apical and basolateral sides of the CFPAC-1 cells with standard HEPES solution, apical perfusion was switched to the standard  $\text{HCO}_3^-/\text{CO}_2$  solution (Figure 2). We then observed a rapid acidification ( $-17.5 \pm 1.5 \text{ mmol/L B/min}$ ,  $n=20$ ) of  $\text{pH}_i$ , most likely caused by the diffusion of  $\text{CO}_2$  into the cells. Following this, the  $\text{pH}_i$  reached a new approximate steady state value ( $6.82 \pm 0.02$ ,  $n=20$ ) and remained at this level until the standard HEPES solution was restored to the apical membrane. Restoration of standard HEPES solution induced a rapid alkalinization of  $\text{pH}_i$  towards the resting  $\text{pH}_i$  value probably brought about by the diffusion of  $\text{CO}_2$  from the cells. These observations suggested that  $\text{CO}_2$  influx was very fast across the apical membrane of CFPAC-1 cells, and that significant  $\text{HCO}_3^-$  influx did not occur.

### Basolateral administration of $\text{HCO}_3^-/\text{CO}_2$

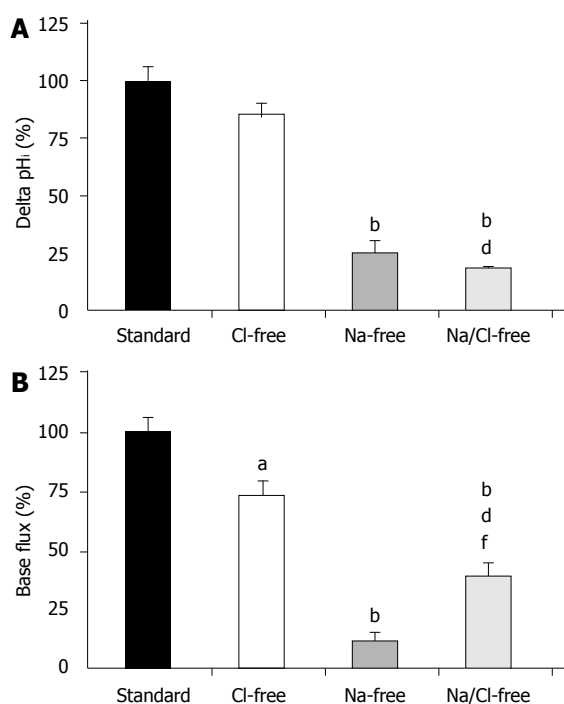

After perfusion of both the apical and basolateral membranes of CFPAC-1 cells with standard HEPES solution, the basolateral perfusion was switched to standard  $\text{HCO}_3^-/\text{CO}_2$  (Figure 2). Upon changing the basolateral perfusate, there was a rapid alkalinization of  $\text{pH}_i$  ( $\Delta\text{pH}_i = 0.48 \pm 0.03$ ,  $J(B) = 15.0 \pm 2.3 \text{ mmol/L B/min}$ ,  $n=12$ ), most likely induced by the transport of  $\text{HCO}_3^-$  into the cells. Removal of the standard  $\text{HCO}_3^-/\text{CO}_2$  solution from the basolateral side induced a further small transient increase in  $\text{pH}_i$  consistent with efflux of  $\text{CO}_2$ , followed by a slow acidification towards the resting  $\text{pH}_i$  value brought about by the extrusion of  $\text{HCO}_3^-$  (Figure 2). These observations suggested that  $\text{HCO}_3^-$  might cross the basolateral membrane of CFPAC-1 cells much faster than  $\text{CO}_2$ . To rule out the possibility that basolateral  $\text{HCO}_3^-$  entry was at least partly due to  $\text{CO}_2$  influx, followed by its rapid hydration to  $\text{HCO}_3^-$  ions, we perfused the apical side of CFPAC-1 cells with a standard  $\text{HCO}_3^-/\text{CO}_2$  solution for 4 min (intracellular  $\text{pCO}_2$  was increased) and then the same solution was added to the basolateral side (Figure 2). Under these conditions we still observed a rapid alkalinization of  $\text{pH}_i$  ( $\Delta\text{pH}_i = 0.40 \pm 0.05$ ,  $J(B) = 14.1 \pm 1.9 \text{ mmol/L B/min}$ ,  $n=6$ ) which was not significantly different compared to the absence of apical  $\text{HCO}_3^-/\text{CO}_2$ .

Taken together with the effects of apical  $\text{HCO}_3^-/\text{CO}_2$  administration, these data showed that CFPAC-1 monolayers exhibited functional polarity with respect to  $\text{HCO}_3^-$  transport. Subsequently, we used the apical administration of  $\text{HCO}_3^-/\text{CO}_2$  to check the functional polarity of monolayers at the beginning of each experiment. The cells were considered to be polarized, if

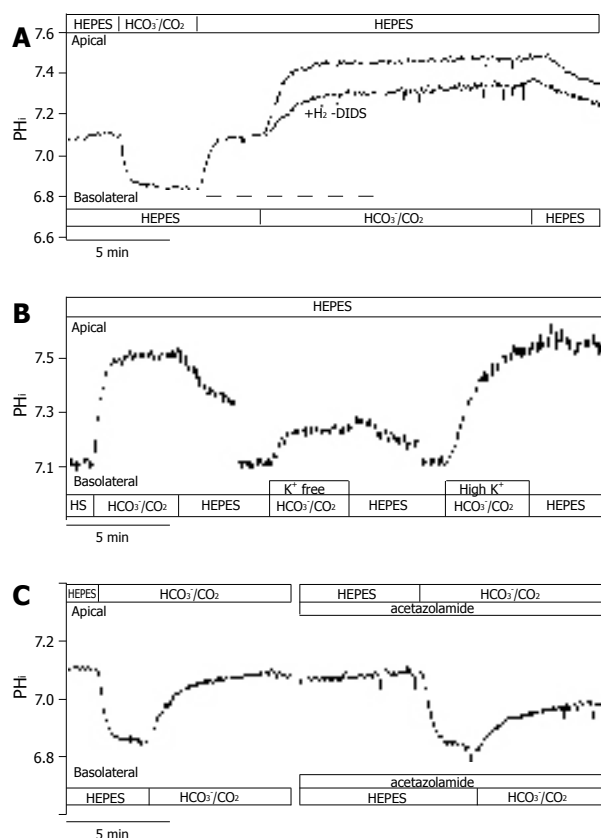

**Figure 3** Basolateral  $\text{HCO}_3^-$  uptake – effects of  $\text{Cl}^-$  and/or  $\text{Na}^+$  withdrawal. The figure shows representative  $\text{pH}_i$  traces. **A:** The rate of  $\text{HCO}_3^-$  uptake was significantly decreased in  $\text{Cl}^-$ -free conditions compared to standard conditions ( $J(B) = 73.1 \pm 7.2\%$  and  $100 \pm 8.5\%$ , respectively,  $n=5$ ); **B:** The administration of basolateral  $\text{HCO}_3^-/\text{CO}_2$  in  $\text{Na}^+$ -free conditions ( $n=6$ ) greatly decreased  $\Delta\text{pH}_i$  and  $J(B)$  compared to standard conditions, suggesting that a large proportion of the  $\text{HCO}_3^-$  uptake was due to a  $\text{Na}^+$ -sensitive process, most likely NBC; **C:** Interestingly, the decrease in the rate of  $\text{HCO}_3^-$  uptake was obviously ameliorated in the absence of both  $\text{Na}^+$  and  $\text{Cl}^-$  ( $n=6$ ) compared to the  $\text{Na}^+$ -free condition.

**Figure 4** Basolateral  $\text{HCO}_3^-$  uptake – changes in **(A)**  $\Delta\text{pH}_i$  and **(B)**  $J(B)$  caused by the withdrawal of  $\text{Cl}^-$  and/or  $\text{Na}^+$ . SE of the control groups (standard, black bar) is somewhat different for each of the respective ion-withdrawal groups. The SEs depicted on the standard bars are the maximum values observed. <sup>a</sup> $P < 0.05$  and <sup>b</sup> $P < 0.01$  vs control group <sup>d</sup> $P < 0.01$  vs  $\text{Cl}^-$ -free group and/or <sup>f</sup> $P < 0.01$  vs  $\text{Na}^+$ -free group.

**Figure 5** Basolateral  $\text{HCO}_3^-$  uptake – effects of  $\text{H}_2\text{-DIDS}$ , acetazolamide and varying extracellular  $\text{K}^+$  concentration. The figure shows representative  $\text{pH}_i$  traces. **A:** The anion transport inhibitor  $600 \mu\text{mol/L}$   $\text{H}_2\text{-DIDS}$  (added to the basolateral membrane of cells for 2 min before and during the administration of basolateral  $\text{HCO}_3^-/\text{CO}_2$ , dashed line,  $n=6$ ) significantly decreased the extent of alkalinization ( $\Delta\text{pH}_i$ ) and rate of  $J(B)$  ( $n=6$ ); **B:** Varying extracellular  $[\text{K}^+]$  caused significant differences in  $\Delta\text{pH}_i$  and  $J(B)$  ( $n=9-11$ ); **C:** The application of the membrane-permeable carbonic anhydrase inhibitor acetazolamide ( $100 \mu\text{mol/L}$ ,  $n=6$ ) significantly decreased the overall  $\Delta\text{pH}_i$  and  $J(B)$ . HS: HEPES.

the  $\text{pH}_i$  remained constant after the initial decrease in  $\text{pH}_i$  caused by the diffusion of  $\text{CO}_2$  into the cells.

### Investigation of basolateral $\text{HCO}_3^-$ uptake

In theory, the alkalinization observed after the administration of basolateral standard  $\text{HCO}_3^-/\text{CO}_2$  could be explained by the action of the NBC and the reversal of  $\text{Cl}^-/\text{HCO}_3^-$  anion exchanger. The initial rate of  $\text{HCO}_3^-$  uptake was significantly decreased in  $\text{Cl}^-$ -free vs standard conditions ( $J(B) = 73.1 \pm 7.2\%$  and  $100 \pm 8.5\%$ , respectively,  $n=5$ , Figures 3A and 4); however, no significant difference was noted for the overall  $\Delta\text{pH}_i$  for the two groups ( $85.5 \pm 6.0\%$  and  $100 \pm 6.3\%$ , respectively). The administration of basolateral  $\text{HCO}_3^-/\text{CO}_2$  greatly decreased  $\Delta\text{pH}_i$  ( $25.6 \pm 5.1\%$ ) and  $J(B)$  ( $11.7 \pm 2.3\%$ ) in  $\text{Na}^+$ -free conditions ( $n=6$ ) compared to those ( $100 \pm 7.5\%$  and,  $100 \pm 10.7\%$ , respectively) in standard conditions, suggesting that a large proportion of the  $\text{HCO}_3^-$  uptake was due to a  $\text{Na}^+$ -sensitive process, most likely via an NBC (Figures 3B and 4). Interestingly, the decrease in the rate of  $\text{HCO}_3^-$  uptake was somewhat attenuated in the absence of both  $\text{Na}^+$  and  $\text{Cl}^-$  [ $n=6$ ,  $J(B)$  changed to  $38.4 \pm 6.9\%$ , Figures 3C and 4].

To further confirm the presence of NBC on the basolateral membrane of CFPAC-1 cells, we examined the recovery from a  $\text{Na}^+$ -free acid load in the presence

**Figure 6** Basolateral  $\text{HCO}_3^-$  uptake – changes in (A)  $\Delta\text{pH}_i$  (B)  $J(\text{B})$  caused by application of  $\text{H}_2\text{-DIDS}$ , acetazolamide, ethoxzolamide, STP and varying extracellular  $\text{K}^+$  concentration. Data are shown as mean  $\pm$  SE ( $n=6-11$ ). SE of the control groups (standard, black bar) is somewhat different for each of the respective ion-withdrawal groups. The SE depicted on the control bar was the maximum values observed. <sup>a</sup> $P<0.05$  and <sup>b</sup> $P<0.01$  vs control group or <sup>c</sup> $P<0.05$  vs  $\text{K}^+$ -free group. ATZ: acetazolamide; ETZ: ethoxzolamide; STP: 1-*N*-(4-sulfamoylphenylethyl)-2,4,6-trimethylpyridine perchlorate. The SE depicted on the standard bars was the maximum values observed.

of  $\text{HCO}_3^-/\text{CO}_2$  by adding basolateral  $\text{Na}^+$  with/without 300  $\mu\text{mol/L}$  amiloride (to block basolateral  $\text{Na}^+/\text{H}^+$  exchange,  $n=6$ ). After acid loading of cells, the basolateral addition of  $\text{Na}^+$  stimulated a  $J(\text{B})$  of  $39.0\pm4.4$  mmol/L B/min (please see below the much lower values in HEPES solution). In contrast, the basolateral addition of  $\text{Na}^+$  in the presence of amiloride decreased this value to  $22.2\pm3.6$  mmol/L B/min, suggesting that a third pathway of acid transport is due to a basolateral NHE. The anion transport inhibitor  $\text{H}_2\text{-DIDS}$  (600  $\mu\text{mol/L}$ , added to the basolateral membrane of cells for 2 min before and during the administration of basolateral  $\text{HCO}_3^-/\text{CO}_2$ ,  $n=6$ ), significantly decreased the extent of alkalization ( $\Delta\text{pH}_i$ ) to  $63.2\pm4.7\%$  and rates of  $J(\text{B})$  to  $43.9\pm5.1\%$  ( $n=6$ , Figures 5A and 6). Varying the extracellular  $\text{K}^+$  concentrations ( $\text{K}^+$ -free, high  $\text{K}^+$ ,  $n=9-11$ ) of the basolateral standard  $\text{HCO}_3^-/\text{CO}_2$  solution induced significant differences between the  $\Delta\text{pH}_i$  values vs the standard  $\text{HCO}_3^-/\text{CO}_2$  solution ( $41.5\pm24.5\%$ ,  $139.6\pm15.0\%$  and  $100\pm11.1\%$ , respectively; Figures 5B and 6). The  $J(\text{B})$  significantly decreased when  $\text{K}^+$ -free  $\text{HCO}_3^-/\text{CO}_2$  ( $73.9\pm6.4\%$ ) was administered to the basolateral membrane, but was not affected by high  $\text{K}^+$ ,  $\text{HCO}_3^-/\text{CO}_2$  ( $96.6\pm11.0\%$ ) vs the standard  $\text{HCO}_3^-/\text{CO}_2$  solution ( $100.0\pm15.8\%$ ). Thus, our experiments showed that alteration of the membrane potential of CFPAC-1 cells, by varying basolateral extracellular  $\text{K}^+$  concentration, modified the extent of  $\text{HCO}_3^-$  uptake. The application of the membrane permeable CA inhibitors acetazolamide (100  $\mu\text{mol/L}$ ,  $n=6$ , Figures 5C and 6) or ethoxzolamide (100  $\mu\text{mol/L}$ ,

**Figure 7** Localization of  $\text{Cl}^-/\text{HCO}_3^-$  exchangers in CFPAC-1 cells. The figure shows representative  $\text{pH}_i$  traces ( $n=6$ ). The localization of  $\text{Cl}^-/\text{HCO}_3^-$  exchangers was performed by measuring the effect of changes in  $\text{Cl}^-$  gradient across the luminal or basolateral membranes on  $\text{pH}_i$ . In the presence of  $\text{HCO}_3^-$ , the removal of  $\text{Cl}^-$  from the apical membrane did not result in changes of  $\text{pH}_i$ . The removal of  $\text{Cl}^-$  from the basolateral membrane caused a  $\Delta\text{pH}_i$  of  $0.08\pm0.01$  and a  $J(\text{B})$  of  $4.37\pm0.46$  mmol/L B/min. Furthermore, the basolateral administration of 250  $\mu\text{mol/L}$   $\text{H}_2\text{-DIDS}$  completely blocked  $\text{pH}_i$  changes caused by the withdrawal of  $\text{Cl}^-$ .

$n=6$ ) in the apical (standard  $\text{HCO}_3^-/\text{CO}_2$  solution) and basolateral (standard HEPES solution) perfusions, 10 min before and during the administration of basolateral standard  $\text{HCO}_3^-/\text{CO}_2$  solution, significantly decreased the overall  $\Delta\text{pH}_i$  to  $56.8\pm4.2\%$  or  $59.0\pm9.8\%$ , and  $J(\text{B})$  to  $50.5\pm4.6\%$  or  $63.7\pm8.3\%$ , respectively. The basolateral addition of the membrane impermeable CA inhibitor STP (10  $\mu\text{mol/L}$ ,  $n=6$ ) in standard HEPES solution (the apical side of the cells was perfused with standard  $\text{HCO}_3^-/\text{CO}_2$  solution), 5 min before and during the administration of basolateral standard  $\text{HCO}_3^-/\text{CO}_2$  solution, did not significantly influence overall  $\Delta\text{pH}_i$  ( $114.3\pm14.3\%$ ) and  $J(\text{B})$  ( $106.7\pm17.9\%$ , Figure 6).

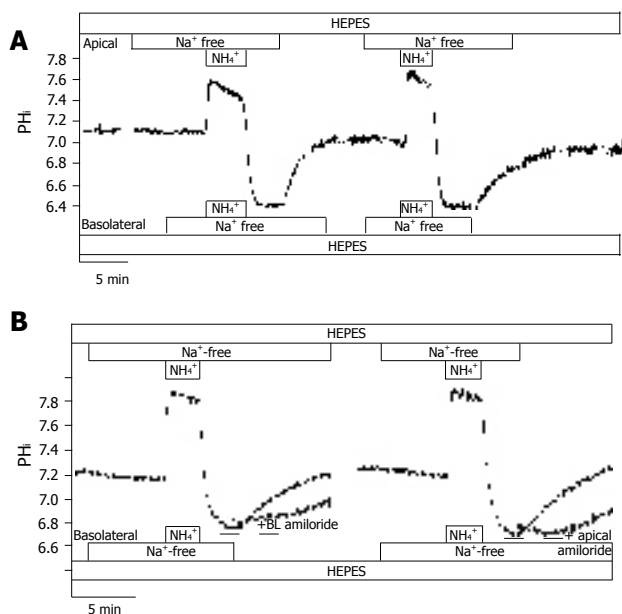

#### Localization of $\text{Cl}^-/\text{HCO}_3^-$ exchangers in CFPAC-1 cells

The localization of  $\text{Cl}^-/\text{HCO}_3^-$  exchangers was performed by measuring the effect of changes in  $\text{Cl}^-$  gradient across the luminal and/or basolateral membranes on  $\text{pH}_i$ . In the presence of  $\text{HCO}_3^-$ , the removal of  $\text{Cl}^-$  from the apical membrane did not result in changes of  $\text{pH}_i$ . The removal of  $\text{Cl}^-$  from the basolateral membrane caused a  $\Delta\text{pH}_i$  of  $0.08\pm0.01$  and a  $J(\text{B})$  of  $4.4\pm0.5$  mmol/L B/min ( $n=6$ , Figure 7). Furthermore, the basolateral administration of 250  $\mu\text{mol/L}$   $\text{H}_2\text{-DIDS}$  (from 2 min before changing the solution to  $\text{Cl}^-$ -free  $\text{HCO}_3^-/\text{CO}_2$ ) completely blocked  $\text{pH}_i$  changes caused by the withdrawal of  $\text{Cl}^-$ . However, 10  $\mu\text{mol/L}$  forskolin, 100  $\mu\text{mol/L}$  acetazolamide or 100  $\mu\text{mol/L}$  ethoxzolamide (from 10 min before changing the solution to  $\text{Cl}^-$ -free  $\text{HCO}_3^-/\text{CO}_2$ ) did not significantly influence  $\text{Cl}^-/\text{HCO}_3^-$  exchange on the apical and basolateral membranes ( $n=6-8$ , data not shown).

#### Localization of $\text{Na}^+/\text{H}^+$ exchangers in CFPAC-1 cells

In HEPES-buffered solutions, the removal of  $\text{Na}^+$  from the perfusing solutions had a small acidifying effect on  $\text{pH}_i$  [ $J(\text{B})=1.00\pm0.13$  mmol/L B/min,  $n=12$ ]. After exposure and then removal of the  $\text{NH}_4^+$  in the absence of  $\text{Na}^+$  on both sides of the duct cells,  $\text{pH}_i$  reduced to  $6.73\pm0.03$  ( $n=12$ ), and stabilized at this level (Figure 8A). We could not detect any active  $\text{H}^+$ -pumps in CFPAC-1 cells, since  $\text{pH}_i$  did not increase in the absence of extracellular  $\text{Na}^+$ . Re-addition of  $\text{Na}^+$  to the apical or the basolateral side caused  $\text{pH}_i$  recovery towards the resting values [ $J(\text{B})=-6.6$

**Figure 8** Localization of Na<sup>+</sup>/H<sup>+</sup> exchangers in CFPAC-1 cells. The figure shows representative pH traces. **A:** After exposure to NH<sub>4</sub><sup>+</sup> in the absence of Na<sup>+</sup> on both sides of the duct cells, pH<sub>i</sub> reduced to  $6.73 \pm 0.03$  ( $n=12$ ), and stabilized at this level. We could not detect any active H<sup>+</sup>-pumps in CFPAC-1 cells, since pH<sub>i</sub> did not increase in the absence of extracellular Na<sup>+</sup>. Upon addition of Na<sup>+</sup> to the apical or the basolateral side prompted the pH<sub>i</sub> to recover towards the resting values ( $n=6-10$ ); **B:** The administration of 300 μmol/L amiloride (dashed line) to the Na<sup>+</sup>-free (from 2 min before the addition of Na<sup>+</sup>) and Na<sup>+</sup>-containing HEPES solutions prevented the recovery of pH<sub>i</sub> in the presence of Na<sup>+</sup> ( $n=6$ ). Removal of amiloride resulted in the recovery of pH<sub>i</sub> to resting values.

$\pm 2.6$  mmol/L B/min and  $-7.5 \pm 1.3$  mmol/L B/min, respectively,  $n=6-10$ ]. The administration of 300 μmol/L amiloride to the Na<sup>+</sup>-free (from 2 min before the addition of Na<sup>+</sup>) and Na<sup>+</sup>-containing HEPES solutions prevented the recovery of pH<sub>i</sub> in the presence of Na<sup>+</sup> ( $n=6$ , Figure 8B). Removing amiloride resulted in the recovery of pH<sub>i</sub> to resting values. Interestingly, the removal of apical Na<sup>+</sup> from the standard HCO<sub>3</sub><sup>-</sup>/CO<sub>2</sub> solution perfusing CFPAC-1 cells caused a sudden but small acidification of pH<sub>i</sub> ( $\Delta\text{pH}_i = 0.14 \pm 0.01$  and  $J(B) = -10.8 \pm 0.8$  mmol/L B/min,  $n=6$ ), whereas we did not see any change in pH<sub>i</sub> when we removed Na<sup>+</sup> from the basolateral side of the cells ( $n=6$ ). Taken together, our experiments showed that there are Na<sup>+</sup>/H<sup>+</sup> exchangers on both the apical and the basolateral membranes. Finding a Na<sup>+</sup>/H<sup>+</sup> exchanger on the apical side was somewhat unexpected. A possible explanation for this would be that the cells were leaky to Na<sup>+</sup> ions. However, despite the great difference in Na<sup>+</sup> concentration (0 mmol/L *vs* 140 mmol/L) of the apical and basolateral perfusates, analysis of the Na<sup>+</sup> concentration of the solutions by mass spectrometry showed no contamination during perfusion.

#### Molecular identification of H<sup>+</sup> and HCO<sub>3</sub><sup>-</sup> transporters

To further investigate the presence of different H<sup>+</sup> and HCO<sub>3</sub><sup>-</sup> transporters in CFPAC-1 cells, we undertook RT-PCR analysis. We could detect mRNA expressions for pNBC1, AE2, and NHE1; the housekeeping gene GAPDH was used to normalize mRNA levels (Figure 9).

**Figure 9** Expression of pNBC1, AE2, NHE1, and GAPDH mRNA in CFPAC-1 cells. Mw: molecular weight ladder (bp indicates number of base pairs).

**Figure 10** H<sup>+</sup> and HCO<sub>3</sub><sup>-</sup> transport mechanisms in CFPAC-1 human pancreatic duct cells. The basolateral membrane expresses Na<sup>+</sup>/HCO<sub>3</sub><sup>-</sup> co-transporters, Na<sup>+</sup>/H<sup>+</sup> exchangers and Cl<sup>-</sup>/HCO<sub>3</sub><sup>-</sup> exchangers plus an unidentified Na<sup>+</sup>-independent HCO<sub>3</sub><sup>-</sup> entry pathway. These transporters facilitate the rapid flux of HCO<sub>3</sub><sup>-</sup> ions into the cell. K<sup>+</sup> channels are also likely to be expressed on the basolateral membrane because altering extracellular K<sup>+</sup> concentration affects HCO<sub>3</sub><sup>-</sup> influx. The apical membrane expresses Na<sup>+</sup>/H<sup>+</sup> exchangers, but not CFTR and Cl<sup>-</sup>/HCO<sub>3</sub><sup>-</sup> exchangers found in normal pancreatic duct cells. The apical membrane is an effective barrier to HCO<sub>3</sub><sup>-</sup> influx from the lumen, but is freely permeable to CO<sub>2</sub>. CA: Carbonic anhydrase.

## DISCUSSION

Our results showed the functional presence of the NBC and Cl<sup>-</sup>/HCO<sub>3</sub><sup>-</sup> exchanger on the basolateral membrane, together with Na<sup>+</sup>/H<sup>+</sup> exchangers on both the apical and basolateral membranes of CFPAC-1 cells (Figure 10). That there was no detectable Cl<sup>-</sup>/HCO<sub>3</sub><sup>-</sup> exchange activity on the apical membrane was not a surprise as CFTR is known to be required for its activation<sup>[3,27]</sup>. RT-PCR revealed the expression of pNBC1, AE2, and NHE1 mRNA.

CFPAC-1 cells clearly demonstrated a differential permeability to HCO<sub>3</sub><sup>-</sup> at the apical and basolateral membranes. We found that the addition of 25 mmol/L HCO<sub>3</sub><sup>-</sup>/CO<sub>2</sub> to the basolateral side of the cells caused a marked alkalinization of pH<sub>i</sub>, whereas exposing the apical membrane to the same solution caused a sustained acidification. These data suggest that the basolateral membrane of CFPAC-1 cells is much more permeable

to  $\text{HCO}_3^-$  than the apical membrane. Plasma membrane  $\text{HCO}_3^-$  and  $\text{CO}_2$  permeabilities have been reported to vary in different species and tissues. In perfused rabbit gastric glands, the luminal membranes of parietal and chief cells were impermeable to  $\text{HCO}_3^-$  and  $\text{CO}_2$ , while the basolateral membranes were permeable to both<sup>[28]</sup>. Apical  $\text{HCO}_3^-$  permeability is relatively low in cultured bovine corneal endothelial cells<sup>[29]</sup>. In contrast,  $\text{HCO}_3^-$  permeability of the apical side of intact colonic mucosa of guinea pig is markedly higher<sup>[30]</sup>. Our results are in accordance with similar observations made by Ishiguro *et al.*<sup>[31]</sup> using guinea pig ducts. Administration of 25 mmol/L  $\text{HCO}_3^-/\text{CO}_2$  to the lumen of microperfused guinea pig pancreatic ducts decreased  $\text{pH}_i$  rapidly. Following this, no subsequent increase in  $\text{pH}_i$  was observed, indicating that little  $\text{HCO}_3^-$  was able to enter the cell from the lumen.  $\text{HCO}_3^-$  entry was detected only when the luminal  $\text{HCO}_3^-$  concentration was raised above 125 mmol/L. A low apical  $\text{HCO}_3^-$  permeability would make physiological sense in species, such as man and guinea pig, which can secrete near isotonic  $\text{NaHCO}_3$ . Our work is the first demonstration of  $\text{HCO}_3^-/\text{CO}_2$  asymmetry in polarized human pancreatic duct cells. Finally, it seems that CFPAC-1 cells, which express  $\Delta\text{F508 CFTR}$ , exhibit the same resistance to  $\text{HCO}_3^-$  influx across the apical membrane as native guinea pig duct cells. This suggests that the presence of functional CFTR in the apical membrane is not required for this membrane to act as an effective barrier to  $\text{HCO}_3^-$  influx from the lumen.

A large proportion of the basolateral  $\text{HCO}_3^-$  uptake was  $\text{Na}^+$ -dependent and was partially inhibited by  $\text{H}_2\text{-DIDS}$ , therefore, it is most likely due to the action of pNBC1. However, we also detected a novel  $\text{Na}^+$ -independent  $\text{HCO}_3^-$  influx mechanism that was significantly increased in  $\text{Cl}^-$ -free conditions, the identity of which remains unknown. NBCs have been detected in the guinea pig<sup>[32,33]</sup>, rat<sup>[34,35]</sup> and mouse<sup>[36]</sup>. In contrast, Novak *et al.*<sup>[37,38]</sup> could not detect any  $\text{HCO}_3^-$  uptake by NBC in freshly prepared rat pancreatic ducts using electrophysiological and  $\text{pH}_i$  measurements. Extracellular  $\text{HCO}_3^-/\text{CO}_2$  did not increase the rate of  $\text{pH}_i$  recovery in experimental acidosis. The expressions of NBC mRNA and protein have been noted in the human pancreas<sup>[39]</sup>. Immunofluorescence localized the transporter to the basolateral but not the apical membrane of the pancreatic duct cells. Interestingly, immunohistological studies have shown the NBC in both the apical and basolateral membranes of rat pancreatic duct cells<sup>[35]</sup>. NBC1 mRNA was also detected in CFPAC-1 cells by Northern hybridization<sup>[13]</sup>. In accordance with our findings, expression of NBC1 was also found in non-polarized cells by recovery from acidosis in the presence of  $\text{HCO}_3^-$ ,  $\text{Na}^+$  and amiloride and its sensitivity to the administration of 200  $\mu\text{mol/L}$  DIDS<sup>[13]</sup>. cAMP had no effect on NBC activity in CFPAC-1 cells, whereas NBC activity was stimulated in CAPAN-1 cells expressing wild-type CFTR<sup>[13]</sup>. The basolateral localization of the NBC was shown by  $^{22}\text{Na}^+$  flux studies in CFPAC-1 cells stably transfected with wild-type CFTR grown on permeable supports (no data was reported for untransfected CFPAC-1 cells)<sup>[13]</sup>.

The application of the membrane permeable CA

inhibitor acetazolamide or ethoxzolamide partially inhibited the rate of basolateral base flux in CFPAC-1 cells, whereas the membrane-impermeable CA inhibitor STP<sup>[40]</sup> had no such effect. Carbonic anhydrases are known to be coupled to  $\text{HCO}_3^-$  transporters, such as  $\text{Cl}^-/\text{HCO}_3^-$  anion exchangers<sup>[41-44]</sup>,  $\text{DRA}$ <sup>[45]</sup> and  $\text{NBC}$ <sup>[46]</sup>. There are at least 14 different isoenzymes in the  $\alpha$ -CA gene family present in vertebrates<sup>[47]</sup>. CA I-III and VII are cytosolic, while CA IV, IX, XII and XIII are membrane-associated, V is mitochondrial and VI is secreted. Of the 14 different isoforms, CA II, IV, IX and XII were shown to be expressed in the human pancreas and cultured pancreatic tumor cells<sup>[48]</sup>. Interestingly, CA II and IV expressions were found to be associated with apical  $\text{HCO}_3^-$  channels in human pancreatic duct cells CAPAN-1<sup>[49]</sup>, although the targeting of CA IV to the apical plasma membrane was impaired in the CFPAC-1 cells<sup>[50]</sup>. Kivela *et al.*<sup>[51]</sup> have clearly detected the transmembrane CA isoenzymes IX and XII on the basolateral membrane of the normal and pathological pancreas by immunohistochemistry. However, it is unlikely that the latter isoenzymes are associated with NBC as STP had no inhibitory effect on  $\text{HCO}_3^-$  uptake. Furthermore, in accordance with our results, Cheng *et al.*<sup>[52]</sup> have shown in CAPAN-1 cells that  $\text{HCO}_3^-$ -dependent forskolin-induced  $I_{sc}$  could be significantly reduced by acetazolamide. Moreover, the CA inhibitor also had an inhibitory effect on dome formation, which was thought to be due to exchange of water and electrolytes<sup>[49]</sup>. Taken together, intracellular CAs may be involved in the rapid basolateral transport of  $\text{HCO}_3^-$  by NBC. The enzyme converts  $\text{HCO}_3^-$  to carbonic acid and possibly maintains a concentration gradient for  $\text{HCO}_3^-$  across the basolateral membrane of CFPAC-1 cells.

Alteration of extracellular  $\text{K}^+$  concentration significantly influenced  $\text{HCO}_3^-$  uptake in our experiments. The presence of  $\text{K}^+$  channels in the basolateral membranes of CFPAC-1 cells is highly likely, and one report has identified ATP-sensitive  $\text{K}^+$  channels<sup>[53]</sup> in these cells. A basolateral  $\text{K}^+$  conductance will influence the rate of  $\text{HCO}_3^-$  secretion by altering the cells membrane potential. In our experiments, high extracellular  $\text{K}^+$  concentrations increased  $\text{HCO}_3^-$  entry, which was likely due to basolateral membrane depolarization, and a consequent increase in the electrochemical driving force for  $\text{HCO}_3^-$  entry on the electrogenic NBC. In contrast, low extracellular  $\text{K}^+$  concentration inhibited  $\text{HCO}_3^-$  uptake, probably due to membrane hyperpolarization.

Novak and Greger<sup>[37]</sup> demonstrated that the basolateral membrane of rat intra- and inter-lobular pancreatic ducts had a relatively large  $\text{K}^+$  conductance, which could be decreased by the  $\text{K}^+$  channel blocker  $\text{Ba}^{2+}$ . The luminal membrane had no significant  $\text{K}^+$  conductance. Interestingly, Fong *et al.*<sup>[54]</sup> detected  $\text{K}^+$  conductances not only on the basolateral but also on the apical sides of HPAP human pancreatic duct cells.

CFPAC-1 cells exhibited  $\text{Na}^+/\text{H}^+$  exchange activity on both the apical and basolateral membranes (the latter is most likely to be due to NHE1).  $\text{Na}^+/\text{H}^+$  exchangers were identified in guinea pig<sup>[10,28-30]</sup>, rat<sup>[55,56]</sup> and mouse<sup>[8]</sup> pancreatic ducts. These exchangers were localized to the basolateral membrane of intra/interlobular duct cells.

However, the main and common segments of the rat pancreatic ducts also showed  $\text{Na}^+/\text{H}^+$  exchange activity in the apical membrane<sup>[10]</sup>. There is also evidence for an apical  $\text{Na}^+/\text{H}^+$  exchanger in bovine main pancreatic duct segments<sup>[57]</sup>. Furthermore, the main pancreatic duct of mice expressed NHE1 in the basolateral membrane, and NHE2 and NHE3 in the luminal membrane<sup>[8]</sup>. Disruption of the NHE2 gene had no effect on luminal  $\text{H}^+$  transport, while disruption of the NHE3 gene reduced luminal  $\text{Na}^+$ -dependent  $\text{H}^+$  efflux by 45%. The remaining 55% of the luminal  $\text{Na}^+$ -dependent  $\text{H}^+$  efflux from NHE3-knockout mice was inhibited by 50  $\mu\text{mol/L}$  HOE694.  $\text{Na}^+$ -dependent  $\text{H}^+$  transport mechanisms were inhibited by cAMP, therefore, they are thought to be inhibited during stimulated secretion and are most likely to be active during the resting state<sup>[8]</sup>. CFTR in the pancreatic duct not only affected the activity, but also the expression of NHE3 protein<sup>[7]</sup>. NHE3 expression was reduced by about 50%, luminal  $\text{Na}^+$ -dependent and HOE694-sensitive recovery from acid load was reduced by 60% in the ducts of  $\Delta 508$  CFTR mice<sup>[7]</sup>. To our knowledge, we are the first to detect NHEs on both the apical and basolateral membranes of human pancreatic duct cells. The presence of NHE on the apical membrane was unexpected, since it acted against  $\text{HCO}_3^-$  secretion. We do not know which section of the pancreatic duct CFPAC-1 cells originate from, but they might be from the main region where the expression of the apical NHEs was noted in animal studies. In accordance with our results, failure of  $\text{pH}_i$  to recover from acid loading in the absence of extracellular  $\text{Na}^+$  suggests that there is little  $\text{H}^+$ -pump activity in the unstimulated guinea pig ducts<sup>[32]</sup>. This is in contrast with the observations made in rat<sup>[10]</sup> and pig<sup>[58]</sup> pancreatic ducts, which showed  $\text{H}^+$ -pump activity.

The role of apical  $\text{Cl}^-/\text{HCO}_3^-$  exchangers in pancreatic ductal  $\text{HCO}_3^-$  secretion is a controversial issue. One hypothesis is that all of the  $\text{HCO}_3^-$  is secreted on an anion exchanger and that CFTR's role is to activate the exchangers and to provide a route for the recycling of  $\text{Cl}^-$  across the apical membrane<sup>[59]</sup>. An alternative proposal is that  $\text{HCO}_3^-$  secretion occurs on the exchanger until the luminal concentration reaches about 70  $\text{mmol/L}$  after which  $\text{HCO}_3^-$  exits the duct cell via CFTR<sup>[60]</sup>. Previously, it has been shown that CFPAC-1 cells express AE2 on their basolateral membrane (which was also confirmed in our study) and SLC26A3 (DRA) and SLC26A6 (PAT1) on their apical membrane, and that expression of the apical SLC26 exchangers is upregulated by CFTR<sup>[14]</sup>. In accordance with these data, we observed basolateral  $\text{Cl}^-/\text{HCO}_3^-$  exchange activity (which was inhibited by  $\text{H}_2\text{-DIDS}$ ) in wild-type CFPAC-1 cells, but no apical activity, presumably due to the lack of CFTR. We also found that forskolin had no effect on either the basolateral or apical anion exchange in CFPAC-1 cells.

In conclusion, apart from the lack of CFTR and apical  $\text{Cl}^-/\text{HCO}_3^-$  exchange activity, CFPAC-1 cells have similar  $\text{H}^+$  and  $\text{HCO}_3^-$  transporters to those observed in native animal tissue. Moreover, intracellular CAs appear to play a role in the basolateral uptake of  $\text{HCO}_3^-$ . Taken together, polarized CFPAC-1 human pancreatic duct cells are likely to be a useful model to study  $\text{H}^+$  and  $\text{HCO}_3^-$  transporters,

and their dependence on CFTR, in human pancreatic duct cells.

## ACKNOWLEDGMENTS

We thank Professor RA Frizzell for kindly providing us with the CFPAC-1 cells, and Professor C Supuran for providing the 1-N-(4-sulfamoylphenylethyl)-2,4,6-trimethylpyridine perchlorate.

## Abstract

**AIM:** To analyze and to compare the effects of interferon (IFN)- $\alpha$ , IFN- $\beta$ , and IFN- $\gamma$  on pancreatic stellate cell (PSC) activation *in vitro* and to elucidate the molecular basis of IFN action.

**METHODS:** PSCs were isolated from rat's pancreatic tissue, cultured and stimulated with recombinant rat IFNs. Cell proliferation and collagen synthesis were assessed by measuring the incorporation of 5-bromo-2'-deoxyuridine (BrdU) into DNA and [ $^3$ H]-proline into acetic acid-soluble proteins, respectively. Apoptotic cells were determined by FACS analysis (sub-G<sub>1</sub> peak method). Exhibition of the myofibroblastic PSC phenotype was monitored by immunoblot analysis of  $\alpha$ -smooth muscle actin ( $\alpha$ -SMA) expression. To assess the activation of signal transducer and activator of transcription (STAT), Western blots using phospho-STAT-specific antibodies were performed. In studies on STAT1 function, expression of the protein was inhibited by siRNA.

**RESULTS:** IFN- $\beta$  and IFN- $\gamma$ , but not IFN- $\alpha$  significantly diminished PSC proliferation and collagen synthesis. IFN- $\gamma$  was the only IFN that clearly inhibited  $\alpha$ -SMA expression. Under the experimental conditions used, no enhanced rate of apoptotic cell death was observed in response to any IFN treatment. IFN- $\beta$  and IFN- $\gamma$  induced a strong increase of STAT1 and STAT3 tyrosine phosphorylation, while the effect of IFN- $\alpha$  was much weaker. Inhibition of STAT1 expression with siRNA was associated with a significantly reduced growth-inhibitory effect of IFN- $\gamma$ .

**CONCLUSION:** IFN- $\beta$  and particularly IFN- $\gamma$  display inhibitory effects on PSC activation *in vitro* and should

## INTRODUCTION

Pancreatic stellate cells (PSCs) are the main source of extracellular matrix (ECM) proteins in pancreatic fibrosis<sup>[1-3]</sup>, a common feature of chronic pancreatitis and pancreatic cancer<sup>[4,5]</sup>. They are closely related with hepatic stellate cells (HSCs), the key effector cells in liver fibrosis<sup>[6]</sup>. In response to pro-fibrogenic cytokines and ethanol metabolites, PSCs exhibit a myofibroblastic phenotype that is characterized by the expression of  $\alpha$ -smooth muscle actin ( $\alpha$ -SMA), proliferative activity, a loss of the typical retinoid-containing fat droplets, and enhanced ECM synthesis<sup>[3,7]</sup>. Similar phenotypic changes, considered as PSC activation, are induced when isolated PSCs are plated on cell-culture dishes<sup>[1,2,8-10]</sup>. The molecular principles of PSC activation *in vivo* and *in vitro* have been extensively analyzed in the past few years. Studies indicate that platelet-derived growth factor (PDGF) exerts strong mitogenic effects on PSCs, while transforming growth factor-beta (TGF- $\beta$ ) has been suggested as the most potent stimulator of ECM synthesis<sup>[11,12]</sup>. Furthermore, intracellular signal transduction pathways mediating PSC activation have, in part, been deciphered. Thus, we and others have recently shown that mitogen-activated protein kinases are key mediators of activation signals<sup>[13-17]</sup>. In contrast, natural antagonists of PSC activation have not been systematically studied so far. Their elucidation, however, may be helpful for the development of antifibrotic therapies.

Interferons (IFNs) are multifunctional cytokines that block viral infection, modulate immune as well as inflammatory responses, and inhibit cell proliferation<sup>[18]</sup>. IFN- $\alpha$  is an effective drug for the treatment of patients with chronic hepatitis B or C associated with liver fibrosis<sup>[19,20]</sup>. Recent studies suggest that IFNs not only block virus replication but also directly affect key functions

of activated HSCs. Thus, IFN- $\gamma$  inhibits HSC survival, cell proliferation and collagen synthesis<sup>[21-23]</sup>. The effects of IFNs on PSCs are largely unknown.

IFNs exert their biological effects on target cells by binding to cell surface receptors with specificity for either type I interferons (IFN- $\alpha$ , - $\beta$ , and - $\omega$ ) or type II interferon IFN- $\gamma$ <sup>[18,24]</sup>. In the transduction of signals from activated IFN-receptors to the nuclei, tyrosine kinases of the Janus family (JAKs) and signal transducer and activator of transcription (STAT) transcription factors play a key role<sup>[18,25]</sup>. IFN- $\alpha$  activates the JAK family proteins (JAK1 and TYK2) as well as the ISGF3 complex (consisting of STAT1, 2 and the IFN regulatory family protein p48)<sup>[26]</sup>. Although tremendous progress has been made, the molecular mechanisms underlying the growth-inhibitory action of these cytokines are only partially characterized so far.

This study was to analyze the biological effects of IFN- $\alpha$ , - $\beta$  and - $\gamma$  on PSCs and to study the molecular determinants of IFN efficiency.

## MATERIALS AND METHODS

### Materials

The enhanced chemiluminescence (ECL) plus kit, horseradish-peroxidase labeled antibodies and [<sup>3</sup>H]-proline were purchased from Amersham Biosciences (Freiburg, Germany), the phospho-STAT1 and STAT3 antibodies from New England Biolabs (Frankfurt, Germany), and anti-STAT1 and STAT3 protein antibodies from Santa Cruz Biotechnologies (Santa Cruz, CA, USA). Hank's buffered salt solution (HBSS), Iscove's modified Dulbecco's medium (IMDM) and all supplements for cell culture were obtained from Biochrom (Berlin, Germany), Nycodenz from Nycomed (Oslo, Norway), simvastatin from Merck Biosciences (Schwalbach, Germany) and the recombinant rat interferons from R&D Systems (Minneapolis, MN, USA). Ascorbat,  $\beta$ -aminopropionitrile and the  $\alpha$ -SMA antibody as well as standard laboratory chemicals were from Sigma-Aldrich (St. Louis, MO, USA).

### Cell culture

PSCs were isolated from the pancreas of male LEW.1W inbred rats by collagenase digestion of the organ and Nycodenz (120 g/L) density gradient centrifugation as previously described<sup>[13]</sup>. PSCs collected from the top of the gradient were washed and resuspended in IMDM supplemented with 170 g/L fetal calf serum (FCS), 10 mL/L non-essential amino acids (dilution of a 100  $\times$  stock solution), 10<sup>5</sup> U/L penicillin and 100 mg/L streptomycin. The cells were cultured at 37°C in a 50 mL/L CO<sub>2</sub> humidified atmosphere. All experiments were performed with cells growing in primary culture, or depending on the experimental settings, with cells of the first passage. If replating of the cells was required, PSCs were harvested by trypsinization on d 7 after isolation and recultured at equal seeding densities.

### Quantification of DNA synthesis

To quantitate cell proliferation, incorporation of

5-bromo-2'-deoxyuridine (BrdU) into newly synthesized DNA was measured using the BrdU labeling and enzyme-linked immunosorbent assay kit (Roche Diagnostics). Therefore, cells were plated in 96-well plates in complete culture medium supplemented with IFN as indicated. After 48 h, BrdU labeling was initiated by adding labeling solution at a final concentration of 20 mL/L. After another 16 h, labeling was stopped, and BrdU uptake was measured according to the manufacturer's instructions.

### Analysis of cellular DNA content by flow cytometry (sub-G<sub>1</sub>-peak)

Cells were grown to about 80% confluency and then incubated for 48 h in complete culture medium with or without IFN as indicated. Then the cells were harvested by trypsinization, washed twice with PBS and resuspended in 2 mL ice-cold 70% ethanol for at least 12 h at -20°C, washed again twice with PBS and incubated for 1 h in 400  $\mu$ L PBS containing 1 mL/L Tween 20 and 1 g/L RNase at room temperature. After the addition of 50  $\mu$ g propidium iodide/10<sup>6</sup> cells, samples were subjected to cytofluorometric analysis using an FACScan (Becton Dickinson) and the CellQuest program. Ten thousand events were measured for each sample and the data were stored in list mode for further analysis.

### Quantification of collagen synthesis

Collagen synthesis was assessed through the quantification of [<sup>3</sup>H]-proline incorporation into acetic acid-soluble proteins. Therefore, cells were plated in 12-well plates and grown to subconfluency. Afterwards, they were cultured for 48 h in complete culture medium supplemented with 2.5 mCi/L [<sup>3</sup>H]-proline (48 Ci/mmol), 50 mg/L ascorbate, 50 mg/L  $\beta$ -aminopropionitrile and IFN as indicated. All further steps were performed essentially as previously described<sup>[27]</sup>. Raw data of [<sup>3</sup>H]-proline incorporation were normalized on the basis of absolute cell counts determined by trypan blue staining of PSCs cultured in parallel under identical conditions, except that no [<sup>3</sup>H]-proline was added.

### Immunoblotting

Protein extracts of PSCs (pretreated as indicated) were prepared, adjusted to identical protein concentrations and subjected to immunoblot analysis as previously described<sup>[13]</sup>. Briefly, proteins (15  $\mu$ g/sample) were separated by SDS-polyacrylamide gel electrophoresis and blotted onto nitrocellulose membrane. Next, the filters were blocked with 1% bovine serum albumin (Sigma-Aldrich) and incubated with the indicated antibodies (diluted according to the manufacturer's instructions) overnight at 4°C. After a final incubation with a horseradish-peroxidase labeled anti-rabbit or anti-mouse Ig antibody for 2 h at room temperature, blots were developed using ECL. For reprobing with additional antibodies, membranes were stripped by incubation in stripping buffer (62.5 mmol/L Tris-HCl, pH 6.7, 20 g/L SDS, 100 mmol/L 2-mercaptoethanol) at 50°C for 30 min.

### Inhibition of STAT1 expression using siRNA

STAT1 siRNA was purchased from Qiagen (Hilden,

**Figure 1** Effects of interferons on PSC proliferation. PSCs growing in primary culture were harvested, replated at equal seeding densities in 96-well plates and treated with IFN-α, IFN-β and IFN-γ at the indicated concentrations for 48 h, the time when the fastest-growing cultures were almost confluent. Cell proliferation was assessed with the BrdU DNA-incorporation assay. One hundred percent cell proliferation corresponds to untreated PSCs. Data are presented as mean ± SE ( $n=6$  separate cell preparations from one rat). <sup>a</sup> $P<0.05$  vs control cultures. The results shown are representative of three experiments using cells from different rats.

**Figure 2** Effects of IFN and simvastatin on PSC survival. PSCs growing in 12-well plates were cultured with IFN-α (10<sup>6</sup> U/L), IFN-β (10<sup>6</sup> U/L), IFN-γ (100 μg/L) and simvastatin (Sim; 5 μmol/L) as indicated. To determine the percentage of cell death by flow cytometry analysis, cells with DNA content lower than the G<sub>1</sub> peak (sub-G<sub>1</sub>) were considered apoptotic. Data are indicated as mean ± SE ( $n=6$  separate cell preparations from one rat). <sup>a</sup> $P<0.05$  vs control cultures. Three experiments using cells from different rats yielded qualitatively identical results.

Germany) and applied according to the manufacturer's protocol for the transfection of adherent cells, using a 1:6 ratio of siRNA to RNAsFect Reagent. Efficiency of siRNA treatment was monitored by analyzing the STAT1 protein level at different times after siRNA application. To study the effects of STAT1 siRNA on PSC growth, cells growing in 96-well plates were pretreated with siRNA at 100 nmol/L for 24 h before IFN-γ was added as indicated. After 48 h of incubation, DNA synthesis was quantitated by the determination of BrdU incorporation into DNA as described above. In all the experiments, a non-silencing siRNA oligonucleotide was included as a negative control.

### Statistical analysis

Results were expressed as mean ± SE for the indicated

**Figure 3** IFN-γ inhibits expression of α-SMA in PSCs. Freshly isolated PSCs growing in 6-well plates were treated with IFN for 9 d as indicated. Cell lysates were normalized for protein concentration and resolved by SDS-PAGE. **A:** Expression of α-SMA assayed by immunoblotting; **B:** Blot stripped and reprobed with an anti-ERK 1/2 protein-specific antibody to control loading. Results are representative of three independent experiments.

number of separate cultures per experimental protocol. Statistical significance was checked using Wilcoxon's rank sum test.  $P<0.05$  was considered statistically significant.

## RESULTS

### Effects of IFNs on PSC functions

To analyze the effects of IFN-α, IFN-β and IFN-γ on PSC proliferation, DNA synthesis after IFN-pretreatment for 48 h was measured (Figure 1). Both IFN-β and IFN-γ inhibited DNA synthesis significantly and in a dose-dependent manner, causing more than 30% reduction at the highest concentration tested. In contrast, IFN-α even at the concentration of 10<sup>6</sup> U/L had no effect on PSC growth. To study if the inhibition of DNA synthesis was in fact due to the induction of apoptosis, an FACS analysis was performed (Figure 2). Under the experimental conditions tested, none of IFN-α, IFN-β or IFN-γ induced a significant increase of the sub-G<sub>1</sub> fraction (representing apoptotic cells). In contrast, PSCs treated with simvastatin significantly accumulated in the sub-G<sub>1</sub> fraction, confirming our previous results of pro-apoptotic effects of hydroxymethylglutaryl coenzyme A reductase inhibitors<sup>[28]</sup>.

Next, we asked how IFNs affect the myofibroblastic phenotype of activated PSCs. IFN-γ incubation for 9 d (starting immediately after isolation) was associated with a dose-dependent reduction of α-SMA protein expression (Figure 3), while the effect of IFN-β (at 10<sup>6</sup> U/L) remained questionable and IFN-α did not display any inhibitory effect at all. Further studies revealed that IFN-γ (at ≥ 1 μg/L) and IFN-β (at ≥ 10<sup>4</sup> U/L), but not IFN-α (at 10<sup>6</sup> U/L) significantly diminished collagen synthesis by PSCs (Figure 4). A further increase of IFN-γ and IFN-β concentrations had no additional effect (data not shown).

To correlate the biological effects of the three IFNs with their molecular action, we analyzed STAT protein activation in IFN-stimulated PSCs (Figure 5). IFN-β and IFN-γ induced a rapid and strong increase of STAT1 and STAT3 tyrosine phosphorylation, while IFN-α was much less effective.

In subsequent experiments, we further studied the role of STAT1 in the mediation of IFN-γ effects on

**Figure 4** Effects of IFNs on [<sup>3</sup>H]-proline incorporation in PSCs. PSCs growing in 12-well plates (one passage) were exposed for 48 h to IFNs as indicated. Collagen synthesis was analyzed through the quantification of [<sup>3</sup>H]-proline incorporation into acetic acid-soluble proteins, and raw data were normalized for differences in cell growth rates as described under "Materials and methods". One hundred percent [<sup>3</sup>H]-proline incorporation corresponds to untreated PSCs. Data are presented as mean ± SE (*n* = 6 separate cell preparations from one rat). <sup>a</sup>*P* < 0.05 vs control cultures. The results shown are representative of three experiments using cells from different rats.

**Figure 5** Tyrosine phosphorylation of STAT1 and STAT3 in PSCs induced by IFN. PSCs growing in 6-well plates (one passage) were treated with IFN-α (10<sup>6</sup> U/L), IFN-β (10<sup>6</sup> U/L) and IFN-γ (100 μg/L) as indicated. Cell lysates were normalized for protein concentration and resolved by SDS-PAGE. **A:** Tyrosine phosphorylation of STAT1 analyzed by immunoblotting using an antibody specific for the tyrosine-phosphorylated protein (upper panel). To control loading, the blot was stripped and reprobed with an anti-STAT1 protein-specific antibody (lower panel); **B:** Immunoblot analysis performed using an antibody specific for tyrosine-phosphorylated STAT3 (upper panel) and the blot stripped and reprobed with an anti-STAT3 protein-specific antibody (lower panel). Results are representative of three independent experiments.

PSC growth. As shown in Figure 6A (upper panel), STAT1 siRNA treatment caused a marked decrease of the STAT1 protein level. Expression of ERK 1 and 2 remained unchanged (lower panel), suggesting that the siRNA inhibited STAT1 expression in a specific manner. Downregulation of the STAT1 protein level was associated with a significant attenuation of the growth-inhibitory effect of IFN-γ (Figure 6B).

**Figure 6** Effects of STAT1 siRNA on PSC growth. **A:** Expression of STAT1 in PSCs 5 d after STAT1 siRNA application determined by immunoblot analysis as well as ERK 1 and 2 expression analyzed using an anti-ERK 1/2 protein-specific antibody; **B:** PSCs treated with STAT1 siRNA and IFN-γ as indicated and control cultures were exposed to a non-silencing control oligonucleotide at the same concentration. PSC proliferation was analyzed through the determination of BrdU incorporation into newly synthesized DNA as described in the section "Materials and methods". One hundred percent cell proliferation corresponds to PSCs treated with control oligonucleotide (left two columns) or STAT 1 siRNA (right two columns) in the absence of IFN-γ. Data are presented as mean ± SE (*n* = 7 separate cell preparations from one rat). <sup>a</sup>*P* < 0.05 vs IFN-γ-treated control cultures. The results shown are representative of three experiments using cells from different rats.

## DISCUSSION

Chronic pancreatitis is associated with an extended fibrosis that contributes to the development of an exocrine and endocrine insufficiency of the gland. Excessive deposition of connective tissue is also typical of pancreatic cancer and has been implicated in the acceleration of tumor progression<sup>[29]</sup>. In both cases, activated PSCs have been identified as the principle ECM-producing cell type<sup>[3,7,30]</sup>. PSCs are therefore considered as a promising target for the development of adjuvant therapies aimed at inhibiting pancreatic fibrogenesis.

The results of this study showed that IFNs displayed direct inhibitory effects on key effector functions of activated PSCs. While both IFN-γ and IFN-β diminished PSC proliferation and collagen synthesis, only IFN-γ efficiently reduced the expression of α-SMA, an indicator of myofibroblastic transdifferentiation. The effects of IFN-α remained insignificant. Whether the latter observation could reflect a peculiarity of the *in vitro* model used in this study, or a general phenomenon of PSC biology, is currently unclear.

The findings described here are largely in agreement with the results of studies on hepatic stellate cells which also showed direct, but distinct inhibitory effects of different IFNs on stellate cell activation. Shen *et al.*<sup>[21]</sup> observed that HSC proliferation is attenuated by IFN-β

and IFN- $\gamma$ , but not by IFN- $\alpha$ . On the other hand, under the experimental conditions used in this study no significant effects of IFNs on cell survival were detected, while in HSCs pro-apoptotic effects of IFN- $\gamma$  and an anti-apoptotic action of IFN- $\alpha$  have been reported<sup>[23]</sup>.

Targeted gene disruption studies have shown that the transcription factor STAT1 plays an essential, non-redundant role in IFN-mediated innate immunity to viral diseases<sup>[31,32]</sup>. Analyzing possible functions of STAT proteins in PSCs, we found a correlation between the efficiency of the different IFNs to inhibit stellate cell functions and their potential to activate STAT1 (as well as STAT3). Further experiments using an siRNA approach to block STAT1 expression revealed a direct involvement of the transcription factor in PSC growth inhibition by IFN- $\gamma$ . The precise functions of STAT3 in PSCs remain to be characterized.

Previous studies in our laboratory have shown that IFN- $\gamma$  in PSCs stimulates the expression of interleukin (IL)-15. In a co-culture model of rat PSCs and lymphocytes, a suppression of spontaneous lymphocyte apoptosis has been observed, which is at least in part mediated by IL-15<sup>[33]</sup>. Together, these data and the results of this study suggest a complex role of IFN- $\gamma$  in the modulation of pancreatic inflammation and fibrosis. It is conceivable that IFN- $\gamma$  displays distinct net effects on the progression of chronic pancreatitis, depending on the activation of auto-reactive lymphocytes and possibly the stage of the disease. To further elucidate the effects of IFN- $\gamma$  on pancreatic fibrogenesis, *in vivo* studies using animal models of pancreatic fibrosis are required.

In summary, the discovery of direct inhibitory IFN-effects on PSC activation encourages further studies with respect to IFN efficiency in chronic pancreatitis. Currently, we are also focusing on a systematic evaluation of IFN target genes in stellate cells.

## Abstract

**AIM:** To approach the elusive function of the SLA/LP molecule, we have characterized genomic organization and conservation of the major antigenic and functional properties of the SLA/LP molecule in various species.

**METHODS:** By means of computational biology, we have characterized the complete SLA/LP gene, mRNA and deduced protein sequences in man, mouse, zebrafish, fly, and worm.

**RESULTS:** The human SLA/LP gene sequence of approximately 39 kb, which maps to chromosome 4p15.2, is organized in 11 exons, of which 10 or 11 are translated, depending on the splice variant. Homologous molecules were identified in several biological model organisms. The various homologous protein sequences showed a high degree of similarity or homology, notably at those residues that are of functional importance. The only domain of the human protein sequence that lacks significant homology with homologous sequences is the major antigenic epitope recognized by autoantibodies from autoimmune hepatitis (AIH) patients.

**CONCLUSION:** The SLA/LP molecule and its functionally relevant residues have been highly conserved throughout the evolution, suggesting an indispensable function of the molecule. The finding that the only non-conserved domain is the dominant antigenic epitope of the human SLA/LP sequence, suggests that SLA/LP autoimmunity is autoantigen-driven rather than being driven by molecular

## INTRODUCTION

Autoantibodies to soluble liver antigen (SLA)<sup>[1]</sup> and to liver/pancreas (LP)<sup>[2]</sup> have been described as specific markers for autoimmune hepatitis<sup>[3]</sup>. Recently, identity of the SLA and LP antigens has been demonstrated, and the target antigen of SLA/LP autoantibodies has been cloned<sup>[4]</sup>. Using the recombinant SLA/LP molecule, the strict specificity of SLA/LP autoantibodies as markers for AIH has been confirmed<sup>[5]</sup>.

The primary biological function of SLA/LP remains unclear. Because the SLA/LP molecule was found to be associated with the UGA tRNP(Ser)Sec complex<sup>[6,7]</sup>, which facilitates the co-translational incorporation of selenocysteine into proteins, it has been speculated that the SLA/LP molecule may have a role in selenoprotein metabolism; the specialized UGA tRNA is initially charged with serine to form seryl-tRNA, which then is enzymatically converted to selenocysteine-tRNA<sup>Sec</sup>. However, there is no direct experimental evidence for such a role of the SLA/LP molecule so far. Nevertheless, a fold recognition study predicted the SLA/LP tertiary structure by comparison to known protein structures to be that of a pyridoxal phosphate (PLP)-dependent transferase<sup>[8]</sup>, which is compatible with a role in selenoprotein metabolism. The active site was proposed to be a cavity with a channel, formed by dimerization of two SLA/LP molecules<sup>[8,9]</sup>. In the three-dimensional model, five amino acids of monomer A (L88, T89, F92, T94, and S118) as well as two amino acids of monomer B (P251 and G252) were involved in dimerization and the amino acids critical for binding and orientation of the co-enzyme PLP were

identified to be G50, S51, S165, D186, H189, K224<sup>[8]</sup> (residue numbering according to GenBank accession number NP\_722547).

The immune mechanisms that drive SLA/LP autoimmunity and the pathogenetic relevance of autoimmunity to SLA/LP are currently not clear. The main antigenic region crucial for the recognition of SLA/LP autoantibodies was identified to locate between amino acids 390 and 428<sup>[4,10]</sup>, thus being easily accessible by antibodies<sup>[8]</sup>. This region contains sequence homologies with various microbial antigens, including proteins of Rickettsia species, human herpesvirus 6, and cytomegalovirus<sup>[4]</sup>; however, the homologous microbial sequences are only poorly recognized by SLA/LP autoantibodies<sup>[10]</sup>. Nevertheless, molecular mimicry of homologous proteins from other species, such as parasites, may be a trigger of SLA/LP autoimmunity.

Due to the human genome project and other genomic sequencing groups, sequences of many different species are now publicly available. While some chromosomes are completely assembled, most genomic fragments are currently still preliminary and await characterization. To approach the elusive biological function of the SLA/LP molecule, we have characterized here the human SLA/LP gene and homologous sequences of other species by means of computational biology. The obtained results support the hypothesis that SLA/LP autoimmunity is autoantigen-driven rather than being driven by molecular mimicry<sup>[10]</sup>.

## MATERIALS AND METHODS

### Identification of the human SLA/LP gene

We have previously identified the human SLA/LP protein and deposited the corresponding mRNA sequence into the GenBank<sup>[11]</sup> with the accession numbers NM\_016955 and NM\_153825. BLASTing the human mRNA sequence against the human genome draft sequence revealed the genomic localization<sup>[12,13]</sup>.

### Identification of SLA/LP homologs in other species

Homologs corresponding to the human SLA/LP were identified by BLAST query with the human SLA/LP protein sequence (NP\_722547) against the non-redundant databases of mouse (*Mus musculus*), zebrafish (*Danio rerio*), fruit fly (*Drosophila melanogaster*) and the nematode worm (*Caenorhabditis elegans*).

### Exon/intron structure and chromosomal localization

Exon/intron structure and chromosomal localization were identified by BLASTing the SLA/LP mRNA sequences of each homolog against the corresponding genome draft sequences of the particular species.

### Locus analysis

Data regarding the genomic loci analysis were obtained from the GenBank<sup>[11]</sup>.

### Analysis of protein structure and conservation

The amino acid sequence was deduced from the

**Figure 1** Organization of SLA/LP genes in man and mouse. The exon/intron structure of the human and mouse SLA/LP gene is represented schematically. Exon sequences (numbered boxes) are highly conserved and of similar size and number in man and mouse. Intron sequences, marked as lines, differ in both species.

obtained mRNA sequences. The alignment of SLA/LP homologous sequences was initially performed using the ClustalW algorithm<sup>[14]</sup>. The sequence alignments in Figure 3 were performed using the longer human SLA/LP variant (CAB89517). The theoretical isoelectric point and molecular weight was calculated with the pI/Mw tool on the Expasy server<sup>[15,16]</sup>. Protein structures and domains were analyzed using two independent algorithms, Pfam<sup>[17]</sup> and NCBI Conserved Domain Search<sup>[18]</sup>.

## RESULTS

### Human SLA gene and corresponding mRNA and protein sequences

We have previously submitted the human mRNA sequences of two alternative splice variants of SLA/LP to GenBank with the accession numbers NM\_016955 and NM\_153825. Using the human SLA/LP protein sequence as a query for BLAST searches against the human mRNA database, additional matching mRNA sequences (splice variants) were not identified. Matching the human mRNA sequence to the available human genomic draft sequence (htgs), the corresponding gene was mapped to chromosome 4p15.2. The gene was found to span a genomic region of approximately 39 kb and to be organized in 11 exons (Figure 1). Most exon sizes were rather small, ranging between 91 and 187 bp, with the exception of exon 11 at the 3' end, which covered 3 224 bp. The two splice variants were fully identical, except for the absence of exon 2 (149 bp) in the shorter variant. Both variants have a large 2 930 bp 3' untranslated region; the 5' untranslated region of the two variants is relatively short with 155 and 174 bp, respectively. The amino acid sequences of the two splice variants, as deduced from their mRNA sequence, differ only in their amino-terminal residues (Figure 2). The theoretical molecular weight and isoelectric point of the longer splice variants is 48.84 kDa and 8.64, respectively; that of the shorter variant is 46.85 kDa and 8.52, respectively.

### Mouse SLA gene and corresponding mRNA and protein sequences

The SLA/LP gene and genomic organization was highly conserved in mouse. BLASTing the human SLA/LP protein sequence against the mouse protein database, revealed a mouse homolog with the accession number NP\_766078. The human and mouse SLA/LP protein sequences are identical at 85% of the residues (Figure 2). Both, the NCBI and Pfam conserved protein domain

**Figure 3** Alignment of SLA/LP protein sequences. The SLA/LP amino acid sequences of various eukaryotic species were aligned by ClustalW. The presumed residues that mediate binding to the cofactor pyridoxal phosphate are highlighted in bold and underlined; residues that function in dimerization are highlighted in bold and italic. The immunodominant epitope sequence (390-428) of the human SLA/LP protein is marked in bold.

**Figure 4** Chromosomal localization of SLA/LP genes. The genes adjacent to the SLA/LP loci on human chromosome 4, mouse chromosome 5, fly chromosome 3R, and worm chromosome V are represented schematically.

algorithms, predicted the existence of SLA/LP structure between amino acids 61 and 458 and amino acids 61 and 459, respectively. BLASTing the protein sequence against the translated mouse genome database revealed the corresponding mRNA NM\_172490.1. BLASTing the mRNA sequence against the draft sequence of the mouse genome, the corresponding SLA/LP gene was mapped to mouse chromosome 5qC1. The genomic region spanned 28.5 kb and the mouse SLA/LP gene was organized into 11 exons like the human homolog (Figure 1). Exon sizes ranged between 91 and 2 927 bp with exon 11 being by far the largest exon. The 3' untranslated region was 2 629 bp and the 5' untranslated region was 19 bp. Although not filed in the GenBank, two murine splice variants are very likely; the mouse genomic organization and exon sequences are very similar to the human gene and a splicing signature similar to that in human beings is present in the homologous mouse sequence. The presumed splice variants in the mouse are shown in Figure 2, aligned to the corresponding human proteins. The theoretical molecular weight and isoelectric point of the longer splice variants is 48.48 ku and 8.86, respectively; that of the shorter variant is 46.5 ku and 8.71, respectively.

#### **Zebrafish SLA gene sequence and corresponding mRNA**

The SLA gene and genomic organization was highly conserved in fish. BLASTing the human SLA/LP protein sequence against the zebrafish protein database, revealed a homolog with the accession number NP\_956448. The zebrafish sequence was identical to the human protein sequence in 69% of the residues. Both, the NCBI and Pfam conserved protein domain algorithms, predicted the existence of SLA/LP structure between amino acids 61 and 459. BLASTing the protein sequence against the translated zebrafish genome database revealed the corresponding mRNA NM\_200154. Chromosomal mapping was not possible, since the genomic fragment containing the SLA/LP sequence was not yet assembled into the genomic context. The corresponding gene could only be mapped to the fragment scaffold Zv4\_NA8411.1. Thus a complete exon/intron structure was not yet available, and potential splice variants could not be identified.

#### **Drosophila SLA gene sequence and corresponding mRNA**

The SLA gene and genomic organization were also

conserved in *Drosophila*. BLASTing the human SLA/LP protein sequence against the *Drosophila* protein database revealed a *Drosophila* homolog (two isoforms) with the accession numbers AAF51994 and AAS65099. The *Drosophila* protein sequence has 42% identity compared to the human protein sequence. However, this may be an underestimation, as it remains unclear whether the recently annotated *Drosophila* SLA/LP sequence is complete. Both, the NCBI and Pfam conserved protein domain algorithms predicted the existence of SLA/LP structure between amino acids 61 and 413 and amino acids 61 and 428, respectively. BLASTing the protein sequence against the translated *Drosophila* genome database revealed the corresponding mRNA NM\_141299.1. BLASTing the mRNA sequence against the draft sequence of the fruit fly genome, the corresponding SLA/LP gene was mapped to *Drosophila* chromosome 3R. The genomic region of the currently annotated *Drosophila* SLA/LP gene spanning approximately 1.6 kb was found to be organized into (at least) 4 exons. Exon sizes ranged between 114 and 1 021 bp with exon 3 being by far the largest exon. A short 3' UTR was shown to consist of 115 bp. Thus far, a 5' UTR was not identified.

#### ***C. elegans* SLA/LP gene sequence and corresponding mRNA**

The SLA/LP gene and genomic organization were also conserved in *C. elegans*. BLASTing the human SLA/LP protein sequence against the *C. elegans* protein database revealed similarity to *C. elegans* protein D1054.13 with the accession number CAA98446. The *C. elegans* protein sequence had 42% identity compared to the human protein sequence. Again, both the NCBI and Pfam conserved protein domain algorithms predicted the existence of SLA/LP structure between amino acids 53 and 450. BLASTing the protein sequence against the translated *C. elegans* genome database revealed the corresponding mRNA NM\_073360. BLASTing the mRNA sequence against the draft sequence of the *C. elegans* genome, the corresponding SLA/LP gene was mapped to *C. elegans* chromosome V. The genomic region spanned 1.8 kb and the *C. elegans* SLA/LP gene was organized in 7 exons. Exon sizes ranged between 67 bp for exon 3 and 636 bp for exon 5. A rather short 5' UTR contained 43 bp, a 3' UTR could not be found in the currently available sequence. Thus, it remains unclear, whether the currently available sequence represents the complete protein sequence of *C. elegans*.

#### **Conservation of SLA/LP homologs**

We aligned the protein sequences of the SLA/LP homologs in human, mouse, fish, fly, and worm (Figure 3). The mammalian sequences were the two closest related sequences. The invertebrate sequences of *Drosophila* and *C. elegans* sequence were most closely related to each other; the zebrafish sequence was equally related to the mammalian and invertebrate sequences.

#### **Chromosomal localization of the human, mouse, fly, and worm SLA/LP genes**

We then studied the neighboring genes in man, mouse, fly, and worm (Figure 4). Upstream of the human SLA/

LP sequence on human chromosome 4 was the gene for extracellular-superoxide dismutase 3<sup>[19]</sup> and the Leucine rich gene, glioma-inactivated 2<sup>[20]</sup>. Downstream of the SLA/LP locus was the phosphatidylinositol 4-kinase type-II beta (PI4K2B)<sup>[21]</sup> and anaphase promoting complex, subunit 4<sup>[22]</sup>. The same structure was found for mouse chromosome 5 that contains the murine SLA/LP locus. The genomic structure of SLA/LP loci in fly and worm did not share these similarities to the mammalian genomes. The fly SLA/LP homolog was flanked by the gene *eIF-5C*, which is involved in long-term memory<sup>[23]</sup> and the gene for a 26 ku E-subunit of the vacuolar ATPase<sup>[24]</sup>, upstream of the SLA/LP locus. Two currently uncharacterized genes, Rga-RA (account number AAF51992) and Atu (account number AAF51991), are located downstream of the fly SLA/LP gene. The worm SLA/LP sequence was flanked by a gene (5L286) encoding protein of unknown function, upstream, and the serpentine receptor class H (srh-184)<sup>[25]</sup>, downstream of the SLA/LP locus.

### Conservation of the main antigenic region and main structural features of folding and dimerization

The dominant autoepitope of SLA/LP autoantibodies had been identified to locate between amino acids 390 and 428 of the longer human SLA/LP protein sequence variant (NP\_722547)<sup>[4,10]</sup>. After aligning the homologous protein sequences (Figure 3), we studied the degree of sequence conservation in the immunodominant antigenic region. Human and mouse sequences showed 57% identity and 71% similarity. All other sequences did not display a considerable level of similarity compared to the human epitope sequence.

We then studied the conservation of the residues that seem to function in protein folding and dimerization<sup>[8]</sup> (Figure 3). The lysine residue at position 224, which is crucial for covalent binding of the coenzyme PLP (pyridoxal-5'-phosphate) was conserved in all homologous sequences investigated. Of the other five residues directly in contact with PLP, G50, S51, and H189 were identical in all the homologs, whereas S165 was replaced by alanine in mouse and D186 was replaced by glutamine in *Drosophila* and aspartic acid in *C. elegans*. Of the residues of monomer A involved in dimerization, only L88 was conserved in all homologous sequences. T89 was conserved in most species, but replaced by serine in *C. elegans*. F92 was replaced by leucine in *Drosophila* and by methionine in *C. elegans*, and otherwise conserved. T94 was conserved in vertebrates, but replaced by serine in non-vertebrates. S118 was replaced by arginine in *Drosophila*. The contact residues of monomer B, P251 and G252, which mediate dimerization, were conserved in all the species.

## DISCUSSION

SLA/LP autoantibodies have been demonstrated to be highly specific markers of autoimmune hepatitis<sup>[4,5]</sup>. A role of SLA/LP autoimmunity in the pathogenesis of AIH is likely, at least in a subgroup of AIH patients. However, our current understanding of both, immunogenicity and biological function of the SLA/LP molecule is rather limited. To approach the elusive function and

immunogenicity of SLA/LP, we have characterized the genomic organization and sequence conservation of the human SLA/LP molecule and homologous proteins in other eukaryotic species.

For all homologs, mRNA and genomic sequences were available from the GenBank<sup>[12]</sup>. However, in contrast to human and mouse protein and mRNA sequences, which seemed to be complete, some genomic sequences have yet to be completely assembled, and thus did not allow for complete and final characterization of the genomic organization. This was especially the case for fish, where no chromosomal assignment could be made. Nevertheless, genomic characterization in man, mouse, fly, and worm was possible.

The two mammalian SLA/LP genes were similar in organization of the exon/intron structure (Figure 1) and genomic localization (Figure 4); exon/intron structure and genomic localization in fish, fly, and worm was clearly different from the mammalian sequences. Nevertheless, all homologs displayed a high degree of similarity and identity in their amino acid sequences (Figure 3). The similarity between the most distant species - man and worm - was as high as 42%. The highest degree of similarity was found between the human and the mouse amino acid sequences (Figure 2); both species also have a highly similar exon/intron structure in the SLA/LP gene (Figure 1). Moreover, both mammalian species seem to generate similar variant proteins (Figure 2) by differential splicing of exon 2. Whether splice variants exist in non-mammalian species is currently not clear. Previously, the residues, which seem to mediate dimerization and binding of PLP, have been identified by molecular modeling<sup>[8]</sup>. These residues are highly conserved among the various species studied (Figure 3). Four of six residues that are crucial for PLP-binding are identical in all the species (G50, S51, H189, K224); the other two residues are homologous (S/A165, D/Q185). Two of the seven residues that mediate dimerization were identical in all the studied species (L88, G252), the other residues were equivalent (T/S89, T/S94, S/A118, P/A251), except for F92, which was conserved in man, mouse and fish, but substituted by leucine in fly and methionine in worm.

The query of human protein databases with the human SLA/LP sequence did not reveal any functional homologs to other proteins and the primary biological function of the SLA/LP protein remains unclear. However, the extraordinary degree of conservation, notably of the presumed functional residues, suggests that the SLA/LP protein has an important biological function that relies on PLP binding. The possible role of the smaller splice variant remains obscure. It may be speculated that the smaller protein variant may act as an inhibitor of the elusive function of the larger variant; the molecular signature of the smaller variant is not compatible with a PLP-dependent transferase, as predicted for the larger variant<sup>[8]</sup>.

The autoimmune response to SLA/LP is not random, but displays a remarkable degree of uniformity: SLA/LP autoantibodies are of a preferred dominant subtype (IgG1) and recognize the same dominant antigenic region, which was mapped to a carboxy-terminal domain between residues 399 and 428 of the longer splice variant (accession

number NP\_722547)<sup>[10]</sup>. Thus, SLA/LP autoimmunity has features of a highly selected immune response and seems to be driven by the same mechanism in all the patients. Of note, the antigenic region is located within the only domain of the molecule that was not conserved among the various species (Figure 3). Thus, it appears that SLA/LP autoimmunity is specific for the self-antigen and not for homologous sequences from other eukaryotic species. The possibility that SLA/LP autoimmunity might be driven by homologous proteins from parasites is hence quite unlikely. SLA/LP-homologous proteins are only found in eukaryotes and archaeobacteria, but not in eubacteria<sup>[10]</sup>. Nevertheless, a few homologous sequences from bacterial or viral proteins with some degree of similarity to the antigenic epitope of the SLA/LP protein do exist; however, these are not recognized by SLA/LP autoantibodies<sup>[10]</sup>. Likewise, the corresponding sequence of an archaeobacterial SLA/LP-homolog is also not recognized by SLA/LP autoantibodies<sup>[10]</sup>. Therefore, SLA/LP autoimmunity in patients is very likely driven by the self-SLA/LP molecule rather than by a mechanism that involves molecular mimicry.

### Abstract

**AIM:** Chronic organ-donor shortage has led to the acceptance of steatotic livers for transplantation, despite the higher risk of graft dysfunction or nonfunction associated with the ischemic preservation period of these organs. The present study evaluates the effects of trimetazidine (TMZ) on an isolated perfused liver model.

**METHODS:** Steatotic and non-steatotic livers were preserved for 24 h in the University of Wisconsin (UW) solution with or without TMZ. Hepatic injury and function (transaminases, bile production and sulfobromophthalein (BSP) clearance) and factors potentially involved in the susceptibility of steatotic livers to ischemia-reperfusion (I/R) injury, including oxidative stress, mitochondrial damage, microcirculatory diseases, and ATP depletion were evaluated.

**RESULTS:** Steatotic livers preserved in UW solution showed higher transaminase levels, lower bile production and BSP clearance compared with non-steatotic livers. Alterations in perfusion flow rate and vascular resistance, mitochondrial damage, and reduced ATP content were more evident in steatotic livers. TMZ addition to UW solution reduced hepatic injury and ameliorated hepatic functionality in both types of the liver and protected against the mechanisms potentially responsible for the poor tolerance of steatotic livers to I/R.

**CONCLUSION:** TMZ may constitute a useful approach in fatty liver surgery, limiting the inherent risk of steatotic liver failure following transplantation.

### INTRODUCTION

The mounting number of patients awaiting liver transplantation and the limited pool of donor organs have led to the acceptance of marginal livers such as steatotic livers, for transplantation, despite the higher risk of graft dysfunction or nonfunction which is associated with their ischemic preservation<sup>[1-3]</sup>.

There is evidence indicating that the composition of preservation solutions is critical for the quality of livers kept for prolonged ischemic periods. University of Wisconsin (UW) preservation solution, considered as the gold standard of such solutions, has proved itself effective in preventing liver damage during cold ischemia and has extended storage time limits<sup>[4,5]</sup>. However, irreversible injury occurring after prolonged cold periods (between 16 and 24 h) has also been reported. The main aims of organ preservation, therefore, are striving to prolong organ tolerance<sup>[6,7]</sup>.

Trimetazidine (TMZ), introduced as an anti-ischemic drug into the heart for over 35 years<sup>[8,9]</sup>, has also been used to protect kidneys exposed to the prolonged cold ischemia (48 h)<sup>[10,11]</sup> and is reported to protect liver against the deleterious effects of warm ischemia<sup>[12,13]</sup>. In addition, recently, it has been demonstrated that TMZ pre-treatment reduces liver injury and improves liver regeneration and survival rate in an experimental model of partial hepatectomy under hepatic blood inflow occlusion<sup>[14]</sup>. Studies examining the underlying protective mechanisms of TMZ suggest that this drug protects mitochondria in cardiomyocytes and isolated perfused heart by releasing the calcium accumulated in the matrix and by restoring mitochondrial membrane impermeability<sup>[8,15]</sup>. TMZ improves energy recovery *in vitro* and *ex vivo* in models of myocardial ischemia<sup>[8,15]</sup> and reduces oxidative stress

in the liver under warm ischemia<sup>[12]</sup>. Additionally, TMZ improves microcirculatory alterations in isolated perfused rat kidneys<sup>[10]</sup>. Taken together, these findings suggest that mitochondria, energy metabolism, oxidative stress, and microcirculation might be important targets through which TMZ exerts its cytoprotective effect. Interestingly, severe mitochondrial damage<sup>[16,17]</sup>, decreased ATP level<sup>[16,18]</sup>, increased reactive oxygen species (ROS) production<sup>[19,20]</sup>, and impaired microcirculation<sup>[21,22]</sup> have also been proposed as factors that might leave steatotic livers vulnerable to ischemia–reperfusion (I/R) injury. Taking these previous observations into account, here we report the results of a study aimed at investigating whether the addition of TMZ to the standard preservation solution (UW) protects steatotic liver grafts against the deleterious effects of I/R injury.

## MATERIALS AND METHODS

Homozygous (obese, Ob) and heterozygous (lean, Ln) Zucker rats (used as reference group), aged 16–18 wk, were purchased from Iffa-Credo (L'Arbresle, France)<sup>[19,20]</sup>. In this study we used isolated perfused rat liver. It is a useful experimental system for evaluating hepatic function, isolated from the influence of other organ systems, undefined plasma constituents, and neural-hormonal effects. Hepatic architectures, microcirculation, and bile production were preserved in this experimental model<sup>[23,24]</sup>. All procedures were performed under isoflurane inhalation anesthesia. This study respected the European Union regulations (Directive 86/609 EEC) for animal experiments.

### Liver procurement and experimental groups

The surgical technique was performed as described elsewhere<sup>[25]</sup>. After cannulation of the common bile duct, the portal vein was isolated, and the splenic and gastroduodenal veins were ligated. The steatotic and non-steatotic livers were flushed and preserved in cold UW solution for 24 h with or without the addition of TMZ (10<sup>-6</sup> mol/L). This dose of TMZ has been shown to be beneficial in various experimental models of I/R<sup>[10,26,27]</sup>. At higher concentration, TMZ exerted no protective effect<sup>[28]</sup>. TMZ was kindly supplied by the Institut de Recherches Internationales Servier (Courbevoie, France).

### Protocol 1: Effect of TMZ on steatotic liver injury after cold ischemia

After 24 h of cold storage, livers from 16 Zucker rats (8 Ln and 8 Ob) preserved in UW solution (UW) and livers from 16 Zucker rats (8 Ln and 8 Ob) preserved in UW solution with TMZ (UW+TMZ) were flushed with Ringer's lactate solution. The aliquots of the effluent flush were sampled for the measurements of cumulative ALT and AST after prolonged ischemia.

### Protocol 2: Effect of TMZ on steatotic liver injury after normothermic reperfusion

After 24 h of cold preservation, and in order to account for the period of rewarming during surgical implantation *in vivo*<sup>[29,30]</sup>, livers from 16 Zucker rats (8 Ln and 8 Ob)

preserved in UW solution and livers from 16 Zucker rats (8 Ln and 8 Ob) preserved in UW+TMZ solution were exposed at 22 °C for 30 min prior to reperfusion. Livers were then connected via the portal vein to a recirculating perfusion system for 120 min at 37 °C<sup>[6,25]</sup>. Time 0 was the point at which the portal catheter was satisfactorily connected to the circuit. As previously reported<sup>[25,31]</sup>, during the first 15 min of perfusion (initial equilibration period), the flow was progressively increased in order to stabilize the portal pressure at 12 mmHg (Pressure Monitor BP-1, Instruments, Inc., Sarasota, FL, USA). The flow was controlled using a peristaltic pump (Minipuls 3, Gilson, France)<sup>[6,25]</sup>. The reperfusion liquid consisted of a cell culture medium (William's medium E, BioWhittaker, Spain) with a Krebs-Henseleit-like electrolyte composition enriched with 5% albumin, as oncotic supply. The buffer was continuously ventilated with 95% O<sub>2</sub> and 50 mL/L CO<sub>2</sub> gas mixture. The buffer was subsequently passed through a heat-exchanger (37 °C) and a bubble trap prior to entering the liver<sup>[25,30]</sup>. During 120 min of normothermic reperfusion, the effluent fluid was collected at 30 min intervals to measure transaminases. After the initial equilibration period of 15 min, flow rate and vascular resistance were assessed continuously throughout the reperfusion period. Bile output and hepatic clearance (expressed as percentage of BSP in bile samples) were determined at 120 min of reperfusion. ATP, adenine nucleotides, and lipid peroxidation were evaluated in the liver samples at 120 min of reperfusion. Light/electron microscopy analysis of the liver was also performed at 120 min of reperfusion.

### Biochemical determinations

**Transaminase assay** Hepatic injury was evaluated according to transaminase levels using commercial kit from Boehringer Mannheim (Munich, Germany).

**Nucleotide analysis** Livers were homogenized in perchloric acid solution, and the adenine nucleotides pool was measured by high-performance liquid chromatography<sup>[32]</sup>.

**Bile output** Liver function was assessed by measuring bile production<sup>[33,34]</sup>. Bile was collected through the cannulated bile duct and output reported as  $\mu\text{L/g liver}$ .

**Hepatic clearance** As with bile output, hepatic clearance was considered as another parameter of hepatic function<sup>[35,36]</sup>. Thirty minutes after the onset of the perfusion ( $t_{30}$ ), 1 mg of BSP (Sigma, Spain) was added to the perfusate. The concentration of BSP in bile samples ( $t_{20}$ ) was measured at 580 nm with an UV-visible spectrometer. Bile BSP excretion was expressed as a percentage of perfusate content ( $t_{20} \text{ bile} / t_{30} \text{ perfusate} \times 100$ )<sup>[35,36]</sup>.

**Flow rate and vascular resistance** Liver circulation was assessed by measuring perfusion flow rate and vascular resistance<sup>[34,37]</sup>. Perfusion flow rate was assessed continuously throughout the reperfusion period and expressed as mL/min g. Vascular resistance was defined as the ratio of portal venous pressure to flow rate and expressed in mmHg min g/mL<sup>[34,37]</sup>.

**Lipid peroxidation assay** Lipid peroxidation was used as an indirect measure of the oxidative injury induced by ROS<sup>[19,38]</sup>. Lipid peroxidation was determined by measuring

**Figure 1** AST (A) and ALT (B) levels in flushing effluent after 24-h cold storage. UW: liver preserved in UW solution; UW+TMZ: liver preserved in UW with TMZ. <sup>a</sup> $P < 0.05$  vs UW.

the formation of malondialdehyde (MDA) with the thiobarbiturate reaction<sup>[19]</sup>.

### Light/electron microscopy

For light microscopy examinations, liver samples were fixed in 10% neutral buffered formalin and embedded in Paraplast, and 5- $\mu$ m sections were stained with hematoxylin and eosin according to standard procedures<sup>[19]</sup>. For electron microscopy, the fixation of hepatic tissue was performed using a 2.5% glutaraldehyde/2% paraformaldehyde. These samples were post-fixed with osmium tetroxide and potassium ferrocyanide, dehydrated in acetone, and embedded in Spurr's medium. Ultrathin sections were prepared with an ultracut-E ultramicrotome and contrasted with uranyl acetate and lead citrate. Stained sections were reviewed under an H 600-AB Hitachi electron microscope<sup>[39]</sup>.

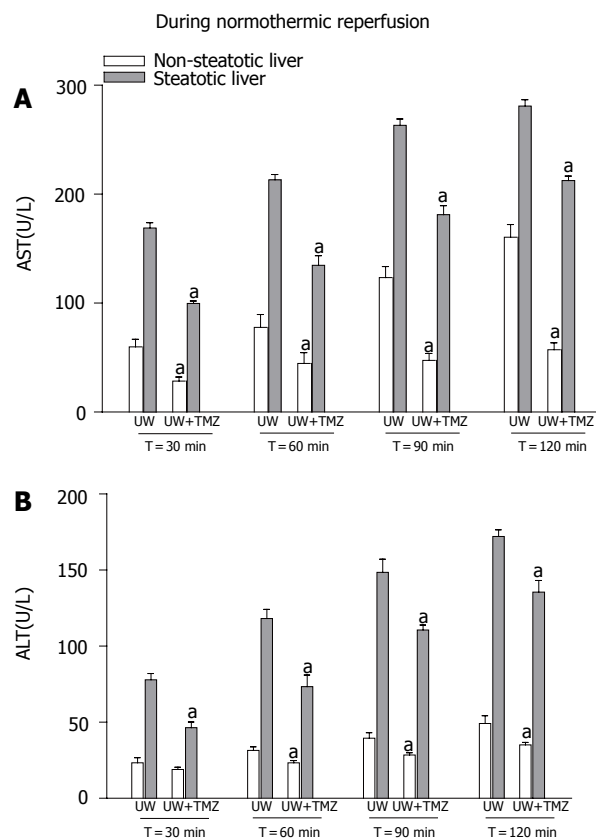

### Statistics

Data were expressed as mean $\pm$ SE, and were compared statistically by variance analysis, followed by Student-Newman-Keuls test.  $P < 0.05$  was considered significant.

## RESULTS

### Protocol 1: Effect of TMZ on steatotic liver injury after 24 h of cold ischemia

Flushing of livers before reperfusion allowed effluent fluid to collect for the determination of transaminases<sup>[6,40]</sup>. This

**Figure 2** AST (A) and ALT (B) levels in perfusate after 30, 60, 90, and 120 min of normothermic reperfusion. UW: liver preserved in UW solution; UW+TMZ: liver preserved in UW with TMZ. <sup>a</sup> $P < 0.05$  vs UW.

measure proved to be a valuable tool for predicting organ damage after cold preservation<sup>[6,40]</sup>. As shown in Figure 1, the higher levels of transaminases released by steatotic livers after cold preservation in UW solution confirm the increased sensitivity of this type of liver to cold ischemia. The addition of TMZ to UW solution (UW+TMZ) reduced transaminase levels in the flushing effluent of non-steatotic livers and, in particular in that of steatotic livers.

### Protocol 2: Effect of TMZ on steatotic liver injury after 24 h of cold ischemia followed by 2 h of normothermic reperfusion

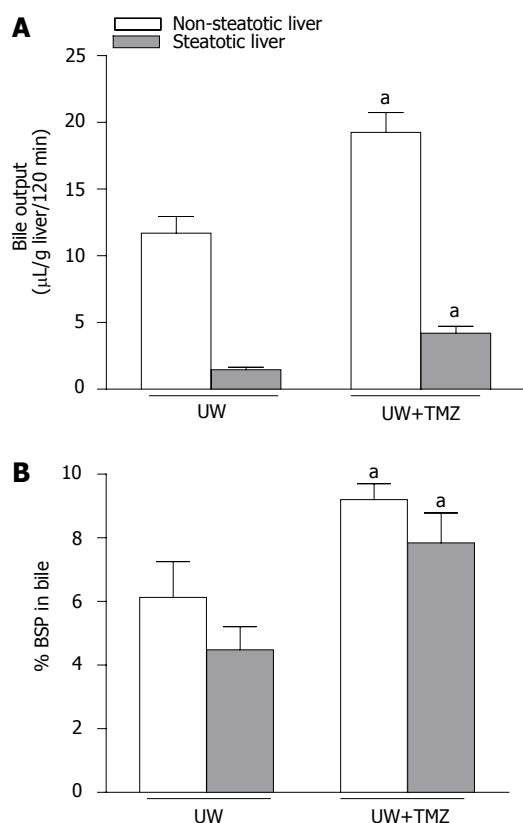

Higher perfusate transaminase levels were observed in steatotic livers as the reperfusion period progressed compared with those found in non-steatotic livers (Figure 2). The addition of TMZ to UW solution reduced the perfusate transaminase release in both types of liver, but especially in steatotic livers. The histological light microscopic study showed a marked disintegration of hepatic architecture in both types of liver preserved in UW solution (Figures 3A and B), but especially in steatotic livers (Figure 3B), whereas in the UW+TMZ group hepatocyte integrity was maintained (Figures 3C and D).

Liver function was assessed by measuring bile production and BSP clearance. Bile output and the percentage of BSP in bile were lower in steatotic livers preserved in UW solution than in non-steatotic livers (Figure 4). Both liver function parameters improved significantly in the two liver types following the addition

**Figure 3** Histological change in steatotic and non-steatotic livers after 120 min of normothermic reperfusion. Non-steatotic (A) and steatotic (B) livers preserved in UW solution: Cell swelling and disintegration of hepatic architecture were more evident in steatotic livers. Non-steatotic (C) and steatotic (D) livers preserved in UW solution with TMZ: Hepatic morphology was better preserved in both types of the liver compared to that recorded in UW solution.

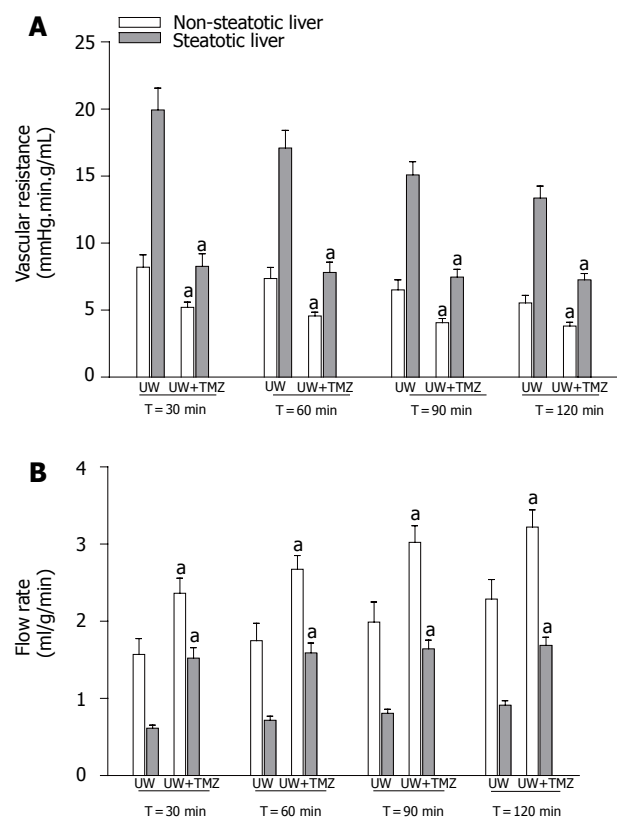

**Figure 4** Bile output (A) and percentage of sulfobromophthalein (BSP) in bile (B) of steatotic and non-steatotic livers after 120 min of normothermic reperfusion. UW: livers were preserved in UW solution; UW+TMZ: liver preserved in UW with TMZ. <sup>a</sup> $P < 0.05$  vs UW.

of TMZ to UW solution (UW+TMZ).

The mechanisms by which TMZ was able to protect steatotic livers against the deleterious effects of I/R injury were also evaluated. As shown in Figure 5, MDA levels during reperfusion increased, particularly in the case of steatotic livers. The addition of TMZ to UW

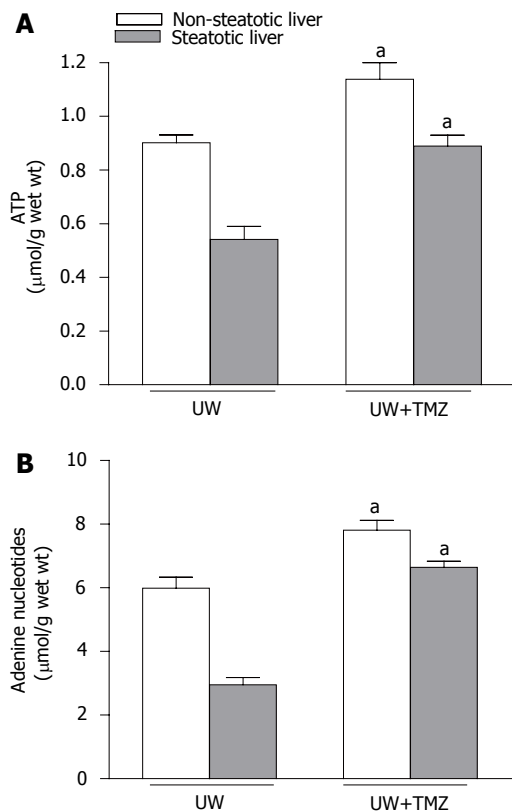

**Figure 5** Hepatic malondialdehyde (MDA) levels after 120 min of normothermic reperfusion. UW: liver preserved in UW solution; UW+TMZ: liver preserved in UW with TMZ. <sup>a</sup> $P < 0.05$  vs UW.

**Figure 6** Vascular resistance (A) and perfusion flow rate (B) of steatotic and non-steatotic livers after 120 min of normothermic reperfusion. UW: livers were preserved in UW solution; UW+TMZ: liver preserved in UW with TMZ. <sup>a</sup> $P < 0.05$  vs UW.

solution (UW+TMZ) brought about a reduction in these levels of increase. Marked increases in the vascular resistance and lower perfusion flow rate were observed in steatotic livers preserved in UW solution during the reperfusion period ( $T_{30,60,90,120}$ ) compared with the rates in non-steatotic livers (Figure 6). The liver weight was not statistically significant in both liver types. Vascular resistance was lower and perfusion flow rate was higher in both types of liver following the addition of TMZ to UW preservation solution (UW+TMZ). The beneficial

**Figure 7** ATP (A) and adenine nucleotide (B) levels of steatotic and non-steatotic livers after 120 min of normothermic reperfusion. UW: livers were preserved in UW solution; UW+TMZ: liver preserved in UW with TMZ. <sup>a</sup> $P < 0.05$  vs UW.

effect of TMZ on the vascular resistance and perfusion flow rate were more evident in the steatotic livers (Figure 6). Lower ATP and adenine nucleotides levels during reperfusion were observed in steatotic livers preserved in UW solution than those recorded for non-steatotic livers (Figure 7). The results reported here show that TMZ led to the preservation of more ATP and adenine nucleotides content in both types of liver.

Mitochondrial damage was evaluated by electron microscopy. Ultra-structural analysis after reperfusion in both types of liver preserved in UW solution revealed swelling of mitochondria, a significant decrease in the electron density of their matrices, while cristae were only seldom visible (Figures 8A and B). These morphological alterations were more evident in steatotic livers (Figure 8B). Following the addition of TMZ to UW preservation (UW+TMZ) a greater degree of mitochondrial preservation in both types of liver was recorded (Figures 8C and D) compared to the results obtained for the livers in UW solution.

## DISCUSSION

The results of the present study indicate that the addition of TMZ to UW solution improved the capacity of this standard preservation solution in both types of liver subjected to prolonged ischemic period especially in steatotic livers.

It is widely accepted that bile analysis is a useful

**Figure 8** Electron microscopy analysis of structural integrity of the mitochondria. Non-steatotic (A) and steatotic (B) livers preserved in UW solution: mitochondria swelling and the alterations in the electron density of their matrices were more evident in steatotic livers. Cristae are only seldom visible in steatotic livers. Non-steatotic (C) and steatotic (D) livers preserved in UW solution with TMZ. Mitochondrial integrity was better preserved in both types of liver compared to that recorded in UW solution.

means for assessing the integrity of biliary epithelial cells after cold ischemia. If cold storage time exceeds 10-12 h, complications in biliary structures occur in more than 25% of liver transplant recipients<sup>[41-43]</sup>. Several factors, including poor recovery after ATP depletion appear to contribute to bile duct cell damage after liver transplantation. Furthermore, isolated rat bile duct epithelial cells are noticeably sensitive to oxidative stress, possibly because their cellular stores of reduced glutathione are seven times lower than those of hepatocytes<sup>[44]</sup>. Taking these observations into account, bile production failure in steatotic livers could be explained, at least partially, by the lower ATP and increased oxidative stress presented by this type of liver compared with non-steatotic liver. Liver transplantation may benefit from strategies such as the addition of TMZ to the preservation solution as this seems to help maintain appropriate bile duct cell functions. Here, this strategy increased ATP recovery and reduced oxidative stress. This was also associated with better bile production.

The lower perfusate flow rate and the higher resistance to flow in steatotic, as opposed to non-steatotic livers indicate that steatotic livers offer greater impediments to perfusion. Fat accumulation in the cytoplasm of the hepatocytes is associated with an increase in cell volume, which may result in the partial or complete obstruction of the hepatic sinusoidal space<sup>[3,21]</sup>. Our results indicate the beneficial effects of TMZ on the flow rate and vascular resistance especially in the steatotic livers which were preserved during prolonged cold ischemia. Various hypotheses could be forwarded in an attempt at explaining the underlying protective mechanisms. In fact, according

to the literature, TMZ reduces the leakage of intracellular potassium, which is a vasoconstrictor; it affects vasoactive mediators including prostaglandins; and it reduces tissue edema, which has been related to the disturbance of microvascular circulation<sup>[10,45,46]</sup>.

Fatty degeneration, which induces a series of ultrastructural and biochemical alterations both in human and animal mitochondria<sup>[17,47]</sup> may render these organelles intrinsically more susceptible to I/R injury. Given that mitochondria are the main sites for ATP and ROS production in I/R<sup>[16]</sup>, the lower ATP and adenine nucleotides content and the increased oxidative stress observed in steatotic livers preserved in UW solution could be attributed to mitochondrial damage. Thus, the identification of new strategies to prevent mitochondrial injury should represent an important research goal in attempts to optimize the use of donor steatotic organs for liver transplantation. Our result indicates that the addition of TMZ to UW preservation solution protects against mitochondrial damage caused by I/R, preserves more ATP and adenine nucleotide content during reperfusion and decreases oxidative stress, thus showing a protective effect against I/R injury. Taken together, these data suggest that mitochondria might be an important target through which TMZ exerts its cytoprotective effect. However, the underlying mechanisms are still far from being defined and other possibilities should not be ruled out. Thus, another possible reason for the higher ATP levels that are induced by TMZ might be improved microcirculation at the time of reperfusion. This could increase the availability of oxygen and, therefore, facilitate ATP production. It is well known that failure of liver perfusion can impair the ability of the steatotic liver to restore ATP levels<sup>[16,22,48]</sup>. Similarly, in addition to mitochondria, the beneficial effects of TMZ on oxidative stress could be exerted on other sources of ROS, including endothelial cells<sup>[10]</sup>.

The addition of TMZ to UW solution ensured that steatotic grafts were less susceptible to the mechanisms involved in I/R injury including microcirculatory diseases, ATP and adenine content, oxidative stress and mitochondrial damage. In addition to allopurinol and glutathione, TMZ could be another antioxidant that should be added to UW solution, considering the benefits of TMZ in terms of oxidative stress and the difficulties for preventing oxidative stress damage in steatotic liver by other pharmacological treatments<sup>[19,33,49]</sup>. The ability of TMZ to protect both types of the liver is particularly attractive since some strategies that are effective in non-steatotic livers may not be useful in the presence of steatosis<sup>[19,20,50]</sup>.

In conclusion, TMZ protected against hepatic injury and ameliorated liver function in steatotic and non-steatotic livers preserved in UW solution. Further studies will be required to elucidate whether TMZ is such a promising drug for the field of liver transplantation, and if this pharmacological substance can reduce the inherent risk of steatotic liver grafts for transplantation.

### Abstract

**AIM:** To investigate the effect of epidural anaesthesia (EA) on pancreatic microcirculation during acute pancreatitis (AP).

**METHODS:** AP was induced by injection of sodium taurocholate into the pancreatic duct of Sprague-Dawley rats. To realize EA, a catheter was introduced into the epidural space between T7 and T9 and bupivacaine was injected. Microcirculatory flow was measured by laser Doppler flowmetry. Arterial blood gas analyses were performed. At the end of the experiment ( $\leq 5$  h), pancreas was removed for histology. The animals were divided into three groups: Group 1 ( $n=9$ ), AP without EA; Group 2 ( $n=4$ ), EA without AP; and Group 3 ( $n=6$ ), AP treated by EA.

**RESULTS:** In Group 1, pancreatic microcirculatory flow prior to AP was  $141 \pm 39$  perfusion units (PU). After AP, microcirculatory flow obviously decreased to  $9 \pm 6$  PU ( $P < 0.05$ ). Metabolic acidosis developed with base excess (BE) of  $-14 \pm 3$  mmol/L. Histology revealed extensive edema and tissue necrosis. In Group 2, EA did not significantly modify microcirculatory flow. BE remained unchanged and histological analysis showed normal pancreatic tissue. In Group 3, AP initially caused a significant decrease in microcirculatory flow from  $155 \pm 25$  to  $11 \pm 7$  PU ( $P < 0.05$ ). After initiation of EA, microcirculatory

flow obviously increased again to  $81 \pm 31$  PU ( $P < 0.05$ ). BE was  $-6 \pm 4$  mmol/L, which was significantly different compared to Group 1 ( $P < 0.05$ ). Furthermore, histology revealed less extensive edema and necrosis in pancreatic tissue in Group 3 than that in Group 1.

**CONCLUSION:** AP caused dramatic microcirculatory changes within the pancreas, with development of metabolic acidosis and tissue necrosis. EA allowed partial restoration of microcirculatory flow and prevented development of tissue necrosis and systemic complications. Therefore, EA should be considered as therapeutic option to prevent evolution from edematous to necrotic AP.

### INTRODUCTION

Among patients suffering from acute pancreatitis (AP), 80% have a favorable evolution and approximately 20% develop a severe disease with significant morbidity and mortality<sup>[1]</sup>. Severe AP is associated with the development of local complications, such as pancreatic and peripancreatic necrosis, abscesses or pseudocysts, and systemic complications, such as adult respiratory distress syndrome or renal failure with a mortality close to 15%<sup>[2]</sup>.

The pathophysiology of AP is incompletely understood but alteration in the pancreatic microcirculatory blood flow has been involved. Thus, a decrease in pancreatic blood flow occurs early in the course of AP and has been suggested to play a role in the conversion of edematous to necrotizing AP<sup>[3-7]</sup>. The microcirculatory dysfunction includes arterial vasoconstriction with hypoperfusion, ischemia-reperfusion injury, and obstruction of the venous outflow<sup>[8-11]</sup>. Other factors that participate in the development of microcirculatory

dysfunction are hemoconcentration, hypercoagulability, and increase in microvascular permeability<sup>[8-11]</sup>. Besides perfusion abnormalities, AP is also characterized by local and systemic inflammatory responses, including leukocyte activation as well as release of free radicals and cytokines<sup>[12-14]</sup>.

Many therapeutic agents, such as dextran, heparin, procaine, L-arginine, antioxidants, or cytokine antagonists, have been tested experimentally and/or clinically to improve pancreatic tissue perfusion during AP, however, no significantly successful result has been achieved<sup>[1,4,15-18]</sup>.

Epidural anesthesia (EA) that is used to induce analgesia in the perioperative period might be an interesting treatment of the microcirculatory blood flow abnormalities. Thus, EA can reduce the incidence of post-operative pulmonary complications, and shorten the duration of the post-operative intestinal paralysis<sup>[19,20]</sup>. In addition, experimental studies have shown that EA increases gut mucosal blood flow and delays the metabolic acidosis due to intestinal ischemia in the presence of a decreased perfusion pressure<sup>[21-22]</sup>. The beneficial effect of EA has been attributed to a sympathetic nerve blockade, which redistributes blood flow to the non-perfused regions of the gut<sup>[21]</sup>. Additionally, EA is useful to decrease pain in patients with AP<sup>[23]</sup>, but no study has investigated the effects of EA on the pancreatic microcirculatory blood flow during AP.

Because we postulated that EA might improve the pancreatic hypoperfusion induced by AP and concomitantly decrease the severity of the disease, we measured the pancreatic microcirculatory blood flow and the severity of the disease in rats injected with taurocholic acid in the biliopancreatic duct, in the presence or in the absence of EA.

## MATERIALS AND METHODS

### Animals

Adult male Wistar rats (275-300 g) were provided by Charles River (L'Arbresle, France). Animals were bred and housed in standard cages and maintained in climate-controlled rooms. Animals were fed with standard laboratory chow, given water *ad libitum*, and randomly assigned to control or treated groups. The protocol was approved by the Animal Ethical Committee of the Geneva University Medical School and by the Geneva Veterinary Authorities.

### Epidural anaesthesia

Epidural catheters were placed in rats under isoflurane anesthesia. A polyethylene catheter (PE10, Portex, Kent, UK) was introduced in the lumbar region and positioned into the epidural region between T7 and T9 according to the technique previously described by Grouls *et al*<sup>[24]</sup>. The external end of the catheter was tunneled subcutaneously and fixed to the occiput.

The animals were allowed to recover from anesthesia and 1 h after epidural catheterization, bupivacaine (4 g/L, 20  $\mu$ L) was injected to test anaesthesia. Hind limb muscle tone was scored by manual inspection and visual observation as previously described during 30 min<sup>[21,24]</sup>. A

normal tone with free movement of the hind limbs was scored 0; weak hypotonia of the hind limbs and of the body was scored 1; moderate hypotonia of the hind limbs and of the body was scored 2; and inability to support the body on the hind limbs and flat body posture was scored 3. After scoring, rats were allowed to recover for 2 h. Animals showing signs of neurologic damage were discarded. To verify the position of the catheter, after rat sacrifice, Evans blue solution was injected in the catheter and the spinal column exposed. Animals that had the catheter tip located intrathecally or outside the region between T7 - T9 were excluded from the study.

### Surgical preparation

Anaesthesia was induced by pentobarbital sodium (50 mg/kg intraperitoneally) and isoflurane inhalation. Rats had tracheotomy under isoflurane anesthesia and were mechanically ventilated (Harvard apparatus, model 683, South Natick, MA) with a Fio2 = 0.5. The left femoral vein was cannulated and continuously perfused with saline solution (2.5 mL/100 g/h). The left femoral artery was cannulated for continuous monitoring of arterial blood pressure and blood gas analysis (ABL 505 Analyzer, Radiometer, Copenhagen, Denmark). Body temperature was kept constant with a warm pad.

Blood samples were harvested every 30 min for blood gas analysis and ventilation was adjusted to obtain pCO<sub>2</sub> between 35 and 45 mmHg. The blood samples were also analyzed for serum amylase concentrations using 4,6-ethylidene (G1)-p-nitrophenyl (G1)- $\alpha$ D-maltoheptoside (Sigma Chemical Co, Zurich, Switzerland) as substrate. Mean arterial pressure was continuously recorded and stored via an analog-digital interface converter (Biopac, Santa Barbara, CA) on an AST microcomputer (AST, Limerick, Ireland).

### Induction of acute pancreatitis

After laparotomy, the pancreatic duct was cannulated with a 22-gauge catheter (Abott, Sligo, Ireland)<sup>[25]</sup>. A clip was placed on the pancreatic duct close to the liver and taurocholic acid (5%, 500  $\mu$ L, Sigma, Saint-Louis, MO) was infused over 4 min with a micropump<sup>[25]</sup>.

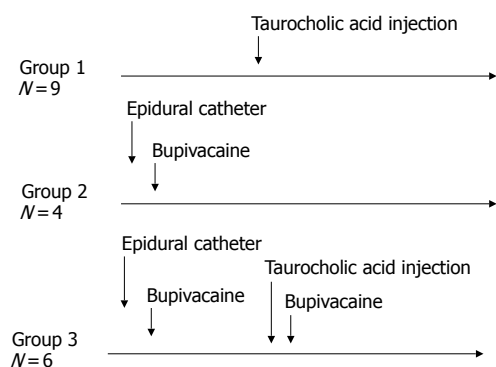

### Pancreatic microcirculatory blood flow

Pancreatic microcirculatory blood flow was measured with a laser Doppler flowmetry (Periflux system 5000, Perimed AB, Järfälla, Sweden). To position the probe, a latex adhesive probe miniholder (model PH07, Perimed, Järfälla, Sweden) and a special articulated laboratory stand were used. The Doppler probe was placed under the pancreatic surface with the light directed upward. After a 10 to 15 min stabilization period, the effect of AP and/or EA on the pancreatic microcirculatory blood flow was measured over time. The pancreatic microcirculatory blood flow was continuously recorded and stored via an analog-digital interface converter (Biopac, Santa Barbara, CA) on an AST microcomputer (AST, Limerick, Ireland).

### Tissue samples

After the rats were sacrificed, pancreatic samples were rapidly collected, fixed in formalin, embedded in paraffin,

**Figure 1** Experimental design. Acute pancreatitis was induced in Groups 1 and 3 by injection of taurocholic acid (5%, 500  $\mu$ L) into the biliopancreatic duct. Epidural anesthesia was induced in Groups 2 and 3 by epidural injection of bupivacaine (4 g/L, 20  $\mu$ L).

and cut into 5- $\mu$ m thick sections. After staining with hematoxylin-eosin, the sections were examined by two experienced morphologists who were not aware of the sample identity. The extent of acinar cell necrosis was quantified by computer assisted morphometry as previously described<sup>[26]</sup> and expressed as a percent of total acinar tissue.

### Experimental design

Three experimental groups were studied (Figure 1). In Group 1 ( $n=9$ ), rats had AP induction and no EA. Pancreatic microcirculatory blood flow was measured before taurocholic acid injection and continued after the induction of AP. In Group 2 ( $n=4$ ), the pancreatic microcirculatory blood flow was determined before and continued after the induction of EA. In Group 3 ( $n=6$ ), 30 min after taurocholic acid injection, bupivacaine was injected via the epidural catheter and the pancreatic microcirculatory blood flow measured over time.

### Statistical analysis

Results were expressed as mean  $\pm$  SD. Nonparametric Wilcoxon Signed ranks test and Kruskal-Wallis tests for comparison between groups were used as appropriate.  $P < 0.05$  was considered statistically significant.

## RESULTS

### Epidural anesthesia in rats

EA was tested by bupivacaine injection in Groups 2 and 3. In all rats, hind limb blockade was complete within 2 min and the motility completely recovered within 25–30 min after the injection. In Group 3, rats had taurocholic acid injection to induce AP and were treated with bupivacaine (Figure 1).

### Pancreatic microcirculatory blood flow

In Group 1, induction of AP caused a significant decrease of mean pancreatic microcirculatory blood flow from  $141 \pm 40$  units to  $9 \pm 6$  units (96%,  $P = 0.008$ ) within 30 min (Figure 2). The decreased blood flow remained unchanged until the end of the experiment. In Group 2, EA slightly increased microcirculatory blood flow, but the

**Figure 2** Pancreatic microcirculatory blood flow (arbitrary units). In Group 1, the mean value of pancreatic blood flow measured prior to and after induction of AP showed a significant decrease of perfusion from  $141 \pm 40$  units to  $9 \pm 6$  units (96%) ( $P = 0.008$ ) within 30 min. In Group 2, the mean value of pancreatic blood flow measured prior to and after induction of epidural anaesthesia showed no significant modification of perfusion. In Group 3, mean value of pancreatic blood flow measured prior to and after induction of AP, and epidural anaesthesia, respectively. Induction of AP caused a significant decrease in pancreatic microcirculatory flow from  $155 \pm 25$  units to  $11 \pm 7$  units (93%) ( $P = 0.004$ ). After induction of epidural anaesthesia, mean pancreatic microcirculatory blood flow increased again significantly to  $81 \pm 31$  units within 45 min, reaching 52% of baseline values ( $P = 0.028$ ).

modification did not reach statistical significance ( $P = 0.7$ , Figure 2). In Group 3, induction of AP caused a similar decrease in pancreatic microcirculatory flow as in Group 1, *i.e.*, from  $155 \pm 25$  units to  $11 \pm 7$  units (93%,  $P = 0.004$ ). After induction of EA, mean pancreatic microcirculatory blood flow increased again significantly to  $81 \pm 31$  units within 45 min, reaching 52% of baseline values ( $P = 0.028$ , Figures 2 and 3).

**Figure 3** Recording of pancreatic microcirculatory blood flow in Group 3. Rats were injected with taurocholic acid and treated 30 min later with bupivacaine (0.4%, 20  $\mu$ L) in the epidural catheter. Induction of AP caused a significant decrease in pancreatic microcirculatory blood flow. After induction of epidural anesthesia, mean pancreatic microcirculatory blood flow increased again significantly within 45 min, reaching approximately 50% of baseline values.

**Figure 4** Arterial blood gas analyses. In Group 1, severe metabolic acidosis developed progressively reaching a maximum base excess (BE) value of  $-14 \pm 3$  mmol/L at the end of the experiment. In Group 2, BE values remained unchanged compared to baseline values. In Group 3, a mild metabolic acidosis developed reaching a maximum BE value of  $-6 \pm 4$  mmol/L at the end of the experiment. This result was significantly improved compared to Group 1 ( $^1P=0.007$ ).

#### Arterial blood gas and serum amylase analyses

In Group 1, severe metabolic acidosis developed progressively reaching a maximum base excess (BE) value of  $-14 \pm 3$  mmol/L at the end of the experiment (Figure 4). In Group 2, BE values remained unchanged compared to the baseline values during experiment (Figure 4). In Group 3, a mild metabolic acidosis developed reaching a maximum BE value of  $-6 \pm 4$  mmol/L at the end of the experiment (Figure 4). This result was significantly improved compared to Group 1 ( $P=0.007$ ).

In Group 1, serum amylase levels increased from  $694 \pm 419$  units/L prior to AP to  $2178 \pm 561$  units/L ( $P<0.05$ ) after 2 h of induction of AP (Figure 5). In Group 2, EA did not modify serum amylase level significantly during the experiment. In Group 3, serum amylase levels increased to a maximum of  $1829 \pm 641$  units/L 2 h after initiation of AP and EA (Figure 5). Although this result was lower compared to Group 1, but did not reach statistical significance.

#### Histopathology

In Group 1, histopathology revealed a severe form of AP with extensive edema and tissue necrosis (Figure 6C). In

**Figure 5** Serum amylase levels. In Group 1, serum amylase levels increased from  $694 \pm 419$  units/L prior to AP to  $2178 \pm 561$  units/L ( $^1P<0.05$ , vs serum amylase levels before induction of AP) after 2 h of induction of AP. In Group 2, epidural anaesthesia did not modify serum amylase levels significantly ( $P=0.9$ ). In Group 3, serum amylase levels increased to a maximum of  $1829 \pm 641$  units/L after 2 h of initiation of AP and epidural anesthesia. Although this result was lower compared to Group 1, but did not reach statistical significance ( $^2P=0.08$ ).

Group 2, almost normal pancreatic tissue was observed at the end of the experiment (Figure 6B). In Group 3, edema and necrosis were less extensive compared to animals in Group 1 (Figure 6D).

The extent of acinar cell necrosis measured as percentage of total surface at high power field (HPF) showed that Group 2 animals had similar cell necrosis as the controls ( $<10\%$ ) (Figure 7). Group 1 animals demonstrated over 40% of acinar cell necrosis at HPF, whereas acinar cell necrosis was below 30% in Group 3 animals (Figure 7).

## DISCUSSION

In our study, taurocholic acid injection in the biliopancreatic duct induced a pancreatic hypoperfusion as reported by previous studies<sup>[3,7,16,25]</sup>. The decrease was 96% within 15 min and pancreatic microcirculatory blood flow remained low until the end of the experiment. The microcirculatory blood flow has been accurately measured by laser Doppler flowmetry. The technique is ideal for monitoring changes in tissue perfusion over time and has successfully been applied to numerous organs in experimental and human studies<sup>[4,6,24,27]</sup>. However, several factors, such as artifacts induced by respiration, external light exposure and temperature, can affect the interpretation of the laser Doppler signals<sup>[4]</sup>. In addition, microcirculatory flow can vary widely over short distances, and small changes in probe angle during measurement can alter the measured values. To prevent these technical problems, we used a new type of probe holder, which allows the tissue to be maintained by gravity, avoiding repeated repositioning of the probe.

More importantly, we showed that after induction of AP, bupivacaine injection in the epidural catheter increased pancreatic microcirculatory blood flow. Concomitantly, the improved microcirculatory blood flow within the pancreas decreased the severity of AP. Serum amylase

**Figure 6** Histopathological features of pancreatic tissue. **A:** A control animal was sacrificed and histopathology showed normal pancreas; **B:** Group 2 animals showing normal pancreatic tissue with minor modifications, possibly related to vasodilatation and surgical manipulations; **C:** Group 1 animals showing a severe form of AP with extensive edema and tissue necrosis; and **D:** Group 3 animals demonstrating less extensive pancreatic edema and necrosis compared to Group 1 animals.

**Figure 7** Acinar cell necrosis (percentage of total pancreatic surface). The measure of acinar cell necrosis by percentage of total surface at high power field (HPF) showed that Group 2 animals had similar cell necrosis as the controls (<10%). Group 1 animals demonstrated over 40% acinar cell necrosis at HPF, whereas acinar cell necrosis was below 30% in Group 3 animals.

concentrations and metabolic acidosis were less severe and the histopathologic scores were improved in comparison to rats with AP and no treatment. These results emphasize the importance of a decreased microcirculatory blood flow in inducing severe AP.

To our best of knowledge, this is the first experimental study showing the beneficial effects of EA on the severity of AP. Previous reports already showed that EA increased splanchnic venous capacitance and decreased arterial tone by blocking sympathetic nerve activity<sup>[21,22,28-30]</sup>. It was also reported that EA might increase sympathetic activity and vasoconstriction in organs distant from the anesthetized area and redistributes blood flow towards splanchnic organs<sup>[21]</sup>.

It has been postulated that several factors, such as local metabolic acidosis which activates various proteases, oxygen-free radical that injures endothelium and parenchyma, or the incapacity of plasma protease inhibitors to circulate through acinar cells, participate in the modifications of pancreatic microcirculation during AP<sup>[3]</sup>. These modifications result in diminished intravascular volume, chemically-induced vasoconstriction, intravascular coagulation, and increased endothelial permeability<sup>[31]</sup>. Finally, pancreatic ischemia, as a consequence of all these local effects, may convert a mild disease to a severe AP with parenchymal necrosis<sup>[31]</sup>. This has been demonstrated by Klar *et al*<sup>[5]</sup> who have shown in anesthetized rabbits that pancreatic blood flow increases when AP is edematous (cerulein injection), whereas pancreatic blood flow decreases when AP is severe (necrotizing form induced by taurocholate injection).

In our study, EA decreased serum amylase concentrations, metabolic acidosis, and the severity of pancreatic necrosis score in comparison to rats that had similar taurocholic acid injection and no treatment. Similar benefit of peridural anaesthesia has been shown on metabolic acidosis during hypoxia in dogs<sup>[29]</sup>.

In conclusion, the current study has shown that EA improves the pancreatic hypoperfusion induced by AP with a concomitant decrease in the severity of metabolic acidosis and a diminished tissue injury. EA should therefore be considered a new therapeutic approach to prevent the progression from an edematous disease to a necrotizing AP.

## Abstract

**AIM:** Enterovirus 71 (EV71) has been implicated as the etiological agent responsible for the recent outbreaks of hand, foot and mouth disease associated with severe neurological diseases in the Asia-Pacific region.

**METHODS:** The assembly process was hypothesized to occur via an orchestrated proteolytic processing of the P1 precursor by the viral protease 3CD. To test this hypothesis, we constructed 3 recombinant baculoviruses: Bac-P1 expressing P1; Bac-3CD expressing 3CD; and Bac-P1-3CD co-expressing P1 and 3CD.

**RESULTS:** Both single infection by Bac-P1-3CD and co-infection by Bac-P1 and Bac-3CD resulted in correct cleavage of P1 to yield individual proteins VP0, VP1 and VP3, while the former approach yielded higher VLP production. In the cells, the structural proteins self-assembled into clusters of virus-like particles (VLP) resembling the authentic EV71 particle aggregates. After ultracentrifugation purification, the dispersed VLPs were indistinguishable from the authentic virus in size, appearance, composition and surface epitopes, as determined by SDS-PAGE, Western blot, transmission electron microscopy and immunogold labeling.

**CONCLUSION:** Our data, for the first time, suggest that in insect cells EV71 structural proteins adopt a processing and assembly pathway similar to poliovirus assembly. The preservation of particle morphology and composition suggest that the VLP may be a valuable vaccine candidate to prevent EV71 epidemics.

## INTRODUCTION

Enterovirus 71 (EV71), like poliovirus, is one of the 69 enterovirus serotypes belonging to the *Picornaviridae* family. EV71 infection manifests most frequently as hand, foot and mouth disease (HFMD) and children under 5 years of age are particularly susceptible to the most severe forms of EV71-associated neurological disease, including aseptic meningitis, brainstem encephalitis and acute flaccid paralysis indistinguishable from poliomyelitis<sup>[1]</sup>. The neurovirulence of EV71 first came to people's attention in 1975 in Bulgaria when 44 people died of a polio-like disease<sup>[2]</sup>. EV71 was further implicated as the causative agent responsible for the epidemics of central nervous system disease occurring in New York, Europe, Australia and Asia<sup>[3-6]</sup>. Recent HFMD outbreaks also affected thousands of children in Taiwan<sup>[7]</sup>, Japan<sup>[8]</sup> and Singapore<sup>[9]</sup>, causing the fatality of more than 80 children. Thus EV71 appears to emerge as an increasingly important neurotropic enterovirus in the upcoming era of poliomyelitis eradication. However, no effective antiviral drugs or vaccines are available yet.

EV71 possesses a positive single-stranded RNA genome that consists of a single open reading frame (ORF). The ORF expresses a large polyprotein that can be co- and post-translationally cleaved into P1, P2 and P3 regions<sup>[10]</sup>. P1 region encodes the four structural proteins VP1, VP2, VP3 and VP4, while P2 and P3 regions encode other nonstructural proteins (e.g., 2A and 3CD) responsible for virus replication and virulence<sup>[11]</sup>. Based on a model derived from poliovirus, protease 2A autocatalytically cleaves P1 at its N-terminus and liberates P1 from the nascent polyprotein<sup>[11]</sup>, while protease 3CD cleaves P1 precursor into VP1, VP3 and VP0 in trans<sup>[12]</sup>. These three structural proteins spontaneously assemble into icosahedral

**Figure 1** Construction of three recombinant baculovirus vectors using pFastBac™ DUAL plasmid as the backbone. The gene fragments encoding P1 and 3CD were cloned separately into MCS I and II of pFastBac™ DUAL under the control of polyhedrin ( $P_{polh}$ ) and p10 promoters ( $P_{p10}$ ), respectively. The resultant plasmids were designated pDual-P1 and pDual-3CD, respectively. The P1 and 3CD genes were cloned together into MCS I and II under the control of polyhedrin and p10 promoters. The resultant plasmid was designated pDual-P1-3CD.

procapsid in an ordered manner and proceed through a series of intermediates, followed by the encapsidation of the RNA genome into the provirion<sup>[13]</sup>. The final encapsidation step involves the cleavage of VP0 into VP2 and VP4, therefore the final mature virion consists of 60 copies each of VP1 and VP3, 58-59 copies of VP2 and VP4 and 2-1 copies of VP0<sup>[13]</sup>.

Besides the mature virions, naturally occurring virus-like particles (VLPs) of poliovirus have been discovered<sup>[14]</sup>. VLPs are empty particles consisting of viral structural proteins but devoid of viral nucleic acids, hence they are non-infectious. VLPs can generally induce broad and strong immune responses thanks to the preservation of many essential epitopes<sup>[15-17]</sup>, therefore VLPs have captured increasing attention as potential vaccine candidates<sup>[17-19]</sup>. To date, numerous VLPs of clinically important viruses, including human immunodeficiency virus<sup>[20]</sup>, SARS coronavirus<sup>[21]</sup> and hepatitis delta virus<sup>[22]</sup>, have been expressed. In addition, recombinant poliovirus VLPs have been produced using the baculovirus/insect cell or vaccinia virus expression system. These particles were produced via the (1) expression of the complete ORF; (2) co-expression of individual VP0, VP1 and VP3 proteins; or (3) co-expression of P1 and 3CD proteins<sup>[23-25]</sup>. Since EV71 and poliovirus share identical genome organization and similar protein functions, we hypothesized that EV71 assembly occurs in a way similar to poliovirus and have previously demonstrated the formation of EV71 VLP by co-infecting insect cells with two recombinant baculoviruses, Bac-P1 expressing P1 and Bac-3CD expressing 3CD<sup>[26]</sup>. However, the factors influencing the VLP yield were not investigated, and the VLPs were not purified or characterized. In this study, we extended our previous work by further constructing a new recombinant baculovirus simultaneously expressing P1 and 3CD. The new virus was used for single infection of insect cells, co-expression of P1 and 3CD and synthesis of VLP. The yields of VLP produced via the single infection and co-infection strategies were compared. Finally, the VLPs were purified and characterized.

## MATERIALS AND METHODS

### Cell culture and media

*Spodoptera frugiperda* (Sf-9) insect cells were cultured in spinner flasks (Bellco) at 27 °C using TNM-FH medium supplemented with 100 mL/L fetal bovine serum (FBS, Gibco BRL) as described elsewhere<sup>[27]</sup>.

### Generation of recombinant baculoviruses

The gene fragments coding for P1 and 3CD were amplified by polymerase chain reaction from the full-length cDNA clone of EV71 *neu* strain<sup>[28]</sup> and subcloned separately into multiple cloning site (MCS) I and II of pFastBac™ DUAL plasmids (Invitrogen) as described previously<sup>[26]</sup>. The resultant plasmids were designated pDual-P1 and pDual-3CD, respectively. Likewise, the P1 gene fragment was cloned into MCS I under the polyhedrin promoter and the 3CD gene fragment was inserted into MCS II under the p10 promoter. The resultant plasmid carrying two gene cassettes was designated pDual-P1-3CD (Figure 1). The recombinant baculoviruses were subsequently generated using Bac-to-Bac® system (Invitrogen) as described previously<sup>[29]</sup> and designated Bac-P1, Bac-3CD and Bac-P1-3CD based on the genes they encoded. The recombinant viruses were propagated, amplified, stored and titered according to standard procedures<sup>[30]</sup>.

### SDS-PAGE and Western blot

To confirm the expression of recombinant P1 and VP1, the infected cells were harvested by low-speed centrifugation and then lysed by incubation in the lysis buffer (0.1% Triton X-100 in Tris-buffered saline) at 4 °C for 30 min. The proteins were resolved on 100 g/L gels as described previously<sup>[26]</sup> and stained by Coomassie blue. For Western blot, the proteins were transferred onto nitrocellulose membranes according to standard procedures (Bio-Rad Laboratories). The transferred membrane was blocked with 50 g/L non-fat milk and probed by mouse anti-VP1 monoclonal antibody (MAb). The secondary antibody was goat anti-mouse IgG conjugated with alkaline phosphatase (Kirkegaard and Perry Laboratories). The membranes were developed with BCIP/NBT color developing reagent (Sigma).

### Purification of VLP by ultracentrifugation

EV71 VLPs were produced by infecting Sf-9 cells with Bac-P1-3CD at a multiplicity of infection (MOI) of 10. Approximately 150 mL cells ( $1.5 \times 10^6$  cells/mL) were harvested at 2 d post-infection (dpi) by centrifugation (1 000 r/min for 5 min) and were re-suspended in 10 mL TE buffer (0.01 mol/L Tris-HCl, 0.001 mol/L EDTA, pH 7.4). The cell suspension was supplemented with 1 mL of 10X HO buffer (0.01 mol/L Tris, 0.25 mol/L NaCl, 0.01 mol/L 2-mercaptoethanol) and 100 g/L NP-40, lysed by sonication for 3 min and centrifuged at 13 000 g (R20A2 rotor, CR22G, Hitachi) for 30 min. The supernatant was passed through a 0.22-μm filter to remove the debris and then ultracentrifuged at 27 000 g (P40ST rotor, CP100MX, Hitachi) for 4 h. The pellets were resuspended in TE buffer, sonicated for 30 s and loaded onto the discontinuous sucrose gradient (15%, 30% and 65%

**Figure 2** Western blot analysis of cell lysates infected by different viruses. The Sf-9 cells were infected by the viruses at a total MOI of 10 and harvested at 3 dpi. The proteins were separated by SDS-PAGE, electrotransferred to a nitrocellulose membrane and probed using anti-VP1 MAb as the primary antibody. Lane 1: mock infection; Lane 2: wild-type baculovirus AcMNPV; Lane 3: Bac-P1; Lane 4: Bac-P1-3CD; Lane 5: Bac-P1 and Bac-3CD.

sucrose dissolved in TE buffer). After ultracentrifugation at 27 000 *g* (P40ST rotor) for 3 h, the milky white band between the interfaces of 15–35% sucrose was collected and layered on top of a 1.33 *g cm*<sup>-3</sup> cesium chloride (CsCl) solution. After ultracentrifugation at 34 000 *g* (P40ST rotor) for 24 h, the bands collected from CsCl gradient were dialyzed against phosphate-buffered saline (pH 7.4) and were ultracentrifuged again at 34 000 *g* for 5 h. The pellets were resuspended in 50  $\mu$ L pure water for SDS-PAGE, Western blot and transmission electron microscopy (TEM) analyses. The purities of the samples and the composition of VLPs were quantified by densitometry using Scion Image Shareware (Scion Corporation).

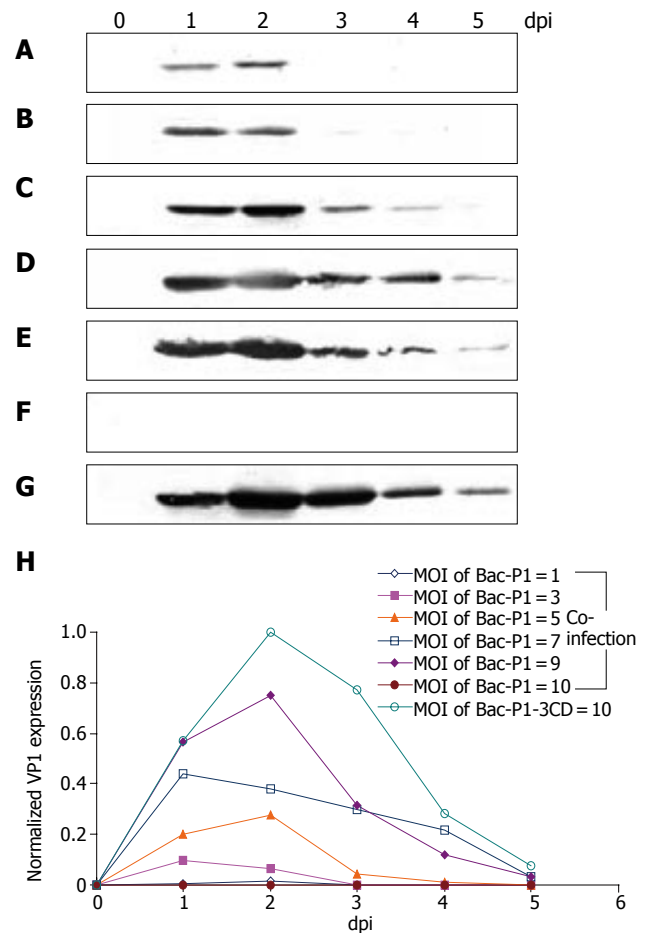

### TEM and immunogold labeling

The VLPs within the insect cells were visualized under a transmission electron microscope (H-7500, Hitachi), prior to which ultrathin sectioning of cells was performed as described previously<sup>[26]</sup>. The particles after purification were adsorbed onto Formvar-coated copper grids, negatively stained by 20 g/L phosphotungstic acid (PTA) and examined by TEM. For immunogold labeling, purified particles were adhered onto copper grids and probed by mouse anti-VP1 MAb. The secondary antibody was goat anti-mouse IgG conjugated with 5 nm gold particles (Sigma). After washing of the unbound gold particles, the grids were stained by 20 g/L PTA and observed by TEM.

## RESULTS

### Expression of recombinant proteins in insect cells

To determine whether the recombinant P1 and 3CD were successfully expressed by Bac-P1-3CD, Sf-9 cells were singly infected by wild-type AcMNPV, Bac-P1, and Bac-P1-3CD (MOI 10), or co-infected by Bac-P1 (MOI 5) and Bac-3CD (MOI 5). The cells were harvested at 3 dpi and lysed for Western blot analysis. As shown in Figure 2, the mock-infected and wild-type AcMNPV-infected cells did not express P1 (lanes 1 and 2), whereas the Bac-P1-infected cells expressed a protein with a molecular mass corresponding to 97 ku, indicating the

**Figure 3** Time course profiles of VP1 production under various infection conditions as analyzed by Western blot. Insect cells were infected at a total MOI of 10 by single infection with Bac-P1-3CD (G), or co-infection at MOI ratios (Bac-P1/Bac-3CD) of 1/9 (b), 3/7 (B), 5/5 (C), 7/3 (D), 9/1 (E) and 10/0 (F). Lanes 0–5 represent the cell lysates collected at 0, 1, 2, 3, 4, and 5 dpi, respectively. The relative VP1 production levels under different conditions were quantified by scanning densitometry (H). The data represent the average values of duplicated experiments.

successful expression of P1 (lane 3). Other P1-associated proteins migrating faster than P1 were also found (lane 3), suggesting a possible degradation of P1 by the cellular proteases, but this non-specific degradation did not yield VP1 (39 ku).

We also noted that no antibody specifically recognizing 3CD was available, hence the 3CD expression was detected indirectly by observing whether P1 was cleaved into VP1 upon co-expression of both proteins. Lanes 4 and 5 depict that either single infection by Bac-P1-3CD (lane 4) or co-infection by Bac-P1 and Bac-3CD (lane 5) led to complete cleavage of P1 into VP1, proving the successful co-expression of functional P1 and 3CD by both approaches.

### Optimization of VP1 production

Since P1 relies on 3CD for cleavage and subsequent VLP assembly, delicately controlling the relative expression levels of P1 and 3CD is crucial for optimal VLP production. To address this issue, the cells were co-infected by Bac-P1 and Bac-3CD at MOI ratios of 1/9, 3/7, 5/5, 7/3, 9/1 and 10/0, or singly infected by Bac-P1-3CD at MOI 10 in order to compare and optimize the VP1 yield. Figures (3A–3G) show the time-course profiles

**Figure 4** Electron microscopy examinations of EV71 VLP aggregates formed in cytoplasm of the Bac-P1-3CD-infected insect cells (100 000 X magnification). The cells were infected at MOI 10, harvested at 3 dpi and ultrathin sectioned for TEM. The arrowhead indicates the VLP aggregate. Bar:100 nm.

**Figure 5** Purification and characterization of EV71 VLP (100 000 X magnification.). The VLPs were produced by infecting 150 mL Sf-9 cells ( $1.5 \times 10^6$  cells/mL) with Bac-P1-3CD at MOI 10, harvested at 2 dpi and purified by ultracentrifugation. The purified VLPs were characterized by SDS-PAGE (A), Western blot (B), TEM examination (C) and immunogold labeling (D). The PAGE gel was stained by Commassie blue and scanned for densitometry analysis. The primary antibody used in the Western blot and immunogold labeling was anti-VP1 MAb. The size of the gold particles was 5 nm. Bar: 100 nm.

of VP1 production, in which lanes 0-5 represent the samples harvested at 0, 1, 2, 3, 4 and 5 dpi, respectively. As shown, both single infection and co-infection approaches resulted in similar expression kinetics (except MOI 10/0), that is, the VP1 concentration rapidly culminated at 1-2 dpi, declined thereafter and virtually vanished at 5 dpi. The concentration peaked slightly earlier compared to those of many other proteins whose maximum concentration occurred at 3 dpi<sup>[27,31]</sup> probably because of proteolytic degradation by cellular proteases (data not shown).

The production levels using different MOI combinations were also compared by scanning densitometry, by which all band intensities were normalized against the strongest band intensity (lane 2, Figure 5G). Figure 5H reveals that in the case of co-infection VP1 concentration increased with the MOI of Bac-P1 provided that the total MOI was fixed at 10. However, the maximum VP1 yield obtained from single infection (by Bac-P1-3CD at MOI 10) was the highest, being  $\approx 30\%$  and  $\approx 120\%$  greater than those obtained from co-infection at MOI 9/1 and 7/3, respectively.

### Formation of intracellular virus-like particle aggregates

Since single infection with Bac-P1-3CD yielded the highest VP1 production, the formation of VLPs by single infection strategy was further examined. The cells were singly infected by Bac-P1-3CD at MOI 10 and subjected to ultrathin sectioning and TEM examination. As shown in Figure 4, clusters of virus-like particles were observed in the cytoplasm. These particles measured 25-27 nm in diameter and appeared icosahedral, thus resembling the authentic enterovirus in size and appearance. Such VLP aggregates were not observed in Sf-9 cells infected by Bac-P1 alone (data not shown), indicating that the particles were not the assembly products of individual structural proteins degraded from P1 precursor.

### Purification and characterization of EV 71 VLP

The subsequent VLP production was performed by infecting insect cells with Bac-P1-3CD (MOI 10). The particles were released from the infected cells, purified by ultracentrifugation and analyzed by SDS-PAGE (Figure 5A) and Western blot (Figure 5B). We observed that the purified sample contained three major proteins whose molecular masses corresponded to those of VP1 (39 ku), VP0 (36 ku) and VP3 (26 ku), and the purity of the sample was greater than 90% (Figure 5A). The molar concentrations of the three proteins as determined by scanning densitometry were roughly equal, agreeing with the notion that the molar ratios of VP0, VP1 and VP3 are identical in the enterovirus provirions<sup>[13]</sup>. Because no antibodies specifically recognizing VP0 and VP3 were available, the Western blot was performed using anti-VP1 antibody only, which further confirmed that the 39 ku protein was VP1. The purified particles were also subjected to TEM examination (Figure 5C), which showed that particles with size and morphology similar to those of the particles observed *in vivo* except the purified VLPs were dispersed. The immunogold labeling using anti-VP1 antibody further revealed gold particles surrounding the distinct particles (Figure 5D), indicating the exposure of VP1 on the outer surface. All these data confirmed that the Bac-P1-3CD infection successfully resulted in the formation of VLP comprising VP0, VP1 and VP3 and these particles could be purified by ultracentrifugation to near homogeneity.

The purified VLPs were also used as the standard to measure the specific yields of VLP. Approximately 10 mg of VLP was expressed per  $10^9$  Bac-P1-3CD-infected cells at MOI 10. This high expression level may contribute to future mass production and downstream purification.

## DISCUSSION

The assembly pathway of EV71 has not been definitely identified, but the assembly model of poliovirus suggests that concerted cleavage of P1 by protease 3CD is required for capsid assembly. In this study, 3 recombinant baculoviruses were employed to express P1 and 3CD simultaneously in order to mimic the natural assembly process. By either single infection with Bac-P1-3CD or co-infection with Pac-P1 and Bac-3CD, successful processing

of P1 into VP1 (Figure 1) was demonstrated, proving the successful expression of both P1 and functional 3CD. Alternative approach by co-expression of individual VP1, VP2, VP3 and VP4 proteins has been tested for VLP assembly, yet the yield was very low (personal communication). The comparison of these approaches suggests that VLP synthesis from the P1 precursor is a more favorable route, which agrees with the assembly pathway of poliovirus VLP<sup>[24]</sup>.

The co-infection experiments further suggested that the amount of P1 required was larger than that of 3CD for VLP assembly as the co-infection at MOI 9/1 yielded considerably larger amounts of VP1 than MOI 5/5 or 1/9 (Figure 3). Intriguingly, we observed that single infection by Bac-P1-3CD was superior to co-infection by Bac-P1 and Bac-3CD with regard to VP1 production (Figure 3H). Since we lacked proper antibodies to detect 3CD, the relative expression levels of P1 and 3CD in the cells singly infected by Bac-P1-3CD remained unclear. However, since P1 expression was driven by polyhedrin promoter which was stronger than p10 promoter regulating the 3CD expression, one may surmise that differential expression of P1 and 3CD arose, namely, the P1 expression exceeded the 3CD expression. Another reason that may account for the higher production by single infection methodology is the VLP-producing cell population distribution as a result of the co-infection approach, whereby only the cells that were co-infected could produce VLP. Using the co-infection methodology, the probability of a cell to be infected by one or two types of viruses and the number of virus entering any given cells follow the modified Poisson distribution as predicted previously<sup>[32]</sup>. Hence, a population of cells that were singly infected by Bac-P1 or Bac-3CD arose, and no P1 processing or VLP assembly occurred in these cells. Even for the cells that were co-infected by both viruses, the number of infecting Bac-P1 and Bac-3CD within one cell might vary<sup>[32]</sup>. In cells where the number of Bac-P1 infection far more exceeded that of Bac-3CD infection, insufficient expression of 3CD and inadequate P1 cleavage could occur. On the contrary, in cells where the Bac-3CD infection considerably outnumbered the Bac-P1 infection, a drought in P1 supply could occur and lead to inadequate VLP assembly. Such heterogeneity could decrease the P1 processing and VLP assembly in many cells. In contrast, the infection of Bac-P1-3CD alone resulted in P1 processing in all cells, leading to a higher VP1 yield.

Despite the lower yield, the significance of co-infection strategy should not be ignored because it offers a new dimension to manipulate the composition of VLPs. For instance, the cells may be co-infected with Bac-P1-3CD and a new recombinant baculovirus expressing VP1 derived from a different EV71 strain (e.g., the prototype BrCr strain). The phenotypic mixing may allow the incorporation of VP1 from BrCr strain into the VLP, thus generating chimeric, multivalent VLPs and broadening the spectrum of protection.

In addition to the higher expression level, single infection strategy resulted in the formation of VLP morphologically indistinguishable from the authentic viruses. Within the cells, clusters of virus-like particles

resembling those observed in EV71-infected human rhabdomyosarcoma (RD) cells<sup>[26]</sup> and in enterovirus-infected skeletal muscle cells<sup>[33]</sup> were observed. The *in vivo* formation of particle aggregates was not previously reported by other researchers studying the poliovirus VLPs<sup>[23,25]</sup>, but was recently noted in BHK-38 cells infected by foot-and-mouth disease virus<sup>[34]</sup>, a relatively genetically distant picornavirus. To date, the biological significance of the particle aggregation remains to be explored, but the resemblance in particle morphology and the aggregation patterns between the VLP and the authentic enterovirus suggests that EV71 VLP adopts an assembly pathway in insect cells in a way similar to the authentic viruses do in their natural host cells. Despite the aggregation within cells, the VLP could be dispersed in solution and purified through CsCl gradient ultracentrifugation to near homogeneity. The purified VLPs comprised VP0, VP3 and VP1 of roughly equal molar ratios, a result consistent with previous findings that poliovirus provirions are composed of 60 copies each of VP1, VP3 and VP0<sup>[13]</sup>. This implied the similarity between the VLP and the authentic virus in composition. Notably, in insect cells VP0 did not appear to undergo further cleavage into VP2 and VP4, a maturation process associated with the acquisition of infectivity and the increase in particle stability<sup>[35]</sup>. The lack of further processing is reasonable as the natural maturation process takes place after the RNA encapsidation, yet in this expression system, no RNA packaging into the central cavity occurred.

Nonetheless, after purification, the size and morphology of VLPs appeared indistinguishable from those of poliovirus VLP. More importantly, the immunogold labeling confirmed the presence of VP1 epitopes on the VLP surface. These data suggest that the VLPs contain the important antigenic sites essential for eliciting the immune responses. This is particularly important because neutralizing epitopes are most densely clustered on VP1 and many of them consist of amino acids from different domains or from different polypeptides<sup>[36,37]</sup>, that is, many of them are conformation-dependent. In this regard, the use of VLP as a vaccine candidate against EV71 infection may be particularly promising. In recent years, VLP-based vaccines have been demonstrated to not only elicit neutralizing antibodies, but also provoke potent cytotoxic and helper T-lymphocyte responses and have been shown to confer protection from virus challenge in the animal models<sup>[38-40]</sup>. Furthermore, papillomavirus-like particles have been shown to induce acute activation of dendritic cells<sup>[16]</sup>. Other VLPs that have been evaluated in pre-clinical studies for their potentials as vaccines include JC virus, human immunodeficiency virus, rotavirus and parvovirus<sup>[41]</sup>. Moreover, the humoral, mucosal and cellular immune responses to Norwalk VLP in humans have been reported<sup>[42]</sup>, while VLP vaccines against human papillomavirus have entered into phase II clinical trials and promising data have been presented<sup>[43]</sup>. All these further justify the development of VLP vaccines.

Since EV71 has caused seasonal morbidity and mortality in children with increasing frequency in recent years, vaccine development has become a top priority among all control strategies. Although other vaccine types,

such as inactivated virus and VP1 subunit vaccines, have been tested<sup>[44]</sup>, only the inactivated virus elicited strong immune responses, again confirming the importance of preserving epitope conformation. However, further assessment of safety and efficacy of the inactivated virus vaccine is required. In this study, we have successfully demonstrated the formation and purification of EV71 VLP via co-expression of P1 and 3CD and a reasonable production yield ( $\approx 10$  mg/ $10^9$  cells) was achieved, thus offering an attractive alternative to the inactivated virus vaccine. At present, the immunological evaluation has been impeded due to the difficulty in obtaining sufficient amounts of pure VLP because the recovery yield of VLP by ultracentrifugation was very low. The poor recovery yield may be attributed to the impaired VLP stability as empty capsids are less stable than mature virions<sup>[45]</sup>. The particle stability may be enhanced by the addition of a stabilizer (e.g., pirodavin, disoxaril or R 78206) that binds the pocket underneath the canyon of the particle<sup>[46]</sup>. The feasibility of enhancing VLP integrity by stabilizers is being evaluated. Furthermore, the development of a more efficient chromatography-based purification scheme is necessary for process scale-up and is underway.

### INTRODUCTION

Esophageal adenocarcinoma (EAC) is one of the most rapidly increasing cancers over the past two decades in Caucasian males in the United States<sup>[1,2]</sup>. After being diagnosed with adenocarcinoma, patients have only a 13-15% 5-year survival rate<sup>[3]</sup>. Most of the EAC are developed from Barrett's esophagus (BE), a pre-malignant disease characterized by replacement of the normal esophageal squamous epithelium with a specialized intestinal metaplasia (SIM)<sup>[4]</sup>. The risk of EAC in BE patients has been estimated to be about 30 -125 times higher than the general population<sup>[2,5]</sup>.

The mechanisms of the evolution from BE to EAC are largely unknown<sup>[6,7]</sup>. During the neoplastic transformation, aberrations in the cell cycle lead to uncontrolled cellular replication, a molecular mechanism is believed to be involved in all carcinogenesis<sup>[8]</sup>. Epidermal growth factor receptor (EGFR) family of receptor tyrosine kinases lies at the head of a complex signal transduction cascade that modulates cell proliferation, differentiation, adhesion and migration<sup>[9]</sup>. EGFR is a transmembrane receptor composed of an extracellular ligand-binding domain and a cytoplasmic region with enzymatic activity. This structure enables signals to be transmitted across the plasma membrane activating gene expression and inducing cellular responses, such as proliferation and differentiation. Over-expression of EGFR has been shown to occur in various malignancies, including esophageal adenocarcinoma<sup>[10]</sup>.

Another important enzyme involved in tumor growth is cyclooxygenase-2 (COX-2)<sup>[11]</sup>. There are two isoforms of COX enzyme. COX-1 is constitutively expressed in most tissues; however, COX-2 has a markedly different expression pattern. Normally, COX-2 is undetectable in most tissues, but can be expressed at high levels after induction with a variety of substances, including inflammatory mediators and mitogens<sup>[12-14]</sup>. Epidemiological studies have shown that intake of aspirin, a nonsteroidal anti-inflammatory drug (NSAID) known as COX enzymes blocker, is associated with an up to 90% decreased risk of developing esophageal

### Abstract

**AIM:** To investigate the expression of cyclooxygenase-2 (COX-2) and epithelial growth factor receptor (EGFR) throughout the progression of Barrett's esophagus (BE).

**METHODS:** COX-2 and EGFR protein expressions were detected by using immunohistochemical method. A detailed cytomorphological changes were determined. Areas of COX-2 and EGFR expression were quantified by using computer Imaging System.

**RESULTS:** The expressions of both COX-2 and EGFR increased along with the progression from BE to esophagus adenocarcinoma (EAC). A positive correlation was found between COX-2 expression and EGFR expression.

**CONCLUSION:** COX-2 and EGFR may be cooperative in the stepwise progression from BE to EAC, thereby leading to carcinogenesis.

cancer<sup>[15,16]</sup>. Experimental studies also have indicated that over-expression of COX-2 is associated with decreased apoptosis and cell-cell adhesion, and with increased proliferation and differentiation<sup>[17,18]</sup>.

Recently, experimental investigations have suggested a close relationship between COX-2 and EGFR. Expression of EGFR was markedly increased in the COX-2-transfected cells, and inhibition of COX-2 could suppress the induction of EGFR in these cells<sup>[19]</sup>. It has also been demonstrated that activation of EGFR can induce COX-2 expression and prostaglandin production<sup>[20]</sup>. Furthermore, a combination of an EGFR inhibitor with a nonselective COX-1/COX-2 inhibitor was shown to prevent the development of intestinal cancer in nude mice<sup>[21]</sup>. Taken together, these data link COX and EGFR, and provide a theoretical basis whereby the COX-2 and EGFR signaling pathway may have additive effects of tumor growth. Some studies on expression of COX-2<sup>[18]</sup> and EGFR<sup>[22]</sup> in the human Barrett's esophagus specimens have been reported. However, to our knowledge, a detailed morphologic description of the esophageal epithelium expressing both COX-2 and EGFR in the BE metaplasia to dysplasia to adenocarcinoma sequence has not yet been performed.

In the present study, we therefore investigated the expressions of both COX-2 and EGFR in biopsy tissues from different histologic stages of BE by using immunohistochemical assay, and addressed the morphological features of Barrett's epithelium with over-expressed protein levels of COX-2 and EGFR in the histologic stages of metaplasia and dysplasia. Furthermore, we set forth to determine the correlation between COX-2 and EGFR in progression from the metaplasia to dysplasia to adenocarcinoma sequence.

## MATERIALS AND METHODS

### *Case selection and review*

The study samples were collected retrospectively from 104 patients who had undergone esophageal biopsy between 1996 and 2004. All of these patients were recruited from the Barrett's Esophagus registry at the University of Louisville with established diagnoses of SIM, indefinite/low-grade dysplasia (I/LGD), high-grade dysplasia (HGD), and EAC. No preoperative radio- or chemotherapy had been performed. None of the patients had received NSAIDs therapy. A microscope examination confirmed the diagnoses of SIM, LGD, HGD and EAC on these esophageal tissues reviewed by two pathologists independently, blinded to the subject's clinical history. Alcian-blue staining was used to identify any presence of SIM. Hematoxylin-eosin staining was used to identify any presence of dysplasia and EAC. A control group consisted of 30 subjects with nondetectable Barrett's (NB), defined by endoscopic findings of columnar-lined esophagus (CLE), but no pathologic evidence of SIM despite alcian-blue staining on all of the four-quadrant biopsies. This study was approved by the Institutional Review Board for Human Study at the University of Louisville.

### *Immunohistochemical assay for COX-2 and EGFR*

COX-2 and EGFR protein expressions were determined

by using an immunohistochemical assay. Staining was carried out on the paraffin-embedded tissues using the DAKO EnVision™+System Kit (DAKO Corporation, Carpinteria, CA) according to the manufacturer's instructions. In brief, the sections were deparaffinized and hydrated. The slides were washed with TRIS-buffer, and peroxidase blocking was performed for 5 min. After rewashing, the slides were incubated separately with the monoclonal mouse COX-2 antibody (1:200) or EGFR antibody (1:200) (SantaCruz Biotechnology Inc, CA) for 30 min at room temperature. The chromogenic substrate diaminobenzidine was added as a visualization reagent. Finally, the slides were counterstained with haematoxylin. A negative control was included in each run.

### *Cytomorphology associated with localization of COX-2 and EGFR*

Microscopic evaluation of the morphological features of epithelium was performed at high-power fields (X 400 magnification) on the COX-2 and EGFR staining sections. Two cytomorphological features were chosen as the criteria of assessment based on observed morphological differences among SIM, I/LGD, HGD and EAC along with NB columnar epithelium: (1) ordering of nuclei; and (2) the presence of basally located nuclei with an apical cytoplasmic layer. We considered the normal cell phenotype (NCP) when the epithelial cells were arranged in a single layer with their long axes orientated towards the center of the lumen, and had a basally located nucleus with a thick apical layer of cytoplasm, whereas the abnormal cell phenotype (ACP) included multiple cell layers, displayed and enlarged nucleus and less cytoplasm. Every slide was examined throughout to identify the NCP cell and ACP cell with COX-2 staining and EGFR staining. Then, the COX-2-stained and the EGFR-stained epithelial cells were categorized to NCP cells and ACP cells. The other cells were ignored during the evaluation.

### *Computer image analysis*

A computer image analysis was performed to quantify the expressions of COX-2 and EGFR in totally 104 subjects diagnosed with SIM, I/LGD, HGD and EAC, and in 30 controls. The imaging fields were chosen randomly from various section levels to ensure objectivity of sampling. Five imaging fields were scanned for each specimen sample. All digital images were acquired with the microscope at 40x magnification using the Spot camera via the MetaMorph® Imaging System (Universal Imaging Corporation., Downingtown, PA) and stored as JPG data files (the resolutions were fixed as 200 pixels/inch). The acquired color images from the immunohistochemical staining were defined a standard threshold according to the software specification. The computer program then quantified the threshold area represented by color images. COX-2 and EGFR protein expressions were defined by the percentages of threshold area in acquired color images.

### *Statistical analysis*

Spearman rank correlation coefficient (R) was used to analyze the correlation between COX-2 and EGFR expressions with the various histologic stages of Barrett's

**Figure 1** COX-2 staining in the sections from different stages of BE along with the sections from normal squamous and CLE nondetectable BE. **A:** Squamous epithelium (SE); **B:** Nondetectable BE in CLE (NB); **C:** Specialized intestinal metaplasia (SIM); **D:** Indeterminate/low-grade dysplasia (I/LGD); **E:** high-grade dysplasia (HGD); **F:** Esophageal adenocarcinoma (EAC). Strong COX-2 staining was detected in both NCP cells and ACP cells in the histological stages of SIM, I/LGD, HGD and EAC. A weak COX-2 staining was observed in the normal squamous epithelium.

**Table 1** Demographics of 104 study subjects with Barrett's esophagus and 30 control subjects

	NB	SIM	I/LDG	HDG	EAC
Subjects	30	37	36	16	15
Gender (male:female)	28:2	34:3	30:6	14:2	14:1
Mean age (yr)	60	55	61	68	66
Short-segment CLE	27	21	7	1	0
Long-segment CLE	3	16	29	15	15

SIM: Specialized intestinal metaplasia; I/LGD: Indeterminate/low-grade dysplasia; HGD: High-grade dysplasia; EAC: Esophageal adenocarcinoma; NB: Nondetectable Barrett's; CLE: Columnar-lined esophagus.

esophagus. Multiple analysis of variance (MANOVA) was used to determine the differences between COX-2 and EGFR expressions, if any, between the different histologic stages of carcinogenesis. *P* values less than 0.05 were considered statistically significant.

## RESULTS

One hundred and four subjects (92 males, 12 females) with Barrett's esophagus were enrolled in this study. The study population consisted of 37 subjects with a diagnosis of SIM without dysplasia, 36 with I/LGD, 16 with HGD, and 15 with EAC. The control group consisted of 30 NB subjects. Patients identified as having no Barrett's were mostly those with a short segment of CLE whereas those identified with SIM, I/LDG, HDG or EAC were mostly found to have a long segment of CLE (Table 1).

### Cytomorphological features associated with localization of COX-2 and EGFR

A very strong COX-2 staining in all Barrett's epithelium compared to a weak staining in normal squamous epithelium and CLE without Barrett's epithelium was observed. In particular, in the regions with COX-2-positive staining, the epithelial cells presented cytomorphological features of both NCP cells and ACP cells in the histological stages of SIM, I/LGD, HGD and EAC (Figure 1). A positive EGFR staining was presented in all Barrett's epithelium, but not as strong as that seen in the COX-2 staining. In contrast to COX-2 staining, the regions of positive EGFR expression exhibited ACP cells while those regions with weak or no EGFR staining exhibited NCP cells (Figure 2).

### Expression of COX-2 in the metaplasia to dysplasia to adenocarcinoma sequence

We observed significant increases in COX-2 expression in specimens with SIM ( $7.8 \pm 0.8$ ), I/LGD ( $10.0 \pm 0.9$ ), HGD ( $14.2 \pm 1.8$ ) and EAC ( $16.0 \pm 2.2$ ) as compared with the control specimens ( $6.9 \pm 1$ ) ( $P < 0.05$ ). Furthermore, COX-2 expression appeared to increase with the histological severity of BE; there was a significant positive correlation between COX-2 expression and histopathologic changes from I/LGD to EAC ( $r = 0.97$ ,  $P < 0.001$ ) (Figure 3).

### Expression of EGFR in the metaplasia-dysplasia-adenocarcinoma sequence

We found significant increases in EGFR expression in specimens with SIM ( $2.1 \pm 0.5$ ), I/LGD ( $2.7 \pm 0.6$ ), HGD ( $3.9 \pm 0.7$ ) and EAC ( $5.2 \pm 0.9$ ) as compared with the control specimens ( $0.8 \pm 0.4$ ) ( $P < 0.05$ ). Furthermore, EGFR expression appeared to increase with the histological severity of BE; there was a significant positive

**Figure 2** EGFR staining in the sections from different stages of BE along with the sections from normal squamous and CLE nondetectable BE. **A:** Squamous epithelium (SE); **B:** Nondetectable BE in CLE (NB); **C:** Specialized intestinal metaplasia (SIM); **D:** Indeterminate/low-grade dysplasia (I/LGD); **E:** high-grade dysplasia (HGD); **F:** Esophageal adenocarcinoma (EAC). Strong EGFR staining was detected in ACP cells (arrowhead) in the histological stages of SIM, I/LGD, HGD and EAC. A weak EGFR staining was found in NCP cells (arrow) and in the normal squamous epithelium.

**Figure 3** COX-2 expression and pathological severity of BE. COX-2 expression is plotted against the 4 stages of Barrett's esophagus. The line enclosed within the box represents the median value; the small circles indicate outlying data points. COX-2 expression in specimens with SIM, I/LGD, HGD and EAC was significantly increased in comparison with that in NB ( $P < 0.01$ ). A significant positive correlation between COX-2 expression and histopathologic changes from SIM to EAC was observed ( $r = 0.97$ ,  $P < 0.001$ ).

**Figure 4** EGFR expression and pathological severity of BE. EGFR expression is plotted against the 4 stages of Barrett's esophagus. The line enclosed within the box represents the median value; the small circles indicate outlying data points. EGFR expression in specimens with SIM, I/LGD, HGD and EAC was significantly increased in comparison with that in NB ( $P < 0.01$ ). A significant positive correlation between EGFR expression and histopathologic changes from SIM to EAC was found ( $r = 0.97$ ,  $P < 0.001$ ).

correlation between EGFR expression and histopathologic changes from I/LGD to EAC ( $r = 0.97$ ,  $P < 0.001$ ) (Figure 4).

#### Correlation between COX-2 and EGFR in metaplasia-dysplasia-adenocarcinoma sequence

The data from computer quantification of COX-2 expression and EGFR expression in all immunohistochemically stained sections were used to determine the correlation between COX-2 and EGFR in the metaplasia-dysplasia-adenocarcinoma sequence. A significant positive correlation between COX-2 expression and EGFR expression was determined in the BE tissues ( $r = 0.94$ ,  $P < 0.001$ ) (Figure 5).

## DISCUSSION

Our results showed a detailed information on localization of COX-2 and EGFR protein within the metaplastic cells, dysplastic cells and cancer cells. We demonstrated a significant increase in both COX-2 and EGFR expressions in the metaplasia-dysplasia-adenocarcinoma sequence. In particular, weak COX-2 and EGFR stainings were found in the normal squamous epithelium and NB epithelium, while strong COX-2 and EGFR stainings were found in the region with histological changes of metaplasia, dysplasia and EAC. To our best of knowledge, this is the first study to examine the relationship between COX-2 and EGFR in respect to the histologic progression from BE

**Figure 5** Relationship between COX-2 expression and EGFR expression in 104 patients. A significant positive correlation between COX-2 expression and EGFR expression was found ( $r=0.94$ ,  $P<0.001$ ).

to EAC. Since both COX-2 and EGFR expression levels increase dramatically in BE, each of these changes could enhance the tumorigenic potential of BE<sup>[10,11,18,22]</sup>.

This study focused on the morphological features of Barrett's epithelium with the expression of COX-2 and EGFR for the following reasons. First, evaluation from BE to EAC is primarily based on the cytomorphological characteristics<sup>[1,7,23,24]</sup>. Neoplasia develops in a series of steps through the development of a morphologically changed cell population. It is widely accepted that COX-2 and EGFR play important roles during carcinogenesis, and the over-expression of COX-2 and EGFR would be expected to predispose the epithelium to tumorigenic morphological change. Second, up-regulations of COX-2 and EGFR have been reported in BE and EAC, but no evidence has been provided for the joint signaling of COX-2 and EGFR in the induction of Barrett's epithelium to adenocarcinoma transition. This induction remains an integral process occurring during critical phase of tumor progression. Third, although COX-2 and EGFR play different biological roles in tumor formation, targeting both COX-2 and EGFR to abrogate both pathways and their downstream targets achieved significant antitumor and antiangiogenic effects in the *in vivo* and *in vitro* studies<sup>[21,25]</sup>. Therefore, the two proteins might be cooperatively carcinogenic, which intensify the transformation effects on Barrett's metaplasia to dysplasia to adenocarcinoma sequence.

The exact function of COX-2 in tumor development and progression *in vivo* is not known as yet. One possibility follows that over-expression of COX-2 leads to high levels of prostaglandins synthesis in the tissues. Prostaglandins produced by COX-2 may subsequently facilitate tumor progression by acting as growth factors, differentiation factors, immunosuppressors and angiogenic agents<sup>[26,27]</sup>. Other possibilities from recent studies indicate that reactive oxygen species (ROS) are generated during the conversion from prostaglandins G2 to prostaglandins H2<sup>[28,29]</sup>, this enhanced level of ROS parallels the levels of COX-2 mRNA. The COX-2-derived oxidative DNA damage may contribute to the accumulation of genetic damage, and the accumulation of genetic and epigenetic aberrations produces one or more clones with tumorigenic potential.

In addition, the COX-2 enzyme itself may promote tumor development and progression by a prostaglandins-independent pathway. This is supported by the evidences that NSAIDs suppressed proliferative activity and inhibited the growth in colon cancer cells without repressing prostaglandins synthesis<sup>[30]</sup>. Over-expression of COX-2 can also up-regulate anti-apoptotic oncoprotein such as BCL-2 and multiple proliferation-promoting cyclins and cyclin-dependent kinases, and down-regulate some tumor suppressor proteins<sup>[17,31]</sup>. The postulation for the involvement of COX-2 over-expression related to the progression in metaplasia to dysplasia to adenocarcinoma sequence is based on extensive studies of the relationship between COX-2 and tumor development and progression in multiple organ system.

Our data demonstrated a strong immunoreactivity for COX-2 protein within metaplastic cells, dysplastic, and malignant cells when compared to normal squamous cells and NB columnar cells. The cytomorphological features of COX-2 distribution in all epithelium may reflect two aspects of the effect of COX in contribution to the development of tumor. COX-2 is an important factor to maintain the microenvironment for tumor growth, and COX-2 may not be the critical factor in contribution to the phenotype changes of pre-malignant cells. COX-2 is undetectable in most tissues in the physiological condition<sup>[13,14]</sup>; the animals lacking COX-2 and prostaglandins synthesis show no innate gastrointestinal pathology<sup>[32]</sup>. These features of COX-2 do not confirm COX-2 expression as a central event in carcinogenesis. On the other hand, it is also possible that duodenal-gastro reflux and/or rapid growth and invasion of cancer cells in BE would stimulate local inflammation to inflammatory mediators and mitogens<sup>[12,13]</sup>, which, in turn, would induce COX-2 synthesis. Nevertheless, the high level of COX-2 synthesis would prolong the survival of these abnormal cells and increase the chance for tumorigenesis.

EGFR signaling module plays a fundamental role in the morphogenesis of a diverse spectrum of organisms, and has been highly conserved through the course of evolution. In humans, the EGFR family, which consists of the EGFR itself and the receptors known as HER 2-4, and more than 30 ligands lie at the head of a complex, multi-layered signal-transduction network<sup>[33]</sup>. The aberrant activity of the members in this family has been shown to play a key role in the development and growth of tumor cells<sup>[9]</sup>. The EGFR family is over-expressed in various types of human neoplasms, such as esophagus, thyroid, breast, testis, bladder, melanoma, pancreas, colon, cervical carcinomas, renal carcinoma, prostate and liver cancer<sup>[10]</sup>. The underlying mechanism for EGFR involvement in carcinogenesis is likely to reduce the requirement for exogenously supplied growth factors to maintain tumorigenic cells proliferation. Over-expression of EGFR can hypersensitize the cells to low concentration of growth factors to maintain their viability, and to facilitate their phenotype transformation mediated by these growth factors<sup>[34,35]</sup>. The aberrant activity of the EGFR might regulate the expression of specific oncogenes or tumor suppressor genes involved in the intracellular signal transduction pathway to synthesize endogenously produced growth factors<sup>[36]</sup>. Several stud-

ies have also supported the notion that the endogenous growth factors might function via an intracrine, juxtacrine, autocrine or paracrine mechanisms to control cell proliferation<sup>[34-36]</sup>.

The results obtained from this study for EGFR staining showed a significant effect of EGFR in contribution to the cytomorphological changes. A large amount of EGFR protein was expressed in the epithelial cells displaying multiple cell layers, enlarged nucleus and less cytoplasm in SIM, I/LGD, HGD and EAC. This over-expression was consistent across the BE progression, thereby indicating an important role of EGFR in the initiation of Barrett's cells transition to adenocarcinoma. The phenotypic effects of abnormal function of EGFR protein are far more dramatic. Recent studies have indicated that animals lacking EGFR have abnormal eyes and epidermal tissues and die due to defects in the development of epithelial organ<sup>[37,38]</sup>. Therefore, EGFR may play a key role in the morphogenesis of metaplasia, dysplasia and adenocarcinoma. In our study, the immunoreactivity of EGFR was observed in the same increasing trend with the metaplasia to dysplasia to adenocarcinoma sequence as that seen in COX-2 immunoreactivity, thus suggesting a cooperative effect of these two proteins.

In summary, our study demonstrates a positive relationship between expression of COX-2 and EGFR in the progression from metaplasia to dysplasia to adenocarcinoma in subjects with BE. This suggests that both COX-2 and EGFR may increase the likelihood of Barrett's cells to undergo abnormal cell cycling or gene expression. Further studies are needed to correlate the COX-2 and EGFR expression pattern with clinical outcome. Animal models and tissue culture are also required to determine the exact mechanism of COX-2 and EGFR action in the metaplasia to dysplasia to adenocarcinoma sequence.

**CONCLUSION:** LCVP is easily achievable in technique. Maintenance of  $CVP \leq 4$  mmHg can help reduce blood loss during hepatectomy, shorten the length of hospital stay, and has no detrimental effects on hepatic or renal function.

## Abstract

**AIM:** To investigate the effect of low central venous pressure (LCVP) on blood loss during hepatectomy for hepatocellular carcinoma (HCC).

**METHODS:** By the method of sealed envelope, 50 HCC patients were randomized into LCVP group ( $n=25$ ) and control group ( $n=25$ ). In LCVP group, CVP was maintained at 2-4 mmHg and systolic blood pressure (SBP) above 90 mmHg by manipulation of the patient's posture and administration of drugs during hepatectomy, while in control group hepatectomy was performed routinely without lowering CVP. The patients' preoperative conditions, volume of blood loss during hepatectomy, volume of blood transfusion, length of hospital stay, changes in hepatic and renal functions were compared between the two groups.

**RESULTS:** There were no significant differences in patients' preoperative conditions, maximal tumor dimension, pattern of hepatectomy, duration of vascular occlusion, operation time, weight of resected liver tissues, incidence of post-operative complications, hepatic and renal functions between the two groups. LCVP group had a markedly lower volume of total intraoperative blood loss and blood loss during hepatectomy than the control group, being  $903.9 \pm 180.8$  mL vs  $2\ 329.4 \pm 2\ 538.4$  ( $W=495.5$ ,  $P<0.01$ ) and  $672.4 \pm 429.9$  mL vs  $1\ 662.6 \pm 1\ 932.1$  ( $W=543.5$ ,  $P<0.01$ ). There were no remarkable differences in the pre-resection and post-resection blood losses between the two groups. The length of hospital stay was significantly shortened in LCVP group as compared with the control group, being  $16.3 \pm 6.8$  d vs  $21.5 \pm 8.6$  d ( $W=532.5$ ,  $P<0.05$ ).

## INTRODUCTION

Hepatectomy remains as the treatment of choice for hepatocellular carcinoma (HCC). Intra-operative blood loss is one of the major causes for post-operative morbidity and mortality. Various techniques, such as Pringle's maneuver and unilateral hepatic hilum occlusion, have been used to control bleeding from hepatic arterial and portal venous systems during hepatectomy in clinical settings. However, for excision of HCC adjacent to major blood vessels, hepatic system could be the major source of hemorrhage, especially after the application of Pringle's maneuver. Hence, effective control of hepatic venous hemorrhage is crucial to minimize intraoperative blood loss. This prospective randomized clinical trial aims at evaluating the role of low central venous pressure (LCVP) in reducing blood loss during hepatectomy for HCC.

## MATERIALS AND METHODS

### Patients' data and grouping

From June 2002 to December 2003, a total of 50 consecutive patients with HCC (40 men and 10 women) underwent hepatectomy by the same group of surgeons at our hospital. By the sealed envelope method, the patients were blindly randomized into LCVP group ( $n=25$ ) and control group ( $n=27$ ) at the beginning of the operation. Two patients in the control group were excluded from the study because hepatectomy was given up due to cardiac arrest in one and unclear tumor demarcation in the other. Eventually, there were 25 patients in each group. The demographic data of the patients are shown in Table 1,

Table 1 Comparison of patient's clinical data between two groups

Groups	Gender (male/female) <sup>1</sup>	Age (yr) <sup>2</sup>	Body weight (kg) <sup>3</sup>	Liver cirrhosis (n) <sup>4</sup>	Liver function (Child-Pugh class) <sup>5</sup>

<sup>a</sup> $P<0.05$ , BUN values in both groups were within normal range (2.5-6.4 mmol/L).

and the preoperative laboratory findings are demonstrated and listed in Table 2.

### Intraoperative management

In the LCVP group, patient's right internal jugular vein was cannulated by a dual-channel catheter following anesthesia, with one channel being connected to the transducer for continuously monitoring CVPs. Arterial pressure was measured by puncture of radial artery. Systolic blood pressure (SBP) was maintained above 90 mmHg by intravenous infusion of dopamine (4-6  $\mu g/kg$ ). During hepatectomy, CVP was maintained at 2-4 mmHg by adopting Trendelenburg's posture (with head 15° lower than low extremities), limiting the volume of infusion and intravenously administering nitroglycerine (0.5-2 mg/time), and furosemide (10-20 mg) was used if necessary. From the beginning of anesthesia to the completion of liver resection, the infusion was maintained at a speed of < 75 mL/h, urine output > 25 mL/h, and SBP > 90 mmHg. If hypotension occurred, the dose of dopamine and the speed and volume of infusion were adjusted. If hemoglobin (Hb) was < 80 g/L during the operation, packed red cells were transfused. After liver resection and hemostasis were completed, the blood volume was restored with crystalloid and colloid solutions. Post-operative Hb value should be kept at above 100 g/L. In the control group, patients were managed in the same way as those in LCVP group, except for manipulation of patient's posture and administration of nitroglycerine and furosemide to lower CVP.

### Hepatectomic technique

The liver was completely separated. The extent of hepatectomy and whether or not applying hepatic blood inflow occlusion were determined based on the tumor situation and severity of liver cirrhosis. For the patients with severe cirrhosis or peripheral tumors, hepatic

blood inflow occlusion was not used. For patients with tumor located at one lobe of the liver, unilateral hepatic hilum occlusion was employed. In hepatic parenchymal transection, method of blunt division but not cavitron ultrasonic surgical aspirator (CUSA) was used. The ductal structures were first ligated and then divided, with reinforced suture for larger blood vessels. The cutting surface of the liver was sprayed with biological glue. The patterns of hepatectomy between the two groups were compared as shown in Table 3.

### Measurement of blood loss during hepatectomy

Total intra-operative blood loss consisted of the following three parts: (1) from the start of the operation to complete separation of the liver (pre-hepatectomic blood loss); (2) during division of hepatic parenchyma (intra-hepatectomic blood loss); (3) from completion of hepatic parenchymal division to the closure of the abdominal wall (post-hepatectomic blood loss). Operation was continued to the next step only after complete hemostasis was achieved. The blood-collection bottle was changed in each step and the volume of the collected blood was measured. All blood-stained gauzes were harvested and weighed. The difference between the weight of the blood-stained gauzes and their initial weight was considered as the weight of blood in the gauze, which was then converted into the volume of blood (the blood specific gravity: 1.054-1.062 g/mL in men with an average of 1.058 g/mL; 1.048-1.062 g/mL in women with an average of 1.055 g/mL).

### Evaluation parameters

The following pre-, intra-, and post-operative data were collected: (1) patient's gender, age, body weight, red blood cell (RBC) count, hematocrit (HCT), hemoglobin (Hb), alanine aminotransferase (ALT), aspartate aminotransferase (AST), total bilirubin (TBIL), serum albumin (ALB), blood urea nitrogen (BUN), creatinine (Cr), prothrombin

**Table 3** Comparison of operative pattern between two groups

Groups	Types of hepatectomy <sup>1</sup>				Types of vascular occlusions (n) <sup>2</sup>		Maximal tumor dimension (cm) <sup>4</sup>	Weight of the resected liver tissues (g)
	Right	Left	≥2 hepatic segments	Single hepatic segments	Unilateral	Portal hepatitis

<sup>1</sup>Rank sum test; <sup>2</sup> $P=0.05$ , <sup>b</sup> $P<0.01$ , <sup>d</sup> $P<0.01$  vs control.

time (PT), presence or absence of liver cirrhosis and liver function grading; (2) pre-hepatectomic, intra-hepatectomic and post-hepatectomic blood loss and total intra-operative blood loss; (3) operation time, pattern of hepatic hilum occlusion and duration, maximal tumor dimension, weight of the excised liver tissue and extent of hepatectomy, transfusion volume of packed RBCs and fresh frozen plasma (FFP); (4) liver and renal functions on post-operative d 1, 3, and 7; (5) post-operative morbidity and length of hospital stay.

