Because NF- κ B has been implicated in the toxicity of STZ (Figure 2), we studied the effect of CCE on the cytokine-stimulated translocation of NF- κ B from the cytosol to the nucleus in RINm5F cells. Nuclear extracts from cytokine-stimulated RINm5F cells showed an increase in NF- κ B binding activity (Figure 7, lane 2), and this was markedly suppressed by adding CCE, implying that CCE inhibits iNOS expression and NO production by inhibiting NF- κ B activation in RINm5F cells. The specificity of the DNA-NF- κ B interaction was demonstrated by competitive

Figure 6 Effect of CCE on cytokine-induced iNOS protein and mRNA expression in RINm5F cells. RINm5F cells (1×10^6) were cultured in 6-well plates and treated with cytokines with or without CCE for 24 h, and then analyzed by Western blotting (A) or RT-PCR (B), as described in "Materials and Methods". The concentrations of the cytokines used were as described in Figure 4. Results are representative of three independent experiments.

assays using a 50-fold excess of unlabeled oligonucleotide (Figure 7, lane 7). These results indicate that the cytokine-induced expression of iNOS protein in RINm5F cells is inhibited by CCE at the transcriptional level.

DISCUSSION

IDDM is an autoimmune disease characterized by the specific destruction of β -cells in the islets of Langerhans^[1]. Cumulative evidence suggest that NF- κ B dependent NO production is a critical component of the destruction and dysfunction of β -cells. NF- κ B activation in β -cells can be triggered by cytokines and by diabetogenic drugs such as STZ and alloxan^[10,14,15]. Therefore, reduced NO production presents a potential means of overcoming β -cell failure.

The use of traditional plant medicines has been practiced for centuries by mankind, and despite a general insufficiency of supportive evidence concerning therapeutic efficacies, herbal medicine usage continues to increase. The present results confirm previous observations that cytokines and STZ induce NF- κ B activation, iNOS expression, NO production, and β -cell dysfunction in both mice pancreases and cultured β -cells, and that CCE abolishes cytokine- and STZ-mediated β -cell damage by blocking NF- κ B translocation to the nucleus. Thereby, these results indicate that CCE can preserve the insulin secreting capacity and viability of β -cells.

In the first series of experiments, we used mice to observe NF- κ B activation by STZ and its prevention by CCE. EMSA studies revealed increased NF- κ B binding activity in pancreatic nuclear extracts derived from STZ-treated hyperglycemic diabetic mice. In contrast, pretreatment with CCE prevented NF- κ B activation and iNOS expression, and this resulted in the maintenance of plasma glucose and insulin levels in the normal range. To further confirm the preventive effect of CCE, histological examinations on pancreatic islets were performed. STZ-treated mice showed marked islet destruction and relative small numbers of insulin-positive β -cells, whereas well-defined islets and strong insulin positive staining were observed in

Figure 7 Effect of CCE on the cytokine-induced translocation of NF- κ B from cytosol to the nucleus. RINm5F cells (5×10^6) were treated with cytokines in the presence or absence of CCE. Following 30 min of incubation, nuclear extracts were prepared and NF- κ B activation levels were analyzed by EMSA, as described in "Materials and Methods". The concentrations of cytokines used were the same as in Figure 4. Results representative of three independent experiments are shown. Lane 1: none; lane 2: IL-1 β + IFN- γ ; lane 3: IL-1 β + IFN- γ + 0.125 mg/mL CCE; lane 4: IL-1 β + IFN- γ + 0.25 mg/mL CCE; lane 5: IL-1 β + IFN- γ + 0.5 mg/mL CCE; lane 6: IL-1 β + IFN- γ + 1.0 mg/mL CCE; lane 7: negative control using 50-fold excess of κ B oligonucleotide as a negative competitor.

CCE pre-treated mice. STZ-induced diabetic rodents were previously reported to show increased iNOS activity and expression in islets at a very early stage^[4,5,8]. In this situation, NO generated may react with oxygen free radicals like the superoxide anion, to form highly oxidizing peroxynitrite, which would lead to more aggressive oxidative and nitrosative stress.

Similar effects of CCE were observed in RINm5F cells exposed to cytokines for 24 h. The reduction in NO production induced by CCE in RINm5F cells was associated with a reduction in NF- κ B activation and iNOS mRNA expression. These findings are in line with recent observations that the extract of *A. xanthoides* reduces iNOS expression and protects β -cells in mice and RINm5F cells from alloxan^[17,18]. Future studies are needed to determine the target pathway that leads to the sequestration of NF- κ B in the cytosol.

The generation of oxygen free radicals is another important mechanism of cytokine- and other diabetogenic drug-mediated toxicities in β -cells. Experimental evidence indicates that oxygen free radicals are generated in both cytokine-stimulated^[6,29,30] and STZ-treated β -cells^[31], and that the overexpression of antioxidant enzymes protects β -cells from such insults^[7,32,33]. Furthermore, oxygen free radicals induce NF- κ B activation and iNOS expression in rodent and human β -cells^[34,35], which suggests a role for hydrogen peroxide in the pathway of NF- κ B activation and iNOS expression induced by cytokines. We cannot exclude the possibility that the protective effect of CCE occurs *via* the reduced generation of oxygen free radicals.

In summary, our results indicate that CCE inhibits cytokines- and STZ-induced β -cell damage *in vivo* and *in vitro*. The primary mechanism underlying this effect is the inhibition of iNOS protein expression, which may be mediated at the transcriptional level through the inhibition of NF- κ B activation and iNOS transcription. These findings suggest that CCE is likely to have a beneficial effect when used to prevent or attenuate the progress of diabetes mellitus.

and *BIK* (22q13.31) were detected in 26 (40%) and 23 (35.4%), respectively. Significant correlations were observed between lymphatic invasion and allelic losses of *BIK* ($P = 0.025$) and D22S283 ($P = 0.041$). Univariate and multivariate Cox regression analysis revealed D22S283 amplification as an independent predictor of good prognosis ($P = 0.006$, death hazard ratio = 0.411, 95% CI = 0.217-0.779) and blood vessel invasion as an independent poor prognostic factor ($P = 0.042$, death hazard ratio = 1.911, 95% CI = 1.022-3.571) in CCA patients.

CONCLUSION: This study provides evidence for the involvement of gene amplification and deletion on chromosome 22q in liver fluke related CCA. This is the first report of D22S283 amplification as an independent indicator of favorable prognosis in liver fluke related CCA.

Abstract

AIM: To analyze the DNA copy number of target genes *NF2*, *TIMP3*, *ST13*, *TOB2*, *BIK*, and *TP* and the reference microsatellite markers D22S283, D22S423, and D22S274 mapped on 22q12-qter in liver fluke related cholangiocarcinoma (CCA) and define its correlation with clinical parameters.

METHODS: Quantitative real time PCR (qPCR) was used for determining allelic imbalances in 65 liver fluke related CCA tissues. Statistical correlations between allelic imbalances and clinicopathological parameters, i.e. age, sex, tumor stage, histological type, blood vessel invasion, nerve invasion and lymphatic invasion were evaluated by means of the χ^2 test. Cox regression analysis was used for determining patient's survival.

RESULTS: Amplifications of the *TP* (22q13.33), *TOB2* (22q13.2-13.31), D22S283 (22q12.3), *TIMP3* (22q12.3) and *NF2* (22q12.2) were found in 35 (53.8%), 28 (43.1%), 27 (41.5%), 24 (36.9%), and 24 (36.9%), respectively. Losses at the D22S423 (22q13.1-13.2)

INTRODUCTION

Cholangiocarcinoma (CCA) which arises from bile duct epithelium is a common hepatobiliary malignancy found in Northeastern Thais. Liver fluke (*Opisthorchis viverrini*) infection related to cholangiocarcinogenesis is strongly supported by evidence from both experimental and epidemiological studies^[1,2]. In addition, exogenous and/or endogenous N-nitroso compounds have also been claimed to be responsible^[1,2]. These studies suggest that liver fluke infection causes chronic inflammatory reactions and enhance the susceptibility of bile duct epithelium to carcinogenic chemicals such as N-nitroso compounds leading to genetic and epigenetic damages in the cells. CCA accounts for about 89% of all liver cancer cases

in Khon Kaen with the highest incidence in the world ($97.4/10^5$ in males and $39.0/10^5$ in females)^[3]. Khon Kaen is one of the largest provinces in Northeast Thailand where the liver fluke is highly endemic. Most patients are diagnosed at late stage and difficult to cure successfully because of advanced metastasis at the time of diagnosis. The 3-year survival rates are 33%, 30% and 12% for stage III, stage IVa, and stage IVb, respectively, whereas 5-year survival rates are 0% for all three late stages^[4]. CCA, like other common epithelial cancers is believed to develop through a multistep process. However, the molecular mechanism of carcinogenesis of CCA remain unclear. A series of different genes and chromosomal regions may be deleted or amplified in the tumor genome. Several genes are reported to be involved in CCA, e.g. *p53* and *MDM2*^[5], *p16*^[6], *K-ras*^[6], *hMLH1* and *hMSH2*^[7,8], and *COX-2*^[9,10]. At the chromosomal levels, changes of several chromosomal arms have been reported, e.g. 13q^[11], 6q, 9p and 17p^[12], 17q, 5p, 6q, and 18q^[13].

There are reports of genetic changes on the chromosomal region 22q in other epithelial cancers such as colorectal cancer^[14,15], oral cancer^[16], breast cancer^[17], gastric carcinoma^[18] and ovarian carcinoma^[19], except CCA. Alteration in gene copy number by amplification or deletion is a common mechanism that leads to deregulation of gene expression and finally to neoplastic transformation. Investigation of the prognostic or predictive significances of these genetic alterations requires a reliable and sensitive method for the measurement of gene copy number in clinical tumor samples. Quantitative real time PCR is increasingly used to quantify copy numbers of nucleic acids in clinical applications^[20]. The measurement of gene copy number by qPCR has frequently been reported for human tumors including stomach cancer^[21], neuroblastoma^[22], and oligodendroglioma^[23]. Our comparative genomic hybridization data in CCA showed copy number alteration at 22q13 at 21%. Taken together, this study aimed to investigate the allelic imbalance of the chromosomal region 22q12-qter by means of SYBR Green I-based qPCR assay and define its candidate genes which may be involved in carcinogenesis and pathogenesis of liver fluke related CCA. We also correlated our findings with clinical parameters including patient survival.

MATERIALS AND METHODS

Samples and DNA extraction

Sixty-five samples were obtained from liver fluke related CCA patients undergoing surgery at Srinagarind Hospital, Khon Kaen University, Khon Kaen, Thailand. The patients' data and survival time are shown in Table 1. Informed consent was obtained from each patient prior to sampling under the guideline approved by the Ethical Committee of Khon Kaen University. Tumor tissues containing 70% or more tumor cells were prepared for DNA extraction following standard method. Peripheral blood samples collected from 50 healthy blood donors were used to extract DNA which was then pooled to yield 5 pooled DNA samples (10 cases each) for normal DNA copy number determination. DNA extracted from normal

placenta was used for setting a standard curve.

Polymorphic markers and gene specific primers

Six target genes and 3 reference microsatellite markers spanning from centromere to telomere of the chromosomal region 22q12-qter were selected for DNA copy number quantification. The genes were *NF2* (Neurofibromin 2), *TIMP3* (Tissue Inhibitor of Metalloproteinase 3), D22S283, D22S423, *ST13* (Suppression of Tumorigenicity 13), *TOB2* (Transducer of ERBB2, 2), *BIK* (BCL2-interacting Killer), D22S274, and *TP* (Thymidine Phosphorylase). The sequence and location of each locus are shown in Table 2.

Quantitative real time PCR system using a standard curve method

Allelic imbalance on the chromosomal region 22q12-qter was analyzed by SYBR Green I based qPCR using Rotor-Gene 2000 Real Time Amplification System (Corbett Research, Australia). Since SYBR Green I dye is a nonspecific dsDNA intercalating dye, we made the reaction specific by analyzing the annealing and signal acquisition temperatures for each primer. A relative standard curve was constructed for each locus using a 2-fold serial dilution of human placental DNA to get 4 different concentrations. Placental DNA with known concentration was used as a control to validate experimental precision. A relative DNA copy number was calculated for each sample as a ratio of DNA copy number for target locus and the average DNA copy number for 2 reference loci GAPDH and β -actin housekeeping genes. Relative DNA copy numbers of 9 tested loci in 5 pooled normal leukocyte DNA ($n = 45$) were calculated for normal reference range. The relative DNA copy number in the sample was interpreted as loss or gain when the ratio was less than mean - 2SD or more than mean + 2SD of normal reference range, respectively.

Quantitative PCR was conducted in triplicate in a 20 μ L reaction volume containing 67 mmol/L Tris Base, 16.6 mmol/L ammonium sulfate in a 10 mL/L Tween 20, 3 mmol/L MgCl₂, 5 pmol each primer, 100 μ mol/L each deoxynucleoside triphosphate (dNTP), 1X SYBR Green I and 1 unit Taq polymerase with different concentration of genomic DNA. Each locus was amplified using optimal conditions. The thermal cycling conditions comprised 94°C for 300 s, and 40 cycles of 94°C for 15 s, 46°C -58°C for 20 s and 72°C for 15 s and hold at 72°C for 600 s. To assure the reproducibility and accuracy of qPCR, experiments were repeated when a coefficient of variation for triplicate samples was higher than 10% or a PCR efficiency lower than 0.85 was observed.

Statistical analysis

The association between allelic imbalance and clinical features was analyzed by χ^2 test using SPSS statistical software version 10.0 for Windows (SPSS Inc, Chicago, Ill). Survival curves were analyzed by Kaplan-Meier and the significant difference confirmed by Log rank test. Univariate and multivariate Cox regression models were also used for survival analysis. $P < 0.05$ was defined as significance.

Table 1 Patients' data including survival time

No.	Age(yr)	Sex	Staging	Histological grading	Invasion			Survival time (wk)

RESULTS

Allelic imbalance of 9 target loci on chromosome 22q12-qter

Sixty-five samples from liver fluke related CCA patients were investigated for aberrations in DNA copy number of 9 target genes on 22q12-qter. The normal reference range statistically calculated from 5 pooled normal leukocyte DNA was 0.82-1.33, which was derived from 1.08 ± 0.13 (mean \pm 2SD; $n = 45$). Amplification frequencies higher than 30% were observed in TP (53.8%), TOB2 (43.1%), D22S283 (41.5 %), TIMP3 (36.9%), and NF2 (36.9%). Loss frequencies more than 30% were detected in D22S423 (40%) and BIK (35.4%). Allelic imbalance of each locus is shown in Figure 1. Fine mapping of chromosomal region 22q12-qter from centromeric (NF2) to telomeric ends (TP) in CCA is shown in Figure 2. The regions of common amplification were observed at TP, TOB2 and the 6.6 cM region between NF2 and D22S283. The regions of common loss were D22S423 and BIK.

Correlation of clinicopathological features and allelic imbalance on chromosome 22q12-qter

Associations between allelic imbalances of 9 target loci and clinicopathological parameters, i.e. age, sex, tumor stage, histological type, blood vessel invasion, nerve

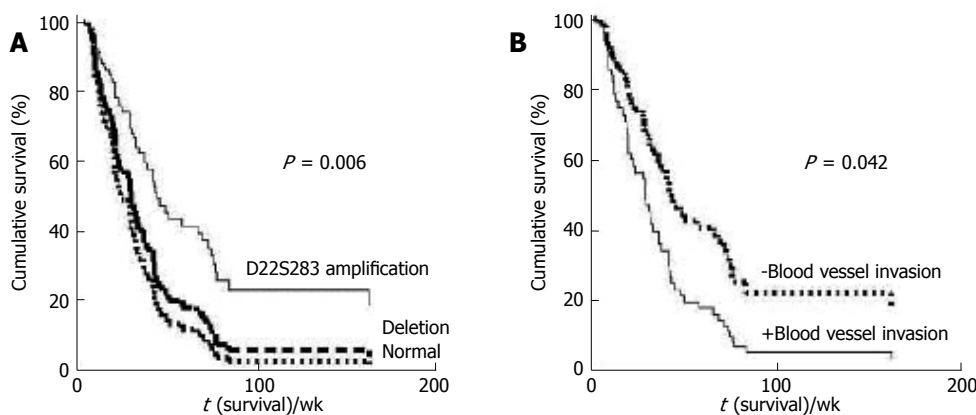

Figure 3 Survival curve by multivariate Cox regression analysis. **A:** Multivariate Cox regression analysis revealed D22S283 copy number amplification as an indicator of favorable prognosis; **B:** blood vessel invasion showed poor prognosis in liver fluke related CCA patients.

invasion and lymphatic invasion were evaluated by means of the χ^2 test. The mean age of the 65 patients was 54 years. Lymphatic invasion was observed in patients with deletion at D22S283 ($P = 0.041$) and *BIK* ($P = 0.025$). Using Kaplan-Meier survival analysis, the median survival time was 30.42 weeks (SE = 4.29, 95% CI = 22.00-38.84), while the 3-yr and 5-yr survival rate were 9.2 % and 1.5 %, respectively. Cox regression analysis by univariate model showed poor outcome for patients with blood vessel invasion ($P = 0.021$, death hazard ratio = 2.080, 95% CI = 1.120-3.877) but improved survival with D22S283 amplification ($P = 0.003$, death hazard ratio = 0.384, 95 % CI = 0.202-0.728) (Table 3). Parameters with $P < 0.1$ in the univariate analysis were included in the multivariate model of Cox regression analysis for survival. The multivariate analysis revealed the significance of D22S283 amplification

as an independent predictor of better prognosis compared with those without ($P = 0.006$, death hazard ratio = 0.411, 95% CI = 0.217-0.779), whereas blood vessel invasion was revealed as an independent poorer prognostic factor in CCA patients ($P = 0.042$, death hazard ratio = 1.911, 95% CI = 1.022-3.571) as shown in Table 3. Survival prediction by multivariate Cox regression analysis of D22S283 and blood vessel invasion is shown in Figure 3.

DISCUSSION

Gene deletion and amplification are common events in tumorigenesis and progression. In this study, we examined the allelic imbalance of chromosomal region 22q12-qter by SYBR Green I-based qPCR assay and determined its association with clinicopathological parameters and

survival in 65 CCA patients. *TP* showed the highest frequency of genomic DNA amplification (53.8%) (Figure 1), suggesting its important role in the development of CCA. *TP* gene located at 22q13.33 is an angiogenic factor, which promotes angiogenesis *in vivo* and stimulates the *in vitro* growth of a variety of endothelial cells. *TP* also has an enzymatic activity involved in pyrimidine metabolism. It catalyzes the phosphorolysis of thymidine to thymine and deoxyribose-1-phosphate and has a pro-angiogenic effect for which deoxyribose-1-phosphate may be responsible^[24-26]. Since gene amplification is reported to play an important role in the initiation and progression of tumors^[27], *TP* amplification and overexpression have been reported in many solid tumors with invasion and metastasis including CCA^[28-30]. These observations indicate that the incidence of amplification and overexpression of *TP* is high in cancer and associated with carcinogenesis. Although we could not find any correlation between clinicopathological parameters and *TP* imbalance or impact of *TP* gene copy number on patient survival when treated with 5-fluorouracil (5-FU)-based chemotherapy (data not shown), its high amplification may be worth further investigation into its involvement in chemotherapeutic activity because normal *TP* protein activity is required for the activation of the cytotoxic activities of anti-tumor drug 5-FU. 5-FU-based chemotherapy is given to patients with advanced cancer and as an adjuvant treatment. 5-FU is a fluorinated pyrimidine that is metabolized intracellularly to its active form, fluorodeoxyuridine monophosphate (FdUMP), by *TP* to inhibit DNA synthesis. Our further studies will investigate whether *TP* expression also associates with chemosensitivity in CCA.

Microsatellite marker D22S423 was the most frequent locus loss (40%) among 9 loci, suggesting that this region may harbor a putative tumor suppressor gene (TSG), which plays a role in the development of CCA. LOH frequency at D22S423 was reported in 26.8% of informative cases in sporadic colorectal cancer^[15]. Putative TSG located 1 cM distal to D22S423 are *ST13* and *EP300*, however, the presence of unknown TSG located within this region cannot be excluded. *ST13* encodes an adaptor protein that mediates the association of the heat shock proteins *HSP70* and *HSP90*. The expression of *ST13* is reported to be downregulated in colorectal carcinoma tissue compared with that in adjacent normal tissue, suggesting that *ST13* is a candidate TSG^[31]. Function and role of *ST13* in tumor development is still unclarified. Further investigation into *ST13* expression and its roles in carcinogenesis of CCA is needed.

D22S283 was deleted in 15 cases, which all had lymphatic invasion, suggesting the deletion of unknown TSG, which functions on inhibiting invasion. D22S283 showed amplification in 27 out of 65 cases, indicating the existence of putative oncogene (s) at this location, for example, *R4B* member of *R4S* oncogene family, RNA binding motif protein 9, and eukaryotic translation initiation factor 3. On the other hand, some TSG at this location may amplify, leading to high expression which may result in good prognosis of patients with D22S283 amplification (Figure 3). Other putative TSG around D22S283 that play a role in apoptosis are caspase recruitment domain family,

member 10 and phospholipase A2, group VI.

All 23 cases of *BIK* gene deletion were associated with lymphatic invasion. Many reports suggest that *BCL2-interacting killer* (apoptosis-inducing) functions as a proapoptotic protein, which enhances programmed cell death. Germain *et al.*^[32] identified *BIK* as an initiator of cytochrome C released from mitochondria operating from a location at the endoplasmic reticulum and activated caspases. Thus, role of *BIK* in pathogenesis and carcinogenesis of CCA needs further investigation. *NF2* gene located at 22q12.2 produces the Merlin protein. It is thought to act as a tumor suppressor protein, however, the mechanism remains obscure. Xiao *et al.*^[33] have shown that merlin inhibits tumor cell proliferation and arrests cells at G₁ phase, concomitant with decreased expression of cyclin D1, inhibition of CDK4 activity, and dephosphorylation of pRB. They suggested a unifying mechanism by which merlin inactivation might contribute to the overgrowth seen in both noninvasive and malignant tumors. DNA amplification of *NF2* was found in 36.9 % of our CCA cases, hence, expression of *NF2* may lead to significant reduction of proliferation and G₀/G₁ arrest in CCA cells.

The development of tumor is a multistep process that requires accumulated mutations or alterations of both oncogenes and tumor suppressor genes. It is generally believed that mutations in 5 to 10 genes are required for the development of a tumor. Thus, *TP*, *BIK*, *NF2*, and candidate genes on D22S423 and D22S283 are likely to play significant roles in carcinogenesis of liver fluke related CCA by this study. In addition, to our knowledge, we first propose that the D22S283 amplification acts as an independent indicator of favorable prognosis in liver fluke related CCA.

Abstract

AIM: To investigate the role of metallothionein and proliferating cell nuclear antigen (PCNA) on the morphological and biochemical effects of zinc sulfate in ethanol-induced liver injury.

METHODS: Wistar albino rats were divided into four groups. Group I; intact rats, group II; control rats given only zinc, group III; animals given absolute ethanol, group IV; rats given zinc and absolute ethanol. Ethanol-induced injury was produced by the 1 mL of absolute ethanol, administered by gavage technique to each rat. Animals received 100 mg/kg per day zinc sulfate for 3 d 2 h prior to the administration of absolute ethanol.

RESULTS: Increases in metallothionein immunoreactivity in control rats given only zinc and rats given zinc and ethanol were observed. PCNA immunohistochemistry showed that the number of PCNA-positive hepatocytes was increased significantly in the livers of rats administered ethanol + zinc sulfate. Acute ethanol exposure caused degenerative morphological changes in the liver. Blood glutathione levels decreased, serum alkaline phosphatase and aspartate transaminase activities increased in the ethanol group when compared to the control group. Liver glutathione levels were reduced, but lipid peroxidation increased in the livers of the group administered ethanol as compared to the other groups. Administration of zinc sulfate in the ethanol group caused a significant decrease in degenerative changes, lipid peroxidation, and alkaline phosphatase and aspartate transaminase activities, but an increase in

liver glutathione.

CONCLUSION: Zinc sulfate has a protective effect on ethanol-induced liver injury. In addition, cell proliferation may be related to the increase in metallothionein immunoreactivity in the livers of rats administered ethanol + zinc sulfate.

INTRODUCTION

The liver is the main site of ethanol biotransformation and it plays a key role in zinc metabolism^[1,2]. Acute ethanol exposure causes liver injury in experimental animals. The mechanisms of ethanol-induced liver injury are not fully elucidated^[3,4]. Metallothionein is an intracellular protein capable of binding metals and can scavenge reactive oxygen species^[5,6]. The mechanism of action for metallothionein is also unknown. Although all tissues are able to synthesize metallothioneins, the main place of synthesis is in the liver^[7]. Ethanol is a potent inducer of liver metallothionein^[8-12]. Proliferating cell nuclear antigen (PCNA) is an essential protein in both DNA replication, DNA repair and possibly cell-cycle control^[13]. Zinc is an essential nutrient that is required in humans and animals for many physiological functions, including antioxidant functions. Zinc has been shown to be essential for the structure and function of a large number of macromolecules and is also essential for over 300 enzymatic reactions^[14]. Zinc is an antioxidative element and it probably mediates the protective action of metallothionein^[15]. Changes in the metabolism of some elements such as zinc can lead to disorders in the antioxidant defense system of liver^[16-17]. It has been shown that zinc plays an important role in the maintenance of glutathione^[18]. Zinc deficiency is important in liver damage, although it is unclear whether zinc supplementation has a place in the treatment of ethanol-induced liver injury^[19,20].

Although some studies have addressed the relationship between zinc-metallothionein and ethanol toxicity, the results obtained from these studies are in conflict^[4,21,22]. The aim of this study was to examine the role of metallothionein and PCNA, and the effects of zinc sulfate on ethanol-induced liver injury morphologically and biochemically.

MATERIALS AND METHODS

Experimental design and treatment of animals

In this study, 2.5-3 mo-old male Wistar albino rats ($n = 41$) from DETAM (Istanbul University, Centre for Experimental Medical Research and Application) were used. The experiments were reviewed and approved by the Local Institute's Animal Care and Use Committees. The animals were fed with pellet chow and tap water *ad libitum*. The animals were randomly divided into four groups. Group I ($n = 8$) was intact control animals. The control rats of group II ($n = 8$) were treated only with 100 mg/kg per day zinc sulfate ($\text{ZnSO}_4 \cdot 7\text{H}_2\text{O}$) (Merck) for 3 d, by gavage technique. The animals of group III ($n = 14$) received 1 ml of absolute ethanol once, by the same method. The animals of group IV ($n = 11$) were treated with zinc sulfate and absolute ethanol at the same dose and time. After 2 h from the time when the last dose of zinc sulfate was given, acute ethanol toxicity on the liver of rats was produced by administration of absolute ethanol. The animals were sacrificed by ether 2 h after treatment with absolute ethanol.

Morphological study

On the 3rd day of the experiment, all of the animals were fasted overnight and sacrificed under ether anesthesia. Liver samples were taken from the animals for morphological studies. The tissues were fixed with Bouin fixative for light microscopic studies and subsequently a routine paraffin embedding method was used. Liver sections of 5 μm thickness were stained by HE and Masson's triple dyes (Masson), and examined under Carl Zeiss Ultraphot II microscope. Liver samples were fixed in 20 g/L glutaraldehyde and post-fixed in 10 g/L of phosphate-buffered osmium tetroxide. The samples were dehydrated in ethanol and embedded in epon. Specimens were examined with JEM 1011.

Immunohistochemical study

Sections were dewaxed and rehydrated. The tissues were rendered permeable with 3 g/L Triton-X 100 for 10 min and then rinsed in phosphate-buffer saline (10 mmol/L, pH 7.5). For antigen retrieval, the slides were kept in 0.01Mol/L citrate buffer for 10 min in a microwave oven. Endogenous peroxidase was blocked with 30 mL/L hydrogen peroxide. An Ultra Vision Detection System for streptavidin-biotin-peroxidase technique (Lab Vision, USA) was employed. Sections were covered with blocking serum for 10 min to block non-specific binding sites. They were then incubated with metallothionein antibody for 1 h (Zymed Laboratories, USA) at room temperature with 1:50 dilution. Slides were then incubated with PCNA mouse monoclonal antibody for 30 min (Neomarkers,

USA) at room temperature with 1:50 dilution. They were incubated for 15 min with biotinylated secondary antibody and then incubated with the streptavidin-peroxidase conjugate for 15 min. The enzyme activity was developed using aminoethylcarbazole (AEC) and then the sections were counterstained with hematoxylin. Negative control sections were prepared by substituting the metallothionein or PCNA antibodies with phosphate-buffer saline. Hepatocytes were viewed using a light microscope (Olympus, CX41) at a magnification of 400X. Approximately 400 cells from 10 randomly selected fields (0.0506 mm^2 per field) of vision were counted. The PCNA and metallothionein labeling indices were expressed as a percentage of positive stained cells relative to the number of counted cells. (i.e., PCNA or metallothionein labeling index = PCNA or metallothionein positive hepatocytes/total hepatocytes per high power field $\times 100$).

Biochemical study

In this study, biochemical investigation was carried out in serum, blood, and liver tissues. The blood samples were taken by a syringe from the heart. Blood glutathione (GSH) levels were measured according to the method of Beutler, Duron and Kelly using Ellman's reagent^[23]. Serum alkaline phosphatase activities (ALP) were determined by the Two Point method^[24]. Serum aspartate transaminase (AST) was assessed by the Reitman-Frankel method^[25]. The liver tissues were homogenized in cold 9 g/L saline by means of a glass homogenizer to make up a 100 g/L homogenate. The homogenates were centrifuged and the clear supernatants were used for GSH, lipid peroxidation (LPO) and protein levels. Liver GSH levels were determined according to Beutler's method, using Ellman's reagent^[26]. Liver LPO levels were measured by Ledwozyw's method^[27], liver protein levels were assessed by Lowry's method using bovine serum albumin as the standard^[28].

Statistical analysis

The biochemical results were evaluated using an unpaired *t*-test and analysis of variance (ANOVA) using the NCSS statistical computer package (Kaysville, Utah, USA)^[29]. The microscopic results were analyzed by one-way ANOVA followed by the Scheffé and Student's *t*-test for multiple comparisons of the control against all other groups using SPSS 13 for Windows. Data were expressed as mean \pm SD. $P < 0.05$ was considered to be significant.

RESULTS

Morphological results

The livers of control and zinc-treated rats were visually normal. Acute ethanol exposure caused degenerative morphological changes in the liver. The hepatocyte of rats exposed to absolute ethanol alone had occasional diffuse vacuolar degeneration. Vacuolar degeneration was found in hepatocytes of zones 2 and 3. In the alcohol group, there was a mild dilation of the sinusoids and hyperemia. Moreover, mononuclear cell infiltrations were evident in this group. These alcohol-induced hepatic pathological changes were significantly inhibited in the zinc-pretreated

Figure 1 Histological appearance of rat liver tissue. Masson X 270. **A:** Intact control; **B:** Control, zinc sulfate; The liver showing vacuolated hepatocytes (\rightarrow) in the centrilobular area with mild dilation of sinusoids (\blacktriangleright) and hyperemia (*); **C:** Absolute ethanol; **D:** Zinc pre-treatment.

rats. A moderate degree of mucosal hyperemia was observed in the group given ethanol and zinc sulfate. In addition, less vacuolar degeneration was observed in this group (Figure 1).

An increase in hepatic metallothionein-producing cells in control rats given only zinc, when compared to intact controls, was observed. In addition, an increase in hepatic metallothionein-producing cells was observed in the rats given zinc and ethanol, when compared to the group given ethanol. Immunoreactive metallothionein-producing cells in the control group were rarely found to be scattered in lobular hepatocytes or around the periportal area. In the control rats given only zinc, more metallothionein-producing cells were observed in hepatocytes of zones 1 around the periportal area as compared with the control group. Metallothionein was observed significantly in the cytoplasm of cells by immunohistochemical staining in the rat livers of all groups. The intensity of immunoreactivity of metallothionein-producing cells in the group given ethanol and zinc was generally higher in hepatocytes of zones 1 compared to zones 2 (Figure 2). The metallothionein labeling index was determined to be $27.27\% \pm 2.02\%$ in the group given zinc sulfate, while in intact control group the index was $2.44\% \pm 0.50\%$. The metallothionein labeling index was increased 55-fold in the group administered ethanol + zinc sulfate ($26.32\% \pm 3.09\%$) compared to the group administered only ethanol ($0.48\% \pm 0.19\%$) ($^bP_{\text{test}} = 0.018$). (Figure 3A)

Hepatocyte proliferation was measured by immunohistochemical identification of PCNA. The PCNA labeling

Figure 2 Immunoreactive metallothionein-producing cells (\blacktriangleright) in rat liver. index was determined to be $0.73\% \pm 0.17\%$ in the intact control group and $0.32\% \pm 0.02\%$ in the group given zinc sulfate. PCNA immunohistochemistry showed that the number of PCNA-positive hepatocytes was increased significantly in the livers of rats administered ethanol + zinc sulfate ($2.40\% \pm 0.57\%$) compared to the group given only ethanol ($0.19\% \pm 0.10\%$) ($^bP_{\text{test}} = 0.007$) (Figure 3B). However, according to semiquantitative evaluations, most of the PCNA-positive hepatocytes were in S phase of proliferation in all groups.

Ultrastructurally, proliferation of smooth endoplasmic reticulum, degenerative mitochondria, condensation of chromatin and increased lipid droplets were observed after alcohol treatment. However, administration of zinc sulfate caused a remarkable decrease in the lipid droplets, smooth endoplasmic reticulum, and mitochondria degeneration of the hepatocytes (Figure 4).

Biochemical results

Blood GSH levels are presented in Table 1. From the obtained results, values of GSH in the blood of the group administered ethanol showed a significant decrease

Figure 3 A: Metallothionein, ^a $P = 0.018$ vs Ethanol; B: PCNA labeling indices, ^b $P = 0.007$ vs Ethanol.

Figure 4 Ultrastructure of the hepatocytes of the rat. TEM X5000. A: Control; B: Ethanol; C: Zinc sulfate + ethanol. An increase in smooth endoplasmic reticulum (SER), lipid vacuoles (L) and degeneration in mitochondria (M) of the hepatocyte of a rat given ethanol. These ultrastructural changes were improved by zinc pre-treatment.

Table 1 Blood glutathione and serum enzymes (mean \pm SD)

Group	n	GSH (mg %)	$P_{t\text{-test}}$	ALP (U/L)	$P_{t\text{-test}}$	AST(U/L)	$P_{t\text{-test}}$
Control	8	52.59 \pm 2.44	0.009	101.12 \pm 1.64	0.0001	122.55 \pm 2.61	0.001
Control + Zinc sulfate	8	46.65 \pm 4.90		73.91 \pm 6.28		106.03 \pm 8.97

P_{ANOVA}		0.0001		0.0001		0.0001	

^b $P_{t\text{-test}} = 0.0001$ vs Control.

when compared to the control group (^b $P_{t\text{-test}} = 0.0001$). Also, a marked increase in blood GSH level was observed in the group administered ethanol + zinc sulfate when compared to the group administered ethanol ($P_{t\text{-test}} = 0.005$). According to Table 1, a significant difference in the blood GSH levels of four groups was observed ($P_{ANOVA} = 0.0001$).

Serum ALP and AST activities are given in Table 1. From the obtained results, values of ALP in the serum of the group administered ethanol showed a notable increase when compared to the control group (^b $P_{t\text{-test}} = 0.0001$). Also a considerable decrease was noted in the group administered ethanol + zinc sulfate when compared to the group administered ethanol ($P_{t\text{-test}} = 0.0001$). According to Table 1, a significant difference in the ALP activities of the four groups were observed ($P_{ANOVA} = 0.0001$). In this study,

a statistically marked increase was observed in serum AST activity of the group administered ethanol, in comparison with the control group (^b $P_{t\text{-test}} = 0.0001$). On the other hand, in the group to which ethanol + zinc sulfate was administered, the AST activity decreased compared to the ethanol group. A significant difference in the serum AST activities of four groups was observed ($P_{ANOVA} = 0.0001$).

Table 2 shows the effects of zinc sulfate on liver GSH and LPO. The GSH levels were significantly reduced in the group administered ethanol as compared to the other groups ($P_{ANOVA} = 0.0001$). A significant decrease of liver GSH levels in the group administered ethanol was determined in comparison to the control group (^b $P_{t\text{-test}} = 0.0001$). After zinc sulfate administration to ethanol-treated rats, liver GSH levels increased greatly when compared

Table 2 Effects of zinc sulfate on the levels of lipid peroxidation and glutathione in the liver (Mean \pm SD)

Group	n	GSH nmol GSH/mg protein	$P_{t\text{-test}}$	LPO nmol MDA/mg protein	$P_{t\text{-test}}$
Control	8	16.64 \pm 1.24	0.589	0.52 \pm 0.12	0.065
Control + Zinc sulfate	8	15.84 \pm 3.87		0.69 \pm 0.06	
Ethanol	14	12.23 \pm 2.92 ^b	0.0001	0.93 \pm 0.06 ^b	0.001

^b $P_{t\text{-test}}$ = 0.0001 *vs* Control.

to the ethanol group ($P_{t\text{-test}}$ = 0.0001). Zinc sulfate had no significant effect on liver GSH levels in the control group ($P_{t\text{-test}}$ = 0.589). An eminent difference in the liver LPO levels of the four groups was observed (P_{ANOVA} = 0.0001). A significant increase of liver LPO levels in the group administered ethanol was determined in comparison to the control group ($P_{t\text{-test}}$ = 0.0001). After the administration of ethanol + zinc sulfate, the liver LPO levels decreased notably when compared to the ethanol group ($P_{t\text{-test}}$ = 0.001).