### Statistical analysis

The results were expressed as mean ± SD. SPSS software package version 10.0 was used to run the statistical analysis. For continuous variables, Student's *t* test, rank test or ANOVA was employed to compare the inter-group difference, and  $\chi^2$  test was adopted for categorical variables. Statistical significance was considered at two-tailed  $P<0.05$ .

## RESULTS

### Patient's general clinical data

There were no significant differences in gender, age, body weight, severity of liver cirrhosis and grades of liver function between LCVP and control groups (Table 1).

### Preoperative laboratory data

Table 2 shows that preoperative RBC count, HCT, Hb, ALT, AST, TBIL, ALB, PT and Cr in LCVP group was not markedly different from those in the control group. Preoperative BUN in both the groups was within the normal range, being higher in control group than in LCVP group ( $P<0.05$ ).

### Operative pattern

All patients had large tumors. There were no remarkable differences in patterns of operation, modes of hepatic

blood inflow occlusion and duration, maximal tumor dimension, weight of the excised hepatic tissue between the two groups (Table 3).

### Operative time, intra-hepatectomic blood loss, blood transfusion, post-operative complications and length of hospital stay

Total intra-operative blood loss and intra-hepatectomy blood loss were dramatically less in LCVP group than in the control group ( $P<0.01$ , Table 4). There were no significant differences in pre- and post-hepatectomic blood losses between the two groups (Table 4). Eight of twenty-five patients in LCVP group and 14 of 25 patients in control group needed blood transfusion, with a significantly lower volume of transfusion in LCVP than in the control group ( $P<0.05$ , Table 5). There was no significant difference in operative time between the two groups (Table 5). Post-operative complications included biliary fistula, gastrointestinal bleeding, pleural effusion and subphrenic fluid collection, with an incidence of 20% (5/25) in LCVP group and 24% (6/25) in control group ( $P>0.05$ ). LCVP group had a remarkably shorter hospital stay than the control group, being  $16.3\pm6.8$  d vs  $21.5\pm8.6$  d ( $P<0.05$ ).

### Post-operative hepatic and renal functions

There were no significant differences in ALT, TBIL, and Cr on post-operative d 1, 3, and 7 between the two groups (Table 6,  $P>0.05$ ). BUN was significantly higher in control group than in the LCVP group, but it was within the normal range in both groups (Table 6,  $P>0.05$ ).

## DISCUSSION

Blood loss during hepatectomy has an adverse effect on the post-operative outcome and increases post-operative morbidity. Intra- or post-operative massive blood transfusion carries risks of causing infectious diseases,

Table 5 Comparison of operation time and incidence of post-operative complications

Groups	Operation time (min) <sup>1</sup>	Intra- and post-operative transfusion (mL)		Incidence of post-operative complications (n) <sup>4</sup>
		Packed RBC <sup>2</sup>	FFP <sup>3</sup>

coagulatory disorder, acute respiratory distress syndrome, multiple organ failure, and also promotes tumor recurrence due to its inhibitory effects on immunologic function<sup>[1,2]</sup>. Hence, various methods, including Pringle's maneuver, unilateral hepatic hilum occlusion and normothermic total hepatic vascular exclusion<sup>[3]</sup>, have been adopted to reduce intra-operative blood loss. In recent years, application of CUSA in liver resection under hepatic hilum occlusion has been reported to significantly lessen the intra-operative blood loss<sup>[4]</sup>. Some studies reported that LCVP during liver resection could significantly cut down the intra-operative blood loss, decrease the incidence of post-operative complications and shorten the hospital stay<sup>[5,6]</sup>. Under hepatic hilum occlusion, blood loss during liver resection mainly derives from hepatic vein and hepatic short vein. Hepatic sinusoidal pressure is directly related to CVP. With lowering of the pressure in inferior vena cava, the hepatic venous pressure and then hepatic sinusoidal pressure would decline. Blood loss during liver resection is proportional to the pressure gradient of vascular walls and the diameter of the injured vessels. Though total hepatic vascular exclusion or clamping inferior vena cava can reduce blood loss from hepatic venous system during hepatectomy<sup>[7]</sup>, they are associated with remarkable injury and technically difficult.

LCVP in hepatectomy was generally referred to as CVP lower than 5 mmHg<sup>[6]</sup>. Maintenance of LCVP should not lower the arterial pressure. In the present study, by maintaining CVP below 5 mmHg during liver resection with manipulation of patient's posture, administration of drugs and control of infusion speed, the arterial pressure

was effectively sustained and blood loss was markedly cut down. Our results suggested that Trendelenburg's posture was helpful to prevent LCVP-induced air embolism. With the maintenance of the arterial pressure, the perfusion of organs was ensured. The post-operative evaluation showed that LCVP would not deteriorate hepatic and renal functions. LCVP group had shorter hospital stay than the control group. It is suggested that LCVP was helpful for post-operative recovery. The LCVP technique was not complicated and achievable even in middle-class hospitals. Hence, it is of clinical value.

Many studies reported that various methods reduced intra-operative transfusion volume<sup>[8]</sup>. However, transfusion volume sometimes could not correctly reflect intra-operative blood loss, since the former was related to the patient's preoperative conditions, tolerance to ischemia, control of intraoperative infusion volume and speed, and anesthetist's mastery of indication for transfusion. Intra-operative blood loss included bleeding not only from hepatic parenchymal division, but also from dissection of perihepatic ligaments, separation of tumors from adjacent tissues, the cutting surface of liver after resection and the accidental tumor rupture. The latter was also affected by the surgeon's experiences and techniques, and patient's coagulation function. Hence, strictly speaking, only bleeding from hepatic parenchymal division accounts for the real blood loss of hepatectomy. In the present study, we have divided the procedure of hepatectomy into three steps, i.e., pre-, intra-, and post-hepatectomic, and blood loss in each step was completely collected and accurately measured. Our results showed that total intra-operative blood loss was markedly less in LCVP group than that in the control group. There were no significant differences in pre-hepatectomic and post-hepatectomic blood losses between the two groups, but intra-hepatectomic blood loss was remarkably lower in LCVP group than in the control group.

It suggested that lowering CVP during hepatectomy could effectively reduce blood loss. Additionally, transfusion volume was markedly cut down in LCVP as compared with the control group. It indicated that decline in intra-hepatectomic blood loss could reduce the transfusion volume, which is helpful for the recovery of patient's immunological function and prevention of tumor recurrence. The present study is a prospective randomized clinical trial. The number of cases is not big enough, and the effect of decline in intra-operative blood loss on prognosis still awaits further observations.

### Abstract

**AIM:** To evaluate whether treatment with the Prometheus<sup>®</sup> system significantly affects cytokines, coagulation factors and other plasma proteins.

**METHODS:** We studied nine patients with acute-on-chronic liver failure and accompanying renal failure. Prometheus<sup>®</sup> therapy was performed on 2 consecutive days for up to 6 h in all patients. Several biochemical parameters and blood counts were assessed at regular time points during Prometheus<sup>®</sup> treatment.

**RESULTS:** We observed a significant decrease of both protein-bound (e.g. bile acids) and water-soluble (e.g. ammonia) substances after Prometheus<sup>®</sup> therapy. Even though leukocytes increased during treatment ( $P < 0.01$ ), we found no significant changes of C-reactive protein, interleukin-6, and tumor necrosis factor- $\alpha$  plasma levels (all  $P > 0.5$ ). Further, antithrombin 3, factor II and factor V plasma levels did not decrease during Prometheus<sup>®</sup> therapy (all  $P > 0.5$ ), and the INR remained unchanged ( $P = 0.4$ ). Plasma levels of total protein, albumin, and fibrinogen were also not altered during Prometheus<sup>®</sup> treatment (all  $P > 0.5$ ). Finally, platelet count did not change significantly during therapy ( $P = 0.6$ ).

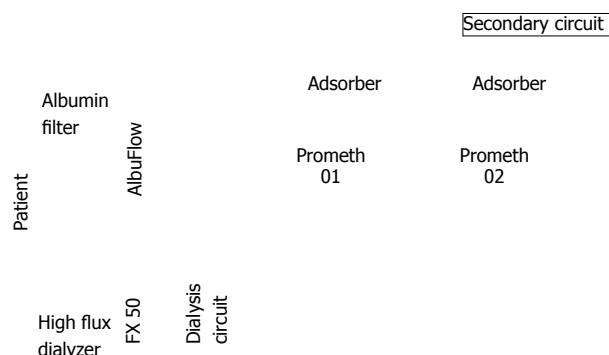

**CONCLUSION:** Despite significant removal of protein-bound and water-soluble substances, Prometheus<sup>®</sup> therapy did not affect the level of cytokines, coagulation factors or other plasma proteins. Thus, the filters and adsorbers used in the system are highly effective and specific for water-soluble substances and toxins bound to the albumin fraction.

### INTRODUCTION

Extracorporeal liver support devices have recently gained much interest. Prometheus<sup>®</sup> is a newly designed system for extracorporeal treatment of liver failure. It is based upon a recently developed method of albumin dialysis, i.e. fractionated plasma separation and adsorption<sup>[1]</sup>. First, an albumin-permeable membrane (AlbuFlow, cut-off 250 ku) separates the albumin fraction together with all albumin-bound substances in a secondary circuit. There, direct purification of the plasma is performed by one or two adsorbers (Prometh01 and Prometh02) in order to remove albumin-bound toxins. In parallel, a conventional high-flux dialysis is performed to remove the water-soluble substances.

Results from past studies have documented that extracorporeal liver support devices can remove cytokines and other important plasma proteins<sup>[2,3]</sup>. Theoretically, removal of these substances may influence spontaneous liver regeneration, similarly as has been proposed for interleukin-6 (IL-6) and tumor necrosis factor- $\alpha$  (TNF- $\alpha$ )<sup>[4]</sup>. Furthermore, development of thrombopenia with an increased risk of bleeding was documented in several patients undergoing albumin dialysis using the MARS system<sup>[5]</sup>. Until now, there are not sufficient controlled studies available that have evaluated whether treatment with the Prometheus<sup>®</sup> device may result in an unspecific removal of cytokines or leads to a decrease of coagulation factors or platelets. In addition, albumin or other plasma proteins may be lost during Prometheus<sup>®</sup> as a result of removal or after clotting in the secondary circuit. Therefore, we performed a prospective clinical study in patients with liver failure and assessed the course of different cytokines, coagulation factors, protein fractions, and thrombocytes during treatment with Prometheus<sup>®</sup>.

**Figure 1** The albumin fraction of the patient's blood is filtered through an albumin-permeable membrane (AlbuFlow®) into a secondary circuit. There, the separated albumin fraction is purified by direct adsorption of albumin-bound toxins using one or two adsorbers (Prometh01® and Prometh02®). The plasma is then pumped back into the primary circuit where a conventional high-flux dialysis (FX 50) is performed.

## MATERIALS AND METHODS

### Patients

The study was approved by the Ethics Committee of the Hannover Medical School. The Declaration of Helsinki and the rules from Good Clinical Practice were followed. Written informed consent was obtained from all patients or next of kin. Nine patients (four males) with liver failure (five with end-stage cirrhosis, two with acute alcoholic hepatitis, two with liver failure late after liver transplantation) and concomitant renal failure were included in the trial. Their mean age was  $52 \pm 8$  years, and the average APACHE II score was  $16.8 \pm 3.2$ . Seven patients (78%) had the highest stage of cirrhosis (C Child-Pugh score) with an average of  $11.3 \pm 1.7$  points. Six patients (67%) were treated in the intensive care unit. All patients were already undergoing hemodialysis and had a functionable double-lumen catheter in place.

### Prometheus® device

Blood coming from the patient by a double-lumen dialysis catheter is pumped into the extracorporeal circuit. There, it passes through an albumin-permeable filter, which is made of polysulfone (AlbuFlow®). The filter has a sieving coefficient that is specially designed. It allows large molecules up to the size of albumin (68 ku) to pass into the secondary circuit. The cut-off is at about 250 ku. Larger molecules cannot pass through the filter. The secondary circuit is filled with isotonic sodium chloride solution. It is driven by a separate plasma pump. By recirculation of the albumin-rich plasma, the filtration and adsorption capacities are enhanced. One or two adsorbers are used to directly purify the filtered albumin-rich plasma: a neutral resin adsorber (Prometh01®) for direct adsorption of the albumin-bound toxins and an anion exchanger (Prometh02®) with chloride used as counterion. The content of the adsorber consists of spherical adsorber particles with 300–1 000  $\mu\text{m}$  in diameter. The adsorbers consist of styrene-divinylbenzene copolymer. Their cylindrical housing has a central inlet and outlet closed

at both ends by sieves with a mesh size of 100  $\mu\text{m}$ . The sieves circumvent a passage of the particles through the inlets. Even in case of leakage, they are held back in the secondary circuit by the albumin filter membrane. After the purification of the fractionated plasma in the secondary circuit, the purified plasma is returned to the primary circuit, i.e. into the blood side of the albumin filter. Here the blood is guided through a high-flux hemodialyzer (FX 50®). There, water-soluble substances are removed by diffusion.

A modified hemodialysis unit (4008 H) is used to integrate the two parts of the Prometheus® system (Fresenius Medical Care AG, Bad Homburg, Germany): a “standard” extracorporeal blood circuit connected to the double-lumen dialysis catheter and a secondary circuit containing the separated plasma (Figure 1). Both circuits are separately monitored by different hardware and software allowing the user to perform hemodialysis with simultaneous albumin detoxification or conventional hemodialysis alone.

### Treatments

Instead of their regular hemodialysis sessions, all patients underwent two Prometheus® treatments for at least 4 h on two consecutive days. In 5/9 patients (56%), the device was equipped with two adsorbers (Prometh01® and Prometh02®), while the other four patients (44%) were treated only with Prometh01®. The average treatment time was  $5.1 \pm 1.1$  h, and mean blood flow rate was  $193 \pm 10$  mL/min. The total processed volume within each treatment was  $58 \pm 14$  L. Anticoagulation during therapy consisted of unfractionated heparin administered as a bolus. Because of the increased risk of bleeding in liver patients, heparin administration was restricted to low doses. The activated coagulation time was used to control anticoagulation. It was targeted between 120 and 150. Blood samples for measurement of cytokines (TNF- $\alpha$  and IL-6), platelets, coagulation factors (antithrombin 3, factors II and V) and plasma proteins (total protein, albumin, and fibrinogen) were taken before the start of Prometheus therapy, after 30 min, 2, and 5 h of treatment as well as 24 h after the end of the treatment.

### Measurements

Plasma concentration of C-reactive protein was measured with a clinically validated nephelometric assay (Dade Behring, Germany); the normal range is below 5 mg/L. Plasma concentrations of inflammatory cytokines, e.g. IL-6 and TNF- $\alpha$ , were measured with an ELISA (R&D Systems, USA). The intra-assay coefficients of variation for these tests ranged between 4.9% and 6.8%, respectively. The other biochemical parameters were measured by certified routine analytical methods.

### Statistical analysis

The SPSS program was used for statistical analysis (version 12.0, SPSS, Chicago, USA). All data are presented as mean  $\pm$  SD. Pre- and post-treatment values were compared using two-tailed *t*-test for paired data. Correlations were assessed with Pearson's correlation analysis. A  $P < 0.05$  was considered as statistically significant.

## RESULTS

A significant decrease of both protein-bound substances (e.g., bile acids;  $P < 0.01$ ) and water-soluble substances (e.g., urea;  $P < 0.001$ ) was observed under Prometheus® therapy (Figure 2A). Even though leukocytes increased from  $15.1 \times 10^3$  to  $22.7 \times 10^3/\mu\text{L}$  ( $P < 0.01$ ), there were no significant changes of plasma concentrations of C-reactive protein ( $P = 0.7$ ), TNF- $\alpha$  ( $P = 1.0$ ; Figure 2B) or IL-6 ( $P = 0.9$ ; Figure 2B). TNF- $\alpha$  and IL-6 were correlated with each other ( $P < 0.03$ ). Furthermore, they were positively associated with body temperature (TNF- $\alpha$ :  $P < 0.03$ ; IL-6:  $P < 0.001$ ), but not with C-reactive protein (both  $P > 0.2$ ). All these parameters were already increased in our patients before Prometheus® therapy.

Platelet count and coagulation factors such as antithrombin 3, factors II and V were substantially decreased in our patients before the start of Prometheus® therapy. However, there was no decrease of platelets during treatment ( $P = 0.6$ ). Furthermore, the coagulation factors and INR did not significantly change under Prometheus® treatment (all  $P > 0.4$ ; Figure 2C). All coagulation factors were highly associated with each other (all  $P < 0.001$ ) and with C-reactive protein (all  $P < 0.01$ ). A strong positive association was found between factors II and factor V on one hand and leukocyte count on the other hand (both  $P < 0.001$ ).

Plasma levels of total protein, albumin, and fibrinogen were reduced in liver patients before the start of Prometheus® therapy. Even though we had two episodes of clotting of the secondary, i.e. albumin-filled circuit occurred, we observed no significant alterations of total protein, albumin, and fibrinogen during treatment (all  $P > 0.5$ ; Figure 2D).

In one patient with hepatitis C cirrhosis and hepatorenal syndrome, we found a marked increase of TNF- $\alpha$  (from 17 to 12 420 ng/L) and IL-6 (from 49 to 15 732 ng/L) already after the 2<sup>nd</sup> h of treatment on the 1<sup>st</sup> day of Prometheus® therapy. In parallel, leukocytes decreased from  $8.1 \times 10^3$  to  $1.6 \times 10^3/\mu\text{L}$ . No specific clinical problems were recorded at that time, so that the Prometheus® treatment was completed. When treatment was stopped, mean arterial pressure was 52 mmHg, whereas body temperature was 38.9°C and leukocytes  $4.4 \times 10^3/\mu\text{L}$ . At this time point, we later measured already decreasing TNF- $\alpha$  plasma levels (1 012 ng/L), whereas IL-6 was still increasing (76 250 ng/L). This episode turned out to be a catheter-related bacteremia, and the catheter was removed immediately. After the catheter had been changed, no clinical problems were observed during Prometheus® therapy on the next day. Plasma levels of TNF- $\alpha$  after the second treatment decreased to 49 ng/L and that of IL-6 to 108 ng/L.

## DISCUSSION

Removal selectivity of extracorporeal blood purification devices is a key to assess their specificity and efficacy. Therefore, it is crucial to evaluate whether particular substances are removed or not. With Prometheus® both protein-bound and water-soluble substances that accumulate in liver failure are removed in a single step, i.e. during

a single passage of the blood through the extracorporeal circuit. The system is based upon the FSPA method, and in contrast to the MARS system, Prometheus® allows direct purification of the albumin fraction in the secondary circuit<sup>[1]</sup>. Furthermore, a high-flux dialyzer is incorporated in the Prometheus® system as well.

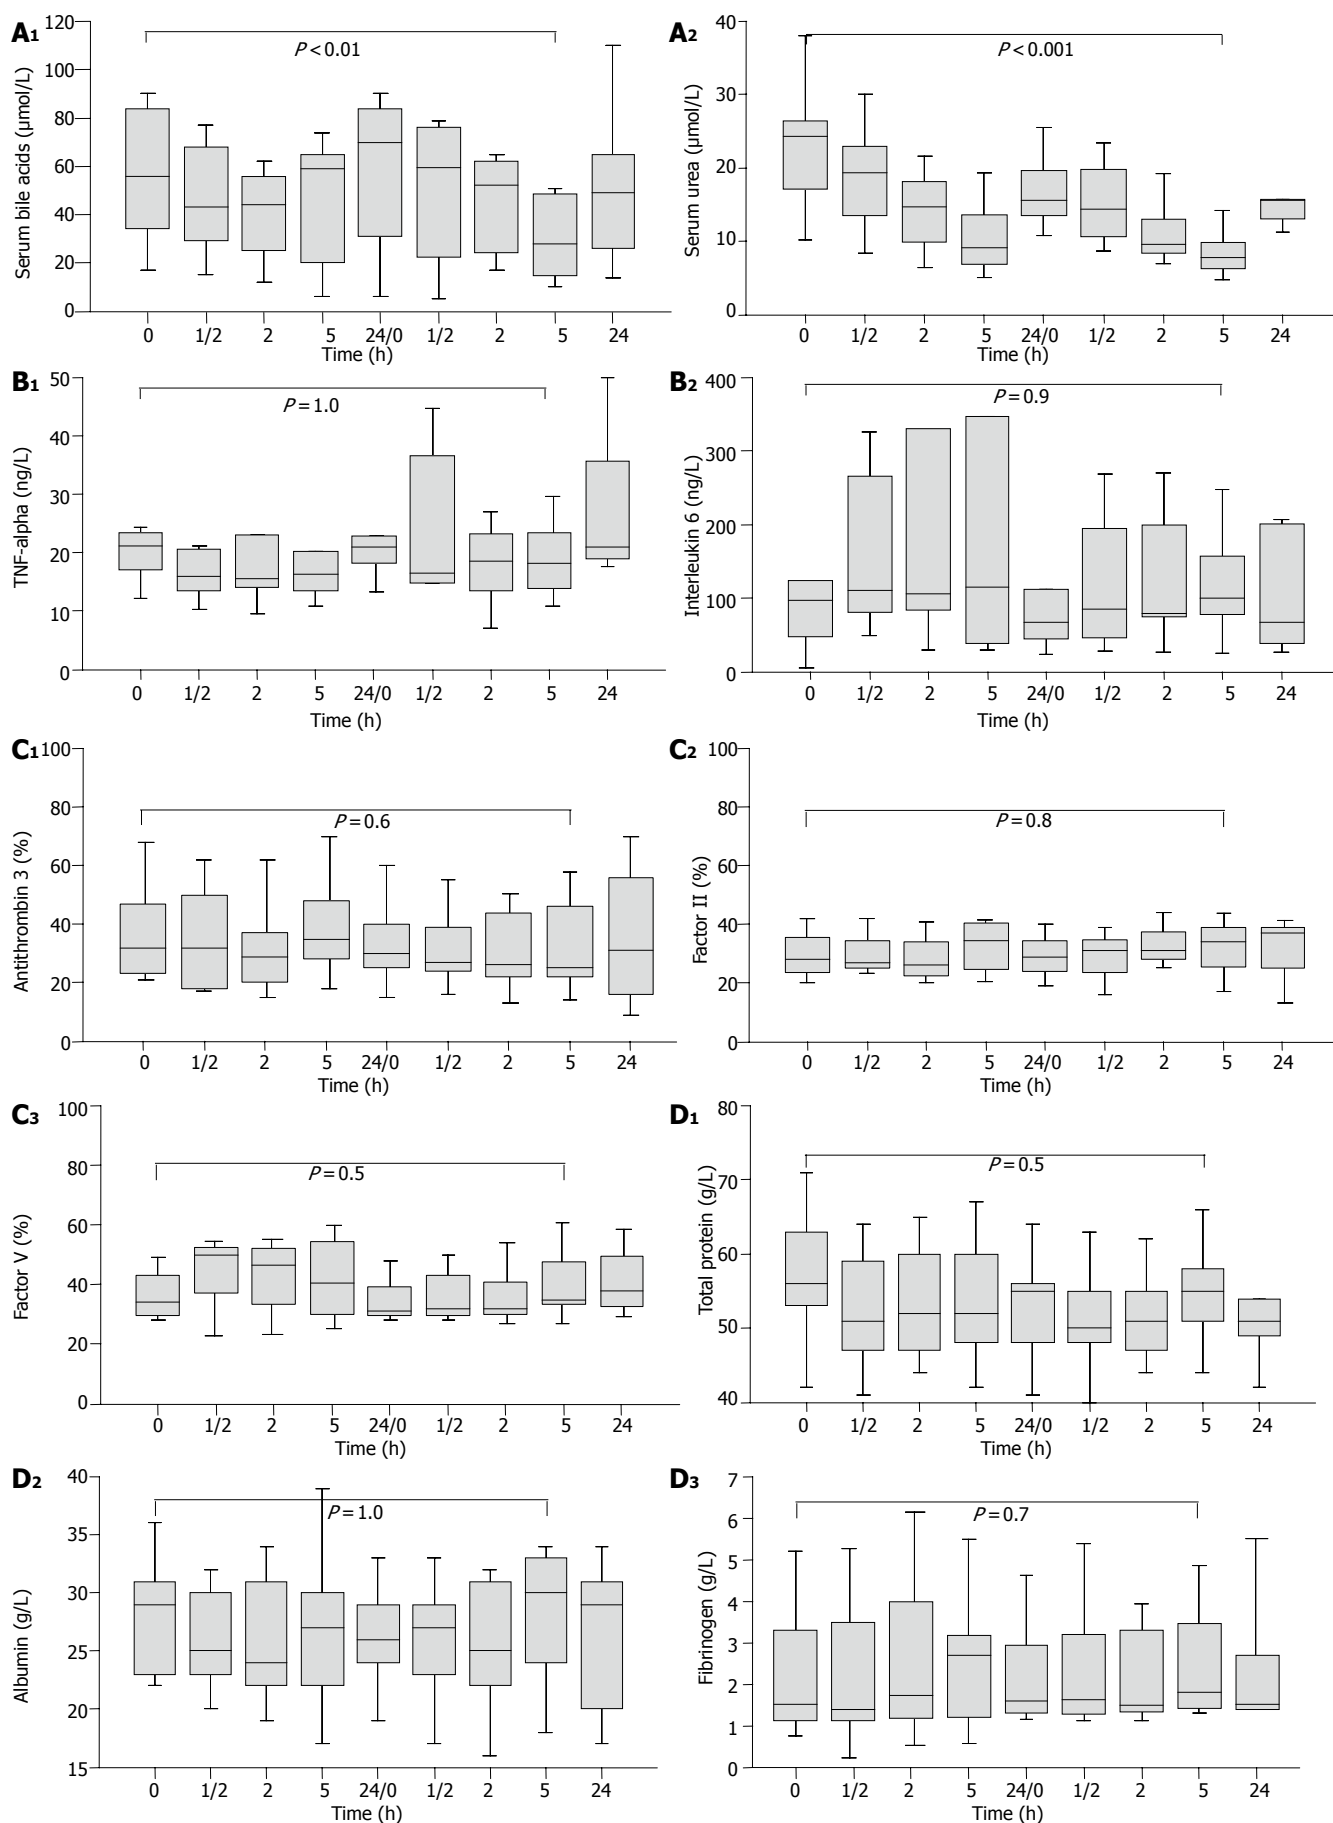

We were able to show that Prometheus® significantly removed protein-bound (e.g., bile acids) and water-soluble substances (e.g., urea), but we did not observe (unspecific) removal of cytokines such as TNF- $\alpha$  and IL-6. In contrast, it has been shown that both cytokines are removed during MARS treatment<sup>[2,3]</sup>. This could be of considerable clinical importance, since these pro-inflammatory cytokines are postulated to play a major role also in the process of liver regeneration<sup>[4]</sup>. Thus, while cytokine removal may have beneficial effects in clinical conditions where activation of pro-inflammatory cytokines is part of the pathophysiological basis of the syndrome, e.g. systemic inflammatory response syndrome (SIRS)<sup>[7]</sup>, it could be potentially even harmful in liver patients by impeding liver regeneration<sup>[8]</sup>. Since large prospective controlled trials on survival are lacking, it remains to be elucidated whether (unspecific) cytokine removal in liver patients is beneficial or whether these patients benefit more if pro-regenerative cytokines such as TNF- $\alpha$  and IL-6 remain in the body.

Another point of interest in our study was the influence of Prometheus® therapy on coagulation factors and platelets. Usually, patients with liver failure present with moderate to severe coagulopathy. In order to prevent bleeding complications in these patients, the coagulation status should not be further worsened by a removal, activation or consumption of coagulation factors. In none of our patients we observed a decrease of platelets, and coagulation factors such as antithrombin 3, factor II or factor V remained stable throughout the therapy without substitution. This is in contrast to data obtained with the MARS system; it may induce thrombopenia in a significant number of patients with a subsequently elevated risk of bleeding complications<sup>[5]</sup>.

An important point in the evaluation of extracorporeal liver support systems is the possible loss of plasma proteins during treatment. This may result from an unspecific removal, from adsorption on the adsorber, or by a clotting of the secondary circuit that is filled with the patients' albumin. Even though two episodes of clotting of the secondary circuit occurred in our study, no significant loss of plasma total protein or albumin developed. Furthermore, the selectivity of protein removal was confirmed by measurement of serum fibrinogen concentrations. Fibrinogen molecules are much larger than albumin and should be held in patients' blood if the sieving coefficient of the membrane used for plasma separation remains unaltered. As expected, fibrinogen levels in our patients remained stable throughout the whole study period.

In conclusion, our data document that the extracorporeal liver support device Prometheus® provides selective removal of protein-bound and water-soluble substances, whereas measured cytokines, coagulation factors or plasma protein fractions as well as platelets remain unaltered. In this aspect the system seems to offer an advantage over the MARS system.

**Figure 2 (A1-A2)** Course of plasma bile acids and urea concentrations before, during and after 2 d of Prometheus<sup>®</sup> therapy. Data are presented as median, quartiles, and minimum/maximum values. **(B1-B2)** Course of plasma TNF- $\alpha$  and IL-6 concentrations before, during and after 2 d of Prometheus<sup>®</sup> therapy. Data are presented as median, quartiles, and minimum/maximum values. **(C1-C3)** Course of antithrombin 3, factors II and V levels before, during and after 2 d of Prometheus<sup>®</sup> therapy. Data are presented as median, quartiles, and minimum/maximum values. **(D1-D3)** Course of plasma total protein, albumin, and fibrinogen before, during, and after 2 d of Prometheus<sup>®</sup> therapy. Data are presented as median, quartiles, and minimum/maximum values.

### Abstract

**AIM:** The beneficial effect of zinc supplementation on the efficacy of interferon as a treatment for chronic hepatitis C had been demonstrated in hepatitis virus genotype 1b of high viral load. This study focused on patients with genotype 2, which is more sensitive to interferon than genotype 1b, and used consensus interferon (CIFN) with or without zinc.

**METHODS:** We randomized 83 patients with chronic hepatitis C to CIFN at 18 MIU six times/wk for 4 wk, followed by CIFN at 18 MIU six times/wk for another 20 wk, in combination with polaprezinc 300 mg (regimen A,  $n=41$ ) or as monotherapy (regimen B,  $n=42$ ). Thirty-one patients in regimen A and 33 patients in regimen B completed the clinical trial; the remaining patients withdrew because of side effects or a transfer to another hospital.

**RESULTS:** Sustained biochemical response, defined as a normal aminotransferase level at the end of the 6-mo post-treatment observation, was 68% and 69%, and sustained virological response, defined as undetectable HCV-RNA at the end of the 6-mo post-treatment observation, was 54% and 67% for regimens A and B, respectively.

**CONCLUSION:** CIFN treatment combined with zinc did not enhance the effect of CIFN as shown by biochemical, virological criteria. No side effects related to polaprezinc were noted.

### INTRODUCTION

Interferon (IFN) is an effective treatment for chronic hepatitis C and is the only method of treatment that eliminates hepatitis C virus (HCV)<sup>[1,2]</sup>. The incidence of hepatocellular carcinoma (HCC) decreases if liver function improves, even if the virus is not eradicated after IFN treatment<sup>[3-6]</sup>, or if HCV RNA becomes undetectable during IFN treatment<sup>[7]</sup>. IFN treatment for chronic hepatitis C plays a pivotal role in the prevention of HCC.

HCV-RNA clearance rates are reported to be approximately 30-40% in patients treated with IFN alone<sup>[8-10]</sup>. However, better results have been reported when IFN- $\alpha$  is used in combination with ribavirin in both naïve patients<sup>[11,12]</sup> and in those who failed to respond to, or relapsed after, IFN- $\alpha$  monotherapy<sup>[13,14]</sup>. However, IFN plus ribavirin treatment for 24 wk causes more frequent side effects leading to dose reduction or discontinuation of treatment in 28% of cases compared that in 21% of cases in IFN alone treatment<sup>[11]</sup>. Furthermore, in Japan, the use of ribavirin is restricted to naïve patients with chronic hepatitis C who have high viral loads greater than 100 KIU/mL.

Consensus IFN (CIFN) is a genetically engineered novel type I IFN molecule derived from commonly observed amino acids of several natural IFN subtypes<sup>[15]</sup>. CIFN has demonstrated higher *in vitro* antiviral effects on an equal mass basis, than IFN- 2 $\alpha$  or 2 $\beta$ <sup>[16,17]</sup>. In Japan, 9-18 MIU CIFN treatment for 6 mo is reported to be well tolerated and 18 MIU CIFN is considered to be the maximum tolerable dose in patients with chronic hepatitis C and is superior in efficacy, without additional toxicity, to 9 MIU CIFN in high-titer chronic hepatitis C patients<sup>[18]</sup>.

Serum zinc levels are low in patients with chronic liver disease because of a trace element metabolism disorder<sup>[19]</sup>. Previously, we have demonstrated that zinc supplementa-

tion in chronic hepatitis C patients with genotype 1b of high viral load enhanced the response to IFN- $\alpha$  monotherapy<sup>[20]</sup>. Although zinc has diverse biological properties including antiviral, anti-inflammatory, and antioxidant functions<sup>[21-24]</sup>, the mechanism responsible for the beneficial effect of zinc during treatment with IFN remains to be elucidated. Treatment efficacy depends on the genotype, HCV load, and staging; HCV genotypes 2a and 2b are more sensitive to IFN than genotype 1a or 1b<sup>[1,25,26]</sup>.

We planned a randomized controlled study for the treatment of genotypes 2a and 2b hepatitis C to determine whether zinc supplementation could also enhance the efficacy of IFN in chronic hepatitis C patients as well as genotype 1b. We used CIFN instead of IFN plus ribavirin for the following reasons. (1) Naïve chronic hepatitis C patients with low viral load could not be treated by the standard treatment, IFN- $\alpha$  2b plus ribavirin or pegylated-IFN plus ribavirin, under the current health insurance regulations in Japan, due to high sensitivity of HCV with low viral load to IFN. (2) Even with high viral loads, HCV genotype 2a/2b can be expected to be relatively sensitive to IFN monotherapy without ribavirin. (3) CIFN has fewer restrictions or contraindications, and is less expensive than the combination of IFN- $\alpha$  2b and ribavirin.

## MATERIALS AND METHODS

### Patient selection criteria

Patients with chronic HCV infection who had never received IFN therapy were eligible for this study. The patients were continuously positive for HCV-RNA genotype 2 using the amplicor HCV monitor assay and were diagnosed with chronic active hepatitis from a liver biopsy. The eligibility criteria included histological evidence of chronic hepatitis, as judged on a liver biopsy performed no longer than 6 mo prior to enrolment, and confirmation of HCV infection by polymerase chain reaction (PCR) analysis. Liver-biopsy specimens were assessed independently by two pathologists who were blinded to the patients' clinical details. Pathological diagnosis was made using the classification established by Desmet *et al*<sup>[27]</sup>. The exclusion criteria included: age lower than 18 years or older than 65 years, pregnancy or lack of appropriate contraceptive measures in women of child bearing age, previous treatment with antiviral or immunosuppressive drugs, current or previous drug addiction, alcoholism, positive HbsAg or HIV test, histological evidence of liver cirrhosis, concomitant metabolic, autoimmune or neoplastic liver diseases, severe concomitant diseases other than liver disease, history of depression or psychiatric diseases.

### Study design

This was a randomized, open-label, controlled study conducted between December 2001 and December 2003. The study was approved by the Ethical Committee of Gunma University. Eighty-three patients gave written informed consent and were randomly assigned to two groups: patients in regimen A received CIFN with polaprezinc and patients in regimen B received CIFN alone. All patients were given CIFN subcutaneously every day for 4 wk and then thrice a wk for 20 wk at a dose of

18 mega units (MU). Forty-one patients in regimen A were given 75 mg of oral polaprezinc twice daily (Plomac; Zeria Pharmaceutical Co., Tokyo, Japan) with CIFN for 24 wk, and zinc administration was discontinued simultaneously with discontinuation of CIFN, for a total of 24 wk. Forty-three patients in regimen B were given CIFN according to the protocol for 24 wk. Serum HCV-RNA was measured before treatment and every mo for one year during and after CIFN therapy. Patient adherence to the protocol and compliance with treatment were encouraged by regular hospital visits.

### Endpoints and definitions

Two endpoints were selected for comparing the efficacy of regimen A with the standard regimen B. The first endpoint involved serum HCV-RNA levels. 'Sustained virological response (SVR)' was defined as undetectable HCV-RNA at the end of the 6-mo post-treatment observation. 'End-of treatment virological response (EVR)' was defined as undetectable HCV-RNA at the end of the treatment. 'Non virological response (NVR)' was defined as detectable HCV-RNA at the end of the 6-mo post-treatment observation. The second endpoint was serum alanine aminotransferase (ALT) levels. Normalization of serum ALT at the end of treatment and at the end of the 6-mo post-treatment observation was defined as 'end-of treatment biochemical response (EBR)' and 'sustained biochemical response (SBR)', respectively. 'Non biochemical response (NBR)' was defined as elevation of serum ALT at the end of the 6-mo post-treatment observation.

### Assessment of safety

We evaluated all adverse events, subjective and objective symptoms, and laboratory test results for safety. All adverse events were checked by the patients using questionnaires, double-checked, and recorded by the investigators. All adverse events were graded for severity based on the World Health Organization (WHO) criteria and the guideline to grading severity of adverse events determined by the Japanese Ministry of Health and Welfare. Global safety assessments were made at the end of post-treatment observation using the following classifications: no abnormality, abnormality requiring no symptomatic treatments, abnormality requiring symptomatic treatments, abnormality requiring study withdrawal, and non-evaluable.

### Statistical analysis

Results were expressed as mean $\pm$ SD of the mean on an intention to treat or per-protocol basis. Statistically significant differences in outcomes between the two regimens were assessed using both parametric and non-parametric tests including the Student's *t*-test for paired and unpaired observations, and Fisher's exact test as appropriate.

A logistic multiple regression model was used to examine the relationship between baseline clinical characteristics and the binary outcome of response to CIFN therapy. Each variable was transformed into categorical data consisting of two simple ordinal numbers for the logistic multiple regression model. Variable selection was an important step in characterizing prognostic relations and identifying variables most strongly related to

Table 1 Characteristics of participating patients

	Regimen A IFN + zinc	Regimen B (CIFN)	P
Number of entry	41	42	
Male/Female	28/13	21/21	NS
Age (yr)	60±8.5	55±21	NS
Body mass index	23±2.4	24±3.7	NS
Pre-treatment zinc concentration (µg/dl)	77.8±13.6	82.5±16.4	NS
Pre-treatment ALT (IU/l)	113±75	101±96	NS
Pre-treatment leukocyte counts (×10 <sup>3</sup> mm <sup>-3</sup> )	5.1±1.3	5.0±1.4	NS
Pre-treatment platelet counts (×10 <sup>3</sup> mm <sup>-3</sup> )	19±5	17±5	NS

Histological findings (grading)	1.6±0.7	1.3±0.9	NS

Mean±SD; NS: not significant

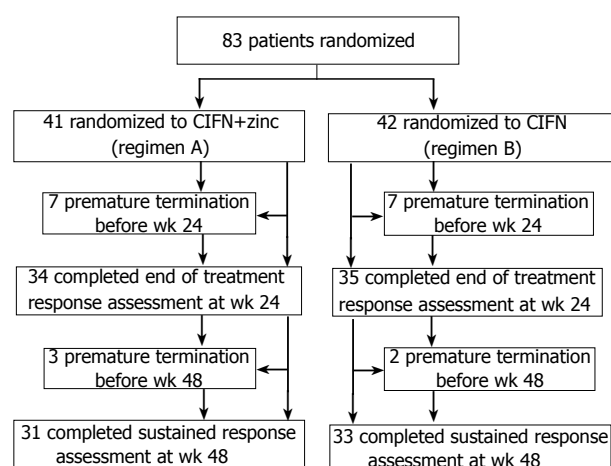

Figure 1 Trial profile.

the outcome. We selected, as candidate predictors of SVR, age, sex, weight, body mass index (BMI), pretreatment platelet counts, pretreatment ALT, pretreatment  $\gamma$ GTP levels, liver histology (staging and grading), pretreatment HCV-RNA viral load, wk of HCV-RNA clearance (less than 1, 4, 8, and 12 wk) and zinc supplementation. Thus, variables ( $P < 0.2$ ) on univariate analysis, that is, zinc supplementation, BMI, staging, pretreatment HCV-RNA viral load (less than 400 KIU/mL), wk of HCV-RNA clearance (less than 8 wk) and pretreatment ALT were included in a logistic multiple regression model. Differences with a  $P < 0.05$  were considered significant.

## RESULTS

Eighty-three patients were enrolled into the trial; 41 were randomized to regimen A and 42 to regimen B. The pre-treatment clinical characteristics of the patients assigned to the two regimens were similar (Table 1).

Table 2 Effect on viremia and serum transaminases

	Regimen A (CIFN + zinc)	Regimen B (CIFN)	P
ALT (U/l):			
Wk 0	113±75	101±96	NS

Wk 48 (SVR)	54%	67%	NS

Mean±SD; EBR: End-of treatment biochemical response; SBR: Sustained biochemical response; EVR: End-of treatment virological response; SVR: Sustained virological response; NS: not significant

## Follow-up and protocol compliance

The progression of randomized patients through the trial is summarized in Figure 1. Seven patients in regimen A withdrew prematurely from the study before wk 24 due to intolerance to IFN in five patients, and personal problems or low compliance in the other two patients. Seven patients in regimen B also withdrew prematurely from the study before wk 24 due to intolerance to IFN in six patients, and low compliance in the other patient. Three more patients, all in regimen A, withdrew prematurely from the study before wk 48 because of job transfer or personal problems. Two patients in regimen B withdrew prematurely due to personal problems.

## Effect of treatment on viremia and serum transaminase

There were 28/41 (68%) end-of treatment virological responders for regimen A and 32/42 (76%) for regimen B when analyzed on an intention to treat basis; the corresponding values were 28/31 (90%) and 32/33 (97%), respectively, when analyzed on a per-protocol basis (Table 2). There were 22/41 (54%) sustained virological responders for regimen A and 28/42 (67%) responders for regimen B when analyzed on an intention to treat basis; the corresponding values were 22/31 (71%) and 28/33 (85%), respectively, when analyzed on a per-protocol basis. There were 19/41 (46%) end-of treatment biochemical responders for regimen A and 21/42 (50%) responders for regimen B when analyzed on an intention to treat basis; the corresponding values were 19/31 (61%) and 21/33 (64%), respectively, when analyzed on a per-protocol basis. There were 28/41 (68%) sustained biochemical responders for regimen A and 29/42 (69%) responders for regimen B when analyzed on an intention to treat basis; the corresponding values were 28/31 (90%) and 29/33 (88%), respectively, when analyzed on a per-protocol basis. There were no significant differences between the two regimens in these four responses.

## Factors contributing to sustained virological response

Variables that correlated with sustained virological response were analyzed by both univariate and multivariate analyses. In univariate analysis, the sustained virological response

**Table 3** Logistic regression model of predictors of response to CIFN treatment

Variables	Odds ratio (95% Confidence Interval)	
Zinc supplementation (regimen B vs. A)	0.254 (0.033-1.948)	0.1873
BMI (<23.4 vs. ≥23.4)	1.245 (0.162-9.579)	0.8330
Staging (0-1 vs. 2-3)	0.213 (0.024-1.877)	0.1635
pretreatment HCV-RNA (<400 vs. ≥400)	0.104 (0.011-0.951)	0.0450
Week of HCV-RNA clearance (<8 vs. ≥8)	0.106 (0.005-2.399)	0.1584
pretreatment ALT (<107 vs. ≥107)	13.709 (0.960-195.749)	0.1873

**Figure 2** Serum zinc concentrations (mean±SD) at wk 0 (baseline) and after 4 wk of CIFN treatment in patients with regimen A (closed circles) and regimen B (open circles). Serum zinc levels at wk 4 were significantly higher in regimen A patients than those in regimen B patients (<sup>a</sup>*P*<0.05). Serum zinc levels at wk 4 were significantly higher than those recorded at wk 0 (baseline) in regimen A patients (<sup>a</sup>*P*<0.05).

correlated significantly with liver histology (staging) and pretreatment HCV-RNA viral load. In multivariate analysis, only pretreatment HCV-RNA less than 400 KIU/mL was associated with a sustained virological response (Table 3). The other factors, including zinc supplementation, BMI, staging, wk of HCV-RNA clearance, and pretreatment ALT level, did not influence sustained virological response.

### Serum zinc concentrations

Serum zinc concentrations at 4 wk after the commencement of polaprezinc treatment were elevated and significantly higher than pretreatment levels in regimen A patients (Figure 2). Serum zinc concentrations in patients of regimen A were significantly higher than those of regimen B patients at 4 wk after the start of administration of polaprezinc (Figure 2).

### Adverse effects

Each of the serious adverse events including depression, thrombocytopenia, leukopenia, and severe elevations in  $\gamma$ GTP was observed in one patient in regimen A. In addition, regimen B was also associated with serious adverse events such as depression in one patient, and severe leukopenia in two patients. Frequent adverse events and laboratory abnormalities recorded during the study are

**Table 4** Incidence of selected adverse events (> 10% frequency)

Adverse event	Regimen A (CIFN + zinc)	Regimen B (CIFN)
<i>n</i>	41	42
Fever	41 (100%)	42 (100%)
Headache	17 (41.5%)	16 (38.1%)
Malaise	15 (36.6%)	12 (28.6%)
Anorexia	14 (34.1%)	19 (45.2%)
Arthralgia	14 (34.1%)	13 (31.0%)
Insomnia	11 (26.8%)	11 (26.2%)
Stomach discomfort	7 (17.1%)	5 (11.9%)
Alopecia	6 (14.6%)	6 (14.3%)
depression	6 (14.6%)	5 (11.9%)
Nausea	6 (14.6%)	5 (11.9%)
Myalgia	5 (12.2%)	6 (14.3%)
Rash	5 (12.2%)	4 (9.5%)

**Table 5** Incidence of selected laboratory abnormalities (> 10% frequency)

Laboratory abnormality	Regimen A (CIFN + zinc)	Regimen B (CIFN)
<i>n</i>	41	42
Thrombocytopenia	31 (78%)	29 (69%)
Leucopenia	24 (59%)	30 (71%)
Increase in AST	20 (49%)	18 (43%)
Increase in ALT	18 (44%)	16 (38%)
Increase in $\gamma$ -GTP	12 (29%)	12 (29%)
Decrease in hemoglobin	7 (17%)	9 (21%)
Increase in ZTT	7 (17%)	7 (17%)

summarized in Tables 4 and 5. The type and frequency of the adverse events, and laboratory abnormalities were similar in both regimens. Five (12.2%) patients and six (14.3%) patients dropped out of the study due to the adverse events before wk 24 in regimen A and regimen B, respectively. There were no significant differences of grading severity of adverse effects as well as incidence of them in the global safety assessment of the two regimens (data not shown).

## DISCUSSION

The metabolism of trace elements is impaired in chronic liver disease<sup>[19]</sup>. Zinc deficiency in chronic hepatitis C is improved by IFN treatment<sup>[28]</sup>. Zinc supplementation enhances the response to IFN- $\alpha$  treatment in patients with genotype 1b chronic hepatitis C<sup>[20]</sup>. Conversely, zinc supplementation did not enhance the response to CIFN treatment in patients with chronic hepatitis C with genotype 2 in this trial. The reasons for the lack of synergy between zinc and IFN are unclear, however, there are several possible reasons that are worthy of consideration. The viral genotype 2 in both regimens may account for the virological response, differing from the previous study that involved patients with genotype 1b. It is also possible

that the relatively higher response rate achieved with CIFN in both regimens in this trial compared with the previous study with IFN- $\alpha$  could have masked any differences in efficacy. In addition, individual differences in serum zinc concentration increases, as a result of zinc administration, may alter the virological response because the extent of the increases in serum zinc concentration varied in regimen A. Furthermore, differences in the type of IFN may affect the virological response, given that natural IFN- $\alpha$  was used in the previous study.

The overall therapeutic efficacy (60% SVR) of CIFN in our study was similar to that (50% SVR) of low-titer or genotype 2 group in a previous report from Japan<sup>[18]</sup>. Recent reports showed that pegylated-IFN plus ribavirin<sup>[29]</sup> had excellent treatment efficacy (100% SVR) in chronic hepatitis C patients with genotype 2<sup>[30]</sup>. SVR rates of IFN- $\alpha$  2b plus ribavirin for chronic hepatitis C patients with genotypes except 1<sup>[11]</sup> or CIFN plus ribavirin for chronic hepatitis C patients with genotypes 2/3 were reported to be from 60% to 70%<sup>[31]</sup>. Given the overall 60% SVR in our study, CIFN without ribavirin can be considered as a good candidate for patients in whom ribavirin is contraindicated.

Interestingly, the cases of undetectable HCV-RNA titer at 1 wk, but not 4 or 12 wk after the start of treatment, showed 95% and 100% of sustained virological response rate in regimens A and B, respectively. Although only a pretreatment HCV-RNA less than 400 KIU/mL was considered to be a predictive factor for sustained virological response, based on a logistic multiple regression model in our trial, earlier responses at 1 wk after the start of treatment may also be a good predictor of sustained virological response.

The type and frequency of adverse events, and laboratory abnormalities were similar in both regimens. Overall, adverse events and laboratory abnormalities were similar to those in previous reports in Japan<sup>[18]</sup>. Although 18 MIU CIFN was relatively well tolerated in our trial, there were a few cases of serious adverse events. Twelve MIU and nine MIU CIFN, which are now available in Japan, may allow us to reduce the incidence of serious adverse events.

In conclusion, our study does not support the use of zinc as an adjunct to CIFN for the treatment of chronic hepatitis C with genotype 2, because combination treatment was not superior to CIFN monotherapy in achieving a sustained virological response. High viral loads of over 400 KIU/mL may indicate a low probability of sustained virological response for CIFN treatment, regardless of zinc supplementation.

### Abstract

**AIM:** Recently, germ-line mutation in the base excision repair gene *MYH* has been identified to cause a novel autosomal recessive form of familial adenomatous polyposis (FAP). Interestingly, a striking evidence for *MYH* mutations within different ethnic groups has been demonstrated. In this study, we screened 30 patients with multiple adenomatous polyps for *MYH* mutations to assess its prevalence and ethnic specificity in Korea.

**METHODS:** Thirty patients (21 men and 9 women; mean age 62.3 years) with multiple adenomatous polyps were examined for *MYH* mutations. The mean number of adenomas per patient was 10.0. Sixteen exonic regions and their intronic sequences were amplified by PCR and subjected to SSCP and DNA sequencing analyses.

**RESULTS:** None of the patients was identified to carry any truncating or sequence alterations in *MYH*. Our screening for the mutational regions, which were recognized from Caucasian patients or affected Indian families, also failed to detect sequence substitutions.

**CONCLUSION:** Mutation in *MYH* may be rarely involved in the pathogenesis of multiple sporadic colorectal adenomas in Korean population, although a large-scale analysis will be required to clarify the presence of specific *MYH* variants in a subset of patients and their role in the predisposition of multiple colorectal adenomas in Korean population.

### INTRODUCTION

It has been well established that genetic factors play a pivotal role in up to 35% of all colorectal cancers (CRC)<sup>[1-3]</sup>. Familial adenomatous polyposis (FAP) is an autosomal dominant disorder with an increased predisposition to multiple colorectal adenomatous polyps, and thence to CRCs<sup>[4]</sup>. Classic FAP is caused by inherited mutations in the adenomatous polyposis coli (*APC*) gene, which encodes a protein that plays a critical role in the regulation of colonic cell growth<sup>[5,6]</sup>. Attenuated FAP (AFAP) is associated with smaller numbers of adenomas and is caused by mutations in the extreme of 5' or 3' ends of *APC* or in the alternatively spliced region of exon 9<sup>[4,5]</sup>.

Somatic mutations of *APC* consist of the substitution of a thymine-adenine pair for a guanine-cytosine pair (G:C→T:A), which is a typical change caused by oxidative damage to DNA<sup>[7-11]</sup>. Oxidative DNA damage produces the stable 8-oxo-7, 8-dihydro-2'-deoxyguanosine (8-oxoG)<sup>[9]</sup>. It is highly mutagenic because it tends to mispair with adenine residues, leading to an increased frequency of spontaneous G:C→T:A transversion mutations in repair-deficient bacteria and yeast cells<sup>[10-13]</sup>.

Recently, Al-Tassan *et al*<sup>[14]</sup> reported a novel autosomal recessive form of FAP. They found that three of seven siblings from a single British Caucasian family were all compound heterozygous for two non-conservative missense variants, Y165C and G382D, in the base excision repair gene *MutY* homologue (*MYH*). This finding first implicated a defect in the base excision repair mechanism in inherited predisposition to colorectal tumors in human beings.

Base excision repair (BER) is cell's mechanism of protection against oxidative DNA damage<sup>[15]</sup>. The BER pathway repairs mutations caused by reactive oxygen species that are generated during aerobic metabolism<sup>[16]</sup>. Three main components of BER have been identified in human. *MutT* homologue (*MTH*) removes oxidized base from 8-oxoG:C pairs to reduce the chances of incorporation of

Table 1 Characteristics of patients

Characteristics	Patient with CRC and adenomatous polyp (n = 10)	Patient with adenomatous polyp only (n = 20)
Sex	3 males : 1 females	15 males : 5 females
Age (yr)	Mean 45.9 (range: 21 ~ 78)	Mean 51.8 (range: 44 ~ 69)

Family history of adenomatous polyps	0	0

CRC: colorectal cancer.

8-oxoG during DNA replication, and 8-oxoG glycosylase (OGG) initiates base-excision of 8-oxoG from 8-oxoG:C pairs<sup>[17]</sup>. Adenine-specific DNA glycosylase *MYH* removes adenine mispaired with 8-oxoG in 8-oxoG:A pairs.<sup>[18-20]</sup>

The prevalence of *MYH* mutations has been determined in patients with multiple colorectal polyps in Caucasian populations. However, to our knowledge, a few studies have been carried out regarding the prevalence of *MYH* mutations in Asian patients with multiple colorectal adenomatous polyps. In the present study, we therefore explored the possible implication of germ-line mutations of *MYH* in the development of multiple sporadic colorectal adenomatous polyps in Korean population.

## METHODS

### Specimens

Thirty patients (21 men and 9 women; mean age, 62.3 years) with multiple sporadic colorectal adenomatous polyps were recruited from Kyung Hee University, Medical Center, Seoul, Korea. All patients were Korean and none had a family history of vertical transmission of colorectal cancer or adenomatous polyps. Five individuals who did not have any recognizable diseases were selected as healthy controls. Informed consent was taken from all patients. Ten milliliters of blood were obtained from all the patients and healthy controls for extraction of genomic DNA. The characteristics of patients are summarized in Table 1.

### PCR amplification of *MYH* gene

Genomic DNA was prepared from venous blood samples using QIAGEN Genomic-tip system (Qiagen, Hilden, Germany) according to the manufacturer's instructions. The concentration of extracted DNA was determined by a spectrophotometric measurement (Schimadzu Scientific Instruments, Inc., Concord, CA). Exons 1-16 of *MYH* and their flanking intronic sequences were amplified by PCR with 14 primer sets which cover the entire coding region of *MYH*. Primer sequences used for PCR amplification are shown in Table 2. PCR was performed with 200 ng genomic DNA as template for 38 cycles at 95°C (1 min), 58-62°C (30 s), and 72°C (30 s) in 1.5 mmol/L MgCl<sub>2</sub>-containing reaction buffer (PCR buffer II, Perkin Elmer-Cetus, Concord, CA). Ten microliters of PCR products were electrophoresed on 20 g/L agarose gel containing ethidium bromide, visualized under ultraviolet light, and photographed.

### Single strand conformation polymorphism analysis

To identify sequence alterations in the *MYH* gene, we

performed nonisotopic PCR-SSCP analysis as described previously<sup>[14]</sup>. Briefly, 20 µL of the PCR products was mixed with 5 µL of 0.5 mol/L NaOH, 10 mmol/L EDTA and 10 µL of denaturing loading buffer (950 mL/L formamide, 20 mmol/L EDTA, 0.5 g/L bromophenol blue, and 0.5 g/L xylene cyanol). After heating at 95°C for 5 min, the samples were rapidly loaded in wells pre-cooled to 4°C and run simultaneously on two 80 g/L non-denaturing polyacrylamide gels with or without 100 g/L glycerol. These two gels were run at 18-20°C and then repeated at 6-10°C in a buffer-jacketed gel apparatus (DGGE-II; Aladin Enterprises, Inc., San Francisco, CA). Following an 8 h run at 400 volts, the gels were stained with ethidium bromide and photographed under ultraviolet light.

### Automated DNA sequencing

PCR amplification products were purified using the PCR purification kit (Qiagen). DNA sequencing was carried out using ABI PRISM 377 automated DNA sequencer (Applied Biosystems, Foster City, CA) according to the

**Figure 1** Genomic status of *MYH* in patients with multiple colorectal adenomas determined by quantitative DNA-PCR analysis. Representative examples for exons 3-9 amplification are shown. Two hundred nanograms of DNA obtained from 30 patients and 5 healthy controls were used as templates for PCR amplification of 16 exonic regions using 14 intronic primer sets. GAPDH was used as an internal control for PCR. Ten microliters of PCR product was resolved on 20 g/L agarose gel and visualized by ethidium bromide staining. No significant reduction of gene levels was identified in samples from patients as compared with normal controls. Lanes N1-N5: Normal controls; Lanes P1-P15: Patients.

manufacturer's instructions. Sequencing was carried out in both directions to confirm the findings.

## RESULTS

To explore the presence of germ-line alterations of *MYH*, we, using quantitative genomic PCR analysis, initially evaluated genomic status of *MYH*. Blood DNA samples from 30 patients with multiple sporadic colorectal adenomatous polyps and 5 healthy individuals were subjected to PCR amplification of *MYH*. All of the 16 exons and flanking intronic sequences of the gene were amplified as 14 fragments using intron-specific primer sets, and their levels in the patients were compared with those in healthy controls. As shown in Figure 1, genomic levels of *MYH*, which were evaluated for 14 separate gene regions, showed no detectable difference between patients and healthy individuals, and none of the patients was found to have structural alteration within these protein-encoding regions of the gene. Although systemic analysis for the genomic status was not carried out in this study, the results suggested that our patients did not harbor germ-line deletion or structural abnormalities of the gene, which could result in loss or significant reduction of *MYH* protein function.

Using PCR-SSCP and DNA sequencing analyses, we next screened for mutations and sequence variants across the entire coding region of the *MYH* gene. To detect the *MYH* variants, such as Y165C, G382D, Y90X and E466X, which are commonly observed in Caucasian patients or affected Indian families, we performed comprehensive SSCP assay under four different running conditions<sup>[14]</sup>. However, we could not observe any truncating *MYH* mutations in patient or control samples. Neither did we identify any likely pathogenic mutations and sequence variants in the patient samples. Representative examples of SSCP analysis are shown in Figure 2.

## DISCUSSION

Germ-line mutation of the *MYH* gene has been known to

**Figure 2** Non-isotopic PCR-SSCP analysis of *MYH*. For detection of sequence alterations, all of the 16 exons and flanking intronic sequences were amplified by PCR as 14 separate fragments, and 20  $\mu$ L of PCR product was subjected to non-isotopic SSCP analysis. Genomic DNA isolated from the healthy controls was used as normal controls. None of patient samples showed abnormal migration shift of single strand DNA molecules. Lane N: Normal control; Lanes 1-7: Patients; Lane E: Exons.

predispose persons in a variety of European populations to recessive inheritance of multiple colorectal adenomatous polyposis and classic FAP<sup>[4, 22]</sup>. In addition, all patients with biallelic *MYH* mutations have an increased predisposition to CRCs.

*MYH* mutation presents with a distinguished genetic pathway in developing colorectal tumors. Many questions regarding its role in pathogenesis of multiple colorectal adenomatous polyps and CRCs still remain open. For example, it has not been identified why germ-line *MYH* mutations are associated with tumors of gastrointestinal tract, or why *MYH* polyposis differs in its phenotype and inheritance from classical FAP<sup>[21]</sup>.

It is difficult to distinguish between patients with *APC* mutations and those with *MYH* germ-line mutation on the basis of clinical features or pathological findings. *MYH* mutations seem to be a more common cause of the multiple adenoma phenotypes than are *APC* mutations<sup>[23-26]</sup>. They are, however, a less common cause of classic colorectal adenomatous polyposis.

Jones *et al*<sup>[4]</sup> could not identify any pathogenic variants in BER genes *OGG1* or *MTH1* in cases with colorectal tumors. Thus, there is a possibility that these genes are less frequently mutated than *MYH*. It is also possible that those mutations do not predispose to tumors in humans due to unknown mechanism. However, further studies are required to determine whether *OGG1* or *MTH1* are involved in CRC predisposition.

On the basis of previous studies, genetic analysis of *MYH* mutation should be considered for patients with a phenotype resembling FAP or AFAP, when no clear evidence of vertical transmission is noted. However, whether it is worthwhile to perform genetic testing in the family of patients with *MYH* mutations is a question that still remains unclear.

In the present study, we failed to detect any truncating or sequence alterations of the *MYH* gene in Korean patients with multiple colorectal adenomas. Although patient numbers enrolled in this study are too small to exclude the association of *MYH* mutations with development of multiple colonic adenoma in Korean population, our data suggests the presence of ethnic difference in contribution of *MYH* mutations to disease development between the Korean patients and the white patients. Previous studies identified four British families that were either homozygous for Y165C or compound heterozygous for Y165C/G382D, three Indian families that were homozygous for E466X, and a single Pakistani family that was homozygous for Y90X<sup>[4]</sup>. Specific *MYH* mutations appear to be identified in different ethnic groups. A question still remains as to how frequently *MYH* mutations contribute to the phenotype of apparently sporadic AFAP/FAP. Further studies of patients from distinct geographical and ethnic groups will help to define the possible ethnic differences in actual mutations.

In conclusion, our observations suggest that *MYH* mutations are not common in patients with multiple colorectal adenomas in Korean population. Considering that number and histology of colorectal polyps are the cornerstones of detection of many CRC predisposition conditions, further larger-scale evaluation including the histologic analyses of the polyps, is required to determine whether *MYH* polymorphisms play a role in predisposition of a subset of multiple sporadic colorectal adenomas in Korean population.

### Abstract

**AIM:** To evaluate the risk factors of acute cholecystitis after endoscopic common bile duct (CBD) stone removal.

**METHODS:** A total 100 of patients who underwent endoscopic CBD stone removal with gallbladder (GB) *in situ* without subsequent cholecystectomy from January 2000 to July 2004 were evaluated retrospectively. The following factors were considered while evaluating risk factors for the development of acute cholecystitis: age, gender, serum bilirubin level, GB wall thickening, cystic duct patency, presence of a GB stone, CBD diameter, residual stone, lithotripsy, juxtaepapillary diverticulum, presence of liver cirrhosis or diabetes mellitus, a presenting illness of cholangitis or pancreatitis, and procedure-related complications.

**RESULTS:** During a mean 18-mo follow-up, 28 (28%) patients developed biliary symptoms; 17 (17%) acute cholecystitis and 13 (13%) CBD stone recurrence. Of patients with acute cholecystitis, 15 (88.2%) received laparoscopic cholecystectomy and 2 (11.8%) open cholecystectomy. All recurrent CBD stones were successfully removed endoscopically. The mean time elapse to acute cholecystitis was 10.2 mo (1-37 mo) and that to recurrent CBD stone was 18.4 mo. Of the 17 patients who received cholecystectomy, 2 (11.8%) developed recurrent CBD stones after cholecystectomy. By multivariate analysis, a serum total bilirubin level of <1.3 mg/dL and a CBD diameter of <11 mm at the time of stone removal were found to predict the development of acute cholecystitis.

**CONCLUSION:** After CBD stone removal, there is no need for routine prophylactic cholecystectomy. However, patients without a dilated bile duct (<11 mm) and jaundice (<1.3 mg/dL) at the time of CBD stone removal

have a higher risk of acute cholecystitis and are possible candidates for prophylactic cholecystectomy.

<http://www.wjgnet.com/1007-9327/12/956.asp>

### INTRODUCTION

Endoscopic sphincterotomy is the treatment of choice for patients with common bile duct (CBD) stones. The high success rate and safety of this modality have been well established by a number of studies<sup>[1-5]</sup>. Because gallstones may pass from the gallbladder (GB) into the CBD, calculous GB is considered to be one of the risk factors for the recurrence of bile duct stones after sphincterotomy<sup>[4,6]</sup>. Some studies have compared the results of the wait-and-see policy and prophylactic cholecystectomy to prevent biliary complications but arrived at contradictory results<sup>[7-9]</sup>. Thus, it still remains controversial as to whether subsequent laparoscopic cholecystectomy is indicated in patients with concurrent GB stones. Most studies have focused on the identification of predictors of CBD stone recurrence, which can be treated again endoscopically without surgery; however, the development of acute cholecystitis is a definite indication of cholecystectomy. So the risk factors of subsequent acute cholecystitis are more important than those of recurrent CBD stones in terms of the decision concerning prophylactic cholecystectomy. However, few studies have identified the risk factors of acute cholecystitis after endoscopic CBD stone removal in patients with GB *in situ*. The aims of this study were to assess the risks of biliary symptom recurrence and to identify the risk factors of acute cholecystitis in patients with GB *in situ* who have received endoscopic CBD stone removal.

### MATERIALS AND METHODS

#### Patients

The medical records of patients with GB *in situ* who

**Table 1** Baseline characteristics and CBD stone recurrence

	Cholecystectomy due to acute cholecystitis	
	Yes ( <i>n</i> =17)	No ( <i>n</i> =83)
Mean age $\pm$ SD	58.9 $\pm$ 16.3	65.4 $\pm$ 12.0
Gender (M/F)	8/9	54/29
Recurrence of CBD stone	2/17 (11.8%)	11/83 (13.2%)

underwent endoscopic CBD stone removal for the first time in our hospital from January 2000 to July 2004 were reviewed. Patients were excluded if another neoplasm or acute cholecystitis was diagnosed at the time of CBD stone removal, and if they had undergone prophylactic cholecystectomy after CBD stone removal.

The diagnosis of CBD stone was made by either ultrasonography (USG) or computed tomography (CT) before endoscopic retrograde cholangiopancreatography (ERCP) in the majority of patients, but a definite diagnosis was defined as visible CBD stones on ERCP. The presence of GB stone was evaluated using USG, CT, and ERCP and the wall thickness of GB was evaluated using either USG or CT. Patients with no visible stone on all imaging modalities were allocated to the no GB stone group. The patients who required treatment for a CBD stone 6 mo after complete endoscopic stone removal were defined as having CBD stone recurrence. Radiological data were analyzed using a digitalized picture archiving communication system (PACS). Patient records were checked in each case to ascertain whether cholecystectomy due to acute cholecystitis was done or not after endoscopic CBD stone removal, and telephone calls were made to determine this in the few patients lost during follow-up.

### Endoscopy protocol

Duodenal endoscopic intubation (TJF-240, Olympus, Tokyo, Japan) was performed under midazolam sedation. Sphincterotomy was performed in all the patients using a standard sphincterotome and/or a needle knife. After visualizing a CBD stone by cholangiography under fluoroscopic guidance, stones were extracted using a stone basket, balloon catheter, or a mechanical lithotripter according to stone size.

### Statistical analysis

Data were analyzed using a statistical software package (SPSS, version 12.0; SPSS Inc.). Differences between the groups were analyzed using the  $\chi^2$  test. Logistic regression analysis was used to estimate odds ratios. The cumulative rate of acute cholecystitis requiring cholecystectomy was calculated using the Kaplan-Meier method.

## RESULTS

### Patient population

During the study, a total of 1 986 patients underwent ERCP at our hospital. The diagnosis of a CBD stone was made for 452 (22.8%) patients, and endoscopic CBD stone removal was performed successfully in 414 (91.6%)

patients. Of these, 198 (47.8%) had a GB *in situ* at the time of endoscopic CBD stone removal. Forty-seven (23.7%) patients had a previous history of endoscopic CBD stone removal more than once, and 38 patients (19.1%) received subsequent cholecystectomy for the management of acute cholecystitis. Another 3 (1.5%) patients who experienced incidental cholecystectomy during cancer surgery (2 for gastric cancer and 1 for hepatoma) and 12 (6.0%) patients with inadequate medical information were omitted from the analysis. The total number of study subjects subjected to analysis was 100. No prophylactic cholecystectomy was planned during the follow-up for these patients.

### Recurrence of biliary complications after endoscopic CBD stone removal

During a mean 18-mo follow-up, 28 (28%) patients developed biliary symptoms; 17 (17%) with acute cholecystitis and 13 (13%) with CBD stone recurrence. No difference was observed between those who received cholecystectomy and those who did not receive cholecystectomy in terms of mean age or gender (Table 1). The mean time elapsed between original CBD stone removal and acute cholecystitis was 10.2 mo (1-37 mo). Of the 17 patients who received cholecystectomy, 2 patients (11.8%) developed recurrent CBD stones after cholecystectomy. The CBD stone recurrence rate in patients without acute cholecystitis was 13.2% (11/83). All cases of CBD stone recurrence were managed by endoscopic stone removal without surgery. The mean time elapsed ( $\pm$ SD) from endoscopic CBD stone removal to the development of acute cholecystitis was 10.2 ( $\pm$ 10.6) mo with a range of 1-37 mo. All the patients in whom acute cholecystitis developed received emergency or elective cholecystectomy. Laparoscopic cholecystectomy was performed for all the patients initially and in 2 of the 17 patients (11.8%) the operation was converted to open cholecystectomy. The mean follow-up time ( $\pm$ SD) of the patients in whom acute cholecystitis did not occur was 18.4 mo ( $\pm$ 9.8) and the range was 4-44 mo.

### Risk factors for acute cholecystitis after endoscopic CBD stone removal

The results of univariate analysis of potential risk factors for the development of acute cholecystitis after endoscopic CBD stone removal are shown in Table 1. Of the 15 variables, total bilirubin  $<1.3$  mg/dL, the presence of a GB stone and a CBD diameter  $<11$  mm were found to be significant by univariate analysis ( $P=0.01$ ,  $0.02$ , and  $0.03$ , respectively). However, multiple logistic regression analysis with forward selection and backward elimination identified only total bilirubin  $<1.3$  mg/dL and CBD diameter  $<11$  mm, and both variables reached statistical significance (Tables 2 and 3). Cumulative rates of acute cholecystitis requiring cholecystectomy, according to these two variables were calculated by the Kaplan-Meier method as shown in Figures 1 and 2.

## DISCUSSION

The present study found that the overall recurrence rate of CBD stone after endoscopic CBD stone removal was 13%

**Table 2** Univariate analysis of potential risk factors for the development of acute cholecystitis after endoscopic CBD stone removal

Variable	n	Acute cholecystitis (%)	OR <sup>1</sup>	95%CI <sup>2</sup>	P value

(13/100), and that the frequency of acute cholecystitis after endoscopic CBD stone removal was 17% (17/100). Because two patients in whom acute cholecystitis developed also experienced CBD stone recurrence and there was no case of cholangitis or CBD stricture, the overall recurrence rate of biliary-related events during follow-up after endoscopic CBD stone removal was 28% (28/100), which is similar to the rates of 5-24% reported

previously<sup>[1,2,4,6,8-28]</sup>.

The advisability of prophylactic cholecystectomy to prevent biliary complications after endoscopic CBD stone removal remains a matter of debate; even

recent prospective<sup>[7]</sup> and large scale cohort studies<sup>[9]</sup> produced contrary conclusions concerning prophylactic cholecystectomy vs the wait-and-see approach. Moreover, because no consensus has been reached, the decision as to whether to operate or not is made empirically on a case-by-case basis<sup>[8,13,17-19]</sup>. However, two important points should not be missed. The first is that, as presented by previous studies and ours, the occurrence of acute cholecystitis requiring cholecystectomy is not uncommon and the second is that morbidities such as bile duct injury and mortality caused by laparoscopic cholecystectomy are not negligible<sup>[29-31]</sup>. Recurrent CBD stones can be retreated endoscopically without surgery but the development of acute cholecystitis is a definite indication for cholecystectomy. Thus the risk factors of subsequent acute cholecystitis are more important than that of recurrent CBD stones with respect to decisions concerning prophylactic cholecystectomy. In the present study, the development of acute cholecystitis (17%) was more common than that of CBD stone (13%) recurrence after CBD stone removal. We believed that if the risk factors of acute cholecystitis in patients who receive an endoscopic CBD stone removal could be identified, we might be able to identify the indicators of prophylactic cholecystectomy, as has been mentioned by earlier investigators<sup>[13]</sup>. Some studies have compared the results of prophylactic cholecystectomy and non-surgical treatment<sup>[7,9,17]</sup>. However, as far as we know, few studies have addressed the risk factors of acute cholecystitis after endoscopic CBD stone removal in patients with GB *in situ*, and thus our report might be the first to focus on this subject.

After conducting univariate and multivariate analyses to identify potential risk factors, we concluded that the occurrence of acute cholecystitis after endoscopic CBD stone removal was significantly more frequent in patients with a serum total bilirubin level of <1.3 mg/dL and a CBD diameter of <11 mm at the time of ERCP. Interestingly, a dilated CBD was identified as a risk factor of bile duct stone recurrence after endoscopic papillotomy by previous studies<sup>[4,6]</sup>. However, our results should be interpreted from a different point of view because the pathogenesis of CBD stone recurrence and the development of acute cholecystitis differ. In East Asia the number of primary CBD stone cases is relatively high compared with the number of secondary CBD stones originating from a GB stone as compared with the situation in the West, although the number of secondary CBD stone cases is increasing over the recent years due to the Westernization of diet<sup>[32-34]</sup>. In patients with GB or CBD stones, the differentiation of primary and secondary CBD stones is practically impossible because GB stones cannot be sampled for chemical analysis endoscopically, even though they are visualized by ERCP. However, considering the fact that patients with a dilated bile duct tend to form new stones in the bile duct and the cystic duct seldom passes large stones, large CBD stones with a dilated CBD are likely to be primary CBD stones<sup>[4,26,35,36]</sup>. On the other hand, small CBD stones in association with a non-dilated CBD are more likely to originate from the GB. If cholecystectomy is not performed in such patients, acute cholecystitis development due to cystic duct obstruction

by a gallstone is a risk during the process of passage<sup>[37,38]</sup>. The same assumption can be applied to patients with a low total bilirubin level who were found to develop acute cholecystitis more frequently. Of the 17 patients with cholecystectomy, 2 patients (11.8%) developed recurrent CBD stones after cholecystectomy. Thus cholecystectomy did not reduce CBD stone recurrence in our study, which suggests that most CBD stones may have been secondary rather than primary stones in our patients.

According to our data, 4 of 48 patients who were classified as acalculous at the time of ERCP developed acute cholecystitis during follow-up. A review of our operative records revealed that 2 of 4 patients had calculous cholecystitis and that the remaining 2 had no evidence of a GB stone. However, for the two acalculous cholecystitis patients, the possibility of calculous cholecystitis with a previously passed be excluded, because none of them had the well-known predisposing factors of acalculous cholecystitis, i.e., severe illness or old age<sup>[39,40]</sup>.

In conclusion, the present study shows that a serum bilirubin level of <1.3 mg/dL and a CBD diameter of <11 mm at the time of endoscopic CBD stone removal are risk factors for the development of acute cholecystitis requiring cholecystectomy. Although our results are limited due to the retrospective nature of our study, we suggest that prophylactic cholecystectomy should be reserved for patients who have the risk factors of acute cholecystitis. Prospective randomized studies are needed to more definitively establish the risk factors of acute cholecystitis after endoscopic CBD stone removal.

## Abstract

**AIM:** To assess the role of transforming growth factor- $\beta$ 1 (TGF- $\beta$ 1), vascular endothelial growth factor (VEGF) and basic fibroblast growth factor (bFGF) in the pathogenesis of fibrosis associated with chronic hepatitis C (CHC) and to evaluate the influence of the antiviral therapy on above parameter levels depending on the treatment results (complete response or no response).

**METHODS:** Study group included 100 patients with CHC, in whom fibrosis in liver specimens was assessed (Scheuer fibrosis score: 1-4 points). Control group included 30 subjects with antibodies anti-HCV present and persistently normal ALT level, without fibrosis (Scheuer fibrosis score: 0 points). Concentration of studied parameters was assayed in the serum by immunoenzymatic method before and after the therapy with interferon alpha-2b and ribavirin.

**RESULTS:** TGF- $\beta$ 1 levels were significantly higher in the study group compared to the control group (35.89 vs 32.37 ng/mL;  $P=0.023$ ). Such differences were not found in VEGF and bFGF levels. In patients showing complete response (negative HCV RNA and normal ALT level), significant increase in VEGF (112.8 vs 315.03 pg/mL;  $P<0.05$ ) and bFGF (2.51 vs 15.79 pg/mL;  $P=0.04$ ) levels were found. Significant decrease in TGF- $\beta$ 1 level was observed both in responders (37.44 vs 30.02 ng/mL;  $P=0.05$ ), and in non-responders (38.22 vs 30.43 ng/mL;  $P=0.043$ ). bFGF levels before the treatment were significantly lower (2.51 vs 5.94 pg/mL;  $P=0.04$ ), and after the treatment significantly higher (15.79 vs 4.35 pg/mL;  $P=0.01$ ) in

patients with complete response than in those with no response.

**CONCLUSION:** Among the analyzed parameters TGF- $\beta$ 1 seems to play the most important role in the pathogenesis of fibrosis in CHC. Levels of this factor are significantly lower in subjects who do not have fibrosis developed in them. Good therapeutic effect in CHC patients is associated with significant changes in TGF- $\beta$ 1, VEGF, and bFGF levels. bFGF seems to have the highest usefulness in the prognosis of treatment efficacy.

## INTRODUCTION

Hepatitis C virus (HCV) is among the main causes of chronic liver diseases. Consequences of chronic HCV infection and high treatment costs make it a significant worldwide epidemiological, clinical, and social problem.

No pathological fibrosis is found during the initial stages of the disease, however in course of its development, the process increases, and the final stage is cirrhosis<sup>[1]</sup>. Fibrosis as an after-effect of chronic liver inflammation is compared to wound healing<sup>[2,3]</sup>. It is supposed that growth factors taking part in classical reaction of wound healing may play an important role in similar repair process occurring in the liver. Nature of fibrogenesis is excessive deposition of collagen and other extracellular matrix (ECM) components in the organ parenchyma. ECM protein synthesis takes place mainly in hepatic stellate cells<sup>[2-4]</sup>. Inhibition and regression of fibrosis is connected with the limitation of excessive

ECM protein production and degradation of components already produced<sup>[5,6]</sup>. Growth factors may be detected in blood that is circulated. There are premises that they could serve as markers of fibrosis and inflammatory activity, and could be useful in non-invasive hepatological diagnostics, especially in those situations when there are contraindications for liver biopsy<sup>[2]</sup>.

Among several known isomeric forms of transforming growth factor- $\beta$  (TGF- $\beta$ ), the most significant role in pathogenesis of liver fibrosis is played by TGF- $\beta$ 1. Main source of TGF- $\beta$ 1 in the liver are activated stellate cells and Kupffer cells. The role of this factor in fibrosis development has been studied for several years<sup>[5-10]</sup>. Results of those studies confirm the existence of a connection between the factor's concentration in the blood and progression of liver lesions<sup>[8-10]</sup>, as well as reduction of those concentrations following treatment leading to the decrease of fibrosis stage<sup>[10]</sup>.

Vascular endothelial growth factor (VEGF) stimulates angiogenesis both in regular conditions and in neoplastic processes<sup>[11-15]</sup>. It has been verified to be closely involved in the development of hepatocellular carcinoma and hepatic metastases<sup>[15]</sup>.

Basic fibroblast growth factor (bFGF, FGF-2) is found in almost all tissues of mesoderm and endoderm origins. Studies conducted on animal models show participation of the cytokine in regeneration of tissues, angiogenesis and in wound healing process<sup>[16,17]</sup>. A role played by bFGF in the processes of liver regeneration and fibrosis is not known. However, mentioned actions of the factor towards other tissues suggest possibility of its influence on fibrosis<sup>[18]</sup>.

The only way of liver fibrosis prevention known so far is effective causal treatment of hepatitis<sup>[19]</sup>. Preferred treatment for patients with CHC is a combined therapy with interferon alpha and ribavirin. In antiviral treatment recombinant interferons alpha (alpha 2a and alpha 2b) are used, recently usage of pegylated interferons has become a standard. Ribavirin is an analog of guanosine. Apart from producing a virostatic effect, the drug shows probably also immunomodulative activity. Aim of CHC treatment is inhibition of HCV replication shown by the disappearance of HCV RNA in peripheral blood, which may lead to the decrease of inflammatory activity and stage of fibrosis found in histopathological examination.

We undertook this study to assess the role of TGF- $\beta$ 1, VEGF, and bFGF in the pathogenesis of liver fibrosis, evaluate effect of antiviral treatment on concentration of these factors depending on the effect of the treatment (full response or lack of response), and define a biochemical marker useful for prognosis of antiviral treatment efficacy.

## MATERIALS AND METHODS

### Patients

Ethical approval for the study was obtained from the Bioethical Committee of Medical University of Silesia. All serum and tissue samples were taken with patients' informed consent.

Study group included 100 patients (48 females and 52 males), aged between 19 and 64 (average  $42 \pm 3$  years) with chronic hepatitis C (CHC).

The diagnosis of CHC was confirmed by the presence of serum HCV-RNA assayed with reverse transcription polymerase chain reaction (RT-PCR) method (Amplicor v.2 Roche Diagnostic test) and persistently elevated alanine aminotransferase (ALT) level for at least 6 mo. All studied patients had liver biopsy performed with Hepafix kit (B. Braun, Melsungen AG, Germany). Grade of inflammatory activity and stage of fibrosis were assessed according to Scheuer numeric scale<sup>[20]</sup>. Patients with pathologically confirmed cirrhosis met the criteria for the A class in Child-Pugh scale.

Control group included 30 patients with present anti-HCV antibodies and normal ALT activity, with no or minimal necroinflammatory activity and no pathological fibrosis found in liver specimen pathological examination.

### Methods

All patients starting the therapy and those belonging to the control group had blood collected in the beginning of the study. Blood samples were also taken from the study group subjects after the completion of therapy. Obtained serum was frozen at  $-70^{\circ}\text{C}$  until assay.

TGF- $\beta$ 1, VEGF, and bFGF concentrations were measured by immunoenzymatic method (Quantikine Immunoassay, R&D Systems Inc, Minneapolis, USA).

In therapy of CHC patients interferon alpha 2b and ribavirin were used (Rebetron<sup>TM</sup>, Schering-Plough). Interferon alpha was administered at 3 MU dose thrice a week, ribavirin at a dose of 1 200 mg/d for patients  $\geq 75$  kg of body weight, or at a dose of 1 000 mg/day for patients with body weight lower than 75 kg. Treatment was continued for 48 wk.

Serum levels of TGF- $\beta$ 1, VEGF, and bFGF were measured before and after the treatment.

In this study, comparison was made between the two groups of patients - those with complete sustained response to applied antiviral treatment (undetectable HCV RNA and normalization of ALT activity 6 mo after the end of therapy) and lack of this response (continuous elevated aminotransferase activity and presence of HCV RNA after conclusion of therapy).

### Statistical analysis

Values were expressed as the mean  $\pm$  SE. Hypothesis of studied parameters, mean values equality between the compared groups were assessed using Student's *t* test for related and unrelated variables preceded with Fisher's test for variance homogeneity and Mann-Whitney *U* test.  $P < 0.05$  was considered statistically significant.

## RESULTS

General characteristics of patients with CHC and subjects belonging to the control group are presented in Table 1.

Figure 1 shows the results of TGF- $\beta$ 1 assays in compared groups. In group of patients with CHC, there was significantly higher serum concentration of the factor compared to control group ( $35.89 \pm 1.28$  vs  $32.37 \pm 1.41$  ng/mL;  $P = 0.023$ ).

VEGF serum levels in compared groups are demonstrated in Figure 2. No significant differences of

Table 1 Characteristics of patients

	<i>n</i>	Male/female	Age (yr)	ALT (U/L)	AST (U/L)	Alkaline phosphatase (U/L)	Bilirubin ( $\mu$ mol/L)
CHC	100	52/48	42.08 $\pm$ 3	108.7 $\pm$ 10.12	75.6 $\pm$ 8.76	141.7 $\pm$ 6.78	18.9 $\pm$ 2.42
Control	30	16/14	40.79 $\pm$ 2	21.3 $\pm$ 1.92	18.5 $\pm$ 1.73	136.4 $\pm$ 6.56	13.8 $\pm$ 1.76

**Figure 1** Serum levels of TGF- $\beta$ 1 (ng/mL) in CHC group and control group. The box represents the interquartile range. The whiskers indicate the highest and lowest values. The line across the box indicates the median value.

**Figure 3** Serum levels of bFGF (pg/mL) in CHC group and control group. The box represents the interquartile range. The whiskers indicate the highest and lowest values. The line across the box indicates the median value.

**Figure 2** Serum levels of VEGF (pg/mL) in CHC group and control group. The box represents the interquartile range. The whiskers indicate the highest and lowest values. The line across the box indicates the median value.

**Figure 4** Comparison of TGF- $\beta$ 1 levels (mean and SE) before and after the antiviral therapy of CHC patients depending on treatment efficacy.

this growth factor concentration were found between the hepatitis C group and control ( $231.84 \pm 24.55$  *vs*  $262.89 \pm 33.99$  pg/mL). Figure 3 presents bFGF concentration. No significant differences were found between CHC group and control ( $4.35 \pm 0.58$  *vs*  $3.30 \pm 0.39$  pg/mL).

In Figure 4, TGF- $\beta$ 1 concentrations measured before and after antiviral treatment are compared. In both groups – responders and non-responders – significant decrease in serum TGF- $\beta$ 1 concentration was found following antiviral treatment. TGF- $\beta$ 1 level in responders decreases from  $37.44 \pm 4.31$  to  $30.02 \pm 4.16$  ng/mL ( $P=0.05$ ) and in non-responders from  $38.22 \pm 3.93$  to  $30.34 \pm 3.7$  ng/mL ( $P=0.043$ ). Figure 5 shows changes of VEGF concentration following treatment with interferon and ribavirin. In group of responders, significant increase of this factor concentration in blood was found ( $112.8 \pm 10.2$

*vs*  $315.03 \pm 29.3$  pg/mL;  $P<0.05$ ), unlike the group of non-responders. In Figure 6, concentrations of bFGF in treated patients are shown. Significant increase of the concentration was demonstrated in patients with complete response to therapy ( $2.51 \pm 0.29$  *vs*  $15.79 \pm 1.8$  pg/mL;  $P=0.04$ ). The concentration did not change significantly in the group of non-responders.

bFGF levels before the treatment were significantly lower ( $2.51$  *vs*  $5.94$  pg/mL;  $P=0.04$ ), and after the treatment significantly higher ( $15.79$  *vs*  $4.35$  pg/mL;  $P=0.01$ ) in patients with complete response than in those with no response.

## DISCUSSION

Process of liver fibrosis has been recently a subject of numerous studies. Attempts are made to recognize

**Figure 5** Comparison of VEGF levels (mean and SE) before and after the antiviral therapy of CHC patients depending on treatment efficacy.

**Figure 6** Comparison of bFGF levels (mean and SE) before and after the antiviral therapy of CHC patients depending on treatment efficacy.

accompanying pathogenetic phenomena and define factors influencing its progression. Reports were published concerning the possibility of fibrosis stage decrease following effective causal treatment, for example, following treatment of CHC with interferon and ribavirin<sup>[6,10,21,22]</sup>. Some authors have reported even cases of regression of cirrhosis that has been considered irreversible so far<sup>[2,6,10,19,23-26]</sup>. This study made an attempt to define the role that may be played by chosen growth factors in processes occurring in course of chronic hepatitis.

TGF- $\beta$ 1 is the growth factor of the best known and confirmed pro-fibrogenic activity. In our study it was demonstrated that TGF- $\beta$ 1 concentration in patients with fibrosis in course of CHC was indeed higher compared to the patients in whom there was no fibrosis development. Tsushima *et al* noted significant decrease of TGF- $\beta$ 1 concentration in serum, and inhibited expression of TGF- $\beta$ 1 mRNA in hepatic tissue following antiviral treatment, regardless of the clinical result (both for responders and non-responders)<sup>[10]</sup>. Similar observations have been made during our study. For both groups of patients significant decrease of the factor concentration was noted, regardless of the final result of treatment. This could suggest existence of direct, inhibitory influence of interferon alpha and/or ribavirin on the expression of TGF- $\beta$ 1 that is independent of the influence of the drug on HCV replication.

VEGF, as a factor specifically inducing proliferation of vascular endothelium cells, plays an important role in angiogenesis, and seems to play an indirect role in regeneration processes. One of the repair processes in which VEGF plays its role is probably "wound healing" process taking place in liver, and being a consequence of chronic inflammatory condition. Studies including analyses of VEGF participation in the development of hepatocellular carcinoma were performed<sup>[11-15]</sup>, but only single attempts to assess its blood concentration and hepatic expression in hepatitis have been reported. Akiyoshi *et al*<sup>[27]</sup> found significant increase of VEGF concentration in the serum of patients with acute hepatitis of typical course, but in cases of fulminant hepatitis those concentrations were lower than in control group

and increased in patients who recovered. Low VEGF concentrations were noted by the authors in cases of cirrhosis, but they did not show significant differences compared to control group in cases of chronic hepatitis. Jinno *et al* obtained different results. In their study VEGF concentrations appeared to be significantly higher in cases of chronic hepatitis and cirrhosis compared to healthy individuals<sup>[28]</sup>. In our study we did not find statistically significant differences of VEGF concentrations in blood between patients with hepatitis C and control group. No papers estimating possible changes in the cytokine concentration following antiviral therapy have been published yet. Our study showed that in patients meeting the criteria of response to this type of treatment there was a significant increase of VEGF serum concentration. The phenomenon was not observed in non-responsive patients. VEGF concentration increase following effective therapy, after which one could expect inhibition of fibrosis, justifies the assumption that stimulation of angiogenesis by this factor may be a key element in regeneration processes accompanying regression of liver fibrosis.

bFGF, a growth factor with well documented participation in classic process of "wound healing", may also play a role in repair processes taking place in liver damaged by inflammatory condition, however, number of published reports on this topic is very low. Jinno *et al* found that bFGF blood concentrations increase with the liver disease progression<sup>[18]</sup>. In our study bFGF levels were not statistically different in case and control groups. Following treatment with interferon and ribavirin, significant increase of the factor concentration was found in patients, for whom the therapy proved to be effective. Moreover, it was noted that complete therapeutic response occurred in patients whose initial concentration of this cytokine was significantly lower, and significantly higher following the treatment than in non-responders group. As one of the probable bFGF activity courses is stimulation of endothelium cells proliferation<sup>[16,17]</sup>, it may be assumed that increase of the cytokine concentration following effective treatment may be linked with intensification of angiogenesis, just like in the case of VEGF.

Studies showed that antiviral treatment, especially effective one, causes significant changes in concentrations of some growth factors. Studies documenting decrease of fibrosis stage following the therapy and concluded with persistent inhibition of virus replication are increasing. Combination of those facts justifies assumption that those cytokines may play an important role in pathogenesis of changes taking place in liver during chronic inflammatory conditions. Studies documenting participation of the growth factors other than TGF- $\beta$ 1 in those processes are, as for now, very sparse. It seems, however, that the topic deserves interest. Precise knowledge concerning processes leading to the development of fibrosis could contribute to elaboration of methods aimed at prevention of the disease progression and complications.

Among the factors analyzed in our study, TGF- $\beta$ 1 plays the most significant role in pathogenesis of fibrosis in course of CHC. It supports results of other studies.

We have demonstrated that good therapeutic effect in patients with CHC is connected with influence of drugs on TGF- $\beta$ 1, VEGF, and bFGF serum concentration. These findings suggest possible usefulness of these factors in assessment of antiviral treatment efficacy and indication of medication failure. It seems that bFGF shows the best prognostic value regarding final antiviral treatment results.

## Abstract

**AIM:** To explore the expression of cadherin isoforms in cultured human gastric carcinoma cells and its regulation.

**METHODS:** The expressions of cell adhesion molecules (including E-cadherin, N-cadherin,  $\alpha$ -catenin,  $\beta$ -catenin) and cadherin transcription factors including snail, slug and twist were determined by reverse transcriptase-polymerase chain reaction (RT-PCR), immunoblotting and immunofluorescence in SV40-immortalized human gastric cell line Ges-1 and human gastric cancer cell lines MGC-803, BGC-823 and SGC-7901.

**RESULTS:** All cell lines expressed N-cadherin, but not E-cadherin. N-cadherin immunofluorescence was detected at cell membranous adherents junctions where co-localization with immunofluorescent staining of inner surface adhesion proteins  $\alpha$ - and  $\beta$ -catenins was observed. The transformed Ges-1 and gastric cancer cell lines all expressed transcription factors (snail, slug and twist) which inhibited the expression of E-cadherin and triggered epithelial-mesenchymal transformation.

**CONCLUSION:** Cadherin isoforms can change from E-cadherin to N-cadherin in transformed human gastric cancer cells, which is associated with intracellular events of stomach carcinogenesis and high expression of corresponding transcription factors.

## INTRODUCTION

Cadherins are a family of transmembranous glycoproteins responsible for calcium-dependent intercellular adhesion, and play a dual role as adhesion ligands and receptors in cell adherents junctions (AJs). They are divided into more than ten subclasses, which are distinct in immunogenic specificities and tissue distribution. AJs are cell-to-cell adhesion sites where classic cadherins, cytoplasmic catenins ( $\alpha$ -,  $\beta$ -,  $\gamma$ -) and actin-based cytoskeleton are assembled. Such protein complex plays a role as a functional unit in mediating cell adhesion and signal transduction and is involved in regulation of cell recognition, migration and cell sorting behavior [1, 2]. E-cadherin and N-cadherin, members of cadherin superfamily, are the most popular adhesion receptors in tissues. E-cadherin is predominantly expressed in epithelia, and loss of E-cadherin expression is a major characteristic of highly invasive and metastatic cancer [4], while re-expression of E-cadherin results in reversion of metastatic phenotypes to benign phenotypes. E-cadherin has been known as a tumor suppressor against invasion and metastasis of tumors [5]. N-cadherin is expressed in mesenchymal cells, but recent study demonstrated that N-cadherin is associated with an increased invasive potential of cancer [6]. Forced expression of N-cadherin exerts a dominant effect over E-cadherin function in breast cancer cells [7].

In early embryonic development, loss of E-cadherin accompanying the acquisition of fibroblastic phenotype occurs through a mechanism called epithelial-mesenchymal transition (EMT). This is an essential event during gastrulation and neural crest formation [8] as well as in early invasion and metastasis of carcinoma cells [9]. Multiple mechanisms can inactivate E-cadherin in cancer cells, such as gene mutation, promoter hypermethylation, chromatin rearrangement, and transcriptional repressors. Several developmentally important genes inducing EMT act as E-cadherin repressors. In vertebrates, snail and its closely related gene slug bind directly to E-boxes in the *E-cadherin* promoter and repress *E-cadherin* expression directly in mouse and human invasive carcinoma cells [10]. A further molecule known to trigger EMT is twist, which is possibly involved in E-cadherin and N-cadherin conversion during

EMT<sup>[11]</sup>. In the present study, we chose a transformed human gastric cell line as control and three human gastric cancer cell lines to detect the expression of E-cadherin and N-cadherin subtypes and their associated adhesion protein ( $\alpha$ - and  $\beta$ -catenins) related to changes of transcription factors (snail, slug and twist), and to analyze the role of snail and other EMT regulators in down-regulating E-cadherin in gastric cancer cells.

## MATERIALS AND METHODS

### Cell culture

Human gastric cancer cell lines MGC-803, BGC-823 and SGC-7901 were cultured in RPMI1640 medium (GIBCO/BRL) containing 10% fetal bovine serum. Ges-1, a non-tumorigenic but immortalized human gastric cell line, was obtained by SV40 viral transformation and cultured in RPMI1640 medium supplemented with 15% fetal bovine serum<sup>[12]</sup>.

### Immunoblotting experiments

Cells of logarithmic growth potential treated with RIPA lysis buffer (50mmol/L Tris-HCl pH 7.4, 150mmol/L NaCl, 1% NP40, 50mmol/L NaF, 0.1mmol/L Na<sub>3</sub>VO<sub>4</sub>, 1mmol/L phenylmethylsulfonyl fluoride, 10 $\mu$ g/mL leupeptin, 0.1% SDS, 0.5% deoxycholic acid, 50mmol/L HEPES, 10mmol/L EDTA, 50mmol/L sodium pyrophosphate, 50mmol/L ammonium molybdate) were used to determine the total protein concentration according to Bradford protein quantification method. Samples of equal amount were loaded onto 10% SDS-PAGE gel and electrophoretically transferred to PVDF membrane, blocked with 5% non-fat milk/TTBS, reacted with primary antibody, washed with TTBS and labeled with goat and anti-mouse or rabbit secondary antibody. The primary antibodies used were mouse anti-N-cadherin monoclonal antibody, rabbit anti-E-cadherin polyclonal antibody, rabbit anti- $\alpha$ - and  $\beta$ -catenin polyclonal antibody (Sigma). Protein signals were detected using ECL chemiluminescence reagent (Amersham Pharmacia).

### Indirect immunofluorescent staining

Cells growing on coverslips were fixed in 2% formaldehyde for 3 min and extracted 3 times (10 min each) with 0.5% Triton X-100. The cell samples were incubated with primary antibodies (described above) at 37°C for 1 h,

**Figure 1** Expression of E-cadherin in SV40-immortalized Ges-1 and gastric cancer cell lines. Negative staining of E-cadherin in Ges-1 and MGC-803 was shown on immunofluorescent micrographs.

washed with PBS containing 0.5% Triton X-100 and then reacted with FITC- or rhodamine-conjugated secondary antibodies (Jackson ImmunoResearch Laboratories, West Grove, PA) at 37°C for 1 h. After washed, the samples were rinsed in 0.9% NaCl, stained with 1 $\mu$ g/L 4, 6-diamidino-2-phenylindole (DAP; Sigma) and mounted in 60% glycerol/PBS. Olympus BH2 fluorescent microscope equipped with FITC- and rhodamine- channel filter systems was used to observe distribution of different proteins in the same fields. Kodak TMAX-400 black and white films were used for photographs.

### RT-PCR

Total RNA was extracted from cells of logarithmic growth potential with Trizol (Invitrogen) as described, then suspended in 50 $\mu$ L RNase-free water and quantified. Reverse-transcription was performed in a final volume of 20 $\mu$ L using superscript III reverse transcriptase (Invitrogen) according to the manufacturer's instructions under the following conditions: 1mmol/L dNTP, 50ng Oligo-dT<sub>15</sub> and 3 $\mu$ g total RNA. The reaction was performed at 50°C for 45 min, followed by inactivation of the enzyme at 70°C for 15 min. The sequences of the specific primers are listed in Table 1. Forty cycles of PCR amplification were performed at 94°C for 1 min, at 58°C for 1 min, at 72°C for 1 min. PCR products were identified by running on 1.2% agarose gel.

## RESULTS

### E-cadherin expression lost in SV40-immortalized Ges-1 and gastric cancer cell lines

The three gastric cancer cell lines MGC-803, BGC-823, and SGC-7901 were negative for E-cadherin expression as demonstrated by RT-PCR, immunoblotting and immunofluorescent staining. The SV40-transformed gastric epithelial cell line Ges-1, non-tumorigenic in nude mice with normal cell morphology, was also negative for E-cadherin expression at mRNA and protein levels (Figure 1).

### N-cadherin expression in SV40-immortalized Ges-1 and gastric cancer cell lines

In order to understand the formation of adherens junctions in these E-cadherin negative cell lines, N-cadherin expression was detected by RT-PCR, immunoblotting and

**Figure 2** Expression of N-cadherin in SV40-immortalized Ges-1 and gastric cancer cell lines. **A:** Distribution of N-cadherin fluorescence on cell membranes in Ges-1 and gastric cancer cell lines; **B:** A band of 135 ku N-cadherin protein detected by Western blotting of N-cadherin; **C:** N-cadherin mRNA expression shown by RT-PCR.

**Figure 4** Expression of E-cadherin transcription repressors (snail, slug) and N-cadherin activator (twist) in Ges-1 and gastric cancer cell lines.

immunofluorescent staining (Figure 2). N-cadherin mRNA was found in all these E-cadherin negative cell lines (SV40-transformed Ges-1, BGC-823, MGC-803, and SGC-7901). In consistence with N-cadherin mRNA expression, a band of 135 ku N-cadherin protein was also shown in these cell lines as detected by Western blotting of N-cadherin. N-cadherin fluorescence was distributed at cell-cell contact membrane regions, suggesting that these cells established adherents junctions through N-cadherin rather than E-cadherin. Alteration of cadherin isoforms from E-cadherin to N-cadherin occurred in the process of carcinogenesis.

**Figure 3** Expression of  $\alpha$ - and  $\beta$ -catenins in Ges-1 and gastric cancer cell lines. **A:** Distribution of  $\alpha$ - and  $\beta$ -catenin fluorescence on cell membranes and cell-cell borders in Ges-1 and MGC-803; **B:** Reactive bands at 102 ku and 94 ku of  $\alpha$ - and  $\beta$ -catenins in Ges-1 and cancer cell lines.

#### Expression of $\alpha$ - and $\beta$ -catenins in SV40-immortalized Ges-1 and gastric cancer cell lines

Immunoblotting of  $\alpha$ - and  $\beta$ -catenins showed reactive bands at 102 ku and 94 ku respectively in Ges-1 and gastric cancer cell lines. The fluorescence of  $\alpha$ - and  $\beta$ -catenins was found at the cell-cell contact borders irrespective of transformed cells or cancer cells (Figure 3). The colocalization of both cadherin and catenins indicated the formation of cadherin/catenin complex at adherents junctions.

#### Expression of E-cadherin transcription repressor and N-cadherin activator in Ges-1 and gastric cancer cell lines

The transcription factors (snail, slug and twist) could repress the expression of E-cadherin and induce the expression of N-cadherin. Thus, we examined the expression of these transcription factors in these cell lines with alteration of E-cadherin to N-cadherin by RT-PCR. They were all expressed in Ges-1 and three cancer cell lines, but their expression levels varied (Figure 4).

## DISCUSSION

It is well known that E-cadherin is an adhesion receptor of normal epithelial cells that binds to cytoplasmic adhesion proteins to form E-cadherin/catenin complex as an anchorage site for actin-based cytoskeleton. The E-cadherin/catenin/cytoskeleton complex plays an important role in the maintenance of structural and functional stability of epithelial tissues. Loss of E-cadherin expression or function in epithelial carcinoma has been considered as a primary reason for disruption of cell-cell contacts. However, there is evidence that other cadherins, such as N-cadherin, are up-regulated in cancer cell lines<sup>[13]</sup>. N-cadherin is present in invasive cancer cell lines and its exogenous expression in tumor cells increases the ability

of invasion and metastasis of tumor cells. Changes in the expression of cadherins occur in the early embryonic development during gastrulation and neural crest formation. The loss of E-cadherin with the acquisition of fibroblastic phenotype occurs through a mechanism called epithelial-mesenchymal transition (EMT) during early invasion and metastasis of carcinoma cells. To investigate the occurrence of cadherin conversion in gastric carcinoma, we determined the expression of E-cadherin and N-cadherin in transformed human gastric cell line and three gastric cancer cell lines. The results demonstrated that three human gastric cancer cell lines were all negative for E-cadherin immunofluorescent staining and immunoblotting, which is in agreement with the reported data, suggesting that E-cadherin expression is inhibited in gastric cancer cells<sup>[14]</sup>. Meanwhile, our finding is in accordance with the report that loss of E-cadherin is a key step in the progression from benign adenoma to malignant carcinoma *in vivo*<sup>[15]</sup>. However, in our study, N-cadherin was expressed in all these E-cadherin negative cell lines and N-cadherin fluorescence was distributed at cell-cell contact membrane regions, suggesting that these cells are established at the adherents junctions through N-cadherin rather than E-cadherin. Apparently, alteration of cadherin isoforms from E-cadherin to N-cadherin occurs in the process of carcinogenesis. SV40-transformed gastric epithelial cell line Ges-1 characterized by immortalization *in vitro* and normal cell morphology, was also negative for E-cadherin expression at mRNA and protein levels, suggesting that inhibition of E-cadherin expression may be an early cellular event in the process of cell malignancy.

The interaction between cytoplasmic cadherins and catenins is critical for the formation of stable and functional AJs. The mutation or homozygous deletion of catenin gene leads to loss of cell-cell adhesion. Moreover,  $\beta$ -catenin can act as a transcription factor in nuclei as an activator of LEF/TCF family of the DNA-binding proteins, which is activated by the Wnt signal pathway<sup>[16]</sup>. We therefore investigated the expression of  $\alpha$ - and  $\beta$ -catenins in the same cell lines. Immunoblotting and immunofluorescence staining showed positive expressions of  $\alpha$ - and  $\beta$ -catenins in transformed Ges-1 and three cancer cell lines. Meanwhile, we did not find the relocalization of  $\beta$ -catenin in nuclei, suggesting that cadherin/catenin complex is formed at adherents junctions. In gastric cancer cells, the formation of N-cadherin/catenin complex at AJs after conversion of cadherin isoforms may imply that the mediated adhesion signals are needed for remote metastasis of cancer cell mass.

Multiple mechanisms can inactivate E-cadherin in cancer cells. Recent reports have highlighted the role of EMT regulator, snail, a strong repressor of E-cadherin gene expression in cancer cell lines<sup>[17, 18]</sup>. Snail is a zinc finger transcription factor which directly represses E-cadherin expression by binding to E-box DNA-binding sequence CAGGTG and is required for mesoderm differentiation and neural crest formation during embryonic development. In human carcinoma and melanoma, the expression of snail correlates with the absence of E-cadherin expression<sup>[19-21]</sup>. Forced expression of snail in cultured epithelial cells represses

the E-cadherin promoter and increases invasion and matrix metalloproteinase-2 expression<sup>[22]</sup>. Slug, which also represses the E-cadherin promoter, can likewise induce EMT, increase cell motility and invasion and confer tumorigenesis<sup>[23]</sup>. Twist is originally identified in *Drosophila* as a protein involved in establishing dorso-ventral polarity and in epithelial-mesenchymal transition. Recent findings indicate that twist is both an E-cadherin repressor and an EMT inducer<sup>[24]</sup>. Furthermore, the findings implicate that twist is involved in tumor cell intravasation and in tumor metastasis. In the present study, strong expressions of snail, slug and twist were observed in the transformed gastric cell line Ges-1 and three gastric carcinoma cell lines. Meanwhile, these cell lines were all negative for E-cadherin expression but positive for N-cadherin expression.

In conclusion, EMT regulators play a critical role in human gastric carcinoma. The transcription factors (snail, slug and twist) are correlated with the alteration of cadherin isoforms in human gastric cancer cells. However, the mechanism of how the transcription factors regulate the alteration of cadherin isoforms remains to be elucidated.

### Abstract

We have described a previously unreported entity of an intussuscepted neuroendocrine carcinoma of the appendix. Our patient was a 70-year-old man whose only complaint was insipient weight loss. Colonoscopy showed a malignant cecal "polyp", and an extended right hemicolectomy was performed. We have reviewed the literature on the causes of appendiceal intussusception and their appropriate treatment options, and clarified the classification of neuroendocrine tumors of the gastrointestinal tract.

### INTRODUCTION

Intussusception of the appendix is a well-recognized, though rare, entity (occurring with an incidence of 0.01% in a large autopsy series<sup>[1]</sup>). Occasionally it is accompanied by an associated appendiceal abnormality, such as an adenoma, endometriosis, carcinoid tumor or adenocarcinoma. Typically, these cases present as acute appendicitis. Less commonly, they present with chronic episodic abdominal pain, cecal mass or even rectal bleeding, for which the patient may have to undergo an endoscopic

examination and the intussuscepted appendix may be interpreted as a cecal polyp. Occasionally, the patient has no gastrointestinal symptoms. Whereas carcinoid tumor (now termed as well-differentiated neuroendocrine tumor) is the commonest tumor of the appendix, neuroendocrine carcinoma of the appendix is a rare entity (occurring in about 0.2% of all appendectomy specimens<sup>[2]</sup>). We here present a case of a previously unreported phenomenon of intussusception of the appendix due to a neuroendocrine carcinoma.

### CASE REPORT

A 70-year-old man presented with an 18-mo history of 13 kg weight loss. He was originally referred to the rheumatologists for investigation as he had a past medical history of rheumatoid arthritis. Other past medical history included cholecystectomy and partial gastrectomy with vagotomy for perforated duodenal ulceration. He had no gastrointestinal symptoms.

He underwent an upper gastrointestinal endoscopy with no abnormalities detected. Colonoscopy revealed a lesion in the ascending colon that appeared macroscopically malignant (Figure 1). Two further benign-looking polyps were also identified, one each in the transverse colon and at the hepatic flexure. Biopsies of the ascending colon lesion suggested adenocarcinoma. A CT scan failed to demonstrate the tumor due to extensive fecal loading. There was no evidence of metastatic disease. Pre-operative blood investigations revealed a mild iron-deficiency anemia (hemoglobin 11.9 g/dL) and no other abnormality.

During the operation, a cecal tumor was found and a large lymph node was present in the mesentery. An extended right hemicolectomy was performed and an end-to-end anastomosis fashioned.

The resected specimen showed complete intussusception of the appendix, with invagination of mesoappendix fat seen at the base on the peritoneal surface. The whole of the appendix was involved by the tumor, and measured 4.5 cm in length and 2.5 cm wide at the base (Figure 2). Microscopic examination revealed a well-differentiated neuroendocrine carcinoma with a trabecular and glandular pattern (Figure 3), which was invading into the invaginated serosal fat of the appendix. Immunohistochemistry showed weak positivity with chromogranin (Figure 4) and synaptophysin, and strong membrane and cytoplasmic positivity with the low molecular weight cytokeratin (CK) marker, CAM

**Figure 1** Endoscopic appearance of polypoid lesion in the cecum.

**Figure 2** Gross specimen of invaginated appendiceal tumor seen on opening cecum.

**Figure 3** Well-differentiated neuroendocrine carcinoma, arranged in nests and trabeculae, beneath uninvolved large-intestinal type appendiceal mucosa (top left hand corner) (hematoxylin and eosin; ×16).

**Figure 4** Chromogranin positive immunohistochemical staining (brown cytoplasmic staining) demonstrating neuroendocrine differentiation of tumor cells (×40, 1:5 000 dilution, DAK-A3 clone, DAKO, Cambridge, UK).

5.2. The tumor cells were negative for CK 20, which is usually positive in primary colorectal adenocarcinoma. The histological pattern and immunoprofile were those of neuroendocrine carcinoma. Lymphovascular invasion was identified and 1 of the 11 dissected lymph nodes contained metastatic carcinoma. The involved node was 2 cm in size and largely necrotic. Five other small polyps were also found within the specimen (2 hyperplastic, 3 adenomatous).

Post-operative recovery was uncomplicated and he was discharged 7 d post-operatively. The case was discussed at the colorectal cancer multidisciplinary (MDT) meeting and consensus was that no further adjuvant treatment was needed. He was to be followed up in the surgical clinic and was well 4 mo post-surgery.

## DISCUSSION

Intussusception of the appendix is rare. In a study by Collins, of 71 000 autopsy appendiceal specimens, prevalence of intussusception was only 0.01%<sup>[1]</sup>. Clinically it is almost never diagnosed pre-operatively, most commonly mimicking acute appendicitis. It can also present with symptoms of chronic, episodic abdominal pain with or without rectal bleeding, painless rectal bleeding, or may be asymptomatic. Cases can be diagnosed

preoperatively by means of radiological examination<sup>[3]</sup>. At barium enema there is an absence of appendiceal filling together with a cecal-filling defect in the anticipated location of the appendix. Ultrasound scanning may show a “target-like” picture or “concentric ring sign”, though neither of these radiological appearances is specific for an intussuscepted appendix<sup>[4]</sup>. CT scans may reveal a mass lesion within the cecum without a discernable appendix. At colonoscopy, the intussusception may be misinterpreted as a cecal polyp. Therefore, in all the cases of cecal polyp identification, the appendiceal orifice should be routinely searched for and noted to be present.

The mechanism and pathogenesis of intussusception of the appendix has been extensively studied by Fink *et al*<sup>[5]</sup>. It may be due to anatomical causes, such as a thin mesoappendix, a mobile appendix, or a wide appendicular lumen, or due to an associated appendiceal abnormality. These include intraluminal factors (fecoliths, foreign bodies, parasites) or intramural factors (lymphoid follicle hyperplasia, endometriosis, and tumors).

Tumors of the appendix, with or without intussusception, are uncommon. Mostly they are benign entities, such as mucocoeles, adenomata, and benign carcinoids tumors. Few are malignant, occurring in only about 1% of appendectomy specimens<sup>[6]</sup>. In one large series, only 20% of these malignant appendiceal tumors

were neuroendocrine carcinomas<sup>[2]</sup>, the majority being adenocarcinomas. Using the WHO classification of endocrine tumors of the gastroenteropancreatic system (2000)<sup>[7]</sup>, classical benign carcinoid tumors have been incorporated under the heading of neuroendocrine tumors, and are now termed as well-differentiated neuroendocrine tumors. They are considered to be of benign or uncertain malignant potential. Those with malignant features (infiltrative growth pattern, invasion into the muscularis propria, greater than 2 cm in diameter, or with nodal metastases), previously called malignant carcinoids, are now termed as neuroendocrine carcinomas, well- or poorly-differentiated. Until now, no poorly-differentiated neuroendocrine carcinomas of the appendix have been described. Classically, well-differentiated neuroendocrine carcinomas of the appendix have organoid, nesting, trabecular, rosette-like or palisading patterns, suggestive of endocrine differentiation<sup>[8]</sup>. They are associated with a worse prognosis than the more commonly diagnosed benign carcinoids/well-differentiated neuroendocrine tumors.

It is important that an intussuscepted appendix is managed appropriately. In those cases uninvolved by a concurrent malignant tumor, reduction at laparotomy or laparoscopy with subsequent appendicectomy, or right hemicolectomy is the surgical treatment of choice. These lesions may be misinterpreted as a broad-based cecal polyp during colonoscopy, and subsequent endoscopic resection may result in unexpected complications, such as perforation and peritonitis<sup>[9]</sup>. Therefore, wide-stalked cecal polyps, where the appendiceal orifice cannot be visualized, should be approached with caution endoscopically. However, in the circumstances when a malignant tumor of the appendix is also present, right

hemicolectomy or ileocecal resection with lymph node dissection should be performed<sup>[1]</sup>. Though a diagnosis of appendiceal intussusception had not been pre-operatively made in our patient, he underwent the correct treatment of an extended right hemicolectomy, because of the pre-operative diagnosis of a presumed malignant cecal polyp.

## Abstract

Infections are a major adverse effect during the treatment with anti-TNF- $\alpha$ . While exclusion of any bacterial infection and screening for tuberculosis are mandatory before initiating a therapy with anti-TNF- $\alpha$ -antibodies, there are no guidelines whether to screen for or how to deal with chronic viral infections such as hepatitis B. In this case report, we have described a patient with Crohn's disease who developed subfulminant hepatitis B after the fourth infusion of infliximab due to an unrecognized HBs-antigen carrier state. He recovered completely after lamivudine therapy was started, but this severe adverse event could have been prevented if screening for HBV and pre-emptive therapy with lamivudine would have been started prior to infliximab. We therefore strongly argue in favor of extended screening recommendations for infectious diseases including viral infections before considering a therapy with infliximab.

Millonig G, Kern M, Ludwiczek O, Nachbaur K, Vogel W. Subfulminant hepatitis B after infliximab in Crohn's disease: Need for HBV-screening? *World J Gastroenterol* 2006; 12(6): 974-976

<http://www.wjgnet.com/1007-9327/12/974.asp>

## INTRODUCTION

Infliximab has become the standard therapy for refractory,

steroid-dependent or fistulizing Crohn's disease<sup>[4,14,19]</sup>. The association between the use of this monoclonal chimeric mouse antibody, and increased risk of severe bacterial infections<sup>[16]</sup> and reactivation of tuberculosis<sup>[6]</sup> has received much attention. The influence of infliximab on viral infections, however, has not been extensively investigated, and data that are available on reactivation of chronic viral infections such as hepatitis B and C and EBV are conflicting. Reijasse *et al*<sup>[15]</sup> studied the viral kinetics of EBV in patients receiving immunosuppressive drugs including infliximab and found no increased viral load in them compared to the control group. Several case studies and investigations of small patient cohorts have reported that Crohn's disease in patients with documented pre-existing chronic hepatitis B or C was successfully treated with infliximab, without the drug causing any deterioration of the liver disease<sup>[11,13,21]</sup>. In contrast to these publications, in their prospective study of Crohn's patients with coexisting chronic HBV-infection treated with infliximab, Esteve *et al*<sup>[1]</sup> observed two severe hepatitis flare-ups during treatment with this drug. Ostuni *et al*<sup>[12]</sup> reported on a patient with reactivated hepatitis B after therapy with infliximab and methotrexate. Michel *et al*<sup>[8]</sup> observed fulminant hepatic failure in a patient with inactive chronic hepatitis B after being treated with infliximab but without signs of HBV-reactivation and therefore of unknown etiology.

Several authors have recommended pre-emptive treatment with lamivudine of HBV-carriers with Crohn's disease before starting infliximab-therapy<sup>[1,8]</sup>.

FDA-recommendations released in December 2004 also alert physicians to the danger of primary hepatotoxicity or reactivation of chronic viral hepatitis caused by the administration of infliximab.

## CASE REPORT

We report here on a 50-year-old patient in whom Crohn's disease with terminal ileitis was diagnosed in January 2001. Initially he received a course of mesalamine. This, proving to be ineffective, was followed by a course of systemic steroids together with mesalamine. Steroid withdrawal was difficult, but in June 2003 steroids were discontinued and the patient was in complete remission until February 2004 when he had a relapse with abdominal pain and loose and bloody stools. Treatment was restarted with budesonide 3 mg t.i.d. and azathioprine 150 mg. Budesonide failed to improve the symptoms and steroid-therapy was switched

**Figure 1** ALT remained within the normal range during therapy with prednisolone, azathioprine and during the infusions with infliximab. Only after the fourth infusion of infliximab, the patient developed a fulminant hepatitis with ALT up to 1 100 IU/L. HBV-DNA ( ) quantification showed 220 mio copies/mL. Lamivudine (150 mg/d) was started and led to a rapid decrease in transaminases and HBV-DNA.

to systemic steroids (methylprednisolone 40 mg) again. Abdominal pain and bloody stools improved under this regimen but tapering of steroids was followed by an immediate relapse despite azathioprine 2 mg/kg for several months. Endoscopy showed ulcerating inflammation in the terminal ileum and capsule endoscopy revealed involvement of the distal jejunum. Bowel surgery was discussed with the patient, but he wished to try every possible medical treatment before going for surgery. We therefore re-assessed the situation and decided to add infliximab 5 mg/kg (total amount 400 mg) because of steroid-dependent disease. Tuberculosis was excluded by tuberculin-testing and chest X-ray. Blood tests showed mild leukocytosis (14 g/L), all other results including renal and liver function tests, c-reactive protein, iron metabolism, and vitamins were within normal ranges. There was no history of any other disease before the diagnosis of Crohn's disease, besides a mild reactive depression for which the patient has been on mirtazapine for more than a year. Transaminases were documented to be within normal ranges since 2001.

Infliximab was administered successfully at week 0, 2, and 6 followed by complete remission and rapid tapering of steroids. Basis therapy consisted at this time of azathioprine 150 mg, mirtazapine 30 mg, pantoprazole 40 mg and brotizolam 0.25 mg at night. The infusion at wk 6 was followed by 3 d of flu-like symptoms. One month after the third infliximab infusion, the patient came to the outpatient clinic because of abdominal discomfort and malaise. Blood tests showed signs of acute hepatitis (ALT 983 [normal <50 IU/L], AST 413 [normal <50 IU/L],  $\gamma$ GT 109 [normal <66 IU/L], LDH 237 [normal <232 IU/L], bilirubin 2.17 [normal <1.28 mg/dL] and a decreased prothrombin time of 63% [normal >70%]) (course of ALT Figure 1). Liver parenchyma was hyperechogenic in sonography but there were no signs of liver cirrhosis and as expected, there were no signs of mechanical cholestasis. The patient mentioned at this point that he had been immunized against hepatitis A and B six months before by his general practitioner because all other members of his family had undergone hepatitis B and he

intended to travel to Southern Europe during the summer holidays. No previous serological examination had been performed before immunization.

Complete work-up was done one week after his admission to the hospital. Hepatitis-serology revealed immunity against hepatitis A and negative serology and PCR for hepatitis C, but circulating HBs-antigen, no HBe-antigen but anti-HBe- and anti-HBc-antibodies, and negative anti-HBc-IgM were detected. Quantification of HBV-DNA showed >220 000 000 copies/mL (38 000 000 IU/mL). Other causes for hepatitis such as EBV, CMV, autoimmune hepatitis and acute Wilson's disease were ruled out. We suspected reactivation of hepatitis B from a previously unknown HBV-carrier state. This was corroborated by serology from a frozen serum sample from a previous visit in 2001 also showing the features of an HBs-antigen carrier but a low viral load with 116 copies/mL (20 IU/mL).

Antiviral therapy (lamivudine 150 mg daily) was started immediately after diagnosis. Despite the therapy, liver synthesis parameters transiently decreased and reached a nadir three weeks after the first manifestation with a prothrombin-time of 42% and bilirubin peak of 35 mg/dL. At the same time, the patient developed mild hepatic encephalopathy with increased sleepiness. One month after the diagnosis, the patient recovered, transaminases decreased and prothrombin-time normalized and HBV-DNA dropped to 2 000 000 copies/mL (340 000 IU/mL). The patient could be discharged and followed up in the outpatient clinic. The most recent visit two months after the acute hepatitis showed normal transaminases and HBV-DNA of 989 copies/mL (170 IU/mL).

## DISCUSSION

While patients undergoing chemotherapy for malignancy have long been screened for chronic hepatitis B and treated prophylactically with lamivudine if positive, this has not been performed on a routine basis in patients with chronic inflammatory bowel disease requiring immunosuppressive regimens including infliximab. Our knowledge about the role of TNF- $\alpha$  in chronic viral hepatitis is sparse but there is evidence that TNF- $\alpha$  synergizes with interferons in suppressing viral replication<sup>[2,7,22]</sup> and is essential in clearing HBV<sup>[17]</sup>. A promoting effect for increased HBV-replication during treatment with anti-TNF-antibodies could be explained on this basis. But why HBs-antigen carriers, upon anti-TNF- $\alpha$  treatment, suddenly lose their tolerance against HBV and switch to a cytotoxic T-lymphocytic activation leading to hepatocyte injury and liver failure remains to be elucidated. At present we can only speculate that TNF- $\alpha$  might play an important role in maintaining tolerance in the HBs-antigen carrier state.

Till date there are only three case reports and one report of a small group of HBs-antigen carriers that suffered HBV-reactivation following administration of infliximab. Four patients developed fulminant hepatitis B<sup>[1,8,12]</sup> while one patient had only moderately elevated transaminases<sup>[20]</sup> that returned to normal without antiviral therapy. Esteve *et al* reported that two of their patients

showed severe reactivation and one died from hepatic failure, but another patient on lamivudine had no worsening of liver disease during infliximab-therapy<sup>[1]</sup>. Stable HBV under lamivudine has also been reported by Oniankitan *et al*<sup>[11]</sup> and Valle Garcia-Sanchez *et al*<sup>[21]</sup>. Keeping these reports in mind and looking for other factors that might influence the course of HBV, we suggest that (1) the number of infliximab-infusions and (2) concomitant immunomodulatory therapy might influence the course of HBV-reactivation (azathioprine in our case and methotrexate therapy in the other cases with severe hepatitis).

In our patient HBV-reactivation was noted after the third infusion of infliximab. Previous treatment with steroids and azathioprine alone had not induced a flare-up in hepatitis B, although it is known that all types of immunosuppressive therapy can lead to a flare-up in hepatitis B. For steroids this has been documented most frequently in patients with hematological malignancies<sup>[18]</sup>. Azathioprine and methotrexate have also been linked with HBV-recurrence. But while this occurred on treatment with azathioprine<sup>[9]</sup>, it took place only after the discontinuation of methotrexate<sup>[3,5,10]</sup>.

In conclusion, our report on a patient with Crohn's disease developing subfulminant hepatitis under infliximab treatment due to reactivation of a previously unknown HBs-antigen-carrier state draws attention to the need for screening patients with inflammatory bowel disease for hepatitis B and for antiviral prophylaxis in HBV-positive patients prior to therapy with anti-TNF- $\alpha$  antibodies.

### Abstract

Crohn's disease is well known to affect any part of the gastrointestinal tract including the oral cavity and anus. Various extraintestinal complications have been reported in Crohn's disease, but extraintestinal involvement characterized by granulomatous lesions is uncommon. Here, we have reported a case about the involvement of the gallbladder in Crohn's disease. A 33-year-old woman was diagnosed having panperitonitis due to intestinal perforation and cholecystitis. The patient was moved to the surgical service for an emergency operation. On the resected specimen, there was a broad longitudinal ulcer at the mesenteric side. The mucosa of the gallbladder was nodular and granular, and the wall was thickened. The surface epithelium of the gallbladder was partially eroded and pyloric gland metaplasia was observed focally. Rokitansky-Aschoff sinuses were also present. From the lamina propria to the subserosal layer, there were several well-formed epithelioid cell granulomas, which were the non-caseating sarcoidal type different from the foreign-body and xanthomatous granulomas. Periodic-acid Schiff and acid fast stains revealed no organism within the granulomas. Lymphoid aggregates were present throughout the gallbladder wall. Sections from the resected ileum showed typical features of the Crohn's disease. When cholecystectomy is performed in a patient with Crohn's disease, the possibility of gallbladder involvement should be carefully examined by histopathological tests.

### INTRODUCTION

Crohn's disease is well known to affect any part of the gastrointestinal tract including the oral cavity and anus. Various extraintestinal complications have been reported in Crohn's disease, but extraintestinal involvement characterized by granulomatous lesions is uncommon. Here, we report a case of the involvement of the gallbladder in Crohn's disease.

### CASE REPORT

The patient was a 33-year-old woman who was admitted to the Shiga University of Medical Science Hospital with complaints of nausea, vomiting, and severe abdominal pain, which had lasted for a couple of hours. Her past history included Crohn's disease (ileocolonic type) and gallbladder stone, which had been diagnosed 2 years ago. She was well controlled with medications (2 250 mg/d 5-aminosalicylate and 2 000 kcal/d elemental diet) in these 2 years. She did not feel any symptoms of gallbladder stone.

At the time of admission, her vital signs were as follows: body temperature 37.4 °C, blood pressure 92/60 Pa, and pulse 98 beats/min. The laboratory data included a white blood count of  $13.1 \times 10^3/\text{mL}$ , and C-reactive protein of 13.6 mg/dL. The values for biochemistry were within the normal range. An abdominal CT scan demonstrated a free-air space located in the dorsal side of the abdomen, ascites, strong contrast enhancement of a thickened ileum, fluid collection in the small intestine, and gallbladder swelling with calcifications (Figure 1). The intra- and extrahepatic bile ducts appeared normal. These findings were suggestive of panperitonitis due to intestinal (ileal) perforation and cholecystitis.

After the admission, the patient was moved to the surgical service for an emergency operation. A perforating hole (diameter 5 mm) was located at the ileum 20 cm oral side from Bauhin's valve, and thus segmental ileotomy (25 cm resection) was performed. On the resected specimen, there was a broad longitudinal ulcer at the mesenteric side. Following an ileotomy, the patient also received a cholecystectomy. The serosal surface of the gallbladder adhered tightly to the greater omentum and duodenal bulb.

The mucosa was nodular and granular, and the wall was

**Figure 1** Abdominal CT scan on admission. CT scan demonstrated gallbladder swelling with thickened wall and stones, ascites, a thickened ileum, and fluid collection in the small intestine.

**Figure 2** Histological findings of the gallbladder. **A:** The mucosa was nodular and granular, and the wall was thickened. Erosion and submucosal bleeding were also observed, but there were no obvious ulcers; **B:** There were several well-formed epithelioid cell granulomas, which was non-caseating sarcoidal type, different from the foreign-body and xanthomatous granulomas.

thickened. Erosion and submucosal bleeding were also observed, but there were no obvious ulcers (Figure 2A). The surface epithelium of the gallbladder was partially eroded and pyloric gland metaplasia was observed focally. The lamina propria showed discontinuous chronic active inflammation. The muscular layer was hypertrophied and the subserosal layer was thickened with marked fibrosis. Rokitansky-Aschoff sinuses were also present. From the lamina propria to the subserosal layer, there were several well-formed epithelioid cell granulomas, which were the non-caseating sarcoidal type, different from the foreign-body and xanthomatous granulomas (Figure 2B). Periodic-acid Schiff and acid fast stains revealed no organism within the granulomas. Lymphoid aggregates were present throughout the gallbladder wall. Sections from the resected ileum showed typical features of Crohn's disease.

Her clinical course was good, and she was discharged from the hospital 1 mo after the operation.

## DISCUSSION

A high prevalence of gallstones in Crohn's disease has been reported<sup>[1]</sup>, but gallbladder involvement in Crohn's disease is very rare. Based on our MEDLINE search of the literature, only three case reports were found<sup>[2-4]</sup>. In all

cases including our patient, the pathological examination of the gallbladder revealed transmural inflammation, granulomatous change and lymphoid aggregation, all of which were similar to those seen in the bowel lesions. Duodenal Crohn's disease has been reported to occasionally involve the surrounding organs<sup>[2,3]</sup>, but our case did not present any duodenal lesions, indicating that the gallbladder lesion might not be a consequence of spread by contiguity. When cholecystectomy is performed in a patient with Crohn's disease, the possibility of gallbladder involvement should be carefully examined by histopathological examinations.

## Abstract

We report here a very rare case of intestinal Behcet's disease with pyoderma gangrenosum. A 16-year-old woman who was diagnosed with intestinal Behcet's disease by the presence of cutaneous pathergy together with two major criteria (oral and genital aphthoses) and one minor criterion (gastrointestinal manifestations), was referred to our hospital with a left lower leg ulcer and abdominal pain in September 1989. Colonoscopy demonstrated flare-up colitis involving the entire colon. Her lower leg lesion was a painful destructive ulcer with an irregular margin and a ragged overhanging edge. Based on these clinical and laboratory findings, we diagnosed her cutaneous ulcer as pyoderma gangrenosum developing with exacerbated intestinal Behcet's disease. Her cutaneous and intestinal lesions were poorly controlled though she received oral prednisolone treatment for a month. Because of aggravated abdominal symptoms with peritoneal irritation, we performed total colectomy in November 1989. The resected specimen was histologically compatible with intestinal Behcet's disease showing severe inflammation with deep ulcerations and neutrophil accumulation. Subsequently, pyoderma gangrenosum rapidly improved. This clinical course may suggest the close relationship between pyoderma gangrenosum and intestinal Behcet's disease.

## INTRODUCTION

Behcet's disease is a multi-system inflammatory disorder of unknown origin, characterized by recurrent oral and genital ulcerations, ocular and cutaneous lesions, arthritis and vascular disease. Cases of Behcet's disease cluster along the ancient Silk Road, which extends from eastern Asia to the Mediterranean basin<sup>[1-3]</sup>. It is often difficult to distinguish Behcet's disease from other inflammatory bowel diseases. Pyoderma gangrenosum is an idiopathic ulcerative skin disease. Because the histological findings of pyoderma gangrenosum are nonspecific and no laboratory confirmation exists, the diagnosis is based primarily on its clinical manifestations. Though this skin lesion is known to be associated with inflammatory bowel diseases, such as ulcerative colitis and Crohn's disease, pyoderma gangrenosum is very rare in Behcet's disease patients. We present a patient with extensive pyoderma gangrenosum whose skin lesions were resolved after surgical removal of the inflamed intestinal lesions.

## CASE REPORT

A 16-year-old woman was referred to our hospital in September 1989 due to painful ulceration on the left foot and lower abdominal pain. She was diagnosed with intestinal Behcet's disease by the presence of cutaneous pathergy together with two major criteria (oral and genital aphthoses) and one minor criterion (gastrointestinal manifestations) in 1984. Her lower leg lesion was a painful destructive ulcer with an irregular margin and a ragged overhanging edge (Figure 1A). She was negative for repeated bacterial, fungal and viral cultures. Colonoscopy demonstrated flare-up colitis involving the entire colon. Based on these clinical and laboratory findings, her skin lesion was considered pyoderma gangrenosum developing with aggravation of her intestinal Behcet's disease. She was treated with prednisolone (20 mg orally per day) for a month, but the skin lesion was poorly controlled. In November 1989, she complained of severe abdominal pain and melena. Laboratory data showed a white blood cell count of 14900/mm<sup>3</sup>, serum C-reactive protein of 4.5 mg/dL and hemoglobin of 12.3 g/dL. Because her abdominal symptoms were aggravated with peritoneal irritation, we performed a total colectomy with partial ileolectomy and ileo-rectal anastomosis. The resected specimen revealed severe inflammation with punched-out ulcerations of the colon and ileum (Figure 2A). Microscopic findings showed active colitis with neutrophil

**Figure 1** Painful destructive ulcer of the foot with an irregular margin and a ragged overhanging edge (A) and intractable leg ulcer without improvement after oral corticosteroid therapy was cured after total colectomy (B).

**Figure 2** Severe inflammation and deep ulcerations of specimens from colon and ileum (A) and active colitis with neutrophil accumulation around the ulcer beds (B) (HE stain, x100).

accumulation around the ulcer beds. Subsequently her abdominal symptoms gradually improved. Surprisingly, intractable ulceration of the left foot disappeared without scarring within two weeks after the surgery (Figure 1B). She was discharged with an uneventful postoperative course. Relapse of pyoderma gangrenosum has not been observed for 10 years after surgery.

## DISCUSSION

Intestinal Behcet's disease has been categorized in a family with inflammatory bowel disease, and causes abdominal pain, diarrhea, melena and even perforation. The ileocecal region is the most commonly affected part of the gastrointestinal tract, but the distal colon may also be involved. It is often difficult to distinguish Behcet's disease

**Table 1** Reported cases of Behcet's disease with pyoderma gangrenosum

Author	Year	Age	Gender	Preceding disease	Treatment
Munro <i>et al</i> <sup>[5]</sup>	1988	43	Female	Behcet	Thalidomide
Lilford <i>et al</i> <sup>[6]</sup>	1989	40	Female	Behcet	Steroid
Rustin <i>et al</i> <sup>[7]</sup>	1990	40	Male	Behcet	Thalidomide
Armas <i>et al</i> <sup>[8]</sup>	1992	52	Male	Behcet	Steroid
Present case	2003	16	Female	Behcet	Total colectomy

from the other inflammatory bowel diseases because of the similar extra-intestinal manifestations including oral aphthosis, uveitis and arthritis. Genital ulceration and positive pathergy test are the extra-intestinal features of Behcet's disease alone, which are not seen in the other inflammatory bowel diseases. Our patient was diagnosed as Behcet's disease by the presence of cutaneous pathergy together with two major criteria (recurrent oral and genital aphthoses) and one minor criterion (gastrointestinal manifestations)<sup>[4]</sup>.

In Behcet's disease, multiple cutaneous lesions, such as erythema nodosum, folliculitis and pustules are seen, but pyoderma gangrenosum is very rare. Pyoderma gangrenosum in the present case did not respond to oral corticosteroids but was improved soon after the resection of inflamed intestinal lesions. Since the first report by Munro and Cox in 1988<sup>[5]</sup>, four cases of pyoderma gangrenosum associated with Behcet's disease have been reported in English literature<sup>[6-8]</sup> (Table 1). Behcet's disease always precedes the onset of pyoderma gangrenosum. These patients are treated with corticosteroids, immunosuppressants or thalidomide. It was reported that cases of pyoderma gangrenosum had no improvement after surgical removal of the intestinal lesions<sup>[9]</sup>. Pyoderma gangrenosum usually responds to systemic corticosteroids and may also be rapidly improved by surgical resection of the associated diseases, such as ulcerative colitis and Crohn's disease. Therefore, the activity of pyoderma gangrenosum is closely related to the activity of associated diseases. In the present case, pyoderma gangrenosum rapidly improved after total colectomy. The skin manifestations of Behcet's disease are classified as neutrophilic vascular reaction<sup>[10]</sup>. The pathergy test is useful for evaluating skin irritability and is a diagnostic criterion of Behcet's disease. However, this test can also be positive in other diseases such as Sweet's syndrome and pyoderma gangrenosum. Pyoderma gangrenosum is a form of cutaneous vasculitis<sup>[11]</sup> and accumulation of neutrophils and mononuclear cells is observed at the reaction site. In both Behcet's disease and pyoderma gangrenosum, primary pustular lesions can occur and neither of them has a characteristic histological appearance. They may belong to the category of the neutrophilic dermatoses.

Though the relationship between Behcet's disease and pyoderma gangrenosum is not referred in diagnostic criteria of Behcet's disease, the occurrence of pyoderma gangrenosum may be highly relevant with the pathogenesis of Behcet's disease.

### CASE REPORT

A 24-year-old male was admitted to our hospital with jaundice and epigastric pain reflecting low in the back. The body temperature was normal. He was a heavy drinker in the previous 4 years and reported a history of infantile hyperbilirubinemia, which resolved spontaneously. He had positive Murphy and Giordano signs and a palpable epigastric mass. The laboratory examination results above normal range were as follows: WBC: 12 500/ $\mu$ L (neutrophil: 93.6%, lymphocyte: 5.1%), SGOT: 159 IU/L, SGPT: 559 IU/L,  $\gamma$ GT: 520 IU/L, ALP: 244 IU/L, LDH: 699 IU/L, CPK: 606 IU/L, bilirubin (total): 7.68 mg/dL, bilirubin (direct): 6.5 mg/dL, and bile in the urine.

Computerized tomography (CT) of the upper abdomen was ordered, and displayed a 9 cm $\times$ 10 cm cyst in the common bile duct (CBD) region, extending from porta hepatis down to the level of the third portion of the duodenum (Figure 1). Distension of intrahepatic bile ducts with stasis was also observed. The findings were consistent with a choledochal cyst (CC). Further investigation with magnetic resonance imaging (MRI) and MR cholangiopancreatography (MRCP) was considered appropriate. It confirmed the intrahepatic duct distension and the large cyst (Figure 2). It was considered to be a large CC type IV<sub>A</sub>. During MRI, the patient developed "acute abdomen" symptoms. Spin echo T<sub>2</sub>-weighed images and MRCP depicted bile leak in the peritoneal cavity (Figure 3).

Immediately after MRCP he underwent urgent abdominal surgery. A 1-cm rupture of the distended CBD was found, with a considerable amount of intraperitoneal bile and focal biliary peritonitis. A Kehr tube was inserted into the CBD at the site of the rupture and the lips of the lesion were appropriately stitched.

In order to verify the adequacy of the urgent surgical intervention, <sup>99m</sup>Tc-mebrofenin hepatobiliary scintigraphy was advocated on the second postoperative day. The study included a 30-min dynamic acquisition, beginning with injection and consisting of 60 30-s images (frames) of the abdomen, followed by planar static images of the upper abdomen at 1½ h and 24 h post-injection. No active leaking in the peritoneal cavity was observed throughout the study. A well-circumscribed fusiform intense tracer

### Abstract

A case of a 24-year-old male with jaundice and epigastric pain is reported. The patient underwent a thorough clinical, laboratory, and imaging investigation. Computerized tomography revealed a 9 cm $\times$ 10 cm choledochal cyst. Magnetic resonance imaging and magnetic cholangiopancreatography were performed, during which he developed an "acute abdomen", with radiological evidence of biliary peritoneal leak. Urgent surgery revealed rupture of the distended malformed common bile duct. A peritoneal drain was instilled and a more definitive surgical procedure was accordingly scheduled. Hepatobiliary scintigraphy following surgery verified these findings, as well as confirmed the adequacy of the urgent surgery. A combination of radiological and nuclear medicine techniques substantially contributes to the diagnosis of choledochal cyst rupture and the adequacy of surgical intervention.

accumulation was observed in the right hepatic lobe near the hepatic hilum. It appeared early in the dynamic phase (Figure 4) and was most prominent in the 90-min static image while not apparent in the 24-h image (Figure 5). It corresponded to the intrahepatic moiety of the CC. A much fainter bulbous accumulation was displayed in the left hepatic lobe, extending well beyond the liver margins, and corresponded to the large extrahepatic CC moiety. It was apparent earlier in the dynamic study and still visible in the 24-h image (Figures 4 and 5).

## DISCUSSION

Choledochal cysts are congenital abnormalities of the bile ducts of unknown etiology. They comprise cystic dilations of the extrahepatic and/or intrahepatic biliary tree<sup>[1]</sup>. They are typically described as a childhood disease. Sixty percent of the patients are diagnosed during the first decade of life. Congenital cysts occur in between 1/100 000 and 1/2 000 000 live births and are more

**Figure 2** Significant distension of the intrahepatic bile ducts (arrowhead) in MRI of the upper abdomen (gradient echo T1-weighted acquisition) (A). The walls of the choledochal cyst (CC) tend to acquire a concave shape, while its volume appears reduced as compared to the CT findings, both signs are considered as indicative of rupture (B). GB: gallbladder.

frequent in females (female-to-male ratio: 3:1 to 4:1). They are usually observed in Asian countries, especially in Japan.

Alonso-Lej *et al.*<sup>[2]</sup> first classified CC into three major types: cystic, diverticular, and choledochocoele. Todani *et al.*<sup>[3]</sup> modified the classification system, which currently includes five types based on cholangiographic morphology and number of intrahepatic and extrahepatic bile duct cysts (Table 1). With regard to the shape of extrahepatic and intrahepatic ducts, type IV is further classified into three subtypes: cystic-cystic, cystic-fusiform, and fusiform-fusiform. Cystic-fusiform IV<sub>A</sub> is the subtype that corresponds to our findings. In this particular subtype, intrahepatic dilatation occurs in both hepatic lobes, with the left being predominantly involved. Yet, in the present case it was the right lobe that was affected.

Ultrasonography is the initial screening examination of choice in suspected CC. Depending on the radiologist's skill it may reveal the type of CC. Nevertheless, inherent limitations (e.g. gas in the bowel, intra-abdominal inflammatory processes, *etc.*) allow for limited anatomic delineation of the non-dilated biliary system<sup>[1]</sup>.

CT imaging can be relied on with a high degree of confidence in confirming an unambiguous diagnosis and providing information regarding CC relationship to the surrounding structures. It usually demonstrates a cyst, which is readily distinguished from the gallbladder as in our case. Depending on patient's age and history, the cystic wall is thickened, especially on the ground of recurrent inflammation and cholangitis.

**Figure 3** Abdominal MRI (spin echo T<sub>2</sub>-weighed, transverse projections - **A** and **B**, coronal projection - **C**) displaying bile leakage into the peritoneal cavity (arrowheads). The study was followed by MRCP (turbo spin echo T<sub>2</sub>-weighed acquisition - **D**) which imaged the bile leak (arrowheads) and moreover revealed the "egg-timer" bicameral shape of the extrahepatic moiety of the choledochal cyst (CC). GB: gallbladder.

**Figure 4** Postoperative <sup>99m</sup>Tc-mebrofenin dynamic study. A well-circumscribed fusiform tracer accumulation in the right hepatic lobe near the hepatic hilum is clearly visible from the 15<sup>th</sup> min of the study (arrow), and corresponds to a dilated intrahepatic duct. A much fainter bulbous accumulation is apparent in the area of the left hepatic lobe, extending well beyond the liver margins (arrowheads) and corresponding to the extrahepatic portion of the choledochal cyst. H: heart blood pool; bd: biliary drainage.

MRI with MRCP is the noninvasive imaging modality of choice for the diagnosis of CC. The cysts appear as large fusiform or saccular dilatations producing a specific signal on T<sub>2</sub>-weighed images. Associated bile duct anomalies can also be demonstrated. On the basis of reported results, MRCP has an estimated diagnostic accuracy of 82-100%<sup>[1]</sup>. Overall, MRCP is a promising technique that may offer as much as endoscopic retrograde cholangiopancreatography (ERCP).

Hepatobiliary scintigraphy is used in the setting of

suspected acute cholecystitis, peritoneal biliary leak, and for the investigation of neonatal jaundice. In addition, it contributes to the diagnosis of CC, although such studies are practically acquired in a limited number of patients. Rajnish *et al*<sup>[4]</sup> evaluated the efficacy of hepatobiliary scintigraphy in classifying CC patients with confirmed Todani types I and IV cysts and found that it has a good accuracy in the diagnosis, correlating with ERCP or surgical findings in 86% of the cases. The false negative results are mainly attributable to its limitation in identifying

**Figure 5** Planar static scintigraphic images of the upper abdomen. At 90-min post-injection the faint tracer accumulation corresponding to the extrahepatic portion of the choledochal cyst (CC) extends beyond the liver margins (arrowheads), while a fusiform tracer accumulation in a cystic dilated intrahepatic duct is prominent (arrow) (A). The latter finding is not visible in the late (24 h) image, nor bowel or peritoneal activity (B). bd: biliary drainage; K: kidney; S: spleen.

small intrahepatic dilatations in type IV<sub>A</sub>. Nevertheless, in our case the fusiform tracer accumulation in the right hepatic lobe corresponds to a dilated intrahepatic duct forming a cyst and its location is uncommon (cysts are usually seen in the left lobe). This intrahepatic cyst was not a continuous extension of the extrahepatic moiety of the CC, but developed secondary to a hepatic hilum ductal stricture, a feature distinguishing CC type IV<sub>A</sub> from type I<sup>[3]</sup>. Furthermore, hepatobiliary scintigraphy can provide useful information regarding liver function, biliary patency, and biliary leak in the peritoneum.

Type IV<sub>A</sub> is observed in 30-40% of CC cases<sup>[5]</sup>. It is often accompanied with a primary ductal stenosis around the hepatic hilum, which causes either cystic or fusiform dilatation of the intrahepatic duct. The fusiform dilatation imaged in the present case mainly resulted from stricture, whereas cystic dilatation may develop due to primary stricture combined with the weakness of the intrahepatic duct epithelium. The stricture can be radiologically detected and needs cautious surgical exploration<sup>[3]</sup>. The primary management of type IV<sub>A</sub> cysts is still controversial. The intrahepatic dilatation tends to gradually reduce in size following sufficient biliary drainage. In addition, lateral hepatic segmentectomy may be necessary, especially in cases of strictures of the upper intrahepatic ducts and when the left hepatic lobe contains gallstones<sup>[6]</sup>. Patients diagnosed with type IV CC are usually adults, who commonly develop hepatolithiasis<sup>[7]</sup>. Formation of gallstones leads to the dilatation of the ducts and sometimes is complicated by intrahepatic abscess<sup>[8]</sup>.

Surgical treatment should be recommended to reduce the risk of other serious complications, such as cholangitis, pancreatitis, rupture, portal hypertension, cirrhosis, and cholangiocarcinoma. Pancreatitis develops in 30-70% of adults with CC<sup>[9]</sup>. Cholangiocarcinoma may evolve in all kinds of cysts, but types I and IV are associated with a higher incidence. In these patients the prognosis is the same as in other cases of cholangiocarcinoma in the general population<sup>[10]</sup>.

On rare occasions, adults may present with an acute abdomen due to CC rupture and biliary peritonitis. The reported incidence ranges between 2-18%<sup>[11]</sup>. CC perforation is generally spontaneous, although sometimes trauma may be implicated. It is more frequent in children, while in adults it is associated with conditions causing increased intra-abdominal pressure, such as pregnancy<sup>[12]</sup>. In the present case, no obvious cause of rupture was

identified, considering that no kind of abdominal pressure was applied during the MRI/MRCP procedure. We thus believe that rupture was an accidental event. The recommended acute therapy for CC rupture is peritoneal drainage, followed by complete cyst resection, cholecystectomy and Roux-en-Y hepaticojejunostomy reconstruction. Our patient was therefore treated primarily as a surgical emergency with peritoneal drainage and a more definitive surgical procedure was accordingly scheduled.

Controversy exists about the role of hepatic resection in types IV and V cysts due to the difficulty of intrahepatic cyst excision, thus rendering these patients to a more intense long-term follow-up. Alternatively, minimally invasive and laparoscopic treatments have been proposed<sup>[9,13,14]</sup>.

In conclusion, apart from the clinical evidence, the diagnostic algorithm in this case as well as postoperative evaluation comprises information acquired by a combination of imaging modalities, namely CT, MRI/MRCP, and hepatobiliary scintigraphy. The proper handling of such patients relies upon good co-operation between several medical faculties, namely gastroenterology, radiology, nuclear medicine, and surgery, and is essential in order to prevent and treat serious complications.

### Abstract

Ultrastructure of Kupffer cells and hepatocytes in liver biopate was evaluated in a 17-year-old boy with Dubin-Johnson syndrome (DJS). The liver tissue obtained by needle biopsy was fixed in glutaraldehyde and paraformaldehyde and routinely processed for electron microscopic analysis. The ultrastructural examinations of liver biopate revealed the accumulation of membrane-bound, electron-dense lysosomal granules within the cytoplasm of hepatocytes, characteristic of DJS. They were located mainly in the vicinity of the biliary pole, and preferentially in the centrilobular region that corresponded to the pigment deposits seen under light microscope. The presence of the granules was accompanied by dilated elements of the granular endoplasmic reticulum and paracrystalline mitochondrial inclusions as well as dilation of the bile canaliculi. The changes in hepatocytes coexisted with marked stimulation and enhanced phagocytic activity of Kupffer cells. This was manifested in the accumulation of pigment deposits within their cytoplasm that corresponded to those observed in hepatocytes. Hyperactive pericentral Kupffer cells which are involved in the response to pigmentary material originating from disintegrated hepatocytes may play an essential role in the development of DJS.

Sobaniec-Lotowska ME, Lebensztejn DM. Ultrastructure of Kupffer cells and hepatocytes in the Dubin-Johnson syndrome: A case report. *World J Gastroenterol* 2006; 12(6): 987-989

### INTRODUCTION

A rise in serum bilirubin concentration above the norm may be caused by its increased production (hemolytic processes, shunt-bilirubinemia), impairment of its uptake, conjugation and discharge from hepatocytes (congenital non-hemolytic functional hyperbilirubinemia) or excretion of unconjugated and conjugated bilirubin from damaged hepatocytes or biliary canaliculi to the blood. Clinical picture can be similar, as jaundice is the predominant and often isolated symptom in the above pathologies. In doubtful cases, morphological examination of a liver biopate is a decisive step<sup>[1-3]</sup>.

The main aim of the paper was to demonstrate the ultrastructure of Kupffer cells and hepatocytes in liver biopsy from a patient with Dubin-Johnson syndrome (DJS). To the best of our knowledge, it is the first report on the ultrastructure of Kupffer cells in this disorder.

### CASE REPORT

Our report presents data concerning a 17-year-old boy suffering from hyperbilirubinemia (up to 119.7  $\mu\text{mol/L}$ ) with concomitant normal activity of aminotransferases from 6 years of age. He was suspected of congenital functional hyperbilirubinemia. However, since abdominal complaints and hepatomegaly were found to coexist with scleral xanthosis, the boy was sent for further diagnosis to the 3<sup>rd</sup> Department of Pediatrics, Medical University of Bialystok. On admission, laboratory tests revealed high serum bilirubin concentration (120.55  $\mu\text{mol/L}$ ) with the predominance of unconjugated fraction (82.94  $\mu\text{mol/L}$ ). However, the activities of aminotransferases (ALT, AST), alkaline phosphatase and GGTP were not increased. Differential diagnosis excluded: hemolytic disorders, infections with hepatotropic viruses (HBV, HCV, CMV, EBV, HSV), metabolic disorders (cystic fibrosis, Wilson's disease,  $\alpha$ -1 antitrypsin deficiency, hemochromatosis), hypothyroidism, autoimmune liver diseases, parasitic and epizootic diseases. The ultrasonographic examination of the abdominal cavity confirmed hepatomegaly with no changes in parenchyma echogenicity. Liver biopsy was performed to elucidate the still unclear cause of jaundice.

For ultrastructural analysis, small, fresh tissue blocks (1 mm<sup>3</sup>) were cut off from the cylinder of liver tissue obtained by needle biopsy. The remaining considerable part of the collected tissue was submitted for examination by the light microscopy.

**Figure 1** Several membrane-bound granules – varying in size, content, and electron density – located near the biliary pole of hepatocytes; broadening of granular endoplasmic reticulum (>); dilation of bile canaliculus (bc) with the loss of microvilli ( $\times 7\,000$ ).

**Figure 3** A hypertrophic, evidently activated Kupffer cell with phagocytized, very thick, black pigment deposits and biliary lamellar material. The cell blocks the sinusoidal vascular lumen. Distinctly dilated Disse's space contains a fine granular material ( $\times 4\,400$ ).

**Figure 2** Fragment of Kupffer cell with phagocytized thick black pigment granules; the cell adheres to a hepatocyte (H) containing a similar pigment deposit ( $\times 7\,000$ ).

The material for electron microscopic analysis was fixed in 10 g/L glutaraldehyde and 8 g/L paraformaldehyde in 0.1 mol/L cacodylate buffer (pH 7.4). Subsequently, fixation was carried out in osmium tetroxide; then the material was routinely processed for embedding in Epon 812. Ultrathin sections were contrasted with uranyl acetate and lead citrate, and examined using an Opton 900 PC transmission electron microscope (Zeiss, Oberkochen, Germany).

The liver specimen obtained by needle biopsy was grossly dark and greenish, the striking characteristics for DJS. Liver histology showed numerous distinct coarse brownish pigment deposits in the cytoplasm of the hepatocytes.

Ultrastructural examination of these cells showed electron-dense, lysosomal granules, characteristic of DJS, that corresponded to the intracytoplasmic pigment deposits seen in the light microscopic sections. This pigmentary material was frequently surrounded by a single, fine continuous or discontinuous membrane; sometimes no such membrane could be found. The lysosomal pigment granules demonstrated great variability in shape, size, content, and electron density and were located mainly in the vicinity of the biliary pole (Figure 1), and preferentially found in the centrilobular region. Moderately

electron-dense finely granular background alternating with denser irregular areas and pleomorphic dark bodies (clearly seen against a finely homogenous granular matrix) characterized these granules. The pleomorphic very dense bodies frequently occupied a considerable part or almost whole lysosomes. Some hepatocytes filled with coarse electron-dense granules were disintegrated. Dilation of bile canaliculi with loss of microvilli typical for DJS was observed (Figure 1). Dilated elements of the granular endoplasmic reticulum (Figure 1), the presence of paracrystalline mitochondrial inclusions, enlarged Golgi complex and dispersed lipid droplets within the cytoplasm of hepatocytes were also noted. The vascular pole of the hepatocytes showed alteration of microvilli including their disintegration; a fine granular material could be occasionally seen in Disse's space. Sometimes this space was discontinued. The basement membrane of some hepatocytes was distinctly outlined, and even thickened.

The ultrastructural examinations of the liver biopsate also showed, especially in the centrilobular region, an increase in hepatic macrophages. Kupffer cells in the lumen of hepatic sinusoidal vessels were frequently hypertrophied and markedly activated, blocking the vascular lumen and demonstrating features of hyperactivity (Figure 3). They contained electron-dense dark pigment granules, varying in shape and size (Figures 2 and 3), often occupying almost whole lysosomes. This material corresponded to the pigment deposits present in hepatocytes (Figure 2). Bile deposits were sometimes observed near the plentiful phagocytized pigment granules (Figure 3).

Since the morphological picture of the liver biopsate was typical of DJS, leaving no doubt, we did not perform very expensive genetic tests (mutation in the ABCC2/ MRP2 gene<sup>[4]</sup>).

## DISCUSSION

Macro- and microscopic, especially ultrastructural, changes observed in the liver biopsate in our patient were characteristic of DJS. The hepatocytes contained numerous electron-dense lysosomal, membrane-bound granules located mainly near the biliary pole that corresponded to

the coarse brownish pigment deposits seen under light microscope. The granules were accompanied by dilated endoplasmic reticulum and paracrystalline inclusions as well as alterations in bile canaliculi of hepatocytes.

However, Kupffer cells demonstrated features of hyper-reactivity. They accumulated pigment granules that corresponded to those observed in hepatocytes.

Morphological abnormalities of hepatocytes observed in the course of our studies were similar to those found by other authors in this syndrome<sup>[3,5-7]</sup>. It is worth noting that although the pigment granules showed characteristic microscopic features, their exact composition has not been clarified<sup>[1,6]</sup>. The results of ultrastructural and histochemical studies by Luo *et al.*<sup>[2]</sup> suggest that this deposit material is a lipofuscin-melanin complex.

Up to now, there have been no reports describing the electron microscope picture of Kupffer cells in DJS.

It has been known that Kupffer cells are the largest population of tissue macrophages, predominantly distributed in the lumen of hepatic sinusoids. According to Naito *et al.*<sup>[8]</sup>, these cells demonstrate unique differentiation mechanisms, metabolic functions and responsiveness to inflammatory agents. They exhibit endocytic activity against blood-borne material entering the liver as well as phagocytic function in relation to cellular debris<sup>[8,9]</sup>. Kupffer cells also play an important role in the modulation of drug metabolic enzymes<sup>[10]</sup>, in the carcinogenesis of hepatocellular carcinoma<sup>[11]</sup> and liver fibrosis<sup>[12]</sup>.

We assume that pigment deposits absorbed by Kupffer cells in the course of DJS may have originated from disintegrating, pigment-load hepatocytes. The present study indicates that it is the process of phagocytosis that plays a significant role in the accumulation of thick black granules within the cytoplasm of these macrophages. This process is strictly connected with the morphological status and function of lysosomes of Kupffer cells. This is confirmed by the fact that the number of lysosomes, both primary and secondary, within the cytoplasm of hyperactivated macrophages was markedly increased in our observations. It can be suggested that in the course of DJS, due to phagocytosis, remnants of pigment-load hepatocytes trapped by the hyperactivated Kupffer cells with the involved macrophage scavenger receptors are shifted to primary lysosomes, i.e. intracytoplasmic reservoirs containing lytic enzymes, which undergo degradation. Then, the lysosomes are transformed into the secondary ones<sup>[8]</sup>.

Unlike in the Gilbert's syndrome, in DJS clinical manifestation of hepatomegaly can be found even in the

neonatal-infantile period<sup>[3,7,13-14]</sup>. In our patient, the cause of hyperbilirubinemia was unknown for many years. DJS was not taken into account because of atypical course of the disease (predominance of unconjugated bilirubin in the blood serum). However, the predominance of non-conjugated bilirubin in the blood serum has been noted in some diagnosed DJS cases<sup>[1]</sup>.

We emphasize that hyperactive pericentral Kupffer cells may play an essential role in the development of the syndrome. They are involved in the response to pigmentary material originating from disintegrated hepatocytes.

## Abstract

Pyogenic liver abscesses usually occur in association with a variety of diseases. Rarely, liver abscess has been reported as the presenting manifestation of colonic tubulovillous adenoma. We report two cases of pyogenic liver abscess without hepatobiliary disease or other obvious etiologies except that one had a history of diabetes mellitus (DM). The pathogen in the patient with DM was *Klebsiella pneumonia* (KP). In both of the patients, ileus developed about two to three weeks after the diagnosis of liver abscess. Colonoscopy revealed large polypoid tumors with pathological findings of tubulovillous adenoma in both cases. Two lessons were learned from these two cases: (1) an underlying cause should be aggressively investigated in patients with cryptogenic liver abscess; (2) DM could be one of the etiologies but not necessarily the only cause of KP liver abscess.

<http://www.wjgnet.com/1007-9327/12/990.asp>

## INTRODUCTION

Pyogenic liver abscess is usually related to hepatobiliary

tract disease or intra-abdominal infections including cholecystitis, suppurative cholangitis, suppurative pyelophlebitis, appendicitis, diverticulitis and peritonitis<sup>[1-3]</sup>. Recently, colorectal cancer without obvious infection was considered as one of the uncommon etiologies of liver abscess<sup>[4,5]</sup>. Furthermore, liver abscess was reported as the presenting manifestation of colonic tubulovillous adenoma<sup>[6]</sup>. However, there are a growing number of reports suggesting a relationship between diabetes mellitus (DM) and *Klebsiella pneumonia* (KP) liver abscess which indicate that a deficiency in the hosts' defense mechanism could be the etiology of this liver infection<sup>[7-9]</sup>. We hereby report two cases of pyogenic liver abscess both of which were found to have colonic tubulovillous adenoma two to three weeks later after the diagnosis of liver abscess. The association of pyogenic liver abscess and colonic tubulovillous adenoma and the implications of these two cases are discussed.

## CASE REPORT

### CASE 1

A 67-year-old man, who was referred from a local hospital, was admitted to our hospital because of fever, chill, and right upper abdominal pain for seven days. On physical examination, his initial body temperature was 37.9°C and blood pressure was 124/67 mmHg. Light palpation of the abdomen revealed tenderness and mild rebounding pain on epigastric and right upper areas, but no abdominal mass was felt. Significant laboratory data included a leukocyte count of 26,330/ $\mu$ L (normal range = 4000-10,400/ $\mu$ L), a hemoglobin of 9.5 gm/dL (normal range = 12-16 gm/dL), an aspartate aminotransferase (AST) of 73 IU/L (normal range = 5-34 IU/L), an alanine aminotransferase (ALT) of 79 IU/L (normal range = 0-40 IU/L), a fasting blood sugar of 118 mg/dl (normal range = 70-110 mg/dL), a total bilirubin of 1.03 mg/dL (normal range = 0.2-1.3 mg/dL), a C-Reactive Protein (CRP) of 17.02 mg/dL (normal <0.8 mg/dL), and a carcinoembryonic antigen (CEA) level of 0.33 ng/dL (normal <5 ng/dL).

Abdominal ultrasonography (US) and computed tomography (CT) showed a 4-cm liver abscess in left lobe of liver (Figure 1A). After three sets of blood cultures were completed and broad-spectrum antimicrobial therapy was initiated, CT-guided percutaneous drainage of the liver abscess was performed and pus like material was aspirated and sent for bacterial culture. However, blood and pus were all negative for bacterial growth. As antimicrobial treatment was continued, the patient's clinical condition improved rapidly and fever subsided four days

**Figure 1** Case 1. **A:** Enhancement abdominal computed tomography (CT) showed a 4-cm liver abscess in left lobe of the liver; **B:** Colonofibroscopy showed a 3-cm pedunculated polyp in the sigmoid colon.

**Figure 2** Case 2. **A:** Enhancement abdominal computed tomography showed a 5-cm liver abscess in right lobe of the liver; **B:** Colonofibroscopy showed a 3-cm polypoid tumor in the sigmoid colon.

later. Then the drainage catheters were removed and the patient was discharged on the 14<sup>th</sup> d of hospitalization.

One week later, he was admitted again with a chief complaint of abdominal fullness. Physical examination showed a distended abdomen with hypertympanic abdominal sounds on percussion. Plain films of the abdomen disclosed evidence of a paralytic ileus with a suspected obstruction at the level of the sigmoid colon. Colonoscopy was performed which showed a 3-cm pedunculated polyp in the sigmoid colon (Figure 1B). Polypectomy was performed and pathological examination revealed tubulovillous adenoma with mild dysplasia. The patient continued to do well during a follow-up period of 6 mo.

## CASE 2

An 84-year-old woman with a history of DM using no regular medication for several years was admitted to the hospital because of fever and right upper abdominal dull pain which was followed by a change of consciousness for the two days preceding admission. On physical examination, her initial body temperature was 37.7°C and blood pressure was 79/30 mmHg. Mild tenderness in the right upper abdomen was noted during performance of light palpation, but no abdominal mass was felt. Significant laboratory data included a leukocyte count of 17,870/ $\mu$ L, a hemoglobin of 12.7 mg/dL, an AST of 59 IU/L, an ALT of 58 IU/L, a fasting blood sugar of 348 mg/dL, a total bilirubin of 2.31 mg/dL, a CRP level of 32.82 mg/dL, and a CEA level of 6.72 ng/dL. Abdominal US and CT showed a 5-cm liver abscess in right lobe of the liver (Figure 2A).

Since the patient could not cooperate for US or CT-guided aspiration, broad-spectrum antimicrobial treatment was started after three sets of blood cultures were performed. The results of blood cultures were positive for *Klebsiella pneumonia* (KP), which was sensitive to the formerly prescribed antibiotics. The patient's clinical condition improved gradually and fever subsided 10 d later. On the 14<sup>th</sup> d of hospitalization, abdominal fullness developed and the plain film of abdomen showed evidence of ileus with a suspected obstruction at the level of the distal colon. Colonoscopy was performed and showed a 3-cm polypoid tumor in the sigmoid colon (Figure 2B). Polypectomy was not done because of technical difficulty. A biopsy was performed and eight pieces of tissue were taken for pathological examination. The pathological findings were consistent with tubulovillous adenoma. Since ileus resolved spontaneously and the patient's general physical condition was not good, the patient's family refused to have further treatment. Her general condition was **stable** during a follow-up period of two months.

## DISCUSSION

The etiologies and pathogenesis of liver abscesses have changed significantly over the past several decades<sup>[1-3,10-11]</sup>. Recent reports suggest that pyogenic liver abscess might be a warning indicator of silent colonic cancer<sup>[4,5,12-14]</sup>, therefore, patients with liver abscess but without apparent etiologies, as in Case 1 of this report, should have further examination. In addition, non-growth in cultures of blood samples and abscess aspirate in Case 1 could be due to

the following two possibilities: (1) the patient had been partially treated at an outside hospital; (2) the pathogen of the liver abscess might be an anaerobe that was most probably originated from the colon. Therefore, although a rapid improvement was noted, a complete evaluation of the GI tract should be performed in Case 1 as per the suggestion of Cohen *et al*<sup>[4]</sup>.

Nevertheless, colonoscopy was performed because of ileus and the examination revealed a large colonic tubulovillous adenoma in the sigmoid colon instead of a "silent colonic cancer". Whether colonic adenoma could be an etiology of pyogenic liver abscess remains to be elucidated. In addition to our report, there is only one other report of pyogenic liver abscess as the presentation of colonic villous adenoma<sup>[6]</sup>. The mechanism for explaining colonic adenoma as an etiology of liver abscess may be the same as that of the colonic cancer, i.e., there are mucosal defects present on the colonic lesions (cancers or adenomas) that allow a route for bacteria invasion into the portal system with subsequent hematogenous spread to the liver.

In recent years, pyogenic liver abscesses have occurred more frequently in immunodeficient patients, including those receiving intensive chemotherapy for hematological or solid malignancies, patients with immunosuppressive therapy after organ transplantation<sup>[15]</sup> and, especially, patients with DM<sup>[8-9]</sup>. Case 2 was a DM patient who had a solitary liver abscess caused by KP. As previous reports showed, KP liver abscesses tend to occur in DM patients who did not have any predisposing factors for the development of liver abscess, therefore, the diagnostic procedures and management in Case 2 seemed reasonable. However, the unexpected occurrence of ileus due to a large colonic villous adenoma indicated that the presence of DM could not completely exclude other possible etiologies of liver abscess.

In conclusion, for patients with cryptogenic liver abscess, an underlying cause should be aggressively searched for. DM could be one of the etiologies but not necessarily the only cause of KP liver abscess.

### Abstract

Creating blow-hole colostomy for decompression could provide a time-saving and efficient surgical procedure for a severely debilitated case with a completely obstructed colorectal cancer. Complications are reported as prolapse, retraction, and paracolostomal abscess. However, complication with an ischemic distal limb has not been reported. We report a case of critical intra-abdominal disease after decompressed colostomy for relieving malignant sigmoid colon obstruction; a potential fatal condition should be alerted. A 76-year-old male visited our emergency department for symptoms related to obstructed sigmoid colon tumor with foul-odor vomitus containing fecal-like materials. An emergent blow-hole colostomy proximal to an obstructed sigmoid lesion was created, and resolution of complete colon obstruction was pursued. Unfortunately, extensive abdominal painful distention with board-like abdomen and sudden onset of high fever with leukocytopenia developed subsequently. Such surgical abdomen rendered a secondary laparotomy with resection of the sigmoid tumor along with an ischemic colon segment located proximally up to the previously created colostomy. Eventually, the patient had an uneventful postoperative hospital stay. In the present article, we have described an emergent condition of sudden onset of distal limb ischemia after blow-hole colostomy and concluded that despite the

### INTRODUCTION

In 8-29% of patients with colorectal cancer, obstruction is the major symptom at presentation, and 85% of patients undergoing emergency colorectal surgery have complete colonic obstruction from colorectal carcinoma<sup>[1-4]</sup>. Obstructed colorectal cancer often dictates poor cancer-related prognosis and higher mortality or morbidity, because they are more advanced and are associated with a higher incidence of distant metastases<sup>[3,5]</sup>. One-stage surgery is believed to be the preferred procedure for an obstructive right colon lesion, and staged operation is favored for the management of malignant left-side colonic obstructions<sup>[6]</sup>. In patients with acute complete colonic obstruction, hemodynamic instability may be debilitated by concomitant medical diseases, and cancer resection may not be possible. Establishing a decompressed colostomy is usually recommended to resolve acute obstructive symptoms prior to cancer resection<sup>[7,8]</sup>.

Obstructive colorectal cancer may be complicated with concomitant proximal ischemic colitis, which would present dramatically with gangrene and/or colonic perforation, if the acute vascular insufficiency is severe<sup>[9]</sup>. In general, colonic decompression by way of self-expanding metal stent or decompressed colostomy could

deliver intraluminal pressure lower enough than intramural vascular perfusion pressure to avoid hypoperfusive status of the intestine proximal to obstructive lesion. It is common to manifest proximal colon distention in left-sided colorectal cancer obstruction if a competent ileocecal valve exists<sup>[10]</sup>, and impending ischemic change of proximal colon would pursue. No fatal intra-abdominal complication for constructing a blow-hole colostomy, such as a gangrenous distal limb with peritonitis, has been reported.

We here report a case of severe intra-abdominal condition despite that a functional decompressed colostomy was created, a potential fatal situation of which the surgeons should keep in mind when relieving malignant colon obstruction using blow-hole colostomy.

## CASE REPORT

A 76-year-old male patient, who had extensive abdominal distention associated with no stools or flatus passage for 2 d, was referred to our emergency department for sudden onset of vomiting with foul-odor and fecal material-like contents. He had a 4-mo history of gradual body weight loss, abdominal bloat, bowel habit change with decreased stool caliber and poor appetite. Abdominal computerized topography revealed an obstructive sigmoid colon lesion with segmental wall thickening and a stenotic lumen. There was a pill within the distended bowel segment immediately proximal to the stenotic lumen of the obstructed lesion. Sigmoid colon tumor with complete bowel obstruction was diagnosed based on history and image studies. The patient had underlying chronic obstructive pulmonary disease with intermittent consumption of inhalational bronchodilator. Physical examinations reviewed a distended abdomen with silent bowel sound; there was tachypnea with central bronchospasm. Hemogram showed WBC as 11 200/ $\mu$ L with a differential count of segment form, 78.4%; band form, 1%; and lymphocyte, 10.8%. Biochemical analysis showed slightly impaired renal function (BUN: 31 mg/dL, Cr: 2.1 mg/dL), normal electrolyte concentration (Na: 136 meq/L, K: 4.0 meq/L and Cl: 103 meq/L) and suboptimal nutritional status (albumin: 2.6 g/dL). Clinically, the patient complained of serious abdominal painful fullness, fever with chills, and dyspnea. Metal stenting to the colon stenotic lesion was attempted but failed. On account of emergent release of the obstructive bowel pressure, the patient underwent a blow-hole colostomy at proximal transverse colon by mini-laparotomy, which took less than 30 min under general anesthesia. The bowel segment at the operation field was severely distended with edema, however, adequate blood perfusion was observed. There was no ascites. A large amount of liquid yellowish stools with foul smell was drained out from the proximal and distal limbs of the colostomy after it was instituted. The patient sustained a smooth operation course.

A rechecked hemogram at the 2<sup>nd</sup> post-operation day, which is routinely given to patients undergoing abdominal surgery in our institute as a baseline for follow-up purpose, found rather unremarkable data (WBC as 8 800/ $\mu$ L with slightly elevated segment form of 84%, without band form).

Gradual remission of abdominal distention with persistent bowel content drainage was observed within the first three post-operation days; the colostomy would be deemed as a normal physical function. Unfortunately, extensive abdominal painful distention with board-like abdominal appearance, and sudden onset of high fever with a body temperature up to 39.8°C were noted afterwards. At follow-up, hemogram reviewed leukocytopenia with dominant left-shifted differential count (WBC: 1 600/ $\mu$ L, segment: 38%, band: 26%). We found such a surgical abdomen that an emergent operation should be done to explore the etiology.

Emergent laparotomy was done immediately to find marked foul-odor bloody ascites. The distal limb of colostomy extending from the colostomy distally to the obstructed sigmoid colon tumor was found to have severe ischemic gangrenous change. The proximal limb of colostomy was fine. Segmental resection of the lesioned colon, comprising the sigmoid colon cancer with a security of cancer-free distal section margin and a short segment of colon proximal to previously created colostomy, was performed. The blow-hole colostomy was then converted to end-T-colostomy. The patient exerted an uneventful postoperative course and scheduled colostomy reversal was undertaken 6 mo later.

## DISCUSSION

Fine construction of a transverse colostomy by drawing out of a loop of the bowel and securing the mesentery to the skin to decompress obstructions from carcinoma of the rectum was first described in 1797<sup>[11]</sup>. Intestinal obstruction from malignancy within the colorectum would carry catastrophic complications of perforation, electrolyte imbalance, bowel ischemia, and sepsis caused by bacterial translocation<sup>[12]</sup>. Moreover, cancer patients, especially those with bowel obstruction, are usually malnourished, older, and dehydrated and may have coexisting disease at the time of presentation<sup>[12-14]</sup>. Therefore, perioperative management of malignant bowel obstruction, inclusive of surgical planning option to minimize morbidity and mortality is a critical issue.

There are different strategies to decompress colon obstruction with different outcomes, including (1) non-surgical approach as balloon dilation, placement of a plastic non-expandable rectal tube, cryosurgical destruction, electrocoagulation, and laser ablation<sup>[15,16]</sup> and (2) surgical approach as blow-hole enterostomy, or resection of tumor-bearing colorectal segment with or without colostomy<sup>[2,4-8]</sup>. Because of the failure of self-expanding metal stent placement in this patient due to severe colon angulations and rather stenotic colon lumen, we recommended a blow-hole proximal transverse colostomy as an emergent procedure for this debilitated patient with severe coexisting medical condition.

To evaluate the surgical planning in malignant large bowel obstruction, it is widely accepted that for malignant colon obstruction from the right colon cancer, resection (right hemicolectomy) should be performed with anastomosis in one stage<sup>[5,17,18]</sup>. Nevertheless, for obstruction from cancer of left colon or rectum, two types

of surgical approach could be used: (1) primary resection and primary anastomosis or Hartmann's procedure with synchronous treatment of carcinoma and obstruction, and (2) staged resection with the treatment of the obstruction prior to resection<sup>[4]</sup>. Some surgeons prefer staged resection with fast resolution of the obstruction, and a delayed radical surgery. The main benefits of staged operation are less surgical trauma which is significant in patients whose general condition is precarious, and reduction of the risk of contamination due to unprepared bowel<sup>[19]</sup>. Poor physical status as this patient, construction of a blow-hole colostomy in a minimal wound (fit to colostomy size) with less time-consumption (less than 30 min) could offer an anticipated decompression effect of the obstruction and prevent further surgical trauma to facilitate scheduled radical resection in the future.

Ischemic episode would take place in malignant large bowel obstruction and present dramatically with gangrene and/or colonic perforation if acute vascular insufficiency is severe<sup>[9]</sup>. It is postulated that colon distention from malignant colon obstruction reduces the blood supply to the bowel wall and enhances the development of ischemia<sup>[10]</sup>. Creation of a decompressed colostomy in malignant colon obstruction should rescue impending elevated intra-luminal pressure and possible development of the proximal colitis. But in our case, the cause of gangrenous distal limb might be due to, first, the development of tumor thrombi or septic emboli in the territory of vessels supplying the distal colon, or second, an underlying undetected ischemic change proximal to the cancerous mass which was not observed for the initial limited surgical field by mini-laparotomy. Clinically, the patient sustained sudden onset of high fever, peritoneal signs, and leukocytopenia with dominant left-shifted differential count on the 4<sup>th</sup> post-operation day, which was in the opposite direction to recovering status. Although, toxic signs presented by this patient alerted us of his deteriorated status, ischemic gangrene change of the distal limb between created stoma and obstructed sigmoid colon cancer was beyond our expectation. Nevertheless, bloody mucoid stools, which are usually in consistent with the clinical features of ischemic colitis, was not identified from the distal stoma ahead of the time in which toxic signs presented.

In conclusion, impending ischemic bowel may progress with a catastrophic peritonitis despite construction of blow-hole colostomy, which rescued malignant sigmoid colon obstruction. Consequently, it is important to monitor leukocyte count change and survey meticulously

abdominal condition for patients with decompressed colostomy created without resection of the obstructed lesion.

## Instructions to authors

### GENERAL INFORMATION

*World Journal of Gastroenterology* (WJG, *World J Gastroenterol* ISSN 1007-9327 CN 14-1219/R) is a weekly journal of more than 48 000 circulation, published on the 7<sup>th</sup>, 14<sup>th</sup>, 21<sup>st</sup> and 28<sup>th</sup> of every month.

Original Research, Clinical Trials, Reviews, Comments, and Case Reports in esophageal cancer, gastric cancer, colon cancer, liver cancer, viral liver diseases, *etc.*, from all over the world are welcome on the condition that they have not been published previously and have not been submitted simultaneously elsewhere.

**Published by**  
The WJG Press

### SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed double-spaced on A4 (297mm×210 mm) white paper with outer margins of 2.5 cm. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, acknowledgements, References, Tables, Figures and Figure Legends. Neither the editors nor the Publisher is responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press, and may not be reproduced by any means, in whole or in part without the written permission of both the authors and the Publisher. We reserve the right to put onto our website and copy-edit accepted manuscripts. Authors should also follow the guidelines for the care and use of laboratory animals of their institution or national animal welfare committee.