DISCUSSION

Ethanol-induced diseases in humans are important in clinical gastroenterology. Animal models in alcohol research have already been applied to study acute and chronic ethanol damage of the liver. Ethanol may accelerate oxidative stress *via* increased production of active oxygen species. Ethanol-induced oxidative stress plays a major role in liver injury^[30]. Ethanol causes a notable fall in the level of zinc in the liver^[1]. Zinc may play a key role in certain alterations observed in alcoholic patients^[31]. The antioxidant defensive system of the liver might be influenced by changes in the zinc content of the liver^[16]. Floersheim^[32] suggested that zinc salts reduce tissue injury caused by a free radical-mediated mechanism. The present study suggests that ethanol-induced hepatic injury is related to the formation of free radicals and pretreatment of zinc prior to the administration of ethanol prevents toxicity. Ethanol treatment is accompanied by the generation of free radicals which stimulate LPO and decrease GSH levels. Therefore, zinc supplementation prevented ethanol-induced decreases in GSH and increases in LPO.

Under light and electron microscopes, the decrease of degenerative changes in the livers of rats administered ethanol + zinc sulfate indicates that zinc ameliorates the damage in the liver tissue of the group given ethanol. An increase in hepatic metallothionein-producing cells in control rats given only zinc as compared to intact controls was observed. This increase shows that metallothionein is required for high zinc levels in liver. In this study, synthesis of metallothionein was shown to increase in the livers of rats given zinc + ethanol, immunohistochemically, in accordance with previous findings^[33]. Our results

indicate that metallothionein induction by zinc sulfate has a protective effect against the injury of acute ethanol administration in liver. Elevation of metallothionein may maintain the integrity of the membrane of the organelles, as observed in the group given ethanol + zinc sulfate. Metallothionein expression may vary with types of tissue and physiological and nutritional factors such as zinc. There are limited studies on hepatic metallothionein levels following acute administration of ethanol to rats^[4,11]. An over-expression of metallothionein serves to protect cells from the alkylating agents^[14]. In the ethanol-intoxicated group, metallothionein levels increased nearly 3.5-times when compared to the control group^[7]. Ebadi *et al*^[22] also reported that the administration of zinc sulfate increased the synthesis of metallothionein mRNAs. It has been reported that hepatic metallothionein synthesis is stimulated by dietary zinc supplementation^[34]. Kotarov^[11] reported that there was a linear dependence of the hepatic levels of metallothioneins with the dosage of alcohol. However, recent studies have shown that zinc inhibition of acute alcohol-induced liver injury is independent of metallothionein^[35,36]. In the present report, the metallothionein labeling index correlated positively with the PCNA index in the rats given zinc + ethanol. It is suggested that enhanced antioxidant proteins such as metallothionein may be involved in hepatocyte proliferation. This finding supports a previous study showing an impairment of liver regeneration in metallothionein-I and metallothionein-II gene knockout mice after partial hepatectomy^[37].

The liver is the most important organ in alcohol metabolism. The increase in AST and ALP activities in serum is an indicator of liver destruction. Their increase in the serum activities of these enzymes was directly proportional to the degree of cellular damage. The activity of AST in the serum of the group administered ethanol showed a statistically significant increase when compared to the control group. AST activity decreased in the group administered ethanol + zinc sulfate. This suggests that zinc pretreatment of rats prevented the elevation of serum AST. Acute ethanol exposure caused a 4-fold increase in the levels of serum AST compared with control animals^[3]. The activity of ALP in the serum of the group administered ethanol has shown a significant increase when compared to the control group. The increase of alkaline phosphatase in the serum may be a result of damage to liver cells. Since zinc is a component of many enzymes, including alkaline phosphatase, a significant decrease was found in the activity of ALP in the group administered ethanol + zinc sulfate when compared to the group administered ethanol.

Glutathione plays a major role as a reductant in oxidation-reduction processes and also serves in detoxification^[38]. Ethanol, or its metabolites, can alter the balance in the liver toward auto-oxidation, either acting as pro-oxidants, or reducing the antioxidant levels, or both^[39]. The pathogenesis of alcohol-induced liver disease involves the adverse effect of ethanol metabolites and oxidative tissue injury^[40]. The most prominent defensive system in the liver is reduced GSH. The values of GSH in blood of the rats administered ethanol have shown a significant decrease when compared to the control

group. Metallothionein shares an important similarity with glutathione due to the fact that one-third of their amino acids are cysteines. Experimental depletion of glutathione in isolated rat hepatocytes has been shown to induce metallothionein expression and to create a new pool of thiol groups in the cell^[41]. Glutathione provides a protective action against damage from reactive oxygen species and free radicals formed during drug metabolism^[42,43]. On the other hand, Dreosti *et al*^[44] reported that ethanol alone had no effect on glutathione levels. Cho *et al*^[45] reported that ethanol and zinc sulfate administration did not affect hepatic glutathione levels in mice. It is reported that zinc supplementation prevented ethanol-induced decreases in glutathione concentration in the liver^[36], in accordance with our findings.

Chronic ethanol administration induces oxidative stress and increases lipid peroxidation of the cell membrane. This leads to increased membrane fluidity, disturbances of calcium homeostasis, and finally results in cell death^[46]. Oxidative stress is characterized by increased lipid peroxidation. A remarkable increase of liver lipid peroxidation levels in the group administered ethanol was determined in comparison to the control group. The present results suggest that zinc sulfate supplementation has a protective effect against lipid peroxidation in liver. Lipid peroxidation was observed to increase prominently in ethanol-fed rats after 4 and 8 wk when compared to the controls^[47]. Patients and experimental animals with acute and chronic ethanol exposure have a depleted liver glutathione content, correlated with an increase in lipid peroxidation^[48,49]. Zinc supplementation for 12 wk caused a decrease in lipid peroxidation, together with an increase in metallothionein concentration in rats^[50]. However, 100 mL/L ethanol ingestion for 8 wk enhanced lipid peroxidation in liver^[51]. Cabre *et al*^[50] reported that zinc is an efficient hepato-protective agent against lipid peroxidation in alcoholic rats.

In conclusion, microscopic and biochemical evaluations reveal that zinc sulfate has a protective effect on ethanol-induced liver injury. Our results demonstrate that zinc acts as an antioxidant agent in hepatic antioxidant systems after acute ethanol administration. In addition, this protective effect against acute ethanol injury has also included proliferation in hepatocytes. Zinc may be a therapeutic agent in the prevention and treatment of ethanol-induced liver injury.

Abstract

AIM: To investigate the influences of enteral, parenteral nutrition and probiotics delivered by gut on intestinal microecology, epithelial tight junctions, immune and barrier function of rats with abdominal infection.

METHODS: Rat abdominal infection models established with cecal ligation and perforation method, were divided into three groups: parenteral nutrition (PN group, $n = 7$), PN+enteral nutrition (EN group, $n = 7$) and PN + EN + probiotics (probiotics group, $n = 7$) *via* the needle jejunostomy and neck vein for five days. The total nutritional supplement of the three groups was isonitrogenic and isocaloric. Probiotics was delivered by jejunostomy 10 mL/d (1×10^8 cfu/mL). The rats were killed on the sixth day. The feces in the cecum were cultured for anaerobic bacterial growth and analyzed with bacterial group DNA fingerprint profile with random amplified polymorphic DNA. The transmembrane binding proteins (occludin) and IgA level in plasma cells of intestine epithelium in colon and terminal ileum were measured by an immunohistochemistry method. The ultrastructure of intestinal epithelial tight junctions in colon and small intestine was observed by electron-microscopy. Vena cava blood and the homogenated tissue of liver, lung and mesenteric lymph nodes were cultured to determine the bacterial translocations, and endotoxin in the blood from portal vein was detected.

RESULTS: (1) The amount of bacteria of gut species in EN group and probiotic group was higher than that in PN group. The DNA-profiles in EN group and probiotic group were similar to that of normal rats. The number of DNA-profiles in probiotics group was much more than that in PN group and EN group. Moreover, there were strange stripes in PN group. (2) The expression of occludin and

IgA in the small and large intestine in EN group (2.309 ± 0.336 , 15.440 ± 2.383) and probiotic group (2.938 ± 0.515 , 16.230 ± 3.183) was improved as compared with PN group (1.207 ± 0.587 , $P < 0.05$, 11.189 ± 2.108 , $P < 0.01$). The expression of occludin in probiotic group (intestine: 2.93 ± 0.515 ; cecum: 3.40 ± 0.617) was higher than that in EN group (intestine: 2.309 ± 0.336 ; cecum: 2.076 ± 0.670 ; $P < 0.05$). The expression of IgA, especially in EN group (intestine: 15.440 ± 2.383) and probiotic EN group (large intestine: 12.516 ± 1.542) significantly increased as compared with PN group (intestine: 11.189 ± 2.108 ; cecum: 10.160 ± 1.643 ; $P < 0.01$). The intestinal epithelial tight junctions and microvilli of the probiotic group were more intact than those in the PN group. (3) The bacterial translocations in blood, liver, lung and mesenteric lymph nodes, and the levels of endotoxin were significantly reduced in probiotic (0.082 ± 0.029) and EN (0.125 ± 0.040) groups as compared with PN group (0.403 ± 0.181 , $P < 0.05$).

CONCLUSION: Application of EN combined with probiotics could improve the expression of transmembrane binding proteins (occludin) and IgA, correct the intestinal flora disturbance, maintain gut barrier functions and tight junctions, and reduce the occurrence of gut bacterial translocation.

INTRODUCTION

Since Deitch^[1] put forward the concept of bacterial translocation in the 1980s, it has been commonly accepted that bacteria and endotoxin translocations are always associated with the destruction of gut barrier, which could also cause systemic infection reactive syndrome (SIRS), pyemia, shock, and multi-organs dysfunction syndrome (MODS), and increase the death rate of patients

with severe illness. Hence, the mechanism of bacterial translocation and the protective and therapeutic agents, as well as the relation between gut original infection and bacteria translocation and their influence on intestinal function have attracted much clinical attention. Though development of new antibiotics has made much progress, the death rate in MODS is still quite high. Under such circumstances, some scholars proposed that the therapy of infection should be directed at its “source” not its “target”^[2]. And methods such as taking the unabsorbed antibiotics orally, implementing enteral nutrition at early stage, and decontaminating the intestine were used to help recover the physiology state of intestinal tract, to reduce the possibility of gut microflora disorder and bacterial translocation and maintain normal gut function.

In recent years, researchers have tried to improve the gut microbial and bacterial translocation by probiotics^[3,4]. However, the thorough and detailed mechanisms are lacking. The present study aimed to determine the effect of probiotics on the ultrastructure of tight junctions, transmembrane protein-occludin expression, enterocyte IgA levels, gut mucus form, gut microflora and bacterial translocation by parenteral nutrition (PN), enteral nutrition (EN) and enteral nutrition combined with probiotics supplied to rats with abdominal infection. It will provide experimental evidence for using probiotics in clinical therapy of abdominal infections.

MATERIALS AND METHODS

The abdominal infection-PN and EN rats model

Fifty-eight SD rats weighing 250-320 g (Fudan University Medical Animal Center, Shanghai) were anesthetized with intraperitoneal injections of 2% saline-ketamin injection liquid (30 mg/g weight). The rats were fixed in a supine position and prepared in a sterile manner for catheterization and operation. A silastic catheter (0.6 mm in inner diameter, 1.0 mm in outer diameter) was inserted through the external jugular vein into the superior vena cava. The catheter was tunneled subcutaneously to the midscapular region and guarded by the flexible spring, and then hooked up to an infusion pump (B. Braun). The abdominal infection model was established by cecum perforation and ligation (CPL)^[5], here one third of the cecum distal was ligated and perforated with holes through which a piece of rubber patch was placed and the pinhead hole (#12) fixed. A silastic catheter (1.2 mm in diameter) was placed by jejunostomy 30-40 cm away from the cecum, and the catheter was tunneled abdominally subcutaneously to the back. The rats were maintained in individual metabolic cages^[6]. The silastic catheters of jejunum and neck vein were traversed together through the spring and linked to the infusion pump on the circumrotate equipment^[7]. The PN and EN nutrient solution was infused at a constant infusion rate by 2 pumps for 5 d during the experimental period.

Animal grouping

After establishment of model, all rats received intravenous 0.9% saline solution at 2.0 mL/h for 24 h. Rats were divided into three groups, PN group ($n = 7$): supported

Table 1 PN solution prepared (contents/100 mL)

Prescription	Dose
50% Glucose (mL)	33
8.5% Novamin (mL)	45
20% Intralipid (mL)	17
Solvita (mL)	1
Addamel (mL)	1
10% KCl (mL)	1
10% NaCl (mL)	1
RI (U)	4
Heparin (U)	40
Non-protein calorie (kJ)	348
Total nitrogen (mg)	504

by PN; PN + EN group (EN group, $n = 7$): supported by PN + EN(peptide), EN was dripped through jejunum tube; PN + EN + probiotic group (probiotic group, $n = 7$): supported by PN + EN(peptide), the probiotics was infused by jejunostomy tube at about 10 mL/d. The 3 groups were isonitrogenic and isocaloric (Table 1) during 1-5 d. In the PN group, 100% calorie and nitrogen were supplied by the PN solution at the infusion speed of 3.3 mL/h and 80 mL/d. In EN groups, 80% calorie and nitrogen were supplied by the PN solution at an infusion speed of 2.6 mL/h, and 64 mL/d, and the other 20% were supported by EN (Pepti-2000) at 16 mL/d, which were diluted 2:1 to 24 mL with saline solution and the infusion speed maintained at 1 mL/h. In the probiotic group, the probiotics (supported by Shanghai Jiaotong University Limited Company) were added at 10 mL/d. The daily dose of amino acids was 2.5 g of nitrogen per kilogram, the amount of non-protein calories was 348 kJ/d and the total nitrogen was 504 mg/d. The rats were killed and samples taken in the morning of the 6th d.

Probiotics containing live lactobacillus plantarum (activity 1×10^8 cfu/mL) was infused at about 10 mL/d by jejunostomy tube twice per day through 1-5 d.

Fecal bacterial anaerobic culture

The fecal sample (0.1 g) in cecum was placed in 9 mL Ringer dilution solution(which contained cysteine) and incubated anaerobically at $36 \pm 1^\circ\text{C}$ supplemented with brucella blood agar (2 d, total anaerobic CFU), bacteroides bile esculin agar (2 d), egg yolk agar (after equal volumes of 95% ethanol were added to the dilutions and the preparations stood for 30 min to select for clostridial spores), and Rogosa SL agar (Difco) (2 d for lactobacilli and 4 d for bifidobacteria, after Lactobacillus colonies were marked at 2 d). The dilutions were removed from the anaerobic glove box and inoculated (100 μL inocula) into plates which contained the following media: supplementary brucella blood agar (2 d, total aerobic CFU), MacConkey agar (Difco) (1 d, enterobacteria), bile esculin azide agar (Difco) (1 d, Cl Perfringens) and were incubated aerobically at 37°C . To analyze the total Lactobacillus population, 10 colonies were picked randomly from a dilution agar plate containing about 100 colonies. The bacterial colonies were counted and identified by Microscan Autoscan-4 Machine (Dade Behringcom).

Gut bacterial DNA fingerprint profiles

The fecal samples in cecum from each subject were also examined by PCR-denaturing gradient gel electrophoresis (DGGE) profiles. To extract bacterial DNA, 1 mL of fecal homogenate in pH 7.0 phosphate buffer (the buffer used for the azoreductase assay) was centrifuged at 14 600 g for 5 min (5°C). DNA was extracted from the resulting pellet with a Fast DNA kit (BIO 101, Vista, CA) by using CLS-TC (a cell lysis solution used for animal tissues and bacteria). The V2-V3 region of the 16S rDNA gene (positions from 339 to 539 in the *Escherichia coli* gene) of bacteria in the fecal samples was amplified by using primers bacteria ITS PS2 (5'-TG(C/T) ACA CACCGC CCG T-3'), PL2 (5'-GGG T (G/C/T) CCC CAT TC(A/G)G-3'). PCR was performed with 0.2-mL tubes by using a PCR Express thermal cycler (Hybaid, Teddington, UK). Each reaction mixture (50 µL) contained reaction buffer (10 mmol/L [final concentration] Tris-HCl, 2.5 mmol/L [final concentration] MgCl₂, 50 mmol/L [final concentration] KCl [pH 8.3]), each deoxynucleoside triphosphate at a concentration of 200 µmol/L, 20 pmol of each primer, 1 µL of fecal DNA, and 2.5 U of Taq DNA polymerase (Boehringer, Mannheim, Germany). The following amplification program was used: 94°C for 3 min, followed by 30 cycles consisting of 94°C for 30 s, 56°C for 30 s, and 68°C for 60 s, and finally 7 min at 68°C. DGGE was performed by using a DCode universal mutation detection system (Bio-Rad, Richmond, CA) and gels that were 16 cm × 16 cm × 1 mm; 6% polyacrylamide gels were prepared and electrophoresed with 1 × TAE buffer prepared from 50 × TAE buffer (2 mol/L Tris base, 1 mol/L glacial acetic acid, 50 mmol/L EDTA). The denaturing gradient was formed by using two 6% acrylamide (acrylamide/bisacrylamide ratio, 37.5:1) stock solutions (Bio-Rad). The gels contained a 22%-55% gradient of urea and formamide that increased in the direction of electrophoresis. A 100% denaturing solution contained 400 mL/L formamide and 7.0 mol/L urea. Electrophoresis was performed at 130 V (constant voltage) and 60°C for about 4.5 h. Electrophoresis was stopped when a xylene cyanol dye marker reached the bottom of a gel. The gels were stained with an ethidium bromide solution (5 µg/mL) for 20 min, washed with deionized water, and reviewed by UV transillumination^[8,9].

Gut mucosa occludin and IgA indirect-immune fluorescence expression

The distal ileum and colon tissue were taken to determine the occludin and IgA expression by indirect-immune histochemical fluorescence.

Occludin: The tissue was embedded into the frozen acetone at -20°C. Then it was sliced, and routinely dehydrated. To remove the endogenous peroxidase enzyme activity, the slides were treated with 0.1%-1% H₂O₂ at 37°C for 5-10 min. Then they were washed with PBS twice, and incubated at room temperature overnight with primary antibody 1:300 (goat anti-rat occludin antibody, Santa Cruz). And then they were washed with PBS 3 times and incubated with the second antibody 1:200 (anti-goat IgG, Santa Cruz) for 30 min, then washed again with PBS 3 times and the formula AB enzyme reagent was added.

Then they were washed with PBS again and incubated with peroxidase enzyme for 30 s-10 min. After that, the slides were washed by H₂O₂, dehydrated and mounted.

IgA: The tissue was embedded into paraffin and sliced, then routinely dewaxed. The slides were washed with PBS 3 times, incubated with 3.3% H₂O₂ at room temperature for 10-15 min to block the endogenous peroxidase enzyme, then washed with PBS again, and albumin interdiction solution was added for 5 min to reduce the nonspecific background staining. Then slides were washed with PBS, and the first antibody 1:500 (mouse anti-rat IgA antibody, Sigma) was added at 4°C refrigerator overnight. After that slides were washed with PBS again, and second antibody 1:100 (anti-mouse antibody, DAKO) labeled with biotin was added. Slides were then washed with PBS again, and visualised with DBA enzyme-substrate illustration system, then dyed again and developed.

The data were analyzed by HPIAS1000 high definition color image manipulation system. Under the same expanding multiple (400), the occludin density was determined per field of vision by light-densimeter (at least five fields per slide).

Tight junction of ileum and cecum by electron microscopy

The gut tissues about 0.5 cm in length were taken from distal ileum and colon 5 cm away from the valva ileocaecalis. One fixation procedure was used for conventional thin-section electron microscopy. The fixation procedure included incubation with OsO₄ alone (1% or 2% in phosphate buffer) at 0°C for 30 min. After fixation, the ileum and cecum were washed extensively in Veronal acetate buffer (90 mmol/L, pH 6.0), stained by incubation at 0°C for 60 min in uranyl-magnesium acetate (0.5%) in the same buffer, washed again, dehydrated, and embedded. Thin sections were doubly stained with uranyl acetate and lead nitrate and the change of tight junction and microvilli were observed (2 × 10⁴) using a Philip EM 400 electron microscope.

Bacterial translocation rate of mesenteric lymph node and remote organ

Blood from vena cava (1 mL), mesenteric lymphatic tissue (5 g), liver and lung tissue, were collected, homogenized and placed into a tube containing cardio-cerebral leachate, incubated at 35°C. After 18-24 h samples were stained with methylene blue-eosin method, and continued to be cultured at 35°C. 18-24 h later, the number of bacterium was counted by Microscan Autoscan-4 machine.

Endotoxin

Blood from the portal vein (1-2 mL) was taken into heparin lithium anticoagulant centrifuged at 500 r/min for 5 min. The supernatants were mixed with the limuluslysate reagent to examine the endotoxin level.

Statistical analysis

Analysis of data was performed by χ^2 and Dunnette *t* test with statistical program SPSS10.0, the experimental data were expressed as mean ± SD of the samples between 3 groups. The level of significance was set at *P* < 0.05 or *P* < 0.01.

RESULTS

General condition and death rate

The CPL model was established successfully in 58 SD rats; 37 rats died, with the total death rate during 6 d of 63.8%. The death rate in PN group (78.7%) was higher than that in probiotic group (41.6%, $\chi^2 = 5.658$, $P = 0.0174 < 0.05$, Table 2) and EN group (46.1%, $\chi^2 = 4.691$, $P = 0.030 < 0.05$, Table 3). Interloop abscess (70%), liver abscess (35%) and lung abscess (20%) were observed in the surviving rats, and the positive rate of the blood culture reached 37%.

Amount of fecal bacteria in the cecum

In the cecum, the amount of all genus (*Enterobacillus*, $t = -0.276$, $P = 0.018 < 0.05$, *Bifidobacteria*, $t = -2.749$, $P = 0.017 < 0.05$, *Lactobacillus*, $t = -8.033$, $P = 0.002 < 0.01$, *Cl Perfringens*, $t = -2.317$, $P = 0.031 < 0.05$) of the EN group were more than that of the PN group. In the probiotic group the amount of *Enterobacillus* ($t = -2.30$, $P = 0.390 < 0.05$), *Lactobacillus* ($t = -9.935$, $P = 0.001 < 0.01$) and *bifidobacteria* ($t = -5.644$, $P = 0.002 < 0.01$) increased, and the amount of *Cl Perfringens* ($t = -3.144$, $P = 0.384 < 0.05$) decreased as compared with PN group.

DNA fingerprint profiles

The profiles of DNA sequence in PN group on electrophoresis (lanes 3-9) were less than that in the normal group (lanes 1-2), EN group (lanes 10-16), and probiotic group (lanes 17-23); lanes 3, 6, 7 presented with a new 16S rDNA sequence in the profile (labeled in Figure 1). The sequence profiles of expression in probiotics and EN groups were

Table 3 Death rate in celiac infection model of three groups

Group	<i>n</i>	Death	Death rate
PN	33	26	78.7%
EN	13	6	46.1% ^a
Probiotic	12	5	41.6% ^a

^a $P < 0.05$ vs PN group.

similar to that in the normal group (lanes 9-10).

Gut mucosa occludin and IgA expression

There was more occludin expression in the probiotic group and EN group on the surface, intracellular and inter-cell spaces of the gut epithelial cells as compared with PN group (Figures 2A-F). The occludin positive expression area per measured-window in EN group (intestine, $t = -4.955$, $P = 0.034 < 0.05$, cecum, $t = -5.407$, $P = 0.019 < 0.05$, Table 4) and probiotics group were higher than that in PN group (intestine, $t = -5.426$, $P = 0.002 < 0.01$, cecum, $t = -6.112$, $P = 0.006 < 0.01$), and that in the probiotic group was higher than that in EN group (intestine, $t = -2.645$, $P = 0.023 < 0.05$, cecum, $t = -2.307$, $P = 0.042 < 0.05$).

The expression of IgA in EN group (intestine, $t = -4.995$, $P = 0.003 < 0.01$, cecum, $t = -2.850$, $P = 0.014 < 0.05$) and probiotic group (intestine, $t = -3.575$, $P = 0.024 < 0.05$, cecum, $t = -4.946$, $P = 0.004 < 0.01$) was higher than that in PN group, especially the small intestine of the EN group and the cecum of the probiotic group.

Tight junction and microvilli micro-structure

There were more integrated tight junctions, less mitochondrion endoplasm and microvilli brushed in EN group and probiotics group as compared with PN group (Figures 3A-F). The readability of the tight junction in probiotics group was clearer than that in PN group and EN group.

Endotoxin and bacterium translocation rate of mesentery lymph node (MLN) and remote organ

Bacterium translocation rate (BTR) in PN group (60.7%) was higher than that in probiotic group (28.6%, $\chi^2 = 5.853$, $P = 0.016 < 0.05$, Table 5) and EN group (32.1%, $\chi^2 = 4.595$, $P = 0.032 < 0.05$, Table 5), whereas there was no marked difference of the BTR between the probiotics group and EN group ($\chi^2 = 0.0845$, $P = 0.7713 > 0.05$).

The endotoxin level of the PN group was higher than that in EN group ($t = 3.954$, $P = 0.002 < 0.01$) and in probiotic group ($t = 4.615$, $P = 0.001 < 0.01$).

DISCUSSION

PN has achieved significant effect as an important therapeutic method for patients with severe illness. However, long-term utility of PN may induce injury of the gut barrier and bacteria translocation. On the other hand, many therapeutic approaches including enteral nutrition and glutamine have been used to improve gut barrier function and positive results have been reported.

Nevertheless, they all have certain shortfalls and defects, especially regarding their effect on the gut microbiota^[6]. With stress impairments such as wounding, surgery, and infection, not only is the gut barrier disrupted, but normal gut microbiota is also destroyed due to the change in the normal physiology of the gut and the use of antibiotics. The conditional pathogen can predominantly reproduce, disperse and translocate to extra intestinal organs and disseminate throughout the body through blood circulation. As the probiotics are autochthonous habitual bacteria, extra supplement with them could inhibit the potential pathogen's activity by adhering and colonizing to the intestinal epithelial cell, depressing the pathogenicity of the pathogens, and restoring the normal physiology of the gut. Utility of microorganism regulators such as lactobacillus, bifydobacteria, enterococci and the toxinless, harmless and safe aerophilic bacillus could improve the microflora, reduce the bacterial translocation and protect the gut barrier, and satisfactory results have been reported^[7]. Considering the specific effect of the probiotics, Bengmark^[10] proposed a new concept of econutrition in 1996, suggesting that. Adding the probiotics to the traditional enteral nutrition, can reduce the excess growth of the pathogen by its antagonist action, improve the environment of the gut by enhancing gut microflora's fermenting activity, thus maintaining the intestinal function and the gut microbiology, improving the nutritional state and immune capability against disease, reducing the infection rate of the patients with critical illness^[7].

In the current study, a model of rats with abdominal infection was established to observe the influences of different nutritional pathway and probiotics on the gut ecology and barrier function by CLP method. In traditional fecal anaerobic cultivation, gut microflora

Figure 2 Intestinal and colon epithelial occludin expression. **A:** Intestinal epithelium occludin expression in PN group (200 ×); **B:** decreased epithelium occludin expression in colon in PN group (200 ×); **C:** Intestinal epithelium occludin expression in probiotics group (200 ×); **D:** Colon epithelium occludin expression in probiotics group (200 ×); **E:** Intestinal epithelium occludin expression in probiotics group (200 ×); **F:** Colon epithelium occludin expression in probiotics group (200 ×).

disorder was observed and conditional pathogenic bacteria (Cl Perfringens) increased markedly in PN group. Microflora partly recovered in EN group because of the effect of the EN itself. Both the amount and the species were more than that of the PN group, but the number of conditional pathogen was increased also. However, while the amount of lactobacillus and bifydobacteria increased by adding the probiotic, the Cl Perfringens were inhibited effectively. Meanwhile the bacteria of normal rats were logarithm mean of the major bacteria: Enterobacillus (5.732), lactobacillus (6.903), bifydobacteria (8.941), Cl Perfringens (5.132). The amount of gut flora in the probiotic group was closer to that of normal rats, suggesting the relevant intestinal pathogens could be controlled using probiotics. In this study, it was difficult to identify the type or

Table 5 Endotoxin and BTR of MLN and remote organs

Group	n	MLN	Liver	Lung	Cava blood	BTR	Endotoxin (EU)
PN	7	6	4	3	4	60.7%	0.403 ± 0.181
EN	7	4	2	2	1	32.1%	0.125 ± 0.040 ^a
Probiotic	7	3	2	1	2	28.6%	0.082 ± 0.029 ^b

^a*P* < 0.05 vs PN group, ^b*P* < 0.01 vs PN group. BTR: Bacterium translocation rate; MLN: Mesenteric lymph node.

subtype of bacterium and only some local bacteria were determined simultaneously by quantitative analysis because of limited experimental condition. Therefore, the common method of anaerobic cultivation could not reflect the whole profiles of gut preponderant bacterial colonies. Fortunately, molecular biology technology (DNA footprint profile of the microbial gene group) has been used in the analysis of the microbiota in recent years, which could not only quantify the amount of the bacteria, but also reflect changes in community profiles to overcome the shortage in this aspect^[8,11]. Our result showed that there were a group of very bright stripes and the number of the stripes in PN group was obviously much more than that in the normal group, EN group and probiotic group, suggesting the gut microflora of the rats only applied with PN were destructed, the species of normal microflora were reduced, and the abnormal intestinal flora increased. The stripes of probiotic group were obviously more than that of the EN group, indicating the species of the rat intestinal microflora increased after adding the probiotics. The 7 stripes in this group were more similar to each other and some specific stripes were identical to the normal group, implying the administration of probiotics was in favor of transferring the rat gut microflora with abdominal infection to the

normal state. On the whole, these results suggest early EN can correct the gut microflora disorder caused by PN, and the balance of gut microflora can be improved after adding the probiotics.

Occludin^[12-16] is one of the major tight junction structural proteins which determine the intestinal selective barrier function. The measurement of the intestinal epithelial transmembrane junction protein (occludin) could reflect the destruction of the gut tight junctions by the pathogen to some degree. Therefore, in our experiment, the expression of occludin on the enterocyte in distal intestine and the colon tissue were detected. The occludin of the PN group was the least in the 3 groups. After EN and probiotics were added, the occludin increased significantly; occludin level in the probiotic group increased more than that in the other two groups. In order to understand the ultrastructure of the tight junction, the samples were primarily observed by electron microscopy. Compared to the PN group, the tight junction form of the small and large intestine was more intact, the arrangement was tighter and the villi kept more integrity in EN group. And the small and large intestinal epithelial forms in probiotic group were more intact and the gut epithelial tight junctions were clearer than other groups. These results suggested the effect of the probiotics on the gut epithelia, especially the large intestine epithelia, was more significant. With improvement of the gut microflora, the expression of the occludin also increased, and the epithelial tight junction appeared more intact by electron microscopy.

There is increasing evidence that probiotic micro-organisms can interact with the gut associated lymphoid tissue (GALT) and influence mucosal and systemic immune systems^[17]. We also studied IgA level of the intestinal tissue. Our result using the EN or probiotics

showed that the recovery of the gut IgA expression was more significant than that of the PN group, in the small intestine of EN group and large intestine of probiotic group. Thus using the EN and probiotics could accelerate the expression of occludin and IgA. They could also affect bacterial translocation. After adding the probiotics and/or EN, the death rate, bacterial translocation rates in the blood, mesentery lymph nodes, liver and lung, and the endotoxin level were much lower than the PN group. The death rates and bacterial translocation rates were also decreased in turn.

In conclusion, the mechanism by which EN combined with probiotics improves the gut barrier of the rats with abdominal infection lies in: (1) inhibiting the growth of pathogen and correcting the gut microflora disorder; (2) increasing the expression of occludin and IgA, strengthening the gut epithelial tight junction and the immune state of the local intestine.

Abstract

AIM: To evaluate the effects of osthole on fatty liver, and investigate the possible mechanism.

METHODS: A quail model with hyperlipidemic fatty liver and rat model with alcoholic fatty liver were set up by feeding high fat diet and alcohol, respectively. These experimental animals were then treated with osthole 5-20 mg/kg for 6 wk, respectively. Whereafter, the lipid in serum and hepatic tissue, and coefficient of hepatic weight were measured.

RESULTS: After treatment with osthole the levels of serum total cholesterol (TC), triglyceride (TG), lower density lipoprotein-cholesterol (LDL-C), coefficient of hepatic weight, and the hepatic tissue contents of TC and TG were significantly decreased. The activity of superoxide dismutase (SOD) in liver was improved. In alcohol-induced fatty liver rats, the level of malondialdehyde (MDA) in liver was decreased. In high fat-induced fatty liver quails, glutathione peroxidase (GSH-PX) in liver was significantly improved. The histological evaluation of liver specimens demonstrated that the osthole dramatically decreased lipid accumulation.

CONCLUSION: These results suggested that osthole had therapeutic effects on both alcohol and high fat-induced fatty liver. The mechanism might be associated with its antioxidation.

Song F, Xie ML, Zhu LJ, Zhang KP, Xue J, Gu ZL. Experimental study of osthole on treatment of hyper-

INTRODUCTION

Fatty liver is the first progression of chronic liver diseases, and without therapy, the disease is apt to develop inflammation, necrosis, fibrosis and finally cirrhosis^[1]. There are currently no ideal pharmacological reagents that can prevent or reverse this disease^[1-2].

Osthole is an active constituent isolated from the fruit of *Cnidium monnieri* (L.) Cusson, a Chinese herbal medicine, which has been clinically used as therapy for diseases for many years. It has many anti-inflammatory, anti-osteoporosis and anti-tumour functions, but there is no report about treatment of fatty liver. We found it could decrease the level of serum triglyceride (TG) in ovariectomized rats occasionally, so we begin to study the therapeutic role of osthole for fatty liver.

The aim of our study was to determine whether osthole could reverse steatosis in the rat model of alcohol and quail model of high fat-induced hepatic fat accumulation, and to investigate potential mechanisms involved in this therapeutic effect. Accordingly, we established alcoholic fatty liver rat model and hyperlipidemic fatty liver quail model, and then these animals were treated with osthole.

MATERIALS AND METHODS

Drugs

Osthole was kindly provided by Dr Jia Zhou of Xi'an Green Fount Natural Product Co. Ltd. (China), the purity of the drug was $\geq 95\%$. Lipanthyl was procured from Laboratories Fournier SA (France).

The establishment of model^[3-4]

Male Sprague-Dawley rats weighing 200 ± 20 g were obtained from Animal Breeding Center of Soochow University, and were housed in regular cages situated in an animal room at 22°C. These experimental rats were fed with standard rat diet and allowed to drink water at will. The animal studies were conducted according to the regulations for the use and care of animal experimentation in Soochow University.

The alcoholic fatty liver rat model was induced by

Table 1 Serum levels of TC, TG, HDL-C, LDL-C, FFA and the relative hepatic weight after treatment with osthole for 6 wk in alcohol-induced fatty liver rats ($n = 10$)

feeding 40% alcohol 1 mL/100 g and corn embryo oil 0.4 mL/100 g. Eight wk after the experiment, three rats were killed and livers were taken out for assessment of fatty hepatic development. After the model developed, the rats were randomly divided into 5 groups ($n = 10$ for each group): fatty hepatic model, osthole 5 mg/kg, osthole 10 mg/kg, osthole 20 mg/kg groups, and lipanthyl 20 mg/kg groups respectively. A solvent control group ($n = 10$) was added simultaneously and given 0.5% CMCNa₂ solution. These medications lasted for 6 wk. The rats were then sacrificed, blood sample was obtained and hepatic tissues were collected for measurement of designing parameters.

Male quails weighing 120 ± 5 g were obtained from Animal Breeding Center of Soochow University, they were housed in regular cages situated in an animal room at 22°C, with a 12 h light/12 h dark cycle. The animals were fed with standard quail diet and allowed to drink water at will.

The hyperlipidemic fatty liver quail model was created by feeding a high-fat diet containing standard diet, 10% lard and 2% cholesterol. After 6 wk the fatty liver was generated, these animals were then randomly divided into 5 groups ($n = 10$ for each group): model, osthole 5 mg/kg, osthole 10 mg/kg, osthole 20 mg/kg and lipanthyl 20 mg/kg groups respectively. A solvent control group ($n = 10$) was added as above. These medications lasted for 6 wk. The quails were sacrificed, blood was obtained and hepatic tissues were collected for measurement of designing parameters.

Measurement of serum TC, TG, lower density lipoprotein-cholesterol (LDL-C) and free fatty acid (FFA)

Blood was obtained after 12 h overnight fasting. The assay kits were purchased from Kexin Biology-Technology Company of Shanghai, China. Serum TC, TG, HDL-C and FFA were determined by colorimetric methods according to the procedures provided, LDL-C was obtained by Friedewald calculation, namely, $LDL-C = TC - (TG/2.2 + HDL-C)$.

Measurement of TC and TG in liver

The hepatic TC and TG was extracted from liver tissue using chloroform/methanol mixed solution (1:1, vol: vol), the prepared sample was then centrifuged at $1200 \times g$ for 10 min, the obtained supernatant was used for measurement of TC and TG according to the colorimetric methods.