Authors should retain one copy of the text, tables, photographs and illustrations, as rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for the loss or damage to photographs and illustrations in mailing process.

#### Online submission

Online submission is strongly advised. Manuscripts should be submitted through the Online Submission System at: <http://www.wjgnet.com/index.jsp>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (<http://www.wjgnet.com/wjg/help/instructions.jsp>) before attempting to submit online. Authors encountering problems with the Online Submission System may send an email you describing the problem to [wjg@wjgnet.com](mailto:wjg@wjgnet.com) for assistance. If you submit your manuscript online, do not make a postal contribution. A repeated online submission for the same manuscript is strictly prohibited.

#### Postal submission

Send 3 duplicate hard copies of the full-text manuscript typed double-spaced on A4(297 mm×210 mm) white paper together with any original photographs or illustrations and a 3.5 inch computer diskette or CD-ROM containing an electronic copy of the manuscript including all the figures, graphs and tables in native Microsoft Word format or \*.rtf format to:

#### Editorial Office

**World Journal of Gastroenterology**  
Editorial Department: Apartment 1066, Yishou Garden,  
58 North Langxinzhuang Road,  
PO Box 2345, Beijing 100023, China  
E-mail: [wjg@wjgnet.com](mailto:wjg@wjgnet.com)  
<http://www.wjgnet.com>

### MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using a word-processing software. All submissions must be typed in 1.5 line spacing and in word size 12 with ample margins. The letter font is Tahoma. For authors from China, one copy of the Chinese translation of the manuscript is also required (excluding references). Style should conform to our house format. Required information for each of the manuscript sections is as follows:

#### Title page

Full manuscript title, running title, all author(s) name(s), affiliations, institution(s) and/or department(s) where the work was accomplished, disclosure of any financial support for the research, and the name, full

address, telephone and fax numbers and email address of the corresponding author should be included. Titles should be concise and informative (removing all unnecessary words), emphasize what is new, and avoid abbreviations. A short running title of less than 40 letters should be provided. List the author(s)' name(s) as follows: initial and/or first name, middle name or initial(s) and full family name.

#### Abstract

An informative, structured abstract of no more than 250 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections: AIM: Only the purpose should be included. METHODS: The materials, techniques, instruments and equipments, and the experimental procedures should be included. RESULTS: The observatory and experimental results, including data, effects, outcome, *etc.* should be included. Authors should present *P* value where necessary, and the significant data should accompany. CONCLUSION: Accurate view and the value of the results should be included.

The format of structured abstracts is at: <http://www.wjgnet.com/wjg/help/11.doc>

#### Key words

Please list 3-10 key words that could reflect content of the study mainly from *Index Medicus*.

#### Text

For most article types, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include in appropriate Figures and Tables. Data should be presented in the body text or in Figures and Tables, but not in both.

#### Illustrations

Figures should be numbered as 1, 2, 3 and so on, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. No detailed legend should be involved under the figures. This part should be added into the text where the figures are applicable. Digital images: black and white photographs should be scanned and saved in TIFF format at a resolution of 300 dpi; color images should be saved as CMYK (print files) but not as RGB (screen-viewing files). Place each photograph in a separate file. Print images: supply images of size no smaller than 126 mm×76 mm printed on smooth surface paper; label the image by writing the Figure number and orientation using an arrow. Photomicrographs: indicate the original magnification and stain in the legend. Digital Drawings: supply files in EPS if created by freehand and illustrator, or TIFF from photoshops. EPS files must be accompanied by a version in native file format for editing purposes. Existing line drawings should be scanned at a resolution of 1200 dpi and as close as possible to the size where they will appear when printed. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes of atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ...

#### Tables

Three-line tables should be numbered as 1, 2, 3 and so on, and mentioned clearly in the main text. Provide a brief title for each table. No detailed legend should be included under the tables. This part should be added into the text where the tables are applicable. The information should complement but not duplicate that contained in the text. Use one horizontal line under the title, a second under the column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

#### Notes in tables and illustrations

Data that are not statistically significant should not be noted. <sup>a</sup>*P*<0.05, <sup>b</sup>*P*<0.01 should be noted (*P*>0.05 should not be noted). If there are other series of *P* values, <sup>c</sup>*P*<0.05 and <sup>d</sup>*P*<0.01 are used. Third series of *P* values can be expressed as <sup>e</sup>*P*<0.05 and <sup>f</sup>*P*<0.01. Other notes in tables or under illustrations should be expressed as <sup>1</sup>*F*, <sup>2</sup>*F*, <sup>3</sup>*F*; or some other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.* in a certain sequence.

#### Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscripts and who endorse the data and conclusions are included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

## REFERENCES

### Coding system

The author should code the references according the citation order in text in Arabic numerals, put references codes in square brackets, superscript it at the end of citation content or the author name of the citation. For those citation content as the narrate part, the coding number and square brackets should be typeset normally. For example, Crohn's disease (CD) is associated with increased intestinal permeability<sup>[1,2]</sup>. If references are directly cited in the text, they would be put together with the text, for example, from references [19,22-24], we know that...

When the authors code the references, please ensure that the order in text is the same as in reference part and also insure the spelling accuracy of the first author's name. Do not code the same citation twice.

### PMID requirement

PMID roots in the abstract serial number indexed by PubMed (<http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=PubMed>). The author should supply the PMID for journal citation. For those references that have not been indexed by PubMed, a printed copy of the first page of the full reference should be submitted.

The accuracy of the information of the journal citations is very important. Through reference testing system (<http://www.aushome.cn/cgi-bin/index.pl>), the authors and editor could check the authors name, title, journal title, publication date, volume number, start page, and end page. We will interlink all references with PubMed in ASP file so that the readers can read the abstract of the citations online immediately.

### Style for journal references

Authors: the first author should be typed in bold-faced letter. The surname of all authors should be typed with the initial letter capitalized and followed by their name in abbreviation (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). Title of the cited article and italicized journal title (Journal title should be in its abbreviation form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634]

Note: The author should test the references through reference testing system (<http://www.aushome.cn/cgi-bin/index.pl>)

### Style for book references

Authors: the first author should be typed in bold-faced letter. The surname of all authors should be typed with the initial letter capitalized and followed by their name in abbreviation (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

### Format

Standard journal article (list all authors and include the PubMed ID [PMID] where applicable)

- 1 **Das KM**, Farag SA. Current medical therapy of inflammatory bowel disease. *World J Gastroenterol* 2000; 6: 483-489 [PMID: 11819634]
- 2 **Pan BR**, Hodgson HJF, Kalsi J. Hyperglobulinemia in chronic liver disease: Relationships between *in vitro* immunoglobulin synthesis, short lived suppressor cell activity and serum immunoglobulin levels. *Clin Exp Immunol* 1984; 55: 546-551 [PMID: 6231144]
- 3 **Lin GZ**, Wang XZ, Wang P, Lin J, Yang FD. Immunologic effect of Jianpi Yishen decoction in treatment of Pixu-diarrhoea. *Shijie Huaren Xiaobua Zazhi* 1999; 7: 285-287

Books and other monographs (list all authors)

- 4 **Sherlock S**, Dooley J. Diseases of the liver and biliary system. 9th ed. Oxford: Blackwell Sci Pub, 1993: 258-296

Chapter in a book (list all authors)

- 5 **Lam SK**. Academic investigator's perspectives of medical treatment for peptic ulcer. In: Swabb EA, Azabo S. Ulcer disease: investigation and basis for therapy. New York: Marcel Dekker, 1991: 431-450

Electronic journal (list all authors)

- 6 **Morse SS**. Factors in the emergence of infectious diseases. Emerg Infect Dis serial online, 1995-01-03, cited 1996-06-05; 1(1):24 screens. Available from: URL: <http://www.cdc.gov/ncidod/EID/eid.htm>

### Inappropriate references

Authors should always cite references that are relevant to their article, and avoid any inappropriate references. Inappropriate references include those that are linked with a hyphen and the difference between the two numbers at two sides of the hyphen is more than 5. For example, [1-6], [2-14] and [1, 3, 4-10, 22] are all considered as inappropriate references. Authors should not cite their own unrelated published articles.

### Statistical data

Present as mean  $\pm$  SD and mean  $\pm$  SE.

### Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as  $\chi^2$  (in Greek), related coefficient as *r* (in italics), degree of freedom as  $\gamma$  (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

### Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose) 6.4  $\pm$  2.1 mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6 24.5  $\mu$ g/L; CO<sub>2</sub> volume fraction, 50 mL/L CO<sub>2</sub> not 5% CO<sub>2</sub>; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format about how to accurately write common units and quantum is at: <http://www.wjgnet.com/wjg/help/15.doc>

### Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further mention.

### Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindII*, *BamHI*, *Kho I*, *Kpn I*, etc.

Biology: *Helicobacter pylori*, *H pylori*, *E coli*, etc.

## SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. Author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, the final check list for authors, and responses to reviewers by a courier (such as EMS) (submission of revised manuscript by e-mail or on the *WJG* Editorial Office Online System is NOT available at present).

### Language evaluation

The language of a manuscript will be graded before sending for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing; (4) Grade D: rejected. The revised articles should be in grade B or grade A.

### Copyright assignment form

It is the policy of *WJG* to acquire copyright in all contributions. Papers accepted for publication become the copyright of *WJG* and authors will be asked to sign a transfer of copyright form. All authors must read and agree to the conditions outlined in the Copyright Assignment Form (which can be downloaded from <http://www.wjgnet.com/wjg/help/9.doc>).

### Final check list for authors

The format is at: <http://www.wjgnet.com/wjg/help/13.doc>

### Responses to reviewers

Please revise your article according to the comments/suggestions of reviewers. The format for responses to the reviewers' comments is at: <http://www.wjgnet.com/wjg/help/10.doc>

### Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

### Publication fee

Authors of accepted articles must pay publication fee.

EDITORIAL and LETTERS TO THE EDITOR are free of charge.

## World Journal of Gastroenterology standard of quantities and units

Number	Nonstandard	Standard	Notice
1	4 days	4 d	In figures, tables and numerical narration
2	4 days	four days	In text narration
3	day	d	After Arabic numerals
4	Four d	Four days	At the beginning of a sentence
5	2 hours	2 h	After Arabic numerals
6	2 hs	2 h	After Arabic numerals
7	hr, hrs,	h	After Arabic numerals
8	10 seconds	10 s	After Arabic numerals
9	10 year	10 years	In text narration
10	Ten yr	Ten years	At the beginning of a sentence
11	0,1,2 years	0,1,2 yr	In figures and tables
12	0,1,2 year	0,1,2 yr	In figures and tables
13	4 weeks	4 wk	
14	Four wk	Four weeks	At the beginning of a sentence
15	2 months	2 mo	In figures and tables
16	Two mo	Two months	At the beginning of a sentence
17	10 minutes	10 min	
18	Ten min	Ten minutes	At the beginning of a sentence
19	50% (V/V)	500 mL/L	
20	50% (m/V)	500 g/L	
21	1 M	1 mol/L	
22	10 μM	10 μmol/L	
23	1N HCl	1 mol/L HCl	
24	1N H <sub>2</sub> SO <sub>4</sub>	0.5 mol/L H <sub>2</sub> SO <sub>4</sub>	
25	4rd edition	4 <sup>th</sup> edition	
26	15 year experience	15- year experience	
27	18.5 kDa	18.5 ku, 18 500u or M:18 500	
28	25 g.kg <sup>-1</sup> /d <sup>-1</sup>	25 g/(kg·d) or 25 g/kg per day	
29	6900	6 900	
30	1000 rpm	1 000 r/min	
31	sec	s	After Arabic numerals
32	1 pg L <sup>-1</sup>	1 pg/L	
33	10 kilograms	10 kg	
34	13 000 rpm	13 000 g	High speed; g should be in italic and suitable conversion.
35	1000 g	1 000 r/min	Low speed. g cannot be used.
36	Gene bank	GenBank	International classified genetic materials collection bank
37	Ten L	Ten liters	At the beginning of a sentence
38	Ten mL	Ten milliliters	At the beginning of a sentence
39	umol	μmol	
40	30 sec	30 s	
41	1 g/dl	10 g/L	10-fold conversion
42	OD <sub>260</sub>	A <sub>260</sub>	"OD" has been abandoned.
43	One g/L	One microgram per liter	At the beginning of a sentence
44	A260 nm <sup>b</sup> P<0.05	A <sub>260</sub> nm <sup>a</sup> P<0.05	A should be in italic. In Table, no note is needed if there is no significance instatistics: <sup>a</sup> P<0.05, <sup>b</sup> P<0.01 (no note if P>0.05). If ther is a second set of P value in the same table, <sup>c</sup> P<0.05 and <sup>d</sup> P<0.01 are used for a third set: <sup>a</sup> P<0.05, <sup>b</sup> P<0.01.
45	<sup>*</sup> F=9.87, <sup>§</sup> F=25.9, <sup>#</sup> F=67.4	<sup>1</sup> F=9.87, <sup>2</sup> F=25.9, <sup>3</sup> F=67.4	Notices in or under a table
46	KM	km	kilometer
47	CM	cm	centimeter
48	MM	mm	millimeter
49	Kg, KG	kg	kilogram
50	Gm, gr	g	gram
51	nt	N	newton
52	l	L	liter
53	db	dB	decibel
54	rpm	r/min	rotation per minute
55	bq	Bq	becquerel, a unit symbol
56	amp	A	ampere
57	coul	C	coulomb
58	HZ	Hz	
59	w	W	watt
60	KPa	kPa	kilo-pascal
61	p	Pa	pascal
62	ev	EV	volt (electronic unit)
63	Jonle	J	joule
64	J/mm <sup>3</sup>	kJ/mol	kilojoule per mole
65	10×10×10cm <sup>3</sup>	10 cm×10 cm×10 cm	
66	N·km	KN·m	moment
67	x±s	mean±SD	In figures, tables or text narration
68	Mean±SEM	mean±SE	In figures, tables or text narration
69	im	im	intramuscular injection
70	iv	iv	intravenous injection
71	Wang et al	Wang <i>et al.</i>	
72	EcoRI	EcoRI	<i>Eco</i> in italic and RI in positive. Restriction endonuclease has its prescript form of writing.
73	Ecoli	<i>E.coli</i>	Bacteria and other biologic terms have their specific expression.
74	Hp	<i>H pylori</i>	
75	Iga	<i>Iga</i>	writing form of genes
76	igA	IgA	writing form of proteins
77	~70 kDa	~70 ku

## Contents

### EDITORIAL

- 1001 The role of ultrasonography in patients with celiac disease  
*Fraquelli M, Sciola V, Villa C, Conte D*

### GASTRIC CANCER

- 1005 Differences in oxidative stress dependence between gastric adenocarcinoma subtypes  
*Bancel B, Estève J, Souquet JC, Toyokuni S, Ohshima H, Pignatelli B*
- 1013 Significance of Survivin and PTEN expression in full lymph node-examined gastric cancer  
*Deng H, Wu RL, Zhou HY, Huang X, Chen Y, Liu LJ*

### LIVER CANCER

- 1018 Effects of *Terminalia arjuna* bark extract on apoptosis of human hepatoma cell line HepG2  
*Sivalokanathan S, Vijayababu MR, Balasubramanian MP*

### COLORECTAL CANCER

- 1025 Identification of differently expressed genes in human colorectal adenocarcinoma  
*Chen Y, Zhang YZ, Zhou ZG, Wang G, Yi ZN*
- 1033 Loss of heterozygosity of Kras2 gene on 12p12-13 in Chinese colon carcinoma patients  
*Wan J, Li H, Li Y, Zhu ML, Zhao P*

### VIRAL HEPATITIS

- 1038 Construction of eukaryotic expression plasmid containing HCV NS3 segment and protein expression in human HL-7702 hepatocytes  
*Li JW, Li K, Jiang J, Xu XL, Huang ZQ*

### Abstract

The aim of the present review was to summarize the current evidence on the role of ultrasonography (US) and doppler-US in the diagnosis of celiac disease.

Several ultrasonographic signs have been reported in the association with celiac disease in studies using real-time US. Firstly, case control studies identified some of these US signs and then in a prospective series some of these parameters, due to their high specificity, have been shown to be of value in confirming CD diagnosis, whereas others, due to their high sensitivity, have been demonstrated to be useful in excluding the presence of the disease.

The pattern of splanchnic circulation in CD have extensively been investigated by several studies all of which reported similar results and identified a hyperdynamic mesenteric circulation that reverts to normal values after successful a gluten-free regimen.

The last part of this review will deal with the possible role of US in identifying the most severe and common intestinal complication of CD, i.e. the enteropathy-associated T cell non-Hodgkin lymphoma.

### INTRODUCTION

Celiac disease (CD) is a chronic systemic autoimmune disorder, whose prevalence in the general population ranges from 0.2 to 0.94<sup>[1]</sup>. It occurs when the small bowel mucosa

of susceptible subjects is damaged by dietary gluten, and its clinical picture ranges from mild to severe forms. The most frequent findings include chronic diarrhea, iron-deficiency anemia and dyspepsia. The diagnosis is supported by the determination of endomysial (EmA) and transglutaminase (tTG) antibodies, characterized by a high sensitivity and specificity (> 85% and nearly 100%, respectively) and confirmed by consistent histological duodenal findings<sup>[2]</sup>. Clinical, serological and histologic characteristics have recently been extensively reviewed<sup>[1]</sup>.

As reported above, clinical manifestations are proteiform and complications include refractory sprue, enteropathy-associated-T-cell-lymphomas (EATL), carcinoma of the oropharynx, esophagus and small bowel, ulcerative jejuno-ileitis and collagenous sprue<sup>[3-7]</sup>.

In patients with gastrointestinal symptoms abdominal ultrasonography (US) represents the initial imaging technique, whose accuracy has recently been markedly improved by the widespread availability of high resolution equipment. In this context several ultrasonographic signs have recently been reported<sup>[8-12]</sup> and some of them have been proved to be of value in supporting or ruling out CD<sup>[13]</sup>. This review deals with the role of abdominal and doppler ultrasonography in detecting the presence of celiac disease and in assessing its most frequent complication, i.e. EATL.

### ABDOMINAL ULTRASOUND IN THE DIAGNOSIS OF CELIAC DISEASE

Different US signs have been proved to be of value in suggesting the presence of CD, case reports<sup>[8-10]</sup> and two preliminary retrospective case-control studies, done in a pediatric<sup>[11]</sup> or adult setting<sup>[12]</sup> respectively. In the former series by Riccabona *et al*<sup>[11]</sup>, which included 39 children with overt malabsorption and histologically proven CD (Table 1), an "abnormal" aspect of small intestine was observed in 36 cases (92%), consisting of increased peristalsis in 32 (82%) and free abdominal fluid in 30 cases (76%); interestingly, a pericardial effusion was observed in half of the cases. Based on the above findings the Authors concluded that even if intestinal biopsy still remains the reference standard for diagnosing CD, the awareness of CD-associated sonographic abnormalities could accelerate diagnostic work-up and the introduction of gluten-free diet (GFD). The second study, by Rettenbacher *et al*<sup>[12]</sup>, included 11 adults with histologically proven CD and 20 healthy subjects (Table 2). An increase in intraluminal fluid content (11 cases), the presence of a moderate small bowel

**Table 1** Number of patients showing a positivity of each of the four US signs studied in the pediatric series of Riccabona *et al*<sup>(11)</sup>.

US signs	Patients with a positive sign (#)
Abnormal aspect of small intestine	36
Increased peristalsis	32
Abdominal fluid	30
Pericardial effusion	18

**Table 2** Number of patients showing a positivity for each of the eight US parameters assessed in the adult series of Rettenbacher *et al*<sup>(12)</sup>.

US signs	Patients with a positive signs (#)
Moderate small bowel dilatation	8/11
Increased intraluminal fluid content	11/11
Small bowel wall thickness	7/11
Increased peristalsis	8/11
Mesenteric lymph node hypertrophy	9/11
Free abdominal fluid	5/11
SMA or portal vein dilatation	7/11
Hepatic steatosis	6/11

dilatation (8 cases) and of an increased peristalsis (8 cases), and the presence of moderate bowel wall thickness (7 cases) represented the most relevant findings. Other extra intestinal signs, as mesenteric lymph node enlargement, free abdominal fluid, superior mesenteric artery or portal vein dilatation, hepatic steatosis were also identified, with an overall frequency ranging from 52 to 84%. None of the healthy controls showed abnormal US signs.

Both the above series were aimed to answer a phase I question (i.e. are the results of the index test in patients with a target disorder different from those in controls?). These type of studies have the advantage of being relatively quick and cheap to perform and serve as a promoter for further studies; however they could be affected by the presence of a possible "spectrum bias" as only patients with fully expressed disease are usually studied<sup>[14]</sup>.

As a consequence, these types of studies should be confirmed in larger prospective cohorts to obtain both higher precision and wider generalizability.

In a recent study<sup>[13]</sup>, we have prospectively evaluated the diagnostic accuracy of different US signs in predicting CD in a cohort of 162 consecutive patients investigated for chronic diarrhea (# 105), iron-deficiency anemia (# 25) and dyspepsia (# 32) (i.e. frequent CD manifestations), and characterized by a pre-test probability of the disease ranging from 5 to 10% as estimated from a previous series<sup>[15]</sup>. All patients underwent anti-endomysial IgA antibodies determination and duodenal biopsy. Two operators, blind to both the clinical, serological and histological findings evaluated six US signs represented by fasting gallbladder volume, transverse diameter of small bowel loops, small bowel wall thickness, peristaltic pattern, presence of free abdominal fluid, and diameter of the mesenteric lymph nodes.

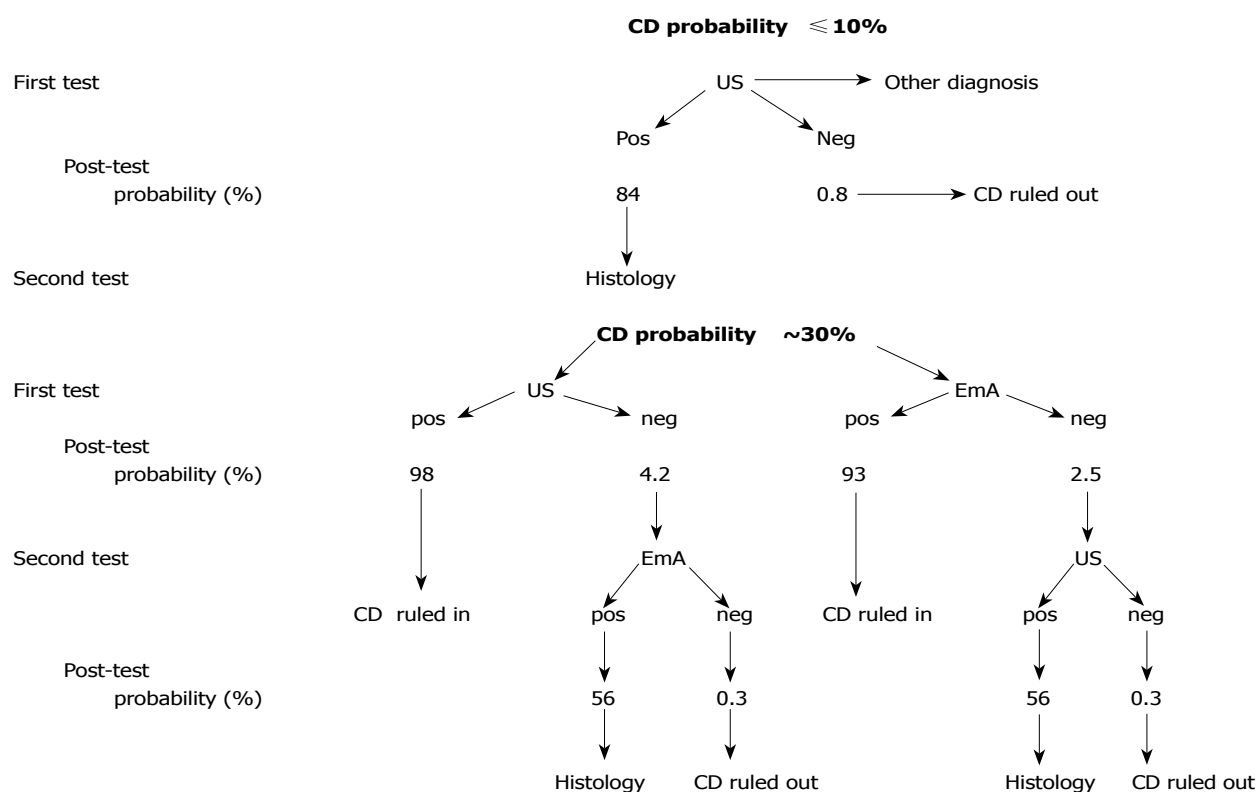

Twelve patients (7%): six male and six female, aged 16-77 years with a mean of  $49 \pm SD 17$  years, had EmA positive and duodenal histologic findings consistent with Marsh's grade III-IV (11 and one cases, respectively). In detail, seven cases were observed among those with chronic diarrhea (6.7%), four among those with iron-deficiency anemia (16%) and one among dyspeptics (3.1%). The frequency of the above mentioned US findings was comparable in pauci-symptomatic celiacs and those with fully expressed disease. Of the 150 EmA negative cases, none had duodenal histology consistent with CD; 72 (48%) and 78 (52%), were eventually diagnosed as having functional or organic disease, respectively. In the latter group, an ileal involvement was observed in nine cases (six with Crohn's disease and the remaining three with a final diagnosis of giardiasis and common variable immunodeficiency, primary lymphangiectasia and ileal carcinoid, respectively). Interestingly, in those patients with ileal Crohn's disease, US pattern differed completely from that observed in celiac patients based on a localised and marked bowel wall thickening. The details concerning the diagnostic accuracy of the six US signs evaluated are given in Table 3. In particular, the positive likelihood ratio (LR+) > 10 observed for increased GB volume, free abdominal fluid and enlarged mesenteric lymph nodes allowed a confirmatory strategy, whereas the negative likelihood ratio (LR-) of 0.1, observed for dilated small bowel loops and increased peristalsis, supported an exclusion strategy.

The k values ranging from 0.76 (for increased peristalsis) to 0.95 (for dilatation of small bowel loops) supported the good inter-observer agreement in the evaluation of the above reported US signs. Interestingly, strict gluten-free regimen obtained EmA negativization and a complete reversal of US abnormalities at one year.

In conclusion, the finding of increased GB volume, abdominal free fluid and mesenteric lymph nodes enlargement reliably and accurately predicts CD, whereas the lack of intestinal dilatation and increased peristalsis makes it possible to rule out the diagnosis. The specificity of US was maximized up to 99% in the presence of all the six US signs considered, with an obvious decrease in sensitivity (33%); moreover an LR + value of 50 allowed a confirmatory strategy accounting for a PPV of 80%. Conversely, in the presence of at least one US sign, sensitivity was 92% with a negative likelihood ratio value of 0.10 and a NPV of 99%, a diagnostic performance that was comparable to that of dilated small bowel loops.

Taking into account the above results, the actual role of US in the diagnostic strategy of celiac disease should be probably modulated according to the prevalence of the disease in the population under examination. As from Figure 1, the choice of the initial test depends on the estimated level of suspicion. In case of low CD prevalence (e.g.  $\leq 10\%$ ), the negativity of the US signs, mainly the lack of "dilated small bowel loops with increased fluid content", can more effectively exclude the diagnosis and also can be very useful in discriminating functional from organic disease. Conversely, the concomitance of all the six US signs increases the probability from 10 to up 84%, still requiring a confirmatory intestinal biopsy. Facing with a moderate probability of CD (e.g. of about 30%) both

**Figure 1** Diagnostic algorithm for celiac disease (CD), according to different pre-test probabilities of the disease. The post-test probability was calculated considering as a negative test the absence of “dilated small bowel loops with increased fluid content” (which showed the highest sensitivity: 92%, and the lowest LR- : 0.10) and as a positive test the presence of “all six US signs” (which has the highest specificity: 99%, and the highest LR+ : 50). The post-test probability for EmA was calculated considering a LR+ of 31 and LR- 0.06 (where LR indicate the likelihood ratio)<sup>[2]</sup>.

**Table 3** Diagnostic performance of six US parameters in predicting celiac disease (CD). Sensitivity, specificity, positive or negative likelihood ratio (LR+ and LR-), positive predictive value (PPV) and negative predictive value (NPV) (with corresponding 95% CI in parentheses).

US parameters	Sens %	Spec %	LR +ve	LR - ve	PPV %	NPV %
Increased gallbladder volume (r.v. $\leq 20$ mL)	73 (46-99)	96 (92-99)	17.0 (7.3-41.0)	0.28 (0.1-0.7)	57 (31-83)	98 (95-100)
Dilated small bowel loops + increased fluid content (r.v. $\leq 2.5$ cm)	92 (76-100)	77 (70-84)	4.0 (2.8-5.5)	0.10 (0.1-0.7)	24 (11-36)	99 (97-100)
Thickened small bowel wall (r.v. $\leq 3$ mm)	75 (50-99)	91 (86-95)	8.0 (4.4-14.5)	0.27 (0.1-0.7)	39 (19-59)	98 (95-100)
Increased peristalsis	83 (62-100)	87 (82-92)	6.6 (4.0-10.7)	0.10 (0.05-0.7)	34 (17-51)	98 (96-100)
Free abdominal fluid	50 (22-78)	96 (93-99)	12.5 (4.7-33)	0.52 (0.3-0.9)	50 (22-78)	96 (92-99)
Enlarged mesenteric lymph nodes (r.v. $\leq 5$ mm)	42 (14-69)	97 (95-99)	15.6 (6.8-50.6)	0.59 (0.4-0.9)	55 (23-88)	95 (92-99)

IgA EmA testing and US can confirm the diagnosis, based on a PPV  $> 90\%$ , a level at which the diagnostic role of histology could be challenged. Finally, independently of the test sequence, in the presence of both US and EmA results negativity, CD diagnosis can be confidently excluded as the post-test probability drops to less than 1% (NPV 99%). Obviously, in case of discordance, duodenal histology remains mandatory.

Overall, ultrasonography can accurately predict celiac disease but its place in the diagnostic algorithm should be varied according to the probability of the disease in a given population.

## SPLANCHNIC CIRCULATION IN CELIAC DISEASE

Basal and postprandial splanchnic blood flow (i.e. that in superior mesenteric artery, SMA, and portal vein, PV) was assessed in celiacs by doppler-US. Uniformly, in fasting condition, there was an increase in SMA velocity and flow, with lower resistivity index, and a higher PV velocity and flow as compared to controls<sup>[16-19]</sup>. As a consequence, when determined in postprandial phase all the above mentioned parameters showed a significantly lower variation as compared to that observed in healthy subjects<sup>[17, 19]</sup>. Once

again, successful long term gluten-free diet reverted all the above abnormalities.

## ABDOMINAL ULTRASOUND IN THE DIAGNOSIS OF THE COMPLICATION OF CELIAC DISEASE INTESTINAL LYMPHOMA AND SMALL BOWEL ADENOCARCINOMA

Enteropathy-associated T cell non-Hodgkin lymphoma (EATL-NHL), whose annual incidence is nearly 0.5-1 per million people, is actually confined to patients with a previously or concomitantly diagnosed CD, and also complicates the refractory form of the enteropathy. Moreover, an increased risk of small bowel adenocarcinoma, an exceedingly rare malignancy with an annual incidence rate of 0.6-0.7 per 100 000 of general population<sup>(6)</sup>, has also been reported.

In the presence of both these neoplasms, the typical US pattern is closely similar with evidence of the so called “bull’s eye”-, “target”- or “pseudokidney” sign related to an eccentric and localized bowel wall thickening<sup>(20)</sup>.

In the above conditions, US is useful in both the disease location and staging; furthermore, it also allows both a detailed characterization of adjacent or distant lymph nodes and their sampling for histology, whenever indicated.

Overall, however, US should not be considered a first level technique in diagnosing superimposed intestinal lymphoma in CD patients, based on its low sensitivity even if performed by well trained operators. Accordingly, US as to be considered as ancillary to endoscopy in identifying and staging EATL in CD patients.

**CONCLUSION:** The iNOS-oxidative pathway may play an important role in TC, but moderately in PolyC and DC. DNA oxidation and protein nitration occur in the three subtypes. Based on the significant differences of NTYR levels, TC and PolyC appear as two distinct subtypes.

### Abstract

**AIM:** To investigate the extent of oxidative stress in pre-neoplastic and neoplastic gastric mucosa in relation to their pathological criteria and histological subtypes.

**METHODS:** A total of 104 gastric adenocarcinomas from 98 patients (88 infiltrative and 16 intraepithelial tumors) were assessed immunohistochemically for expression of iNOS and occurrence of nitrotyrosine (NTYR)-containing proteins and 8-hydroxy-2'-deoxyguanosine (8-OH-dG)-containing DNA, as markers of NO production and damages to protein and DNA.

**RESULTS:** Tumor cells staining for iNOS, NTYR and 8-OH-dG were detected in 41%, 62% and 50% of infiltrative carcinoma, respectively. The three markers were shown for the first time in intraepithelial carcinoma. The expression of iNOS was significantly more frequent in tubular carcinoma (TC) compared to diffuse carcinoma (DC) (54% vs 18%;  $P=0.008$ ) or in polymorphous carcinoma (PolyC) (54% vs 21%;  $P=0.04$ ). NTYR staining was obviously more often found in TC than that in PolyC (72% vs 30%;  $P=0.03$ ). There was a tendency towards a higher rate of iNOS staining when distant metastasis (pM) was present. In infiltrative TC, the presence of oxidative stress markers was not significantly correlated with histological grade, density of inflammation, the depth of infiltration (pT), lymph nodes dissemination (pN) and pathological stages (pTNM).

### INTRODUCTION

Gastric carcinoma is one of the most common neoplasms in the world, and most are adenocarcinomas. According to the Lauren classification<sup>[5]</sup>, two epidemiologically distinct types<sup>[1-4]</sup> exist. Intestinal-type carcinoma (tubular carcinoma, TC) is associated with *H. pylori* infection, chronic gastritis, atrophy, intestinal metaplasia, and dysplasia that evolve as a multi-step process into this type of cancer. Diffuse-type carcinoma (DC), which occurs more often in younger patients, is also associated with *H. pylori* infection but not with atrophy and intestinal metaplasia, and is associated with a worse prognosis. Mixed polymorphous carcinoma (PolyC) encompasses tumors showing both glandular and diffuse components.

Inducible nitric oxide synthase (iNOS), which is synthesized *de novo* in response to mucosal inflammation in *H. pylori*-associated gastritis<sup>[6-10]</sup>, produces large amounts of nitric oxide (NO) over long periods of time. Inflammatory cells also produce reactive oxygen species such as superoxide anion which is subsequently converted into hydrogen peroxide and hydroxyl radical<sup>[11]</sup>. The reaction of NO with oxygen and superoxide produces nitrogen oxides and peroxynitrite, respectively. Overproduction of such reactive species leads to oxidation, nitration and nitrosation, resulting in protein, DNA and tissue damage. Nitrotyrosine (NTYR), formed by nitration of tyrosine

residues in proteins, can be used as a marker of nitrate damage *in vivo*<sup>[12,13]</sup>, and we<sup>[6,14]</sup> and others<sup>[8,9]</sup> have shown that its levels are elevated in *H. pylori*-infected gastric mucosa. 8-Hydroxy-2'-deoxyguanosine (8-OH-dG) is one of the most commonly used markers of oxidative DNA damage<sup>[15]</sup>. We<sup>[6]</sup> and others<sup>[16-18]</sup> have demonstrated increased levels of 8-OH-dG in *H. pylori*-infected gastric mucosa. Oxidative stress has been suggested to play a major role in carcinogenesis<sup>[19,20]</sup>, but the mechanisms involved still remain unclear. Expression of iNOS in various carcinomas has been reported<sup>[21-25]</sup>, but the studies of stomach cancer were performed with small numbers of cases<sup>[26-29]</sup> and they considered only limited pathological data<sup>[30-34]</sup>. The presence of NTYR in some carcinomas was previously reported<sup>[35-37]</sup>, but no data, to our knowledge, on gastric cancer are available. Elevated levels of 8-OH-dG were demonstrated in some carcinomas<sup>[35,36,38,39]</sup>, but in only two studies on gastric carcinoma<sup>[30,40]</sup>.

In this study, we therefore aimed to investigate the extent of oxidative stress in pre-neoplastic and neoplastic gastric mucosa in relation to the cell compartment concerned and pathological criteria, especially the cancer subtype, and to identify subsets of cancers with a distinctive profile for the oxidative stress markers.

## MATERIALS AND METHODS

### Subjects

Our retrospective study included 98 consecutive French patients with gastric adenocarcinoma and 26 non-tumorous patients. All subjects were endoscopically biopsied for diagnostic purposes, between 1989 and 2000. Demographic information and medical history were obtained in all patients from the hospital records. The 104 carcinomas from the 98 patients were either infiltrative ( $n=88$ ; 58 men and 30 women; mean age 70 years, range 30-98 years), or intraepithelial (*i.e.*, high-grade dysplasia;  $n=16$ ), of which 6 had an adjacent infiltrative tumor (4 men and 2 women; mean age 64 years, range 54 to 75 years) and 10 had no coexisting infiltrative cancer (6 men and 4 women; mean age 70 years, range 44 to 85 years). Of the 88 infiltrative cancers, 57 were classified as tubular/intestinal (TC) (38 men and 19 women; mean age 64 years, range 44 to 76 years), 17 as diffuse (DC) (12 men and 5 women; mean age 68 years, range 49 to 92 years), and 14 as polymorphous (PolyC) (8 men and 6 women; mean age 70 years, range 57 - 98 years). *H. pylori* was detected in 21% (19/92) of patients with carcinoma, including 10% (1/10) with intraepithelial carcinoma, 19% (11/54) with TC, 33% (4/12) with PolyC, and 19% (3/16) with DC.

Diagnostic biopsy samples with precursor lesions ( $n=94$ ) were obtained from 57 of the 98 patients with gastric adenocarcinoma and from 26 randomly selected non-tumorous subjects. They were classified as low-grade dysplasia ( $n=19$ ), of which 12 had no coexisting carcinoma (9 men and 3 women; mean age 68 years, range 43 to 88 years), and 7 were associated with invasive carcinoma, either adjacent ( $n=3$ ) or distant ( $n=4$ ). Of the 75 atrophic gastritis lesions, all but seven in association with intestinal metaplasia, 51 cases were in patients with intraepithelial or infiltrative cancer, either adjacent ( $n=36$ ) or distant ( $n=15$ ),

and 24 cases had no coexisting cancer. Among the latter 24 cases, 10 also showed low-grade dysplasia, and of the remaining 14, all but one had intestinal metaplasia (11 men and 3 women; mean age 64 years, range 24 to 90 years). *H. pylori* infection was found in 32% (6/19) of patients with low-grade dysplasia and in 33% (25/75) of those with atrophic gastritis.

Diagnostic biopsy samples without precursor lesions ( $n=48$ ) were obtained from non-tumorous mucosa of 38 of the 98 patients with gastric carcinoma and from 5 of the 12 non-tumorous patients with isolated low-grade dysplasia. The 43 biopsies from 38 gastric cancer patients were taken from mucosa surrounding ( $n=36$ ) or distant from ( $n=7$ ) the tumor. Mucosa was classified as normal ( $n=8$ , including 3 from non-cancerous subjects), or non-metaplastic gastritis ( $n=40$ , including 2 from non-cancerous subjects). *H. pylori* infection was found in 23% (10/43) of subjects.

### Histopathology and assessment of *H. pylori* infection

We examined Bouin-fixed, paraffin-embedded archival biopsies from gastric mucosa. Sections (5- $\mu$ m thick) were stained using hematoxylin-eosin-saffron for histological diagnosis and with a modified Giemsa stain for identification of *H. pylori*. Additional serial sections were used for immunohistochemistry. *H. pylori* infection was graded as absent, mild, moderate or severe<sup>[41]</sup>. In addition, a rapid urease test (CLO test) was performed in one third of cases.

The histological criteria were based on previous descriptions. According to the Lauren's classification<sup>[5]</sup>, infiltrative gastric cancers were classified as intestinal-type or tubular (TC), diffuse-type (DC), or mixed polymorphous (PolyC), the latter encompassing all tumors showing 5% or more glandular as well as 5% or more diffuse components<sup>[42]</sup>. The DC consisted of dispersed cells or of minute cellular aggregates. Tumor grade was classified into three categories (well, moderately, or poorly differentiated). Dysplasia was categorized as low-grade or high-grade based on the severity of neoplastic features<sup>[43,44]</sup>. High-grade dysplasia, as an intra-epithelial non-invasive neoplasia, was grouped with intraepithelial carcinoma according to the consensus terminology<sup>[43,44]</sup>.

Gastritis was classified and intestinal metaplasia (IM) was noted according to the guidelines of the updated Sydney system<sup>[41]</sup>. In view of the small number of cases with severe gastritis ( $n=4$ ), they were combined with the moderate gastritis cases ( $n=36$ ) to form one group.

### Pathologic stage (pTNM)

The pathologic stage (pTNM) was determined according to the newly revised classification of the American Joint Committee on Cancer (AJCC) and the International Union Against Cancer [UICC]<sup>[45]</sup> for 53 patients who benefited from a curative resection either by gastrectomy ( $n=42$ ), or endoscopy ( $n=11$ ). Staging laparoscopy was performed for four subjects because of peritoneal metastasis. No surgery was performed for some cases because of either distant metastasis ( $n=8$ ) or associated neoplasm ( $n=5$ ). No staging data were available for 28 patients who underwent surgery in another centre.

We defined early gastric carcinoma as a tumor restricted to the mucosa or to the mucosa and submucosa (pT1) regardless of nodal status.

### Immunohistochemistry

Bouin-fixed paraffin-embedded sections (4- $\mu$ m thick) were routinely deparaffinized in xylene and rehydrated through a series of ethanol solutions. The immunohistochemical procedures were performed as previously described<sup>[6,7]</sup>. The avidin-biotin complex method was applied to the serial sections mounted on poly-L-lysine-coated plates. Briefly, after deparaffinization and inactivation of endogenous peroxidases, non-specific immunolabelling was blocked and overnight incubation was carried out with the primary antibody at 4°C. Primary antibodies used were as follows: (1) Polyclonal antibodies raised in the rabbit against iNOS (dilution 1:100), purified from rat livers with acute liver necrosis induced by iv administration of *Propionibacterium acnes* and lipopolysaccharide provided by one of us (HO)<sup>[7,46,47]</sup>; (2) mouse monoclonal antinitrotyrosine antibody (dilution 1:250) supplied by Upstate Biotechnology (Lake Placid, NY); and (3) purified mouse monoclonal antibody against 8-hydroxy-2'-deoxyguanosine (N45.1, 3  $\mu$ g/mL)<sup>[48,49]</sup>. A secondary biotinyl-labeled goat antirabbit or horse antimouse IgG serum and avidin-biotinylated horseradish peroxidase macromolecular complex (ABC Kit, Elite Vectastain, Vector Lab, Burlingame, CA) were sequentially used as previously described<sup>[7]</sup>. Colorimetric reaction was performed with 3,3'-diaminobenzidine tetrachloride and counterstaining was carried out with hematoxylin. The degree of immunopositivity was expressed according to the percentage of positive cells as follows: <2%, negative (score 0); 2-10%, slightly positive (score 1); 10-50%, positive (score 2); and >50%, strongly positive (score 3). In addition, the intensity of staining was rated from weak to intense. Because the scoring system and the rating of intensities (data not shown) brought a great complexity that was useless for interpretation of the study, the results were simplified by collapsing in positive or negative groups. Sections in which the primary antibody was omitted or those treated with normal mouse serum instead of the primary antibody showed no staining. Furthermore, immunostaining of iNOS and NTYR was completely removed by absorption tests with iNOS purified from rat liver or with free NTYR (data not shown).

### Statistical analysis

Statistical analysis was performed using the Fisher and Chi-square tests for contingency tables.  $P < 0.05$  was considered statistically significant.

## RESULTS

Correlations of the three markers with clinicopathological data and with pTNM pathologic classification and stage grouping are shown in Table 1, Table 2 and Table 3, respectively. The co-occurrence of staining for all the three markers is shown in Table 4.

### iNOS immunostaining

Immunostaining for iNOS was located in the cytoplasm of

tumor cells (Figure 1A). It was more frequently observed in men than in women (Table 1), but the correlation was borderline ( $P = 0.06$ ). Of the 85 infiltrative carcinoma cases, 41% showed weak to strong immunoreactivity. The staining was significantly correlated with infiltrative cancer histological subtype (Table 1), being markedly higher in TC than in DC ( $P = 0.008$ ) and than in PolyC ( $P = 0.04$ ). Comparing TC with DC + PolyC, the correlation remained significant ( $P = 0.04$ ). However, in infiltrative TC, the iNOS immunoreactivity was not significantly correlated with either the depth of invasion (pT) or lymph node dissemination (pN) (Table 2). A higher rate of iNOS staining was observed when distant metastasis (pM) was present (Table 2), but this correlation did not reach statistical significance, presumably because of the small number of patients. The importance of iNOS in TC metastasis was reflected by its higher staining rate in stage IV than that in other stages (Table 3), although the difference was not statistically significant. The frequency of iNOS in intraepithelial carcinoma (not coexisting with infiltrative cancer - pTis) was lower than that in infiltrative TC (Table 1), but this was not statistically significant ( $p = 0.10$ ). Similarly, staining was less common in early cancer than in other stages (Table 3), but not statistically significant ( $p = 0.48$ ). The small number of DC and PolyC samples did not permit the study of any correlation of iNOS with pTNM and stage grouping criteria. There was no significant association of iNOS expression with histological grade for infiltrative TC [well ( $n = 32$ ), moderately ( $n = 3$ ) and poorly ( $n = 9$ ) differentiated; iNOS positivity 56%, 46%, and 56%, respectively], *H pylori* infection (Table 1) or density of inflammation [weak ( $n = 36$ ) vs strong ( $n = 56$ ); iNOS positivity 42% and 38%]. In addition, iNOS expression was not found to depend on the cancer site (Table 1), such as body, cardia, gastric stump, and antrum with angulus and pylorus.

Non-metaplastic mucosa in the same patient, either adjacent to or distant from the tumor, showed lower epithelial reactivity than atrophic metaplastic gastritis mucosa from cancer and non-cancer patients (Table 1), but the tendency was not statistically significant ( $P = 0.13$ ). A similar observation was found when comparing non-metaplastic mucosa and low-grade dysplasia.

Moreover, we detected iNOS expression in 44% (39/89) of infiltrating lymphocytes, regardless of their density and the carcinoma subtype.

### NTYR immunostaining

NTYR immunostaining was also observed in the cytoplasm of tumor cells (Figure 1B). Of the 65 infiltrative carcinoma cases, 62% showed weak to strong immunoreactivity. The staining was significantly correlated with the histological subtype of infiltrative cancer, being significantly higher in TC than in PolyC ( $P = 0.03$ ) (Table 1). However, when comparing TC with DC or PolyC + DC, the correlation was not statistically significant. In infiltrative TC, NTYR was not significantly correlated with the depth of invasion (pT), lymph node dissemination (pN) or distant metastasis (pM) (Table 2), nor was any relationship observed with pathological stages in TC (Table 3). The level of NTYR in intraepithelial carcinoma (not coexisting with infiltrative

(a) TC: Intestinal or tubular carcinoma; DC: Diffuse carcinoma; PolyC: Mixed polymorphous carcinoma; N: Normal; IM: Intestinal metaplasia; G: Gastritis. (b) iNOS: Inducible nitric oxide synthase; NTYR: Nitrotyrosine; 8OH-dG: 8-hydroxy-2'-deoxyguanosine. <sup>1</sup>TC vs DC  $P = 0.008$ ; TC vs PolyC,  $P = 0.04$ ; TC vs DC+PolyC,  $P = 0.04$ ; <sup>2</sup>TC vs PolyC,  $P = 0.03$ ; <sup>3</sup>non-metaplastic mucosa vs atrophic metaplastic mucosa low-grade dysplasia,  $P = 0.005$ .

cancer – pTis) was not significantly different from that in infiltrative TC (Table 1). Similarly, the level of NTYR in early gastric cancer was not different from that of other stages (Table 3). There was no significant association between NTYR expression and sex, cancer site (Table 1), histological grade in TC [well ( $n = 28$ ), moderately ( $n = 10$ ) and poorly ( $n = 5$ ) differentiated; NTYR positivity 75%, 60%, and 80%, respectively], *H. pylori* infection (Table 1) or density of inflammation [weak ( $n = 27$ ) vs strong ( $n = 45$ ); NTYR staining 63% and 64%].

Non-metaplastic mucosa in the same patient, either adjacent to or distant from the tumor, showed lower epithelial staining for NTYR than atrophic metaplastic mucosa from cancer and non-cancer patients (Table 1), but the tendency was not statistically significant ( $P = 0.18$ ). A similar observation was found when comparing non-metaplastic mucosa and low-grade dysplasia (Figure 1F).

In addition, immunostaining of NTYR was detected in the cytosol of inflammatory cells at a higher rate in intraepithelial carcinoma ( $n = 7$ , 71%) than that in inflammatory cells in all subtypes of infiltrative cancer ( $n = 67$ , mean 33%).

### 8-OH-dG immunostaining

Staining was predominantly confined to the nuclei of tumor cells (Figures 1C and 1D). Because the lymphoid follicles were strongly reactive, they could be used as internal positive controls (Figure 1C). Of the 82 cases of infiltrative cancer, 50% showed strong immunoreactivity.

In contrast with iNOS and NTYR, no significant difference in the percentage of positive staining was observed among different histological subtypes of infiltrative cancer (Table 1). The presence of 8-OH-dG was not significantly associated with sex, cancer site (Table 1), histological grade in TC [well ( $n = 32$ ), moderately ( $n = 12$ ) and poorly ( $n = 10$ ) differentiated; positivity 47%, 67%, and 50%, respectively], *H. pylori* infection (Table 1), depth of invasion (pT), lymph node dissemination (pN), distant metastasis (pM) (Table 2), or pathological stage in TC (Table 3). The levels of 8-OH-dG in intraepithelial carcinoma (not coexisting with infiltrative cancer – pTis) (Figure 1E) and in infiltrative TC were not significantly different (Table 1). Immunostaining of 8-OH-dG in early cancer was similar to that in all other stages (Table 3).

Staining of 8-OH-dG in non-metaplastic mucosa from cancer patients was significantly lower than that in atrophic metaplastic mucosa from cancer and non-cancer patients and than that in low-grade dysplasia ( $P = 0.005$ ) (Table 1). Immunoreactivity of 8-OH-dG was significantly higher in the nuclei of inflammatory cells in cases with mild inflammatory stroma (38%, 12/32) than that with dense inflammatory stroma (24%, 12/49).

### Co-staining for iNOS, NTYR and 8-OH-dG

The expressions of all three markers were determined simultaneously in 62 cases (Table 4). The absence of all three markers was more frequent in PolyC (50%), but less frequent in TC (12%) and DC (16%). When iNOS was the

only positive marker found, its frequency was similar in the three infiltrative cancer subtypes (5-10%). When the only positive marker found was either NTYR or 8-OH-dG, its frequency was similar for both of them in the three cancer subtypes, but higher in DC (17%) compared to PolyC (10%) and TC (5-10%). The couple NTYR + 8-OH-dG was the only one found in PolyC and occurred at a similar frequency in the three cancer subtypes (20-25%). It was also the most common one in DC (25%) among the three possible couples. In TC, the two couples iNOS + NTYR and NTYR + 8-OH-dG occurred at the same frequency (20%). The couple iNOS + 8-OH-dG occurred rarely in TC and DC (8% and 2.5%). All three markers were simultaneously observed only in TC (25%).

## DISCUSSION

The current study investigated the expression of iNOS, NTYR, and 8-OH-dG, as markers of NO production, nitrative damage of proteins, and oxidative DNA damage respectively, in gastric adenocarcinoma and pre-neoplastic mucosa. The expression of these markers was studied in relation to clinicopathological characteristics, including histological subtype, metastasis and pathological stages.

(a) Determination according to the newly revised classification of the AJCC and UICC. (b) TC: Intestinal or tubular carcinoma; DC: Diffuse carcinoma; PolyC: Mixed polymorphous carcinoma. (c) iNOS: Inducible nitric oxide synthase; NTYR: Nitrotyrosine; 8OH-dG: 8-hydroxy-2'-deoxyguanosine.

We found, for the first time, a positive correlation of gastric cancer subtype with both iNOS expression and NTYR staining, but not with 8-OH-dG staining. Indeed, the prevalence of iNOS staining in TC (54%) greatly exceeded that in DC (18%) and PolyC (21%), suggesting that iNOS probably plays an important role in TC, but is weakly involved, if at all, in DC and PolyC subtypes. We also found for the first time, nitrated proteins present in all cancer subtypes. Similarly to iNOS expression, the prevalence of NTYR staining in TC (72%) greatly exceeded that in PolyC (30%), but the difference was not significantly different from that in DC (50%). Half of the infiltrative carcinoma cases showed 8-OH-dG staining in cancerous cells, regardless of the subtypes.

The prevalence of iNOS staining we found in gastric infiltrative carcinoma (41%) was very similar to that reported by Feng *et al.*<sup>[32]</sup>, but was slightly lower than that reported in two other studies<sup>[26,31]</sup> that used immunohistochemistry as we did. However, two studies from the same laboratory reported different results. Using RT-PCR, Son *et al.* found expression of iNOS in 100%<sup>[27]</sup> and 65%<sup>[34]</sup> of gastric cancer. Rajnakova *et al.*<sup>[50]</sup> were not able to detect iNOS staining in 80% of gastric adenocarcinomas (in their first paper), whereas the same authors found it in all cases in a more recent study<sup>[33]</sup>. Chang *et al.*<sup>[30]</sup> reported higher iNOS expression in cancerous tissue than that in adjacent non-cancerous mucosa, for which the pathological status was not reported. Concerning iNOS, histological subtype was not considered in four studies<sup>[27,29,30,34]</sup>. Two studies<sup>[26,33]</sup> did not

report a difference in relation to Lauren's classification, but one of them included only 19 cases (53% positive)<sup>[26]</sup> and all cases were stained in the other one<sup>[33]</sup>. We<sup>[6]</sup> and others<sup>[8,9]</sup> have previously shown the occurrence of NTYR-containing proteins in *H. pylori*-associated gastritis preceding TC, but no data are available on gastric cancer. The marker of oxidative DNA damage, 8-OH-dG, has been reported in only two studies<sup>[30,40]</sup>. Our findings can not be compared with these published data because of a difference in methodologies. Lee *et al*<sup>[40]</sup> and Chang *et al*<sup>[30]</sup> found 8-OH-dG in DNA extracted from cancer tissue using HPLC-electrochemical detection. This technique does not allow localization of the cellular compartment concerned (tumor cells and/or inflammatory cells), unlike our immunohistochemical method. This is particularly important because of the strong reactivity of 8-OH-dG in lymphoid follicles. Our results also supported the previous observations concerning the absence of an association of iNOS with the degree of differentiation<sup>[31-33,50]</sup>. In addition, we found an absence of relationship of NTYR and 8-OH-dG with the degree of differentiation.

In contrast with previous reports which studied relationships with respect to only some pTNM categories (*e.g.*, pM often missing), we investigated the presence of the three markers as a function of all components of pTNM and complete staging. We found a tendency towards higher levels of iNOS in TC when distant metastasis (pM) was present, suggesting that high levels of iNOS oxidative stress may stimulate tumor progression<sup>[51]</sup>. However, the levels of NTYR and 8-OH-dG were not related to the presence of distant metastasis. In agreement with previous findings<sup>[31]</sup>, we found no correlation between iNOS staining and depth of invasion (pT). One study<sup>[32]</sup> showed increased staining of iNOS with depth of invasion, but without statistical significance. Similarly, in our study, the levels of NTYR and 8-OH-dG were not related to the depth of invasion. To our best of knowledge, this is the first study to investigate the three markers in gastric intraepithelial (pTis) and early gastric cancers. There is a tendency for a lower level of iNOS in

**Figure 1** Immunohistochemical staining in human gastric adenocarcinoma and precancerous mucosa. **A:** Intense cytoplasmic immunostaining of iNOS in tumor cells of tubular infiltrative carcinoma (TC), well differentiated; **B:** Intense cytoplasmic immunostaining of NTYR in tumor cells of TC, moderately differentiated; **C:** Intense nuclear immunostaining of 8-OH-dG in tumor cells of TC, well differentiated, note the reactivity of the lymphoid follicle (upper left); **D:** Intense nuclear immunostaining of 8-OH-dG in tumor cells of diffuse carcinoma, note the weak reactivity of some cells of a normal crypt (right); **E:** Intense nuclear immunostaining of 8-OH-dG in high-grade dysplastic epithelium, note the weak reactivity of a normal crypt (right); and **F:** Intense cytoplasmic immunostaining of NTYR in low-grade dysplastic epithelium, note the absence of reactivity of a normal crypt (right).

intraepithelial carcinomas and early gastric cancer than that in infiltrative carcinomas, but further studies with larger number of patients would be required to judge the statistical significance. In contrast to a previous report<sup>[32]</sup>, we neither found any relationship of iNOS with lymph node dissemination (pN), nor any relationship of NTYR or 8-OH-dG with pN.

The levels of the three markers did not vary significantly according to cancer site (especially gastric stump, at high risk for cancer), or with the density of inflammation or *H. pylori* infection. During the sequential steps from gastritis to TC, we<sup>[6,7]</sup> and others<sup>[8,16]</sup> have shown that iNOS produced continuously by *H. pylori*-induced inflammatory cells plays a crucial role in the initiation of the carcinogenic process. In cancer, the absence of any relationship between iNOS and the two other markers with inflammation suggests that inflammation-induced damage does not contribute markedly to the final stages of the neoplastic disease. Only iNOS was more often expressed in males as compared with females, consistent with the higher frequency of gastric cancer in males as compared with females, but this reached only borderline significance.

Sequential steps (atrophic gastritis, intestinal metaplasia, and dysplasia) of precancerous changes precede the intestinal-type of gastric carcinoma<sup>[2]</sup>. We found an increase

in epithelial levels of iNOS, NTYR, and 8-OH-dG from non-metaplastic non-atrophic gastritis to atrophic metaplastic gastritis and low-grade dysplasia, but reached statistical significance only for 8-OH-dG, thus supporting our previous results<sup>[6]</sup>. Therefore, epithelial over-expression of these three markers is an early event in the neoplastic process leading to the intestinal cancer which occurs at the precancerous stage, in which certain genetic modifications are also observed frequently<sup>[11]</sup>.

Our study suggests that the iNOS-oxidative pathway plays a minimal role in PolyC, as none of the three markers measured were found in half of the patients, and NTYR was detected less frequently in PolyC compared to the other cancer subtypes. In DC, one or two markers were present in 83% of subjects, suggesting a higher level of oxidative processes, but DC was not dependent mainly on the iNOS-oxidative pathway. In contrast, in TC, the strong oxidative process mediated through iNOS may be important in gastric carcinogenesis, as only 12% of subjects had none of the three markers measured, and 25% of subjects showed all these markers simultaneously. In addition, our study suggests that iNOS-associated oxidative stress is an early event in intestinal-type carcinogenesis. These findings support the traditional identification of TC and DC as two distinct tumor entities. Our study is also in accordance with the identification of PolyC as a distinct histotype of gastric carcinoma.

In conclusion, our study shows (1) the occurrence of iNOS, NTYR and 8-OH-dG in tumor cells of infiltrative gastric adenocarcinoma and epithelial cells of precancerous mucosa, as well as in intraepithelial carcinoma, (2) a correlation of both iNOS and NTYR with cancer subtype, (3) no association of the three markers with the degree of inflammation or with *H. pylori* infection, and (4) that oxidative stress occurs in the three cancer subtypes, and the iNOS-oxidative pathway may be important in gastric carcinogenesis in TC, but its involvement is minimal in PolyC and moderate in DC.

## ACKNOWLEDGMENTS

We thank Dr. J.L. Gaudin for performance of endoscopy and collection of biopsy specimens, Dr J. Cheney for editorial help and P. Collard for secretarial assistance.

## Abstract

**AIM:** To study the relationship between Survivin and PTEN expression and lymph node metastasis, depth of invasion and prognosis of gastric cancer patients in China.

**METHODS:** Specimens of gastric cancer tissue were collected from the Affiliated Hospital of Jiangnan University. All the 140 patients had complete examination data. All lymph nodes were found by the fat-clearing method. The interrupted serial 4-micron sections, routine hematoxylin and eosin staining and immunohistochemical methods were used to detect the lymph node metastases. Gastric cancer tissue microarray was performed to test the expression of Survivin and PTEN (17A) in gastric cancer by immunohistochemical method. All data were processed using  $\chi^2$  test, Fisher's exact test, Kaplan-Meier Log-rank method and Cox multivariate analysis (SPSS 12.0 software).

**RESULTS:** One hundred and eighteen specimens were used in our tissue microarray (utilization rate was 82.4%). A total of 7580 lymph nodes were found. Metastases were found in 90 specimens and 1618 lymph nodes were detected. The positive rate of Survivin and PTEN expression was 52.5% (62/118) and 76.2% (90/118), respectively. A highly positive correlation was found between Survivin and PTEN expression ( $\chi^2=4.17$ ,  $P=0.04$ ). Survivin expression was positively correlated with UICC N stage ( $\chi^2=8.69$ ,  $P=0.03$ ) and histological classifica-

tion ( $\chi^2=4.41$ ,  $P=0.04$ ) by  $\chi^2$  tests. PTEN expression was positively correlated with depth of invasion ( $P=0.02$ ) and histological classification ( $\chi^2=5.47$ ,  $P=0.02$ ). But Survivin and PTEN expressions were not related with prognosis of gastric cancer patients. A significant correlation between lymph node metastasis and prognosis was demonstrated by Cox multivariate analysis ( $\chi^2=4.85$ ,  $P=0.028$ ).

**CONCLUSION:** Survivin is positively correlated with PTEN expression in gastric cancer and is a molecular marker of lymph node metastasis while PTEN expression is a molecular marker of advanced gastric cancer. UICC N stage is the most important prognostic factor of gastric cancer in China.

## INTRODUCTION

Gastric carcinoma is one of the commonest malignancies and the first killer among all tumors in China<sup>[1]</sup>. When the disease is diagnosed, it has been in its advanced stage with lymph node metastasis. Looking for molecular markers to predict the depth of invasion and lymph node metastasis of gastric cancer has important significance.

Repression of apoptosis has been observed in gastric cancer<sup>[2]</sup>. Survivin, a new member of IAP family, is a powerful apoptosis repression factor. It has been implicated in the control of cell cycle kinetics and cell proliferation<sup>[3]</sup>. Survivin can be found during embryonic and fetal development but is completely down-regulated and undetectable in normal adult tissues and is prominently expressed in many human malignancies<sup>[4]</sup>. PTEN/MMAC1/TEP1, a novel tumor suppressor gene, is located on chromosome band 10q 23.3. This gene has three different names: PTEN (phosphatase and tensin homologue deleted on chromosome ten)<sup>[5]</sup>, MMAC1 (mutated in multiple advanced cancer 1)<sup>[6]</sup> and TEP1 (TGF- $\beta$ -regulated and

**Figure 1** Paraffin block for gastric cancer microarray with 288 tissue cylinders (A) slide for gastric cancer microarray with 420 tissue cylinders (B)

epithelial cell-enriched phosphatase 1)<sup>[7]</sup>, and codes for the 403 amino acid protein with tyrosine phosphatase activity. It contains a region of homology to tensin and auxillin, cytoskeletal proteins that interact with adhesion molecules. PTEN encoding products could dephosphorate PIP3 that could inhibit cell growth and increase cell apoptosis. It also could inhibit cell invasion and metastasis by dephosphorating focal adhesion kinase (FAK) and restrain cell differentiation by inhibiting mitogen-activated protein kinase (MAPK) signal pathway<sup>[8-10]</sup>.

It is still controversial about the correlation between Survivin and PTEN expression and depth of invasion and lymph node metastasis as well as the prognosis significance of Survivin and PTEN expression in gastric cancer. In this study, we used tissue microarray and immunohistochemical technologies to study the relationship between Survivin and PTEN expression in gastric cancer and their relation with the depth of invasion, lymph node metastasis of gastric cancer and the prognosis of gastric cancer patients.

## MATERIALS AND METHODS

### Materials

Specimens of gastric cancer tissue were collected from the Affiliated Hospital of Jiangnan University. All the 140 patients had complete examination data (99 males and 41 females, median age 58 years, ranging 26 - 77 years). No patients received radiotherapy and chemotherapy before surgery. Depth of invasion and lymph node metastasis were staged by the standards of UICC. No patients were diagnosed as having gastric adenocarcinoma which was classified into well-differentiated and poorly-differentiated adenocarcinoma. Size was calculated according to the biggest diameter of tumor.

### Pathological examination

All the 140 specimens of gastric cancer tissue were taken at the distance of 0.5-1 cm. Routine pathological examination was performed to determine the depth of invasion and histological classification of gastric cancer. All lymph nodes were found by the fat-clearing fat method (>15/case)<sup>[11]</sup>. The interrupted 4-micron sections, routine hematoxylin and eosin staining and immunohistochemical SP methods (CK18 + EMA, Vector Laboratory Co.) were used

to detect the lymph node metastasis.

### Tissue microarray

We took core needle biopsies with a diameter of 0.6 mm from donor paraffin-embedded cancer tissue blocks (2-4 dots per specimen) using a dedicated tissue array instrument (Beecher Instruments, New Jersey, USA). Slides for tissue microarray were read as previously described<sup>[12]</sup>. Standard dots which could not be analyzed, included dots having no tumor tissue, the area of defection being higher than 50% of dots, the area of tumor being less than 10% of dots, location of dots being unclear.

### Immunohistochemistry

The primary polyclonal antibody to Survivin (RAB-0536, NeoMarkers; ready-to-use), monoclonal antibody to PTEN (clone 17A, NeoMarkers; ready-to-use) and SP kit were purchased from Fujian Maxin Ltd (China). Immunohistochemical staining of Survivin and PTEN was performed. Diaminobenzidine (DAB) was used for color development. The positive result of Survivin and PTEN showed brown color of cytoplasm.

### Statistical analysis

Statistical software package SPSS 12.0 was used. Depth of invasion and lymph node metastasis associated with Survivin expression were analyzed by  $\chi^2$  test or Fisher's exact test. Survival analysis was conducted by the Kaplan-Meier method and survival characteristics were compared using the log rank test. The Cox proportional hazard regression model was used to compare the relative influences of different prognostic factors.  $P < 0.05$  was considered statistically significant.

## RESULTS

### Tissue microarray

All the 140 specimens were embedded for two tissue microarrays. One included 288 cores, the other included 420 cores. According to the standard dots that could not be analyzed, 118 specimens could be analyzed in our study (Figure 1). The utilization rate of tissue microarray was 84.3%.

Figure 2 Immunohistochemical results of Survivin expression (A:  $\times 100$ ; B:  $\times 200$ ; C  $\times 400$ )

Figure 3 Immunohistochemical results of PTEN expression (A:  $\times 100$  B:  $\times 200$  C:  $\times 400$ )

Table 1 Correlation between Survivin and PTEN expression and pathological features

	Survivin expression (n = 118)		P	PTEN expression (n = 118)		P
	+	-		+	-	
Gender						
Male	46	36		59	23	
Female	16	20		31	5	
Age(yr)						
<60	33	31		44	20	
$\geq 60$	29	25		46	8	
Size						
D<5cm	26	25		41	10	
D $\geq 5$ cm	36	31		49	18	
Depth of invasion						0.02
T <sub>1</sub>	4	7		5	6	
T <sub>2</sub>	12	6		14	4	
T <sub>3</sub>	19	19		34	4	
T <sub>4</sub>	27	24		37	14	
Histological type			0.04			0.02
Well-differentiated	28	15		38	5	
Poorly-differentiated	34	41		52	23	
Lymph node metastasis			0.03			
N <sub>0</sub>	18	10		23	5	
N <sub>1</sub>	18	9		19	8	
N <sub>2</sub>	14	15		21	8	
N <sub>3</sub>	12	22		27	7	

### Pathological features

All the 118 patients had complete examination data (82 males and 36 females, median age 58 years, ranging 26 - 77

years). The median size of tumor was 5.4 cm (ranging 0.8 - 15 cm). The depth of invasion was T<sub>1</sub> in 11, T<sub>2</sub> in 18, T<sub>3</sub> in 38, and T<sub>4</sub> in 51 patients, respectively. A total of 7580 lymph nodes were found in 118 cases (64.2/case, ranging 17 - 157 nodes, median number being 62 nodes) and 1618 lymph node metastases were found in 90 cases (UICC N stage, N<sub>0</sub> in 28, N<sub>1</sub> in 27, N<sub>3</sub> in 29, and N<sub>4</sub> in 34 cases, respectively) by the fat-clearing method. Well-differentiated gastric adenocarcinoma was found in 43 cases and poorly-differentiated gastric adenocarcinoma was found in 85 cases.

### Correlation between expressions of Survivin and PTEN

Among the 118 patients, accumulation of Survivin in cytoplasm was found in 62 (52.5%, 62/118) cases and PTEN was detected in 90 cases (76.3%, 90/118) (Figure 2). There was a positive correlation between expressions of Survivin and PTEN ( $\chi^2 = 4.17$ ,  $P = 0.04$ ) (Figure 3).

### Correlation between Survivin expression and pathological features

The positive rate of Survivin expression in UICC N stage was 65.5% (18/28) for N<sub>0</sub>, 67.9% (18/27) for N<sub>1</sub>, 48.3% (14/29) for N<sub>2</sub>, 36.1% (12/34) for N<sub>3</sub>, respectively. There was a significant correlation between Survivin and N stages of UICC ( $\chi^2 = 8.69$ ,  $P = 0.03$ ) by  $\chi^2$  tests. The positive rate of Survivin expression was 67.5% (28/43) in well-differentiated adenocarcinoma and 46.2% (34/75) in poorly-differentiated adenocarcinoma. There was a significant correlation between Survivin expression and histological classification ( $\chi^2 = 4.41$ ,  $P = 0.04$ ) by  $\chi^2$  test. No correlation

was found between Survivin expression and other pathological features (Table 1).

### Correlation between PTEN expression and pathological features

The positive rate of PTEN expression was 45.5% (5/11) for T1, 77.8% (14/18) for T2, 89.5% (34/38) for T3, 72.6% (37/51) for T4, respectively. A highly positive correlation was found between depth of invasion and PTEN expression ( $P=0.02$ ) by Fisher's exact test. The positive rate of PTEN expression was 88.4% (38/43) in well-differentiated adenocarcinoma and 69.3% (52/75) in poorly-differentiated adenocarcinoma. There was a significant correlation between PTEN expression and histological classification ( $\chi^2=5.47$ ,  $P=0.02$ ) by  $\chi^2$  test. No correlation was found between PTEN expression and other pathological features (Table 1).

### Survival characteristics

Univariate analysis showed that depth of invasion ( $\chi^2=12.25$ ,  $P<0.0001$ ) and UICC N stage ( $\chi^2=20.23$ ,  $P<0.0001$ ) were significantly related with survival time. Multivariate analysis of these predictive variables revealed that only the UICC N stage ( $\chi^2=4.85$ ,  $P=0.028$ ) was not related with survival time.

The expression of Survivin and PTEN was not related with survival time. But when the survival time was longer than 7 mo, Survivin positive group had a worse prognosis than Survivin positive group ( $P=0.047$ ).

## DISCUSSION

Survivin, a structurally unique member of IAP family, is expressed in mitosis in a cell cycle-dependent fashion and localized in components of the mitotic apparatus<sup>[3]</sup>. It is potentially involved both in inhibition of apoptosis and in control of cell division<sup>[13,14]</sup>. Survivin is found in most human cancers but undetectable at a very low level in differentiated adult tissues<sup>[4]</sup>. In most cancers, expression of Survivin is correlated with reduced apoptotic index, poor prognosis, and increased risk of recurrence<sup>[15-18]</sup>. The relation between Survivin expression, depth of invasion and lymph node metastasis in gastric cancer is not well known. Miyachi *et al*<sup>[19]</sup> found that Survivin expression is related with lymph node metastasis but not with depth of invasion. Tsuburaya *et al*<sup>[20]</sup> showed that Survivin mRNA expression is related with depth of invasion but not with lymph node metastasis. The concordance of mRNA and protein is controversial. Our results were based on tissue microarray, immunohistochemistry, complete pathological data and complete lymph node examination data. We found that Survivin expression was higher in well-differentiated gastric adenocarcinoma than in poorly-differentiated gastric adenocarcinoma and was correlated with lymph node metastasis. The prognosis significance of Survivin expression is not well known. Wang *et al*<sup>[21]</sup> found that Survivin positive expression in nuclei is correlated survival time, but its positive expression in cytoplasm is not correlated with survival time. We did not find any relation between Survivin expression and survival time.

But when the survival time was longer than 7 mo, Survivin positive group had a worse prognosis than PTEN positive group.

PTEN, a tumor suppressor gene, is located on chromosome band 10q 23.3. PTEN encoding products could inhibit cell growth and increase cell apoptosis by dephosphorylating PIP3. It also could inhibit cell invasion and metastasis by dephosphorylating focal adhesion kinase (FAK) and restrain cell differentiation by inhibiting mitogen-activated protein kinase (MAPK) signal pathway<sup>[8-10]</sup>. The relation between PTEN expression, depth of invasion and lymph node metastasis is still unknown. Zheng *et al*<sup>[22]</sup> found that PTEN expression is related with lymph node metastasis and depth of invasion. Dong *et al*<sup>[22]</sup> found that PTEN expression is related with lymph node metastasis but not with depth of invasion. Our results showed that PTEN expression was higher in advanced gastric cancer than in early gastric cancer and was not related with lymph node metastasis. The prognosis significance of PTEN expression in gastric cancer is still unknown. Li *et al*<sup>[23]</sup> found that PTEN expression is not related with survival time. We did not find any correlation between PTEN expression and survival time using tissue microarray and PTEN monoclonal antibody (17A).

Survivin and PTEN can regulate cell cycle and apoptosis, but they have adverse biological effects. Dong *et al*<sup>[22]</sup> showed that PTEN expression is negatively related with Survivin expression. However, we found a positive relation between Survivin and PTEN expression.

Lymph node metastasis is the most important marker of prognosis of gastric cancer patients<sup>[4,14]</sup>. Our study has confirmed that lymph node stage of gastric cancer is an independent prognosis marker of gastric cancer.

In conclusion, Survivin expression is positively related with PTEN expression in gastric cancer. They are not related with prognosis of gastric cancer. Survivin and PTEN expression is a molecular marker of advanced gastric cancer but not a molecular marker of lymph node metastasis in gastric cancer. UICC N stage is the most important prognostic factor in gastric cancer.

## Abstract

**AIM:** To investigate the effects of *Terminalia arjuna* (*T. arjuna*) extract on human hepatoma cell line (HepG2) and its possible role in induction of apoptosis.

**METHODS:** Human hepatoma cells were treated with different concentrations of ethanolic extract of *T. arjuna* and its cytotoxicity effect was measured by trypan blue exclusion method and lactate dehydrogenase leakage assay. Apoptosis was analyzed by light and fluorescence microscopic methods, and DNA fragmentation. The mechanism of apoptosis was studied with expression of p53 and caspase-3 proteins. Glutathione (GSH) content was also measured in HepG2 cells after *T. arjuna* treatment.

**RESULTS:** *T. arjuna* inhibited the proliferation of HepG2 cells in a concentration-dependent manner. Apoptotic morphology was observed in HepG2 cells treated with *T. arjuna* at the concentrations of 60 and 100 mg/L. DNA fragmentation, accumulation of p53 and cleavage of procaspase-3 protein were observed in HepG2 cells after the treatment with *T. arjuna*. The depletion of GSH was observed in HepG2 cells treated with *T. arjuna*.

**CONCLUSION:** *T. arjuna* induced cytotoxicity in HepG2 cells *in vitro*. Apoptosis of HepG2 cells may be due to the DNA damage and expression of apoptotic proteins. Depletion of GSH may be involved in the induction of apoptosis of HepG2 cells.

## INTRODUCTION

Human hepatocellular carcinoma (HCC) constitutes about 85% of primary liver cancers recorded in cancer data banks. Globally, around 440 000 new cases of HCC occur annually, accounting for around 5.5% of all human cancer incidences [1]. The synchronous occurrence of HCC may be due to different risk factors, such as chronic viral hepatitis B or hepatitis C infection, aflatoxin exposure, alcohol consumption and iron overload [2]. Even though curative therapy can be achieved by surgical treatments such as resection or liver transplantation, treatment of unresectable HCC is very disappointing because many tumors stay asymptomatic for a long time and in the absence of effective screening programs [3]. Furthermore, chemotherapeutic agents such as doxorubicin or its derivative epirubicin and cisplatin, have exhibited response rates up to 15-20% after systemic administration [4]. Interestingly, a number of non-nutrient chemicals from plants and fruits have also been reported to possess anticancer activity. Certain products from plants are known to induce apoptosis in neoplastic cells but not in normal cells [5].

*Terminalia arjuna* (Roxberg), locally known as kumbuk belonging to the family of *Combretaceae*, has a long history of medicinal uses in India including cancer treatment. Besides, HepG2 cell line represents one of the most widely used experimental model for *in vitro* studies on HCC [6]. Therefore, it is of interest to investigate the effects of ethanolic extract of *T. arjuna* bark on human hepatoma cell line (HepG2).

## MATERIALS AND METHODS

### Chemicals and antibodies

RPMI-1640 and sodium pyruvate were purchased from Biochrom, Berlin, Germany. Penicillin, streptomycin and fetal bovine serum (FBS) were purchased from Gibco, Germany. Primary antibodies such as anti-p53 and anticaspase-

pase-3 were purchased from Novocastra Laboratories Ltd, Newcastle, UK and Transduction Laboratories, Lexington, UK, respectively.

### Drug preparation

*T. arjuna* bark was coarsely powdered and soaked in 95% ethanol and kept for 10 d at room temperature for maceration, filtered, concentrated and dried in a vacuum evaporator. Ethanolic extract of *T. arjuna* was dissolved in 1% DMSO [final concentration of the DMSO did not exceed 1% (v/v) and did not affect the cell proliferation] prepared in serum free RPMI medium and filtered by 0.3 mm syringe filter and stored.

### HepG2 cell maintenance

Human hepatoma cell line (HepG2) was obtained from National Center for Cell Science, Department of Biotechnology, Pune, India. Cells were grown as monolayers in RPMI-1640 medium, supplemented with 10% (v/v) heat-inactivated FBS, antibiotics (penicillin 100U/mL, streptomycin 10 µg/mL) and 1mmol/L sodium pyruvate under standard conditions (37°C) in a controlled humidified atmosphere containing 50 mL/L CO<sub>2</sub>.

### Cytotoxicity

**Trypan blue exclusion method** The cytotoxicity of the ethanolic extract of *T. arjuna* was assessed by cell viability using trypan blue exclusion method. For the determination of cell viability, cells were plated at the density of  $5 \times 10^4$  cells/well and cultured for 48 h. The medium was replaced with serum-free medium [RPMI-1640 medium, supplemented with antibiotics (penicillin 100 U/mL, streptomycin 10 µg/mL, 1 mmol/L sodium pyruvate) and the cells were treated with various concentrations of *T. arjuna* (20, 40, 60, 80 and 100 mg/L) for 48 h and incubated with 1% DMSO as solvent control.

**Lactate dehydrogenase leakage assay** Lactate dehydrogenase (LDH) leakage assay was performed by the method of Grivell and Berry<sup>[7]</sup>. One hundred microliters of conditioned media of control and *T. arjuna*-treated HepG2 cells was added to 1-mL cuvette containing 0.9mL of a reaction mixture to yield a final concentration of 1mmol/L pyruvate, 0.15 mmol/L NADH and 104 mmol/L phosphate buffer, pH7.4. After thoroughly mixed, the absorbance of the solution was measured at 340 nm for 45 s. LDH activity was expressed as µ moles of NADH used per minute per well.

### Apoptosis

**Light microscopic studies** HepG2 cells were grown in 35 mm sterile petri plates and treated with *T. arjuna* extract at the concentrations of 60 and 100 µg/L for 48 h. The cells were then fixed for 5 min with 10% methanol/phosphate buffer saline (PBS) and morphological changes were observed under inverted microscope (Nikon, Japan).

**Fluorescent microscopic studies** Apoptotic morphology was studied by staining the cells with a combination of the fluorescent DNA-binding dye. After treatment with *T. arjuna* (60 and 100 mg/L for 48 h), cells were collected, washed and suspended in PBS. After stained with the equal mixture of acridine orange and ethidium bromide (each

dye was dissolved in 100 µg/mL of PBS), the cells were examined<sup>[8]</sup>. The differential uptake of these two dyes allowed the identification of viable and non-viable cells under fluorescent microscope and the results were recorded.

**DNA fragmentation** DNA fragmentation was followed by the method of Chen *et al.*<sup>[9]</sup>. The HepG2 cells were plated in a 60 mm culture dish at a density of  $5 \times 10^5$  cells and treated with *T. arjuna* extract (60 and 100 mg/L) for 48 h. The cells attached at the bottom were scraped off and collected together with unattached cells by centrifuging at 1 500 r/min for 5 min at 4 °C. DNA was prepared from the pelleted cells. Briefly, the cells were lysed with lysis buffer and extracted with 2mL of phenol (neutralized with TE buffer, pH 7.5) followed by extraction with 1mL of chloroform and isoamyl alcohol in the ratio of 24:1. The aqueous supernatant was precipitated with 2.5 volume of ice-cold ethanol with 10% volume of sodium acetate at – 20 °C overnight. After centrifugation at 13 000 r/min for 10 min, the pellets were air-dried and resuspended with 50 µL of Tris–EDTA (TE) buffer. Equal quantities of DNA were electrophoresed in 1.8% agarose gel containing 0.5 mg/L of ethidium bromide. After electrophoresis, the gel was photographed under UV light.

**Western blotting** HepG2 cells ( $1 \times 10^6$ /mL) were treated with *T. arjuna* extract at the concentration of 60 and 100 µg/mL for 48 h at 37 °C. Cells were lysed with 10 µL of lysis buffer (150mmol/L Tris-HCl, 2 mmol/L N-ethylmaleimide, 2 mmol/L phenylmethyl sulfonyl fluoride, 4% sodium dodecylsulfate, 4% dithiothreitol, 20% glycerol, 0.01% bromophenol blue, 2 mol/L urea and 10mmol/L Na-EDTA) (pH 6.8). Cells were then sonicated three times for 10 s. Cell lysates were centrifuged at 15 000 r/min for 20 min at 4 °C. The protein levels were quantified using Biorad protein assay kit, USA. Equivalent amounts of proteins (60µg) were resolved by SDS-PAGE and transferred onto a nitrocellulose membrane overnight at 25 mA. Membranes were blocked with blocking solution (2% BSA in PBS) for 1 h at 37 °C followed by incubation with primary antibodies (anti-p53 1:100; anticaspase-3 1:1 000) for 1 h under gentle agitation. The blots were washed three times and incubated with horse raddish peroxidase-conjugated antimouse IgG antibody for 1 h at 37 °C. Diaminobenzidine reagent was used to develop the immunoblots.

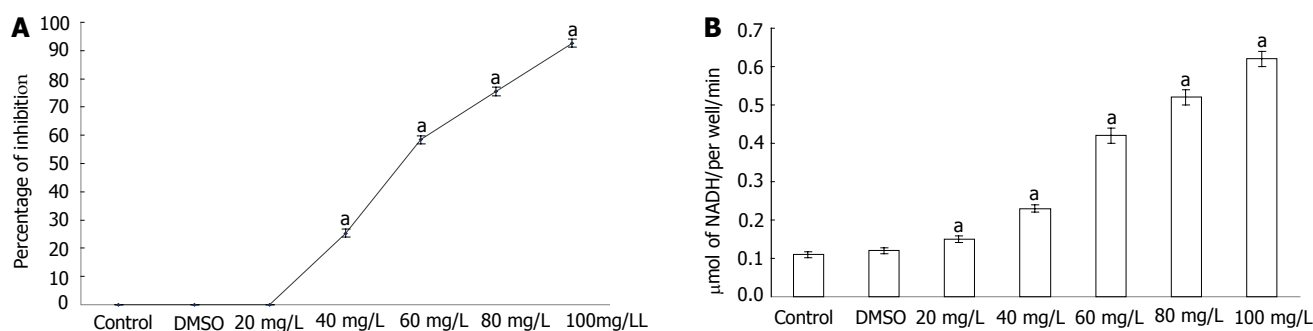

### Estimation of glutathione

Total reduced glutathione (GSH) was determined by the method of Moron *et al.*<sup>[10]</sup>. Five percent TCA was added to HepG2 ( $1 \times 10^6$  cells). The precipitate was removed by centrifugation. To an aliquot of the supernatant, 2mL of DTNB reagent was added to make a final volume of 3 mL. The absorbance was read at 412 nm against a blank containing TCA instead of sample. Aliquots of the standard solution were treated similarly. The amount of GSH was expressed as nmoles/10<sup>6</sup> cells.

### Statistical analysis

Values were expressed as mean ± SD. Difference between the drug-treated group and control group was analyzed with independent sample-*t* test using SPSS 7.5 student

**Figure 1** Viability (A) and LDH level (B) in control and HepG2 cells. Cells were exposed to different concentrations of *T. arjuna* extract for 48 h and percentage of viable and dead cells was determined using trypan blue exclusion method. Results were expressed as the percent of total cell number and the percentage of LDH leakage was analyzed. Values are mean  $\pm$  SD ( $n = 6$ ).  $^aP < 0.05$  represents the statistical significance between control and *T. arjuna* treated HepG2 cells.

**Figure 2** Morphological changes of HepG2 cells under light and fluorescence microscope. HepG2 cells were incubated for 48 h with *T. arjuna* extract. The medium was removed and the cells were rinsed and visualized under light microscope in control (A), 60 mg/L (B), 100 mg/L (C) of *T. arjuna* extract. Cells were stained with ethidium bromide and acridine orange and observed under fluorescence microscope in control (D), 60 mg/L (E) and 100 mg/L (F) of *T. arjuna* extract.

version.  $P < 0.05$  was considered statistically significant.

## RESULTS

### Trypan blue exclusion method

The cytotoxicity of *T. arjuna* to HepG2 cells was examined by trypan blue exclusion and LDH leakage assay. Figure 1 (A) shows the viability of control and *T. arjuna*-treated (20, 40, 60, 80 and 100 mg/L) HepG2 cells. In the present study, the plant extract induced cytotoxicity to HepG2 cells in a concentration-dependent manner after 48 h of treatment. The results showed that treatment with *T. arjuna* could increase the number

of apoptotic cells and decrease the number of normal HepG2 cells. Apoptotic cells were detached from the surface and suspended in the medium.

### Lactate dehydrogenase leakage assay

The levels of LDH released into the medium of control and *T. arjuna*-treated (20, 40, 60, 80 and 100  $\mu$ g/mL) HepG2 cells are presented in Figure 1 (B). LDH activities were significantly elevated after 48 h of exposure to *T. arjuna* extract in the medium when compared to the control.

### Light microscopic observation

In *T. arjuna*-treated HepG2 cells, destruction of monolayer was observed, which was not seen in HepG2 cells not treated with it. *T. arjuna* treatment resulted in swelling and rounded morphology of HepG2 cells with condensed chromatin and their membrane also became crooked and vesicle shaped. Progressive structural alterations and reduction of HepG2 cell populations were observed [Figure 2 (A-C)].

### Fluorescence microscopic observation

The morphological changes were observed in HepG2 cells treated with *T. arjuna* for 48 h. As shown in Figure 2 (D-F), normal live cells were bright green in color whereas *T. arjuna*-treated HepG2 cells were bright orange in color with condensed nuclei. Besides, normal nuclei showed chromatin with an organized structure, while apoptotic nuclei showed highly condensed chromatin in HepG2 cells treated with *T. arjuna*.

### DNA fragmentation

In the control, no fragmentation was observed in agarose gel. However, the signal appeared in *T. arjuna* extract (60 and 100 mg/L) treated HepG2 cells showed the fragmented laddering pattern of DNA, indicating the characteristics of apoptotic cells (Figure 3).

### Expression of p53 and caspase-3 proteins

*T. arjuna* extract treatment increased the band intensity of 53-ku protein in HepG2 cells compared to the control (Figures 4A and 4B). The accumulation of p53 protein induced apoptosis in *T. arjuna* extract-treated HepG2 cells. On the contrary, HepG2 cells treated with *T. arjuna* extract (60 and 100 mg/L) reduced the intensity of 32-ku protein

**Figure 3** DNA fragmentation in HepG2 cells. HepG2 cells were treated with *T. arjuna* extract and incubated for 48 h at the concentration of 60 and 100 mg/L, respectively. DNA fragmentation was carried out as described in MATERIALS AND METHODS. Lane 1: 100 bp DNA marker; Lane 2: control HepG2 cells without any treatment; Lanes 3 and 4: HepG2 cells treated with *T. arjuna* extract at the concentration of 60 and 100 µg/mL, respectively.

and appearance of 17-kDa protein measured by densitometric analysis (Figures 4C and 4D). This results indicated that *T. arjuna* treatment stimulated the proteolytic cleavage of caspase-3 protein and initiated the apoptosis pathway in HepG2 cells.

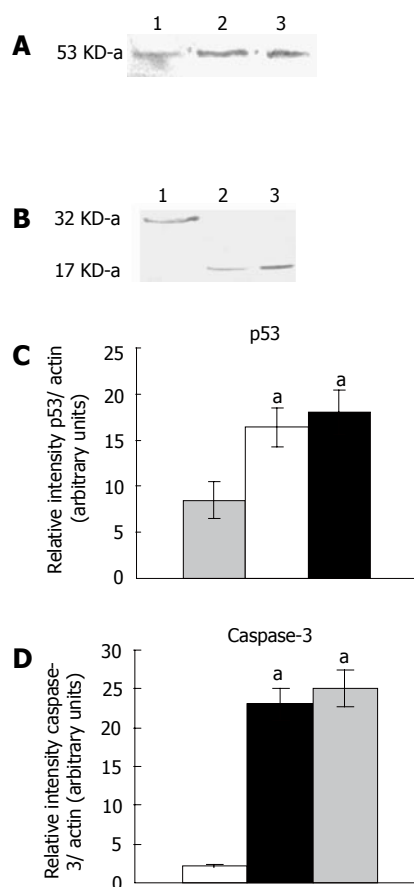

### GSH levels

The level of GSH content in control was  $24.38 \pm 1.37$  n moles/ $10^6$  cells. After treatment with *T. arjuna* (60 and 100 mg/L) the GSH level decreased to  $18.57 \pm 1.56$  n moles/ $10^6$  cells and  $16.62 \pm 1.46$  n moles/ $10^6$  cells, respectively. There was a significant difference between the *T. arjuna* extract-treated group and control group.

## DISCUSSION

In the present investigation, *T. arjuna* extract markedly reduced the cell viability in a concentration-dependent manner. The suppression of cell proliferation induced by this extract may be due to the induction of cell death. Thus, the inhibitory activity of *T. arjuna* extract provides evidence for the *in vitro* cytotoxicity.

Recent studies suggest that LDH is a more reliable and accurate marker of cytotoxicity, because damaged cells are fragmented completely during the course of prolonged incubation with substances [7]. In the present study, the LDH leakage increased significantly in *T. arjuna* extract-treated HepG2 cells when compared to the control cells. Extensive reports have documented on medicinal plant extract-induced cytotoxicity to cancer cells. It was reported that the acetone and methanolic extracts of *T. arjuna* inhibit the growth of transformed cells such as osteosarcoma cells (U2OS) and glioblastoma cells (U251) *in vitro* at the concentration of 30 and 60 mg/L [11]. Thus, the inhibition of HepG2 cells strongly proves the cytotoxic nature of *T. arjuna* extract. Pasquini *et al.* [12] also found that various fractions of *T. arjuna* inhibit the mutagenicity of 4-nitroquinoline-4-oxide in the salmonella/microsome test, suggesting that the inhibition may be due to the presence of antitu-

**Figure 4** Expression of p53 and caspase-3 proteins. Western blotting analysis of p53 and caspase-3 in HepG2 cells cultured for 48 h in the presence and absence of *T. arjuna* extract at the concentration 60 and 100 mg/L was carried out. Cell lysates were prepared as described in MATERIALS AND METHODS, and resolved by 12% SDS-PAGE, immunoblotted and detected using specific antibodies which recognized p53 (A) and caspase-3 (B). Densitometric analysis of the p53 (C) and caspase-3 band (D) was performed. Each value is mean  $\pm$  SD of three observations. <sup>a</sup> $P < 0.05$  represents the statistical significance between control and *T. arjuna* extract-treated HepG2 cells.

mor promoters of the plant extract. Hence, the LDH leakage in HepG2 cells may be due to the cytotoxic nature of the plant extract and confirms its antitumor activity.

Light microscopic observation of *T. arjuna* extract-treated HepG2 cells at the concentrations of 60 and 100 mg/L after 48 h of exposure showed the typical morphological features of apoptosis in HepG2 cells. The morphological changes observed were reduction in cell volume, cell shrinkage, reduction in chromatin condensation and formation of cytoplasmic blebs. However, the control HepG2 cells had a higher confluency of monolayer.

Fluorescence microscopic study showed apoptosis in *T. arjuna* extract-treated HepG2 cells after exposed to the concentrations of 60 and 100 mg/L. In the present investigation, control HepG2 cells were stained green in color with acridine orange, because of cell membrane integrity. On the other hand, the drug-treated HepG2 cells were stained bright orange in color with ethidium bromide. This may be due to loss of cell membrane integrity and apoptotic nature of the plant extract.

Apoptotic cells often produce a unique ladder composed of nucleotide fragments at an interval of 180-200

base pairs, which can be visualized by DNA-agarose gel electrophoresis. It is generally assumed that the toxicity of antitumor drugs is the consequences of their ability to cause genomic DNA damage in cancer cells<sup>[13]</sup>. In this context, Bai and Cederbaum<sup>[14]</sup> reported that many chemotherapeutic drugs, including Vp16 and mitomycin C, induce cells to undergo apoptosis through damage of nuclear DNA. In the present study, DNA ladders appeared in *T. arjuna* extract-treated HepG2 cells after exposed to the concentrations of 60 and 100 µg/mL for 48 h. However, the control HepG2 cells did not show any DNA fragmentation. In general, cytotoxic drugs induce a massive breakage of DNA into oligonucleosome fragments. The degradation of DNA down to oligonucleosomal fragments is a late event of apoptosis<sup>[15]</sup>. Thus, the *T. arjuna* extract induces DNA damage in HepG2 cells and thereby causes apoptosis.

It is well known that p53 acts as a guardian of the genome, and is one of the major factors controlling cell proliferation, growth and transformation. The p53 tumor suppressor gene is mutated in over 50% of human cancers, and the oncogenetic activity of p53 mutation is due to its ability to interfere with p53-dependent apoptosis by a dominant negative mechanism<sup>[16]</sup>. Tumor suppressor gene p53 is one of the critical genes regulating the onset of DNA replication around G1/S boundary. Also, p53-mediated tumor suppression appears to be critical for therapeutic potential in the treatment of tumors<sup>[17]</sup>. p53 is implicated in cell cycle control, DNA repair and apoptosis<sup>[18,19]</sup>. Thus, apoptotic modulators may be promising agents for treatment of HCC. p53 contributes to apoptosis induced by a variety of cellular stresses, including DNA damage, oxidative stress and chemotherapeutic drugs<sup>[20]</sup>.

Activation of p53 is often deduced with natural chemotherapeutic agents and p53 negative tumors are generally less sensitive or even insensitive to these agents. In the present study, *T. arjuna* extract-treated HepG2 cells showed upstream regulation of p53 protein expression after exposed to the concentrations of 60 and 100 mg/L for 48 h. Hence, *T. arjuna* extract may possibly enhance the susceptibility of HepG2 cells to apoptosis by attenuating the tumor suppressor protein.

In cells undergoing apoptosis, there is a activation of proteases known as caspases, which have an obligatory cystein residue within the active site and cleave peptides adjacent to an aspartic acid residue<sup>[21]</sup>. Caspase cascade has been demonstrated to be involved in apoptotic signal transduction and execution<sup>[22]</sup>. Human caspases 1-10 have been described and activation of the caspase cascade is involved in chemical-induced apoptosis<sup>[23]</sup>, including degradation of DNA repair enzyme poly ADP ribosepolymerase<sup>[24]</sup> and DNA-dependent protein kinase as well as cleavage of chromatin at inter-nucleosomal sites mediated by caspase-activated DNase<sup>[25]</sup>. Generally, caspases are present as inactive proenzymes, most of which are activated by proteolytic cleavage. Caspases-8, -9 and -3 are situated at pivotal junctions in apoptotic pathways<sup>[26]</sup>. Caspase-3 may then cleave vital cellular proteins or activate additional caspases by proteolytic cleavage. In the present investigation, *T. arjuna* extract-treated HepG2 cells showed a low intensity of 32-ku protein band and 17-ku protein band

was observed. According to Busihardjo *et al*<sup>[27]</sup>, caspase-3 usually exists as an inactive procaspase-3 that becomes proteolytically activated by multiple cleavages of its 32-ku precursor to generate the 20/11 or 17/11 ku active forms in cells undergoing apoptosis. Thus, the appearance of 17-ku protein may be one of the active forms of caspase-3 protein. It may be due to proteolytic cleavage of inactive caspase-3 induced by the plant extract. This occurs before the further activation of caspase-3-mediated apoptosis. Recent studies have also suggested that the proteolytic degradation of specific substrates is responsible for many of the morphological features of apoptosis<sup>[28,29]</sup>.

It was reported that certain products from plants can induce apoptosis in neoplastic cells but not in normal cells<sup>[30,31]</sup>. Studies have shown that cytotoxic effect of the phenolic compounds on different tumors is mediated through apoptosis. For instance, gallic acid selectively induces cell death in various transformed cell lines such as PLC/PRF/5 (human hepatoma), HL-60, RG (human promyelocytic leukemia) and P-388D<sub>1</sub> (mouse lymphoid neoplasma) the<sup>[32]</sup>.

It has been reported that several putative compounds isolated from *T. arjuna* such as tannic acid, especially flavonoid (luteolin) are potent antitumor promoters and inhibitors of a series of solid tumors and leukemia<sup>[33,34]</sup>. Nagpal *et al*<sup>[11]</sup> have reported that the growth of osteosarcoma (U2OS) and glioblastoma (U251) is inhibited after treated with *T. arjuna* extract, suggesting that the induction of apoptosis in HepG2 cells may be due to the antitumor property of *T. arjuna* extract.

Numerous data indicate that intracellular oxidative metabolites play a significant role in the regulation of apoptosis. The reduced tripeptide GSH is a hydroxyl radical and a singlet oxygen scavenger, participating in a wide range of cellular functions such as protein and DNA synthesis, intermediary metabolism and transport<sup>[35]</sup>. The maintenance of GSH levels and the reducing environment of cells are crucial<sup>[36]</sup>. Depletion of GSH leads to increased accumulation of lipid peroxides and loss of cell viability<sup>[37]</sup>. It is known that the toxicity of antitumor drugs may largely depend on the intracellular level of reduced GSH. Because GSH is the main antioxidant system in cells, a possible explanation is that GSH depletion facilitates reactive oxygen species (ROS) accumulation in cells treated with antitumor drugs<sup>[38]</sup>, which in turn increases their lethality. In the present study, the level of GSH significantly decreased in *T. arjuna* extract-treated HepG2 cells at the concentration of 60 and 100 µg/mL, indicating that the decrease in GSH levels may initiate redox imbalance in HepG2 cells and subsequently induces apoptosis. Depletion of GSH has been described for several agents such as oxidative and alkylating agents in various cell types<sup>[39]</sup>. Cells with reduced GSH levels either undergo apoptosis or become more sensitive to various death inducing agents<sup>[40,41]</sup>. Liu *et al*<sup>[42]</sup> also found that *Salvia miltiorrhiza* inhibits human hepatoma HepG2 cell growth and induces apoptosis involving intracellular GSH depletion. Hall<sup>[43]</sup> has demonstrated that onset of apoptosis is associated with a fall of intracellular GSH in different cellular systems. Loss of GSH is tightly coupled with a number of downstream events in apoptosis<sup>[44]</sup>.

Studies in a variety of cell types suggest that cancer

chemotherapeutic drugs induce tumor cell apoptosis in part by increasing the formation of ROS. According to Simizu *et al.*<sup>[45]</sup>, some anticancer agents, including vinblastin and camptothecin, induce cell apoptosis with the generation of ROS. Previous reports suggest that quercetin and related phenolic compounds containing a catechol moiety in their chemical structures are oxidized under certain *in vitro* conditions, resulting in lipid peroxidation<sup>[46, 47]</sup>. Accordingly, it is speculated that *T. arjuna* extract may induce ROS production in HepG2 cells and subsequently causes apoptosis. However, ROS may not necessarily be the direct factor to cause apoptosis induced by the drug, but intracellular ROS may modulate the genes involved in apoptosis, which may regulate apoptosis. Thus, *T. arjuna* extract-induced oxidative stress is upstream of signaling events that might alter the pro and antiapoptotic balance in HepG2 cells. Phenolic compounds are generally known to show not only their antioxidant effects but also pro-oxidant actions under *in vitro* conditions. Hence, it is possible that treatment of HepG2 cells with *T. arjuna* extract can deplete the GSH levels and promote oxidation induction, which switches the mode of death via apoptosis. Therefore, the cytotoxic action of this drug may be attributed to its pro-oxidant action on the cells. This may be able to account for the discrepancy between *in vitro* cytotoxicity and *in vivo* antitumor activities of *T. arjuna* extract.

In conclusion, *T. arjuna* extract has profound effects on human hepatoma cell line HepG2 and exhibits its cytotoxicity to these cells and the cell death is mediated by apoptosis. The mechanism of apoptosis may be accumulation of p53 protein and proteolytic cleavage of caspase-3 protein. In addition to these, GSH depletion may also play a role in apoptosis through redox imbalance in HepG2 cells. Thus, our results provide the basis for further *in vivo* and clinical research.

## Abstract

**AIM:** To investigate the differently expressed genes in human colorectal adenocarcinoma.

**METHODS:** The integrated approach for gene expression profiling that couples suppression subtractive hybridization, high-throughput cDNA array, sequencing, bioinformatics analysis, and reverse transcriptase real-time quantitative polymerase chain reaction (PCR) was carried out. A set of cDNA clones including 1260 SSH inserts amplified by PCR was arrayed using robotic printing. The cDNA arrays were hybridized with fluorescent-labeled probes prepared from RNA of human colorectal adenocarcinoma (HCRAC) and normal colorectal tissues.

**RESULTS:** A total of 86 genes were identified, 16 unknown genes and 70 known genes. The transcription factor Sox9 influencing cell differentiation was downregulated. At the same time, Heat shock protein 10 KDis downregulated and Calmoulin is up-regulated.

**CONCLUSION:** Downregulation of heat shock protein 10 KD lost its inhibition of Ras, and then attenuated the Ras GTPase signaling pathway, increased cell proliferation and inhibited cell apoptosis. Down-regulated transcription factor Sox9 influences cell differentiation and cell-specific gene expression. Down-regulated Sox9 also decreases its binding to calmodulin, accumulates calmodulin as receptor-activated kinase and phosphorylase kinase due to the activation of PhK.

## INTRODUCTION

The lifetime risk of colorectal cancer in the general population is about 5-6% and about 30-40% of patients have cancer-related deaths<sup>[1]</sup>. It is of great importance to elucidate the mechanisms involved in human colorectal gene carcinogenesis at cellular and molecular levels. It has been demonstrated that colorectal tumor undergoes multiple and sequential morphological and molecular changes<sup>[2]</sup>. In the process of the disease, cell division, differentiation and apoptosis are related to the expression disorder of a group of genes and protein interaction. Oncogenes such as myc, K-ras, src, and erbB2 are activated, while the suppressive cancer genes p53, DCC, APC lose their activation and mismatch repair leads to microsatellite instability<sup>[3-9]</sup>. However, the exact gene expression profiling for human colorectal adenocarcinoma (HCRAC) is still unclear.

Suppression subtractive hybridization (SSH) techniques based on suppression polymerase chain reaction (PCR) can identify the gene expression profiling<sup>[10]</sup>. We have described recently the successful use of SSH using HCRAC and normal colorectal tissues<sup>[11]</sup>. Combined with cDNA microarray techniques, the gene expressing profiling of HCRAC can be obtained with four additional pairs of normal colorectal and HCRAC tissues. In this study, 86 genes were identified. According to the results of sequencing and bioinformatics analyses, three genes were selected, which differed strongly between HCRAC and normal colorectal tissues, and four genes were evaluated in 10 pairs of matched normal colorectal and HCRAC tissues by QRT-PCR technique.

Table 1 QRT-PCR parameters

Gene	Primer	Sequence	Length of primer (bp)	Length of product (bp)	Location of product
HSE1	Forward prime	5'-TGGCAGGACAAGCGTTTGA-3'	20	66	43-108

## MATERIALS AND METHODS

### Tissue sample

Normal colorectal and HCRAC tissue samples from HCRAC patients in West China Hospital were snap-frozen in liquid nitrogen immediately after surgery and stored at -80 °C. Ten pairs of HCRAC and normal colorectal tissues were used. All the tumor samples containing >50% of tumor cells were confirmed as colorectal adenocarcinoma according to the result of pathologic diagnosis.

### RNA extraction

Isolation of RNA was performed using the TRIzol method (Invitrogen) according to manufacturer's instructions. RNA from each sample was assessed by visualization of the 28S/18S ribosomal RNA ratio on 1% agarose gel. RNA yield was determined by measuring the absorbency at 260 nm.

### Suppression subtractive hybridization

PCR-based cDNA subtraction method and PCR-select subtraction method (Clontech Laboratories) were performed using the SMART PCR cDNA synthesis as described previously<sup>[10,11]</sup>. Total RNA was isolated from HCRAC and normal rectum tissues, respectively, and reversely transcribed into single-strand cDNAs with reverse transcript enzyme superscript II. Double-strand cDNA was then synthesized and digested with restriction enzyme *RsaI*, resulting in fragments with a different size of 400-600 bp. HCRAC cDNAs were divided into two groups and ligated to the specific adaptors 1 and 2R, respectively. After HCRAC cDNAs were hybridized with normal rectum cDNA twice for 10 h at 68 °C and the resulting cDNAs were amplified with nested PCR twice, the amplified cDNAs containing enriched differently expressed transcripts were cloned into plasmid vector arms of T/A. The ligated cDNAs were transformed into *E. coli* strain JM109.

### cDNA microarrays

A cDNA gene chip containing 1260 SSH clones was

made. The inserted fragments in the pMD-18T (TaKaRa Company) were amplified with PCR using primers from the franking cloning site. Then the amplified PCR products were spotted onto silylated slides (CEL Associates, Houston, TX, USA) using a Cartesian PixSys 7500 motion control robot (Cartesian Technologies, Irvine, CA, USA) fitted with ChipMaker Micro-Spotting Technology (TeleChem International, Sunnyvale, CA, USA). The total RNA from the four pairs of samples taken from grade A patients was used to prepare cDNA fluorescent probes for hybridization to microarray. Probes were prepared by reverse transcription of total RNA in the presence of either Cy-5 or Cy-3 labeled dUTP (Amersham Pharmacia) using superscript II (Gibco-BRL). The two color probes were then mixed, and the denatured probe mixtures were applied onto the pre-hybridized chip under a cover glass. The chips were hybridized at 42 °C for 15-17 h and scanned with a ScanArray 3000 (GSI Lumonics, Billerica, MA, USA) at two wavelengths to detect emission from both Cy3 and Cy5. The acquired images were analyzed using ImaGene 3.0 software (BioDiscovery, Inc., Los Angeles, CA, USA). The intensities of each spot at the two wavelengths represented the quantity of Cy3-dUTP and Cy5-dUTP, respectively, hybridized to each spot. Genes were identified as differently expressed, if the absolute value of the natural logarithm of the ratios was >0.69. To minimize artifacts arising from low expression values, only genes with raw intensity values for both Cy3 and Cy5 >800 counts were chosen for differential analysis. The clustering algorithm separated tumor and normal tissues into different clusters. We used an algorithm based on the hierarchical clustering algorithm to organize the data matrix of the four colorectal adenocarcinoma samples in a binary tree.

### Sequence and data analysis

Sequencing was carried out for the cDNA clones using the Thermo Sequenase fluorescent labeled primer cycle sequencing (Amersham Pharmacia Biotech, UK). CR-r6d4cts were run on SequaGel (Biozyme, Oldendorf, Germany) and the sequences were analyzed by a LiCOR

**Figure 1** Digestion plasmids of *EcoRI/HindIII*. Lane M: DNA size markers; 1-15 lanes: Fragment of about 500 bp after *EcoRI/HindIII* digestion.

**Figure 2** Reduction of G3PDH after PCR-select subtraction. M: DNA size markers; 1-4 lanes: Subtracted PCR products as template, G3PDH3' and 5' as primers at cycles 18, 23, 28, 33; 5-8 lanes: PCR products not subtracted as template, G3PDH3' and 5' as primers at cycles 18, 23, 28, 33.

sequencer (MWG Biotech, Ebersberg, Germany). The qualified expressed sequence tags (ESTs) were referred to the ESTs containing less than 3% ambiguous bases and longer than 100 bp. These ESTs were subjected to BLAST analysis. The EST was considered as part of a known gene, if the homology to the known gene was over 80%. The EST was considered as part of a known EST, if it shared 95% homology with at least 100 bp of human EST. The EST with no match to human EST was considered as a novel EST.

#### **cDNA synthesis and real-time PCR**

The total RNA from 10 pairs of patients was treated with RNA-free DNAase I (TaKaRa Company) to remove any genomic DNA contamination, then subjected to reverse transcription using M-MuLV reverse transcriptase (Qiagen Company, Germany).

PCR primers were designed using Primer Express 1.5 (PE Company) with the following parameters: length of the amplicon was between 50 and 150 bp,  $T_m$  of the primers was between 58 °C and 60 °C, and span of an intron (Table 1). Real time quantitative (RTQ) PCR was performed using Taqman MGB reagent kit (Qiagen Company, Germany) according to the manufacturer's instructions. PCR was performed on an ABI Prism 700 fluorescent quantitative PCR.

## **RESULTS**

### **Suppression subtractive hybridization**

**Generation of subtracted cDNA populations** SSH was performed in human rectum adenocarcinoma and normal rectum tissues from one patient. A total of 1 260 clones were obtained by SSH. To evaluate the quality of the libraries, plasmid DNA isolated from 36 clones was digested with restriction enzyme, and agarose gel electrophoresis showed that all plasmids contained 400-600 bp fragments (Figure 1). Sequence analysis of 31 clones demonstrated that 28 fragments were differentially homologous to known genes in the GenBank (acquired gene accession number and dbEST number: Accn

BM360856-BM360883).

**Analysis of subtraction efficiency** To estimate the efficiency of subtraction in subtractive cDNA library, the amount of cDNA for G3PDH and oncogene c-myc was analyzed using subtracted and unsubtracted PCR products as templates. Eighteen, 23, 28 and 33 cycles of PCR reactions were performed in a total reaction volume of 30  $\mu$ L. The result demonstrated that the non-specifically expressed housekeeping gene G3PDH was greatly decreased in the reaction (Figure 2). In contrast, the specifically expressed oncogene c-myc was greatly increased in the reaction (Figure 3). These results indicated that the present suppression subtractive cDNA library was highly efficient in enriching the highly expressed genes in HCRAC.

### **cDNA microarray**

The cDNA inserts of each clone were amplified with PCR and spotted on a microarray using robotic printing. Multiple housekeeping genes and randomly selected cDNAs were also printed on the same array to serve as internal controls. The cDNAs from cancer tissue of four patients were labeled with cyanine5 (Cy5), and the cDNAs from normal colon tissue of four patients were labeled with cyanine3 (Cy3). The microarrays were hybridized with cDNA probes labeled with fluorochrome in the forward direction as group 1 (Figure 4A). Then, the cDNAs from cancer tissue of four patients were labeled with Cy3, and the cDNAs from normal colon tissue of four patients were labeled with Cy5. The microarrays were hybridized with cDNA probes labeled with fluorochrome by reverse direction as group 2 (Figure 4B). Red and green fluorescence indicated greater relative expression in the tissues of HCRAC and normal colon, yellow fluorescence indicated equal expression. According to the changes in signal intensity, a total of 143 ESTs were identified. Fifty-four ESTs were differently expressed in group 1, 37 ESTs were upregulated and 17 ESTs were downregulated by forward hybridization. ESTs were differently expressed in group 2 by reverse hybridization, 49 ESTs were upregulated, 40 ESTs were downregulated. The identified

Table 2 Differently expressed genes in subtracted cDNA populations

	Name of gene	Accession number	cDNA	cDNA array ratio	
				Group 1	Group 2
Proto-oncogene and tumor suppressor genes	ITGA6: integrin, alpha 6	ck570352	C60		2.277

**Figure 3** Increased c-myc after PCR-select subtraction. M: DNA size markers; 1-4 lanes (left): PCR products not subtracted as template, c-myc 3' and 5' as primers at cycles 18, 23, 28, 33; 5-8 lanes: No PCR products subtracted as template, c-myc 3' and 5' as primers at cycles 18, 23, 28, 33; 1-4 lanes (right): PCR products subtracted as template, c-myc 3' and 5' as primers at cycles 18, 23, 28, 33.

43 ESTs representing 3.41% of total genes examined were differently expressed in the two groups (Table 2).

## DISCUSSION

### Controlling reliability of SSH

HCRAC is a multi-gene disease similar to other malignant tumors<sup>[1]</sup>. Although the expression of some genes such as APC, DCC and p53 is related with the occurrence of HCRAC, the underlying mechanisms and the whole gene expression profile involved in the pathogenesis of HCRAC are still unclear<sup>[5-9]</sup>. In this study, according to the SSH technique based on suppression PCR<sup>[10]</sup>, the cDNA subtractive library of HCRAC was constructed. The subtraction efficiency was estimated by PCR analysis. The amount of G3PDH was relatively decreased and the amount of c-myc was relatively increased. Thirty-six randomly selected clones were sequenced. Bioinformatics analyses showed human ESTs and dbEST with their accession numbers in the GenBank<sup>[11]</sup>.

### cDNA microarray and quantitative PCR

SSH combined with cDNA microarray or real-time-PCR technique has been used as an efficient method to identify differently expressed genes in breast cancer cells, renal cells, colon cancer cells, non-metastatic and metastatic cancer cells, lung cancer cells, bronchial epithelial cells, fibroblast growth factor 2-transformed endothelial cells<sup>[12-19]</sup>. It was reported that some differently expressed tissue-specific genes have been identified in nasopharyngeal epithelial tissue and two novel full-length genes have been isolated in human glioma specimens<sup>[20,21]</sup>.

Cancer is a highly variable disease with multiple heterogeneous genetic and epigenetic changes. Functional studies are essential to understand the complex polymorphisms of cancer. Microarray is a new powerful tool for studying the molecular basis of interaction. This technique makes it possible to examine the expression of thousands of genes simultaneously<sup>[23]</sup>. To further confirm

**Figure 4** cDNA microarray hybridized with fluorescent labeled probes prepared from HCRAC (A) and total RNA from normal colorectal tissue (B).

the different expression of genes identified in subtractions in the present study, four pairs of samples of patients were chosen for cDNA microarray analysis. The results of the forward and reverse hybridizations were identical.

Both thermodynamic and physical parameters are known to influence hybridization intensities on DNA microarray, and they may fail in discriminating highly similar genes within a gene family during heterologous probe hybridization. Among the techniques available to validate the DNA microarray data, we chose quantitative real-time RT-PCR (qRT-PCR), since it could offer confirmatory quantitative results under stringent conditions. qRT-PCR can be used for measuring low concentrations of mRNA, and is highly accurate, reproducible, and amenable to high throughput analysis<sup>[23-31]</sup>. Three differently expressed ESTs were selected and their expression was analyzed by reverse transcriptase real-time quantitative PCR in the ten pairs of patients. The expression of the four cDNA fragments tested displayed the expected different patterns of expression (Figure 5).

### Global molecular change in carcinogenesis

Carcinogenesis is a complex process in which many molecules are changed at transcriptional and translational levels, and then manifested as structural and functional changes of cancer cells. In forward microarray hybridization, eukaryotic translation initiation factor 3 and SRY Sox are downregulated. Furthermore, heat shock proteins 10 and 60 KD, ribosomal protein S 17, ribosomal protein S 25, ribosomal protein S 28, ribosomal protein L7, tubulin alpha and beta, E-cadherin and integrin alpha 6 proteasome are transiently downregulated. The up-regulated calmodulin 1, nuclear gene encoding mitochondrial protein, protease, ATPase, Na<sup>+</sup>/K<sup>+</sup> beta

**Figure 5** Results of QRT-PCR. Blue/brown:  $\beta$ -actin N/ $\beta$ -actin T; green/bright green: CaMT/CaMn; green/red: Hsp10T/Hsp10N; blue: Sox-9N/Sox-9T.

transporting polypeptide, Zinc finger protein, and putative ribosomal RNA apurinic site-specific lyase have been demonstrated in forward microarray hybridization. The results of reverse microarray hybridization coincided with it.

Translation initiation in eukaryotes is a rate-limiting step in protein synthesis. It is a complex process involving many eukaryotic initiation factors (eIFs). Altering the expression level or the function of eIFs may influence the synthesis of some proteins and consequently cause abnormal cell growth and malignant transformation<sup>[32]</sup>. Ribosomes that catalyze synthesis of proteins consist of a small 40S subunit and a large 60S subunit. These subunits are composed of four RNA species and approximately 80 structurally distinct proteins<sup>[33]</sup>. The down-regulated tubulin has been observed. This experiment renders further support to the hypothesis that activation of both the transcriptional and posttranscriptional machinery may constitute an integral part of the mechanism underlying carcinogenesis.

Down-regulated E-cadherin and integrin alpha 6 can decrease cancer cell adhesion and increase its invasion. Up-regulated nuclear genes encoding mitochondrial protein, ATPase,  $\text{Na}^+/\text{K}^+$  beta transporting polypeptide reflect that cancer cells need enough energy to grow.

### Signal transmission of carcinogenesis

We observed that Sox9 was strongly down-regulated (0.426-fold). Sox, a high-mobility-group domain containing transcription factor, with a DNA-binding domain similar to that of the mammalian testis-determining factor SRY, is a key transcription factor that is essential for chondrocyte differentiation and chondrocyte-specific gene expressions<sup>[34,35]</sup>. Sox9 has been demonstrated to be a "master regulator" gene that controls distinct pathways of mesenchymal differentiation. Sox9 is a target of cAMP signaling and phosphorylation of Sox9 by protein kinase A (PKA) enhances its transcriptional and DNA-binding activity<sup>[36-38]</sup>. Sox9 harbors a number of highly conserved regions, including two domains required for maximal trans-activation. The heat shock protein HSP70 recognizes a specific region of Sox9 with unknown function which may facilitate the assembly of multi-protein complexes

at promoter enhancer regions. The Sox9 HMG domains carry two nuclear localization signals (NLSs). The N-terminal NLS binds to calmodulin while the C-terminal NLS binds to importin beta<sup>[39]</sup>.

We also found that heat shock protein 10 KD (chaperonin 10) was downregulated (0.562-fold). Heat shock protein 10 KD can reduce myocyte death by its mitochondrial function or by interacting with cytoplasmic signaling pathways. The Ras GTPase signaling pathway indicates that inhibition of Ras is required for the protection by HSP10. In abnormal situations, oncogenic activation of Ras signal transduction pathways leads to continuous upregulation of key elements of translational machinery. The Ras signal transduction pathways play a critical role in regulating mRNA translation and cellular transformation. On the other hand, tumor suppressor genes downregulate ribosomal and tRNA synthesis, and their inactivation results in uncontrolled production of these translational components. Heat shock proteins (chaperonins) are also a subgroup of oligomeric molecular chaperones. Chaperonins 10 and 60 can be found on the surface of various prokaryotic and eukaryotic cells, and release from cells. Secreted chaperonins can interact with a variety of cell types, including leukocytes, vascular endothelial and epithelial cells, and activate key cellular activities such as the synthesis of cytokines and adhesion proteins<sup>[40-42]</sup>.

We further observed that some receptor subunits (calmodulin) related to ion channels (potassium channel protein) were strongly upregulated (3.265-fold). Calmodulin (phosphorylase kinase delta) is a major cytoplasmic calcium receptor that performs multiple functions in cells including cytokinesis<sup>[43]</sup>. Calmodulin is a small protein involved in calcium signaling and is able to bind to many different targets. The targets of calmodulin are a number of kinases, including myosin light chain kinase (MLCK), calmodulin-dependent kinase and phosphorylase kinase. The phosphorylase kinase holoenzyme (PhK) including alpha-beta, gamma and delta alters the interaction between its regulatory alpha and catalytic gamma subunits. The gamma subunit is also known to interact with the delta subunit, an endogenous molecule of calmodulin that mediates the activation of PhK by  $\text{Ca}^{2+}$  ions<sup>[44]</sup>.

In conclusion, the down-regulated transcription factor Sox9 can influence cell differentiation and cell-specific gene expression. Down-regulation of heat shock protein 10 KD loses its inhibition of Ras, and attenuates the Ras GTPase signaling pathway, increases cell proliferation and inhibits cell apoptosis, which is a hallmark of aggressive malignant colorectal adenocarcinoma. Down-regulated Sox9 also decreases its binding to calmodulin, accumulates calmodulin as receptor-activated kinase and phosphorylase kinase due to the activation of PhK by  $\text{Ca}^{2+}$  ions. Upregulated nuclear DNA-encoded mitochondria supply increases cancer cell proliferation energy.

## Abstract

**AIM:** To study the loss of heterozygosity (LOH) on 12p12-13 in Chinese colon carcinoma patients.

**METHODS:** DNA was extracted from 10 specimens of cancer tissue, 10 specimens of adjacent tissue and 10 specimens of normal tissue, respectively. LOH of Kras2 gene was analyzed by polymerase chain reaction (PCR) and denaturing polyacrylamide gel electrophoresis using 11 microsatellite markers on 12p-12-13.

**RESULTS:** LOH of Kras gene was detected at least on one marker of 12p-12-13 in 30% (3/10) of adjacent tissue specimens. The highest frequency of LOH was identified on D12S1034 in 28.57% (2/7) of adjacent tissue specimens. LOH was detected at least on one marker of 12p12-13 in 60% (6/10) of carcinoma tissue specimens, the most frequent LOH was found on D12S1034 and D12S1591 in 42.86% (3/7) of carcinoma tissue specimens. LOH was detected in 30% (3/10) of carcinoma tissue specimens, 30% (3/10) of adjacent tissue specimens, and no signal in 1% (1/0) carcinoma tissue specimen. The occurrence of LOH did not correlate with sex, age, tumor size and lymph node metastasis.

**CONCLUSION:** Genomic instability may occur on 12p-12-13 of Kras2 gene in the development and progression of colon carcinoma. The high LOH of Kras2 gene may directly influence the transcription and translation of wild type Kras2 gene.

## INTRODUCTION

Clinical and experimental studies have shown that point mutation of Kras2 gene plays an important role in the development and progression of tumors<sup>[1-4]</sup>. However, it has been reported that wild type Kras2 gene has inhibitory effects on tumor growth and proliferation<sup>[5]</sup>. Inactivation of cancer suppressor gene is a frequently encountered early event in the development of tumors, leading to loss of heterozygosity (LOH)<sup>[6-10]</sup>. This study was to investigate the possible genetic variation of wild type Kras2 gene in the carcinogenesis of colon carcinoma by analyzing LOH in tumor and its adjacent tissues.

## MATERIALS AND METHODS

### Specimens

Ten specimens of primary carcinoma tissue, 10 specimens of its adjacent tissue and 10 specimens of normal tissue at the distal incision margin were taken respectively from patients with pathologically confirmed colon carcinoma before and after surgery at the Department of Surgery, General Hospital of the Chinese PLA from January to December 2003. The patients did not receive radiotherapy and chemotherapy before surgery.

### DNA extraction from genome

Specimens of carcinoma and its adjacent tissues as well as normal tissue at the distal incision margin were suspended respectively in 50 µL DNA lysate containing 50 mmol/L Tris-HCl, 1 mmol/L EDTA, 0.1% Tween 20, 200 mg/L protease K, pH8.0, and digested overnight at 50°C. Protease K was denatured and inactivated at 95°C. Then the supernatant was centrifuged and stored at -20°C for use.

### Primer design

Microsatellite-labeled primers on 12p12-13 were retrieved from the UniSTS database. The sequences of D12S89, D12S358, D12S310, D12S1606, D12S1596, D12S1592,

D12S1617, D12S1057, D12S1591 are listed in Table 1.

### Polymerase chain reaction (PCR)

One  $\mu$ L 10xPCR buffer, 0.5 mmol/L magnesium ion, 0.2 mmol/L 4x dNTP, 0.4  $\mu$ mol/L upstream primer, 0.4  $\mu$ mol/L downstream primer, 1U Taq DNA polymerase/reaction and 0.5  $\mu$ L DNA template were added into 10  $\mu$ L PCR system at 94°C for 5 min. Fourteen PCR cycles of amplification were performed at 94°C for 30 s, at 60°C for 30 s, at 72°C for 30 s, followed by 16 cycles at 94°C for 30 s, at 55°C for 30 s, at 72°C for 30 s, and a final extension at 72°C for 5 min.

### Denaturing polyacrylamide gel electrophoresis

PCR products (0.3  $\mu$ L) were added to the loading buffer containing GENESCAN-500 molecular weight as internal control and mixed with formamide, then denatured at 72°C for 2-3 min and electrophoresed by the AB1377 fluorescence sequencer. The standard sequencing PAGE 64-well denaturing polyacrylamide gel was used for electrophoresis. The electrophoresis was performed at the temperature higher than 42°C for 2.5-3 h. The electrophoresis channels were analyzed using GENESCAN version 3.1 Software. The types and intensity of fluorescence were collected for each channel, the size of amplified PCR products was determined using the molecular weight as internal control. Data of the type, intensity and molecular weight of the amplified microsatellite DNA fluorescence were obtained using GENOTYPE version 2.0 Software. The fluorescence intensity could indicate the amplified DNA within the linearity (relative fluorescence intensity was 200-300).

### LOH analysis

Based on the principles of fluorescence labeling of primers, a fluorescence labeled primer group-matched

**Figure 1** LOH on D12S1591 (A) and gene type (B) in carcinoma and normal tissues. The arrowhead shows the allele loss. 10-1: tumor, 10-2: adjacent tumor, 10-3: normal.

sequence was linked to the 5' end of a specific primer, so that the PCR products were labeled with the fluorescence group in the process of PCR. The fluorescence labeled PCR products were electrophoresed using the AB 1377 fluorescence sequencer. Data collected by the electrophoresis were analyzed using the GENESCAN and GENOTYPE Softwares to obtain the peak and size of the map. Gene typing was performed. The peak was found in 2 allelic gene segments and compared to the normal value of the adjacent channels. The allelic ratio was calculated according to the following formula: allelic ratio = peak ratio of carcinoma tissue / peak ratio of normal tissue. LOH was considered when the allelic ratio was higher than 1.5 or lower than 0.67. Microsatellite instability (MSI) was considered when no abnormal peak point was found in DNA of carcinoma tissue compared to normal tissue.

### Statistical analysis

The correlation between LOH and clinical and pathological parameters was evaluated by chi-square test. All statistical analyses were carried out by SPSS 10.0.  $P < 0.05$  was considered statistically significant.

## RESULTS

### Frequency of LOH in carcinoma adjacent tissue

No LOH was detected in 70 (7/10) of adjacent tissue specimens (1, 2, 4-6, 8, 9) on all markers. LOH was detected in 30% (3/10) of adjacent tissue specimens (3, 7, 10) at least on one marker, 28.5% (2/7) of adjacent tissue specimens on D12S1034, 25% (1/4) on D12S1617, 14.29% (1/7) on D12S1596, 12.5% (1/8) on D12S89, and 0% on other markers (Table 2 and Table 3, Figure 1).

### Frequency of LOH in carcinoma tissue

No LOH was detected in 40% (4/10) of primary colon carcinoma tissue specimens (1, 4-6) on all markers. LOH

was detected in 60% (6/10) of colon carcinoma tissue specimens (2, 3, 7-10) at least on one marker, 42.86% (3/7) on D12S1034 and D12S1591, 33.33% (1/3) on D12S310, and 0% (0/4) on D12S1592 (Tables 2 and 3).

### Correlation between LOH on 12p12-13 and clinicopathological parameters

Chi-square test was used to evaluate the correlation between LOH and clinicopathological parameters. The results showed that LOH did not correlate with age, sex, tumor size and lymph node metastasis (Table 4).

## DISCUSSION

RASp21 consisting of Hras1, Nras and Kras2, is a GTP-coupled protein and can transfer signals from cell surface into cells. Its normal expression is necessary to maintain the normal physiological activities of cells. Activated Ras proto-oncogenes, especially Kras2, play an important role in the carcinogenesis of human and rodent tumors. Mutations of Kras2 gene have been found in tumor tissues of human organs, including bladder<sup>[11]</sup>, breast<sup>[12]</sup>, rectum<sup>[13]</sup>, kidney<sup>[14]</sup>, liver<sup>[15]</sup>, lung<sup>[16]</sup>, ovary<sup>[17]</sup>, pancreas<sup>[18]</sup>, stomach<sup>[19]</sup> and hematopoietic system<sup>[20]</sup>. In general, about 30% cancers display ras gene mutations, while the highest mutation rate is found in colonic and pancreatic cancer<sup>[21-25]</sup>. In samples

of mutated ras gene, most mutations occur in Kras2 gene. Mutation and activation of ras gene usually occur at codons 12 and 13 or 61, leading to the transformation of proto-oncogene to oncogene<sup>[26]</sup>. This kind of activation can up-regulate the expression of ras/ErK signal channel in the absence of external stimuli and further increase the abnormality of associated signal channels, leading to malignant transformation of cells. Activated ras gene is usually considered as the dominant oncogene because of the existing expression of wild type ras and malignant transformation of activated ras<sup>[27]</sup>. However, is still controversial the effect of the dominant gene-ras is still controversial since wild type ras has been found in human and mouse pulmonary adenocarcinomas<sup>[28,29]</sup>.

*In vivo* and *in vitro* experiments<sup>[28]</sup> have shown that tumors are found more frequently in normal mice with 2 wild type Kras2 copies than in those with LOH of one wild type Kras2 copy after they are treated with 2 carcinogens. The occurrence of tumor is 50-fold higher in mice with LOH of one wild type Kras copy than in normal mice with 2 wild type Kras copies. The tumor in the former group of mice is poorly-differentiated adenocarcinoma, while the tumor in the later group of mice is adenoma. Zhang *et al*<sup>[28]</sup> reported that wild type Kras2 gene can inhibit cell growth, formation of clones, and induce tumors in naked mice. In addition, LOH has

**Table 4 Correlation between LOH on chromosome 12p12-13 and clinical pathologic factors**

Lymph node metastasis					
Yes	4	2	6	60	0.598161
No	2	2	4	40	

been found in pulmonary adenocarcinoma induced by various chemical carcinogens. Point mutation of Kras2 gene is detected in 67-100% mice with LOH of wild type Kras 2 gene. These important findings will certainly query the established carcinogenesis of dominant Kras2 gene.

It was reported that the development and progression of colon carcinoma are a process involving multiple genes and factors, and characterized by its stages: normal mucosa → atypical hyperplasia including intestinal metaplasia → adenoma → adenocarcinoma<sup>[30]</sup>. Kras2 gene as a dominant oncogene due to its point mutation plays an important role in the progression of canceration, which is one of the reasons why the inhibitory effect of wild type kras2 gene on cancer is concealed. Since cancer suppressor gene can be inactivated by deleting mutation, we studied LOH of Kras 2 gene on 12p12-13 in primary colon carcinoma. LOH was detected in 30% (3/10) of adjacent tissue specimens at least on one marker, 28.5% (2/7) on D12S1034, suggesting that 12p12-13 is genomically insin precancerous cells, and that LOH on 12p12-13 may influence the expression of wild type Kras2 gene in early colon carcinoma. LOH was detected in 60% colon carcinoma tissue specimens at least on one marker, which was higher than that in adjacent tissue, and 42.86% (3/7) on D12S1034, suggesting that the genomic instability of 12p12-13 exacerbates with the progression of carcinoma as demonstrated not only by the increasing number of allelic gene loss points but also by the increasing frequency of allelic gene loss at the same point. Such changes lead to a decrease of Kras2 gene copies used for transformation. When another point mutation occurs in the process of carcinogenesis and produces dominant oncogene effects, the cancer suppressing function of wild type Kras2 gene can be completely covered up.

In conclusion, Kras2 gene can exert inhibitory effects on the proliferation of colon carcinoma cells. LOH on 12p12-13 does not correlate with the clinical and pathological parameters obtained from colon carcinoma.

## Abstract

**AIM:** To construct the eukaryotic expression plasmid containing HCV NS3 segment and to analyze the expression of NS3 protein in normal human hepatocyte HL-7702.

**METHODS:** We amplified HCV NS3 fragment from plasmid pBRTM/HCV 1-3011 containing the whole length of HCV genome, recombined it with expression vector pcDNA3.1(-) to form the eukaryotic expression vector pcDNA3.1(-)/NS3, and transfected human HL-7702 hepatocytes with the recombined plasmid by cationic polymers. The expressed HCV NS3 protein was detected and analyzed by immunohistochemical method and Western blot.

**RESULTS:** The amplified NS3 fragments had correct molecule weight and sequence. The successfully constructed eukaryotic expression plasmids were transfected to HL-7702 cells. The expressed NS3 proteins had correct molecular weight 70000.

**CONCLUSION:** Eukaryotic expression vector pcDNA3.1(-)/NS3 containing NS3 segment of HCV can be constructed, the sequence of NS3 fragments is consistent with the template. Normal human HL-7702 hepatocytes can efficiently express specific HCV NS3 protein *in vitro*.

## INTRODUCTION

Hepatitis C virus (HCV) genome has only one open reading frame, which encodes for a precursor protein polymer containing 3000 amino acids. The protein products, including core, NS3, NS4B and NS5A, have an effect on hepatocellular carcinoma (HCC) induced by HCV. The non-structural protein 3 (NS3) segment plays a key role in replication of virus and is closely related with the growth of host cells. NS3 has attracted attention in many research fields of HCV. In this experiment, we constructed the eukaryotic expression vector containing HCV NS3 segment, which could express NS3 protein in normal human hepatocytes *in vitro*.

## MATERIALS AND METHODS

### Enzymes and reagents

PCR primers were synthesized by Shanghai Sangon Biological Engineering and Technology and Service (Shanghai, China). Restriction endonucleases *EcoRI* and *BamHI*, T4 DNA ligase, RNase A and Ex Taq DNA polymerase and markers DL 15 000 and DL 2000 were purchased from TaKaRa Biological Technology (Dalian, China). Protein radiant markers were purchased from Bioin Technology (Zhuhai, China). Plasmid purification kit and transmaster were purchased from BoLi Bioin Technology (Beijing, China). Anti-HCV NS3 monoclonal antibody was purchased from Bidesign(American). Donkey anti-sheep IgG-HRP was purchased from Kangchen Bio-tech (Shanghai, China). Immuno histochemical SP-HRP kit was purchased from Dingguo Biological Technology (Beijing, China). Western blot ECL kit was purchased from Bioin Technology (Zhuhai, China).

### Vectors and experimental cells

Recombination plasmid pBRTM/HCV1-3011 containing the whole genome of HCV was donated by Professor

Rice(Washington, USA). Expression vector pcDNA3.1(-) containing CMV promoter ahead of multiple cloning sites, replication initiating site SV40ori as well as anti-ampicillin and anti-G418 sites, was donated by Doctor Shun Fenyong (College of Life Science and Technology , Jinan University). pMD 18-T simple vectors were purchased from TaKaRa Biological Technology (Dalian, China). *E.coli* JM109 was provided by Biochemistry Department Jinan University. HL-7702 cells were purchased from Shanghai Institute of Cell Biology (Shanghai, China).

### Experimental groups

Non-transfected HL-7702, HL-7702 transfected with pcDNA3.1 (-)/NS3 and HL-7702 transfected with pcDNA3.1(-) .

### Construction of expression vector pcDNA3.1 (-)/NS3

Based on published sequences, the primers [5'-GAA TTC ATG GCG CCC ATC ACG GCG TAC GC-3' (upriver) and 5'-CTG GAC CTC CAG CAG TGC ATT CCT AGG-3' (downriver)] were used to amplify the whole sequence of HCV NS3 region. Thirty cycles of PCR were performed at 94 °C for 60 s, at 55 °C for 30 s, at 72 °C for 120 s, and at 72 °C for 10 min in 50µl reaction mixture containing 0.3 µL (1 U/µL) Taq polymerase, 5 µL 10×PCR buffer, 1 µL dNTPs (20 mmol/L), 0.625 µL each primer (20 µmol/L), 1µL DNA as template, and 41.45 µL distilled water. The PCR products were subjected to electrophoresis on 0.8% agarose gel for 60 min(voltage:80V),visualized by DNA viewer staining. The PCR products were connected to clone vector pMD 18-T after purification. Plasmid pMD 18-T/NS3 was transferred into *E. coli* with calcium chloride. The *E.coli* was cultured to amplify the plasmid. Successfully transferred *E.coli* was screened at 50 mg/L ampicillin. Then the constructed pMD 18-T/NS3 was recombined with expression vector pcDNA3.1(-)/NS3, thus the eukaryotic expression plasmid pcDNA3.1(-)/NS3 came into being .

### Cell culture and growth curve

HL-7702 cells were cultured and passaged in RPMI 1 640 medium supplemented with 10% fetal calf serum in an incubator containing 50 mL/L CO<sub>2</sub> at 37°C Cells were digested by 0.25% trypsin and seeded (2.5×10<sup>4</sup> cells per well) in 48-well culture plates. Cells were digested and counted at an interval of 24h with the average number of cells in 3 wells calculated per time.The detection was continued for 8 d. Then the population doubling time was calculated and growth curve of the cells was plotted.

### Immunohistochemical staining

We used S-P method to detect the expression of HCV NS3 protein in HL-7702 cells transfected with plasmid pcDNA3.1 (-)/NS3. Cells transfected with and without plasmid pcDNA3.1 (-) served as negative and blank control groups. Cells were cultured in 25-flasks till 85% convergence. The cells were washed three times with pre-cooled PBS before harvested. Then 1 milliliter lysis reagent containing 50 mmol/L TrisHCl (pH8.0),150 mmol/L NaCl , 0.02% sodium aijide, 0.1%SDS, 100 mg/LPMSF

(dissolved in isopropyl alcohol, 1 mg/L aprotinin , 1% Nonidet P-40, 0.5% sodium deoxycholate) was added and incubated at 4 °C for 20 min. Then the lysis reagent mixed with broken cells was harvested and centrifuged at 12 000 r/min for 5 min. Twenty microliters of supernatant protein was resolved by SDS-8% polyacrylamide gel electrophoresis. After electrophoresis, the proteins were transferred onto a PVDF membrane, blocked in 5% skimmed milk for 1h, probed with monoclonal antibody to HCV NS3(1:1000) overnight at 4°C. After washed three times with TBS containing 0.1% Tween 20, the membrane was treated with horseradish peroxidase-conjugated donkey anti-goat antibody for 3 h. Protein binding was detected by chemiluminescence reagent (ECL). Then the bands on X-film were assayed by densitometric scanning.

## RESULTS

### Construction of expression vector pcDNA3.1(-)/NS3

The PCR product of NS3 had correct molecule weight. Recycled PCR fragments were connected to T vector, *E.coli* was used to amplify the recombined vector pMD 18-T/NS3. Plasmid extracted from the positive clones could be digested by *EcoRI* and *BamHI* to two fragments (3000bp and 1900kb) as expected. DNA sequence analysis confirmed that the inserted fragment was a HCV NS3 segment containing 1893 nucleotides with right direction and reading frame. Initial codon, terminal codon and restriction sites of *EcoRI* , *BamHI* were successfully added to the ends. Vector pMD 18-T/NS3 was successfully recombined with plasmid pcDNA3.1(-). The length of the recombined vector pcDNA3.1(-) / NS3 was 7 300bp. After digested by *EcoRI* and *BamHI*, pcDNA3.1(-) / NS3 was cloven into two fragments (5 400 bp and 1900 kb) as expected (Figure 1A-1C).

The incubation condition of HL-7702 cells and the cell growth curve were obtained (Figure 2 A, 2B)

Immunohistochemical analysis showed that the blank control group was negative, pcDNA3.1 (-)/NS3 transfection group was positive for HCV NS3 protein in cytoplasm. SDS-PAGE analysis showed that among the separated protein bands (distilled from cytoplasm), a band was found at molecular weight 70 000 as expected (Figure 3A-3D)

## DISCUSSION

Hepatitis C virus(HCV) , the major etiological agent of non-A non-B hepatitis identified by the end of 1 980s, has infected more than 170 million persons worldwide and 85% of them could develop chronic hepatitis, liver function failure or hepatocellular carcinoma. Among all the gene segments of HCV, NS3 segment has many important physiological functions. Genetic variability of NS3 protein lies in different kinds of HCV-infected patients<sup>[2]</sup>. Nowadays little has been known about the nonstructural protein of HCV. NS3 protein contains many enzymes such as helicase , NTPase and serine protease, which can degrade the nonstructural segments of HCV polyprotein<sup>[3-5]</sup>. HCV core, NS3, NS5A and NS5B

**Figure 1** PCR results of NS3 gene(A), pMD 18-T/NS3 (B) and pcDNA3.1(-)/NS3 (C) digested with Eco and BamHI.

**Figure 2** Convergence (A) and growth curve (B) of HL-7702 cells.

**Figure 3** Immunohistochemical staining of NS3 protein expressed in non-transfected (A), transfected with pcDNA3.1(-)/NS3 (B), pcDNA3.1(-) (C) HL-7702 cells SDS-PAGE and Western blot as well as of NS3 protein expression in HL-7702 cells (D1-D2).

proteins can modulate cell proliferation independently by expressing p53<sup>[6]</sup>. Chronic hepatitis C induced by HCV could do great harm to human body, yet little has been known about the pathogenetic mechanism. HCV can impair the innate immunity system. It was reported that interaction between HCV NS3 protein and host TBK1 protein leads to inhibition of cellular antiviral responses<sup>[7]</sup>. Conserved C-terminal threonine of HCV NS3 can regulate autophosphorylation<sup>[8]</sup>. NS3 protein can down-regulate activities of protease peptide which could interfere with the activity of viral antigens, which may protect HCV from host immune surveillance, leading to persistent viral infection<sup>[9]</sup>. Besides, NS3/4A-mediated cleavage of TIR domain-containing adaptor protein potentially limits expression of multiple host defense genes, promoting

persistent infections with this medically important virus<sup>[10]</sup>.

Dolganiuc *et al*<sup>[11]</sup> showed that core protein and nonstructural protein 3 of HCV can induce production of IL-10 and mediate immunosuppression of against HCV. Some HCV proteins, such as core protein, NS3 and NS5A, not only regulate cell growth and interact with other cellular proteins, but also participate in programmed cell death under certain circumstances<sup>[12]</sup>. HCV can interfere with JAK/STAT signal pathway, leading to IFN production by down-regulating the expression of STAT1<sup>[13]</sup>. Additionally, NS3 can bind to a host protein (Sm-D) which interferes with the formation of small nuclear ribonuclear protein (snRNP) complexes, so that occurrence of autoimmune disease can be reduced<sup>[14]</sup>.

It was reported that nonstructural protein 3 of HCV

can inhibit dendritic cell differentiation by inducing pro- and anti-inflammatory cytokines<sup>[15]</sup>. Core, NS3, NS5A, NS5B proteins of hepatitis C virus can induce apoptosis of mature dendritic cells<sup>[16]</sup> and inhibit cellular immune responses through impairment of maturation of dendritic cells<sup>[17]</sup>. Dolganiuc *et al.*<sup>[18]</sup> found that HCV core and NS3 proteins could activate monocytes. NS3 protein can activate innate immunity to recognize virus more efficiently through inducing inflammation<sup>[18]</sup>. Studies indicate that persistent HCV infection is closely related with hepatocellular carcinoma, replication and protein expression of HCV have been observed in HCC tissues<sup>[19-21]</sup>, suggesting that interaction between HCV gene segments and expressed protein plays a key role in malignant transformation of hepatocytes<sup>[22]</sup>. Feng *et al.*<sup>[23]</sup> showed that HCV NS3 N-terminal peptide may up-regulate the activation of MAPK, but not affect the expression of MAPK in normal liver cells. Additionally, Sakamuro *et al.*<sup>[24]</sup> reported that NS3 gene-expressed protein in NIH3T3 cells and mouse fibroblasts can be transfected with NS3 gene segment, which induces tumors in nude mice. NS3 protein can inhibit actinomycin D-induced apoptosis<sup>[25]</sup> and inhibit phosphorylation mediated by cAMP-dependent protein kinase<sup>[26]</sup>. Activation of c-Jun NH2-terminal kinase (JNK) signaling pathway is essential for the stimulation of HCV non-structural protein 3 (NS3)-mediated cell growth<sup>[27]</sup>. It has been shown that cells consistently expressing low concentration of NS3 protein is prone to apoptosis induced by the Fas molecule<sup>[28]</sup>.

In this experiment, we used pcDNA3.1(-) vector to construct the eukaryotic expression vector pcDNA3.1(-)/NS3. DNA sequence analysis revealed that the inserted NS3 gene had correct reading frame and length(1893nt). Initial and terminal codons were successfully inserted into the ends of NS3 segment, which assured the correct expression of NS3 protein. We chose adult human HL-7702 hepatocytes as the host cells. The cells originate from embryonic liver, and were continuously cultivated *in vitro*. HL-7702 cells are slightly larger than normal human hepatocytes *in vitro*. The nuclei/cytoplasm ratio is high and cells are joined to each other tightly<sup>[29]</sup>. We transfected the constructed eukaryotic plasmid pcDNA3.1(-)/NS3 to HL-7702 cells, and detected the expressed protein by immunohistochemical staining. NS3 protein was expressed in the transfected cells, but not in blank cells and cells transfected with pcDNA3.1 (-). Western blot analysis showed that the expressed NS3 protein had correct molecular weight (70 000). The successful construction of eukaryotic plasmid pcDNA3.1 (-)/NS3 and correct expression of HCV NS3 protein in HL-7702 cells may contribute to the establishment of a system that can produce NS3 protein. These results may help further investigation of how NS3 protein affects immunity against virus.

## Abstract

**AIM:** To investigate the biological function of HBcAg in pathogenesis of HBV replication in peripheral blood mononuclear cells (PBMCs).

**METHODS:** HBcAg region was amplified by polymerase chain reaction (PCR) and HBV HBcAg bait plasmid pGBKT7-HBcAg was constructed by routine molecular biological methods. Then the recombinant plasmid DNA was transformed into yeast AH109. After the HBV core protein was expressed in AH109 yeast strains (Western blot analysis), yeast-two hybrid screening was performed by mating AH109 with Y187 containing leukocyte cDNA library plasmid. Diploid yeast cells were plated on synthetic dropout nutrient medium (SD/-Trp-Leu-His-Ade) (QDO) and synthetic dropout nutrient medium (SD/-Trp-Leu-His-Ade) (TDO). The second screening was performed with the LacZ report gene (yeast cells were grown in QDO medium containing X- $\alpha$ -gal). The interaction between HBV core protein and the protein obtained from positive colonies was further confirmed by repeating yeast-two hybrid. After plasmid DNA was extracted from blue colonies and sequenced, the results were analyzed by bioinformatic methods.

**RESULTS:** Eighteen colonies were obtained and sequenced, including hypermethylated in cancer 2 (3 clones), eukaryotic translation elongation factor 2 (2 clones), acetyl-coenzyme A synthetase 3 (1 clone), DNA polymerase gamma (1 clone), putative translation initiation factor (1 clone), chemokine (C-C motif) receptor 5 (1 clone), mitochondrial ribosomal protein

L41 (1 clone), cytochrome binding protein genes (1 clone), RanBPM (1 clone), HBcAg-binding protein 3 (1 clone), programmed cell death 2 (1 clone). Four new genes with unknown function were identified.

**CONCLUSION:** Successful cloning of genes of HBV core protein interacting proteins in leukocytes may provide some new clues for studying the biological functions of HBV core protein.

## INTRODUCTION

Hepatitis B virus (HBV) infection is a global challenge with 350 million chronic carriers world wide. Individuals with chronic HBV infection have a high risk of developing liver cirrhosis and primary hepatocellular carcinoma<sup>[1, 2]</sup>. HBV is a partially double-stranded DNA with compact circular genome of about 3200 base pairs (bp) containing four overlapping open reading frames P, preS/S, preC/C and X. C region coding for the HBV core antigen (HBcAg)<sup>[3, 4]</sup> is a 21-22 kD protein that self-assembles to form the subviral 30-32 nm nucleocapsid particles packing the viral polymerase and pregenomic RNA during HBV replication. HBcAg can prevent the degradation of mRNA by RNA-enzyme and plays a very important role in assembling pregenome and synthesizing genome<sup>[5-7]</sup>.

Some researchers have detected HBV nucleic acids including replicating intermediates, covalently closed circular DNA(cccDNA), viral RNA transcripts and DNA sequences integrated with the cell genome in PBMCs from patients with active chronic hepatitis B (CHB)<sup>[8-13]</sup>. It was reported that patients with hepatocellular carcinoma (HCC) display a higher prevalence of HBV in PBMCs

**Figure 1** pGBKT7- HBcAg cut by *EcoRI* and *PstI* on 0.9% agarose/EtBr gel. Lanes 1 and 3: Marker; lane 2: HBcAg fragment cut by *EcoRI* and *PstI*.

than asymptomatic carriers and CHB patients or liver cirrhosis patients, although the detection rate of viral replication is low in HCC patients<sup>[14]</sup>. Viral load in serum is thus not always associated with the prevalence of HBV DNA in PBMCs, and cccDNA may exist even in patients with undetectable HBV DNA from serum by PCR. The pathogenesis of replication and integration of HBV in PBMCs is unclear. However, it may contribute to viral escape from the immune system and pathogenesis of lympho-proliferative disorders<sup>[15]</sup>.

In order to further reveal the biological role of HbcAg in pathogenesis of replication and integration of HBV in PBMCs, we tried to identify its associated proteins in the present study by the GAL4-based yeast two-hybrid system using HbcAg as bait to screen the human leukocyte cDNA library.

## MATERIALS AND METHODS

### Yeast strains, chemical agents and cultural media

Bacterial yeast strains and plasmids for yeast-two hybrid experiments were obtained from Clontech Co., USA. Yeast strain AH109 (MATa, trp1-901, leu2-3, 112, ura3-52, his3-200, gal4Δ, gal80Δ, LYS2: GAL1UAS-GAL1TATA-HIS3, GAL2UAS-GAL2TATA-ADE2 URA3: MEL1 TATA-lacZ MEL1) containing pGBKT7-53, coding for DNA-BD/mouse p53 fusing protein and AH109 was used for cloning of bait plasmids. Yeast strain Y187 (MATa ura3-52, his3-200, Ade2-101, trp1-901, leu2-3, 112, gal4Δ, gal80Δ, met-, URA3::GAL1UAS-GAL1TATA-lacZ MEL1) containing pTD1-1, in which pACT2 coding for AD/SV40 large T antigen fusing protein and Y187 was used for cloning of library plasmids. Bacterial strain DH5α was used for cloning of each shuttle plasmid. TEMED was from Boehringer Mannheim Co., USA. Tryptone and yeast extracts were from OXOID Co., USA. X-α-Gal and cultural media were from Clontech Co., USA. The primers of PCR were from Boya Co., Shanghai, China.

### Construction of "bait" plasmid

Plasmid pGBKT7-HBcAg (Figure 1) containing full-length HBV core gene was constructed by inserting HBV core gene in-frame into *EcoRI*/*PstI* site, which could directly

express DNA binding domain, *c-myc* and core fusion protein. The construct was verified by restriction digestion and sequencing (Figure 1). The plasmid was transformed into yeast strain AH109 by the lithium acetate method<sup>[16]</sup>. Transformed AH109 was cultured on quadruple dropout media to exclude its auto-activity.

### Expression of HBV core protein

Denatured cell extracts were subjected to electrophoresis using 4-12% SDS-polyacrylamide gels and transferred to nitrocellulose membranes as previously described<sup>[17]</sup>. The membranes were blocked with 5% nonfat dry milk for 1 h and then incubated with monoclonal anti-*c-myc* antibody (Santa Cruz Biotechnology INC, Santa Cruz, CA, USA) for 2 h followed by HRP-conjugated secondary antibody for another 1 h prior to detection of antibody reactive proteins.

### Yeast-two hybrid screening

The screening of leukocyte cDNA library was performed as previously described<sup>[18, 19]</sup>. One large (2-3 mm) fresh (<2 mo old) colony of AH109 [bait] was inoculated into 50 mL of SD/-Trp and incubated at 30 °C overnight (16-24 h) with shaking at 250-270 r/min. Then the cells were spun down by centrifuging the entire 50-mL culture at 1000r/min for 5 min and supernatant decanting the cell pellet was re-suspended in the residual liquid by vortexing. The entire AH109 [bait] culture (beyond 1:10<sup>3</sup>) and 1 mL library (beyond 1:10<sup>3</sup>) were combined and cultured in a 2 L sterile flask and 45 mL of 2 X YPDA/Kan was added and swirled gently. After 20 h mating, the cells were spun down, re-suspended and spread on 25 large (150 mm) plates containing 200 mL of SD/-Ade/-His/-Leu/-Trp (QDO) or 200 mL of SD/-His/-Leu/-Trp (TDO). After 6-18 d, the yeast colonies larger 3 mm in diameter were transferred onto the plates containing X-α-Gal to check expression of the MEL1 reporter gene (blue colonies).

### Isolation of plasmid DNA from putatively positive yeast clones and bioinformatic analysis

Yeast plasmid was isolated using the lyticase method (Clontech Co., USA). The plasmid was transformed into *E. coli* strain DH5α. Transformants were plated on ampicillin LB selection media (SOB) and plasmids were isolated from *E. coli*. Restriction digestion and sequencing analysis were carried out. After the positive colonies were sequenced, the sequence was blasted with GenBank to analogize the function of the genes<sup>[20, 21]</sup>.

### New genes cloned

The coding sequence of new gene was obtained from the cDNA library of proteins binding to core protein of hepatitis B virus by bioinformatic methods, named C1. Standard PCR cloning technique was used to amplify C1 gene. Cytoplasmic RNA of Jurkat cells was isolated and used for RT-PCR. The primer sequences of the sense and antisense are 5'-GAA TTC ATG GAG GAG GTC ATA C-3' and 5'-GGA TCC TTA CCA GGG ACA CAG T-3', respectively. The PCR products were cloned with pGEM-T vector (Promega Co., USA). Primary structure of the insert was confirmed by direct sequencing.

**Table 1** Sequence analysis of 18 clones interacted with the HBcAg protein

Known genes	Clone number	Homology (%)
Homo sapiens hypermethylated in cancer 2 (HIC2)	3	98-100
Homo sapiens eukaryotic translation elongation factor 2 (EEF2)	2	100
Homo sapiens acetyl-Coenzyme A synthetase 3	1	99
Homo sapiens DNA polymerase gamma (POLG), nuclear gene encoding mitochondrial protein	1	99
Homo sapiens putative translation initiation factor(SUI1)	1	99
Homo sapiens chemokine (C-C motif) receptor 5	1	100
Homo sapiens mitochondrial ribosomal protein L41 (MRPL41), nuclear gene encoding mitochondrial protein	1	100
Homo sapiens Kyot binding protein	1	99
Homo sapiens mRNA for RanBPM	1	99
Homo sapiens HBcAg-binding protein 3 (HBEBP3)	1	99
Homo sapiens programmed cell death 2 (PDCD2)	1	100
New genes with unknown function	4	97-100

### Interaction between HBV core protein and new gene C1-translated protein in yeast

PGADT7-C1 plasmid was constructed and transformed into yeast strain Y187 using the lithium acetate method after sequencing analysis. Mating experiments were carried out by mating yeast strain AH109 containing pGBKT7-HBcAg plasmid with Y187 containing pGADT7-C1. The diploid yeasts were plated on media lacking leucine, tryptophan, histidine and adenine<sup>[22]</sup>.

## RESULTS

### Construction of "bait" plasmid pGBKT7-HBcAg and expression of "bait" fusion protein

The full-length HBcAg gene was cloned into the yeast two-hybrid BD vector at the *EcoR* I and *Pst* I sites. The construct was verified by restriction digestion and sequencing (Figure 1).

Western blotting was performed to confirm the expression of the fusion protein using *c-myc* monoclonal antibody. Yeast strain AH109 transformed with pGBKT7-HBcAg could stably express the fusion protein at a high level but could only grow on SD/-Trp medium (Figure 2).

### Yeast-two hybrid cloning of protein interacting with HBcAg

HBV-core protein was used as the bait for screening

human yeast-two hybrid leukocyte cDNA library. The clones growing in the absence of tryptophan, leucine, histidine and adenine were processed for  $\beta$ -galactosidase assay, and blue colonies were picked. As the plasmid pACT2 contains two sites for *Bgl*/II enzyme digestion, we could get the screening gene fragment of leukocyte library by *Bgl*/II enzyme digestion (Figure 3). The different size of DNA segments showed that the screening colonies were positive clones.

### Sequence analysis of positive clones

Nucleotide sequences of the clones from the cDNA library were analyzed, the full-length sequences were obtained with Vector NTI 6 and BLAST database homology search (<http://www.ncbi.nlm.nih.gov/>) (Table 1).

### Confirmation of new gene expression by RT-PCR

The PCR products were cloned with pGEM-T vector. The direct sequencing showed the ORF of C1 (Figure 4, Figure 5). The full length of the coding rank contained 366 nucleotides, and the coding product consisted of 121 amino acid residues (GenBank accession number: AY555145).

of HBcAg and new gene C1-translated protein) in yeast, mating experiments were carried out by mating yeast strain AH109 containing the plasmid of pGBKT7-HBcAg with Y187 containing pGADT7-C1. The diploid yeast cells were plated on QDO (Figure 6).

## DISCUSSION

The interaction of proteins is the basement of life, and gene shows its function only by this way. The yeast-two hybrid system relies on the modulating properties of eukaryotic site-specific transcriptional activators for the detection and analysis of protein-protein, protein-DNA and protein-RNA interactions. This onslaught of genomic information calls for the development of efficient experimental strategies to gain insight into the organization and function of the encoded proteins. The yeast-two hybrid system can detect protein-protein interactions. Yeast-two hybrid system 3 is based on the originally designed system<sup>[23-25]</sup>. In this system, the promoters controlling HIS3, ADE2, and MEL1 expression in AH109 have significantly fewer false positives and the simple mating protocol significantly reduces the labor and time involved in performing a yeast-two hybrid library screening and improves the chances of finding rare protein-protein interactions and leads to more reproducible results<sup>[26,27]</sup>.

HBcAg has a conservative three-dimensional structure, 21 kD. Its C-terminal 150-185 aa is rich in arginine region. One function of the arginine-rich region is to provide interactions between core protein and RNA pregenome. Packaging the viral pregenomic RNA into HBV nucleocapsid (core particle) is a crucial function of the core protein<sup>[28]</sup>. The C-terminal is in the region of interaction between HBcAg and RNA/DNA and is phosphorylated by cell kinase. Phosphorylation is very important for the synthesis and replication of DNA. Phosphorylation of the core protein is an important step in viral replication cycle necessary for transport of the viral genome to the nuclei<sup>[29, 30]</sup>. HBV capsid or core protein binds to nucleic

acid through a carboxy-terminal protamine region containing nucleic acid-binding motifs organized into four repeats (I to MV). Core proteins contain nuclear localization signals (NLS) in their COOH termini and mediate HBcAg into nuclei<sup>[29, 31]</sup>. HBcAg showing a high immunogenicity can directly activate B lymphocytes by binding to the region of FR1-CDR1 of B cells<sup>[7]</sup>.

HBV has been found in numerous extrahepatic cells including PBMCs. However, their role in HBV infection and viral persistence remains unclear. The presence of HBV-DNA and HBV-RNA in PBMCs has been demonstrated by Pontisso *et al*<sup>[32]</sup>. Polymerase chain reaction (PCR) showed that HBV infection of PBMCs is a common event in acute and chronic hepatitis B<sup>[33]</sup>. Since HBV is cytopathogenic, viral proteins elicit a modulating influence on the gene expression of infected immunocompetent cells<sup>[34]</sup>.

In our study, the bait plasmid pGBKT7-HBV core was constructed and the gene of HBcAg was expressed in yeast AH109. We identified 18 colonies coding for 11 different proteins. These genes encode proteins involving in cell signal transduction, cancer development, and immunity pathogenesis. The two families of chemokines were distinguished on the arrangement of the first two of four conserved cysteines. The  $\alpha$ -chemokine is characterized by two cysteine amino acids separated by another amino acid (C-X-C motif), while the  $\beta$ -chemokine has two adjacent cysteine residues (C-C motif). The majority of  $\beta$ -chemokines are monocyte chemoattractants. Chemokine receptors are members of the seven receptors of transmembrane or serpentine family<sup>[35, 36]</sup>. The receptors are G-protein-linked and transducer signals via phospholipase C. This subsequently leads to a rise in intracellular calcium concentration and activation of protein kinase C. Chemokine (C-C motif) receptor 5 contains monocytes, but it was reported that CCR5 can be expressed on Th1 and Th2 cells selectively<sup>[37]</sup>. HIV can infect the Th1 cells by synergistic action of CCR5, and cause fusion of the infected cells and HIV diffusion<sup>[38]</sup>.

A candidate tumor suppressor gene hypermethylated in cancer (HIC-1) has been identified because of its association with a "CpG island" at 17p13.3 that is hypermethylated and transcriptionally inactivated in several common types of human cancers<sup>[39]</sup>. HIC encodes a typical nuclear BTB/POZ protein with five Kruppel-like C<sub>2</sub>H<sub>2</sub> zinc finger motifs in its C-terminal and a BTB/POZ domain at its N-terminal. BTB/POZ protein found in developmentally regulated transcription factors and actin-binding proteins is associated with C<sub>2</sub>H<sub>2</sub> zinc finger motifs in proteins involved in transcriptional regulation through chromatin modeling<sup>[40, 41]</sup>. Kyot binding protein genes code for KBP1, KBP2, KBP3. KyoT2 binds to KBP in LIM, which is rich in amino-3-mercaptopropionic acids and can bind to ZN and protein kinase C<sup>[42]</sup>. RanBPM cDNA codes for a 90 kD protein. RanBPM is a peripheral membrane protein. Integrins and RanBPM interact *in vitro* and *in vivo* and co-localize on the cell membrane. RanBPM may constitute a molecular scaffold that contributes to coupling. The leukocyte integrin lymphocyte function-associated antigen 1 (LFA-1) and other integrins are found to intracellular signaling pathways. Ran is a Ras-like GTPase, which can transport nucleoplasm, assemble microtubules and form nuclear membrane. RanBPM exists in the center of cells as a receptor of Ran related with transport nucleoplasm<sup>[43-45]</sup>.

In our study, 4 new genes with unknown function were identified. One of these new genes was named C1 with no homology sequence in GenBank. By electron splicing, the opening reading code framework and full-length of this gene were concluded. The gene can be transcribed from the mRNA of Jurkat cells by RT-PCR. The PCR product was analyzed by T-A sequence. The full length of the coding rank contained 366 nucleotides, and the coding product consisted of 121 amino acid residues. The pGADT7-C1 plasmid was constructed and transformed into the yeast strain Y187. The Y187 and AH109 were mated, the result showed that the two proteins could bind to each other.

In conclusion, HBcAg can bind to proteins in leukocytes.

## Abstract

**AIM:** To investigate the *in vivo* effect of atrial natriuretic peptide (ANP) and its signaling pathway during orthotopic rat liver transplantation.

**METHODS:** Rats were infused with NaCl, ANP (5 µg/kg), wortmannin (WM, 16 µg/kg), or a combination of both for 20 min. Livers were stored in UW solution (4 °C) for 24 h, transplanted and reperused. Apoptosis was examined by caspase-3 activity and TUNEL staining. Phosphorylation of Akt and Bad was visualized by Western blotting and phospho-Akt-localization by confocal microscopy.

**RESULTS:** ANP-pretreatment decreased caspase-3 activity and TUNEL-positive cells after cold ischemia, indicating antiapoptotic effects of ANP *in vivo*. The antiapoptotic signaling of ANP was most likely caused by phosphorylation of Akt and Bad, since pretreatment with PI 3-kinase inhibitor WM abrogated the ANP-induced reduction of caspase-3 activity. Interestingly, analysis of liver tissue by confocal microscopy showed translocation of phosphorylated Akt to the plasma membrane of hepatocytes evoked by ANP.

**CONCLUSION:** ANP activates the PI-3-kinase pathway in the liver *in vivo* leading to phosphorylation of Bad,

## INTRODUCTION

Ischemia reperfusion injury (IRI) is responsible for primary liver dysfunction and failure after transplantation or liver resection<sup>[1,2]</sup>. Therefore, reduction of IRI is of high clinical interest. In order to develop preventive strategies, knowledge of the mechanisms leading to cell death after IR is pivotal. The mode of cell death after IR is originally considered to be necrotic, but there is increasing evidence that apoptosis plays a role<sup>[3-5]</sup>. Apoptosis is a highly regulated process resulting in nuclear fragmentation and condensation as well as disintegration of cells into apoptotic bodies without release of cell contents. Subsequently, tissue macrophages such as Kupffer cells phagocytose the apoptotic bodies. In contrast to apoptosis, necrosis is a passive process characterized by cell lysis. Usually, necrosis of cells causes a local inflammation. However, it has been recognized that apoptotic cells also induce inflammatory response by triggering neutrophil accumulation into the liver<sup>[6]</sup>. Thus antiapoptotic strategies convey protection against hepatic IRI. Apoptosis occurs during the early phase of reperfusion after liver ischemia and after transplantation<sup>[3,5,7]</sup>. However, the extent to which it occurs and most importantly its relevance in IRI is still a matter of debate, which might be due to different experimental models for liver IRI<sup>[5,7]</sup>.

Atrial natriuretic peptide (ANP) belongs to the natriuretic peptide family including a number of peptides possessing vasodilating, hypotensive and natriuretic activities<sup>[8]</sup>. In addition to this cardiovascular profile there

is ample evidence that ANP exerts cytoprotective actions in various cells and organs besides the liver<sup>[9-12]</sup>.

In the model of isolated perfused rat liver we observed a rather low amount of apoptotic cells after cold ischemia compared to other reports<sup>[3]</sup>. We could further show that pretreatment of liver with ANP could lead to a significant reduction of hepatocyte apoptosis and necrosis<sup>[3]</sup>. ANP-treatment has also been shown to be beneficial in isolated rat hepatocytes exposed to hypoxia<sup>[13]</sup>.

This study was to examine the effect of ANP-preconditioning in an *in vivo* model of liver IRI (rat orthotopic liver transplantation IRI) and the mechanism of cell protection.

## MATERIALS AND METHODS

### Materials

Rat ANP, wortmannin and protein kinase A assay kit were purchased from Calbiochem/Novabiochem (Bad Soden, Germany), Complete<sup>®</sup> was from Roche Diagnostics GmbH (Mannheim, Germany). Rabbit anti-Akt antibody, monoclonal mouse anti-phospho Akt (Ser473) antibody, rabbit anti-phospho Akt (Ser473) antibody, rabbit anti-phospho Bad (Ser136) antibody, rabbit anti-phospho Bad (Ser112) antibody and rabbit anti-Bad antibody were from New England Biolabs GmbH (Frankfurt, Germany). Goat anti-rabbit-IgG was from Dianova (Hamburg, Germany) and goat anti-mouse-IgG1 antibody conjugated to horseradish peroxidase was from BIOZOL (Eching, Germany). The secondary antibody (Alexa Fluor 488 goat anti-mouse) and rhodamine-conjugated phalloidin were from MoBiTec (Göttingen, Germany), [ $\gamma$ -<sup>32</sup>P]-ATP was from Amersham-Pharmacia (Braunschweig, Germany) and the ApopTaq<sup>®</sup> peroxidase *in situ* apoptosis detection kit was from Inter-gen (New York, USA). All other materials were purchased from either Sigma (Taufkirchen, Germany) or VWR International<sup>™</sup> (Munich, Germany).

### Animals and orthotopic liver transplantation

Syngeneic male Lewis rats (donors: 207±12 g; recipients: 276±18 g) were purchased from Charles River Wiga (Sulzfeld, Germany) and housed in a temperature- and humidity-controlled room under a constant 12 h light/dark cycle. Animals had free access to water and rat chow (SSniff, Soest, Germany), but were fasted with free access to water 12 h prior to the operation. All animals received humane care according to the criteria outlined in the "Guide for the Care and Use of Laboratory Animals" published by the National Institute of Health (NIH publication 86-23 revised 1985). Studies were performed with the permission of the government authorities.

In transplantation experiments donor animals obtained either an intravenous infusion of NaCl or ANP (5 µg/kg). For investigation of signalling pathways additional rats were treated with wortmannin (16 µg/kg), DMSO (0.1%), or a combination of ANP and wortmannin for 20 min prior to hepatectomy. Blood pressure and heart rate were continuously monitored by a catheter in the carotid artery. A jugular venous catheter served to apply substances and substitute plasma volume. Body temperature was kept at 36.5 - 37.5 °C by means of a heating pad. Donor liv-

ers were preserved by retrograde aortal flush with 10 mL UW-solution and stored at 4 °C for 24 h. Before implantation, the livers were rinsed with cold Ringer's solution (10 mL) *via* the portal vein at a hydrostatic pressure of 10 cm H<sub>2</sub>O. Orthotopic liver transplantation was performed as previously described<sup>[4]</sup>. Grafted livers were simultaneously reperfused after completion of the arterial anastomosis. Portal clamping time was less than 20 min in all experiments.

The graft's common bile duct was cannulated with a PE-tube and bile was collected with its volume determined. Plasma samples (400 µL) were obtained from the recipient before hepatectomy and 60 and 120 min after reperfusion of the transplanted liver. The volume of the blood drawn was replaced by saline. After starting reperfusion, rats received 1.0 mL of albumin (5%) and 0.5-1.0 mL sodium bicarbonate to maintain blood pressure and physiological pH. To avoid fluid loss and drying of the liver, the abdominal cavity was covered with Saran wrap. After 20 min preconditioning, 24 h cold ischemia, or 120 min reperfusion, organs were placed in 4% paraformaldehyde or snap frozen in liquid nitrogen.

### Histological analysis of tissue

Liver samples were fixed in paraformaldehyde, embedded in paraffin, and cut into 6 µm sections. TUNEL positive cells<sup>[15]</sup> were determined by staining of liver sections with the ApopTaq<sup>®</sup> peroxidase *in situ* apoptosis detection kit according to the manufacturer's instructions. The ApopTaq<sup>®</sup> staining results were evaluated in combination with morphological criteria. For counting of apoptotic cells, an area of 1.96 mm<sup>2</sup> (approximately 4000 hepatocytes) was observed by a Leitz Laborlux S microscope.

For analysis of pAkt snap frozen livers were cut into 6 µm sections. Slices were dried overnight at room temperature. Staining of pAkt was performed using the monoclonal anti-pAkt antibody in 0.2% BSA as the primary antibody (1 h, RT) and Alexa Fluor 488 goat anti-mouse antibody (1 h, RT). Sections were observed under confocal laser microscope (LSM 510 Meta, Zeiss, Jena, Germany). All histological evaluations were performed in a blinded fashion.

### Homogenization of liver tissue for Western blotting

Fifty mg of liver tissue was homogenized in 1.5 mL of lysis buffer (50 mM Tris-HCl, 5 mM EGTA, 1 mM PMSE, 1 mM Na-vanadate pH 7.0, 40 µL Complete<sup>®</sup>) containing 1% Triton<sup>®</sup> X-100 (Roth, Karlsruhe, Germany) with a dounce homogenizer. After centrifugation of samples (14 000 r/min, 15 min, 4 °C), the supernatant was diluted with SDS-containing sample buffer. Samples were stored at -20 °C for Western blotting.

### Immunoprecipitation

Liver tissue was homogenized as described above, 100 µg of protein in 100 µL lysis buffer was incubated with 2.5 µL of primary antibody (rabbit anti-Bad) shaking overnight at 4 °C. The antibody-antigen complex was precipitated by incubation with 10 µL of washed agarose-A-beads for 2 h, followed by centrifugation. The beads were washed three times with cold lysis buffer, and resuspended in 40 µL of 3

**Figure 1** Effect of ANP pretreatment on apoptotic cell death after 24 h ischemia. Animals received an intravenous infusion of NaCl (Co) or ANP (5 µg/kg) for 20 min and livers were kept in cold UW-solution for 24 h. **A:** Caspase-3 activity: Snap-frozen tissue was homogenized and caspase-3 like activity was determined as described. Data were expressed as percentage of caspase-3 activity in untreated livers (100%). Columns show mean  $\pm$  SE,  $n=4$  animals in each group. <sup>b</sup> $P<0.01$  vs NaCl treatment. **B:** TUNEL assay: Snap-frozen tissue was cut into 6 µm slices. TUNEL staining was performed as described and apoptotic liver cells per field of view (1.96 mm<sup>2</sup>) were counted. Results were expressed as means  $\pm$  SE,  $n=4$  in each group. <sup>a</sup> $P<0.05$  vs NaCl treatment.

$\times$  SDS-containing sample buffer. After addition of 40 µL 1 $\times$  sample buffer samples were boiled at 95 °C for 5 min followed by centrifugation.

### Western blotting

Homogenized livers were treated as described before. Proteins in total liver homogenates or immunoprecipitates were separated by SDS-Page and visualized after electrophoretic transfer via binding of specific primary and HRP-conjugated secondary antibodies followed by chemoluminescent detection. Detection and quantification were performed with a Kodak image station (NEN, Cologne, Germany).

### PKA activity assay

A commercial PKA assay kit was used. Samples (100 µg) were homogenized in "extraction buffer" and centrifuged

as described in the manufacturer's manual. Supernatants were used for measurement of phosphorylation activity of PKA by *in vitro* phosphorylation of the specific peptide substrate kemptide with [ $\gamma$ -<sup>32</sup>P]-ATP.

### Caspase-3 like activity assay

After homogenization of 100 mg liver tissue in 1 mL lysis buffer (25 mM HEPES, 5 mM MgCl<sub>2</sub>, 1 mM EGTA, pH 7.5, Complete<sup>®</sup>), samples were centrifuged (14 000 r/min, 10 min, 4 °C). Caspase-3 like activity in the supernatants was determined as previously reported<sup>[3]</sup>. Generation of free fluorescent 7-amino-4-trifluoro-methylcoumarin was measured with a Fluostar analyser (BMG GmbH, Offenburg, Germany).

### Statistical analysis

All experiments were performed at least three times per treatment group. Results were expressed as mean  $\pm$  SE. Statistical significance between groups was determined with one sample or Student's *t* test using GraphPad Prism<sup>®</sup> Version 3.02 for Windows (GraphPad Software Inc., San Diego, USA).  $P<0.05$  was considered statistically significant.

## RESULTS

### Reduction of apoptotic cell death *in vivo* induced by ANP-pretreatment

Apoptotic processes were monitored by measuring caspase-3 activity and TUNEL staining of liver sections. After 24 h cold ischemia, an increase of hepatic caspase-3 activity (40.5%) compared to sham operated animals was observed, which sustained after 2 h reperfusion (25%). Figure 1A demonstrates a significant attenuation of caspase-3 activity by ANP-preconditioning, which was also observed in 2 h reperused organs after 24 h cold storage.

TUNEL-staining of corresponding liver sections confirmed these data. After 24 h cold ischemia apoptotic cells were most prominent. Both hepatocytes and endothelial cells showed positive TUNEL staining combined with characteristic apoptotic morphology.

Figure 1B shows that preconditioning of donor livers with ANP (5 µg/kg) significantly decreased the number of TUNEL-positive cells after 24 h cold ischemia. A similar although less pronounced effect was observed after 2 h reperfusion.

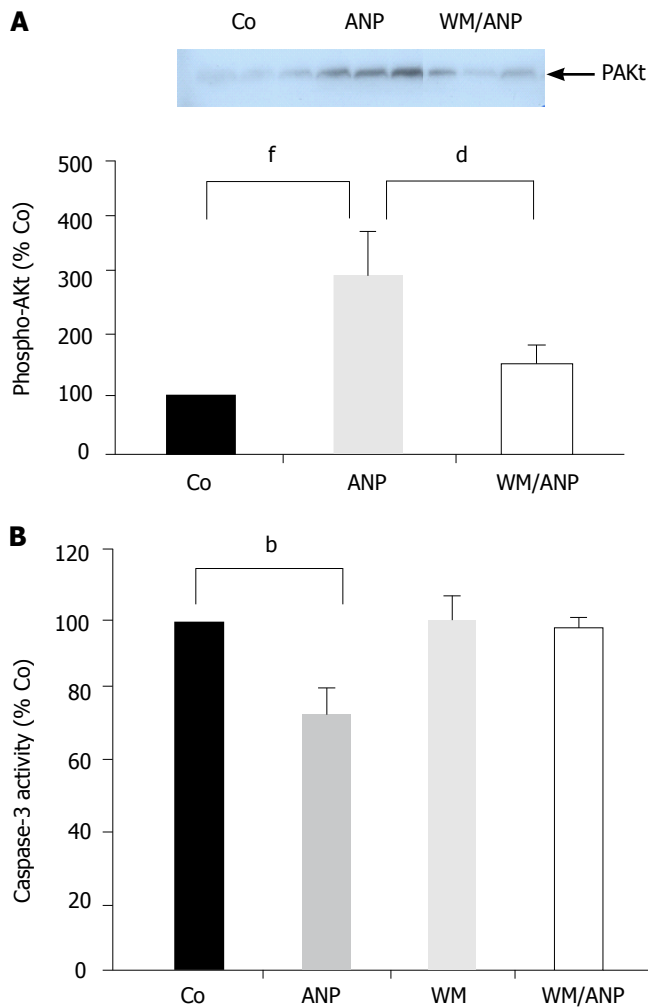

### Activation of PI-3-Kinase/Akt pathway induced by ANP pretreatment

Infusion of ANP (5 µg/kg) for 20 min into the donor animals resulted in a marked increase of phosphorylated Akt (pAkt) in the liver, which was abrogated in the presence of the PI-3-Kinase inhibitor wortmannin (Figure 2A).