Measurement of SOD, MDA, GSH-PX and protein in liver

Liver tissue was taken at the time of animal sacrifice and rapidly put in ice-cold saline; the tissue homogenate (10% wt/vol) was prepared. Contents of SOD, MDA and GSH-PX were determined by colorimetric methods according to the procedure provided, respectively. Protein in liver was also measured by colorimetric method.

Histological observation

Liver specimens were fixed in 10% formaldehyde and embedded in paraffin for HE staining. The degree of fatty degeneration was graded by estimating the proportion of hepatocytes containing fat droplets and expressed as “-, +, ++, +++”. “-” means no fat present, “+” less than 1/3 of the hepatic lobule, “++” 1/3 to 2/3, and “+++” more than 2/3. The histological evaluation of the liver sections was blindly performed.

Statistical analysis

Data are expressed as mean \pm SD, t -test was used for comparisons between groups, χ^2 -test was used for histopathological evaluation. $P \leq 0.05$ was considered statistically significant.

RESULTS

Results from rats

After 6 wk of osthole administration, rat serum TC, TG and LDL-C levels were significantly lower in osthole groups than in model group, the relative hepatic weight in osthole groups was also decreased, but no significant difference was found in serum FFA and HDL-C levels between osthole and model groups (Table 1). The hepatic tissue levels of TC, TG and MDA in osthole groups were significantly lower than those in the model group, and the activity of SOD in osthole groups was increased significantly. The osthole had no obvious effect on GSH-PX activity (Table 2). Histological evaluation of liver specimens demonstrated that osthole could decrease lipid accumulation (Table 3 and Figure 1). The results of the present study suggested osthole could decrease the alcohol-induced liver injury in rats.

The serum levels of TC, TG, LDL-C, FFA and the relative hepatic weight in model group were significantly higher than those in control group, whereas the level of HDL-C was decreased markedly. After treatment with

^a $P < 0.05$, ^b $P < 0.01$ vs control animal. ^c $P < 0.05$, ^d $P < 0.01$ vs model animal.

osthole 5-20 mg/kg for 6 wk, serum levels of TC, TG, LDL-C and the relative hepatic weight were decreased by 31.7%-36.5%, 25.4%-29.4%, 51.5%-67.4% and 16.0%-18.4%, respectively. Serum levels of FFA and HDL-C were decreased or increased to some degree, but the effects were not significant compared with those in the model group. In lipanthyl group, serum levels of TC, TG and LDL-C were decreased, but the level of HDL-C was not increased, the level of FFA and the relative hepatic weight were inversely increased.

The tissue levels of TC, TG and MDA in the model group were significantly higher than those in the control group, while the activity of SOD in model group was depressed significantly. Treatment of rats with osthole 5-20 mg/kg for 6 wk, resulted in a significant decline in levels of TC, TG and MDA, and increase in activity of

SOD. In lipanthyl group, the levels of TC, TG and MDA were decreased, but the SOD activity was not increased. There was no obvious effect on GSH-PX activity.

Histological evaluation of liver specimens demonstrated that administration of osthole dramatically decreased lipid accumulation. Thus, our results demonstrated a therapeutic effect of osthole in alcohol-induced fatty liver of the rats.

Results from quails

In quails treated with osthole for 6 wk, serum TC, TG, LDL-C and FFA levels, the relative hepatic weight in osthole groups, particularly in 20 mg/kg group, were significantly lower as compared with model group. No significant difference was observed in HDL-C level between osthole and model groups (Table 4). The hepatic tissue levels of TC and TG in osthole groups

were significantly lower than those in model group, and the activities of SOD and GSH-PX were significantly improved. There were no obvious effects on FFA and MDA levels (Table 5). Histological evaluation of liver specimens demonstrated that osthole could decrease lipid accumulation (Table 6 and Figure 2). These results suggested that osthole could decrease the high fat-induced liver injury in quails.

The serum levels of TC, TG, LDL-C, FFA and the relative hepatic weight in model group were significantly higher than those in the control group. Serum levels of TG, FFA and the relative hepatic weight in osthole groups were decreased, while serum levels of TC and LDL-C only in 20 mg/kg group were significantly decreased. In lipanthyl group, serum levels of TC, TG, LDL-C and the relative hepatic weight were also decreased, but serum FFA level was not.

The hepatic tissue levels of TC and TG in model group were significantly higher than those in control group, and the activity of SOD was significantly depressed. Levels of TC and TG in liver in osthole groups were decreased by 37.6%-47.3% and 7.4%-25.2%. Notably, continuous administration of the drug for 6 wk significantly increased the activities of SOD and GSH-PX in hepatic tissue. In lipanthyl group, level of TC was decreased, activities of SOD and GSH-PX in liver were increased, level of FFA was inversely increased, but it had no obvious effects on TG levels.

Histological evaluation of liver specimens demonstrated that administration of osthole dramatically decreased lipid accumulation. Thus, our results demonstrated that osthole possessed a therapeutic effect on high fat-induced fatty liver in quails.

**Figure 2** Histopathological changes of quail liver (hematoxylin and eosin staining, 25 ×). No steatosis was observed in control group (A) and the fatty degeneration was seen in the model group (B). Fatty degeneration of liver was alleviated after treated with osthole 5 mg/kg (C), 10 mg/kg (D), 20 mg/kg (E) and lipanthyl 20 mg/kg (F) for 6 wk.

DISCUSSION

Fatty liver can be induced by alcoholic and non-alcoholic aetiologies. It commonly occurs in the general population and has the potential to progress to fibrosis and cirrhosis^[5-6]. The spectrum of pathology is wide, ranging from benign steatosis to cirrhosis, hepatocellular carcinoma and hepatic failure^[6]. The prevalence of hepatic damage in fatty liver is difficult to determine accurately. However, it has been estimated that amongst a population of obese/diabetic individuals approximately 50%-70% will have fatty change, 20%-30% will progress to steatohepatitis/fibrosis and 2%-5% will eventually become cirrhosis^[7-9]. But fatty liver is reversible with abstinence or medicine therapy. To prevent the occurrence of hepatic fibrosis and cirrhosis, treatment of fatty liver is an important step.

Non-alcoholic fatty liver (NAFL) has been extensively reported over the world. In general population studies, screening with ultrasound or CT has shown that a prevalence ranging of NAFL is from 16% to 23%. In liver biopsy studies, the prevalence ranges are 15%-39%^[10-12]. Obesity type 2 diabetes mellitus (DM), female gender and hyperlipidaemia are frequently associated with NAFL^[6,13]. Because the typical dyslipidaemia of NAFL is also characteristic of the commonly occurring insulin resistance syndrome, and there is a strong link between hyperlipidemia and obesity which associate with visceral fat accumulation^[14], so our study emphasized particularly on the hyperlipidemic fatty liver.

Alcohol is also a major cause of fatty liver. Alcoholic

fatty liver (AFL) has a common pathophysiology with NAFL^[15]. At least 80% of heavy drinkers develop fatty liver. It is reversible with abstinence, whereas it may progress to cirrhosis without abstinence.

At present the treatment for fatty liver mainly includes dietary intervention, treatment of associated insulin resistance, lipid-lowering medications, antioxidants and ursodeoxycholic acid and so on. An ideal and effective drug has not been found to prevent and treat this disease^[6].

Our experimental results show that after treatment with osthole for 6 wk, the levels of serum TC, TG, LDL-C, the relative hepatic weight and the hepatic tissue contents of TC and TG were decreased significantly in alcohol-induced fatty liver rats or in high fat-induced fatty liver quails. The histological evaluation of liver specimens demonstrated that osthole dramatically decreased lipid accumulation. These results suggest that osthole has a new function to protect the liver from fat accumulation. It decreased high fat-induced liver injury in quails and alcohol-induced liver injury in rats.

To develop fatty liver, it has been recently suggested that one prerequisite condition should exist, i.e., a source of oxidative stress capable of initiating significant lipid peroxidation^[16]. Both animal data and human studies have shown a link between fatty liver and oxidative stress and lipid peroxidation. Mitochondria are thought to be the source of the reactive oxygen species (ROS) leading to lipid peroxidation. The increased hepatic influx of FFA that results from the reduced ability of insulin to suppress lipolysis is thought to increase the rate of mitochondrial [beta] oxidation and produce the ROS. There are other potential sources of oxidative stress including the cytochrome P450 enzymes (CYP2E1 and CYP3A4) and increased hepatic iron content. Chronic alcohol exposure may also result in oxidant production^[16].

Our experimental results showed in the alcohol-induced fatty liver test that administration of osthole promoted SOD production, depressed MDA production, and lightened the degree of steatosis in liver tissue. In the high fat-induced fatty liver test, administration of osthole had same effects as in the alcohol-induced fatty liver test. Furthermore, osthole also promoted GSH-PX production in liver tissue. These results demonstrated that the therapeutic effect of osthole on fatty liver was partly due to its antioxidation against ROS. From the findings of

present studies, we suggested that the mechanism of fatty liver generation was related to the extra production of ROS.

Abstract

AIM: To investigate the dynamic change and role of neuronal nitric oxide synthase (nNOS) and inducible nitric oxide synthase (iNOS) in neonatal rat with intestinal injury and to define whether necrotizing enterocolitis (NEC) is associated with the levels of nitric oxide synthase (NOS) in the mucosa of the affected intestine tissue.

METHODS: Wistar rats less than 24 h in age received an intraperitoneal injection with 5 mg/kg lipopolysaccharide (LPS). Ileum tissues were collected at 1, 3, 6, 12 and 24 h following LPS challenge for histological evaluation of NEC and for measurements of nNOS and iNOS. The correlation between the degree of intestinal injury and levels of NOS was determined.

RESULTS: The LPS-injected pups showed a significant increase in injury scores versus the control. The expression of nNOS protein and mRNA was diminished after LPS injection. There was a negative significant correlation between the nNOS protein and the grade of median intestinal injury within 24 h. The expression of iNOS protein and mRNA was significantly increased in the peak of intestinal injury.

CONCLUSION: nNOS and iNOS play different roles in LPS-induced intestinal injury. Caution should be exerted concerning potential therapeutic uses of NOS inhibitors in NEC.

INTRODUCTION

Necrotizing enterocolitis (NEC) is a common and devastating gastrointestinal condition of neonatal infants^[1]. In spite of extensive epidemiological, clinical, and basic research, the pathogenesis of NEC remains elusive, and there is no effective preventative treatment for this disease. Several lines of evidence suggest that neonatal risk factors of prematurity, intestinal asphyxia/ischemia, formula feeding and bacterial colonization all contribute to the occurrence of the disease^[1-4]. These components probably act in concert to upset an already immature and delicate intestinal mucosal barrier^[5].

Nitric oxide (NO) is a weak radical produced from L-arginine via the nitric oxide synthase (NOS) isoforms: the constitutive neuronal NOS (type I, nNOS), the inducible NOS (type II, iNOS), and the endothelial NOS (type III, eNOS). The endogenous NO is important in defending against bowel injury and mortality^[3,6]. Previous studies suggest an important role for iNOS in the pathogenesis of NEC. These include the terminal ileum from rats with abnormal histology demonstrated increased iNOS expression^[4,7]. Not all studies, however, have found inhibition of NO production to be beneficial in septic animals or animals challenged with endotoxin. For example, Park *et al*^[8] found that mice receiving a lethal dose of endotoxin and L-NMMA died earlier and had increased lung, liver, and kidney tissue damage than mice receiving endotoxin only. A recent study^[9] reported that iNOS knockout mice exhibited an aggravated intestinal injury and inflammation with enhanced neutrophil infiltration in response to acetic acid instillation. Qu *et al*^[10] reported that constitutive NOS is the predominant NOS in the intestine and its activity is inversely correlated with the level of tissue injury. But these experiments were not conducted in newborn animals.

Therefore, the purpose of the present study was to investigate the dynamic change and role of nNOS and iNOS in neonatal rat with LPS-induced intestinal injury and to define whether NEC is associated with the levels of NOS in the mucosa of the affected intestine tissue.

MATERIALS AND METHODS

Animal model

Wistar rats less than 24 h in age (mean weight, 6.24 ± 0.81 g) were given an intraperitoneal (IP) injection of 5 mg/kg *E coli* O55:B5 endotoxin (LPS; Sigma Chemical Co., St. Louis, Mo, USA) or similar volume of saline^[11-13]. All pups were killed respectively at 1, 3, 6, 12 and 24 h after receiving LPS IP ($n = 8$). Control pups ($n = 8$) were killed at 1 h after saline IP. The pups which died before collection of the specimens were excluded from the study.

Specimens collection

All surviving animals were killed via decapitation. The gastrointestinal tract was carefully removed. The small intestine was then divided into two halves: jejunum and ileum. A 3 cm segment of distal ileum 4 cm proximal to the ileocecal valve from each animal was cut, and fixed for histological evaluation of NEC and immunohistochemical analysis. The rest of the ileum was snap frozen at -80°C for measurements of mRNA.

Experimental methods and analysis marker

NEC evaluation: The segment of distal ileum was harvested, fixed in 4% paraformaldehyde, embedded in paraffin, microtome-sectioned at 5 μm , and counterstained with hematoxylin and eosin for histological evaluation of intestinal injury. Histological changes in the ileum were scored by a blinded evaluator and were assigned a necrotizing enterocolitis (NEC) score on a scale of 0 to 4 as follows: 0 = normal, intact villous epithelium with normal histology; 1 = mild villous edema, with epithelial sloughing confined to the tips of the villi; 2 = mild midvillous necrosis; 3 = moderate midvillous necrosis, with crypts still readily detectable; and 4 = severe necrosis of entire villi with complete absence of epithelial structures^[13,14].

Immunohistochemistry: The localization of nNOS and iNOS was performed by the SABC immunohistochemical technique. The paraffin slices were routinely dewaxed and the antigens were retrieved by microwave. Intrinsic peroxidases were inactivated by 3% hydrogen peroxide solution. The slices were blocked at room temperature for 10 min by normal goat serum. Primary antibody (rabbit anti-rat nNOS and iNOS antibody) in 1:200 dilution was added and left overnight at 4°C . The slices were then washed with PBS, and after biotinylated goat anti-rabbit IgG was added they were left at 37°C for 35 min. They were then washed with phosphate-buffered saline (PBS) and avidin-peroxidase conjugates were added and they were then left at 37°C for 35 min. They were then washed with PBS 3 times (5 min each time) and DAB solution was added for staining at room temperature. The reaction time (5 min) was controlled under the microscope. Slices were then routinely washed and gently restained with hematoxylin and sealed. (The above-mentioned antibody and reagent were purchased from Beijing Zhongshan Biotechnology Co., Ltd). For the negative control group, PBS was used instead of rat nNOS and iNOS antibody. The cells with yellow-brown particle deposition in cytoplasm were judged to be positive.

Five clearly dyed slices at each time point were taken randomly. Then 5 random fields for every slice were selected under microscope ($\times 40$), and the windows' square was fixed. The contents of nNOS and iNOS were semi-quantitatively measured through optical density average by Meta Morph and computer image process software.

RT-PCR for nNOS, iNOS and β -actin: Total RNA was extracted using the BiotragentsTM reagent (Sino-American Biotechnology Co., Luoyang, China) and 2 μL RNAs were used to synthesize cDNA in the presence of an oligo dT 15-primer, RNase inhibitor and the AMV reverse transcriptase in a final volume of 20 μL . Sequence-specific oligonucleotide primers (Bioasia Biotechnology Co., Ltd, Shanghai, China) were designed according to rat podocin, nNOS, sense: 5'-GAA TAC CAG CCT GAT CCA TGG AA-3', antisense: 5'-TCC TCC AGG AGG GTG TCC ACC GCA TG-3'; iNOS, sense: 5'-ATC CCG AAA CGC TAC ACT T-3', antisense: 5'-TCT GGC GAA GAA CAA TCC-3'; β -actin, sense: 5'-CAC CCT GTG CTG CTC ACC GAG GCC-3', antisense: 5'-CCA CAC AGA TGA CTT GCG CTC AGG-3'. The expected size of amplification was 602 bp for nNOS, 690 bp for iNOS and 314 bp for β -actin. PCR was performed in a 25 μL reaction system which contained 3 μL cDNA, 17.1 μL ddH₂O, 10 \times PCR buffer 2.5 μL , 2.5 mmol/L dNTPs 2 μL , Taq DNA polymerase 0.2 μL (TaKaRa Biotechnology Co., Ltd, Dalian, China), 0.1 μL of each primer. Amplification cycles of nNOS were 94°C for 3 min, followed by 30 cycles at 94°C for 30 s, 55°C for 30 s and 72°C for 1 min and terminated by a final extension of 72°C for 10 min. Amplification cycles of iNOS were 95°C for 1.5 min, followed by 45 cycles at 94°C for 45 s, 55°C for 45 s and 72°C for 1.5 min and terminated by a final extension of 72°C for 10 min.

The PCR products were subjected to electrophoresis with 2% agarose gel and stained with ethidium bromide. The band intensity was determined by gel image analysis system (Kodak 1D, USA). Relative concentrations of mRNA were normalized for β -actin. Expression levels of nNOS mRNA and iNOS mRNA were calculated by dividing the intensity of the internal control, β -actin.

Statistical analysis

Software SPSS 11.0 for Windows was used in all statistical tests. Comparisons between the groups were calculated using one-way analysis of variance (ANOVA), and all data are expressed as mean \pm SD. When P was less than 0.05, the difference was considered statistically significant. The degree of correlation was described using the Spearman's rank-correlation test.

RESULTS

Incidence and severity of NEC

There was a normal, intact villous epithelium with normal histology of ileum tissue in the control group. Mild villous edema, with epithelial sloughing confined to the tips of the villi could be seen at 1 h following LPS injection, and midvillous necrosis was aggravated from top to the lower part and the amount of the midvillous necrosis in neonate rats was increased with time. The most deteriorating

change was at 12 h and the incidence of NEC was 87.5% (7/8). There was severe necrosis of entire villi with complete absence of epithelial structures. The injury score of ileum tissue in the LPS group was also significantly increased than the control group pups ($P < 0.01$) (Table 1).

Expression of nNOS and iNOS proteins

The positive expression of nNOS was mainly shown in the nerve plexus and nerve fiber of the small intestinal wall. The myenteric nerve plexus had relatively higher levels of nNOS expression in comparison with the submucous nerve plexus. The positive expression of nNOS was decreased after LPS injection, and was significantly different at 6-24 h following LPS treatment ($P < 0.01$). The lowest level of its expression was at 12 h ($P < 0.001$) (Table 2). There was a negative significant correlation between the nNOS and the grade of median intestinal injury within 24 h ($\gamma = -1.000$, $P < 0.01$). The iNOS protein was localized almost exclusively to the epithelial cells (enterocytes) in the surface villi, with some staining detected in the lamina propria. The positive expression of iNOS in LPS group only increased at 12 h ($P < 0.05$) (Table 2). There was no a significant correlation between the nNOS and the grade of median intestinal injury within 24 h ($\gamma = 0.400$, $P > 0.05$).