### Antiapoptotic effects of ANP induced by Akt activation

Figure 2B demonstrates that application of wortmannin (16 µg/kg) prior to ANP infusion completely blocked the inhibition of caspase-3 activity by ANP seen in ischemic liver tissue (24 h). Thus, the PI-3-Kinase pathway was intimately involved in the antiapoptotic effect of ANP-

**Figure 2** Effect of ANP-preconditioning on PI-3-kinase/Akt pathway. **A:** After intravenous infusion of NaCl (Co), ANP (5 µg/kg), wortmannin (WM, 16 µg/kg), or a combination of both (WM/ANP) for 20 min livers were excised and snap frozen. pAkt was examined via Western blotting. Data obtained from densitometry were presented as percent of Co (100%) and expressed as mean ± SE,  $n=4$  in each group.  $^aP < 0.01$  vs ANP treatment;  $^bP < 0.001$  vs Co treatment. **B:** Animals were treated as described under A. After 24 h ischemia livers were homogenized and caspase-3 activity was determined as described before. Data were expressed as percent of caspase-3 activity in untreated livers (Co, 100%) and mean ± SE,  $n=4$  in each group.  $^bP < 0.01$  vs WM treatment.

preconditioning.

#### Translocation of activated Akt to plasma membrane induced by ANP

Analysis of pAkt in liver tissue by confocal microscopy confirmed that ANP-pretreatment could lead to a marked increase of pAkt. Interestingly, confocal microscopy revealed a strong localization of pAkt at the plasma membrane of hepatocytes (Figures 3A, 3B). Cotreatment of animals with wortmannin abrogated both the increase as well as the plasma membrane localization of pAkt induced by ANP (Figure 3C).

#### Phosphorylation of antiapoptotic Bad due to Akt activation by ANP

To further examine the antiapoptotic signalling in the liver induced by ANP *in vivo*, a pivotal downstream target of pAkt (the Bad protein) was investigated. A representative Western blot indicated that Bad was phosphorylated at

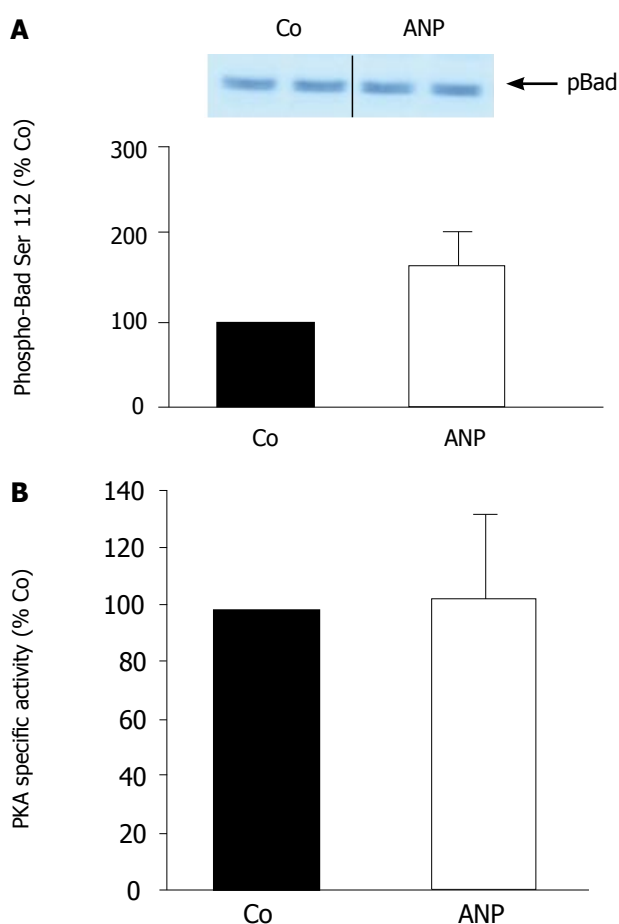

**Figure 3** Effect of ANP-preconditioning on distribution and amount of pAkt in liver by confocal microscopy. Animals were infused with NaCl (Co, **A**), ANP (**B**), or a combination of ANP and wortmannin (WM/ANP, **C**) for 20 min. Livers were snap-frozen, cut into 6 µm slices and stained with rhodamine-conjugated phalloidin (F-actin, cytoskeleton, red), HOECHST dye (nuclei, blue), and anti-pAkt antibody, followed by incubation with Alexa Fluor 488 goat anti-mouse antibody (green) as described before. Liver sections were observed under confocal laser microscope ( $\times 63$  amplification).

**Figure 4** Effect of ANP-preconditioning on phosphorylation of Bad at Ser136. After intravenous infusion of NaCl (Co), ANP (5  $\mu$ g/kg), or a combination of ANP and wortmannin (WM/ANP) for 20 min livers were excised and snap frozen. Homogenized livers were immunoprecipitated using anti-Bad antibody. Examination of pBad (Ser136) was done via Western blotting. Data obtained by densitometry were presented as mean  $\pm$  SE,  $n=4$  in each group. Co was set as 100%. <sup>b</sup> $P < 0.001$  vs control.

**Figure 5** Effect of ANP pretreatment on phosphorylation of Bad at Ser112 and PKA-activity. **A:** Animals received an intravenous infusion of NaCl (Co) or ANP (5  $\mu$ g/kg) for 20 min. Homogenized livers were immunoprecipitated using anti-Bad antibody. Examination of phospho-Bad (Ser112) was done via Western blotting. Data obtained in densitometric analysis were presented as mean  $\pm$  SE,  $n=3$  in each group. Co was set as 100%. **B:** PKA activity was determined in liver homogenates used under (A) by *in vitro* phosphorylation as described. Results were expressed as percent of PKA activity in untreated livers and mean  $\pm$  SE,  $n=4$  in each group.

Ser136 by pAkt induced by ANP (Figure 4). ANP *in vivo* did not activate PKA and consequently phosphorylated Bad at Ser112 (Figure 5A, Figure 5B).

## DISCUSSION

This study showed that pretreatment of rats with ANP could reduce apoptotic processes mainly occurring after 24 h cold ischemia in orthotopic rat liver transplantation. In this setting ANP activated the PI-3-Kinase/Akt pathway leading to Bad phosphorylation and inhibition of caspase-3 activity, revealing that the PI-3-Kinase/Akt pathway is an important cytoprotective mechanism in IRI *in vivo*.

PI-3 Kinases are heterodimers composed of a catalytic subunit (p110) and a regulatory subunit (p85) activated by receptors with protein tyrosine kinase activity as well as G-protein-coupled receptors<sup>[16, 17]</sup>. Various growth factors such as IGF-1 activate PI-3-Kinase leading to the generation of phosphoinositides [PI(3,4,5)P<sub>3</sub>] and activation of Akt, a 57 kDa Ser/Thr kinase. PI-3-kinase regulates Akt kinase activity by generated phospholipids<sup>[16, 17]</sup>. One mechanism is through the direct binding of phosphoinositides to the pH domain of Akt, which seems to be critical for the *in vivo* activation of Akt. A consequence of Akt binding to phospholipids is the translocation of Akt from cytoplasm to the inner surface of plasma membrane<sup>[16, 17]</sup>. This translocation which we also observed in hepatocytes pretreated with ANP, is important for Akt activation. In fact, protection from apoptotic stimuli in cardiomyocytes and liver has been demonstrated using adenovirally mediated gene transfer of membrane-targeted constitutively activated Akt<sup>[18-21]</sup>. However, the constitutively activated form of Akt targeted to the cell membrane results in supraphysiological levels of kinase activity having the potential to induce oncogenic transformation. These issues of feasibility and safety concerning an Akt gene therapy are certainly much less relevant in a setting of Akt activation by endogenous stimulators such as ANP or others<sup>[22-25]</sup>.

Up to now, protective effects of ANP against IRI have only been demonstrated in *ex vivo* and *in vitro* settings such as isolated perfused rat liver<sup>[3]</sup>, isolated liver cells<sup>[13, 26]</sup>, and isolated ischemic heart<sup>[27]</sup>. The underlying mechanisms seem to be highly dependent on the experimental model used. For instance, as recently described in the *ex vivo* model, ANP protects hepatocytes from apoptosis after cold ischemia by activation of PKA<sup>[28]</sup>. ANP treatment of hypoxic isolated rat hepatocytes confers its cytoprotection *via* PKC  $\sigma$  and activation of p38 MAPK<sup>[13]</sup>. This difference might be explained by different modes of cell death analyzed. Focusing on apoptotic cell death, our data showed that the *in vivo* setting revealed a different protective signaling, i.e. activation of the PI-3-kinase/Akt pathway compared to the isolated perfused rat liver subjected to IR. Accordingly, activation of Akt can also protect livers against warm IRI<sup>[21]</sup>. Importantly, both pathways, PKA activation and Akt activation, lead to phosphorylation and inactivation of Bad protein, suggesting that this protein plays a key role in ANP-induced prevention of ischemia-induced apoptosis.

Bad is a member of the family of Bcl-2 proteins func-

tioning as apoptosis-regulating factors<sup>[29, 30]</sup>. Bad in its unphosphorylated form binds to and inactivates antiapoptotic proteins such as Bcl-2 and Bcl-XL leading to proapoptotic functions. Phosphorylation of Bad at either of the two potential sites (Ser112, Ser136) causes Bad to dissociate from Bcl-2 or Bcl-XL respectively and to associate instead with cytoplasmic 14-3-3 proteins preventing Bad from dephosphorylation<sup>[16]</sup>. Akt phosphorylates Bad at Ser136 *in vivo* and mutation of Bad Ser136 to alanine abrogates the blocking effect of Akt in Bad-induced apoptosis. In any case, Bad plays a key role in the Akt survival signalling since Bad phosphorylation leads to prevention of cytochrome C release from mitochondria, a hallmark of apoptosis induction<sup>[16]</sup>.

We would like to point out that besides acting through Bad phosphorylation Akt brings about its function also by a variety of other downstream targets, such as caspase-9, forkhead family members or the eNOS enzyme<sup>[16]</sup>. Akt-mediated phosphorylation and activation of the eNOS enzyme have been reported to be involved in the antiapoptotic effect of insulin in myocardial IR<sup>[25]</sup>. In line with this report a blockade of the NO synthase worsens hepatic apoptosis and liver transplant preservation injury<sup>[31]</sup>. Since we did not observe increased phosphorylation of eNOS in ANP-pretreated livers (data not shown), this mechanism does not contribute to the antiapoptotic action of ANP.

In conclusion, Bad inactivation by phosphorylation should be considered as an important therapeutic target preventing IRI during liver transplantation.

## ACKNOWLEDGEMENTS

## Abstract

**AIM:** Pouchitis develops in ileoanal pouches in up to 50% of patients with ulcerative colitis during the first 10 years after pouch surgery while being rare in patients after proctocolectomy for familial adenomatous polyposis coli (FAP) syndrome. Defensins are major components of the innate immune system and play a significant role in gastrointestinal microbial homeostasis. Pouch defensin and cytokine expression were correlated with states of pouch inflammation to study their role in pouchitis.

**METHODS:** Patients with ulcerative colitis and FAP syndrome were stratified into groups with pouches after surgery, pouches without or with pouchitis. Biopsies from terminal ileum from a healthy intestine or from normal terminal ileum of patients with ulcerative colitis served as controls. mRNA from pouches and controls was analysed for defensin and cytokine expression.

**RESULTS:** Expression of defensins was increased in all pouches immediately after surgery, compared to ileum of controls. Initially, pouches in ulcerative colitis revealed higher defensin expression than FAP pouches. Defensin expression declined in both patient groups and increased again slightly in pouchitis in patients with ulcerative colitis. FAP pouches without pouchitis had strong expression of  $\beta$ -defensin hBD-1, while all other defensins remained at low levels. Cytokine expression in ulcerative colitis pouches was high, while FAP pouches showed moderately elevated cytokines only after surgery.

**CONCLUSION:** Development of pouchitis correlates

## INTRODUCTION

Pouchitis is a major long term complication after proctocolectomy and ileoanal pouch anastomosis. Up to 50% of patients with ulcerative colitis experience at least one episode during the first ten years after surgical pouch construction while pouches in patients with familial adenomatous polypoid (FAP) syndrome have pouchitis rates below 5%<sup>[1,2]</sup>. The causes of primary pouchitis remain uncertain, while secondary pouchitis is usually being caused by conditions that respond to surgical treatment (e.g. fistulas, local ischemia). Pouchitis develops when the faecal stream is re-diverted towards the pouch after closure of a protective ileostomy indicating the involvement of bacteria in the pathomechanism of pouchitis<sup>[3]</sup> which is further substantiated by the effective treatment of pouchitis with antibiotics<sup>[4]</sup>.

Ulcerative colitis is a chronic inflammatory disorder of the intestine of unknown aetiology. Immunologic and genetic determinants appear to be major disease factors, but environmental factors and impaired host defense mechanisms emerge to be of significant importance<sup>[5,6,7]</sup>. The epithelial defense lines against microbial insults comprise co-ordinated actions of the innate and the acquired immune responses. Thus, defects of these mechanisms might result in an overgrowth of normal colonic flora with increases in aerobic bacteria in addition to the appearance of atypical bacteria and fungi<sup>[8]</sup>. Finally, local invasion of microbials and induction

of inflammatory responses causes self-destructive injury.

The FAP syndrome is caused by genetic changes leading to growth of colonic polyps. For both disorders, ulcerative colitis and FAP syndrome, ileoanal pouch procedure is a valuable therapeutic option to prevent development of colorectal cancer.

$\alpha$ - and  $\beta$ -defensins are major components of the epithelial mammalian innate immune system<sup>[9]</sup>. Defensins are small cationic peptides with high activity against a variety of microbes, encoded by genes and some are regulated in response to challenge with bacterial antigens. Gastrointestinal  $\alpha$ -defensins (HD5 and HD6) are almost exclusively expressed in and secreted from Paneth cells of the small intestine, while  $\beta$ -defensins (hBD-1, hBD-2, hBD-3) are secreted by virtually all gastrointestinal epithelial cells to a varying extent<sup>[10,11]</sup>. Defensins are envisaged to play significant roles in intestinal microbial homeostasis and in the primary defence against enteric and systemic infections<sup>[9,12]</sup>. In the present study we analysed defensin expression in ileoanal pouches of patients with ulcerative colitis and FAP syndrome. Pouches were stratified into groups with ileostoma-protected pouches after surgery, and pouches (after closure of the ileostomy) without or with pouchitis. Expression data of antimicrobial peptides were related with expression of cytokines and the pouch groups to analyse the potential role of defensins as protectors for the development of pouchitis.

## MATERIALS AND METHODS

### Patients

Pouch patients with ulcerative colitis or FAP syndrome as the underlying disease were included. After construction of ileoanal pouches the patients were followed by pouchoscopy and biopsies were collected for histology and RNA analysis. Pouches from patients with ulcerative colitis or FAP syndrome were further stratified into the following groups (Table 1): 1) pouches soon after surgery (without faecal load and with protective ileostoma), 2) pouches after closure of the ileostoma, no signs of pouchitis, 3) pouches with pouchitis. Severity of pouchitis was scored by the pouchitis disease activity index (PDAI), comprising clinical, endoscopic and histologic features<sup>[13]</sup>

and the Moskowitz score to classify histology of pouch biopsies<sup>[14]</sup>.

Biopsies from control patients or from control patients with ulcerative colitis were collected from a macroscopically and histologically healthy terminal ileum. Patients characteristics were comparable between controls, ulcerative colitis and FAP groups, as shown in Table 1.

Two biopsies were examined by histology and two others were immediately snap-frozen in liquid nitrogen for RNA analysis. Microscopy (not shown) of pouch biopsies showed features of metaplasia in all pouches when pouches had been exposed to faeces for several months. There was an increase of mucin-containing cells and with a reduction of villi in the ileal mucosa as previously reported<sup>[15,16,17]</sup>. Electron microscopy also demonstrated an increase of mucin-containing cells while Paneth cells remained stable in number and morphology (not shown). Changes were most pronounced in biopsies from pouches with the most severe signs of pouchitis in endoscopy.

The study was approved by the Ethics Committees of the University of Kiel, Germany and the University of Poznan, Poland (Ref.No. A158/01). All patients gave their written informed consent prior to investigation.

### RNA isolation and cDNA synthesis

Total RNA was extracted from frozen biopsies using silica gel-based spin columns (RNeasy Kit, QIAGEN, Hilden, Germany). Genomic DNA was digested by thorough treatment with deoxyribonuclease I (QIAGEN, Hilden, Germany). Reverse transcription of 2  $\mu$ g RNA was performed using 0.5  $\mu$ g oligo(dT)<sub>15</sub>-primers (You prime First strand cDNA synthesis kit; Amersham Biosciences, Freiburg, Germany) following the manufacturers instructions.

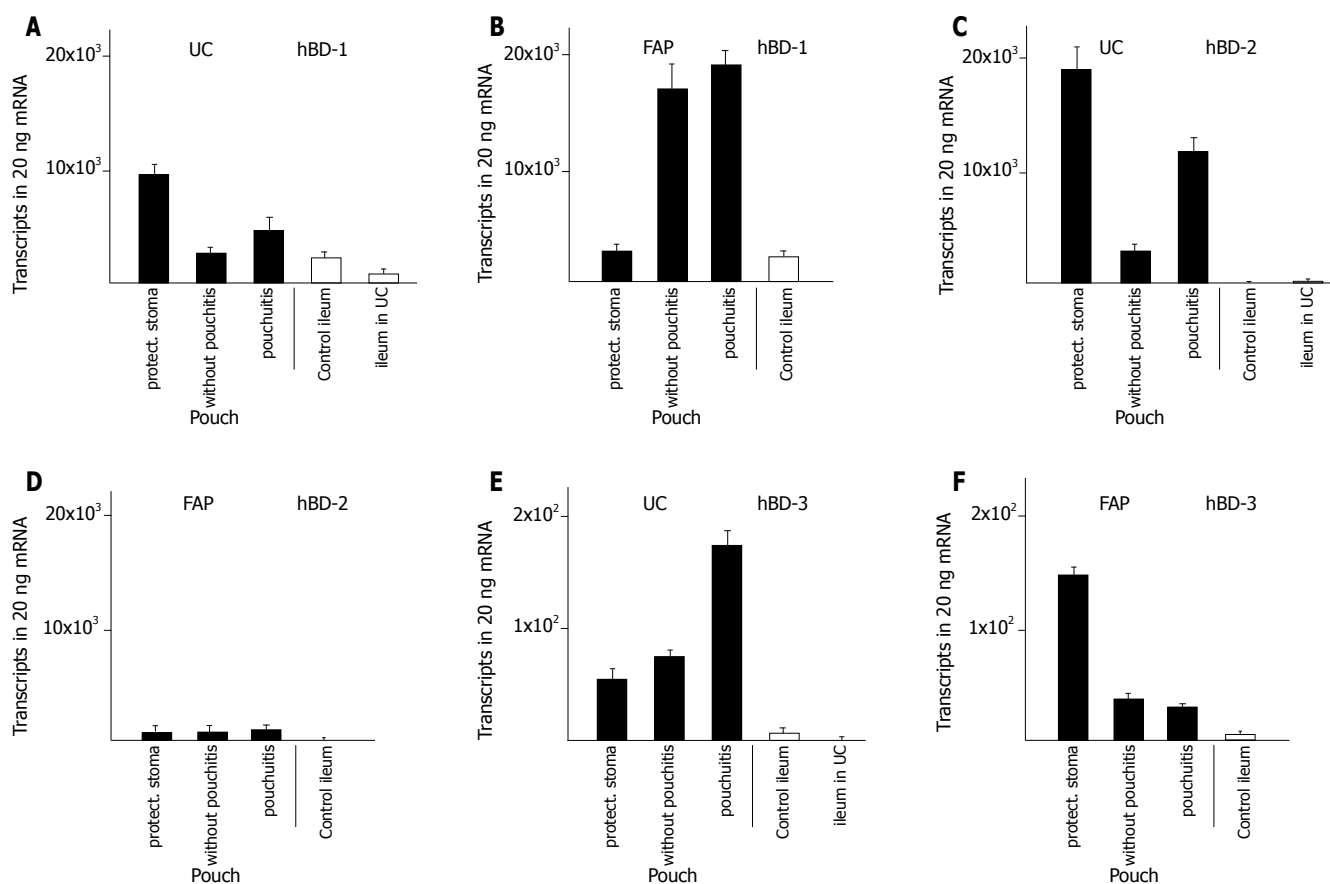

### Primer

Specific intron spanning primers were designed based on the published mRNA sequences using the Primer3 software<sup>[18]</sup> (also available under <http://www-genome.wi.mit.edu/genome-software/other/primer3.html>). Oligonucleotides were obtained from Sigma ARK (Darmstadt, Germany), sequences and product sizes for each primer pair used are depicted in Table 2.

**Figure 1**  $\alpha$ -defensin mRNA expression in pouches of patients with ulcerative colitis (UC) and FAP syndrome. mRNA was extracted from biopsies, reverse transcribed and analysed by quantitative real time RT-PCR. Expression of HD5 (A, B) and HD6 (C, D) in patients with UC (A, C) and FAP (B, D). Control ileum was from healthy individuals. Ileum in UC was from patients with active UC but with completely normal ileum. Values represent mean  $\pm$  SE.

### Quantification of gene expression by real time PCR

Real-time RT-PCR analyses were performed in a fluorescence temperature cycler (LightCycler, Roche Molecular Biochemicals) according to the manufacturer's instructions. Standard curves for each specific defensin were constructed by cloning the purified PCR-products containing the target sequence into pCR-Blunt II-TOPO vector with 3519 bp (Invitrogen). Clones were sequenced on ALP Express (Pharmacia, Uppsala, Sweden). Concentration of the reference plasmid was measured spectrophotometrically and converted into number of copies /  $\mu\text{L}$  by using the formula: number of copies/ $\mu\text{L}$  =  $(X \text{ g}/\mu\text{L} \text{ plasmid DNA} / Y \times 660) \times 6.023 \times 10^{23}$ , where X is the measured plasmid concentration, Y is the number of nucleotide pairs for the plasmid plus the size of the insert, 660 g/mol is the average molecular weight of a nucleotide pair, and  $6.023 \times 10^{23}$  is Avogadro's number (number of copies/mol). To generate standard curves, the plasmids were serially diluted (1: 10) over the appropriate concentration range. The solvent included unrelated, defensin- sequence free cDNA in a final concentration of 10 ng/ $\mu\text{L}$ . To achieve a reliable standard curve for each measured defensin, the plasmids were PCR- amplified in three replicates for each standard dilution point over the complete range ( $10^7$  to  $10^0$ ). Standard curves were measured repeatedly to calculate averages. The reverse transcribed cDNA from the biopsies corresponding to 20 ng of RNA served as template in a 10  $\mu\text{L}$  PCR reaction containing 4 mmol/L  $\text{MgCl}_2$ , 0,5  $\mu\text{mol/L}$  of each primer and 1x LightCycler-Fast Start DNA Master SYBR Green I mix (Roche Molecular Biochemicals, Mannheim, Germany). Samples were loaded into capillary tubes and incubated in the fluorescence thermocycler (LightCycler) with initial denaturing at 95 °C for 10 min, followed by 45 cycles, each cycle consisting of 95 °C for 15 s for denaturation, primer

specific annealing temperature for 10 s, and 72 °C for 10s for elongation. SYBR Green I fluorescence was detected at the end of each cycle to monitor the amount of PCR product formed during the cycle. At the end of each run, melting curve profiles were produced (cooling the samples to 65 °C for 15 s and then heating slowly at 0.2 °C/s to 95 °C with continuous measurement of fluorescence) to exclude non-specific amplification of transcripts. The absolute mRNA transcript number in each sample was calculated by use of calibration curves. Identical results were obtained in control experiments when the standard plasmids were mixed with cDNA obtained from a variety of sources including cDNA from cultured intestinal mouse STC-1 cells which do not contain defensin transcripts (not shown).

### RT-PCR of cytokines

Reverse transcribed cDNA from biopsies corresponding to 20 ng RNA was used as template in a 10  $\mu\text{L}$  PCR reaction using Taq polymerase in a Thermal cycler (Gene Amp PCR System 2400, Perkin Elmer). PCR started with initial denaturation at 95 °C for 10 min, followed by 30 cycles each consisting of denaturation at 95 °C for 45 s, annealing at 60 °C for 45 s and elongation at 72 °C for 60 s. Elongation in the final PCR cycle was for 7 min. PCR products were resolved by 8% agarose gel electrophoresis

## RESULTS

We established control groups of normal ileum from healthy patients and ileum from patients with active ulcerative colitis but without macroscopic or microscopic involvement in order to obtain parameters to which defensin expression in diseases could be correlated. The expression of  $\alpha$ -defensins HD5 (Figure 1A) and HD6 (Figure 1C) in ileum of patients with ulcerative colitis was

**Table 3 Cytokine expression in ulcerative colitis or FAP pouches**

(+): weak expression in some samples

increased by two to three fold, resp, compared to ileum of healthy controls. The  $\beta$ -defensins HBD-2 (Figure 2C) or hBD-3 (Figure 2E) were present at very low levels in the healthy ileum. HBD-2 expression was increased (from  $3 \pm 1$  to  $149 \pm 110$  transcripts per 20 ng mRNA) in the ileum in patients with ulcerative colitis but remained still at insignificant levels, and hBD-3 remained unchanged. Surprisingly, hBD1 (Figure 2A) expression in the not affected ileum of patients with ulcerative colitis is reduced to levels below 30% of hBD-1 expression in a normal ileum.

Expression of both  $\alpha$ - and  $\beta$ - defensins in pouches of ulcerative colitis and FAP patients was most pronounced during the first three to nine months after surgical construction. Pouches at that time were not exposed to the faecal stream because of the presence of an upstream protective ileostoma.  $\alpha$ -Defensin expression was increased by 5- fold (HD6), and 10- fold (HD5), compared with the expression in the not affected ileum in patients with ulcerative colitis (Figure 1). In pouches of ulcerative colitis patients, hBD-1 showed a 15- fold increase compared to the ileum in patients with ulcerative colitis (Figure 2A). HBD-2 is virtually absent in the normal ileum, but in pouches after surgery hBD-2 is expressed at  $18 \times 10^3$  copies per 20 ng mRNA which is a strong increase compared to normal ileum mucosa or to the ileum of patients with ulcerative colitis (Figure 2C). HBD-3 is expressed at very low levels in the ileum or in healthy or inflamed pouches while a slight increased expression is found in pouches after surgery (Figure 2F).

When pouches in ulcerative colitis patients are in use after closure of the protective ileostoma and pouchitis was not present, HD5 (Figure 1A), HD6 (Figure 1C), hBD-1 (Figure 2A), and hBD-2 (Figure 2C) expression levels declined from the initially present high levels to levels similar to or slightly increased above (2- to 4- fold ) the defensin expression level in ileum of patients with ulcerative colitis. When pouchitis develops, a rise in defensin expression is observed between 2- fold (HD5, Figure 1A; HD6, Figure 1C; hBD-1, Figure 2A; hBD-3, Figure 2E) or 3- fold (hBD-2, Figure 2C) compared with the expression levels present in pouches without pouchitis.

Pouches of FAP patients after pouch surgery showed only minor changes of defensin expression, compared to normal ileum. Levels of HD5 and HD6 expression was increased 3- and 5 fold, respectively. (Figure 1B and D), while hBD-1 expression was unchanged (Figure 2B). HBD-2 and hBD-3 expression was increased, but total expression levels remained at very low transcript numbers (Figure 2D, F). When pouches were exposed to the faecal stream, the initial increased HD5 (Figure 1B) and HD6 (Figure 1D) defensin expression levels declined, and hBD-2 expression remained stable (Figure 2D). Pouchitis in FAP pouches did not cause an increase of HD5 (Figure 1B) and HD6 (Figure 1D) expression as pouchitis in ulcerative colitis patients, and hBD-2 (Figure 2D) expression levels remained unchanged. In contrast to all other defensins, hBD-1 (Figure 2B) expression levels in FAP pouches after surgery remained identical to hBD-1 expression levels in the normal ileum. Furthermore, hBD-1 expression increased markedly (6- fold) in the group of FAP pouches without pouchitis compared with normal ileum and hBD1 expression slightly increased further in FAP pouches under pouchitis.

Cytokine expression in pouch biopsies showed significant differences between the various pouch groups. Pouches from ulcerative colitis patients after surgery had strong expression of the proinflammatory cytokines TNF- $\alpha$ , IL-1 $\beta$  and the immunomodulatory cytokine IL-10, when compared with unaffected ileum from ulcerative colitis patients (Table 3). Expression of IL-8 was intermediate while IL-4 and IL-6 were poorly detectable. The expression of TNF- $\alpha$ , IL-1 $\beta$ , IL-8 and IL-10 remained largely unchanged in pouches from patients with ulcerative colitis, irrespective of the presence or absence of pouchitis and indicating a predominant TH1 response in the pouch patients with ulcerative colitis. Pouches from FAP patients immediately after surgery showed a similar pattern of cytokine expression as measured in pouches in ulcerative colitis, although cytokine expression levels were lower in the FAP patients. Cytokine expression declined in FAP pouches exposed to faeces. Interestingly, cytokine expression was undetectable for IL-4, IL-6, IL-8, and IL-10 while very minor expression was found for TNF- $\alpha$ .

and IL-1 $\beta$  in FAP pouches with pouchitis.

## DISCUSSION

Surgical construction of an ileoanal pouch results in massive increases of  $\alpha$ - and  $\beta$ -defensin levels in the ileum type pouch mucosa. In general, the expression of defensins in pouches is significantly higher than in the normal ileum. Furthermore, pouches in ulcerative colitis initially show much higher  $\alpha$ - and  $\beta$ -defensin levels than pouches in FAP. When pouches are in use and exposed to faeces, they undergo metaplastic changes<sup>[15,16,17]</sup> and show reduced defensin expression compared to pouches early after surgery which are protected by an upstream ileostomy. In the presence of pouchitis, there is an up regulation of  $\alpha$ - and  $\beta$ -defensins in the inflamed pouches of ulcerative colitis patients. In contrast, FAP pouches show a down regulation of the initially elevated  $\alpha$ - defensin expression in pouches without or with pouchitis. The most prominent changes are observed in the expression of the  $\beta$ -defensin hBD-1, which is markedly upregulated in FAP pouches after closure of the protective ileostoma and expressed at low levels in pouches of patients with ulcerative colitis. Furthermore, cytokines in pouches of patients with ulcerative colitis are strongly expressed in all stages while FAP pouches show a transient and weaker cytokine expression.

The pathomechanisms of pouchitis remain undetermined with potential genetic, microbial, and immunologic causes<sup>[2,5,6,7]</sup>. The most obvious difference between ileoanal pouch mucosa and the normal ileum is metaplasia of the typical ileum mucosa to a more or less colonic epithelial type<sup>[15,16,17]</sup>. Pouch mucosa has immunohistochemical features and enzymatic markers of both ileum and colon, but complete metaplasia does not occur. Paneth cells remain stable in cell number over several months after pouch construction<sup>[17]</sup>. The observed changes in defensin expression in the present study can only partially be correlated to histologic changes or colonic metaplasia. The healthy ileum has a much higher expression of HD5 and HD6 than a healthy colon and an identical expression of the  $\beta$ -defensins (unpublished data). The initial extreme upregulation of  $\alpha$ - defensins and to a lesser degree of  $\beta$  defensins after pouch construction could be due to Paneth and epithelial cell stimulation but can not be correlated to metaplasia which occurs at later times. Furthermore, the decrease in  $\alpha$ -defensin expression upon time in older pouches or pouchitis cannot be correlated with a decrease of Paneth cell number. Thus,  $\alpha$ -defensin transcription appears to be regulated after pouch surgery by unknown mechanisms, which cause multiplication of defensin expression during this time.

Pouches in ulcerative colitis develop pouchitis at a much higher incidence than pouches in FAP<sup>[1]</sup> which has been related to the elevated cytokine levels in ulcerative colitis<sup>[19,20]</sup>. Except for TNF- $\alpha$  and IL-10, cytokine expression pattern is largely similar in the colon and in pouches of patients with ulcerative colitis<sup>[21]</sup>. The expression of cytokines (TNF- $\alpha$ , IL-1 $\beta$ , IL-8 and IL-10) in pouches of ulcerative colitis patients is steadily upregulated independent of the presence or absence of pouchitis, which further

contrasts to FAP pouches, where cytokines are expressed only during the initial time after pouch construction but not in older pouches or in pouchitis. Regulation of defensin expression by TNF $\alpha$ , IL-1 $\alpha$  and IL-1 $\beta$  cytokines has been described for hBD-2, hBD-3, and HD5 in cell culture systems, while expressional changes of hBD-1, hBD-4 and HD6 have not been observed in these model systems<sup>[11, 22, 23, 24, 25]</sup>. In inflammatory bowel disease, reduced expression of hBD-2 and hBD-3 has been described in Crohn's disease, while increases have been found in the colon of ulcerative colitis in the inflamed areas<sup>[26]</sup>. Together, a modulating effect of cytokines on the up- or down regulation of defensins in pouchitis can be postulated. The  $\beta$ -defensin hBD-1 expression shows the most striking difference between ulcerative colitis pouches and FAP pouches with strong increases in the non inflamed FAP pouches and relatively low expression in UC pouches. The inverse correlation of hBD-1 and cytokine expression is obvious. Thus, the increased levels of hBD-1 and the low cytokine levels are correlated with low incidence of pouchitis.

Microbials or their products could be involved in defensin regulation in pouches after surgery and in pouchitis.  $\beta$ -defensins are upregulated in response to bacterial antigens or in the presence of cytokines<sup>[22]</sup>. Thus, the rise of hBD-2 and hBD-3 in pouchitis reflects mucosal damage and infection. The gene regulatory mechanisms that control hBD-1 expression remain speculative, since hBD-1 was previously classified as being steadily expressed by previous in vitro studies<sup>[11]</sup>. Fehlbaum *et al.*<sup>[27]</sup> described the induction of  $\beta$ -defensin expression by L-isoleucin, which as an essential amino acid must arise from external sources or from degradation of host proteins liberated by bacterial proteases. In this context, L-isoleucin could serve as a marker for microbial presence or for host tissue degradation. Presence of L-isoleucin in turn would then signal to the host the need to increase defence mechanisms.

Faecal stream and faecal stasis in pouches have been postulated to be involved in the pathomechanisms of primary pouchitis<sup>[3, 28]</sup>. As long as the faecal stream is diverted from the pouch through a protective ileostomy, pouches do not develop primary pouchitis. In addition, the ileum of the ileostomy does not react with inflammation, although faeces pass through the ileostomy. A variety of pathogenic bacteria have been found in patients with pouchitis, e.g. *Clostridium perfringens*<sup>[29]</sup>. A shift from the normal enteric microbial spectrum towards a pronounced presence of anaerobes, a reduction of bacterial diversity and an increase in fungal diversity have been described in ulcerative colitis<sup>[8]</sup>. Since each individual defensin has a characteristic pattern of antimicrobial activity, an alteration of defensin expression or a general reduction of defensins is likely to result in marked quantitative and qualitative changes of the luminal microbial contents. Future studies have to focus on the interaction of various protective mucosal factors and the intestinal contents.

In conclusion, the present data correlate the development of pouchitis in ulcerative colitis with changes of defensin expression pattern and cytokine expression. Surgical construction of an ileoanal pouch resulted in massive increases of  $\alpha$ - and  $\beta$ - defensin levels in the ileum type pouch mucosa. In general, the expression of defensins in

pouches was significantly higher than in the normal ileum. The initial high levels of  $\alpha$ - defensins after pouch surgery in ulcerative colitis appear to be protective for the pouch mucosa, since the decrease of  $\alpha$ - defensins upon time correlates with the incidence of pouchitis in ulcerative colitis. Especially for the FAP pouches, hBD-1 could be another protector for the development of pouchitis. Cytokines, metaplastic changes of the ileum mucosa and inappropriate expression of defensin antimicrobial peptides appear to play major roles in the pathomechanism of pouchitis.

## Abstract

**AIM:** To examine the differences in the responses of normal and cirrhotic livers to partial hepatectomy in relation to the factors influencing liver regeneration.

**METHODS:** Cirrhosis was induced in rats by administration of thioacetamide. Untreated rats were used as controls. The control rats as well as the cirrhotic rats were subjected to 70% partial hepatectomy. At different time points after hepatectomy, the livers were collected and the levels of cytokines, growth factors and cell cycle proteins were analyzed.

**RESULTS:** After hepatectomy, the cirrhotic remnant expressed significantly lower levels of cyclin D1, its kinase partner, cdk4, and cyclin E as compared to the controls up to 72 h post hepatectomy. Significantly lower levels of cyclin A and cdk2 were also observed while the cdk inhibitor, p27 was significantly higher. In addition, the cirrhotic group had lower IL-6 levels than the control group at all time points up to 72 h following resection.

**CONCLUSION:** The data from our study shows that impaired liver regeneration in cirrhotic remnants is associated with low expression of cyclins and cdks. This might be the consequence of the low IL-6 levels in cirrhotic liver remnant which would in turn influence the actions of transcription factors that regulate genes involved in cell proliferation and metabolic homeostasis during the regeneration process.

## INTRODUCTION

A healthy liver has the capacity to regenerate itself after injury. This results in the restoration of liver mass and function<sup>[1,2]</sup>. In the healthy state, hepatocytes are in the resting G0 state and rarely divide. However, following injury or hepatectomy, the process of regeneration is activated. Hepatocytes then undergo transition into the G1 phase, followed by the S phase, G2 phase and mitosis. The passage through the cell cycle is modulated by the interplay between cyclins, cyclin-dependent kinases (cdks) and inhibitors of cdks<sup>[3-6]</sup>.

Liver regeneration is influenced by a multitude of factors. These include cytokines and growth factors which are necessary to make quiescent hepatocytes replicate<sup>[1,2,7]</sup>. It has now been established that a set of priming events is necessary before the normally quiescent hepatocytes can respond to the growth factors. Both tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ) and interleukin-6 (IL-6) have been shown to be the factors that facilitate the priming events in regeneration<sup>[8,9]</sup>. Following the priming events, growth factors then play an important role as mitogens generating a cascade of signals leading to DNA synthesis and cell division<sup>[10]</sup>.

In humans, surgical resection is often carried out on a diseased liver and is the main therapeutic intervention for hepatocellular carcinoma<sup>[11]</sup>. The remnant liver is usually cirrhotic with impaired regenerative capacity. In this study, we examine the differences in the responses of normal and cirrhotic livers to partial hepatectomy in relation to the factors influencing hepatocyte proliferation and division. The thioacetamide-induced rodent model of liver cirrhosis was employed as induction of cirrhosis with thioacetamide is highly reproducible, irreversible and produces morphological features similar to that observed in human cirrhosis<sup>[12]</sup>.

## MATERIALS AND METHODS

### Reagents

Mouse monoclonal antibodies against cyclin D1 and cdk2, and rabbit polyclonal antibodies against cyclin A, cyclin D3, cyclin E, cdk4 were from Santa Cruz Biotechnology (Santa Cruz, CA, USA). Acrylamide, N, N'-methylene-bis-acrylamide, glycine, sodium dodecyl sulfate, 2-mercaptoethanol, isopropyl alcohol and mineral oil were from Sigma (St. Louis, MO, USA). Tween 20 was from Ducheфа (Haarlem, Netherlands). Enhanced chemiluminescence western blotting detection kit, high performance film and nitrocellulose membrane were from Amersham Biosciences (Little Chalfont, Buckinghamshire, England). Sucrose, Bio-Rad protein assay dye, N, N, N', N'-tetra-methylethylenediamine, ammonium persulfate and prestained SDS-PAGE Standards Broad Range were from Bio-Rad (Hercules, CA, USA). Trizol reagent was from GIBCO BRL. Chloroform and sodium chloride were obtained from Merck (Darmstadt, Germany). Access reverse transcription-PCR system was from Promega (Madison, WI, USA). Rat TNF- $\alpha$  and IL-6 ELISA kits were from Bender MedSystems (Vienna, Austria).

### Induction of cirrhosis and partial hepatectomy

The induction of cirrhosis, partial hepatectomy (PH) and harvesting of the livers has been previously described<sup>[13,14]</sup>. In brief, cirrhosis was induced in ten-week-old male Wistar-Furth rats by intraperitoneal injection of 300 mg thioacetamide/kg thrice weekly for 10 wk. Healthy, control animals were kept under the same conditions without any treatment. After one week acclimation to allow for the washout of thioacetamide, all animals underwent 70% PH as described by Higgins and Anderson<sup>[15]</sup>. Two experimental groups were studied. Healthy rats in the control groups as well as cirrhotic rats in the cirrhotic group were submitted to PH. Within each group, six rats were sacrificed at 3, 6, 24, 48 and 72 h after surgery. The excised and the resected livers were harvested and used for further analysis.

### Preparation of rat liver lysates

The liver was chopped into small pieces and homogenized in 5 volumes of buffer containing 0.25 mol/L sucrose, 5 mmol/L HEPES and 0.5 mmol/L EGTA, pH 7.5. The homogenate was centrifuged at  $12\,000 \times g$  at 4°C for 10 min. The supernatant (the liver lysate) was then stored in small aliquots at -80°C till required. The protein concentration was determined using the Bio-Rad protein assay dye reagent with bovine serum albumin as the standard. For each time point, the lysates (containing equal amount of protein from each liver,  $n=6$ ) were pooled and then used for Western blot and ELISA analysis.

### Western blotting

25  $\mu$ g of the pooled sample was resolved on SDS-PAGE and transferred onto nitrocellulose membrane. Mouse monoclonal antibodies against cyclin D1 and cdk2, and rabbit polyclonal antibodies against cyclin A, cyclin D3, cyclin E, cdk4 were used to detect the respective proteins. The bound antibodies were visualized by using enhanced

chemiluminescence. The bands were then quantified using the Analytical Imaging Station software (Imaging Research Inc, St. Catharines, Ontario, Canada).

### Quantitative assay for TNF- $\alpha$ and IL-6

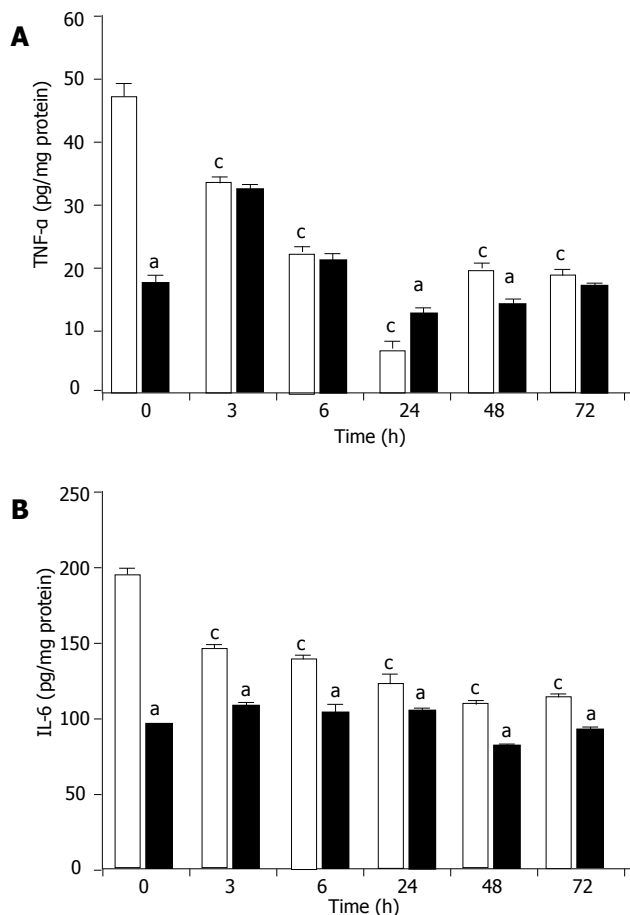

The concentrations of TNF- $\alpha$  and IL-6 present in the liver lysates were determined using the Rat TNF- $\alpha$  and IL-6 ELISA kits. The assays were carried out according to the protocol described in the manufacturer's manual.

### RNA extraction, reverse transcription, and PCR

Total RNA was extracted from the liver samples using the Trizol reagent. The extraction was carried out according to the manufacturer's instructions. For each time point, the total RNA (containing equal amount of RNA from each liver as determined by absorbance at 260 nm,  $n=6$ ) was pooled and then used for reverse transcription-PCR.

Six sets of primers were used for PCR and the sequences are shown in Table 1. The isolated RNA was subjected to reverse transcription-PCR using the Access reverse transcription-PCR system (Promega, USA). A typical 25  $\mu$ L reverse transcription-PCR reaction contained 0.4  $\mu$ g of RNA, 0.1 mmol/L dNTPs, 0.5  $\mu$ mol/L of the forward and corresponding reverse primers, 0.5 mmol/L of MgSO<sub>4</sub>, and 0.05 U/ $\mu$ L of AMV reverse transcriptase and 0.05 U/ $\mu$ L of T7 DNA polymerase. The reverse transcription was carried out at 48°C for 45 min followed by denaturation at 94°C for 2 min. Following reverse transcription, the cDNA was subjected directly to PCR. Each cycle consists of denaturation at 94°C for 30 s, annealing at 60°C for 1 min and extension at 68°C for 2 min. At the end of the last cycle, a final extension at 68°C for 7 min was carried out. The number of PCR cycles used was the lowest needed to produce a product which could be visualized on the gel. The product was separated by agarose-gel electrophoresis and visualized by ethidium-bromide staining. The gel image was captured and the bands were then quantified using the Analytical Imaging Station software (Imaging Research Inc, St. Catharines, Ontario, Canada).

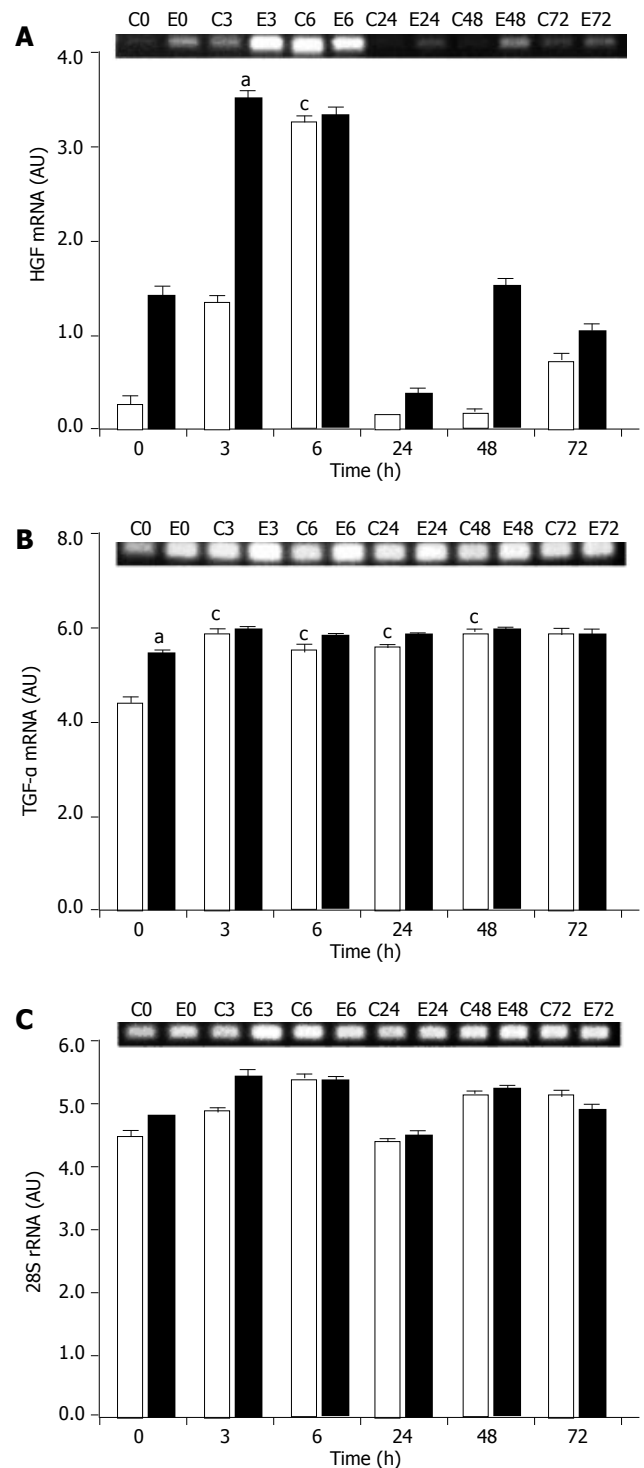

**Figure 1** Hepatic **A:** TNF- $\alpha$  and **B:** IL-6 concentrations after PH on healthy rats (white bars) and cirrhotic rats (black bars). At different time points after the operation, the remnant liver was harvested, homogenized and the supernatant was used for analysis. For each time point, the supernatant from 6 animals was pooled and used for ELISA analysis. All analyses were carried out in triplicates and the results are expressed as mean  $\pm$  SD.  $^{\circ}P < 0.05$ , ANOVA analysis, for comparison between control rats before (at 0 h) and after PH.  $^{\circ}P < 0.05$ , ANOVA analysis, for comparison between the cirrhotic group and the corresponding control group at each time point.

## RESULTS

Two groups of animals were used in the study. The control group and the cirrhotic group were subjected to 70% PH. All data generated in this study were first examined to determine the changes that occur after PH in the controls. This was followed by comparisons to determine if there were significant differences between the control group and the cirrhotic group both before and after 70% PH.

### Hepatic TNF- $\alpha$ and IL-6

Prior to PH, TNF- $\alpha$  and IL-6 were both detected in the liver extracts from the control group and the cirrhotic group. The levels in cirrhotic livers were significantly lower than that in healthy livers. Following resection, the hepatic levels of both TNF- $\alpha$  and IL-6 were significantly lowered from 3 h till 72 h post-resection in the control group. Significantly different TNF- $\alpha$  levels between the controls and cirrhotics were only observed at 24 h and 48 h post-PH. Reduced IL-6 levels were observed in the cirrhotic group before and up to 72 h following PH (Figure 1A and B).

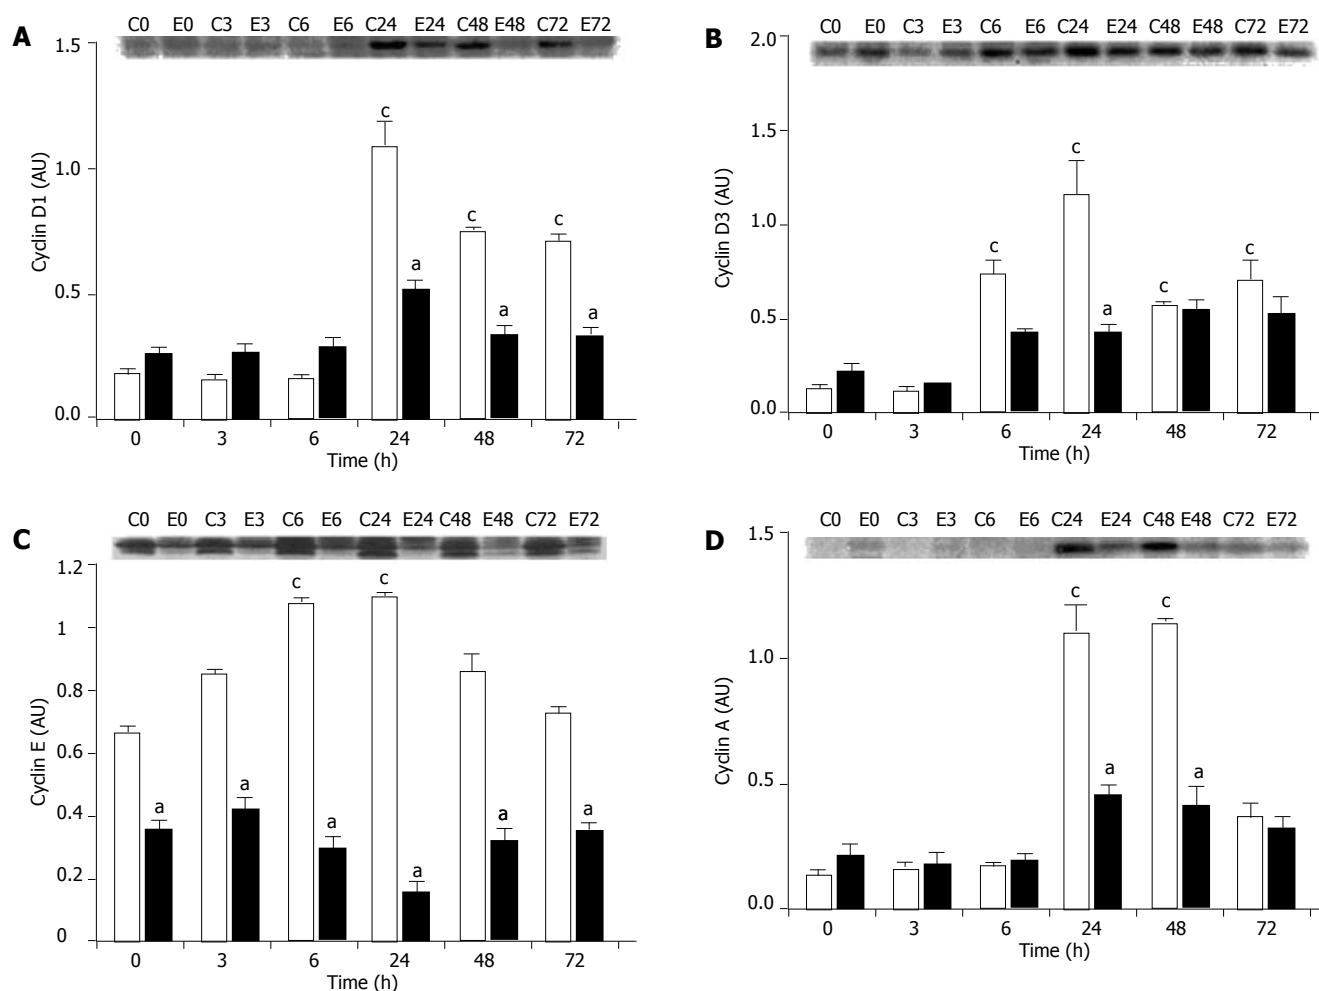

**Figure 2** Hepatic **A:** HGF, **B:** TGF- $\alpha$  and **C:** 28S rRNA expressions after PH on healthy rats (white bars) and cirrhotic rats (black bars). At different time points after the operation, the remnant liver was harvested, and RNA was extracted. For each time point, the RNA from 6 animals was pooled and used for reverse-transcription followed by PCR. The PCR product was separated by agarose-gel electrophoresis and visualized by ethidium-bromide staining. The gel image was captured and the bands were quantified using the Analytical Imaging Station software. All analyses were carried out in triplicates. A representative gel (C, control, healthy rats; E, cirrhotic rats; the number indicates the time post-PH in h) and the quantification analysis expressed as mean  $\pm$  SE (AU = arbitrary units) are shown.  $^{\circ}P < 0.05$ , ANOVA analysis, for comparison between control rats before (at 0 h) and after PH.  $^{\circ}P < 0.05$ , ANOVA analysis, for comparison between the cirrhotic group and the corresponding control group at each time point.

### Expression of growth factors

Total RNA was extracted from the liver samples and sub-

**Figure 3** Effect of PH on cyclin expressions in healthy rats (white bars) and cirrhotic rats (black bars). At different time points after the operation, the remnant liver was harvested, homogenized and the supernatant was used for analysis. For each time point, the supernatant from 6 animals was pooled and used for Western blot analysis. The blot image was captured and the bands were quantified using the Analytical Imaging Station software. All analyses were carried out in triplicates. A representative blot (C, control, healthy rats; E, cirrhotic rats; the number indicates the time post-PH in h) and the quantification analysis expressed as mean $\pm$ SE (AU = arbitrary units) are shown. **A:** Cyclin D1 expression. **B:** Cyclin D3 expression. **C:** Cyclin E expression. **D:** Cyclin A expression.  $^{\circ}P < 0.05$ , ANOVA analysis, for comparison between control rats before (at 0 h) and after PH.  $^{\circ}P < 0.05$ , ANOVA analysis, for comparison between the cirrhotic group and the corresponding control group at each time point.

jected to reverse transcription-PCR analysis for transcripts encoding for the hepatocyte growth factor (HGF) and the transforming growth factor alpha (TGF- $\alpha$ ). A transient increase in HGF was observed at 6 h post-PH for the control group. The trend was also similar for the cirrhotic group, although a significant increase was also observed at 3 h post-PH (Figure 2A).

In contrast, TGF- $\alpha$  was significantly higher at all time points up till 48 h post-resection in the control group. TGF- $\alpha$  level in the cirrhotic livers was significantly higher than controls before PH. After PH, the levels remained high and there were no differences between the control group and the cirrhotic group (Figure 2B). The 28S rRNA was used as a control and no significant differences in the expression were observed (Figure 2C).

#### Markers of cell cycle progression, cdk inhibitors and p53 expression

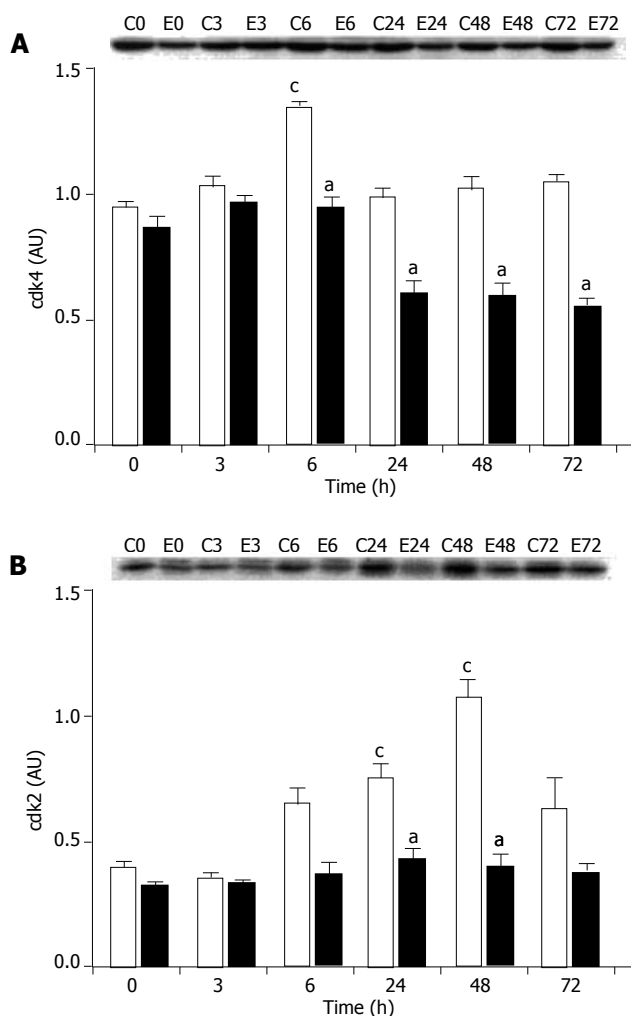

Western blot analysis was carried out to examine the changes in cyclins and cdk. In the control group, cyclin D1 levels were elevated from 24 to 72 h post-PH (Figure 3A) while cyclin D3 levels peaked at 24 h post-PH and

remained significantly elevated up till 72 h post-PH (Figure 3B). In addition, cdk4 was also significantly increased at the 6 h time point (Figure 4A). Comparison of the cirrhotic group with the corresponding controls showed that cyclin D1 levels were significantly lower at 24 to 72 h post-PH and the peak in cyclin D3 expression was not observed. The cdk4 levels were also lower than that of the corresponding controls from 6 to 72 h post-resection (Figure 3A, 3B and 4A).

As previously described, the antibody against cyclin E recognized multiple isoforms<sup>[16,17]</sup>. These represent alternative spliced variants of the gene. Cyclin E levels in the controls increased significantly within 24 h following resection. However, in the cirrhotic group, this increase was not evident and cyclin E levels were lower than the controls at all time points (Figure 3C). For the control animals, the highest levels of cyclin A and cdk2 expression were at 24 and 48 h after resection. At these time points, the levels of cyclin A and cdk2 in the cirrhotic animals were significantly lower than that in the corresponding controls (Figure 3D and 4B).

Reverse transcription-PCR analysis showed that for

**Figure 4** Effect of PH on cyclin-dependent kinase expressions in healthy rats (white bars) and cirrhotic rats (black bars). At different time points after the operation, the remnant liver was harvested, homogenized and the supernatant was used for analysis. For each time point, the supernatant from 6 animals was pooled and used for Western blot analysis. The blot image was captured and the bands were quantified using the Analytical Imaging Station software. All analyses were carried out in triplicates. A representative blot (C, control, healthy rats; E, cirrhotic rats; the number indicates the time post-PH in h) and the quantification analysis expressed as mean±SE (AU = arbitrary units) are shown. **A:** Expression of cdk4. **B:** Expression of cdk2. <sup>c</sup>*P* < 0.05, ANOVA analysis, for comparison between control rats before (at 0 h) and after PH. <sup>a</sup>*P* < 0.05, ANOVA analysis, for comparison between the cirrhotic group and the corresponding control group at each time point.

both p21 and p53, the increase in expression was before the 24 h time point for the control group and the cirrhotic group (Figure 5A and C). However, the expression of p27 in the cirrhotic group was significantly higher than the controls before as well as after resection (Figure 5B).

## DISCUSSION

In this study, the thioacetamide-induced rodent model of liver cirrhosis was used to examine the factors that may contribute to impaired regeneration of cirrhotic livers after PH. Changes in the expression patterns of cytokines, growth factors and cell cycle proteins were examined over a period of 72 h.

Cyclins, cdks and cdk inhibitors were all detected in healthy livers, similar to previous observations<sup>[16]</sup>. Cirrhotic

livers also expressed comparable levels of D-type cyclins, cyclin A, cdks, p21 and p53 as the healthy livers. However, cyclin E was significantly lowered while p27 was significantly raised.

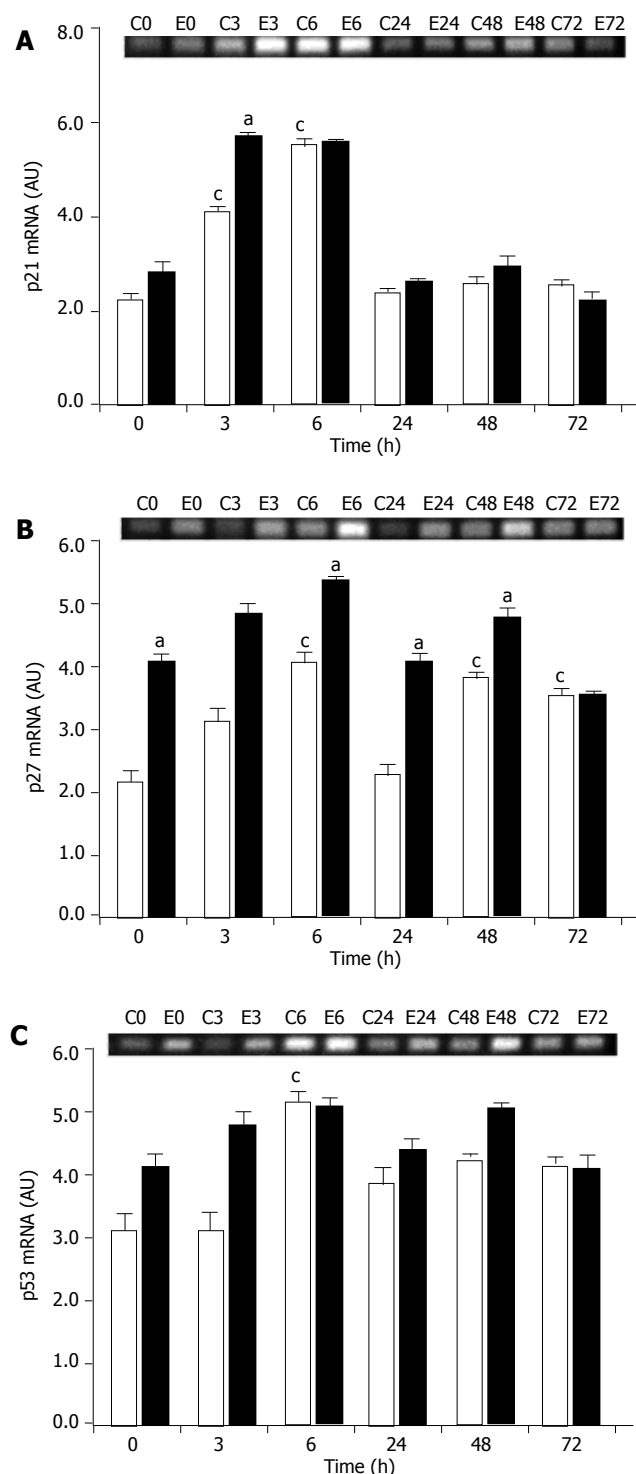

Following PH, quiescent hepatocytes are induced to proliferate. Cyclins and their kinase partners play key roles in regulating the progress through the different phases of the cell cycle<sup>[18,19]</sup>. The D-type cyclins together with their kinase partners play a key role in regulating G1 progression<sup>[20]</sup>. The cyclinE/cdk2 complex regulates G1 to S phase transition<sup>[21]</sup>, while the cyclinA/cdk2 complex is necessary for initiation of DNA replication in the S phase<sup>[22-24]</sup>. As expected, the expression of cyclin D1, cyclin E and cyclin A increased significantly in the controls after resection as the liver undergoes regeneration. This is congruent with other studies which showed that after PH, there is firstly an induction of G1 cyclins preceding S phase followed by subsequent induction of cyclin A and cyclin B<sup>[4,25,26]</sup>.

Transient increases in the mRNA levels of cdk inhibitors p21 and p27, as well as p53 were also observed at 3-6 h after PH in the controls. Similar observations have been previously described in various other studies using rodent models<sup>[6, 27-30]</sup>. It is thought that in the regenerating liver, p53 plays a dual role<sup>[30]</sup>. The first is as a cell cycle check resulting in a delay in the G1 phase to allow damage repair<sup>[29]</sup>. The second is the induction of the expression of growth factors or their receptors. Indeed, p53 responsive elements have been found on the promoters of HGF and TGF- $\alpha$ , both of which are involved in the proliferative response<sup>[31,32]</sup>. The expression of the cdk inhibitor, p21 is also induced post PH, probably in part as a response to p53 induction<sup>[33]</sup>. This may serve to prevent premature progression through G1 phase<sup>[34]</sup> or to stabilize the cyclinD-cdk4 complex and promote its translocation to the nucleus<sup>[35]</sup>. p27 acts as a brake on cyclinE-cdk2 activity and has to be sequestered by cyclin D1 for cdk2 to be active<sup>[36]</sup>.

Comparison between the control and cirrhotic groups showed that the changes in cyclin/cdk expressions after PH were not mirrored in the cirrhotic livers. Cyclin D1 and its kinase partner, cdk4 were expressed at much lower levels at 24-72 h post PH, cyclin A and cdk2 were decreased at 24-48 h post PH while cyclin E was persistently lowered up to 72 h post PH. In addition, the expression of the cdk inhibitory protein, p27 was also elevated at 6-48 h post PH. Thus, unlike healthy livers, cirrhotic livers expresses significantly lower levels of cyclins [this study and those by Zhao *et al.*<sup>[37]</sup> and Masson *et al.*<sup>[38]</sup>]. Given the persistent low levels of G1 cyclins, it is likely that the block to cell cycle progression occurs at the G1 phase.

The key factors that influence liver regeneration include the cytokines TNF- $\alpha$  and IL-6 and the growth factors HGF and TGF- $\alpha$ . The cytokines TNF- $\alpha$  and IL6, are necessary to prime and initiate liver regeneration after PH<sup>[2,8,9]</sup>. Signals to initiate liver regeneration for TNF- $\alpha$  are mediated by TNF receptor 1. Knockout mice lacking this receptor have diminished ability to restore liver mass after PH leading to increased mortality<sup>[39]</sup>. High postoperative mortality and impaired response to PH were also observed in IL-6 deficient mice<sup>[40]</sup>. Besides the cytokines, growth factors also play important roles in liver regeneration. TGF- $\alpha$  and HGF are potent mitogens for hepatocytes<sup>[10]</sup>. The re-

**Figure 5** Hepatic **A:** p21, **B:** p27 and **C:** p53 expressions after PH on healthy rats (white bars) and cirrhotic rats (black bars). At different time points after the operation, the remnant liver was harvested, and RNA was extracted. For each time point, the RNA from 6 animals was pooled and used for reverse-transcription followed by PCR. The PCR product was separated by agarose-gel electrophoresis and visualized by ethidium-bromide staining. The gel image was captured and the bands were quantified using the Analytical Imaging Station software. All analyses were carried out in triplicates. A representative gel (C, control, healthy rats; E, cirrhotic rats; the number indicates the time post-PH in h) and the quantification analysis expressed as mean + SE (AU = arbitrary units) are shown. <sup>a</sup> $P < 0.05$ , ANOVA analysis, for comparison between control rats before (at 0 h) and after PH. <sup>b</sup> $P < 0.05$ , ANOVA analysis, for comparison between the cirrhotic group and the corresponding control group at each time point.

In conditional met mutant mice, impaired regeneration occurs after PH and this is due to a defective exit from quiescence and diminished entry into S phase<sup>[41]</sup>. In addition, HGF also upregulates the expression of TGF- $\alpha$  and the presence of anti-TGF $\alpha$  antibodies can block DNA synthesis in regenerating livers<sup>[42]</sup>.

Cirrhotic livers have significantly lower TNF- $\alpha$  and IL-6 levels compared to healthy livers prior to PH. It is unclear why this should be so. However, similar reductions have been observed in patients with primary biliary cirrhosis and fulminant hepatitis<sup>[43,44]</sup>. This is not simply due to a general depression in RNA synthesis in the diseased livers as the expression of other genes such as IL-1 and interferons were unaffected<sup>[44]</sup>. In addition, unchecked fibrosis will lead to impaired diffusion of nutrient and hepatotropic factors and this may also be a contributing factor to the reduced levels of TNF- $\alpha$  and IL-6. In contrast, HGF expression was unchanged in cirrhotic livers. TGF- $\alpha$  expression was significantly increased in cirrhotic livers and this is consistent with the role of TGF- $\alpha$  in the chronic regeneration that occurs in the cirrhotic process<sup>[45]</sup>.

Following resection of healthy controls, it was observed that both TNF- $\alpha$  and IL-6 levels in the liver decreased progressively over a period of 72 h. This is to be expected as TNF- $\alpha$  and IL-6 are necessary mainly for the initial priming events. In addition, TNF- $\alpha$  is a pro-inflammatory cytokine and high levels are not desirable once the priming signals have been initiated. In this study, a peak in both cytokines was not observed after PH. This is probably due to the fact that the increase in both cytokines was expected to be at an early time point after resection<sup>[39,46]</sup> and the first time point in this study may be too late for this observation. A peak in the expression of HGF was observed at 3-6 h post PH while that of TGF- $\alpha$  was elevated up to 48 h post PH. Similar to that observed by Zhao *et al*, hepatic expression of the growth factors HGF and TGF- $\alpha$  was not significantly different in both normal and cirrhotic livers after PH<sup>[37]</sup>.

In contrast to the growth factors, it was observed that following partial hepatectomy, the IL-6 levels in cirrhotic livers are significantly lower than that of the healthy controls. The role of IL-6 in liver regeneration has been extensively examined. To date, the roles of IL-6 in liver regeneration include the activation of acute phase response, induction of proliferation and hepatoprotection. The binding of IL-6 to the gp130-IL-6 receptor complex results in the activation of Janus kinase (JAK). This in turn activates the mitogen-activated protein kinase (MAPK) and STAT3 signaling pathways<sup>[7,9]</sup>. In IL-6 deficient mice, liver failure and defective hepatocyte regeneration is observed following PH. Subcutaneous injection of IL-6 which results in sustained action of IL-6 was able to completely reverse the high post-operative mortality of IL-6 deficient mice<sup>[47]</sup>. It is interesting to note that both IL-6 and cyclin D1 levels were reduced in the regenerating cirrhotic liver. AP1 activity was also markedly inhibited in regenerating cirrhotic livers with reduced expression levels of c-Jun and JunD<sup>[37]</sup>. Taken together, these observations are comparable to that in IL-6 deficient mice which shows marked reduction in STAT3 activation and depressed AP-1, myc and cyclin-D1 expressions<sup>[40]</sup>.

sponse to HGF is mediated by its interaction with c-met, a protooncogene which encodes a receptor tyrosine kinase.

IL-6 also mediates the induction of C/EBP expression<sup>[48]</sup>. Impaired C/EBP $\beta$  activities have been observed in cirrhotic livers following resection<sup>[37]</sup> and this could account for the reduction in cyclin E and cyclin A. In C/EBP $\beta$  -/- mice, cyclins A, B and D were reduced near the peak of DNA synthesis during liver regeneration<sup>[49]</sup>. Although it is still uncertain as to whether C/EBP $\beta$  regulates cyclin expression via transcriptional or post-transcriptional mechanisms, it is clear that in C/EBP $\beta$  -/- hepatocytes, cell cycle progression is blocked close to or at the G1/S phase transition<sup>[49]</sup>.

The data from our study thus shows that impaired liver regeneration in cirrhotic remnants is associated with low expression of cyclins including cyclin D1. In rats with carbon tetrachloride-induced cirrhosis, similar changes in the expression of cyclins and IL-6 were also observed<sup>[38]</sup>. Markedly reduced IL-6 levels could influence the action of transcription factors (such as STAT3, AP1, C/EBP $\beta$  and HNF-1 $\alpha$ ) which are necessary for the regulation of genes that coordinate the balance between cell proliferation and metabolic homeostasis during liver repair and growth. In addition, liver regeneration is also critically dependent on ATP stores and the reduction in liver proliferation in cirrhotic livers may be due in part to inadequate mitochondrial respiratory function. Cirrhotic livers indeed have reduced complex I activity and lower respiratory control ratios following PH as shown by us and others<sup>[13,50,51]</sup>.

### **Abstract**

**AIM:** To examine the effect of *Eubacterium limosum* (*E. limosum*) on colonic epithelial cell line *in vitro*, and to evaluate the effect of *E. limosum* on experimental colitis.

**METHODS:** *E. limosum* was inoculated anaerobically and its metabolites were obtained. The growth stimulatory effect of the *E. limosum* metabolites on T84 cells was evaluated by SUDH activity, and the anti-inflammatory effect by IL-6 production. The change in mRNA of toll like receptor 4 (TLR4) was evaluated by real time PCR. Colitis was induced by feeding BALB/C mice with 2.0% dextran sodium sulfate. These mice received either 5% lyophilized *E. limosum* ( $n = 7$ ) or control diet ( $n = 7$ ). Seven days after colitis induction, clinical and histological scores, colon length, and cecal organic acid levels were determined.

**RESULTS:** The *E. limosum* produced butyrate, acetate, propionate, and lactate at 0.25, 1.0, 0.025 and 0.07 mmol/L, respectively in medium. At this concentration, each acid had no growth stimulating activity on T84 cells; however, when these acids were mixed together at the above levels, it showed significantly high activity than control. Except for lactate, these acids significantly attenuated IL-6 production at just 0.1 mmol/L. In addition, under TNF- $\alpha$  stimulation, butyrate attenuated the production of TLR4 mRNA. The treatment with *E. limosum* significantly attenuated clinical and

histological scores of colitis with an increase of cecal butyrate levels, compared with the control group.

**CONCLUSION:** *E. limosum* can ameliorate experimental colonic inflammation. In part, the metabolite of *E. limosum*, butyrate, increases mucosal integrity and shows anti-inflammatory action modulation of mucosal defense system *via* TLR4.

### **INTRODUCTION**

Inflammatory bowel disease (IBD), which includes ulcerative colitis (UC) and Crohn's disease, is a chronic and aggressive idiopathic inflammatory disorder of the gastrointestinal tract.<sup>[1]</sup> The detailed mechanism and causes of IBD are not fully understood; however, abundant experimental observations suggest that luminal bacteria (microflora) play a crucial role in the pathogenesis of IBD.<sup>[2,3,4]</sup> In experimental colitis models, colitis has not occurred without the presence of intestinal flora. This indicates that microflora are likely to induce colonic inflammation and its recurrence.<sup>[5]</sup> Recently, therapeutic approaches to modifying microflora have been attempted by the use of antibiotics, probiotics, and prebiotics.<sup>[4,6,7]</sup>

Germinated barley foodstuff (GBF), which consists mainly of dietary fiber and glutamine (Gln)-rich protein, is a prebiotic product for UC patients.<sup>[8]</sup> In our previous studies, GBF exhibited preventive and therapeutic effects in experimental colitis models, especially an improvement of severe bloody diarrhea and attenuation of colonic mucosal damage, accompanied by the modulation of microflora.<sup>[9]</sup> In colitis models, GBF or its fiber fraction

significantly increased cecal butyrate production, and GBF significantly increased the number of butyrate producing *Eubacterium limosum* (*E. limosum*), with a decrease in colonic pH.<sup>[9,10]</sup> As a result, in this colitis model, GBF was considered to be efficiently fermented and converted by *E. limosum* into short-chain fatty acids (SCFAs), including butyrate.<sup>[8,9,11]</sup>

Furthermore, a clinical trial of GBF showed that this treatment can benefit UC patients by increasing the level of stool butyrate. This clinical efficacy was also associated with an increase in the number of *Bifidobacterium* and *E. limosum*, both of which are regarded as beneficial bacteria, in the stool.<sup>[12,13]</sup> However, the mechanism of the therapeutic effect of GBF and *E. limosum* has been incompletely understood. The detailed metabolism of *E. limosum* in gastrointestinal tract is also little understood, differing from *Lactobacillus* or *Bifidobacterium* as representative probiotics.<sup>[8]</sup> The net viability in human gastrointestinal tract and resistance to gastric or bile acids were not clear in detail, and these difficulties might be caused by the obligate anaerobic character. The only distinct effect of *E. limosum* is increase of butyrate production in ulcerative colitis<sup>[14]</sup> and experimental colitis.<sup>[12]</sup> Thereupon, we pointed out the major metabolites of *E. limosum* (short chain fatty acids including butyrate) and the minute role in colonic epithelium. Although this study is preliminary, we focus on the role of *E. limosum* *in vivo* and its metabolites on colonic epithelium *in vitro*.

## MATERIALS AND METHODS

### Preparation of *E. limosum*<sup>[11]</sup>

*E. limosum* (JCM6421 Riken Bioresource Center, Saitama, Japan) was inoculated with modified GAM medium (Nissui Pharmaceutical Co., Tokyo, Japan) anaerobically at 37 °C. AnaeroPack (Mitsubishi Gas Chemical Co., Tokyo, Japan) was used to obtain the anaerobic condition. The *E. limosum* and supernatant were separated by centrifugation and filtration, sequentially lyophilized. The number of *E. limosum* after lyophilization was of the same order as before being cultured (10<sup>9</sup> CFU/1 g). The organic acid content of the supernatant (residual medium) was determined by HPLC using the method described in our previous study.<sup>[9]</sup> Briefly, the supernatant was filtered through a membrane filter and separated with an ion-exclusion column (Shodex Rspak KC-811, 8 mmID × 30 cm long, Showa Denko Co., Ltd., Tokyo, Japan). Organic acids were detected using bromothymol blue as the post-column reagent. The column temperature was 60 °C, and the mobile phase was a 0.75 mmol/L sulfuric acid solution (flow rate : 0.8 mL/min).

### Cell culture

The methods for maintenance of T84 (ATCC CCL-248, Rockville, MD) cells in culture were as previously described in other studies.<sup>[15,16]</sup> Briefly, T84 cells were grown in monolayers in a 1:1 mixture of Dulbecco's modified Eagle's Medium/Nutrient Mixture F-12 Ham (Sigma St. Louis MO, USA) supplemented with, 50 U/mL penicillin, 50 µg/mL streptomycin and 5% fetal bovine serum. Confluent monolayers were subcultured by trypsinization

with 0.5% trypsin and 5.3 mmol/L EDTA in Ca<sup>2+</sup> and Mg<sup>2+</sup> free phosphate-buffered saline.

### Growth activity and IL-6 production

For the determination of cell growth activity, succinate dehydrogenase (SUDH) activity was evaluated. Since SUDH was reported to be well related to the proliferative and viability activity<sup>[17]</sup>, 6 × 10<sup>4</sup> cells were plated onto each well of 96-well plates and the cells were treated with the respective mediums for 24 h, Cell Counting Kit-8 (Dojin Chemicals Co., Ltd. Kumamoto Japan) was used, then SUDH activity was measured as per the manufacturer's instructions.<sup>[17]</sup> For the determination of IL-6, cells were plated onto each well of 48-well plates. The cells were grown to confluence in cell culture dishes. They were treated with TNF-alpha (50ng/mL; Funakoshi Co., Tokyo, Japan) for another 24 h and the supernatants were harvested for measurement of IL-6, IL-6 ELISA (Genzyme Cambridge MA) as per the manufacturer's instructions.

### Expression of mRNA level of toll like receptor 4<sup>[18]</sup>

For the determination of expression of TLR4 mRNA, T84 cells were plated into each well of 60mm × 15mm cell culture dishes. The cells were grown to confluence in cell culture dishes. They were treated with TNF-alpha (25ng/mL; Funakoshi Co., Tokyo, Japan) with sodium butyrate (0, 0.5, 1.0, and 2.0 mmol/L) for another 6 hrs. Then total RNA extraction was carried out by RNeasy Mini Kit (QIAGEN-JAPAN KK Tokyo) and RT-PCR was performed (Applied Biosystems 7300 real time PCR system, Applied Biosystem-Japan Tokyo Japan). RT-PCR was carried out with specific primers and probes for TLR4 receptor components and housekeeping gene, beta-actin (Taqman gene expression assay, Applied Biosystem-Japan Tokyo Japan). The primer pairs used for amplification of TLR4 were (5'-3') CAG AGT TTC CTG CAA TGG ATC A and GCT TAT CTG AAG GTG TTG CAC AT. TaqMan MGB probes (labeled with fluorescent reporter dye 6FAM) were used for analysis of TLR4 (CGT TCA ACT TCC ACC AAG AGC TGC CT). Respective data were shown after normalized to housekeeping gene (beta-actin).

### Animals and diets

Fourteen 8-wk-old female BALB/c mice were purchased from Charles River Japan (Kanagawa, Japan). The mice were housed individually in cages in a room kept at 20 to 25°C and 40 to 70% relative humidity with a 12 h lighting cycle (conventional conditions).<sup>[12]</sup> They were allowed free access to diet and drinking water. First, the 14 mice were fed laboratory chow for 1 wk during their acclimatization period. They were then divided into two groups of 7: a 5% *E. limosum* group (*E. limosum* group) and a cellulose-diet control group (control group). The total volume of protein and dietary fiber in both diets was adjusted to 14.6% protein and 3.0 % dietary fiber.<sup>[19,12]</sup> The compositions of the two diets are shown in Table 1.

After one week of pre-feeding, the mice weighing 20 to 22 g in the two groups were given 2% dextran sodium sulfate (mol wt, 5000; Wako Pure Chemical Co., Osaka, Japan) in their diet to induce colitis. The animals were

**Table 1** Composition of experimental diets

	CE	<i>E. limosum</i> (g/kg diet)
Casein	146.0	100.0
Vitamin mixture	10.0	10.0
Mineral mixture	35.0	35.0
Choline chloride	2.0	2.0
Cellulose	30.0	
<i>E. limosum</i>		50.0
Corn oil	50.0	50.0
DSS	20.0	20.0
Corn starch	707.0	733.0
(without DSS)	(727.0)	(753.0)

CE; Cellulose

*E. limosum* ( $3 \times 10^{12}$  cells/g)

sacrificed at d 7, and the colon and cecal contents were removed. This animal experiment was approved by the local ethical committee.

### Evaluation of disease activity

In all the mice, the body weight, occult blood, and rectal bleeding, as well as stool consistency were monitored daily. The presence of blood in feces was evaluated using a hemocult test kit (Beckman Coulter, Fullerton, CA). The disease activity index was determined by scoring changes in weight, hemocult positivity, gross bleeding, and stool consistency, described in our previous study.<sup>[12]</sup> Briefly, we used five grades of weight loss (0: no loss or weight gain, 1: 1 to 5%, 2: 5 to 10%, 3: 10 to 20%, 4: loss of more than 20%), three grades of stool consistency (0: normal, 2: loose, 4: diarrhea) and three grades of occult blood (0: normal, 2: occult blood positive, 4: gross bleeding). And disease activity score was sum of above parameters.

### Histological evaluation

The entire colon was removed, and its length was measured. After removal, the colon was immediately divided into three segments (proximal: 1cm from ileo-cecal valve, middle, and distal: 1.5cm from anal columns), and a part of each segment was fixed in 10% neutral buffered formalin. After fixation, the specimens were stained with hematoxylin and eosin.<sup>[12]</sup> Six sections from each segment were scored for colitis severity (crypt scores) based on the method of Cooper *et al* by two blind examiners.<sup>[20]</sup> Briefly, this scoring method is: grade 0, intact crypt; grade 1, cystic dilatation of crypts; grade 2, loss of the basal one-third of the crypt; grade 3, loss of the basal two-thirds of the crypt; grade 4, loss of entire crypts with the surface epithelium remaining intact; grade 5, loss of both the entire crypt and surface epithelium.<sup>[10,12]</sup> The average damage score was shown in Figure 5.

### Cecal organic acid determination

The cecal contents were removed immediately after the dissection. Because the cecal contents of the mice were very small, we had to gather all the samples in the two groups. Organic acids were measured by the HPLC methods described in Experiment 1.<sup>[9]</sup>

**Figure 1** Effect of organic acids (A) and the cocktail mixture of organic acids (B) on SUDH activity in T84 cells. Cells were incubated with various concentrations of fatty acids for 24 hours. The data is expressed as means  $\pm$  SD ( $n=4$ ). <sup>a</sup> $P<0.05$  vs control. <sup>†</sup>The cocktail was an organic acid mixture adjusted to that of 10 % *E. limosum* supernatant (butyrate [0.25 mmol/L], acetate [1 mmol/L], propionate [0.025 mmol/L], and lactate [0.07 mmol/L]).

### Statistical analysis

Results are expressed as means  $\pm$  SD. Differences in the disease activity were evaluated by chi-square analysis. The Student *t* test (two-tailed) was used to test all other comparisons. Significance was accepted at  $P<0.05$ .

## RESULTS

The effects of organic acids on growth activity of T84 are shown in Figure 1A and B. Figure 1A shows the effects of sodium-butyrate, sodium-acetate, sodium-propionate, sodium-lactate, and sodium-succinate at different levels (0, 0.1 mmol/L, 0.5 mmol/L, 1 mmol/L, and 10 mmol/L) on the growth activity of T84 as determined by SUDH activity. Butyrate significantly increased the growth activity of T84 at 1 mmol/L. Acetate and lactate promoted a significantly high growth activity at just 10 mmol/L. With regards to the propionate, at 0.1 and 10 mmol/L, significant increases were observed. There were no statistical differences in succinate supplementation at all dose levels.

In our previous study, *E. limosum* produced butyrate (2.5 mmol/L), acetate (10 mmol/L), propionate (0.25 mmol/L), and lactate (0.7 mmol/L) in the medium and the addition of 10 % *E. limosum* supernatant to T84 significantly increased SUDH activity.<sup>[21]</sup> Therefore, the organic acid mixture adjusted to that of 10 % of *E. limosum* supernatant (butyrate (0.25 mmol/L), acetate (1 mmol/L), propionate (0.025 mmol/L), and lactate (0.07 mmol/L) was simultaneously added as a cocktail to T84. This cocktail significantly increased the growth activity, as shown in Figure 1 B.

Three kinds of short-chain fatty acids (butyrate, acetate, propionate) promoted a significant decrease of IL-6 production in a dose-dependant manner. Lactate only showed a decrease of IL-6 production at 0.1 mmol/L, and succinate had no anti-inflammatory effects at any dose level. (Figure 2). In this experiment, the cocktail also significantly attenuated IL-6 production (77 % of control,  $P<0.05$ ). However, it does not seem the synergistic effects as in growth stimulatory effect.

Figure 3 showed the effect of butyrate on expression

**Table 2 Organic acid analysis of pooled cecal content in colitis model**

	Succinate	Lactate	Acetate ( $\mu\text{mol} / \text{g}$ content)	Propionate	<i>n</i> -Butyrate
CE	0.689 $\pm$ 0.572	3.211 $\pm$ 2.373	17.105 $\pm$ 9.653	2.144 $\pm$ 0.881	1.644 $\pm$ 0.294
EL	1.624 $\pm$ 0.439	7.445 $\pm$ 2.882	38.106 $\pm$ 4.258	7.168 $\pm$ 1.000	2.523 $\pm$ 0.552

Values are the means  $\pm$  SD of pooled samples analyzed three times.

**Figure 2** Effect of organic acids on secretion of IL-6 by TNF- $\alpha$  stimulation in T84 cells. Cells were incubated with TNF- $\alpha$  (50 ng/mL) and various concentrations of organic acids for 24 hours, then supernatant was applied for determination of IL-6 production by ELISA. Data is expressed as means  $\pm$  SD ( $n=3$ ).  $^aP<0.05$  vs control.

**Figure 3** Inhibition of response to TNF- $\alpha$  (25 ng/mL) induced the mRNA level of toll-like receptor 4 (TLR4) in T84 by exposure to butyrate. Cells were treated with 0 to 2.0 mmol/L sodium butyrate for 6 hr prior to extraction of RNA and real time PCR (RT-PCR). RT-PCR was performed with specific primers and probes for indicated receptor components and housekeeping gene beta-actin. All data were normalized to the expression of beta-actin, and presented as % value of control (without TNF- $\alpha$  treatment). Data is expressed as means  $\pm$  SD.

of TLR4 mRNA in T84. Interestingly, butyrate attenuated the expression of TLR4 mRNA at low-level 0.5 mmol/L.

The change in body weight after initiation of colitis is shown in Figure 4. The *E.limosum* group showed a significant retention of body weight on d 6 and 7, compared with the control group. The change in disease activity of both dietary groups is shown in Figure 5. Prior to the change in body weight, the disease activity on d 4 was significantly attenuated in the *E.limosum* group. The organic acid contents in both dietary groups are shown in Table 2. This data is for pooled samples ( $n=7$  in respective groups), so statistical analysis was not possible; however, the level of each organic acid dramatically increased.

Figure 6 A shows representative histological photographs of colonic mucosa in both groups (magnification X 50). The colon length and damage scores of the groups are shown in Figure 6B. The *E.limosum*

**Figure 4** Changes in body weight after initiation of dextran sulfate sodium-induced colitis. control indicates the control diet (cellulose diet) group. *E.limosum* indicates the Eubacterium limosum diet group. Data is expressed as means  $\pm$  SD ( $n=7$ ).  $^aP<0.05$  vs control.

**Figure 5** Disease activity index after initiation of dextran sulfate sodium-induced colitis. Control indicates the control diet (cellulose diet) group. *E.limosum* indicates the Eubacterium limosum diet group. Data is expressed as means  $\pm$  SD ( $n=7$ ).  $^aP<0.05$  vs control. Disease activity index was determined by scoring changes in body weight, hemoccult positivity, and stool consistency.

**Figure 6** Light histological section of colonic mucosa (A) and changes in colon length and colonic mucosal damage score (B) of dextran sulfate sodium-induced colitis control and *E.limosum* diet groups. (magnification X 50). Control indicates the control diet (cellulose diet) group. *E.limosum* indicates the Eubacterium limosum diet group. Data is expressed as means  $\pm$  SD ( $n=7$ ).  $^aP<0.05$  vs control.

diet significantly attenuated the mucosal damage and shortening of colon length compared to those in the control group.

## DISCUSSION

IBD is considered to be a dysfunctional response of the mucosal immune system to luminal antigens and commensal microbiota in genetically susceptible individuals. Therefore, it is a rationally therapeutic strategy to eliminate the pathogenic bacterial component.<sup>[22,23]</sup> It has already been reported that manipulation of microflora by antibiotics, probiotics, and prebiotics was effective in IBD treatment. Antibiotic therapy is recognized to have an essential role in IBD. For example, metronidazole decreases perianal complications in Crohn's disease patients and ciprofloxacin reduces the presence of *Clostridium difficile*, which is an aggravating bacteria in IBD, and improves clinical symptoms.<sup>[24]</sup> With regards to the probiotic therapy, it is also considered a rational therapeutic option in IBD. Recent studies have shown that restoring the microbial balance using probiotics might contribute to the normalization of microflora and the attenuation of symptoms in IBD.<sup>[4]</sup> Prebiotic administration can also modulate the microflora by increasing the populations of beneficial bacteria and thereby quantitatively changing the composition of the microflora.<sup>[25]</sup> These alterations may act beneficially, in part by causing a luminal induction of short-chain fatty acids (SCFAs), which are the major probiotic metabolites, are important nutrients for the intestine, and induce an acidic environment. Especially, butyrate plays a trophic role as a first nutrient for colonocytes.<sup>[12,26]</sup> It has also been reported to act as an anti-inflammatory agent by inactivating transcriptional factor (NF- $\kappa$ B or STAT3).<sup>[12]</sup>

GBF stimulated growth of *Bifidobacterium* species and *E. limosum* and production of its metabolites butyrate and other short-chain fatty acids. Four-week administration of 20 to 30 g of GBF to patients with mild to moderate UC decreased clinical and endoscopic evidence of inflammation in a trial. This treatment increased fecal density of *Bifidobacterium* species and *E. limosum*.<sup>[8]</sup> A longer term (24 wk) open-label study reached similar conclusions.<sup>[13,27]</sup> In our previous study, the metabolites of *E. limosum* obtained as the supernatant of the medium after inoculation increased the cell growth rate as determined by SUDH activity and attenuated the production of IL-6 by TNF- $\alpha$  stimulation in T84.<sup>[21]</sup> However, the detailed role of *E. limosum* metabolites on mucosa has not been determined.

In this study, the role of the main composition of metabolites, a mixture of organic acids, on mucosa was examined. Except for succinate, the organic acids we used significantly increased the growth activity of T84. Interestingly, the cocktail containing acids at low levels, which had no stimulatory effects, significantly increased the growth rate compared to that in the control. The epithelium may require the coexistence of multiple organic acids to stimulate its growth. The cocktail significantly attenuated IL-6 production as well as the production of all short-chain fatty acids. Compared with a single acid, multiple, coexisting organic acids may increase the barrier function and anti-inflammatory effects on inflammatory colonic mucosa at a relatively low level. In the future, we need to evaluate the detailed mechanism of organic acids

on mucosa, while considering the influence of the other, soluble unknown factors in metabolites.

In this study, a powder of *E. limosum* was administered to experimental colitis model, and an *E. limosum* diet significantly prevented body-weight loss and disease activity compared with the control group. Also, the *E. limosum* diet dramatically increased the levels of 3 kinds of short chain fatty acids and 2 organic acids. As described in the method section, we could not evaluate the microbial data in cecal content, because its volume was very low. In addition, it is still not clear that the net viability in gastrointestinal tract and resistance to gastric or bile acids was derived from its obligate anaerobic character. It is speculated that the number of dietary *E. limosum* changed (decreased) day by day, in the diet since this bacterium is an obligate anaerobe and may have been adversely affected by ambient oxygen exposure during dietary administration. Care was excersiced in the preparation of sufficient *E. limosum* due to its slow growth rate and culture yields. Additional microbiological data is required to determine precise growth requirements of this microbiota.

However, the present data may suggest that *E. limosum* might be able to reproduce in the gastrointestinal tract, although the obligate anaerobe *E. limosum* was treated under aerobic conditions for use in as an animal diet for a relatively long time. The observed increase of cecal organic acid may strongly support this conjecture.

Microbiota itself contains many kinds of chemical component (peptide-glycan, enzyme, nucleic acid, protein, lipids, and so on). It is very difficult to identify the active component responsible for the anti-inflammatory effect in *E. limosum*. At first, we pointed out its metabolites, especially butyrate in this study. As shown in a previous study, butyrate demonstrated unique characteristics in colitic rats fed GBF.<sup>[9]</sup>

The monolayer of intestinal epithelial cells (IEC) plays a role in sensing the external gastrointestinal environment. Disruption or breakdown in the signaling function of IEC is important in the development of IBD.<sup>[28]</sup> It was reported that IEC recognized pathogen or bacteria is based on the conserved signature molecules in microbes (microbe or pathogen-associated molecular patterns; PAMPs).<sup>[28,29]</sup> PAMPs are found in lipopolysaccharides (LPS) of gram-negative bacteria, and lipoteichoic acids (LTA) of gram-positive bacteria. One of pattern recognition receptor families mediated the response of immune cells to PAMP is TLR family. TLR4 and TLR2, which recognize LPS, peptideglycan and LTA, respectively were well studied. In this study, we investigated the role of the major metabolites butyrate by *E. limosum* on the mucosal innate immune response *via* TLR4. It is very difficult to isolate the cell wall components of *E. limosum* and to evaluate the respective components, since these components might be modified or hydrolyzed by other microflora in gastrointestinal tract, so that, first of all, we applied the metabolites butyrate.

Remarkably butyrate decreased the expression of TLR4 mRNA level with decrease of IL-6 production in T84 cell line. Since a detailed mechanism is still unclear, we needed to evaluate of the role of butyrate in different concentrations or cell lines. However, it was considered

that butyrate had an innate immune modulatory effect.

With regards to the cell wall fraction of *E. limosum*, we do not have experimental data, and a detailed study will be needed, however, an unidentified peptidoglycan or a CpG-DNA fraction derived from *E. limosum* may contribute to the colonic mucosal immune response via TLR 2 or 9.<sup>[30]</sup> In our previous preliminary study, GBF peculiarly decreased the number of CD4+ lymphocytes in the colonic intrarepithelial layer and lamina propria in RAG2-/- CD45RB high-transfer colitis mice, together with an increase of cecal butyrate content.<sup>[31]</sup> It might also be considered that an increase of butyrate production is evidence of the presence of modulating microflora in this chronic colitis model. Considering the above results, the effects of GBF on colitis could be partly caused by a change in the mucosal immune system via modulation of microflora and its metabolic organic acids, especially butyrate production.

In this paper, we described the effects of the special bacteria (*E. limosum*) and its metabolites on colitis and colonic epithelium. In research regarding the pathogenesis of IBD and medical therapeutic approaches to IBD, we may have to consider the role of microflora and the interaction between epithelium and bacteria in the intestinal tract in more detail. Although these strategies hold great promise and appear to be useful in certain settings, more studies for example, the relationship between mucosa and microflora and its metabolites will be needed. This therapy may provide a new nutraceutical approach to IBD treatment.

### Abstract

**AIM:** To investigate if cisplatin alters vitamin status and if VR modulates cisplatin induced intestinal apoptosis and oxidative stress in Wistar/NIN (WNIN) male rats.

**METHODS:** Weanling, WNIN male rats (n = 12 per group) received *ad libitum* for 17 wk: control diet (20% protein) or the same with 50% vitamin restriction. They were then sub-divided into two groups of six rats each and administered cisplatin (2.61 mg/kg bodyweight) once a week for three wk or PBS (vehicle control). Intestinal epithelial cell (IEC) apoptosis was monitored by morphometry, Annexin-V binding, M30 cytodeath assay and DNA fragmentation. Structural and functional integrity of the villus were assessed by villus height / crypt depth ratio and activities of alkaline phosphatase, lys, ala-dipeptidyl amino-peptidase, respectively. To assess the probable mechanism(s) of altered apoptosis, oxidative stress parameters, caspase-3 activity, and expression of Bcl-2 and Bax were determined.

**RESULTS:** Cisplatin *per se* decreased plasma vitamin levels and they were the lowest in VR animals treated with cisplatin. As expected VR increased only villus apoptosis, whereas cisplatin increased stem cell apoptosis in the crypt. However, cisplatin treatment of VR rats increased apoptosis both in villus and crypt regions and was associated with higher levels of TBARS, protein carbonyls and caspase-3 activity, but lower GSH concentrations. VR induced decrease in Bcl-2 expression

### INTRODUCTION

Although vitamin deficiency is encountered infrequently in developed countries, inadequate intake of several vitamins is associated with chronic diseases like cancer, coronary heart disease and osteoporosis<sup>[1]</sup>. About 35% of all cancers are associated with various nutritional deficiencies or excesses and a poor nutritional status of various water and fat-soluble vitamins has been demonstrated in populations more prone to cancers, without symptoms of clinical vitamin deficiencies<sup>[2]</sup>. In addition, the prospect that high intake of certain vitamins may confer protection against cancer and its side effects during chemo/radiotherapy has drawn substantial attention during the last decade<sup>[3]</sup>. In this context, we have recently shown that low intake of vitamins (50% reduction) *per se* can increase the intestinal epithelial cell apoptosis through increased oxidative stress and result in lowered functional integrity of the intestinal mucosa<sup>[4,5]</sup>.

The cytotoxic actions of chemotherapeutic agents are not tumor specific, and injury to normal but rapidly proliferating cells in the bone marrow and intestinal crypt often complicates the treatment of patients with neoplastic disease<sup>[6, 7]</sup>. Systemic chemotherapy exerts cytoablative actions via several different mechanisms, ultimately leading to cell cycle arrest and/or apoptosis and produces changes

in the structure of the intestinal mucosa<sup>[8-10]</sup> that are associated with increased permeability of the intestine<sup>[11]</sup>.

Cisplatin (cis-diamminedichloroplatinum, II) is one of the most frequently used anticancer drugs. The therapeutic efficacy of cisplatin derives from its ability to form complexes with DNA<sup>[12]</sup>, which exert their cytotoxicity by directly inhibiting DNA and RNA synthesis and inducing apoptosis<sup>[13,14]</sup>. In addition, cisplatin has been shown to induce production of reactive oxygen species (ROS) that are reported to be important mediators of stress response in many cell types<sup>[15-17]</sup>. ROS accumulation and reduced glutathione (GSH) levels are critical to the bioactivity of cisplatin<sup>[18-20]</sup>. Importantly, inhibitors of ROS can block cisplatin-induced apoptosis indicating that pathways involved in and/or activated by oxidative stress are critical to cisplatin bioactivity<sup>[17]</sup>. In fact, increased intracellular GSH concentrations are found in cells resistant to cisplatin<sup>[18]</sup>, and cisplatin-induced toxicity can be blunted by systemic administration of antioxidants like N-acetyl cysteine<sup>[20]</sup>. It has been demonstrated earlier that mitochondrial damage is an early event in the pathogenesis of gastric toxicity due to cisplatin<sup>[21]</sup>. However, cisplatin-induced apoptosis also involves events that are not ROS-dependent<sup>[22]</sup>.

Whether vitamin status can modulate apoptosis in normal proliferating cells is particularly important for cancer chemotherapy as it has immediate clinical ramifications. Therefore, we have investigated the effect of sub-optimal intake of vitamins mimicking a general fall of vitamin status seen in cancer patients on the intestinal toxicity of cisplatin using rat as an animal model.

## MATERIALS AND METHODS

### Chemicals and reagents

Cisplatin was obtained from Dabur Pharmaceuticals, India. Annexin V-Biotin, M30 CytoDEATH and Streptavidin peroxidase were procured from Roche Diagnostics, Mannheim, Germany. Primary antibodies for Bcl-2 and Bax were from Oncogene Research products, San Diego, CA, USA and the substrate for caspase-3 (Ac-DEVD-pNA) was from Calbiochem, San Diego, CA, USA. Biotinylated secondary antibodies, RNase, proteinase K, Nonidet NP-40, agarose, lys, ala- 7-amido-4-methyl coumarin and the vitamins used in the diets were from Sigma chemical company, St Louis, MO, USA. All other chemicals were of the highest analytical grade and procured from local sources.

### Animals and study design

The animal studies were approved by the Ethical committee for animal experimentation at the National Institute of Nutrition, Hyderabad, India, which ensures that the guidelines set by the government of India in this regard are strictly implemented. A total of 24 Wistar/NIN (WNIN) weanling male rats were obtained from the National Center for Laboratory of Animal Sciences at National Institute of Nutrition, Hyderabad. They were divided randomly into two groups of 12 animals each and were housed individually in polypropylene cages in a room maintained at  $24 \pm 2^\circ\text{C}$ , 50-60% relative humidity, with

a 12 h light-dark cycle. They were fed for 17 wk, a casein based (20% protein) control diet or the same with 50% restriction of vitamin mixture<sup>[23]</sup>. After 17 wk, control and vitamin restricted (VR) rats were further divided into two groups of six rats each and administered cisplatin (CDDP - dissolved in PBS, at a dose of 2.61 mg/kg bodyweight) once in a week for three wk or PBS (vehicle control). The rats had free access to food and water and their food intake (daily) and body weights (weekly) were recorded periodically during the course of the experiment.

At the end of the feeding and treatment regimen, venous blood was collected from all rats after a 17 h fasting, through orbital sinus vein puncture into heparin containing vials. Plasma was separated immediately and stored at  $-20^\circ\text{C}$  for analysis of riboflavin, folic acid and vitamin E. Three rats from each group were euthanized in a CO<sub>2</sub> chamber and sacrificed each day. A 20-cm segment of the jejunum, beginning 12-cm distal to the ligament of Treitz, was immediately excised via a midline abdominal incision and freed from mesentery and fat. It was then processed for evaluating the changes in apoptotic rates.

### Processing of jejunum

The 20-cm segment of jejunum was gently washed with ice-cold phosphate buffered saline (PBS), divided randomly into three segments of 5, 5 and 10 cm each and processed as reported earlier<sup>[14]</sup>. They were used respectively for light microscopic observations, isolation of epithelial cells and extraction of DNA and determination of enzyme activities, parameters of oxidative stress and antioxidant status in addition to the expression of pro and anti apoptotic proteins, as described earlier<sup>[14,15]</sup>.

### Detection of apoptosis

Samples of rat jejunum fixed in buffered formalin for 24 h were dehydrated, embedded in paraffin and the number of apoptotic cells were scored in 4- $\mu\text{m}$  thick serial sections under a light microscope, after: (i) staining with hematoxylin and eosin (ii) M30 staining and (iii) by Annexin V binding, as described by us earlier<sup>[14,15]</sup>. Also, the DNA isolated from the jejunal epithelial cells was resolved on an agarose gel and the DNA fragments visualized under a UV trans-illuminator after ethidium bromide staining (BioRad).

### Oxidative stress, antioxidant status and expression of proteins modulating apoptosis

The frozen samples of the mucosal scrapings were processed and the activities of caspase-3, Cu, Zn-SOD, glutathione peroxidase, catalase were determined as described by us earlier<sup>[14,15]</sup>. Tissue oxidative stress was quantified by the estimation of TBARS and protein carbonyls and the expression of apoptotic modulatory proteins Bcl-2 and Bax was assessed by immuno-precipitation and western blotting<sup>[14,15]</sup>.

### Structural and functional integrity of villus

Structural integrity of the villus was assessed from the ratio of villus height: crypt depths, which were measured under a light microscope (100 $\times$  magnification) using a calibrated ocular micrometer. The values of the villus height and

**Table 1 Plasma levels of fat and water-soluble vitamins in control and vitamin restricted rats treated with cisplatin**

Group	Folate ( $\mu\text{g/dL}$ )	Riboflavin ( $\mu\text{g/dL}$ )	$\alpha$ -Tocopherol ( $\mu\text{g/dL}$ )
CON	4.85 <sup>a</sup> ±0.10	4.74 <sup>a</sup> ±0.06	74.1 <sup>a</sup> ±2.59
VR	2.08 <sup>b</sup> ±0.50	2.42 <sup>b</sup> ±0.12	46.4 <sup>b</sup> ±2.74
CON+CDDP	4.23 <sup>c</sup> ±0.11	4.05 <sup>c</sup> ±0.07	63.2 <sup>c</sup> ±2.93
VR+CDDP	1.28 <sup>d</sup> ±0.11	1.85 <sup>d</sup> ±0.03	33.1 <sup>d</sup> ±2.61

Values are mean  $\pm$  SE of 6 observations; Means in a column with different superscripts are significantly different from each other ( $P \leq 0.05$ ), by one-way ANOVA, followed by post-hoc least significant difference (LSD) test. CON - control rats; VR - vitamin restricted rats; CON+CDDP - control rats treated with cisplatin and VR+CDDP - vitamin restricted rats treated with cisplatin.

crypt depth in each animal were obtained from the mean of measurements made in seven different fields of the tissue section as described earlier [14]. Activities of alkaline phosphatase and lys, ala dipeptidyl amino peptidase were measured 12000 g supernatant, as markers of functional integrity of the mucosal membrane [14, 15].

### Plasma vitamin status

Plasma vitamin E and riboflavin levels were quantified on an RP-HPLC (Agilent Tech Inc., CA, USA) [14], whereas folic acid was determined by a solid phase competitive binding assay as described earlier [15].

### Statistical analysis

All the results are expressed as mean  $\pm$  SE. Data was analyzed statistically by one way analysis of variance (ANOVA) followed by Post Hoc multiple comparison tests of significance using the SPSS package (Version 10.0, Chicago, USA). Since no heterogeneity of variance was observed with any of the parameters tested, differences among the groups were tested by the parametric, least significant difference (LSD) test. The differences were considered significant only if  $P < 0.05$ .

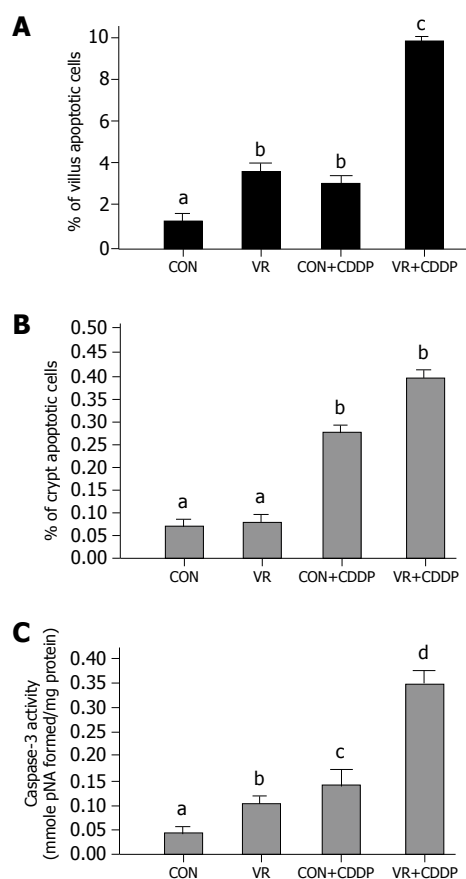

## RESULTS

### Body weight

Feeding vitamin restricted diet for 17 wk showed no significant changes in body weight of rats compared to controls. However, cisplatin administration during the next 3 wk resulted in loss of body weight to an extent of 10 % in control rats and 18 % in VR rats, due to reduced food intake (data not given).

### Plasma vitamin status

Plasma concentration of folate decreased by 13 % in control rats treated with cisplatin compared to those treated with saline. On the other hand they decreased by 38% in VR rats treated with cisplatin compared to saline treatment. Plasma riboflavin concentration decreased by 14% in cisplatin treated compared to saline treated control rats, where as this decrease was 24% in cisplatin treated compared to saline treated VR rats. Plasma vitamin E level fell by 15% in control rats treated with cisplatin compared to those treated with saline, where as the decrease was

**Figure 1** Apoptotic index and caspase-3 activity of the intestinal mucosa of control and vitamin restricted rats treated with cisplatin or saline (vehicle). Vertical bars are means with standard error, of IEC apoptotic indices in villus (Panel A) and crypt (Panel B) regions of control, vitamin restricted rats treated with saline and cisplatin ( $n = 6$  per group). Intestinal sections were stained with hematoxylin and eosin and studied by morphometry under a light microscope. Caspase-3 activity (Panel C) was measured in 12000 g supernatant using a colorimetric substrate.

29 % in cisplatin treated compared to saline treated VR rats (Table 1).

### Jejunal mucosal apoptosis

Vitamin restriction *per se* increased the jejunal villus apoptosis by 2 - fold, but not the crypt apoptosis. Cisplatin increased jejunal villus apoptosis by 1.7 and 2.4 fold respectively in control and VR rats (Figure 1A). However, crypt apoptosis in jejunum increased by 4 and 5 fold in control and VR rats respectively by cisplatin treatment (Figure 1B). Vitamin restriction *per se* increased Caspase - 3 activity by 2.4-fold. Cisplatin treatment increased caspase-3 activity by 3.5-fold in control and VR rats, compared to their saline treated controls (Figure 1C). There were 14% Annexin V positive cells in VR rats. Cisplatin treatment resulted in 13 and 25 % Annexin V positive cells in control and VR rats respectively (data not given). On the other hand M 30 positive cells were 25% in VR rats. Cisplatin treatment resulted in 30% of cells positive for M 30 in control rats whereas M 30 positive cells were 70% in VR rats (Figure 2). VR rats showed a clear inter-nucleosomal DNA fragmentation pattern characteristic of apoptosis. Interestingly DNA fragmentation increased further with cisplatin treatment.

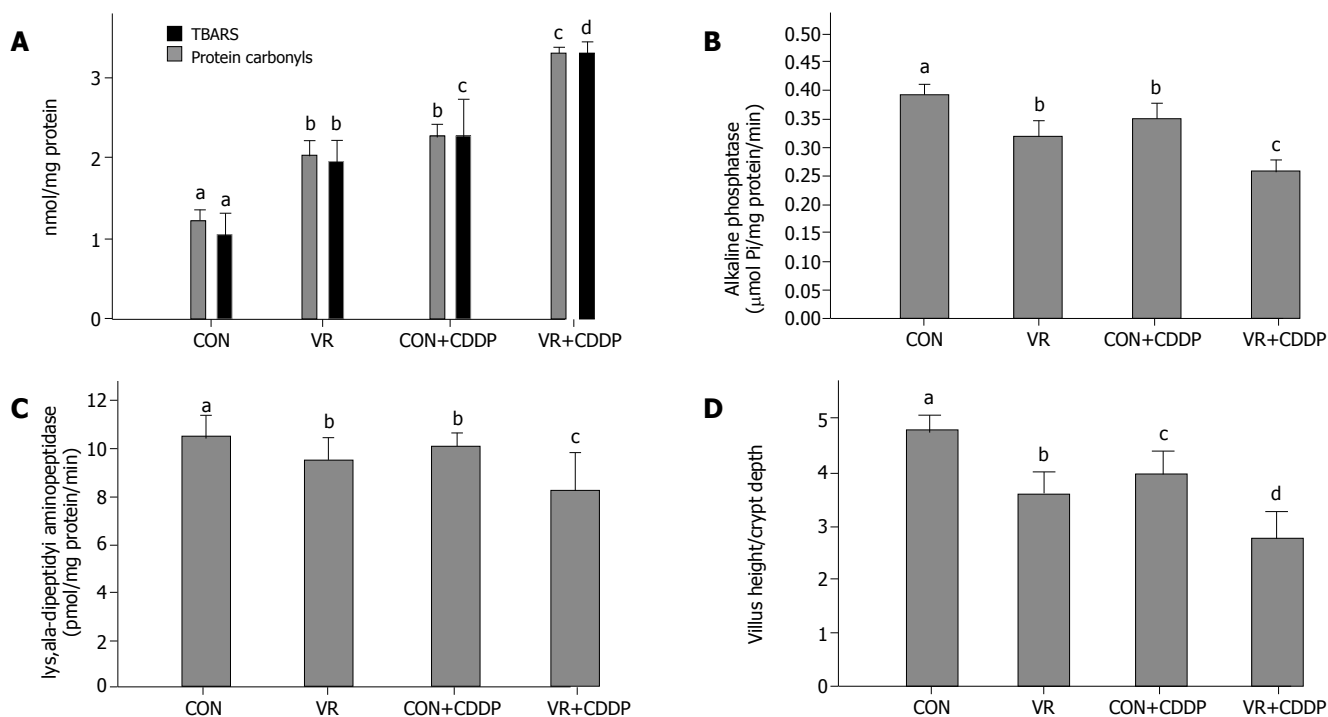

**Figure 2** Photomicrographs of apoptotic cells showing positivity for M30 antibody. Representative photomicrographs of intestinal sections immuno-histochemically stained with M 30 antibody. De-paraffinized, intestinal sections were hydrated and probed with M 30 antibody and the positive cells detected by enzymatic color reaction. Number of the brown colored positive cells were counted in a total of 1000 cells and expressed as the percentage.

**Figure 3** DNA fragmentation pattern in intestinal epithelial cells of control and vitamin restricted treated with saline or cisplatin. Epithelial cells were separated from a portion of rat jejunum, DNA extracted and resolved on a 1.5% agarose gel and stained with ethidium bromide.

**Figure 4** Effect of vitamin restriction and cisplatin on oxidative stress, structural and functional integrity of the intestinal mucosa. Levels of lipid peroxides (TBARS) and protein carbonyls are shown in panel A. Lowered activities of alkaline phosphatase (Panel B), lys, ala-dipeptidyl aminopeptidase (Panel C), are indicative of compromised functional integrity. Panel D indicates the ratio of villus height: crypt depth in control and vitamin restricted rats treated with saline and cisplatin, indicating structural integrity of the mucosa.

However, control rats treated with cisplatin showed relatively less fragmentation of DNA compared to VR rats (Figure 3).

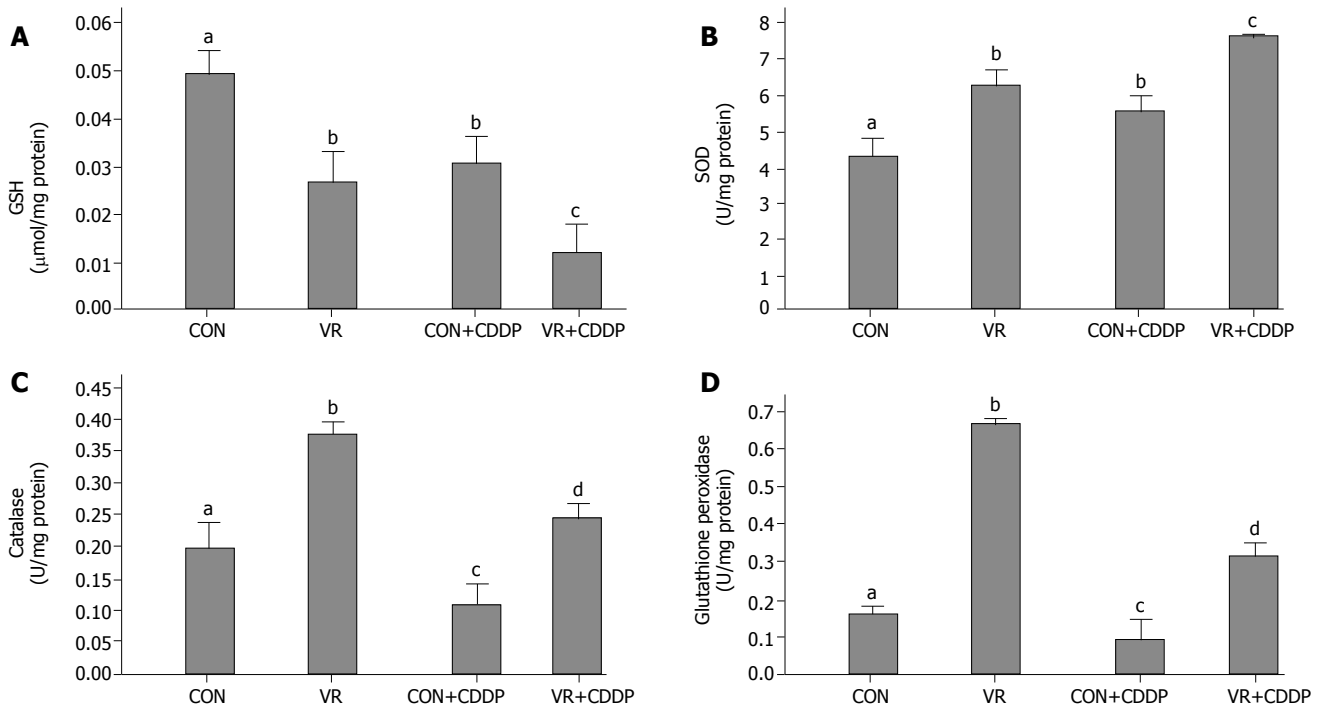

#### Tissue oxidative stress

Levels of TBARS and protein carbonyls in intestinal epithelial cells increased significantly with vitamin restriction compared to control rats. Cisplatin administration increased the levels of TBARS and protein carbonyls both in control and VR rats, but to a lesser extent in control than VR rats (Figure 4A).

#### Structural and functional integrity of the jejunal villi

Activities of alkaline phosphatase and lys, ala - dipeptidyl amino-peptidase decreased significantly in the intestinal epithelial cells of rats fed vitamin restricted diet. Cisplatin treatment decreased their activities not only in control rats but also decreased it further in VR rats, compared to their saline treated controls (Figure 4B, C). Ratio of Villus height to Crypt depth, indicative of structural integrity of the intestinal mucosa, significantly decreased with vitamin restricted diet and showed a further decline with cisplatin treatment (Figure 4D).

**Figure 5** Intestinal glutathione levels and antioxidant enzyme activities in control and vitamin restricted rats treated with saline or cisplatin. Glutathione (GSH) levels are shown in panel A, whereas activities of SOD, catalase and glutathione peroxidase (GPX) are shown in panels B to D, respectively.

### Tissue antioxidant status

Vitamin restriction significantly decreased the intestinal epithelial cell GSH concentration compared to control rats. Cisplatin treatment *per se* lowered GSH levels in control rats compared to saline treated ones. Cisplatin treatment further lowered the GSH levels in VR rats compared to saline treated VR rats (Figure 5A).

Vitamin restriction as well as cisplatin administration increased the SOD activity significantly (Figure 5B). Catalase activity increased significantly in VR rats compared to control rats. Cisplatin administration in control and VR rats significantly decreased the catalase activity compared to saline treated rats (Figure 5C). Glutathione peroxidase activity increased significantly with vitamin restriction. Similar to catalase, cisplatin administration in control and VR rats significantly decreased the glutathione peroxidase activity compared to saline treated rats (Figure 5D).

### Expression of pro- and anti-apoptotic proteins in intestinal epithelial cells

Figure 6 shows the levels of Bcl-2 and Bax in control and vitamin restricted rats treated with saline or cisplatin. Cisplatin treatment as also vitamin restriction decreased Bcl-2 levels significantly. The levels decreased further in VR rats on cisplatin treatment. On the other hand Bax levels increased significantly in VR rats compared to controls. Cisplatin treatment elevated the levels of Bax protein not only in control rats but also increased them further in VR rats.

## DISCUSSION

### Low intake of vitamins increased cisplatin action on epithelial cell apoptosis

Cisplatin is a free radical-producing drug that significantly

**Figure 6** Expression of apoptosis regulatory proteins (Bcl-2 and Bax) in the intestinal epithelial cells. Bcl-2 and Bax were immunoprecipitated from the 12,000 g supernatant of the intestinal mucosal scrapings using monoclonal Bcl-2 / Bax antibodies. The immuno-precipitates were resolved on 12% SDS-PAGE, transferred electrophoretically to PVDF membrane and the immuno-blot developed using the same antibodies and detected / quantified with HRP conjugated anti-rabbit antibodies. Lane 1 - 4 are: CON, VR, CON+CDDP, VR+CDDP respectively. Upper panel shows Bcl-2 expression and bottom panel shows Bax expression. Panel B: Quantification of the IP / Western blots of Bcl-2 and Bax proteins. Immuno-blot was scanned using a densitometer (BioRad) and densities quantified using the Quantity One software from BioRad. Each bar represents the mean  $\pm$  SE of three immuno-blot. Bars with different superscripts are significantly different from one another ( $P \leq 0.05$ ) by one-way ANOVA and post-hoc least significant difference test.

decreases the plasma concentrations of antioxidants (24) and induces intestinal epithelial cell apoptosis. Earlier, we showed that chronic low intake of vitamins decreased the plasma vitamin status and significantly increased intestinal villus epithelial cell apoptosis compared to control rats (14). In line with these findings, feeding 50% vitamin restricted diet for 20 wk significantly lowered the plasma levels of both fat and water soluble vitamins, with no significant effect either on food intake or body weight (data not shown). Interestingly, cisplatin administration *per se* decreased the plasma vitamin levels to about 85% of controls and it reduced further, the plasma vitamin levels in VR rats to 30-40% of controls. These results indicate that cisplatin treatment *per se* impairs the vitamin status, but also worsens the vitamin status in VR rats further.

Therefore, to understand if reduced vitamin status has any role in cisplatin induced intestinal toxicity, we assessed IEC apoptosis in control and VR rats treated with cisplatin. Unlike vitamin restriction, which increased the villus apoptosis alone, cisplatin increased apoptosis both in villus and crypt regions by 2.3 and 4.0- fold respectively (over saline treated controls) as assessed by morphometry. On the other hand, cisplatin treatment of VR rats increased villus and crypt apoptosis by 2.7 and 5.0- fold (over saline treated VR rats) respectively (Figure 1A and B). In line with earlier reports that chemotherapy causes intestinal damage with apoptosis of intestinal crypts, which precedes hypo proliferation resulting in crypt hypoplasia<sup>[25]</sup>, the stem cell region (crypt) showed greater sensitivity to cisplatin both in control and VR rats. Although VR *per se* had no effect on crypt apoptosis, it appeared to sensitize the crypt region to cisplatin induced apoptosis and in the villus region, VR appeared to synergistically increase cisplatin induced apoptosis. These results show for the first time to the best of our knowledge, different effects of VR on cisplatin induced apoptosis in proliferating and differentiated cells of the intestinal mucosa. Higher rates of apoptosis as assessed by morphometry correlated well with increased staining of IECs with Annexin V (data not shown) and M 30 antibodies (Figure 2). Indeed, 70% of the IECs were M 30 positive in VR rats treated with cisplatin while only 30% were positive in control rats treated with cisplatin.

Caspase 3 is an effector caspase activated by many apoptotic stimuli. To confirm that the increased IEC death in cisplatin treated VR rats is truly apoptotic and not necrotic, we assessed whether cisplatin and VR induced increase in IEC apoptosis correlated with an increase in effector caspase activation. Indeed caspase - 3 in VR rats was activated about 2.4 fold over controls whereas it increased about 3.0 fold both in control and VR rats treated with cisplatin (Figure 1C). Further, the increased Caspase 3 activity is in line with the synergistic effect of VR on cisplatin induced IEC apoptosis. That cisplatin treated VR rats showed 8-fold increase in caspase-3 activity compared to saline treated controls (Figure 1C) corroborates the increased IEC apoptosis in cisplatin treated VR rats and confirms that low intake of vitamins increases the sensitivity of intestinal epithelium to cisplatin induced apoptosis.

Modulation of the sensitivity of IECs to cisplatin-induced apoptosis by VR was further assessed by DNA

fragmentation in these cells. Despite a constitutive low rate of apoptosis in IECs of control rats, no DNA fragmentation was detectable, where as low amounts of fragmented DNA were observed in VR rats (Figure 3). Cisplatin treatment *per se* significantly increased DNA fragmentation, while priming with low vitamin intake further increased the abundance of DNA fragments.

### **Increased apoptosis is associated with increased oxidative damage of protein and lipids in intestinal epithelial cells**

Since VR increases IEC apoptosis by increasing oxidative stress, we determined whether cisplatin also affects the IEC oxidative stress. The significantly higher levels of TBARS and protein carbonyls, the oxidative products of lipids and proteins, in the IECs of cisplatin treated control rats indicates increased oxidative stress in them (Figure 4A). That their levels increased further and were the highest in cisplatin treated VR rats indicates that VR modulated cisplatin induced oxidative stress. The data suggests that cisplatin treatment substantially increased the ROS formation in the intestinal mucosa.

### **Vitamin restriction and cisplatin administration compromised the structural and functional integrity of villi**

In view of our earlier finding that VR induced increase in IEC apoptosis affected the structural and functional integrity of the intestinal mucosa<sup>[14, 15]</sup>, we assessed next, whether the increased IEC apoptosis induced by cisplatin in control and VR rats has similar effects. Cisplatin administration significantly decreased the ratio of villus height / crypt depth (Figure 4D) as well as mucosal marker enzyme activities (Figures 4B & C) in IECs of control rats and these indices were decreased further in cisplatin treated VR rats, indicating altered structural and functional integrity of mucosa and the synergism between cisplatin treatment and VR in this regard. These results indicate that cisplatin *per se* increases oxidative stress in general and lipid peroxidation in particular, which damage the membranes facilitating the leakage of solutes and VR appears to enhance this effect further. This appears to be responsible at least in part, for the lowered vitamin status in cisplatin treated rats.

### **Lowered antioxidant status and an imbalance in antioxidant enzyme activities with vitamin restriction increased mucosal sensitivity to cisplatin action**

To gain insight into the oxidant-antioxidant balance in rats treated with cisplatin and the effect of VR on it, we monitored the GSH levels in addition to determining the antioxidant enzyme activities. Elevated intracellular levels of GSH, the cellular antioxidant involved in free radical scavenging activity, is associated with resistance to chemotherapeutic agents<sup>[26]</sup>. VR *per se* decreased the GSH levels in the IECs and cisplatin further decreased them markedly. (Figure 5A). Endogenous antioxidant systems are of singular importance in limiting oxidative cellular damage. To assess the increased sensitivity if any, of intestinal epithelium to cisplatin in VR rats was also associated with altered activities of anti-oxidant enzymes, we monitored the activities of antioxidant enzymes. Vitamin restriction *per se* increased the activities of all the

three enzymes. While cisplatin treatment increased SOD and decreased catalase and GPX activities in control rats, it increased SOD further, and significantly decreased catalase and GPX activities in VR rats. These changes in the antioxidant enzymes observed in this study are in general agreement with the following literature reports: Up regulation / over expression of SOD and catalase are known to decrease the toxicity of cisplatin<sup>[27]</sup>, whereas down regulation of GPX is associated with mitochondrial dysfunction in the kidney epithelial cells<sup>[28]</sup>. It appears that the possible increase in the accumulation of H<sub>2</sub>O<sub>2</sub> or R<sub>2</sub>O<sub>2</sub> as a consequence of the imbalance in the antioxidant enzyme activities could enhance the intrinsic sensitivity of the intestinal mucosa to cisplatin-induced apoptosis.

### **Vitamin restriction and cisplatin administration lowered Bcl-2 and increased Bax expression**

To determine, if the increased IEC apoptosis seen in vitamin restriction and cisplatin treatment is associated with altered expression of the pro and anti-apoptotic proteins, the levels of Bax and Bcl-2 were measured by IP - Western blotting. Whereas Bcl-2 expression significantly decreased in VR rats (than controls), it was barely detectable in cisplatin treated control rats (Figure 6A). On the other hand, Bax expression was not altered in VR rats, but cisplatin increased its expression both in control and VR rats, albeit the increase was not significant (Figure 6B). The increased Bcl-2 expression is shown to stabilize mitochondria, prevent cytochrome c release and thereby reduce the cytotoxic potential of most anticancer drugs<sup>[29]</sup>. These results thus seem to suggest that up-regulation of Bax and the down-regulation of Bcl-2 were involved in cisplatin induced IEC apoptosis and that VR may not affect the action of cisplatin in this regard.

Anticancer drugs are known to operate principally by “forcing” the actively proliferating tumor cells into apoptosis<sup>[30]</sup>. However, these drugs also affect other proliferating cells like stem cells in the crypt of the intestinal mucosa and bone marrow either due to altered cellular redox status and / or deregulation of pro and anti-apoptotic protein expression. Since our studies indicate such effects to be more pronounced in vitamin restriction and that cisplatin treatment impairs vitamin status, it appears possible that intestinal toxicity of anticancer drugs can at least partly be due to a fall in vitamin status caused by cancer chemotherapy. Further, as VR potentiates the apoptotic response of IECs to cisplatin, vitamin deficiencies common among cancer patients may alter their intestinal tissue homeostasis and when they are exposed to a stress like chemical or radiation insult, result in frank tissue injury and loss of functional integrity. Our results provide qualitative and quantitative evidence, which support the hypothesis that vitamin restriction markedly amplifies the toxicity of cisplatin in the intestine. Therefore the need to fix the dose of anticancer drug based on the subjects’ vitamin status appears imperative to avoid the toxicity of the drug to the normal IECs. Further, it appears pertinent to study whether vitamin supplementation either singly or as a mixture can reverse such changes associated with cisplatin administration.

## **ACKNOWLEDGMENTS**

We are grateful to Dr. N. Balakrishna for his help in the statistical analysis of the data. We thank Mr. B. Sreedhar for his valuable suggestions and critical comments during manuscript preparation.

### Abstract

**AIM:** To determine whether increased blood flow of the liver can cause oxidative stress and hepatocyte damage, and to elaborate methods suitable for measuring the antioxidant defence during hepatic surgery on rat model.

**METHODS:** In nembutal narcosis, the left lateral and the medial lobes of the liver were clipped for 45 min to make the total blood supply flow through the other lobes. Total antioxidant status, glutathione peroxidase and superoxide dismutase activity, as well as the concentrations of diene conjugates and free sulphhydryl groups, H-donating ability and reducing power of the liver samples were determined. Chemiluminescent intensity of the liver was also measured. Metal ions (Al, Ca, Cu, Fe, Mg, Mn, Zn) and P and S concentrations of the liver were determined with an inductively coupled plasma optical emission spectrometer and Se content was measured by cathodic stripping voltammetry.

**RESULTS:** Glutathione peroxidase and superoxide dismutase activities of the liver decreased significantly in the hyperemia group compared to those observed in the sham operated group. The level of total antioxidant status was also significantly lower in the hyperemia group. H-donating ability, reducing power and free sulphhydryl group concentration showed the same tendency. A significant correlation ( $P < 0.05$ ) was found between the changes in non-specific antioxidant activities. This pointed to simultaneous activity of the

### INTRODUCTION

Acute hyperemia (hyperperfusion) occurs during operations of the liver when the blood flow of part of the liver is selectively occluded by the surgeon, therefore the non-occluded lobes have to deal with a greater amount of blood. This type of operation is relatively rare, but the mechanism of this kind of damage can be of great interest since very few data on this topic are available in the literature. After liver resection the non-resected liver tissue receives the whole blood volume of the portal vein and the hepatic artery, therefore it may be assumed that hepatic overflow is related to these operations. The same mechanism occurs during liver transplantation from a living donor both in the liver of the donor and in the recipient. Owing to the relatively small size of the liver it is rather difficult to handle hemodynamic changes<sup>[1]</sup>.

Hemodynamic changes due to the regeneration of the liver may have effect on the above mentioned hepatic hyperperfusion, therefore long-term investigation on this model may be an interesting field of research in the future<sup>[2-4]</sup>.

Along with the increased blood flow, oxygen tension of the hepatic tissue is also high. High oxygen tension

is connected to the generation of oxygen-related free radicals, such as hydroxyl radical, superoxide-anion or hydrogen peroxide. Oxidative stress causes major disturbances in the redox-homeostasis of the liver cells, therefore it also affects the main cellular functions through signal transduction<sup>[5]</sup>.

Especially in liver tissue, oxidative stress activates the Kupffer cells and Ito cells first, which are responsible for most of the liver damage<sup>[6]</sup>. Great amounts of free radicals are generated by Kupffer cells during their respiratory burst, which is a most important source of reactive oxygen species. Kupffer cells generate other mediators (cytokines, prostaglandines) as well, and these agents increase the damage of the liver tissue<sup>[7]</sup>.

Oxidative stress causes lipid peroxidation of the cellular membranes, and diene conjugates and malondialdehyde are generated<sup>[8]</sup>. The injury of the cellular membranes destroys the homeostasis of hepatocytes, which leads finally to apoptosis or necrosis<sup>[9]</sup>.

The great amount of free radicals and fast blood flow increase the risk of thrombosis, which can be related to greater liver cell damage<sup>[10]</sup>. Platelet aggregation is also affected by superoxide anions and hydroxyl radicals<sup>[11, 12]</sup>. The disturbance in the circulation of the liver may cause endothelial dysfunction by changing the ratio of vasoconstrictor and vasodilator agents<sup>[13, 14]</sup>. The role of the white blood cells in thrombotic mechanisms related to ischaemia-reperfusion is well known. The same reactions may occur in intact liver lobes<sup>[15, 16]</sup>.

Oxidative stress and the generation of free radicals are closely related to transition metals and the antioxidant defence system is dependent on metal elements and selenium<sup>[17, 18]</sup>. Therefore, determination of the element content in liver is relevant.

The aim of this study was to determine whether increased blood flow of the liver may cause oxidative stress of hepatocytes and to find methods suitable for measuring antioxidant defence during hepatic surgery on rat model.

## MATERIALS AND METHODS

### Materials

Luminol, microperoxidase, hydrogen peroxide, and 1,1-diphenyl-2-picryl-hydrazyl radical were obtained from SIGMA (St. Louis). TAS (NX2332), SOD (SD 125) and GSHPx (RS 506) kits were bought from Randox (Crumlin, UK). The standard solution for ICP measurements was made from Merck ICP standards, and other chemical reagents were purchased from Reanal Chemical Company (Budapest).

### Surgical model

Male Wistar rats (250 g) were purchased from Charles River Hungary and housed in a temperature- and humidity-controlled room under a constant 12-h light/dark cycle. Animals had free access to water and standard rat chow. All experiments were performed with rats fasted for 12 h prior to operations. All studies were performed with the permission of the Animal Health and Food Control Station (770/004/04).

Surgery was performed under deep nembutal narcosis (35 mg/body weight kg). Body temperature was kept between 36.5 °C and 37.5 °C. After laparotomy, circulation occlusion of the left lateral and the medial liver lobes was induced. Reflow was initiated by the removal of microclips, which selectively clamped the branches of the portal vein and hepatic artery.

### Experimental design

For evaluation of the hepatic overflow injury, a control group and a sham operated group were compared with two intervention groups respectively.

The rats were divided into control group ( $n=6$ ) in which rats were not operated; sham operated group ( $n=6$ ) in which laparotomy was performed for 45 min without damage to the liver; hyperemia (hyperperfusion) group ( $n=6$ ) in which the peduncles of the right, left medial and lateral lobes were clipped to make the total blood volume of the portal vein and the hepatic artery flow through the lesser lobes of the liver for 45 min and then liver samples were taken as reperfusion group ( $n=6$ ) in which the clips were removed from the peduncles of the ligated lobes to restore the original hemodynamic conditions of the liver after the 45-min-hyperemia period, modelling selectively induced ischaemic resection type of the liver. After 15 min of reperfusion the livers were stored at -20 °C for further examinations. The rats were exsanguinated from the arterial vein after the experiments.

### Measurement of enzyme activity and concentration of metal ions

Concentration of the diene-conjugates was measured based on the method of AOAC<sup>[19]</sup>. Free SH-groups were determined by the Sedlack method based on the Ellmann reaction<sup>[20]</sup>. The H-donating ability of the samples was determined by Blois's method modified by Blázovics *et al.*<sup>[21]</sup> in the presence of a 1,1-diphenyl-2-picryl-hydrazyl radical. Absorbance of the methanolic DPPH-dye was detected spectrophotometrically at 517 nm. For characterization of the ability, inhibition (%) was given to the DPPH degradation<sup>[22, 23]</sup>. Oyaizu's method was adopted for the determination of the reducing power (RP) of the samples. The change in absorbance was measured, which accompanied  $\text{Fe}^{3+}$ - $\text{Fe}^{2+}$  transformation at 700 nm, and the RP was compared to that of ascorbic acid<sup>[24]</sup>. All spectrophotometric measurements were carried out with a Jasco V 550 instrument.

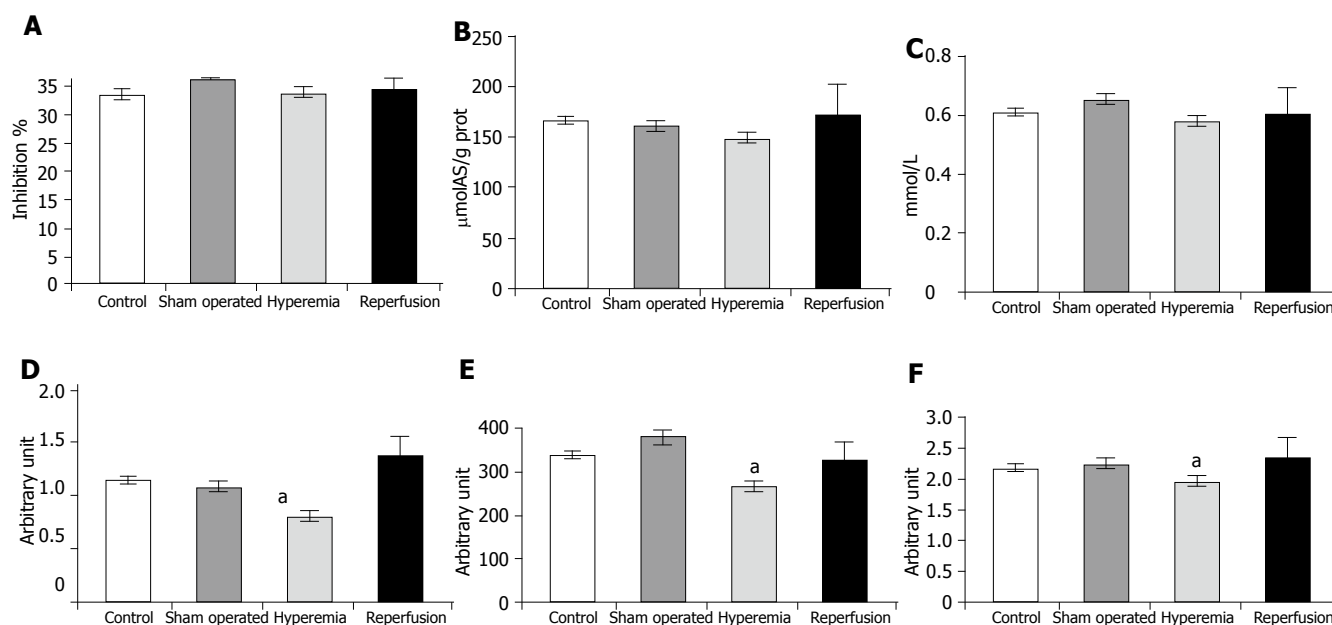

A recently developed chemiluminescence assay adapted to a Berthold Lumat 9501 instrument was applied. The procedure was carried out by the method of Blázovics *et al.*<sup>[21]</sup>. The volume of liver homogenate samples (protein content was 10 mg/mL) was 0.06 mL. Chemiluminescent intensity of the samples was expressed in RLU% (relative light unit %) of the standard (basic chemical reaction means:  $\text{H}_2\text{O}_2$ -luminol-microperoxidase reaction).

The levels of total antioxidant status (TAS), superoxide dismutase (SOD) and glutathione peroxidase (GSHPx) were determined from the supernatants of liver homogenates (10 mg/mL protein content) with Randox kits. The results were expressed in arbitrary units calculated

**Figure 1** Changes of diene-conjugates (A) and chemiluminescent intensity (B) in different groups. <sup>a</sup>*P*<0.05 vs control group.

**Figure 2** Changes of H-donating ability (A), reducing power (B), concentration of free SH groups (C), SOD activity (D), glutathione-peroxidase activity (E) and TAS level (F) in different groups. <sup>a</sup>*P*<0.05 vs control group and sham operation group.

from the absorbance detected by spectrophotometry. Protein content was measured by the method of Lowry<sup>[25]</sup>.

Element concentration in the pooled liver homogenate samples was determined in three parallel measurements with an inductively coupled plasma optical emission spectrometer (ICP-OES). Type of instrument used was Atom Scan 25 (Thermo Jarrell Ash Co.). After digestion of the liver samples (1 mL) with a mixture of nitric acid (5 mL) and hydrogen peroxide (2 mL) diluted to 10 mL with deionised water, the concentration of 9 elements (Al, Ca, Cu, Fe, Mg, Mn, P, S, Zn) was determined three times, three seconds each time. Integration time, blank subtraction and background correction were applied during the measurements<sup>[26]</sup>.

Se content in the liver was determined by a cathodic stripping voltammetric method with hanging mercury drop electrode (instrument: Trace Lab 50). The digested samples for the element measurement (previous paragraph) was measured in 1 mol/L HCl as supporting electrolyte by preconcentration at -350 mV. Electrolysis time: 100; potential: -300 mV up to -900 mV; step duration; -50 mV/s.

### Statistical analysis

One-way ANOVA statistical analysis was performed to evaluate significant levels between the different groups of rats. Pearson's correlation matrix was used to evaluate the correlation between measured parameters. The data were expressed as present mean  $\pm$  SD. Five parallel measures were carried out from each of the pooled samples, in this case the data showed mean values when c.v. was below 5.00 % *P*<0.05 was considered statistically significant.

## RESULTS

The amount of generated diene conjugates is shown in Figure 1A. The concentration of diene conjugates increased significantly in the sham operated rats, which was significantly higher in the hyperemia group than that (0.171 $\pm$ 0.001) in the control group and (0.201 $\pm$ 0.007) in the hyperemia group  $\Delta E_{232\text{ nm}}$ . When the circulation of the liver returned to normal, the level of diene conjugates also tended to return to the normal value.

**Table 1** Element concentrations ( $\mu\text{g/g}$ ) in rat liver (mean  $\pm$ SD)

	Control	Sham-operated	Hyperemia	Reperfusion

<sup>a</sup> $P < 0.05$  vs sham operated group, <sup>c</sup> $P < 0.05$  vs hyperemia group, <sup>e</sup> $P < 0.05$  vs control group

Chemiluminescent intensity was significantly higher in the sham operated group ( $1.339 \times 10^4 \pm 1.42 \times 10^4$  RLU) (as well as during hyperemia) than in the control group ( $1.612 \times 10^7 \pm 1.03 \times 10^6$  RLU). Chemiluminescent intensity was normalized by reperfusion of the ligated lobes (Figure 1B). The concentration of diene conjugates as well as the chemiluminescent intensity pointed to oxidative damage to the liver tissue.

H-donating ability was lower in the hyperemia group ( $36.05 \pm 0.12$ ) than in the sham operated group ( $33.53 \pm 2.85$ ). The changes in reducing power ( $159.36 \pm 5.76$  versus  $140.16 \pm 13.68$   $\mu\text{molAS/g}$  protein) and in the concentration of free SH-groups ( $0.649 \pm 0.054$  versus  $0.579 \pm 0.042$  mmol/L) showed the same tendency, although the changes were not significant (Figures 2A, 2B, 2C), indicating a decrease in non specific antioxidant defence. In the reperfusion group these parameters showed enormous deviation, suggesting that the antioxidant system had to exert a great ability.

A positive correlation ( $P < 0.05$ ) was found between the changes in H-donating ability, reducing power and the concentration of free SH-groups ( $r = 0.81$  between H-donating ability and reducing power,  $r = 0.82$  between H-donating ability and SH-groups and  $r = 0.56$  between reducing power and SH-groups), indicating the parallel work of the antioxidant defence system.

The SOD activity (in arbitrary unit) of the liver decreased significantly in the hyperemia group ( $0.634 \pm 0.133$ ) compared to that in the sham operated group ( $1.073 \pm 0.122$ ) (Figure 2D). The glutathione-peroxidase (GSHPx) activity (in arbitrary unit) was significantly lower in the hyperemia group ( $263.11 \pm 45.17$ ) than in the sham operated group ( $380.70 \pm 33.88$ ). When the hepatic flow became normal, the activity of the enzyme approached the basic state ( $328.38 \pm 51.87$ ) (Figure 2E). The level of TAS (in arbitrary unit) was also significantly lower in the hyperemia group ( $1.936 \pm 0.027$ ) than in the sham operated group ( $2.214 \pm 0.165$ ) (Figure 2F).

The concentration of elements (Al, Ca, Cu, Fe, Mg, Mn, P, S, Se and Zn) was also determined from pooled liver samples by ICP-OES and polarography. The concentration of Al, Cu, Mn, Zn, and S was lower in the hyperemia

**Table 2** Significant correlations between metal elements in liver during experiment

Metal ions	Correlations	Metal ions	Correlations
Al-Fe	$r = -0.92$ ; $P < 0.05$	P-Zn	$r = -0.73$ ; $P < 0.05$
Ca-Fe	$r = 0.85$ ; $P < 0.05$	P-S	$r = 0.99$ ; $P < 0.05$
Ca-Mg	$r = 0.92$ ; $P < 0.05$	Se-Cu	$r = 0.75$ ; $P < 0.05$
Ca-S	$r = 0.86$ ; $P < 0.05$	Se-Mn	$r = 0.83$ ; $P < 0.05$
Ca-P	$r = 0.87$ ; $P < 0.05$	Se-Ca	$r = 0.75$ ; $P < 0.05$
Cu-Mn	$r = 0.72$ ; $P < 0.05$	Se-Mg	$r = 0.95$ ; $P < 0.05$
Mg-S	$r = 0.85$ ; $P < 0.05$	Se-S	$r = 0.77$ ; $P < 0.05$
Mg-P	$r = 0.79$ ; $P < 0.05$		

group than in the sham operated group, while the level of Ca, Fe, Mg, Se and P ions increased during hyperemia. The tendency was the same in the case of Cu, Mn, Se and Zn level during reperfusion, which were essential for the activity of SOD and GSHPx enzymes (Table 1).

The correlations between the changes in metal ion content are listed in Table 2.

## DISCUSSION

Hepatic overflow has not been studied thoroughly so far. The intact liver lobes of the rat ischaemia-reperfusion model are generally considered unharmed, whereas oxidative damage has been verified in our investigations. The injury is probably due to the generation of free radicals. The presence of oxidative stress causes disturbances in the cell cycle and initiates apoptosis<sup>[27]</sup>. Hepatic apoptosis is related to the generation of interferon- $\gamma$ , which is able to produce oxygen-related free radicals as well<sup>[28]</sup>.

The production of reactive oxygen substances leads to hepatocyte damage, therefore, poor liver function becomes even worse<sup>[29]</sup>. A better understanding of these mechanisms is important, since the generation of free radicals and the decrease in antioxidant level can be compensated with scavenger molecules such as glutathione and multivitamin infusion<sup>[30-32]</sup>. Moreover, aged patients after liver surgery have significantly weaker antioxidant defence than young ones<sup>[33]</sup>.

Compared to the control group, the level of diene conjugates and the chemiluminescent intensity were significantly higher in the sham operated animals as well as in the animals with liver overflow. The high level of lipid peroxidation is one of the markers of oxidative stress, which along with the changes in chemiluminescent intensity point to hepatocyte injury. Chemiluminescent intensity is considered as the amount of generated free radicals. The generation of free radicals is related to the production of cytokines and other inflammatory agents, and NF- $\kappa$ -B is also activated in the process<sup>[34]</sup>, which finally leads to apoptosis and/or necrosis.

Apoptosis may occur in a physiological setting without

inflammation. In pathophysiological settings apoptosis frequently induces inflammation because of the onset of secondary necrosis and stimulation of cytokine and chemokine formation. In liver, mitochondrial permeability transition represents a shared pathway that leads to both necrosis and apoptosis (adenosine triphosphate depletion, cytochrome C release), which makes discrimination between the two forms of cell death difficult sometimes<sup>[35]</sup>.

Signal transducer and activator of transcription-3 (Stat3) are the most important molecules involved in the initiation of liver regeneration. Stat3 activation protects against Fas-mediated liver injury by inhibiting caspase activities in redox-dependent and -independent mechanisms<sup>[36]</sup>. Stat3 provides hepatoprotection against Fas-mediated apoptotic liver damage by two mechanisms: direct inactivation of caspases and reduction of reactive oxygen species<sup>[37]</sup>.

During hepatic overflow the antioxidant system is injured as well. The non-enzymatic defence system can be described by determining the values of H-donating ability, reducing power and the concentration of free SH-groups, which were found to be lower in this experiment. When the defence activity is lower, free radicals induce severer damage, suggesting that these factors are of great importance. The changes in enzymatic defence (TAS, SOD, GSHPx) show the same tendency, as observed in non-enzymatic defence. These changes may be suitable markers of hepatocyte damage. The joint effect of the high amount of reactive oxygen species produced and the decrease in the defence system may be the key to a better understanding of the damage during hepatic hyperemia.

In the present study, the high amount of blood flow caused the transfer of some metal ions into the liver cells. Especially the Ca, Fe, Mg, and P content in the liver increased during hyperemia, which can be explained by the injury of cellular membranes. The amount of the generated diene conjugates also pointed to the injury of cellular membranes. The concentration of most of the essential metal ions increased in the liver of sham operated rats. The accumulation of Fe during hepatic overflow and after surgery is important, since this element can induce the production of free radicals through the Fenton reaction. A strong positive correlation was found between the changes in concentrations of Ca-Fe, Ca-Mg, Ca-S, Ca-P, Cu-Mn, Mg-S, Mg-P, and P-S, while there was a strong negative correlation between the levels of Al-Fe and P-Zn. The accumulation of certain elements in the liver during surgery may be harmful.

Since the presence of Mn, Zn and Cu is essential for the function of SOD enzymes, their lower ability may be attributed to the loss of the above elements<sup>[38]</sup>. Se is relevant to the action of glutation-peroxidase, which is also important in the antioxidant defence of liver cells. During our experiment the behaviour of Se was surprising. Therefore, measuring Se concentration under these conditions may lead to a new and important field of research<sup>[39]</sup>. These findings also underline the changes in the homeostasis of liver cells due to hyperperfusion.

Compared to the ischaemia-reperfusion damage<sup>[40]</sup>, the injury caused by hyperemia is related to less hepatocyte dysfunction, an important risk factor for liver surgery. In conclusion, the methods applied by us are suitable for

measuring compensatory mechanisms in hyperemia and ischaemia-reperfusion.

permeability that is inhibitable by  $\text{HgCl}_2$  was detected in porcine erythrocytes and CHO cells stably transfected with pAQP1 cDNA. Immunoblot analysis of porcine erythrocytes and pAQP-transfected CHO cells revealed an unglycosylated 28 ku band and larger glycosylated proteins.

**CONCLUSION:** pAQP1 is the first porcine aquaporin that can be molecularly identified so far. The broad distribution of pAQP1 in epithelium and endothelium of porcine digestive organs may suggest an important role of channel-mediated water transport in fluid secretion/absorption as well as in digestive function and pathophysiology of the gastrointestinal system.

## Abstract

**AIM:** To clone and characterize the porcine aquaporins (AQPs) in the gastrointestinal system.

**METHODS:** A PCR-based cloning strategy and RACE were used to clone full-length AQP coding sequence from reversely transcribed pig liver cDNA. Stopped-flow light scattering and a YFP-based fluorescence method were used to measure the osmotic water permeability of erythrocytes and the stably transfected CHO cells. RT-PCR, Northern blot, and immunohistochemistry were used to determine the gastrointestinal expression and localization of cloned AQPs. Protein expression in transfected cells and red blood cells was analyzed by Western blot.

**RESULTS:** An 813 bp cDNA encoding a 271 amino acid porcine aquaporin (designated pAQP1) was cloned from liver mRNA (pAQP1 has a 93% identity with human AQP1 and contains two NPA motifs conserved in AQP family, one consensus sequence for N-linked glycosylation, and one mercury-sensitive site at cysteine 191). RT-PCR analysis revealed extensive expression of pAQP1 mRNA in porcine digestive glands and gut. Northern blot showed a single 3.0 kb transcript in selected digestive organs. pAQP1 protein was localized at central lacteals of the small intestine, microvessels of salivary glands, as well as epithelium of intrahepatic bile ducts by immunoperoxidase. High osmotic water

## INTRODUCTION

Aquaporins (AQPs) are water channel proteins located on membranes of various cell types where they create high water permeability. So far at least 12 mammalian members of AQP family have been molecularly localized in diverse fluid transporting tissues have been molecularly identified. Recent studies on human subjects with AQP gene mutations using transgenic AQP knockout mice indicate that AQPs have important functions in multi-tissue physiology and pathophysiology<sup>[1,2]</sup>. In the gastrointestinal (GI) system, several aquaporins (including AQPs 1, 3-5, 7-10) are localized on various epithelial and endothelial cell membranes of human and rodent GI organs and provide a trans-cellular pathway for fast water movement during fluid secretion and absorption<sup>[3-6]</sup>. Studies on AQP knockout mice demonstrated that AQP5 plays a role in saliva secretion<sup>[7]</sup>, AQP1 a role in dietary fat processing<sup>[8]</sup>, and AQP4 a role in colonic fluid absorption and fecal dehydration<sup>[9]</sup>. On the other hand, localization of AQPs

in some mouse GI organs does not indicate physiological importance. For example, AQP4 deletion in gastric parietal cells does not affect gastric acid secretion<sup>[10]</sup>, AQP1 deletion in micro-vessels of salivary glands does not affect saliva secretion, AQP1 deletion in intra-hepatic bile ducts does not affect the flow rate and components of bile<sup>[8]</sup>. GI phenotype in AQP1-null human subjects has not been reported so far, which may indicate species differences of AQP involvement in digestive physiology.

Although significant progresses have been made in molecular biology and physiology of AQP family in the GI system, identification and characterization of AQPs in GI organs of mammalian species other than in those of human and rodents have been poorly studied. The pig GI system more resembles the human GI system both structurally and physiologically in model animals<sup>[11]</sup>. However, no porcine AQP member has been identified molecularly so far. In the present study, we cloned the first porcine aquaporin, pAQP1 from pig liver, by a PCR-based homologous cloning strategy. Its functional properties and distribution in pig GI system were analyzed.

## MATERIALS AND METHODS

### cDNA cloning of pAQP1

Full-length coding sequence of pig AQP1 cDNA was cloned using a PCR-based homologous cloning strategy<sup>[12]</sup>. Total RNA was extracted from pig liver using TRIZOL reagent (Invitrogen). mRNA was isolated from the total liver RNA using an Oligotex mRNA kit (Qiagen). cDNA was reversely transcribed from the mRNA using a first strand cDNA amplification kit (Invitrogen) and used as template for 30 cycles of PCR amplification at 94 °C for 30 s, at 55 °C for 30 s, at 72 °C for 1 min with degenerate oligonucleotide primers designed according to amino acid sequences around the two NPA motifs of aquaporin family: sense: 5'-CA(C-T)IT(CA)AA(CT)CCIGCIGTIAC-3'; antisense: 5'-(G C) C I (A G) (A G) I (A - G)(AT)GC(TG)IGC(AT)GG(AG)TT-3'. PCR products of about 360 bp were subcloned into pCR2.1TOPO TA cloning vector (Invitrogen) and sequenced. A sequence with open reading frame that is most homologous to dog AQP1 water channel was identified. To clone the full length coding sequence of the candidate water channel, 5'- and 3'-RACE (rapid amplification of cDNA ends) were performed using the Marathon cDNA amplification kit (BD Biosciences-Clontech) following the provided protocol. The sequences of gene-specific primers (GSP) are as follows: 5'-RACE GSP: 5'-CACACACTGGGCAA TGATGTACATG-3'; 5'-RACE NGSP: 5'-GACACTGA TCTGGCAGCTGAGCAG-3'; 3'-RACE GSP: 5'-CCTT GCCATCGGCTTCTCTGTGGC-3'; 3'-RACE NGSP: 5'-CTGGGACACCTGCTGGCGATTGAC-3'. An Expond long PCR kit (Roche) was used for 30 cycles of RACE amplification at 94 °C for 30 s, at 65 °C for 30 s, at 68 °C for 4 min. PCR products were subcloned to pCR2.1TOPO TA cloning vector and sequenced. The longest open reading frame was obtained by joining the 5'-RACE and 3'-RACE sequence and the sequence between the two NPA motifs. The protein encoded by the longest open reading frame was designated as pAQP1.

### RT-PCR and Northern blot

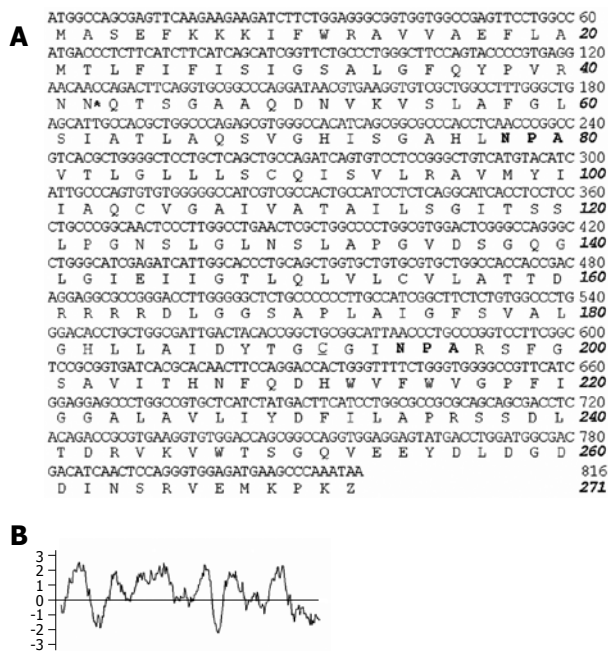

Total RNA was extracted from pig salivary glands, liver, pancreas, esophagus, stomach, small intestine and colon respectively, using TRIZOL reagent. For RT-PCR analysis, cDNAs were reversely transcribed from 5 µg of each total RNA using first strand cDNA amplification kit and 30 cycles of PCR amplification were performed at 94 °C for 30 s, at 62 °C for 30 s, at 72 °C for 2 min with primers flanking the coding sequence of pAQP1 (sense: 5'-CG-GATCCATGGCCAGCGAGTTCAAGAAG-3'; antisense: 5'-GCTCTAGATTATTTGGGCTTCATCTCCACC-3'). For Northern blot, total RNA (20 µg) from liver, salivary gland, small intestine and colon was resolved on 1.2% formaldehyde gel and transferred to a Hybond-N<sup>+</sup> nylon membrane (Amersham). The membrane was prehybridized at 68 °C for 1 h in a rapid hybridization buffer (Amersham) and then hybridized for 1 h with a <sup>32</sup>P-labeled probe corresponding to the full-length pAQP1 coding sequence. The membrane was washed three times in 0.2 x SSC, 0.1% SDS at 68 °C, each for 15 min, and autoradiographed for 16 h with double intensifying screens. The membrane was boiled in water and re-probed with a 600 bp pig β-actin cDNA sequence.

### Transfection and water permeability measurement of pAQP1 in CHO cells

A cell-based fluorescence microassay employing a Cl<sup>-</sup>-sensitive EYFP mutant<sup>[13]</sup> was developed to measure the channel-mediated water permeability of plasma membrane. The 720 bp EYFP-H148Q-V163S DNA fragment encoding the Cl<sup>-</sup>-sensitive EYFP mutant was PCR-amplified using Vent DNA polymerase (New England Biolabs) and primers with engineered restriction sites *Hind*III (5' primer) and *Xba*I (3' primer). The fragment was digested with *Hind*III/*Xba*I and ligated to the mammalian expression vector pcDNA3.1 Hygro (hygromycin-resistant, Invitrogen) predigested with *Hind*III/*Xba*I to form expression plasmid pcDNA3.1 Hygro-EYFP-H148Q-V163S. For pAQP1 expression, the 813 bp pAQP1 full length coding sequence was PCR-amplified using Vent DNA polymerase and primers with engineered restriction sites *Bam*HI (5' primer) and *Xba*I (3' primer). The amplified pAQP1 fragment was digested with *Bam*HI/*Xba*I and ligated to the mammalian expression vector pcDNA3.1(+) (G418-resistant, Invitrogen) predigested with *Bam*HI/*Xba*I to form expression plasmid pcDNA3.1 pAQP1.

CHO-K1 cells were first transfected with expression plasmid pcDNA3.1Hygro-EYFP-H148Q-V163S using Lipofectin reagent (Invitrogen). After selection by hygromycin (Roche) at 500 µg/mL, highly expressed CHO clones were isolated by judging brightness of survived cell colonies under fluorescence microscope. The YFP-expressing cell clone, CHO-K1/EYFP-H148Q-V163S, was then transfected with pcDNA3.1 pAQP1 and selected with G418 (Invitrogen) at 500 µg/mL. pAQP1 expression in survived CHO cell clones was analyzed by immunoblot. CHO cell clones with high cytoplasmic expression of Cl<sup>-</sup>-sensitive EYFP mutant and plasma membrane expression of pAQP1 were selected for water permeability measurement.

**Figure 1** cDNA and deduced amino acid sequences of pig AQP1 water channel. **A:** Two NPA sequences conserved in water channel proteins of aquaporin family (in bold). \*indicates the consensus sequence for N-linked glycosylation and the mercurial-sensitive site cysteine 201 near the second NPA motif is underlined; **B:** Kyte-Doolittle hydropathy profile of the deduced pAQP1 amino acid sequence.

For water permeability measurement, the CHO-K1/EYFP-H148Q-V163S/pAQP1 cells were plated in 96-well clear bottom of black-walled microplates (Costar) at the density of 20000 cells per well in F-12 Ham's medium supplemented with 10% FBS and 0.5 mg/mL G418. After incubation at 37 °C in an atmosphere containing 5% CO<sub>2</sub> with 90% humidity for 18 h, the cells in 96-well plates were washed twice in PBS buffer (200 µL/wash), leaving 100µL PBS after the last wash. Measurement was performed on FLUOstar Optima plate reader (BMG Technology) equipped with syringe pumps and HQ500/20X (500 ± 10 nm) excitation and HQ535/30M (535 ± 15 nm) emission filters. Cells in each well of the plate were assayed individually for osmotically driven pAQP1-mediated water influx across the plasma membrane that dilutes the cytoplasmic Cl<sup>-</sup> by recording fluorescence increase continuously (0.2 s per point) for 2 s (baseline) and then for 21 s (water transport into the cells) after rapid injection (< 1 s) of 100 µL distilled water. Water permeability was expressed as half time (t<sub>1/2</sub>) needed from water injection to the point when the cytoplasmic fluorescence reached the maximum. The smaller t<sub>1/2</sub> represented the higher water permeability.

#### Measurement of erythrocyte water permeability

Pig blood was drawn from the ear by venipuncture, and the washed erythrocytes were diluted into phosphate buffered saline (PBS) at a 0.1 vol %. Osmotic water permeability was measured by a stopped-flow light scattering technique in which the diluted erythrocyte suspension was mixed rapidly with PBS containing 100 mmol/L sucrose<sup>[14]</sup>. Erythrocyte volume was measured continuously by 90 s light scattering for 90 s at a 520-nm wavelength.

#### Immunohistochemistry

Paraffin-embedded blocks were prepared from fresh normal pig salivary gland, liver, and small intestine fixed in 4% formalin. For immunohistochemistry, 3-µm sections of pig tissues were prepared by standard procedures and exposed to the primary affinity-purified rabbit-antirat AQP1 antibody (AB3065, Chemicon International) diluted at 1:1000 for 1 h at room temperature. In some experiments, the primary AQP1 antibody was preincubated with the immunizing peptide before administered to the tissue sections. After washed, the sections were exposed to a horseradish peroxidase-conjugated goat antirabbit IgG (A6154, Sigma) secondary antibody at 1:2000 dilution followed by development with 3,3'-diaminobenzidine (DAB) liquid substrate dropper system (D7679, Sigma). The sections were counterstained with haematoxylin as the last step.

#### Western blotting

Stably transfected CHO cells were lysed in 10 mM HEPES buffer containing 0.5% SDS, 100 mmol/L DTT and 57.4 µmol/L PMSF (pH 7.5). Red blood cells from pigs, human beings and mice were first burst in hypoosmotic solution, and then the ghosts were centrifuged and lysed in SDS buffer. Protein concentrations in CHO cell and ghost lysates were determined spectrophotometrically. For immunoblotting, 20 µg proteins from the CHO cell lysate or 5 µg proteins from the ghost lysate of red blood cells from pigs, human beings and mice were dissolved in protein sample buffer, heated at 65 °C for 10 min, and then resolved on 12% SDS-PAGE minigels. Proteins were blotted into PVDF membranes, blocked for 1 h, washed with TBS-T (pH 7.4), and incubated for 1 h at room temperature with anti-AQP-1 antibody diluted at 1:1000. After washed, membranes were incubated with HRP-conjugated goat anti-rabbit IgG (1:3000, Sigma), and immunoreactive sites in membranes were revealed by enhanced chemiluminescence (Amersham).

## RESULTS

#### Cloning and analysis of pAQP1 cDNA

The full-length cDNA coding sequence and the predicted amino acid sequence of pAQP1 (Genbank accession no. AY585335) are shown in Figure 1A. The 813 bp open reading frame encoded a 271-amino acid protein containing the two conserved NPA motifs found in most AQP family members and a cysteine residue located just upstream of the second NPA motif, which could confer mercurial sensitivity in several cloned mammalian AQPs<sup>[15,16]</sup>. Compared to human and mouse AQP1 coding sequences, an additional segment of GCGGCC at nt 138–143 encoding two alanines (residues 47 and 48) was found only in the porcine sequence. Figure 1B shows the Kyte-Doolittle hydropathy plot for pAQP1, suggesting six membrane spanning domains similar to those of human and rat AQP1. Figure 2 shows an amino acid sequence alignment of pAQP1 with its homologues from dogs, human beings, and mice. pAQP1 had the greatest amino acid identity to dog AQP1 (94%) and high homology to human AQP1 (93%) and mouse AQP1 (91%). **Figure 2** Amino acid sequence alignment of pAQP1 with its dog, human and mouse orthologs. Conserved amino acids are shielded, NPA motifs are boxed and cyteines near the second NPA motifs are underlined. The consensus N-linked glycosylation sites are shown in bold.

**Figure 3** mRNA expression of pAQP1 water channel in pig gastrointestinal organs. **A:** Expression of pAQP1 transcript by RT-PCR analysis. Lanes 1, Salivary gland; 2, Liver; 3, Pancreas; 4, Esophagus; 5, Stomach; 6, Jejunum; 7, Ileum; 8, Colon; **B:** Northern blotting of total RNA (20 µg) from salivary gland (lane 1), liver (lane 2), ileum (lane 3) and colon (lane 4) probed with the pAQP1 coding sequence (upper) and the same membrane probed with a 600 bp pig β-actin cDNA sequence (lower).

**Figure 4** Immunolocalization of pAQP1 in pig gastrointestinal tract and exocrine glands. Specific pAQP1 labeling of central lacteals was seen by immunoperoxidase staining of longitudinal (**A**) and transverse (**B**) sections of the small intestinal villi using an affinity-purified AQP1 antibody. Arrows indicate the endothelium of central lacteals; A salivary gland section showing specific labeling of microvessel endothelium indicated by arrows (**C**); Specific pAQP1 labeling was seen in the epithelium of intrahepatic bile ducts in longitudinal (**D**) and transverse (**E**) sections. Arrows indicate heavy pAQP1 staining in the apical domain of bile duct epithelial cells. Arrowhead indicates pAQP1 labeling in the endothelium of periductal microvessels; A consecutive section of **E** showing immunostaining with AQP1 antibody preabsorbed with the immunizing peptide (**F**).

pAQP1 had a 29 - 52% similarity in amino acid sequences to other mammalian aquaporin members<sup>[15, 16]</sup>. There were two consensus sequences for phosphorylation by protein kinase-C like in human and mouse AQP1. However, pAQP1 contained only one consensus site at residue 42 for N-linked glycosylation compared to two sites in human and mouse AQP1 sequences at residues 42 and 205. In addition, there were two more amino acids in the pig and dog AQP1 sequences at residues 47 and 48 instead of in the human and mouse sequences.

### Expression and immunolocalization of pAQP1 in digestive organs

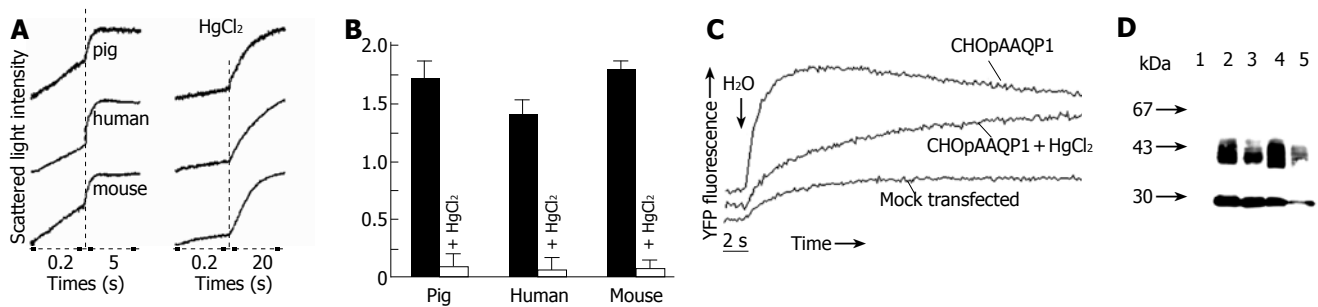

Multitissue RT-PCR analysis indicated broad expression of pAQP1 mRNA in pig digestive organs including salivary glands, pancreas, liver and different segments of the gut (Figure 3A). Figure 3B shows Northern blot analysis of total RNA from pig salivary glands, liver, small intestine, and colon respectively using the full length pAQP1 cDNA

as a probe. A single transcript of about 3.0 kb was seen in liver ~ small intestine > colon > salivary glands. Figure 4 shows an immunoperoxidase staining of pAQP1 in selected digestive organs. Specific AQP1 labeling was seen both in the endothelia of central lacteals in villi of the small intestine (Figures 4A and 4B) and in the endothelia of microvessels in salivary glands (Figure 4C). In the liver, AQP1 staining was mainly seen both in the epithelium of small bile ducts and endothelium of some small vessels (Figures 4D and 4E). AQP1 labeling was predominant in the apical domain of most stained bile ducts.

### Functional characterization of pAQP1

Since AQP1 is a erythrocyte water channel, osmotic water permeability of pig red blood cells was analyzed using stopped-flow light scattering and compared with human and mouse red blood cells. Figure 5A shows the time course of osmotic cell shrinking in response to a 100 mmol/L inwardly directed osmotic gradient.

**Figure 5** Functional properties of pAQP1 in erythrocytes and stably transfected CHO cells. **A:** Osmotic water permeability of pig, human and mouse erythrocytes measured by stopped-flow light scattering from the time course of erythrocyte volume in response to a 100 mmol/L inwardly directed sucrose gradient in the absence (left panel) and presence (right panel) of 0.3 mmol/L HgCl<sub>2</sub>; **B:** Summary of osmotic water permeability coefficient (Pf) for erythrocytes from pig, human and mouse measured in A (mean ± SE, n=4); **C:** Osmotic water permeability of CHO cells stably transfected with pAQP1 cDNA measured by YFP-based fluorescence assay. Water permeability of CHO cells was expressed as half time (t<sub>1/2</sub>) needed from water injection to the point when the cytoplasmic fluorescence reached the maximum. t<sub>1/2</sub> of pAQP1 transfected CHO cells in the absence and presence of 0.1 mmol/L HgCl<sub>2</sub> was 1.2 s and 4.6 s separately. t<sub>1/2</sub> > 20 s in mock-transfected CHO cells; **D:** Immunoblot of erythrocytes and transfected CHO cells. Lanes 1-4: erythrocytes from AQP1<sup>-/-</sup> mice, AQP1<sup>+/+</sup> mice, pigs and human beings. Lane 5: CHO cells stably transfected with pAQP1 cDNA.

Two contiguous time scales were used to plot the full time course of decreasing cell volume (increasing light intensity). The computed osmotic water permeability of pig, human and mouse erythrocytes is summarized in Figure 5B. The pig erythrocyte membrane showed a high osmotic water permeability that was inhibited > 90% by 0.3 mmol/L HgCl<sub>2</sub>, similar to that of human and mouse erythrocytes. Water channel function of pAQP1 was also analyzed in heterologous expression system. Figure 5C shows the time course of YFP fluorescence of CHO cells stably transfected with pAQP1 cDNA in response to extracellular hypotonicity (50% PBS). The t<sub>1/2</sub> of fluorescence dynamics for pAQP1-transfected cells was 1.2 s compared to 4.6 s for the same cells incubated with 0.1 mmol/L HgCl<sub>2</sub> and > 20 s for mock-transfected cells, indicating that a high membrane water permeability was mediated by pAQP1 water channel inhibited by mercurial compounds. Figure 5D shows Western blot analysis of red blood cells and pAQP1-transfected CHO cells using an affinity-purified AQP1 antibody. An unglycosylated 28 ku band and glycosylated proteins at a higher molecular weight were determined both in red blood cells of human beings, pigs, wildtype mice and in pAQP1-transfected CHO cells, but missed in AQP1-knockout mouse erythrocytes. There was a significant decrease of glycosylated protein in pAQP1 compared to human AQP1 and mouse AQP1 in red blood cells. Western blot analysis of pig gastrointestinal tissues was not done because of the difficulty to remove red blood cell contamination.

## DISCUSSION

We have successfully cloned pAQP1, the first molecularly identified porcine AQP water channel. The amino acid sequence of pAQP1 has a high identity to dog, human and mouse AQP1 and contains the two highly conserved NPA motifs and the mercurial-sensitive cysteine residue before the second NPA motif in several cloned AQPs in other mammals<sup>[16-19]</sup>. pAQP1 contains only one consensus sequence compared to two consensus sequences for N-linked glycosylation in human and mouse AQP1<sup>[20, 21]</sup>. Immunoblot analysis showed that glycosylated protein of pAQP1 was decreased compared to human

and mouse AQP1 in red blood cells, indicating that the second consensus site at asparagine 205 of human and mouse AQP1 contributes significantly to the N-linked glycosylation of the protein.

Like its human and mouse orthologs, pAQP1 conferred a high osmotic water permeability in a mercurial-sensitive manner both in pig red blood cells and in heterologous expression system, indicating a similar functional water channel in erythrocyte and somatic cell membranes. pAQP1 mRNA and protein were expressed extensively in endothelia and epithelia of pig gastrointestinal system involving digestive glands responsible for secretion of saliva, bile, and pancreatic juice as well as all the intestinal segments responsible for absorption of fluids and nutrients, suggesting that channel-mediated transcellular water pathway plays a role in broad physiological processes of secretion and absorption in various porcine digestive organs. The molecular cloning of pAQP1 makes it possible to investigate its expression and regulation during development and in various physiological and pathophysiological conditions of the pig gastrointestinal system.

### Abstract

**AIM:** To investigate the results of radiofrequency ablation (RFA) in obtaining the necrosis of hepatocellular carcinoma (HCC) in cirrhotic patients and to assess the results of RFA in relation to recurrence of HCC and survival of the treated patients.

**METHODS:** Fifty-six consecutive cirrhotic patients with 63 HCCs were treated with RFA between May 2000 and May 2004. The diameter of the HCCs ranged from 1 cm to 5 cm (mean 2.8 cm). In all cases RFA was performed with percutaneous approach under ultrasound guidance using expandable needle electrode (LeVeen needle). Treatment efficacy and recurrence were evaluated with dual-phase spiral computed tomography (CT).

**RESULTS:** Complete necrosis after single or multiple treatment was achieved in 96.8% (61/63) tumors. We observed recurrence after complete necrosis in 23 patients (41%) during a mean follow-up of 32.3 months. The recurrences were local in 2 patients (8.6%) and in different segments in 21 (91.4%). Major complications occurred in 3 patients (4%). During follow-up period, 32 (57.1%) patients died; 15 due to progression of HCC, 11 from liver failure, 3 from esophageal varices bleeding and 3 from the causes not related to liver disease.

**CONCLUSION:** RFA with LeVeen needle is an effective and safe treatment for HCC < 5 cm in cirrhotic patients. It has yet to be established how far this treatment influences the survival rate of patients. It becomes important to establish treatments to prevent recurrences in different segments, such as interferon therapy.

### INTRODUCTION

Hepatocellular carcinoma (HCC) is a common malignant neoplasm throughout the world and surgical resection is thought to be the best curative approach in the treatment of HCC<sup>[1-3]</sup>. However, few patients with HCC are suitable for resection due to age, location of the lesion, advanced cirrhosis of the liver and concomitant diseases; as a consequence less invasive treatment methods have been pursued, especially echo-guided percutaneous ethanol injection (PEI) and radiofrequency (RF) thermal ablation<sup>[4-9]</sup>. PEI was the first method used starting in the eighties, followed by the introduction of RF in order to overcome some of the limitations of PEI, such as the difficulty in ensuring the distribution of ethanol throughout the lesion and the need for multiple sessions due to the reduced volume of necrosis that can be achieved in the single session<sup>[10]</sup>. At present RF is certainly the first choice of interstitial therapy method in the majority of cases of HCC that can not be treated surgically. The two types of RFA needles most used are the cool-tip needle with internally circulating cool saline (Radionics, Burlington, MA, USA) and the expandable 10-hooks LeVeen needle (Radio Therapeutics Corporation, Sunnyvale, CA, USA). Compared with the Cool-Tip, the LeVeen needle electrode can theoretically create a more even flux of the radiowave, producing thermal effects with a greater spherical area. Because this needle uses a gradual augmentation sequence of the RF output to prevent excess heating of the target tissue, this RFA system does not require circulation of cool saline in the needle electrode for preventing charring of the target tissue as in the Cool-Tip RFA system<sup>[9]</sup>. The LeVeen needle has a larger diameter than the Cool-Tip (15 Gauge vs 18 Gauge), but no significant differences in complications have been reported in the literature between the two types of needle electrodes<sup>[11]</sup>.

Herein, we report our experience in performing

percutaneous echo-guided RF thermal ablation of HCCs with the LeVeen needle electrode system in a gastroenterological Italian service. We aimed to assess the efficacy of the system in obtaining the necrosis of the target tissue and the clinical outcome of the treated patients.

## MATERIALS AND METHODS

From May 2000 to May 2004, a total of 56 consecutive cirrhotic patients (37 males and 19 females, age range 45-81 years, mean age 68.7 years), who underwent RFA for non-surgically resectable HCC due to the location of the tumor, severity of the cirrhosis, age, associated diseases or refusal of surgery, were enrolled in the study. Inclusion criteria were HCC diameter < 5 cm, absence of portal thrombosis or extrahepatic diffusion, absence of significant ascites, prothrombin activity > 50% and platelet count more than 50 000, and a maximum of three HCCs, each not more than 3 cm in maximum diameter.

The etiology of the cirrhosis was viral in 51 cases (48 due to HCV infection and 3 due to HBV infection), alcoholic in 4 and autoimmune in 1 case (primary biliary cirrhosis). On the basis of the Child-Pugh classification, 16 patients were class A, 37 class B and 3 class C (Table 1).

As regards the characteristics of the HCCs, 50 patients had a single tumor, 5 had two tumors and 1 had three tumors; a total of 63 tumors were detected in the 56 patients studied. None of the HCCs had an infiltrating appearance at imaging. The dimensions of the HCCs were between 1 and 2 cm in 19 cases, between 2 and 3 cm in 27 cases, between 3 and 4 cm in 12 cases and between 4 and 5 cm in 5 cases; the mean size was 2.8 cm (Table 2). The pre-treatment diagnosis of the nature of the lesion was histological with echo-guided fine needle biopsy in 42 patients, performed in 19/19 nodules <2 cm, 20/27 nodules <3 cm, 3/12 nodules <4 cm and 0/5 nodules <5 cm. In the remaining 14 patients, the diagnosis was based on non-invasive criteria, radiological with typical arterial hypervascularization at color power Doppler ultrasound, contrast-enhanced ultrasound, computerized tomography (CT) or magnetic resonance (MR) (11 patients) or combined with one typical imaging technique associated with AFP levels >400 ng/mL (3 patients). Starting in October 2000, as far as the non-invasive diagnosis was concerned, we followed the indications of the EASL Conference on clinical management of hepatocellular carcinoma, held in Barcelona, Spain in September 2000<sup>[12]</sup>. It should however be pointed out that all the patients underwent pre-treatment contrast dual-phase spiral CT for the staging and baseline assessment of the vascularization of the HCC.

### Technique

The RF delivery system was an RF 2000 generator system (Radio Therapeutics) in monopolar mode, used in conjunction with a LeVeen monopolar array needle electrode and two large dispersive electrodes. The RF generator supplies voltage at a frequency of 460 KHz and a maximum power output of 100 W. The RF generator display indicates power, tissue impedance and procedure

time. The active expandable needle electrodes have a 15 gauge, 15 cm long stainless steel insulated cannula with 10 retractable lateral hooks each oriented at an angle of 36° from the two adjacent hooks. The maximum deployment diameter of the hooks was 3.0 or 3.5 cm. We used the 3.0 cm hooks for lesions equal to or less than 3 cm in diameter and the 3.5 cm hooks for lesions greater than 3 cm.

Treatment was performed only in inpatients, fasting 12 h before treatment, and they received mild sedation with an intramuscular administration of 10 mg of diazepam and 0.5 mg of atropine sulphate 30 min before the procedure. If necessary during treatment, 40 to 50 mg of pethidine was administered intravenously for analgesic purposes.

Using a multifrequency convex probe, RF ablation was performed with real-time ultrasound guidance (HID 3000, ATL, Bothell, WA, USA) by the same gastroenterologist (L.S.) with longstanding experience in interventional ultrasound. The needle was inserted using free-hand technique with subcostal or intercostal approach depending on the easiest access route according to the ultrasonographic picture. Once the needle electrode was located in the correct position, the hooks were deployed and the RF generator was activated. After maintaining the baseline power output at 50 W for 1 min, the output was increased by 10 W every minute until the power output reached 90 W, and then it was kept at 90 W until "roll-off" occurred. After a 20 to 60 s pause, power was reapplied at 75% of the maximum power achieved until power "roll-off" again occurred. If the "roll-off" did not occur within 15 min of the RF power output application, the RF power stopped automatically. After a 20 to 60 s pause, power was reapplied following the same procedure as before. Hematologic assays, such as red blood cell count and hemoglobin, serum alanine aminotransferase, serum aspartate aminotransferase and total serum bilirubin levels, were measured 24 h after treatment. The patients were discharged from the hospital 48 h after the treatment, if there were no any complications.

### Assessment of therapeutic efficacy

To evaluate the response to RF therapy, contrast-enhanced CT with the same parameters as the pre-treatment scanning was performed 1 mo after the procedure; tumor necrosis was considered complete when no foci of enhancement were seen within the tumor or at its periphery on CT scans. Safety margin surrounding the ablated tumor was obtained in all the cases where tumor necrosis was considered complete. Every three months, the patients subsequently underwent color power Doppler ultrasound associated with AFP dosage; and in the event of modifications of the ultrasound picture or a progressive increase in AFP value, a CT scan was performed.

## RESULTS

A total of 63 HCCs were treated with RFA in the 56 patients enrolled in the study. Two HCCs, measuring 3.5 and 4 cm in diameter, were non-responders to the treatment with RFA with persistence of the vascular signal after two sessions together with an increase in volume in the second (4-4.7 cm in maximum diameter). They were therefore subjected to chemoembolization with a positive result for the first but a progression of the disease in the second despite the additional therapy. The overall percentage of complete necrosis was 96.8% (61/63 of the lesions treated). In 54 HCCs, corresponding to 85.5% of the total, complete necrosis was achieved with just one session with a single insertion of the needle, while a second session was carried out in the remaining 7 HCCs after the first control CT scan due to persistence of vascularized areas of the tumor, again with a single insertion; a total of 68 treatments were necessary to achieve complete necrosis of the 61 responder HCCs. The diameters of the HCCs that required two sessions for complete necrosis were 3 cm in one case, 4 cm in one case and larger than 4 cm in the remaining 5 cases. The RF application time ranged from 2.5 to 15 min for each electrode insertion; the mean RF time was 10.4 min per session. All patients had an increase of echogenicity in the ablated region during RFA, suggesting generation of microbubbles in the ablated hepatic tissue.

As regards complications, 34 (60.7%) patients reported pain requiring the administration of analgesics during the treatment, while practically all subjects presented a moderate and transitory increase in transaminases at the 24 h hematological checks with no other laboratory test alterations. Major complications occurred in 3 of 72 cases (4%), including right pleural effusion in 1 case, cholecystitis in 1 case and liver failure in 1 case.

The post-treatment follow-up varied from 8 to 56 mo with a mean of 32.3 mo; during the follow-up, we detected 23 cases of recurrence (41%), with onset varying from 3 to 30 months after treatment and a mean of 13 mo. The recurrence was unifocal in 7 cases and multifocal in 16 case; two of the unifocal cases were local recurrences, while the remaining five were localized in another segment. Of the 23 cases of recurrence, the previously treated HCC was a single lesion in 22 cases and two lesions in 1 case; there was no relationship with the dimensions of the primary HCC which varied from 1.5 cm to 4.5 cm. Of the 22 previously treated single lesions, recurrence was unifocal in 7 cases and multifocal in the remaining 15 cases. In the unifocal recurrences, we carried out a new cycle of RFA therapy. Of the 16 multifocal cases, chemoembolization was performed in 5 cases, while treatment was limited to support therapy in view of the tumor diffusion and the general clinical conditions in the remaining 11 cases. The seven patients who underwent a new cycle of RFA therapy had positive results and were disease-free with a follow-up varying from 4 to 15 mo (mean 9 mo); four of the five patients treated with chemoembolization died due to progression of the HCC, while the other patient had a stable tumor situation 5 months after the treatment (Table 3).

Finally, 32 (57.1%) patients died during the follow-up, 15 from HCC, 11 from liver failure, 3 from esophageal varices bleeding, 1 from head stroke, 1 from cerebral hemorrhage and 1 from esophageal carcinoma. Among the patients who died from liver failure, 9 were Child-Pugh B and 2 were with Child-Pugh C (Table 4). Twenty-one patients were alive and disease-free at the end of the study.

**Table 4 Clinical findings in 32 deceased cirrhotic patients treated with RFA for HCC**

Causes of death	Number of patients	Child-Pugh status		
		A	B	C
HCC recurrence	15	4	12	
Liver failure	11		9	2
Esophageal varices bleeding	3		3	
Head stroke	1		1	
Brain hemorrhage	1	1		
Esophageal cancer	1	1		

## DISCUSSION

The limitations to the surgical treatment of HCC due to site, age and associated clinical conditions have led to the development of alternative locoregional therapies of which PEI is the first and most widely used example. RF was subsequently introduced by Rossi *et al*<sup>[8]</sup> in the attempt to overcome some of the limits of PEI, such as the need for multiple sessions, the difficulty in foreseeing the diffusion of the ethanol, and is now being used more and more as the first choice technique in the locoregional treatment of HCC<sup>[13]</sup>. Also, in our department, RFA has gradually replaced PEI which we had been using since the mid 80 s and which is now reserved for selected cases. Our experience in RFA with the LeVeen needle electrode has given us satisfactory results in terms of therapeutic efficacy, achieving complete necrosis in 85.5% of the lesions with just a single treatment, increasing to 96.8% with a second session, which are in agreement with the data reported in the literature<sup>[10,14,15]</sup>. Necrosis was not achieved with RFA in two cases of HCC, as shown by the post-treatment CT scan, and we were unable to identify the reason for the lack of response with certainty; the diameters were 3.5 and 4 cm and the lesions were not close to large vessels whose blood flow could have dispersed the heat<sup>[16]</sup>. Both were localized immediately under the hepatic dome and we therefore think it probable that the site interfered with the correct positioning of the electrode, reducing the efficacy of the treatment as previously reported<sup>[15]</sup>. Among the 7 HCCs which required a second session, 6 cases had a diameter of 4-5 cm, while only in one case had the diameter of 3 cm; therefore, if we consider only the HCCs up to 3 cm in diameter, the percentage of complete necrosis with just a single treatment would rise to 97.8%. Our experience also confirms that diameter < 3 cm is the ideal condition for locoregional treatment with RFA as with PEI<sup>[13,14,17]</sup>. However, in lesions measuring 3-5 cm, RFA with a LeVeen needle gave acceptable results with complete necrosis at the first treatment in 64.7% of cases, the remaining 35.3% required a second session for complete necrosis. As previously reported by Livraghi *et al*<sup>[10]</sup>, the lesser number of treatment sessions with respect to PEI makes it possible to reduce the time employed by the hospital staff and to considerably shorten the duration of the treatment and eliminate the stress of repeated sessions in most cases. One factor that can increase the volume of the area of necrosis and reduce the number of necessary treatment sessions is represented by

what Livraghi *et al*<sup>[10]</sup> defined as the “oven effect” caused by the fact that cirrhotic liver surrounding individual HCC nodules acts as a thermal insulator that increases tissue heating during RF therapy, making it possible to treat non-infiltrating tumors in a single treatment session in the majority of the cases.

The LeVeen needle electrode we used in this study has ten expandable inner hooks in a single outer sheath to obtain even greater flux of the radio wave in the ablated tissue. Through this, the needle produces a greater spherical area of thermal ablation than can be obtained by the previous four expandable hooks needle, assuring a safety margin if the tumor is within the range of ablation. Furthermore, the LeVeen needle can hold itself securely within the area of ablation by expanding the hooks; this may help in the treatment of tumors in areas susceptible to the respiratory movement of tissue. The LeVeen needle has some limitations, the first represented by the 15 gauge caliber and a greater risk of bleeding can be expected; however, we did not experience any hemorrhagic complications, and the literature also has not reported a greater incidence of hemorrhagic complications with respect to smaller gauge needles, such as 18 gauge cool-tip needle<sup>[11]</sup>. An 18-gauge LeVeen needle with 2.5 cm and 3 cm maximum deployment diameter of the hooks has recently become available, eliminating the difference in gauge; in the two cases treated with this finer needle, we did not encounter problems compared to the traditional one. A second limitation is the low visibility of the tips of the hooks under ultrasonography which sometimes makes it difficult to assess the correct location of the hooks with possible unexpected complications<sup>[15]</sup>.

In our experience, not only was RFA with the LeVeen needle effective, it also proved safe with a low incidence (4%) of major complications, similar to the percentage reported in the literature<sup>[3,11,18,19,20]</sup>. In two cases (pleural effusion and cholecystitis), the complication was because the HCC was close, respectively, to the diaphragm and the gall bladder with consequent thermal irritation of the pleura and of the gall bladder wall. In spite of being quickly resolved with medical therapy and without sequelae, this confirms the need to take particular care in treating lesions in the sites at risk as previously described<sup>[21]</sup>. In the third case, functional liver failure occurred with ascites after treatment of a 2.3-cm HCC of liver segment III in a Child-Pugh class C patient. The HCC had been subjected to a single session of RFA lasting 7.8 min. Medical therapy achieved a partial improvement of the clinical conditions; however, the patient subsequently died 4.5 months after treatment from liver failure without HCC recurrence. It should be further stressed that in patients with HCC on Child-Pugh class C cirrhosis locoregional treatments should not be carried out due to the greater risks and the advanced stage of the cirrhosis which *per se* involves a poor prognosis for survival<sup>[22]</sup>. The exception to this rule is treatment of patients on the waiting list for orthotopic liver transplant (OLT) when there is a long waiting time, as is frequently the case in almost all the transplant units in Italy<sup>[23,24]</sup>. Two of the three Child-Pugh class C patients that we treated, including the one in whom the complication occurred, were on the waiting list for OLT. The second

patient on the waiting list underwent OLT 15 months ago and is alive and free of recurrence.

We did not find any cases of post-RFA tumor seeding. In contrast, a study by Spanish authors has reported a high incidence of post-RFA seeding<sup>[25]</sup> which has not, however, been confirmed in any of the other studies reported in the literature. A recent study has demonstrated an incidence of post-RFA seeding even lower than that of post-PEI, both with expandable needles and with cooled needles<sup>[11]</sup>.

As far as complications are concerned, a recent Italian study showed that despite achievement of complete local necrosis, rapid intrahepatic neoplastic progression was observed in four patients (4.5%) after treatment. The authors experienced that high AFP levels and location of the tumor near the portal vein branches were associated with this complication<sup>[26]</sup>. Moreover, 75% (3/4) patients had a poor differentiation of the tumor<sup>[26]</sup>. This is the only report of this type in the literature to date and, while attention should be paid to this possibility, further studies are necessary for its confirmation. However, in our series, we have not found any similar occurrences to date.

Evaluation of the tissue necrosis is fundamentally important in order to decide whether further treatment is necessary and is currently mainly based on imaging techniques to assess the persistence of lesion vascularization, rather than on a biopsy which can not give a complete sampling of the lesion. The gold standard technique is certainly the contrast-enhanced CT scan, and we, based our post-treatment evaluation on this technique, performed it in all patients after thirty days. This is the most common interval as it allows any remaining vital tissue to be detected within a period of time that is short enough to prevent significant progression of the disease and to not burden an already overloaded radiology service with an excessive number of CT scans. It also prevents the risk of interpreting the hyperdense rim present in the majority of cases on CT scans obtained in a earlier period after RFA. This hyperdense rim is the expression of the early parenchymal inflammatory rim around the treated tumor as proved in resected specimens<sup>[27]</sup>. In our series, the HCCs with signs of activity at the one-month CT scan underwent a second session of RFA with complete necrosis in 100% of cases; the time lapse did not have any negative effect on the result of the treatment. The first data on the use of contrast-enhanced ultrasound (CEUS) with second generation contrast medium have recently been reported and are extremely encouraging, particularly as regards early 24 h evaluation of post-RFA persistence of activity<sup>[28-30]</sup>. The possibility to obtain by CEUS data comparable with the ones obtained by CT would make it possible to use a more rapid method and, if necessary, to carry out a second treatment during the same session, thus further reducing the duration of the therapeutic cycle with advantages for both patients and hospital staff.

In our series, HCC recurrence occurred in 41% (23/56) patients, a lower percentage than those reported in the literature<sup>[31]</sup>. This may be due to the lower number of patients and to the shorter follow-up compared to other studies. The percentage of local recurrence was only 3.1% (2 patients), in line with what was reported by other authors<sup>[31]</sup>, while recurrence occurred in other liver

segments with respect to the initial one in the remaining 21 patients, thereby confirming the validity of RFA in achieving complete necrosis of the treated HCCs. In both cases of local recurrence, the lesion diameter was > 3 cm (4 cm and 4.5 cm), confirming the limits of locoregional therapy in larger tumors. One factor that may contribute in determining recurrence is the presence of satellite nodules that can not be identified by imaging<sup>[32]</sup>. Livraghi *et al*<sup>[13]</sup> supposed that the "oven effect" may partially explain the limited success in treating satellite lesions. They believe that peritumoral fibrotic tissue that is interposed between the main tumor and satellite lesions may limit heat diffusion from the tumor center to the satellites. The association of RFA and transcatheter arterial chemoembolization (TACE) has been proposed as a means of reducing the number of local recurrences and the initial results seem encouraging<sup>[33,34]</sup>. The problem is different for recurrence in other sites, which remains high regardless of the type of treatment used, with values ranging from 60% to 80% after four years follow-up in series reported by Japanese authors<sup>[31]</sup>.

In our experience, it was possible to treat all 7 patients with unifocal recurrence with RFA, achieving complete necrosis of the lesion in all cases, but only 5 of the 16 multifocal recurrences with TACE and with a positive result in only one case. It is becoming important in the clinical setting to establish treatment methods to prevent recurrences at other sites, such as the use of interferon or anti-inflammatory therapy particularly to decrease the incidence of multicentric recurrences<sup>[35-38]</sup>. Therefore, even after achieving the local curative ablation by RFA, it is important to closely follow-up the patients for early detection and treatment of recurrence.

The rather limited number of patients and the too short mean follow-up period in our study do not allow us to draw conclusions on the efficacy of RFA of HCCs in improving survival. Nevertheless, by analyzing the causes of death in the patients who died during follow-up, it can be seen that while none of the Child-Pugh class A patients died from cirrhosis-linked causes, 9 patients in class B and 2 out of 3 in class C died as a result of progression of the cirrhosis, and the third patient in class C is alive after OLT. In addition, another 3 patients in class B died as a result of bleeding from esophageal varices. This further confirmed the importance of the stage of cirrhosis in patient survival, so as to exclude class C patients from any ablation treatment except for those on the waiting list for OLT. In our series, however, 46.8% (15/32) patients died as a direct result of the HCC; our data also indicated that, as mentioned earlier, it is extremely important to improve the prognosis of patients who have undergone local ablation therapy by treating the background liver disease, using chemopreventive drugs, such as interferon. Regarding the previous data on the long-term survival of patients treated with RFA for HCC, it should be pointed out that although the history of RFA is not long enough for analysis, when analysis was limited to cases of primary liver cancer in which local curative therapy was achieved, the 5-year survival rate was relatively high (66-82%), comparable to that of resection<sup>[17,31,39-41]</sup>.

In conclusion, percutaneous RFA by means of the

LeVeen needle electrode appears to be an effective, safe and relatively simple procedure for the treatment of HCC lesions in patients with cirrhosis, obtaining the best results in HCCs < 3 cm in diameter. We currently prefer to use RFA rather than PEI because RFA is capable of achieving complete tumor necrosis in fewer treatment sessions compared with multi-session PEI, reserving PEI for HCCs that are difficult to approach or located in areas where RFA is considered unsafe, such as HCC adjacent to large vessels, the main bile duct or the gall bladder. Despite the good results as regards the necrosis of the HCC lesions, it is not yet possible to define the effect of RFA on the long-term survival of treated patients, even though the initial data are encouraging. Notwithstanding the importance of the stage of cirrhosis for survival, HCC recurrence after RFA is a significant cause of death in these patients. On the basis of the recent data reported in the literature, it is probable that in the future the prognosis can be improved by the use of chemopreventive drugs, such as interferon for the prevention of recurrence after curative local treatment.

## Abstract

**AIM:** To assess the expression of myeloid dendritic cells (CD11c+) subset during acute HCV hepatitis and its possible involvement in natural history of the infection.

**METHODS:** We enrolled 11 patients with acute hepatitis C (AHC) (Group A), 10 patients with acute hepatitis A (AHA) (as infective control-Group B) and 10 healthy donors (group C) in this study. All patients underwent selective flow cytometry gating strategies to assess the peripheral number of the myeloid dendritic cells (mDCs) to understand the possible role and differences during acute hepatitis.

**RESULTS:** Eight of 11 patients with acute HCV hepatitis did not show any increase of mDCs compared to healthy individuals, while a significant decrease of mDCs was found in absolute cell count ( $z = -2.37$ ;  $P < 0.05$ ) and percentage ( $z = -2.30$ ;  $P < 0.05$ ) as compared with AHA. On the contrary, the remaining three patients of the group A had a higher mDCs number and percentage as occur in group B. Interestingly, after six months, those patients did not show any increase of mDCs subset were chronically infected, while the three subjects with an increase of peripheral mDCs, as in HAV acute infection, resolved the illness.

**CONCLUSION:** The lack of increase of mDCs during acute hepatitis C might be an important factor involved in chronicization of the infection.

## INTRODUCTION

Hepatitis C virus (HCV) infection represents one of the most important causes of chronic viral hepatitis, liver disease, and hepatocellular carcinoma<sup>[1]</sup>. Many mechanisms have been proposed to account for the ability of HCV to elude the host defense and progress towards chronic disease: the high rate of the mutation as well as the ability of the virus to influence T helper cell subsets during the acute infection. Indeed, an early Th2 predominant immune response seems to influence the natural history of the infection<sup>[2,3]</sup>. Even if, several research studies have focused attention on the T lymphocytes (CD4+ and CD8+) activity in acute and chronic hepatitis C<sup>[4,5]</sup>, however, the frequency of the cells involved in the presentation of the antigen (APCs) and so in the immune response activation is not fully elucidated. Among these subsets, the dendritic cells (DCs) have one of the most important roles in the host defense, but few data are available on these cells during the acute hepatitis C. That subset, divided in plasmacytoid DCs (pDCs) and myeloid DCs (mDCs), expresses high levels of MHC class I and II antigens, as well as costimulatory molecules, playing an essential role in triggering primary immune response<sup>[6]</sup>. Particularly, the mDCs are involved in Th1 network activation<sup>[7]</sup>, that is fundamental to clear HCV infection<sup>[2,3]</sup>. The aim of the present study was to use flow cytometry as a tool to enumerate mature mDCs in peripheral blood of patients with acute HCV infection and consequently to assess the ability to present the antigen and activate the immune response against the virus as well as its possible influence on disease progression. Thus, we

presented, for the first time to our knowledge, a study on the frequency of peripheral myeloid dendritic cells (mDCs) (CD11c+) in two hepatitides due to RNA hepatotropic virus characterized by a common natural immune system pathway<sup>[8-10]</sup>: one HCV which frequently leads to chronicity; and the other HAV which normally leads to a self-limited infection with a complete resolution, thus as control population, we investigated healthy individuals.

## MATERIALS AND METHODS

### Patients

Following the approval of our Local Ethical Committee, the study was carried out on 31 subjects, who were divided into three groups. Group A: 11 patients with acute C hepatitis; Group B: 10 patients with acute A hepatitis; Group C: 10 normal individuals as controls. All patients had been admitted to our Infectious Disease Emergency Unit during the symptomatic phase, at least after one week from the first symptoms. Regarding to the group A, the criteria for diagnosis of acute hepatitis C were: (1) at admittance, HCV-RNA positive and anti-HCV negative or documented HCV-RNA negativity before admission otherwise seroconversion from anti-HCV negative to positive ELISA test; (2) negative clinical history of autoimmune disease, chronic viral hepatitis or other viral infections, including HIV; (3) serum alanine aminotransferase (ALT) levels at least  $10 \times$  upper limit of normal value (ULN  $< 40$  IU/mL); and (4) absence of alcohol or drug abuse. Of note that our hospital is a reference center for infectious disease, moreover, most of our patients were ex-prisoner and so they underwent to periodical control.

All HAV-infected patients were negative for other chronic viral hepatitis (HBV and HCV), alcohol/drug abuse, other associated autoimmune disorders or infectious disease.

Since none of patients of group A underwent IFN treatment, they were evaluated at time 0 (T0) and after at least six months Time 6 (T6) following their laboratory parameters to assess a possible progression towards chronic infection (positive HCV-RNA qualitative assay and hypertransaminasis) or its resolution, as well as their mDCs frequencies.

Blood samples were collected from all patients on admittance to our unit, at the beginning of clinical symptoms (T0). All biochemical and viral assays were performed at our centralized laboratory. The HCV-RNA qualitative and quantitative assays were performed using the Amplicor Roche system with the cut-off values set to 50 and 600 UI/mL, respectively.

The mDCs assessment was executed at our immunological laboratory by a three-color flow cytometry using a Beckman Coulter Profile system. The mDCs assay involved the use of anti-ILT3, anti-CD14 and anti-CD11c monoclonal antibodies (mAb) labelled with the fluorochromes -PC5, -FITC, -PE, applying a particular gate strategy, according to the criteria of Beckman Coulter. All monoclonal antibodies were applied following the manufacturer's instructions and on the basis of our previous experiences. Briefly, after the cells were gated using a side scatter profile to exclude granulocyte and possible debris,

the cells were further gated using CD14+ mAb marker to select a population of monocytes and pro-myeloid dendritic cells, such marker is not expressed on plasmacytoid cells and so its usage gives us the ability to early select the mDCs<sup>[11]</sup>. In addition, the cells were further gated using ILT3-mAb to obtain purified mDCs population<sup>[12]</sup>. Finally, a third gate was applied using CD11c to obtain the only mature mDCs (CD11c+)<sup>[13]</sup> (Figure 1). Coupled to this cytometry analysis, we also evaluated the total CD4+ T cells to assess the possible correlation between T lymphocytes and mDCs.

### Statistical analysis

Considering the small number of patients, we used non-parametric test. Spearman test was applied particularly to assess possible correlation, and on the other hand, *U* Mann-Whitney test (two tailed) was performed to evaluate difference among the groups. The results were considered statistically significant at  $P < 0.05$ .

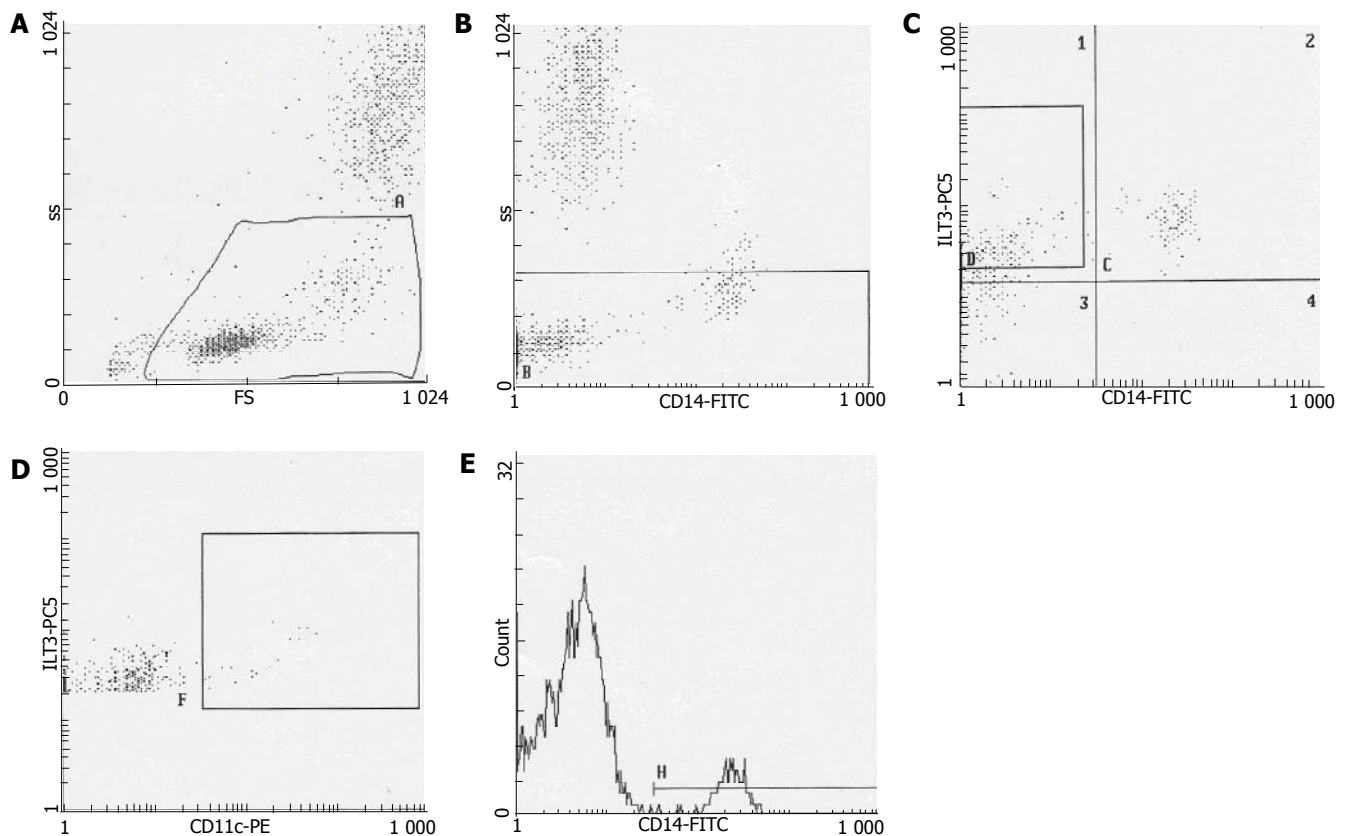

## RESULTS

Table 1 shows the descriptive analysis of the standard laboratory, virological and immunological parameters. In group A, nine patients were genotype 1b, while the other two had genotype 2a/2c. The mean value of mDCs in the normal donors was 1350 cells, representing about the 15% of the ILT3 cells. Eight of 11 patients with acute hepatitis C showed to have a lower absolute cell count percentage of peripheral blood mDCs when compared to acute hepatitis A (Mann-Whitney *U* test;  $z = -2.37$ ,  $P < 0.05$  and  $z = -2.30$ ,  $P < 0.05$ ) (Figure 2), while they did not display any statistical significant differences with respect to group C (healthy individuals), thereby suggesting the lack of enrollment in peripheral blood of this dendritic cell subset during the acute infection. The remaining 3 patients (3/11; two with genotype 2a/2c and one genotype 1) showed an increase of mDCs presenting an absolute cell count and percentage analogous to patients with acute hepatitis A (Table 1). After six months, patients who at T0 showed an absolute number and percentage of mDCs like healthy individuals had positive HCV-RNA qualitative assay, hypertransaminases (2 times upper limit normal value, 92 IU/mL) and also preserved the same frequency of mDCs (Table 1). Of note that 3/11 of patients who showed an increase of mDCs were found to be negative for hypertransaminasemia and HCV-RNA after 9 months when they came back our department. Finally, a strong positive correlation (Spearman's test;  $r = 0.90$ ,  $P < 0.05$ ) between the mDCs and CD4+ was found in group B, while it was not demonstrated in group A. Noteworthy, no correlation was pointed out among HCV-RNA, transaminases and the mDCs both at T0 and T6, suggesting the lack of a direct involvement in liver necrosis of viral cycle.

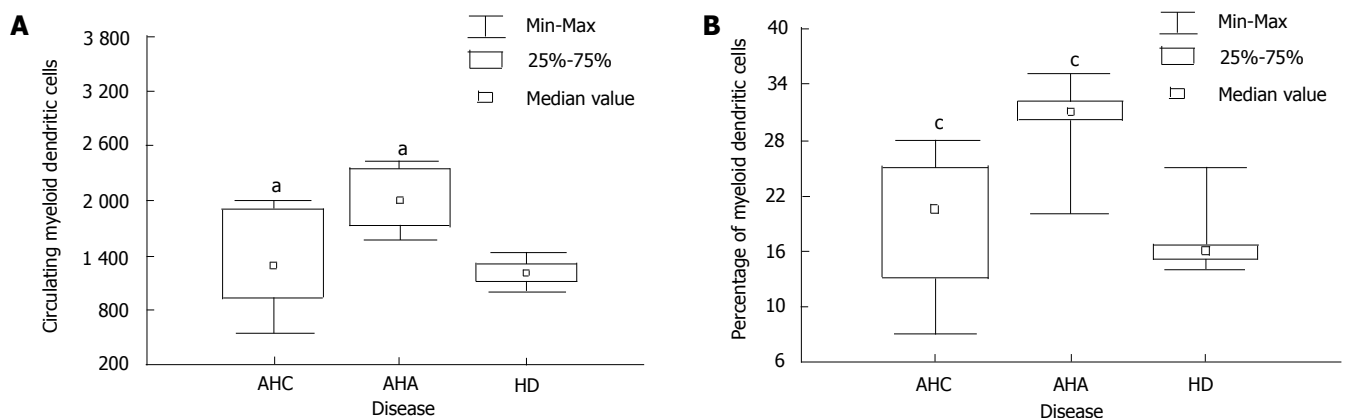

## DISCUSSION

mDCs have an important role during the infection<sup>[6,14]</sup>, therefore, one of the most vital strategies of the virus could be to inhibit or interfere with their function. Indeed,

**Figure 1** Gate strategies for the mDCs CD11c+ evaluation. The letter's order represents the sequential gates used to measure the frequency of mDCs. (A) Side scatter vs forward scatter gate analysis; (B) CD14+ cells analysis vs side scatter to select CD14+ cells avoiding debris; (C) characterization of the cells having high expression of ILT3, as marker of purified myeloid dendritic lineage, on CD14+ subset; (D) evaluation of cells expressing CD11c+, as marker of mature myeloid dendritic cells, on the whole ILT3 gated cells to obtain the mDCs; and (E) histogram of CD14-FITC mAb fluorescence.

**Figure 2** Differences in absolute cell count and percentage of mDCs among the examined groups. The patients having HAV acute infection (AHA) displayed an increase of mDCs as compared to the subjects with acute hepatitis C (AHC) who displayed to have the same frequency as the healthy donor (HD). : Significant differences in absolute cell count ( $z = -2.37$ ;  $^aP < 0.05$ ) and percentage ( $z = -2.30$ ;  $^cP < 0.05$ ) (Mann Whitney *U* test).

some viruses can evolve to present strategies to diminish the circulating dendritic cells evading the immune surveillance. Previous studies reported a decrease of DCs during different viral infectious disease and most recently in chronic hepatitis C<sup>[14,15]</sup>. Particularly during chronic HCV infection, it has also been shown that the virus is able to slow down the DCs by direct infection<sup>[15]</sup>. Nevertheless, it is unknown if the virus has influence on the circulating DCs during acute infection too. Although the present

investigation was carried out on a small group of patients, however, this simple gate strategy in flow cytometry is probably the first to show that patients who demonstrated to have the same absolute number and percentage of mDCs as healthy individuals evolved towards a chronic disease, while those having an increase of mDCs, such as in HAV, were not chronically infected. Even if the number of patients resolving the infection is too small to be suitable for any statistical test, it is clear considering the

Table 1 Laboratory and immunological parameters of the enrolled patients (mean  $\pm$  SD, n, %)

Parameters	A-T0	A-T6	A-res	B	C

flow cytometry data that this subset has a possible connection to the pathogenesis of a persistent infection. In this regard, the results relatively to the increase of mDCs during a self-limited RNA viral hepatitis like HAV, seem to confirm the hypothesis of a role for those peripheral blood professional APCs subset in the resolution of the viral infection, probably enrolling CD4+ T cells as the correlation suggested. The mechanisms hidden behind these events, through which HCV could participate in decreasing mDCs in peripheral blood, are still unclear. Nevertheless, it has recently been shown the ability of HCV to interfere with TLR 3 activity during the immune system response<sup>[16]</sup>, since it has an important role in mDCs life cycle and function<sup>[6,9,10,17]</sup>. Thus, the lack of expansion occurring in patients during acute HCV infection by different ways could represent an important additional skill of the virus to elude the first line of host defense represented by the innate immunity. Although our study did not assess the direct viral infection of DCs, it clearly documents that HCV is able to evolve a kind of strategy to boost its survival by preventing the increase of mDCs during the acute infection in patients evolving in chronic hepatitis. Of note that mDCs are able to activate a Th1 immune network, and that it is well known to be necessary to clear HCV<sup>[4,5,18]</sup>, so their inactivation might have a great influence on host defense during acute infection.

In conclusion, we speculate that during acute hepatitis C, the virus might prevent the activation of circulating myeloid dendritic cells (ILT3/CD11c+) conditioning the natural history of the hepatitis. Thus, an early assessment by means of flow cytometry of mDCs using our gate strategy could give useful suggestions about the possible progression of infection, thereby proposing the early enrolment of the patients in IFN-treatment, particularly for the genotype 1. Supplementary studies, using flow cytometry assay

coupled to functional analysis as well as assaying the possible variation of mDCs peripheral blood expression after interferon plus ribavirin treatment, should be carried out on a wider population. In fact, this subset could be a possible target for an immunotherapy to ameliorate the antigen presenting function and so the immune response

### Abstract

**AIM:** To investigate the effect of *Patrinia scabiosaefolia* (PS) on the cholecystokinin (CCK) octapeptide-induced acute pancreatitis (AP) in rats.

**METHODS:** Wistar rats weighing 240-260 g were divided into three groups: (1) Normal saline-treated group; (2) treatment with PS at 100 mg/kg group, in which PS was administered orally, followed by subcutaneous administration of 75 µg/kg CCK octapeptide three times after 1, 3 and 5 h, and this whole procedure was repeated for 5 d; (3) treatment with saline group, in which the protocols were the same as in treatment group with PS. We determined the pancreatic weight/body weight ratio, the levels of pancreatic HSP60, HSP72 and the secretion of pro-inflammatory cytokines. Repeated CCK octapeptide treatment resulted in the typical laboratory findings of experimentally induced pancreatitis.

**RESULTS:** PS reduced the pancreatic weight/body

weight ratio, the levels of serum amylase and lipase, and inhibited expressions of pro-inflammatory cytokines in the CCK octapeptide-induced AP. Furthermore, PS pretreatment increased the pancreatic levels of HSP60 and HSP72.

**CONCLUSION:** Pretreatment with PS has an anti-inflammatory effect on CCK octapeptide-induced AP.

### INTRODUCTION

Acute pancreatitis (AP) is characterized by local pancreatic inflammation as well as a systemic inflammatory response<sup>[1,2]</sup>. Histologically, AP is characterized by interstitial edema, vacuolization, inflammation, and acinar cell necrosis<sup>[3,4]</sup>. A widely used model to study these responses is acute pancreatitis induced in rats and mice by high doses of cholecystokinin (CCK) or its analogue, cerulein<sup>[5]</sup>. CCK is a major physiologic regulator of digestive enzyme secretion by the pancreatic acinar cell; however, supraphysiologic doses of CCK (in excess of those that stimulate maximal secretion of digestive enzymes) are injurious to the pancreas, causing pancreatitis that mimics many features of the human disease<sup>[5-8]</sup>.

Cells could respond to heat shock or other stress with the rapid synthesis of heat-shock proteins (HSPs). The induction of the heat shock response enhances the ability of the cells to overcome the effects of the stress<sup>[9]</sup>. These proteins are classified by their molecular mass (e.g., HSP60 and HSP72). It was reported that the pre-induction of HSP expression has a protective effect against cerulein-induced pancreatitis in rats or choline-deficient ethionine-supplemented diet model pancreatitis in mice<sup>[10-12]</sup>.

Besides, with increasing neutrophil migration to the pancreas, a variety of inflammatory cytokines are released.

Pro-inflammatory mediators, such as tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ), interleukin-1 $\beta$  (IL-1 $\beta$ ) and IL-6, have been related to inflammatory changes in AP. There are considerable evidences that pro-inflammatory cytokines play a central role in AP and may mediate the systemic complications of AP<sup>[13,14]</sup>.

Iridoid compounds represent a large group of the cyclopentano[d]pyran monoterpenoids found in many plants. These compounds exhibit various antimicrobial, antitumoral, hemodynamic, and anti-inflammatory activities<sup>[15]</sup>. *Patrinia scabiosaefolia* (PS) (Valerianaceae) is well-known in oriental traditional medicine. Its roots or whole plants have been used for treatment of various diseases, including edema, appendicitis, endometritis, and inflammation<sup>[16]</sup>. However, the effect of PS on AP has not been investigated as yet. Hence, in this study, we aimed to investigate the effect of PS on the CCK octapeptide-induced AP. We examined pancreatic weight/body weight ratio, serum amylase and lipase levels, and also investigated the effect of PS on pancreatic HSP60 and HSP72 expression in CCK octapeptide-induced AP. We wished to evaluate whether PS can block pro-inflammatory cytokine synthesis during CCK octapeptide-induced AP.

## MATERIALS AND METHODS

### Materials

Avidin-peroxidase and 2'-AZINO-bis (3-ethylbenzothiazoline-6-sulfonic acid) tablets substrate and CCK-8 were purchased from Sigma (St. Louis, MO, USA). Anti-HSP60 and anti-HSP72 antibodies were purchased from Stressgen (British Columbia, Canada). Anti-rat TNF- $\alpha$ , anti-rat IL-1 $\beta$  and anti-rat IL-6 antibodies were purchased from R&D Systems (Minneapolis, MN, USA).

### Preparation of PS

PS was prepared by decocting the dried prescription of herbs with boiling distilled water. The decoction time was about 3 h. Their voucher specimens were deposited at the Herbarium at the College of Oriental Medicine, Kyung-Hee University.

### Animal models

Male Wistar rats weighing 240-260 g were kept at a constant room temperature of 25 °C with a 12-h light-dark cycle, and were allowed free access to water and standard laboratory chow. The rats were fasted for 16 h before the induction of AP. Rats were divided into three groups, each group containing 6-8 rats. The experiments performed in this study were approved by the Animal Care Committee of the University.

### In vivo models of pancreatitis

In PS-treated group, 100 mg/kg PS was systemically administrated orally, followed by subcutaneous administration of 75  $\mu$ g/kg CCK octapeptide three times after 1, 3, and 5 h, and this whole procedure was repeated for 5 d. In AP group, saline was systemically administered orally instead of PS, but otherwise the protocol was the same as in treatment group with PS. Normal untreated

group received physiological saline orally instead of PS. The animals were sacrificed by exsanguinations through the abdominal aorta 12 h after the last CCK octapeptide injection. The pancreas was quickly removed, cleaned from fat and lymph nodes, weighed, and frozen at -70 °C until use. Rats were treated in accordance with the current law and the NIH Guide for Care and Use of Laboratory Animals.

### Pancreatic weight/body weight ratio

This ratio was utilized to evaluate the degree of pancreatic edema.

### Western blotting

Western blot analysis of pancreatic HSP60 and HSP72 levels was performed from the cytosolic fraction of the pancreas homogenate. Thirty micrograms of protein was loaded per lane. Samples were electrophoresed on a 100 g/L SDS-PAGE according to the method of Laemmli<sup>[17]</sup>. The gels were either stained with Coomassie brilliant blue (to demonstrate equal loading of proteins for Western blot analysis) or transferred to a nitrocellulose membrane for 2 h at 300 mA. Membranes were blocked in 50 g/L nonfat dry milk for 1 h and incubated with anti-HSP60 and anti-HSP72 antibodies. After washing in PBS/Tween-20 three times, the blot was incubated with secondary antibody for 30 min, and the antibody-specific proteins were visualized by the enhanced chemiluminescence detection system according to the recommended procedures (Amersham Corp. Newark, NJ).

### Enzyme-linked immunosorbent assay (ELISA)

ELISA for TNF- $\alpha$ , IL-1 $\beta$  and IL-6 was carried out in duplicate in 96-well plates (Nunc, Denmark) coated with each of 100  $\mu$ L aliquots of anti-rat TNF- $\alpha$ , anti-rat IL-1 $\beta$  and anti-rat IL-6 monoclonal antibodies at 1.0  $\mu$ g/mL in PBS (pH 7.4), followed by incubation overnight at 4°C. The plates were washed with PBS containing 0.5 g/L Tween-20 (Sigma, St. Louis, MO, USA) and blocked with PBS containing 10 g/L BSA, 50 g/L sucrose and 0.5 g/L NaN<sub>3</sub> for 1 h. After additional washes, standards were added and incubated at 37 °C for 2 h, followed by washing of the wells, addition of each of 0.2 mg/L of biotinylated anti-rat TNF- $\alpha$ , anti-rat IL-1 $\beta$  and anti-rat IL-6 antibodies, and incubation at 37 °C for 2 h. After washing the wells, avidin-peroxidase was added and plates were incubated for 20 min at 37 °C. Wells were again washed and ABTS substrate was added. Color development was measured at 405 nm using an automated microplate ELISA reader. A standard curve was run on each assay plate using recombinant TNF- $\alpha$ , IL-1 $\beta$  and IL-6 in serial dilutions.

### Measurement of serum amylase and lipase

Arterial blood samples for determinations of serum amylase and lipase were obtained 12 h after induction of pancreatitis. Rats were anesthetized with intraperitoneal injection of ketamine (80 mg/kg) and xylazine (4 mg/kg). After anesthetization, blood was withdrawn from heart of each rat into syringes. Serum amylase was measured by using an ADIVA 1650 (BAYER, USA). Serum lipase was

**Figure 1** Effect of PS on pancreatic weight/body weight ratio (pw/bw) in CCK octapeptide-induced AP. Data are expressed as mean  $\pm$  SE for 6 animals per group.  $P < 0.05$  vs control group.

**Figure 2** PS inhibition of serum amylase and lipase levels in CCK octapeptide-induced AP in rats. Values are expressed as mean  $\pm$  SE for at least 6 animals per group.  $P < 0.05$  vs control group.

**Figure 3** Western blot analysis of effect of PS on HSP60 and HSP72 expressions in CCK octapeptide-induced AP. **A:** HSP60; **B:** HSP72.

**Figure 4** Effect of PS on TNF- $\alpha$ , IL-1 $\beta$  and IL-6 secretion in CCK octapeptide-induced AP. Data are expressed as mean  $\pm$  SE for 6 animals in each group.  $P < 0.05$  vs control group.

measured by using a Cobas-mira (Roche, USA).

### Statistical analysis

Results were expressed as means  $\pm$  SE. The significance of changes was evaluated using student's *t* test. Differences between the experimental groups were evaluated by using analysis of variance. *P* values less than 0.05 were considered statistically significant.

## RESULTS

### Effect of PS on pancreatic weight/body weight ratio

It has been shown that pancreatic weight (pw)/body weight (bw) ratio is increased in CCK octapeptide-induced pancreatitis in rats<sup>[18]</sup>. To assess the effect of PS on the pw/bw ratio during CCK octapeptide-induced AP, we divided the pancreatic weight by the body weight of rats. We found that PS significantly decreased pw/bw ratio compared with saline-treated group ( $P < 0.05$ ) (Figure 1).

### Pancreatic serum amylase activity and lipase activity

The levels of serum amylase and lipase are most commonly obtained as biochemical markers of pancreatic disease, particularly AP. Amylase activity in serum has been used for many years for the evaluation of patients with acute abdominal pain and suspected pancreatic disorders<sup>[19]</sup>. Elevation of the levels of pancreatic lipase in plasma or serum is often considered to be the most sensitive and specific marker of AP<sup>[20]</sup>. PS reduced the

activities of serum amylase and lipase in CCK octapeptide-induced AP (Figure 2).

### Effect of PS on HSP60 and HSP72 expression in CCK octapeptide-induced AP

It was reported that the pre-induction of HSP expression has a protective effect against cerulein-induced pancreatitis or CCK octapeptide-induced pancreatitis in rats<sup>[18,21,22]</sup>. We next investigated the effect of PS on HSP60 and HSP72 expressions in CCK octapeptide-induced AP. PS increased pancreatic HSP60 and HSP72 expression in CCK octapeptide-induced AP compared with saline (Figure 3).

### Effect of PS on cytokines secretion in CCK octapeptide-induced AP

Various cytokines (TNF- $\alpha$ , IL-1 $\beta$  and IL-6), released locally and systemically, have been implicated in the inflammatory response associated with pancreatitis. The production of these cytokines has been shown to increase in serum during CCK octapeptide-induced AP<sup>[23-25]</sup>. In this study, we found that PS pretreatment significantly decreased the levels of TNF- $\alpha$ , IL-1 $\beta$  and IL-6 production during CCK octapeptide-induced AP (Figure 4).

## DISCUSSION

PS has been used for treatment of various diseases, including edema, appendicitis, endometritis, and inflammation<sup>[16]</sup>. On the basis of the idea that the expressions of HSPs, such as HSP 60 and HSP72, in pancreas play a key role in the inflammatory response of pancreatitis, we determined whether PS could increase expression of HSP in CCK octapeptide-induced AP. HSPs play a universal role in the maintenance of cellular homeostasis<sup>[22]</sup>. They are expressed constitutively and/or at elevated levels upon the exposure of cells to a variety of stress conditions in every organ, including pancreas<sup>[21,26]</sup>. Previous reports of the effects of cerulein-induced AP on pancreatic HSP levels are somewhat conflicting<sup>[27-31]</sup>. Ethridge *et al.*<sup>[28]</sup> found that the pancreatic heat shock factor 1 (HSP-1) binding activity was increased during cerulein-induced AP, with concomitant increases in HSP70 and HSP27, while the levels of HSP60 and HSP90 were not affected. Similarly, Weber *et al.*<sup>[27]</sup> demonstrated that cerulein induced pancreatic HSP70 mRNA and protein expressions. However, secretagogue treatment did not alter the level of ubiquitin mRNA. Using antisense oligonucleotides, Bhagat *et al.*<sup>[29]</sup> have shown that cerulein-induced HSP72 expression acts to limit the severity of the disease in rat. Strowski *et al.*<sup>[30]</sup> observed that cerulein time- and dose-dependently increased mRNA but paradoxically reduced protein levels of rat pancreatic HSP60 and HSP72. In accordance with their study, we demonstrated that repeated injections of supramaximal doses of CCK octapeptide for 5 d reduced the pancreatic HSP60 and HSP72 levels<sup>[18,32]</sup>. However, this decrease was recovered by the administration of the PS. Therefore, PS acted against the effect of CCK octapeptide-induced pancreatitis to decrease the levels of these HSPs, and clearly increased the protection against the disease as discussed below. Since we only examined the quantities of the most widely investigated HSP60 and HSP72, we could not rule out that other HSPs were induced and contributed to the protective effects of PS.

These cytokines (TNF- $\alpha$ , IL-1 $\beta$  and IL-6) are thought to mediate the systemic effects of pancreatitis, such as fever, hypotension and shock<sup>[8]</sup>. Serum levels of TNF- $\alpha$ , IL-1 $\beta$  and IL-6 are used to evaluate the systemic cytokine response. TNF- $\alpha$  has been shown to be an important initiator of the local and systemic damage occurring in AP<sup>[33]</sup>. The overall rise in both tissue and serum TNF- $\alpha$  concentrations correlates directly with the severity of pancreatic damage and inflammation<sup>[34]</sup>. Additionally, serum levels of TNF- $\alpha$  have been found to correlate with severity of AP in humans<sup>[24]</sup>. IL-1 $\beta$  is another potent pro-inflammatory cytokine, which, like TNF- $\alpha$ , is derived predominantly from macrophages<sup>[35]</sup>. Combined infusions of TNF- $\alpha$  and IL-1 $\beta$  have synergistic pro-inflammatory effects<sup>[36]</sup>. Using knockout (-/-) mice deficient in IL-1 type 1 receptors, TNF type 1 receptors, or both, it has been shown that IL-1 $\beta$  and TNF- $\alpha$  make an equivalent contribution to the severity of an attack. Preventing the activity of both cytokines concurrently has no additional effect on the degree of pancreatitis<sup>[37]</sup>.

IL-6, a principal mediator of acute phase response, is primarily released from activated mononuclear phagocytes.

Pooran *et al.*<sup>[38]</sup> showed that IL-6 levels in severe pancreatitis were significantly elevated compared with mild pancreatitis<sup>[38,39]</sup>. As aforementioned, we demonstrated that PS could reduce TNF- $\alpha$ , IL-1 $\beta$  and IL-6 production during CCK-induced AP in rats.

Repeated supramaximal doses of CCK octapeptide stimulation for 5 d are known to induce a prolongation of the morphological (increased pw/bw) and biochemical changes (increased serum amylase and lipase activity) in CCK octapeptide-induced acute interstitial pancreatitis in rats<sup>[5-8]</sup>. We have found that PS pretreatment reduced typical laboratory parameters (increased pw/bw) and biochemical changes (increased serum amylase and lipase activity) in the CCK octapeptide-induced AP. From these results, we suggest that these cytoprotective effects maybe due to the induction of HSPs. Absolutely decisive proof of the protective effects of HSPs in this AP model would require the blockade of expression or function of these proteins. Unfortunately, there are as yet no specific inhibitors of these.

In conclusion, our study has shown that PS pretreatment ameliorates the severity of CCK octapeptide-induced pancreatitis in rats. In accordance with others, we have demonstrated that PS increases synthesis of HSP60 and HSP72 and reduces the production of TNF- $\alpha$ , IL-1 $\beta$  and IL-6 in CCK octapeptide-induced AP in rats. Additionally, PS pretreatment ameliorates typical laboratory parameters (increased pw/bw) and biochemical parameters of the disease. Thus, our study suggests that PS protects against CCK octapeptide-induced AP in rats.

### Abstract

**AIM:** To analyze the major complications after exenteration of gynecological and rectal malignancies.

**METHODS:** Twenty-two patients with gynecological malignancy and 6 with rectal malignancy underwent pelvic exenteration (PE) between 1996 and 2005. PE was performed for primary malignancy in 71.4% of cases (vulvar cancer in 13, cancer rectal in 5, cervical cancer in 1 and Bartholin's gland cancer in 1 cases respectively and recurrent malignancy in 28.6% of cases (cervical cancer in 5, ovarian cancer in 1, uterine sarcoma in 1 and rectal cancer in 1 cases respectively). Posterior PE, total PE and anterior PE were most often performed.

**RESULTS:** Major complications in the operative field involving the urinary tract infection or the wound dehiscence occurred in 12 patients (42.9%). Early complications included massive bleeding from the sacral plexus, adult respiratory distress syndrome (ARDS), thrombophlebitis, acute renal failure, urinary bladder dysfunction, ureter damage, re-operation and pulmonary embolus. Urinary incontinence was observed in 2 women as a late complication. In 1 patient a nephrostomy was performed in 1 patient due to extensive hydronephrosis and 1 patient had complications connected with the gastrointestinal tract. The mortality rate was 7%, of which inter-operative mortality accounted for 3.5%. Major complications often occurred in advanced primary vulvar cancer affecting those with recurrent malignancies.

**CONCLUSION:** PE is more beneficial to patients with primary vulvar and rectal cancer than to those with recurrent cancer. Knowledge of the inherent complications and morbidity of PE is essential.

### INTRODUCTION

Total pelvic exenteration (TPE) has been used as a salvage therapy. Candidates are those who have failed radiation therapy or primary surgical or combined treatment of the recurrence in the central pelvis<sup>[1-3]</sup>. Pelvic exenteration (PE) is also a method of treatment in cases of locally advanced primary pelvic tumors.

PE is carried out at the site of extensive pelvic tumor, and cervical, vulvar, vaginal, ovary, rectal cancer or bladder cancer which can not be removed by standard radical pelvic surgical techniques<sup>[2, 4]</sup>. PE may result significant complications, its major complications can affect 62% of patients<sup>[5-9]</sup>. The distribution of complications has changed over the years due to the advances in antibiotic therapy and improved supportive care including hyper-alimentation. At present the most threatening complications are those involving the gastrointestinal and urinary systems. Urinary fistulae and obstruction following PE are the frequent and life threatening complications, which increase the mortality and morbidity rates after PE of gynecological cancers<sup>[10]</sup>.

The present study was to review the literature and report our experience with the complications arising from PE as a radical surgery in the treatment of advanced pelvic malignancies.

### MATERIALS AND METHODS

Twenty-two patients with gynecological malignancy and 6 with rectal cancer underwent PE in 1996 - 2005 at the Department of Gynecology, Medical University of Gdansk, Poland. Exenteration was performed because of vulvar cancer in 13 cases, rectal cancer in 6 cases, cervical cancer in 6 cases, ovarian cancer in 1 case, uterine sarcoma in 1 case and Bartholin's gland cancer in 1 case.

The clinical and pathological records were reviewed to determine the primary disease, previous treatment, type

of PE, postoperative morbidity and mortality as well as complications. The primary malignancies (71.4%) included advanced carcinoma of the vulva in 13 cases, rectal cancer in 5 cases, cervical cancer in 1 case, Bartholin's gland cancer in 1 case. The recurrent tumors (28.6%) included carcinoma of cervical cancer in 5 cases, ovarian cancer in 1 case, uterine sarcoma in 1 case, rectal cancer in 1 case.

Posterior pelvic exenteration (PPE), total pelvic exenteration (TPE) and anterior pelvic exenteration (APE) were most often performed.

All the vulvar and cervical cancers were squamous cell carcinoma (SCC). Surgery was performed by a team of gynecological surgeons or together with a team of urologists in cases requiring urinary diversion. All patients were operated under mixed anesthesia consisting of conduction anesthesia (spinal or epidural) and general anesthesia. Closure of the empty pelvic cavity was achieved by mobilization of omentum from the left side of the sigmoid colon or by reperitonization using the mobilized caecum. Re-operation was needed for early and late complications. Early complications were those arising within 30 days after surgery and late complications were those over 30 days after surgery.

## RESULTS

The clinical characteristics of 28 patients who underwent pelvic exenteration are summarized in Table 1.

The mean age of the 28 patients at diagnosis was 53.3 years (range, 34-82 years).

The estimated blood transfusion during operation ranged from 240 mL to 3580 mL with a mean of 1100 mL. The operating time ranged from 4 h to 11 h and 45 min with a mean of 6 h and 36 min. Patients stayed 8 - 66 d in hospital after operation with a mean of 27 d.

The overall complication rate after PE was 53.6% (15 of the 28 patients). Wound dehiscence (wd) occurred in 9 cases (32.1%), urinary infection in 3 cases (10.7%), urinary incontinence in 2 cases (7.1%), massive bleeding in 2 cases (7.1%). ARDS, thrombophlebitis, ureter damage, acute renal failure, pulmonary embolism, resuture, and urinary bladder dysfunction occurred in 1 case (3.6%).

The mortality rate was 7%, of which 3.5% was interoperative.

In our study, major complications often occurred in advanced primary vulvar cancer (mainly wound dehiscence), affecting those with recurrent malignancies.

### Early complications

Massive bleeding occurred in 2 patients during operation. One patient with uterine sarcoma died of massive bleeding from sacral vessels during PPE although he received 1800 mL blood. The other patient had massive bleeding from the sacral plexus during PPE for vulvar cancer. An attempt was made for haemostasis. Disseminated intravascular clotting occurred and haemorrhage was massive and lasted for a long time. Because of the continuing bleeding and the poor general state of the patient, five large laparotomy sponges were left in the pelvis to cover the pelvic, iliac and sacral vessels under pressure. The emergency pelvic packing was successful and

the sponges were removed after 24 h. Twenty-eight days after the operation, the patient was transferred to the Department of Radiotherapy for supplementary treatment.

Gastrointestinal complications occurred after APE in 1 patient with cervical cancer. During the operation it was impossible to implant the ureter into the ileum by the Bricker method because of a lack of blood supply in the isolated intestinal loop, and uretero-cutaneostomy was performed.

The patient also suffered from acute renal failure as an early complication. Two days after APE the parameters of renal failure decreased gradually and a considerable worsening was found on day 8. Acute renal failure was confirmed. One patient with recurrent cervical cancer underwent APE and died of pulmonary embolism 2 wk after discharge from hospital. Another patient underwent TPE for recurrent cervical cancer and he received re-operation because of bleeding 2 h later. Haemorrhage was identified in the venus plexus surrounding the urethra but not fully achieved and one laparotomy sponge was applied under pressure for 48 h. After removal of the sponge no further bleeding was observed.

### Late complications

Late complications occurred as urinary incontinence in 2 patients (7.1%) with vulvar cancer after PPE. A unilateral nephrostomy was performed in 1 patient with vulvar cancer due to extensive hydronephrosis and chronic renal failure one year after PPE.

A urinary fistula was diagnosed 6 mo after PPE for recurrent cervical cancer in 1 patient. During surgery to remove the fistula, a progression of disease was diagnosed and a cystectomy was performed to create an ileal conduit.

## DISCUSSION

Primary radiation therapy or surgery in combination with radiotherapy has been the standard treatment for years in patients with advanced cancer. Although some changes have taken place in radiation techniques, the cure rate for advanced cancer still remains disappointing. Severe radiation complications may occur in these patients and PE should be performed for salvage therapy in combination with chemotherapy and radiotherapy as the first line treatment<sup>[5]</sup>.

TPE is often the only hope for women who have failed non-conservative therapy<sup>[11, 12]</sup>. PE can provide a good chance of long-term survival in carefully selected patients but the role of palliative exenteration in patients with non-resectable disease is still controversial<sup>[13]</sup>. PE is also the treatment of choice for the control of locally advanced recurrent gynecological malignancies unresponsive to therapy<sup>[4]</sup>.

We have performed PPE mainly for advanced vulvar cancer without the need to make an ileal conduit in patients who had no previous operation, radiotherapy or chemotherapy.

Physiological age and absence of co-morbidity appear to be more important when patients are selected for exenteration than chronological age. Careful pre-operative staging either by computed tomography scan

Wd = wound dehiscence; ARDS = adult respiratory distress syndrome; SCC = squamous cell carcinoma

or by magnetic resonance imaging can usually identify patients with distant metastases, extrapelvic nodal disease, or disease involving the pelvic sidewall (which generally precludes surgery). Recent application of intraoperative radiotherapy or postoperative high-dose brachytherapy in patients with advanced pelvic disease involving pelvic sidewall, may expand the standard indications for exenteration. However, this procedure with or without radiotherapy, should be the resection of all tumors since the site of palliative exenteration is controversial<sup>[14]</sup>.

A successful operation can free patients from the potential discomfort caused by aggressive tumor. To a certain extent it can also reduce the pain in the pelvic

area<sup>[6, 13]</sup>.

The most serious and common complications after exenteration are acute enteric complications (which can exceed 20%), enteric obstruction, fistulization, pelvic infection, sepsis, wound infection, pyelonephritis. Acute renal failure is a rare complication after pelvic exenteration<sup>[7-9,15-18]</sup>.

Inguinal lymphadenectomy combined with PE increases the total incidence of complications in patients with vulvar carcinoma. Necrosis of the skin over inguinal and symphysis pubis areas is the most common complication which is present in 75% of cases<sup>[18]</sup>.

The long operating time and huge blood loss associ-

ated with exenteration increase the risk of wound infection which may adversely affect anastomosis site healing. Concomitant transfusion requirements and the entry of contaminated viscera- vagina, urethra, rectum are inherent to the operation. Most patients who undergo the procedure have advanced cancer and have received high-dose radiotherapy to the operative field. This compromises healing ability and makes the procedure even more risky<sup>[4]</sup>.

Experience shows that irradiation produces relative ischemia of the exposed area with diminished cellular vitality, thereby impairing the healing process<sup>[19]</sup>. The dose of previous radiation therapy (especially higher than 4000cGy) is the most important risk factor for major surgical complications. The incidence of postoperative urinary or gastrointestinal complications is significantly higher in previously irradiated gynaecological patients<sup>[4,7,10,20]</sup>. Averette *et al*<sup>[15]</sup> reported an operative mortality of 40% is associated with surgical correction of fistula and 93% of these patients have received previous radiation therapy. The fistulized loop of bowel is attached to the pelvic floor at reoperation. In our study, fistulization after PE was found only in 1 patient with recurrent cervical cancer. This low incidence can be attributed to the majority of patients presenting primary tumors, who did not undergo primary radiation but reperitonisation at closure of the pelvic cavity to prevent small bowel prolapse. Rodriguez-Bias *et al*<sup>[21]</sup> showed that 67% of patients who did not receive prior radiation therapy and 26% of patients who did not receive prior irradiation develop postoperative complications. Other authors have implicated prior radiation therapy as a risk factor for increased morbidity after PE<sup>[15,22]</sup>.

The type of urinary diversion is also significantly related to the development of complications. A modified Indiana pouch and transverse colon for the reservoir are reported to have a lower incidence of complications than the sigmoid colon or Kock pouch<sup>[10,12,23,24]</sup>. Compared to cutaneous ureterostomy and ileal conduit, a continent reservoir provides a better quality of life and a low incidence of pyelonephritis and chronic renal failure. However, the early complication of wound infection is higher<sup>[4]</sup>.

Urinary fistulae and obstruction following pelvic exenteration are the frequent and life threatening complications, which increase the mortality and morbidity rates of large resections performed during PE for gynecological cancers. Major early urinary complications are significantly increased in patients who have received previous pelvic radiotherapy or have had an intestinal conduit for urinary diversion. Late complications are associated with urinary diversion, including stenosis, chronic or recurrent pyelonephritis, prolapsed stoma, incontinent or obstructed reservoir and calculi in the reservoir<sup>[10]</sup>.

Patients after PE are at high risk of developing cardiac complications, ARDS and pulmonary emboli<sup>[25,26]</sup>. Contrary to other authors we have performed PPE mainly in advanced vulvar cancer without the need to make an ileal conduit in patients did not receive radiotherapy or chemotherapy. The majority of these patients had recurrence after prior surgery and radiotherapy. After exenteration, the 5-year survival was 40-60% in patients with gynecological cancer and 25-40% in patients with colorectal cancer<sup>[14]</sup>. We present a review of complications and their

percentages as cited in literature<sup>[3,5,7-9,15-18]</sup>

### Early postoperative complications

Intestinal obstruction rate was 5.3-21.1%, skin flap necrosis (in vulvar cancer) 75%, hemorrhage 1-16.6%, intestinal fistula 5-16.3%, enterocutaneous fistula 4-23.8%, urinary fistula 1-15.7%, pyelonephritis / pyelonephrosis 3.8-21.6%, wound infection 2-14%, peritonitis 4%, pelvic abscess 2.6-17.9%, stoma separation 5.8%, ureteral obstruction or necrosis 1-5%, uremia (without obstruction) 5.7%, stoma stenosis 2%, prolonged ileus 15%, postoperative psychosis/depression 1.9-5%, pelvic cellulitis 7.4%, stomal hernia 10.5%, colostomy necrosis 2.4-5.2%, loop necrosis 3.7%, iliac artery thrombosis 0.4-1.1%, arterial thrombosis 2.4%, hydronephrosis 15.4%, hyperchloremic acidosis 7.4%, thrombophlebitis 2-8.3%, pulmonary embolus 2-4.3%, neurogenic bladder 8.3%, urinary incontinence 5.3%, cerebrovascular incident 2.2%, shock 3.3%, calculi 2%, myocardial infarction 2.2%, heart failure 0.9%, perineal evisceration 2-6%, metabolic disorders 21%, pneumonia 1%.

### Late postoperative complications

Intestinal obstruction rate was 4.4-15.4%, small bowel ileus 10%, hydronephrosis 1.4-21.6%, enteroperineal fistula 1-5%, pyelonephritis 2-10.5%, colostomy necrosis 5%, perineal abscess 1-3.4%, perineal hernia 1.9-3.3%, renal calculus 0.9-6.2%, stomal hernia 3.7-5%, stomal stricture 1-5.5%, uretero-ileal stricture 1-9.2%, recurrent infection 27.2%, small bowel fistula 5.5-8%, wound dehiscence 9.8%, urinary incontinence 8.3%, chronic lymphoedema 16.6%, perineal evisceration 4%, metabolic disorders 8%, urinary fistula 3%.

Robertes *et al*<sup>[9]</sup> reported that 29% of patients after PE need re-operation. Re-operation after PE is extremely difficult and often leads to further morbidity if not mortality in such a situation. Re-operation for small bowel fistula and obstruction has 40% and 50% operative mortality, respectively. In our study, only 1 out of 28 patients (3.6%) had indications for re-operation.

PE is a high-morbidity procedure and its major complications correlate with preoperative pelvic radiotherapy and previous pelvic surgery. However sufficient postoperative nutrition (hyper-alimentation), antibiotics and antithrombotic therapy, use of tissue less affected by radiation (such as transverse colon, jejunum) and the creation of a continent reservoir can decrease the incidence of complications and improve the quality of life after this radical procedure<sup>[4]</sup>.

Although significant advances have been made in radiotherapy and chemotherapy, PE still remains an important part of the armamentarium of pelvic surgery and is the primary and occasionally the only treatment for the control of advanced malignancies.

In conclusion, PE should be considered as the treatment of choice for the control of locally advanced primary and recurrent pelvic malignancies unresponsive to therapy. An understanding of post-exenteration morbidity and complications is necessary. We are continuing to revise and update the procedures to minimize complications and increase survival.

### Abstract

**AIM:** To investigate the ABH and Lewis antigen expression in erythrocytes, saliva and gastric epithelium, as well as the association between *H pylori* and the presence of gastric epithelial lesions.

**METHODS:** The distribution of ABH and Lewis blood group antigens in erythrocytes, saliva and gastric mucosa of *H pylori*-infected gastric ulcer patients was analyzed. Forty-two patients with gastric ulcer were studied, and fifty healthy individuals were used as control group. The blood group antigens were determined by direct hemagglutination, dot-ELISA and immunohistochemical methods in erythrocytes, saliva and gastric mucosa specimens, respectively. Diagnosis for *H pylori* infection was performed by conventional optical microscopy and ELISA.

**RESULTS:** A higher seroprevalence of IgG *H pylori* specific antibodies was observed in gastric ulcer patients (90%) compared to the control group (60%). We observed a significant increase of phenotypes O, A<sub>2</sub> and Lewis b in *H pylori*-infected patients. The expression of these antigens had progressive alterations in areas of ulcerous lesions and intestinal metaplasia.

### INTRODUCTION

The presence of *H pylori* in gastric mucosa is associated with chronic active gastritis and more severe gastric diseases, including chronic atrophic gastritis, peptic ulcers, stomach cancer, and lymphoma<sup>[1, 2]</sup>. However, only a minority of *H pylori*-infected patients develop gastric diseases. In order to explain this fact, the influences of additional factors such as the genetic predisposition of the host and the genotype of *H pylori* strains have been analyzed<sup>[3]</sup>. Biochemical studies<sup>[4, 5]</sup> have discovered a blood group antigen binding adhesin (BabA), which can mediate bacterial adherence to epithelial cells and seems necessary for *H pylori* pathogenicity by facilitating the subsequent action of the other virulent factors such as VacA and CagA. Borén *et al*<sup>[6, 7]</sup> demonstrated that the receptors for *H pylori* on gastric epithelial cells are the H and Le<sup>b</sup> antigens of the ABH and Lewis (Le) blood group systems. It has been known for decades that individuals of O blood group phenotype have a higher risk of developing duodenal ulcers<sup>[8, 9]</sup> and also a higher incidence of gastric ulcers<sup>[8, 10]</sup>. In ulcer disease patients infected with *H pylori* little is known about the presence of ABH and Lewis antigens in erythrocytes, saliva and gastric epithelium. However, alterations in these blood group antigen expressions have been extensively described in stomach cancer and precursor lesions<sup>[11, 12]</sup>. This study was to investigate the ABH and Lewis antigen expression in erythrocytes, saliva and gastric epithelium

**Table 1** Distribution of ABO and Lewis phenotypes in erythrocytes and saliva of gastric ulcer patients and controls

Lewis erythrocytes	Saliva		Secretor	Lewis phenotypes Blood/Saliva	ABO Phenotypes									
	Le <sup>a</sup>	Le <sup>b</sup>			A <sub>1</sub>		A <sub>2</sub>		B		AB		O

Total					6	11	4	3	6	8	1	1	25	27

I = gastric ulcer patients, II = control, S = secretor status

in *H pylori*-infected patients as well as the association of *H pylori* status with these blood group phenotypes and the presence of gastric epithelial lesions.

## MATERIALS AND METHODS

### Patients and control sample

The study included a total of 42 patients with gastric ulcer who were examined by routine upper endoscopy at Ofir Loiola Hospital (Belém, PA, Brazil) between May and December 2000, and comprised 76% males (32/42) and 24% females (10/42). The mean age was 53 years, ranging 28-80 years. Blood and saliva samples and gastric biopsy specimens were collected from each patient. These selected patients did not take non-steroidal anti-inflammatory drugs, H2 receptor antagonists, proton pump inhibitors or antimicrobial drugs for at least 60 d before the samples were obtained. Peripheral blood and saliva samples were collected from 50 patients asymptomatic for gastric diseases. These patients did not receive upper endoscopy. The mean age of these individuals was 49 years, ranging 25 - 80 years. This study was approved by the Ethics Committee at the Tropical Medicine Nucleus of the Pará Federal University and informed consent was obtained from the patients before sample collection.

### Histopathological analysis of gastric biopsies

For histological analysis, biopsies from the ulcer lesion border and the adjacent area (perilesion) of each patient were obtained. Paraffin-embedded biopsy specimens were sectioned at 4 µm thickness and stained with haematoxylin - eosin and evaluated using the Sydney classification<sup>[13]</sup> with regard to the presence of intestinal metaplasia (IM) and the degree of granulocytic and lymphocytic infiltration (mild, moderate, severe). The density of *H pylori* was determined in the sections using a modified Gram staining and graded into absent, mild, moderate and strong, based on the above classification system<sup>[13]</sup>.

### Serological detection of specific antibodies against *H pylori* and *CagA*

The serum samples were tested for IgG-class antibodies against *H pylori* by an indirect hemagglutination assay and anti-*CagA* with a commercial kit based on recombinant *Helicobacter* antigens p120 EIA. Both tests were performed according to the manufacturer's instructions (Viva

Diagnostika, Hürth, Germany). *H pylori* infection diagnosis of the control group was performed using only serological methods. However in the ulcer disease patients *H pylori* status was determined by serological and conventional optical microscopic methods.

### Detection of ABO and Lewis blood group antigens

Blood and saliva samples were collected after the endoscopy. In blood the ABO and Lewis phenotypes were determined with a conventional direct hemagglutination technique. The characterization of ABH and Lewis specificities in saliva was tested using the dot-ELISA technique on nitrocellulose<sup>[14]</sup>. Immunohistochemistry for ABO and Lewis blood group antigen expression in gastric biopsies (ulcer lesion border and perilesion) in the foveolar and fund epithelium was performed using an indirect immunoperoxidase technique<sup>[15]</sup>. The reaction pattern of these antigens in gastric mucosa was classified as positive (homogeneously with more than 50% of stained cells or heterogeneous with 5-50% of stained cells) and negative (without or lower than 5% of stained cells).

### Statistical analysis

Statistical tests using Bioestat 3.0 were performed to verify the significance of the differences observed in our study<sup>[16]</sup>. The chisquaretest ( $\chi^2$ ) was used as a global test for any relationship. The Mann-Whitney U test was used to compare unpaired data. Spearman's rank and contingency correlation tests were used to examine the relationship between density of *H pylori*, polymorph nuclear activity and chronic inflammation.  $P < 0.05$  was considered statistically significant.

## RESULTS

### Seroprevalence of *H pylori* infection and *CagA* strains

Endoscopic diagnosis of patients with gastric ulcer indicated 74% (31/42) ulceration in the antral region and 26% (11/42) in the corpus region. The presence of IgG *H pylori* specific antibodies was observed in 90% (38/42) of all patients. Approximately 84% (32/38) of these *H pylori*-infected patients were also *CagA* seropositive. In the control group, seroprevalence of IgG *H pylori* specific antibodies was observed in 60% (30/50) of the individuals and 36% (18/50) were also infected with *CagA* strains. These distributions were significantly lower in *H pylori*-infected patients than in gastric ulcer patients ( $P < 0.01$ ).

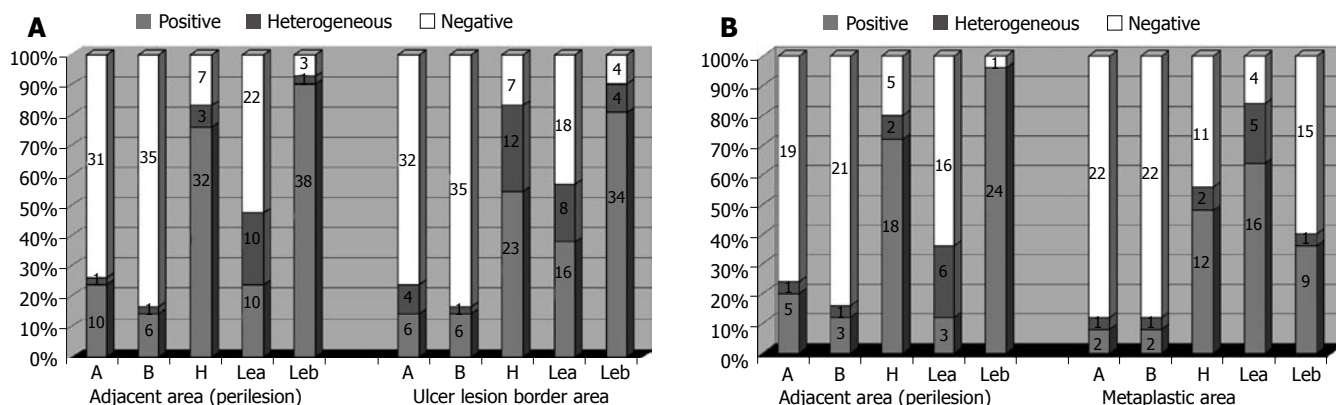

Figure 1 ABO and Lewis antigen distribution pattern in ulcer lesion borders (A) and intestinal metaplastic area (B) of gastric ulcer patients.

### Distribution of ABO and Lewis phenotypes in erythrocytes and saliva of patients and control group

A comparison of the ABO blood group phenotype distributions in blood and saliva of gastric ulcer patients and control group is showed in Table 1. Regarding the Lewis blood group system in saliva, the Le<sup>b</sup> antigen was detected in approximately 95% of the patients and in the control group. The distribution frequency of ABO ( $P>0.05$ ) and Lewis saliva ( $P>0.05$ ) phenotypes observed in gastric ulcer patients had no difference in relation to the control group. We observed a discrepancy in the expression of Lewis antigens in erythrocytes and saliva in some patients (Table 1), which were divided in two groups: concordant (individuals with similar expression of Lewis antigens in blood and saliva) and discordant (individuals with different expressions of Lewis antigens in blood and saliva). A discordant phenotype was observed in 57% (24/42) of the patients. Of these, 83% (19/24) belonged to the negative erythrocyte Lewis phenotype. A difference in the blood and saliva Lewis antigen expression (Table 1) was observed in only 22% (11/50) of the control group.

### Distribution of ABH and Lewis antigen expression in gastric mucosa regions

The pattern of ABH and Lewis antigen distribution in the foveolar epithelium of the perilesion areas compared with ulcer lesion borders showed a loss of A, H and Leb antigen expression, resulting in a decrease of homogeneous expression and an increase in the heterogeneous pattern. At the same time, an increased expression of Le<sup>a</sup> antigen was observed in the ulcerous lesion border areas (Figure 1A). The presence of incomplete intestinal metaplasia (IM) was observed in 25 out of 42 ulcer patients. In these patients the same abnormal pattern of ABH and Lewis blood group antigen expression was found to be more intensive, with a significant increase ( $P<0.01$ ) in the expression of Le<sup>a</sup> antigen and a decrease in A, H and Le<sup>b</sup> antigen expression (Figure 1B).

### Correlation of ABH and Lewis blood group antigen expressions in saliva, erythrocytes and foveolar epithelium of gastric mucosa

In the perilesion area of the foveolar gastric epithelium,

Table 2 Distribution of ABO and Lewis blood group phenotypes in relation to serological diagnosis of *H pylori* infection in ulcer patients and controls

Blood group phenotypes	<i>H pylori</i> infection					
	Patients <sup>a</sup>			Controls <sup>b</sup>		
	N	Positive	Negative	N	Positive	Negative
A <sub>2</sub> Le(a-b+) ou	27	26	1	30	25	5
O Le(a-b+)						
A <sub>1</sub> /AB/B/Le(a-b+) ou O Le(a-b-)	15	12	3	20	5	15
Total	42	38	4	50	30	20

<sup>a</sup> $P>0.05$  vs bacterial density, lymphocytic and granulocytic infiltration

the ABH antigen expression was in agreement with that in erythrocytes and saliva. All the patients belonging to the A blood group (10/42) expressed antigens A and B. Six of them also expressed antigen H. Likewise, patients of the B blood group (a total of six) expressed antigen B, antigen H was expressed in four of them. Patients of AB blood group expressed antigens A and B. Antigen H was expressed in all O blood group patients (a total of 25 individuals). Analysis of the Lewis phenotype in the perilesion region showed a similar antigen expression pattern to that in saliva of all patients, including those with discordant Lewis phenotypes in saliva and blood. Only one patient had discordant and concordant expression with the erythrocyte phenotype.

### Association of ABH and Lewis blood group antigen distribution with *H pylori* infection and histopathological findings

The Lewis saliva phenotype was used to associate *H pylori* status and the development of gastric ulcers, because this expression was similar to that in the foveolar epithelium in gastric biopsies. Furthermore, the presence of ABO and Lewis antigens in the control group was determined only in saliva and erythrocytes but not in gastric mucosa. In relation to the seroprevalence of *H pylori* infection, a significantly higher level was observed in a defined combination of O-/A<sub>2</sub> Le (a-b+) blood groups than in the set of other blood group phenotypes of the control group (Table 2). However, no significantly different proportions were found in this subdivision, a finding that

might be explained by the high prevalence of the infection. A significant positive correlation was found between bacterial density and degree of chronic inflammation ( $P < 0.05$ ) as well as the polymorph nuclear activity ( $P < 0.05$ ). The degree of chronic inflammation was found to be positively correlated with polymorph nuclear activity ( $P < 0.01$ ). Subsequently, no significant correlation was found by contingency analysis for the variability of histological scores in regard to bacterial density between O-/A<sub>2</sub> Le (a-b+) individuals and the set of other blood group phenotypes ( $P > 0.05$ ), lymphocytic ( $P > 0.05$ ) and granulocytic infiltration degrees ( $P > 0.05$ ) in biopsies from ulcer patients.

## DISCUSSION

The sero-prevalence of IgG *H pylori* specific antibodies is 90% in patients with gastric ulcer, much higher than in asymptomatic individuals (60%). Additionally, the *cagA* seropositive phenotype shows a significant association with gastric ulcer patients. The frequencies obtained in patients agree with the reported results in previous studies<sup>[17]</sup>, in which a high rate of infection was found in symptomatic adults. The same occurs with the rate obtained in asymptomatic adults. This fact also corroborates the studies of seroprevalence in developing countries, which describe a 60% infection rate in the adult populations<sup>[18, 19]</sup>. The Lewis blood group antigens in saliva and blood of patients and the control group demonstrated a high frequency of discordant Lewis phenotype. Among these individuals, most of them were grouped in the non-genuine negative Lewis phenotype according to the Ørntoft classification<sup>[20]</sup>, where Lewis antigens are present in saliva but not in the erythrocytes, which is different from the genuine Lewis phenotype, in which the Lewis antigens are present neither in saliva nor in erythrocytes. The expression of ABH and Lewis blood group antigens in the foveolar epithelium in perilesion areas was similar to that observed in saliva, with no differences in relation to the normal synthesis of these antigens. This can be explained by the fact that circulating Lewis antigens in the serum are only acquired by red cell membranes<sup>[21]</sup>. In some physiological conditions and diseases, such as neoplasia, a reduction in the synthesis of these antigens can occur, so that the quantities of these antigens in the blood are not sufficient to be detectable by serological methods, however the salivary phenotypes do not alter<sup>[21]</sup>. Probably, the increased degree of inflammation in the gastric mucosa due to infection with *H pylori*, affects the metabolism of glycoconjugates, leading to a decrease in the quantity of Lewis antigens circulating in the plasma. The ABO blood group phenotype frequencies in ulcer patients and the control group were not different. This finding is in contradiction to many studies, which have described the increased prevalence of ulcers among O group individuals<sup>[9, 10]</sup>.

An interesting finding of our study is the observation that all A<sub>2</sub> subgroup individuals were *H pylori* positive, which has been described in another study regarding gastritis patients<sup>[18]</sup>. The reason for this finding is not clear. Theoretically, the qualitative structural difference between A<sub>1</sub> and A<sub>2</sub> subgroups is based on glycosphingolipids ex-

pressed in erythrocytes, so that A<sub>1</sub> transferase is more efficient for converting specific carrier types (H type 3 chains or H type 4 chains) into a determinant than A<sub>2</sub> transferase, resulting in a higher level of H epitope in A<sub>2</sub> subgroup, almost like that in O blood group<sup>[20]</sup>. Therefore, we believe that analogue fucosylated structures might exist as a mucosal gastric component relating to the different A subgroups, since glycosphingolipids present in gastric mucosa can function as receptors for the bacterium<sup>[22]</sup>. Besides, complex gangliosides (i.e. repetitive N-acetylglucosamine units, fucose branches and di- or multivalency) have been demonstrated in the binding assays as preferred structural requirements for mediating *H pylori* adherence to gastrointestinal epithelial cells<sup>[23]</sup>.

Furthermore, our study regarding ABO and Lewis phenotype and *H pylori* infection indicated that individuals with O Le (a-b+) and A<sub>2</sub> Le (a-b+) phenotypes had a tendency towards a higher rate of *H pylori* infection. Studies performed by Bóren *et al.*<sup>[6, 7]</sup> in 1993 and 1994 have suggested that *H pylori* uses carbohydrate structures with terminal fucose as receptors in the gastric mucosa containing Le<sup>b</sup> and H blood group specificities. Later on, Ilver *et al.*<sup>[5]</sup> in 1998 and Gerhard *et al.*<sup>[24]</sup> in 1999 showed that there is a higher susceptibility to *H pylori* infection in individuals of O and Le<sup>b</sup> blood groups, because they have a higher quantity of fucosylated antigens.

In the current study, the association of ABH and Lewis blood group phenotype distributions with the histological scores was not significantly different. But if one considers that Le<sup>b</sup> is absent only in 2 out of 42 patients, this result is inappropriate for comparison with other histopathological studies<sup>[25-27]</sup>. By comparing the ABH and Lewis antigen expression between the ulcerous lesion border and the adjacent areas (perilesion), we observed an increase in the heterogeneous expression pattern, demonstrating the loss of A, H and Le<sup>b</sup> antigen expression and appearance of Le<sup>a</sup> reactivity in inflammation regions. Colonization of the gastric mucosa by *H pylori* is a relevant factor that can alter the normal pattern of homogeneous expression.

Some studies have demonstrated that the expression of these blood group antigens is altered in metaplastic areas<sup>[17, 28]</sup>. The main alterations described are the increase of Le<sup>a</sup> and the decrease of H and Le<sup>b</sup> antigens, as was also found in this study. One explanation for this observation is the repression of the secretor enzyme activity, leaving more type I precursor chains available to be transformed into Le<sup>a</sup> by the Lewis enzyme, consequently reducing the expression of the H antigen and its transformation into A and/or B and Le<sup>b</sup> antigens in these tissues<sup>[29]</sup>.

In conclusion, the rate of *H pylori* infection seems to be higher among O, A<sub>2</sub> and Le(a-b+) phenotype individuals. The pattern of Lewis expression changes in ulcer disease patients with *H pylori* presence, mainly in intense inflammation and/or intestinal metaplastic areas, showing the increase of Le<sup>a</sup> and loss of H and Le<sup>b</sup> antigens in the gastric mucosa. Therefore, it is important to understand how ABH and Lewis antigens are regulated in gastric cancer, as well as the interaction of these histo-blood group antigens with *H pylori* adhesion, which needs to be further investigated.

### Abstract

**AIM:** To determine the efficacy and potential complications of oral naltrexone used in the treatment of pruritus in cholestatic patients and to compare them with other studies.

**METHODS:** Thirty-four enrolled cholestatic patients complaining of pruritus were studied. In the initial phase, pruritus scores during day and night were evaluated. Subsequently, patients were given a placebo for one week followed by naltrexone for one week. In each therapeutic course (placebo or naltrexone) day and night pruritus scores were distinguished by a visual analogue scale (VAS) system and recorded in patients' questionnaires.

**RESULTS:** Both naltrexone and placebo decreased VAS scores significantly. Naltrexone was more effective than placebo in decreasing VAS scores. Both day and night scores of pruritus decreased by half of the value prior to therapy in thirteen patients (38%). Daytime pruritus improved completely in two patients (5.9%), but no improvement in the nighttime values was observed in any patient.

Sixteen patients (47%) suffered from naltrexone complications, eleven (32%) of them were related to its withdrawal. Complications were often mild. In the case of withdrawal, the complication was transient (within the first 24-28 h of therapy) and self-limited. We had to cease the drug in two cases (5.9%) because of severe withdrawal symptoms.

### INTRODUCTION

Pruritus is one of the most annoying symptoms in cholestatic hepatic diseases<sup>[1-3]</sup>. Several therapeutic methods with varying degrees of success have been used in its treatment. However, although we can not ignore the positive effects of cholestyramine<sup>[4]</sup>, urodeoxy colic acid<sup>[5-7]</sup>, rifampin<sup>[8-12]</sup> and antihistaminic agents on pruritus, many patients do not show unequivocal response to any of these therapeutic options. Even liver transplantation has been indicated in patients with refractory pruritus<sup>[13-15]</sup>. The classic explanation for pruritus during cholestasis is the accumulation of bile acids<sup>[16, 17]</sup>. However, recent studies show that endogenous opioids in the central nervous system have a role in creating the feeling of pruritus in these patients<sup>[18-20]</sup>. Plasma levels of endogenous opioids including enkephalin increase in patients with chronic cholestasis<sup>[21]</sup>. Pruritus can be controlled by opioid antagonists such as naloxone<sup>[22, 23]</sup>. Injection of cholestatic patient's serum to monkey's medulla can cause pruritus that is controlled by naloxone<sup>[24]</sup>. Several recent studies indicate that opioid antagonists such as naloxone and nalmefene are effective in reducing pruritus in patients with primary biliary cirrhosis<sup>[18, 25-27]</sup>. Unfortunately, these drugs have some limitations in use. Naloxone has a short half-life and low bioavailability. Therefore, the only way to use it is by injection<sup>[27, 28]</sup>. Furthermore, these opioid antagonists frequently cause severe withdrawal reactions in patients<sup>[29-31]</sup>.

Naltrexone is an oral opiate antagonist that is commonly used in reducing alcohol dependence and opioid addiction<sup>[28, 32, 33]</sup>. It has been used more recently for rapid opiate detoxification<sup>[34]</sup>. Acute naltrexone withdrawal reactions have also been reported<sup>[35]</sup>. Its half-life and bioavailability are between naloxone and nalmefene and it has a considerable first pass effect (95%). Naltrexone clearance from serum is mostly in kidneys<sup>[28, 36, 37]</sup>. We performed this study to evaluate the effects of naltrexone on cholestatic pruritus and its complications.

## MATERIALS AND METHODS

Thirty-four patients (age range: 32-72 years; average age:  $54 \pm 11.34$  years) with cholestatic pruritus were selected for study. These patients had different types of cholestatic diseases including primary biliary cirrhosis (PBC), primary sclerosing cholangitis (PSC), cirrhosis (in compensated stage), overlap syndrome, choledocholithiasis, cholangiocarcinoma, periampullary tumors and pancreatic head carcinoma. The duration of pruritus ranged from eight days to thirteen months. Criteria for exclusion of patients from the study included age less than 15 years, serum creatinine  $>1.5$  mg/dL, pregnancy, use of opioids, and cirrhosis with B or C Child Paugh score. The study was performed between April 2003 and June 2004 in the Imam Hospital in Tehran, Iran. We conducted the study on admitted patients with the approval of the Ethics Committee of Tehran University of Medical Sciences. All enrolled patients gave their informed consent.

The study was carried out using a single blind, self-controlled trial method. After the day and night pruritus scores were obtained, patients were given a placebo for one week and then the scores were recorded. Subsequently, a naltrexone therapy (50 mg daily) for one week, was begun. Pruritus scores were characterized by a VAS system between 0 and 10. Daytime pruritus was considered as pruritus occurring before sleep and nighttime implied pruritus after waking from nocturnal sleep. A score of zero signified no pruritus while 10 meant sleep or work-disturbing pruritus or of such severity that skin damage occurred.

Scoring was performed in the middle and at the end of the therapeutic course of treatment (placebo or naltrexone) and the mean of the scores was used. Laboratory tests including total and direct bilirubin, alkaline phosphatase (ALP), aminotransferases (AST, ALT) and creatinine were performed for all patients before therapy and recorded in the questionnaires. The mean scores of day and night pruritus were compared before therapy and after placebo and naltrexone courses by Wilcoxon rank test with SPSS10.0.5 software.  $P < 0.05$  was considered statistically significant.

## RESULTS

The numbers of patients with PBC, PSC, cirrhosis, overlap syndrome, choledocholithiasis, cholangiocarcinoma, periampullary tumors and pancreatic head carcinoma were 4, 6, 11, 7, 1, 2, 2, and 1, respectively.

### Naltrexone effect on pruritus

Table 1 Characteristics of patients before therapy ( $n = 34$ )

Characteristics	Range	Mean $\pm$ SD
Age (yr)	32-72	$53.97 \pm 11.93$
ALP	190-1150	$657.76 \pm 266.36$
Total bilirubin	5.8-37.00	$16.60 \pm 9.03$
Direct bilirubin	4-32.5	$13.14 \pm 8.05$
ALT	32-145	$66.03 \pm 27.13$
AST	35-110	$60.47 \pm 19.73$
Creat.	0.7-1.3	$1.01 \pm 0.14$
Pruritus in day before therapy	6-10	$8.30 \pm 1.07$
Pruritus in night before therapy	8-10	$9.13 \pm 0.78$

The characteristics of patients before therapy are summarized in Table 1. In both cases of therapy with placebo or naltrexone, the mean scores of daytime and nighttime pruritus decreased significantly (Table 2). Naltrexone significantly decreased the pruritus score compared to the placebo (Table 2).

In this investigation, two of the thirty-four patients were forced to withdraw from the study because of drug complications. Thirteen patients (38%) showed at least 50% decrease in their pruritus scores and two (5.9%) became completely free of pruritus. Three (8.8%) showed no change in their scores during the therapy and the score even increased in one case.

The onset of naltrexone therapeutic effects was within the first 48 h of therapy. The decrease in pruritus gradually slowed down and returned to some extent in three patients. There was no obvious change in biochemical parameters after therapy. The bilirubin and ALP levels did not significantly differ before or after therapy (without considering the result of therapy).

### Complications

Sixteen patients (47%) suffered from naltrexone complications which were generally mild and improved without additional treatment in the first 2-3 d of therapy. The most common complication was a withdrawal reaction in eleven patients (32.4%). The general and gastrointestinal complications (including dizziness, nausea, vomiting, headache, abdominal cramps, lethargy, weakness, irritability, dry oral mucous membrane and insomnia) were seen in other patients and one patient had also dermatologic complications. Two patients did not finish their therapeutic course because of severe withdrawal reactions. However, pruritus decreased relatively to its initial condition in one of the two patients. Except for the withdrawal reactions, other complications were not sufficiently severe to cause drug cessation.

## DISCUSSION

The results of this study indicate that oral naltrexone, an opioid antagonist, can reduce or improve cholestatic pruritus. The results agree with the other reports<sup>[38-41]</sup>. Some researchers believe that the VAS system for evaluating pruritus severity is not reliable and prefer to use a mechanical instrument attached to fingers to show and record patients' pruritus<sup>[25]</sup>. Although such instruments may be helpful

Table 2 Comparison of pruritus scores in patients before and after placebo and naltrexone therapy (mean  $\pm$  SD)

Patients (n = 34)	1 Before therapy	2 After placebo	3 After therapy	1 and 2 Significance	1 and 3 Significance	2 and 3 Significance
Pruritus in day	8.30 $\pm$ 1.07	7.54 $\pm$ 1.38	4.91 $\pm$ 2.56	P < 0.001	P < 0.001	P < 0.001
Pruritus in night	9.13 $\pm$ 0.78	8.29 $\pm$ 1.02	5.54 $\pm$ 2.51	P < 0.001	P < 0.001	P < 0.001

in evaluating pruritus objectively, their use has some difficulties. On the other hand, the VAS system can control pruritus quite well<sup>[4, 8-12, 42]</sup>. It was reported that the pruritus index is significantly correlated with the pruritus score obtained by the VAS system<sup>[25, 26]</sup>. It has been shown that decreased pruritus index and its perception are similar<sup>[43]</sup>.

In three patients of the present study, the rate of pruritus score decrease was lower after a few days of therapy. The reason is unclear though it may be due to secondary adaptation to opioid or drug resistance (tachyphylaxis). This effect has already been reported in earlier studies on nalmefene<sup>[27, 38, 39, 44]</sup>.

Some researchers believe that cessation of drug therapy for two days during a week ("drug holidays") can reduce drug adaptation effects in such patients<sup>[38]</sup>. However, others consider that this method is ineffective<sup>[40]</sup>. Increasing the naltrexone dose to 100 mg/day may be effective in such circumstances. Although side effects were relatively common (47%), most of them were mild, self-limited and transient, requiring no additional therapy in our study. On the other hand, in the placebo group 26% of patients had drug complications. Two patients had to stop the therapy because of severe opioid withdrawal effects. Both of them had a positive opioid addiction history but they were not addicted to it at the time of the study. In comparison with nalmefene, naltrexone leads to fewer and milder complications<sup>[18-27]</sup>.

To decrease naltrexone complications, synchronous prescription of clonidine<sup>[18]</sup> or naltrexone at a low dose, at least for the first few days of therapy<sup>[27]</sup>, is recommended. Also we can divide the total dose into 25 mg BD instead of decreasing it during the first few days of therapy<sup>[38, 39]</sup>. Examples of naltrexone hepatotoxicity have been reported<sup>[45]</sup>, but there is no report on the hepatotoxicity at the low dose of naltrexone in normal people or patients with hepatic diseases<sup>[38, 39, 46]</sup>.

Endogenous opioids play a role in producing cholestatic pruritus, but opioid antagonists cannot improve pruritus completely<sup>[27, 38, 39, 47, 48]</sup>. Studies indicate that naltrexone is a drug that can be well tolerated by patients and its complications are often mild and transient not requiring additional therapy<sup>[41, 49, 50]</sup>. Naltrexone can also be used in treatment of severe and intractable pruritus of varying origins<sup>[41]</sup>.

In conclusion, naltrexone can be used in the treatment of pruritus in cholestatic patients.

### Abstract

**AIM:** To investigate the effect of a four-week consumption of a special Hungarian probiotic agent (Biofir®) on the faecal microflora in human healthy subjects.

**METHODS:** The effect of Biofir® with  $10^6/\text{cm}^3$  initial germs on the faecal microflora was studied in 120 healthy volunteers (71 females, 49 males). The traditional Russian type kefir was used as control. The various germ groups and pH values were determined in wk 2, 4 and 6.

**RESULTS:** The number of all microbes increased during the 4-week probiotic treatment. The number of microbes increased 4.3-fold in the control group and 6.8-fold in Biofir-treated group. The probiotic kefir caused multiplication of the probiotic flora, meanwhile the undesired bacteria multiplied in the control group. No significant change of pH values of the faeces was found in both groups.

**CONCLUSION:** The Hungarian probiotic kefir (Biofir®) is capable of promoting multiplication of probiotic bacterial flora in the large bowel.

### INTRODUCTION

Human intestinal flora contains as many as  $10^{14}$  bacteria classified into 400-500 species, which are ten times higher than all the cells in the human body. Some bacteria of the intestinal flora such as Clostridia, Proteus and Pseudomonas aeruginosa can be harmful, while others like bifidobacteria and Lactobacilli belonging to the so-called probiotic strains are favorable for the organism. The microflora in the large intestine plays an important part in the life of the host organism<sup>[1, 2]</sup>. Its composition may change several times during our life. However it can still be regarded as nearly constant. Non-pathogenic, pathogenic and potentially pathogenic microorganisms living in a state of equilibrium determined by their own ecosystem within the large intestine take part in the local immunological and metabolic processes as well as in those affecting the organism as a whole<sup>[3, 4]</sup>.

Some strains produce metabolites, such as short chain fatty acids and bactericins, which are of antibacterial effects. As a consequence of the relationship between cells of the mucous membrane and the microflora, the expression of certain mucosal genes may change, the cytokin release may increase, the proliferation of mucous membrane may change and produce a significant effect on the intestine-associated lymphoid tissue which is the largest immune organ of the organism containing 80% of cells producing antibodies<sup>[5-9]</sup>. Certain strains of bacteria are capable of improving the barrier function of the mucous membrane and increase the differentiation of B cells as well as IgA secretion<sup>[4, 6]</sup>.

The increasing data raise the idea of enriching foods with probiotics, prebiotics and symbiotic, a mixture of these two. Probiotics which are beneficial non-pathogenic bacteria live in the intestinal canal and play a role in the preservation of health<sup>[10, 11]</sup>. The majority of prebiotics are oligosaccharides, i.e. the indigestible constituents of our plant food, which promote the multiplication, growth and efficacy of the strains of probiotic bacteria in the large intestine. Nowadays several strains of probiotic bacteria are known, but their utilization is restricted by the fact that an effective probiotic is supposed to proceed along the acidic pH of the stomach and is able to resist the digestion of bile and pancreatic juice and finally sticks to the surface of some cells in the intestinal wall. The lifespan of the stuck probiotic is short, ranging from a few days to a few weeks and it usually lasts for a short period of time following its regular intake. Colonizing probiotics compete with other microorganisms for nutrients and appropriate binding sites. Only probiotics capable of colonizing even if only temporarily, can exert the required immunological effect<sup>[1, 7, 8]</sup>.

Table 1 Composition of kefir

Components	Kefir: control product	Biofir
Fat content	3.5%	3.5%
Prebiotic content	-	0.4%
Number of microbes $\times 10^6$ Cfu		
Lactobacilli	0.15	1.48
Streptococci	165.00	227.50
Yeasts	0.40	0.18

The *in vitro* efficacy of the well-known probiotic strains has already been proved in clinical practice<sup>[12]</sup>. The most widely used strains are those taken from sour dairy products and the intestinal system. The most frequently studied species include various species of Lactobacilli, Streptococcus, thermophilus, bifidobacteria, Saccharomyces boulardii, but under certain conditions other strains in the intestinal microflora, such as *Escherichia coli* (*E. coli*) can also be used as probiotics<sup>[13, 14]</sup>. In order to become suitable for producing health improving foods, namely functional foods, individual probiotic strains need to meet certain requirements<sup>[15, 16]</sup>. The following criteria are listed for effective probiotic bacteria<sup>[17, 18]</sup>: maintenance of the biotic potential, good taste and flavor following fermentation, mild acidity in the course of storage, preservation of the capability of colonizing in the course of food technology and storage, high degree of stability during storage, stability in the course of freeze-drying or other drying procedures, accurate and reliable determination of the strain, and the dose-dependent effects

Biofir® is a traditional, so-called Russian type of kefir based on probiotic lactic acid bacteria culture composed of thermophilic strains (producing exopolysaccharides) developed by the Hungarian Dairy Research Institute. The present study was undertaken to investigate the effect of a four-week-long consumption of Biofir® on the faecal microflora.

## MATERIALS AND METHODS

### Patients

One hundred and twenty healthy volunteers (71 females and 49 males) were included in the study following the permission of the Ethical Committee. Their age ranged from 18 to 59 years. The basic selection criterion was that no antibiotics were taken by the subjects 2 mo prior to the investigation.

### Composition of kefirs (Table 1)

Kefir containing 3.5% of fat was made by stirring the frozen kefir culture. The initial number of cells was  $10^6/\text{cm}^3$ . Biofir® containing 3.5% of fat was a mixture of curd kefir made by stirring the symbiolact-1 culture. The ratio of ingredients was 1:1. The initial number of cells was  $10^6/\text{cm}^3$ .

Prior to the investigation, blood, urine and faeces samples were taken from the subjects for routine laboratory analysis and faecal microflora examination. The investigations lasted for 6 wk, while the subjects followed standard diet which was free of sour dairy products and other probiotic foods. The diet was controlled regularly by the

Table 2 Germ groups and cultures used in study

Germ groups	Cultures
All germs	Plate count skim milk agar
Streptococci	M-17-agar according to Terzaghi
Lactobacilli	MRS-agar De Man, according to Rogosa and Sharpe
Bifidobacteria	MGLP modified Garcke agar
Bacteroids	Anaerob blood agar base according to CDC
Coliforms	Violet red bile (VRB) agar
Escherichia coli	Lauryl sulfate broth
	Eosin methylene-blue lactose sucrose (EMB) agar
Enterobacteria	Violet red bile dextrose (VRBD) agar according to Mossel
-Lactose- positive	Hektoen enteric agar
Lactose-negative	
Enterococci	Citrate azide tween carbonate (CATC) agar base
Anaerob spora	Reinforced clostridial agar
	Anaerobic agar according to Brewer
Yeasts and moulds	Yeast extract glucose chloramphenicol (YGC) agar

dietitian. Then the control group (60 persons) consumed 0.5 L of Russian type kefir daily for four week, while those included in the study group (60 persons) consumed a daily amount of 0.5 L of probiotic kefir.

Faeces samples were taken in the 2<sup>nd</sup>, 4<sup>th</sup> and 6<sup>th</sup> weeks. The screening type of blood sample analysis was repeated in the 4<sup>th</sup> wk. Faeces samples were stored in sterile containers at 4 °C and sent to the Hungarian Dairy Research Institute in 4-6 h, where determination of the various germ groups was carried out in internationally accepted cultures. In addition to the analysis of the microflora, the pH value of the faeces was also determined (Table 2).

### Statistical analysis

Evaluation of the data included calculation of the changes in percentage. Determination of the differences with regard to the self-control was carried out using one sample T probe, while two-sample T probes were used for the comparison of the two groups.

## RESULTS

The essential question in the course of analyzing the faecal microflora was how the consumption of each type of kefir influenced the number of primary probiotic Streptococci, Lactobacilli and bifidobacteria within the total number of germs.

The effect of the tested dairy products on the essential faecal microflora during the 4-wk clinical investigation is listed in Table 3.

The results indicated that the number of all microbes increased 4.3-fold in the control group consuming the traditional Russian type of kefir and 6.8-fold in the group consuming the probiotic Biofir®, respectively after 4 wk. A very important difference was found between the two groups. The rate of probiotic microbes decreased from 8.9% to 2.7% in the control group by the end of the 4<sup>th</sup> wk and increased from 12.7% to 72% in the target group. Within the total number of the probiotic germs, the greatest increase (59.7-fold) resulting from the consumption of Biofir® could be observed in bifidobacteria, a lower increase (6.8 fold) was found in Streptococci, while the index

**Table 3** Effect of consumption of tested dairy products on the essential microflora in 4-wk clinical investigation

Dairy product consumed	Number of subjects	Germ group	Unit	Germ values of faece samples		
				wk 0	wk 2	wk 4

			10 <sup>6</sup> /g			

of Lactobacilli showed no change. No significant change was found in faece pH values in both groups.

The participants followed the prescribed diet but consumed no probiotic food for another two weeks following the 4-wk period of consumption. Microflora analysis of the faeces was repeated in the 6th wk. The results indicated that both the total number of germs and the number of probiotic germs returned to the initial values in both groups.

## DISCUSSION

Various types of medical treatment may damage the probiotic flora in human organ. Besides, similar damage can result from the lack of appropriate nutrients in the normal flora. The findings of several controlled studies in the field have proved that various probiotic strains are capable of shortening the duration of gastroenteritis induced by rotavirus. The beneficial effects of probiotics on chronic inflammatory intestinal conditions have been reported. These effects may be attributed to the proteolytic activity of the intestinal flora, which contributes to the breaking up of enteral antigens, reduces secretion of inflammation mediators, helps the normal activity of the intestinal mucosal barrier, normalizes intestinal permeability and increases the production of mucosal IgA<sup>[19,21]</sup>. The production of specific IgE, which prevents the allergic reactions, is inhibited by the healthy intestinal microflora<sup>[19,22]</sup>.

A well-known probiotic effect is that some bacteria produce beta galactozidase, which makes their use desirable and beneficial in the case of lactose intolerance. The decreased activity of faecal enzymes and the low levels of

faecal toxins are due to the healthy intestinal flora, which is an important factor for the prevention of large intestine cancer.

Prebiotics play an important part in the maintenance and regeneration of healthy intestinal flora as they are components of several plant foods and oligosaccharides with beneficial effect on the host organisms by selectively increasing the multiplication of probiotic bacteria and their activity in the large intestine.

One of the probiotic strains of bacteria used in the present study is capable of producing mucus. The mucus produced by it is a polysaccharide, which serves as a prebiotic agent for other probiotic strains. Besides, it increases the preservability of food products containing it and prevents their acidification.

The present study proved that Biofir®, a probiotic kefir, was capable of promoting the multiplication of the probiotic flora in the large intestine but the traditional Russian type kefir could not. As a result of the consumption of Biofir® most probiotic microbes grew significantly but the consumption of traditional kefir did not change the number (index) of these microbes.

In the present study, the initial heterogeneous color and the consistency of faecal samples were totally homogeneous after four weeks of Biofir® consumption, probably due to the advantageous bio-physiological processes caused by the multiplication and ultimate predominance of the useful probiotic microbes.

In conclusion, Biofir® meets all the criteria of functional foods and can be used in the prevention and treatment of various acute and chronic inflammatory conditions and nutritional allergies. Further investigations should be

undertaken to determine the effect of probiotic strains on various pathological conditions.

### **Abstract**

**AIM:** To investigate the effect of *Tripterygium hypoglaucum* Hutch (THH) on the assembly and disassembly process of tubulin and its possible mode of action.

**METHODS:** *In vitro* porcine brain tubulin assembly assay was employed to analyze the inhibitory effects of THH at different concentrations (0.05 µg/L, 0.07 µg/L, 0.09 µg/L). Colchicine (0.0025 mmol/L, 0.0050 mmol/L, 0.0075 mmol/L) was used as a positive control.

**RESULTS:** THH could significantly inhibit the assembly of isolated porcine brain tubulin at all tested concentrations.

**CONCLUSION:** THH is capable of inducing aneuploidy in mammals via tubulin polymerization inhibition pathway and may pose a genetic risk to human beings.

### **INTRODUCTION**

Aneuploidy is an important genetic change associated with birth defects, infertility, spontaneous abortions and cancer development<sup>[1]</sup>, which are dependent upon the functioning of a variety of cell organelles and/or a number of division-specific metabolic activities, such as synthesis and functioning of the proteins of the nuclear spindle, attachment and movement of chromosomes on the spindle apparatus. A variety of chemicals are capable of modifying certain functions of spindle apparatus components which may lead to chromosome mal-segregation<sup>[2]</sup>. The frequency of aneuploidy can be increased by chemical treatment in various experimental cells. If human beings are exposed to aneugens, the risk of developing aneuploidy is increased, which is a matter of concern. Therefore, it is necessary to analyze the aneugenic potential of chemicals in safety assessment since chemically-induced aneuploidy in human beings can not be excluded.

Cochicine and vinblastine are known aneugens which affect tubulin polymerization and depolymerization, and disrupt microtubule formation during cell cycle<sup>[3,4]</sup>. As tubulin is the main constituent of the spindle, the balance between microtubule assembly and disassembly is critical for the spindle function. *In vitro* tubulin assembly assay is a useful screening system which could give information about the possible functional mechanism(s) of tested chemicals and their potential to cause aneuploidy.

The study of compounds and functions of plant origin has generated a great interest in the fields of food and medicine. Many of them have chemo-preventive properties which need to be tested for their effects on human beings. THH is a traditional Chinese medicinal herb belonging to the genus Celastraceae. The water extract from THH contains alkaloids, dulcitol, terpenes, lactones and pigments. The dry root can be immediately used in the form of decoction or the unpurified water extract can be compacted to tablets for clinical use. THH has been widely used in the treatment of various human immunological diseases, such as systemic lupus erythematosus, rheumatoid arthritis, and others. It was reported that the use of THH can lead to reversible inhibition of germinal cell development both in human beings and in rats. Previous research showed that THH is a potent aneugen<sup>[5]</sup>. THH induces a significantly higher number of kinetochore

**Figure 1** Scheme of *in vitro* tubulin assay. The tubulin assembly was achieved at the end of the absorption after 20 min incubation and kept a steady state level at 37 °C. The disassembly was carried out at 4 °C and after the assembly (40-min incubation).

positive micronuclei both in mouse bone marrow and in mouse NIH 3T3 cells [6, 7]. Recently, we also found that THH could induce aneuploidy of chromosome 8 both in mouse bone marrow cells and in sperm cells by fluorescence *in situ* hybridization (FISH) [8]. The aim of the present study was to investigate the effect(s) of THH on tubulin assembly and disassembly and its possible mode of action. The study may help us to understand the potential adverse effects of THH on human health.

## MATERIALS AND METHODS

### Chemicals

Dithioerythritol, PIPES, and colchicines (COL) were purchased from Sigma. Guanosine-5'-triphosphate (GTP; Sigma) was a gift from Dr. ID Adler, Germany. Glycerol, MgSO<sub>4</sub> dry herb of THH were purchased from Shanghai Chemical Company, and Kunming Medicine Company, China, respectively.

All the chemicals and THH were freshly prepared. COL was dissolved in sterile distilled water according to the test concentrations (0.0025 mmol/L, 0.0050 mmol/L, 0.0075 mmol/L), and 100g of mashed THH sample was extracted in 1000mL boiling water for 5 min and cooled down to room temperature for 30 min. The procedure was repeated three times to ensure maximum extraction. The supernatant was filtered and lyophilized. The yield of the crude THH extract was about 4.8%. THH extract was dissolved again in sterile distilled water before use according to the test concentrations (0.05 µg/L, 0.07 µg/L, 0.09 µg/L). The chemical and compound concentrations selected in the present study were selected in accordance to our preliminary mitotic block study in V79 cells and their solubility.

### Purification of tubulin

The brains were obtained from 3 pigs within 2 h after

sacrifice. Purified tubulin was obtained from porcine brain tissue by two cycles of assembly-disassembly procedure following the method of Williams and Lee [9]. The protein concentrations of the final preparation were determined by the method of Bradford with bovine serum albumin as standard. The resultant tubulin concentration was 3.34-3.75 µg/L. SDS-PAGE was performed to determine the purity of each tubulin preparation. Bovine serum albumin (66.2 Ku) and rabbit actin (43 Ku) were used as standard markers when the average MW of tubulin was 52.5 Ku.

### Tubulin assembly-disassembly assays

Tubulin assembly was assayed photometrically by measuring the increase in the absorption at 350 nm (OD<sub>350nm</sub>). Six hundred µL PM-4M buffer containing 0.1mol/L PIPES, 2 mmol/L EGTA, 1 mmol/L MgSO<sub>4</sub>, 4 mol/L glycerol, 2 mmol/L dithioerythritol, pH6.9, as well as 30µL of 50 mmol/L GTP and 1400 µL tubulin solution were mixed thoroughly and poured immediately into a cuvette placed in the temperature-controlled compartment (37°C) of a recording spectrophotometer. The changes of OD<sub>350nm</sub> were recorded at an interval of 1 min. The absorption remained at the steady state level at the end of the assembly. The temperature of temperature-controlled compartment was decreased to 4°C in 2 min to start the disassembling of tubulin. The OD<sub>350nm</sub> was again recorded (Figure 1).

### Treatment and analysis

*In vitro* assembly analysis of porcine brain tubulin was carried out by adding 5 µL of THH (0.05 µg/L, 0.07 µg/L, 0.09 µg/L) or positive control (COL, 0.0025 mmol/L, 0.0050 mmol/L, 0.0075 mmol/L) into a ice-both cuvette containing 600µL PM-4M buffer (50, 70, 100 µg/mL), 30 µL of 50 mmol/L GTP and 1400 µL of tubulin solution. The contents were mixed thoroughly and placed immediately in the temperature-controlled compartment of a recording spectrophotometer (37°C). The net OD<sub>350nm</sub> was recorded at an interval of 1 min. The highest concentration of test compound was selected in accordance with previous laboratory results obtained by *in vitro* mitotic block assay with V79 cells. The solubility was considered as well.

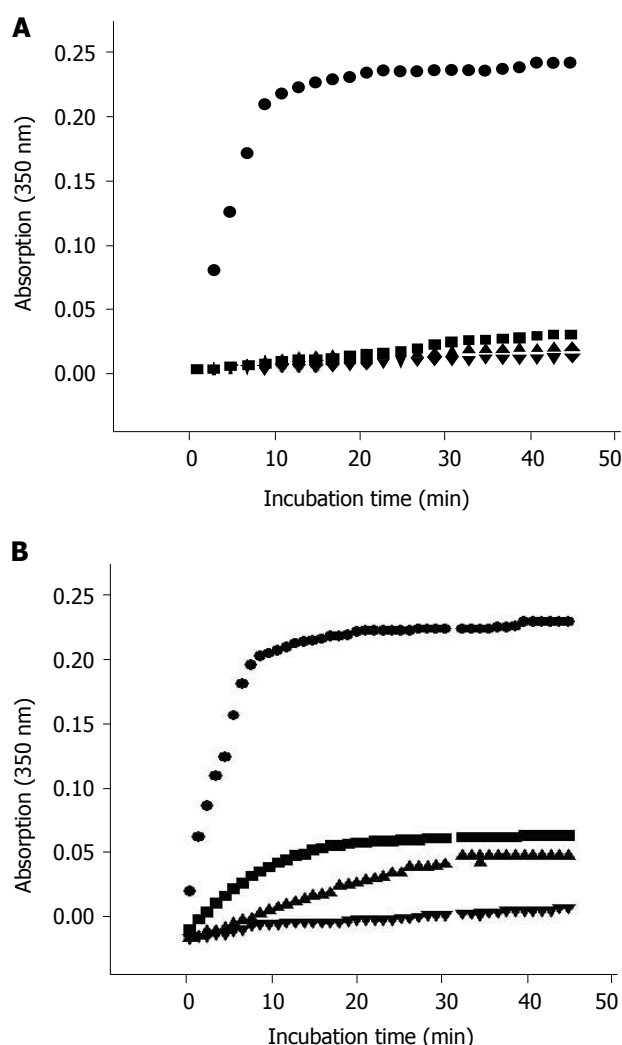

## RESULTS

The results of porcine brain tubulin assembly assay with COL and THH are shown in Figure 2. COL led to a very strong inhibition of the *in vitro* polymerization of tubulin at all concentrations. THH resulted in a dose-dependent inhibition of polymerization. However, the potency of assembly inhibition by THH was weaker than COL at all concentrations.

## DISCUSSION

Aneuploidy plays a crucial role in the initiation and progression of tumorigenesis as well as in inherited disorders and fetal wastages. Chromosome segregation is dependent on different cell organelles, which is

**Figure 2** Inhibition of *in vitro* tubulin assembly by COL at the concentration of ■:0.0025 mmol/L, ▲:0.0050 mmol/L, ▼:0.0075mmol/L (A) and THH at the concentration of ■:0.05mg/mL, ▲:0.07g/mL, ▼:0.09mg/mL (B). ●: Solvent control

controlled by a number of metabolic pathways. However, the mechanisms and the cellular targets leading to non-disjunction are largely different from those leading to gene and chromosomal mutations where DNA is the principle target. Aneuploidy-inducing factors include damage to essential elements required for proper chromosome function(s), reduction in chromosomal pairing, induction of chromosome interchange, effect on chromosome condensation, persistence of nucleoli in mitosis or meiosis, increased chromosome stickiness, damage to centrioles or kinetochores, impairment of chromosome alignment, alterations in ion concentrations during mitosis, damage to nuclear membrane, and physical disruption of chromosome segregation [1]. A number of methods have been described for the detection of chemically-induced aneuploidy. However, none of these methods is sufficiently validated for routine screening. Although no conclusive evidence for aneuploidy induction can be obtained from tubulin assembly and disassembly assay, *in vitro* tubulin

assay can be used to pinpoint the aneugenic potential of chemicals by inhibiting the microtubule assembly.

THH has been used to treat many immunological diseases. Both human somatic cells and germ cells are exposed to THH itself or its metabolites during long term clinical use. Since its administration leads to reversible inhibition of germinal cell development both in humans and in rats, there is a great need to evaluate the genetic safety of THH. Our research has shown that THH is a mammalian aneugen both in somatic cells and in germinal cells [5-8]. The results in the present study are in accordance with our previous results, suggesting that either THH itself or its components are capable of inducing aneuploidy via interaction with spindle proteins such as tubulin and probably actin or myosin(s) contained in the contractile ring during cell division. THH may pose a genetic risk to human beings. It seems important for Chinese medical professionals to consider a possible genetic risk of THH and cautiously advise patients to abstain from reproduction within 6 months after the treatment with THH. Further studies are needed to identify the aneugen from THH and to study its possible mode of action.

## ACKNOWLEDGMENTS

The authors thank Dr. Lu Yuan, Kunming Institute of Zoology, Chinese Academy of Sciences for his technical support for tubulin isolation.

### Abstract

**AIM:** To investigate the genetic relationship between Hirschsprung's disease (HD) and intestinal neuronal dysplasia (IND) in Chinese population.

**METHODS:** Peripheral blood samples were obtained from 30 HD patients, 20 IND patients, 18 HD/IND combined patients and 20 normal individuals as control. Genomic DNA was extracted according to standard procedure. Exons 11,13,15,17 of RET proto-oncogene were amplified by polymerase chain reaction (PCR). The mutations of RET proto-oncogene were analyzed by single strand conformational polymorphism (SSCP) and sequencing of the positive amplified products was performed.

**RESULTS:** Eight germline sequence variants were detected. In HD patients, 2 missense mutations in exon 11 at nucleotide 15165 G→A (G667S), 2 frameshift mutations in exon 13 at nucleotide 18974 (18974insG), 1 missense mutation in exon 13 at nucleotide 18919 A→G (K756E) and 1 silent mutation in exon 15 at nucleotide 20692 G→A(Q916Q) were detected. In HD/IND combined patients, 1 missense mutation in exon 11 at nucleotide 15165 G→A and 1 silent mutation in exon 13 at nucleotide 18888 T→G (L745L) were detected. No mutation was found in IND patients and controls.

**CONCLUSION:** Mutation of RET proto-oncogene is involved in the etiopathogenesis of HD. The frequency of RET proto-oncogene mutation is quite different between IND and HD in Chinese population. IND is a distinct clinical entity genetically different from HD.

### INTRODUCTION

Hirschsprung's disease (HD) is a frequent congenital malformation affecting one in 5000 births. It is characterized by the absence of ganglion cells in both the myenteric and submucosal plexuses along variable lengths of the hindgut leading to intestinal obstruction in neonates and severe constipation in infants and adults. The occurrence of most HD cases is sporadic, but 15-20% are in familial form<sup>[1]</sup>. Genetic analyses have illustrated several genes coding for components of signaling pathways including RET<sup>[2-9]</sup>, GDNF<sup>[10-12]</sup>, EDN3<sup>[10,13-15]</sup> and EDNRB<sup>[10,15-18]</sup> involved in occurrence of HD. Mutations of RET gene are responsible for a dominant form of HD and account for half of the familial cases and 0-50% of sporadic cases<sup>[4,6,7]</sup>.

Intestinal neuronal dysplasia (IND), first described in 1971 by Meier-Ruge<sup>[20]</sup>, is a malformation of the enteric nervous system and shows the clinical features similar to those of HD. The incidence of IND ranges 5-60% of all patients biopsied for suspected HD. The prominent histological features of IND are hyperganglionosis of submucosal and myenteric plexuses, giant ganglia containing more than seven nerve and ectopic ganglion cells<sup>[19,20]</sup>. IND often occurs proximal to the aganglionic segment in HD<sup>[19]</sup> and less frequently as an isolated condition. The etiology of IND is still unknown. Since IND and HD often occur in combination, the genesis gene of HD may also be involved in occurrence of IND. To clarify the genetic relationship between HD and IND in Chinese population, we performed genetic analysis of exons 11, 13, 15, 17 of RET proto-oncogene in 30 HD patients, 20 IND patients, 18 HD/IND combined patients and 20 normal individuals as controls.

### MATERIALS AND METHODS

#### Case selection and extraction of DNA

The diagnosis of all patients was confirmed histologically

**Table 1 Mutations of RET proto-oncogene in HD and IND patients**

Case	Group	Exon	Nucleotide change	Amino acid change	Mutation type
1	HD	11	G15165→A	G667S	Missense mutation
2	HD	11	G15165→A	G667S	Missense mutation
3	HD	13	18974insG	---	Frameshift mutation
4	HD	13	18974insG	---	Frameshift mutation
5	HD	13	A18919→G	K756E	Missense mutation
6	HD	15	G20692→A	Q916Q	Silent mutation
7	HD/IND	11	G15165→A	G667S	Missense mutation
8	HD/IND	13	T18888→G	L745L	Silent mutation

by rectal biopsy and resected bowel specimens. The criteria for HD and IND were based on the guidelines put out by Holschneider *et al*<sup>[19]</sup> and Merier-Ruge *et al*<sup>[20]</sup>. Peripheral blood samples were obtained from all the patients and controls. All samples were anti-coagulated with sodium citrate. After white blood cells were isolated from each blood sample, genomic DNA was extracted according to standard procedure.

### Polymerase chain reaction

Two hundred nanograms of genomic DNA was amplified in 50 µL reaction containing 10 mmol/L Tris-HCL (pH8.4), 50mmol/L KCL, 1.5 mmol/L MgCl<sub>2</sub>, 0.5 µmol/L each of two fragment specific primers, 100 µmol/L each of dATP, dGTP, dCTP and dTTP, 2 units of Tap DNA polymerase. The primers were synthesized by Shanghai Shengong Biology Company. Exon11 (forward): 5'-ACACCACCCCCACCCACAGAT-3'; (reverse):5'-AAGCTTGAAGGCATCCACGG-3' (273bp). Exon13 (forward):5'-GACCTGGTATGGTCATGGA-3'; (reverse):5'-AAGAGGGAGAACAGGGCTGTA-3' (253bp). Exon15 (forward):5'-GACTCGTGCTATTTTCCTAC-3'; (reverse):5'-TATCTTTTCCTAGGCTTCCC-3'(234bp). Exon17(forward): 5'-CCCCACTAGATGTATAAGGG-3'; (reverse): 5'-TCACTGGTCCTTTCACCTCTCT-3' (232bp). After denaturation at 94°C for 5 min, 30 cycles of PCR amplification were carried out at 94°C for 50 s, at 58°C - 62°C for 50 s, at 72°C for 50s, and a final extension at 72°C for 10 min.

### SSCP and sequence analysis

The amplified fragments of RET proto-oncogene were analyzed for mutations by SSCP performed on a Mini Electrophoresis Unit (Bio-Rad Company, USA). Ten microliters of PCR products was mixed with 10 µL of loading buffer (90% formamide, 0.05% bromphenol blue dye and 0.05% xylene cyanol), heat denatured at 100°C for 8 min, immediately placed on ice for 3 min, and analyzed by 8% PAGE in 45 Mm-Tris-borate (pH8.0)/1Mm-EDTA (TBE) buffer under 13 v/cm at 10°C. After the gels were stained with silver, the bands were analyzed and photographed. Abnormal PCR products screened by SSCP were purified by VIOGENE kit and sequenced using PE377 automated sequencer.

## RESULTS

To determine the mutation of RET proto-oncogene and genomic relationship between HD and IND in Chinese population, we performed PCR-SSCP and sequence

analysis of RET gene mutation in exons 11,13,15,17 in 30 HD patients, 20 IND patients, 18 HD/IND combined patients and 20 normal controls. Eight germline sequence variants were detected. In HD patients, 2 missense mutations in exon 11 at nucleotide 15165 G→A resulting in a G667S exchange in codon 667 and 2 frameshift mutations in exon 13 at nucleotide 18974 (18974insG), 1 missense mutation in exon13 at nucleotide 18919, and 1 silent mutation in exon 15 at nucleotide 20692 (Q916Q) were detected. In HD/IND combined patients, 1 missense mutation in exon 11 at nucleotide 15165 G→A and 1 silent mutation in exon 13 at nucleotide 18888 T→G (L745L) were found. All these mutations were heterozygous (Table 1). No mutation found in IND patients and controls.

## DISCUSSION

The RET proto-oncogene is first detected by transfection of NIH 3T3 cells with human lymphoma DNA<sup>[21]</sup> which lies on chromosome band 10q11.2 and comprises 20 exons<sup>[22,23]</sup>. The product of the RET proto-oncogene is a RET protein, a member of the receptor tyrosine kinase superfamily consisting of a cadherin-like ligand-binding extracellular domain, a transmembrane domain, and an intracellular tyrosine kinase domain<sup>[24]</sup>. Genetic studies have demonstrated that the germline mutations of RET gene cause endocrine neoplasia and familial medullary thyroid carcinoma<sup>[25,26]</sup>. It was reported that the RET proto-oncogene is expressed in the early stage of embryogenesis and plays an important role in the differentiation of peripheral nervous system and the excretory system<sup>[27,28]</sup>. A number of studies showed that RET proto-oncogene is the causative gene for the development HD<sup>[2-11]</sup>.

IND as a cause of severe chronic constipation remains controversial and shows the clinical features similar to those of HD. Both IND and HD demonstrate hyperplasia of mast cells (MC) and decreased synaptophysin (SY) activity in abnormal bowel<sup>[29,30]</sup>. Histological features of IND are hyperganglionosis of submucosal and myenteric plexuses, giant ganglia containing more than seven nerve and ectopic ganglion cells while HD is characterized by the absence of ganglion cells in myenteric and submucosal plexuses. Cajal hyperplasia has been found in IND not in HD<sup>[31,32]</sup>. In contrast to the aganglionic segments, the mucin composition of the IND-B segments is normal<sup>[29]</sup>. The etiology of IND is still unknown. Kobayashi *et al*<sup>[33]</sup> reported that patients with IND have defective innervation at the neuromuscular junction of the affected bowel<sup>[33]</sup>. However, IND is not a neuromuscular junction disorder<sup>[34]</sup>. Wheatley *et al*<sup>[35]</sup> reported that

IND is correlated with deficiency of substance P (SP) in myenteric axons. Although the occurrence of most INDs is sporadic, IND may have dominant autosomal inheritance<sup>[36,37]</sup>. Since IND shows the clinical features and certain immunohistochemistry activity similar to those of HD, mutations of RET proto-oncogene, a major causative gene for HD, may also cause IND.

In this study, 6 RET proto-oncogene mutations were detected in 30 HD patients including 1 silent mutation, 3 missense mutations and 2 frameshift mutations. The frequency of RET proto-oncogene mutation was 20% in Chinese HD patients, which is consistent with the reported frequency ranging 0-50%<sup>[4,6,7]</sup>. These mutations are heterozygous, suggesting that 50% of the RET proto-oncogene is likely to cause HD<sup>[38]</sup>.

Two RET proto-oncogene mutations (1 silent mutation and 1 missense mutation) were detected in 18 HD/IND combined patients. However, we could not confirm that the mutation of RET proto-oncogene in HD/IND combined patients can cause IND or HD or both. No RET proto-oncogene mutation was detected in 20 IND patients and 20 normal controls. Our data confirm that the frequency of RET gene mutation is quite different between IND and HD in Chinese population. Gath *et al*<sup>[10]</sup> reported that 3 RET proto-oncogene mutations have been detected in 29 HD patients and no RET proto-oncogene mutation has been found in IND or IND/HD patients<sup>[10]</sup>. Barone *et al*<sup>[39]</sup> performed linkage analysis in two IND pedigrees and demonstrated that IND is not linked to RET proto-oncogene mutation.

In conclusion, IND is a distinct clinical entity genetically different from HD. Further investigation is necessary to elucidate the pathogenesis of IND.

## Abstract

**AIM:** To evaluate the effect of antisense vascular  
endothelial growth factor (VEGF) RNA (PCMV-FGEV)  
transfection on the profile of hepatocellular carcinoma  
(HCC) SMMC-7721 cells *in vitro* and *in vivo*.

**METHODS:** SMMC-7721 cells were transfected  
with PCMV-FGEV antisense, PCMV-VEGF sense and  
empty vector plasmid encapsulated by lipofectamine  
as antisense group, sense group and control group  
respectively. The positive cell clones were selected  
with G418. The stable transfection and expression  
of VEGF in the cells were determined by RT-PCR and  
immunohistochemistry. Cell proliferation was observed  
by MTT assay. FACS analysis was used to determine the  
effect of PCMV-FGEV transfection on cell apoptosis. The  
growth of transfected cells *in vivo* was also observed in  
nude mice.

**RESULTS:** VEGF expression was reduced in SMMC-7721  
transfected with PCMV-FGEV, which was confirmed by  
RT-PCR and immunohistochemistry. No effect of PCMV-  
FGEV transfection was found on cell proliferation and  
cell apoptosis of SMMC-7721 *in vitro*. The growth of cells  
transfected with PCMV-FGEV was slow in nude mice  
and accompanied with obvious apoptosis. The latent  
time of tumors in the antisense group was  $25.0 \pm 1.8$   
d, which was longer than that in sense and control  
groups ( $F = 19.455$ ,  $P < 0.01$ ). The average tumor weight  
in antisense group ( $0.96 \text{ g} \pm 0.28 \text{ g}$ ) was the smallest  
among the three groups ( $F = 21.501$ ,  $P < 0.01$ ).

**CONCLUSION:** The expression of VEGF can be inhibited  
by antisense PCMV-FGEV. Antisense PCMV-FGEV has no

## INTRODUCTION

Angiogenesis plays an essential role in the proliferation  
and metastasis of tumor cells by supplying them with nu-  
trition and oxygen and disposing waste products. Vascular  
endothelial growth factor (VEGF) is an important element  
in angiogenesis and permeability in normal and pathologi-  
cal tissue<sup>[1-6]</sup>. Hepatocellular carcinoma (HCC) with an ex-  
tremely poor prognosis is known to have abundant blood  
supply. VEGF has been reported to play an important role  
in the angiogenesis of HCC<sup>[7-11]</sup>. Due to the high expres-  
sion level of VEGF mRNA in HCC, antisense RNA is  
used to elucidate the possible therapeutic effects on HCC.  
Using this experimental approach, we explored the effects  
of antisense PCMV-FGEV transfection on the profile of  
HCC SMMC-7721 cells *in vitro* and *in vivo*.

## MATERIALS AND METHODS

### Reagents

TRIzol, RPMI1640 medium, 10% fetal bovine serum  
(FBS), lipofectamine, G418 were purchased from GIBCO  
(Carlsbad, CA, USA). VEGF and factor VIII antibody  
were purchased from Boster (Wuhan, China). PI and MTT  
were purchased from Sigma (St. Louis, MO, USA). VEGF  
sense, antisense vector PCMV-VEGF, PCMV-FGEV and  
empty vector pCDNA3.1 were given as gifts by NIH, USA.

### Experimental animals

Twelve female athymic BALB/c-nu/nu nude mice at the age of 4-6 wk were purchased from Chinese Academy of Sciences and maintained under conditions that met all requirements for use in an approved facility.

### Cell culture

Human HCC SMMC-7721 cells were obtained from the Central Laboratory of Tianjin Cancer Hospital and cultured in RPMI1640 medium containing 100 U/mL penicillin G sodium and 100 U/mL streptomycin sulfate, supplemented with 10% fetal calf serum at 37°C in a 50mL/L CO<sub>2</sub> atmosphere.

### Transfection

Cells were transfected with antisense PCMV-FGEV (antisense group), sense PCMV-VEGF (sense group) and empty vector PcDNA3.1 (control group) encapsulated by lipofectamine. Forty-eight hours after transfection, cells were diluted and plated into tissue culture dishes for 4 wk in complete growth medium containing 400 µg/mL G418. Colonies resistant to G418 were isolated.

### Immunohistochemistry

Immunohistochemical analysis was performed on formalin-fixed, paraffin-embedded sections using a three-step indirect method for VEGF and factor VIII expression.

### RT-PCR

Guanidinium isothiocyanate-phenol single-step method was used to extract total RNA from cells using TRIzol following instructions of the kit. The integrity, purity and concentration of the extracted mRNA were detected with ultraviolet spectral photometer and agarose gel electrophoresis. The RNA extract dissolved in DEPC was stored at -70°C. According to the sequences of human mRNA of VEGF, the primers were designed, synthesized and supplied by Boya Biotech, Shanghai, China (VEGF positive primer: 5'-AATGCTTTCTCCGCTCTG-3', negative primer: 5'-TTGCTGCTCTACCTCCAC-3'; β-actin positive primer: 5'-TTGCGCTCAGGAGGAGC AAT-3', negative primer: 5'-TTCCAGCCTTCCTTCCTG G-3'). First-strand cDNA was synthesized from 2µg RNA dissolved in water administered with DEPC, in which 0.2 µL oligo dT was added at 70°C for 5 min and placed on ice for 1 min, followed by 1µL M-MLV reverse transcriptase (200IU/µL), 0.5µL RNasin (40 IU/µL), 8µL 5×RT buffer, and 3µL dNTPs (10 mmol/L) at 42°C for 60 min. The reverse transcriptase was inactivated at 95°C for 5 min, then 5µL cDNA, 5µL 10×buffer, 3µL 2mmol/L dNTPs, 1µL 5 IU/L LA Taq enzyme and water were added to a volume of 40µL. The final concentrations of positive and negative primers were both 1µM/L. VEGF was amplified for 35 cycles at 94°C for 1 min, at 55°C for 1 min, at 72°C for 2 min, and a final extension at 72°C for 7 min. The area of electrophoresis bands (AREA), the absorption of mean optical density (A) and product of AREA and A were quantitatively analyzed after the PCR product was detected with auto image manipulating system following agarose gel (2%) electrophoresis and stained with EB. The samples were controlled with blank and β-actin.

### MTT assay

For analysis of the transfected SMMC-7721 cell proliferation, SMMC-7721 cells were seeded in a 96-well plate (6000 cells/well), untransfected SMMC-7721 cells were used as negative control. After further incubated for 24, 48, 72, 96, 120, 144 h, cell proliferation activity was determined by MTT assay. The absorbance of each well was measured at 580nm in a microtiter reader. The survival rate of tumor cells was calculated according to the formula: survival rate (%) = (A/B) × 100, where A is the absorbance of treated cells, and B is the absorbance of negative control cells.

### Flow cytometry of apoptosis

To investigate the influence of transfection on apoptosis, cells grown as a monolayer were incubated for 24 h, trypsinized, washed with PBS and fixed with 70% ethanol overnight at 4°C. Then cells were intensively washed three times with PBS and incubated with 1% RNase for 30 min at 37°C. Cells were measured with a FACScan flow cytometer (BD Biosciences) equipped with a 488 nm argon-ion laser and a Macintosh Power PC (G4). In general, 25 000 events were acquired using CellQuest Pro 4.0.1. Apoptotic cells were then calculated in percent using ModFIT Vers. 3.0 (BD Biosciences).

### Tumorigenesis in nude mice

Cells were resuspended at the density of  $5 \times 10^7$  cells in 400 µL of RPMI1640 and injected subcutaneously into the flank region of athymic nude mice. Twelve mice were distributed to antisense group, sense group or negative control group, 4 per group at random. All animals were observed for up to 10 wk following the injection, and then the tumor was excised.

### Transmission electron microscopy

For electron microscopy, small blocks of tumor tissue were fixed in 1% glutaraldehyde and 4% paraformaldehyde, postfixed in 1% osmium tetroxide and embedded in Epon 812, double-stained with uranyl acetate and lead citrate, and observed under a transmission electron microscope.

### Statistical analysis

One-way analysis of variance (ANOVA) was used to compare the results between the different groups. All data were processed with SPSS10.0 statistical software.  $P < 0.05$  was considered statistically significant.

## RESULTS

### Immunohistochemistry and RT-PCR of SMMC-7721 cells

VEGF protein expression was high in sense group, moderate in control and 7721 groups and weak in antisense group ( $F=16.786$ ,  $P<0.01$ ). The same results were also confirmed by VEGF mRNA expression in RT-PCR analysis (Figure 1). The mRNA expression of VEGF was seen in all groups. However, compared to the control and sense groups, the expression was decreased in the antisense group ( $F=19.693$ ,  $P<0.01$ ), suggesting that SMMC-7721 cells transfected with PCMV-FGEV could effectively inhibit VEGF expression at protein and RNA level.

**Figure 1** Expression of VEGF mRNAs. Lanes 1- 5: 7721 group, control group, sense group and antisense group respectively (418 bp and 490 bp indicate VEGF, 240 bp indicates  $\beta$ -actin).

### Proliferation and apoptosis of transfected SMMC-7721 cells

We used MTT assay to assess the proliferation of transfected SMMC-7721 cells *in vitro*. The difference in survival rates of the cells in sense group, antisense group, and control group was not significant ( $F=0.869$ ,  $P>0.05$ ). Further we used flow cytometry to compare the extent of cell apoptosis among the different groups and did not find the characteristic changes of cell apoptosis in each group.

### Time of tumorigenesis in nude mice and weight of tumors

The time of tumorigenesis was  $25.0 \pm 1.8$  d in antisense group,  $15.7 \pm 2.5$  d in sense group and  $18.5 \pm 2.1$  d in control group ( $F=19.445$ ,  $P<0.01$ ). The weight of tumor was  $0.96 \pm 0.28$  g in antisense group, which was obviously lighter than that in sense group ( $2.18 \pm 0.36$ g) and control group ( $1.88 \pm 0.47$ g) ( $F=21.505$ ,  $P<0.01$ ) (Figure 2).

### Immunohistochemistry for VEGF and VIII factor expression

VEGF immunohistochemical staining showed faint signals in antisense group. The number of positive cells and intensity of staining were significantly lower than those in sense or control group ( $F=21.365$ ,  $P<0.01$ ). Factor VIII staining showed that the number of tumor vessels in antisense group was significantly less than that in sense or control group ( $F=9.985$ ,  $P<0.01$ ).

### Tumor apoptosis assay

Electron micrographs of the tumor cells in antisense group showed characteristic chromatin condensation forming a crescentic-like cap, which was characteristic appearance of apoptosis. Comparatively, such chromatin change of the cells was not detectable in control or sense group ( $F=24.548$ ,  $P<0.01$ ).

## DISCUSSION

Hepatocellular carcinoma (HCC) is one of the most common malignant neoplasms. All the treatment strategies used today have no good curative effect<sup>[12]</sup>. Gene therapy

**Figure 2** Gross appearance of tumor growth in sense group (A), control group (B) and antisense group (C). The weight of tumor in antisense group was obviously lighter than that in sense and control groups ( $F=21.505$ ,  $P<0.01$ ).

might be a promising way. Gene transfer is a key technique in gene therapy. Antisense gene technologies have been proven to be powerful tools for selective regulation of gene expression in experimental settings and are under evaluation for their therapeutic potential in clinic<sup>[13-16]</sup>. Antisense agents down-regulate the expression of specific target genes at mRNA level by pairing with their complementary RNA and preventing their translation into proteins. Theoretically, antisense molecules could be used to cure a variety of diseases, especially some cancers<sup>[17-20]</sup>.

VEGF plays an important role in the angiogenesis of HCC. VEGF, known as a vascular permeability factor, has two major biological functions: growth stimulatory activity for a variety of vascular endothelial cells and increasing microvascular permeability<sup>[21-23]</sup>. Use of antisense VEGF RNA for inhibiting vessel formation in HCC might be a rational approach. Our study showed that antisense VEGF RNA could effectively inhibit the expression of VEGF in HCC cell line SMMC-7721, but could not significantly inhibit growth of the cells *in vitro*, which is in accordance with the report of Gu *et al*<sup>[24]</sup>. The reasons may be as follows: VEGF is specific to endothelial cells and there is no vessel in the HCC cells. Although antisense VEGF RNA can inhibit the expression of VEGF, it can not effectively inhibit tumor cells without vessels. Furthermore If we use the vascular endothelial cells as the model to study the inhibitory effect of antisense VEGF RNA on them, the results may be that antisense RNA could inhibit not only the expression of VEGF but also the growth of vascular endothelial cells.

This study also demonstrated that antisense VEGF RNA could inhibit the growth of tumor *in vivo*. The secretion of VEGF and the vessels of tumor in antisense group were significantly decreased, leading to inhibition of tumor growth and metastasis. Becker *et al*<sup>[25]</sup> reported that transfecting the gene of soluble vascular endothelial growth factor receptor flk-1 to the prostate cancer nude model can inhibit tumor growth and metastasis. Zhang *et al*<sup>[26]</sup> found that angiogenic inhibition mediated by DNase targeting at vascular endothelial growth factor receptor -2 could inhibit the formation of vessels and the growth of tumor.

In conclusion, antisense VEGF RNA has inhibitory effect on the growth of HCC cells *in vitro* and *in vivo* and can be used in the treatment of HCC.

### Abstract

**AIM:** To study the effect of fluoride on oxidative stress, DNA damage and apoptosis as well as cell cycle of rat oral mucosal cells and hepatocytes.

**METHODS:** Ten male SD rats weighing 80~120 g were randomly divided into control group and fluoride group, 5 animals each group. The animals in fluoride group had free access to deionized water containing 150 mg/L sodium fluoride (NaF). The animals in control group were given distilled water. Four weeks later, the animals were killed. Reactive oxygen species (ROS) in oral mucosa and liver were measured by Fenton reaction, lipid peroxidation product, malondialdehyde (MDA), was detected by thiobarbituric acid (TBA) reaction, reduced glutathione (GSH) was assayed by dithionitrobenzoic acid (DTNB) reaction. DNA damage in oral mucosal cells and hepatocytes was determined by single cell gel (SCG) electrophoresis or comet assay. Apoptosis and cell cycle in oral mucosal cells and hepatocytes were detected by flow cytometry.

**RESULTS:** The contents of ROS and MDA in oral mucosa and liver tissue of fluoride group were significantly higher than those of control group ( $P < 0.01$ ), but the level of GSH was markedly decreased ( $P < 0.01$ ). The contents of ROS, MDA and GSH were ( $134.73 \pm 12.63$ ) U/mg protein, ( $1.48 \pm 0.13$ ) mmol/mg protein and ( $76.38 \pm 6.71$ ) mmol/mg protein in oral mucosa respectively, and ( $143.45 \pm 11.76$ ) U/mg protein, ( $1.44 \pm 0.12$ ) mmol/mg protein and ( $78.83 \pm 7.72$ ) mmol/mg protein in liver tissue respectively. The DNA damage rate in fluoride group was 50.20% in oral mucosal cells and 44.80% in hepatocytes, higher than those in the control group ( $P < 0.01$ ). The apoptosis rate in oral mucosal cells was ( $13.63 \pm 1.81$ ) % in fluoride group, and ( $12.76 \pm 1.67$ ) % in hepatocytes, higher than those in control group. Excess fluoride could differently lower the number of oral mucosal cells and hepatocytes at G<sub>0</sub>/G<sub>1</sub> and S G<sub>2</sub>/M phases ( $P < 0.05$ ).

**CONCLUSION:** Excess fluoride can induce oxidative

stress and DNA damage and lead to apoptosis and cell cycle change in rat oral mucosal cells and hepatocytes.

### INTRODUCTION

Fluoride is an essential trace element for human beings and animals. Fluoride can prevent caries and enamel fluorosis. Caries is the demineralization of the enamel by acids produced by plaque bacteria, leading to cavitation. Enamel fluorosis is a subsurface hypomineralization of the dental enamel caused by chronic ingestion of high fluoride concentration while the dentition is forming<sup>[1]</sup>. Other manifestations of fluoride toxic effects include skeletal fluorosis and damage to kidney, liver, parathyroid glands and brain<sup>[2-4]</sup>. Lipid peroxidation is implicated as an important mechanism of fluorosis. A close association between fluoride toxicity and oxidative stress has been reported in human beings<sup>[5]</sup>, experimental animals<sup>[3]</sup> and cultured cells<sup>[2]</sup>. Studies have shown that excess fluoride can cause DNA damage, trigger apoptosis and change cell cycle<sup>[2, 6]</sup>. Jeng *et al*<sup>[7]</sup> studied the effects of sodium fluoride on human oral mucosal fibroblasts and found that sodium fluoride is toxic to oral mucosal fibroblasts *in vitro* by inhibiting protein synthesis, disturbing mitochondrial function and depleting cellular ATP. The effects of sodium fluoride on cultured human oral keratinocytes have been investigated with respect to induction of unscheduled DNA synthesis. These researches indicate that fluoride has harmful effects on oral mucosa. In the present study, we investigated the effects of sodium fluoride (NaF) on lipid peroxidation, DNA damage and apoptosis in rat oral mucosal cells and hepatocytes.

### MATERIALS AND METHODS

#### Animals

Male SD rats weighing 80-120 g were used in the

experiments and housed in polycarbonated cages with compressed fiber bedding. Commercial pellet diet and water were provided *ad libitum*. The animals were divided into control group and fluoride group, 5 animals each group. The control group was given distilled water and the fluoride group was provided with distilled water containing 150 mg/L sodium fluoride. The animals were sacrificed four weeks later and their oral mucosa and liver were removed immediately for use.

#### **Determination of fluoride concentration in urine and blood**

At the end of experiments, the animals were held in plastic metabolic cages for 8 h, and urine was collected in the container. Concentration of fluoride in urine and blood was determined with fluoride ion-selective electrodes as described by Zhang *et al.*<sup>[8]</sup>.

#### **Preparation of tissue extract**

Oral mucosa and liver were minced and homogenized in 50 mmol/L cold sodium phosphate buffer (pH 7.0) containing 0.1 mmol/L EDTA to produce 10% homogenates (W/V). The homogenates were then centrifuged at 1000 r/min for 10 min at 4 °C. The supernatants were separated and used for enzyme assays and protein determination.

#### **Determination of GSH, LPO and ROS**

The reduced glutathione (GSH) was determined in tissues by the method of Kum-Talt and Tan<sup>[9]</sup> using dithionitrobenzoic acid (DTNB) reagent and the absorbance at 412 nm was measured. Lipid peroxidation products (LPOs) were determined by measuring the levels of malondialdehyde (MDA)<sup>[10]</sup>. To 0.2 mL of homogenates 0.2 mL 8.1% (w/v) sodium dodecyl sulphate and 1.5 mL 20% acetic acid were added, and pH was adjusted to 3.2 with 20% (w/v) sodium acetate solution. After the addition of 1.5 mL of thiobarbituric acid (0.8%, w/v) the mixture was diluted to 4 mL with water, heated for 60 min in boiling water bath and cooled to room temperature. Then 1 mL of water and a mixture of n-butanol and pyridine (15:1) were added. The mixture was shaken vigorously and centrifuged at 1500 r/min for 15 min. The absorbance of organic layer was measured at 532 nm and the results were expressed as mmol MDA/mg protein. Reactive oxygen species (ROS) was measured with test kit (Nanjing Jiancheng Biological Technology Company) by Fenton reaction. Gress reagent was used to initiate color reaction and the absorbance was read at 510 nm on a spectrophotometer. Protein content was determined by the method of Lowry using bovine serum albumin as a reference<sup>[11]</sup>.

#### **Detection of DNA damage**

Single cell gel electrophoresis assay (also known as comet assay) was performed as previously described<sup>[12]</sup> with some modifications. Approximately  $1.0 \times 10^5$  cells were embedded in low melting agarose (0.65%) that was layered onto fully frosted microscope slides coated with a layer of 0.75% normal agarose (diluted in  $\text{Ca}^{2+}$  and  $\text{Mg}^{2+}$  free PBS buffer). A final layer of 0.65% low-melting agarose was placed on top. Slides were immersed in a jar containing cold lysate solution (1% Triton X-100, 10% DMSO and 89% of 10 mmol/L Tris, 1% sodium laurylsarcosine, 2.5 mol/L NaCl,

100 mmol/L  $\text{Na}_2\text{EDTA}$ , pH 10) at 4 °C for 1-2 h. Then, slides were pretreated for 15 min in electrophoresis buffer (300 mmol/L NaOH/1 mmol/L  $\text{Na}_2\text{EDTA}$ , pH 12) and exposed to 25 V/300 mA for 20 min. Pre-incubation and electrophoresis were performed in ice bath. Slides were neutralized for 3 - 5 min in 0.4 M Tris, pH 7.5 and DNA was stained by adding 50  $\mu\text{L}$  of ethidium bromide (20  $\mu\text{g}/\text{mL}$ ) onto each slide. After staining for 5 min, slides were rinsed in distilled water and covered again for microscopic examination. All steps were conducted under red light to prevent additional DNA damage.

Image analysis was performed with  $200 \times$  magnification using a fluorescence microscope (Olympus B-60F5) equipped with an excitation filter of 549 nm and a 590 nm barrier filter, coupled to a CCD camera (Kodak, USA). One hundred randomly selected cells per slide were scored. In this test, DNA damage of the cells was evaluated using the ratio of tail DNA content/the whole cellular DNA content.

#### **Detection of apoptosis**

DNA fragmentation during apoptosis could lead to extensive loss of DNA content and a distinct sub- $\text{G}_1$  peak when analyzed by flow cytometry. Apoptosis was analyzed by the determination of sub- $\text{G}_1$  cells. At the end of designated treatments (such as cell separation), cells were washed, fixed and permeated with 70% ice-cold ethanol at 4 °C for 2 h. Cells were then incubated with freshly prepared propidium iodide (PI) staining buffer (0.1% Triton X-100, 200  $\mu\text{g}/\text{mL}$  RNase A, and 20  $\mu\text{g}/\text{mL}$  PI in PBS) at 37 °C for 15 min, followed by flow cytometry of 20 000 cells from each animal. The histogram was abstracted and percentage of cells in the sub- $\text{G}_1$  phase was then calculated to reflect the percentage of apoptotic cells. In addition, cell cycle was analyzed with ModFit LT software.

#### **Statistical analysis**

The data were tested with statistical programs. Student's *t* test or Chi-square test was used.  $P < 0.05$  was considered statistically significant.

## **RESULTS**

#### **Amount of fluoride in urine and concentration of fluoride in blood**

Animals in fluoride group were provided with distilled water containing 150 mg/L NaF for four weeks. The amount of fluoride in urine and concentration of fluoride in blood were higher than those in control group ( $P < 0.01$ ), demonstrating that animals in fluoride group were in excess fluoride status (Table 1).

#### **Content of ROS, MDA and GSH in oral mucosa and liver**

ROS and MDA contents in oral mucosa and liver were higher in fluoride group than in control group, but GSH content in oral mucosa and liver was lower in fluoride group than in control group, indicating that oxidative stress was induced in fluoride group (Table 2).

#### **DNA damage in oral mucosal cells and hepatocytes**

Table 3 shows the effects of fluoride at the dose of 150

<sup>a</sup>*P* < 0.05 vs control group.

mg/L for 4 wk on the grades of DNA damage based on the comet assay. Statistical analysis yielded significant

differences between oral mucosal cells and hepatocytes based on chi-square test (*P* < 0.01). Although the grades of DNA damage in oral mucosal cells were higher than those in hepatocytes, there was no significant difference (*P* > 0.05).

### Apoptosis in oral mucosal cells and hepatocytes

Table 4 shows the effects of fluoride at the dose of 150 mg/L for 4 wk on apoptosis in oral mucosal cells and hepatocytes based on flow cytometry. There was a statistically significant difference between fluoride and control groups in apoptotic rate of oral mucosal cells and hepatocytes. Although the apoptotic rate was higher in oral mucosal cells than in hepatocytes, there was no significant difference (*P* > 0.05).

### Changes of cell cycle in oral mucosal cells and hepatocytes

Table 5 shows the effects of fluoride on rat cell cycle and proliferation index (PI) of oral mucosal cells and hepatocytes. The number of oral mucosal cells and hepatocytes at G<sub>0</sub>/G<sub>1</sub>, S and G<sub>2</sub>/M phase induced by fluoride was lower than that in control group. PI of oral mucosal cells and hepatocytes was lower in fluoride group than in control group (*P* > 0.05), suggesting that fluoride at the dose of 150 mg/L in drinking water for 4 wk interfered with normal cell cycle in oral mucosa and liver.

## DISCUSSION

Fluorosis is one of the diseases caused by biogeochemical factors. Fluorosis in human beings is mainly caused by drinking water, burning coal and drinking tea. China is one of the countries where fluorosis is most endemic<sup>[2]</sup>. Fluoride intoxication causes damages to osseous tissue (teeth and bone) and soft tissues (liver, kidney, brain, mucosa, etc.). There are many reports on the mechanisms of skeletal and dental fluorosis<sup>[13, 14]</sup>, but how fluoride interferes with soft tissue has not been clarified. In our study, male SD rats were provided with distilled water containing 150 mg/L sodium fluoride for four weeks. The concentration of fluoride in blood and the amount of fluoride in urine in fluoride group were significantly higher than those in control group, suggesting that the experimental animals are in excess fluoride status. The content of ROS and MDA was increased, but content of GSH was decreased in oral mucosa and liver, demonstrating that lipid peroxidation can be induced by fluoride intoxication in oral mucosa and liver.

Studies have shown that fluoride can induce excessive production of oxygen free radicals and decrease the biological activities of some substances, such as catalase, superoxide dismutase, xanthine oxidase and glutathione peroxidase, which play an important role in antioxidation and eliminating free radicals. Karaoz *et al*<sup>[15]</sup> showed that chronic fluorosis can lead to lipid peroxidation and kidney tissue change in first- and second-generation rats<sup>[15]</sup>. Shanthakumari *et al*<sup>[3]</sup> showed that the level of lipid peroxides is increased but the activities of superoxide dismutase (SOD), catalase (CAT), glutathione peroxidase (GSH-Px) are decreased in rats after administered fluoride. Shivarajashan-

kara *et al*<sup>[16]</sup> reported that long-term high-fluoride intake at the early developing stages of life enhances oxidative stress in blood, disturbing the antioxidant defense of rats, suggesting that increased oxidative stress may be one of the mediating factors in the pathogenesis of toxic manifestations of fluoride. Reddy *et al*<sup>[17]</sup> evaluated the antioxidant defense system (both enzymatic and non-enzymatic) and lipid peroxidation both in human beings from an endemic fluorosis area (5 ppm fluoride in drinking water) and in rabbits receiving water containing 150 ppm of fluoride for six months, and found that there is no significant difference in lipid peroxidation, glutathione and vitamin C in blood of fluorosis patients and fluoride-intoxicated rabbits as compared to the controls. They also found that there are not any changes in the activities of catalase, superoxide dismutase, glutathione peroxidase, or glutathione S-transferase in the blood due to fluoride intoxication (of rabbits) or fluorosis in human beings<sup>[17]</sup>. Our results are concordant with other studies<sup>[2, 3, 5, 15, 16]</sup>. Liver is one of the target organs attacked by excessive amount of fluoride. Evidence of toxic changes in liver has been revealed by long term investigations of industrially-induced fluorosis, including abnormal metabolic functions, reduced activity of detoxication reactions and altered structure of subcellular organelles<sup>[18]</sup>. Our results also displayed that excess fluoride could induce oxidative stress not only in liver, but also in rat oral mucosa.

It was reported that DNA damage results from excess fluoride in human embryo hepatocytes<sup>[2, 6]</sup> and pallium neurons<sup>[19]</sup>. Our results showed that DNA damage was induced in rat oral mucosal cells and hepatocytes by sodium fluoride at the dose of 150 mg/L in drinking water for four weeks. Apoptosis is a programmed physiological process of cell death characterized by a distinct set of morphological and biochemical changes, including cytoplasmic membrane blebbing, apoptotic body formation, nuclear condensation and chromosomal DNA fragmentation. Apoptosis can be triggered in a wide variety of cell lines by diverse stimuli, ranging from extracellular signals to intracellular events<sup>[20]</sup>. Previous studies have shown that fluoride induces apoptosis in human embryo hepatocytes<sup>[2, 6]</sup>, human epithelial lung cells<sup>[21]</sup>, human and rat pancreatic islets and RINm5F cells<sup>[22]</sup> as well as in HL-60 cells<sup>[23]</sup>. In the present study, we investigated the effects of fluoride on apoptosis of rat oral mucosal cells and hepatocytes. As regards to the mechanisms of apoptosis induced by fluoride, Wang *et al*<sup>[2]</sup> concluded that fluoride could cause lipid peroxidation, DNA damage and apoptosis, and there is a positive relationship among these changes. Lipid peroxidation and apoptosis may co-exist in the beginning when tissues are exposed to excess fluoride and generates a lot of free radicals that may be sufficient to cause apoptosis. Anuradha *et al*<sup>[23]</sup> showed that sodium fluoride (NaF) induces apoptosis by oxidative stress-induced lipid peroxidation, and thereby releasing cytochrome C into the cytosol and further triggering caspase cascade leading to apoptotic cell death in HL-60 cells. Refsnes *et al*<sup>[21]</sup> reported that NaF induces apoptotic effects and increases PI-positive A549 cells via similar mechanisms, involving protein kinase C (PKC), protein kinase A (PKA), tyrosine kinase and Ca<sup>2+</sup>-linked enzymes. Thrane *et al*<sup>[24]</sup>

found that activation of mitogen-activated protein (MAP) kinases p38 and possibly c-Jun N-terminal kinase (JNK) are involved in NaF-induced apoptosis of epithelial lung cells, whereas extracellular signal regulated kinase (ERK) activation seems to counteract apoptosis in epithelial lung cells. These studies indicate that fluoride induces apoptosis through mechanisms of oxidative stress, caspase and PKC activation, MAPK signal pathway and DNA damage.

Our study also demonstrated that the number of oral mucosal cells and hepatocytes in G<sub>2</sub>/M phase was significantly lower in fluoride group than in control group, although there were no obvious changes in cell number in G<sub>0</sub>/G<sub>1</sub> and S phase. In our study, proliferation index of oral mucosal cells and hepatocytes was also decreased in fluoride group. Wang *et al*<sup>[2]</sup> showed that the number of human embryo hepatocytes in S phase is significantly higher in fluoride treated groups than in control group, but there were no changes in cell number in G<sub>0</sub>/G<sub>1</sub> and G<sub>2</sub>/M phase. This may be due to the differences in cell sensitivity to fluoride in different phases of cell cycle<sup>[25]</sup>.

In the present study, the results in oral mucosal cells were not different from those in hepatocytes significantly. Oxidative stress, DNA damage, apoptosis and modifications of membrane lipids can be induced in hepatocytes by excess fluoride<sup>[2, 3, 6, 18]</sup>. It is difficult to get liver tissue but easy to get oral mucosal cells from patients with fluorosis. Squier *et al*<sup>[26]</sup> reported that ethanol exerts its effect on lipid metabolism and epithelial permeability barrier of oral mucosa in rats. Hansson *et al*<sup>[27]</sup> have analyzed proliferation, apoptosis and keratin expression in cultured normal and immortalized human oral mucosal keratinocytes. Dhillon *et al*<sup>[28]</sup> showed that oral mucosa cells have a smaller increase in gamma-ray-induced DNA strand breaks than lymphocytes, suggesting that oral mucosal cells can be used as experimental materials to study oxidative stress, DNA damage and apoptosis as well as other effects of fluoride *in vivo*.

In conclusion, excess fluoride induces oxidative stress, DNA damage, apoptosis and cell cycle changes in rat oral mucosal cells and hepatocytes. Further investigation is needed to clarify the exact mechanisms.

### Abstract

Liposarcoma is the most common soft tissue sarcoma in adult life while esophageal liposarcoma is an extremely rare tumor. In the world literature, only 14 cases of esophageal liposarcomas have been described. We report a 72-year old male patient who was urgently admitted to our hospital for acute epigastric pain with a burning retrosternal sensation, persistent nausea, vomiting and dysphagia. Barium swallow, upper gastrointestinal (GI) endoscopy, esophageal manometry and CT scan, failed to accurately diagnose the lesion. After surgical resection of an esophageal polypoid tumor, the histological examination revealed a well-differentiated grade I liposarcoma. Diagnostic and therapeutic tools were discussed and the results of literature were reviewed.

### INTRODUCTION

Liposarcoma is the most common soft tissue sarcoma in

adult life and usually occurs in the retroperitoneum and deep soft tissues of the trunk and lower extremities<sup>[1-3]</sup> representing around 20% of mesenchymal neoplasms. It is very rare in the gastrointestinal (GI) tract, exceedingly in the esophagus. Esophageal liposarcomas grow as polypoid masses within the esophageal lumen, usually causing no symptoms until they reach a substantial size when impaired esophageal transit develops. The first case of a primary esophageal liposarcoma was reported by Mansour *et al*<sup>[2]</sup> in 1983. The review of the literature revealed another 13 cases that have been reported since. We described a male patient who, to our belief, represents the 15<sup>th</sup> case reported in the literature, as he was found to have a well-differentiated esophageal liposarcoma arising from the wall of the lower thoracic esophagus exceeding down to the gastroesophageal (GE) junction.

### CASE REPORT

A 72-year-old obese male (BMI > 30) was urgently admitted to our hospital because of an acute epigastric pain with a burning retrosternal sensation, persistent nausea, vomiting and complete dysphagia. He suffered from intermittent dysphagia in the last few years which was increasingly worsened in the last 2 mo. The day before his admission to our hospital he had an esophagogram and an esophageal manometry which showed a slightly dilated lower thoracic esophagus without any stricture and an achalasia like motor dysfunction. His past medical history revealed 5 mild episodes of a bleeding duodenal ulcer (from May 1962 to February 1995) which were treated with blood transfusions, antacids and PPIs. He was also under treatment with captopril and furosemide for arterial hypertension in the last ten years.

On initial urgent upper GI endoscopy, a smooth and ulcerated hemorrhagic tumor like protrusion in the lower thoracic esophageal mucosa down to the level of the GE junction was found (Figure 1).

CT scan of the chest and upper abdomen demonstrated a well-circumscribed mass at the lower thoracic esophagus with lipoma like density (-30.84 Hounsfield Units). No other lesions or enlarged lymph nodes at the lower mediastinum were found (Figure 2).

The patient was put on parenteral nutrition and nil by mouth and on the 7<sup>th</sup> post admission day a second upper GI endoscopy clearly demonstrated an esophageal submucosal polypoid mass originating from the wall of the lower esophagus 4-5 cm above the GE junction. The tumor was covered by normal esophageal mucosa with

**Figure 1** upper GI endoscopy A big hemorrhagic polypoid lesion as a haematoma in the hiatus hernia at upper GI endoscopy

**Figure 2** Intraluminal mass with a lipoma-like density in the lower esophagus.

**Figure 3** The lesion is covered by yellowish exudates at the second upper GI endoscopy.

central ulceration (Figure 3) and it seemed that it could be easily and intermittently intussuscepted through the GE junction into the stomach. A small sliding diaphragmatic hernia was also found. The stomach and the duodenum appeared to be normal. Multiple biopsies were taken especially from the ulcerated part of the tumor which failed to reveal any malignancy.

The patient was scheduled for an operation. Through a left posterior-lateral thoracotomy, a dilated lower thoracic esophagus with edematous muscle wall layers was found. The sliding diaphragmatic hernia was also noted. After a longitudinal incision just above the GE junction, the esophageal lumen was entered which was almost com-

**Figure 4** Intraoperative view of the esophageal liposarcoma (A) and the specimen (B) (5 cm x 3.5 cm x 2 cm).

**Figure 5** Neoplasm infiltrating smooth muscle layer of esophagus and ulcerating surface epithelium (A), HE 100x; and neoplasm consisting of differently-sized lipocytic element and multi-vacuolated lipoblasts (B), HE 400x. A small amount of sclerotic stroma was focally identified with the presence of atypical stromal cells.

pletely obstructed by a big polypoid submucosal mass. A central necrosis of the overlying esophageal mucosa

**Figure 6** No evidence of tumor recurrence in gastrointestinal endoscopy after 6 mo of surgery.

revealed a lipoma like tumor which seemed to originate from the muscle layer of the esophageal wall, 5cm above the GE junction. We performed a local resection including a part of the esophageal muscle wall (Figures 4A and 4B). The esophageal incision was closed in 2 layers with interrupted absorbable sutures.

The postoperative period was uneventful, and the patient was discharged on the 8<sup>th</sup> postoperative day on a liquid - soft diet, with complete resolution of his preoperative symptoms.

Macroscopically the tumor was measured 5 cm × 3.5 cm × 2cm. Its surface was covered by normal esophageal mucosa measuring 3.5 cm × 1.5 cm with a central ulceration 1cm in diameter. The cut end of the mass revealed the adipocytic nature of the neoplasm and its color ranged from ivory to deep yellow with light brown areas. Histologically the neoplasm consisted predominantly of mature looking fat tissue which showed severe size and shape variation of adipocytic element with the presence of numerous multi vacuolated lipoblasts. It was divided by few focally sclerotic fibrous septa containing atypical stromal cells. Smooth muscle layer of the esophagus was extensively infiltrated close to the surgical margin (5mm). Surface epithelium was ulcerated. Areas of liponecrosis were often observed. The tumor had characteristic features of well-differentiated grade I liposarcoma with lipoma-like component (Figures 5A and 5B).

The patient was followed up and 6 mo after the operation, CT scan of the chest and upper abdomen and upper GI endoscopy showed no tumor recurrence or distal metastases (Figure 6).

## DISCUSSION

Lipomatous tumors of the gastrointestinal tract are usually found in the distal ileum and the large bowel. Primary esophageal liposarcoma is exceedingly rare and slow growing tumor arising from mucosa and submucosa esophageal layers. The first case was described by Mansour *et al*<sup>[2]</sup> in 1983. In the world literature 14 cases have been reported<sup>[2-15]</sup>. The mean age varies between 43 and 73 years with a male: female ratio of 1.16:1. The clinical symptoms of esophageal lipomatous tumors include progressive

dysphagia, loss of weight, regurgitation, retrosternal pain, respiratory distress, odynophagia, sensation of a lump in the throat, hemorrhage, anemia, sudden death (asphyxia), vomiting (food or tumor fragments), fever and cough. The location of most tumors is the upper esophagus. There has been reported 5 myxoid, 1 pleiomorphic and 9 well-differentiated, with our case, esophageal liposarcomas<sup>[3,5,7,8,15]</sup>.

Barium swallowing, esophageal manometry, radiological and endoscopic examinations could be confused with usual esophageal pathologies, such as megaesophagus, achalasia or bezoars. The only diagnostic methods for these tumors are surgical excision and histological examination<sup>[8,14,15]</sup>.

Surgical treatment varies from simple enucleation or endoscopic resection to partial or total esophagectomy or trans-cervical, transthoracic, transgastric resections<sup>[2-15]</sup>. Local recurrences can be decreased with post-operative radiation. The most reliable prognostic factors are liposarcoma grade, histological subtype, location and adequacy of surgical treatment<sup>[8,10]</sup>.

Local recurrence could take place in patients with well-differentiated liposarcomas who have a 5-year survival of 75 - 100%. Patients with other types of liposarcomas have a lower survival and a higher recurrence rates. The survival of the reported cases varies between 7 to 104 mo<sup>[2,5,7,8,10]</sup>.

Our case presented with acute pain of epigastrium, retrosternal sensation of burning, persistent nausea, vomiting and dysphagia. The differential diagnosis of several studies (barium swallow, esophagomanometry and esophagogram) confused us and included megaesophagus, achalasia, mediastinitis, haematoma or trauma from esophagomanometry. The measurement of tumor density with CT scan and secondary upper GI endoscopy showed that this mass was an esophageal lipomatous tumor. Although the biopsies were negative for malignancy we proceeded to tumour enucleation. Only surgical removal and histologic examination could diagnose esophageal malignancies such as liposarcoma. Our patient was followed up and 6 mo post-operation the CT scan of the chest and upper abdomen and upper GI endoscopy showed no tumor recurrence or distal metastases.

We believe that our case is considerable because of the rarity of esophageal liposarcoma. Esophageal lipoma or liposarcoma can be diagnosed if a patient has a history of slow growing esophageal mass with a low tumor density in CT in combination with surgical resection and histologic examination.

## Abstract

Tuberculosis (TB) is a very rare cause of biliary stricture that is difficult to diagnose and usually requires surgical intervention in order to rule out underlying malignant etiology. We report a 56-year-old man presented with jaundice, weight loss and poor appetite. Initial work up showed the dilated biliary system secondary to distal common bile duct stricture. Investigations to define the etiology of this stricture showed inconclusive brush cytology with absent abdominal masses and lymph nodes but enlarged mediastinal lymph nodes. Biopsy from these lymph nodes showed a non-caseating epithelioid granuloma with negative acid fast bacilli (AFB) stain. The patient had a dramatic response to empirical anti-tuberculosis therapy. Six weeks later, culture from lymph nodes was positive for *Mycobacterium tuberculosis*.

Three months later, follow-up cholangiogram showed complete resolution of the stricture with normalization of liver enzymes 6 mo after starting anti-tuberculosis therapy. Treatment was continued for 12 mo and the patient had a normal life with normal liver enzymes and regression of the mediastinal lymph nodes at the time when he was reported in this paper.

Although 16 cases of tuberculous biliary stricture are available in the English literature, up to our knowledge, this is the second published report of tuberculous biliary stricture, which resolved completely after medical therapy alone and the second reported case from the Middle East. This report emphasizes the importance of keeping TB as a possibility of biliary stricture in this part of the world.

## INTRODUCTION

Although tuberculosis (TB) of the hepatobiliary system is not uncommon, it is an extremely rare cause of biliary stricture. Many cases of lymph node, gall bladder, duodenal and pancreatic tuberculosis are reported<sup>[1-5]</sup>, but only sixteen cases of biliary stricture caused by tuberculosis are available in the English literature<sup>[6-16]</sup>, and only one case has been reported from the Middle East<sup>[13]</sup>. The main symptoms of TB biliary stricture including jaundice and weight loss are usually indistinguishable from those of other diseases such as cholangiocarcinoma. Although the presence of past history or chest X-ray changes of tuberculosis may raise the suspicion of this etiology, most of the reported cases are diagnosed based on surgical pathology. We report here a middle age gentleman who had tuberculous biliary stricture with an excellent outcome after anti-TB therapy alone.

## CASE REPORT

A previously healthy 56-year-old Saudi male presented with a 4-mo history of fatigue, 15 kg weight loss, poor appetite, pruritus, progressive jaundice, dark urine, and pale stool. He had no history of fever, night sweat, alcohol or herbal medicine use. Past history was negative for TB, gall bladder or biliary disease or abdominal surgery.

Physical examination revealed that he was afebrile and thin with a body mass index of 19 kg/m<sup>2</sup>, muscle wasting, deep yellow sclera, no palpable lymph nodes or stigmata of chronic liver disease. Abdominal examination showed palpable liver with a span of 9 cm and moderate ascites, and nor remarkable findings in other systems.

Liver enzymes showed a cholestatic pattern with 155 µmol/L total bilirubin, 102 µmol/L direct bilirubin, 352 u/L alkaline phosphatase, 77 u/L alanine aminotransferase and 27 g/L albumin. He had normal complete blood count with prolonged INR (1.7). Ascetic fluid analysis showed normal cell count, with high serum ascites albumin gradient of 18 g/L, suggestive of portal hypertension etiology. Gram, Ziehl-Neelsen (Z-N), routine and TB cultures from ascetic fluid as well as tuberculin skin test were

**Figure 1** Initial ERCP showing dilated proximal biliary system (white arrow) with a tight short distal common bile duct stricture (black arrow).

**Figure 2** Computed tomography scan of the chest showing enlarged mediastinal (Para-tracheal, sub-carinal) lymph nodes (arrow).

negative.

Chest X-ray was normal. Abdominal ultrasonography (US) showed features of cirrhosis with extra- and intra-hepatic biliary dilatation. The diameter of the common bile duct (CBD) was 12 mm. Doppler US revealed portal vein thrombosis but patent hepatic veins. The patient underwent endoscopic retrograde cholangiopancreatography (ERCP) which revealed no duodenal or ampullary mass, but single short tight irregular distal CBD stricture with dilated biliary tree (Figure 1). A plastic biliary stent was placed for drainage. Brush cytology was negative for malignant cells. Computed tomography (CT) scanning of the abdomen showed shrunken liver with no evidence of abdominal masses or lymphadenopathy, while CT chest showed multiple significant mediastinal lymph nodes (Figure 2).

Cholangiocarcinoma was found with probable mediastinal lymph node metastasis. However, given this location of lymph nodes, other possibilities such as lymphoma, tuberculosis or infiltrative diseases should be excluded.