**Figure 1** Gene expression of nNOS in ileum of neonatal rats. 2% ethidium bromide stained agarose gel molecular marker (Kodak 1D) was used as an indicator. M: DNA Marker DL2000; 0: Control group; 1: LPS 1 h; 2: LPS 3 h; 3: LPS 6 h; 4: LPS 12 h; 5: LPS 24 h.**Figure 2** Gene expression of iNOS in ileum of neonatal rats. 2% ethidium bromide stained agarose gel molecular marker (Kodak 1D) was used as an indicator. M: DNA marker DL2000; 0: Control group; 1: LPS 1 h; 2: LPS 3 h; 3: LPS 6 h; 4: LPS 12 h; 5: LPS 24 h.

Expression of nNOS mRNA and iNOS mRNA

Expression of nNOS mRNA in ileal tissue was gradually diminished after LPS injection. The level of its expression was significantly lower at 6 and 12 h ($P < 0.05$) (Table 3, Figure 1). The expression of iNOS mRNA was significantly increased at 6, 12 h following LPS treatment ($P < 0.05$) (Table 3, Figure 2).

DISCUSSION

In the present study, we detected substantially lower levels of nNOS in ileal tissue with complicated intestinal injury when compared with a cohort of control rats. These findings demonstrated a potential role for a deficiency of nNOS in the progression of NEC. There was a significant negative correlation between the levels of nNOS and the degree of intestinal injury. These results showed that decreased levels of nNOS of the ileum result in a dramatic increase of the incidence and severity of NEC. The iNOS

mRNA and protein expression was significantly increased during the peak of intestinal injury. The production of NO may lead to consequent enterocyte necrosis, gut barrier failure with further bacterial invasion, and damage to the intestinal wall.

NEC is the most frequent and most lethal disease that affects the gastrointestinal tract of premature infants in neonatal intensive care units, with reported mortality of 10%-30%^[15,16]. The reasons for a predilection for prematurity are unclear, but an immature mucosal barrier and immune response likely contribute to the premature neonates' susceptibility^[3,5,17]. Perinatal insults that impair mesenteric circulation may therefore induce intestinal mucosal injury and permit local intestinal microbial flora to breach the mucosal barrier. This process, in turn, initiates an inflammatory cascade leading to NEC^[15,18,19].

Over the past decade, an abundance of research has been directed toward the role of NO in intestinal inflammation. NO can exert both beneficial and deleterious effects and that NOS exists in three distinct isoforms: constitutively expressed nNOS and eNOS or iNOS^[6]. More than 90% of the total NOS in the small intestine is nNOS. Although iNOS is constitutively present, it accounts for less than 10% of the total NOS activity, and eNOS is barely detectable in the intestine^[3,10,20]. iNOS is induced by cytokines or endotoxin and produces large amounts of NO.

The main function of nNOS in the intestine is generally believed to be mediation of the neuronal signal transmission in the NANC components of the nervous system and regulating gut motility. Since eNOS accounts for only a very small part of intestinal NOS activity, it is possible that nNOS in the intestine also functions as the protective eNOS^[21].

In the intestine, constitutive NOS may have important physiological functions. The relatively small amounts of NO production by constitutive NOS have been implicated as scavengers of oxidants that may thus protect an organ in the early stages of injury. For example, NO may protect the gastrointestinal mucosa from a variety of stimuli including endotoxin by maintaining mucosal perfusion, inhibiting leukocyte and platelet adhesion to the endothelium, preventing mast cell activation, and acting as an antioxidant^[6,22-24]. Our present study showed that the positive expression of nNOS was decreased after LPS injection, which was significantly different at 6-24 h following LPS challenge. The lowest level of its expression was at 12 h. There was a negative significant correlation between the nNOS and the grade of median intestinal injury within 24 h. The expression of nNOS mRNA in the ileum tissue was gradually diminished after LPS injection. LPS may downregulate the expression of nNOS mRNA in damaged ileum and may lead to decreased NO production, which results in impairment of endogenous protective mechanisms in the mucosal barrier^[3,6,25]. It may be one of the most important mechanisms resulting in NEC.

The overproduction of NO by iNOS can interact with other reactive oxygen metabolites, such as superoxide, resulting in the propagation of the highly reactive species, peroxynitrite^[26,27]. This potent oxidizing agent can initiate lipid peroxidation and thus produce extreme

gastrointestinal mucosal damage and injury^[4,9,28]. However, recent studies have challenged this simple paradigm providing evidence that iNOS could also be protective against inflammatory response under certain circumstances^[9]. McCafferty *et al.*^[29] reported that iNOS deficiency was not important in IL-10 deficient mice with spontaneous chronic intestinal inflammation. Our data showed that the positive expression of iNOS protein only increased at 12 h and the expression of iNOS mRNA was significantly increased at 6, 12 h following LPS injection. The iNOS mRNA and protein expression was significantly increased in the peak of intestinal injury. The production of NO may lead to consequent enterocyte necrosis, gut barrier failure with further bacterial invasion, and damage to the intestinal wall. However, the present study failed to show a clear correlation between the nNOS protein and the grade of median intestinal injury.

In conclusion, the nNOS and iNOS play different roles in neonatal rats with LPS-induced intestinal injury. Caution should be exerted concerning potential therapeutic uses of NOS inhibitors on NEC.

Abstract

AIM: To assess whether treatment with insulin-sensitizing agents (ISAs) in combination with ezetimibe and valsartan have greater effect on hepatic fat content and lipid peroxidation compared to monotherapy in the methionine choline-deficient diet (MCDD) rat model of non-alcoholic fatty liver disease (NAFLD).

METHODS: Rats ($n = 6$ per group) were treated with different drugs, including MCDD only, MCDD diet with either metformin (200 mg/kg), rosiglitazone (3 mg/kg), metformin plus rosiglitazone (M+R), ezetimibe (2 mg/kg), valsartan (2 mg/kg), or combination of all drugs for a total of 15 wk. Liver histology, lipids, parameters of oxidative stress and TNF- α were measured.

RESULTS: Fatty liver (FL) rats demonstrated severe hepatic fatty infiltration ($> 91\%$ fat), with an increase in hepatic TG ($+1263\%$, $P < 0.001$), hepatic cholesterol ($+245\%$, $P < 0.03$), hepatic MDA levels ($+225\%$, $P < 0.001$), serum TNF- α (17.8 ± 10 vs 7.8 ± 0.0 , $P < 0.001$), but a decrease in hepatic alpha tocopherol (-74% , $P < 0.001$) as compared to the control rats. Combination therapy with all drugs produced a significant decrease in liver steatosis (-54%), hepatic TG (-64%), hepatic cholesterol (-31%) and hepatic MDA (-70%), but increased hepatic alpha tocopherol ($+443\%$) as compared to FL rats. Combination therapy with ISA alone produced a smaller decrease in liver steatosis (-32% vs -54% , $P < 0.001$) and in hepatic MDA levels (-55% vs -70% , $P < 0.01$), but a similar decrease in hepatic lipids when compared with the all drugs combination. TNF- α levels decreased significantly in all treatment

groups except in ISA group.

CONCLUSION: Combination therapies have a greater effect on liver fat content as compared to monotherapy. Rosiglitazone appears to improve hepatic steatosis to a greater extent than metformin.

INTRODUCTION

The clinical implications of fat accumulation in the liver are derived mostly from its occurrence in the general population and it has potential to progress to fibrosis, cirrhosis and hepatocellular carcinoma^[1-3]. Non-alcoholic fatty liver disease (NAFLD) is a component of the metabolic syndrome with a clinical spectrum ranging from simple FL to steatohepatitis, bridging fibrosis and cirrhosis^[4,5]. Obesity and diabetes type 2 are considered the most powerful predisposing risk factors for the development of more severe manifestations of NAFLD^[5,6]. The primary event of non-alcoholic steatohepatitis (NASH) is the accumulation of triglycerides in hepatocytes which seems to be determined by insulin resistance^[3]. These fats stem mainly from increased splanchnic lipolysis of visceral and subcutaneous abdominal fat and from continuous delivery of free fatty acids to the liver after ingestion of fatty foods, both of which increase hepatic insulin resistance^[7]. The secondary event is hepatocellular injury which includes factors, such as oxidative stress, pro-inflammatory cytokines, mitochondrial dysfunction, iron overload, bacterial overgrowth and genetic predisposition^[8]. A recent study by Wanless and Shiota^[9] describes an inflammatory injury to hepatic veins due to release of fat followed by venous obstruction with secondary collapse

and ultimately bridging fibrosis and progressing from fatty liver to NASH to cirrhosis. More recently, deregulated adipocytokines such as adiponectin, interleukin-6 and TNF- α have been examined as causative candidates of insulin resistance^[7,10] and it was reported that oxidative stress in accumulated fat causes deregulated adipocytokine production^[11].

The methionine choline-deficient diet (MCDD) model of fatty liver in rats is characterized by increased insulin resistance, hypertriglyceridemia, and increased lipid peroxidation^[12,13]. Moreover, it has been shown that in the MCDD model of steatohepatitis, there is down-regulation of insulin signaling with decreased phosphorylation of IRS-1, IRS-2 and Akt and increased oxidative stress with over-expression of CYP2E1^[14]. In light of these findings, it seems possible that NAFLD can be successfully treated by the reduction of fat absorption and delivery, oxidative stress and systemic inflammation, as well as reduction of insulin resistance. To date, no consistently effective therapy for FL disease has been identified. The need to use drugs with different and complementary mechanisms of action frequently arises in daily clinical practice. Possible therapeutic agents for fat-induced hepatic insulin resistance include metformin, which acts by decreasing gluconeogenesis and by enhancing peripheral glucose uptake^[15] and thiazolidinediones, a peroxisome proliferator-activated receptor- γ (PPAR- γ) agonist that acts by increasing insulin sensitivity in adipose tissues, shifting fat away from the liver into fat stores (adipocytes)^[16]. The combination of metformin and rosiglitazone may be complementary. Other therapeutic agents for insulin resistance include valsartan, an angiotensin 11 type-1 receptor blocker which stimulates the insulin signaling cascade and enhances glucose transporter type 4 (GLUT 4) translocation^[17] and ezetimibe, the cholesterol absorption inhibitor which improves insulin resistance by decreasing low-density lipoprotein (LDL) tendency to peroxidation^[18]. In the present study, we aimed to examine the impact of these different therapeutic interventions, alone or in combination, on hepatic fat content, hepatic lipid composition and parameters of oxidative stress, anti-oxidant capability and systemic inflammation in FL rats fed by MCDD.

MATERIALS AND METHODS

Animal and protocol

This study consisted sixty male Sprague Dawley rats (Harlan Laboratories Limited, Jerusalem, Israel), weighing 200-280 g. Rats were housed in regular cages situated in an animal room at 22°C, maintained on standard rat chow diet (Koffolk, Tel Aviv, Israel) and given tap water to drink *ad libitum*. All animal studies were conducted according to the regulations for the use and care of experimental animals and treatment groups.

FL was induced in rats fed by MCDD diet for 9 wk as previously described^[19,20]. The rats were randomly divided into nine groups. Group 1 comprised of 6 rats serving as control group and was maintained on standard chow diet (control liver, CL). Group 2 (FL group or NAFLD

group) was given MCDD only for 9 wk (MCDD Harlan Teeklad, Madison, WI). The following groups were given various pharmaceutical interventions for additional 6 wk: Group 3 received MCDD diet with metformin (200 mg/kg); Group 4 received MCDD diet with rosiglitazone (3 mg/kg); Group 5 was fed MCDD diet with metformin + rosiglitazone; Group 6 received MCDD diet with ezetimibe (2 mg/kg); Group 7 were fed MCDD diet with valsartan (2 mg/kg); Group 8 received MCDD diet with metformin + rosiglitazone + valsartan; and Group 9 received MCDD diet with metformin + rosiglitazone + valsartan + ezetimibe. All treatment groups were treated for a total of 15 wk (9 + 6 wk). The dosage selected for each intervention was based on the results of previous studies using these agents in various liver diseases and the dose of each drug was controlled by semi-quantitative analysis^[16-18]. Diets were supplied in pellet form. The medication was given with food and in drinking water. Simply the MCD diet was supplemented with the respective drug and not with a semi-purified diet. All the drugs were water soluble and there was no need for additional solvents. The drugs were monitored daily and were supplied by the local pharmacy of the Sieff Hospital, Safed, Israel and not by pharmaceutical companies. Rats were then sacrificed and liver histology, hepatic and plasma lipid content, parameters of oxidative stress, and TNF- α were measured.

Biochemistry

Serum triglyceride (TG) concentration was measured with an automated analyzer (Olympus AU2700; Hamburg, Germany). Additional biochemical parameters, such as serum total cholesterol (TC) and glucose, were measured using an automatic biochemical analytical system. Alanine (ALT) transaminase activities were performed spectrophotometrically using a commercially available kit test (ALT Reagents, Sigma-Aldrich). Tumor necrosis factor alpha (TNF- α) was assayed by rat-specific kit (R&D Systems). Insulin was assayed by a rat-specific RIA kit (Incstar, Stillwater, MI). Blood insulin resistance was estimated using the homeostasis model assessment (HOMA-IR) derived from the following equation: $IR = (\text{fasting plasma glucose level mg\%} \times 0.055) \times (\text{fasting plasma insulin level mU/L} / 22.5)$. This insulin resistance reflects both peripheral and hepatic insulin resistance^[21].

Determination of hepatic lipid composition

Total hepatic lipids were extracted from freeze-dried samples by chloroform: methanol (2:1) and measured as previously described by Folch *et al*^[22]. Triglycerides, TC and phospholipids in hepatic tissue extract were determined enzymatically in an auto analyzer (Hitachi 736, Tokyo, Japan) using commercial kits (Triglycerides, Infinity Cholesterol Reagent and Reagents for inorganic phosphorous assay, Sigma-Aldrich) as previously described^[23-26].

Determination of hepatic pro-oxidant and anti-oxidants

Tissue tocopherol-alpha was determined following the methods described by Gowenlock *et al*^[27]. Hepatic maleic dialdehyde (MDA) level was determined as previously described by Yagi *et al*^[28].

Histology

A 5- μ m thick section of liver tissue was cut from the center of each hepatic lobe and fixed in 40 g/L buffered formaldehyde, processed by standard techniques and embedded in paraffin. The sections were stained with hematoxylin-eosin. Fat extension, necroinflammatory grade and stage of fibrosis were assessed as previously described by Brunt *et al*^[29]. Steatosis was assessed by a morphological semiquantitative approach and graded as follows: mild = 5%-30%, moderate = 30%-60%, and severe > 60% of hepatocytes affected. The specimens were also examined for histological features of Mallory's bodies, ballooning degeneration, acidophilic necrosis, sinusoidal fibrosis and polymorph nuclear infiltrates. The histological evaluation of the liver sections was performed blindly.

Statistical analysis

Results are expressed as mean \pm SE. Analysis of variance was used to compare the means of multiple groups, followed by the Newman-Keuls test to determine statistical significance between two groups. When the data were not normally distributed, the Kruskal-Wallis test was performed to compare the means of multiple groups, followed by Mann-Whitney test. Correlation analysis was performed using spearman rank correlation. The statistical comparisons were performed using the unit values rather than percentages. $P < 0.05$ was considered statistically significant. The statistical analysis was performed using the Winstat program for windows (Kalmia, MA).

RESULTS

Effect of methionine choline-deficient diet

The methionine choline FL model used in this experimental study showed features of the fatty liver observed in humans, including hypertriglyceridemia, increased oxidative stress, increased insulin resistance and increased ALT and TNF- α levels (Tables 1 and 2). FL induced by the MCDD diet had a 68% increase in the liver weight/rat weight ratio when compared to CL (Figure 1, $P < 0.02$). Hepatic TG and hepatic cholesterol concentrations were significantly higher in the rats fed MCDD diet than that in the control rats (+1263% increase, $P < 0.001$ and +245% increase, $P < 0.03$, respectively). Triglycerides represented the highest proportion of lipid components of the fat vesicles. FL rats showed a 100% increase in plasma triglycerides and 157% increase in HOMA-insulin resistance index ($P < 0.05$ and $P < 0.001$, respectively). FL rats had significantly lower concentrations of alpha-tocopherol when compared with CL group ($P < 0.03$). The hepatic levels of MDA were significantly greater and hepatic alpha-tocopherol/MDA ratio was significantly lower in FL group as compared with CL group (2.01 ± 0.04 *vs* 0.6 ± 0.1 ; $P < 0.03$ and 0.03 *vs* 0.05 , $P < 0.03$, respectively). Specimens from the rats fed with methionine choline-deficient diet showed massive fatty infiltration (> 91%), predominantly macrovesicular. Features of steatohepatitis, including ballooning degeneration and pericellular fibrosis, were seen mildly but no pronounced fibrosis.

Table 1 Liver-related parameters, plasma biochemistry and cytokines in rats fed with methionine choline-deficient diet (MCDD) or choline-supplemented diet (Chow diet) (mean \pm SD, $n = 6$)

Parameters	CL Chow diet	FL MCDD diet	<i>P</i> values
Baseline rat mass (g)	227 \pm 7	226 \pm 6	0.5

CL: Control liver; FL: Fatty liver; HOMA-IRI: Insulin resistance index; MDA: Malondialdehyde.

Figure 1 Effect of different pharmacological interventions on liver mass/body mass ratio.

Effect of pharmacologic intervention

All the drug regimens included in this study significantly decreased the liver weight/body weight ratio as compared to FL rats fed with the methionine choline-deficient diet alone (range 24%-33%, Figure 1)

Effect of insulin-sensitizing agents

Rosiglitazone improved insulin resistance (-39%, $P < 0.03$) and reduced hepatic and plasma triglycerides by -54% ($P < 0.01$) and -59% ($P < 0.001$), respectively, but not hepatic cholesterol as compared to FL group. Moreover, this decrease in hepatic TG was obviously greater than that with metformin monotherapy ($P < 0.01$). It increased the hepatic tocopherol-alpha/MDA ratio by 233% compared to FL group ($P < 0.01$), and most importantly, reduced hepatic fat content by 46% ($P < 0.01$). Rosiglitazone reversed the liver weight/body weight ratio approximately close to CL because of the decrease in the liver weight rather than increase in total body weight (Table 2). A

significant inverse correlation ($r = -0.6$) was found between hepatic alpha-tocopherol and hepatic MDA concentrations in the rosiglitazone group. Rosiglitazone did not significantly reduce the TNF-α levels as compared to FL group.

Metformin markedly reduced insulin resistance (-33%, $P < 0.03$), decreased hepatic TG (-40%, $P < 0.01$) and most effectively improved the tocopherol-alpha/MDA ratio (+833%, $P < 0.03$) as compared to FL group. However, it only mildly decreased the hepatic fat content (-14%, $P < 0.05$). Metformin decreased serum TNF-α levels by 44% ($P < 0.01$) when compared to FL group, and reduced hepatic TG to a lesser extent than rosiglitazone and had no effect on hepatic cholesterol content.

The combination of metformin and rosiglitazone was beneficial in many ways: it reduced insulin resistance by -50% ($P < 0.03$) and decreased hepatic and plasma TG by -64% ($P < 0.02$) and by -50% ($P < 0.03$) respectively; decreased hepatic cholesterol by -27% as compared to FL group ($P < 0.01$) and a significant increase in tocopherol-alpha/MDA ratio (566%, $P < 0.01$) as well as a 32% reduction in hepatic fat ($P < 0.03$) were observed. Surprisingly, this reduction of liver fat content was less important than rosiglitazone monotherapy (32% *vs* 46%, $P < 0.01$) but greater than metformin monotherapy (32% *vs* 14%, $P < 0.001$). And also, the combination of ISAs significantly increased TNF-α levels when compared to FL alone ($P < 0.02$, Tables 2 and 3).

Effect of ezetimibe

Ezetimibe, a cholesterol absorption inhibitor, reversed the liver weight/body weight ratio and improved insulin resistance by -28% ($P < 0.03$), improved oxidant-antioxidant status, reduced TNF-α levels and mildly decreased the hepatic fat content (-14%). Ezetimibe also decreased hepatic and plasma triglycerides by 53% ($P < 0.01$) and 56% ($P < 0.03$), respectively when compared to FL rats. In addition, a 25% decrease ($P < 0.03$) in hepatic cholesterol and a 39% decrease ($P < 0.02$) in plasma cholesterol were observed when compared to CL group, suggesting an apparent effect on cholesterol absorption. Of all aforementioned drugs, ezetimibe monotherapy exerted the most powerful antioxidant effect, whereby it caused the highest increase in the alpha-tocopherol/MDA ratio (900%, $P < 0.001$) followed by metformin monotherapy (+ 833%). Ezetimibe also decreased TNF-α level by 32% ($P < 0.01$) and hepatic fat content by 14% ($P < 0.01$) (Tables 2 and 3). This mild reduction in hepatic fat content might be partially related to a significant effect on cholesterol absorption.

Effect of valsartan

Although valsartan had no significant effect on insulin resistance, it decreased hepatic and plasma triglycerides by -54% ($P < 0.02$) and -50% ($P < 0.01$), respectively and improved the tocopherol-alpha/MDA ratio by +266% ($P < 0.02$). However, it had no beneficial effect on hepatic

cholesterol (+ 19%). Finally, it significantly decreased hepatic fat content (-28%) when compared to FL fed with MCCD ($P < 0.01$). Valsartan did not add much to the effect of metformin and rosiglitazone combination therapy regarding fat content but had significant effect on TNF- α levels (-49%, $P < 0.01$). The dosage used in this study was low and demonstrated no significant effect on blood pressure (Tables 2 and 3).

Effect of combined drug therapy

Combined drug therapy was most effective in improving the insulin resistance index (-55%, $P < 0.001$) followed by the combination of insulin-sensitizing agents alone (-50%, $P < 0.02$). The combined administration of drugs caused similar decrease in hepatic and plasma triglycerides as the combination of ISA alone (Tables 2 and 3). Furthermore, the combination therapy decreased hepatic and plasma cholesterol by 31% ($P < 0.02$) and 21% ($P < 0.03$), respectively when compared to FL. They demonstrated a powerful antioxidant activity by decreasing hepatic MDA levels and increasing tocopherol-alpha/MDA ratio by 1 900% ($P < 0.01$ and $P < 0.02$, respectively). Finally and most importantly, the combination of all the above drugs improved hepatic steatosis to a greater extent than ISA alone (54% *vs* 32%, $P < 0.001$) and greater than rosiglitazone monotherapy (54% *vs* 46%, $P < 0.01$). Combined therapy also decreased the serum TNF- α level

by -27% (Tables 2 and 3, Figure 2). The combination of all drugs had a greater effect on hepatic tocopherol-alpha, hepatic MDA, and hepatic cholesterol than the combination of three drugs (R+M+V) (Table 3). The effect of various drugs on hepatocellular injury is shown in Table 4.

DISCUSSION

There are currently no approved therapeutic regimes for treatment of NAFLD. Given the strong associations of NAFLD with features of the metabolic syndrome, including insulin resistance, hyperlipidemia and hypertension, it is reasonable to suppose that agents ameliorating these conditions might also attenuate the development of NAFLD, and considering also that NAFLD is likely to be multifactorial in etiology, it is also sound to predict that combination treatment may be more effective than monotherapy. The present study clearly indicates that combination of insulin-sensitizing agent, cholesterol absorption inhibitor and angiotensin antagonist have greater effect on liver fat content and on lipid peroxidation than monotherapy in the MCDD rat model of NAFLD. Hepatic steatosis and hepatic TG accumulation lead to hepatic insulin resistance by stimulating gluconeogenesis and by activation of protein kinase PKC and JNK-1, which may interfere with tyrosine phosphorylation of IRS-1 and IRS-2 and impair the ability of insulin to activate glycogen synthase and diminish the ability of the liver to store glucose as glycogen^[30]. Rosiglitazone appears to improve hepatic steatosis to a greater extent than metformin and the same effect was observed when examining hepatic triglyceride but not hepatic cholesterol content. The present study is in keeping with previous data showing a similar decrease in liver fat using either pioglitazone^[31] or rosiglitazone^[32,33]. In a human study, rosiglitazone decreased liver fat content by 22% as assessed by magnetic resonance spectroscopy^[34]. Several mechanisms may underlie the ability of rosiglitazone to reduce liver fat content. First, it has been suggested that rosiglitazone doubles fatty acid uptake into subcutaneous adipose tissue and decreases hepatic fatty acid uptake into liver by 40% and in muscle by 30%, i.e., “the lipid steal mechanism”^[35]. Second, rosiglitazone activates PPAR-gamma which decreases free

fatty acid availability for hepatic lipogenesis and reduces the release of TNF- α cytokine by adipocytes^[16,36]. Finally, rosiglitazone has also been shown to increase insulin sensitivity by improving downstream insulin signaling by increasing insulin stimulation of IRS-1 tyrosine phosphorylation and p85 association with IRS-1^[37]. Consistent with the reduction of free fatty acids flux to the liver is the decrease in hepatic TG concentration^[35] and the improvement in insulin sensitivity. Rosiglitazone may also increase adiponectin expression which in turn increases hepatic insulin sensitivity, activates fatty acid oxidation and inhibits phosphoenolpyruvate carboxykinase expression^[38]. Unfortunately, concentrations of adiponectin and free fatty acid were not measured in this study.

We found metformin sensitizes the liver but has little effect on hepatic fat content. The ability of metformin to increase hepatic insulin sensitivity has been documented in a previous study^[39], but liver fat content was not measured. In isolated hepatocytes and metformin-treated rats, lipogenesis was inhibited because of adenosine 5' monophosphate-activated protein kinase (AMPK)-induced inactivation of acetyl-CoA carboxylase and suppression of lipogenic enzyme and transcription factor expression^[40]. Additionally, metformin has been shown to inhibit oxidative phosphorylation and lower cellular ATP levels at high doses^[41]. The dose used in the present study (200 mg/kg) was smaller than that used in the study by Zhou *et al*^[40] (286 mg/kg). In ob/ob mice with FL, metformin was found to reverse hepatomegaly and steatosis^[41]. The therapeutic mechanism of metformin likely involves hepatic expression of TNF- α and TNF- α inducible factors that promote hepatic lipid accumulation and ATP depletion^[42]. In the current study, plasma TNF- α decreased with metformin when compared to untreated FL. It remains to be determined whether metformin also increases adiponectin levels or impacts on free fatty acid uptake and distribution. Although rosiglitazone and metformin activate different signaling pathways, there was no additive effect of the combination of both drugs on liver fat content compared to rosiglitazone monotherapy. In contrast, there was an additive effect of the combination of ISA on hepatic triglyceride, hepatic cholesterol content, and on anti-oxidant/oxidant ratio (Table 3); the reason for this is unclear. It could be related to up-regulation of TNF- α expression which was observed in the R+M group. There was no significant increase in body weight by combined rosiglitazone and metformin therapy. This effect may have been counterbalanced by metformin treatment.

Ezetimibe inhibits the transport of dietary and biliary cholesterol across the intestinal wall^[43]. It was chosen rather than a statin because statins are not very effective in the treatment of NAFLD (atorvastatin) and because ezetimibe is safe and may help in reducing the cholesterol absorption from food intake. The other rational for using ezetimibe was the high corn oil component (100 g/kg) in the MCD diet. Ezetimibe decreased hepatic fat content with an apparent mild decrease in cholesterol absorption, suggesting that its antioxidant and anti-inflammatory effects are via other mechanisms for reducing liver fat. The dose used in our experiment is considered high dose because the effective dose at which 50% inhibition is

observed (ED₅₀) for rat is 0.0016 mg/kg. This dose was chosen in order to capture any effect ezetimibe might have on the hydrolysis of cholesterol ester^[43]. Usually, ezetimibe does not affect the acute absorption of TG^[44]. In our study, ezetimibe, however, reduced hepatic and plasma TG, which is in accordance with the companion study in which ezetimibe decreased the plasma concentration of TGs^[45].

Treatment with valsartan had modest antioxidant activity as compared to ezetimibe. The molecular mechanism was not investigated in this study, but Siuchi *et al*^[17] have postulated that valsartan treatment exaggerates the insulin-induced phosphorylation of IRS-1, the association of IRS-1 with the p85 regulatory subunit of PI3-K activity and translocation of GLUT 4 to the plasma membrane. Whether valsartan has a selective additional PPAR- γ modulating activity as Telmisartan remains to be determined^[46]. The therapeutic efficacy of another angiotensin 11 receptor antagonist in patients with NASH has recently been documented^[47]. The antifibrotic effect of valsartan was not seen in our rats because rats were fed with the MCCD for a short time (9 wk) and did not produce enough fibrosis.

Abrogation of oxidative stress improves whole body insulin resistance^[48]. In this respect, our study showed that alpha-tocopherol/MDA ratio improved mostly with the combination of all drugs, followed by ezetimibe and by metformin (+1900, +900%, +833%, respectively). Hypertriglyceridemia and increased hepatic TG were prominent features in rats fed with MCDD^[19,20]. Nevertheless, reduction of TG did not improve liver fat content in all study groups. For example, metformin reduced hepatic TGs and hepatic steatosis by 40% and 17%, respectively. This implies that another mechanism of hepatic fat reduction is implicated in addition to lowering hepatic triglycerides. The mean levels of plasma TNF- α were relatively low in all treatment groups because rats were examined in early phase of the disease progression and with mild overt NASH with inflammation, ballooning and pericellular fibrosis. The reason for increased TNF- α in rats fed with MCDD diet with rosiglitazone plus metformin is unclear, but appears to be unrelated to overweight or to lipid peroxidation in any case. Whether it is related to an early activation of NF-kappa B or to a potentiation of IL-6 and IL-8 expression by rosiglitazone plus metformin treatment remains unknown^[49].

Although the MCDD model of fatty liver is the most commonly used in experimental studies, one limitation of our study is that MCDD model is not the ideal model for studying insulin-sensitizing drugs and an extensive number of additional experiments would be required to perform in order to derive definitive data in insulin-resistant models^[50]. Another concern is that rats fed with MCDD for 9 wk did not develop the same phenotype as previous reports of MCDD-induced NASH in mice (as short as 10 d of MCDD). The phenotype described here largely consisted of marked steatosis with mild inflammation and mild fibrosis^[51].

In conclusion, the current study shows for the first time that combination therapy of rosiglitazone and metformin with ezetimibe and valsartan in parallel has a greater effect on the extent of fatty infiltration and on lipid

peroxidation compared to insulin-sensitizing agents only and to monotherapy with either drug. Improving insulin resistance together with decreasing TNF- α and reduction of oxidative stress remains the best targeted treatment to date for NAFLD.

Abstract

AIM: To investigate loss of heterozygosity (LOH) and microsatellite instability (MSI) on the chromosomal region 1p36-pter in cholangiocarcinoma (CCA) patients and determine the association between microsatellite alterations and clinicopathological parameters.

METHODS: Ten polymorphic microsatellite markers were determined for LOH and MSI using GS-3000 gel scan fragment autoanalyzer.

RESULTS: Sixty-eight out of 90 cases (75.6%) showed LOH in one or more loci. LOH was found most frequently at D1S199 (40.0%), D1S507 (34.6%), D1S2845 (30.5%), and D1S2734 (30.1%). MSI was found in 34 of 90 cases (37.8%) at one or more loci. Fine mapping at 1p36 showed two distinctive regions of common loss, which were D1S2845 and the 25.5-cM region between D1S507 and D1S2734, indicating the existence of putative tumor suppressor genes that is likely to play important roles in the development of CCA. Patients with LOH at D1S234 showed less lymphatic invasion ($P = 0.017$), whereas patients with LOH at D1S2676 exhibited more lymphatic invasion than those without ($P = 0.031$). LOH at D1S2845 showed a significant correlation with

INTRODUCTION

Cholangiocarcinoma (CCA) is a malignant tumor arising from bile duct epithelium and commonly found in the northeastern region of Thailand with the highest incidence in Khon Kaen^[1,2]. In Thailand, chronic infection with the liver fluke, *Opisthorchis viverrini* (OV), is the major risk factor for the development of CCA^[3]. Prolonged inflammation induced by parasitic infection causes continuous production of free radicals that not only combat the infection, but also act as carcinogens causing mutations and chromosomal breakage and aberrations within the body^[4,5]. Patients with CCA are often diagnosed clinically and cholangiographically but mostly are in advanced stage and difficult to cure successfully. The prognosis of CCA is extremely poor^[6]. Moreover, the molecular events involved in the development of CCA are not well understood.

Microsatellites are short tandem repeat sequences of unknown function scattered throughout the human genome. Loss of heterozygosity (LOH) and microsatellite instability (MSI) are the phenotypes of genetic instability caused by the abnormalities of tumor suppressor and DNA mismatch repair (MMR) genes, respectively. MSI

is associated with slippage of DNA polymerase during DNA synthesis resulting in changing units of repetitive sequences. The instability of microsatellites is detected by the difference of the lengths of the repeat sequences between tumor and normal DNA from the same patient. As allelic loss at a certain region of chromosome is thought to indicate the presence of a tumor suppressor gene, LOH analysis is presently the most common method used to identify potential locations of these genes.

Frequent allelic losses on specific chromosomal regions have been reported in CCA^[7-11]. On the other hand, only a few studies on microsatellite instability have been performed in this cancer^[12-15]. Our data on comparative genomic hybridization (CGH) in CCA showed the most frequent decrease in DNA copy number at 1p36-pter (34%). Moreover, the chromosomal region 1p36 appears to harbor critical tumor suppressor genes important to tumorigenesis and progression in many human cancers^[16-20]. Therefore, this study aimed to investigate the incidence of LOH and MSI at chromosome 1p36-pter in liver fluke related CCA using 10 polymorphic microsatellite markers. We also determined the correlation between microsatellite alterations and clinicopathological parameters.

MATERIALS AND METHODS

Patients and DNA preparation

Blood and liver resection samples were obtained from 90 patients with intrahepatic cholangiocarcinoma who underwent surgery at Srinagarind Hospital, Faculty of Medicine, Khon Kaen University, Khon Kaen, Thailand. Informed consent was obtained from each patient according to the guidelines of the Ethical Committee of Khon Kaen University. DNA was extracted from microdissected tissues using DNA isolation kit according to manufacturer's instructions (Puregene, Gentra systems,

USA). Matched peripheral blood leucocytes were prepared for DNA by the method described previously^[13].

Microsatellite markers

Ten microsatellite markers specific for the chromosomal region 1p36-pter were used. The forward primer of each marker was labeled at 5' end with 4,7,2',4',5',7'-hexachloro-6-carboxyfluorescein (HEX). Primer sequences were obtained from the Human Genome Database as shown in Table 1. D1S468 is located at telomeric end while D1S2676 is located toward centromeric end.

PCR amplification

PCR was performed in a 25 µL reaction containing 50 ng of DNA, 100 µmol/L of each deoxynucleoside triphosphate (dNTP), 5 pmol of each primer, 3 mmol/L MgCl₂, 50 mmol/L KCl, 10 mmol/L Tris HCl pH 8.3, and 1.5 units of Taq DNA polymerase. Additives such as 0.4 mL/L Triton X-100 or 0.4 mL/L Tween 20 were added in the amplification of tissue DNA. The PCR conditions were denaturation at 94°C for 5 min, followed by 35 cycles of denaturation at 94°C for 30 s, annealing at 57°C for 30 s (or at 56°C for D1S468 and D1S2845, at 59°C for D1S199, and at 54°C for D1S2734), extension at 72°C for 30 s, and final extension at 72°C for 10 min.

Analysis of LOH and MSI

PCR products were denatured by 950 mL/L formamide and electrophoresed on 6% or 8% polyacrylamide gels containing 7 mol/L urea using GS-3000 gel scan fragment autoanalyzer (Corbett Research, Australia). MSI was defined as changes of size bands observed in tumor DNA but not visible in the corresponding normal DNA. For informative cases, allelic loss (LOH) was assessed if the signal of one allele was at least 50% reduced in the tumor DNA as compared with the corresponding normal allele. Our previous study^[13] showed the same pattern between non-tumorous tissue and leucocyte DNA, therefore in this study only leucocyte DNA was used as the corresponding normal DNA. Each assay was performed twice in order to ensure experimental reproducibility.

Statistical analysis

LOH and MSI frequencies were correlated with several clinical parameters using χ^2 test. Survival curves were calculated using Kaplan-Meier and log rank test. The result was considered statistically significant when $P < 0.05$.

RESULTS

LOH and MSI analysis

The percentage of LOH was analyzed based on informative cases while that of MSI could be analyzed within 90 cases. Representative examples of LOH and MSI at various loci are shown in Figure 1. LOH at one or more loci was observed in 68 out of 90 cases (75.6%). If a percentage of LOH at a locus was more than 30%, we determined that LOH frequency of the locus was significantly high. The percentage of LOH at each microsatellite marker varied from 17.3% to 40.0%. Among 10 loci, we observed

Figure 1 Representative examples of LOH and MSI at various loci of chromosome 1p36 (L, leucocyte DNA; T, tumor DNA). Arrows indicate the abnormalities

Figure 2 LOH and MSI frequencies at each locus of chromosome 1p36-pter.

4 loci with significantly high LOH frequency, which were D1S199 (40.0%), D1S507 (34.6%), D1S2845 (30.5%), and D1S2734 (30.1%). MSI was found in 34 (37.8%) of 90 cases at one or more loci. Among 10 loci, 3 loci showed percentage of MSI more than 10%, which were D1S234 (12.2%), D1S228 (11.2%), and D1S450 (10.1%). The percentages of LOH and MSI at each locus are shown in Figure 2. Interestingly, the percentage of MSI at each locus was much less than that of LOH, suggesting that LOH is a preferable pathway to MSI for the alterations of microsatellite markers on the chromosome 1p36 in liver fluke associated CCA.