Meanwhile a full workup for liver cirrhosis etiology showed only positive hepatitis B virus core antibodies (HBc-IgG). The other viral markers, anti-nuclear antibodies, anti-smooth muscles antibodies and anti-mitochondrial antibodies were negative. Alpha-1-antitrypsin, serum copper, ceruloplasmin and iron profile were normal. Liver biopsy showed a minimal bile duct proliferation with portal tract fibrosis and cholestasis but no granuloma or malignant cells (Figure 3A). Upper gastrointestinal endoscopy showed grade-4 esophageal varices with congestive gastropathy.

These results indicated that the most likely cause of

**Figure 3** Hematoxylin and eosin (H and E) staining of liver tissue (A) and mediastinal lymph node (B) showing bile pigments (thick arrow) with bile duct proliferation (thin arrow) and inflammatory cell infiltrate and epithelioid granuloma with many langerhans cells but no caseation (arrows).

liver cirrhosis was previous exposure to hepatitis B infection.

Then patient underwent mediastinoscopy with lymph node excisional biopsy, which showed epithelioid granuloma with numerous langerhans cells but no caseation (Figure 3B). Z-N stain was negative for acid fast bacilli and biopsy was sent for TB culture.

Based on the result of lymph node biopsy, we decided to start empirical first line anti-tuberculosis (anti-TB) drugs in a full dose (isoniazid, 300 mg/d; rifampicin, 600 mg/d; ethambutol, 1 g/d; pyrazinamide, 1.5 g/d) while waiting TB culture result and observing the response. The patient tolerated well anti-TB therapy and had dramatic clinical and biochemical improvements (Table 1). Six weeks later, lymph node biopsy culture showed *Mycobacterium tuberculosis* which was sensitive to all these medications.

Three months after starting the anti-tuberculous therapy, repeated ERCP showed complete resolution of the biliary stricture with normal extra- and intra-hepatic biliary tree, and the biliary stent was removed (Figure 4).

During the follow-up, significant improvement was found in the ascites. The patient required small doses of diuretics to control it, and had prophylactic variceal band ligation. Additional Doppler ultrasound showed recanalization of the portal vein. The patient had a normal life and gained weight (around 25 Kg) with normal liver

**Figure 4** ERCP showing complete resolution of the previous distal common bile duct stricture three months after anti-tuberculous therapy.

enzymes and function at the time when he was reported in this paper.

## DISCUSSION

Tuberculous biliary stricture as a cause of obstructive jaundice is extremely uncommon. It involves all parts of the biliary tree, namely the intrahepatic biliary radicles, right and left hepatic ducts, common hepatic duct, cystic duct and CBD<sup>[6-16]</sup>.

Obstructive jaundice due to hepatobiliary TB is most often attributed to mechanical obstruction of the biliary tract by tuberculous lymph nodes or mass lesions. Our patient had no tuberculous lymph nodes or mass lesions, but the stricture was due to a secondary endoluminal inflammatory process.

The clinical and cholangiographic features of tuberculous biliary stricture are usually not helpful in differentiating tuberculosis from other common causes of endoluminal biliary stricture such as primary sclerosing cholangitis or cholangiocarcinoma. Alvarez and Sollano<sup>[17]</sup> have proposed the characteristic cholangiographic patterns of hepatobiliary tuberculosis, including a tight hilar stricture with dilated intrahepatic ducts, a long smooth stricture involving the distal bile duct, pruning of the distal intrahepatic ducts, and sclerosing cholangitis-like changes. However, the cholangiographic findings in our patient could not be differentiated from those caused by other factors.

Most of the reported cases of tuberculous biliary stricture are diagnosed until laparotomy is performed. The histopathologic findings of tuberculosis include caseating granulomatous inflammation and Langhans giant cells<sup>[8,14]</sup>. However, in some cases the diagnosis is achieved by detection of acid fast bacilli (AFB) after staining or culture in the biliary fluid aspirate during ERCP<sup>[7]</sup>, but the yield of these tests is low. PCR technique for *Mycobacterium tuberculosis* from biliary fluid may be helpful<sup>[13,16]</sup>. Prasad and Pandey<sup>[15]</sup> reported that AFB of the aspirated bile can diagnose tuberculous biliary stricture.

In our patient, both diagnosis and management were challenging. The diagnosis was difficult because of clinical presentations mimicking other common etiology, lack of constitutional symptoms of tuberculosis such as fever and night sweat, absence of past history of tuberculosis, negative tuberculin skin test, lack of radiological evidence of old or active tuberculosis. However, the presence of mediastinal lymphadenopathy, an unusual site for a meta-

static cholangiocarcinoma, raises the possibility of other diseases such as tuberculosis, lymphoma or sarcoidosis. Therefore, mediastinoscopy with excisional biopsy from the mediastinal lymph nodes is essential for confirming the diagnosis of tuberculosis as the likely cause of biliary stricture and excluding other possibilities.

The challenge in the management is the high risk of anti-TB hepatotoxicity, especially in the setting of liver cirrhosis and the uncertainty of the diagnosis. The possibility of cholangiocarcinoma or lymphoma can be completely ruled out based on the dramatic clinical, biochemical and radiological responses to Anti-TB drugs as well as the positive TB culture.

In most of the reported cases, the biliary stricture does not resolve with medical therapy alone and requires surgical intervention and biliary metallic stent placement<sup>[7,13]</sup>. However, to our knowledge, biliary stricture is completely resolved only in one case after medical therapy without surgery or permanent biliary drainage procedure<sup>[16]</sup>. In our patient, the biliary stricture was completely resolved within 3 mo of anti-TB therapy without any further intervention. The reason for this is likely due to no permanent fibrotic changes.

In conclusion, tuberculous biliary stricture can be completely resolved after medical therapy alone, highlighting that the diagnosis of such cases is often difficult and a high index of suspicion must be kept in mind especially in areas where TB is relatively common.

### Abstract

Primary liver liposarcoma is a rare disease. Because of its rarity, the knowledge of the clinical course, management, and prognosis of primary liver liposarcoma are all limited for clinicians. A 61-year-old female patient who suffered from a huge primary liposarcoma in the central portion of the liver had the clinical presentations of fever, nausea, vomiting, jaundice, and body weight loss. The huge tumor was resected successfully. However, the tumor recurred repeatedly and she had repeated hepatectomies to remove the tumor. The tumor became aggravating after repeated surgeries. Eventually, the patient had cervical spinal metastasis of liposarcoma and she survived for 26 months after liver liposarcoma was diagnosed. Although the tumor may become aggravating after repeated surgeries, repeated hepatectomies are still the best policy to achieve a long-term survival for the patients.

### INTRODUCTION

Liver neoplasm is not an uncommon disease in Asian countries. Cavernous hemangioma, adenoma, and focal nodular hyperplasia are the most common benign tumors in the liver. Hepatocellular carcinoma and cholangiocarcinoma are the most common malignant ones. Liver tumors derived or transformed from other mesenchymal cells, however, are rare. Therefore, the

precise diagnosis of a benign tumor other than cavernous hemangioma, adenoma and focal nodular hyperplasia, or a malignant tumor other than hepatocellular carcinoma and cholangiocarcinoma is difficult.

Liposarcoma is not an uncommon malignant mesenchymal neoplasm. However, it is extremely rare in the liver. To our knowledge, most liposarcomas are found in lower extremities, shoulders and retroperitoneum<sup>[1]</sup>. Only few cases of primary liver liposarcoma have been reported<sup>[2]</sup>. Furthermore, most of the articles describing liver liposarcoma focus only on histopathologic and image studies. The clinical course and prognosis of primary liver sarcoma are rarely mentioned. Hence, we have presented a case of a primary huge liver liposarcoma with the clinical course and have described the outcome of the patient.

### CASE REPORT

A 61-year-old woman was admitted because she had fever, nausea, vomiting, jaundice, and tea-colored urine for a week. She had lost 5 kg of body weight within a month. Physical examination revealed that she had hepatomegaly, icteric sclera, and a palpable mass over the right upper quadrant of the abdomen. Laboratory studies showed 61 mg/L total bilirubin, 702 u/L alkaline phosphate, 277 u/L gamma-glutamyl-transpeptidase, 61 u/L aspartate aminotransferase, and 18 u/L alanine aminotransferase. Virologic examination revealed that she was not infected with hepatitis B or C virus. Serum levels of  $\alpha$ -fetoprotein and CEA were measured and both were within the normal limits. However, CA-199 was up to 92.2 U/mL (normal: <37 U/mL at this hospital). Abdominal ultrasonography showed a huge lobulated cystic lesion in the central portion of the liver. Computed tomography (CT) scan was done and demonstrated that a huge cystic lesion was located at segments 4, 5, and 8, and bilateral intrahepatic ducts were compressed (Figure 1). Aspiration cytology was done but failed to demonstrate any malignant cells. Since this patient had fever and her bilateral intrahepatic ducts were compressed by the tumors, biliary tract infection could not be ruled out as she was treated with antibiotics first. Although the tumor was difficult to locate, surgical resection was still feasible according to the imaging studies. Therefore, surgical resection of the tumor was done and a three-segmentectomy with the preservation of bilateral main intrahepatic ducts was performed. Grossly, the tumor was a cystic tumor, 11 cm  $\times$  11 cm  $\times$  13 cm in size, with multiple septa (Figure 2). Microscopically, the tumor showed the picture of a myxoid liposarcoma (Figure 3). Postoperative course was uneventful and she was dis-

**Figure 1** A low-attenuation cystic mass located in segments 4, 5, and 8 with bilateral biliary tract compression in a non-cirrhotic liver by CT.

**Figure 2** A lobulated liver liposarcoma with intra-tumor hemorrhage.

**Figure 3** Numerous lipoblasts and capillaries in the myxoid liposarcoma (hematoxylin-eosin staining, 400  $\times$ ).

**Figure 4** A big recurrent liver liposarcoma locating in the right lobe of the liver by CT.

charged on the tenth postoperative day. She was followed up at our out patient clinics and liver ultrasonography was performed every 2 or 3 mo.

A big tumor, 9.5 cm  $\times$  10 cm  $\times$  12.4 cm in size, recurred in the right lobe of the liver 10 mo after the first surgery although liver sonography was performed regularly and no tumor was found in previous examinations (Figure 4). Hepatectomy was performed again to excise the tumor. Pathologic pictures showed that the tumor was a recurrent myxoid liposarcoma. The patient was then discharged and was followed up at our outpatient clinics. Nevertheless, a tumor, 7 cm  $\times$  9 cm  $\times$  12 cm in size, occurred again in the liver 11 months after the second surgery. Whole body bone scan with Tc-99m MDP was performed and showed negative for bony metastasis. Thereafter, hepatectomy was performed again to excise the tumor. The pathologic pictures showed undifferentiated sarcoma of the liver (Figure 5). However, the patient complained about neck pain 2 wk after the third hepatectomy. A cervical spine metastasis (C3-C4) was noted. Laminectomy was performed to remove the spinal tumor and release the spinal cord compression.

Although aggressive surgical treatments were employed to treat this liposarcoma, tumor recurred in the liver 2 mo

after the last surgery. Since the patient could not tolerate further surgical interventions, radiotherapy was performed. But the tumor did not respond to radiotherapy, and her condition deteriorated. The patient died of liver failure and aspiration pneumonia five months after the last hepatic resection surgery.

## DISCUSSION

Primary liver liposarcoma is rare. The experience for a surgeon or a gastroenterologist is also limited. In this case study, the patient survived for 26 mo after an aggressive treatment. Wolloch *et al*<sup>[3]</sup> described the first liver myxoid liposarcoma patient. The patient underwent a right hemihepatectomy and survived for 46 d only after the surgery. Subsequently, only few cases have been described<sup>[2]</sup>. Moreover, the clinical course and management of primary liver liposarcoma are rarely mentioned in these reports (Table 1). Therefore, the knowledge of primary liver liposarcoma is still limited. The results of surgical resections are unknown. The long-term prognosis for liver liposarcoma is unknown either.

Clinical course and management of primary liver liposarcoma are scarcely mentioned in previous reports because the patients were too old or had serious underlying

Table 1 Location, management, and result of previously reported cases of primary liver liposarcoma in adults

**Figure 5** A high grade of undifferentiated liposarcoma composed of spindle cells with marked nuclear pleomorphism (hematoxylin-eosin staining, × 400).

ing diseases to receive a surgery, or the tumor was big-sized or located in a position difficult for complete resection. In this case, curative hepatectomy was performed although the tumor was huge. According to the clinical course, liver liposarcoma has a high rate of recurrence, which is similar to those at other sites<sup>[1,4]</sup>. Aggressive surgery can prolong the life of patients. Thus, this case provides a good experience about the clinical course of primary liver liposarcoma.

Early diagnosis of liver liposarcoma is not easy. Liver is the largest organ in the abdomen, and symptoms and signs of a tumor in the liver are usually trivial unless the tumors are large. The usual symptoms and signs of primary liver liposarcoma include jaundice, fever, nausea, vomiting, abdominal fullness, right upper quadrant pain, and body weight loss<sup>[2]</sup>. Most of the symptoms are caused either by displacement or compression of nerves, vessels, biliary tract, and intestinal structure. Our case had similar clinical presentations because of the massive effect of tumor and central location of the tumor to compress biliary tracts. Abdominal ultrasonography usually is a good tool to do preoperative screening and postoperative follow-up. In this case, abdominal ultrasonography was performed

regularly at an interval of 12 wk. However, the recurrent tumor was always large when the tumor was found by ultrasonography. This implies that recurrent tumor grows rapidly between two ultrasonography examinations. Computed tomography is still the best tool to evaluate the resectability of liver liposarcoma before surgery.

Five major histologic categories of liposarcoma are mentioned<sup>[5]</sup> and patients with myxoid or well-differentiated type have a lower local recurrence rate than other types<sup>[1]</sup>. In our case, surgical specimens showed myxoid liposarcoma in the first and second time. However, the tumor exhibited high grade of undifferentiated sarcoma in the third time. The interval to recurrence in the first and second time was 10 mo and 11 mo, respectively, but recurrence interval in the third time reduced to 2 mo. The tumor pathology became aggravating after repeated surgery.

In conclusion, primary liposarcoma of the liver is rare. The experience in dealing with this malignant neoplasm is limited. In our experience, the tumor becomes aggravating with the time course or after repeated surgeries, and resists to radiotherapy. Curative and aggressive hepatectomies are still the best policy to achieve a long-term survival of the patients.

## Meetings

### MAJOR MEETINGS COMING UP

Digestive Disease Week  
107th Annual Meeting of AGA, The American  
Gastroenterology Association  
May 20-25, 2006  
Loas Angeles Convernion Center, California  
www.ddw.org

### EVENTS AND MEETINGS IN THE UPCOMING 6 MONTHS

10 th World Congress of the International Society  
for Diseases of the Esophagus (ISDE 2006)  
February 22-25, 2006  
Adelaide  
isde@sapmea.asn.au  
www.isde.net

EASL 2006 - The 41<sup>st</sup> Annual Meeting  
April 26-30, 2006  
Vienna, Austria

International Gastrointestinal Fellows Initiative  
February 22-24, 2006  
Banff, Alberta  
CAGOffice@cag-acg.org  
www.cag-acg.org

Canadian Digestive Disease Week  
February 24-27, 2006  
Banff, Alberta  
CAGOffice@cag-acg.org

## Instructions to authors

### GENERAL INFORMATION

*World Journal of Gastroenterology* (WJG, *World J Gastroenterol* ISSN 1007-9327 CN 14-1219/R) is a weekly journal of more than 48 000 circulation, published on the 7<sup>th</sup>, 14<sup>th</sup>, 21<sup>st</sup> and 28<sup>th</sup> of every month.

Original Research, Clinical Trials, Reviews, Comments, and Case Reports in esophageal cancer, gastric cancer, colon cancer, liver cancer, viral liver diseases, *etc.*, from all over the world are welcome on the condition that they have not been published previously and have not been submitted simultaneously elsewhere.

**Published by**  
The WJG Press

### SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed double-spaced on A4 (297mm×210 mm) white paper with outer margins of 2.5 cm. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, acknowledgements, References, Tables, Figures and Figure Legends. Neither the editors nor the Publisher is responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press, and may not be reproduced by any means, in whole or in part without the written permission of both the authors and the Publisher. We reserve the right to put onto our website and copy-edit accepted manuscripts. Authors should also follow the guidelines for the care and use of laboratory animals of their institution or national animal welfare committee.

Authors should retain one copy of the text, tables, photographs and illustrations, as rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for the loss or damage to photographs and illustrations in mailing process.

#### Online submission

Online submission is strongly advised. Manuscripts should be submitted through the Online Submission System at: <http://www.wjgnet.com/index.jsp>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (<http://www.wjgnet.com/wjg/help/instructions.jsp>) before attempting to submit online. Authors encountering problems with the Online Submission System may send an email describing the problem to [wjg@wjgnet.com](mailto:wjg@wjgnet.com) for assistance. If you submit your manuscript online, do not make a postal contribution. A repeated online submission for the same manuscript is strictly prohibited.

#### Postal submission

Send 3 duplicate hard copies of the full-text manuscript typed double-spaced on A4(297 mm×210 mm) white paper together with any original photographs or illustrations and a 3.5 inch computer diskette or CD-ROM containing an electronic copy of the manuscript including all the figures, graphs and tables in native Microsoft Word format or \*.rtf format to:

#### Editorial Office

**World Journal of Gastroenterology**  
Editorial Department: Apartment 1066, Yishou Garden,  
58 North Langxinzhuang Road,  
PO Box 2345, Beijing 100023, China  
E-mail: [wjg@wjgnet.com](mailto:wjg@wjgnet.com)  
<http://www.wjgnet.com>

### MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using a word-processing software. All submissions must be typed in 1.5 line spacing and in word size 12 with ample margins. The letter font is Tahoma. For authors from China, one copy of the Chinese translation of the manuscript is also required (excluding references). Style should conform to our house format. Required information for each of the manuscript sections is as follows:

#### Title page

Full manuscript title, running title, all author(s) name(s), affiliations, institution(s) and/or department(s) where the work was accomplished, disclosure of any financial support for the research, and the name, full

address, telephone and fax numbers and email address of the corresponding author should be included. Titles should be concise and informative (removing all unnecessary words), emphasize what is new, and avoid abbreviations. A short running title of less than 40 letters should be provided. List the author(s)' name(s) as follows: initial and/or first name, middle name or initial(s) and full family name.

#### Abstract

An informative, structured abstract of no more than 250 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections: AIM: Only the purpose should be included. METHODS: The materials, techniques, instruments and equipments, and the experimental procedures should be included. RESULTS: The observatory and experimental results, including data, effects, outcome, *etc.* should be included. Authors should present *P* value where necessary, and the significant data should accompany. CONCLUSION: Accurate view and the value of the results should be included.

The format of structured abstracts is at: <http://www.wjgnet.com/wjg/help/11.doc>

#### Key words

Please list 3-10 key words that could reflect content of the study mainly from *Index Medicus*.

#### Text

For most article types, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include in appropriate Figures and Tables. Data should be presented in the body text or in Figures and Tables, but not in both.

#### Illustrations

Figures should be numbered as 1, 2, 3 and so on, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. No detailed legend should be involved under the figures. This part should be added into the text where the figures are applicable. Digital images: black and white photographs should be scanned and saved in TIFF format at a resolution of 300 dpi; color images should be saved as CMYK (print files) but not as RGB (screen-viewing files). Place each photograph in a separate file. Print images: supply images of size no smaller than 126 mm×76 mm printed on smooth surface paper; label the image by writing the Figure number and orientation using an arrow. Photomicrographs: indicate the original magnification and stain in the legend. Digital Drawings: supply files in EPS if created by freehand and illustrator, or TIFF from photoshops. EPS files must be accompanied by a version in native file format for editing purposes. Existing line drawings should be scanned at a resolution of 1200 dpi and as close as possible to the size where they will appear when printed. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes of atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ...

#### Tables

Three-line tables should be numbered as 1, 2, 3 and so on, and mentioned clearly in the main text. Provide a brief title for each table. No detailed legend should be included under the tables. This part should be added into the text where the tables are applicable. The information should complement but not duplicate that contained in the text. Use one horizontal line under the title, a second under the column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

#### Notes in tables and illustrations

Data that are not statistically significant should not be noted. <sup>a</sup>*P*<0.05, <sup>b</sup>*P*<0.01 should be noted (*P*>0.05 should not be noted). If there are other series of *P* values, <sup>c</sup>*P*<0.05 and <sup>d</sup>*P*<0.01 are used. Third series of *P* values can be expressed as <sup>e</sup>*P*<0.05 and <sup>f</sup>*P*<0.01. Other notes in tables or under illustrations should be expressed as <sup>1</sup>*F*, <sup>2</sup>*F*, <sup>3</sup>*F*; or some other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.* in a certain sequence.

#### Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscripts and who endorse the data and conclusions are included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

## REFERENCES

## Coding system

The author should code the references according the citation order in text in Arabic numerals, put references codes in square brackets, superscript it at the end of citation content or the author name of the citation. For those citation content as the narrate part, the coding number and square brackets should be typeset normally. For example, Crohn's disease (CD) is associated with increased intestinal permeability<sup>[1,2]</sup>. If references are directly cited in the text, they would be put together with the text, for example, from references [19,22-24], we know that...

When the authors code the references, please ensure that the order in text is the same as in reference part and also insure the spelling accuracy of the first author's name. Do not code the same citation twice.

## PMID requirement

PMID roots in the abstract serial number indexed by PubMed (<http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=PubMed>). The author should supply the PMID for journal citation. For those references that have not been indexed by PubMed, a printed copy of the first page of the full reference should be submitted.

The accuracy of the information of the journal citations is very important. Through reference testing system (<http://www.aushome.cn/cgi-bin/index.pl>), the authors and editor could check the authors name, title, journal title, publication date, volume number, start page, and end page. We will interlink all references with PubMed in ASP file so that the readers can read the abstract of the citations online immediately.

## Style for journal references

Authors: the first author should be typed in bold-faced letter. The surname of all authors should be typed with the initial letter capitalized and followed by their name in abbreviation (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). Title of the cited article and italicized journal title (Journal title should be in its abbreviation form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634]

Note: The author should test the references through reference testing system (<http://www.aushome.cn/cgi-bin/index.pl>)

## Style for book references

Authors: the first author should be typed in bold-faced letter. The surname of all authors should be typed with the initial letter capitalized and followed by their name in abbreviation (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

## Format

Standard journal article (list all authors and include the PubMed ID [PMID] where applicable)

- 1 **Das KM**, Farag SA. Current medical therapy of inflammatory bowel disease. *World J Gastroenterol* 2000; 6: 483-489 [PMID: 11819634]
- 2 **Pan BR**, Hodgson HJF, Kalsi J. Hyperglobulinemia in chronic liver disease: Relationships between *in vitro* immunoglobulin synthesis, short lived suppressor cell activity and serum immunoglobulin levels. *Clin Exp Immunol* 1984; 55: 546-551 [PMID: 6231144]
- 3 **Lin GZ**, Wang XZ, Wang P, Lin J, Yang FD. Immunologic effect of Jianpi Yishen decoction in treatment of Pixu-diarrhoea. *Shijie Huaren Xiaobua Zazhi* 1999; 7: 285-287

Books and other monographs (list all authors)

- 4 **Sherlock S**, Dooley J. Diseases of the liver and billiary system. 9th ed. Oxford: Blackwell Sci Pub, 1993: 258-296

Chapter in a book (list all authors)

- 5 **Lam SK**. Academic investigator's perspectives of medical treatment for peptic ulcer. In: Swabb EA, Azabo S. Ulcer disease: investigation and basis for therapy. New York: Marcel Dekker, 1991: 431-450

Electronic journal (list all authors)

- 6 **Morse SS**. Factors in the emergence of infectious diseases. *Emerg Infect Dis* serial online, 1995-01-03, cited 1996-06-05; 1(1):24 screens. Available from: URL: <http://www.cdc.gov/ncidod/EID/eid.htm>

## Inappropriate references

Authors should always cite references that are relevant to their article, and avoid any inappropriate references. Inappropriate references include those that are linked with a hyphen and the difference between the two numbers at two sides of the hyphen is more than 5. For example, [1-6], [2-14] and [1, 3, 4-10, 22] are all considered as inappropriate references. Authors should not cite their own unrelated published articles.

## Statistical data

Present as mean  $\pm$  SD and mean  $\pm$  SE.

## Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as  $\chi^2$  (in Greek), related coefficient as *r* (in italics), degree of freedom as  $\gamma$  (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

## Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose) 6.4  $\pm$  2.1 mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6 24.5  $\mu$ g/L; CO<sub>2</sub> volume fraction, 50 mL/L CO<sub>2</sub> not 5% CO<sub>2</sub>; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format about how to accurately write common units and quantum is at: <http://www.wjgnet.com/wjg/help/15.doc>

## Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further mention.

## Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindII*, *BamHI*, *Kho I*, *Kpn I*, etc.

Biology: *Helicobacter pylori*, *H pylori*, *E coli*, etc.

## SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. Author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, the final check list for authors, and responses to reviewers by a courier (such as EMS) (submission of revised manuscript by e-mail or on the *WJG* Editorial Office Online System is NOT available at present).

## Language evaluation

The language of a manuscript will be graded before sending for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing; (4) Grade D: rejected. The revised articles should be in grade B or grade A.

## Copyright assignment form

It is the policy of *WJG* to acquire copyright in all contributions. Papers accepted for publication become the copyright of *WJG* and authors will be asked to sign a transfer of copyright form. All authors must read and agree to the conditions outlined in the Copyright Assignment Form (which can be downloaded from <http://www.wjgnet.com/wjg/help/9.doc>).

## Final check list for authors

The format is at: <http://www.wjgnet.com/wjg/help/13.doc>

## Responses to reviewers

Please revise your article according to the comments/suggestions of reviewers. The format for responses to the reviewers' comments is at: <http://www.wjgnet.com/wjg/help/10.doc>

## Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

## Publication fee

Authors of accepted articles must pay publication fee.

EDITORIAL and LETTERS TO THE EDITOR are free of charge.

## World Journal of Gastroenterology standard of quantities and units

Number	Nonstandard	Standard	Notice
1	4 days	4 d	In figures, tables and numerical narration
2	4 days	four days	In text narration
3	day	d	After Arabic numerals
4	Four d	Four days	At the beginning of a sentence
5	2 hours	2 h	After Arabic numerals
6	2 hs	2 h	After Arabic numerals
7	hr, hrs,	h	After Arabic numerals
8	10 seconds	10 s	After Arabic numerals
9	10 year	10 years	In text narration
10	Ten yr	Ten years	At the beginning of a sentence
11	0,1,2 years	0,1,2 yr	In figures and tables
12	0,1,2 year	0,1,2 yr	In figures and tables
13	4 weeks	4 wk	
14	Four wk	Four weeks	At the beginning of a sentence
15	2 months	2 mo	In figures and tables
16	Two mo	Two months	At the beginning of a sentence
17	10 minutes	10 min	
18	Ten min	Ten minutes	At the beginning of a sentence
19	50% (V/V)	500 mL/L	
20	50% (m/V)	500 g/L	
21	1 M	1 mol/L	
22	10 μM	10 μmol/L	
23	1N HCl	1 mol/L HCl	
24	1N H <sub>2</sub> SO <sub>4</sub>	0.5 mol/L H <sub>2</sub> SO <sub>4</sub>	
25	4rd edition	4 <sup>th</sup> edition	
26	15 year experience	15- year experience	
27	18.5 kDa	18.5 ku, 18 500u or M:18 500	
28	25 g.kg <sup>-1</sup> /d <sup>-1</sup>	25 g/(kg·d) or 25 g/kg per day	
29	6900	6 900	
30	1000 rpm	1 000 r/min	
31	sec	s	After Arabic numerals
32	1 pg L <sup>-1</sup>	1 pg/L	
33	10 kilograms	10 kg	
34	13 000 rpm	13 000 g	High speed; g should be in italic and suitable conversion.
35	1000 g	1 000 r/min	Low speed. g cannot be used.
36	Gene bank	GenBank	International classified genetic materials collection bank
37	Ten L	Ten liters	At the beginning of a sentence
38	Ten mL	Ten milliliters	At the beginning of a sentence
39	umol	μmol	
40	30 sec	30 s	
41	1 g/dl	10 g/L	10-fold conversion
42	OD <sub>260</sub>	A <sub>260</sub>	"OD" has been abandoned.
43	One g/L	One microgram per liter	At the beginning of a sentence
44	A260 nm <sup>b</sup> P<0.05	A <sub>260</sub> nm <sup>a</sup> P<0.05	A should be in italic. In Table, no note is needed if there is no significance instatistics: <sup>a</sup> P<0.05, <sup>b</sup> P<0.01 (no note if P>0.05). If ther is a second set of P value in the same table, <sup>c</sup> P<0.05 and <sup>d</sup> P<0.01 are used for a third set: <sup>a</sup> P<0.05, <sup>b</sup> P<0.01.
45	<sup>*</sup> F=9.87, <sup>§</sup> F=25.9, <sup>#</sup> F=67.4	<sup>1</sup> F=9.87, <sup>2</sup> F=25.9, <sup>3</sup> F=67.4	Notices in or under a table
46	KM	km	kilometer
47	CM	cm	centimeter
48	MM	mm	millimeter
49	Kg, KG	kg	kilogram
50	Gm, gr	g	gram
51	nt	N	newton
52	l	L	liter
53	db	dB	decibel
54	rpm	r/min	rotation per minute
55	bq	Bq	becquerel, a unit symbol
56	amp	A	ampere
57	coul	C	coulomb
58	HZ	Hz	
59	w	W	watt
60	KPa	kPa	kilo-pascal
61	p	Pa	pascal
62	ev	EV	volt (electronic unit)
63	Jonle	J	joule
64	J/mm <sup>3</sup>	kJ/mol	kilojoule per mole
65	10×10×10cm <sup>3</sup>	10 cm×10 cm×10 cm	
66	N·km	KN·m	moment
67	x±s	mean±SD	In figures, tables or text narration
68	Mean±SEM	mean±SE	In figures, tables or text narration
69	im	im	intramuscular injection
70	iv	iv	intravenous injection
71	Wang et al	Wang <i>et al.</i>	
72	EcoRI	EcoRI	<i>Eco</i> in italic and RI in positive. Restriction endonuclease has its prescript form of writing.
73	Ecoli	<i>E.coli</i>	Bacteria and other biologic terms have their specific expression.
74	Hp	<i>H pylori</i>	
75	Iga	<i>Iga</i>	writing form of genes
76	igA	IgA	writing form of proteins
77	~70 kDa	~70 ku

## Abstract

The thrombophilia which can be either congenital or acquired in adult life has major implications in the abdominal vessels. The resulting portal vein thrombosis, Budd-Chiari syndrome and mesenteric vein thrombosis have a variety of consequences ranging from acute abdomen to chronic hepatomegaly and even totally asymptomatic patient in whom the only finding is pancytopenia. The complications like esophageal varices, portal gastropathy, ascites, severe hypersplenism, liver failure requiring liver transplantation are well known. Interesting features of collateral venous circulation showing itself as pseudocholeangioma sign and its possible clinical reflection as cholestasis are also known from a long time. The management strategies for these complications of intraabdominal vessel thrombosis are not different from their counterpart which is cirrhotic portal hypertension, but the prognosis is unquestionably better in former cases. In this review we presented and discussed the abdominal venous thrombosis, etiology and the resulting clinical pictures. There are controversial issues both in nomenclature, and management including anticoagulation problems and follow up strategies. In light of the current knowledge, we discussed some controversial issues in literature and presented our experience and our proposals about this group of patients.

## INTRODUCTION

The thrombosis in the major vessels of abdomen causes a wide spectrum of clinical pictures ranging from a totally asymptomatic patient to a patient with acute abdominal pain and even impending liver failure in patients with underlying chronic liver disease. As liver is the main organ of synthesis of many essential proteins in the body, it bears the burden of thrombosis of major vessels in the abdomen whether this may be a partial or total thrombosis with resulting liver disease, portal hypertension and cirrhosis requiring different management strategies including liver transplantation.

In this clinical setting, the thrombosis of the abdominal vessels has a special place in medicine since the clinicopathological pictures and courses of these processes are usually heterogeneous, protean and fluctuant in nature. In general practice physicians pay extra attention to the thrombosis of coronary, pulmonary, mesenteric or cerebral circulation but not to abdominal venous circulation. We believe that the thrombotic occlusion of all major vessels of abdominal cavity has severe clinical consequences and chronic complications.

In this review we will describe thrombophilic conditions and discuss the potential consequences of thrombosis in the major abdominal vessels with potential clinical implications.

## THROMBOPHILIA

Normal coagulation hemostasis involves the interaction of an initial vascular reaction (vasoconstriction), thrombocytic activation (white clot formation) and formation of thrombin via activation of coagulation cascade. The balance between the forces favoring formation of a clot and forces against it is the normal state which is controlled with very delicate systems. Although very complicated and several mechanisms play a role in the vascular and thrombocytic steps of clot formation, these steps are beyond the scope of this review and will not be discussed further.

Thrombophilia is a term which is proposed as an opposite term against hemophilia. Thrombophilia can be defined as a disturbed state of the coagulation-fibrinolysis balance in favor of thrombosis formation (congenital or acquired in adult life) in which thrombosis (in arterial and/

or venous vasculature) is observed more frequently than normal population. For the gastroenterologists and surgeons, the congenital and acquired causes of the thrombophilia are important not only due to their potential risks to patients' lives but also their preventability with the advent of genetic tests and surveillance and their treatability with new invasive techniques and new anticoagulant drugs.

Thrombophilia can be grouped under two major headlines: inherited and acquired.

## CAUSES OF INHERITED THROMBOPHILIA

### Factor V Leiden mutation (FVLM)

The most common cause of inherited thrombophilia is FVLM. This mutation was firstly defined by Bertina *et al*<sup>[1]</sup> in 1994, after studies of Dahlback and colleagues<sup>[2]</sup> who showed a resistance factor against activated protein C (APC). The prevalence of this mutation differs between populations throughout the world. The prevalence of this mutation is very heterogeneous that some native populations of Africa, America and Asia show no mutation whereas in some districts of Scandinavian peninsula the prevalence rises to 15%. In Turkey, the prevalence is about 8-9% and this prevalence rate decreases going west from Asia Minor towards Europe to 2-4%<sup>[3]</sup>.

Factor V (FV) is synthesized in liver and megakaryocytes which must be activated into form of FVA to play a crucial role in prothrombinase complex along with activated factor X to produce thrombin. The mutation involves a point at the 1691st nucleotide of the exon 10 in first chromosome making G-C change. This results in a change in aminoacid sequences which is depicted as A506G (Arginine at 506 changed by Glutamine). The mutation containing FVA is resistant to degradation by protein C (which is a natural anticoagulant protein) and undegraded factor rises over time increasing the risk of uncontrolled thrombin and therefore thrombus formation. The diagnosis of FVLM depends partially on the activated protein C resistance (APCR) as a screening tool but direct PCR test to detect mutation can also be applied. APCR is a standard test which is widely available in most laboratories but modified APCR has a very high level of sensitivity and specificity and should be applied to patients who are on warfarin treatment, anti-phospholipid syndrome patients, pregnant women, protein S (PS) deficiency and patients with high levels of factor VIII<sup>[4]</sup>.

When compared with normal population, the impact of FVLM on thrombosis formation is a risk about 3-7 times higher in heterozygotes and 50-100 times higher in homozygotes.

### Prothrombin mutation (PM)

PM is firstly defined in 1996 by Poort *et al*<sup>[5]</sup>. The mutation involves a base pair change in the 20210th position (guanosine vs. adenosine) resulting in excessive generation of prothrombin which forms excessive procoagulant accumulation<sup>[6]</sup>. This mutation has a general population prevalence of about 2% compared to the prevalence increased to 6% in patients who had their first attack of venous thrombosis. Like FVLM, the genetic basis is also important for the prevalence. In African and

Asian populations the PM is rare when compared to Caucasians<sup>[7]</sup>.

### Protein C (PC) and protein S (PS) deficiency

PC is synthesized in liver by a vitamin K dependent mechanism. During coagulation cascade, this protein is activated by thrombin into its active form, namely activated PC (APC). PC is encoded in chromosome 2 and up to date about 160 mutations have been defined<sup>[4,8-10]</sup>. The PC activity is usually determined by functional tests. The heterozygote PC deficiency reveals itself by PC activity less than 50%, whereas in homozygote deficiency PC activity is below 5%. The prevalence of PC deficiency is about 0.2% in general population and in the population who had first venous thrombosis attack the prevalence is found to be about 3%<sup>[11]</sup>. An important factor to point out is that the acquired PC deficiency occurs in patients with liver disease (due to decreased synthetic capacity), oral anticoagulation treatment and acute thrombosis cases (due to utilization).

PS is naturally a cofactor of activated PC during inactivation processes of activated factors V and VIII. This protein is synthesized from liver, endothelial cells, megakaryocytes and in testis by vitamin K dependent reactions. There are many mutations responsible for PS deficiency so that genotyping and analysis for a suspected PS deficiency is not practical. The screening for PS deficiency is functional activity testing. The protein S deficiency is accepted as a weak risk factor for thrombosis formation which is about 2 times more than normal population. The importance of liver disease in assessing these natural anti-coagulant deficiencies is discussed later.

### Antithrombin (AT) deficiency

AT is a natural serine protease inhibitor with a very potential controlling functions over coagulation cascade. AT inhibits the steps of coagulation depending on mainly thrombin and less importantly activated factors IX, X, XI, and XII. In the presence of heparin or heparin like molecules the inhibitor function is 1000 times more potent<sup>[12]</sup>. The prevalence of deficiency of AT in the general population is about 0.02-0.2%, while it accounts for 1% of venous thrombosis etiologies<sup>[11,13]</sup>.

## CAUSES OF ACQUIRED THROMBOPHILIA

In young adults, the annual risk of venous thrombosis is 1/10000 for event/person but this figure increases to 1/100 for event/person in patients over 70 years of age<sup>[14]</sup>. Age is considered as an independent risk factor for venous thrombosis mainly due to inactivity (related with venous congestion), comorbid illnesses related with age and degenerative changes in the vasculature that occur with aging<sup>[15]</sup>.

Malignant disease is also an important cause of thrombosis. Cancer patients have a crude risk of 10-20% to have venous thrombosis in the rest of their lives. The thrombosis related deaths row in the second place in all causes of deaths in this patient population<sup>[16-18]</sup>. Myeloproliferative disorders (MPD) merit a special discussion in this section. MPD forms a group of special blood disorders which may be termed as half-malignant due to their natural course

**Table 1** Relative risks and comparison of common thrombophilic conditions<sup>[21,22]</sup>.

Thrombophilic condition	Relative risk of thrombosis
<b>Inherited</b>	
Heterozygote deficiency of natural anticoagulants (PC, PS, AT)	10-fold
Heterozygote FVLM	5-8 fold
Homozygote FVLM	50-80 fold
Heterozygote PM	2-4 fold
Homozygote PM	10-fold
<b>Acquired</b>	
Oral contraceptive use	4-fold
Surgery	6-fold
Immobilization	11-fold
Anti-phospholipid syndrome	10-fold
<b>Combined</b>	
Oral contraceptive use + Heterozygote FVLM	35-fold

and this group of patients frequently suffer from venous thrombosis. Thrombocytosis and the increased hematocrit which are natural characteristics of this disorders which also cause thrombosis in the venous systems<sup>[19]</sup>.

Other well known acquired thrombophilic conditions are surgery (orthopedic and neurosurgery), drugs (i.e., oral contraceptives, hormone replacement treatment, tamoxifen, L-Asparaginase), antiphospholipid syndrome, pregnancy and Behcet's disease<sup>[20]</sup>.

The relative risks of common thrombophilic conditions<sup>[21,22]</sup> are shown in Table 1.

## PORTAL VENOUS THROMBOSIS: ETIOLOGY, CLINICAL CONSEQUENCES

Portal vein thrombosis (PVT) refers to the total or near-total obstruction of blood flow secondary to thrombus formation. This thrombus may extend towards liver involving intrahepatic portal veins or may extend distally to involve splenic veins or mesenteric veins. On some occasions extensive involvement of all of these vessels may occur with an increased risk of intestinal ischemia. Therefore, the involved segment of portal venous system and the degree of compensatory mechanisms determine the clinical presentation. Although PVT has been observed most commonly in the setting of cirrhosis, discussion presented in the text from this point specifies chronic, non-cirrhotic PVT unless otherwise specified.

PVT has considerable consequences for the liver. Upon cessation of blood flow liver loses about two thirds of its blood supply. Interestingly, while the acute arterial blockage usually results in severe hepatic failure or death, this condition is tolerated well and the patients are almost asymptomatic due to compensatory mechanisms. First compensatory mechanism is the well known "arterial vasodilation" of the hepatic artery (which is a vascular reflex seen in every dual-vessel supplied organ) also observed during portal vein clamping in liver surgery<sup>[23]</sup>. This "arterial rescue" stabilizes the liver functions at a normal level in the very acute stages of PVT. The second rescue mechanism is the "venous rescue" involving rapid

**Figure 1** Conventional splenoportography showing a case of portal cavernomatous transformation with portosystemic collaterals, and extensive esophageal-gastric varicose veins.

**Figure 2** CT-angiography of portal system. Arrow shows the portal cavernomatous transformation with portosystemic collaterals.

development of collateral vessels to bypass the obstructed segment. These vessels begin to form in a few days after the obstruction and organize into a cavernomatous transformation (Figures 1 and 2) (see later section for detailed discussion) in 3-5 wk<sup>[24,25]</sup>. We believe that when symptomatic, acute PVT rather be called "acute mesenteric thrombosis" due to extensive co-involvement of the superior mesenteric vein and branches. This condition has very acutely developing deleterious effects over intestinal circulation compromising the patient's life before development of portal hypertension and its consequences.

Besides these compensatory mechanisms, liver bears the burden of decreased blood to some extent. The decreased portal blood flow stimulates apoptosis in hepatocytes of rats when portal vein is obliterated in a gradual fashion<sup>[26]</sup> and increases mitotic activity of hepatocytes in the unaffected lobe. The latter effect is well known from selective pre-surgery portal vein obliteration performed in an intention to stimulate the hypertrophy of the opposite lobe of the liver used in cancer surgery. Gradual loss of hepatic mass may be responsible for the occurrence of mild to moderate degree of hepatic synthetic dysfunction observed in advanced stages.

### Etiology

PVT has various causes. The design of the studies and the parameters evaluating the cause of PVT have changed in parallel to the evolution in medical and genetic technology. In previous studies between 1979-1997, PVT were mostly attributed to trauma (5-17%), intra-abdominal sepsis (5-36%), umbilical sepsis (5-12%)<sup>[27]</sup> (important cause of PVT in children), pancreatitis (4-5%) and prothrombotic

Table 2 Role of genetic thrombophilic factors in development of PVT

<sup>1</sup>NS, not studied.

disorders (2-28 %), but in nearly 50% of the patients etiology remained unidentified<sup>[28-32]</sup>. But with the advent of better medical care, potent antibiotic treatment, advanced medical technology, discovery of various causes of genetic thrombophilia and with better understanding of the coagulation system, this profile has also changed.

Identification of etiology usually starts by exclusion of local factors such as cirrhosis, primary or metastatic cancer of liver, pylephlebitis, liver cysts, vascular abnormalities (like webs or aneurysms) and pancreatitis. Besides routine investigations such as liver biopsies or Doppler-USG studies, magnetic resonance or CT based (3 dimensional angiographic images also available) techniques are very helpful at this stage. If no local lesion is found, then the studies are directed for a possible thrombophilic condition. After all, if no factor can be found, then the condition should be named as "idiopathic PVT".

In a study by Denninger *et al*<sup>[33]</sup>, the underlying prothrombotic condition was identified in 72 % of PVT patients. There was one or more prothrombotic condition in 26 out of 36 patients studied and primary myeloproliferative disorders were the leading cause with a prevalence of 30 % in this study. Other studies by Valla *et al*<sup>[34-36]</sup> and De Stefano *et al*<sup>[37]</sup> report the similar figure that as a cause of PVT, myeloproliferative disorders (overt or occult) rank first in the thrombophilic conditions. Valla *et al* also proposed that overt or latent myeloproliferative disorders may be responsible for thrombophilic milieu for PVT in 48% of patients.

The importance and impact of genetic thrombophilic factors in PVT are investigated in various studies. Table 2 shows the recent and most comprehensive studies about this topic published between 1999-2005. One of the most interesting findings about the results of these studies is the differences between them. Although all of the studies investigated the same patient population, the results are totally different from each other. The explanations for this situation may be the patient selection bias which is the problem of the tertiary care facilities, small number of patients, non-standard evaluation of the same parameters and genetic differences of the patient population.

The investigation of PC, PS and AT deficiencies in patients with PVT is a challenge for the clinician to interpret when the results are found to be lower than normal. There are studies investigating whether the low values are result of liver dysfunction or indicate a frank deficiency. One

of the most important studies is performed in children. Mack *et al*<sup>[42]</sup> studied the coagulation parameters (including factors synthesized exclusively in liver) in 11 children with PVT who underwent a surgical correction (mesenterico-left portal vein bypass: Rex Shunt) of the portal venous system before and after surgery. The investigators found a significant correction of both coagulation factors (factors II, V and VII) indicated also by improvement in prothrombin time and of PC and PS levels after surgery. The same parameters studied in other 2 children receiving distal splenorenal shunt in this study and 7 children in another study receiving H-type mesocaval shunt<sup>[43]</sup> did not improve as the Rex shunting supporting the importance of lower portal vein flow in the development of secondary PC and PS deficiencies. Fisher *et al*<sup>[44]</sup> studied the same topic by combining the family investigation of PC and PS deficiencies in patients with PVT. They found out that there were only 3 familial cases of natural anticoagulant deficiencies out of 18 patients indicating a secondary finding. Another support to this finding and the previous results is that they have found significant reductions in AT, PC and PS concentrations after distal splenorenal shunt surgery (3 patients). All of the mentioned studies confirm that the lower portal blood flow has a great impact over the synthesis of natural anticoagulant and coagulant proteins. The shunt procedures directing the blood from portal system towards systemic circulation may worsen this as evidenced from comparison of results of splenorenal shunt vs. Rex shunt. In our opinion this phenomenon of secondary loss of coagulant and anti-coagulant proteins must be considered carefully in clinical practice when anticoagulation with warfarin is considered.

Secondary deficiencies of genetic thrombophilia factors like AT, PC and PS is still a matter of diagnostic challenge. To overcome this problem, there seems to be a very narrow range of solutions such as family study (first degree relatives) of deficient proteins in an attempt to detect familial aggregation of mutant genes and primary genetic studies of the patient to detect the mutant gene(s). These studies are important but not practical and not applicable in every facility. A practical screening method for detection of natural anticoagulant deficiencies in patients with liver disease was proposed by Pabinger *et al*<sup>[45]</sup> and used firstly by Janssen *et al*<sup>[39]</sup> in a clinical study which utilizes the ratio of natural anti-coagulant factor to coagulation factors (synthesized exclusively in liver). The formula is the ratio of PS or PC or AT (whichever tested) to [(factor II + factor X) / 2]. If the result of this ratio is lower than 70 %, then this may indicate a deficiency of the tested natural anti-coagulant protein significantly disproportionate to decreased synthesis of proteins from liver. This formula is easy to use in clinics and is practical to determine a possible genetic deficiency.

The concept of PVT can not be solely attributed to one factor. It is now widely accepted that the PVT occurs from both a primary thrombophilic milieu and a factor that triggers the formation of the pathological thrombus in portal circulation. The aforementioned factors are currently considered as thrombophilic background rather than the primary etiologic factor according to the concept of multifactorial theory of thrombogenesis. The other co-

factors required to develop a thrombus can be grouped as local and systemic factors most of which are potentially curable or preventable factors.

### Clinical consequences

The consequences of the PVT vary from one patient to another and depend on some important factors. The condition may present itself as one of the complications but due to lack of convincing evidence in the literature, the most common type of initial presentation of PVT (not related with cirrhosis) is still not known. In our personal experience, most common type of presentation is variceal bleeding followed by pancytopenia due to hypersplenism. Undefined cholestasis related with pseudocholangiocarcinoma sign (without icterus) is also one of the rare presentations.

With the advent and widely distribution of USG and Doppler-USG, the condition is becoming to be diagnosed very earlier and a patient presenting with ascites (which is a very late finding in course of PVT) is almost not seen. Webb and Sherlock<sup>[27]</sup> reported in 1979 that out of 97 patients with PVT 13 presented with ascites which seems to be a very high rate (13.5%). There are still some PVT cases presenting as ascites in underdeveloped parts of the world related with absence of early diagnosis with similar rates around 13%<sup>[46]</sup>.

**Varices** Esophageal and gastric varices related bleeding contribute to the most important cause of morbidity and hospitalization in this group of patients. When the characteristics of variceal bleeding are considered, major differences between cirrhosis *vs* PVT related bleeding must be pointed out. Firstly, the risk of variceal bleeding in cirrhosis is approximately 80-120 times more than PVT (non-cirrhotic) related variceal bleeding<sup>[47-49]</sup> and esophageal varices (irrespective of size) are observed in about 90% of patients. Gastric varices are mostly seen concomitantly with esophageal varices in about 40% of the patients in PVT while portal gastropathy is also a rare feature of this condition<sup>[49, 50]</sup>. Compared to portosystemic varices observed in cirrhotic patients, the varices in PVT patients have some special characteristics: (1) “varice-on-varice” finding is less commonly observed; (2) the sizes of the varices are smaller; (3) associated portal gastropathy is less commonly present<sup>[50]</sup>. The retrospective study (investigated the determinants of survival in a heterogenous group of patients including 124 non-cirrhotic *vs* 48 cirrhotic PVT cases) of Janssen *et al*<sup>[47]</sup> showed that either the presence of varices or bleeding episodes of varices had no impact on survival rates and the most common cause of death was malignancy related causes. Twenty four percent of the study population had malignancies like hepatocellular cancer, pancreatic cancer, or other malignancy elsewhere metastatic to the liver which presented itself in liver as PVT indicating end stage malignancies.

Although the risk of variceal bleeding is low in non-cirrhotic patients, the management of bleeding varices is not different from cirrhotic patients. Unfortunately there is not any study in the literature comparing endoscopic procedures *vs* surgical procedures in acutely bleeding varices and about the topic of primary prophylaxis. We believe that primary prophylaxis with endoscopic procedures in

**Figure 3** ERCP of a patient with portal cavernomatous transformation. Arrow shows the site of depression in the main bile duct.

an effort to clear varices should be applied with careful monitoring and secondary prophylaxis with combination of endoscopic procedures and medical treatment despite beta-blockers may work although there is no objective and sufficient evidence.

In contrast, beta-blockers may result in more sluggish portal flow as is the same issue for nitrates and terlipressin increasing the risk of progression of thrombosis and even worsening of portal hypertension. This decision must be adjusted with the patient's condition rather than a standard medical care.

**Pseudocholangiocarcinoma sign** One of the interesting and misleading clinical conditions that may occur during the course of the PVT is “pseudocholangiocarcinoma sign” (PSCS). After the obstruction in the portal system, the “venous rescue” begins to occur immediately which takes about 5 wk<sup>[24]</sup> forming new vessels around intrahepatic, extrahepatic biliary tracts and around gallbladder (majorly, vascular plexus of Saint and Petren enlarge and dilate to become large serpentine vessels) named as “portal cavernomatous transformation”. Sometimes these vessels can be very small in caliber to visualize depending on the extent of portal flow and capacity of new vessel formation, but if a careful ERCP is performed (Figure 3) the direct effects of these vessels on biliary ducts or main bile duct as strictures, displacements, thumbprinting effects or irregularity can be seen in at least 80% of the patients<sup>[49]</sup>. This condition mimics a cholangiocellular cancer in ERCP and therefore called PSCS<sup>[51, 52]</sup>.

The clinical impact of these changes results in a wide spectrum of findings ranging from totally normal biochemical and physical findings to overt cholestasis with elevated cholestatic enzymes and liver injury (very rarely observed). Although a term called “portal biliopathy” and a classification system are proposed<sup>[53]</sup>, we believe that this term and classification system are impractical to use because: (1) new collaterals form depending on the site and level of portal vein obstruction, (2) wide range of anatomical variations between human beings in this anatomical site resulting in different types of cavernous transformations, (3) the nature of new vessel formation is unpredictable and not standard in all portal vein thrombosis patients, (4) the classification system does not have impact over treatment or follow up strategy. We propose that only defining the presence or absence of PSCS is a satisfactory practice not to complicate the picture further because the clinically evident cholestasis and/jaundice is observed in only about

5%<sup>[54]</sup>. Therefore this physiological compensatory response is not a “-pathy” but just an adaptive change with a low degree of clinical importance.

The clinically evident cholestasis either presenting itself as repeating biliary stones or cholangitis or liver injury can be treated with conventional methods including stenting, papillotomy or even surgery.

### **3Hypersplenism and issue of anticoagulation treatment**

Hypersplenism is a finding of latent or chronic PVT and this complication is important when anticoagulation treatment is considered. Hypersplenism is almost always present except in the rare patient with a partial thrombus in one branch of the portal vein with the other branch remaining intact presenting with a mild degree of portal hypertension. The levels of all blood elements begin to decrease as the condition worsens and severe hypersplenism is now considered one of the most important indications in this group of patients to undergo a shunt surgery combined with or without a splenectomy. In the clinical setting of hypersplenism with low platelet counts combined with esophageal varices it raises concerns about the safety of anticoagulation. Unfortunately, the literature lacks information about the safety and long-term results of anticoagulation in well designed prospective controlled studies. A study to clarify this controversial topic was a retrospective analysis. In this study Condat *et al*<sup>[48]</sup> included 136 PVT patients in whom 84 received anticoagulant treatment. The study has some limitations like heterogenous groups (pre-treatment endoscopies of all patients and standardization of a homogenous varice distribution between two groups were not accomplished) and lack of information about comorbid conditions of the participating patients, but the study has a low statistical degree of evidence to favor anticoagulation treatment. Anticoagulation was not found to be a risk factor for bleeding in this study while non-anticoagulation resulted in more thrombotic recurrences as expected. In our personal experience it may be a good practice to select patients according to their co-morbid conditions, degree of hypersplenism (low platelet counts may be a relative contraindication for anticoagulation) and the condition of varices (eradication combined with or without medical prophylaxis before start of treatment may be considered to decrease bleeding related risks).

## **BUDD-CHIARI SYNDROME: ETIOLOGY, CLINICAL CONSEQUENCES**

Budd-Chiari syndrome (BCS) is a disorder which (besides its rarity and heterogenous clinical presentations) can potentially result in mortality and severe morbidities including liver failure requiring transplantation and even hepatocellular cancer. Veno-occlusive liver disease (also defined as sinusoidal obstruction syndrome) is a different pathology and therefore not included in this discussion.

There are various classifications of BCS in the literature. Classification systems include; 1) differences of etiology (primary: related with thrombophilia and secondary: due to tumor or a mass occupying lesion), 2) differences of anatomical involvement (site of obstruction: small and/or large hepatic veins, isolated inferior vena cava involvement, or combination of all), 3) progression

of disease (acute/fulminant and chronic/indolent). The forthcoming discussion about BCS involves primary BCS unless otherwise specified.

### **Etiology**

Major underlying mechanism resulting in BCS is thrombosis. The etiology of thrombosis is very similar to PVT as discussed earlier, myeloproliferative disorders are the leading cause in 20-50% of all causes which may be overt or latent in presentation<sup>[33,39]</sup>. The latent myeloproliferative disorders (for instance; endogenous erythroid colonies) are not easily detectable and requires an expert laboratory and sensitive tests (bone marrow is cultured *in vitro* to observe whether there is spontaneous erythroid colonies formed in the absence of erythropoietin stimulation). The mirror image of relation between myeloproliferative diseases and BCS is also interesting. In an autopsy study by Wanless *et al*<sup>[55]</sup>, the hepatic vein thrombosis was found in 6% of all subjects having a history of myeloproliferative disease. Paroxysmal nocturnal hemoglobinuria is also an acquired thrombophilic disorder characterized by occasional hemoglobinuria, venous thrombosis and anemia. It poses a high risk for development of BCS, about up to 10 % of all paroxysmal nocturnal hemoglobinuria patients have thrombosed hepatic veins<sup>[56]</sup>.

Behcet's disease is a subtype of large vessel vasculitis observed mostly in Turkish population which is related with hepatic vein thrombosis very frequently. Behcet's disease is associated with recurrent oral and genital ulcers with skin findings (erythema nodosum, pathergy reaction), neurologic involvement and eye inflammation. BCS occurring in Behcet's disease must be treated with an appropriate combination of colchicine, thalidomide, penicillins and anti-coagulating agents<sup>[20,57,58]</sup>.

Pregnancy and use of oral contraceptives are also related with BCS but studies in the literature have conflicting results due to study designs and the number of subjects included. The studies will not be discussed in detail but the exact relation of both conditions must be studied with adequate number of patients, defining other concurrent acquired and inherited thrombophilic conditions, estrogen content of the oral contraceptive studied. Nevertheless, both of these conditions have a theoretical risk for BCS.

Inherited causes of thrombophilia like FVLM, AT, PC and PS deficiencies account for a considerable percent age in the list of etiology of BCS. FVLM is found to be associated with 25-30% of all cases<sup>[59,60]</sup>, whereas PC deficiency (accounts for 9-20%) leads in all natural anticoagulant deficiencies<sup>[33,39]</sup>.

Other acquired causes of BCS include oral contraceptive use, pregnancy, Behcet's disease and inflammatory bowel disease.

### **Clinical consequences**

The obstructed hepatic veins present to clinic in variable forms. The most common findings are ascites, hepatomegaly, pain in the abdomen and less frequently jaundice. Although the clinical findings are more florid with drastic consequences in fulminant forms, indolent

**Figure 4** An MRI venography of hepatic veins and inferior vena cava. Arrow shows the site of obstruction in vena cava and invisible hepatic veins.

BCS is an insidious process in which development of findings mimic chronic liver disease of any other kind. The latter course results in development of portal hypertension and eventually cirrhosis combined with classical complications like variceal bleeding, intractable ascites and hypersplenism. Indolent course of BCS is characterized by pathological changes involving a variety of histological patterns like veno-portal fibrosis, veno-centric cirrhosis and nodular regenerative hyperplasia.

The studies describing the pathological changes unique to liver in chronic BCS have found that 1) the liver has an evolving change in terms of vascular dynamics to eventually result in changes in portal system (either intrahepatic or extrahepatic portal system becomes affected in time which shows itself as micro- or macro-thrombosis), 2) the liver is heterogenous, and there is great variability in random sampling (indicating that the liver biopsy must be multiple in number to clearly define the pathology and histological stage in BCS), 3) the regenerative hyperplasia with nodule formation of changing sizes are common which represents the areas with increased arterial supply with a patent venous drainage<sup>[61,62]</sup>.

Portal venous system must always be kept in mind when clinical presentation and management is considered. Portal system is almost always affected in patients with BCS. This results from various reasons: 1) perfusion of the portal system has a profound decrease since the sinusoidal pressure abruptly increases after initiation of BCS, 2) the enlarged and hypertrophied caudate lobe in response to BCS has a mass effect over main portal branches and intrahepatic portal venules resulting in stasis and vulnerability to thrombosis and further depleting liver perfusion. In patients with chronic BCS, the portal system is found to be involved in nearly 50% of patients when adequately studied either confined to the liver or as PVT.

The diagnosis of BCS can be made by utilizing Doppler-USG with a sensitivity of more than 85% in most cases<sup>[63]</sup>. We believe that when combined with clinical presentation, Doppler-USG is readily the diagnostic tool of option when compared with CT or MRI techniques. One option that can be applied is directly having a non-invasive venography with CT or MRI (Figure 4) to clear out lesions in inferior vena cava, hepatic veins and portal veins. But this is expensive and not widely available. The portal vein involvement must always be investigated during initial evaluation for further follow-up and management decisions

since portal vein thrombosis has been shown to be a poor prognostic finding<sup>[64]</sup>. The liver biopsy must also be a part of routine evaluation of BCS since it may be related with concomitant liver diseases, but there is no consensus in literature for the definition of an adequate biopsy in BCS. We believe there must be multiple biopsies from both lobes to clearly define, diagnose and estimate prognosis of BCS due to heterogenous nature of liver involvement.

Chronic liver disease eventually develops in nearly all BCS patients depending on the severity of liver involvement, potential of collateral development, co-morbid conditions (especially renal involvement, congestive or ischemic heart disease), thrombosis of other organs, progression of thrombosis in liver. Independent factors predicting survival include Child-Pugh score, age of the patient (younger age predicts better prognosis), renal functions and presence of portal vein involvement.

Management of the patients is directed towards prevention of recurrence of thrombosis and activate the natural thrombolytic potential (anticoagulation and antiplatelet treatment), treatment of complications of liver dysfunction (ascites, infections, renal failure) and relief of hepatic venous obstruction. In this sense, medical treatment has been proved efficacious in patients with an indolent, non-progressive (both histologically and biochemically) course<sup>[65,66]</sup>. The repeated biopsies (in every 4-5 years) combined with biochemical follow-up usually suffices for this purpose. Doppler USG also must be a part of controls for both hepatic and portal venous system evaluations. The risk of anticoagulation and potential bleeding elsewhere including esophageal varices will not be discussed in detail. But we recommend that anticoagulation must be tailored for every patient according to the presence and stage of varices, history of previous bleeding, presence of thrombophilic condition and presence of portal vein thrombosis.

A failing liver with signs of decompensation indicated by refractory ascites, deterioration of Child-Pugh scores and renal failure preventing adequate medical therapy is definite and urgent indications for the need of relief of hepatic venous obstruction by means of vascular interventions including angioplasty, transjugular intrahepatic portosystemic shunt (TIPS) or surgery. TIPS and hepatic vein angioplasty are cost-effective techniques with a potential risk of recurrence of thrombosis<sup>[67,68]</sup>. The effectiveness of vascular interventions has decreased the need for a shunt surgery which is rarely performed now. In selected patients with refractory, progressive disease despite adequate medical therapy and vascular interventions liver transplantation should be an option for absolute treatment. Sometimes presence of portal venous thrombosis itself precludes an angiographic intervention and results in need for a liver transplantation.

Liver transplantation performed for BCS has a five-year survival rate as high as 95%<sup>[69]</sup>. Complications of transplantation are recurrence of thrombosis and development of secondary malignancies due to long-term immunosuppression. The presence of a myeloproliferative disorder underlying the BCS is not accepted as a contraindication for transplantation<sup>[70]</sup>.

## MESENTERIC VEIN THROMBOSIS: ETIOLOGY, CLINICAL CONSEQUENCES

Mesenteric vein thrombosis (MVT) is an acute thrombotic disorder of vessels before formation of main portal vein. Some authors proposed to use the time-dependent definition for MVT, namely acute, subacute and chronic. We believe this classification should be abandoned and the term "MVT" be used for only acute venous obstruction of superior and/or inferior mesenteric veins, whereas chronic MVT itself is already PVT. Subacute thrombosis is an intermediary form of thrombosis in which the patient has abdominal pain and other intestinal symptoms. Therefore, the term MVT is used for acute mesenteric venous thrombosis in the rest of the discussion.

MVT presents itself mostly as a severe abdominal pain located mostly at periumbilical area with a blunt and colicky nature. It may be associated with nausea, vomiting, increased bowel movements and sometimes bloody diarrhea. With progression in time, the clinical picture converts itself into an acute abdomen with findings of rebound tenderness, fever, septicemia and finally a full blown peritonitis which is an inevitable consequence of erroneous diagnosis and treatment. Therefore, early diagnosis and rapid initiation of treatment is mandatory for a good clinical outcome.

### Etiology

With the improving diagnostic tests in thrombophilia research, the number of idiopathic cases has decreased to 20 %. We believe this percentage will also decrease in time with advent of new techniques and development of new concepts of research. Currently the most important risk factors are considered as presence of a large spleen, cirrhosis, surgery, abdominal inflammation (pancreatitis, abscess, inflammatory bowel disease, diverticulitis), intraabdominal cancer, thrombophilic conditions (acquired or inherited). The importance of inherited thrombophilia is difficult to evaluate (sparing mutations like FVLM and PM) since the measurements of PC, PS and AT in the acute thrombosis stage and in the anti-coagulation treatment stage of the disease is not useful. The literature is lacking convincing evidence about the importance and prevalence of these disorders in the setting of MVT. One good example for this topic is the study by Kumar *et al*<sup>[71]</sup>. In this study, the risk factors for MVT (comparing isolated MVT *vs* combined MVT with portosplenic venous thrombosis) are studied and they reported the inherited thrombophilic conditions (PC, PS and AT deficiencies, FVLM) in 27% and 5% of isolated MVT and combined MVT with portosplenic thrombosis, respectively. Interestingly, they found out that the risk of inherited thrombophilia was lower in patients with more extensive vessel involvement. Although the method and criteria of diagnosis of deficiencies of natural anticoagulants are not explained in detail due to retrospective design, this study is important to point the etiology and clinical characteristics of MVT in detail.

Although myeloproliferative disorders play a great role both in PVT and BCS, it does not seem to play the same role in case of MVT. This difference in presentation

between MVT and PVT has important clinical implications for further investigations.

### Consequences

The mortality rate of MVT is about 20-50%, increasing in parallel to the older age and presence of comorbid clinical conditions (cirrhosis, cardiac failure, etc.). We believe the most important factor to determine the morbidity and mortality is the prompt diagnosis and rapid initiation of treatment. Clinical suspicion has utmost importance in early diagnosis due to the obscure nature of the initial clinical presentation. History of venous thrombosis, older age, use of oral contraceptives, presence of other thrombophilic conditions are indications to rule out a possible MVT. Although the gold standard diagnostic modality is a conventional angiography, CT establishes diagnosis in nearly 90 % of patients<sup>[72,73]</sup>.

After diagnosis the treatment must be initiated with anti-coagulation unless the patient has peritoneal irritation findings in which surgery is indicated. The most extensive analysis including 45 studies (a total of 3692 patients) about survival in mesenteric ischemia was performed by Schoots *et al*<sup>[74]</sup>. They found that MVT has a better survival (including study populations requiring surgical resection of bowel and conservative treatment groups) compared to arterial or non-thrombotic ischemia of the bowel. This finding seems to be related with a limited involvement of bowel in MVT.

## CONCLUSION

Thrombophilia has a wide range of clinical presentations but abdominal organs like liver and intestines bear the most important and interesting sequelae. The consequences of thrombophilia like PVT, BCS and MVT are potentially treatable if only diagnosed early and prompt treatments are initiated. With the advent of new technologies in research of thrombophilia, clinicians will be able to diagnose the idiopathic thrombosis group of patients which is a topic of controversy. Although anticoagulant treatment is mandatory, some limitations and contraindications may prevent their use. Lastly, these group of patients must be followed with a consulting surgeon who has experience in this field to decide the best timing for a shunt surgery and for possible acute operation indications.

## Abstract

Hepatocellular carcinoma (HCC) is one of the most frequent malignant tumors and is the second most common cause of cancer death in China. Therefore, it is very important to detect this disease and the recurrence at its earlier period. Serum tumor markers, as the effective method for detecting hepatocellular carcinoma for a long time, could be divided into 4 categories: oncofetal antigens and glycoprotein antigens; enzymes and isoenzymes; genes; and cytokines. Serum alpha fetoprotein (AFP) is the most widely used tumor marker in detecting patients with hepatocellular carcinoma, and has been proven to have capability of prefiguring the prognosis. However, it has been indicated that AFP-L3 and DCP excel AFP in differentiating hepatocellular carcinoma from nonmalignant hepatopathy and detecting small hepatocellular carcinoma. Some tumor markers, such as human cervical cancer oncogene and human telomerase reverse transcriptase mRNA, have also been indicated to have higher accuracies than AFP. Furthermore, some other tumor markers, such as glypican-3, gamma-glutamyl transferase II, alpha-L-fucosidase, transforming growth factor-beta1, tumor-specific growth factor, have been indicated to be available supplementaries to AFP in the detection. AFP mRNA has been shown to correlate with the metastasis and recurrence of HCC, and it may be the most useful marker to prefigure the prognosis. Some other markers, such as gamma-glutamyl transferase mRNA, vascular endothelial growth factor, and interleukin-8, could also be used as available prognostic indicators, and the simultaneous determination of AFP and these markers may detect the recurrence of HCC at its earlier period.

**Key words:** Hepatocellular carcinoma; Serum tumor markers; Sensitivity; Specificity; Prognosis

## INTRODUCTION

Hepatocellular carcinoma (HCC), one of the most frequent malignant tumors, is the second common cause of cancer death in China, where its mortality rate is 20.37/100 thousand<sup>[1]</sup>. Surgical resection is the most effective method for curing this disease, but a large amount of cases are not adapted to surgery because of their intrahepatic or distant metastases at the time of diagnosis. Furthermore, the long-term survival of postoperative HCC patients is unsatisfactory for the high incidence of recurrence. Therefore, it is very important to detect HCC and the recurrence at its earlier period. By reasons of convenience, inexpensiveness, and the satisfactory accuracy, serum tumor markers have been used as an effective method for detecting malignant tumors for a long time, and they could be valuable supplementaries to ultrasonography and computer tomography in the diagnosis of HCC. Using the appropriate single or combination of tumor markers may improve the effectiveness in screening HCC patients.

## ONCOFETAL ANTIGENS AND GLYCOPROTEIN ANTIGENS

### *Alpha-fetoprotein and alpha-fetoprotein-L3*

Alpha fetoprotein (AFP) is a fetal specific glycoprotein produced primarily by the fetal liver. Normally, its serum concentration falls rapidly after birth and its synthesis in adult life is repressed. However, greater than 70% of HCC patients have a high serum concentration of AFP because of the tumor excretion. Forty years after its discovery, serum AFP remains a most useful tumor marker in screening HCC patients. The serum concentration of 20 ng/mL is the most commonly used cut-off value to differentiate HCC patients from healthy adults in clinical researches. However, some investigations have showed that the cut-off value is fluctuant in different ethnic groups.

The best cut-off value of AFP has been reported to be 30 ng/mL (sensitivity of 65%, specificity of 89%) in Sicilian population compared with 200 ng/mL (sensitivity of 70%, specificity of 100%) in Burman population<sup>[2,3]</sup>. One of possible reasons for this difference is the diverse living circumstance which has a great influence on epidemiology. Besides the purpose of screening HCC, serum and tissues AFP could also be used as prognostic indicators<sup>[4]</sup>. HCC patients with a high AFP concentration ( $\geq 400$  ng/mL) tend to have greater tumor size, bilobar involvement, massive or diffuse types, portal vein thrombosis, and a lower median survival rate<sup>[5,6]</sup>. This is partially caused by the expression of ephrin-A1 (an angiogenic factor) and the ability of AFP to elicit the escape of carcinoma cells from the host's lymphocytes immune surveillance<sup>[7,8]</sup>. Though the measurement of AFP serves as an important tool in screening HCC patients, some reports have indicated that it has limited utility of differentiating HCC from benign hepatic disorders for its high false-positive and false-negative rates, and patients with acute exacerbation of viral hepatitis but no HCC may also have markedly increased AFP levels<sup>[9]</sup>. Using the cut-off value of 20 ng/mL to differentiate HCC from HCV-infected patients, sensitivities merely range from 41% to 65% with specificities of 80% to 94% correspondingly<sup>[10]</sup>. Moreover, the positive predictive value (PPV) of AFP is significantly lower in detecting HCC patients with viral etiology than that in detecting HCC patients with non-viral etiology (70% *vs* 94%,  $P < 0.05$ ), and it will not reach 100% in HCC patients with viral etiology unless their serum concentration of AFP is greater than 400 ng/mL<sup>[2,11]</sup>. Therefore, AFP is more useful in detecting HCC patients with non-viral etiology.

Total AFP can be divided into three different glycoforms, namely AFP-L1, AFP-L2 and AFP-L3, according to their binding capability to lectin lens culinaris agglutinin (LCA). AFP-L1, as the non-LCA-bound fraction, is the major glycoform of AFP in the serum of nonmalignant hepatopathy patients. On the contrary, AFP-L3, as the LCA-bound fraction, is the major glycoform of AFP in the serum of HCC patients, and it can be detected in approximately 35% of patients with small HCC ( $< 3$  cm), especially when the tumor mass is supplied by the hepatic artery. At the cut-off level of 15%, sensitivities of AFP-L3 in detecting HCC range from 75% to 96.9% with specificities of 90% to 92.0% correspondingly<sup>[3,12]</sup>. Furthermore, some clinical researches have indicated that the high percentage of AFP-L3 is closely related to poor differentiation and biologically malignant characteristics (especially portal vein invasion) of HCC<sup>[12,13]</sup>, and HCC patients with positive AFP-L3 would have worse liver function, poorer tumor histology, and larger tumor mass<sup>[14]</sup>. Compared with those with serum concentration of des-gamma-carboxyprothrombin (DCP) over 100 mAU/mL, HCC patients with percentage of serum AFP-L3 over 15% also showed a higher incidence of infiltrative-type HCC with an irregular margin ( $P < 0.05$ ) and a higher frequency of poorly differentiated HCC ( $P < 0.01$ )<sup>[15]</sup>. Therefore, it could be used as a valuable indicator of poor prognosis.

### Glypican-3

Glypican-3 (GPC3) is a heparan sulfate proteoglycan anchored to the plasma membrane. It has been demonstrated to interact with growth factors and modulate their activities. The expression of GPC3 (at both mRNA and protein levels) in the serum of HCC patients is significantly higher than that in the serum of healthy adults ( $P < 0.001$ ) or patients with nonmalignant hepatopathy ( $P < 0.01$ ), and it can be detected in 40-53% of HCC patients and 33% of HCC patients with seronegative for both AFP and DCP<sup>[16-18]</sup>. Some clinical researches have indicated that the simultaneous determination of GPC3 and AFP could significantly increase the sensitivity in the diagnosis of HCC<sup>[16]</sup>. Furthermore, it has been shown that soluble GPC3 (sGPC3), the NH2-terminal portion of GPC3, is superior to AFP in the sensitivity of detecting well or moderately differentiated HCC, and the simultaneous determination of both markers improves overall sensitivity from 50% to 72%<sup>[17]</sup>. Thus, it can be seen that GPC3 could be a good supplementary to AFP in the detection. Some other investigators have reported that GPC3 mRNA is upregulated significantly in tumor tissues of HCC compared to paraneoplastic tissues of HCC, liver tissues of healthy adults and liver tissues of patients with nonmalignant hepatopathy, thus it could also be a good molecular marker for HCC<sup>[16,19-21]</sup>.

## ENZYMES AND ISOENZYMES

### Gamma-glutamyl transferase

Serum gamma-glutamyl transferase (GGT) in healthy adults is mainly secreted by hepatic Kupffer cell and endothelial cell of bile duct, and its activity increases obviously in tissues of HCC and fetal liver. Total GGT can be divided into 13 isoenzymes (I, I', II, II',  $\beta$ ,  $\delta$ ,  $\epsilon$ ,  $\varphi$ A, VIIb,  $\varphi$ C,  $\gamma$ A,  $\gamma$ B) by using polymeracrylamide gradient gel electrophoresis, and some of them (I', II, II') can only be detected in the serum of HCC patients. Sensitivities of GGTH have been reported to be 74.0% in detecting HCC and 43.8% in detecting small HCC<sup>[22]</sup>. Furthermore, the simultaneous determination of GGTH, DCP, and AFP can significantly improve the sensitivity over AFP alone<sup>[22]</sup>. It should be a valuable tumor marker in detecting small HCC and a good supplementary to AFP in the diagnosis of HCC.

### Alpha-L-fucosidase

Alpha-L-fucosidase (AFU) is a sort of enzyme to hydrolyze fucose glycosidic linkages of glycoprotein and glycolipids. Its activity increases obviously in the serum of HCC patients ( $1\,418.62 \pm 575.76$  nmol/mL per hour) compared with that in the serum of healthy adults ( $504.18 \pm 121.88$  nmol/mL per hour,  $P < 0.05$ ), patients with cirrhosis ( $831.25 \pm 261.13$  nmol/mL per hour), and patients with chronic hepatitis ( $717.71 \pm 205.86$  nmol/mL per hour)<sup>[23,24]</sup>. It has been reported that the sensitivity and specificity of AFU at the cut-off value of 870 nmol/(mL per h) are 81.7% and 70.7%, respectively, in contrast with 39.1% and 99.3% of AFP at the cut-off value of 400 ng/mL, and the

simultaneous determination of both markers can improve the sensitivity to 82.6%<sup>[23]</sup>. This indicates that AFU could serve as a valuable supplementary to AFP in the detection. Furthermore, it has been indicated that HCC will develop within a few years in 82% of patients with liver cirrhosis, if their serum AFU activity exceeds 700 nmol/(mL per h), and the activity of AFU is already elevated in 85% of patients at least 6 months before the detection of HCC by ultrasonography<sup>[24]</sup>. Thus, it can be seen that AFU could be a good tumor marker in detecting HCC at the earlier period.

### **Des-gamma-carboxyprothrombin**

DCP, also known as a protein induced by vitamin K absence or antagonist II (PIVKA-II), is an abnormal product from liver carboxylation disturbance during the formation of thrombogen, and acts as an autologous mitogen for HCC cell lines<sup>[25]</sup>. Its mean serum concentration, which is not correlated to serum levels of AFP, is obviously elevated in HCC patients compared with that in healthy adults and patients with nonmalignant hepatopathy<sup>[26,27]</sup>. Though a few researches have an opposite result<sup>[28]</sup>, serum and tissues DCP have been proved to be more useful than AFP in differentiating HCC from nonmalignant hepatopathy and in detecting patients with small HCC<sup>[6,26,27,29]</sup>. Cui *et al.*<sup>[26]</sup> reported that the sensitivity and specificity of serum DCP (at the most commonly used cut-off value of 40 mAU/mL) in discriminating HCC from cirrhosis were 51.7% and 86.7%, respectively, which were much better than those of AFP at the cut-off value of 20 ng/mL, and 36.84% of patients with small HCC had serum DCP values above this level. Marrero *et al.*<sup>[27]</sup> reported that the sensitivity and specificity of serum DCP (at the cut-off value of 125 mAU/mL) in discriminating HCC from nonmalignant hepatopathy were 89% and 86.7%, respectively, which were much better than those of AFP at the cut-off value of 11 ng/mL. Furthermore, the simultaneous determination of DCP and other tumor markers, such as AFP and AFP-L3, may have a greater accuracy than the determination of each of them alone<sup>[26,30-32]</sup>. It has been reported that the electrochemiluminescence enables measurement of low-concentration of DCP (high-sensitive DCP) in the serum, and the simultaneous determination of high-sensitive DCP (at the cut-off value of 40 mAU/mL), AFP (at the cut-off value of 20 ng/mL), and AFP-L3 (at the cut-off value of 10%) gives the highest accuracy (sensitivity of 82.1%, specificity of 82.4%, and accuracy of 82.2%)<sup>[32]</sup>. Besides the purpose of screening HCC, serum DCP could also be used as a clinicopathological or prognostic indicator for HCC patients, and may be more useful than AFP in reflecting the invasive characteristics of HCC<sup>[28,33,34]</sup>. It has been reported that patients with DCP seropositive and AFP seronegative have a higher frequency of HCC with a distinct margin, large nodule more than 3 cm, few nodules, and moderately to poorly differentiation<sup>[33,34]</sup>. Moreover, the simultaneous determination of serum DCP levels and tissue DCP expression is more valuable than either factor alone in predicting the prognosis of HCC patients<sup>[35]</sup>.

## **GENES**

### **Alpha-fetoprotein mRNA**

Though a few researches have an opposite result<sup>[36]</sup>, HCC cells spread into blood circulation and become the source of recurrence after operation, which may be the primary reason for the unsatisfactory long-term survival after surgery, and the presence of circulating HCC cells may be indicative of metastasis if AFP mRNA is detected in peripheral blood<sup>[37]</sup>. A large number of clinical researches have indicated that serum AFP mRNA detected by reverse-transcription polymerase chain reaction (RT-PCR) may be a valuable indicator of poor prognosis for HCC patients, and its expression is correlated with portal thrombosis, nodules of tumor, tumor diameter, and TNM stage ( $P < 0.05$ )<sup>[38-42]</sup>. The recurrence-free interval of HCC patients with postoperative serum AFP mRNA positivity has been reported to be significantly shorter than that of HCC patients with postoperative negativity (53% *vs* 88% at 1 year, 37% *vs* 60% at 2 years,  $P = 0.014$ )<sup>[42]</sup>, and the recurrence-free survival rates of HCC patients with postoperative serum AFP mRNA positivity have been reported to be significantly lower than those of HCC patients with preoperative positivity (52.6% *vs* 81.8% at 1 year, 15.6% *vs* 54.5% at 2 years, and 0% *vs* 29.2% at 3 years,  $P < 0.001$ )<sup>[43]</sup>. From the result of meta-analysis, the expression of AFP mRNA one week after surgery has also been showed to be correlated with the recurrence of HCC<sup>[44]</sup>. Moreover, the simultaneous determination of AFP mRNA and melanoma antigen gene (MAGE-1) mRNA may have a higher sensitivity and specificity<sup>[41]</sup>.

### **Gamma-glutamyl transferase mRNA**

GGT mRNA can be detected in the serum and liver tissues of healthy adults or patients with HCC, nonmalignant hepatopathy, hepatic benign tumor, and secondary carcinoma of liver. It can be divided into three types: fetal liver (type A), HepG2 cells (type B), and placenta (type C). Type A is predominant in normal liver tissues or liver tissues with nonmalignant hepatopathy, benign tumor, and secondary carcinoma ( $P < 0.05$ ). On the contrary, type B is predominant in cancerous tissues of HCC ( $P < 0.05$ )<sup>[45-48]</sup>. During the development of HCC, the expression of GGT mRNA in liver tissues may shift from type A to type B<sup>[48]</sup>. It has been indicated that HCC patients with positive type B would have a worse outcome, earlier recurrence, and more post-recurrence death ( $P = 0.0107$ )<sup>[49]</sup>. Therefore, the expression of tissues type B may be a valuable indicator of poor prognosis for HCC patients. The same as in liver tissues, the serum levels of type B have also been reported to be significantly higher in HCC patients than in healthy adults ( $P < 0.05$ )<sup>[46]</sup>. Therefore, serum type B may be an available supplementary to AFP in the diagnosis of HCC.

### **Human telomerase reverse transcriptase mRNA**

Human telomerase reverse transcriptase (hTERT) mRNA has been reported to be detectable in the serum of patients with breast cancer. Furthermore, it has also been demonstrated to be a novel and available marker for HCC diagnosis. The expression of hTERT mRNA in the serum

of HCC patients is significantly higher than that in the serum of healthy adults or patients with nonmalignant hepatopathy<sup>[50, 51]</sup>, and the use of newly developed real-time quantitative reverse transcription polymerase chain reaction may improve the effectiveness of determination<sup>[50]</sup>. It has been reported that the sensitivity and specificity of hTERT mRNA in detecting HCC are 88.2% and 70.0%, respectively, which excel those of conventional tumor markers, such as AFP mRNA, AFP and DCP<sup>[50]</sup>. Moreover, it has been indicated that the expression of serum hTERT mRNA, which is associated with the serum concentration of AFP, tumor size, and tumor differentiation degree ( $P < 0.001$ , each), may be a valuable indicator of poor prognosis for HCC patients<sup>[50, 51]</sup>.

There are some other markers in this category, which could be used as diagnostic or prognostic indicators for HCC. It has been reported that the simultaneous determination of p53 antigen and anti-p53 antibodies has a sensitivity of 41.1% in the diagnosis of HCC<sup>[52]</sup>, and the over-expression of p53 in the serum or liver tissues of HCC patients prefigures the poorer prognosis and a shorter survival time ( $P = 0.0014$ )<sup>[52-56]</sup>. HCC patients with positive MAGE-1 or MAGE-3 mRNA die earlier because of metastasis or recurrence<sup>[57]</sup>. The sensitivity and specificity of serum human cervical cancer oncogene (HCCR) at the cut-off value of 15  $\mu\text{g/mL}$  in detecting HCC are 78.2% and 95.7%, respectively. Moreover, its sensitivities could achieve 76.9% in detecting HCC patients with seronegative for AFP and 69.2% in detecting HCC patients with tumor size less than 2 cm<sup>[58]</sup>.

## CYTOKINES

### **Vascular endothelial growth factor**

Vascular endothelial growth factor (VEGF) is a secreted homodimeric cytokine that positively regulates tumor neovascularization<sup>[59]</sup>. Recent researches have suggested that angiogenesis is essential in tumor growth and progression, including that of HCC, which are typically characterized by a high level of vascularization<sup>[60-62]</sup>. In fact, it has been shown that the expressions of VEGF in cancerous tissues of HCC and HCC with microscopic venous invasion are significantly higher than that in normal liver tissues and HCC without microscopic venous invasion ( $P < 0.05$ ), and HCC patients with over-expression of VEGF have a lower survival rate ( $P < 0.05$ )<sup>[63, 64]</sup>. Platelets have been reported to act as transporters of tumor-originated VEGF. It has been indicated that serum VEGF per platelet count, as an indirect theoretical estimate of VEGF in platelets, in HCC patients is significantly higher than that in healthy adults and patients with nonmalignant hepatopathy ( $P < 0.01$ ), and the high serum VEGF per platelet count ( $> 1.4 \text{ pg}/10^6$ ) is associated with advanced stage of HCC, portal vein thrombosis, poor response to treatment, and shorter overall survival ( $P < 0.01$ )<sup>[65]</sup>. Therefore, it may be an available diagnostic or prognostic indicator for HCC.

### **Interleukin-8**

Interleukin-8 (IL-8) is a multifunctional CXC chemokine that affects human neutrophil functions, including

chemotaxis, enzyme release, and expression of surface adhesion molecules. It has direct effects on tumor and vascular endothelial cell proliferation, angiogenesis, and tumor migration. Recent researches have indicated that IL-8 regulates tumor cell growth and metastasis in liver<sup>[66]</sup>. It has been reported that the preoperative serum IL-8 levels in HCC patients are significantly elevated compared with those in healthy adults ( $17.6 \text{ pg/mL}$  vs  $1.0 \text{ pg/mL}$ ,  $P = 0.046$ ), and its high serum levels correlate with a large tumor size ( $> 5 \text{ cm}$ ), absence of tumor capsule, presence of venous invasion, advanced pathological tumor-node-metastasis stage, and a poorer disease-free survival<sup>[67]</sup>. Therefore, it may be an available diagnostic or prognostic indicator for HCC.

### **Transforming growth factor-beta 1**

Transforming growth factor-beta1 (TGF- $\beta$ 1) is a negative growth factor which correlates with cellular immunosuppression during the progression of HCC, and its serum levels in HCC patients have been shown to be obviously elevated compared with those in healthy adults and patients with nonmalignant hepatopathy ( $P < 0.0001$ )<sup>[68, 69]</sup>. At the cut-off value of 800  $\text{pg/mL}$ , the specificity of serum TGF- $\beta$ 1 in detecting HCC has been reported to be over 95% which is similar to AFP at the cut-off value of 200  $\text{ng/mL}$ , but the sensitivity of serum TGF- $\beta$ 1 is 68% which excels AFP with the sensitivity of 24%<sup>[68]</sup>. Moreover, the elevated serum TGF- $\beta$ 1 can be detected in 23% of HCC patients with normal serum AFP values<sup>[69]</sup>. These researches have indicated that TGF- $\beta$ 1 may be a good supplementary to AFP in the diagnosis of HCC.

### **Tumor-specific growth factor**

Malignant tumor can release tumor-specific growth factor (TSGF), which results in blood capillary amplification surrounding the tumor, into peripheral blood during its growing period. Therefore, the serum levels of TSGF can reflect the existence of tumor. It has been indicated that TSGF can be used as a diagnostic marker in detecting HCC, and its sensitivity can reach 82 % at the cut-off value of 62 U/mL<sup>[70]</sup>. Furthermore, the simultaneous determination of TSGF and other tumor markers has been shown to give a higher accuracy. It has been reported that the simultaneous determinations of TSGF, AFP, CEA, TSA, and serum ferritin have a sensitivity of 97.5%<sup>[70]</sup>, and the simultaneous determinations of TSGF (at the cut-off value of 65 U/mL), AFP (at the cut-off value of 25  $\text{ng/mL}$ ) and serum ferritin (at the cut-off value of 240  $\mu\text{g/mL}$ ) have a sensitivity of 98.4% and specificity of 99%<sup>[71]</sup>.

There are some other markers, which could be used as diagnostic or prognostic indicators for HCC, in this category. It has been reported that the determination of serum insulin-like growth factor-II (IGF-II) (at the cut-off value of 4.1  $\text{mg/g}$ , prealbumin) has a sensitivity of 63%, specificity of 90%, and accuracy of 70% in the diagnosis of small HCC. Moreover, the simultaneous determination of IGF-II and AFP (at the cut-off value of 50  $\text{ng/mL}$ ) can improve the sensitivity to 80% and accuracy to 88%<sup>[72]</sup>. The over-expression of granulin-epithelin precursor (GEP) in cancerous tissues of HCC is associated with venous infiltration and early intrahepatic recurrence ( $P < 0.05$ )<sup>[73]</sup>.

## CONCLUSION

Serum AFP is the most widely studied screening test for detecting HCC. The normal range for serum AFP levels is 10-20 ng/mL and a level >400 ng/mL is usually regarded as diagnostic. Furthermore, some reports have indicated that the high serum concentration of AFP correlates with the poor prognosis of HCC patients. However, two thirds of HCC patients with the nodule less than 4 cm have serum AFP levels less than 200 ng/mL and up to 20% HCC patients do not produce AFP<sup>[74]</sup>. Moreover, it has limited utility of differentiating HCC from benign hepatic disorders for the high false-positive and false-negative rates. Serum AFP-L3 and DCP are also widely used as tumor markers for HCC, and have been indicated to be more valuable than AFP in differentiating HCC from nonmalignant hepatopathy, detecting small HCC, and predicting the prognosis. Considering the large population with cirrhosis and chronic hepatitis in our country, AFP-L3 and DCP may be more useful than AFP in the diagnosis of HCC. hTERT mRNA and HCCR have been shown to have a higher accuracy than AFP in detecting HCC, but there are not enough researches to manifest their superiority. Therefore, they may not be the first choice in the detection of HCC. IGF-II has been reported to be more valuable than AFP in the diagnosis of small HCC, however, more studies are needed to demonstrate its superiority. There are some serum markers, such as GPC3, GGT II, AFU, TGF- $\beta$ 1, and TSGF, that have been indicated to be available supplementaries to AFP and DCP in the detection of HCC, and some of them even can be detected in HCC patients with seronegative for both AFP and DCP, the simultaneous determination of these markers may improve the accuracy. Serum AFP mRNA, which has been shown to be correlated with the metastasis and recurrence of HCC, may be the most useful marker to prefigure the prognosis of HCC patients. Some other markers, such as p53, MAGE-1, MAGE-3, GGT mRNA, VEGF, GEP, and IL-8, have also been indicated to be able to serve as prognostic indicators of HCC patients, the simultaneous determination of AFP and these markers may discover the recurrence of HCC at earlier period. In addition, there are some tumor markers, such as CYFRA 21-1<sup>[75]</sup>, activin-A<sup>[76]</sup> and proliferating cell nuclear antigen<sup>[54,77,78]</sup>, which do not belong to each of the categories above, but they can also be used as prognostic or screening indicators for HCC patients, especially when combined with AFP.

In a word, AFP, AFP-L3 and DCP are the most useful serum tumor markers for the detection of HCC, and the simultaneous determination of these markers could improve the accuracy, especially in differentiating HCC from nonmalignant hepatopathy. Other tumor markers, which have been mentioned in our review, could be used as supplementaries to AFP and DCP in the diagnosis of HCC, but each of them has no satisfactory accuracy in detecting HCC or prefiguring the prognosis when used alone.

## Abstract

**AIM:** To identify the clinicopathological characteristics of lymph node-negative gastric carcinoma, and also to evaluate outcome indicators in the lymph node-negative patients.

**METHODS:** Of 2848 gastric carcinoma patients, 1524 (53.5%) were lymph node-negative. A statistical analysis was performed using the Cox model to estimate outcome indicators.

**RESULTS:** There was a significant difference in the recurrence rate between lymph node-negative and lymph node-positive patients (14.4% vs 41.0%,  $P < 0.001$ ). The 5-year survival rate was significantly lower in lymph node-positive than in lymph node-negative patients (31.1% vs 77.4%,  $P < 0.001$ ). Univariate analysis revealed that the following factors influenced the 5-year survival rate: patient age, tumor size, depth of invasion, tumor location, operative type, and tumor stage at initial diagnosis. The Cox proportional hazard regression model revealed that tumor size, serosal invasion, and curability were independent, statistically significant, prognostic indicators of lymph node-negative gastric carcinoma.

**CONCLUSION:** Lymph node-negative patients have a favorable outcome attributable to high curability, but the patients with relatively large tumors and serosal invasion have a poor prognosis. Curability is one of the most reliable predictors of long-term survival for lymph node-negative gastric carcinoma patients.

## INTRODUCTION

The presence or absence of lymph node metastasis is one of the most important prognostic indicators among several clinicopathological factors that influence the prognosis of patients with gastric carcinoma<sup>[1-4]</sup>. Several studies have been conducted to identify prognostic indicators in patients with lymph node-negative gastric carcinoma, but these studies have involved small numbers of patients<sup>[5-9]</sup>. In the present study, we compared lymph node-negative patients with lymph node-positive ones to identify the clinicopathological characteristics of lymph node-negative gastric carcinoma. We also evaluated outcome indicators for lymph node-negative carcinoma.

## MATERIALS AND METHODS

### Patients and specimens

From 1986 to 2000, 2848 patients with gastric carcinoma were treated in the Division of Gastroenterologic Surgery, Department of Surgery, Chonnam National University Medical School, Gwangju, Korea. Of these, 1524 (53.5%) were in the lymph node-negative group.

The clinicopathologic features of these patients with lymph node-negative gastric carcinoma were retrospectively reviewed. Information on the patient's age, sex, tumor size, tumor location, macroscopic appearance, depth of invasion, hepatic metastasis, peritoneal dissemination, stage at the initial diagnosis, operative type, recurrence pattern, curability, and survival rate was obtained from the hospital records. The American Joint Committee on Cancer (AJCC) TNM Staging system was used for clinical and pathologic staging<sup>[10]</sup>. Histological evaluation was performed according to the Japanese General Rules for Gastric Cancer Study in Surgery and Pathology<sup>[11]</sup>.

### Statistical analysis

The survival rates of the patients were calculated using the Kaplan-Meier method and the relative prognostic

importance of the parameters was investigated using the Cox proportional hazards model. The  $\chi^2$  was used to evaluate the statistical significance of differences and *P* values less than 0.05 were considered statistically significant.

## RESULTS

Table 1 summarizes the clinical findings in 1524 (53.5%) patients with lymph node-negative gastric carcinoma and 1324 (46.5%) patients with lymph node-positive gastric carcinoma. There was no significant difference in the mean age between lymph node-negative and lymph node-positive patients (56.9 vs 57.1 years, respectively). Of the 1524 patients with lymph node-negative gastric carcinoma, 988 (64.8%) were male and 536 (35.2%) were female. There were 889 males (67.1%) and 435 females (32.9%) in the group of 1324 lymph node-positive patients. Although there were more males than females in each group, the gender ratio was the same in both groups. Dissection above the D2 lymph node was performed in most patients in each group (82.8% and 81.4% of the lymph node-positive and lymph node-negative patients, respectively). Subtotal gastrectomy was the procedure performed most frequently (80.4%) in patients with lymph node-negative gastric carcinoma. The curative resection rate was significantly higher (97.9%, 1492/1534) in lymph node-negative patients than in node-positive patients (77.3%; 1,024/1,324; *P* < 0.001), and the recurrence rate was significantly lower (14.4%) in lymph node-negative than in lymph node-positive patients (41.1%; *P* < 0.001). Peritoneal recurrence was the predominant type of recurrence in both groups.

The histopathological features are listed in Table 2. The mean tumor size in patients with lymph node-negative

gastric carcinoma (2.9 cm) was significantly smaller than that in lymph node-positive patients (5.0 cm; *P* < 0.001). Most gastric carcinomas were located in the lower third of the stomach in both lymph node-negative (946 cases; 62.1%) and lymph node-positive patients (783 cases; 59.1%). There were no significant differences between the groups with respect to the locations of the carcinomas. An invasion depth limited to T2 was found more frequently in patients with lymph node-negative (75.3%) than in lymph node-positive patients (21.3%; *P* < 0.001). Hepatic metastases were found in 0.3% of the lymph node-negative patients and in 4.2% of the lymph node-positive patients. Peritoneal dissemination was present in 1.0% of the lymph node-negative patients and in 11.0% of the lymph node-positive patients. There was a significant difference between the groups in the number of cases with

hepatic metastases and peritoneal dissemination. Poorly differentiated adenocarcinoma was found more frequently in patients with lymph node-positive gastric carcinoma than in lymph node-negative patients (48.5% *vs* 35.1%,  $P<0.001$ ). Of the lymph node-negative patients, 1470 (96.4%) were classified as either stage I or II at the time of initial diagnosis.

The overall survival rate of the lymph node-negative patients (77.4%) was higher than that of the lymph node-positive patients (31.1%;  $P<0.001$ ) (Figure 1). The 5-year survival rate of patients with early lymph node-negative gastric carcinoma was significantly higher than that of patients with early lymph node-positive gastric carcinoma (93.3% *vs* 84.3%,  $P=0.0147$ ). Patients with advanced lymph node-negative gastric carcinoma also had a significantly higher 5-year survival rate than that of patients with advanced lymph node-positive gastric carcinoma (66.9% *vs* 33.1%,  $P<0.001$ ). The clinicopathological variables tested by univariate analysis are shown in Table 3. The factors that influenced the 5-year survival rate were patient's age, tumor size, depth of invasion, tumor location, operative type, and tumor stage at initial diagnosis. Using the Cox proportional hazard regression model, tumor size, presence of serosal invasion, and

## DISCUSSION

In Korea, gastric carcinoma is the leading cause of death as a result of a malignant neoplasm. Although most patients with lymph node-negative gastric carcinoma have a better prognosis than lymph node-positive ones, some lymph node-negative patients have recurrence and poor survival. The identification of factors associated with poor survival in patients with lymph node-negative gastric carcinoma is important. In this study, we compared node-negative and node-positive patients in order to identify the clinicopathological characteristics of lymph node-negative gastric carcinoma. We also evaluated outcome indicators in lymph node-negative patients.

In addition to lymph node invasion, the depth of wall invasion emerged as one of the most important prognostic indicators of lymph node-negative gastric carcinoma<sup>[12]</sup>. Adachi *et al*<sup>[13]</sup> reported that the depth of wall invasion provided useful prognostic information in patients with gastric carcinoma. In the present study, serosal invasion also emerged as a statistically significant independent prognostic indicator using the Cox proportional hazard regression model.

Whether age is a prognostic indicator for lymph node-negative gastric carcinoma is controversial<sup>[13,14]</sup>. Moriguchi *et al*<sup>[15]</sup> reported that age at operation was a significant prognostic indicator in patients with early gastric carcinoma. Similarly, Adachi *et al*<sup>[13]</sup> reported that patient's age was the second most important prognostic indicator in patients with lymph node-negative gastric carcinoma. Furthermore, some investigators have reported that survival rates were lower in elderly patients with gastric carcinoma<sup>[16,17]</sup>. Contrary to the aforementioned reports, our study of patients with lymph node-negative gastric carcinoma revealed that age did not affect the survival rate.

Whether tumor size independently correlates with the prognosis for gastric carcinoma is also controversial. In the present study, there was a significant difference in tumor size between lymph node-negative and lymph node-positive patients (2.9cm *vs* 5.0cm), and node-negative patients with large tumors had poor survival. Some investigators have stressed that tumor size is an

independent prognostic indicator for gastric carcinoma, whereas others believe that tumor size does not independently influence survival. Adachi *et al*<sup>[13]</sup> reported that tumor size served as a simple prognostic indicator for gastric carcinoma. By contrast, Yokota *et al*<sup>[18]</sup> reported that the presence of lymph node metastasis, depth of invasion, and tumor location were more important prognostic indicators than tumor size. Maruyama<sup>[2]</sup> reported findings that supported the conclusions of Yokota *et al*.

Surgical resection is the only potentially curative modality for localized gastric carcinoma. Adachi *et al*<sup>[13]</sup> stated that it was reasonable to conclude that the extent of lymph node dissection did not influence the survival of patients without lymph node metastasis. They stressed that the macroscopic diagnosis of lymph node involvement was unreliable and recommended D2 lymph node dissection for curative treatment of node-negative gastric carcinoma. Harrison *et al*<sup>[19]</sup> also recommended extended lymph node dissection for the improvement of survival of patients with lymph node-negative gastric carcinoma. We concurred with the aforementioned recommendations, and performed dissection above the D2 lymph node in most patients with lymph node-negative gastric carcinoma. In accordance with most reports, curative resection offered the only chance of long-term survival. In our series, this approach allowed us to achieve a high rate of curative resection (97.0%) and favorable outcomes in the lymph node-negative patients.

In this study, 5-year survival rates were different between patients with lymph node-negative and lymph node-positive gastric carcinoma. The 5-year survival rate was significantly lower for lymph node-positive patients than for lymph node-negative ones (35.8% *vs* 79.2%). Bruno *et al*<sup>[8]</sup> and Harrison *et al*<sup>[19]</sup> reported overall survival rates of 72% and 79%, respectively, for patients with lymph node-negative gastric carcinoma. Many factors influence the 5-year survival rate. Yokota *et al*<sup>[20]</sup> reported that tumor size, vascular microinvasion, and the cancer-stromal relationship were the most reliable predictors of 5-year survival for patients with lymph node-negative gastric carcinoma, while Adachi *et al*<sup>[21]</sup> reported that depth of wall invasion and patient's age were the most important prognostic

indicators. Bruno *et al*<sup>[8]</sup> found that serosal invasion, residual disease, and poor differentiation were independent prognostic indicators of gastric carcinoma. Our univariate analysis revealed that age, tumor size, depth of invasion, tumor location, operative type, and tumor stage at initial diagnosis were prognostic indicators of lymph node-negative gastric carcinoma. In addition, in the present study, the Cox proportional hazard regression model revealed that tumor size, presence of serosal invasion, and curability were prognostic indicators of lymph node-negative gastric carcinoma.

In conclusion, we found that lymph node-negative gastric carcinoma is associated with a favorable outcome. We also found that tumor size, serosal invasion, and curative resection are the most reliable predictors of long-term survival for patients with lymph node-negative gastric carcinoma.

## Abstract

**AIM:** To understand the role of P120ctn in E-cadherin-mediated cell-cell adhesion and signaling as well as in hepatoma cell biological function.

**METHODS:** We stably overexpressed p120ctn isoform 3A in BEL-7404 human hepatoma cells and studied the effect of p120ctn on  $\beta$ -catenin and E-cadherin binding as well as p120ctn and  $\beta$ -catenin subcellular localization using immunoprecipitation, Western blotting and confocal microscopy. We also investigated the inhibitory effect of p120ctn transfection on the expression of apoptotic protein survivin and cell cycle regulator cyclin D1 in the cells.

**RESULTS:** Western blotting indicated that p120ctn expression increased after cells were transfected with p120ctn isoform 3A. The protein was located mainly at membrane under immunofluorescent microscope.  $\beta$ -catenin nuclear expression was reduced after overexpression of p120ctn isoform 3A. The p120ctn-E-cadherin binding increased after transfection of p120ctn isoform 3A. Furthermore, overexpression of p120ctn down regulated the expression of apoptotic protein survivin and cell cycle regulator cyclin D1. These effects led to reduction of cell proliferation.

**CONCLUSION:** Our results indicate that p120ctn plays an important role in regulating the formation of E-cadherin and  $\beta$ -catenin complex, cell apoptosis, cell cycle and cancer cell biological function.

## INTRODUCTION

P120ctn is a catenin family member<sup>[1,2]</sup>. Studies indicated that p120ctn plays an important role in E-cadherin-mediated epithelial cell adhesion and cell signaling<sup>[3-6]</sup>. Recent studies demonstrated that p120ctn plays a critical role in certain cancerous diseases<sup>[7-13]</sup>. Nuclear translocation of  $\beta$ -catenin is correlated with tumor progression and has been defined as an oncogene<sup>[14]</sup>. P120ctn acts as a modulator in E-cadherin-mediated cell-cell adhesion and signaling including  $\beta$ -catenin turnover<sup>[11,15]</sup>. However, the exact role of p120ctn in cell biological function remains unclear. Tyrosine phosphorylation of p120ctn enhances its nuclear translocation and displays hepatoma cell malignant features<sup>[16,17]</sup>. In order to further understand the role of p120ctn in E-cadherin-mediated cell biological function and its mechanism, we studied the effects of p120ctn overexpression on  $\beta$ -catenin subcellular localization, regulation of cell cycle and apoptotic proteins as well as cell proliferation in hepatoma cells.

## MATERIALS AND METHODS

### Cell culture

BEL-7404 human hepatoma cell line was purchased from the Institute of Biochemistry and Cell Biology, Chinese Academy of Sciences in Shanghai. Cells were maintained in RPMI 1640 medium (Gibco BRL, Grand Island, NY, USA) supplemented with 100 mL/L of fetal bovine serum, 10000 U/L of penicillin and 10000  $\mu$ g/L of streptomycin, in humidified atmosphere containing 50 mL/L of CO<sub>2</sub> at 37 °C.

**Figure 1** Western blotting (A) and confocal microscopy (B) showing increased expression of p120ctn and its subcellular localization after cells transfected with p120ctn isoform 3A.

### DNA transfection

P120ctn isoform 3A plasmid and empty vector were a generous gift from Dr. Albert B. Reynolds in the department of Cancer Cell Biology, Vanderbilt University, USA. Plasmid DNA was propagated using a conventional protocol. Lipofectamine transfection reagent (Gibco BRL) was used following the manufacturer's instructions. G418 (Gibco BRL) was used as a selection antibiotic.

### Immunoprecipitation and Western blot

Cells were lysed in lysis buffer containing 40 mmol/L  $\text{Na}_2\text{PO}_4$  (pH 7.2), 250 mmol/L NaCl, 50 mmol/L NaF, 5 mmol/L EDTA, 10 mL/L Triton X-100, 10 mL/L deoxycholate (Sigma-Aldrich, St. Louis, MO, USA) for 20 min on ice. Cellular debris and nuclei were removed by centrifugation at 13 000 r/min for 15 min at 4 °C. Protein concentration was determined using Bio-Rad protein assay kit (Bio-Rad Laboratories, Hercules, CA, USA), 1 000 μg of total protein from each sample was immunoprecipitated with 10 μg of anti-E-cadherin monoclonal antibody (BD Pharmingen, San Diego, CA, USA), and 50 μL of protein G agarose (Gibco BRL) was added and samples were mixed by rotation at 4 °C for 1 h. The beads were pelleted and washed four times, then 50 μL of 2×SDS sample buffer was added and boiled for 5 min, and 30 μL of supernatant was loaded to SDS-PAGE gel for protein resolving. Proteins were then transferred to PVDF membrane (Bio-Rad) and incubated with anti-p120ctn (BD Pharmingen), anti-β-catenin (BD Pharmingen) or anti-survivin (Santa Cruz Biotechnology, Santa Cruz, CA, USA) and anti-cyclin D1 (Santa Cruz) for Western blotting at 4 °C overnight. Membranes were incubated with HRP-conjugated secondary antibody at room temperature for 1 h, and illuminated by ECL solution (Amersham Biosciences, Piscataway, NJ, USA). Protein bands were visualized using Kodak X-ray film and processed by Kodak film processor (Kodak, Rochester, NY, USA).

### Confocal microscopy

Cells were grown on coverslips coated with poly lysine or laminin. The cover slips were rinsed with PBS, then fixed with 12 g/L of formaldehyde at room temperature for 15 min, followed by blocking with 30 mL/L BSA at room temperature for 30 min, the cover slips then were incubated with primary antibodies for 1 h at room temperature and were washed with TBS-T and incubated with FITC-conjugated secondary antibody for 1 h at room temperature. The cover slips were mounted on slides and examined under a Leica laser confocal microscope.

### Cell proliferation assay

A total of 200 000 of different types of cells were seeded into 60 mm dishes and grown for 3 d. Cells were trypsinized and trypan blue exclusion assay was used in cell counting. Experiment was performed in triplicate.

## RESULTS

### P120ctn expression after transfection

BEL-7404 cells were stably transfected with p120ctn isoform 3A, and the transfection efficiency was determined by Western blotting using mouse anti-p120ctn antibody. The result showed that the expression of p120ctn increased after transfection (Figure 1A). Confocal microscopy result indicated that membranous and cytoplasmic expression of the protein increased mainly at cell-cell contact region (Figure 1B).

### Effect of transfection on the binding of p120ctn to E-cadherin

In order to understand the effect of p120ctn overexpression on the binding of p120ctn to E-cadherin, we immunoprecipitated E-cadherin and immunoblotted it with anti-p120ctn. The result showed that the level of p120ctn in E-cadherin-p120ctn complex was increased (Figure 2).

**Figure 2** Binding of p120ctn to E-cadherin after cells transfected with p120ctn isoform 3A.

**Figure 4** Binding of β-catenin to E-cadherin after cells transfected with p120ctn isoform 3A.

**Figure 3** Changes of β-catenin subcellular localization after cells transfected with p120ctn isoform 3A.

#### Subcellular relocation of β-catenin after overexpression of p120ctn

In order to understand the relationship between p120ctn and β-catenin in E-cadherin-mediated cell adhesion and signaling, we examined the alteration of β-catenin subcellular localization after overexpression of p120ctn isoform 3A under confocal microscope. Figure 3 shows the changes of β-catenin expression pattern, namely the obvious expression of membranous protein and the reduction of nuclear expression.

#### Effect of p120ctn overexpression on the binding of β-catenin to E-cadherin

Since overexpression of p120ctn reduced the nucleic but increased membranous β-catenin expression, we immunoprecipitated E-cadherin and immunoblotted it with anti-β-catenin. The result showed that the expression level of β-catenin in E-cadherin and β-catenin complex increased after p120ctn isoform 3A transfection (Figure 4).

#### P120ctn transfection down regulated survivin expression

Survivin could be highly expressed in cancer but undetectable in nonproliferating normal adult tissues<sup>[18-20]</sup>. Our Western blot result showed that overexpression of p120ctn reduced survivin expression, in some extent, in the cells (Figure 5A).

#### P120ctn expression down regulated cyclin D1 expression

We performed Western blotting to detect cyclin D1 expression after cells were transfected with p120ctn isoform 3A. The result indicated that cyclin D1 was down regulated after transfection (Figure 5B).

#### Effect of p120ctn transfection on cell proliferation

Our above results showed that overexpression of

**Figure 5** Down regulation of survivin (A) and cyclin D1 (B) expression after transfection of p120ctn.

p120ctn could reduce β-catenin nuclear expression, enhance binding of p120ctn and β-catenin to E-cadherin. Moreover, overexpression of p120ctn isoform 3A could down regulate survivin and cyclin D1 expression in cells. Thus, the effect of p120ctn overexpression on the proliferation of BEL-7404 hepatoma cells was examined. Using trypan blue exclusion cell counting method, we found that transfection of p120ctn decreased cell proliferation (Figure 6).

## DISCUSSION

P120ctn binds to the cytoplasmic tail of E-cadherin in epithelial cells<sup>[1,4]</sup>. Studies indicated that perturbing p120ctn-E-cadherin binding can lead to nuclear translocation and affect cell biological behavior<sup>[21-23]</sup>,

Figure 6 Effect of p120ctn transfection on cell proliferation.

suggesting that p120ctn acts as an oncogenic protein like  $\beta$ -catenin. On the other hand, alterations in E-cadherin and its cytoplasmic regulators, catenins, have been implicated as central to this process, and p120-catenin is frequently altered and/or lost in tumors of the colon, bladder, stomach, breast, prostate, lung, and pancreas<sup>[5,11]</sup>. Moreover, loss of p120ctn appears to be an early event in tumor progression, possibly preceding loss of E-cadherin, suggesting that p120 plays a role as a “dual modulator” in different cell types<sup>[5,7]</sup>.

In our study, overexpression of p120ctn isoform 3A could enhance its binding to E-cadherin in BEL-7404 human hepatoma cell line, the expression was mainly found at membrane, and cytoplasmic expression could be seen as a minor event. Our results are consistent with a previous report<sup>[17]</sup>, indicating that p120ctn binds to E-cadherin, forming an E-cadherin-p120ctn adhesion complex.

In order to better understand the relationship between p120ctn and  $\beta$ -catenin in E-cadherin-mediated cell-cell adhesion and signaling in liver cancer cells, we examined  $\beta$ -catenin subcellular localization and its binding to E-cadherin after transfection of p120ctn isoform 3A. Our results showed that  $\beta$ -catenin translocation could be seen after transfection of p120ctn.  $\beta$ -catenin became nuclear “exporting”, namely its nuclear expression was reduced while membranous and cytoplasmic expression was increased. Transfection of p120ctn also increased  $\beta$ -catenin binding to E-cadherin, demonstrating that p120ctn can recruit  $\beta$ -catenin from nucleus to cytoplasm and strengthen the formation of E-cadherin-catenin complex. Since  $\beta$ -catenin is an oncoprotein, it binds to the TCF/LEF transcription factor and triggers cell cycle progression, thus influencing cell biological function. Our results are consistent with a previous report<sup>[22]</sup>. We were unable to detect other pathways of the turnover of nuclei-exported  $\beta$ -catenin, such as APC or ubiquitinous degradation pathway due to certain study limitations.

It was reported that  $\beta$ -catenin and p120ctn play an important role in cell proliferation, and TCF/ $\beta$ -catenin signaling participates in regulation of survivin transcription in colon cancer<sup>[23,24]</sup>. Monoclonal anti-Wnt-2 antibody induces melanoma cell apoptosis by inactivating survivin<sup>[25]</sup>. Pizem *et al*<sup>[26]</sup> reported that the expression of survivin is associated with aberrant activation of the WNT (wingless) pathway in medulloblastoma patients. Our results indicated that overexpression of p120ctn could down regulate survivin expression, which could be

explained by the fact that survivin is reduced due to the recruitment of  $\beta$ -catenin to E-cadherin- $\beta$ -catenin complex and the free portion of  $\beta$ -catenin could be degraded by APC and ubiquitization after p120ctn overexpression, leading to decrease of nuclear  $\beta$ -catenin and transcription factor inactivation.

$\beta$ -catenin plays an important role in cell biological function<sup>[27,28]</sup>. It was reported that cyclin D1 transcription involves Wnt signaling in gastric cancer cell line<sup>[29]</sup>. In skeletal myocytes, beta-catenin overexpression increases proliferation and cyclin D1 expression while decreases apoptosis and induces hypertrophy<sup>[30]</sup>. It has been shown that in HeLa and squamous cells, differentiation-inducing factor-1 inhibits tumor cell proliferation and reduces the expression of cyclin D1 mRNA and the amount of beta-catenin<sup>[31]</sup>, suggesting that there is a close correlation between  $\beta$ -catenin and cyclin D1 in tumor cell biology. In our study, transfection of p120ctn isoform 3A could reduce cyclin D1 expression, resulting in the decrease of hepatoma cell proliferation.

In conclusion, overexpression of p120ctn in hepatoma cells can recruit  $\beta$ -catenin from nucleus to membrane and cytoplasm, enhanced E-cadherin-catenin adhesion complex, down regulated apoptosis related protein survivin and cell cycle related protein cyclin D1 expression, and finally, inhibited cell proliferation.

## ACKNOWLEDGMENTS

The authors thank Dr. Albert B. Reynolds, Department of Cancer Biology, Vanderbilt University for providing p120ctn isoform 3A and empty vector.

hMSH2 gene might be responsible for the development of colon cancers. In family members where the exon 7 mutation is not coupled with this missense mutation, colon cancer appears after the age of 40. The association of these two mutations seems to decrease the age of manifestation of the disease into the early thirties.

### Abstract

**AIM:** To screen a suspected Hungarian HNPCC family to find specific mutations and to evaluate their effect on the presentation of the disease.

**METHODS:** The family was identified by applying the Amsterdam and Bethesda Criteria. Immunohistochemistry was performed, and DNA samples isolated from tumor tissue were evaluated for microsatellite instability. The identification of possible mutations was carried out by sequencing the hMLH1 and hMSH2 genes.

**RESULTS:** Two different mutations were observed in the index patient and in his family members. The first mutation was located in exon 7, codon 422 of hMSH2, and caused a change from Glu to STOP codon. No other report of such a mutation has been published, as far as we could find in the international databases. The second mutation was found in exon 3 codon 127 of the hMSH2 gene, resulting in Asp→Ser substitution. The second mutation was already published, as a non-pathogenic allelic variation.

**CONCLUSION:** The pedigree analysis suggested that the newly detected nonsense mutation in exon 7 of the

### INTRODUCTION

According to published data, about 15-20 % of colorectal carcinomas (CRC) follow a familial pattern. Familial adenomatous polyposis coli syndrome (FAP) and its subtypes are responsible for only about 1 % of all CRCs, while hereditary nonpolyposis colon cancer (HNPCC) accounts for approximately 3-8 % of cases<sup>[1-3]</sup>. The characteristic presentation of HNPCC is frequently right-sided localization, the presence of synchronous and metachronous CRCs, and its association with other HNPCC-related extracolonic tumors, including gastric, endometrial, and urinary and biliary tract cancers in afflicted families<sup>[2,3]</sup>. Compared to sporadic colorectal carcinomas, HNPCC has an earlier age of onset, Crohn's disease-like lymphocytic infiltration in tumor tissues, increased mucin production, and a lower degree of histological differentiation<sup>[3-5]</sup>. The classic adenoma-carcinoma sequence can be observed in HNPCC patients as well, but the conversion of polyps to malignant proliferation is accelerated, taking only 1-3 years, as opposed to sporadic adenomas, where this can take as long as 10-15 years<sup>[1]</sup>. The number of polyps in the colon is not so high as in cases of FAP. The genetic background of HNPCC has been identified in the germline defect of DNA mismatch repair genes (MMR). The syndrome is in-

herited in an autosomal dominant fashion, with an estimated penetrance of 80%<sup>[1-3,6]</sup>. At present, seven MMR genes are known (hMLH1, hMLH3, hMSH2, hMSH3, hMSH6, hPMS1, hPMS2); however, the influence of a specific mutation on the pathogenesis of the disease shows great diversity<sup>[7-10]</sup>. In about 90-95% of the cases, germline mutations of the hMLH1 or hMSH2 genes can be demonstrated, while only a low percentage is caused by the mutations of hMSH6, hPMS1 and hPMS2<sup>[1]</sup>. The detection of afflicted families must be initiated by taking a thorough family history, embracing at least three generations, applying the widely accepted Amsterdam and Bethesda Criteria<sup>[6]</sup>. If the diagnosis of HNPCC is further supported by the immunohistology of the MMR proteins, the microsatellite status must be determined. The hallmark of mismatch repair deficiency is microsatellite instability (MSI), variability of the lengths of short repetitive DNA stretches scattered in the genome (microsatellites) compared to normal tissue DNA<sup>[11-14]</sup>. Finally, sequencing of the MMR genes can accurately identify mutations and makes screening of other family members possible<sup>[6]</sup>. It is emphasized in the literature that only around 40% of the families identified by the Amsterdam Criteria will actually present detectable mutations. This fact influences both therapeutic plans and the required long-term follow-up<sup>[3,13,15,16]</sup>.

In this study, our goal was to perform the genetic analysis of a young male patient and the members of his family who had been selected by the Amsterdam Criteria, and to identify the genetic alterations in the MMR genes hMLH1 and hMSH2. We also attempted to establish a correlation between the occurrence of mutations and disease pattern.

## MATERIALS AND METHODS

### *Patient and surgery*

A 32-year-old male patient (index person) with recurrent hematochesia was received at an outpatient clinic in North-Eastern Hungary. Colonoscopy was performed and a friable, bleeding lesion was found at the lienal flexure of the large bowel with circular narrowing of the lumen. The histopathological report of the biopsy showed a mucinous adenocarcinoma infiltrating the muscularis propria, pT2, Grade 2. Ultrasound and computer tomography ruled out evidence of liver metastases, enlarged lymph nodes in the mesocolon or spread to neighboring organs. Since the disease was localized, a left hemicolectomy was performed with an end-to-end transverso-rectostomy. The family and the index person were evaluated using the Amsterdam and Bethesda Criteria<sup>[2]</sup>. Based on the family history, the possible diagnosis of HNPCC was suspected and, following discussions about the disease, the patient and his family agreed to further genetic evaluation.

### *Immunohistochemistry*

Routine 5 µm, paraffin-embedded tissue sections were dewaxed, rehydrated, and treated in a microwave oven in 10 mmol/L citrate buffer (pH 6.4) for 20 min, in order to retrieve antigenicity. Unspecific protein binding was blocked with 1% bovine serum albumin containing PBS for 30 min at 37 °C, then slides were incubated overnight with the pri-

mary antibodies (clone 2 MSH01, mouse monoclonal anti-MSH2, 1:100 and clone M074581 mouse monoclonal anti-MLH1, Labvision Corp., Fremont, CA, USA), respectively. Primary antibodies were detected by a biotin-streptavidine detection kit (LSAB, Dako, Carpinteria, CA, USA) using VIP chromogen. Negative controls were stained with the omission of the primary antibodies.

### *DNA extraction*

DNA was extracted from a paraffin-embedded cancerous tissue sample of the index patient following deparaffinization and proteinase K digestion, according to the protocol of the High Pure PCR Template Purification kit (Roche Diagnostics GmbH, Mannheim, Germany). DNA samples of the patient and family members were also isolated from whole blood using the Wizard DNA Purification System (Promega Corporation, Madison WI, USA) according to Promega's Technical Manual (TM050).

### *Microsatellite analysis*

DNA samples isolated from the tumor tissue were tested for microsatellite instability. Two mononucleotide markers (BAT25 and BAT26) were evaluated using the technique described by Dietmaier *et al*<sup>[17]</sup>. A multiplex PCR was performed using sequence specific hybridization probes (HyProbes) labeled with LightCycler dyes, LCRed640 and LCRed705. Amplification of microsatellites by LightCycler (Roche Diagnostics GmbH, Germany) was followed by melting point analysis to display alterations in the length of repetitive sequences.

### *Heteroduplex and single strand conformation polymorphism (SSCP) analysis*

All exons of hMLH1 and hMSH2 genes were analyzed in the blood sample of the index patient. Primers and PCR conditions were used as previously described<sup>[18]</sup>. Primers are available upon request. After denaturation or heteroduplex formation, the PCR products were loaded to electrophoresis on MDE gel (Cambrex Bio Science Rockland Inc., Rockland, MA, USA) according to manufacturer's instructions and visualized by silver staining.

### *Sequencing of hMSH2 and hMLH1 genes*

PCR products showing altered migration patterns on MDE gel were purified and sequenced in both directions. Sequencing reactions were performed using a BigDye thermocycler sequencing kit v.3.1 (Applied Biosystems, Foster City, CA, USA). The semi-automated fluorescence analysis was performed with an ABI-PRISM 310 Genetic Analyzer (Perkin Elmer, Boston, MA, USA).

## RESULTS

After a comprehensive evaluation of three generations, the index person's family was found to fulfill several points of the Amsterdam and Bethesda Criteria. In the maternal line of the pedigree, seven persons carry the exon 7 mutation. In this line, four cases of colorectal cancer and one case of breast cancer were recognized spanning three generations among first degree relatives. Analyzing the history of the paternal line, pulmonary carcinoma and gastric carcinoma

Table 1 Details of the pedigree analysis

Classification	Degree of relationship	7 exon mutation	3 exon mutation	Type of the tumor, age at tumor detection	Age at investigation
I/1	Sister of the mother of the index person's mother			Breast cancer, 61 yr	Died
I/2	Mother of the index person's mother				76 yr

CRC:colorectal carcinoma.

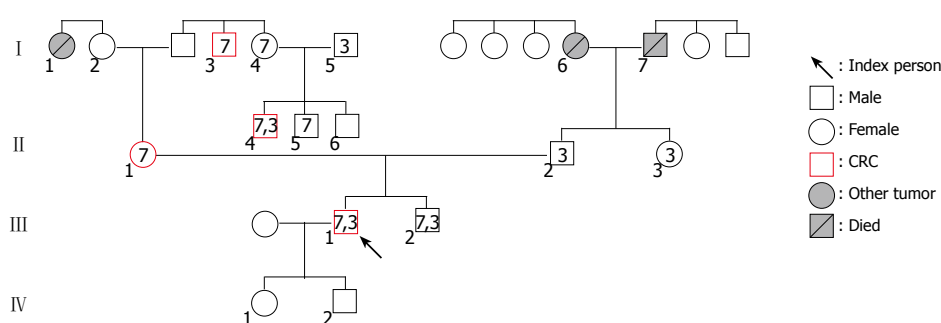

Figure 1 Pedigree of the index person.

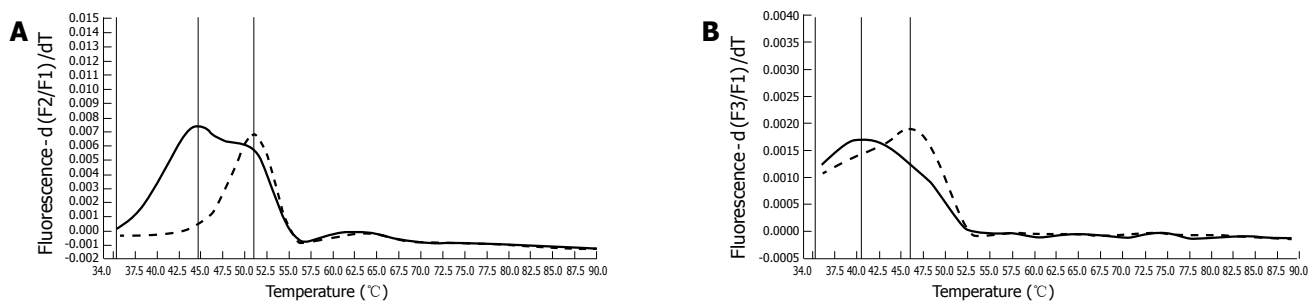

**Figure 2** Immunostaining for hMLH1 and hMSH2. Nuclei of tumor and normal colon mucosa cells show reactivity for hMLH1 (left), whereas hMSH2 staining is missing from the tumor cells (right, arrows). LSAB, original magnification, x200.

(one case each) were detected (Figure 1 and Table 1). We found two generations (I./5 and II./2) in the maternal line, where exon 3 mutations join from two different families. In both cases of mutation associations, the tumor manifestation could be observed at a younger age than in the other family members, who carried the exon 7 mutation only. Numbers in icons mean the location of hMSH2 exon mutations. Numbers below icons identify the investigated family members. The younger brother of the index person (III./2.) was 28 years old at the time of the investigation and was disease-free.

Immunohistochemistry of the index person's tumor tissue showed a complete loss of hMSH2 reactivity. The hMLH1 staining was retained in the nuclei of the tumor cells (Figure 2). Furthermore, this tumor tissue was also proved to be MSI-High, as was demonstrated by melting point analysis of both mononucleotide markers, BAT25 and BAT 26 (Figure 3).

Sequencing of all the exons of hMSH2 and hMLH1 genes from the same tumor tissue showed two mutations of the hMSH2 gene. We were not able to demonstrate any alterations in the hMLH1 gene. The first mutation was a

**Figure 3** LightCycler T<sub>m</sub> estimation of Bat26 (A) and Bat25 (B) microsatellite markers. Dotted lines represent MSS control. T<sub>m</sub> is 51°C for Bat26 and 46°C for Bat25. The solid lines show decreased T<sub>m</sub> values corresponding to the MSI-H status of tumor tissue. T<sub>m</sub> is 44.6°C for Bat26 and 40.5°C for Bat25 respectively.

**Table 2** Type and location of detected mutations

Gene	Exon	Codon	Mutation	Type
hMSH2	7	422	gaa→taa Glu→STOP	Nonsense
hMSH2	3	127	aat→agt Asn→Ser	Missense

nonsense mutation, located in exon 7, codon 422 causing a glutamine→STOP codon change (Table 2). The second one was a missense mutation, located in exon 3, codon 127 resulting in substitution of Asp for Ser.

Targeted sequencing of these two identified mutations was performed on DNA samples isolated from the peripheral blood leukocytes of fourteen other family members. On the paternal side, the missense mutation of exon 3 was identified in the index patient's younger brother and his father, as well as in the sister of the father. Interestingly, the exon 3 mutation was also found in two members of the maternal line. The nonsense mutation of exon 7 was found in seven members of the maternal side and four of these subjects have been diagnosed as CRC (Table 1).

## DISCUSSION

A characteristic feature of HNPCC is a tendency to develop metachronous tumors in affected individuals. In a 15-year follow-up study, Jarvinen and coworkers demonstrated convincingly that recurrence of CRC can be eliminated effectively by regular interval colonoscopies and polypectomies. Out of the 133 individuals who underwent regular interval follow-up examinations, 18% developed colon cancer, but no patients died. Whereas, among the 119 patients who deferred colonoscopy at three-year intervals, 41% were diagnosed as CRC and 9 deaths occurred<sup>[19]</sup>. Since the correct identification of HNPCC families is still an unsolved issue, considerable effort is dedicated to the task of uncovering further details of the disease. The most widely applied initial screening tools are the Amsterdam and Bethesda Criteria<sup>[2,3,6]</sup>. Unfortunately, neither of them is accurate enough to identify all HNPCC families with complete certainty. The most reliable, currently available technique is the demonstration of mutations in the MMR genes of suspected index persons, followed by a comprehensive search for the specific mutation in their family members. A promising way to reach an effective screening

tool is to find and describe the nature and frequency of population specific mutations and to test these first in patients from a particular geographic location. Currently, more than 300 different MMR gene mutations have been published from different parts of the world. Some of these are recurrent, and have been described as founder mutations in particular populations<sup>[20-24]</sup>.

Our group, applying the previously suggested protocol, initiated an investigation in Hungary. A 31-year-old male patient was selected by the Bethesda criteria and genetic testing identified him as having HNPCC. A double mutation of the hMSH2 gene was found and subsequently compared with the available international databases (The Human Gene Mutation Database, Cardiff, International Society for Gastrointestinal Hereditary Tumors). The nonsense mutation of exon 7 has not been published before; therefore, it may potentially be characteristic in Hungarian families. The genetic error clearly appears to be pathogenic, since all the family members with CRC carry this mutation. The newly identified mutation causes development of a STOP codon, leading to a non-functional, truncated protein, which could not be detected by immunohistochemistry. The human MSH2 protein interacts with MSH6 forming the complex called hMutS $\alpha$  and with hMSH3 protein forming the complex named hMutS $\beta$ . Each subunit of these heterodimers is formed by five flexible domains which are defined as I. mismatch binding, II. connector, III. core, IV. DNA clamp, and V. ATPase domains. The mismatch binding and DNA clamp domains act in binding to mismatched DNA whereas the core and connector domains constitute the backbone of each subunit. The latter two transmit allosteric information of bound DNA co-factor to the ATPase domain. Our detected mutation at codon 422 causing Glutamine→STOP change results in the loss of more than half of the expressed MSH2 protein (truncated by 513 aminoacids from 934), involving core, DNA clamp and ATPase domains. This nonfunctional truncated protein cannot take a part in forming normal heterodimers and disintegrated quite soon after expression. To the best of the authors' knowledge there was only one publication in Hungary of a novel hMSH2 germline mutation causing truncated protein expression. Czákó *et al.* investigated a 62 year old female patient who suffered from colon cancer at the age of 46, rectum cancer at the age of 60, endometrial cancer at the age of 56 years, basosquamous and squamous cell cancer of the face at the ages of 53, 54, 62, and 58 years respectively. This patient's family fulfilled

the Amsterdam criteria. The DNA sequencing analysis revealed a mutation as a single nucleotide change at codon 2292 in exon 14 of the hMSH2 gene. This guanine to adenine change altered the 764 amino acid, the tryptophan to STOP codon. Thus the hMSH2 protein was truncated by 171 aminoacids<sup>[25]</sup>.

The missense mutation of exon 3 has already been described by several authors as a single amino acid change, and represents a non-pathogenic polymorphism of the gene. Samowitz *et al* published data showing 3 cases of this polymorphism in 1066 screened subjects. One of the 3 affected carriers was also found to have another missense mutation (exon 6, codon 328, Ala→Pro change, of hMSH2 gene), and in another carrier it was coupled with a pathogenic frameshift mutation of the hMLH1 gene (exon 16, codon 626).<sup>[26]</sup> De la Chapelle *et al* published another interesting double mutation, where this polymorphism was associated with an MSH2, exon 6, codon 333 mutation (International Society for Gastrointestinal Hereditary Tumors). The allele frequency of this polymorphism, according to the database of The National Institute of Environmental Health Sciences Genome Project, is 0.02, which would lead to as much as a 4% prevalence of heterozygous carriers in the general population.

Both mutations identified in this study are single nucleotide changes of the hMSH2 gene. Large genomic deletions and/or rearrangements, on the other hand, can account for 36% of all hMSH2 mutations according to the Dutch HNPCC mutation analysis study.<sup>[27]</sup> Unlike the hMSH2 mutations, the majority of hMLH1 mutations are single nucleotide changes, but interestingly, a 3.5 kb deletion encompassing exon 16 of hMLH1 has been observed in Finland, as a founder mutation<sup>[23]</sup>.

The presence of the exon 7 mutation alone resulted in a tumor manifestation at an age of 43 and 56 years (Table 1). When the missense and nonsense mutations were inherited together, the age of manifestation shifted to a younger age of 31 and 34 years.

It is well known that the penetrance of the MMR genes is less than 100%, which might explain why two of the older family members carrying the pathogenic mutation have not acquired the disease yet. Young age may answer the same question in the case of the younger brother of the index person, who was 28 years old at the time of the investigation (Table 1). On the other hand, all these family members must be considered "high-risk" patients, and be placed under close regular interval surveillance. To date, three family members carrying only the exon 3 mutation are disease-free. Three other members of the family, who suffered from breast, gastric and pulmonary cancers, respectively, could not be investigated because of their deaths before the initiation of the study.

Both the paternal and maternal lines of the evaluated family in this study came from the same small village in Hungary, which may explain the high prevalence of the exon 3 mutation of MSH2 in the tested individuals. It will be interesting to see whether the exon 7 mutation is truly characteristic for Hungarian families, or whether this mutation can be found in different populations elsewhere.

## ACKNOWLEDGMENTS

We are grateful to all the family members for their full cooperation during this study.

## Abstract

**AIM:** Hepatitis C virus often establishes chronic infections. Recent studies suggest that viral and bacterial infections are more common in HCV-infected patients compared to controls. Pathogens are recognized by Toll-like receptors (TLRs) to shape adaptive and innate immune responses.

**METHODS:** In this study, to assess the ability of HCV-infected host to recognize invading pathogens, we investigated Toll-like receptor expression in innate (monocytes) and adaptive (T cells) immune cells by real-time PCR.

**RESULTS:** We determined that RNA levels for TLRs 2, 6, 7, 8, 9 and 10 mRNA levels were upregulated in both monocytes and T cells in HCV-infected patients compared to controls. TLR4 was only upregulated in T lymphocytes, while TLR5 was selectively increased in monocytes of HCV-infected patients. MD-2, a TLR4 co-receptor, was increased in patients' monocytes and T cells while CD14 and MyD88 were increased only in monocytes.

**CONCLUSION:** Our data reveal novel details on TLR expression that likely relates to innate recognition of pathogens and immune defense in HCV-infected individuals.

## INTRODUCTION

Hepatitis C virus (HCV) infection is the cause of chronic hepatitis in more than 4 million people in the USA<sup>[1]</sup>. Patients with chronic HCV infection experience a various severity of liver diseases ranging from mild hepatitis to cirrhosis and hepatocellular carcinoma. Liver cirrhosis that appears decades after the initial infection often predisposes to spontaneous bacterial peritonitis and sepsis<sup>[2]</sup>. HCV is the most frequent indication for liver transplantation, and transplant recipients suffer from recurrent HCV and infections associated with immunosuppression<sup>[3]</sup>. HCV, a blood borne pathogen, is frequently associated with human immunodeficiency virus (HIV) infection acquired through the same route of invasion<sup>[4]</sup>. According to clinical data, HCV is not only the cause of morbidity due to liver disease, but it is also associated with other infections. A recent study by El-Sarag *et al*<sup>[5]</sup> suggested that infections with other viral and bacterial pathogens were more common in HCV-infected patients who otherwise had no immunocompromise compared to non-HCV infected controls. The pathogens causing infections at a higher rate in HCV patients included cytomegalovirus, cryptococcus, Mycobacterium tuberculosis and those causing sexually transmitted diseases<sup>[5]</sup>. It remains to be evaluated whether recognition of pathogens and/or mounting appropriate immune responses is impaired in HCV infection.

Bacterial and viral pathogens are recognized as "danger" signals by the family of Toll-like receptors (TLRs) that alert innate immunity against the invading pathogens<sup>[6]</sup>. The known 11 mammalian TLRs have distinct extracellular domains but share common intracellular mechanisms of cell activation that culminate in production of inflammatory cytokines. Each TLR has specific ligands, which allow the host to sense a wide diversity of pathogens. TLR1, TLR6 and possibly TLR10 form heterodimers with TLR2 to recognize fungi (*Sarcomyces cerevisiae*, *Candida albicans*, and *Aspergillus fumigatus*), parasites (*Trypanosoma cruzi*), Gram positive bacteria-derived peptidoglycan (PGN) and bacterial lipoproteins, lipoarabinomannan from *Mycobacterium tuberculosis*, *Treponema pallidum*-derived glycolipid

and lipoteichoic acid<sup>[6,7]</sup>. TLR2 can also recognize certain viruses such as cytomegalovirus, measles virus and core and NS3 proteins of HCV<sup>[8-10]</sup>. TLR3 recognizes poly(I-C) and double-stranded viral RNA, whereas TLR4 agonists include Gram-negative bacterial LPS, respiratory syncytial virus, *Cryptococcus neoformans* and the plant product Taxol<sup>[6,7,11]</sup>. Bacterial flagellin has been identified as a TLR5 ligand, synthetic components imiquimod and resiquimod 848 and single stranded RNA stimulate TLR 7 and 8, while unmethylated CpG-containing DNA and herpes simplex virus have been identified as TLR9 agonists<sup>[6,7,12]</sup>.

The presence of TLRs was originally discovered in innate immune cells<sup>[13]</sup>. Monocytes express all TLRs of which TLRs 1, 2, and 4 are present at high levels<sup>[14]</sup>. Latest research, however, indicates that TLR expression is not restricted to innate immune cells and TLRs can be detected in adaptive immune cells as well as in parenchymal cells. In particular, T cells express all TLRs at low levels with the exception of TLR5, which is present abundantly<sup>[14, 15]</sup>.

In order to dissect the ability of HCV-infected host to respond to invading pathogens, we investigated Toll-like receptor expression in innate (monocytes) and adaptive (T cells) immune cells. We determined that TLR2, 7, 8, 9 and 10 were upregulated in both immune compartments in HCV-infected patients compared to controls. In addition, TLR4 was upregulated in lymphocytes and TLR6 was upregulated in monocytes only. Our data reveal new insights into immune defense of HCV-infected individuals.

## MATERIALS AND METHODS

### Blood donors

Healthy individuals (controls, *n* = 14) and treatment-naïve patients chronically infected with hepatitis C virus (HCV patients, *n* = 14) were enrolled in the study. All individuals were free of acute infections. The study was approved by the Committee for the Protection of Human Subjects in Research at the University of Massachusetts Medical School and informed consent was obtained. The clinical characteristics of the patients are detailed in Table 1. The blood was collected from cubital vein with anti-coagulant (heparin sodium) and processed immediately. Controls and patients were matched for age and gender where possible.

### Cells

Peripheral blood mononuclear cells (PBMCs) were separated by centrifugation on Ficoll gradient. In order

to separate monocytes from lymphocytes, the PBMCs were plated (10<sup>7</sup>/well in 2 mL of RPMI1640 media supplemented with 10 % FBS) in 6 well plates (Corning, Corning, NY) and incubated at 37 °C in 50 ml/L CO<sub>2</sub> atmosphere for 3 h. Monocytes were separated based on their adherence to plastic and the purity of the population, based on CD14 expression, was greater than 95% as determined by flow cytometry (data not shown). Non-adherent cells were washed and T lymphocytes were purified using T cell negative isolation kit (DynaL Biotech Inc, Lake Success, NY), as manufacturer recommended. Briefly, non-adherent cells were incubated with a cocktail of antibodies for CD14, CD16a, CD16b, CD56, HLA class II DR/DP and CD235A, followed by incubation with depletion magnetic Dynabeads. The non-T cells bound to the Dynabeads and were separated in a strong magnetic field while T cells were washed and subjected to RNA extraction.

### Real-time PCR

Total cellular RNA was extracted using RNeasy kits (Qiagen, Valencia, CA), according to manufacturer's recommendations. All samples were co-processed to eliminate technical variations. Equal amounts of RNA from controls and HCV-infected patients were analyzed. Reverse transcription of 1 µg of RNA into cDNA was performed using reverse transcription System (Promega, Madison, WI). The real-time PCR primers were synthesized by IDT (Coralville, Iowa), except for 18S (Quantum RNA Classic II 18S Internal Standard, Ambion, Austin, TX). The real-time PCR was performed using the ICycler (Biorad Laboratories, Hercules, CA). The PCR primers are described in Table 2. The reaction mixture contained 12.5 µL qPCR

**Figure 1** Higher TLRs 2, 5, 6, 7, 8, 9 and 10 RNA expression by monocytes of HCV-infected patients compared to controls. RNA was purified from adherence-isolated monocytes and real-time PCR for TLRs 1-10 and 18 S RNA (as endogenous control) was performed as described in Materials and Methods. For each individual, TLR-coding RNA expression was normalized to corresponding 18 S RNA. Results are expressed as fold increase of each TLR in HCV-infected patients compared to controls. Results are from 14 HCV-infected patients and 14 controls.

MasterMix Plus with 2 x SYBR Green (Eurogentec, Seraing, Belgium), 0.5  $\mu$ mol/L of forward and reverse primer and 1  $\mu$ L of cDNA (corresponding to 50 ng of RNA) in a total volume of 25  $\mu$ L. All amplifications and detections were carried out in a BioRad optical 96-well reaction plate with optical tape. At each cycle, accumulation of PCR products was detected by monitoring the increase in fluorescence by dsDNA-binding SYBR Green. After the PCR was performed, a dissociation/melting curve was constructed in the range of 55°C to 95°C. Data were analyzed using the Biorad ICycler software. As a first step in data analysis 18S was used for normalization of all experiments (normalizer) and it was closely compared between controls and HCV patients. For second step in data analysis we used comparative Ct method ( $\Delta\Delta$ Ct method) with the following formula:  $\Delta$ Ct = Ct (target, TLR) - Ct (normalizer, 18S). The comparative  $\Delta\Delta$ Ct calculation involved finding the difference between  $\Delta$ Ct of HCV patient and the mean value of the  $\Delta$ Ct from normals for each analyzed molecule. Fold increase in the expression of specific mRNA in HCV patients compared to normal controls was calculated as  $2^{-(\Delta\Delta\text{Ct})}$ .

### Statistical analysis

The non-parametric Wilcoxon test from StatView on a G4 Machintosh platform (Cupertino, CA) was employed to determine the statistical difference between controls and HCV patients.

## RESULTS

### HCV-infected patient selection and their characteristics

Our study population included patients with chronic HCV infection but without cirrhosis or cancer, thus, HCV infection-specific imprints on the immune system were present but cirrhosis or cancer-related non-specific immune alterations could be excluded. All patients in the study had viremia and elevated levels of liver transaminases consistent with chronic hepatitis. Patients

infected with different viral genotypes (1A, 1B, 3A and 4A) were included, as viral genotype could affect host immune response<sup>[16]</sup>. Our patients had never been treated with anti-viral therapy, thus possible influence of therapy on TLR expression was eliminated. This is important because Ribavirin was shown to augment signaling in TLR-transfected cells<sup>[17]</sup>.

### Monocytes of HCV-infected patients express higher levels of TLRs 2, 3, 5, 6, 7, 8, 9 and 10 RNA compared to controls

Chronic HCV infection is associated with increased serum levels of inflammatory cytokines<sup>[18]</sup>. Blood monocytes and tissue macrophages are major sources of these cytokines. We recently reported increased monocyte production of TNF $\alpha$  in patients with chronic HCV infection<sup>[10]</sup>. In this study, we used real-time PCR to evaluate TLR expression in monocytes of HCV-infected patients and healthy controls. Monocytes both from controls and HCV-infected patients expressed TLRs 1-10 (Figure 1), as expected based on previous studies<sup>[14]</sup>. We found that monocytes from patients with chronic HCV infection expressed significantly higher levels of RNA coding for TLR2, TLR5, TLR6 and TLR10. Different TLRs reside at different locations in the cell. TLRs 1, 2, 4, 5, 6 and 10 are expressed mostly on the surface of the cellular membrane, while TLRs 3, 7, 8 and 9 are localized inside the cells<sup>[6,7]</sup>. Surprisingly, we found that not only some outer cellular membrane-associated TLRs, but also the intracellularly localized TLRs, TLRs 7, 8 and 9, were upregulated in HCV patients' monocytes. The level of TLR3 mRNA was also significantly higher in HCV-infected patients compared to controls.

Ligand recognition and signaling of TLR2 and TLR4 is augmented by co-receptors<sup>[6,7]</sup>. Thus, we further analyzed the expression of TLR co-receptors and adaptors in both controls and HCV-infected patients. We found that the mRNA level of CD14, a co-receptor for TLR2 and TLR4, was upregulated in HCV patients compared to controls (Figure 2). In addition to CD14, MD-2 is another accessory protein of the TLR4 that is necessary

**Figure 2** Monocytes of HCV-infected patients express higher levels of TLR co-receptors MD2 and CD14, and TLR adaptor MyD88 compared to controls. RNA was purified from adherence-isolated monocytes and real-time PCR for MD2, CD14, MyD88 and 18 S RNA (as endogenous control) was performed as described in Materials and Methods. For each individual protein of interest-coding RNA expression was normalized to corresponding 18 S RNA. Results are expressed as fold increase of each protein of interest in HCV-infected patients compared to controls. Results are from 14 HCV-infected patients and 14 controls.

for assembling the TLR4-containing receptor complex to sense low quantities of lipopolysaccharide<sup>[19]</sup>. We found that MD2 mRNA was expressed at significantly higher levels in monocytes of HCV infected patients compared to controls. The mRNA for MyD88, an intracellular adaptor molecule that is recruited to the intracellular domain of TLRs 2, 4, and 9 upon engagement with specific ligands, was also higher in patients compared to controls. These results suggest that increased RNA expression of various TLRs and their co-receptors may predispose monocytes to increased TLR-mediated activation in chronic HCV.

#### **Lymphocytes of HCV-infected patients express higher levels of TLRs compared to controls**

We next investigated the expression of TLRs in CD3+ T cells of the adaptive immune cells. T cells from controls and HCV infected patients expressed mRNA for TLRs1-10 (Figure 3) as expected based on previous publications<sup>[14,15]</sup>. There was no CD14 mRNA expressed in T lymphocytes of either controls or HCV-infected patients, confirming the purity of the cell population (data not shown). We found that levels of RNA coding for membrane-localized TLR1, 2, 4, 6 and 10 as well as the TLR4 co-receptor, MD2, were significantly higher in HCV infected patients compared to controls. No differences in levels of RNA coding for MyD88 or TLR3 and TLR5 (Figure 3) between controls and patients were identified. In contrast, the RNA levels of intracellularly localized TLRs 7, 8 and 9 were significantly higher in T lymphocytes of HCV infected patients compared to controls.

## **DISCUSSION**

Monocytes and lymphocytes, respectively, are representative populations of innate and adaptive immunity and their cooperation is required to recognize, limit and eliminate invading microbes<sup>[20]</sup>. Here we show that patients infected with HCV have a unique pattern of TLR expression in

both the innate and adaptive immune compartments and have elevated RNA expression of both membrane-associated and intracellularly localized TLRs. Recent reports demonstrate that HCV-infected patients have a higher prevalence of infections with cytomegalovirus, *Cryptococcus*, *Mycobacterium tuberculosis* and sexually transmitted diseases compared to controls<sup>[5]</sup>. Recognition of these pathogens requires TLR-mediated signals. For example, sensing of *Cryptococcus* by the innate immune system requires TLR2, TLR4, MyD88 and CD14<sup>[1]</sup>, while TLR2 and TLR4 are instrumental in the host's response against *Mycobacteria*<sup>[21]</sup>. The pathogens implicated in sexually-transmitted diseases, found more often in HCV-infected patients, are also recognized by TLR. *Chlamydia* elicits an unusual set of inflammatory responses via TLR2 and TLR4 *in vivo*, and TLR2 is essential for development of oviduct pathology in chlamydial genital tract infection<sup>[22]</sup>, while *Neisseria gonorrhoeae* stimulates cytokine release and NF- $\kappa$ B activation in epithelial cells in a TLR2-dependent manner<sup>[23]</sup>. In addition, some TLRs may play a protective or even therapeutic role in defense against sexual disease pathogens: TLR3 agonists protect against genital herpes infection<sup>[24]</sup> and Imiquimod, a TLR7&8 ligand and the first FDA-approved imidazoquinoline, has been approved for the therapy of genital warts<sup>[25]</sup>. Increased expression of TLR2 and TLR4 is a bad prognostic factor in patients with sepsis<sup>[26]</sup>, while low TLR expression may protect the host against excessive inflammation and tissue damages<sup>[27]</sup>, thus, differential expression of TLRs in HCV infected patients may contribute to susceptibility to infections as well as to the underlying disease progression and this remains to be determined.

The observation of increased expression of TLR2 in patients was not totally unexpected, since chronic HCV infection is associated with elevated levels of circulating LPS, which upregulates the expression of TLR2 in different cell types, including monocytes<sup>[1,21,22]</sup>. We have previously shown that HCV core and non-structural protein 3 (NS3), activate cells through TLR2<sup>[10]</sup>. We found elevated levels of the TLR co-receptors, CD14 and MD2, and adaptor molecule MyD88, in HCV-infected patients compared to controls, suggesting that MyD88-mediated TLR signal transduction may also be affected in patients. Indeed, we have previously found that monocytes from HCV infected patients are hyper-responsive to stimulation with TLR4 and TLR2 ligands<sup>[10,31]</sup>. Although we did not find a role for CD14 in TLR2-mediated cell activation by HCV-derived core and NS3 proteins (unpublished data), increased CD14 expression may be relevant to cell activation mediated by other TLR2 and TLR4 ligands, as previously reported for LPS, lipoteichoic acid and even viruses<sup>[9]</sup>.

Intracellularly-localized TLR 3, 7, 8 and 9 are of specific interest in patients with chronic viral infections since these receptors can recognize virus-derived molecular patterns<sup>[6,7]</sup>. We found that TLR3 expression was higher in monocytes of HCV-infected patients compared to controls. TLR3 is a sensor for double-stranded RNA and it has been implicated in pathogenesis of viral infections<sup>[32,33]</sup>. Synthetic RNA compounds, such as polyI:C activate cells expressing TLR3<sup>[34]</sup>. In a recent study by Edelmann *et al*<sup>[35]</sup> the role of TLR3 was investigated in four differ-

**Figure 3** Higher TLRs 1, 2, 4, 6, 7, 8, 9 and 10 and MD2 RNA expression by lymphocytes of HCV-infected patients compared to controls. RNA was isolated from lymphocytes and real-time PCR for TLRs 1-10, MD2 and 18S RNA (as endogenous control) was performed as described in Materials and Methods. For each individual, TLR- or MD2-coding RNA expression was normalized to corresponding 18S RNA. Results are expressed as fold increase of each TLR or MD2 in HCV-infected patients compared to controls. Results are from 14 HCV-infected patients and 14 controls.

ent infectious viral models [lymphocytic choriomeningitis virus (LCMV), vesicular stomatitis virus (VSV), murine cytomegalovirus (MCMV), and reovirus in TLR3<sup>-/-</sup> mice]. The investigators found that TLR3 is not always required for the generation of effective antiviral responses, as the absence of TLR3 did not alter either viral pathogenesis or host's generation of adaptive antiviral responses to those viruses. Interestingly, intracellular transduction of poly(I:C) initiates activation of an IFN response in a TLR3-independent manner, thus limiting the role of TLR3 in the IFN pathway<sup>[34]</sup>. A recent report by Li *et al*<sup>[33]</sup> indicates that HCV may use TLR3 pathway to evade immune surveillance via HCV NS3/4A protease-mediated cleavage of the TLR3 adaptor protein TRIF. Furthermore, HCV NS3/4A interferes with retinoic acid-inducible gene-I (RIG-I), a key factor in TRIF-independent signaling<sup>[34]</sup>. Our finding of increased TLR3 mRNA levels in monocytes of HCV patients awaits further investigation. It is tempting to speculate that HCV RNA may trigger cellular activation via TLR3, and indeed, all our patients had high levels of viremia, however no clear relationship between HCV RNA levels and TLR3 expression has been proven to date.

TLR7 and TLR8 are stimulated by synthetic compounds imiquimod and resiquimod 848<sup>[6,7,34]</sup>. In a recent publication, Lund *et al*<sup>[12]</sup> showed that TLR7 recognizes the single-stranded RNA viruses, vesicular stomatitis virus and influenza virus. The recognition of these viruses by plasmacytoid dendritic cells and B cells through TLR7 results in cellular activation and the production of cytokines. However, the specific role of TLR7 and TLR8 in innate immune response to HCV is yet to be understood. HCV is a single stranded RNA virus, thus, it could theoretically act as a ligand for TLR7. Our data show that TLR7 mRNA is significantly upregulated in HCV patients compared to controls, and all patients had detectable levels of HCV RNA in their plasma, thus suggesting that TLR7 may be implicated in the pathogenesis of HCV infection.

We found that both monocytes and T cells of HCV-infected patients expressed elevated levels of TLR9

mRNA compared to controls. CpG-containing DNA acts as a stimulatory ligand for TLR9<sup>[6,7,28,31]</sup>. TLR9 is regulated at the transcriptional level by multiple nuclear regulatory factors, co-repressors and co-activators, including CREB1, Ets2, Elf1, Elk1, and C/EBP and HCV may regulate these transcription factors<sup>[36,37]</sup>. Toll-like receptors 9 and 3 are essential components of innate immune defense against cytomegalovirus infection in mice<sup>[38]</sup>. While we found that TLR9 mRNA was upregulated in patients, others have shown that infections with cytomegalovirus are more frequent in HCV-infected patients compared to controls<sup>[5]</sup>. It remains to be elucidated if the increased TLR9 RNA levels in monocytes or T cells have a role in increased susceptibility to infections with CMV, as seen in HCV patients.

To date little is known about the role of TLR expression in T cells of the adaptive immune compartment. Caramalho *et al*<sup>[39]</sup> recently reported that LPS, a TLR4 ligand, promotes survival of activated CD4<sup>+</sup> cells and stimulates regulatory T cell (T reg) activity. Here we found that TLR4 mRNA expression was higher in HCV-infected patients compared to controls only in lymphocytes, but not in monocytes. It is tempting to speculate that elevated levels of TLR4 and its co-receptor, MD-2, in patients' T cells may provide ongoing activation in the presence of serum LPS found in chronic HCV and provide preferential survival signals for T regs<sup>[29]</sup>. Recent data suggest a role for T regs in immune alterations associated with chronic HCV. Cabrera *et al*<sup>[40]</sup> reported that Tregs appear to play a role in viral persistence by suppressing HCV-specific T cell responses in a cell-cell contact manner, while MacDonald *et al*<sup>[41]</sup> showed that Tregs could be induced against the same epitopes on the HCV core protein.

A limitation of our study is that it did not distinguish between TLR expression in CD4<sup>+</sup> and CD8<sup>+</sup> T cells. Differential CD4<sup>+</sup> and CD8<sup>+</sup> T-cell responsiveness in hepatitis C virus infection has been reported, thus, leading to the hypothesis that if TLRs are of any functional role in T cells, there may be differences in TLR expression between CD4<sup>+</sup> and CD8<sup>+</sup> T cells in HCV-infected patients. Due to

the presence of anti-CD56 mAbs in the separation cocktail, we also lost CD56<sup>+</sup> T cells, known as gamma delta, with an important role in HCV infection<sup>[42]</sup>.

In conclusion, we showed that patients with chronic HCV infection express elevated levels of selected TLRs in both adaptive and innate compartments of the immune system. Our data may suggest additional therapeutic targets.

## Abstract

**AIM:** To estimate the contribution of autoimmune thrombocytopenia to hepatitis C virus-related liver cirrhosis (type C cirrhosis), we evaluated the influence of splenectomy upon platelet-associated immunoglobulin G (PAIgG) levels and platelet numbers.

**METHODS:** PAIgG titers and immune markers were determined in 24 type C cirrhotic patients with an intact spleen, 17 type C cirrhotic patients submitted to splenectomy, and 21 non-C cirrhosis with an intact spleen.

**RESULTS:** Thrombocytopenia ( $PLT < 15 \times 10^4/\mu L$ ) in type C cirrhosis was diagnosed in all patients with an intact spleen, 8 patients submitted to splenectomy, and in 19 non-C cirrhosis with intact spleen. Elevated titers of PAIgG at more than 25.0 ng/ $10^7$  cells were detected in all cirrhotic patients except for one splenectomized patient. PAIgG titers (ng/ $10^7$  cells) were significantly higher in the type C cirrhosis with an intact spleen ( $247.9 \pm 197.0$ ) compared with the splenectomized patients ( $125.6 \pm 87.8$ ) or non-C cirrhosis ( $152.4 \pm 127.4$ ). PAIgG titers were negatively correlated with platelet counts in type C cirrhotic patients with an intact spleen. In comparison with the type C cirrhosis with an intact spleen, the splenectomized patients had a reduced CD4/CD8 ratio and serum neopterin levels. The spleen index ( $cm^2$ ) was negatively correlated with platelet counts in the non-C cirrhosis, but not in the type C cirrhosis.

**CONCLUSION:** Our data indicate that the autoimmune mechanism plays an important role in thrombocytopenia complicated by HCV-positive cirrhosis. In addition, splenectomy may impair T cells function through, at least in part, a reduction of CD4/CD8 ratio, consequently suppressing PAIgG production.

## INTRODUCTION

Accompanying thrombocytopenia in patients with liver cirrhosis was initially attributed to an increase in platelet sequestration in the enlarged spleen secondary to portal hypertension<sup>[1]</sup>. Elevated platelet counts after procedures, such as transjugular intrahepatic portosystemic shunt<sup>[2,3]</sup>, partial splenic embolization<sup>[4,5]</sup>, splenectomy<sup>[6]</sup>, and shunt operation<sup>[7,8]</sup>, confirmed this theory. Nevertheless, controversial results on the relief of portal hypertension by surgical means have shown a reduction in spleen size with no concomitant persistent rise in platelet counts unless accompanied by liver transplantation<sup>[9]</sup>. Thus, the clinical significance of portal hypertension in the pathogenesis of thrombocytopenia in liver cirrhosis remains to be elucidated. Recently, not only impaired production of thrombopoietin, which regulates megakaryocyte development<sup>[10,11]</sup>, but also immune disturbance is thought to be responsible for thrombocytopenia associated with cirrhosis. In autoimmune-mediated thrombocytopenia, patients with chronic liver disease had a high incidence of platelet-associated immunoglobulin G (PAIgG)<sup>[12-16]</sup>. Pereira *et al*<sup>[12]</sup> detected autoantibodies that reacted specifically with platelet membrane glycoprotein in chronic liver disease, suggesting that an immune mechanism may participate in the induction or aggravation of thrombocytopenia.

Hepatitis C virus (HCV) has been identified as a major causative agent for parenterally transmitted non-A non-B hepatitis throughout the world<sup>[17]</sup>. Approximately 85% of HCV-infected individuals fail to clear the virus and develop persistent chronic hepatitis which leads to cirrhosis<sup>[18]</sup>. Chronic HCV infection is associated with an increased risk of liver cancer, and most cases of HCV-

related hepatocellular carcinoma occur in the presence of cirrhosis. In addition, HCV infection is often associated with immune disturbance, including the development of autoantibodies and an increased frequency of immune-mediated disease<sup>[19]</sup>. We already hypothesized that chronic HCV infection may cause autoimmune thrombocytopenia because of prevalence of elevated levels of PAIgG and an inverse correlation between PAIgG titers and platelet counts<sup>[20]</sup>. On the other hand, Kosugi *et al*<sup>[21]</sup> reported that hepatitis C patients had a high incidence of PAIgM but relatively low levels of PAIgG, insisting that thrombocytopenia in hepatitis C patients was not due to anti-platelet autoantibodies. Substantial evidence exists that PAIgG is frequently identified in HCV-positive patients<sup>[20,22]</sup>, but whether this immunoglobulin acts as a specific anti-platelet antibody remains unclear.

The role of spleen in PAIgG production and modification of cell-mediated immunity was previously reported in patients with idiopathic thrombocytic purpura (ITP), in whom the prevalence of PAIgG was found to contribute to the development of autoimmune thrombocytopenia<sup>[23]</sup>. Chronic ITP patients characteristically had varied PAIgG levels post-splenectomy<sup>[24]</sup>, but showed immediate normalization in splenectomy-responders<sup>[25]</sup>. In ITP patients, CD4+ and HLA-DR-restricted T cells to platelet membrane GPIIb-IIIa were found to involve in the production of anti-platelet autoantibodies<sup>[26]</sup>. These results suggest that splenectomy may modify PAIgG production and immune mediators in patients with chronic HCV infection. In the present study, we, in order to elucidate the role of autoimmune thrombocytopenia in the development HCV-positive liver cirrhosis, retrospectively evaluated the influence of splenectomy on PAIgG levels and platelet counts, as well as cellular and humoral immune mediators.

## MATERIALS AND METHODS

### Patients

In the present study, 41 patients with type C cirrhosis, who were referred to our hospital, were enrolled. They were found to be seropositive for HCV antibodies detected a second or third generation enzyme-linked immunosorbent assay (Ortho Diagnostic System Co., Ltd., Tokyo, Japan) and/or recombinant immunoblot assay (Chiron RIBA-2 and/or RIBA-3). Seventeen patients had undergone splenectomy in association with surgery for esophageal varices (the splenectomies). The mean duration of follow-up after splenectomy was  $11.5 \pm 4.7$  years (range, 2 to 19 years). Twenty-four consecutive cirrhotic patients had an intact spleen (the non-splenectomies). In addition, 20 cirrhotic patients including 10 hepatitis B, 4 autoimmune hepatitis, 3 alcoholic and 3 idiopathic cirrhosis served as the non-C cirrhosis. All the non-splenectomies and non-C cirrhosis had esophageal varices complication, and eight of the non-splenectomies and five of the non-C cirrhosis received treatment for the varices by endoscopic sclerotherapy and/or band ligation.

Morphological diagnosis of cirrhosis was performed in all the splenectomies, 15 non-splenectomies and 12 non-C cirrhosis. The others were diagnosed clinically, and they had typical laboratory findings of liver cirrhosis and

Table 1 Characteristics of the patients (*n*, mean $\pm$ SD)

Non-C cirrhosis consisted of 10 hepatitis B, 4 autoimmune hepatitis, 3 alcoholic and 3 idiopathic cirrhosis. HCC: hepatocellular carcinoma.

characteristic liver imaging on computed tomography or ultrasonography. Patients' characteristics are shown in Table 1. Clinical features were similar among the three groups. Informed consent was obtained from each patient according to the Helsinki Declaration.

### Assays

Quantitative HCV-RNA was analyzed from serum samples by a combined reverse transcription PCR assay (Amplicor-HCV monitor). Peripheral blood counts and liver function parameters were measured by an autoanalyzer.

Quantity of PAIgG was determined by a competitive micro enzyme-linked immunosorbent assay (ELISA) as described by Kawaguchi *et al*<sup>[27]</sup>. Briefly, platelets were separated from whole blood collected in EDTA, and washed with phosphate-buffered saline containing 11 g/L bovine serum albumin. The ELISA was performed in 96-well microplates coated with purified human IgG. A horseradish peroxidase-conjugated anti-human IgG antibody was incubated simultaneously with the samples, and visualized with o-phenylenediamine. PAIgG titers from 49 healthy individuals were within 25.0 ng/10<sup>7</sup> cells (mean,  $16.4 \pm 4.2$  ng/10<sup>7</sup> cells)<sup>[20]</sup>.

The proportion of CD4 and CD8 subsets of peripheral bloods was assayed by flow cytometry. The levels of neopterin and soluble interleukin-2 receptor (sIL2R) were measured using HPLC and Cell Free IL-2R EIA kit, respectively. Immunological markers and PAIgG were determined using fresh blood samples.

Spleen size in cirrhotic patients was evaluated as spleen index using ultrasonography as previously reported<sup>[28]</sup>, in which spleen index correlated well with the volumes of resected spleens. Briefly, the spleen index was calculated as the product of the transverse diameter and its perpendicular diameter measured on the maximum cross-sectional image of the spleen, and expressed in cm<sup>2</sup>. Values obtained from healthy individuals were below 20 cm<sup>2</sup>, and the mean values of 28 healthy controls were  $15 \pm 7$  cm<sup>2</sup><sup>[28]</sup>.

### Statistical analysis

Values were expressed as mean $\pm$ SD. Comparisons of the serum measurements among patients of the splenectomies, non-splenectomies and non-C cirrhosis were carried out using analysis of variance (ANOVA), and analyses of

**Table 2** Laboratory findings in the type C cirrhotic and non-C cirrhotic patients (*n*, mean±SD)

non-parametric data between two groups were carried out by Mann-Whitney *U* test. A correlation was calculated with the Spearman's rank correlation coefficient.

## RESULTS

### Laboratory findings and spleen index

Thrombocytopenia ( $\text{PLT}<15\times 10^4/\mu\text{L}$ ) was diagnosed in all the non-splenectomies (100%), eight of the splenectomies (47.1%), and 19 of the non-C cirrhosis (95.0%) (Table 2). Marked thrombocytopenia at less than  $10\times 10^4/\mu\text{L}$  was obviously found in the non-splenectomies (79.2%) and the non-C cirrhosis (65.0%) as compared with the splenectomies (11.8%). Peripheral platelet and white blood cells were significantly higher in the splenectomies than that in the non-splenectomies and non-C cirrhosis ( $P<0.01$ ). Platelets and white blood cells were similar in the non-splenectomies and non-C cirrhosis. Red blood cell counts were not changed among the three groups. No difference was found among the three groups for liver function parameters except for total bilirubin levels and HCV-RNA titers.

Spleen index ranged widely from 9.6 to 42.0  $\text{cm}^3$ . The

**Figure 1** PAIgG titers in the type C cirrhosis with an intact spleen, type C cirrhosis submitted to splenectomy, and non-C cirrhosis. The type C cirrhosis with an intact spleen had significant higher titers of PAIgG as compared with those of the splenectomized patients with type C cirrhosis and non-C cirrhosis.

mean spleen index was above the upper limit of normal individuals (20  $\text{cm}^3$ ) in both type C cirrhosis ( $24.6\pm 8.0\text{ cm}^3$ ) and non-C cirrhosis ( $23.5\pm 8.0\text{ cm}^3$ ).

### Immunological markers

An elevation of PAIgG at more than 25.0  $\text{ng}/10^7\text{ cells}$  was observed in all cirrhotic patients except for one splenectomized patient. The mean PAIgG titers were significantly higher in the non-splenectomies as compared with the splenectomies ( $297.9\pm 197.0$  vs  $125.6\pm 87.8$   $\text{ng}/10^7\text{ cells}$ ,  $P<0.05$ ) and non-C cirrhosis ( $297.9\pm 197.0$  vs  $152.4\pm 127.4$   $\text{ng}/10^7\text{ cells}$ ,  $P<0.05$ ). There was no significant difference in PAIgG titers between the splenectomies and the non-C cirrhosis (Figure 1). In comparison with the type C cirrhotic patients, the splenectomies had reduced percentage of CD4 and similar percentage of CD8, resulting in a lower ratio of CD4/CD8 than those of the non-splenectomies. In addition, neopterin levels were significantly lower in the splenectomies as compared with the non-splenectomies, while sIL2R levels were similar between the two groups (Table 3).

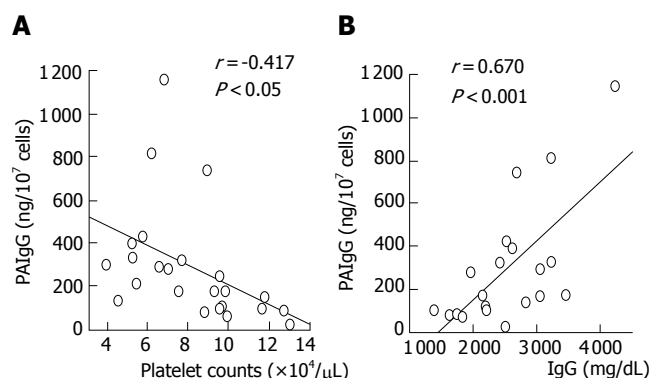

### Correlation between peripheral blood cells, immunological markers and spleen index

In the non-splenectomies, PAIgG titers were negatively correlated with platelet counts, and positively correlated with IgG and  $\gamma$ -globulin levels (Figure 2). In the non-C cirrhosis, PAIgG titers were neither correlated with platelet counts nor with IgG and  $\gamma$ -globulin levels. A significant negative correlation between the spleen index and platelet counts was found in the non-C cirrhosis, whereas not in the type C cirrhosis (Figure 3). In addition, the spleen index was negatively correlated with white blood cell counts in both type C and non-C cirrhosis. In the splenectomies, PAIgG titers were not correlated with platelet counts,  $\gamma$ -globulin levels, or the duration of follow-up after splenectomy.

## DISCUSSION

Our data demonstrated that the HCV-positive cirrhosis (type C cirrhosis) with an intact spleen had a significant rise

**Figure 2** Relationships among PAIgG titers, platelet counts, and IgG levels in the type C cirrhosis with an intact spleen. PAIgG titers are negatively correlated with platelet counts, and positively correlated with IgG levels.

of PAIgG as compared with the non-C cirrhosis, including hepatitis B infection, autoimmune hepatitis, alcohol abuse, and idiopathic cirrhosis. PAIgG titers were negatively correlated with platelet counts in the type C cirrhosis with an intact spleen. The type C cirrhotic patients submitted to splenectomy showed a significant elevation of platelet counts and reduction in PAIgG titers compared with those of the patients with an intact spleen. Similar PAIgG and platelet levels following splenectomy are commonly found in ITP patients, in whom the thrombocytopenia is responsible for the autoimmune mechanism mediated by a specific IgG bound to platelet membrane proteins<sup>[24,25]</sup>. There exist controversies regarding the clinical significance of PAIgG in pathogenesis of thrombocytopenia in the patients with liver disease<sup>[7,14,29,30]</sup>. Two studies on partial splenic artery embolization in patients with hypersplenism clearly confirmed an immunological mechanism mediated by PAIgG-induced thrombocytopenia accompanying liver cirrhosis<sup>[7,14]</sup>. These studies reported a significant rise in platelet numbers and a significant fall in PAIgG levels after partial splenic artery embolization. In the present study, the changes in PAIgG levels and platelet numbers among the type C cirrhotic patients with or without an intact spleen are practically similar to those previous results. These data support a key role of spleen in PAIgG production and that an autoimmune mechanism plays an important role in the development of thrombocytopenia associated with HCV-positive cirrhosis. On the contrary, a non-specific adsorption of elevated  $\gamma$ -globulin by platelets was suspiciously reported on chronic liver disease<sup>[27]</sup>. Our data found a negative correlation between PAIgG titers and platelet counts in the type C cirrhosis with an intact spleen, but not in the non-C cirrhosis. Presumably, the elevated PAIgG in the type C cirrhosis may act as anti-platelet autoantibodies. However, we found a positive correlation between PAIgG titers and IgG levels in the type C cirrhosis with an intact spleen. This result is in agreement with that of de Noronha *et al*<sup>[31]</sup> in the patients with various liver diseases. The methods used for quantitating PAIgG in their study as well as in our study appear to measure total PAIgG, which is not equivalent to platelet-specific autoantibodies. They suggested that increased platelet IgG was due to enhanced retention of plasma IgG in the platelets.

**Figure 3** Relationship between the spleen index and platelet counts. A significant negative correlation is shown in the patients with non-C cirrhosis, but not in the type C cirrhosis with an intact spleen.

In our study, despite similar  $\gamma$ -globulin levels, a relationship between PAIgG and  $\gamma$ -globulin was found neither in the splenectomized patients with type C cirrhosis nor in the non-C cirrhotic patients. Consequently, the theory of 'enhanced retention of IgG in the platelets' proposed by de Noronha *et al*<sup>[31]</sup> is deniable in the present study.

Sample *et al*<sup>[32]</sup> indicated that CD4<sup>+</sup> T-helper cells from patients with ITP are stimulated by normal platelet antigen(s) to secrete IL-2 and may modulate the enhanced anti-platelet autoantibody response. The underlying mechanisms for the production of anti-platelet autoantibodies require CD4<sup>+</sup> and HLA-DR-restricted T cells to GPIIb-IIIa in ITP patients<sup>[26]</sup>. GPIIb<sup>+</sup> cells isolated from spleens of patients with chronic ITP strongly expressed HLA-DR, and splenic T cells had a high level of *in vitro* platelet-stimulated IL-2 secretion as compared with the controls<sup>[33]</sup>. Thus, the spleen is such an important site for antibody production in patients with chronic ITP that the levels of PAIgG rapidly normalize in response to a splenectomy<sup>[24,34]</sup>. Our data showed that compared with the type C cirrhosis with an intact spleen, the type C cirrhosis submitted to splenectomy had lower CD4/CD8 ratio because of a reduced percentage of CD4<sup>+</sup> T cells. Neopterin is secreted by macrophages when stimulated for helper functions in the proliferation and activation of T cells. This immune marker was significantly decreased in the type C cirrhosis submitted to splenectomy compared to the type C cirrhotic patients with an intact spleen, supporting impaired T cell function following splenectomy. Taken together, previous and present results indicate that splenectomy may impair T cell function in HCV-positive liver cirrhosis through, at least in part, a reduction in CD4/CD8 ratio, which thereby suppresses PAIgG production. The data from the present study provide some indications that the spleen induces helper T-cell proliferation, but a further research is necessary to clarify the role of spleen in PAIgG production and T helper lymphocyte cytokine production.

Hypersplenism due to portal hypertension is believed as a major cause of thrombocytopenia complicated with liver cirrhosis; however, studies on the relief of portal hypertension have yielded the controversial results that observable reduction in spleen size is not associated with a concomitant persistent rise in platelet counts, unless accom-

panied by liver transplantation<sup>[8,9]</sup>. Thus, the role played by immune disturbance as well as thrombopoietin is an attractive possibility in the pathogenesis of thrombocytopenia concomitant with liver cirrhosis. Noguchi *et al*<sup>[5]</sup> observed the improved numbers and survival time of platelets and reduction in the raised PAIgG levels by partial splenic artery embolization in cirrhotic patients with hypersplenism. Owing to a negative correlation between platelet numbers and splenic volume before and after the procedure, they concluded that partial splenic artery embolization may not only reduce the increased platelet pool in the spleen, but also improve the autoimmune thrombocytopenia induced by cirrhosis. In the present study, the elevated platelets and reduced PAIgG levels in the splenectomized patients support their results. In addition, the present study showed that spleen size was correlated with platelets counts in the non-C cirrhotic patients. The data suggested that hypersplenism due to portal hypertension is assumed to be a major cause of thrombocytopenia observed in the non-C cirrhotic patients. If no significant relationship is found between the spleen index and platelet counts in HCV-positive cirrhotic patients, autoimmune disturbance may be the most likely principal mechanism for thrombocytopenia rather than sequestration and/or destruction of platelets secondary to hypersplenism.

In the present retrospective study, we confirmed that the autoimmune disturbance induces thrombocytopenia associated with liver cirrhosis which is related to HCV-infection. Prospective pre- and post-splenectomy studies should elucidate the role of spleen in PAIgG production, platelet sequestration and destruction, as well as cellular and humoral immunity.

### Abstract

**AIM:** To evaluate the possible differences in morphology and immunohistochemical expression of CD3, transforming growth factor  $\beta$ 1 (TGF- $\beta$ 1), Smad7,  $\alpha$ -smooth muscle actin ( $\alpha$ -Sma), and collagen types I-VII of small and large intestine in Smad3 null and wild-type mice.

**METHODS:** Ten null and ten wild-type adult mice were sacrificed at 4 mo of age and the organs (esophagus, small and large bowel, ureters) were collected for histology (hematoxylin and eosin, Masson trichrome, silver staining), morphometry and immunohistochemistry analysis. TGF- $\beta$ 1 levels of intestinal tissue homogenates were assessed by ELISA.

**RESULTS:** No macroscopic intestinal lesions were detected both in null and wild-type mice. Histological and morphometric evaluation revealed a significant reduction in muscle layer thickness of small and large intestine in null mice as compared to wild-type mice. Immunohistochemistry evaluation showed a significant increase of CD3+T cell, TGF- $\beta$ 1 and Smad7 staining in the small and large intestine mucosa of Smad3 null mice as compared to wild-type mice.  $\alpha$ -Sma and collagen I-VII staining of small and large intestine did not differ between the two groups of mice. TGF- $\beta$ 1 levels of colonic tissue homogenates were significantly higher in null mice than in wild-type mice. In preliminary experiments a significant reduction of TNBS-induced intestinal fibrosis was observed

### INTRODUCTION

Smads are a family of eight related proteins which function as signalling intermediates for the transforming growth factor  $\beta$  (TGF- $\beta$ ) superfamily of ligands<sup>[1-3]</sup>. Upon ligation and activation of TGF- $\beta$  with its receptors (I, II and III), the phosphorylated Smad2 and 3 form a complex with the common mediator Smad4. The Smad2/3- Smad4 complex can translocate into the nuclei where they enhance specific TGF- $\beta$  target genes. The inhibitory Smad7 antagonizes TGF- $\beta$  signalling by interfering with the ligation of Smad2/3 with the activated receptor complex. Experimental evidence from several research groups suggests that disruption of the TGF- $\beta$ /Smad signalling pathway plays a central role in sustaining both chronic tissue inflammation and fibrosis<sup>[4-6]</sup>.

TGF- $\beta$  is a multifunctional polypeptide hormone influencing different functions in a variety of cells including regulation of cell proliferation, differentiation and apoptosis, immunoregulation, regulation of the inflammatory response, restitution and healing<sup>[5,7,8]</sup>. At cellular level, TGF- $\beta$  affects virtually all stages of the chronic inflammatory and fibrotic disease processes. The effects of TGF- $\beta$  on the extracellular matrix are more complex than those of any other growth factor and are central to its effects in increasing the maturation and strength of wounds, as well as in the pathological matrix accumulation, characteristic of fibrotic disease<sup>[4,9,10]</sup>. TGF- $\beta$  regulates the transcription

of a wide spectrum of matrix proteins including collagen, fibronectin, glycosaminoglycans, and matrix-degrading proteases (metalloproteinases) and their inhibitors.

TGF- $\beta$ /Smad signalling plays an important role in chronic inflammatory diseases, especially in Crohn's disease (CD)<sup>[5,7,11,12]</sup>. The transmural infiltrate of CD is responsible for initiating and maintaining a series of connective tissue changes not only involving the mucosa but also the submucosa and *muscularis mucosae* and *propria* where a marked increase of type I, III and V collagens and RNA transcripts are observed<sup>[13-15]</sup>. In CD, there is a marked overexpression of TGF- $\beta$ 1 and TGF- $\beta$  receptors in the colonic mucosa<sup>[16-18]</sup>. Fibrosis in CD can therefore be viewed as an aberrant healing response to injury<sup>[19]</sup>. In addition, TGF- $\beta$  appears to be involved in intestinal fibrosis present in other enteropathies, such as radiation enteritis, collagenous colitis and intestinal graft-versus-host disease<sup>[20-22]</sup>.

Experimental transgenic animal models are useful tools to study the *in vivo* function of individual molecules<sup>[23-25]</sup>. TGF- $\beta$  knock-out mouse model is characterized by the loss of a critical regulator of immune function which leads to an excessive inflammatory response with massive infiltration of leukocytes in several organs<sup>[26]</sup>. This condition develops rapidly with onset during the first week of life and results in severe wasting and death by the fourth week of life<sup>[27,28]</sup>. Unlike the targeted disruptions of Smad2 and 4 which are lethal<sup>[29,30]</sup>, the disruption of Smad3<sup>[31]</sup> results in the birth of mice which are viable and can survive to adulthood (up to 8 mo of age). Since the Smad3 knock out model provides pivotal information concerning cutaneous wound healing<sup>[32-34]</sup>, it is thought that this model might also be useful to investigate the *in vivo* role of the TGF $\beta$ /Smad signalling pathway in intestinal inflammation and fibrosis.

The present study was to evaluate the small bowel and colonic morphology as well as the immunohistochemical expression of collagens I-VII,  $\alpha$ -smooth muscle actin ( $\alpha$ -SMA), TGF $\beta$ 1, Smad7, and CD3 in Smad3 wild-type and null mice.

## MATERIALS AND METHODS

### Animals

Colonies of Smad3 wild-type, heterozygous and null mice (black Swiss strain) were bred in our laboratory. These animal colonies were developed using pairs of Smad3 heterozygous mice kindly provided by A. Roberts (NCI, Bethesda, MD, USA). Smad3<sup>ex8/ex8</sup> mice were generated by targeted disruption of the Smad3 gene by homologous recombination. Targeted embryonic stem-cell clones were injected into a C57BL blastocyst to obtain germline transmission. Mice heterozygous for the targeted disruption were intercrossed to produce homozygous offspring<sup>[31]</sup>.

All mice were maintained in a specific pathogen-free (SPF) facility and routinely monitored. Mice were kept in microisolator cages and allowed free access to food and water. All mice were examined 4 times a week for signs of colitis including weight loss, diarrhea, rectal bleeding and prolapse<sup>[35]</sup>, as well as signs of systemic inflammation such as piloerection, lethargy and periorbital exudates<sup>[36]</sup>.

**Figure 1** Genotyping of animal offsprings by PCR of cDNA (tail extracts). Lane 1= molecular weight ladder of 100 bp; lane 2= null mice; lane 3= wild-type (Wt) mice; lane 4= heterozygous(Ht) mice.

### DNA extraction and genotype analysis

Mouse tail DNA extraction was performed according to the protocol reported elsewhere<sup>[37]</sup>.

Genotype analysis was carried out by the polymerase chain reaction (PCR) method in which the wild type Smad3 allele was detected using primer 1 (5'-CCAGACTGCCTTGGGAAAAGC-3') and primer 2 (5'-CCCGAACAGTTGATTCACACA-3'). Primer 1 is located 5' to the deletion and primer 2 is located within the deletion. This primer pair amplified a fragment of ~ 400 bp from wild-type and Smad3<sup>ex8/+</sup> mice, but not from Smad3<sup>ex8/ex8</sup> mice (Figure 1). DNA was also amplified using primer 1 and primer 3 (5'-CCAGACTGCCCTTGGGATGCCCTG-3'), which is located in the pLoxpneo, to detect the mutant Smad3 allele. In this case, a 250 bp fragment was detected in mice, heterozygous or homozygous for the mutant Smad3 allele, while no signal was detected in wild-type mice.

### Sample recovery and preparation

A total of 20 mice (10 wild-type and 10 null for the Smad3 allele) were sacrificed at 4 mo of age. Laparotomy was performed under ether anesthesia. The esophagus, small bowel, colon and ureters were visualized, rapidly excised and placed in a Petri dish containing sterile saline solution. Tissue samples from the esophagus, small bowel, colon, and ureters were processed for structural and immunohistochemical studies.

### Histology and morphometry

Specimens obtained from the esophagus, small bowel, colon and ureters of all animals were washed and immediately immersed in 10% buffered formalin in phosphate buffer saline (PBS) (pH 7.4) for 3 h at room temperature followed by the standard procedure for paraffin embedding. Serial 3  $\mu$ m sections were stained with hematoxylin and eosin (HE) to assess the degree of inflammation and with Masson trichrome and silver stain to detect connective tissue. The stained sections were then observed under an Olympus BX51 light microscope (Olympus, Optical Co. Ltd., Tokyo, Japan). The degree of intestinal inflammation was scored as absent, mild, moderate or severe according to the density and extent of both acute and chronic inflammatory infiltrate, loss of goblet cells and

**Table 1** Muscle layer thickness of gastrointestinal and urinary tract segments from Smad3 wild-type and null mice (mean $\pm$ SD)

	Wild-type (n)	Null (n)	P value
Colon	221.79 $\pm$ 99.78 (6)	104.68 $\pm$ 50.73 (7)	0.02
Small bowel	95.55 $\pm$ 38.45 (6)	46.44 $\pm$ 25.96 (6)	0.03
Esophagus	189.36 $\pm$ 42.60 (5)	188.49 $\pm$ 43.94 (6)	NS
Ureters	32.85 $\pm$ 3.74 (5)	30.31 $\pm$ 1.91 (5)	NS

(n)=Number of mice evaluated. Muscle layer thickness is expressed in micron. NS=not significant.

bowel wall thickening<sup>[35,38]</sup>. Intestinal fibrosis was scored as mild, moderate or severe depending on the density and extent of trichrome-positive connective tissue staining and disruption of tissue architecture<sup>[38]</sup>. A quantitative estimate of mucosa, submucosa and muscular layer thickness of distal esophagus, proximal and distal small bowel, proximal and distal colon, and distal ureters was performed. Morphometric analysis was done in all animals by ten measurements randomly taken in 4 different fields (x 40) in a double blind fashion by two independent pathologists with an agreement always higher than 90%. Light microscopic and IHC microphotographs were taken by Olympus BX-51 Light Microscopy (Olympus, Optical Co. Ltd., Tokyo, Japan) with a videocam (Spot Insight, Diagnostic Instrument, Inc., Sterling Heights, MI, USA) and processed with an image analysis system (IAS-Delta Sistemi, Rome, Italy) software.

### Immunohistochemistry

Samples from small bowel and colon obtained as previously described, were also promptly fixed with 10% buffered formalin in PBS (pH 7.4) for 3 h, dehydrated in graded ethanols and embedded in low-temperature-fusion paraffin. Serial 3  $\mu$ m sections were incubated for 40 min in methanol and 3% hydrogen peroxide solution and then rinsed in PBS. Thereafter, sections were incubated overnight at 4 °C with monoclonal antibodies to CD3, TGF $\beta$ -1, Smad7 and  $\alpha$ -SMA (Santa Cruz Biotechnology Inc., Santa Cruz, CA, USA), used at a dilution of 1:100, 1:250, 1:100 and 1:400 respectively in PBS. Additional sections were incubated with a cocktail of monoclonal antibodies to collagen types (I, III, IV, V, VII) (Santa Cruz Biotechnology Inc., Santa Cruz, CA, USA) in order to demonstrate the morphological and topographic features of collagen distribution in different layers of small bowel and colonic wall.

Samples were then rinsed with PBS for 5 min and incubated with a labeled streptavidin-biotin-peroxidase conjugate kit (Dako LSAB, cod. K0675, Dako-Cytomation, Milan, Italy). After rinsed in PBS for 10 min, the sections were incubated with 3,3-diaminobenzidine-tetrahydrochloride (DAB, Sigma Aldrich, Milan, Italy) for 1-3 min.

To control specificity of the immune reaction, sections were incubated omitting the primary antibody, i.e., incubated with the secondary antibody alone. Finally, the samples were counterstained with Mayer's hematoxylin and observed under photomicroscope (Olympus BX51 light microscope; Olympus, Optical Co. Ltd, Tokyo, Japan).

**Figure 2** Morphology of Smad3 null and wild-type mice. The majority of Smad3 null mice exhibited a reduced size compared to littermate controls. Severe bending of forepaw joints was present in Smad3 null mice.

### Measurement of colonic TGF- $\beta$ 1 protein levels

TGF- $\beta$ 1 protein was determined by ELISA. Briefly, tissue was homogenized in the presence of a mixture of protease inhibitors with a broad specificity for the inhibition of serine, cysteine, aspartic proteases and aminopeptidases (1 mL/20 g). The mixture contained 4, (2-aminoethyl) benzenesulphonyl fluoride (AEBSF), pepstatin A, E-64, bestatin, leupeptin and aprotinin without metal chelators. For determination of TGF- $\beta$ 1 levels, an aliquot of the supernates was treated with 1 mol/L HCl to activate TGF- $\beta$ 1, followed by neutralization with 1 mol/L NaOH using a standard ELISA procedure (Quantikine, R&D Systems, Minneapolis, MN, USA).

### Statistical analysis

All statistical analyses were performed in a double-blind fashion and results were computed using an appropriate program (SAS/STAT software). Results were expressed as mean $\pm$ SD. Statistical significance was performed by the two-tailed Student's *t* test for paired data and *P*<0.05 was considered statistically significant.

## RESULTS

### Animal gross phenotype

The phenotype of Smad3 null mice at birth was identical to that in heterozygous and wild-type littermate controls. Nevertheless, the Smad3 null mice at three weeks of age were characterized by the following hallmarks: short body length compared to the tail and a predominant deformity of the anterior paws (Figure 2). About 20% of Smad3 null animals developed a wasting disease (Figure 3) and died between 3-6 mo but none of them developed diarrhea or hematochezia, and only a marked dilatation of the colon was observed in two Smad3 null mice.

About 80 % of null mice survived up to 6 mo of age, while a mortality rate of 6% and 2% was observed at 18 mo of age in heterozygous and wild-type mice, respectively. No serosal or mucosal macroscopic lesions of the small or large intestine were detected either in wild-type mice or in null mice.

### Histologic and morphometric evaluation

HE staining of the small and large bowel showed a normal morphology both in wild-type mice and in Smad3 null mice (Figure 4). Masson trichromic staining and silver

**Figure 3** Body Weight changes of wild-type and Smad3 null mice. Each point represents mean weight data pooled from 10 mice. Standard deviations are indicated. Plot of weight (g) vs age (days). Wild-type are indicated as  $\square$  (squares), and null as  $\diamond$  (diamonds).

**Figure 4** Haematoxylin and eosin-stained sections (x 20) analysis of small and large bowel from wild-type and Smad3 null mice shows normal morphology.

**Figure 5** Masson trichrome staining (x 20) of small and large bowel from Smad3 mice. Significant reduction of muscular layer of descending colon of Smad3 null (A) is observed compared to colon from wild-type (WT) mice (B), reduction of muscle layer in cross sections of the proximal small bowel from Smad3 null (C) as compared to wild-type mice (D). Haematoxylin and eosin staining (x 20) of ureter and esophagus of Smad3 mice. Cross section of esophagus from Smad3 null (E) and wild-type mice (F) shows no differences in muscle layer. Cross section of ureter from Smad3 null (G) and wild-type mice (H) shows no differences in muscle layers.

staining of the colon and small intestine showed a similar collagen distribution in all intestinal layers both in wild-type mice and in Smad3 null mice (Figure 5).

A significant reduction in muscle layer thickness confined to the colon and small intestine was observed in Smad3 null mice compared to wild-type mice, while the mucosa and submucosa layers were similar in the two groups (Table 1, Figure 5). No differences in the thickness of the mucosa, submucosa and muscle layers of the ureter and esophagus were observed either in wild-type mice or in Smad3 null mice (Figure 5).

#### Immunohistochemistry evaluation

In the colonic and small intestine mucosa of Smad3 null mice, a significant staining of CD3+ T cells, TGF- $\beta$ 1 and Smad7 was observed compared to the intestinal mucosa of wild-type mice (Figure 6). TGF- $\beta$ 1 and Smad7 staining was localized mainly in lymphocytes of the intestinal lam-

ina propria from Smad3 null mice. In small intestine and colon,  $\alpha$ -SMA staining was limited to the smooth muscle cells of muscularis mucosa, muscularis propria as well as myocytes of the median vessel layer, with a comparable pattern both in wild-type mice and in null mice (Figure 7). Staining of collagens I-VII of the small intestine and colon was localized mainly in the submucosa and muscularis propria connective tissue and did not differ between the wild-type and null mice (Figure 7).

#### TGF- $\beta$ 1 levels in colon homogenates

TGF- $\beta$ 1 levels in colonic tissue homogenates were significantly higher in null mice than in wild-type mice (Figure 8).

## DISCUSSION

In this study, we characterized the changes in intestinal structures which may occur in a Smad3 knock out mouse

**Figure 6** Immunohistochemical analysis (x 20) of CD3+ T cells, TGF- $\beta$ 1 and Smad7 in colon obtained from Smad3 null and wild-type mice. CD3+ T cells were significantly increased within large intestine of Smad3 null mice as compared to the wild-type mice. TGF- $\beta$ 1 and Smad7 were significantly increased within large intestine of Smad3 null mice compared to wild-type mice.

model compared to the littermate wild-type controls. In particular, attention was focused on evaluation of intestinal alterations present in healthy adult animals that could be used as a model to investigate the role of the TGF $\beta$ 1/Smad3 pathway in the development of chronic intestinal inflammation and fibrosis. The animals studied did not develop any signs of colitis, but Smad3 null mice had a deficit in body weight gain as compared to their controls. Smad3 null mice were smaller than wild-type littermates and about 40% of them showed the presence of medially torqued forepaws associated with kyphosis sometimes. Some aspects of this phenotype are similar to those of mice expressing a transgenic dominant negative type II TGF- $\beta$  receptor<sup>[39]</sup>. We did not observe any significant macroscopic intestinal lesions except for colonic dilatation in 20% of Smad3 null mice.

Histopathological analysis of small and large intestine specimens did not reveal any neoplastic lesions, significant

**Figure 7** Immunohistochemical analysis (x 20) of  $\alpha$ -SMA and collagens I-VII in colon from Smad3 null and wild-type mice. A similar localization of  $\alpha$ -SMA antibody was found in myocytes of muscularis mucosae, muscle layer and vessels of both groups of animals. Staining of collagens I-VII in large intestine of Smad3 null and wild-type mice was localized mainly within connective tissue of submucosa and muscularis propria showing identical staining pattern between the two groups of mice.

**Figure 8** TGF- $\beta$ 1 ELISA of colon homogenates from Smad3 null (solid column) and wild-type mice (dashed column). Data are given as mean $\pm$ SD. <sup>a</sup> $P$ <0.05 vs wild type mice.

intestinal mucosa inflammation (i.e., chronic abscesses or marked neutrophil/monocyte infiltrate) or changes in intestinal connective tissue distribution. On the contrary, mice that died prematurely (1-3 mo of age) often showing signs of systemic inflammation, presented severe histologic lesions of the intestinal mucosa (data not shown) similar to the findings described earlier<sup>[31]</sup>. These animals were not included in the present study since the aim of the investigation was to evaluate the intestine of healthy adult mice in which an intestinal fibrosis could be experimentally induced.

A significant reduction in smooth muscle layer thickness of small and large intestine was present in Smad3 null mice as compared to wild-type mice. These alterations of colonic smooth muscle layers could account for the colonic dilation observed in Smad3 null mice. In this respect, immunostaining of the colonic mioenteric plexus was also performed which showed a normal appearance (data not shown). Smooth muscle layer thickness from the esophagus and ureters was normal and similar in the two groups of mice. The reason why the intestinal muscle layer thickness was reduced in Smad3 null mice is unknown. Nevertheless, several lines of evidence suggest that TGF- $\beta$ /Smad3 signalling plays an important role in the development of smooth muscle cells from totipotent or multipotent embryonic stem cells<sup>[40,41]</sup>. Furthermore, TGF- $\beta$ /Smad3 signalling is also involved in the differentia-

tion and proliferation of smooth muscle cells<sup>[42,43]</sup>.

A number of phenotypic changes as observed in our mice with a targeted disruption of Smad3 in exon 8<sup>[31]</sup>, are similarly present also in mice with a disruption of Smad3 in exon 1 or 2<sup>[44,45]</sup>. In fact, in all these three models a decrease in size and growth rate, and the presence of skeletal abnormalities have been observed. They also show a decreased survival. The deletions of both exon 8 and 1 are associated with different degrees of intestinal inflammation<sup>[31,44]</sup>, while the deletion of exon 2 accompanies the development of metastatic colorectal cancer<sup>[45]</sup>. The reason for this discrepancy is unknown. This discrepancy could be related to differences in genetic background of the Smad3 null animals used. It is possible that in mice a differential activation of downstream targets exists with a disruption in exons 1, 2 and 8. This hypothesis is supported by *in vitro* studies indicating that different domains of the Smad3 protein may be involved in activation of diverse downstream pathways<sup>[46,47]</sup>.

Although no evident intestinal mucosa inflammation was found, the immunohistochemical analysis showed an increase in CD3+ T cells within the intestinal mucosa of Smad3 null mice, compared to wild-type mice, which is consistent with previous data<sup>[31]</sup>. In addition, increased TGF- $\beta$ 1 and Smad7 staining was observed in the intestinal mucosa of Smad3 null mice. The constitutively high TGF- $\beta$  expression in the intestine could account for the positive counteractive mechanism due to the loss of intracellular transduction signals in Smad3 null mice. TGF- $\beta$  overexpression could not be attributed to monocytes and macrophages not increased in the intestinal mucosa<sup>[31,32]</sup>, nor to TGF- $\beta$  autoinduction under the control of Smad3<sup>[32,33]</sup>. On the other hand, increased TGF- $\beta$  expression could be attributed to the increased T cells in the intestinal mucosa or to the platelet degranulation not assessed in this study. The mechanism that may upregulate Smad7 expression is not clear. Moreover, Smad7 is strongly and rapidly induced by TGF- $\beta$  itself<sup>[48]</sup>. Efficient expression of Smad7 appears to depend upon the cooperation of Smad, Sp1 and AP-1 transcription factors<sup>[49]</sup>. In Smad3 null mice, the overexpression of TGF- $\beta$ 1 may induce Smad2 phosphorylation which in turn could upregulate Smad7 intracellular expression even in the absence of Smad3. In some cell types, Smad7 expression is induced by other signalling pathways, such as Jak1/Stat1 pathway following stimulation with interferon (INF)- $\gamma$  and activated nuclear factor (NF)- $\kappa$ B following stimulation with tumor necrosis factor (TNF)- $\alpha$ <sup>[50,51]</sup>. Whatever the main inducible Smad7 factor is, high Smad7 expression levels interfere with activation of Smad2 and Smad3 or accelerate degradation of TGF- $\beta$  receptors, inhibiting TGF- $\beta$ /Smad signalling.

The lack of significant neutrophil/monocyte infiltrate in intestinal mucosa of Smad3 null mice could be related to the impaired chemotactic response toward TGF- $\beta$  shown by mutant neutrophils and monocytes<sup>[32,33]</sup>. In contrast, mutant-activated T cells are resistant to the suppressive effect of TGF- $\beta$  leading to their significant increase in the intestinal mucosa<sup>[31]</sup>. Furthermore, a reduced number of IgA+ plasma cells has been detected in the intestine of severely affected Smad3 null mice<sup>[31]</sup>. These data suggest that Smad3 plays a pivotal role in TGF- $\beta$ -mediated

regulation of mucosal immunity and local inflammatory response. Loss of these functions may also be responsible for infection and the high mortality rate of Smad3-null mice.

It has been reported that mice lacking Smad3 show accelerated healing of cutaneous incisional wounds with reduced inflammation and accumulation of matrix<sup>[32,33]</sup>, and decreased cutaneous lesions and fibrosis after exposure to ionizing radiation<sup>[34]</sup> or subcutaneous injection of bleomycin<sup>[52]</sup>. Furthermore, loss of Smad3 could attenuate bleomycin-induced lung fibrosis<sup>[53]</sup>, CCl4-induced liver fibrosis<sup>[54]</sup>, and glomerular fibrosis induced by different methods<sup>[55]</sup> in mice, suggesting that Smad3 plays a pivotal role during tissue injury that leads to skin, lung, liver and kidney fibrosis<sup>[56]</sup>.

Recently, it has also been reported that reduction of Smad3 accelerates re-epithelization in a murine model of colitis<sup>[57]</sup>. Amelioration of cutaneous radiation-induced fibrosis has also been obtained by halofuginone, which inhibits the formation of phospho-Smad2 and Smad3, increases inhibitory Smad7 expression, and decreases cytosolic and membrane TGF- $\beta$  type II receptors<sup>[58]</sup>. There is increasing evidence that Smad3 may take part in recruitment of fibroblasts to the site of injury, differentiation of fibroblasts to myofibroblasts and regulation of collagen synthesis<sup>[33,34,59]</sup>. Since loss of Smad3 interferes with the effects of TGF- $\beta$  on chemotaxis and autoinduction in inflammatory cells, and as well as induction of many ECM genes by TGF- $\beta$  is also Smad3-dependent, this may explain why Smad3 null mice are resistant to cutaneous<sup>[33,34,52]</sup>, pulmonary<sup>[53]</sup>, hepatic<sup>[54]</sup> and renal fibrosis<sup>[55]</sup>. Based on these observations, we may hypothesize that mice lacking Smad3 would be also resistant to chronic intestinal inflammation and fibrosis. In fact, by inducing intestinal fibrosis with TNBS according to the protocol of Lawrance *et al*<sup>[38]</sup>, we observed a significant reduction of intestinal fibrosis in knock out mice as compared to the wild-type mice in preliminary experiments (data not shown).

In conclusion, about 80% of Smad3 knock-out mice survive up to 6 mo of age without developing significant macroscopic and histological lesions of the small and large intestine, with the exception of a reduction in intestinal muscle layer thickness. Preliminary data shown that Smad3 knockout mice are resistant to intestinal fibrosis. This model could be a useful tool to unravel the molecular mechanisms of chronic intestinal inflammation and fibrosis.

## Abstract

**AIM:** To determine whether neutrophil depletion and Kupffer cell inhibition might combine their protective effects to decrease the severity of acute pancreatitis.

**METHODS:** Mice had cerulein administration to induce acute pancreatitis and were pretreated with either anti-mouse neutrophil serum or gadolinium chloride ( $GdCl_3$ ) to prevent Kupffer cell activation, or both treatments. Injury was assessed in pancreas and lungs. Myeloperoxidases (MPO) assessed neutrophil infiltration. Interleukin-6 (IL-6) and IL-10 were measured in serum, pancreas, lungs and liver.

**RESULTS:** In mice with acute pancreatitis, neutrophil depletion reduced the severity of pancreatitis and pancreatitis-associated lung injury. Kupffer cell inactivation by  $GdCl_3$  had less protective effect, although IL-6 and IL-10 concentrations were significantly decreased. The protective treatment brought by neutrophil depletion was not enhanced by Kupffer cell

inactivation and both treatments did not combine their protective effects.

**CONCLUSION:** Our results confirm the role of activated neutrophils in aggravating organ injury in acute pancreatitis while the role of Kupffer cell activation is less obvious.

## INTRODUCTION

During acute pancreatitis, the pathophysiology of pancreatic injury includes inflammatory processes and, following early activation of trypsinogen in acinar cells, recruitment of inflammatory cells aggravates pancreatic damage<sup>[1,2]</sup>. Upon activation, circulating inflammatory cells adhere to vascular endothelial cells and transmigrate across the endothelial barrier within injured areas in pancreas as well as in remote organs. Thus, mice deficient in adhesion molecules such as intercellular adhesion molecule 1 (ICAM-1)<sup>[3]</sup> on endothelial cells or animals treated with an antineutrophil serum (ANS)<sup>[3,4]</sup> are protected from pancreatitis and remote injuries. However, the protection remained incomplete<sup>[3,4]</sup>.

In contrast to the severe lung injury frequently associated with pancreatitis, hepatic injury is minor during acute pancreatitis<sup>[5]</sup>. Nevertheless, hepatic functions are modified by pancreatitis. Detoxification is altered early in the evolution of the disease<sup>[6,7]</sup> and this decreased hepatic detoxification is compensated by an increased detoxification in blood, lungs, and intestine macrophages<sup>[7]</sup>. Moreover, mediators released from the damaged pancreas directly activate Kupffer cells and promote important inflammatory responses in the liver.

Elastase administration, either in the peritoneum<sup>[8]</sup> or in perfused livers<sup>[9]</sup> mimics this important inflammatory response. The role of the liver in acute pancreatitis is then to propagate pancreatic injury to lungs. Portocaval shunts (that dilute harmful pancreatic mediators in the systemic circulation)<sup>[5,10]</sup> and inhibitors of Kupffer cell activation such as gadolinium chloride ( $\text{GdCl}_3$ )<sup>[11]</sup> and liposome-encapsulated dichloromethylene diphosphonate (DMDP)<sup>[12]</sup> decrease acute pancreatitis-associated-lung injury.

Because neutrophil depletion or prevention of Kupffer cell activation is only partially effective in decreasing the severity of acute pancreatitis, the aim of our study was to determine whether both treatments might combine their protective effects.

## MATERIALS AND METHODS

### Animals

Breeding pairs of C57BL/6 mice were purchased from Charles River (Saint-Germain sur l'Arbresles, France) and bred and housed in temperature-controlled ( $23 \pm 2^\circ\text{C}$ ) cages with a 12 h light/dark cycle. They were fed with standard laboratory chow, given water *ad libitum*, and randomly assigned to control or experimental groups. The experimental protocol was reviewed and approved by the Ethics Committee for Animal Research of the University of Geneva and the Veterinary Office in Geneva and followed the guidelines for care and use of laboratory animals.

### Induction of acute pancreatitis

Male mice (20–22 g) were intraperitoneally injected hourly for 10 h (10 injections) with a supramaximally stimulating dose of cerulein (CER, 50  $\mu\text{g}/\text{kg}$  in 0.2 mL saline solution) to elicit a secretagogue-induced pancreatitis. Cerulein, the analog of the pancreatic secretagogue cholecystokinin was purchased from Research Plus (Bayonne, NJ, USA). Control (CONT) mice were injected with saline solution. One hour after the final injection, mice were sacrificed by a lethal intraperitoneal injection of pentobarbital.

### Neutrophil depletion

Twelve hour before the start of cerulein administration, mice were treated with 0.2 mL rabbit anti-mouse neutrophil serum (ANS, ip injection, Accurate Chemical and Scientific Corp, Westbury, NY) as previously described<sup>[3]</sup>.

### Kupffer cell inactivation

To prevent Kupffer cell activation, gadolinium chloride ( $\text{GdCl}_3$ , 1 mg/100 g of body weight, Sigma, Basel, Switzerland) was injected into mice tail vein 12 h and 1 h before the start of cerulein or saline administration. Another experimental group received both treatments.

### Experimental groups

Five experimental groups were studied: CONT mice had saline injection and no treatment; CER mice had cerulein administration and were treated with saline; CER + ANS mice had cerulein administration and were treated with

anti-mouse neutrophil serum; CER +  $\text{GdCl}_3$  mice had cerulein administration and were treated with gadolinium chloride; CER + ANS +  $\text{GdCl}_3$  mice had cerulein administration and were treated with ANS and  $\text{GdCl}_3$ .

### Quantification of cerulein-induced injuries

At the time of sacrifice (1 h following the last cerulein injection), blood was collected from the heart, centrifuged for 10 min, and the serum was kept at  $-80^\circ\text{C}$  until assayed. Serum amylase activity was measured using 4,6-ethylidene (G1)-p-nitrophenyl (G1)- $\alpha$ D-malto-heptoside (Sigma Chemical Company, St. Louis, Missouri) as substrate.

To quantify pancreatic edema, part of the pancreas was removed to measure tissue water content. Pancreatic tissue was weighed before and after desiccation at  $95^\circ\text{C}$  during 24 h. The difference between the wet and dry tissue weights was calculated and expressed as a percent of tissue wet weight. The other parts of pancreatic tissues were frozen in liquid nitrogen for cytokine measurements.

Neutrophil sequestration within pancreas was detected by measuring tissue myeloperoxidase activity (MPO)<sup>[13]</sup>. Pancreatic samples were thawed, homogenized in 1 mmol/L in 20 mmol/L phosphate buffer (pH 7.4), centrifuged (10000 g, 10 min), and the resulting pellet was resuspended in 50 mmol/L phosphate buffer (pH 6.0) containing 0.5% hexadecylmethylammonium bromide. The suspensions were subjected to four cycles of freezing and thawing and sonicated. The samples were centrifuged (10000 g, 5 min) and the supernatants were used to measure MPO activity. The reaction solution included 1.6 mmol/L tetramethylbenzidine (Sigma, Switzerland), 80 mmol/L sodium phosphate buffer (pH 5.4) and 0.3 mmol/L hydrogen peroxide (Sigma, Switzerland). Samples in solution were incubated at  $37^\circ\text{C}$  for 2 min and the absorbance was read by an autoanalyzer. MPO activity was expressed as U/mg tissue dry weight.

Pulmonary microvascular permeability was evaluated by quantitating the leakage of intravenously injected fluorescein isothiocyanate (FITC)-labeled bovine albumin (0.5 mg/kg in 0.2 mL) into the bronchoalveolar space (BAL)<sup>[14]</sup>. Immediately after sacrifice, the trachea was exposed and the lungs were injected three times with saline solution (1 mL). The lavage fluid was collected and FITC fluorescence was measured in the lavage fluid and serum using a Hitachi fluorospectrophotometer (excitation wave: 494 nm; emission wave: 520 nm). The ratio of fluorescence between BAL and blood was calculated and expressed the pulmonary permeability index.

### Measurements of cytokines

Interleukin-6 (IL-6) and interleukin-10 (IL-10) were quantified in serum, pancreas, lung and liver using the commercially available enzyme linked immunosorbent assay kits (R&D, Abingdon, UK). Freshly isolated tissues were homogenized in 1.5 mL phosphate buffer (20 mmol/L, pH 7.4). After centrifugation (14000 g for 5 min at  $4^\circ\text{C}$ ), IL-6 and IL-10 concentrations were measured in the supernatant according to the manufacturer's recommendations and expressed as pg per mg proteins in tissues and pg/mL in serum. The mean concentrations of IL-6 and IL-10 mea-

**Figure 1** Pancreatic myeloperoxidase (MPO, U/mL tissue dry weight) activity in mice injected with cerulein and saline (CER), cerulein and antineutrophil serum (CER+ANS), cerulein and gadolinium chloride (CER+GdCl<sub>3</sub>), CER+ANS+GdCl<sub>3</sub>.  $n \geq 5$  in each group. Kruskal Wallis analysis with Dunn posthoc test found a significant difference between CER and CER+ANS or CER+ANS+GdCl<sub>3</sub> mice.

sured in CER mice served as the 100% baseline values.

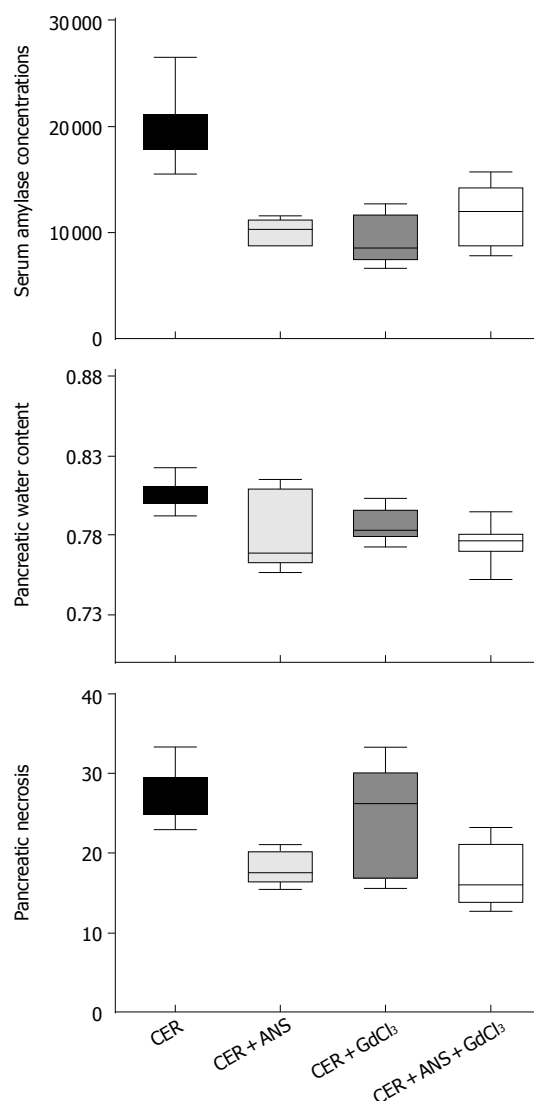

### Morphology

At the time of sacrifice, pancreatic tissues were rapidly removed, fixed in 4% neutral phosphate-buffered formalin, embedded in paraffin, and sectioned (5  $\mu$ m). After staining with hematoxylin-eosin, sections were examined by two morphologists who were not aware of the sample identity. The extent of acinar cell necrosis was quantified by computer-assisted morphometry and expressed as a function of total acinar tissue. Acinar cell necrosis included destruction of normal pancreatic architecture in combination with inflammation. After exclusion of non-acinar cells (islets of Langerhans and perivascular and periductular adventitial tissue), the amount of acinar necrosis were morphometrically quantified using a computerized image analysis video unit (Zeiss Camera, Zeiss, Bern, Switzerland).

For pulmonary morphology, a polyvinyl catheter was inserted into the trachea and used to instill 4% neutral buffered formalin into the lungs with a hydrostatic pressure of 30 cm H<sub>2</sub>O. Formalin-distended lungs were harvested, fixed, paraffin-embedded, sectioned (5  $\mu$ m) and stained.

### Statistical analysis

Data are median [minimum - maximum] and differences

**Figure 2** Serum amylase concentration (UI/L), pancreatic water content (% wet weight), and pancreatic necrosis (%) in mice injected with cerulein and saline (CER), cerulein and antineutrophil serum (CER+ANS), cerulein and gadolinium chloride (CER+GdCl<sub>3</sub>), CER+ANS+GdCl<sub>3</sub>.  $n \geq 5$  in each group. Kruskal Wallis analysis with Dunn posthoc test found a significant difference between CER and CER+ANS, CER+GdCl<sub>3</sub>, and CER+ANS+GdCl<sub>3</sub> (amylase concentrations) and CER and CER+ANS or CER+ANS+GdCl<sub>3</sub> mice (pancreatic water content and pancreatic necrosis).

between groups were analyzed by Mann-Whitney test (comparison between CONT and CER mice) or Kruskal-Wallis and Dunn posthoc tests (comparisons between CER, CER+ANS, CER+GdCl<sub>3</sub>, and CER+ANS+GdCl<sub>3</sub>). A  $P$  value  $< 0.05$  was considered significant.

## RESULTS

### Acute pancreatitis

Cerulein administration induced severe acute pancreatitis. Serum amylase concentrations and pancreatic water content markedly increased in CER mice in comparison to CONT mice (Table 1). Pancreatic injury was also characterized by an increase in acinar cell necrosis and MPO activity.

Pre-treatment with ANS before acute pancreatitis induction significantly decreased pancreatic MPO activity ( $P < 0.001$ , Figure 1) with a concomitant decrease in

**Figure 3** Representative sections of pancreas (upper panels) and lung (lower panels) stained with hematoxylin and eosin. Mice were injected with saline solution (CONT, A and F), cerulein (CER, B to E and G to J) and treated with antineutrophil serum (CER + ANS, C and H), gadolinium chloride (CER + GdCl<sub>3</sub>, D and I) or both treatments (CER + ANS + GdCl<sub>3</sub>, E and J). These illustrations represent sections from  $\geq 3$  mice. Magnification x400.

**Figure 4** Pulmonary myeloperoxidase activity (MPO, U/mg tissue dry weight) and pulmonary permeability index in mice injected with cerulein and saline (CER), cerulein and antineutrophil serum (CER + ANS), cerulein and gadolinium chloride (CER + GdCl<sub>3</sub>), CER + ANS + GdCl<sub>3</sub>.  $n \geq 5$  in each group. Kruskal Wallis analysis with Dunn posthoc test found a significant difference between CER and CER + ANS or CER + ANS + GdCl<sub>3</sub> mice (pulmonary MPO and permeability index).

**Table 2** Pulmonary injury in control (CONT) mice and mice treated with cerulein (CER)

	CONT	CER	
Pulmonary MPO activity (U/mg tissue dry weight)	947 [782 - 1145]	10173 [8710 - 12035]	$P < 0.0001$
Pulmonary permeability index	0.57 [0.5 - 0.8]	3.9 [3.1 - 5.1]	$P = 0.0002$

MPO = myeloperoxidase. Pulmonary permeability index: ratio of FITC-labeled bovine albumin between bronchoalveolar lavage and serum.  $n \geq 5$  in each group. Pulmonary MPO activity and pulmonary permeability index were compared by Mann-Whitney test.

pancreatic injury: serum amylase concentration ( $P < 0.01$ , Figure 2), pancreatic water content ( $P < 0.01$ , Figure 2), and acinar cell necrosis significantly decreased ( $P < 0.01$ , Figure 2). However, pre-treatment with ANS did not fully protect against pancreatic injury. Morphologic studies confirmed these findings (Figure 3).

Prevention of Kupffer cells activation by GdCl<sub>3</sub> decreased serum amylase concentration ( $P < 0.05$ ) but did not change significantly pancreatic necrosis and pancreatic water content (Figure 2). GdCl<sub>3</sub> had no effect on pancreatic MPO activity (Figure 1). The decreased pancreatic injury was similar CER + ANS and CER + ANS + GdCl<sub>3</sub> mice.

### Acute pancreatitis-associated lung injury

Because acute pancreatitis is frequently associated with injury in remote organs, we determined the consequences of both treatments on lung injury. CER administration increased pulmonary MPO activity and the pulmonary permeability index (Table 2). Lung injury is also evidenced by a marked thickening of the alveolar-capillary membrane (Figure 3).

**Table 3** IL-6 and IL-10 concentrations in serum, pancreas, lungs, and livers in control (CONT) mice and mice treated with cerulein (CER)

	CONT	CER	
Serum IL-6 (pg/mL)	8.9 [8.7 - 11.4]	267.5 [98.0 - 312.0]	$P = 0.02$
Serum IL-10 (pg/mL)	11.8 [8.9 - 14.7]	18.7 [10.9 - 21.6]	$P = 0.23$
Pancreatic IL-6 (pg/mg protein)	1.2 [0.5 - 1.9]	8.4 [6.4 - 13.2]	$P = 0.02$
Pancreatic IL-10 (pg/mg protein)	0.08 [0.03 - 0.20]	0.32 [0.20 - 0.79]	$P = 0.03$
Pulmonary IL-6 (pg/mg protein)	1.5 [0.5 - 2.1]	3.0 [2.4 - 6.9]	$P = 0.004$
Pulmonary IL-10 (pg/mg protein)	0.10 [0.01 - 0.20]	0.87 [0.42 - 3.80]	$P = 0.06$
Hepatic IL-6 (pg/mg protein)	1.15 [0.80 - 1.60]	8.20 [5.60 - 11.52]	$P = 0.006$
Hepatic IL-10 (pg/mg protein)	0.12 [0.05 - 0.20]	0.43 [0.33 - 0.48]	$P = 0.06$

$n \geq 5$  in each group. Data in CER and CONT groups were compared by Mann-Whitney test.

Pre-treatment with ANS significantly decreased MPO activity ( $P < 0.001$ ) and the pulmonary permeability ( $P < 0.01$ ) induced by CER, while GdCl<sub>3</sub> did not (Figure 4). Pulmonary injury was similarly prevented in CER + ANS and CER + ANS + GdCl<sub>3</sub> mice.

### Cytokine expression

CER administration greatly increased IL-6 concentrations in serum but not that of IL-10 (Table 3). CER administration increased expression of both cytokines in liver, pancreas, and lungs.

GdCl<sub>3</sub> pretreatment significantly attenuated IL-6 and IL-10 concentrations in liver ( $P < 0.01$  for both IL),

**Figure 5** Interleukin-6 (IL-6, %) concentrations in serum, pancreas, lung and liver the 100% value corresponding to the mean value measured in mice injected with cerulein (CER). Mice were injected with cerulein and saline (CER), cerulein and antineutrophil serum (CER+ANS), cerulein and gadolinium chloride (CER+GdCl<sub>3</sub>), and CER+ANS+GdCl<sub>3</sub>.  $n \geq 5$  in each group. <sup>a</sup> $P < 0.05$  vs CER.

**Figure 6** Interleukin-10 (IL-10, %) concentrations in serum, pancreas, lung and liver the 100% value corresponding to the mean value measured in mice injected with cerulein (CER). Mice were injected with cerulein and saline (CER), cerulein and antineutrophil serum (CER+ANS), cerulein and gadolinium chloride (CER+GdCl<sub>3</sub>), and CER+ANS+GdCl<sub>3</sub>.  $n \geq 5$  in each group. <sup>a</sup> $P < 0.05$  vs CER.

pancreas ( $P < 0.05$  and  $P < 0.01$  respectively), and serum ( $P < 0.05$  for both IL-6 and IL-10) (Figures 5 and 6). IL-6 concentrations in lungs were decreased by GdCl<sub>3</sub> ( $P < 0.05$ ) but IL-10 concentrations were not. ANS did not significantly modify IL-6 and IL-10 concentrations in liver, pancreas, and lungs. IL-6 concentrations in serum was decreased ( $P < 0.05$ ) but serum IL-10 concentrations were not modified by ANS pretreatment.

## DISCUSSION

In mice with acute pancreatitis, neutrophil depletion reduced the severity of pancreatitis and pancreatitis-associated lung injury. Kupffer cell inactivation by GdCl<sub>3</sub> had less protective effect, although IL-6 and IL-10 concentrations in tissues were significantly decreased. The protective treatment brought by neutrophil depletion was not enhanced by inhibition of Kupffer cell activation and both treatments did not combine their protective effects.

### Neutrophil infiltration in pancreas and lungs

Following cerulein injections in mice, neutrophil infiltration (assessed by MPO activity) was observed 12 h after the first injection. However, we previously showed that MPO activity peaks later by 24 h in pancreas and 36 h in lungs after the first injection and remains elevated by d 7<sup>[14]</sup>. This neutrophil infiltration in tissues plays an important role in the development of acute pancreatitis and pancreatitis-associated lung injury. Thus, mice deficient in adhesion molecules such as intercellular adhesion molecule 1 (ICAM-1) on endothelial cells<sup>[3]</sup> or animals treated with an antineutrophil antibody<sup>[3,4]</sup> are protected from pancreatitis and remote injuries. However, the protection remained partial<sup>[3, 4]</sup>. This incomplete protection suggests that either the dose of ANS used is insufficient to completely remove all neutrophils or that additional pathways must be targeted to obtain a full protection. We previously showed that ANS injection (0.2 mL) in mice reduced the circulating neutrophils by 85%<sup>[3]</sup> while 0.5 mL/100 g in rats decreased

the circulating neutrophils to below 200 cells/mL<sup>[4]</sup>. Thus, neutrophil depletion with ANS is correct and the residual MPO activities in lungs and pancreas after ANS treatment (Figures 2 and 4) might reflect the presence of local macrophages. An incomplete protection by ANS has already been shown in mice<sup>[3]</sup> or rats<sup>[4]</sup> treated with cerulein. Consequently, an additional independent pathway, Kupffer cell inactivation, was targeted to further prevent acute pancreatitis.

### Role of the liver in acute pancreatitis

The role of the liver in propagating pancreatic injury to lungs has been evidenced by inactivating Kupffer cell or diverting blood from the pancreatic vein to the systemic circulation. Thus, portocaval shunts (that dilute harmful pancreatic mediators in the systemic circulation)<sup>[5,10]</sup> and inhibitors of Kupffer cell activation such as gadolinium chloride (GdCl<sub>3</sub>)<sup>[11]</sup> and liposome-encapsulated dichloromethylene diphosphonate (DMDP)<sup>[12]</sup> significantly decrease acute pancreatitis-associated-lung injury. As expected, we showed that GdCl<sub>3</sub> pretreatment decreased IL-6 and IL-10 concentrations in the liver (Figures 5 and 6). In isolated rat livers, perfusion of pancreatic elastase activates Kupffer cells with subsequent NF- $\kappa$ B activation and TNF- $\alpha$  overproduction and this effect is abolished by GdCl<sub>3</sub> pre-treatment<sup>[9]</sup>. GdCl<sub>3</sub> is specifically taken up by Kupffer cells and is not toxic by itself (when the injected dose is 100 mg/kg, iv), as previously published by Gloor *et al*<sup>[15]</sup>. However, in our study, the pulmonary permeability index and MPO activity were not significantly decreased in comparison to CER mice (Figure 4). Pulmonary IL-6 concentrations in CER + GdCl<sub>3</sub> mice were lower than in CER mice but the IL-10 concentration decrease did not reach significance.

GdCl<sub>3</sub> pretreatment also decreased serum IL-6 and IL-10 concentration as previously published<sup>[15]</sup>. In contrast to Gloor *et al*<sup>[15]</sup> we found that GdCl<sub>3</sub> also decreased pancreatic IL-6 and IL-10 concentrations, as well as serum amylase concentration. Pancreatic necrosis, water content, and pancreatic MPO were not different between CER + GdCl<sub>3</sub> mice and CER mice, as previously described<sup>[15]</sup>. Our results either question the specific inactivation of hepatic macrophages by GdCl<sub>3</sub> or suggest that the decreased cytokine concentrations in pancreas reflect a decreased systemic inflammatory response. In a severe form of acute pancreatitis, GdCl<sub>3</sub> pretreatment was able to reduce the mortality rate<sup>[15]</sup>. The beneficial effect of GdCl<sub>3</sub> on the mortality rate remains puzzling because GdCl<sub>3</sub> administration decreases IL-10 concentrations, a cytokine which has a protective effect on the evolution of acute pancreatitis<sup>[16,17]</sup>.

Kupffer cell inactivation has also been induced by other drugs such as liposome-encapsulated dichloromethylene diphosphonate which decreases apoptosis and TGF- $\beta$  production in liver<sup>[12]</sup> or CNI-1493 which reduced pancreatitis-associated liver injury through TNF- $\alpha$  and IL-1 expression<sup>[18]</sup>.

In conclusion, our results confirm the role of activated neutrophils in aggravating organ injury in acute pancreatitis while the role of Kupffer cell activation is less obvious. Another more early event should probably be targeted in

combination with neutrophil depletion to fully prevent the initiation of the disease.

## Abstract

**AIM:** To evaluate the mechanical and biochemical parameters of colonic anastomotic healing in hypercholesterolemic rats.

**METHODS:** Sixty rats were divided into two groups of 30 each according to their dietary regimens. The test group was fed with a high cholesterol-containing diet for two months while the control group had standard diet. These two groups were further divided into three subgroups consisting of ten rats each. After hypercholesterolemia was established, left colon resection and anastomosis were performed in both groups and samples from liver and abdominal aorta were taken to evaluate the systemic effects of hypercholesterolemia. Anastomotic wound healing, blow-out pressures and tissue hydroxyproline levels were evaluated.

**RESULTS:** The test group had a significant weight gain in two months. Microscopic examination of the abdominal aorta revealed no atherosclerotic change in none of the groups, but liver tissue specimens showed significant steatosis in the test group. Tissue hydroxyproline levels and anastomotic blow-out pressures were significantly lower in the test group than in the controls.

**CONCLUSION:** Hypercholesterolemia not only increases hydroxyproline levels and blow-out pressures but also worsens anastomotic wound healing.

## INTRODUCTION

Hypercholesterolemia is the major etiologic factor for atherosclerosis in Western countries<sup>[1]</sup>. However, the effects of hypercholesterolemia on anastomotic wound healing have not been studied.

Leakage in colonic anastomosis has a higher incidence of morbidity and mortality rate compared with that in small intestinal anastomosis. The overall leakage incidence of intestinal anastomosis is 2-35%<sup>[2]</sup>. Most of them are minimal and can be limited by the host defense mechanisms. Systemic and local factors play a role in anastomotic wound healing. Anemia, hypovolemia, low arterial PO<sub>2</sub>, neutropenia, low O<sub>2</sub> saturation, malnutrition, vitamin deficiencies, zinc deficiency, jaundice, uremia and high dose corticosteroids are some of the systemic factors, while local factors include infection, intestinal contents, prophylactic antibiotics, technique of suturing and suture material, radiation and mesenteric vascular occlusion<sup>[2-4]</sup>.

In experimental studies, microscopic healing in small intestine is better than that in the colon<sup>[5,6]</sup>. Intestinal anastomotic wound healing can be evaluated mechanically, biochemically and histopathologically. Mechanical evaluation depends on the blow-out pressure of the anastomotic line. This pressure can change with the inflation rate of the intestine or the in situ procedure<sup>[2,7-9]</sup>. Continuous suturing technique has no effect on this pressure<sup>[10]</sup>.

Biochemically, collagen production rate and amount in the anastomosis line are the factors to be measured. Since the majority of the collagens are hydroxyproline, all measurements are made by detecting the hydroxyproline content<sup>[7,11,12]</sup>. Histopathologically, the only evidence is the infiltration of several kinds of inflammatory cells<sup>[2,7]</sup>.

In this study, the mechanical and biochemical parameters of colonic anastomotic wound healing were evaluated in rats fed with a high cholesterol containing diet (2% cholesterol + 1% colic acid: Sigma Co., Manchester, UK) for two months<sup>[13]</sup>. Abdominal aortic and liver tissue samples were also obtained to evaluate the systemic effects of hypercholesterolemia.

## MATERIALS AND METHODS

### Experimental animals and grouping

Sixty rats of both sexes weighing 240-300 g used in this study were divided into two groups according to their dietary regimens. The test group consisted of 30 rats fed with a high cholesterol diet for two months while the control group had standard diet for the same period. The test group had a significant weight gain at the end of this period (Table 1).

These two groups were further divided into three subgroups, ten rats each group. Ten milliliter blood was taken from each rat for measurement of serum total cholesterol and triglyceride levels. In the test group, serum total cholesterol and triglyceride levels were significantly higher than in the control group (Figure 1). After hypercholesterolemia was established, left colon resection and anastomosis were performed in both groups and tissue samples were taken from liver and abdominal aorta.

### Surgical technique

After an overnight fasting, intramuscular ketamin HCl (Ketalar, Parke Davies) was administered (50 mg/kg). One percent povidon-iodine was used for local cleansing. A midline laparotomy was performed and a segment of left colon (1 cm) was resected. Colo-colonic anastomosis was made using 7/0 polypropylene (Prolene, Ethicon Inc., UK) with 8-10 stitches for a layer. There was no postoperative mortality.

**Figure 2** Insertion of an infusion pump into the colon.**Figure 3** Anastomosis line.

In both groups, 10 rats underwent relaparotomy on the third day and 10 rats on the seventh day. Colon lumen was obliterated 10 cm distal to the anastomosis using 3/0 silk ligature. Colon was transected 10 cm proximal to the anastomotic line and an infusion set was inserted into the lumen. This set was connected to an infusion pump (Life Care 5000 Infusion System, Abbot, Illinois, USA) and isotonic sodium chloride was given at a rate of 2 mL/min into the lumen (Figure 2). The pressure at the moment of the first leakage observed from the suture line was recorded as the blow-out pressure. All measurements were done *in situ*. After the measurements, tissue samples were taken from the liver and abdominal aorta for histopathological examination. The experiment was terminated by creating a pneumothorax.

In all groups, one centimeter segment of colon (including 0.5 cm proximal and 0.5 cm distal to the anastomotic line) was resected (Figure 3). The suture material was removed and the samples were kept in liquid nitrogen until the assay day.

Biochemical measurements were done as described previously<sup>[14]</sup>. The volume of hydroxyproline was defined as micromoles of hydroxyproline per gram of wet weight.

### Statistical analysis

Mann Whitney U test was used for statistical analysis compare the blow-out pressures and hydroxyproline contents between groups.  $P < 0.05$  was considered statistically significant.

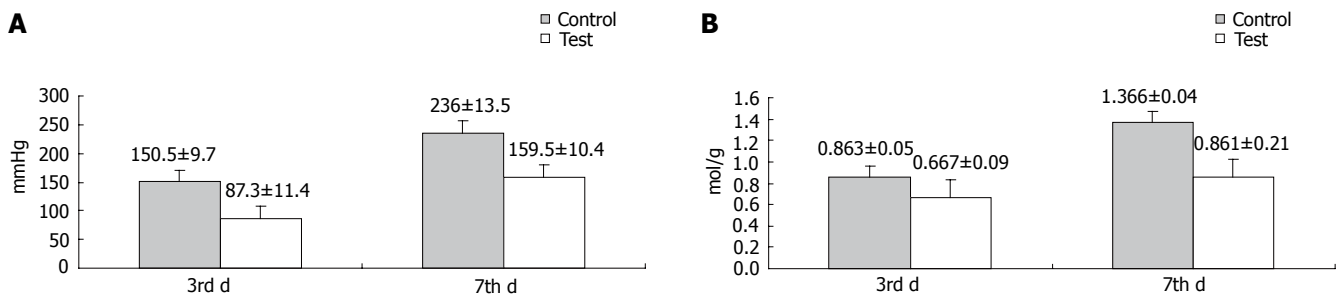

Figure 4 Mean blow-out pressure (A) and hydroxyproline level (B) in test and control groups.

Figure 5 Macroscopic (A) and microscopic (B) steatosis in liver.

## RESULTS

The rats in the test group gained significant weight (Table 1). The weight difference between the pre and post-feeding periods was statistically significant ( $P < 0.05$ ).

After feeding with a high cholesterol containing diet for two months, a statistically significant difference serum cholesterol and triglyceride levels between the test and control groups was observed ( $P < 0.05$ , Figure 1). In the test group, serum total cholesterol level was  $951 \pm 72.4$  mg/L and triglyceride level was  $1425 \pm 98.1$  mg/L, while they were  $423 \pm 10.3$  mg/L and  $538 \pm 23.6$  mg/L in the control group, respectively.

On the third postoperative day, the mean blow-out pressure was  $87.3 \pm 11.4$  mmHg in the test group and  $150.5 \pm 9.7$  mmHg in the control group (Figure 4A). This difference was statistically significant ( $P < 0.05$ ). The mean hydroxyproline level was  $0.667 \pm 0.09$  in test group and  $0.863 \pm 0.05$  in control group ( $P < 0.05$ ) (Figure 4B).

On the seventh postoperative day, the blow-out pressure was  $159.5 \pm 10.4$  mmHg in the test group and  $236 \pm 13.5$  mmHg in the control group, while the hydroxyproline level was  $0.861 \pm 0.21$  in the test group and  $1.366 \pm 0.06$  in the control group, respectively. The difference in the parameters between the two groups was statistically significant ( $P < 0.05$ ) (Figures 4A and 4B).

Liver tissue samples of the test group had a significant macroscopic steatosis compared to the control group (Figure 5A). In microscopic examination with hematoxylin-eosin staining, significant steatosis was also found in the test group (Figure 5B). No difference in microscopic results of the aortic specimens was found between the two groups.

## DISCUSSION

In this study, left colon anastomosis was performed in hy-

percholesterolemic rats and the mechanical and biochemical parameters of anastomotic wound healing were investigated. Anastomotic wound healing in the test group was worse than that in the control group in terms of hydroxyproline levels and blow-out pressures. Significant steatosis was found in the liver specimens but no atherosclerotic changes in the aortic specimens. This finding is in accordance with several studies<sup>[15-17]</sup>.

Factors influencing colonic healing have been widely studied<sup>[2,4]</sup>. Since blood flow is the major component of wound healing, hypercholesterolemia-induced atherosclerosis has a detrimental effect on intestinal anastomotic wound healing. However, the effects of hypercholesterolemia start long before the onset of atherosclerosis<sup>[16-20]</sup>. There are also reports on how hypercholesterolemia worsens vascular functions using different pathways of microendocrine system inside the endothelium<sup>[21-23]</sup>. Ross *et al.*<sup>[24]</sup> have shown that monocytes accumulate on endothelium and damage it. Besides the macrovascular system, hypercholesterolemia also plays an important role in microvascular endothelial injury.

The cause of hypercholesterolemia-induced endothelial damage is predominantly determined by loss of endothelium-mediated relaxation. The mechanisms are as follows: decrease in the relaxing effect of NO/EDRF, ADP, thrombin,  $\text{Ca}^{++}$ -ionophore A 23187 on endothelium<sup>[2,16,21,25,26]</sup>; increase in platelet aggregation and turnover as well as the sensitivity of platelets to aggregating substances due to the modification of effects of  $\text{PGI}_2$  and  $\text{TXA}_2$ <sup>[27-29]</sup>; increase in the release of endothelium-derived vasoconstrictor substances such as serotonin and  $\text{TXA}_2$  through the cyclooxygenase pathway<sup>[22,27]</sup>.

The above effects have been shown *in vivo* and *in vitro* in experimental models of rabbit aorta, monkey iliac artery, pig coronary artery and human coronary arteries<sup>[28]</sup>. Our study did not investigate these effects, but the effect of hypercholesterolemia on hydroxyproline level and blow-out pressure was emphasized.

Why hypercholesterolemia worsens anastomotic wound healing is still unknown. Luminal narrowing is the net result of atherosclerosis in both macro and microvascular systems. Consequently, ischemia and related injuries occur. Hypercholesterolemia is the major risk factor for atherosclerosis. In early phase of hypercholesterolemia, no morphological change takes place in arterial wall but vasospasm occurs due to neurohumoral mechanisms<sup>[30]</sup>. Atherosclerosis is an irreversible process but hypercholesterolemia is reversible and these effects are preventable.

In our study, anastomotic wound healing in the test group was worse than that in the control group. Since hypercholesterolemia predominantly affects the endothelium, this can partly be explained as a result of endothelial damage-induced vasospasm. But we did not measure the anastomotic blood flow or assess the endothelial injury. Although a relationship between hypercholesterolemia and wound healing was demonstrated, our results could not fully explain the mechanisms. Further studies are needed to reveal the relationship between hypercholesterolemia and anastomotic wound healing.

## Abstract

**AIM:** To study the cloning of  $\alpha$ - $\beta$  fusion gene from *Clostridium perfringens* and the immunogenicity of  $\alpha$ - $\beta$  fusion expression.

**METHODS:** Cloning was accomplished after PCR amplification from strains NCTC64609 and C58-1 of the protective antigen genes of  $\alpha$ -toxin and  $\beta$ -toxin. The fragment of the gene was cloned using plasmid pZCPAB. This fragment coded for the gene with the stable expression of  $\alpha$ - $\beta$  fusion gene binding. In order to verify the exact location of the  $\alpha$ - $\beta$  fusion gene, domain plasmids were constructed. The two genes were fused into expression vector pBV221. The expressed  $\alpha$ - $\beta$  fusion protein was identified by ELISA, SDS-PAGE, Western blotting and neutralization assay.

**RESULTS:** The protective  $\alpha$ -toxin gene (cpa906) and the  $\beta$ -toxin gene (cpb930) were obtained. The recombinant plasmid pZCPAB carrying  $\alpha$ - $\beta$  fusion gene was constructed and transformed into BL21(DE3). The recombinant strain BL21(DE3)(pZCPAB) was obtained. After the recombinant strain BL21(DE3)(pZCPAB) was induced by 42°C, its expressed product was about 22.14% of total cellular protein at SDS-PAGE and thin-layer gel scanning analysis. Neutralization assay indicated that the antibody induced by immunization with  $\alpha$ - $\beta$  fusion protein could neutralize the toxicity of  $\alpha$ -toxin and  $\beta$ -toxin.

**CONCLUSION:** The obtained  $\alpha$ -toxin and  $\beta$ -toxin genes are correct. The recombinant strain BL21(DE3)(pZCPAB) could produce  $\alpha$ - $\beta$  fusion protein. This protein can be used for immunization and is immunogenic. The antibody induced by immunization with  $\alpha$ - $\beta$  fusion protein could neutralize the toxicity of  $\alpha$ -toxin and  $\beta$ -toxin.

## INTRODUCTION

*Clostridium perfringens* is an anaerobe, forming a part of normal intestinal flora in humans and animals<sup>[1]</sup>. This organism is the causative agent of diseases such as gas gangrene, hemorrhagic enteritis, enterotoxemia<sup>[2]</sup>. It is also a secondary pathogen in various diseases, such as necrotic enteritis<sup>[3]</sup>. *Clostridium perfringens* can produce extra cellular toxins and enzymes including  $\alpha$ -toxin and  $\beta$ -toxin produced by *Clostridium perfringens* types A and C respectively. These toxins are significant virulence factors in case of gas gangrene or clostridial myonecrosis<sup>[4,5]</sup>.

In this study,  $\alpha$ -toxin and  $\beta$ -toxin protective antigen genes were amplified by PCR from *Clostridium perfringens* type A strain NCTC64609 and type C strain C58-1 respectively. The recombinant plasmid pZCPAB carrying  $\alpha$ - $\beta$  fusion gene was constructed by transforming it into BL21(DE3). The fusion protein that could produce  $\alpha$ - $\beta$  was obtained. The expressed  $\alpha$ - $\beta$  fusion protein could resist the attack of  $\alpha$ -toxin or  $\beta$ -toxin.

## MATERIALS AND METHODS

### Materials

*Clostridium perfringens* type A strain NCTC64609 and type C strain C58-1 were purchased from China Institute of Veterinary Drug Control. Plasmid pBV221 and *E. coli* DH5 $\alpha$ , BL21(DE3) were kept in our Laboratory. Plasmid pMD18-T was purchased from TaKaRa Company. Taq DNA polymerase, T4 DNA ligase, restriction endonuclease and DNA markers DL2000 were purchased from TaKaRa Company. DNA fragment recover kit, SDS, IPTG, Rnase A and lysozyme were purchased from Promega Company. Other reagents if not described, were of analytic purity.

### Extraction of genomic DNA of *clostridium perfringens*

*Clostridium perfringens* strains were incubated in TYG me-

dium at 37 °C overnight. Bacterium cells were harvested by centrifugation, dissolved in TE buffer containing lysozyme(2 g/L) and incubated at 37°C for 1 h. Then SDS(final concentration was 1%), EDTA(final concentration was 50 mmol/L) and proteinase K(final concentration was 150 mg/L) were added. The reaction mixture was incubated at 58 °C for 4 h and extracted three times with equal volume of saturated phenol. The aqueous phase was transferred to an Eppendorf tube. Then 0.2 volume of ammonium acetate(10 mol/L) and 2 volumes of ice-cold absolute alcohol were added, mixed well and deposited for 10 min at room temperature. Chromosome DNA deposition like clew was picked with a glass stick to another Eppendorf tube. Appropriate TE was added to dissolve DNA and stored at 4 °C.

### PCR amplification of $\alpha$ -toxin and $\beta$ -toxin protective antigen genes

Chromosome DNA of *Clostridium perfringens* was amplified by PCR from genomic DNA using forward primers designed from the available sequence.

One set of primers of  $\alpha$ -toxin protective antigen gene (cpa906) was synthesized. The *EcoR* I and *BamH* I sites were inserted to the 5' and 3' ends of  $\alpha$ -toxin genes via PCR. The sequence of  $\alpha$ -toxin primers is as follows:

Up-stream primer:

P1: CCGGAATTCATGGGTCGGGATCCTGAT  
*EcoR* I

Down-stream primer:

P2: GGCGGATCCCCTAATTATATTATA  
*BamH* I

Another set of primers of  $\beta$ -toxin protective antigen gene was synthesized. The *BamH* I and *Pst* I sites were inserted to the 5' and 3' ends of  $\beta$ -toxin genes via PCR. The sequence of  $\beta$ -toxin primers is as follows:

Up-stream primer:

P1: 5'-CGCGGATCCAATGATATAGGTAAACT-3'  
*BamH* I

Down-stream primer:

P2: 5'-CCGCTGCAGCTACTTAATAGCTGT-3'  
*Pst* I

The following components were added into a 500  $\mu$ L microcentrifuge tube. Each PCR contained 0.1  $\mu$ mol/L primer1, 0.1  $\mu$ mol/L primer2, 0.25 mmol/L dNTP, 1.5 mmol/L  $MgCl_2$ , 10  $\mu$ L 10 $\times$ PCR buffer and appropriate template DNA. Sterile distilled water was added into a 100  $\mu$ L reaction system. After the tubes were heated at 95 °C for 5 min, 5 u *Taq* DNA polymerase was added into each tube. Thirty cycles of PCR were performed (denaturation at 94 °C for 1 min, annealing at 55 °C for 1 min, and extension at 72 °C for 1 min). The amplified  $\alpha$ - and  $\beta$ -toxin genes were purified separately by agarose gel electrophoresis to remove primers and extraneous amplification products.

### Cloning and sequencing of $\alpha$ -toxin and $\beta$ -toxin protective antigen genes

The  $\alpha$ -toxin and  $\beta$ -toxin protective antigen genes were separated and purified by agarose gel electrophoresis alongside DNA marker DL2000 and sequentially ligated to the pMD18-T cloning vector. Sequencing was performed with ABI 377 sequencer from Takara Company.

### Construction of expression vector carrying $\alpha$ - $\beta$ fusion gene

The  $\alpha$ -toxin protective antigen gene and expression plasmid pBV221 were digested by restrictive enzymes *EcoR* I and *BamH* I respectively to generate cohesive ends. The  $\alpha$ -toxin gene was inserted into the vector pBV221 and the recombinant vector pZBVA1 containing  $\alpha$ -toxin protective antigen genes of *Clostridium perfringens* was constructed. Then the  $\beta$ -toxin protective antigen gene and the recombinant vector pZBVA1 were digested by restrictive enzymes *BamH* I and *Pst* I respectively to generate cohesive ends. The  $\beta$ -toxin gene was inserted into the vector pZBVA1 and recombinant expression vector pZCPAB containing  $\alpha$ - $\beta$  fusion gene was obtained. The sequence of inserted fragment was confirmed by DNA sequencing.

### Growth condition for $\alpha$ - $\beta$ fusion gene expression

The recombinant was transformed into *E. coli* BL21(DE3) and selected by agar plate containing ampicillin and confirmed by restriction enzyme mapping. *E. coli* BL21(DE3) cells transformed with the plasmids described above were grown in LB medium with 50 mg/mL ampicillin (1/50) at 30 °C to OD<sub>600</sub>=0.4~0.6. The growth was conditioned at 42 °C for 5 h in order to express  $\alpha$ - $\beta$  fusion protein.

### Analysis of bacterial samples

The cultured cells were collected by centrifugation at 5000 r/min for 10 min at 4 °C. The optimum time of maximum expression of proteins was analyzed through SDS-PAGE. The expressed protein was tested through Western blot with specific antiserum. SDS-PAGE and Western blotting were performed as previously described<sup>[6,7]</sup>. The antigen-binding activity of the  $\alpha$ - $\beta$  fusion protein was determined by ELISA as previously described<sup>[8]</sup>. For determination of protein expression, the absorption value at 560 nm was measured by thin-layer chromatogram scanner type CS-9000.

### Protective effect of $\alpha$ - $\beta$ fusion protein on mice

The 8-wk old Kunming mice were divided into 8 groups randomly, 10 mice in each group. In treatment groups, each mouse was inoculated with inactive recombinant strains that could express  $\alpha$ - $\beta$  fusion protein. In control groups, each mouse was inoculated with strains that could not express  $\alpha$ - $\beta$  fusion protein. After 4 wk, each mouse of 4 groups was treated with one minimum lethal dose (MLD) of  $\alpha$ -toxin or  $\beta$ -toxin. Another 4 groups were treated with 2 MLD of  $\alpha$ -toxin or  $\beta$ -toxin. The survived mice/total mice were counted in a week. The segments of liver, lung, heart, spleen and intestines of mice in treatment group and control group were tested by LM assay.

## RESULTS

### Gene cloning and identification of $\alpha$ -toxin gene from *clostridium perfringens* type A

The  $\alpha$ -toxin gene from *Clostridium perfringens* type A strain NCTC64609 was isolated from genomic DNA-extracted template by PCR amplification. The reaction yielded a single product. Electrophoresis of PCR products confirmed

the length of PCR fragment, which was approximately 900 bp (Figure 1A). The  $\alpha$ -toxin gene was purified with DNA fragment recover kit and evaluated by agarose gel electrophoresis. The  $\alpha$ -toxin gene fragment was ligated to the cloning vector pMD18-T with T4 DNA ligase. The cloning vector containing the  $\alpha$ -toxin gene was introduced into competent *E. coli* DH5  $\alpha$  cells by  $\text{CaCl}_2$  transformation. Transformed *E. coli* were grown at 37°C in medium containing X-gal/IPTG and ampicillin. The positive plasmids were identified via sequential digestion with *EcoR* I and *BamH* I and  $\alpha$ -toxin protective antigen gene about 900 bp was obtained (Figure 1B). Sequence of inserted DNA was analyzed with automatic sequence analyzer and about 906 bp in size and encoded 302 amino acid residues (Figure 2).

**Figure 3** Identification of  $\beta$ -toxin gene product amplified by PCR (A) and recombinant plasmid by enzyme digestion (B). In A, lanes 1,17: DNA markers; lanes 2-16: product of  $\beta$ -toxin gene amplified by PCR; In B, lane 1: pMD930/EcoR I; lane 2: pMD930/ Pst I; lane 3: DNA Markers; lane 4: pMD930/BamH I+Pst I

The recombinant plasmid was named pMD 906.

### Cloning and identification of $\beta$ -toxin gene from *clostridium perfringens* type A

The  $\beta$ -toxin protective antigen genes were amplified from *Clostridium perfringens* type C and strain C58-1 by PCR. The PCR products were approximately 930 bp in length (Figure 3A). The  $\beta$ -toxin gene was purified and ligated to the cloning vector pMD18-T as  $\alpha$ -toxin gene. The positive plasmids were identified via sequential digestion with *Pst* I and *BamH* I and about 930 bp  $\beta$ -toxin genes were obtained (Figure 3B). Sequence of inserted DNA was analyzed with automatic sequence analyzer and about 930 bp in length and encoded 310 amino acid residues (Figure 4). The recombinant plasmid was named pMD 930.

### Construction of recombinant expression vector pZCPAB

The recombinant expression plasmids containing  $\alpha$ - $\beta$  fusion gene were constructed. The positive plasmids were identified via sequential digestion with *EcoR* I and *Pst* I and about 1.8 kb  $\alpha$ - $\beta$  fusion genes were obtained (Figure 5). Sequence of  $\alpha$ - $\beta$  fusion genes was analyzed with automatic sequence analyzer and about 1842 bp in length and encoded 614 amino acid residues. The recombinant plasmid was named pZCPAB.

### Expression of $\alpha$ - $\beta$ fusion gene in *E. coli* BL21 (DE3) (PZCPAB)

The recombinant plasmid pZCPAB carrying  $\alpha$ - $\beta$  fusion gene was transformed into *E. coli* BL21(DE3) and the

recombinant strain BL21(DE3)(pZCPAB) was obtained. SDS-PAGE and Western blotting of the bacterial protein showed that a specific protein band with a molecular weight of 66 kD emerged in the bacterial protein of *E. coli* BL21(DE3)(pZCPAB). SDS-PAGE gel-scanning showed that the expressed  $\alpha$ - $\beta$  fusion protein accounted for 22.14% of the total bacterial protein (Figure 6). ELISA results indicated that the expressed fusion protein could be recognized by anti- $\alpha$  toxin antibody and anti- $\beta$  toxin antibody respectively (Table 1).

#### Bioactivity assay of expressed $\alpha$ - $\beta$ fusion protein

The expressed  $\alpha$ - $\beta$  fusion protein yielded in bacteria could provide protection of mice against the challenge of lethal doses of  $\alpha$ -toxin or  $\beta$ -toxin of *Clostridium perfringens* (Table 2).

#### Pathological changes in different organs

The segments of liver, lung, heart, spleen and intestine were sampled from the control group in which mice died of toxicosis and the treatment group in which survived mice were immunized with  $\alpha$ - $\beta$  fusion protein. Then they were observed by LM assay.

In treatment group, the structure of liver was seen

necrotic, one or many of intestinal villi fell into the enterocoele (Figure 7J).

## DISCUSSION

*Clostridium perfringens* is ubiquitous in the environment and has been found in soil, decaying organic matter and a member of the gut flora in humans and animals. Different strains of *C. perfringens* can be classed into one of the five biotypes (A-E) according to the spectrum of toxins produced<sup>[9]</sup>. *Clostridium perfringens* is a Gram-positive anaerobic spore-forming bacterium which is widely found in the environment and also in the intestinal tract of humans and animals. Due to the production of several exotoxins, *C. perfringens* is of great importance as a pathogen in humans, domestic animals and wildlife<sup>[10]</sup>. The production of four major toxins alpha ( $\alpha$ ), beta ( $\beta$ ), epsilon ( $\epsilon$ ) and iota ( $\iota$ ) allows the discrimination into five types from A to E. In veterinary medicine, each of these types has been linked to specific diseases<sup>[11]</sup>. *Clostridium perfringens* enterotoxin (CPE) serves as an additional virulence factor which is believed to cause enteritis in pigs, cats and dogs<sup>[12]</sup>. The Gram-positive pathogen *Clostridium perfringens* is a major cause of human and veterinary enteric disease largely because this bacterium can produce several toxins when present inside the gastrointestinal tract<sup>[13]</sup>.

Biotype A strains of *Clostridium perfringens* are of particular importance as the aetiological agents of gas gangrene in humans. Gangrenous disease is of increasing significance in elderly and diabetic population, especially in those who have undergone lower limb surgery, where impaired blood supply to tissues can lead to anoxic conditions suitable for proliferation of bacteria<sup>[14]</sup>. The disease can also arise in patients who have undergone surgery of the gastrointestinal tract when contamination of damaged tissues with gut contents can result in the establishment of disease<sup>[15]</sup>. *Clostridium perfringens*  $\beta$ -toxin is known to be the primary pathogenic factor of necrotic enteritis in type C strains that produce  $\beta$ -toxin. Necrotizing enteritis is believed to be due to the production of  $\beta$ -toxin by *Clostridium perfringens* type C. *Clostridium perfringens*  $\beta$ -toxin can

also cause dermonecrosis and oedema in the dorsal skin of animals<sup>[16-18]</sup>.

This paper describes the successful isolation and cloning of  $\alpha$ -toxin and  $\beta$ -toxin genes from the strains NCTC64609 and C58-1 of *Clostridium perfringens* respectively. The construction and expression of  $\alpha$ - $\beta$  fusion gene, and the biological activities of  $\alpha$ - $\beta$  fusion protein have a significant impact on mice. To our knowledge, this is the first successful experiment of the development of a recombinant  $\alpha$ - $\beta$  fusion protein. We believe that it could serve as a model for development and construction of novel fusion protein for  $\alpha$ -toxin,  $\beta$ -toxin and other potential toxins. In this study, the expressed  $\alpha$ - $\beta$  fusion protein could provide protection of mice against the challenge of lethal dose of  $\alpha$ -toxin and  $\beta$ -toxin of *Clostridium perfringens*. These findings indicate that the expressed  $\alpha$ - $\beta$  fusion protein can be applied in preventing toxicosis of  $\alpha$ -toxin and  $\beta$ -toxin of *Clostridium perfringens*.

### Abstract

**AIM:** To determine whether prior appendectomy modifies the phenotype and severity of Crohn's disease.

**METHODS:** Appendectomy status and smoking habits were specified by direct interview in 2838 patients consecutively seen between 1995 and 2004. Occurrence of complications and therapeutic needs were reviewed retrospectively. Additionally, annual disease activity was assessed prospectively between 1995 and 2004 in patients who had not had ileocecal resection and of a matched control group.

**RESULTS:** Compared to 1770 non-appendectomized patients, appendectomized patients more than 5 years before Crohn's disease diagnosis ( $n=716$ ) were more often females, smokers, with ileal disease. Cox regression showed that prior appendectomy was positively related to the risk of intestinal stricture (adjusted hazard ratio, 1.24; 95% confidence interval, 1.13 to 1.36;  $P=0.02$ ) and inversely related to the risk of perianal fistulization (adjusted hazard ratio, 0.75; 95% confidence interval, 0.68 to 0.83;  $P=0.002$ ). No difference was observed between the two groups regarding the therapeutic needs, except for an increased risk of surgery in appendectomized patients, attributable to the increased prevalence of ileal disease. Between 1995 and 2004, Crohn's disease was active during 50% of years in appendectomized patients (1318 out of 2637 patient-years) and 51% in non-appendectomized patients (1454 out of 2841 patient-years; NS).

**CONCLUSION:** Prior appendectomy is associated with a more proximal disease and has an increased risk of stricture and a lesser risk of anal fistulization. However, the severity of the disease is unaffected.

### INTRODUCTION

Two common environmental factors, cigarette smoking and appendectomy, have been found to play a role in inflammatory bowel diseases (IBD). Smoking has a role both in disease onset and disease course, and it is well established that it has opposite effects on the two diseases, beneficial in ulcerative colitis (UC) and deleterious in Crohn's disease<sup>[1,2]</sup>. Previous appendectomy has a favourable effect on UC. Patients who have been appendectomized have a lesser risk of developing UC. Moreover, in the few appendectomized patients who develop UC, disease course is less severe, with a decreased need of colectomy compared to non-appendectomized patients<sup>[3,4]</sup>. Of note, the effects of smoking and appendectomy are additive<sup>[4]</sup>. In Crohn's disease, the effect of previous appendectomy remains debated. Some series reported an increased risk of Crohn's disease after appendectomy<sup>[5-7]</sup>, and others did not<sup>[8-11]</sup>. These discrepancies may be partly linked to the inclusion or not of appendectomies performed close to the time of diagnosis. However, the largest study to date showed that the risk of Crohn's disease is increased up to 20 years after appendectomy<sup>[7]</sup>. Data concerning the effect of appendectomy on the clinical course of Crohn's disease are scarce and contradictory, one study reporting no effect<sup>[3]</sup> and another suggesting that previous appendectomy was associated with an increased risk of surgery<sup>[12]</sup>. In the study by Andersson *et al*<sup>[7]</sup>, an increased risk of surgery for Crohn's disease was observed only in patients with perforated appendicitis.

The aim of the present study was to analyse the phenotype and clinical course of Crohn's disease in a large cohort of patients subjected to appendectomy compared with non-appendectomized patients.

### MATERIALS AND METHODS

#### Patient population

From January 1995 to December 2004, all consecutive patients with Crohn's disease who came to our unit were

included in the study. The diagnostic criteria for Crohn's disease were those of Lennard-Jones<sup>[13]</sup>

### **Appendectomy status and smoking habits**

Appendectomy and smoking status were specified during a direct interview of the patients. The date of appendectomy was noted and patients were classified according to the time span between appendectomy and diagnosis. Patients were classified as smokers if they had smoked more than 7 cigarettes per week for at least six months during the six months preceding diagnosis of Crohn's disease and/or thereafter<sup>[14]</sup>.

### **Characteristics of Crohn's disease**

The characteristics of Crohn's disease were completed according to the retrospective analysis of medical charts. The time of diagnosis was defined as the date of first detection of unequivocal inflammatory abnormalities of the intestine, as assessed from radiological, or endoscopic, or peroperative observations. The initial location of Crohn's disease lesions was determined by colonoscopy and small bowel X-ray. After diagnosis, patients were followed clinically with 3 to 4 visits per year, and only investigated again in case of flare-up or development of new symptoms. Morphological investigations included proctosigmoidoscopy, colonoscopy, and small bowel X-ray. Upper gastrointestinal endoscopy was only performed in case of gastroesophageal symptoms. Subjects were explored for ano-perineal disease at each visit.

Location and behavior of Crohn's disease were classified according to the Vienna classification<sup>[15]</sup>. First morphological demonstration of narrowing or penetrating complication was used to date the occurrence of the complication defining behavior<sup>[16]</sup>.

### **Treatment of Crohn's disease**

Our treatment policy has been exposed elsewhere<sup>[16]</sup>. Flare-up episodes were treated with mesalamine (3-4 g daily) or prednisolone (1 mg/kg per day, progressively tapered after four weeks), according to the clinical severity. When steroid therapy failed, patients seen before 1999 were given a 3-wk course of enteral or parenteral nutrition; those seen after June 1999, when Infliximab became available in France, received Infliximab 5 mg/kg.

As maintenance treatment, we used aminosalicylates (sulphasalazine, olsalazine or mesalamine, 2-3 g daily) for asymptomatic or moderately active forms of the disease, and immunosuppressive drugs for severe forms (steroid-dependent or poorly responsive to steroids). Azathioprine 2 mg/kg per day was used as first line immunosuppressive drug. In case of repeated flare-ups or chronic active disease in a patient receiving azathioprine, its dosage was increased to 2.5-3 mg/kg per day. Intramuscular methotrexate (20-25 mg weekly) was used in patients unresponsive or intolerant to azathioprine. Its dosage was tapered progressively to 10-15 mg, and re-augmented in case of clinical relapse.

Although the overall strategy remained mostly unchanged, there was a clear tendency over time to initiate immunosuppressants earlier in the disease course. Surgery

was reserved for stenotic and extra-parietal complications, or intractable forms after a well-conducted medical management.

### **Phenotype and severity of Crohn's disease**

Phenotyping Crohn's disease took into account disease location and the occurrence of a stricturing or penetrating complication. Overall severity of the disease was assessed in two ways: first retrospectively, taking into account the importance of the medical therapy, i.e. need for glucocorticoid, nutritional support, immunosuppressive drugs, and Infliximab, and finally incidence of excisional surgery. Second, patients who had not had ileo-cecal resection prior to inclusion were followed-up prospectively from the date of inclusion to December 2004, and activity of the disease was assessed prospectively by analyzing the occurrence of a flare-up each year. A patient-year was considered as active if a flare-up or a complication occurred during the year, and inactive otherwise.

### **Statistics**

Continuous data are expressed as mean (standard deviation), and differences between the groups were tested for significance by Student's *t* test. Discrete data are given as percentages, and comparisons were made with Pearson's Chi-square test.

The retrospective study analyzed the effect of prior appendectomy on the long-term course of Crohn's disease. For this purpose, non-appendectomized patients were included in the control group until the time an ileo-cecal resection was eventually performed. To avoid biases related to the effect of ileo-cecal resection on the subsequent evolution of Crohn's disease, appendectomized patients were also censored at the time of ileo-cecal resection. For actuarial analysis, the Kaplan-Meier model was used, with the date of diagnosis as starting point. The curves were compared by the Log-rank test. Multivariate analyses were performed with Cox proportional hazards regression to adjust for confounding. All baseline variables suspected to be possible predictors of complication or intestinal surgery [young age (< 20 years), old age (equal to or above 40 years), gender, ethnicity (Caucasian or not), socioeconomic status (high or low-moderate), diagnosis after 1987, familial history, extra-intestinal manifestations, smoking status, initial disease location (esophago-gastro-duodenal, jejunal, ileal, colonic, and anoperineal lesions)], were entered into the model. Diagnosis after 1987 was retained as a variable because the use of immunosuppressive therapy became frequent since that year. Results of analysis are presented as hazard ratios (HRs) with 95% confidence intervals.

The prospective analysis included consecutive Crohn's disease patients seen between 1995 and 2004 who had had appendectomy but no ileo-cecal resection before 1995. Those patients were matched for sex, birth date (boxes of five years), date of diagnosis (boxes of five years), and Vienna classification disease location, with non-appendectomized patients without previous ileo-cecal resection. Patients of both groups were censored at the time of ileo-cecal resection. Calculations were performed using GB-stat statistical software.

**Figure 1** Characteristics of patients and Crohn's disease (given as percentages) according to appendectomy status and the time span between appendectomy and diagnosis of Crohn's disease. Numbers indicate the number of patients in each group. <sup>a</sup> and ns represent the *P* value of the comparison between the subgroup and the group of never appendectomized patients (<sup>a</sup>*P* < 0.05; ns: not significant).

## RESULTS

### Appendectomy in relation to disease onset

Among 2926 patients with Crohn's disease, 1068 patients (38% of those with appendectomy status known) had been appendectomized, including 87 after Crohn's disease diagnosis. Compared to non-appendectomized patients, the 981 appendectomized patients before or at diagnosis were more often females (69 *vs* 58%, *P* < 0.001), Caucasians (90 *vs* 84%, *P* < 0.001), and active smokers (61 *vs* 48%, *P* < 0.001). They were also older at diagnosis (29.5 ± 12.1 *vs* 27.4 ± 12.7 years, *P* < 0.001), and the time span between first symptom attributable retrospectively to Crohn's disease and Crohn's disease diagnosis was longer (21.9 ± 48.9 *vs* 16.5 ± 38.3 months in non-appendectomized patients, *P* = 0.003). Disease location differed significantly between the two groups, with a predominance of ileitis (L1 location) counterbalanced by a decrease of colitis (L2 location) in appendectomized patients (43 and 20%, *vs* 28 and 31%, respectively, in non-appendectomized patients, *P* < 0.001), without significant differences in the proportion of ileocolitis (L3) and upper digestive tract location (L4). Important differences were seen regarding gender distribution and disease location according to the time span between appendectomy and Crohn's disease diagnosis (Figure 1). A significant female predominance was observed only in patients appendectomized more than one year prior to Crohn's disease diagnosis. L1 was the main disease location whatever the interval between appendectomy and Crohn's disease diagnosis, however this increase was particularly marked in patients appendectomized at or within one year preceding the diagnosis. Compared to this latter subgroup, subgroups of appendectomized patients who had had appendectomy at various intervals prior to Crohn's disease differed significantly by a higher proportion of females, a lower prevalence of L1 location and a higher prevalence

**Table 1** Main characteristics of Crohn's disease in non-appendectomized and appendectomized patients

	Non-appendectomized	Appendectomized	<i>P</i>

of L2 location. Finally, there was a higher proportion of smokers in appendectomized patients whatever the date of appendectomy. To avoid inclusion of patients for whom appendectomy could have been performed for a missed diagnosis of Crohn's disease, we excluded from further analysis, in addition to the 180 patients appendectomized within the year of diagnosis, the 85 patients in whom appendectomy had been performed within the five years before disease onset. Thus 716 patients were included in the retrospective analysis (Figure 2). Among those patients, appendectomy had been performed 5 to 76 years (median, 16 years) before diagnosis of Crohn's disease, at a median age of 11 years (range 0-67).

### Retrospective analysis

The comparison of these 716 appendectomized patients with non-appendectomized patients is given in Table 1. The results were similar to the whole group of appendectomized patients, with a Crohn's disease diagnosis later in life and a predominance of both women and active smokers. In addition, appendectomized patients were more often Caucasian, of low-to-moderate socioeconomic status, without family history, and had less extra-intestinal manifestations. The most frequent disease location according to Vienna classification was ileum only in appendectomized patients, whereas it was colon only in non-appendectomized patients. More detailed comparison of initial and cumulative disease location revealed that prior appendectomy was associated with a higher prevalence of ileal involvement, while distal colon, rectum, and anus were more frequently spared (Figure 3). Cumulative disease behavior was inflammatory (B1) in 46%, stricturing (B2) in 15%, and penetrating (B3) in 39% of appendectomized patients, *vs* 43% (B1), 11% (B2), and 46% (B3), respectively, in non-appendectomized patients. Because disease behavior is highly dependent on disease location

Figure 2 Flow chart of patients studied.

Figure 3 Initial and cumulative Crohn's disease involvement of various segments of the digestive tract in non-appendectomized and appendectomized patients. The numbers above the columns indicate the *P* values comparing the frequencies of cumulative involvement of each segment between the two groups.

and duration<sup>[16]</sup>, the respective risks of stricture, intestinal perforation, and perianal perforation were calculated in each location group cumulatively (Table 2). These calculations demonstrated in appendectomized compared to non-appendectomized patients an increased risk of stricture in the L1 group, and a decreased risk of perianal perforating disease in the L2 group. Cox analysis in the whole population pooling the four location groups (2486 patients) confirmed that prior appendectomy was positively related to the risk of intestinal stricture (adjusted hazard ratio, 1.24; 95% confidence interval, 1.13 to 1.36;  $P=0.02$ ) and inversely related to the risk of perianal perforation (adjusted hazard ratio, 0.75; 95% confidence interval, 0.68 to 0.83;  $P=0.002$ ). The respective proportions of appendectomized and non-appendectomized patients who required oral steroids, enteral or parenteral nutrition, immunosuppressive therapy, infliximab, and

surgery were not significantly different in the whole population nor in each location group (Table 3). In the whole population, the 10-yr cumulative need for first excisional surgery was significantly higher in appendectomized *vs* non-appendectomized patients ( $54 \pm 2\%$  *vs*  $48 \pm 2\%$ , respectively;  $P=0.02$ ). However, multivariate analysis selected as predictive factors of surgery young age (adjusted hazard ratio, 0.80; 95 % confidence interval, 0.74 to 0.86;  $P=0.002$ ), ileal involvement (adjusted hazard ratio, 1.73; 95% confidence interval, 1.60 to 1.87;  $P<0.001$ ) and colonic involvement (adjusted hazard ratio, 0.66; 95 % confidence interval, 0.62 to 0.71;  $P<0.001$ ) and did not confirm the specific role of appendectomy ( $P=0.33$ ). Within each location group, the 10-yr cumulative need for first excisional surgery did not differ significantly (L1  $74 \pm 4\%$  *vs*  $67 \pm 3\%$ ; L2  $27 \pm 4\%$  *vs*  $38 \pm 3\%$ ; L3  $50 \pm 5\%$  *vs*  $39 \pm 3\%$ ; L4  $51 \pm 8\%$  *vs*  $51 \pm 4\%$ ).

No difference between the two groups was significant

### Prospective study

The prospective study included 591 appendectomized patients and 591 non-appendectomized matched controls, both selected on the basis of not having had ileo-cecal resection at inclusion into follow-up. The two groups were well matched (Table 4). One hundred and forty-five appendectomized (25%) and 143 non-appendectomized patients (24%), respectively, had an ileo-cecal resection after inclusion. After censoring, the median length of follow-up for the two cohorts was 4 years and encompassed a total of 5478 patient-years. The rate of years with active disease was 50% in appendectomized patients (1 318 out of 2 637 patient-years) vs 51% in non-appendectomized patients

**Figure 4** Percentages of patient-years with active disease (grey columns) and hospitalization (black columns), respectively, according to appendectomy and smoking status (App: appendectomized; Sm: smokers). Numbers indicate the number of patient-years in each group. <sup>a</sup>*P* < 0.05 vs App, non-Sm.; <sup>b</sup>*P* < 0.001 vs App, non-Sm.; <sup>d</sup>*P* < 0.001 vs non-App, non-Sm.

(1 455 out of 2 841 patient-years, NS). By contrast, in the same series of patients, non- or ex-smoking was associated with a decreased activity rate (1 521 out of 3 210 patient-years, 47%), compared to current smoking (1 252 out of 2 268, 55%; *P* < 0.001). Figure 4 gives the percentage of patient-years with active disease and hospitalization respectively, according to both smoking and appendectomy status. Previous appendectomy had no effect on year-by-year disease activity while smoking was significantly deleterious.

## DISCUSSION

The present results show that previous appendectomy, while associated with some particularities in the location and behaviour of Crohn's disease, has no effect upon the course of the disease. Appendectomized patients are more prone to ileal disease and to formation of strictures, and less to distal colonic involvement and penetrating perianal disease. However, previous appendectomy does not change disease severity retrospectively assessed from therapeutic needs or prospectively assessed from year-by-year activity.

The role of appendectomy in Crohn's disease is difficult to assess because various biases may jeopardize the analysis. First, appendicitis may be the first manifestation of Crohn's disease. The appendix is frequently involved by Crohn's disease<sup>[17]</sup>, granulomatous appendicitis may in some cases reveal Crohn's disease<sup>[18,19]</sup>, and resection of a Crohn's disease appendix may be followed by a long period of remission<sup>[20,21]</sup>. However, most pathological studies concluded that idiopathic granulomatous appendicitis is nosologically distinct from Crohn's disease<sup>[22]</sup> and that most of these patients do not develop subsequent Crohn's disease. Moreover, when analyzing a cohort of Crohn's disease patients, Crohn's disease confined to the appendix was very unusual, observed in less than 1% of Crohn's disease patients<sup>[23]</sup>. Although the pathology reports of the removed appendix were not available in our series, the data suggest that the great majority of our patients had appendectomy performed not for Crohn's disease. Moreover, the frequency of appendectomy in our series is similar to other series<sup>[12]</sup> and not different from controls without Crohn's disease<sup>[24,25]</sup>. Another difficulty is to accurately define in time the patient population in which the effect of appendectomy may be assessed. On one hand, inclusion of all appendectomized patients whatever the time span between appendectomy and the onset of Crohn's disease may lead to an overrepresentation of ileal disease cases, as an acute abdominal pain in the lower right quadrant may reveal ileal Crohn's disease. On the other hand, prolonging the time span between appendectomy and Crohn's disease may select cases of Crohn's disease occurring later in life and thus susceptible to share a lesser activity. Actually, in the present study, the comparison of patients subgroups defined by the duration of the interval between appendectomy and onset of Crohn's disease showed that only patients appendectomized within one year prior to Crohn's disease diagnosis clearly differed from other subgroups through a higher prevalence of ileal disease, as it could be expected (Figure 1). The characteristics of the subgroup of appendectomized patients one to five years prior to Crohn's disease diagnosis were intermediate between the two adjacent subgroups. This led us to define the cutoff at five years prior to appendectomy. Such a cutoff is in agreement with the data of Frisch *et al*<sup>[6]</sup> who found that, five years after appendectomy, the relative risk of Crohn's disease was not further elevated. Finally, in the present study, selection bias were minimal, as we did not use a postal questionnaire, but included prospectively all consecutive patients seen over a 10-year period. The criteria used to assess the severity of the disease were objective, and were based on therapeutic needs. Both surgical and immunomodulator history are

accepted as useful indicators of the over-all severity of Crohn's disease because these interventions are both easy to document retrospectively, and their use and the effects of their use may be complementary<sup>[14, 26]</sup>. Moreover, the prospective part of the study confirmed the results of the retrospective analysis.

Crohn's disease patients with prior appendectomy differed from non-appendectomized Crohn's disease patients in many aspects. There were more often females, smokers, of low-to-moderate socioeconomic status, and of Caucasian origin. In fact, these particularities might be more a consequence of appendectomy as such, than related to a particular Crohn's disease phenotype. Indeed, an epidemiological national survey in 1978-82 in France showed that appendectomy, but not appendicitis, was more frequent in females than in males<sup>[24]</sup>, and an association has been shown between appendectomy and passive or active smoking<sup>[27]</sup>. Other epidemiological studies from UK have also reported an increased rate of incidental appendectomies in women<sup>[28]</sup>. Similarly, the contrast between a higher proportion of Caucasian patients and a lower proportion of patients of high socio-economic status fits better with what is known about epidemiology of appendicitis than with IBD<sup>[29,30]</sup>. In the Western world, appendectomy is performed more often in whites than in blacks<sup>[31]</sup>, whereas data from UK suggest that the incidence of IBD in immigrants is similar to that of Europeans<sup>[32]</sup>. Changes in hygiene and water supply increased the risk of appendectomy<sup>[33]</sup> which in the last four decades has preferentially concerned populations of low-to-moderate socioeconomic status, whereas patients with IBD seem to be better educated<sup>[34]</sup>. We believe that the overrepresentation of ileal disease in appendectomized Crohn's disease patients may be at least in part a consequence of the high prevalence of smokers in this group, smoking being associated with ileal Crohn's disease and not colonic Crohn's disease<sup>[35]</sup>. Alternative explanations of the more frequent ileal involvement in appendectomized patients would be a larger use of explorative procedures such as barium follow-through or colonoscopy because patients with previous appendectomy are more prone to small bowel obstruction<sup>[36,37]</sup> and non specific abdominal pain<sup>[38]</sup>. The occurrence of abdominal pain may give the opportunity to find out a paucisymptomatic ileitis which could have been ignored otherwise.

Comparisons of disease behaviour between appendectomized patients and controls revealed some subtle differences within each disease location group. The former patients were more exposed to stricture formation and less to penetrating anal disease. Actually, within the colon only group (L2 group), disease location tended to be more distal in non-appendectomized patients, perianal lesions were more frequent, and it could be expected that perianal perforating complications occurred more frequently. The increased prevalence of intestinal strictures in patients with prior appendectomy, although weak, seems more relevant. It may be hypothesized that the presence of intra-abdominal adhesences and/or vasculature modifications secondary to prior laparotomy has a role in stricture formation.

The most important and unequivocal result of the pres-

ent study is the lack of effect of prior appendectomy on the severity of Crohn's disease. We observed an increased risk of surgery in appendectomized patients, but multivariate analysis revealed that this was related to confounding factors. Riegler *et al*<sup>[12]</sup> have reported an increased risk of surgery in 41 Crohn's disease patients with previous appendectomy when compared to 88 non-appendectomized patients, but patients appendectomized within one year prior to diagnosis of Crohn's disease were included in the analysis. In the study by Andersson, compared to Crohn's disease controls, Crohn's disease patients with a history of perforated appendicitis had a higher incidence of intestinal resections, those with appendectomy for other diagnoses had a lower incidence, but the incidence for the whole group with prior appendectomy was similar to controls<sup>[7]</sup>. Radford-Smith *et al*<sup>[3]</sup> have reported similar results in a retrospective analysis of 335 patients with Crohn's disease, of whom 36 had had prior appendectomy. Thus the effect of prior appendectomy on the risk of surgery seems nil or weak, or not related to appendectomy per se. Besides, therapeutic needs in terms of steroid and immunosuppressants requirements were very similar in appendectomized and non-appendectomized patients, whatever the disease location. Finally, the prospective follow-up of our appendectomized patients compared with controls matched for gender, age, and disease location, clearly demonstrated the lack of effect of prior appendectomy on the disease activity. This study was powered enough to support a firm conclusion, since concomitantly among the same patients, the deleterious effect of current smoking was highly significant.

In conclusion, this study shows that prior appendectomy is associated with a distinct phenotype of Crohn's disease. However these particularities may be attributable more to appendectomy than to Crohn's disease. Besides, in contrast to smoking, appendectomy has no effect on Crohn's disease severity. Taken together, these data indicate that appendectomy and Crohn's disease share common environmental or genetic characteristics whereas appendectomy per se does not exert any immune modulating effect. The response of IBD to the only environmental factors clearly documented so far, smoking and appendectomy, is quite different in UC and in Crohn's disease.

### Abstract

**AIM:** To evaluate the reproducibility of a modified  $^{13}\text{C}$  breath test-based measurement of solid phase gastric emptying (GE) within the frames of a simple-repeated measure study protocol.

**METHODS:** Twelve healthy subjects (6 females and 6 males, mean age  $24.9 \pm 0.7$  years) were recruited to undergo three identical GE examinations. In six subjects the first two examinations were performed 2 d apart, and the third session was carried out at a median interval of 19.5 d (range 18 - 20 d) from the second one. In another six subjects the first two measurements were taken 20 d apart (median, range: 17-23 d), whereas the third session took place 2 d after the second one. Probes of expiratory air collected before and during six hours after intake of a solid meal (378 kcal) labelled with 75  $\mu\text{L}$  (68 mg)  $^{13}\text{C}$ -octanoic acid, were measured for  $^{13}\text{CO}_2$  enrichment with the nondispersive isotope-selective infrared spectrometry NDIRS apparatus.

**RESULTS:** Taking coefficients of variation for paired examinations into account, the short-term reproducibility of the GE measurement was slightly but not significantly better than the medium-term one: 7.7% and 11.2% for the lag phase (T-Lag), 7.3% and 10.9% for the gastric half emptying time ( $T_{1/2}$ ). The least differences in GE parameters detectable at  $P=0.05$  level in the 12 paired examinations were 9.6 and 15.6 min for T-Lag, 11.6 and 19.7 min for  $T_{1/2}$  by a two-day or two to three-week time

gap, respectively.

**CONCLUSION:** The low-cost modification of the breath test involving a lower dose of  $^{13}\text{C}$ -octanoic acid and NDIRS, renders good short- and medium-term reproducibility, as well as sensitivity of the measurement of gastric emptying of solids.

### INTRODUCTION

Since its first description and validation in 1993<sup>[1]</sup>,  $^{13}\text{C}$ -octanoic acid breath test ( $^{13}\text{C}$ -OABT) has dug its way towards the top of the list of the most widely used methods for the measurement of gastric emptying of solids. For example, recently published epidemiologically-oriented studies addressing the features of gastric emptying kinetics in large cohorts of patients involving hundreds of subjects suffering from functional dyspepsia, have been performed with  $^{13}\text{C}$ -OABT<sup>[2-4]</sup>. Also the introduction of less expensive and technically demanding apparatus, based on the non-dispersive isotope-selective infrared spectrometry (NDIRS), is an undeniable milestone which has opened the gate for a widespread use of  $^{13}\text{C}$  breath tests<sup>[5-7]</sup>, the  $^{13}\text{C}$ -OABT making no exception in this respect<sup>[8-13]</sup>.

Reproducibility is a vital feature of any measurement or diagnostic method used in medical practice. Few data are available on the repeatability of the  $^{13}\text{C}$ -OABT in humans, and reports addressing this subject appear unsatisfactory<sup>[14,18]</sup>. Moreover, no previous study has reported reproducibility of the NDIRS variety of the  $^{13}\text{C}$ -OABT. The aim of this study was to establish the short- and medium-term repro-

ducibility of the  $^{13}\text{C}$ -OABT with NDIRS and a reduced dose of the  $^{13}\text{C}$  substrate.

## MATERIALS AND METHODS

### Subjects

Twelve healthy subjects (6 females and 6 males) were recruited to participate in this study, their mean age was  $24.9 \pm 0.7$  years, and the average body mass index amounted to  $22.37 \pm 1.06 \text{ kg/m}^2$ .

During a screening interview, the participants declared themselves to be in full health according to the World Health Organisation criteria. Exclusion criteria comprised a history of surgery affecting the digestive tract anatomy with the exception of appendectomy, current use of any drugs which might affect gastrointestinal motility, and pregnancy. The recruitment procedure involved performance of a standard breath test with  $^{13}\text{C}$ -urea, so that exclusively subjects with a negative test result for *Helicobacter pylori* infection were admitted. Except for three persons, all the participants were non-smokers. The study was conducted in accordance with the Helsinki Declaration, and each volunteer gave a written consent after getting information as to the aim, protocol and methodology of the study. During the introductory interview, the subjects were committed not to eat any food of naturally increased  $^{13}\text{C}$  content, such as products made of maize, cane sugar, pineapple, kiwi fruit for 48 h preceding the examination.

### Experimental protocol

Each subject underwent three sessions of gastric emptying measurement held on separate days. In six subjects the first two examinations were performed 2 d apart, and the third session was carried out at a median interval of 19.5 d (range 18-20 d) from the second one. In another six subjects, the first two gastric emptying measurements were taken 20 d apart (median, range 17-23 d), whereas the third session took place 2 d after the second one. The assignment of the order of intervals separating the sessions (short-long or long-short) was randomized. Ultimately the short-term reproducibility assessment involved performance of 12 pairs of gastric emptying examinations separated by a two-day break, whereas twelve pairs of examinations accomplished at a median interval of 21.5 d (range 17-23 d) were dedicated for the evaluation of the medium-term reproducibility.

The research was performed on volunteers who reported themselves to the laboratory in the morning, after a 12-h overnight fasting and abstaining from cigarette smoking (if applicable). At the beginning, a basal fasted probe of the exhaled air was put into an aluminium-covered plastic bag of about 1 L capacity (Fisher Analysen Instrumente GmbH, Germany). At the time point of "0", the subjects were given a solid test meal, a pancake made of two eggs, 30 g wheat flour and 0.1 g baking powder, which was additionally smeared with 50 g of strawberry jam before serving. The total energy content of the meal was 1574 kJ (378 kcal) and it contained 15.5 g proteins, 16.8 g fat, and 43.0 g carbohydrates. During the preparation procedure of the pancake, the two-egg yolks were temporarily separated from the egg whites and thoroughly mixed with 75  $\mu\text{L}$  (68

mg) of  $^{13}\text{C}$ -octanoic acid (INC610P, lot #T012A-L3241, Euriso-Top, France) which was instilled with a precision digital micropipette (Calibra 822-20/200, Socorex, Switzerland). Thereafter the yolks were added to and stirred with the remaining ingredients with an electric mixer. Finally the dough was transferred into a pan and fried to firm consistency with addition of 5 mL of sunflower oil. The time needed to consume the test meal did not exceed 10 min. No drink was served with the meal because the study intended to assess strictly the reproducibility of the solid phase gastric emptying.

Reckoning the passage of time from the defined "0" point, 26 probes of the expiratory air were collected post-prandially every 10 min during the first hour, and then every 15 min for an additional 5 h. After ingestion of the meal, the subjects were asked not to take any additional food or drink for 6 h. They were enabled to rest sitting in a comfortably furnished room and allowed to watch video films.

### Measurement of $^{13}\text{CO}_2$ and derivation of gastric emptying parameters

Concentrations of  $^{13}\text{CO}_2$  in the probes of the exhaled air were measured with the NDIRS apparatus (IRIS, Wagner Analysen Technik Vertriebs GmbH, Germany; a model equipped with 16 ports for simultaneous mounting of bags with air samples was used). Repeatability of the  $^{13}\text{CO}_2$  measurement with the NDIRS technique was checked by double measurements performed on 96 probes of the exhaled air originating from 3 randomly selected gastric emptying examinations. The procedure was performed in such a way that the second measurement was taken instantly without removing the bags containing the probes from the apparatus.

The determined  $^{13}\text{CO}_2$  content within the total pool of the exhaled  $\text{CO}_2$  was expressed in  $\delta\text{‰}$  PDB units, i.e. relative to the international standard - the calcium carbonate of the fossil Belemnite of the cretaceous Pee Dee formation in South Carolina, USA (zero  $\delta\text{‰}$  PDB corresponds to 1.12372%  $^{13}\text{C}$  atoms within  $\text{CaCO}_3$ ). The obtained  $\delta\text{‰}$  PDB data were exported to an ASCII file for a subsequent analysis with a user-created Excel spreadsheet.

The changes in  $^{13}\text{CO}_2$  concentration were recalculated to net increments expressed in  $\text{‰}$  DOB (*delta over baseline*) units according to the formula:

$$\text{DOB}_i = \delta\text{‰ PDB}_i - \delta\text{‰ PDB}_0$$

where  $i$  stands for the probe number, and the 0 index pertains to the basal probe of the expiratory air.

The momentary  $^{13}\text{C}$  recovery at time  $i$ ,  $\text{D}^0\text{‰}_{i-13}\text{C}$ , expressed in percent age of administered dose per hour ( $\text{‰}$  dose per hour), was computed according to the equation:

$$\text{D}^0\text{‰}_{i-13}\text{C} = 100 \cdot (\text{DOB}_i / 1000 \cdot 0.0112372 \cdot \text{TCO}_2) / \text{dose}$$

where  $\text{TCO}_2$  = total expiratory  $\text{CO}_2$  production in mmol/h and dose = amount in mmol of  $^{13}\text{C}$ -octanoic acid given to the subjects. The  $\text{TCO}_2$  was derived by multiplication by the rate of 300 mmol/ $\text{m}^2$  per hour by the body surface area computed according to the formula by Haycock *et al*<sup>[19]</sup>.

The  $^{13}\text{C}$  recovery within a given period,  $\text{C}_i-^{13}\text{C}$ , ex-

**Figure 1** Repeatability of the measurement of  $^{13}\text{CO}_2$  enrichment ( $\delta$ ) in expiratory air after intake of a solid meal labeled with 75  $\mu\text{L}$  (68 mg)  $^{13}\text{C}$ -octanoic acid. Ninety-six pairs of  $\delta$  measurements taken from three randomly selected examinations were considered.

**Figure 2** Individual curves reflecting the increment in  $^{13}\text{CO}_2$  enrichment in exhaled air after intake of a 378 kcal solid meal containing 75  $\mu\text{L}$  (68 mg)  $^{13}\text{C}$ -octanoic acid (the 36 curves were obtained in 12 healthy subjects at three separate days).

pressed in percent age of dose, was computed following the trapezoid rule:

$$C_i^{13}\text{C} = 0.5 \cdot (\text{DOB}_{i-1} + \text{DOB}_i) / 1000 \cdot \Delta t \cdot 0.0112372 \cdot \text{TCO}_2 / \text{dose}$$

where  $\Delta t$  = the time span between consecutive DOB measurements

The cumulative  $^{13}\text{C}$  recovery  $T_i$  -  $^{13}\text{C}$  in percent age of administered dose was then derived from a stepwise summation of  $C_i^{13}\text{C}$  for  $i$  within the domain of 1 - 26.

Using algorithms of non-linear regression implemented in the Statistica 6.1 software<sup>[20]</sup>, the curves of momentary  $^{13}\text{C}$  recovery were fitted to the function:

$$D\%_{\text{oi}}^{13}\text{C} = a t^b e^{-ct}$$

where  $t$  stands for time, and  $a$ ,  $b$ ,  $c$  are parameters of the function

which enables computation of three gastric emptying parameters<sup>[11,21]</sup>: the lag phase,  $T\text{-Lag} = b/c$ ; the gastric half emptying time,  $T_{1/2} = \text{Gamma inv.}(0.5; b+1; 1/c)$ ; and the gastric emptying coefficient,  $\text{GEC} = \ln(a)$

### Statistical analysis

A null hypothesis, assuming a zero difference between repeated measurements, was checked with the paired

**Figure 3** Momentary (empty squares) and cumulative (filled squares)  $^{13}\text{C}$  recovery in exhaled air after ingestion of a 378 kcal solid meal containing 75  $\mu\text{L}$  (68 mg)  $^{13}\text{C}$ -octanoic acid. The data are grand means with standard errors (bars) calculated on average values obtained in 12 healthy volunteers during three examinations carried out on separate days.

Student's  $t$  test. The reproducibility of the gastric emptying parameters was expressed in terms of the coefficient of variation for paired examinations,  $\text{CV}_p$ <sup>[22,23]</sup>. Moreover Bland and Altman statistics was applied in order to calculate the repeatability coefficient,  $\text{RC}$ <sup>[24,25]</sup>. Finally,  $\Delta_{0.05}$  - the least statistically significant difference detectable at  $P=0.05$  level (two-tailed) was calculated for each gastric emptying parameter<sup>[26]</sup>. Results were presented as mean  $\pm$  SE. All statistical analyses were performed with the Statistica 6.1 software, licence # adbp409a903816ar<sup>[20]</sup>.

## RESULTS

### Repeatability of NDIRS measurement of $^{13}\text{CO}_2$ enrichment in exhaled air

Bland and Altman statistics performed on the paired measurements of the  $^{13}\text{CO}_2$  content within 96 samples of the expiratory air yielded a repeatability coefficient of 0.40‰, and the mean difference between the repeated measurements amounted to 0.07‰ (95% confidence interval: 0.34 - 0.46‰) (Figure 1). If the data pertaining to the  $^{13}\text{CO}_2$  content within the expiratory air were expressed in terms of the delta over baseline values, the respective repeatability coefficient amounted to 0.62‰, with a mean difference of 0.28‰ between repeated measurements (95% confidence interval: 0.34 - 0.90‰).

### Reproducibility of parameters characterizing gastric emptying kinetics

Ingestion of the solid test meal labeled with 75  $\mu\text{L}$  of  $^{13}\text{C}$ -octanoic acid brought about an expected increase of the  $^{13}\text{CO}_2$  concentration in the exhaled air (Figure 2). The maximum net increment in the  $^{13}\text{CO}_2$  concentration amounted to 9.1‰ (mean, 95% confidence intervals 5.3‰ to 12.9‰) during the 36 gastric emptying examinations. The maximum momentary  $^{13}\text{C}$  recovery in the exhaled air was observed at 165 min (mean, 95% confidence intervals 112 min to 219 min) postprandially, and amounted on average to  $11.50 \pm 0.36$  % dose per hour (Figure 3). During the whole 6 h observation period  $41.80 \pm 1.13$  % of the administered tracer was eliminated in the form of  $^{13}\text{CO}_2$  within the expiratory air (Figure 3).

**Figure 4** Bland and Altman statistics (plot of differences between pairs vs their names) of the short-(open symbols) and medium-term( filled symbols) reproducibility of the measurement of the lag phase (T<sub>Lag</sub>, panel A), the gastric half emptying time (T<sub>1/2</sub>, panel B), and the gastric emptying coefficient (GEC, panel C) of the solid phase gastric emptying with a breath test using 75  $\mu$ L (68 mg) <sup>13</sup>C-octanoic acid and the isotope-selective nondispersive infrared spectrometry. On each panel the respective borders of the 95% confidence intervals are plotted - cf. the legend of the GEC graph, panel C.

A graphical depiction of the Bland and Altman statistics pertaining to the gastric emptying parameters is given in Figure 4, and a comprehensive statistical description of the reproducibility data is provided in Table 1. In no instance the null hypothesis of a zero difference between the repeated measurements had to be discarded. According to the data assembled in Table I, greater values of RC and CV<sub>p</sub> characterized the medium-term compared to the short-term reproducibility. A comparison of the absolute values of the differences between the paired measurements implied rejection of a hypothesis that reproducibility of the

gastric emptying was significantly worse when the examinations were separated by an extended time gap.

## DISCUSSION

The novelty of the results furnished by the current study consists in: for the first time the reproducibility of the <sup>13</sup>C-OABT was evaluated with the NDIRS, a reduced dose of the <sup>13</sup>C-octanoic acid was applied for the test, the test meal was administered without allowance of any intake of liquids so that pure repeatability of the solid phase gastric emptying could be discerned, and a distinguishment was made between the short- and medium-term reproducibility.

Typically the <sup>13</sup>C-OABT is performed with 100  $\mu$ L of <sup>13</sup>C-octanoic acid which is equivalent to 91 mg <sup>13</sup>C-octanoic acid [2-5,8-12,14,16-18]. It was reported that a lower dose - 50 mg <sup>13</sup>C-octanoic acid can be used to examine the solid phase gastric emptying [21]. The NDIRS apparatus coped well with the 68 mg (75  $\mu$ L) amount of <sup>13</sup>C-octanoic acid applied for labelling the test meal in the current study. This contention is supported by the finding of a low value of the repeatability coefficient (0.40%) and a narrow 95% confidence interval of the differences between paired measurements of <sup>13</sup>CO<sub>2</sub> enrichment (0.34 - 0.46%) derived from a large number of breath samples covering a typical range of <sup>13</sup>CO<sub>2</sub> concentration encountered throughout the 6 h of the <sup>13</sup>C-OABT. Since baseline fluctuation of <sup>13</sup>CO<sub>2</sub> concentration in breath is expected to approach a standard deviation of 0.72‰ [27], our results clearly indicate that the measurement error involved in the NDIRS technique is less than the natural baseline fluctuation of <sup>13</sup>CO<sub>2</sub> concentration in breath. The finding quoted is in concordance with our previously published results [6,7,28].

While performing the <sup>13</sup>C-OABT, we generously allowed for a frequent sampling of the expiratory air (a total of 27 samples were collected throughout a single examination including the basal specimen) over a long observation period of 6 h. This approach was substantiated by findings of other authors clearly stating that too short a collection period and/or an infrequent sampling of the expiratory air may lead to erroneous estimation of the parameters of gastric emptying with the <sup>13</sup>C-OABT [16,17,29]. According to Choi *et al* [16,17], duration of the <sup>13</sup>C-OABT obligatory should be extended to six hours, since largely overestimated values of T<sub>Lag</sub> and T<sub>1/2</sub> would be derived from the data truncated to four hours.

Three parameters are originally proposed as quantitative descriptors of the gastric emptying kinetics examined with the <sup>13</sup>C-OABT, namely: T<sub>Lag</sub>, T<sub>1/2</sub>, and GEC [1,21]. Nowadays researchers are increasingly inclined to use the T<sub>1/2</sub> only when reporting on their results with the <sup>13</sup>C-OABT. This apparently minimalistic approach has quite firm grounds. The shortcomings of GEC consist in the fact that its estimation is not independent of the endogenous CO<sub>2</sub> production, and in the case of fast gastric evacuation patterns this parameter may underestimate gastric emptying [1]. T<sub>Lag</sub> of the <sup>13</sup>C-OABT is originally conceived to reflect the duration of the first phase of gastric evacuation, while the solid meal is ground to particles of 1-2 mm in diameter before the actual emptying can start. This assumption has not found any convincing corroboration in vali-

**Table 1** Reproducibility of solid gastric emptying measurement with breath test at a 68 mg (75 µL) dose of <sup>13</sup>C-Octanoic acid and isotope-selective nondispersive infrared spectrometry

Observed values <sup>1</sup>	T-Lag, lag phase 149.7 ± 4.6 min		T½, gastric half emptying time 195.6 ± 4.2 min		GEC, gastric emptying coefficient 2.56 ± 0.09	
	Short-term	Medium-term	Short-term	Medium-term	Short-term	Medium-term
RC (min)	31.6	46.7	39.1	59.1	0.61	0.87
CVp (%)	7.7	11.2	7.3	10.9	8.3	12.5
△ 0.05 (min)	9.6	15.6	11.6	19.7	0.17	0.29

Short-term reproducibility involved twelve paired examinations performed 2 d apart, whereas medium-term reproducibility involved twelve paired examinations at a median interval of 21.5 d (range 17 - 23 d)

RC = repeatability coefficient, CVp = coefficient of variation for paired examinations, △ 0.05 = the least statistically significant difference detectable at *P* = 0.05 level, two-tailed

<sup>1</sup> These data are grand means calculated on average values obtained during three examinations carried out on separate days

dation studies of the <sup>13</sup>C-OABT against the scintigraphic determination of gastric emptying, which is the so called 'golden standard' in the field of gastro-emptology<sup>[16,17]</sup>. Quite recently it was even demonstrated by Doppler ultrasonography that transpyloric flow starts already during ingestion of a <sup>13</sup>C-labelled solid meal, which results in a detectable excretion of <sup>13</sup>CO<sub>2</sub><sup>[30]</sup>. It has been shown that trituration of the solid meal can lead to a pronounced shortening of this parameter<sup>[31]</sup>. Nevertheless, T\_Lag will be more and more willingly replaced by the term 'time to reach the maximum of the momentary <sup>13</sup>CO<sub>2</sub> excretion' which is the revised representation of what the T-Lag derived mathematically from the function fitted to a <sup>13</sup>CO<sub>2</sub> excretion curve actually is<sup>[1,8,9,21]</sup>.

In the present study, we controlled rigorously and kept constant a number of factors which might affect reproducibility of the <sup>13</sup>C-OABT, namely meal composition, time of the day when the gastric emptying measurement was taken, posture of the subjects during the test. Ingestion of the test meal took place irrespective of actual phase of the duodenal migrating motor complex (MMC), because monitoring of the duodenal motor activity would require insertion of a manometric tube into the lumen of the duodenum - an invasive manoeuvre which might interfere with physiological conditions assumed for the <sup>13</sup>C-OABT performance; observation of a particular phase of the duodenal MMC could not ameliorate the reproducibility of the scintigraphic measurement of the gastric emptying of the solid phase of a meal<sup>[32]</sup>. Homogeneity was the important feature of the test meal we applied, that is the pancake was uniformly labelled with <sup>13</sup>C-octanoic acid and eaten without addition of any liquid to assure the sole assessment of the reproducibility of the solid phase gastric emptying<sup>[33]</sup>.

Because there are no other reports on the <sup>13</sup>C-OABT performed with the NDIRS, our data can be compared only to the results obtained by other authors applying the isotope ratio mass spectrometry (IRMS). Choi *et al*<sup>[17]</sup> reported that the reproducibility of T-Lag and T½ is 14% and 15% respectively. In the study by Delbende *et al*<sup>[18]</sup> the pertinent RC and CV<sub>p</sub> amounted to 35.5 min and 14.3%, respectively. The reproducibility results of those two studies look very much alike indeed. The results of the present study indicated that the reproducibility of gastric emptying of solids determined by <sup>13</sup>C-OABT and the NDIRS was not worse than that by IRMS. Moreover, both the reproducibility and sensitivity (as assessed by the magnitude

of the least detectable differences in the gastric emptying parameters) were preserved when the examinations were separated by a two- three-week time gap. Finally, it should be emphasized that the results obtained by others<sup>[17,18]</sup> and coming from our current study clearly demonstrate that the reproducibility of the measurement of gastric emptying of solids by the <sup>13</sup>C-OABT is equivalent to the intra-subject variability of the solid-phase gastric emptying observed with gamma scintigraphy<sup>[22,23]</sup>. This is an important finding due to the inherently indirect nature of <sup>13</sup>C-OABT. The reproducibility of <sup>13</sup>C-OABT would be affected by more factors than a scintigraphic GE measurement, namely the intestinal absorption of the <sup>13</sup>C-octanoic acid, its oxidation to <sup>13</sup>CO<sub>2</sub> within the liver, as well as kinetics of the subsequent transfer of <sup>13</sup>CO<sub>2</sub> to the expiratory air.

In conclusion, the low-cost modification of the breath test involving a lower dose of <sup>13</sup>C-octanoic acid and NDIRS, renders a good short- and medium-term reproducibility, as well as sensitivity of the measurement of gastric emptying of a solid meal.

### Abstract

**AIM:** To observe if the total amount of platelet P-selectin (tP-selectin) in patients with inflammatory bowel disease (IBD) was related to disease entity or activity, 5-aminosalicylic acid (5-ASA) medication or gender.

**METHODS:** tP-selectin was measured by immunoassay in seventeen IBD patients and twelve healthy controls.

**RESULTS:** Compared to controls, there was no difference of tP-selectin in patients related to disease entity or activity and 5-ASA medication. When the groups were split according to gender the male patient group showed higher levels of tP-selectin compared to male controls (153 ng/mL vs 94 ng/mL,  $P < 0.05$ ).

**CONCLUSION:** Increased tP-selectin levels may alter the inflammatory response and susceptibility to thromboembolic disease. As previously shown with soluble P-selectin, tP-selectin shows gender dependent differences important to consider in future studies.

### INTRODUCTION

Upon platelet activation, intracellular P-selectin is expressed on the membrane surface and released from the platelets<sup>[1]</sup>. In addition to P-selectin, platelets release various inflammatory mediators that regulate both hemostasis and inflammation<sup>[2]</sup>.

Ulcerative colitis (UC) and Crohn's disease (CD) are disorders of unknown aetiology, jointly referred to as inflammatory bowel disease (IBD). Current research suggests platelet dysfunction as a contributor to the disease since increased risk of thromboembolic disease and abnormal platelet activity have been found. Increased surface expression of platelet P-selectin in patients with IBD did not appear to reflect disease activity<sup>[3,4]</sup>, whereas soluble P-selectin in plasma recently was suggested to be parallel to the severity of UC<sup>[5]</sup>. Using a new technique to quantify the total amount of P-selectin in platelets, patients with hypertension have been reported to have higher levels of platelet P-selectin<sup>[6]</sup>. Our aim of this study was to observe if total amount of platelet P-selectin (tP-selectin) differs between IBD patients and healthy controls and if there is a difference regarding disease entity, disease activity, 5-aminosalicylic acid (5-ASA) medication and gender.

### MATERIALS AND METHODS

Controls and patients with intake of anti-platelet drugs or steroids two weeks prior to sample collection were excluded. Seven female and five male healthy blood-donors served as a controls (mean age 44.9, range 25-65 years). The patient group consisted of six female and eleven male IBD patients (mean age 44.4, range 19-69 years). Diagnosis was verified with histological examination (biopsy and colonoscopy); twelve patients had UC and five patients had CD. Patients were sub-grouped according to disease activity, 5-ASA medication and gender. In UC eight patients were in relapse and in CD all patients were in remission. Ten patients had 5-ASA medication.

Isolated platelets (IP) were prepared as previously described<sup>[7]</sup>. Frozen IP samples were thawed and incubated with 0.5% Triton X-100 (Sigma Chemical Co., St. Louis, MO, USA) at 37 °C for 1 h. Thereafter, the permeabilised IP samples were gently mixed prior to measurement of tP-selectin levels according to standard procedures using an immunoassay from R&D Systems (Abingdon, Oxfordshire, UK).

**Figure 1** Total P-selectin in permeabilised platelets from 5 healthy male subjects and 11 male patients with inflammatory bowel disease. Horizontal lines represents the mean value. <sup>a</sup> $P < 0.05$  vs unpaired  $t$  test with Welch's correction.

### Statistical analysis

All values are presented as mean  $\pm$  standard error of the mean (SE). Statistical analyses were calculated by unpaired  $t$  test with Welch's correction for samples with different variances. Differences were considered significant when  $P < 0.05$ .

## RESULTS

All values are in ng/mL. There was no significant difference of tP-selectin between controls,  $133 \pm 20.1$  ( $n = 12$ ), and patients,  $154 \pm 8.1$  ( $n = 17$ ). When samples were sub-grouped according to gender the male patients showed significant higher levels compared to the male controls;  $153 \pm 8.2$  and  $94.1 \pm 21.1$  (Figure 1). In the sub-grouped male group the mean and range of age were 46.8 and 32–55 years in the control group and 46.4 and 24–65 years in the male patient group, denoting that age is not the cause of the different levels. Both the female controls and the female patients tended to have higher levels compared to male controls, although insignificantly. There were no significant differences between the female controls and female patients;  $161 \pm 27.7$  ( $n = 7$ ) and  $156 \pm 18.7$  ( $n = 6$ ). The levels of tP-selectin in UC compared to CD were  $151 \pm 9.6$  ( $n = 12$ ) and  $163 \pm 16.3$  ( $n = 5$ ). Values regarding disease activity showed following results; remission,  $157 \pm 11.2$  ( $n = 9$ ) and relapse,  $152 \pm 11.7$  ( $n = 8$ ). None of the groups showed significant difference in comparison with the controls. The levels in male patients in remission compared to male patients in relapse were;  $155 \pm 13.7$  ( $n = 6$ ) and  $152 \pm 9.2$  ( $n = 5$ ). Patients with 5-ASA compared to patients without 5-ASA had tP-selectin levels of  $152 \pm 9.1$  ( $n = 10$ ) and  $159 \pm 15.6$  ( $n = 7$ ), respectively. There was no significant difference between the male patients with 5-ASA,  $151 \pm 8.4$  ( $n = 6$ ) compared to male patients without 5-ASA,  $156 \pm 16.0$  ( $n = 5$ ).

## DISCUSSION

Plasma levels of soluble P-selectin has recently been

suggested to relate to the severity of UC<sup>[5]</sup> and increased tP-selectin has been found in hypertensive patients<sup>[6]</sup>. Our previous study showed that patients with IBD in remission had higher basal platelet P-selectin surface expression<sup>[4]</sup>. To investigate if this was related to higher platelet P-selectin content we analysed tP-selectin in patients with IBD. There was no difference of tP-selectin in patients taken as one group compared to controls, irrespectively of disease entity or activity and 5-ASA medication. When the groups were split according to gender the male patient group showed significantly higher levels compared to male controls. Both healthy and patient females showed greater variance compared to the male groups. This may be caused by a hormonal influence on tP-selectin, since sP-selectin fluctuates during the menstrual cycle<sup>[8]</sup> and age (pre- and post-menopausal). Other sex-based differences that influence the disease activity in IBD have recently been reported<sup>[9]</sup>. In the present study, male patients had higher tP-selectin levels regardless of disease entity, disease activity and 5-ASA medication. Taken together with our previous findings<sup>[4]</sup>, we suggest that male IBD patients have higher levels of tP-selectin and exhibit higher basal platelet P-selectin expression when in remission. This could have an exaggerated influence on the inflammatory response and susceptibility to thromboembolic disease.

### Abstract

**AIM:** To investigate the major steps of thrombogenesis and to identify the differences in these steps between idiopathic patient group and control group.

**METHODS:** Fibrinogenesis was studied by measuring the activated factor VII, total and free levels of tissue factor pathway inhibitor (TFPI). The fibrinolysis step was investigated by determining the global fibrinolytic capacity. The endothelial function was assessed by measuring the levels of soluble adhesion molecules, namely soluble intercellular adhesion molecule 1 (sICAM-1), soluble vascular cell adhesion molecule 1 (sVCAM-1) and soluble E-selectin molecule. The exclusion criteria from "idiopathic" patient group were abdominal surgery, pregnancy, use of oral contraceptives, anti-phospholipid syndrome, Behçet's disease, cancer, myeloproliferative diseases. The congenital factors like mutations of factor-V Leiden and prothrombin, deficiencies of proteins C and S, antithrombin, hyperhomocysteinemia and hyperfibrinogenemia were ruled out. The total number of patients was reduced from 96 to 9 (7 with portal vein thrombosis, 2 Budd Chiari syndrome) by exclusion criteria.

**RESULTS:** The levels of adhesion molecules sICAM-1, sVCAM-1, free TFPI levels and global fibrinolytic capacity were significantly different ( $P < 0.05$ ) in the patient group indicating an endothelial dysfunction and a lower fibrinolytic activity.

**CONCLUSION:** These results show that this patient group should be tested by means of endothelial dysfunction

### INTRODUCTION

Thrombosis in the hepatic vascular system (hepatic veins and portal veins) is an established risk factor for both morbidity and mortality due to inevitable consequences of disturbed liver vascular physiology and anatomy. The primary mechanism resulting in this condition may be clinically evident (ie, a mass-forming lesion adjacent to a major vessel resulting in compression and occlusion, which is called a "secondary" thrombosis) and by definition these patients are treated with therapeutic techniques to eliminate the cause. On the other hand, in some patients there may be a thrombophilic condition resulting in a "primary" thrombosis which usually is the case in this patient population. The clinical importance of presence or absence of a thrombophilic condition lies in the fact that the presence of a thrombophilic condition increases the mortality by a factor of 4<sup>[1]</sup>.

Studies investigating the etiology of thrombosis in hepatic vasculature indicate that the most commonly-found predisposing thrombophilic conditions are deficiencies of proteins C and S as well as antithrombin (AT), mutations of factor V Leiden and prothrombin followed by myeloproliferative diseases and other less commonly-observed disorders including Behçet's disease<sup>[2-6]</sup>. On the other hand, there seems to be a patient population in whom there is not any obvious thrombophilic condition that can be found utilizing routine techniques but mortality risk increases still in the high risk group due to undiagnosed thrombophilic condition. This unique population is called "idiopathic" thrombosis group and their contribution to the main patient population is about

Table 1 Applied exclusion criteria

Exclusion criteria
Acute thrombosis of portal or hepatic veins
Any ultrasonographic (including Doppler studies) finding compatible with mass occupying lesion in liver
Positivity of viral hepatitis markers
Any finding in the liver biopsy suggesting parenchymal liver disease (including autoimmune liver diseases and metabolic liver diseases)
Acquired hematological abnormality leading to thrombophilia (myeloproliferative diseases, paroxysmal nocturnal hemoglobinuria, history of use of oral contraceptive or estrogen replacement treatment, anti-phospholipid syndrome, history of cancer, history of hepatobiliary surgery, history of pancreatitis)
Genetic hematological abnormality leading to thrombophilia (mutation of factor V Leiden, mutation of prothrombin, deficiencies in proteins C and S or antithrombin, hyperfibrinogenemia, hyperhomocysteinemia)
Severe and widespread atherosclerosis, uncontrolled or newly diagnosed malignancy elsewhere, systemic inflammatory diseases, history of recent operation

7%-22%<sup>[7,8]</sup>. In the current knowledge, hematological changes of this remaining “idiopathic” group is unclear, hence giving opportunity to investigate this patient population with advanced markers of thrombosis formation.

According to the current concept of pathologic thrombus formation, a thrombus is the result of convergence of multiple factors which may be either genetic or acquired. Therefore, it seems crucial to clarify the underlying possible pathogenetic factors or predisposing conditions in the “idiopathic” patient population in terms of tests not routinely used for the investigation of thrombogenesis.

In our study, we aimed to investigate the general characteristics of patients with idiopathic portal or hepatic vein thrombosis, to compare the “idiopathic” patient group with healthy adults in terms of major steps of thrombogenesis and fibrinolytic potentials, and to reconcile the “thrombophilia theory” in etiology of idiopathic portal hypertension with idiopathic portal vein thrombosis. The advanced tests that we used to investigate possible thrombophilia included activated factor VII (FVIIa) which is the most potent initiator of thrombin formation via tissue factor and its potent controller called tissue factor pathway inhibitor (TFPI; total and free fractions), adhesion molecules, namely soluble vascular cell adhesion molecule-1 (sVCAM-1), soluble intercellular adhesion molecule-1 (sICAM-1) and soluble E-selectin molecule as markers of endothelial dysfunction and global fibrinolytic capacity (GFC) to assess the steps of fibrinolysis.

This study was designed to investigate the endothelial dysfunction, steps of fibrinogenesis and fibrinolytic capacity in a patient group named as “idiopathic” after use of current techniques to investigate thrombophilia.

## MATERIALS AND METHODS

### Patient and control groups

All the patients diagnosed to have chronic portal vein or hepatic thrombosis with any appropriate diagnostic technique (Doppler-ultrasound, conventional angiography,

Figure 1 Splenoportal angiography showing cavernous transformation (bold arrow), esophageal varices (white arrow) indicating severe portal hypertension.

computerized tomographic angiography or magnetic resonance angiography) between January 2000 and December 2003 were evaluated for possible inclusion to the study. One splenoportal angiography of our patient group showed portal vein cavernous transformation (Figure 1). The exclusion criteria (as shown in Table 1) were applied to eliminate chronic parenchymal liver diseases including cirrhosis, mass occupying lesion around great vessels and any genetic or acquired abnormality leading to thrombophilia.

All the patients underwent a series of evaluation comprised of viral markers of hepatitis, screening tests of metabolic liver diseases (Wilson's disease, hemochromatosis), liver biopsy, red blood cell count, full biochemical tests, reticulocyte counts and peripheral blood smear in order to rule out silent liver diseases or myeloproliferative blood diseases. Any increased hematocrit more than 50% indicated a scintigraphic total red cell mass count, whereas any abnormality in reticulocyte count or any suspicious finding in peripheral smear indicated a bone marrow aspiration. Biopsy studies were carried out to exclude silent or latent hematological diseases.

Genetic and other thrombophilic risks were evaluated by determining the levels of factor V Leiden and prothrombin mutations, proteins C and S, antithrombin, IgG and IgM classes of anti-cardiolipin and anti-phospholipid antibodies, homocysteine and fibrinogen. CD 55 and CD 59 clusters in peripheral blood were studied in all patients to rule out paroxysmal nocturnal hemoglobinuria after all hematological investigations.

In view of potential interference with the tests to be used in the study, patients with a history of uncontrolled diabetes and hypertension, severe and widespread atherosclerosis, oral contraceptive use or estrogen replacement treatment, use of anticoagulation drugs, uncontrolled or newly diagnosed malignancy elsewhere, systemic inflammatory diseases and recent (last 3 mo) major operation were excluded. Application of the exclusion criteria reduced the total number of 96 patients (portal vein involvement in 70, hepatic vein involvement in 26) to 9 patients comprised of 7 cases of portal vein thrombosis (PVT) including cavernous transformation of the portal vein, and 2 cases of hepatic vein thrombosis (HVT). After all these investigations, bone marrow biopsies were taken from patients with

**Table 2** General characteristics of the patients (results were given as minimum, maximum and median)

Test	Result
Age	28-74 (48)
Female/Male	6/3
PVT (n)	7
HVT (n)	2
Hemoglobin (gr/L)	9.5-16.6 (13.5)
Platelet (count/mL)	62.000-358.000 (168.000)
ALT (U/L)	13-38 (23)
AST (U/L)	18-38 (27)
ALP (U/L)	87-355 (200)
GGT (U/L)	16-123 (34)
Total Bilirubin (mg/L)	0.24-2.08 (0.65)
INR	1.06-1.47 (1.14)
Protein C (%)	55-137 (87)
Protein S (%)	58-113 (85)
AT (%)	75-109 (90)
Homocysteine (umol/L)	9-19 (15)
Fibrinogen (mg/L)	181-420 (271)

a diagnosis of idiopathic thrombosis to rule out any silent hematological diseases.

In excluded patients, the most common thrombophilic conditions were deficiency in proteins C and S and anti-thrombin III (28 patients, 29.1%), followed by myeloproliferative disorders (10 patients, 10.4%), factor V Leiden mutations (10 patients, 10.4%), prothrombin mutations (6 patients, 6.25%). The other conditions related with possible thrombophilia included cyst hydatid disease of the liver, Behcet's disease, metastasis of cancer, mastocytosis invasion of the liver, tuberculosis of the choleduct and abdominal surgery.

The control group comprised of 14 healthy adults (6 males, 8 females) with no history of cigarette smoking, hypertension, atherosclerotic vascular disease, systemic inflammatory condition and no use of medication (oral contraceptives and estrogen replacement treatment). An informed consent was obtained from each patient and control subject. The study protocol recieved approval of Ethical Committee of Hacettepe University.

### Blood samples

Blood samples from patient and control groups were drawn from antecubital veins with a 20 G needle at 08:00 am after an overnight fasting. All samples were collected in 0.129 mol/L trisodium citrate tubes and centrifuged at 3000 r/min for 10 min, while plasma samples were stored at -30 °C for studies.

### Evaluation of endothelial function

The endothelial function was tested by measuring serum concentrations of adhesion molecules, namely sVCAM-1, sICAM-1 and soluble E-selectin. The concentrations of these adhesion molecules were evaluated quantitatively by sandwich enzyme immunoassay (Parameter<sup>®</sup>, R&D systems, UK).

### Evaluation of initial step of thrombogenesis and its control

The most potent initial step during formation of thrombin, tissue factor-(released from damaged endothelium) related

**Figure 2** Results from our study and possible associations with other processes.

activation of factor VII was evaluated by quantitative measurement of activated factor VII (Staclot<sup>®</sup> VIIa-TF, Diagnostica Stago, Asnieres, France). The major controlling step of this pathway, namely the TFPI (both total and free fractions) level, was tested quantitatively by one-step ELISA (Diagnostica Stago, Asnieres, France).

### Fibrinolytic potential

Fibrinolytic capacity of each sample was evaluated by GFC, a semi-quantitative method designed to detect low potentials of given samples. This technique uses the measurement of generated D-dimer in the given sample when a standard amount of fibrin is added into it. The generated D-dimer was measured using macrolatex agglutination (Diagnostica Stago, Asnieres, France). Therefore, the results from this test were semi-quantitatively expressed as "normal GFC", "moderately low GFC" and "severely low GFC".

### Statistical analysis

All the data were presented as minimum, maximum and median unless otherwise specified. Statistical tests used for evaluation of significant differences were Mann-Whitney U test and Fisher's exact test.

## RESULTS

The general characteristics of the patients are shown in Table 2 and Figure 2. Four patients had portal vein cavernous transformation and 3 patients had pure portal vein thrombosis in the portal vein group, whereas HVT group had only large hepatic vein involvement. As the blood cell count was taken into account, patient group showed a general tendency towards thrombocytopenia due to presence of increased portal venous pressure leading to mild degree of hypersplenism. Liver enzymes were all normal or very slightly elevated owing to the strict exclusion criteria. One important fact was that the international normalized ratio (INR) of the patient group was normal, thus not affecting the hematological tests

**Table 3 Comparison of patient and control groups by advanced tests (results were given as minimum, maximum and median)**

Test (normal limits)	Patient group (n)	Control group (n)	Significance
FVIIa (25.5-96.9 mU/mL)	27-1232 (96)	39-325 (129)	NS <sup>1</sup>
Total TFPI (81.2±30.4 ng/mL)	22-114 (87.2)	43-112 (79)	NS
Free TFPI (10.0±4.8 ng/mL)	5-41 (19)	9-20 (13)	<sup>a</sup> P<0.05
sVCAM (395-714 ng/mL)	489-1890 (915)	410-890 (517)	<sup>c</sup> P<0.05
sICAM (115-306 ng/mL)	148-400 (252)	24-260 (164)	<sup>b</sup> P<0.05
E-Selectin (29.1-63.4 ng/mL)	14-68 (20)	11-64 (29)	NS

<sup>1</sup>NS: Not significant; <sup>a</sup>P<0.05, <sup>c</sup>P<0.05, <sup>b</sup>P<0.05 vs control group.

**Table 4 Results and comparisons of GFC (global fibrinolytic capacity)**

Group	Severely low GFC	Moderately low GFC	Normal GFC
Patient group	0	4	5
Control group	0	0	14
Fisher's exact test			P<0.05

during the study. Proteins C and S showed that the values near the lower normal limits and even mildly low values were due to the decreased synthesis from liver as a result of abnormal blood flow dynamics of liver rather than a congenital deficiency.

The results of hematological evaluation of patient and control groups with advanced tests are shown in Table 3. The comparisons of FVIIa in both groups were similar, so were total TFPI levels. The results obtained from comparisons of free TFPI and adhesion molecules sVCAM-1 and sICAM-1 were striking. Levels of free TFPI, sVCAM-1 and sICAM-1 were significantly higher in patient group than in control group. sE-selectin levels did not differ between the two groups.

The results obtained from patient and control groups by GFC are shown in Table 4. The patient group showed a significant tendency towards moderately low fibrinolysis whereas fibrinolysis was normal in control group.

## DISCUSSION

The overall results and our proposals are shown in Figure 2. Firstly, the significant differences in vascular adhesion molecules indicated that there was an overall activation of endothelium comparable to normal subjects, suggesting that there is an unknown abnormality in endothelial functions. Adhesion molecules are synthesized from endothelium in response to bacterial endotoxins, interleukins and inflammatory mediators like tumor necrosis factor- $\alpha$ <sup>[9-11]</sup>, indicating that this endothelial dysfunction is a pure result of endothelial dysfunction of splenoportal or hepatic venous systems. Since other external risk factors affecting endothelial function and our tests such as diabetes mellitus, hypertension, cigarette smoking or atherosclerosis were excluded in both patient and control groups, this finding may be of importance.

The comparable difference in free TFPI could be explained also by this endothelial dysfunction. TFPI is a protein molecule formed of three Kunitz particles syn-

thesized and secreted from endothelium. Its main function is to inhibit the activated FVII-tissue factor complex before coagulation cascade becomes uncontrollable<sup>[12,13]</sup>. Severe deficiency in TFPI may lead to overt thrombosis in veins<sup>[14]</sup>. After synthesized from endothelium, the active component of this protein circulates in free form accounting for approximately 2.5 % of total TFPI pool and it is this free form that exhibits the main TFPI activity whereas the low density lipoprotein-bound TFPI shows no activity at all<sup>[12]</sup>. Our findings (a significant difference in free TFPI levels between two groups but no difference in total TFPI levels) were parallel to the findings of endothelial dysfunction confirmed by adhesion molecules, since the increased free TFPI levels indicated a stimulated synthesis from malfunctioning endothelium.

The results obtained from GFC studies indicated that in patient group there was a significant tendency towards moderately low GFC. This in a way is consistent with the recent thrombogenesis theory which accepts that thrombogenesis is not attributable to only one factor. In fact, thrombogenesis requires more than one risk factor for potent initiation of the pathway. From this point, we propose that either low GFC or endothelial dysfunction forms an appropriate milieu for development of this kind of "idiopathic" thrombosis.

The study presented can be questioned in some ways. Firstly, the number of patients studied was small to be conclusive about the hypothesis proposed before. But as discussed before, this patient population was a very rarely confronted group and similar studies are few. Secondly, the patient group had two different vessel involvements and could not be studied as they were homogenous. But if the liver functions and the patterns of thrombus formation were examined in detail, these two different vessel involvements would be similar in terms of idiopathic thrombus formation in milieu of normal liver function. Thirdly, the laboratory tests applied were not informative enough for our assumptions. Formation of thrombus can be evaluated in many ways including quantification of thrombin-antithrombin complexes or prothrombin fragments 1+2 or many other sophisticated tests. However, our hypothesis is not to test the presence of abnormal activation of prothrombin, but to find any possible factors triggering coagulation cascade, resulting in abnormal clot formation. Therefore we tested the most potent initiator of coagulation cascade. It can be argued to study the endothelial functions with other tests like plasminogen activator inhibitor-1 (PAI-1), von-Willebrand factor or thrombomodulin.

To our knowledge, there is no evidence that these tests with adhesion molecules can show endothelial dysfunction. These tests have no superiority over each other for estimation of the degree of endothelial dysfunction.

There is an ongoing debate over the presence of portal vein thrombosis in case of idiopathic portal hypertension (IPH). The pro-thrombogenesis theoreticians believe that there is a tendency towards thrombosis which manifests itself in any life time of a patient with IPH<sup>[15]</sup>. The anti-thrombogenesis theoreticians believe that although thrombophilia and repeated micro-thrombi over a long time may be one of the possible etiological factors, the presence of portal thrombosis is a finding against diagnosis of IPH<sup>[16]</sup>. We believe that thrombogenesis and silent or unknown risk factors may contribute to the development of IPH<sup>[17]</sup>.

In conclusion, major idiopathic hepatic thrombosis (hepatic or portal veins) is not as rare as it was thought and our study may be an important clue to further studies in respect of endothelial dysfunction and other possible accompanying coagulation control defects like deficient fibrinolysis.

## Abstract

**AIM:** To assess the efficacy of intravenous cyclophosphamide pulse therapy for refractory inflammatory bowel disease (IBD).

**METHODS:** We included in our cohort eight patients with (moderate/severe) steroid refractory IBD (4 with ulcerative colitis and 4 with Crohn's disease). They all received 6 cycles of intravenous cyclophosphamide (800 mg) per month.

**RESULTS:** Patients entered into remission after the second/third cyclophosphamide pulse. Disease activity decreased. There were no side effects and toxicity. All the patients went into long lasting remission. All Crohn's disease patients and 3 of 4 ulcerative colitis patients achieved complete remission. One patient with ulcerative colitis showed an impressive clinical response but did not enter into remission. For the maintenance, patients with Crohn's disease were treated with methotrexate (15 mg/wk) and patients with ulcerative colitis were treated with azathioprine (2.5 mg/kg body weight/d).

**CONCLUSION:** Remission was maintained in all patients for 6 mo on the average. The drug was well tolerated. These findings suggest that aggressive immunosuppressive therapy may be useful in some refractory patients and further controlled study should be considered in order to fully evaluate this type of treatment as a potential therapy for IBD.

**Key words:** Crohn's disease; Ulcerative colitis; Cyclophosphamide

Barta Z, Tóth L, Zeher M. Pulse cyclophosphamide therapy

## INTRODUCTION

Crohn's disease (CD) and ulcerative colitis (UC), collectively referred to as inflammatory bowel disease (IBD), are relatively common inflammatory diseases of the gastrointestinal (GI) tract. Histopathologically and anatomically, these two conditions are distinct, with CD characterized by transmural inflammation that can occur throughout the GI tract, and UC characterized by more superficial inflammation confined to the colon and rectum. The etiology and pathogenesis of IBD are not yet completely understood. Although the details of the pathogenesis of IBD remain elusive, it is believed that exposure of genetically susceptible individuals to environmental factors (e.g., dietary antigens, luminal bacteria) seems to be an important factor for the development and chronicity.

Pharmacotherapy for IBD has essentially been unchanged for over twenty years, with therapy based on 5-aminosalicylic acid (5-ASA) preparations, corticosteroids, antibiotics and immunosuppressants. Many of the controversies about optimal use of these drugs in IBD arise as a consequence of methodological deficiencies in many of the trials combined with the difficulty in consistent patient selection due to the heterogeneous nature of both UC and CD. Current therapy for IBD is neither sufficient nor disease-modifying. The first-line therapy for IBD flares is typically medical in nature. Long-term treatment with non-specific anti-inflammatory drugs such as aminosalicylates, corticosteroids and immunosuppressants is often accompanied with undesirable and potentially serious side effects. Glucocorticoids are a mainstay for the treatment of severe inflammatory bowel disease. Aminosalicylates are efficacious in the treatment of active mild to moderate disease. Infliximab, a chimeric monoclonal anti-TNF alpha antibody can be used in treatment of refractory Crohn's disease<sup>[1]</sup>. Novel biologically-driven therapies are targeted to specific pathophysiological processes, offering the potential for better treatment outcomes.

The management of refractory, severe IBD is yet an unsolved problem. Accurate assessment of specific organ involvement and disease severity is vital if we are

going to tailor appropriate therapy for certain patient. In common with other disease, the aims of therapy for IBD fall into three categories, namely induction of remission, maintenance of remission, and prevention of relapse. All should be undertaken with minimal mortality and morbidity either from the disease itself or from the therapy

Cytotoxic drugs prevent cell division or cause cell death. They act predominantly on rapidly dividing cells such as T lymphocytes, and are therefore immunosuppressive and anti-inflammatory. When cytotoxic drugs are initially used in the treatment of cancer, they have profound effects on the immune system. This “unwanted” side effect has subsequently been exploited for the treatment of non-malignant disease where autoimmune mechanisms are considered important in the pathogenesis. Based on the previous observations of improvement in autoimmune diseases (i.e., vasculitides), cyclophosphamide can be the primary cytotoxic drug<sup>[2-4]</sup>. Pulse intravenous cyclophosphamide is probably equally effective as oral cyclophosphamide at inducing remission and this remission is usually maintained by continuing cyclophosphamide for 3-6 mo before changing to a combination of other per os therapy. Cyclophosphamide can be administered intravenously at 500-1000 mg/m<sup>2</sup> pulses monthly. The optimal duration of treatment with intravenous cyclophosphamide has not been determined for IBD, but treatment for six months with monthly pulses would be typical, followed by maintenance therapy with azathioprine or methotrexate. Therapy must be continued to prevent relapse and for maintenance.

Only sporadic but promising cases are reported and experiences with cyclophosphamide in severe IBD are very limited but most patients entering into remission have no major adverse events or side effects<sup>[5]</sup>. We here report some other cases to enrich the experiences. We designed a non-controlled prospective pilot study to investigate the effects of pulse cyclophosphamide therapy for IBD patients. The aim of this study was to examine the effect of this kind of therapy on UC and CD.

## MATERIALS AND METHODS

### *Patient selection and treatment*

All patients were recruited in this prospective uncontrolled pilot study from our out-patient clinic specializing in chronic inflammatory bowel diseases (at the 3<sup>rd</sup> Department of Medicine, University of Debrecen). Between September 2002 and December 2003 we included in our cohort eight patients with (moderate/severe) steroid refractory IBD (four patients with CD and four with UC).

All patients were diagnosed according to the standard criteria and underwent endoscopy and/or radiological studies, including ileo-colonoscopy, CT and/or double-contrast barium air enteroclysis during 6 mo of the study. Video endoscopy of the large intestine, including the terminal ileum, was performed before the first cyclophosphamide pulse and at wk 12. All the patients did not respond to conventional therapy (this was the only selection criteria for this study) and were treated with pulse cyclophosphamide therapy monthly (6 cycles). The bolus dose was

applied independent of body weight. Cyclophosphamide (800 mg) was given during a 4 h hospital stay in 500 mL physiologic or normal saline (0.9%) in a period of 120 min. White blood cell (WBC) counts and urine tests for incidental microscopic haematuria were obtained on pre- and post-cyclophosphamide therapy day (0, 7, 14).

### *Outcome measurement*

All the patients were informed of the potential risks and benefits of cyclophosphamide therapy and a written informed consent was given in advance. We defined treatment failure as any of the followings: lack of an initial response, relapse after an initial response, and intolerance to cyclophosphamide necessitating discontinuation of the drug. We used the modified Truelove and Witts activity index for ulcerative colitis and best index (Crohn's disease activity index) for Crohn's disease as others<sup>[6,7]</sup>. We used working definitions for the assessment of the response both in UC and CD. Active disease was defined as symptomatic UC with a Truelove-Witts score greater than 6 points and symptomatic CD with a CDAI score greater than 150 points. Significant (moderate-severe) relapse was defined as symptomatic UC with a Truelove-Witts score greater than 10 points and symptomatic CD with a CDAI score greater than 150 points and/or the need for systemic steroid therapy (including oral budesonide), and treatment failure was defined as relapse, colectomy or any serious adverse event.

## RESULTS

Patient histories are summarized in Table 1. CD patients were all females aged 36-65 years (mean 49 years) and UC patients were all males aged 29-59 years (mean 40.25 years). Each patient received six monthly treatment. All patients were continued on a daily regimen of methyl prednisolone and the daily dose was decreased according to individual clinical activity. Azathioprine (2.5 mg/kg body weight per day) and methotrexate (15 mg/wk) were initiated orally for UC and CD patients respectively to maintain remission following cyclophosphamide treatment.

The patients entered into remission after the second/third cyclophosphamide pulse. Disease activity decreased. There were no side effects and no toxicity. All the patients went into long lasting remission. Remission seemed stable (except for case 5: relapse after 6 mo). These findings suggested that aggressive immunosuppressive therapy might be useful in some refractory patients and further controlled study should be considered in order to fully evaluate this type of treatment as a potential therapy for IBD.

## DISCUSSION

Current therapy for IBD is unsolved. Many drugs are prescribed for inflammatory bowel disease, either for treating active disease or for maintaining remission. However, no drug provides a completely satisfactory response in a large percentage of patients. Corticosteroids (steroids) at dosages equivalent to 40-60 mg/d prednisone are commonly prescribed for acute exacerbations of Crohn's disease and ulcerative colitis. Steroids are not

Table 1 Patient histories

Patient No	Age/sex	Disease	Duration of IBD (yr)	Localization	CDAI before/after 6 cycles	UC-DAI before/after 6 cycles	Maintenance therapy for remission
1	46/female	CD	26	colon-rectum	168/79		methotrexate
2	65/female	CD	18	ileum-colon-rectum	231/86		methotrexate
3	49/female	CD	22	ileum-colon	198/91		methotrexate
4	36/female	CD	5	ileum-colon	242/98		methotrexate
5	59/male	UC	5	rectum		14/6	azathioprine
6	44/male	UC	5	rectum		15/8	azathioprine
7	29/male	UC	4	recto-sigmoid		13/6	azathioprine
8	29/male	UC	8	recto-sigmoid		14/7	azathioprine

UC-DAI: Modified Truelove and Witts activity index for UC; CDAI: CD activity index; Methotrexate: 15 mg/wk; Azathioprine: 2.5 mg/kg body weight per day.

effective for maintenance of remission in either disease. However, some patients require long-term steroids for suppression of disease, particularly Crohn's disease. Taking steroids for a prolonged period can cause reversible or irreversible adverse effects<sup>[8-10]</sup>. These adverse effects are of sufficient concern to prompt consideration of alternative treatment strategies. Infliximab, human growth hormone, and other novel biotechnology treatments have been investigated as therapy for patients with inflammatory bowel disease. Although these biotechnology-derived treatments are promising, their cost is prohibitive for many patients. Because cyclophosphamide is effective for other inflammatory conditions and is relatively less expensive than some other agents, it is considered in the treatment of inflammatory bowel disease.

IBD continues to pose a challenge to clinicians. Over the past few years there have been significant advances in our understanding of its pathogenesis and treatment. These advances may lead to more specific and targeted treatments, with consequent improvements in clinical outcomes. Intravenous pulse cyclophosphamide therapy may be a safe and effective treatment for patients with severe IBD unresponsive to conventional treatment as a first-line adjunct to or replacement of systemic corticosteroids in the treatment of IBD. Last but not the least, costs of this kind of treatment are relatively low.

In conclusion, pulse cyclophosphamide therapy can be used in treatment of selected IBD patients. However, larger placebo-controlled studies in more diverse patient population are warranted.

### Abstract

**AIM:** To establish a method detecting porcine endogenous retrovirus (PERV) in China experimental minipigs and to evaluate the safety of PERV in three individuals treated with bioartificial liver support systems based on porcine hepatocytes.

**METHODS:** Porcine hepatocytes were isolated with two-stage perfusion method, then cultured in the bioreactor, which is separated by a semipermeable membrane (0.2 µm) from the lumen through which the patients' blood plasma was circulated. After post-hemoperfusion, patients' blood was obtained for screening. Additionally, samples of medium collected from both intraluminal and extraluminal compartments of the laboratory bioreactor and culture supernate *in vitro* was analyzed. The presence of viral sequences was estimated by polymerase chain reaction (PCR) and reverse transcriptase-polymerase chain reaction (RT-PCR). Finally, the infection of virus in the supernate of common culture was ascertained by exposure to the fetal liver cells.

**RESULTS:** PERV-specific gag sequences were found in the porcine hepatocytes using RT-PCR, and were detected in all samples from the intraluminal, extraluminal samples and culture supernate. However, culture supernatant from primary porcine hepatocytes (cleared of cellular debris) failed to infect human fetal liver cells. Finally, RT-PCR detected no PERV infection was found in the blood samples obtained from three patients at various times post-hemoperfusion.

**CONCLUSION:** The assays used are specific and

### INTRODUCTION

Fulminant hepatic failure (FHF), which remains a disease with high mortality, cannot be reversed by conventional treatments<sup>[1-3]</sup>. Meanwhile, the complications of liver failure, such as, encephalopathy, cerebral edema and multi-organ failure made it more difficult to cure. Orthotopic liver transplantation has improved the survival rate to 70%~80% of patients with this almost deadly disease. However, many patients died while waiting for the organ because of the lack of donor liver. Therefore, more curiosity has been aroused to deal this with biological treatments, such as extracorporeal bioartificial liver support system (EBLSS)<sup>[2-6]</sup>. The shortage of human organs leads to the use of non-human donors as the main hepatic cell source. Porcine hepatocytes, including transgenic pig, have become an important cell source widely used in bioartificial liver support systems. Concerns have been raised about the safety of this potential therapy, especially the possibility of cross species transmission of porcine endogenous retroviruses (PERV) since *in vitro* infection of human cell lines has been demonstrated in 1997<sup>[4,8-11]</sup>. PERVs are integrated into the genome of all pigs. They belong to the gammaretroviruses previously termed type C retroviruses. At least two subtypes of PERV, PERV-A and PERV-B, infect human cells *in vitro*. Viral particles have been shown to be released by mitogen stimulated porcine peripheral blood mononuclear cells (PBMC), *etc*<sup>[10,12-13]</sup>. Clinical trials did not find provirus integration, indicating

that no virus infection had taken place. However, further study and more retrospective research should be done in this field.

PERV infection can be measured directly by PCR, RT-PCR<sup>[10,13]</sup>. Here, we present the methods for the detection of PERV and investigation of patients who had been treated with EBLSS based on porcine cells. All methods were specific and sensitive, and it was revealed that in all patients no PERV infection had occurred.

## MATERIALS AND METHODS

### Isolation of porcine hepatocytes

Liver cells were isolated by an adaptation of the two-step perfusion method<sup>[14,19-20]</sup>. Briefly, the animals were anesthetized with barbitol (30 mg/kg, b.w, intraperitoneally) and their livers were removed intact. The liver was first perfused *in vitro* via the portal vein with warmed (37 °C) Ca<sup>2+</sup> and Mg<sup>2+</sup> free Hanks balanced salt solution at a flow rate of 5-8 mL/min for 10-15 mL/min, and then perfused with 0.05% collagenase (Sigma, Type IV) in the same solution supplemented with 5 mmol/L CaCl<sub>2</sub> and 50 mmol/L HEPES. The reperfusion with collagenase solution lasted 20 min at a rate of 5 mL/min at 37 °C. After 10 min of incubation (37 °C) with gentle shaking, the suspension was filtered and hepatocytes were sedimented at 50×g for 3 min. The viability of the isolated liver cells was determined by the trypan blue exclusion test.

### PERV proviral PCR assays

DNA was extracted from porcine liver tissue using the preparation kits (Qiagen). For the detection of provirus, primers specific for the gag gene (forward primer 5'-GCGACCCACGCGAGTTGCATA-3', and reverse primer 5'-CAGTTCCTTGCCCAGTGTCTT-3') were used, and a second PCR was carried out to test the products using the primers 5'-TGATCTAGTGAGAGAGGCAGAC-3' and 5'-CGCACACTGGTCTTGTGCG-3'. For PCR amplification, the standard PCR program of one cycle of 95 °C for 10 min, 35 cycles of 95 °C for 1 min, 55 °C for 1 min, and 72 °C for 1 min and one cycle of 72 °C for 7 min was applied. Liver tissues of human and experimental animals (rabbit and mice) were also gathered to analyze the specificity of PCR.

### RT-PCR detection of PERV gag RNA sequences

For the detection of virus released from the cultured cells, viral RNA from supernatants of cultured cells was isolated. Cells were removed from supernate by centrifugation at 200×g for 10 min, thereafter cell debris was removed by centrifugation at 3500×g for 10 min and an additional centrifugation step at 10000×g for 30 min. Viral RNA was extracted using the RNA isolation kits (Qiagen)<sup>[15-18]</sup>. RNA was reverse transcribed using a one-step RT-PCR kit (promega) with no-RT PCR controlled.

### Porcine hepatocytes cultured in fiber weaven bioreactor

Primary cells were harvested from 1 wk China Experimental minipigs by a modified two-step collagenase perfusion method<sup>[19]</sup>. After testing the viability of the

cells by trypan blue exclusion, single porcine hepatocyte suspensions were cultivated in the extralumen of the fiber weaven bioreactor (developed by our institute (porous, 0.2 μm)). The bioreactor was filled with porcine hepatocyte about  $1.0 \times 10^8 \sim 1.4 \times 10^9$  in co-culture with non-parenchymal cells. DMEM containing EGF was circulated with an artificial capillary cell culture system from Cellmax. Both the biological function and enzyme release of the bioreactor were examined.

### Patients

Patients included in the study were FHF, which was defined as occurring within 8 wk of onset of the precipitation illness (in the absence of pre-existing liver disease), and acute-on-chronic hepatic failure listed for liver transplantation with a progressive hepatic encephalopathy.

### Extracorporeal liver support with the CellMax bioreactor

FHF patients were treated with hybrid liver support system, including a blood circuit with a continuous plasma separation unit and a second circuit for plasma perfusion of the CellMax bioreactor. Briefly, the bioreactor was filled with porcine hepatocyte about  $6.0 \times 10^8 \sim 1.4 \times 10^9$  in co-culture with non-parenchymal cells. Venous blood of FHF patients was elicited via a double-lumen dialysis catheter from the internal jugular vein and blood plasma were separated. Continuous hollow fibre plasma separation was performed at a rate of 100-150 mL/min and then stored in sterile chamber. For anticoagulation a continuous infusion of heparin was performed. After one or two days' circulatory culture, the bioreactor was then connected and plasma was continuously perfused at a rate of 150-200 mL/min from the chamber. Treated plasma was reunited with the blood cell and returned to the patients. A roller pump (Millipore ultrafiltration device) was used to circulate blood and a heater was used to maintain the temperature of patients and bioreactor at 37 °C-39 °C. After the perfusion, the patients' plasma samples were detected. Blood samples were obtained after the treatment.

### In vitro infection experiments

For infection experiments, cell-free supernatants from cultured porcine hepatocytes were used to infect fetal liver cells in order to mimic the bioartificial liver support system *in vitro*. That is, cell-free supernatants from primary cultured porcine hepatocytes were collected and cell debris was removed by centrifugation at 10000× for 30 min, then was used to infect fetal liver cells.

## RESULTS

### Cell yield and viability

The total isolated hepatocytes and non-parenchymal liver cells by the simplified two step perfusion method were  $6.0 \sim 14.0 \times 10^8$  cell per liver. The estimated viability judged by the trypan blue test was 92%-96%.

### Specificity of the PERV DNA assays

All these PCR assays gave negative results on tissue and serum samples from 2 HBV patients, as well as 2 HCV

**Figure 1** PCR analysis of PERV proviral DNA in different liver tissues. Left: 1: normal person liver tissue, 2: HBV positive liver tissue, 3: HCV positive liver tissue, 4: second PCR of pig liver tissue, 5: Marker. Right: 1, 2, 3, 4: pig liver cells, 5: negative control.

patients and 1 rabbit, and positive results on tissue of China experimental swine, demonstrating 100% sensitivity, as shown in Figure 1. The detection of product with second PCR gave the same results, showing the usefulness and specificity of the method in observing PERV infection.

#### PERV release of cultured porcine hepatocytes in bioreactor

As depicted in Figure 2A, PERV could be released from porcine hepatocytes cultured not only in common flasks but also in fiber woven bioreactor without the stimulation of mitogen. In the early stage, the quantity of virus so small that it could not be detected by PCR assays. From third day on, a large amount of PERVs could be released from the cells till their death. We also found that the semipermeable membrane (0.2  $\mu$ m) of bioreactor could not separate the virus, because in the both sides of the lumen we had evidence of the existence of PERV (Figure 2B).

#### PERV detection of patients using EBLSS

Continuous EBLSS treatment over a period of 4-6 h was safely performed and well tolerated by all the patients. No complications associated with therapy were observed during the treatment and the follow-up period of 1-2 years. After treatment, patients' blood was obtained for screening with the method mentioned above. No PERV RNA was detected in the serum of any of the 3 patients (Figure 3).

#### PERV infection experiments in vitro

PERV infection experiments with human fetal liver cells were performed. Supernatants from the cultured porcine hepatocytes were positive for PERV detection. Although it has been demonstrated that human kidney cells can be infected, it was also important to evaluate PERV infection of other human cells. In all fetal cells at one week post-infection, no evidence showed that PERV infection occurred with PCR and RT-PCR assays (Figure 4).

## DISCUSSION

EBLSS based on porcine hepatocytes catches more interest as an effective temporary treatment to improve the chance of survival and a bridge to liver transplantation<sup>[5,6,20-24,38-41]</sup>. Because of the shortage of human cells, porcine endogenous retrovirus (PERV), found in 1970's, was focused for its safety in xenotransplantation and treatments based on porcine tissues or cells as *in vitro* infection of human cell lines HEK 293 was demonstrated in 1997<sup>[4,34-37]</sup>. Laboratory surveillance of PERV infection in pig xenograft recipients and the treatments is critical for determining the safety of pig xenotransplantation. We used here highly specific PCR based assays for the molecular detection of PERV DNA and RNA sequences. In addition, we included a control PCR reaction without RT to confirm that the positive RT-

**Figure 3** infection of PERV. 1,2 RT-PCR and second PCR of cultured fetal hepatocytes, 3,4: positive control.

**Figure 4** PERV detection of patients treated with EBLSS. 1:second PCR of positive control, 2: positive control, 3:control; 4-9:RT-PCR and second PCR of patients.

PCR results were due to PERV RNA. we have developed polymerase chain reaction (PCR) and reverse transcription polymerase chain reaction (RT-PCR) assays to detect proviral PERV gag sequences and PERV RNA sequences in serum samples by using specific primers. All these PCR assays gave positive results on tissue of China experimental swine, and the identification of product with second PCR gave the same results, showing the sensitivity and specificity of this method in observing PERV infection.

Viral particles have been shown to be released by pig PBMC, by cultured aorta endothelial cells stimulated with mitogen<sup>[10,12,13,25,26]</sup>. In several trials, human diabetic patients who were treated with pig pancreatic islet cells, with pig skin or with extracorporeal perfusion of pig liver did not show provirus integration<sup>[27,42]</sup>, indicating that no virus infection had taken place. *In vitro* infection experiments revealed that PERVs infect not only human cell lines and primary cells, but also a variety of cells of other species including non-human primates. However, no transmission of PERVs *in vivo* was observed in non-human primates and several small animals gave high doses of PERV. Additional data showing the same results about the safety of PERV have been obtained from several experiments<sup>[16,29]</sup>. Nevertheless, considering the results of initial clinical xenotransplantations in humans, which found that persistent microchimerism was observed in 23 patients( totally 160) for up to 8.5 years, and the establishment of PERV infection model<sup>[27,28]</sup>, it was worth paying more attention to its safety in xenotransplantation and EBLSS.

In this study, the retrospective investigation of the three patients with the treatment of EBLSS based on porcine hepatocytes was performed for possible PERV transmission. Our data are in agreement with other studies showing lack of PERV transmission. And in laboratory experiment we also found PERV could not be prevented by the hollow fibre membranes, indicating different opinion from the foregoing research that PERV particles could be prevented by using PES hollow fibre membranes with a molecular weight cut-off of 400000 kD<sup>[31]</sup>. In fact, the pore size of bioreactor should be large enough to make material exchange possible, so, any efforts trying to block

the virus with semipermeable membrane was probably in vain. The lack of PERV transmission in the patients investigated could be owing to short-term contacting with the EBLSS, lasting for 4-6 h during the treatments. And an effective inactivation of PERV released from pig cells may be another reason. Although cells of human could be infected productively with PERV as reported, no transmission was observed in patients treated with EBLSS in our study.

The latest data about the safety of xenotransplantation using porcine cells, tissues and organs has been obtained from experiments involving transplantation of encapsulated pig islet cells into diabetic rats and assessment of PERV infection in patients treated with a bioreactor based on porcine liver cells<sup>[29-33]</sup>, demonstrating no PERV transmission occurred. Although no data indicated that PERV infection had occurred in any of the patients treated with the BALSS containing porcine hepatocytes, longer and larger patient follow-up is required to supervise porcine retroviruses and EBLSS.

## Abstract

**AIM:** To explore the prevalence of gallstone disease (GSD) in Taiwan and condition-associated factors related to it.

**METHODS:** We studied a total of 2386 healthy adults (1235 males and 1151 females) voluntarily admitted to Cheng Hsin General Hospital for a paid physical check-up between January 2002 and December 2002. Blood samples and ultrasound sonography results were collected.

**RESULTS:** The overall prevalence of GSD among this study-population was 5.3%, including 1.7% ( $n=40$ ) having a single stone, 2.3% ( $n=55$ ) having multiple stones, and 1.3% ( $n=31$ ) having cholecystectomy. The prevalence revealed a statistically significant increase with increasing age ( $P<0.0001$ ). Females exhibited a greater prevalence of multiple stones than did males (3.0% vs 1.7%,  $P=0.04$ ). Using multiple logistic regression analysis, the following appeared to be significantly related to the prevalence of GSD: older age (40-49 years vs <40 years, OR = 1.63 [95% CI: 0.76-3.48], 50-59 years vs <40 years, OR = 4.93 [95%

## INTRODUCTION

Gallstone disease (GSD) is one of the most common diseases in developed countries. Recent studies indicate varying prevalence of GSD with several predisposing factors in different study populations<sup>[1-9]</sup>. From a medical economic perspective, the direct and indirect costs of treating GSD patients were estimated at \$16 billion and account for more than 800 000 hospitalizations yearly in the United States<sup>[9,10]</sup>. In Taiwan, the prevalence of GSD in the general population was 4.3% in 1989<sup>[8]</sup> while another voluntary screening revealed that the prevalence of GSD was 10.7% among healthy subjects in 1995<sup>[2]</sup>. For this reason, due to westernization of the diet and the environment, GSD is not rare in the Chinese population and has become one of the major health problems in Taiwan<sup>[7]</sup>. Without an appropriate and effective screening program for symptomatic GSD, the medical treatment of GSD and related complications contributes substantially to health care costs.

From the viewpoint of preventive medicine, it is

not only important to be cognizant of the background prevalence of GSD regionally, but also to explore the complete spectrum of demographic and biological markers which may be related to development of GSD. Although most epidemiologic studies of GSD, demographic factors and biochemical markers have used case-control designs and cross-sectional data<sup>[1-9]</sup>, to the best of our knowledge, some uncertainty still exists regarding the prevalence of the disease and the identity of the associated risk factors for the development of GSD. The present study was designed to explore potential associated risk factors and to improve understanding of the overall pathogenesis of GSD. The purpose of this study was to explore the context of associated risk factors for GSD prevalence amongst the general population aged 20 years or more, as determined by the application of a healthy volunteer subjects screening program at Cheng Hsin General Hospital, a fully certified regional hospital and teaching hospital in Taipei, Taiwan.

## MATERIALS AND METHODS

### Data resource and data collection

This cross-sectional study was conducted with a total of 2386 healthy adults (1235 males and 1151 females) voluntarily admitted to Cheng Hsin General Hospital for a paid physical check-up between January 2002 and December 2002. Blood samples and ultrasound sonography results were collected. Overnight-fasting blood samples were drawn via venipuncture from study participants by clinical nurses. Serum and plasma samples (from whole blood preserved with EDTA and NaF) were kept frozen (-20 °C) until ready for analysis. The study-used definition of type-2 diabetes was from the 1997 ADA criteria<sup>[11]</sup>. Definitions of the following diseases / conditions were obesity: a body mass index (BMI)  $\geq 27$  Kg/m<sup>2</sup>, high systolic blood pressure (SBP)  $\geq 140$  mmHg, high diastolic blood pressure (DBP)  $\geq 90$  mmHg, hyper-

cholesterolemia ( $\geq 200$  mg/dL), hypertriglyceridemia ( $\geq 200$  mg/dL), low HDL ( $< 35$  mg/dL), high BUN ( $\geq 20$  mg/dL), high creatinine ( $\geq 1.4$  mg/dL), and hyperuricemia ( $\geq 7$  mg/dL for males or  $\geq 6$  mg/dL for females). Serum ALT or AST levels  $\geq 40$  U/L were classified as elevated<sup>[12]</sup>. In addition, information on HBV and anti-HCV were collected using radioimmunoassay kits.

### Diagnosis of gallstone disease

In the present study, GSD was diagnosed by a panel of specialists using real-time ultrasound sonography (TOSHI-BA nemio SSA-550A, Japan) to examine the abdominal region after fasting for at least 8 h based on the presence of “movable hyper-echoic foci with acoustic shadow. Cases of GSD were classified as follows: single gallbladder stone, multiple gallbladder stones, and cholecystectomy, excluding gallbladder polyps. Cases were identified as any type of GSD study population.

### Interobserver reliability in ultrasound sonography

In order to set up a consistent diagnosis of GSD between specialists, the Kappa statistic was used to assess the agreement of inter-observer reliability among study specialists. A pilot study was performed using 100 randomly selected healthy subjects other than the study participants. For inter-observer reliability, the Kappa value for diagnosis of GSD between specialists was 0.79 (95%CI: 0.61-0.95).

### Statistical analysis

Statistical analysis was performed using SAS for Windows, (SAS version 9.0; SAS Institute Inc., Cary, NC, USA). A *P*-value of  $< 0.05$  was considered statistically significant between two test populations. For univariate analysis, the two-sample, independent *t*-test method was adopted to assess differences in the mean value of continuous variables between subjects with and without GSD. Crude and adjusted odds ratios (adjustment for gender and age) were estimated and 95% confidence intervals were used. Multiple logistic regression was also performed in order to investigate the independence of risk factors associated with the prevalence of GSD.

## RESULTS

The prevalence of each type of GSD amongst study subjects is presented in Table 1. The overall prevalence of GSD was 5.4%, including 1.7% ( $n = 40$ ) having a single stone, 2.3% ( $n = 55$ ) having multiple stones, and 1.3% ( $n = 31$ ) having cholecystectomy. Females (3.0%) had a significantly higher prevalence of multiple stones than males (1.7%) ( $P = 0.04$ ). There were no statistically significant differences in gender for other types of GSD. In addition, from the Cochran-Armitage trend test, the prevalence of each type of GSD showed an increase with age ( $P < 0.0001$ ). Subjects aged 50 years and over ( $96/918 = 10.5\%$ ) had a more than 5-fold risk for GSD compared with the subjects aged 50 years and less ( $30/1468 = 2.0\%$ ).

Figure 1 shows the gender- and age-specific prevalence of all types of GSD. Although there was no gender difference ( $\chi^2 = 1.30$ ,  $P = 0.25$ ) for the overall prevalence

AST (U/L)	32.79 ± 30.13	27.59 ± 17.59	27.88 ± 18.54	0.06
ALT (U/L)	37.84 ± 54.27	30.01 ± 34.49	30.45 ± 35.91	0.11

of GSD, there was a statistically significant increase with increasing study-subject age by means of the trend test ( $z = 9.66$ ,  $P < 0.0001$ ). The prevalence of GSD also showed an interaction effect between gender and age, that is, males proved to have a substantially greater overall prevalence of GSD than females among those aged less than 50 years, whereas there was a lower overall prevalence of GSD among those aged more than 50 years.

The results of the comparison of a variety of test characteristics and their potential association with the prevalent GSD for study subjects are illustrated in Table 2. Using a two-sample independent *t*-test, the associated factors that were significantly related to GSD included age (yes [58.63 ± 13.04 years] *vs* no [46.57 ± 13.22 years]), BMI (yes [24.83 ± 3.64 Kg/m<sup>2</sup>] *vs* no [23.50 ± 3.55 Kg/m<sup>2</sup>]), fasting plasma glucose (FPG) (yes [109.22 ± 33.21 mg/dL] *vs* no [96.98 ± 25.21 mg/dL]), SBP (yes [130.06 ± 20.07 mmHg] *vs* no [122.55 ± 18.40 mmHg]), and BUN (yes [14.94 ± 6.28 mg/dL] *vs* no [13.55 ± 5.56 mg/dL]).

Table 3 presents the crude and adjusted odds ratios for the association between certain relevant associated risk factors and the prevalence of GSD. Compared to individuals without GSD, in addition to older age (40 - 49 years *vs* <40 years, OR = 1.80 [95% CI: 0.85 - 3.81], 50-59 years *vs* <40 years, OR = 5.75 [95% CI: 2.92-11.32], 60-69 years *vs* <40 years, OR = 9.02 [95% CI: 4.45-18.29], ≥ 70 years *vs* <40 years, OR = 12.76 [95% CI: 6.16-26.43]), subjects featuring GSD revealed a more-pronounced prevalence of: higher BMI (≥27 kg/m<sup>2</sup> *vs* <24 kg/m<sup>2</sup>, adjusted OR = 2.04 [95% CI: 1.28-3.26]), higher FPG (≥ 126 mg/dL *vs* <110 mg/dL, OR = 1.95, 95% CI: 1.16-3.30), and higher AST (adjusted OR = 1.96, 95% CI: 1.16-3.32) subsequent to adjustment for gender and age.

The effect of independent associated risk factors on GSD was examined using a multiple logistic regression model. As depicted in Table 4, subsequent to adjustment for confounding factors, the following appeared to be significantly related to GSD prevalence: age (40-49 years *vs* <40 years, OR = 1.63 [95% CI: 0.76-3.48], 50-59 years *vs*

**Table 4 Multiple logistic regression of associated factors for gallstone disease among 2386 Chinese subjects**

Variable	Gallstone disease (yes vs no)	
	OR	95%CI
Gender (female vs male)	1.34	0.90-1.99
Age (40-49 vs <40 yr)	1.63	0.76-3.48
(50-59 vs <40 yr)	4.93	2.43-9.99
(60-69 vs <40 yr)	6.82	3.19-14.60

<40 years, OR = 4.93 [95%CI: 2.43 - 9.99], 60 - 69 years vs <40 years, OR = 6.82 [95% CI: 3.19 - 14.60], ≥70 years vs <40 years, OR = 10.65 [95% CI: 4.78 - 23.73]), the higher BMI (≥27 kg/m<sup>2</sup> vs <24 kg/m<sup>2</sup>, adjusted OR = 1.74 [95% CI: 1.04 - 2.88]), and higher FPG (≥126 mg/dL vs <110 mg/dL, OR = 1.71, 95% CI: 1.01 - 2.96).

## DISCUSSION

### Prevalence of gallstone disease in the general population

One of the important benefits of early screening for GSD is that ultrasonography can lead to the discovery of an increasing proportion of asymptomatic cases for which one can use therapeutic nonsurgical approaches, such as litholytic bile acids, local solvents, and lithotripsy<sup>[13]</sup>. However, it appears that only a few published studies have attempted to determine the prevalence and possible etiology of GSD prevalence for the general population of Taiwan<sup>[2,8,14]</sup>, which also face a GSD burden. In the present study, GSD appeared to be fairly common for the test population, affecting an estimated 5.3% of the general population in Taiwan. The prevalence of GSD amongst different test populations appears to vary, differing among different studies conducted in different countries<sup>[1,3-6]</sup>. In addition to different methods of GSD assessment, this disparity might be due to differences between different population stocks. The prevalence of GSD for our study population (5.3%) was lower than the corresponding figure presented in a previous hospital-based study conducted in the Veterans General Hospital (VGH), Taipei, Taiwan, which was reported to be 10.7%<sup>[2]</sup>. The apparent lower prevalence rate in our study may have been due to younger age of the participants. Another possible reason for such

differences between the results of the VGH study and our results may simply have been related to the fact that although the kappa value for agreement of interobserver reliability seemed good<sup>[14]</sup>, non-differential misclassification-bias identification could still be occurring and could lead to underestimation of GSD prevalence.

### The implications of associated risk factors for gallstone disease

Our results reveal that older age represents a significant risk factor for GSD. Such a finding is consistent with results of other hospital-based and community-based studies conducted elsewhere<sup>[2-5,7,8]</sup>. GSD is very seldom found in children, and in that age group is mainly associated with haemolytic causes<sup>[15]</sup>. The long-term exposure to many other risk factors among elder persons may also account for the increased probability of developing GSD. Cholelithiasis is also an acquired disease contributed to by chronic environmental factors plus an aging effect<sup>[7]</sup>. In addition, it has been suggested that among the elderly, larger amounts of cholesterol are secreted by the liver, and the catabolism of cholesterol to bile acid is decreased<sup>[16,17]</sup>.

Most previous epidemiologic studies have shown that females have a higher prevalence of GSD than males in the Western world. However, the male to female ratio seems to have changed from early reports, which showed figures of 1:4-6 to more recent studies where the ratio is 1:2 or less<sup>[3,4,18]</sup>. Pregnancy and sex hormones could be involved by altering biliary secretion or gallbladder motility, or both may play an important role in sex-related differences in the prevalence of GSD<sup>[13]</sup>. Another possible reason might be that estrogen replacement therapy or oral contraceptives are used<sup>[19]</sup>. Our findings showed that, except for multiple stones, females do not have a significantly higher prevalence of all types of GSD than males. This result is similar to that from other hospital-based or population-based studies conducted in Taiwan<sup>[2,7,8]</sup>.

After adjustment for confounding factors, the present study also suggests that obesity is highly correlated with GSD prevalence. Supersaturated bile is the linkage between obesity and cholesterol GSD. Obesity can raise the saturation of bile by increasing biliary secretion of cholesterol - the latter probably depending on a higher synthesis of cholesterol in obese subjects<sup>[7,13,20]</sup>. While cholesterol GSD is common in Western countries, pigment GSD is still the principal component in Taiwan<sup>[2]</sup>. Our results also implied that obesity may be an independent associated risk factor leading to prevalent pigment GSD in the Chinese population.

It has been a matter of controversy whether diabetes mellitus is associated with GSD or not<sup>[7]</sup>. Consistent with previous studies<sup>[4,7]</sup>, our results showed that diabetes mellitus is highly associated with GSD prevalence. From a clinical perspective, hyperglycemia inhibits bile secretion from the liver and disturbs gallbladder contraction<sup>[2]</sup>. Supersaturated bile in the gallbladder induces cholelithiasis in diabetic subjects<sup>[21]</sup>. The association of diabetics with GSD is stronger in subjects with a history of treated diabetes mellitus than in those with a simple history of diabetes and this could be an effect of hyperglycemia on gallbladder motility<sup>[22]</sup>. Furthermore, diabetes mellitus

combined with GSD may induce acute cholecystitis more frequently and have a higher possibility of progression to septicemia<sup>[7]</sup>.

An increasing prevalence of cholecystolithiasis has been associated with the etiology and severity of chronic liver disease and cirrhosis<sup>[23]</sup>. Possible explanatory factors include overproduction and over-secretion of bilirubin due to increased extracorporeal hemolysis, a reduction in the production and transportation of biliary salts and cholesterol secretion, stasis and changes in bile acidification, or even mucous hypersecretion and subtle alterations in gallbladder mucosal function<sup>[24,25]</sup>. However, although early liver dysfunction such as abnormal ALT, HBV, and HCV infection are endemic in Taiwan<sup>[12,26,27]</sup>, the present study did not reveal liver function associated factors to be related to GSD prevalence. This finding is consistent with other hospital-based studies for the general population in Taiwan<sup>[2]</sup>. Further epidemiological and etiologic investigations are needed to clarify the pathophysiological mechanisms between early liver damage and pigment GSD among general Chinese populations.

### Perceived limitations

A major limitation of the present study is the potential self-selection bias due to the hospital-based study design, that is, of it not being exactly representative of the whole general population. Second, it is well established that a large proportion of GSD patients remain asymptomatic and they are therefore often ignored for many years. Thus the present study may be representative of the clinical and not of the true prevalence. Thirdly, we do not detail to distinguish between cholesterol stones and pigment stones in this study, some measurement errors and different pathogenicity could occur. Fourthly, we did not consider how many individuals had progressive liver disease and explore the relationship between GSD and liver disease. Finally, our measurements were done only at a single time point and could not be able to reflect long-term exposure to various demographic or biochemical aspects or factors, factors which might be important influencers of GSD. The solution to such a quandary is to conduct a number of prospective longitudinal analogous studies, the results of which would be expected to complement the cross-sectional findings of this study.

### CONCLUSION

In conclusion, older age, obesity ( $\text{BMI} \geq 27 \text{ kg/m}^2$ ), and type 2 diabetes ( $\text{FPG} \geq 126 \text{ mg/dL}$ ) are associated with GSD prevalence. Further studies are needed not only to elucidate the temporal sequence of events that typically lead to GSD, but also to further explore the pathogenesis of GSD in the general Chinese population.

### Abstract

**AIM:** To evaluate the validity of ultrasonographic and pathologic diagnosis of liver fibrosis in patients with chronic viral hepatitis.

**METHODS:** The liver fibrosis status in 324 patients was evaluated by both needle biopsy and ultrasonography. Liver fibrosis was divided into S0-S4 stages. S4 stage was designated as definite cirrhosis. The ultrasonographic examination included qualitative variables, description of liver surface and parenchyma, and quantitative parameters, such as diameter of vessels, blood flow velocity and spleen size.

**RESULTS:** Ultrasonographic qualitative description of liver surface and parenchyma was related with the severity of fibrosis. Among the quantitative ultrasonographic parameters, cut-off value of spleen length (12.1 cm) had a sensitivity of 0.600 and a specificity of 0.753 for diagnosis of liver cirrhosis. The diameters of spleen (8 mm) and portal vein (12 mm) had a diagnostic sensitivity of 0.600 and 0.767, and a diagnostic specificity of 0.781 and 0.446, respectively. The diagnostic accuracy for liver cirrhosis was moderately satisfactory, and the negative predictive values of these parameters reached near 0.95.

**CONCLUSION:** Ultrasonography can predict the degree of liver fibrosis or cirrhosis. A single ultrasonographic parameter is limited in sensitivity and specificity for the diagnosis of early cirrhosis. The presence or absence of liver cirrhosis in patients with chronic virus hepatitis can be detected using 2 or 3 quantitative and qualitative parameters, especially the length of spleen, the diameter of spleen vein and echo pattern of liver surface.

### INTRODUCTION

Chronic hepatitis virus B or C infection results in damage to hepatocytes and may eventually lead to liver fibrosis, cirrhosis and/or hepatocellular carcinoma<sup>[1-3]</sup>. The diagnosis of liver fibrosis and cirrhosis in patients with chronic virus hepatitis is of therapeutic and prognostic importance.

Although histologic examination of percutaneous biopsy specimens is the gold criterion for the severity of fibrosis and cirrhosis, biopsy is invasive and cannot be used repeatedly in follow-up. Moreover, liver biopsy can yield false negative results in nearly 20-30% of cases<sup>[4-7]</sup>. Therefore, it is important to use noninvasive methods in differentiation between liver fibrosis and cirrhosis.

Ultrasonography (US) is a noninvasive and inexpensive procedure for diagnosis of focal and diffuse parenchymal disease of liver. Although US cannot detect minute changes, it can show liver cirrhosis in patients with decompensated liver function<sup>[8-11]</sup>. However, correlation between US and histologic diagnosis has not been fully investigated in large series of patients. We conducted a prospective study to evaluate the validity of US for diagnosis of liver fibrosis in patients with chronic liver hepatitis without clinical or biochemical evidence of cirrhosis.

### MATERIALS AND METHODS

#### Patients

From July 1999 to August 2002, 324 patients with chronic viral hepatitis undergoing US and histologic examination, were enrolled. Inclusion criteria included positive HBsAg and HBV-DNA or anti-HCV and HCV-RNA determined by PCR methods for at least 6 mo, and abnormal serum alanine transaminase level in recent 6 mo. Patients who had clinical or biochemical evidence of decompensated liver

**Table 1** Relation between US quantitative parameters and fibrosis stages

Parameters	Stage of fibrosis	Mean±SD	F	P
Length of spleen (cm)	S0	10.81±1.32	5.1947	0.0005
	S1	10.82±1.45		
	S2	11.35±2.02		
	S3	13.31±2.68		
	S4	12.66±2.06		
Diameter of portal vein (cm)	S0	1.17±0.11	1.0369	0.3882
	S1	1.18±0.17		
	S2	1.19±0.13		
	S3	1.20±0.12		
	S4	1.27±0.13		
Diameter of spleen vein (cm)	S0	0.62±0.16	6.7896	0.0000
	S1	0.67±0.15		
	S2	0.72±0.18		
	S3	0.69±0.15		
	S4	0.81±0.20		

function or portal hypertension, positive HIV antibody, serum titer of antinuclear antibody >1:160, serum creatinine level over 1.5 upper limit of normal value, or known liver diseases of other etiologies, were excluded.

### Histologic examination

Percutaneous liver biopsy specimens were obtained from the anterior segment of the right lobe in each patient under the guidance of US using the quick-cut or Menghini biopsy needle. The satisfactory size of specimens was longer than 1 cm. The liver tissue samples were stained with hematoxylin-eosin, Gordon-Sweet and van-Gieson methods. Three pathologists performed the histological examination. To evaluate the inter-observer variation, Kappa analysis was conducted to control the quality of pathological diagnosis. The average Kappa value was 0.8144, indicating the excellent consistency for the staging of liver fibrosis.

According to the Guidelines of Prevention and Treatment of Viral Hepatitis of Chinese Medical Association (2000), liver fibrosis was divided into S0-S4 stages: S0 stage-no fibrosis, S1 stage-enlarged portal tracts with fiber proliferation, S2 stage-fibrosis of portal tract with formation of fiber septa and intact architecture of liver lobule, S3 stage-fibrosis with distortion of lobule architecture but without cirrhosis, S4 stage-definite cirrhosis. Liver inflammation was divided into grades from G1 (mild) to G4 (severe)<sup>[12]</sup>.

### US examination

US examination was performed within 2 wk before or after liver biopsy. Acuson Aspen system with a 3.5-5.0 MHz curved probe was utilized. The two US operators were unaware of the clinical details and the results of biopsy. The results were recorded on video-tapes and the final report was given based on the consensus of both operators. The standard protocol of US examination included variables describing the liver size, surface and parenchyma, the ves-

sel structure, the blood flow velocity and spleen size.

### Statistical analysis

Statistical analysis was performed using the SPSS 9.0 software. The significance of differences between subgroups was tested by the *F* test. *P*<0.05 was considered statistically significant. A receiver-operating characteristic (ROC) curve was used to determine the best cut-off values of US parameters for diagnosis of liver cirrhosis.

## RESULTS

A total of 324 patients were collected, 272 men (83.9%) and 52 women (16.1%). Their age ranged from 18 to 60 years with a mean ± SD of 35.56 ± 9.9 years. Based on virus markers, 306 patients had hepatitis B and 18 patients had hepatitis C. The mean duration of hepatitis, namely the duration from the date of clinical diagnosis to the date of liver biopsy, was 4.14 years. The histopathology showed S0 stage in 32 patients (9.9%), S1 stage in 116 patients (35.8%), S2 stage in 111 patients (34.3%), S3 stage in 35 patients (10.8%), S4 stage in 30 patients (9.3%), and inflammation G1 in 117 patients (36.1%), G2 in 110 patients (33.9%), G3 in 70 patients (21.6%) and G4 in 27 patients (8.3%).

The results of qualitative US were different in patients with various stages of liver fibrosis. The appearance of nodularities or irregular lines on liver surface and heterogenous distribution of nodularities in liver parenchyma, were related with advanced stages of liver fibrosis. But these descriptions could not definitely reflect the histopathologic diagnosis, because 97% patients in S0 subgroup and 66% patients in S4 subgroup showed smooth surface echo pattern. Only 13.7% patients in S4 stage subgroup showed moderate saw-teeth like liver surface echo pattern. No severe nodular surface was noted. The echo pattern of liver parenchyma and heterogenous distribution were significantly different in patients with various stages of liver fibrosis and were related to the severity of fibrosis. But coarse nodularity was frequently encountered: 25% in S0 subgroup patients, and 41% in S4 subgroup patients.

Table 1 summarizes the relation between liver fibrosis stages and quantitative US parameters, which showed the differences in subgroups with various stages of liver fibrosis. Among the quantitative US parameters, the spleen length and diameter of spleen vein were correlated with fibrosis stages (*P*<0.05). The spleen lengths were significantly different in S1/S3, S2/S3, and S1/S4, but not significant in S3/S4 (*P*=0.43). The diameter of spleen vein was significantly different in S2/S4 and S3/S4 (*P*=0.0068 and *P*=0.0036). However, the diameter of portal vein only increased significantly in patients with S4 stage of liver fibrosis. These data suggested that the length of spleen began to increase at S3 of liver fibrosis, so that the difference in S3/S4 was insignificant. The diameter of portal vein began to increase later than the length of spleen and diameter of spleen vein.

Based on receiver-operating characteristic (ROC) curve, the maximal sum of diagnostic sensitivity and specificity was considered as the best cut-off value of US parameters for prediction of the severity of liver fibrosis. The diag-

Table 2 Diagnostic values of three US parameters for early liver cirrhosis

Parameters and cut-off value	Sensitivity	Specificity	Accuracy	Positive predicative value	Negative predicative value
Length of spleen (12.1 cm)	0.600	0.753	0.737	0.198	0.948
Diameter of spleen vein (8 mm)	0.600	0.781	0.765	0.220	0.950
Diameter of portal vein (12 mm)	0.767	0.446	0.475	0.124	0.949

nostic values of three quantitative US parameters are listed in Table 2.

## DISCUSSION

Liver cirrhosis can be detected by US in patients with portal hypertension. Schalm<sup>[13]</sup> reviewed the diagnostic methodology of liver cirrhosis and found that percutaneous liver biopsy has a sensitivity of below 85% in detection of liver cirrhosis. Liver biopsy could yield false negative results in nearly one third of cases, but it is currently considered the criterion for establishing a precise diagnosis and assessing the extent of fibrosis. The diagnostic sensitivity and specificity of US examination for liver cirrhosis vary widely with a diagnostic sensitivity of 0.125- 0.95 and a diagnostic specificity of 0.285- 1.0<sup>[14-16]</sup>. The diagnostic accuracy of US for early liver cirrhosis in patients with chronic virus hepatitis and compensated liver function has not been fully investigated.

At US scanning, liver surface nodularity reflects the presence of regenerative nodules and fibrous septa. Nodularity on liver surface and in parenchyma is independently associated with the diagnosis of cirrhosis and US is reliable for diagnosis of liver fibrosis. It was reported that the high frequency US transducer (7.5-12 MHz) can obtain satisfactory results for diagnosis of liver cirrhosis<sup>[17]</sup> while the low frequency US is not a reliable test for liver cirrhosis<sup>[18]</sup>.

Gaiani *et al*<sup>[19]</sup> showed that 80.4% of cirrhosis can be detected in patients with compensated liver diseases of various etiologies using a US scoring system based on two US parameters. Colli *et al*<sup>[20]</sup> reported that US can detect severe fibrosis or cirrhosis with a specificity of 0.95 and a sensitivity of only 0.54. Moreover, surface nodularity could also be influenced by different factors, mainly local fatty infiltration. Hung *et al*<sup>[21]</sup> evaluated the validity of US in diagnosis of cirrhosis with a diagnostic sensitivity of liver cirrhosis of 0.775 and a specificity of 0.92 in patients with HBV infection. Zheng *et al*<sup>[22]</sup> studied the value of US in evaluation of liver fibrosis and compensated cirrhosis in comparison with serology and histology and found that hepatic parenchymal echo pattern, liver surface and thickness of gallbladder wall are three independent predictors of liver fibrosis. The diagnostic accuracy of US for compensated cirrhosis is 80.7%.

The accuracy of Doppler US measurement for diagnosis of early liver cirrhosis is still controversial. It was reported that decreased flow velocity in portal vein is sufficiently accurate in diagnosis of liver cirrhosis<sup>[23-25]</sup>. While other studies<sup>[26-28]</sup> showed that substantial variability exists in measurement of portal venous blood flow velocity and volume. Doppler US measurement does not represent the hepatic venous pressure gradient<sup>[29]</sup>. This controversy could

be explained by the lack of standard technique of Doppler measurement. Furthermore, changes of hemodynamics in hepatic blood flow are influenced by multiple factors, such as extent of fibrosis, chronic inflammation, presence and size of esophageal varices, as well as porto-systemic shunts.

The results of this study showed that the maximal velocity of blood flow in portal vein was weakly related with liver cirrhosis, but the standard deviation of data was wide, suggesting that this Doppler US parameter is not important in evaluation of liver fibrosis.

Schalm<sup>[13]</sup> suggested that if histology shows no cirrhosis (nodules surrounded by fibrosis) but fibrosis and architectural distortion, diagnosis of cirrhosis should still be made when there is a US diagnosis of cirrhosis. Afdhal and Nunes<sup>[30]</sup> argued that a proper US examination can identify patients with cirrhosis when the biopsy findings are equivocal, or at variance with the clinical impression.

The results of this study showed that different stages of hepatic fibrosis could not be determined satisfactorily by US parameters. A single US parameter was limited in sensitivity and specificity for diagnosis of early cirrhosis. Early liver cirrhosis could be excluded using two or three quantitative and qualitative US parameters, especially the spleen length, diameter of spleen vein and echo pattern of liver surface, because the negative predictive values of these three quantitative US parameters were high. US can also be used in follow-up of patients with chronic virus hepatitis.

The limitations of our study are the relatively small number of patients with S0- S4 stages of liver fibrosis and no application of the high-frequency US probe in examination of liver surface.

In conclusion, US cannot be used as a specific diagnostic tool for chronic viral hepatitis, but US should be stressed in screening and follow-up of patients with chronic virus hepatitis. However, the results of this study do not decrease the value of liver biopsy because it has other indications in clinical practice of hepatology.

## ACKNOWLEDGMENTS

The authors express their thanks to the Department of Statistics of Shanghai Second Medical University for performing the statistical analysis in the study.

### Abstract

**AIM:** To evaluate the risk of esophagectomy for carcinoma of the esophagus in the elderly (70 years or more) compared with younger patients (<70 years) and to determine whether the short-term outcomes of esophagectomy in the elderly have improved in recent years.

**METHODS:** Preoperative risks, postoperative morbidity and mortality in 60 elderly patients ( $\geq 70$  years) with esophagectomy for carcinoma of the esophagus were compared with the findings in 1 782 younger patients (<70 years) with esophagectomy between January 1990 and December 2004. Changes in perioperative outcome and short-time survival in elderly patients between 1990 to 1997 and 1998 to 2004 were separately analyzed.

**RESULTS:** Preoperatively, there were significantly more patients with hypertension, pulmonary dysfunction, cardiac disease, and diabetes mellitus in the elderly patients as compared with the younger patients. No significant difference was found regarding the operation time, blood loss, organs in reconstruction and anastomotic site between the two groups, but elderly patients were more often to receive blood transfusion than younger patients. Significantly more transhiatal and fewer transthoracic esophagectomies were performed in the elderly patients as compared with the younger patients. Resection was considered curative in 71.66% (43/60) elderly and 64.92% (1 157/1 782) younger patients, which was not statistically significant ( $P > 0.05$ ). There were no significant differences in the prevalence of surgical complications between the two groups. Postoperative cardiopulmonary medical complications were encountered more frequently in elderly patients. The hospital mortality rate was 3.3% (2/60) for elderly patients and 1.1% (19/1 782) for younger patients without a significant difference. When the study period was divided into a former (1990 to 1997) and a recent (1997 to 2004) period,

operation time, blood loss, and percentage of patients receiving blood transfusion of the elderly patients significantly improved from the former period to the recent period. The hospital mortality rate of the elderly patients dropped from the former period (5.9%) to the recent period (2.3%), but it was not statistically significant.

**CONCLUSION:** Preoperative medical risk factors and postoperative cardiopulmonary complications after esophagectomy are more common in the elderly, but operative mortality is comparable to that of younger patients. These encouraging results and improvements in postoperative mortality and morbidity of the elderly patients in recent period are attributed to better surgical techniques and more intensive perioperative care in the elderly.

### INTRODUCTION

Perioperative management of elderly patients after a major operation is an important issue because of the recent worldwide increase in the elderly population. Esophagectomy for esophageal carcinoma is a major procedure associated with a high mortality and morbidity, and advanced age is often considered a significant risk factor and even a relative contraindication to esophagectomy despite advances in modern surgical practice<sup>[1-3]</sup>.

There have been a small number of studies on the relationship between the clinicopathologic characteristics and age of patients after esophagectomy for esophageal carcinoma. However, whether the prognosis of elderly patients after esophagectomy is more unfavorable than that in younger patients remains still controversial. Some reports emphasized the worse prognosis in elderly patients after esophagectomy<sup>[4,5]</sup>, whereas others emphasized similar outcome irrespective of the age<sup>[6-8]</sup>.

The purpose of this study was to evaluate the risk of esophagectomy for the esophageal carcinoma in the elderly (70 years or more) as compared with younger patients (<70 years) and to determine whether the short-term outcome of esophagectomy in the elderly have improved with increased experience of the surgical team and improved preoperative management in recent years.

## MATERIALS AND METHODS

### Patients

The subjects included 1 842 consecutive patients with primary carcinoma of the esophagus, who had been treated by esophageal resection and reconstruction between January 1990 and December 2004 in our institute. Our patients were unselected and consisted of all of the patients after esophagectomy for esophageal carcinoma during the study period. The patients comprised 1 563 men and 279 women. Sixty were elderly (≥70 years) and 1 782 were younger patients (<70 years). Among the elderly, 17 patients were operated during the period 1990 to 1997, and data obtained were compared with those of 43 patients operated during the period 1998 to 2004.

All patients had detailed preoperative risk assessments based on history of chronic lung or heart disease, chest x-ray, electrocardiogram (ECG), arterial blood gas analysis, pulmonary function tests, and biochemical and hematological tests. The preoperative risk factors analyzed included weight loss more than 10%, anemia (hemoglobin less than 12 g/L), hypertension (prescribed history of hypertension, systolic blood pressure more than 140 mm Hg, and/or diastolic pressure more than 90 mm Hg), chronic pulmonary disease or abnormal lung dysfunction (forced expiratory volume at 1 second [FEV<sub>1</sub>] < 70%

Table 2 Preoperative risks *n* (%)

Risks	≥70 years ( <i>n</i> = 60)	< 70 years ( <i>n</i> = 1 782)	<i>P</i> value
Weight loss	17 (28.3)	564 (31.6)	0.67
Anemia	13 (21.7)	344 (19.3)	0.62
Hypertension	26 (43.3)	512 (28.7)	0.02
Pulmonary dysfunction	43 (71.7)	479 (26.9)	0
Cardiac disease	23 (38.3)	324 (18.2)	0
Cirrhosis	8 (13.3)	155 (8.7)	0.24
Chronic renal disease	11 (18.3)	236 (13.2)	0.25
Diabetes mellitus	24 (40.0)	395 (22.2)	0.003

of predicted normal), cardiac disease (history of ischemic heart disease, heart failure, or abnormal ECG), cirrhosis, chronic renal disease, and diabetes mellitus. Clinicopathologic characteristics, therapeutic methods, and the postoperative morbidity and mortality between elderly and younger patients were compared. Hospital mortality was defined as death within the same hospital admission after surgery, up to 6 mo after surgery. Resection was defined as curative when the tumor was confined to the esophagus with or without involvement of adjacent lymph nodes and all macroscopic tumors had been removed. Resection was palliative when there was infiltration of the tumor beyond the esophagus into mediastinal organs or when there was residual tumor after resection.

### Statistical analysis

Comparisons between groups were performed using the Student's *t* test and  $\chi^2$  test or Fisher's exact test. A *P* value of less than 0.05 was considered statistically significant.

## RESULTS

### Clinicopathologic characteristics and preoperative risks

The clinicopathologic characteristics between the elderly and younger groups are shown in Table 1. There were no significant differences in sex, tumor location, tumor size, histological type, histological differentiation, TNM stage and preoperative radiochemotherapy between the two groups. There were significantly more patients with hypertension, pulmonary dysfunction, cardiac disease, and diabetes mellitus in the elderly group, whereas weight loss, anemia, cirrhosis and chronic renal disease status were not statistically different between the two groups (Table 2).

### Surgical treatment

Operative variables are shown in Table 3. No significant difference was found regarding the operation time, blood loss, organs in reconstruction and anastomotic site between the two groups, but elderly patients were more often to receive blood transfusion than younger patients. Significantly more transhiatal and fewer transthoracic esophagectomies were performed in the elderly patients. Resection was considered curative in 71.66% (43/60) elderly and 64.92% (1 157/1 782) younger patients, which difference was not significant (*P* > 0.05).

Table 3 Surgical treatment *n* (%)

Variables	≥70 years ( <i>n</i> = 60)	< 70 years ( <i>n</i> = 1782)	<i>P</i> value
Operation time (min)	239±147	225±139	0.88

Cerebrovascular accident	0 (0.0)	2 (0.1)	1

### Postoperative morbidity and mortality

Postoperative morbidity and mortality in the elderly and younger groups are shown in Table 4. There were no significant differences in the prevalence of surgical complications between the two groups. Although the anastomotic leakage rate was low, it was still the most common surgical complication in each group. Postoperative medical complications were encountered more frequently in the elderly, mainly pulmonary and cardiac, whereas other medical complications were not statistically different between the two groups. No patient died on the operation table. The hospital mortality rate was 3.3% (2/60) for elderly patients and 1.1% (19/1 782) for younger patients without a significant difference. There was no significant difference in the types of complication as the causes of death between the two groups.

When the study period was divided into a former (1990 to 1997) and a recent (1997 to 2004) period, operative time, blood loss, and percentage of patients receiving blood transfusion of the elderly patients significantly improved from the former period to the recent period

Table 5 Postoperative morbidity and mortality in elderly patients during the two periods *n* (%)

Variables	1990-1997 ( <i>n</i> = 17)	1998-2004 ( <i>n</i> = 43)	<i>P</i> value
Operation time (min)	255±157	212±104	0.008
Blood loss (mL)	520±375	402±249	0.003
Blood transfusion	13 (76.4)	19 (44.2)	0.04
Surgical complications			
Anastomotic leakage	1 (5.9)	1 (2.3)	0.49
Hemorrhage	0 (0.0)	1 (2.3)	1
Chylothorax	1 (5.9)	1 (2.3)	0.49
Recurrent nerve paralysis	1 (5.9)	0 (0.0)	1
Wound dehiscence	0 (0.0)	1 (2.3)	1
Medical complications			
Pulmonary	11 (64.7)	15 (34.9)	0.046
Cardiac	10 (58.8)	13 (30.2)	0.04
Renal	0 (0.0)	1 (2.3)	1
Hospital mortality rate	1 (5.9)	1 (2.3)	0.49

(Table 5). No significant differences in surgical complications were observed, but there was a significant decrease in postoperative cardiopulmonary complications from the former period to the recent period. The hospital mortality rate of the elderly patients dropped from the former period (5.9%) to the recent period (2.3%), but it was not statistically significant.

## DISCUSSION

Esophageal carcinoma in the elderly has increased in part because of increasing life expectancy. Esophagectomy for carcinoma probably has the highest operative mortality of any elective surgical procedures<sup>[9]</sup>. Therefore, it is important to evaluate the risk of esophagectomy for carcinoma in elderly patients. Advanced age was once considered a relative contraindication to esophagectomy because of the high operative mortality rate<sup>[4,5]</sup>. At the same time, the malignant potential of neoplasms in elderly patients has occasionally been reported to be much less aggressive than that in younger patients<sup>[10]</sup>. Whether the prognosis of elderly patients with esophagectomy for esophageal carcinoma is more unfavorable than that in younger patients remains controversial.

Recently, more and more reports emphasized that esophagectomy could be performed in a high percentage of elderly patients and thus advanced age alone should not be considered as a contraindication for esophagectomy<sup>[6-8]</sup>. We shared this opinion and believed that resection should be offered whenever possible because it offered the only hope of cure and the best method of palliation<sup>[11]</sup>. The presence of risk factors has great impact on surgical outcome, hence thorough preoperative assessment should be carried out in all patients. Even in the presence of medical risk factors, resection is still preferred for the elderly unless the risk is prohibitively high. Most of our patients who did not have resection were unresectable because of extensive local or metastatic disease, and only a small portion (about 20%) of elderly patients were deemed unresectable because of poor physical conditions or cardiopulmonary status.

Preoperative risk assessment is an important aspect of patient selection for esophagectomy, as a significant number of these patients had cardiopulmonary or diabetes mellitus in the preoperative period and cardiopulmonary complications in the postoperative period. Pulmonary complication was one of the most common causes of surgical complication-related deaths in both groups. These results strongly suggest that greater preoperative precautions must be taken to manage cardiopulmonary complications in the elderly patients<sup>[12]</sup>. The anastomotic leakage and chylothorax rate were low in both elderly and younger patients, but these remained the main surgical complications. Pulmonary complication was the most common cause of postoperative death in both elderly and younger patients.

Although a significant number of patients had postoperative surgical or medical complications, only a few of them succumbed to death because of those complications. The mortality rate caused by surgical or medical complications in elderly patients was slightly higher but comparable to that of younger patients, despite higher cardiopulmonary risk and more cardiopulmonary complications in the elderly. The similar outcome was probably the result of significant improvement in surgical technique and more intensive perioperative patient care in our institution. For example, chest physiotherapy was instituted early before operation, and during the postoperative period, cricothyroidotomy was often performed to keep the airway clear of sputum. The more frequent use of transthiatal over transthoracic esophagectomy in elderly patients may also have contributed to the low cardiopulmonary-related mortality<sup>[13]</sup>. Moreover, shorter operative time, reduced blood loss and fewer perioperative blood transfusion in recent years may all have important impact on the reduced incidence of cardiopulmonary complications during this period<sup>[14-17]</sup>. Finally, there has been considerable improvement in postoperative pain control by epidural anesthesia block. Adequate analgesia decreases pulmonary complications by decreasing the disturbances of pulmonary mechanics after thoracotomy or laparotomy and enabling patients to generate effective cough<sup>[18]</sup>. The pulmonary complication rate decreased to only 34.9% in recent years in contrast to 64.7% in the previous era.

In conclusion, our study showed that preoperative medical risk factors and postoperative cardiopulmonary complications after esophagectomy are more common in the elderly, but operative mortality was comparable to that of younger patients. These encouraging results and improvements in postoperative mortality and morbidity in recent period are attributed to better surgical techniques and more intensive perioperative care in elderly patients. However, a careful patient selection procedure must be used to exclude the high-risk elderly patients from the operative list and thus will help to reduce the postoperative morbidity and mortality rate in this group of patients.

### Abstract

**AIM:** To establish a new, reliable vomit model of minks.

**METHODS:** Adult male minks were randomly divided into 8 groups ( $n=6$ ): cisplatin (7.5 mg/kg) intraperitoneal injection (ip) group, copper sulfate (40 mg/kg) intragastric injection (ig) group, apomorphine (1.6 mg/kg) subcutaneous injection (sc) group, and 18 Gy whole-body X-irradiation group, ondansetron injection group (2 mg/kg ip) 30 min later followed by cisplatin (7.5 mg/kg) ip, normal saline (NS) ip injection control group, metoclopramide injection group (4 mg/kg ip) 30 min later followed by apomorphine (1.6 mg/kg) sc, NS ig control group. The frequency of retching and vomiting was calculated. After behavioral experiment, distribution of 5-HT in the ileum was detected by immunohistologic method.

**RESULTS:** Cisplatin, apomorphine, copper sulfate and X-irradiation administered to minks evoked a profound emetic response in the animals. However, retching and vomiting were significantly inhibited by pretreatment with ondansetron and metoclopramide in cisplatin and copper sulfate groups ( $P=0.018$ ). Immunohistologic result showed that 5-HT released from enterochromaffin cells (EC cells) was involved in vomiting mechanism.

**CONCLUSION:** Mink vomit model has a great value in studying the vomiting mechanism and screening new antiemetic drugs.

Zhang F, Wang L, Yang ZH, Liu ZT, Yue W. Value of mink vomit model in study of anti-emetic drugs. *World J Gastroenterol* 2006; 12(8): 1300-1302

### INTRODUCTION

In the treatment of malignant disease, potentially curative chemotherapy and radiotherapy are commonly associated with a wide range of adverse events, including intractable nausea and vomiting, which can challenge patient compliance with a treatment regimen. Other forms of emesis, including those experienced post-operatively or in other diseases, can also present as serious problems. Studying the vomiting mechanism and screening for new anti-emetic drugs urge us to establish appropriate animal models with similar vomiting behavior to that of human beings. Ferret (*Mustela putorius furo*) is a relative ideal animal model in vomiting study worldwide<sup>[1]</sup>. However, its use is limited because of its high feeding cost and difficulties to survive. Fortunately minks (*Mustela vison*) and ferrets belonging to the same stoat genus are characterized by their inexpensiveness, wide availability and ease of feeding and raising. However, there are no reports on the use of minks in medical researches. This study was to establish a new and reliable vomit model of minks based on the effects of a variety of emetogens.

### MATERIALS AND METHODS

#### Materials

Cisplatin powder was obtained from Qilu Pharmaceutical Factory, Jinan, China. Ondansetron hydrochloride injection was from Ningbo Tianheng Pharmaceutical Factory, Ningbo, China. Copper sulfate was from Shanghai Hengda Chemical Co., Shanghai, China. Apomorphine was from Sigma in St Louis, USA. Metoclopramide dihydrochloride injection was from Tianjin People's Pharmaceutical Factory, Tianjin, China. SABC immunohistology test kit was from Boster Biotechnology Co., Wuhan, China. Varian 6 MeV 2100-C X-irradiation Linear Accelerator was from Varian Corp., USA. Microscope was from Olympus, Japan. Adult male minks weighing 1.3-1.8 kg were provided by Qingdao Special Animal Center.

#### Animal experiments

Animals were used in the present study in accordance with the Qingdao University Guide for the Care and Use of Laboratory Animals.

To examine the effects of emetogens, the minks were divided into 4 groups ( $n=6$ ), and housed individually in an iron cage of 75 cm × 50 cm × 50 cm with free access to

Table 1 Effects of emetogens on minks ( $n = 6$ , mean $\pm$ SD)

Emetogens	Dose (mg/kg)	Latency (min)	Retching (n)	Emesis (n)	Vomiting ratio

Apomorphine	1.6	Metoclopramide	4	-a	1.3 $\pm$ 3 <sup>b</sup>	0.3 $\pm$ 0.8 <sup>d</sup>

<sup>a</sup> $P=0.018$ ,  $t=2.93$  vs vehicle-pretreated cisplatin group; <sup>b</sup> $P=0.0022$ ,  $t'=4.08$ , <sup>d</sup> $P=0.003$ ,  $t'=5.94$  vs vehicle-pretreated apomorphine group; -a: only 1 monk had retching and vomiting.

food and water

The minks in the first group were first given NS (5 mL/kg ip). After 24 h, the animals were administered cisplatin (7.5 mg/kg ip) in a volume of 5 mL/kg diluted with NS.

The minks in the second group were first given NS (15 mL/kg ig). After 24 h, the animals were given copper sulfate (40 mg/kg ig) in a volume of 15 mL/kg diluted with NS.

The minks in the third group were first given NS (0.4 mL/kg sc). After 24 h, the animals were given apomorphine (1.6 mg/kg sc) in a volume of 0.4 mL/kg diluted with NS.

The minks in the fourth group were first exposed to pseudo-irradiation. After 24 h, the animals received 18 Gy whole-body X-irradiation for 4.5 min.

To investigate the effects of anti-emetic agents on emesis induced by cisplatin or apomorphine, the minks in the first group were injected intraperitoneally with ondansetron injection (2 mg/kg) in a volume of 1 mL/kg 30 min before the intraperitoneal administration of cisplatin (7.5 mg/kg).

The minks in the second group were pretreated with NS (1 mL/kg ip) as control. After 30 min, the animals were administered cisplatin (7.5 mg/kg).

The minks in the third group were pretreated with metoclopramide injection (4 mg/kg ip) in a volume of 0.8 mL/kg, followed by apomorphine (1.6 mg/kg sc) after 30 min.

The minks in the fourth group were pretreated with NS (0.8 mL/kg ip) as control, followed by apomorphine (1.6 mg/kg sc) later 30 min.

All experiments were carried out starting at 9:00 am. After treatment, retching and vomiting were observed for 6 h, following the vomit criteria for ferrets described by Minami *et al.*<sup>[2]</sup>. No observers were aware of the treatments. Salivating, flinching and other behaviors resembling the nausea of human beings were observed. During vomiting,

the mink's head was protruding downwards ahead with open mouth, shrugging shoulder, contracting abdomen and occasional sound of vomiting. A vomiting cycle started the minute when vomiting began until smooth breaths recovered. A retching/vomiting referred to a vomiting action without or with stomach content spat out. The frequency of retching and vomiting was calculated.

### Immunohistologic analysis

Minks in control group ( $n=3$ ) and cisplatin group ( $n=3$ , 3 h after 7.5 mg/kg ip) were killed by cervical dislocation. A 3 cm long section was dissected 20 cm from the pylorus, and the distribution of 5-HT was detected under microscope by the immunohistologic method according to the instructions of the SABC test kit.

### Statistical analysis

Data were expressed as mean $\pm$ SD and analyzed by Student's  $t$  test.  $P<0.05$  was considered statistically significant.

## RESULTS

### Animal experiments

Cisplatin, apomorphine, copper sulfate and X-irradiation administered to the minks evoked a profound emetic response, and the manifestations of retching and vomiting in minks were similar to those in ferrets<sup>[2]</sup>. No vomiting occurred in control groups. The effects of emetogens over a 6 h period are shown in Table 1.

All minks in the NS + cisplatin group suffered from retching and vomiting. Vomiting started after 60 min and reached its peak after about 2 h. Five minks in the ondansetron pretreatment group suffered from retching and vomiting. The frequency of cisplatin-induced retching and vomiting after 6 h was significantly reduced by pretreatment with ondansetron.

All minks in the NS+apomorphine group and only one in the metoclopramide pretreatment group, suffered from retching and vomiting. The frequency of apomorphine-induced retching and vomiting after 6 h was significantly reduced by pretreatment with metoclopramide.

No significant difference was found between the pretreatment and control groups in terms of the latency and duration of emesis induced by cisplatin or apomorphine (Table 2).

### Immunohistologic analysis

In the cisplatin group, 5-HT was released from EC cells which seemed to have a tail. In the control group, 5-HT was not released from EC cells which was round with a clear rim. Similar phenomena were also observed in other groups (Figure 1).

## DISCUSSION

It is widely known that vomiting cannot be induced in rodents such as mice (except for the special strains), rats, and guinea pigs. Pigeons, cats and dogs are occasionally used in vomiting research and screening for new anti-emetics. Since pigeons often carry infectious viruses to human beings, no reports are available on vomiting induced by anticancer drugs in pigeons. Cats and dogs have a good learning ability. When vomiting is induced by emetogens, it often continues even anti-emetics<sup>[3]</sup> are administered. Ferret is a widely accepted animal model in vomiting study at present, mainly because its vomiting behavior resembles that of human beings<sup>[4]</sup> in terms of behavior, responses to emetogens and anti-emetic agents, and biochemistry change in vomit response. Ondansetron, a potential anti-emetic agent, was developed in ferret vomit model by Glaxo Company. However, since ferret is so expensive and difficult to raise, its wide use cannot be realized. In fact, no laboratory has carried out experiments in ferrets so far in China. Minks belong to the same stoat family of ferrets. As a vomit model, they not only share

the advantages with ferrets, but also are inexpensive and can be raised quite easily and widely.

In the present study, the effects of a variety of emetogens, including cisplatin, copper sulfate, apomorphine and X-irradiation at the doses evoking a profound emetic response in ferrets, were identical in minks. The manifestations of retching and vomiting were similar to those in ferrets. As shown in our experiment, ondansetron and metoclopramide can inhibit emesis induced by cisplatin and apomorphine in minks.

5-HT immunohistologic analysis showed that emetogens increased the release of 5-HT from EC cells in intestine, which may be an important mechanism involved in vomiting. This finding is consistent with the results reported previously<sup>[5]</sup>. However, it must be acknowledged that this study has its limitations because our experiments were mainly focused on the behavior of minks and the vomiting mechanism was studied in the initial stage. A further study is needed.

In conclusion, the mink vomit model is of great value in studying the vomiting mechanism and screening for new anti-emetic drugs.

### Abstract

**AIM:** To investigate the effect of arg-gly-asp-mannose-6-phosphate (RGD-M6P) on the activation and proliferation of primary hepatic stellate cells *in vitro*.

**METHODS:** Hepatic stellate cells (HSCs) were isolated from rats by *in situ* collagenase perfusion of liver and 18% Nycodenz gradient centrifugation and cultured on uncoated plastic plates for 24 h with DMEM containing 10% fetal bovine serum (FBS/DMEM) before the culture medium was substituted with 2% FBS/DMEM for another 24 h. Then, HSCs were cultured in 2% FBS/DMEM with transforming growth factor  $\beta$ 1, M6P, RGD, or RGD-M6P, respectively. Cell morphology was observed under inverted microscope, smooth muscle  $\alpha$ -actin ( $\alpha$ -SMA) was detected by immunocytochemistry, type III procollagen (PCIII) in supernatant was determined by radioimmunoassay, and the proliferation rate of HSCs was assessed by flow cytometry.

**RESULTS:** RGD-M6P significantly inhibited the morphological transformation and the  $\alpha$ -SMA and PC III expressions of HSCs *in vitro* and also dramatically prevented the proliferation of HSCs *in vitro*. Such effects were remarkably different from those of RGD or M6P.

**CONCLUSION:** The new compound, RGD-M6P, which has a dramatic effect on primary cultured HSCs *in vitro*, can inhibit the transformation of HSCs in culture caused by TGF $\beta$ 1, suppresses the expression of PCIII and decreases proliferation rate of HSC. RGD-M6P can be applied as a selective drug carrier targeting at HSCs, which may be a new approach to the prevention and treatment of liver fibrosis.

### INTRODUCTION

Liver fibrosis is characterized by an excessive deposition of extracellular matrix constituents, resulting from an enhanced synthesis of matrix proteins (fibrogenesis) and decreased removal by matrix degrading enzymes (fibrolysis) in consequence of liver cell damage of various causes<sup>[1-3]</sup>. The major cell type responsible for hepatic fibrogenesis is the activated hepatic stellate cells (HSCs). Therefore, this cell type is an important target for antifibrotic therapy<sup>[4,5]</sup>. Pharmacotherapeutic intervention to alter HSC functions may act at different levels: inhibition of activation and transformation of HSCs, inactivation of profibrogenic cytokines, interference with matrix synthesis and stimulation of matrix degradation<sup>[6-11]</sup>. *In vivo*, however, antifibrotic drugs may not be efficiently taken up by HSCs or may produce undesirable side effects. Drug targeting may be explored to elicit cell-specific uptake of drugs, but in contrast to other cell types in the liver, a specific carrier agent to go into HSCs is not yet known<sup>[12]</sup>. Therefore, we focused on the development of a specific carrier for HSCs. The binding sites expressed on activated HSCs were considered for their ability to serve as potential targets for carrier molecules. Two of these are integrin and mannose 6-phosphate/insulin like growth factor II (M6P/IGF-II) receptors, which are over-expressed on activated rat HSCs, particularly during fibrosis<sup>[13,14]</sup>. Additionally, extracellular matrixes (ECM) regulate the morphology and biological activities of HSCs through integrins on the cell membrane<sup>[13]</sup>. It has been certified that the RGD sequence plays a vital role in the linkage between ECM and integrins<sup>[13]</sup>. This study was to synthesize a new compound, RGD-M6P targeting at integrins and/or M6P/IGF-II receptors over-expressed on activated HSCs and to study its effects on the activation and proliferation of primary cultured HSCs in order to find a new approach for regulating HSC activation and anti-hepato-fibrotic therapy. If successful, this may be of value in the design of other receptor-specific carriers.

**Figure 1** Small and round HSCs in the presence of vitamin-A droplets in cytoplasm (A) and spindle-like or asteroid membranous processes in HSCs (B).

## MATERIALS AND METHODS

### Animals

Male Sprague-Dawley rats weighing 400-500 g were purchased from the Shanghai Laboratory Animal Center, Chinese Academy of Sciences.

### Main reagents

RGD, M6P and RGD-M6P were synthesized in Gastroenterological Laboratory of Xinhua Hospital, Shanghai Second Medical University. DMEM was purchased from Gibco Company. Procollagen III (PCIII) radioimmunoassay kits were purchased from Institute of Naval Medicine, Shanghai.  $\alpha$ -SMA monoclonal antibody was provided from by Cruz Company.

### Isolation of HSCs and grouping

HSCs were isolated and cultured. Briefly, the rats were anesthetized with an intraperitoneal injection of pentobarbital. After cannulation into the portal vein, the liver was perfused with calcium-free balanced NS containing 0.5 mg/mL collagenase and 1 mg/mL pronase E. Then the liver was removed, cut into small pieces and incubated in a solution containing 0.5 mg/mL collagenase. After washed, HSCs were purified by density gradient centrifugation with 18% Nycodenz, collected from the top layer, washed and suspended in DMEM supplemented with 10% FBS at the concentration of  $1 \times 10^6$  cells/mL, and seeded on uncoated 24-well plastic plates at  $1 \times 10^5$ /well supplemented with 20% FBS/DMEM for 24 h. Then the HSCs were subjected to tetrandrine treatment after cultivation in 2% FBS/DMEM for another 24 h. Over 90% of isolated HSCs were viable as assessed by trypan blue exclusion with a purity of higher than 90% as determined by direct cell counting under a phase-contrast microscope and intrinsic vitamin A autofluorescence.

HSCs were subjected to different treatments for 5 d as follows: control group: without any treatment; TGF $\beta$ 1 group: supplemented with 5 ng/mL TGF $\beta$ 1; M6P group: supplemented with 100  $\mu$ g/mL M6P and 5 ng/mL TGF $\beta$ 1; RGD group: supplemented with 100  $\mu$ g/mL RGD and 5 ng/mL TGF $\beta$ 1; RGD-M6P group: supplemented with 200  $\mu$ g/mL RGD-M6P and 5 ng/mL TGF $\beta$ 1.

### Immunocytochemical analysis of $\alpha$ -SMA

HSCs were cultured on 24-well plates with different treatments as described above. HSCs were fixed with ethanol/acetic acid after 5 d of treatment.  $\alpha$ -SMA antibody, horse radish peroxidase-conjugated secondary

antibody and diaminobenzidine were added sequentially according to the standard protocol. Semi-quantitative assessment of protein expression was performed using pathological image analysis system. The expression of  $\alpha$ -SMA was estimated by gray value.

### PCIII content

PCIII in supernatant was measured with a radioimmunoassay kit according to the manufacturer's instructions.

### Flow cytometry

The cell cycle was analyzed by flow cytometry to assess the proliferation rate of HSCs. Adherent and floating cells were collected from a 6-well plate, centrifuged and washed twice with PBS at room temperature. Cell pellets were re-suspended in ice-cold 70% ethanol for overnight fixation at 4 °C, centrifuged and re-suspended in 0.8 mL PBS. One microlitre 10 mg/ $\mu$ L RNase and 20  $\mu$ L propidium iodide (1 mg/mL) were added and samples were incubated at 37 °C for 30 min before analysis by flow cytometry using a Beckman Coulter FC500. Proliferation was quantitatively measured as the percentage of cells in the G<sub>2</sub>/M phase.

### Statistical analysis

All data were expressed as mean  $\pm$  SD. Statistical analysis of values was performed with SPSS software (10.0 version).  $P < 0.05$  was considered statistically significant.

## RESULTS

### Morphological study of isolated HSCs *in vitro*

Over 90% of isolated HSCs were viable as assessed by trypan blue exclusion, which were small and round in appearance (Figure 1A). HSCs stimulated by 327 nm-length laser, showed a blue-green intrinsic autofluorescence due to vitamin-A rich droplets. After cultured for 72 h, HSCs presented a wall-adhesive growth pattern and many spindle-like or asteroid membranous processes and a reduction of vitamin-A droplets (Figure 1B). Overall, these findings indicated that HSCs freshly isolated from normal rats showed an activated form after 5 d of *in vitro* culture.

### Expression of $\alpha$ -SMA in culture-activated HSCs

Immunocytochemical assay was used to evaluate the percentage of  $\alpha$ -SMA-positive HSCs in different groups. The percentage of  $\alpha$ -SMA-positive HSCs was significantly higher in TGF $\beta$ 1 and M6P groups (Figures 2B and 2C)

**Figure 2** Immunocytochemical analysis of HSCs after cultured for 5 d (A), after treatment with TGFβ1 (B) and M6P (C), weak positivity of α-SMA RGD (D) and RGD-M6P (E), and elevated expression of α-SMA (F) in HSCs. <sup>a</sup>*P*<0.05 vs control groups; <sup>c</sup>*P*<0.05 vs TGFβ1.

**Table 1** PCIII level in different groups (mean±SD)

Group	n	Concentration of PCIII (ng/mL)
Control group	5	323.59±16.14
TGFβ1 group	5	403.56±7.97 <sup>a</sup>
M6P group	5	399.70±2.25 <sup>a</sup>
RGD group	5	370.87±13.07 <sup>a,b</sup>
RGD-M6P group	5	357.61±13.07 <sup>a,b</sup>

<sup>a</sup>*P*<0.01 vs control groups; <sup>b</sup>*P*<0.01 vs TGFβ1 group.

than in control, RGD and RGD-M6P groups (Figures 2D and 2E). Even condensed α-SMA positive granules could be found (Figure 2B). No difference was found in the immunohistochemical study between RGD and RGD-M6P groups (Figure 2F). The cytomorphology study showed that the primary isolated HSCs were positive for α-SMA and the positivity was intensified through auto-activating characteristics of HSCs *in vitro*. Additionally, RGD and RGD-M6P could inhibit the activation of HSCs stimulated by TGFβ1.

#### PCIII excretion from culture-activated HSCs

PCIII is the most acceptable parameter of fibrogenesis as compared to other ECM contents, such as collagens I, III, IV, fibronectin, laminin and proteoglycans<sup>[15,16]</sup>. The level of PCIII in the control group was lower than that in the other groups (*P*<0.01, Table 1), and higher in TGFβ1 and M6P groups than in RGD and RGD-M6P groups. No difference was found in the level of supernatant PCIII between RGD and RGD-M6P groups. The results showed that the effect of RGD-M6P was better than that of M6P on inhibiting PCIII expression after stimulated by TGFβ1.

#### Proliferation of cultured HSCs

The activation of HSCs resulted in over-expression of

α-SMA and increased proliferation of HSCs. Cell cycle analysis was used to evaluate the proliferation rate by flow cytometry. The primary isolated HSCs showed a characteristic proliferation (Figure 3A), which was further increased by TGFβ1 (Figure 3B). M6P showed no effect on the proliferation of HSCs (Figure 3C). On the contrary, RGD and RGD-M6P inhibited the proliferation of isolated HSCs significantly (Figures 3D and 3E).

## DISCUSSION

In the past decade, significant advances have been made in anti-fibrosis therapy due to a better understanding of the cellular and molecular mechanism of hepatic fibrogenesis<sup>[1-3,8]</sup>. The key factors in the pathogenesis of liver fibrosis include the activation and proliferation of HSCs and their transformation into myofibroblasts<sup>[5]</sup>. Therefore, HSCs are the important target for antifibrotic therapies<sup>[4,12,17,18]</sup>. However, contrary to *in vitro* data, *in vivo* studies<sup>[13,14,19]</sup> demonstrated that most antifibrogenic agents cannot be efficiently taken up by HSCs and the binding sites expressed on (activated) HSCs can serve as potential targets for carrier molecules. Two of these are integrin and M6P/IGF-II receptors and their expressions are increased on activated rat HSCs, particularly during fibrosis. Some anti-fibrotic reagents targeting at HSCs have been developed<sup>[12,20]</sup>, which allow cell-specific delivery of antifibrotic drugs to HSCs, thus enhancing their effectiveness *in vivo*.

Specific interactions between cells and ECM components are mediated by transmembrane proteins, especially heterodimeric integrins. Cell-matrix interactions guide or modulate cellular activities, such as adhesion, migration, differentiation, proliferation, and apoptosis<sup>[13]</sup>. Most integrins can recognize and bind to the amino acid sequence of RGD present in various matrix proteins. The expression of integrins is increased during liver fibrosis,

**Figure 3** Flow cytometry analysis of cell cycle. PI histogram shows the details of cell cycle, in which the gates of D, F and G represent the G0/G1, S and G2/M phases, respectively, shown in corresponding figure. **A:** Proliferation of primary cultured HSCs; **B:** Increased proliferation of primary cultured HSCs in the presence of TGFβ1; **C:** Increased proliferation of primary cultured HSCs in the presence of M6P; **D** and **E:** Enlarged fraction of G2/M phase cells after treatment with RGD and RGD-M6P; **F:** Distribution of cell cycle phases was calculated using Multicycle I.O. <sup>b</sup>*P* < 0.01 vs control, RGD and RGD-M6P groups; <sup>c</sup>*P* < 0.05 vs control.

especially on the membrane of activated HSCs, suggesting that integrins can be used as a homing device to target at HSCs in fibrotic livers<sup>[19,21]</sup>. About 10%-20% of M6P/IGF-II receptors are expressed in cell membrane and over-expressed with the activation of HSCs<sup>[14]</sup>. It was reported that integrin antagonists can reduce the level of serum PCIII in fibrotic rats and inhibit the stimulating action of TGFβ1 on ECM expression<sup>[22-24]</sup>. Beliaars *et al*<sup>[25,26]</sup> showed that M6P-modified albumin accumulates in slices of normal and fibrotic liver and is taken up by HSCs. In the present study, we synthesized RGD-M6P and investigated its effects on the activation and proliferation of the primary HSCs *in vitro*.

The isolated primary HSCs in culture undergo auto-activation<sup>[27]</sup>. During this process, the expression of α-SMA is raised<sup>[28]</sup> and HSCs transform into fibroblast-like cells with increased proliferating activity<sup>[27]</sup>, which might lack microenvironment *in vitro*. HSCs supplemented with TGFβ1 put forth more processes on their cell membrane, and the supernatant PCIII level is increased<sup>[29,30]</sup>. At the same time, the proliferation of HSCs is increased. Both RGD and RGD-M6P could inhibit the effect of TGFβ1 on the activation and proliferation of HSCs as well as PCIII expression. Though the M6P molecule participates in the activation of latent TGFβ1<sup>[31]</sup>, it can be used as a candidate in the study of anti-fibrosis. In the present study, we could not find its anti-fibrosis activity because M6P acted on the activated TGFβ1 rather than the latent form. Moreover,

RGD-M6P may have a more effective anti-fibrotic activity than RGD because RGD-M6P targets at the integrin and M6P/IGFII receptors on HSC membrane, thus more effectively modulating the HSC activity. But our present results failed to support the hypothesis. Further study is needed to explore the precise mechanism of this new complex.

In conclusion, integrins are related with TGFβ1 signal transduction and influence other signal transduction molecules such as JNK and NF-κB.

### Abstract

**AIM:** To establish a rapid and accurate method for the detection of lamivudine-resistant mutations in hepatitis B virus and monitor of lamivudine resistance during lamivudine treatment in patients with chronic hepatitis B virus infection.

**METHODS:** We established a real-time PCR method using a universal template and TaqMan probe to detect YMDD mutants. Variants of YVDD and YIDD were tested by individual reactions (reaction V and reaction I) and total hepatitis B viruses were detected in another reaction for control (reaction C). Results were determined by  $\Delta Ct < 3.5$  ( $\Delta Ct = Ct$  of reaction V or I -  $Ct$  of reaction C). Clones of the HBV polymerase gene containing different YMDD mutations were tested. Serum samples from 163 lamivudine-treated patients with chronic hepatitis B virus infection were detected using this method and the results were confirmed by DNA sequencing.

**RESULTS:** As many as 1000 copies per milliliter of wide-type plasmid were detected and nonspecific priming was excluded. In the 163 samples from patients treated with lamivudine, lamivudine-resistant mutations were detected in 51 samples.

**CONCLUSION:** This universal real-time PCR is a rapid and accurate method for quantification of YMDD mutants of HBV virus in lamivudine-treated patients and can be used to monitor lamivudine-resistant mutations before and during lamivudine therapy.

### INTRODUCTION

It is estimated that approximately 350 million persons worldwide are chronically infected with hepatitis B virus (HBV)<sup>[1,2]</sup>. HBV is the leading cause of liver cirrhosis and hepatocellular carcinoma (HCC) and is responsible for 60 - 80% of all HCC cases<sup>[2,3]</sup>. Treatment of HBV infection has been revolutionized by the introduction of antiviral drugs such as lamivudine. However, long-term monotherapy commonly does not result in complete suppression of viral replication and is associated with the emergence of resistant mutants<sup>[4-7]</sup>. Specific mutations that result in replacement of methionine (M) in tyrosine-methionine-aspartate-aspartate (YMDD) motif of HBV reverse transcriptase (rt) by valine (V), isoleucine (I), or serine (S) confer resistance to lamivudine<sup>[8]</sup>.

Mutations leading to lamivudine resistance can be detected by direct sequencing of HBV DNA after PCR amplification of a selected part of the viral polymerase gene. However, this is expensive, laborious and time-consuming with low level of sensitivity, usually detecting 20% the total virus population<sup>[9]</sup>. Other molecular techniques, such as restriction fragment length polymorphism (RFLP)<sup>[10]</sup>, 5' nuclease assay<sup>[11]</sup>, line probe assay<sup>[12]</sup>, peptide nucleic acid-mediated PCR clamping<sup>[13,14]</sup>, and oligonucleotide chips<sup>[15]</sup>, overcome some of the limitations of DNA sequencing, but they are also time-consuming and expensive. Recent studies using real-time PCR have obtained quantitative results but cannot avoid nonspecific amplification<sup>[16,17]</sup>.

In the present study, we established a rapid and accurate method for the detection of lamivudine-resistant mutations in HBV based on real-time PCR using a universal template. Positive and negative controls were included to evaluate the quality of the assay.

### MATERIALS AND METHODS

#### Patients and extraction of HBV DNA

Serum samples were collected from 163 patients with chronic HBV infection who had received lamivudine monotherapy for one to two years. The ethical committee of our hospital approved the study and oral consent was obtained from the patients. HBV DNA was extracted from serum samples using the QIAamp blood kit (Qiagen,

Table 1 Primers and probe used in universal RT-PCR

Reaction I	5'-CCCCCAATACCACATCATCA-3'
Reaction C	5'-CCCCCAATACCACATCATC-3'
Forward primers	5'-tgaggagcagagacggaagtATACAA CACCTGTATCCCATCCCAT-3'
Probe	5'-FAM ACTTCCGTCCTGCTCCTCA TAMRA-3'

Chatsworth, California) as described elsewhere<sup>[11]</sup>.

### Primers and probe

The primers and probe used in this study are summarized in Table 1. Two different reverse primers that would selectively amplify the YVDD (rtM204V) and YIDD (rtM204I) quasispecies and a common reverse primer to a highly conserved sequence within the polymerase open reading frame were used to discriminate different mutants. The amplicon was detected by real-time PCR with a TaqMan probe that annealed to the universal template linked to the primers. A universal forward primer was used in the control for amplification of all kinds of quasispecies. A universal template was linked to each primer as described previously<sup>[18]</sup>. In brief, the universal template (UT) sequence with a size of 21 bp was attached to the 5' end of the primers specific to YMDD variants<sup>[17]</sup>. The UT probe was labeled with 6-carboxyfluorescein (FAM) at the 5' end and DABCYL quencher at the 3' end. During the annealing phase, the UT probe specifically annealed to the 5' end of the UT-PCR primer and the 3' end of the UT-PCR primer specifically annealed to the target sequence and was extended. Due to the 5' exonuclease activity of DNA polymerase, the hybridized UT probe was hydrolyzed, leading to the separation of the reporter moiety from the quencher moiety and the generation of a fluorescent signal. The signal could be detected by ABI 7000 real-time PCR system (Applied Biosystems Inc. California, USA).

### Real-time PCR

The amplification was performed on ABI 7000 with a final volume of 50 µl by incubating the reaction mixture at 50 °C for 2 min and at 95 °C for 5 min, followed by 40 cycles of PCR amplification at 94 °C for 20 s and at 55 °C for 30 s. The reaction mixture contained the following components: 1×PCR buffer, 100 nmol/L primers and probes, 400 µmol/L each of dATP, dGTP, dCTP and dUTP, 1.5 units of hot-start Taq DNA polymerase, 0.2 units of Amperase uracil N-glycosylase (UNG), 3 mmol/L MgCl<sub>2</sub>, 20 mmol/L KCl. The amplification was optimized in Fosun Diagnostics (Fosun Diagnostics, Shanghai, China). Variants of YVDD and YIDD and total HBV virus were amplified in individual reactions (reactions V, I and C for YVDD, YIDD and HBV virus respectively). The positive results were determined by  $\Delta Ct < 3.5$ .  $\Delta Ct = Ct$  of reaction V or I -  $Ct$  of reaction C.

### DNA sequencing

The DNA sequence of the domain C of HBV polymerase

gene was analyzed as described elsewhere<sup>[11]</sup>. In brief, HBV DNA extracted from serum samples was amplified by PCR. PCR products were purified and sequenced by ABI 310 sequencer (Applied Biosystems Inc., California, USA).

## RESULTS

### Specificity of primers and probe

Mismatched templates and primers (mutant primers to wild-type templates and vice versa) were used to validate this assay. Dilution series of 10<sup>8</sup>, 10<sup>6</sup>, 10<sup>4</sup> copies per milliliter were used and PCR was performed with the mismatched primers. Nonspecific priming to the alternate template was observed at the template concentrations of 10<sup>6</sup> and 10<sup>8</sup> copies per milliliter but not at 10<sup>4</sup> copies per milliliter. Similar to previous study<sup>[17]</sup>, the degree of cross-priming was at least 4 logs. For exclusion of nonspecific priming, the positive results were determined by  $\Delta Ct < 3.5$ .  $\Delta Ct = Ct$  of reaction V or I -  $Ct$  of reaction C.

### Sensitivity and limit of detection

Mixing experiments were performed to determine the sensitivity of the assay. Mutant and wild-type plasmids were mixed with the ratio of 0:1, 1:1, 1:10, 1:100 and 1:1000 at end concentrations of 10<sup>5</sup>, 10<sup>6</sup>, 10<sup>7</sup> and 10<sup>8</sup> copies per milliliter respectively (five replicates for each mixture). In all the mixtures, the detection limit of the assay was 1000 copies per milliliter.

### Comparison of real-time UT-PCR and sequencing

The assay was evaluated using serum from 163 lamivudine-treated patients with chronic HBV infection. All the patients treated with lamivudine alone for one to two years were HBV DNA positive by real-time PCR. Real-time UT-PCR was performed with all the samples together with positive and negative controls. Fifty-one (31%) of 163 samples were detected with YVDD (Figure 1) or YIDD mutants (YMDD in 112, YIDD in 21, YVDD in 27 and YIDD + YVDD in 3). YMDD mutations were detected in 19% (14 of 73) of the patients treated with lamivudine for one year and in 40% (37 of 90) of the patients treated for two years. The results of real-time UT-PCR and sequencing were concordant in 15 randomly selected samples (Table 2).

## DISCUSSION

A more accurate and rapid method than DNA sequencing and RFLP is needed to detect and quantify the YMDD mutants in sera of chronic HBV infection patients before and during lamivudine therapy. A real-time UT-PCR assay has been developed for detection of YMDD mutations in a large number of patients. The detection limit of this assay is 1000 copies per milliliter of mutants and 1% within a mixed virus population at a concentration of 10<sup>5</sup> copies per milliliter of serum. This real-time UT-PCR assay is more sensitive than DNA sequencing. In addition, the result of the assay can be easily determined by the difference between  $Ct$  values of the mutant and the control and no quantitative standards are needed.

**Figure 1** Detection of YMDD mutants using real-time UT-PCR. Three parallel reactions showed YVDD mutant.

**Table 2** Comparison of results obtained by real-time PCR and sequencing

Samples	HBV DNA (Copies/mL)	Result of UT-PCR	Result of sequencing
1	$2.49 \times 10^5$	YMDD	5'-TATATGGATGAT-3'
2	$4.73 \times 10^7$	YIDD	5'-TATATTGATGAT-3'
3	$6.10 \times 10^3$	YMDD	5'-TATATGGATGAT-3'
4	$6.24 \times 10^6$	YIDD	5'-TATATTGATGAT-3'
5	$2.98 \times 10^9$	YIDD	5'-TATATTGATGAT-3'
6	$8.13 \times 10^6$	YMDD	5'-TATATGGATGAT-3'
7	$1.35 \times 10^4$	YMDD	5'-TATATGGATGAT-3'
8	$3.57 \times 10^3$	YMDD	5'-TATATGGATGAT-3'
9	$2.74 \times 10^6$	YVDD	5'-TATGTGGATGAT-3'
10	$9.10 \times 10^4$	YVDD	5'-TATGTGGATGAT-3'
11	$7.02 \times 10^4$	YMDD	5'-TATATGGATGAT-3'
12	$5.18 \times 10^5$	YMDD	5'-TATATGGATGAT-3'
13	$3.51 \times 10^3$	YMDD	5'-TATATGGATGAT-3'
14	$8.04 \times 10^4$	YMDD	5'-TATATGGATGAT-3'
15	$4.29 \times 10^6$	YMDD	5'-TATATGGATGAT-3'

Real-time UT-PCR has two major advantages, namely the universal probe can be used for many target sequences and it is less expensive compared with other sequence-specific fluorescent PCR techniques<sup>[18]</sup>. In the present study, different YMDD variants were detected using different primers specific to the target DNA and a probe specific to the universal template, showing that it is cost-effective and convenient to detect different sequences simultaneously.

The overall prevalence of the YMDD mutations in the patients treated with lamivudine for one and two years in this study was 19% (14 of 73) and 40% (37 of 90), respectively, which is consistent with prevalence reported by previous studies<sup>[4,5,19]</sup>. Mixture of YIDD and YVDD variants was observed in three samples.

In the present study, the primer used to detect rtM204I was specific to sequence ATT. Sequences of ATG and ATC could not be detected by this assay. However, this could be improved by adding two reverse primers specific to ATG and ATC into the reaction used to detect YIDD (data not shown).

Several real-time PCR methods are available for the detection of YMDD mutations<sup>[16,17,20,21]</sup>. Selective primers have been used<sup>[16,17]</sup>. One of the most important

advantages of this study is that the result of mutants could be easily determined by the difference between Ct values of the mutant and the control without additional quantitative standards. Furthermore, nonspecific priming could be excluded by the cut-off of  $\Delta Ct < 3.5$  because the degree of cross-priming was at least 4 logs in this study and elsewhere<sup>[17]</sup>. The impact of the intra-assay variability is reduced in this assay. However, this arbitrarily determined cut-off value reduces the sensitivity of the assay. The real-time UT-PCR is cost effective and convenient for large scale screening in clinical practices.

In conclusion, the real-time PCR assay established in this study is a rapid and accurate tool for detection of lamivudine-resistant mutations before and during lamivudine therapy.

### INTRODUCTION

Acute hepatic failure (ALF) is a disease with a high mortality. Although significant improvements have been achieved in critical care therapy, the mortality rate of ALF patients is about 80%. In many patients liver failure is reversible and if short-term liver support is provided, the liver may regenerate. Survivors may recover full liver function and a normal life expectancy. For many years, liver transplantation has been the only curative treatment for this condition, subjecting many patients to replacement of a potentially self-regenerating organ, with the lifetime danger of immunosuppression and its attendant complications, such as malignancy. Additionally, because of the shortage of livers available for transplantation, many patients die before a transplant can be performed, or are too ill to undergo surgery at the time a liver becomes available. The survival of patients excluded from liver transplantation or those with potentially reversible ALF might be improved with temporary artificial liver support. Among a variety of liver support therapies, bioartificial liver (BAL) therapy is marked as the most promising solution. Some BAL devices are under trials in animals<sup>[1-4]</sup> and human beings<sup>[5-8]</sup>. The major problem is how to configure a BAL system. To attain enhanced efficacy of liver support, several BAL configurations have been proposed. The long-term maintenance of hepatocyte function is crucial for any BAL system. Some systems use hepatocytes attached to microcarrier beads or multicellular spheroid aggregates<sup>[9-11]</sup>. In regard to bioreactor design, various bioreactor configurations have been proposed that employ glass plates, hollow fiber membranes, encapsulation in biological matrices, and 3-dimensional carrier materials<sup>[12-15]</sup>.

In this study, porcine hepatocytes were isolated by *in situ* recirculating collagenase perfusion method and cultured with spinner culture method to prepare hepatocyte spheroids. A new BAL system was configured by inoculating hepatocyte spheroids into cell circuit of a BIOLIV A3A hollow fiber bioreactor and the functions of the BAL system were evaluated *in vitro* as previously described<sup>[16,17]</sup>. At same time, the efficacy evaluation of the

### Abstract

**AIM:** To evaluate the functions of a new bioartificial liver (BAL) system *in vitro* and *in vitro*.

**MEHTODS:** The BAL system was configured by inoculating porcine hepatocyte spheroids into the cell circuit of a hollow fiber bioreactor. In the experiments of BAL *in vitro*, the levels of alanine aminotransferase (ALT), total bilirubin (TB), and albumin (ALB) in the circulating hepatocyte suspension and RPMI-1640 medium were determined during 6 h of circulation in the BAL device. In the experiments of BAL *in vitro*, acute liver failure (ALF) model in canine was induced by an end-side portocaval shunt combined with common bile duct ligation and transaction. Blood ALT, TB and ammonia levels of ALF in canines were determined before and after BAL treatment.

**RESULTS:** During 6 h of circulation *in vitro*, there was no significant change of ALT, whereas the TB and ALB levels gradually increased with time both in the hepatocyte suspension and in RPMI-1640 medium. In the BAL treatment group, blood ALT, TB and ammonia levels of ALF in canines decreased significantly.

**CONCLUSION:** The new BAL system has the ability to perform liver functions and can be used to treat ALF.

## MATERIALS AND METHODS

### Materials

Chinese experimental male and female miniature pigs ( $n=13$ ) weighing 2.5–4.0 kg, were provided by Beijing Agricultural University. The pigs were allowed free access to water and fasted for 12 h before the experiment. Hybrid male and female dogs ( $n=16$ ) weighing 10–15 kg, were provided by the Experimental Animal Center of Drum Tower Hospital. Collagenase IV, RPMI-1640 medium, hepatocyte growth factor, nerve growth factor, and N-2-hydroxyethylpiperazine-N'-2-ethanesulfonic acid (HEPES) were from Gibco BRL Life Technologies, Grand Island, NY, USA. Insulin, glucagon, transferrin, linoleic acid, glutamine, bovine serum albumin,  $\text{Na}_2\text{SeO}_3$ ,  $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ ,  $\text{ZnSO}_4 \cdot 7\text{H}_2\text{O}$ , poly (2-hydroxyethyl methacrylate) (poly-HEMA), penicillin, and streptomycin were from Sigma-Aldrich Chemie GmbH, Steinheim, Germany. BIOLIV A3A hollow fiber cartridges with abnormal molecular weight cut-off of 70 Ka, a pore size of 200 nm, and a surface area of  $1.06 \text{ m}^2$ , were provided by Cell Biotech Ltd, Hong Kong, China.

### Hepatocyte isolation and culture

Porcine hepatocytes were isolated by *in situ* recirculating collagenase perfusion method<sup>[18]</sup>. Hepatocytes were inoculated at a density of  $5 \times 10^7/\text{mL}$  in serum-free RPMI-1640 medium supplemented with 200  $\mu\text{g}/\text{L}$  hydrocortisone, 1  $\text{mg}/\text{L}$  hepatocyte growth factor, 10  $\mu\text{g}/\text{L}$  nerve growth insulin, 4  $\mu\text{g}/\text{L}$  glucagon, 6.25  $\text{mg}/\text{L}$  transferrin, 10  $\text{mg}/\text{L}$  linoleic acid, 2  $\text{mmol}/\text{L}$  glutamine, 0.5  $\text{g}/\text{L}$  bovine serum albumin, 3  $\text{nmol}/\text{L}$   $\text{Na}_2\text{SeO}_3$ , 0.1  $\mu\text{mol}/\text{L}$   $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ , 50  $\text{pmol}/\text{L}$   $\text{ZnSO}_4 \cdot 7\text{H}_2\text{O}$ , 15  $\text{mmol}/\text{L}$  N-2-hydroxyethylpiperazine-N'-2-ethanesulfonic acid (HEPES), 200  $\text{mg}/\text{L}$  cefoperazone sodium, 100 000 U/L penicillin, and 100  $\text{mg}/\text{L}$  streptomycin<sup>[19]</sup>. To inhibit cell attachment and induce the formation of cell spheroids in suspension, 250 mL bottles were coated with poly-HEMA. About 100 mL of hepatocyte suspension was placed in each bottle. The bottles were placed in an incubator (50 mL/L  $\text{CO}_2$ ,  $37^\circ\text{C}$ ) for 20 h and slowly rotated (12 revolutions/h) as previously described<sup>[20, 21]</sup>.

### Configuration of BAL system

The BAL system was configured by inoculating the hepatocyte spheroids into the cell circuit of a hollow fiber bioreactor (BIOLIV A3A, Cell Biotech Limited, HK, China). The total cell circuit volume was 250 mL. Hepatocyte spheroids in serum-free RPMI-1640 medium containing  $1.0 \times 10^{10}$  primary porcine hepatocytes were infused into the outer space of the hollow fibers and the medium was circulated at 20 mL/min with continuous  $\text{O}_2$  input (2 L/min) (Figure 1). The bioreactor was kept at  $37.5^\circ\text{C}$  in an incubator<sup>[16]</sup>.

### Canine ALF model

Canine ALF model was induced by end-side portocaval

**Figure 1** Schematic picture of the BAL system.

shunt combined with common bile duct ligation and transaction as previously described<sup>[22]</sup>. All canines developed ALF 14 d after operation.

### Determination of functions of BAL system *in vitro*

Independent experiments were performed 5 times with the BAL device. The RPMI-1640 medium flowed through the lumen of the hollow fibers at a rate of 30 mL/min. Samples of the hepatocyte suspension and RPMI-1640 medium were obtained at 2 h intervals during 6 h of circulation. Changes of alanine aminotransferase (ALT), total bilirubin (TB), and albumin (ALB) levels in the circulating hepatocytes and medium were determined with an automatic biochemical analyzer (Hitachi 7600, Japan).

### Determination of functions of BAL system *in vivo*

Independent experiments were performed 8 times with the BAL device. Hemoperfusion was performed from femoral artery to femoral vein through the bioreactor at a rate of 30 mL/min. The ALF model canines were divided into two groups: the BAL treatment group ( $n=8$ ) consisting of canine ALF models was perfused using the above serum-free medium inoculated with porcine hepatocyte spheroids for 6 h, and the control group ( $n=8$ ) consisting of the canine ALF model was perfused using the above serum-free medium without porcine hepatocytes for 6 h.

Blood samples were obtained before (pre-circulation) and after the treatment (post-circulation). Blood ALT and TB were determined with an automatic biochemical analyzer (Hitachi 7600, Japan). Blood ammonia was determined with a biochemical analyzer (DT60II, Johnson and Johnson Medical Ltd., USA).

### Statistical analysis

Results were expressed as mean  $\pm$  SD. Statistical differences were evaluated by analysis of variance (ANOVA).  $P < 0.05$  was considered statistically significant.

## RESULTS

### ALT, TB and ALB levels in hepatocyte suspensions and RPMI-1640 media during circulation

The average viability of the isolated hepatocytes was 97% by trypan blue exclusion. The formation of hepatocyte spheroids was observed after a culture of 20 h. In the hepatocyte suspensions, there were no significant changes of ALT during 6 h of circulation, whereas the TB and

**Table 1** Changes of ALT, TBi and ALB in hepatocyte suspensions and RPMI-1640 media during circulation (mean±SD)

Portion	Time (h)	Biochemical parameters		
		ALT(U/L)	TB(μmol/L)	ALB(g/L)
Hepatocyte suspensions (n=5)	0	13.7±3.5	3.5±2.4	2.8±1.5
	2	15.2±4.5	5.0±1.6 <sup>c</sup>	3.1±1.6
	4	17.9±4.3	6.2±1.8 <sup>c</sup>	3.6±0.9 <sup>c</sup>
	6	18.4±3.2	8.4±2.6 <sup>c</sup>	3.8±1.2 <sup>c</sup>
RPMI1640 media (n=5)	0	0.8±0.2 <sup>a</sup>	0.0±0.0 <sup>c</sup>	0.5±0.1 <sup>a</sup>
	2	1.5±0.5 <sup>a</sup>	4.8±1.3 <sup>c</sup>	1.8±0.3 <sup>ac</sup>
	4	1.3±0.3 <sup>a</sup>	5.7±1.6 <sup>c</sup>	2.5±0.2 <sup>ac</sup>
	6	1.4±1.0 <sup>a</sup>	6.8±2.5 <sup>c</sup>	2.8±0.3 <sup>ac</sup>

<sup>a</sup>*P*<0.05 vs hepatocyte suspensions at the same circulation time, <sup>c</sup>*P*<0.05 vs 0 h.

ALB levels increased gradually (*P*<0.05). The pre-circulation levels of ALT, TB and ALB were lower in the RPMI-1640 media than in hepatocyte suspensions (*P*<0.05). During 6 h of circulation, there was no significant change of ALT, whereas the TB and ALB levels gradually increased (*P*<0.05). At 2, 4, and 6 h of circulation, there were no significant differences of TB levels in RPMI-1640 media and hepatocyte suspensions, but the ALB concentration was lower in RPMI-1640 media than in hepatocyte suspensions at all times (*P*<0.05, Table 1).

#### Changes of biochemical parameters in ALF canines after BAL circulation

The two groups were comparable in terms of body weight (12.6±2.2 kg in BAL group and 13.2±2.1 kg in controls) and biochemical parameters before circulation. The parameters after circulation are shown in Table 2. In the BAL treatment group, blood ALT, TB and ammonia levels significantly decreased from 455.1±225.2 U/L, 74.6±25.4 μmol/L and 131.2±28.3 μmol/L before circulation to 273.3±151.3 U/L, 33.1±11.7 μmol/L and 33.4±21.7 μmol/L after circulation. While in the control group, there were no significant differences in blood ALT, TB and ammonia levels between pre-circulation and post-circulation, though these indices were declined slightly (*P*>0.05). Blood ALT, TB and ammonia levels were lower in BAL group than in control group after circulation (*P*<0.05). The viability of hepatocytes was about 90% at the end of BAL treatment.

#### Survival rate of ALF canines

The survival rates of ALF canines 7 d after treatment were 100% (8/8) and 62.5% (5/8) in BAL group and control group respectively with no significant difference (*P*>0.05).

#### Adverse reaction related to BAL treatment

The ALF canines had no apparent signs of toxicity during and after BAL treatment.

## DISCUSSION

Treatment of ALF is a formidable clinical challenge. Currently, liver transplantation is the most effective therapy. Although advances have been achieved in

transplantation techniques, donor organ shortage remains a serious problem. The mortality of ALF is still high. However, many ALF patients can recover through liver regeneration after short-term liver support, which has prompted the design of an extracorporeal liver support device to “bridge” patients over until they either recover or receive a liver transplant. Among these devices, the BAL system is most promising. Various types of hepatocytes are inserted and different device designs have been proposed [23-25]. The BAL system differs from non-biologic artificial liver devices in the synthesis of essential metabolites and the selective removal of toxic substances, which are carried out by the cultured hepatocytes. An ideal BAL system can provide all the hepatic functions.

In this study, we configured a new BAL system by inoculating porcine hepatocyte spheroids into the cell circuit of a hollow fiber bioreactor and evaluated its functions *in vitro* and *in vivo*.

Nagaki *et al* [26] demonstrated that primary hepatocytes are superior to transformed hepatocytes as a source of biotransformation functions in the BAL system. The BAL system we developed uses viable porcine hepatocytes in the bioreactor to exert liver functions.

Since 10-30% of hepatocytes in the normal human liver are needed to maintain normal hepatic functions [27], Matsura *et al* [28] proposed that a BAL requires 150-450 g of liver. Our BAL device contains 1.0×10<sup>10</sup> hepatocytes to meet the need of patients with ALF. The liver of an adult canine weighs about 335 kg and contains 3.35×10<sup>9</sup> hepatocytes. Therefore, the BAL device could be used in this experiment.

It has been reported that cell-cell interaction has an important role in maintaining the viability and the functions of hepatocytes [29]. In the present study, hepatocytes were incubated in serum-free medium and poly-HEMA-coated bottles by a continuous rotational method in order to restrict their attachment to the wall and promote the formation of hepatocyte spheroids. This method could not only facilitate cell-cell interaction and maintain cell functions, but it also meet the requirement of high-density culture in BA, thus reducing the possibility of immunoreaction by using serum-free medium with hormone and various growth factors [19].

The ideal bioreactor should provide a good environment for growth and metabolism of hepatocytes

as well as the efficient exchange of substances. At present, the most commonly used device is a hollow fiber bioreactor with many small hollow fibers made from semipermeable membranes. The device has two independent compartments that are separated by hollow fiber semipermeable membranes. The intratubular space is used to perfuse blood, while the extratubular space is used to culture hepatocytes. The blood or plasma of patients flows into the bioreactor, exchanging substances with hepatocytes through the semipermeable membranes. The membranes also provide immuno-isolation. In view of the molecular weight of albumin (68 ku), a hollow fiber membrane with 200 nm pore size and a MWCO of 70 ku was chosen for this study. The membrane allows passage of some relatively small molecules such as albumin, but restricts the passage of lymph cells and high molecular weight proteins. Blood-borne toxins and metabolic precursors are free to diffuse across the membrane to hepatocytes where they are metabolized. Metabolic products and detoxified toxins are free to diffuse back across the membrane to the flowing blood. Hepatocytes in the bioreactor also synthesize molecules (proteins, coagulation factors, enzymes, carrier molecules) that pass across the hollow fiber cartridge into blood. Continuous O<sub>2</sub> input could ensure hepatocytes to gain sufficient oxygen. Therefore, our BAL device has such a novelty as it uses hepatocyte spheroids and serum-free medium compared to previously reported BAL<sup>[13-16]</sup>.

Experiments of BAL *in vitro* showed that TB and ALB levels in hepatocyte suspensions and in RPMI-1640 media increased during 6 h of circulation. There were no significant differences of TB levels in RPMI-1640 medium and hepatocytes suspensions after 2 h of circulation. ALB level was lower in RPMI-1640 samples than in hepatocyte suspensions at all periods of circulation. ALB levels in RPMI-1640 medium and hepatocyte suspension averaged 2.8 g/L and 3.8 g/L, respectively, after 6 h of circulation. During the 6 h of circulation, there were no significant changes of ALT levels in RPMI-1640 medium or hepatocyte suspensions. ALT level was lower in RPMI-1640 medium than in hepatocyte suspensions at all time points. Bilirubin and albumin could readily cross the semi-permeable membrane because of their low molecular weights. The results indicate that albumin synthesized by hepatocytes in the BAL system can cross into the circulating stream in the intratubular space of hollow fibers.

In the experiments of BAL *in vivo*, blood ALT, TBI and ammonia levels significantly decreased after 6 h of circulation in the BAL group. There were no significant differences in blood ALT, TB and ammonia between pre-circulation and post-circulation in the control group, though these indices were slightly decreased after circulation. These results suggest that our BAL system has the potential not only to protect against hepatocyte destruction but also to dilute excess ALT in the systemic serum, which is consistent with the previous report<sup>[30]</sup>. The survival rate was higher in BAL group than in control group, but there was no statistical significance, which may be related to the quantity of the samples. The viability of

hepatocytes was about 90% at the end of BAL treatment, indicating that our BAL device has its advantages.

In conclusion, the new BAL system configured in this research has a certain liver support effect and appears to have potential advantages for its clinical use in patients with ALF.

## Abstract

Small bowel adenocarcinomas are remarkable for their rarity, difficult diagnosis and poor prognosis. Here we report an unusual case of a 33-year-old patient in whom infiltrative adenocarcinoma of the small bowel was diagnosed after a 10-year history of Crohn's disease. In most previously reported cases, detection of Crohn's disease was subsequent to that of carcinoma of the small bowel or the patients involved had an even longer history of the disease. Our literature review suggests that the risk of small bowel adenocarcinoma is higher in patients with Crohn's disease than in the overall population. We present details on epidemiology as well as clinical and diagnostic aspects of this rare disease entity.

## INTRODUCTION

The incidence of inflammatory bowel disease (IBD) is increasing since World War II with levels around 6/100 000 for Crohn's disease (CD) and 15 to 20/100 000 for ulcerative colitis, a marked rise in the age group between twenty to forty years for both entities<sup>[1]</sup>.

The ulcerations occur primarily in the small and large intestines, but may appear anywhere in the digestive tract from the mouth to the anus. Common symptoms of CD are abdominal pain, often in the lower right area, and

diarrhoea, but rectal bleeding, weight loss and fever may also appear. Children with CD may suffer stunted growth and delayed development. The severity of the symptoms fluctuates erratically over time. Patients experience flare-ups between intervals of remission or reduced symptoms. The causes of this disease have not been identified yet; but both genetic factors that induce continued abnormal activation of the immune system<sup>[2,3]</sup> and environmental triggers, like *Mycobacterium avium* subspecies *paratuberculosis*<sup>[4]</sup>, are likely to be involved.

Oral or topical preparations of 5-aminosalicylates represent first line therapy, and steroids and azathioprine are used in severe cases; metronidazole and TNF-alpha antibodies are used in fistulating disease. Fifty to seventy percent of Crohn's patients undergo surgery for progression of disease indicated by the presence of fistulas, tumor in the abdomen and development of ileus.

IBD is linked to large and small bowel carcinoma, especially to adenocarcinomas<sup>[5-7]</sup>. In the last twenty years, colorectal cancer has become the fourth most common cancer worldwide, and in Europe colorectal cancer represents the second most frequent cause of death from any cancer in men<sup>[8]</sup>. Even though only about 1% of all colorectal cancers is associated with ulcerative colitis or Crohn's colitis, the risk of colorectal cancer for any ulcerative colitis patient is found to be 2% at 10, 8% at 20 and 18% at 30 years, duration of disease, regardless of disease extent<sup>[9,10]</sup>.

Small bowel carcinomas are uncommon representing only 1% to 5% of all gastrointestinal tract malignancies. The first observations suggested that particularly surgically bypassed bowel segments were exposed to high risk of small bowel adenocarcinoma<sup>[11,12]</sup>. However, the risk of small bowel carcinoma in patients with CD is much higher, being up to 60-fold of that in the general population<sup>[13,14]</sup>.

Neither clear risk factors nor methods for early diagnosis have been established by the few studies on this distinctly uncommon complication within this rare disease. Here we report on a patient in whom infiltrative adenocarcinoma of the ileum was diagnosed after a 10-year history of CD and also discuss possible risk factors, symptoms, feasible diagnostic approaches and treatment options on the basis of published reports.

## CASE REPORT

A 33-year-old man presented in 1992 with recurrent pyrexia and abdominal pain but no diarrhoea. Enteroclysis

was performed and a diagnosis of ileal CD was made. His family history was negative for this disease. For persistent abdominal pain under therapy with 5-aminosalicylates, he was put on corticosteroids (prednisone, 12.5 mg daily). In the following four years the patient experienced repeated episodes of abdominal pain without diarrhoea.

Two years later, an abdominal ultrasound performed for reassessment of the disease, showed a thick intestinal loop from the left to the right upper abdomen. Unfortunately no further diagnostic or therapeutic steps were undertaken at that time.

In 2002, the patient, complaining of increasing abdominal pain, underwent ileocolonoscopy, which yielded no suspicious macroscopic or histopathological findings. Blood tests showed mild anaemia, signs of malabsorption (low proteins, phosphorous and iron deficiency) but none for inflammation. The recommended enteroclysis of the small bowel was not performed. In order to reduce corticosteroids, therapy with azathioprine was initiated (2 mg/kg weight/ per day).

In June 2003 he presented again with abdominal pain, vomiting and distended abdomen. Enteroclysis showed a dilated intestinal loop of the ileum, a pseudotumor in the right abdomen and two stenotic areas, one of which was high-grade and located in the right upper abdomen (Figure 1). Prednisone was increased to 50 mg/day, in addition to metronidazole and ciprofloxacin. Three weeks later, with a deterioration of obstructive symptoms, the patient underwent surgery.

The surgical specimens consisted of a 45 cm and a 7 cm long resected segments. Macroscopic examination showed high-grade inflammatory alteration of the ileum along a 20 cm segment and two upstream high-grade stenoses. The external surface of the diseased segment appeared brownish discoloured with adhering connective tissue. The internal surface of the ileum showed discontinuous mucous membrane, streaks of ulcers and whitened swelling of the bowel wall. Some foci had a 'cobblestone' appearance. The 7 cm long segment had a stenotic 'sandglass' formation.

Extensive histopathological examination in the first stricture revealed a poorly differentiated adenocarcinoma infiltrating the serosa, incipient infiltration of the mesenteric fat and lymphangiosis carcinomatosa as well as a metastatic peritoneal range. Tumor had seeded seven out of eleven lymph nodes examined. The resected specimen also showed adenoma's dysplasia adjacent to the carcinoma. Extended antral metaplastic lesions within agglutinated villi up to one margin were found.

The second specimen revealed proper margins of resection. In the centre of the macroscopic stricture was another focus of the adenocarcinoma. In addition, moderately florid inflammatory infiltrates with acute erosions were detected, compatible with Crohn's disease.

Immunohistochemistry was negative for NSE and chromogranin, only a few tumor cells were slightly positive for synaptophysin. CEA level determined only after surgery was 54.2 ng/ml (normal <50 ng/ml).

The patient recovered well from surgery and then underwent chemotherapy according to Folfox IV-scheme with oxaliplatin, 5-fluorouracil and leucovorin in six cycles.

**Figure 1** Enteroclysis: dilated intestinal loop of the ileum; altered Crohn's area (big arrow), one high grade and one low grade tumor stenosis in the right upper abdomen (two small arrows).

The patient tolerated the therapy quite well.

The computed tomography (CAT-scan) in October 2004 revealed up to two centimetres enlarged mesenteric and up to one centimetre enlarged retroperitoneal lymph nodes, without any further evidence for metastases. In November 2004 the patient presented with headache, vertigo and ambliopia and was diagnosed with meningeosis carcinomatosa. Intrathecal chemotherapy with methotrexate was started. He is now undergoing intrathecal chemotherapy with sustained-released cytarabine.

## DISCUSSION

According to Parkin *et al* the age-standardized incidence of small intestine cancer (ICD-10 C17) ranges from 0.2 to 2.4 for males and from 0.2 to 1.8 for females worldwide<sup>[15]</sup>. The 'Statistik Austria' National Registry has 1384 documented cases of small intestine cancer between 1983-2000<sup>[16]</sup>.

The association of CD with small bowel carcinoma is uncommon and to date only about 130 cases of small bowel carcinomas in patients with CD have been reported in the literature since the first description of this disease entity in 1956<sup>[17]</sup>. Cases and studies published in the last few decades, however, bear out from a 12-fold to an over 60-fold increased risk of small bowel cancer in CD<sup>[13, 14, 18]</sup>. This is in contrast to publications that still emphasize the popular position that CD is primarily associated with carcinoma of the colon. Adenocarcinoma is the most common forms of all small bowel malignancy and there appears to be an increased risk for developing ileal carcinoma in CD patients<sup>[19-23]</sup>.

Most of ileal carcinoma in CD are located in strictures<sup>[11, 24, 25]</sup> and are often incidentally diagnosed postoperatively as in our case report. The occult carcinomas in strictures pose a challenge to diagnostic investigations using conventional modalities such as small bowel series and upper and lower gastrointestinal endoscopy. CT is now considered the imaging modality of choice<sup>[26-28]</sup>, and a fat density target sign in CT<sup>[29]</sup> is also getting greater attention as reliable marker for diagnosing CD or even small bowel carcinoma. Abdominal MRI<sup>[30]</sup>, double-contrast enteroclysis<sup>[31]</sup> and endoscopy<sup>[32]</sup>, especially video wireless capsule endoscopy<sup>[33, 34]</sup>, are promising new diagnostic tools.

Other interesting characteristics are adjacent metapla-

sia, adenoma and epithelial dysplasia<sup>[35-38]</sup>, which underline the importance of further research with respect to sequence-dysplasia in ileal adenocarcinomas in relation to Crohn's disease.

Risk factors for small intestine carcinoma in CD are chronic active course with stricture, fistulas and onset of disease before the age of 30 years<sup>[25,39,40]</sup>. Further reported risk factors are: early onset, age between 30 and 50 years, male sex and smoking<sup>[13,14,41-45]</sup>. Therapy of CD with corticosteroids, azathioprine and TNF-alpha antibodies are also considered as potential risk factors. It has been suggested in previous studies that azathioprine, administered mostly combined with steroids to patients with a long history of Crohn's disease, frequent recurrence or those allergic to 5-aminosalicylates has a carcinogenic potential<sup>[14,46-49]</sup>. In the light of these reports, it is interesting to raise the question whether azathioprine therapy initiated in our patient after normal ileocolonoscopy 18 mo before diagnosis of carcinoma might have contributed to the acceleration of the malignant disease. In contrast to azathioprine, 5-aminosalicylates are considered preventive against the development of large and small bowel adenocarcinoma in inflammatory bowel disease<sup>[13,23,50-53]</sup>. Mesalazine is now used for treating light to moderate Crohn's colitis and ileitis postoperatively to maintain remissions, but its potential to prevent malignancy needs to be evaluated. TNF-alpha antibodies, also mostly combined with immunosuppression, are used in patients with refractory, steroid-dependent and fistulating CD. There is a theoretical risk of increased rate of malignancies due to antagonism of TNF-alpha, but to date there is no clear proof of such an effect<sup>[54-56]</sup>.

Prognosis of small bowel adenocarcinoma is poor, and the mortality at 1 and 2 years ranges from 30-60% dependent on the stage of the cancer<sup>[13,21,57-59]</sup>.

Further prognostic factors are based on histologic findings such as positive surgical margins, poor differentiation, depth of tumor invasion, positive lymph nodes and extramural venous spread in small bowel adenocarcinoma<sup>[60]</sup>.

## CONCLUSION

Small bowel adenocarcinoma in Crohn's disease is rare and preoperative diagnosis continues to present challenges. Long-term prognosis is poor - all the more it is important to be vigilant. Patients with increased risk are those with longstanding complicated CD presenting with a 'de novo' clinical picture of obstruction. Male patients, in particular smokers, are considered to be at increased risk. Since the diagnosis is difficult to make, attending physicians must exercise a high level of clinical suspicion for operative cure. The preventive potential of 5-ASA in adenocarcinoma of the colon suggests that this drug should be preferred to azathioprine in patients to maintain remission.

### Abstract

We present a case of a 72-year-old man with a common bile duct cancer, who was initially believed to have multiple liver metastases based on computed tomography findings, and in whom magnetic resonance cholangiography (MRC) revealed a diagnosis of bile duct hamartomas. At exploration for pancreaticoduodenectomy, liver palpation revealed disseminated nodules at the surface of the liver. These nodules showed gray-white nodular lesions of about 0.5 cm in diameter scattered on the surface of both liver lobes, which were looked like multiple liver metastases from bile duct cancer. Frozen section of the liver biopsy disclosed multiple bile ducts with slightly dilated lumens embedded in the collagenous stroma characteristics of multiple bile duct hamartomas (BDHs). Only two reports have described the MRC features of bile duct hamartomas. Of all imaging procedures, MRC provides the most relevant features for the imaging diagnosis of bile duct hamartomas.

### INTRODUCTION

Multiple bile duct hamartomas (BDHs) are small benign neoplasms of the liver, pathologically containing cystic dilated bile ducts embedded in a fibrous stroma<sup>[1]</sup>. In almost all cases, these patients are believed to have multiple liver metastases following initial imaging<sup>[2]</sup>, and diagnosis of BDHs is frequently not considered until after liver biopsy<sup>[3]</sup>. It is difficult to be certain that all of the lesions identified radiologically, such as ultrasonography (US), computed tomography (CT), are definitely BDHs, necessitating referral for open biopsy to exclude liver metastases. Although the magnetic resonance imaging (MRI) appearance has been reported in 14 cases previously, only two reports have been published for BDHs with illustration of magnetic resonance cholangiography (MRC) features<sup>[3,4]</sup>. In this report, MRC may be useful to allow accurate characterization of the liver lesions, thereby permitting the diagnosis of von Mayenburg complexes to be made with careful analysis of the MRI, and MRC images.

### CASE REPORT

A 72-year-old man was admitted to our hospital in September 2003 with a history of epigastralgia. The physical examination was unremarkable. His serum levels of hepatobiliary enzymes were increased, however, that of total bilirubin (T Bil, 0.7  $\mu\text{mol/L}$ ) and direct bilirubin (D Bil, 0.3  $\mu\text{mol/L}$ ) were normal. Tumor markers, carbohydrate antigen 19-9 (CA19-9) and carcinoembryonic antigen (CEA) were almost within normal range. Ultrasonography showed a dilatation of the common bile duct (CBD) and intrahepatic bile duct. Endoscopic retrograde cholangiography (ERC) showed the irregular stenosis of the lower CBD (1.5 cm in length) and upper part of CBD was dilated. Biopsied specimens from this tumor histologically revealed adenocarcinomas. On the basis of these findings, we diagnosed this tumor as a carcinoma of the CBD. Additionally, multiple, very small and hypodense nodules with ring-like enhancement in both hepatic lobes were found on early phase of enhanced CT (Figure 1).

The lesions were too small to characterize accurately by either modality, but were consistent with disseminated liver metastases. On MRC images (TR 16 000 ms TE 107.8 ms), multiple irregularly delineated hyperintense nodules were seen, not communicating with the biliary tree (Figure 2). These findings suggested the bile duct hamartoma (BDH) (von Mayenburg complexes).

**Figure 1** Contrast-enhanced computed tomography showing multiple, very small and hypodense nodules with ring-like enhancement (0.5 cm in diameter) in both hepatic lobes.

**Figure 3** Intraoperative macroscopic view showing gray-white nodular lesions (about 0.5 cm in diameter) scattered on the surface of the both liver lobes.

**Figure 2** MR cholangiography (TR 16 000 ms TE 107.8 ms) showing multiple irregularly delineated hyperintense nodules, not communicating with the biliary tree.

**Figure 4** Microscopic view of liver biopsy showing multiple bile ducts with slightly dilated lumens embedded in the collagenous stroma (Hematoxylin and eosin, x100).

At exploration for pancreatoduodenectomy, liver palpation revealed disseminated nodules at the surface of the liver. These nodules showed gray-white nodular lesions (about 0.5 cm in diameter) scattered on the surface of the both liver lobes, which were looked like multiple liver metastases from the bile duct cancer (Figure 3). Frozen section of the liver biopsy disclosed multiple bile ducts with slightly dilated lumens embedded in the collagenous stroma characteristics of BDHs with no evidence of malignancy (Figure 4).

## DISCUSSION

On gross pathology, Von Meyenburg complexes of the liver present as gray-white nodular lesions scattered throughout the liver parenchyma, usually measuring between 0.1 and 1.0 cm in diameter<sup>[3]</sup>. In this case, enhanced CT showed low density small nodules with ring-like enhancement, therefore multiple liver metastases were suspected. The major differential diagnoses, especially on frozen section, are intrahepatic cholangiocarcinoma and metastatic adenocarcinoma. The clinical importance of bile duct hamartomas is its ability to mimic metastatic disease of the liver. Chamlou *et al*<sup>[5]</sup> reported that, in the pancreatic cancer patient, the bile duct hamartoma was erroneously confused intraoperatively with hepatic metastasis on frozen sections, and the pancreatoduodenectomy was therefore not performed at the first operation. Because of prevalence of biliary hamartomas, these entities should

be considered as possibilities when liver lesions are noted intraoperatively.

MRI can aid in the differentiation of liver cysts and liver metastases by identifying the hyperintense signal from liver cysts on heavily T2-weighted sequences. To our best of knowledge, only two reports have described the MRC features of BDHs<sup>[3,4]</sup>. MRC can be extremely important in evaluating anomalies of bile ducts. Additionally, it allows differentiation between dilated biliary ducts, saccular dilatation of biliary duct system (Caroli's diseases), and periductal non-communicating cystic lesion, including polycystic disease, bile duct hamartomas and multiple abscess. In previous reports, MRC images showed multiple hyperintense cystic lesions of small diameter scattered in both liver lobes with normal appearance of the intrahepatic and extrahepatic bile ducts. No communication between the hamartomas and the intrahepatic bile ducts was observed. In this case, MRC findings are similar to the previous reports and compatible with BDHs. MRC offers the ability to characterize small liver lesions characteristics of BDH.

## Meetings

### MAJOR MEETINGS COMING UP

Digestive Disease Week  
107th Annual Meeting of AGA, The American  
Gastroenterology Association  
May 20-25, 2006  
Loas Angeles Convernion Center, California  
www.ddw.org

### EVENTS AND MEETINGS IN THE UPCOMING 6 MONTHS

10 th World Congress of the International Society  
for Diseases of the Esophagus (ISDE 2006)  
February 22-25, 2006  
Adelaide  
isde@sapmea.asn.au  
www.isde.net

EASL 2006 - The 41<sup>st</sup> Annual Meeting  
April 26-30, 2006  
Vienna, Austria

International Gastrointestinal Fellows Initiative  
February 22-24, 2006  
Banff, Alberta  
CAGOffice@cag-acg.org

## Instructions to authors

### GENERAL INFORMATION

*World Journal of Gastroenterology* (WJG, *World J Gastroenterol* ISSN 1007-9327 CN 14-1219/R) is a weekly journal of more than 48 000 circulation, published on the 7<sup>th</sup>, 14<sup>th</sup>, 21<sup>st</sup> and 28<sup>th</sup> of every month.

Original Research, Clinical Trials, Reviews, Comments, and Case Reports in esophageal cancer, gastric cancer, colon cancer, liver cancer, viral liver diseases, etc., from all over the world are welcome on the condition that they have not been published previously and have not been submitted simultaneously elsewhere.

**Published by**  
The WJG Press

### SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed double-spaced on A4 (297mm×210 mm) white paper with outer margins of 2.5 cm. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, acknowledgements, References, Tables, Figures and Figure Legends. Neither the editors nor the Publisher is responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press, and may not be reproduced by any means, in whole or in part without the written permission of both the authors and the Publisher. We reserve the right to put onto our website and copy-edit accepted manuscripts. Authors should also follow the guidelines for the care and use of laboratory animals of their institution or national animal welfare committee.

Authors should retain one copy of the text, tables, photographs and illustrations, as rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for the loss or damage to photographs and illustrations in mailing process.

#### Online submission

Online submission is strongly advised. Manuscripts should be submitted through the Online Submission System at: <http://www.wjgnet.com/index.jsp>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (<http://www.wjgnet.com/wjg/help/instructions.jsp>) before attempting to submit online. Authors encountering problems with the Online Submission System may send an email you describing the problem to [wjg@wjgnet.com](mailto:wjg@wjgnet.com) for assistance. If you submit your manuscript online, do not make a postal contribution. A repeated online submission for the same manuscript is strictly prohibited.

#### Postal submission

Send 3 duplicate hard copies of the full-text manuscript typed double-spaced on A4(297 mm×210 mm) white paper together with any original photographs or illustrations and a 3.5 inch computer diskette or CD-ROM containing an electronic copy of the manuscript including all the figures, graphs and tables in native Microsoft Word format or \*.rtf format to:

#### Editorial Office

**World Journal of Gastroenterology**  
Editorial Department: Apartment 1066, Yishou Garden,  
58 North Langxinzhuang Road,  
PO Box 2345, Beijing 100023, China  
E-mail: [wjg@wjgnet.com](mailto:wjg@wjgnet.com)  
<http://www.wjgnet.com>

### MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using a word-processing software. All submissions must be typed in 1.5 line spacing and in word size 12 with ample margins. The letter font is Tahoma. For authors from China, one copy of the Chinese translation of the manuscript is also required (excluding references). Style should conform to our house format. Required information for each of the manuscript sections is as follows:

#### Title page

Full manuscript title, running title, all author(s) name(s), affiliations, institution(s) and/or department(s) where the work was accomplished, disclosure of any financial support for the research, and the name, full

address, telephone and fax numbers and email address of the corresponding author should be included. Titles should be concise and informative (removing all unnecessary words), emphasize what is new, and avoid abbreviations. A short running title of less than 40 letters should be provided. List the author(s)' name(s) as follows: initial and/or first name, middle name or initial(s) and full family name.

#### Abstract

An informative, structured abstract of no more than 250 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections: AIM: Only the purpose should be included. METHODS: The materials, techniques, instruments and equipments, and the experimental procedures should be included. RESULTS: The observatory and experimental results, including data, effects, outcome, etc. should be included. Authors should present *P* value where necessary, and the significant data should accompany. CONCLUSION: Accurate view and the value of the results should be included.

The format of structured abstracts is at: <http://www.wjgnet.com/wjg/help/11.doc>

#### Key words

Please list 3-10 key words that could reflect content of the study mainly from *Index Medicus*.

#### Text

For most article types, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include in appropriate Figures and Tables. Data should be presented in the body text or in Figures and Tables, but not in both.

#### Illustrations

Figures should be numbered as 1, 2, 3 and so on, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. No detailed legend should be involved under the figures. This part should be added into the text where the figures are applicable. Digital images: black and white photographs should be scanned and saved in TIFF format at a resolution of 300 dpi; color images should be saved as CMYK (print files) but not as RGB (screen-viewing files). Place each photograph in a separate file. Print images: supply images of size no smaller than 126 mm×76 mm printed on smooth surface paper; label the image by writing the Figure number and orientation using an arrow. Photomicrographs: indicate the original magnification and stain in the legend. Digital Drawings: supply files in EPS if created by freehand and illustrator, or TIFF from photoshops. EPS files must be accompanied by a version in native file format for editing purposes. Existing line drawings should be scanned at a resolution of 1200 dpi and as close as possible to the size where they will appear when printed. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes of atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ...

#### Tables

Three-line tables should be numbered as 1, 2, 3 and so on, and mentioned clearly in the main text. Provide a brief title for each table. No detailed legend should be included under the tables. This part should be added into the text where the tables are applicable. The information should complement but not duplicate that contained in the text. Use one horizontal line under the title, a second under the column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

#### Notes in tables and illustrations

Data that are not statistically significant should not be noted. <sup>a</sup>*P*<0.05, <sup>b</sup>*P*<0.01 should be noted (*P*>0.05 should not be noted). If there are other series of *P* values, <sup>c</sup>*P*<0.05 and <sup>d</sup>*P*<0.01 are used. Third series of *P* values can be expressed as <sup>e</sup>*P*<0.05 and <sup>f</sup>*P*<0.01. Other notes in tables or under illustrations should be expressed as <sup>1</sup>*F*, <sup>2</sup>*F*, <sup>3</sup>*F*; or some other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, etc. in a certain sequence.

#### Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscripts and who endorse the data and conclusions are included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

## REFERENCES

### Coding system

The author should code the references according the citation order in text in Arabic numerals, put references codes in square brackets, superscript it at the end of citation content or the author name of the citation. For those citation content as the narrate part, the coding number and square brackets should be typeset normally. For example, Crohn's disease (CD) is associated with increased intestinal permeability<sup>[1,2]</sup>. If references are directly cited in the text, they would be put together with the text, for example, from references [19,22-24], we know that...

When the authors code the references, please ensure that the order in text is the same as in reference part and also insure the spelling accuracy of the first author's name. Do not code the same citation twice.

### PMID requirement

PMID roots in the abstract serial number indexed by PubMed (<http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=PubMed>). The author should supply the PMID for journal citation. For those references that have not been indexed by PubMed, a printed copy of the first page of the full reference should be submitted.

The accuracy of the information of the journal citations is very important. Through reference testing system (<http://www.aushome.cn/cgi-bin/index.pl>), the authors and editor could check the authors name, title, journal title, publication date, volume number, start page, and end page. We will interlink all references with PubMed in ASP file so that the readers can read the abstract of the citations online immediately.

### Style for journal references

Authors: the first author should be typed in bold-faced letter. The surname of all authors should be typed with the initial letter capitalized and followed by their name in abbreviation (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). Title of the cited article and italicized journal title (Journal title should be in its abbreviation form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634]

Note: The author should test the references through reference testing system (<http://www.aushome.cn/cgi-bin/index.pl>)

### Style for book references

Authors: the first author should be typed in bold-faced letter. The surname of all authors should be typed with the initial letter capitalized and followed by their name in abbreviation (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

### Format

Standard journal article (list all authors and include the PubMed ID [PMID] where applicable)

- 1 **Das KM**, Farag SA. Current medical therapy of inflammatory bowel disease. *World J Gastroenterol* 2000; 6: 483-489 [PMID: 11819634]
- 2 **Pan BR**, Hodgson HJF, Kalsi J. Hyperglobulinemia in chronic liver disease: Relationships between *in vitro* immunoglobulin synthesis, short lived suppressor cell activity and serum immunoglobulin levels. *Clin Exp Immunol* 1984; 55: 546-551 [PMID: 6231144]
- 3 **Lin GZ**, Wang XZ, Wang P, Lin J, Yang FD. Immunologic effect of Jianpi Yishen decoction in treatment of Pixu-diarrhoea. *Shijie Huaren Xiaobua Zazhi* 1999; 7: 285-287

Books and other monographs (list all authors)

- 4 **Sherlock S**, Dooley J. Diseases of the liver and billiary system. 9th ed. Oxford: Blackwell Sci Pub, 1993: 258-296

Chapter in a book (list all authors)

- 5 **Lam SK**. Academic investigator's perspectives of medical treatment for peptic ulcer. In: Swabb EA, Azabo S. Ulcer disease: investigation and basis for therapy. New York: Marcel Dekker, 1991: 431-450

Electronic journal (list all authors)

- 6 **Morse SS**. Factors in the emergence of infectious diseases. *Emerg Infect Dis* serial online, 1995-01-03, cited 1996-06-05; 1(1):24 screens. Available from: URL: <http://www.cdc.gov/ncidod/EID/eid.htm>

### Inappropriate references

Authors should always cite references that are relevant to their article, and avoid any inappropriate references. Inappropriate references include those that are linked with a hyphen and the difference between the two numbers at two sides of the hyphen is more than 5. For example, [1-6], [2-14] and [1, 3, 4-10, 22] are all considered as inappropriate references. Authors should not cite their own unrelated published articles.

### Statistical data

Present as mean  $\pm$  SD and mean  $\pm$  SE.

### Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as  $\chi^2$  (in Greek), related coefficient as *r* (in italics), degree of freedom as  $\gamma$  (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

### Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose) 6.4  $\pm$  2.1 mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6 24.5  $\mu$ g/L; CO<sub>2</sub> volume fraction, 50 mL/L CO<sub>2</sub> not 5% CO<sub>2</sub>; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format about how to accurately write common units and quantum is at: <http://www.wjgnet.com/wjg/help/15.doc>

### Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further mention.

### Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindII*, *BamHI*, *Kho I*, *Kpn I*, etc.

Biology: *Helicobacter pylori*, *H pylori*, *E coli*, etc.

## SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. Author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, the final check list for authors, and responses to reviewers by a courier (such as EMS) (submission of revised manuscript by e-mail or on the *WJG* Editorial Office Online System is NOT available at present).

### Language evaluation

The language of a manuscript will be graded before sending for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing; (4) Grade D: rejected. The revised articles should be in grade B or grade A.

### Copyright assignment form

It is the policy of *WJG* to acquire copyright in all contributions. Papers accepted for publication become the copyright of *WJG* and authors will be asked to sign a transfer of copyright form. All authors must read and agree to the conditions outlined in the Copyright Assignment Form (which can be downloaded from <http://www.wjgnet.com/wjg/help/9.doc>).

### Final check list for authors

The format is at: <http://www.wjgnet.com/wjg/help/13.doc>

### Responses to reviewers

Please revise your article according to the comments/suggestions of reviewers. The format for responses to the reviewers' comments is at: <http://www.wjgnet.com/wjg/help/10.doc>

### Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

### Publication fee

Authors of accepted articles must pay publication fee.

EDITORIAL and LETTERS TO THE EDITOR are free of charge.

## World Journal of Gastroenterology standard of quantities and units

Number	Nonstandard	Standard	Notice
1	4 days	4 d	In figures, tables and numerical narration
2	4 days	four days	In text narration
3	day	d	After Arabic numerals
4	Four d	Four days	At the beginning of a sentence
5	2 hours	2 h	After Arabic numerals

### Abstract

**AIM:** To determine the performance of novice readers (4<sup>th</sup> year medical students) for detecting capsule endoscopy findings.

**METHODS:** Ten capsule endoscopy cases of small bowel lesions were administered to the readers. Gold standard findings were pre-defined by gastroenterologists. Ten gold standard "targets" were identified among the 10 cases. Readers were given a 30-min overview of Rapid Reader software and instructed to mark any potential areas of abnormalities. A software program was developed using SAS to analyze the thumbnail findings.

**RESULTS:** The overall sensitivity for detecting the gold standard findings was 80%. As a group, at least 5 out of 10 readers detected each gold standard finding per recording. All the gold standard targets were identified when the readers' results were combined. Incidental finding/false positive rate ranged between 8.2-59.8 per reader.

**CONCLUSION:** A panel of medical students with minimal endoscopic experience can achieve high

sensitivity in detecting lesions on capsule endoscopy. A group of novice readers can pre-screen recordings to thumbnail potential areas of small bowel lesions for further review. These thumbnails must be reviewed to determine the clinical relevance. Further studies are ongoing to assess other cohorts.

### INTRODUCTION

Capsule endoscopy is a new diagnostic procedure developed for the complete examination of the small intestine through video images transmitted from an ingestible camera<sup>[1-3]</sup>. Briefly, the PillCam<sup>TM</sup> capsule endoscopy and diagnostic imaging system (GIVEN Imaging, Yoqneam, Israel) is a commercially available system consisting of three major components: PillCam<sup>TM</sup> capsule which captures images and transmits digital pictures (at 2 frames/s) over an 8-h period, sensor array and data recorder, which receives and records the data transmitted from the PillCam<sup>TM</sup> capsule and RAPID<sup>TM</sup> Workstation, which is used to initialize the data recorder and to download and process the raw data from the data recorder<sup>[4,5]</sup>. The processed information, composed of approximately 50 000 still images collected over an 8-h period, can be reviewed as a continuous video stream. The reported time range typically needed for a complete review of a single capsule endoscopy recording case is anywhere from 50<sup>[6,7]</sup> to 120 min<sup>[8]</sup>.

Numerous studies have now demonstrated that the sensitivity and specificity of capsule endoscopy are advantageous over the traditional diagnostic methods of small bowel lesions<sup>[5-7,9-11]</sup>. Capsule endoscopy may also reduce total medical utilization and costs as well as improve patient's quality of life in certain circumstances<sup>[12]</sup>.

One feature that can affect the diagnostic yield of capsule endoscopy is the image analysis process, i.e. the ability of the person reviewing the images (reader) to accurately detect significant lesions and interpret the findings. This process is time consuming and requires individuals to focus their undivided attention viewing the large number of images.

Currently, the process of capsule endoscopy image analysis has not been standardized with respect to the selection and training of individual readers, determination of the gold standard to which findings are compared to assess sensitivity and false positive rates or reporting of findings and diagnoses. Unfortunately, these important issues have not been well studied previously. Studies of inter-observer variability have been limited to anecdotal reports between 1 and 4 different readers<sup>[13-20,23,24]</sup>. Furthermore, since capsule endoscopy image analysis is a time consuming process, the arduous process of image recognition and analysis is often delegated to individuals having received minimal pre-training with little consideration of their ability to achieve competency in reading capsule endoscopy recordings. A survey was conducted at the 2003 Given International Capsule Endoscopy Conference and found that 82% of gastroenterologists reported that they are the first readers to interpret the capsule endoscopy recordings, while 18% use a resident physician assistant and/or nurse to interpret the capsule endoscopy recordings first<sup>[21]</sup>.

In this clinical study, our aim was to determine the sensitivity, incidental finding and/or false positive rate, and intraclass correlation of novice capsule endoscopy readers who were 4<sup>th</sup> year US medical students with minimal endoscopic background for detecting pre-specified capsule endoscopy findings. Previous studies have shown that it is not a simple task to achieve 100% sensitivity on capsule endoscopy recording<sup>[13-20]</sup>. In addition, it was reported that since the pathology is visualized in more than a small percentage of images from each capsule endoscopy recording, a fatigue gastroenterologist may analyze the capsule endoscopy recording at a very rapid speed, being likely to miss lesions<sup>[14]</sup>. Hence, we propose that analysis of the same capsule endoscopy recording by multiple readers might be an effective method to achieve 100% sensitivity and decrease medical errors. If the combined results of the novice readers show a high sensitivity, then perhaps novice readers can be considered as physician extenders in analyzing capsule endoscopy recordings. In our study, instead of manually analyzing the capsule endoscopy readers' results, we used statistical software to perform the analysis in an attempt to decrease the time required for this process. The reason is that manual comparison of the readers' findings can be labor intensive and time consuming, if a large number of readers are evaluated. Finally, the method of using medical students as novice readers to analyze the images of a diagnostic modality has been described in the literature<sup>[25]</sup>.

## MATERIALS AND METHODS

### *Capsule endoscopy recordings*

Ten recordings with definitive sites of small bowel lesions were administered to the readers in a pre-set order

(lesions - AVM-3, small bowel tumor - 1, radiation enteritis - 1, ulcers/aphthous lesions - 3, and foreign body with ulceration - 2). Two gastroenterologists (attending physicians at the tertiary medical center) selected these 10 recordings.

### *Capsule endoscopy readers*

The novice capsule endoscopy readers consisted of a group of ten 4<sup>th</sup> year medical students with minimal endoscopic background from David Geffen School of Medicine at UCLA (Los Angeles, CA, USA). All the participating medical students signed an informed consent agreement as approved by the local institutional review board.

The readers were blinded to the patients' clinical history because this study was to assess the readers' abilities to detect small bowel lesions on capsule endoscopy recordings rather than to test their medical knowledge. Furthermore, the readers were blinded to each other's capsule endoscopy findings.

### *Gold standard*

The gold standard for the true positive findings was pre-defined by the two gastroenterologists (over 150 capsule endoscopy cases each at the time when this study was started) who independently reviewed all the available data for each of the 10 recordings, including pertinent medical history; previous endoscopic, radiologic and surgical examinations; the complete 8-h capsule endoscopy recording. The experts' consensus of positive findings was used to calculate the sensitivity and false positive measures for each individual reader as defined below. Ten gold standard "targets" were identified among the 10 cases. We did not include any negative findings in this study because our aim was to evaluate the readers' ability to detect positive findings. However, the readers did not know that there was at least one gold standard finding per case.

### *Capsule endoscopy image analysis*

Each reader reviewed the entire 8-h recordings for all 10 cases to localize the thumbnailled significant lesions within the small intestine. Significant upper and lower gastrointestinal lesions could be detected by capsule endoscopy, but the lesions of esophagus, stomach, and colon were not analyzed. Presumably, lesions in these areas were detected during routine endoscopic evaluation.

The readers analyzed the 10 recordings in a consecutive order over a 30-90 d period. They were also asked to record how long it took for them to interpret each case and were told to use a cautious and highly inclusive approach, while interpreting the capsule endoscopy recordings in order to minimize the chance of missing any clinically significant lesions. All findings identified by each reader were marked, thumbnailled and annotated using the Rapid Reader software program (GIVEN Imaging, Yoqneam, Israel). The readers were given a 30-min overview of the Rapid Reader software and instructions for thumbnailling. Active gastrointestinal bleeding was often detected by the Suspected Blood Indicator program (two capsule endoscopy cases we used had active gastrointestinal bleeding lesions); however, we did not allow the readers to

Table 1 Gold standard findings and time intervals

Location	Case	Time intervals	Findings
1	1	22 500–32 900	Aphthous ulceration (from NSAIDS use)
2	2	4 542–6 842	Aphthous ulceration (from NSAIDS use)
3	3	16 144–16 157	Duodenal bleeding (AVM)
4	4	25 302–25 372	Staples and ulcerations (from prior Surgery)
5	5	24 244–24 700	Small bowel tumor
6	6	23 596–23 692	Aphthous ulceration (from Crohn's disease)
7	7	32 657–50 000	Radiation enteritis
8	8	20 000–26 000	Chicken bone
9	9	1350–2434	Bleeding angiodysplasia
10	10	12 600–12 800	Bleeding angiodysplasia

use the Suspected Blood Indicator program on the Rapid Reader, since we wanted to assess the readers' true abilities to detect the lesions on capsule endoscopy recordings. Furthermore, we felt that active bleeding lesions on the capsule endoscopy recordings should be easily and consistently detectable by the readers.

### Outcome accuracy measures and analysis

The percentage of cases where a reader had at least one finding in the gold standard areas of a case was expressed as the reader's sensitivity. If a reader had a finding outside the gold standard time interval, it was considered an incidental finding/false positive rate.

The time series for each case was divided into time intervals using the PROC MIXED procedure in SAS (SAS Institute Inc., Cary, NC, USA). Within each time interval, it was noted whether or not each reader had at least one finding. For a given time interval size, a time interval could be designated as being in a true problem area (part of the time interval was in the "gold standard" area for that case) or not. Each time interval could also be designated as having a "finding" or not, where the "finding" was yes if  $X/10$  readers had a finding in that time interval.  $X$  was the reader's threshold. Reader's threshold was defined as the minimum number of readers out of all the readers who had to have a finding in a given time interval in order to consider it as a true positive finding (namely a true problem area). The clinical implication of the optimal time interval size and reader's threshold analyses was that this method could inform the capsule endoscopy readers, where the time series and the thumbnailed findings occurred the most. Therefore, the readers would know to which parts of the capsule endoscopy recording they needed to pay extra attention during the image analysis and review process. This is especially important and perhaps shortens the time needed for the gastroenterologists reviewing the thumbnailed findings of the screeners (in this case, the novice readers).

There were a total of 128 time interval size/reader's threshold combinations per case. In each of these time interval size/reader's threshold combinations, sensitivity and specificity were estimated for each case. Sensitivity was estimated as the probability of a finding, given the finding being in a region with a true finding (in the "gold standard" region), while specificity was estimated as the prob-

ability of no finding, given that the finding was not in an incidental/false positive region. Among the time interval size/reader's threshold combinations with 100% sensitivity, we calculated the incidental finding/false positive rate (the number of time intervals with a finding outside the gold standard area divided by the total number of time intervals outside the gold standard area) and the standardized number of minutes viewing incidental finding/false positive time intervals (the incidental finding/false positive rate multiplied by the average number of true negative time intervals for that reader's threshold/time interval size, multiplied by the time interval size in minutes). For each of these quantities, we calculated the average and the maximum value across all 10 capsule endoscopy cases. Separate analyses were conducted using different time interval sizes, which ranged in length from 20 to 25 000 s, in order to determine the impact of time interval size on the results.

Intraclass correlation was assessed separately for each case. The intraclass correlation among all 10 readers measured the agreement among the readers in their evaluation of capsule endoscopy recordings, above the agreement was expected by chance. The intraclass correlation coefficient was estimated for each time interval size and for each capsule endoscopy recording.

## RESULTS

Based on the gold standard findings, 10 targets were specified in the 10 recordings used in this study (Table 1). The average time taken by the readers to interpret each case was 118 min. The overall sensitivity among the 10 readers was 0.80 (80%) for time interval size of 20 s. All findings were detected in 6 out of 10 readers. On a case level, the gold standard finding was identified by all the 10 readers in case #2 but only 5 readers for case #6. The individual reader sensitivity ranged between 60–100%, with reader #8 achieving 100% sensitivity, while reader #5 achieving only 60% sensitivity (Table 2). The readers were able to identify all the gastric, duodenal, and cecal images accurately. The number of incidental false positive finding ranged from a minimum of 8.2 in reader #1 to a maximum of 59.8 in reader #10 per recording (Table 3). By case, the number of incidental false positive findings ranged from 12 in case #9 to 40.1 in case #5. Intraclass correlation varied with case, but seemed to increase with increased time interval size. The overall intraclass correlation was  $<0.40$  but cases #2 and #9, being low compared to fair agreement (Figure 1).

In the time interval size and reader's threshold analyses, the minimum time interval size for which sensitivity in all 10 recordings achieved 100% was 3 000 s. All possible reader thresholds achieved 100% sensitivity for all 10 recordings in at least one of the time interval sizes examined. The average percentage of incidental false positive findings in the 10 cases ranged from 28% with a reader's threshold of 7 and time interval of 5 000 s to 66% with a reader's threshold of 3 and a time interval of 10 000 s (Figure 2A). The maximum percentage of the incidental false positive findings in the 10 recordings ranged from 56% for time interval of 5 000 s and reader's threshold of 7–100% for several combinations (Figure 2B).

Overall, in the optimal time interval size and reader's threshold

Figure 1 Inter-reader concordance analyzed separately by case.

analyses, the combination of 5 000 s and reader's threshold of 7/10 was the most optimal. This combination resulted in a reader's sensitivity of 100%, a low average incidental finding/false positive percentage and a low number of minutes viewing incidental finding/false positive time

interval video images. However, while this time interval was still relatively large (83 min), smaller time interval sizes had higher rates of errors and/or failed to yield 100% sensitivity.

## DISCUSSION

Capsule endoscopy is a newly developed diagnostic modality that allows visualization of the entire small intestine. However, the process of selecting, training, and validating an individual's ability to accurately perform capsule endoscopy image analysis has not been well studied. Therefore, we performed a systemic study to compare and validate the capsule endoscopy readers' performance on capsule endoscopy image analysis. The goal of our study was to determine the sensitivity and incidental finding/false positive rate as well as the intraclass correlation of novice readers and to determine if the concept of analyzing the same capsule endoscopy recording by multiple novice readers was an effective and accurate approach for capsule endoscopy image interpretation.

We hypothesized that novice readers could reliably

**Figure 2** Average (A) and maximum (B) incidental finding/false positive rate across 10 cases by reader's threshold and time interval size.

detect small bowel lesions with a high sensitivity and a large number of incidental/false positive findings. In our study, each reader made a moderate number of incidental or false positive findings per recording. The following factors can help explain the moderate number of incidental or false positive findings: 1) the novice readers were asked to perform the capsule endoscopy analysis in a detailed, thorough and highly cautious fashion in an attempt to minimize the possibility of missing small bowel lesions; 2) the readers were untrained in interpreting capsule endoscopy images; 3) the “lodging” of capsule around the same spot in the small bowel caused some of the readers to thumbnail the same lesion several times; and 4) some of the incidental or false positive findings were small lesions, such as focal petechiae, areas of erythema or “mucosal breaks” with their clinical significance being still debatable.

We found that novice readers with minimal endoscopic experience were able to detect lesions on capsule endoscopy with a moderate-to-high sensitivity. Though the majority of the readers were unable to achieve 100% individual sensitivity, if we view the results by this panel of novice readers as a whole, every single gold standard target was detected. Therefore, perhaps the concept of analyzing the same capsule endoscopy recording by multiple novice readers may be an alternative yet effective and accurate method to interpret the capsule endoscopy images. This alternative approach might decrease the risk of having any lesions undetected by a single reader.

Inter-observer variability in analyzing capsule endoscopy recordings has been studied by Levinthal *et al.*<sup>[14]</sup>. The combined sensitivity of the group of novice readers from our study is comparable with the result achieved by Levinthal *et al.*<sup>[14]</sup>. In another published series, inter-observer variability was evaluated by comparing the interpretation results on 20 capsule endoscopy cases of an attending gastroenterologist and a 4<sup>th</sup> year therapeutic endoscopy student who has reviewed 15 capsule endoscopy cases prior to the participation of this study<sup>[15]</sup>. The authors found that there is a complete agreement between the two readers in 18/20 cases. Nonetheless, this

study only compared the clinically significant findings and did not report the number of incidental/false positive findings.

However, studies on inter-observer variability on capsule endoscopy interpretation are mostly documented in abstract forms. Hoffman *et al.*<sup>[16]</sup> showed that physician extenders could save gastroenterologists' time in capsule endoscopy interpretation.

Analyzing capsule endoscopy recordings requires a significant time commitment from the gastroenterologist. As a result, a few studies have investigated the potential of using physician extenders to serve as screeners for interpreting capsule endoscopy images. The results from our study showed that novice readers could achieve a high sensitivity in capsule endoscopy analysis when their results were combined as a group. Therefore, to analyze the same capsule endoscopy recordings by multiple novice readers may be the most effective and accurate method for detecting all significant lesions on capsule endoscopy. This is especially important because some lesions may appear in a single frame and could be easily missed by a single reader. An analogy to this method is the airport luggage screening process, in which the luggage is screened through the X-ray/CT scanners, whereby the television screen is monitored by “highly trained” individuals who detect the “high risk items” (analogous to lesions). Suspicious bags are subsequently re-X-rayed and screened by several individuals and then high-risk items are manually inspected (analogous to endoscopy, push enteroscopy or surgical investigation).

Our study is the first systematic study to date addressing the issues of inter-observer variability in capsule endoscopy image analysis by a large group (>4 individuals) of readers. The most important clinical conclusion of our study is that a panel of novice readers with minimal endoscopic experience can detect small bowel lesions on capsule endoscopy recordings and pre-screen recordings to thumbnail potential abnormalities with a high sensitivity, allowing the gastroenterologists to review only the thumbnailed potential abnormalities. This concept serves as an alternative method to those proposed

in the previous studies (i.e. using gastroenterology students or endoscopy nurses). Furthermore, perhaps the most effective way to accurately detect all abnormalities on capsule endoscopy recordings is to analyze the same capsule endoscopy case by a number of readers. This approach to capsule endoscopy image analysis may decrease the number of medical errors. Our results suggest once again that physician extenders can serve as screeners for interpreting capsule endoscopy images and save a significant amount of time of the gastroenterologists and make capsule endoscopy more cost-effective and attractive to practising gastroenterologists. However, due to the moderate number of incidental/false positive findings, gastroenterologists must review these thumbnails to determine the clinical relevance of each finding. Future studies should also estimate the amount of time that gastroenterologists have to spend on the assessment of all the incidental and false positive findings by the physician extenders. Additional studies are ongoing to assess other reader cohorts' (endoscopy nurses, gastroenterology students, medical residents, non-medical personnel) abilities to detect abnormalities on capsule endoscopy before physician extenders begin to screen capsule endoscopy in everyday clinical practise.

### Abstract

**AIM:** To investigate the prevalence and clinical significance of "anti-HBc alone" in an unselected population of patients and employees of a university hospital in southern Germany.

**METHODS:** All individuals with the pattern "anti-HBc alone" were registered over a time span of 82 mo. HBV-DNA was measured in serum and liver samples, and clinical charts were reviewed.

**RESULTS:** Five hundred and fifty two individuals were "anti-HBc alone" (of 3004 anti-HBc positive individuals; 18.4%), and this pattern affected males (20.5%) more often than females (15.3%;  $P < 0.001$ ). HBV-DNA was detected in serum of 44 of 545 "anti-HBc alone" individuals (8.1%), and in paraffin embedded liver tissue in 16 of 39 patients tested (41.0%). There was no association between the detection of HBV genomes and the presence of biochemical, ultrasonic or histological signs of liver damage. Thirty-eight "anti-HBc alone" patients with cirrhosis or primary liver carcinoma had at least one additional risk factor. HCV-coinfection was present in 20.4% of all individuals with "anti-HBc alone" and was the only factor associated with a worse clinical outcome.

**CONCLUSION:** In an HBV low prevalence area, no evidence is found that HBV alone causes severe liver damage in individuals with "anti-HBc alone". Recommendations for the management of these individuals are given.

### INTRODUCTION

Antibodies to hepatitis B virus (HBV) core antigen (anti-HBc) are the most important marker of HBV infection. They are present when symptoms of hepatitis first appear and usually persist for life, irrespective if the infection resolves or remains chronic. Complete recovery from acute and chronic hepatitis B is associated with the loss of HBV surface antigen (HBsAg) and appearance of HBsAg-specific antibodies (anti-HBs) in serum. Thus, anti-HBc is usually accompanied by HBsAg or anti-HBs. However, the detection of "anti-HBc alone" (as the only marker of HBV infection) is not an infrequent serological pattern. In areas with low HBV prevalence (most parts of Europe and the United States) "anti-HBc alone" is found in 10-20% of all individuals with HBV markers, according to 1-4% of the general population<sup>[1,2]</sup>. This pattern poses problems because it provides no exact diagnosis. It is seen in acute infections, in the interval between the loss of HBsAg and the appearance of anti-HBs, as well as in chronic and past infections. Some individuals with "anti-HBc alone" carry HBV in their serum, their proportion varies greatly between 0.2% in blood donors and 47% in iv drug abusers<sup>[1]</sup>.

The clinical significance of "anti-HBc alone" is greatly unknown. Longitudinal studies to explore the long-term clinical outcome are hardly practicable. We therefore investigated all individuals found positive for "anti-HBc alone" in our diagnostic laboratory over a period of 82 mo in regard to their virological and clinical findings.

### MATERIALS AND METHODS

#### Study design

From July 1996 through April 2003, all individuals were registered whose sera tested reactive for anti-HBc and negative for HBsAg and anti-HBs for the first time. Our laboratory routinely received samples from patients and employees of a University hospital in Southern Germany.

Table 1 Distribution of HBV, HCV and HIV markers (tested with AxSYM™) in all individuals referred to the laboratory

	HBsAg neg anti-HBs neg	Anti-HBc pos HBsAg pos Anti-HBs neg	HBsAg neg anti-HBs pos	Anti-HBc neg
Study period		82 mo (6/96-4/03)		12 mo (1/03-12/03)
<i>n</i> (% of anti-HBc pos)	552 (18.4 %)	412 (13.7 %)	2040 (67.9 %)	4398
Male/female (ratio)	370/180 (2.06 : 1)	251/145 (1.73 : 1)	1185/851 (1.39 : 1)	2631/1766 (1.49 : 1)
Age (yr; mean±SD)	58.5±16.5	42.8±17.4	57.4±16.7	50.4±19.6
Anti-HCV pos/ <i>n</i> tested (%)	112/550 (20.36 %)	20/323 (6.19 %)	144/1983 (7.26 %)	95/4285 (2.22 %)
Anti-HIV pos/ <i>n</i> tested (%)	17/540 (3.15 %)	8/206 (3.88 %)	23/1571 (1.46 %)	7/3768 (0.19 %)

Totally 552 individuals ( $\geq 12$  mo of age) with reactivity to “anti-HBc alone” were included in a database, and results of previous or follow-up testing for HBV markers were added when available for the study period. Clinical charts were reviewed to collect data about the medical history and clinical status of each individual.

### Serological test

HBsAg, anti-HBs, anti-HBc, and anti-HBe were tested with microparticle enzyme immunoassays (AxSYM HBsAg™, AxSYM AUSAB™, AxSYM CORE™, AxSYM Anti-HBe™; Abbott Laboratories, Abbott Park, IL). Reactivity to “anti-HBc alone” (HBsAg and anti-HBs negative) was confirmed with a second microparticle enzyme immunoassay (IMx Core, Abbott, Delkenheim, Germany). When the new chemiluminescent microparticle immunoassay ARCHITECT anti-HBc™ (Abbott Laboratories, Abbott Park, IL) became available, all newly identified “anti-HBc alone” patients were additionally tested with this assay if there was enough serum available ( $n=113$ ).

Antibodies against HCV and HIV were measured with microparticle enzyme immunoassays (AXSYM HCV™, AXSYM HIV-1/ HIV-2™; Abbott Laboratories, Abbott Park, IL). Positive test results were confirmed with Western blot assays Abbott MATRIX HCV 2.0 (Abbott Diagnostics, Wiesbaden-Dielkenheim, Germany) and NEW LAV BLOT I and II (BIORAD Laboratories, Munich, Germany), respectively.

### PCR assays

HBV-DNA was isolated from serum with the QIAmp™ blood kit (Qiagen, Hilden, Germany). Paraffin embedded liver tissue was available for 39 patients from liver biopsies (hepatitis C,  $n=16$ ; cirrhosis of the liver,  $n=5$ ; liver abscess,  $n=2$ ; deteriorating liver function after gastric perforation,  $n=1$ ) or from liver surgery (liver transplantation for HCV associated cirrhosis,  $n=4$ ; liver transplantation for alcohol associated cirrhosis,  $n=3$ ; hepatocellular carcinoma,  $n=4$ ; liver metastases,  $n=2$ ; thrombosis of the portal vein,  $n=1$ ; planned organ donation after brain death due to cerebral hemorrhage,  $n=1$ ). Five to ten 5- $\mu$ m sections were deparaffined as described before<sup>[3]</sup> and DNA was prepared using the QIAmp™ blood and tissue kit (Qiagen, Hilden, Germany). HBV-DNA was quantitatively measured using a kinetic fluorescence detection system (TaqMan PCR)<sup>[4]</sup>. The lower detection limit of this assay was 50-100 genomic copies per mL.

Figure 1 Distribution of HBV markers in 2986 anti-HBc positive individuals of different age groups, all referred to one virological laboratory over a period of 82 mo.

HCV-RNA in serum was detected using the Cobas AmpliCor 2, 0 (Roche Diagnostics, GmbH, Mannheim, Germany).

### Statistical analysis

The SPSS program package version 10.0 (SPSS Inc., Chicago, IL) was utilized to perform Fisher's exact test,  $\chi^2$  test and *t*-test. The significance level was set at 5%, all *P*s resulted from two-sided tests.

## RESULTS

### HBV serology

From July 1996 through April 2003, 3004 individuals tested positive for anti-HBc (Table 1) and 552 showed reactivity to “anti-HBc alone” (18.4%). “Anti-HBc alone” was seen more often in males (370/1806; 20.5%) than in females (180/1176; 15.3%;  $P<0.001$ ). The percentage of individuals positive for “anti-HBc alone” was highest in the age group 71-80 years (139/613; 22.7%) and lowest in the youngest group 1-30 years of age (28/299; 9.4%; Figure 1).

In 113 “anti-HBc alone” individuals, apart from the confirmatory test, an additional assay for anti-HBc was performed (ARCHITECT™): anti-HBc was positive in 111 individuals, negative in one individual, and alternating negative and positive in two consecutive samples from another individual.

### HCV and HIV coinfection

One hundred and twelve of 550 “anti-HBc alone” individuals (20.4%) were positive for anti-HCV. HCV-RNA was detected in 98 of 108 anti-HCV positive patients tested (90.7%). Five hundred and forty “anti-HBc alone” individuals were tested for anti-HIV and 17 (3.1%) were positive.

**Figure 2** Percentage of HBV-DNA positive individuals (in serum) of all "anti-HBc alone" reactive individuals of different age groups.

### Detection of HBV-DNA in serum and liver

Sera from 545 "anti-HBc alone" individuals were tested for the presence of HBV-DNA by PCR and 44 were positive (8.1%). The viral load was between 50 (lower limit of detection) and 1000 copies/ml serum. The percentage of HBV-DNA positive individuals was highest in the youngest group 1-30 years of age (4/27; 14.8%) and lowest in the age group > 80 years (1/21; 4.8%; Figure 2).

Paraffin embedded liver tissue was available from 39 patients. HBV-DNA was detected in 16 (41.0%): in 12 of 32 liver samples (37.5%) which had originally been taken because a chronic liver damage was suspected, and in 4 of 7 liver samples (57.1%) taken for other reasons. Considering the results of the histological examination, HBV-DNA was detected in 2 of 17 livers with cirrhosis, in 3 of 9 primary liver cancers and in 11 of 13 livers without cirrhosis or primary carcinoma.

Only 2 of the 39 patients with available liver samples were HBV-DNA positive in serum: one patient with chronic hepatitis C (no cirrhosis or carcinoma) was HBV-DNA positive both in serum and liver, and one patient with hepatocellular carcinoma was HBV-DNA positive only in serum but not in liver. Thus, liver HBV-DNA was positive in 1 of 2 patients with serum HBV-DNA and in 15 of 37 patients without serum HBV-DNA.

### Clinical presentation

The 552 "anti-HBc alone" individuals were initially tested for HBV markers due to the following reasons: routine screening prior to invasive procedures ( $n=416$ ); diagnostic evaluation of cirrhosis of the liver ( $n=20$ ), hepatocellular carcinoma ( $n=11$ ), or elevation of transaminases ( $n=10$ ); diagnostic evaluation of a known HCV ( $n=28$ ) or HIV ( $n=16$ ) infection; routine screening of health care workers ( $n=6$ ); follow up evaluation of a known hepatitis B infection ( $n=4$ ); and evaluation of a needle stick injury recipient ( $n=3$ ). No diagnosis or cause of testing was given in 38 cases. In 90 patients (16.3%), the positive anti-HBc status was known prior to the actual investigation. Thirteen patients (2.4%) had suffered from jaundice of unknown origin earlier in their life. Information about suspected modes of infection or risk factors was available for 141 patients (25.5%): origin from an HBV hyperendemic area

( $n=95$ ), intravenous drug abuse ( $n=21$ ), HIV-infection ( $n=17$ ), previous blood transfusion or transplantation ( $n=17$ ), health care worker ( $n=10$ ), and HBV-positive sex partner ( $n=4$ ). Twenty individuals had more than one of these risk factors.

Alanine transaminase (ALT) activity was measured in 445 individuals and was normal in 279, up to twofold elevated in 89 and more than twofold elevated in 77 patients. Ultrasonic investigation of the liver was performed in 237 patients and revealed enlargement/steatosis of the liver in 69, signs of cirrhosis in 20, liver carcinoma in 10, and was non-distinctive in 20 patients. Histological examination of the liver was performed in 43 patients and showed cirrhosis in 16, hepatocellular carcinoma with cirrhosis in 10, active viral hepatitis in 8 (all with chronic HCV infection, HBV-DNA in serum positive in 1/8), steatosis of the liver in 3, liver abscess in 2, metastases of colon carcinoma in 2, primary biliary cirrhosis in one, and combined hepatocellular-cholangiocarcinoma without cirrhosis in one patient.

Combining all results of clinical, ultrasonic and histological examinations, we identified 38 "anti-HBc alone" patients with severe chronic liver damage (cirrhosis of the liver,  $n=27$ ; hepatocellular carcinoma,  $n=10$ ; combined hepatocellular-cholangiocarcinoma,  $n=1$ ). All 38 patients had at least one additional risk factor capable of causing the severe liver damage: chronic HCV infection ( $n=18$ ), alcohol abuse ( $n=14$ ), combined alcohol abuse and HCV infection ( $n=5$ ), and non-alcoholic steatohepatitis ( $n=1$ ).

"Anti-HBc alone" reactive individuals with positive and negative HBV-DNA in serum were compared regarding sex, age, ALT level, liver pathology, anti-HBs-titer, anti-HBe-status, HCV- and HIV coinfection. Statistically significant differences were not found (Table 2).

In those patients investigated, the detection of anti-HCV antibodies was associated with an elevation of ALT activity ( $P<0.001$ ) and with the presence of cirrhosis or primary carcinoma of the liver (Table 3).

### Serological and clinical course

In 151 of the 552 "anti-HBc alone" patients (27.4%), more than one serum was investigated during the study period. In 111 individuals, reactivity to "anti-HBc alone" was confirmed by subsequent testing after a mean follow up period of 17.1 mo (minimum-maximum, 0-77 mo). Eleven individuals were anti-HBs positive ( $16.8 \pm 8.4$  IU/L) when retested after a mean of 11.5 months (1-38 mo), and 10 individuals had anti-HBs titers fluctuating slightly above and below 10 IU/L over a period of 44.9 mo (10-82 mo).

One "anti-HBc alone" patient (male, 45 years, HBV-DNA in serum positive) showed HBV reactivation with reappearance of HBsAg, HBeAg, increase of HBV-DNA and loss of anti-HBs - but normal ALT activity - after treatment with rituximab (humanized monoclonal antibody to CD 20) and chemotherapy (cyclophosphamide, doxorubicin, vincristine, prednisone) for non-Hodgkin lymphoma.

For 18 patients, a previous serum sample was available not showing the "anti-HBc alone" pattern. Twelve patients were anti-HBs positive ( $16.6 \pm 4.7$  IU/L) at an average of

Table 2 Clinical data in individuals with reactivity to "anti-HBc alone"

		HBV-DNA-PCR in serum <sup>1</sup>

<sup>1</sup> There were no statistically significant differences between "anti-HBc alone" individuals with positive and negative HBV-DNA in serum regarding all parameters listed in Table 2.

<sup>2</sup> Missing numbers - not available/ not tested.

31.3 mo (1-59 mo) before being detected as "anti-HBc alone".

Six patients were previously HBsAg positive. Three of them had an acute HBV infection recently: (1) one female patient (14 years old) lost HBsAg after 9 mo, but remained HBV-DNA positive and anti-HBs negative during an additional 34 mo; (2) one male patient (45 years old) was "anti-HBc alone" (HBV-DNA positive) 4 mo after the acute infection and tested anti-HBs-positive after additional 4 mo; (3) one male patient (17 years old) was "anti-HBc alone" (HBV-DNA negative) 4 mo after the acute infection and was anti-HBs positive when retested after an additional 10 mo. Two patients just cleared a chronic HBV infection: one male patient (37 years old) had a chronic HBV and HCV infection for at least 6 years and cleared HBsAg (but not HBV-DNA or HCV-RNA) after treatment with PEG-interferon and ribavirin; the other male patient (59 years old) was discovered to be HBsAg positive by routine screening (ALT normal, HBV-DNA negative), and was "anti-HBc alone" when retested after 5 mo. The sixth patient (male, 41 years old) showed reverse seroconversion (reappearance of HBsAg and loss of anti-HBs) and moderate ALT elevations 14 mo after allogeneic hematopoietic stem cell transplantation<sup>[5]</sup>. He lost HBsAg again after 4 mo and had alternating anti-HBs positive and negative ("anti-HBc alone") but HBV-DNA negative during follow up (53 mo).

## DISCUSSION

The present study has primarily been undertaken to assess the clinical significance of the serological pattern "anti-HBc alone". Over a period of 6 years and 8 mo,

Table 3 Clinical data in "anti-HBc alone" individuals and anti-HCV status

		Anti-HCV		P-value
		Positive	Negative

<sup>1</sup> Missing numbers: not available/ not tested.

<sup>2</sup> NS: not significant.

552 individuals with this pattern were identified in our laboratory, accounting for 18.4% of all individuals with positive anti-HBc. Forty-four of 545 "anti-HBc alone" patients had circulating HBV-DNA with less than 1000 copies/ml. Depending on the sensitivity of the PCR assay, the proportion of HBV-DNA carriers in this study (8.1%; detection limit 50 HBV-DNA-copies/ml) complies with other studies reporting carrier rates of 3.3% and 7.7% (detection limits of 5000 and 100 HBV-DNA copies/mL, respectively) in unselected German individuals or blood donors<sup>[2,6]</sup>. Even more "anti-HBc alone" individuals with very low viremia would probably be found if the sensitivity of the assay were increased. In paraffin embedded liver tissue, we detected HBV-DNA in 16/39 "anti-HBc alone" patients (41.0%), only one of them was also PCR positive in serum. Thus, a significant fraction of "anti-HBc alone" individuals carry HBV genomes. However, HBV-DNA has also been detected in individuals with anti-HBs antibodies. Two German studies have reported a total of six HBV-DNA-positive blood donors with anti-HBs levels greater than 100 IU/L<sup>[7,8]</sup>. After the resolution of an HBV infection, a periodical release of virions from hepatocytes, as first described by Rehman *et al*<sup>[9]</sup>, can occur in HBsAg-negative, anti-HBc positive individuals, although more often in persons who lack anti-HBs compared to those with detectable anti-HBs<sup>[10]</sup>.

The essential question about these "occult" infections applies to their clinical impact. Since HBV-DNA has been found in serum and liver samples of HBsAg-negative patients with cirrhosis or primary liver cancer<sup>[11-13]</sup>, it has been suggested that "anti-HBc alone" individuals may suffer from chronic liver injury with the associated oncogenic potential. Herein, we identified 38 "anti-HBc alone" patients with severe chronic liver damage. All 38 patients had at least one other risk factor which could cause the liver damage by itself. In addition, HBV-DNA was less often detected in the liver of these patients (2/17 with cirrhosis, 3/9 with primary carcinoma) than in liver samples from patients without chronic liver damage

(11/13). When all “anti-HBc alone” individuals of this study were analyzed, there was no association between the detection of HBV-DNA in serum and ultrasonic, histological or biochemical evidence of liver damage. Therefore, the present study provides no evidence that HBV alone causes liver damage in “anti-HBc alone” individuals.

Although an occult HBV infection in “anti-HBc alone” individuals seems to be inoffensive, it might become injurious in the case of immunosuppression leading to viral reactivation. In patients with past infection (anti-HBs and anti-HBc positive), HBV reactivation has been reported during chemotherapy, HIV infection, and after kidney and bone marrow transplantation<sup>[14-17]</sup>. In the present study, HBV reactivation with reappearance of HBsAg was observed in one “anti-HBc alone” patient after treatment with rituximab (humanized monoclonal antibody to CD 20) and chemotherapy for non-Hodgkin lymphoma. This patient had no clinical hepatitis, but there are at least two reported cases of HBV reactivation with liver inflammation after rituximab and chemotherapy: one patient died from liver failure<sup>[18]</sup>, and the other reactivation occurred in a patient with preexisting anti-HBs and anti-HBc antibodies<sup>[19]</sup>. Our findings justify the cautious use of rituximab in “anti-HBc alone” patients and emphasize that these patients carry the risk for HBV reactivation during immunosuppression in general.

When a patient is diagnosed to be reactive for “anti-HBc alone”, several explanations might apply to this phenomenon. First, a certain proportion of “anti-HBc alone” individuals will be false positive, depending both on the anti-HBc test used and on the HBV prevalence of the population investigated. We aimed to minimize false positives by including only individuals who were anti-HBc positive in a second confirmatory assay. When a subset of 113 individuals was investigated with a third anti-HBc test, reactivity was confirmed in 111 (98%). Although all three assays were from the same manufacturer, we estimated that the population was truly anti-HBc reactive. An alternative assay from a different manufacturer might provide a better confirmation, but there was no serum for additional assays available.

Second, “anti-HBc alone” individuals might be in the window phase of an acute HBV infection when HBsAg disappears followed by anti-HBs a few weeks later. Herein, only 6 of 552 “anti-HBc alone” individuals were known to be HBsAg positive before: three were in the window period after an acute infection, two probably just cleared a chronic infection, and one lost HBsAg again after HBV reactivation following bone marrow transplantation. In a low HBV prevalence area as in Germany, the proportion of “anti-HBc alone” individuals in the window period is very low, but individuals in this period are probably infectious.

Third, “anti-HBc” alone can also reflect an HBV infection which has resolved many years or decades earlier. In the majority of our patients, reactivity for anti-HBc was an incidental finding, most were healthy and not aware of a previous liver inflammation. In 151 of the 552 “anti-HBc alone” individuals, more than one sample was investigated during the study period: 12 individuals were anti-HBs

positive before being detected as “anti-HBc alone”, 10 individuals had anti-HBs titers fluctuating around 10 IU/L during follow up, and 11 individuals were weakly anti-HBs positive when retested. These findings suggest that a significant proportion of “anti-HBc alone” individuals are comparable to those still showing anti-HBs.

Fourth, a large fraction of “anti-HBc alone” patients is assumed to have an unresolved chronic infection with low grade, possibly intermittent virus production. These individuals have detectable HBV-DNA in serum (8.1% in this study) and are potentially infectious. The negative HBsAg assay is unclear in these cases, but can be caused by very low concentrations of HBsAg, fixation of HBsAg in immune complexes, or by HBsAg mutations<sup>[20,21]</sup>. From a practical point of view, there seems to be no clear-cut distinction between “late immunity” and “unresolved infection”: HBV-DNA has also been detected in anti-HBs positive individuals, and HBV reactivation can occur both in anti-HBs positive and in “anti-HBc alone” patients. In the present study, there was no difference in the clinical picture between HBV-DNA negative and positive individuals with “anti-HBc alone”.

One final explanation for the phenomenon “anti-HBc alone” is the suppression of HBV replication by an HCV coinfection. In the present study, 112/550 “anti-HBc alone” individuals (20.4%) were coinfecting with HCV, and patients with HCV coinfection more often had an elevated ALT activity or chronic liver damage. The detrimental effect of HCV coinfection has previously been reported in HBsAg positive patients with chronic HBV infection<sup>[22,23]</sup>.

In conclusion, we performed an extensive study including 552 “anti-HBc alone” individuals of all age groups and found no single patient who had severe liver damage and no additional risk factor other than the “anti-HBc alone” pattern. There was also no association between the detection of HBV genomes in serum and/or liver and damage of the liver. Therefore, the probability that HBV alone causes severe liver damage in “anti-HBc alone” patients seems to be low.

This study supports suggestions for the practical management of “anti-HBc alone” individuals which have previously been made by a group of experts<sup>[1]</sup>: When this pattern is observed for the first time, a false positive anti-HBc reactivity should be ruled out by a second anti-HBc test, preferably an assay with a different format. In some cases, anti-HBe will also be present and confirm the authenticity of the hepatitis B markers. All “anti-HBc alone” individuals must be screened for an HCV coinfection. To search for a chronic HBV infection (or an infection in the window phase), viral DNA should be measured with the most sensitive DNA amplification method (capable of detecting  $\leq 100$  genomes per mL), and the ALT activity should be determined. It appears sufficient to re-evaluate individuals without HBV-DNA and with normal ALT level after a longer period of time, e.g. every five years. In case of a relevant ALT elevation, a liver biopsy seems appropriate to reach a conclusion concerning therapy. Antiviral treatment should be considered if HBV-DNA and biochemical and histological signs of active hepatitis are present. Since “anti-HBc alone” patients with this constellation are rare, they should be monitored by an

experienced hepatologist. Individuals with positive HBV-DNA PCR and normal ALT values should be assessed in yearly intervals. When "anti-HBc alone" individuals are subjected to severe immunosuppression (e.g. during anti-tumor chemotherapy or transplantation), HBV-DNA assays should be applied to recognize viral reactivation. Individuals with "anti-HBc alone" must be advised not to donate blood.

Further research is needed to answer open questions about the pattern "anti-HBc alone", e.g. concerning the reason for the male predominance and the infectivity of affected individuals.

## Abstract

**AIM:** To determine the real association between serum lipid levels and colonic polyp formation.

**METHODS:** We performed a large scale retrospective study to analyze the correlation between the incidence of colorectal adenoma or carcinoma and the fasting serum levels of total cholesterol (TC) and triglycerides (TG) in patients who underwent total colonoscopy for screening for colon cancer.

**RESULTS:** Both levels were significantly elevated in patients with adenomas as compared with patients without any neoplastic lesion (TC  $207.6 \pm 29.5$  vs  $199.5 \pm 34.3$ ,  $n=4883$ ,  $P<0.001$ ; TG  $135.0 \pm 82.2$  vs  $108.7 \pm 71.5$ ,  $n=4874$ ,  $P<0.001$ ). The difference was significant in patients with tubular adenoma but not in those with villous or serrated adenoma. Multiple logistic regression analysis including age and sex revealed that TG was an independent correlation factor in male ( $P<0.01$ ), but not in female patients. The level of TG in patients with invasive carcinoma did not show a significant elevation from that in patients with adenoma. These findings suggest that hypertriglyceridemia is an independent risk factor for colonic adenoma in men.

**CONCLUSION:** Although a high level of serum triglyceride does not appear to be mechanically involved in the development of carcinoma, reduction of serum TG and intensive surveillance with total colonoscopy may have benefit in men with hypertriglyceridemia.

## INTRODUCTION

Many studies have suggested that a high intake of dietary fat tends to promote colon carcinogenesis<sup>[1-4]</sup>. Regarding serum lipid levels, early studies showed an inverse association between cholesterol levels and colon cancer, whereas many contradictory results have also been reported later<sup>[5-8]</sup>. These findings suggest that the association of low serum cholesterol with malignancies is a consequence of the impaired nutritional status rather than a cause of cancer.

As compared with total cholesterol, less information is available on the relationship between serum triglyceride and colorectal neoplasm. The striking similarity of lifestyle risk factors for colorectal cancer and insulin resistance suggests that hypertriglyceridemia as well as hyperinsulinemia and hyperglycemia associated with insulin resistance support the development of colon cancer<sup>[9-12]</sup>. Moreover, recent animal studies showed direct evidence suggesting a positive effect of triglyceride on the development of aberrant crypt foci<sup>[13]</sup> and adenomatous polyps<sup>[14,15]</sup>. This suggests overlapping mechanisms that increase the risk of colon cancer and hyperlipidemia. On the contrary, other reports failed to detect a significant association between serum levels of triglyceride as well as cholesterol and risk of colorectal cancer in human<sup>[16,17]</sup> and animal studies<sup>[18]</sup>.

Thus, the true association between circulating lipid levels and colonic neoplasm development has not been satisfactorily determined in humans. In our clinic, we have performed a large number of total colonoscopies for screening for colon cancer, and intensively attempted to find colonic adenomatous polyps, since it is generally accepted that most colorectal cancers arise from adenomatous polyps<sup>[19]</sup>. From our experience, we retrospectively analyzed the relationship between serum lipid levels and the presence of colonic adenoma as well as carcinoma.

**Figure 1** The average mean  $\pm$  SD of total cholesterol (TC) and triglyceride (TG) of patients with adenoma without cancer ( $n=3821$ ), with adenoma as well as mucosal cancer ( $n=386$ ), with invasive cancer as well as adenoma (110), and without any neoplastic lesions ( $n=956$ ); a means  $P$  value less than 0.05 by ANOVA.

## MATERIALS AND METHODS

### Patients

A total of 4887 patients underwent total colonoscopy to screen for colon cancer from 1995 to 2003 in our clinic. The entire colon was carefully examined with a high resolution magnifying chromo-endoscope. More than 30 min was spent performing each colonoscopy, in order to avoid overlooking small lesions. All the adenomatous polyps including mucosal cancers were simultaneously resected by endoscopic polypectomy technique and examined histopathologically. Invasive cancer was found in 110 (2.3%) of 4887 patients even without subjective complaints. All the patients also had 1 to 77 adenomatous polyps in other parts of the colon. In the remaining 4777 patients, no adenomas were found in 956 (19.6%) patients, whereas at least one adenoma could be detected in the other 3821 (78.2%) patients, and all of them were endoscopically removed simultaneously. In 386 cases, 1 to 3 adenomas were histologically diagnosed to contain mucosal carcinoma. In these 3931 patients with adenomas (including patients with invasive cancer), only one adenoma was detected in 660 (13.5%) patients, 2 in 549 (11.2%) and 3 in 458 (9.4%) patients. In the other patients, 1934 (39.6%) had 4 to 9 adenomas, while the other 788 (16.1%) patients had 10 or more adenomas in the entire colon. Histological examination revealed mucosal cancer in 386 (9.9%) patients and that most of the resected adenomas were diagnosed as tubular adenoma, and that tubular adenoma was detected in 3928 (80%) of the total patients. Villous adenoma and serrated adenoma were observed in 53 (1.4%) and 36 (0.9%) cases, patients.

### Determination of serum cholesterol and triglycerides

The fasting serum levels of two major lipids, total cholesterol (TC) and triglycerides (TG), were measured just before colonoscopy in 4883 and 4874 cases, respectively. Then, the relationship between the incidence of colonic

neoplasm and fasting serum levels of these lipids was retrospectively evaluated.

### Statistical analysis

Statistical analysis was performed with JUMP software. The serum lipid levels in patients were analyzed by ANOVA and Fisher's exact test. The odds ratios were evaluated by multiple logistic regression tests. Values of  $P$  less than 0.05 were considered statistically significant.

## RESULTS

### Serum levels of TC and TG in patients with tubular, villous and serrated adenomas

The serum levels of TC and TG in patients with adenoma versus those with mucosal or invasive cancer showed a significant difference by ANOVA (Figure 1). Both values were significantly elevated in patients with adenomas as compared with patients without any neoplastic lesions (TC  $207.6 \pm 29.5$  vs  $199.5 \pm 34.3$ ,  $P < 0.001$ ; TG  $135.0 \pm 82.2$  vs  $108.7 \pm 71.5$ ,  $P < 0.001$ ). Patients with invasive or mucosal cancer showed very similar levels of TG ( $142.0 \pm 75.1$ ,  $139.3 \pm 91.6$ , respectively) to those with adenomas, which were significantly higher than that in patients without adenomas ( $P < 0.001$ ). For TC, however, patients with mucosal cancer also showed a very similar level to those with adenomas ( $206.2 \pm 28.7$ ), while patients with invasive cancer showed a relatively reduced level ( $200.8 \pm 28.3$ ), which was similar to that in patients without neoplastic lesions. LDL cholesterol was examined in 1483 patients and showed a similar profile to TC (data not shown).

Next, we examined the difference in these lipid levels in patients with adenomas of different histology. As shown in Table 1, the serum levels of these lipids were significantly different in patients with tubular adenomas, but not in patients with villous or serrated adenomas. This indicates that hyperlipidemia has a specific association

**Table 1** Serum levels of Total cholesterol (TC) and Triglyceride (TG) in patients with tubular, villous and serrated adenomas

Pathological finding	TC	n	P value	TG	n	P value

with the development of tubular adenoma, but not the development of carcinomas or other types of adenomas.

### Analysis of risk factors for tubular adenomas

We then performed multivariate analysis to determine the real association between serum lipid levels and tubular adenomas. Since univariate analysis showed that male and aged patients had colonic adenomas more frequently than their counterparts, we separately calculated the odds ratios for a change of one standard deviation (SD) adjusted for age in male and female patients (Tables 2 and 3). Multiple logistic regression analysis showed a clear contrast between TC and TG. When age and sex were considered, TC lost the independent relationship with adenoma, possibly because of the strong association with age. In contrast, TG was determined to be an independent correlation factor with tubular adenoma in total (*P*<0.05) and male (*P*<0.01) patients, but not in female patients.

## DISCUSSION

Epidemiologic studies have suggested that a high fat intake is strongly related to the development of colorectal cancer, although it is unclear whether serum lipid levels

can predict the high risk population for colon cancer. Our results clearly indicate that hyperlipidemia is associated with the development of adenomatous polyps with tubular histology in the colon. Although a positive association between hyperlipidemia and colonic neoplasm has already been reported, this large scale study revealed two additional findings.

The first is that the serum levels of cholesterol and triglycerides are increased in patients with adenoma compared to those without adenoma, while serum levels in patients with cancer are not elevated compared to those with adenoma. This indicates that a high fat intake that increases serum lipid levels may play a role in the development of adenoma but not in the development of carcinoma from adenoma.

The other important finding is that TG, but not TC, was independently correlated with the development of tubular adenoma, and the association was observed only in male but not in female patients. Recent studies have demonstrated that APC-deficient FAP model mice showed a hyperlipidemic state, possibly due to reduced activity of lipoprotein lipase, and that systemic administration of pioglitazone, a PPAR ligand, to the mice markedly reduced the serum level of triglycerides as well as intestinal polyp

formation<sup>[14,15]</sup>. These results are in agreement with our findings, and suggest the possibility that pioglitazone may be clinically effective to prevent polyp formation in humans.

The reason that the association was evident in male, but not in female patients, is yet unknown. The triglyceride level was significantly lower in women than in men in our series ( $106.17 \pm 63.00$  vs  $145.90 \pm 86.39$ ,  $P < 0.001$ ), and tubular adenoma was observed in 70.5% of female patients versus 86.6% of male patients ( $P < 0.001$ ). Since it was reported that the usage of estrogen reduced the incidence of colon adenoma as well as carcinoma by about 30%, resulting in reduced colon cancer-related mortality<sup>[20]</sup>, hormonal effects may be mechanically involved in the suppression of adenoma formation in the colon.

In summary, hypertriglyceridemia was shown to be an independent risk factor for colonic adenoma in men, although a high level of serum triglyceride did not appear to be directly involved in the development of colon carcinoma. Since all the adenomas were exclusively polypectomied in this clinic, no invasive cancers were detected at annual follow-up of those patients. Reduction of serum TG and intensive surveillance with total colonoscopy may be effective to prevent colon cancer in men with hypertriglyceridemia.

## Abstract

**AIM:** To study the therapeutic effect of interferon (IFN) and ribavirin with zinc supplement on patients with chronic hepatitis C viral (HCV) infection.

**METHODS:** A total of 102 patients confirmed histologically to have chronic HCV infection with genotype 1b and more than 100 KIU/mL of HCV were randomly assigned to each arm of the study and each received 10 million units of pegylated interferon (IFN-alpha-2b) daily for 4 wk followed by the same dose every other day for 20 wk plus ribavirin (600 or 800 mg/d depending on body weight), with or without polaprezinc (150 mg/d) orally for 24 wk. The primary endpoint was sustained virological response (SVR) defined as negative HCV-RNA in the serum 6 mo after treatment.

**RESULTS:** There were no differences in the clinical background between the two groups except for more females in the dual therapy group than in the other group ( $P < 0.05$ ). SVR was observed in 33.3% of the triple therapy group and 33.3% of the dual therapy group. The side effects were almost the same in both groups except for gastrointestinal symptoms, which were less in the triple therapy group ( $P = 0.019$ ).

**CONCLUSION:** Considered together, triple therapy of zinc plus IFN and ribavirin for HCV infection patients with genotype 1b and high viral load is not better than dual therapy except for lower incidence of gastrointestinal side effects.

## INTRODUCTION

Chronic hepatitis C is a major cause of liver cirrhosis and hepatocellular carcinoma. It has become the most common indication for liver transplantation in many centers<sup>[1,2]</sup>. Improvement of antiviral therapy for patients with chronic HCV infection has been recently achieved by the introduction of pegylated interferon (IFN-alpha-2b) combined with ribavirin<sup>[3-5]</sup>. Because the sustained virological response rate in patients with HCV genotype 1b and high viral load is still insufficient, the search continues for new treatment strategies.

On the other hand, patients with chronic liver disease exhibit metabolic imbalances of trace elements such as high levels of iron and copper, and low levels of zinc, selenium, phosphorus, calcium and magnesium<sup>[6]</sup>. Of these trace elements, zinc is a constituent of a number of enzymes involved in a large number of metabolic processes. Mild-to-severe zinc deficiency disturbs several biological functions such as gene expression, protein synthesis, immunity, skeletal growth and maturation, gonad development, pregnancy outcomes, taste perception and appetite<sup>[7,8]</sup>. Zinc has been studied for its antiviral effects on HIV<sup>[9]</sup>, rhinovirus<sup>[10]</sup> and herpes virus<sup>[11]</sup>. In addition to its anti-inflammatory effects, zinc has an antioxidant effect<sup>[12]</sup> and induces metallothionein (MT) which has radical scavenging and immunomodulatory effects<sup>[13]</sup>. Because zinc has many beneficial effects on viral eradication, we performed a preliminary study which showed the beneficial effect of IFN combined with zinc supplementation on chronic hepatitis C<sup>[14,15]</sup>. Here we present the results of a randomized controlled study of IFN with or without zinc supplementation for the treatment of chronic hepatitis C.

## MATERIALS AND METHODS

### Patients

Adult patients of both genders aged 24 - 70 years with

compensated chronic HCV infection were chosen. Each of the recruited patients fulfilled the following inclusion criteria: genotype 1b, more than  $10^5$  copies/mL of HCV in the serum, elevated serum alanine aminotransferase (ALT) concentration for at least 6 mo before initiation of treatment, and a liver biopsy specimen taken in the preceding 6 mo of study entry showing chronic hepatitis. Patients were excluded when they suffered from any of the following conditions: decompensated liver disease, other causes of liver disease such as hepatitis B infection, autoimmune disorders, hemoglobin value  $< 11$  g/dL, white blood cell count  $< 3/\text{nL}$ , thrombocytopenia  $< 70/\text{nL}$ , neoplastic disease, severe cardiac disease, other severe concurrent diseases such as preexisting psychiatric conditions, and pregnancy or lactation. Informed consent was obtained from all patients enrolled in the study after a thorough explanation of the aims, risks and benefits of this therapy.

### Study design

This randomized trial was conducted between January 2001 and December 2003 at 13 hospitals in Gunma, Japan. Eligible patients were randomly assigned to two study treatment groups with a ratio of 1:1 without stratification. Patients who met the entry criteria were randomly allocated into one of the two groups. The first group (triple therapy group) received oral triple therapy of 75 mg polaprezinc twice daily (Plomac; Zeria Pharmaceutical Co., Tokyo, Japan), IFN- $\alpha$ -2b (Intron A; Schering-Plough, Tokyo), and 600 mg or 800 mg ribavirin per day adjusted according to body weight (600 mg for weight below 60 kg and 800 mg for weight  $\geq 60$  kg) for 24 wk. The second group (dual therapy group) received combination therapy of IFN- $\alpha$ -2b and ribavirin at doses similar to those listed above, but no zinc supplementation. Since 75 milligrams of polaprezinc contained 17 mg of zinc, the patients received 34 mg of zinc per day. All patients were intramuscularly injected with 10 million units of IFN every day for 4 wk followed by three times a week for 20 wk. Patients were followed-up for another 24 wk after the treatment, i.e., until week 48.

The response to treatment was assessed as follows. Sustained virological response (SVR) was defined as undetectable HCV RNA in serum at the end of follow-up by analysis with Ampliform HCV version 2 with a lower limit of detection of 100 copies/mL. Analyses were performed in all patients who were randomized to one of the treatment groups. All the other patients whose HCV-RNA was positive 24 wk after the treatment were classified as non-responders.

### Histopathological examination of liver

In all patients, a liver biopsy was performed in the preceding 6 mo before therapy. Hepatic inflammation (grade) and fibrosis (stage) were assessed by the semiquantitative histological score proposed by Scheuer<sup>[16]</sup> and Desmet *et al*<sup>[17]</sup>. Portal/periportal inflammatory activity, lobular inflammatory activity and degenerative liver cell changes were scored using a scale of 0 to 3 for the criterion of inflammatory activity (1: mild, 2: moderate, 3: severe). The degree of fibrosis was scored using a scale of 0 to 4 (0: absent, 1: mild without septa, 2: moderate with a few septa, 3: numerous septa without cirrhosis, 4: cirrhosis).

**Table 1** Comparison of clinical data of patients with chronic hepatitis C who received dual or triple therapy

	Triple therapy group	Dual therapy group	P value
Demography

NS, not significant.

### Statistical analysis

Chi-square test and Fisher's exact test (two-tailed) for frequency tables were used for statistical analysis. A logistic multiple regression model was used to examine relationships between baseline clinical characteristics and the binary outcome of response to therapy. Each variable was transformed into categorical data consisting of two simple ordinal numbers for the logistic multiple regression model. Variable selection was an important step in characterizing prognostic relations and identifying variables most strongly related to the outcome. The final model was then obtained by fitting only the main effect terms.  $P < 0.05$  (two-sided) was considered statistically significant. Statistical analyses were conducted by the StatView 5.0 and SAS version 8.2 statistical analysis packages.

## RESULTS

### Response to treatment

We recruited 102 patients with genotype 1b and more than 100 KIU/mL of HCV-RNA who met the predefined inclusion and exclusion criteria. The clinical background of the two treatment groups was not different except for gender (Table 1).

Twenty-four patients dropped out because of side effects and inability of follow-up due to unknown reasons. Thus, 78 patients including 39 patients on triple therapy and 39 who did not receive zinc supplementation were the subjects of this study (Figure 1). At the end of the study (48 wk), the SVR rate was 33.3% (13/39) in both the dual therapy and triple therapy groups (Figure 2). One week after the beginning of treatment, the viral disappearance rate in the triple therapy group (20.0% [5/25]) was not significantly different from that in the dual therapy group (10.3% [3/29]). Four weeks after the beginning of treatment, the viral disappearance rate in the triple therapy group was 69.7% (23/33), which was not significantly different from that in the dual therapy group (57.1% [16/28]).

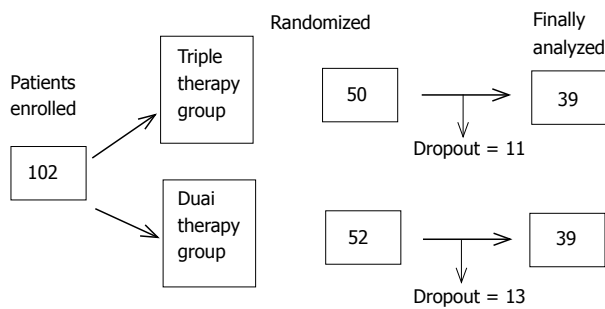

Figure 1 Profile of enrolled patients.

Figure 2 Rates of sustained virological response (SVR) to dual and triple therapies. Zinc supplementation had no significant effect on SVR.

					NS	NS	NS	NS

Fisher's exact test. NS, not significant.

While there were no significant differences between the two groups, patients of the triple therapy group tended to show an earlier decrease of the viral load compared to the dual therapy group (Table 2).

With regard to HCV-RNA load in the serum, the SVR rate of patients with HCV-RNA between 100 and 499 KIU/mL was 64.3% (8/13) in the triple therapy group, which was not different from that in the dual therapy group (46.2% [6/13]). Similarly, the SVR rate of patients with HCV-RNA >500 KIU/mL was not significantly different between the triple therapy and dual therapy groups

(5/26 [19.2%] and 7/26 [26.9%], respectively).

### Factors associated with sustained virological response

A logistic multiple regression model was used for statistical analysis including HCV-RNA, body weight and pre-treatment platelet count. The analysis identified HCV-RNA level as a significant determinant of SVR when data of both groups were pooled together (Table 3).

### Adverse effects

The side effects of the treatment were almost the same in both groups, including flu-like symptoms, mild reduction in hemoglobin, mild thrombocytopenia and leukopenia (Tables 4 and 5). The number of dropouts due to adverse effects was similar in the two groups (11 of 50 in the zinc group and 13 of 52 in the control group). The main reasons for dropout were anemia, fatigue, appetite loss and psychosomatic complaints (Table 6). The treatment protocol did not correlate significantly with the number of cases with adverse effects listed in Tables 4 - 6 except for abdominal discomfort. Fewer patients of the triple therapy group developed this side effect than those of the other group (P=0.019, Table 4).

## DISCUSSION

The metabolism of trace elements is distorted in chronic

Table 5 Laboratory abnormalities

	Triple therapy group	Dual therapy group	
Decrease in WBC (<2 000 $\mu$ L)	5	5	NS

liver disease<sup>[6]</sup>. We have previously reported that zinc deficiency in patients with chronic HCV can be improved by treatment with IFN<sup>[18]</sup>. In our previous pilot study, the beneficial effects of combined treatment of zinc and IFN have been confirmed with regard to both eradication of the virus and lowering or normalization of ALT<sup>[15]</sup>.

In view of the clinical background of patients before treatment, the number of female patients in our study was greater than that of male patients in the triple therapy group, but univariate analysis did not reveal a significant sex difference in the effect of treatment.

Although patients on triple therapy showed early disappearance of HCV-RNA, the results 24 wk after the treatment showed no overall beneficial effect of zinc supplementation and are similar to those of previous reports<sup>[15]</sup>. Furthermore, the triple therapy tended to have the same beneficial effects of IFN + ribavirin dual therapy in patients with moderate viral load (between 100 and 499 KIU/mL). It is possible that longer treatment (more than 24 wk) and perhaps higher dosages of IFN and ribavirin may produce different results. Based on the adverse effects of the treatment, the only advantage of the triple therapy is the significantly lower incidence of abdominal discomfort compared to the dual therapy.

Polaprezinc, a synthetic agent, N- (3-aminopropionyl)-L-histidinate zinc, is a chelating compound for ulcer healing and has been used experimentally to prevent gastric ulceration in rats as well as clinically as an antipeptic ulcer drug<sup>[19,20]</sup>. Zinc present in the orally administered polaprezinc is absorbed, leading to a rise in serum concentration of zinc<sup>[21]</sup>. In this respect, absorption of polaprezinc is more favorable than other zinc-containing derivatives such as zinc sulfate<sup>[21]</sup>. While the dose of polaprezinc could increase serum zinc concentration and possibly improve the SVR, caution should be exercised with regard to the side effects of higher doses of polaprezinc, as it is known to induce abdominal discomfort in some patients (personal communication).

In conclusion, 24-wk zinc supplementation has no additive effect on the anti-HCV dual therapy of IFN- $\alpha$ -2 and ribavirin, apart from reducing the incidence of abdominal discomfort.

## ACKNOWLEDGMENTS

This study was performed by Gunma Liver Study Group, Japan.