Fine mapping of chromosomal region 1p36-pter

Fine mapping of the chromosomal region 1p36-pter in 90 CCA cases is shown in Figure 3. Four distinctive loci with high LOH frequencies were denoted giving rise to two common loss regions; D1S2845 and the 25.5-cM region between D1S507 and D1S2734.

Correlation between microsatellite alterations and clinicopathological data

The associations between LOH and MSI at each locus and clinicopathological parameters of CCA patients were analyzed. Patients with LOH at D1S2845 showed significantly more nerve invasion than those without ($P = 0.029$). Samples with moderately differentiated adenocarcinoma rarely found LOH at D1S234 ($P = 0.035$).

Figure 3 Fine mapping of the chromosome 1p36-pter in 90 CCA. The common loss regions were located at D1S2845 and the 25.5-cM region between D1S507 and D1S2734. — Normal; ■ LOH; ▨ MSI; ▤ Non informative; ▧ PCR failed

Patients who had LOH at D1S234 exhibited significantly less lymphatic invasion ($P = 0.017$), whereas patients with LOH at D1S2676 showed significantly more lymphatic invasion ($P = 0.031$). Clinical features of patients with and without LOH at loci D1S2845, D1S234, and D1S2676 are summarized in Table 2. A survival curve by the Kaplan-Meier method showed a poor prognosis for patients who demonstrated MSI at D1S228 (Figure 4). The log-rank test confirmed a significant association between poor prognosis and MSI at D1S228 ($P = 0.0026$).

DISCUSSION

Microsatellite polymorphisms provide a large number of highly informative loci, which may allow simultaneous, rapid screening of LOH and MSI using very small amounts of DNA samples. Our finding of LOH at one or more loci was observed in 68 (75.6%) out of 90 cases. This finding is different from that of Momoi *et al.*^[11]. They determined fine mapping of chromosome 1p36 using 13 markers in 22 CCA patients and showed LOH at one or more loci in 13 (59.1%) cases. The differences

in percentage of LOH from Momoi *et al* and our studies suggest the differences in type and number of samples and type and number of markers used. The type of samples studied by Momoi *et al* was frozen tissues which may have dilution effects from normal tissues, whereas the samples in our study were microdissected tissues among which only tumor cells were selected. Our study used a large number of samples (90 cases). The number of markers used in our study was 10 with 5 markers similar to those studied by Momoi *et al*, suggesting that the locations of different markers may lead to different percentages. However, by comparison of 5 similar markers used in Momoi *et al* and our studies, the LOH frequencies at D1S450 (5%),

D1S507 (18.7%), and D1S199 (22.2%) detected by Momoi *et al* were lower than those of our study, whereas the LOH frequencies at TP73 (54.5%) and D1S228 (29.4%) were higher than those of our study. This suggests differences in tumor etiology. In our study, all tumors were obtained from patients who were residents of northeastern region of Thailand where liver fluke infection remains highly endemic. Genetic alterations in CCA caused by liver fluke infection may be different from those caused by others such as hepatolithiasis and primary sclerosing cholangitis. The different percentages also suggested the specificity of genetic alterations in each tumor type.

The *p73* gene is mapped to 1p36 at D1S468 and *p73* protein is structurally similar to the *p53* protein within its DNA-binding, transactivating, and oligomerization domains but C-terminal extension contains Sterile Alpha Motif (SAM) domain^[21,22]. The *p73* protein also shares some functional characteristics with *p53*, including the ability to promote apoptosis when overexpressed *in vitro* and up-regulate *p53* responsive genes involved in cell-cycle control such as *p21*^[23]. In neuroblastomas, the incidence of *p73* LOH was found to be significantly higher in advanced tumors than in earlier stage^[24]. In breast carcinomas, LOH in the *p73* region could be pathogenically related to breast cancer and possibly to a poor tumor prognosis^[25]. A relatively high frequency of LOH at D1S468 (19.4%) in our study suggests that inactivation of *p73* may play a role in CCA development. Fine mapping of chromosome 1p36 showed two regions of common allelic loss. The first region was at D1S2845 and the second region was from D1S507 to D1S2734 loci. A relative large area of deletion involving markers D1S507, D1S199, and

D1S2734 encompasses a 25.5-cM region. Candidate tumor suppressor genes located at D1S2845, D1S507, D1S199, and D1S2734 are DNA fragmentation factor, 40 ku, beta polypeptide (*DFFB*); caspase 9, apoptosis-related cysteine protease (*CASP9*); paired box homeotic gene (*PAX7*); and inhibitor of DNA binding 3 (dominant negative helix-loop-helix protein, *ID3*), respectively.

Statistical analyses were performed to determine whether the frequency of individual microsatellite marker showing alterations was correlated with clinical parameters. We found that MSI at marker D1S228 showed a significant correlation with poor survival ($P = 0.0026$). On the physical map, the retinoblastoma interacting zinc finger gene (*RIZ*) is adjacent to the polymorphic marker D1S228^[17]. In addition, *RIZ* harbors intragenic microsatellites and polyadenosine tracts within its coding region, it is a candidate for an inactivating mutation in MSI mediated carcinogenesis^[26,27]. MMR defect may cause not only MSI at D1S228 but also at the microsatellite coding sequences of *RIZ*, resulting in frame shift mutation of this gene and contributing to poor survival. However, our study showed that LOH at D1S228 did not affect patient survival, suggesting that LOH was not a major pathway of *RIZ* inactivation. An alternative pathway such as mutation and promoter hypermethylation may be a major pathway for *RIZ* inactivation in CCA, on which further study is needed. The high frequency of MSI found in this study (37.8%) suggests the involvement of MMR defect in liver fluke related CCA. However, the frequency of *bMLH1* alteration found in MSI (+) tumors showed no significant difference from that of MSS tumors (data not shown), suggesting that other MMR members may be defective. In contrast, infrequent MSI in CCA was reported by Liengswangwong *et al.*^[13]. This may be due to the differences in types of samples and markers.

D1S2845 located at 1p36.3 showed a significant correlation with nerve invasion ($P = 0.029$). The putative tumor suppressor gene located on this region is *DFFB*, which function is involved in apoptosis^[19,28]. Deletion at this region may lead to tumor progression. Marker D1S234 is located at 1p36.1 in the same region of cell division cycle 42, *Cdc42*. *Cdc42*, a member of the Rho subfamily, is plasma membrane-associated small GTPase, which cycles between an active GTP-bound and an inactive GDP-bound state. In active state, it binds to a variety of effector proteins to regulate cellular responses involved in epithelial cell polarization processes. *Cdc42*, Rac and RhoA influences cell shape and structure by initiating actin cytoskeleton remodeling. RhoA and Rac1 generate actin stress fibers and lamellipodia/membrane ruffles, respectively, whereas *Cdc42* stimulates the formation of microspikes and filopodia^[29]. Loss of D1S234 showed less lymphatic invasion, suggesting that lack of *Cdc42* may cause tumor cells to be less invasive ($P = 0.017$). Our previous study on microsatellite alterations at loci D2S119, D3S1611 and TP53 showed the association with poor prognosis^[13]. The previous and present studies indicate the value of microsatellite alterations as prognostic indicators for liver fluke related CCA. With regard to the significant correlations of microsatellite alterations with clinicopathological parameters such as survival, lymphatic

invasion and nerve invasion in this study, we propose the putative tumor suppressor genes; *RIZ*, *Cdc42*, and *DFFB*, which may play important roles in the development and progression of liver fluke related CCA.

Abstract

AIM: To determine the response of the proximal stomach to small intestinal nutrients in critically ill patients.

METHODS: Proximal gastric motility was measured in 13 critically ill patients (49.3 ± 4.7 years) and 12 healthy volunteers (27.7 ± 2.9 years) using a barostat technique. Recordings were performed at baseline, during a 60-min intra-duodenal infusion of Ensure® (2 kcal/min), and for 2 h following the infusion. Minimum distending pressure (MDP), intra-bag volume and fundic wave activity were determined.

RESULTS: The MDP was higher in patients (11.7 ± 1.1 vs 7.8 ± 0.7 mmHg; $P < 0.01$). Baseline intra-bag volumes were similar in the 2 groups. In healthy subjects, a 'bimodal' proximal gastric volume response was observed. In patients, the initial increase in proximal gastric volume was small and delayed, but eventually reached a maximal volume similar to that of healthy subjects. In healthy subjects, the proximal gastric volume rapidly returned to baseline level after nutrient infusion (median 18 min). In contrast, the recovery of volume to baseline was delayed in critically ill patients (median 106 min). In 6 patients, the volume had not returned to baseline level 2 hours after nutrient infusion. In patients, fundic volume waves were less frequent ($P < 0.05$) and had lower amplitude ($P < 0.001$), compared to healthy subjects.

CONCLUSION: In critical illness, proximal gastric motor

INTRODUCTION

Gastric intolerance to enteral feeding occurs frequently in critical illness and is a major obstruction to the provision of enteral nutrition^[1,2]. Inadequate nutritional support adversely affects both morbidity and mortality^[3,4]. The most common cause of feed intolerance is delayed gastric emptying^[1,2,5], which has a prevalence of up to 50% in tertiary intensive care units^[6]. Moreover, the mechanisms underlying poor gastric emptying in critical illness are not well understood.

Both proximal and distal gastric motility is considered important in normal gastric emptying of liquids^[7,8]. In healthy subjects, there is a relaxation of the proximal stomach, reduction in antro-duodenal motility and an increase in isolated pyloric pressure waves in response to small intestinal feed-back^[9,10]. This feed-back response is triggered by a caloric load of 2-3 kcal/min^[9,10].

In critically ill patients, a marked reduction in antral motility and a poor coordination of antro-duodenal contractions has been reported during fasting^[2,11]. There are, however, no data on the motor activity of the proximal stomach, during fasting or in response to small intestinal nutrients in these patients. The aim of the current study was to assess proximal gastric motor activity during small intestinal nutrient infusion in critically ill patients. We hypothesized that small intestinal feed-back to the proximal stomach in response to duodenal nutrients would be intensified, and increased proximal gastric relaxation would be observed. To minimize a variation in stimulation

due to erratic gastric emptying in critically ill patients, nutrient was infused directly into the duodenum. This provided a constant nutrient delivery at a physiological level to the small intestinal receptors.

MATERIALS AND METHODS

Subjects

Studies were performed in 13 medical, critically ill patients (11 male, mean age 49.3 ± 4.7 years), who were admitted to a level 3 intensive care unit between January and September 2004. Any patient aged greater than 17 years was eligible to be enrolled into the study if they were sedated, mechanically ventilated, required enteral nutrition and had no history of diabetes mellitus. Exclusion criteria comprised recent major abdominal surgery, any contra-indication to the passage of an enteral tube, usage of opioid analgesia, benzodiazepines or prokinetic therapy within the previous 24 h, previous gastric, oesophageal or intestinal surgery, unstable intra-cranial pressure or cervical spine injury. As part of the standard clinical practice in our intensive care unit, all subjects received a sliding scale insulin infusion to maintain blood glucose concentrations between 6 and 8 mmol/L. The demographic characteristics of the subjects are summarized in Table 1.

Studies were also performed in 12 healthy volunteers (8 male, mean age 27.7 ± 2.9 years), none of whom had a history of systemic or gastrointestinal disease, or was taking any medication. Volunteers were instructed to refrain from smoking for 24 h prior to the study.

Written informed consent was obtained from healthy subjects and the next of kin of the critically ill patients prior to enrolment into the study. The protocol was approved by the Human Research Ethics Committee of the Royal Adelaide Hospital.

Measurements

Proximal gastric motility: Proximal gastric motility was measured using an electronic gastric barostat (Distender Series II; G&J Electronics, Ontario, Canada)^[12,13]. A thin flaccid-walled bag with a maximum capacity of 1000 mL was attached to the distal end of the assembly, which was connected to the system via pressure and volume ports. Changes in proximal gastric volume were measured indirectly by changes in the volume of the polyethylene bag.

Data were stored onto a Powermac 7100 computer (Apple Computer, Cupertino, CA), using custom-written data-acquisition software (Labview: National Instruments, Austin, TX). This software was also used to program the barostat to perform distensions in stepwise increments^[14]. Recorded data were imported into a display and analysis program (Acqknowledge, Biopac System, Goleta, CA) for manual analysis. Intra-bag volumes were determined at 2 min intervals and the mean baseline volume was measured over 10 min immediately before the infusion. Changes in intra-bag volume during nutrient infusion were calculated as the difference between the actual bag volume and the mean baseline volume. The serial changes in bag volume during the infusion were plotted and compared. Proximal gastric relaxation was indirectly inferred by an increase in

Table 1 Demographic characteristics of the studied subjects

	Critically ill patients (n = 13)	Healthy subjects (n = 12)
Age (yr)	49.3 ± 4.7^b	27.7 ± 2.9
Sex (M:F)	11:2	8:4

intra-bag volume^[12].

Assessment of fundic slow volume waves was also performed. These were defined as changes in proximal gastric volume of greater than 30 mL that reverted in less than 2 min to a volume within 50% of the previous level^[15]. The number and volume amplitude of fundic slow waves (per 10 min) were determined during fasting and in response to small intestinal nutrient infusion.

Blood glucose concentration: Marked hyperglycaemia is one of the humoral factors that may play a role in mediating small intestinal feed-back and adversely affects gastric motility^[16]. Blood glucose concentrations were measured using a portable glucometer (Precision Plus, Abbott Laboratories, Bedford, USA)^[17] at timed intervals during the study.

Protocol

Patients and healthy subjects were studied after at least 6-hours fasting and in a 30 degree recumbent position. To standardise the sedative regime in patients, propofol alone was used, and opioids, benzodiazepines or prokinetic agents were not administered for 24 h prior to and during the study. In the healthy subjects, the barostat catheter and infusion tube were swallowed and allowed to pass into the correct position spontaneously, without the assistance of endoscopy. After insertion of the barostat catheter to a depth of 55 cm, the balloon was inflated with 400 mL of air and the catheter was pulled back until resistance was felt^[18]. Duodenal nutrient infusion was achieved by inserting a silicon-rubber catheter (Dentsleeve, Adelaide, Australia) with a central feeding lumen and lead-weighted tip into the duodenum. The correct positioning of the infusion catheter was determined by continuous measurement of the antro-duodenal trans-mucosal potential difference (TMPD) gradient^[18]. Radiological confirmation was not performed.

In patients, placement of both the barostat catheter and post-pyloric feeding tube was performed at the bedside with endoscopic assistance, without additional sedation to that required for ventilation. A 12 French x 114 cm naso-duodenal feeding tube (Flexiflo, Abbott,

Figure 1 Changes in proximal gastric volume during the 2 kcal/min infusion, in healthy (dotted line, $n = 12$) and critically ill (solid line, $n = 13$) subjects. Data are mean \pm SE. $^aP < 0.05$ vs healthy subjects.

Ireland) was inserted into the duodenum over a guide-wire (THSF-35-260, Cook, Australia). The barostat catheter was then guided through the mouth into the stomach by the endoscope. The barostat balloon was inflated with 400 mL of air and gently retracted into the fundus under direct vision. Gastric contents (air and fluid) were completely aspirated prior to withdrawal of the endoscope. Correct placement of the naso-duodenal feeding tube was confirmed at the time of placement by measurement of the TMPD gradient^[18], and subsequently by radiography^[11].

After confirming that the catheters were positioned correctly, air in the barostat balloon was aspirated and the catheter was connected to the barostat. The minimum distending pressure (MDP), defined as the first pressure level that provided an intragastric bag volume of more than 30 mL, was determined^[19]. The baseline pressure for the study was then set at MDP + 2 mmHg^[12]. All studies began with a 15-min baseline recording, during which normal saline was infused into the duodenum at 240 mL/h. Each subject then received a 60-min duodenal infusion of Ensure[®] (Abbott Laboratories, Ohio, USA; nutrient content: 13% protein, 64% carbohydrate, 21% fat; energy density: 1 kcal/mL) at 2 kcal/min. Barostat recordings were performed during the nutrient infusion and continued for 2 h after the infusion was ceased. Blood samples for the measurement of blood glucose concentrations were collected at baseline and at 20-min intervals during the nutrient infusion.

Statistical analyses

Data are presented as mean \pm SE. The differences in demographic characteristics, baseline volume, MDP and fundic volume waves between the healthy subjects and critically ill patients were compared using Student's unpaired *t*-test. A repeated measures mixed-model analysis of variance (ANOVA) was used to compare the proximal gastric volume and blood glucose responses between the groups, with time and treatment as the factors. Student's unpaired *t*-test was used to compare the maximum changes in proximal gastric volume between the 2 groups. The time required for the proximal stomach to return to baseline volume following nutrient stimulation was expressed as median and interquartile range (IQR), and differences

Figure 2 Changes in proximal gastric volume from baseline at the 10th minute and at peak level during the nutrient infusion, in healthy (open circle, $n = 12$) and critically ill (closed circle, $n = 13$) subjects. $^cP < 0.001$ vs healthy subjects.

between the groups were assessed using the Mann-Whitney test. A $P < 0.05$ was considered statistically significant.

RESULTS

Oral intubation of the assembly was well tolerated by both patients and healthy subjects and no complications occurred in either group. At endoscopy, 2 patients had a small amount of feed residue (< 100 mL) in the stomach and duodenum.

Baseline measurements

The MDP was higher in critically ill patients than in healthy subjects (11.7 ± 1.1 mmHg *vs* 7.8 ± 0.7 mmHg, $P = 0.006$). Baseline proximal gastric volumes were similar between the two groups (patients: 211 ± 48 mL *vs* healthy: 191 ± 24 mL).

Proximal gastric volume response to small intestinal nutrients (Figures 1 and 2)

In the healthy subjects, there was a “bimodal” proximal gastric volume response to small intestinal nutrients, with the first peak occurring within 15 min of the infusion. The proximal gastric volume had reduced by $57 \pm 4\%$ (mean volume reduction = 184 ± 24 mL) at 30 min of the infusion, after which it increased to a second smaller peak at 50 min. In critically ill patients, the increase in proximal gastric volume in response to small intestinal nutrients was initially slower and smaller than in healthy subjects (change in volume at 10th min: 45 ± 26 *vs* 196 ± 29 mL; $P < 0.001$). The proximal gastric volume did not peak until 40 min after the start of the infusion, but eventually reached a similar level to the healthy subjects. The maximal increase in proximal gastric volume did not differ between the two groups (patients: 199 ± 35 mL *vs* healthy: 233 ± 76 mL) (Figures 1 and 2).

Recovery of proximal gastric volume after duodenal nutrient stimulation (Figure 3)

The time course for the proximal stomach to return to baseline volume after nutrient stimulation was assessed

Figure 3 Time course for the proximal gastric volume to return to baseline level after nutrient stimulation, in healthy (dotted line, $n = 12$) and critically ill (solid line $n = 13$) subjects. Data are mean \pm SE.

Figure 4 Fundic slow volume waves (per 10 min) during the 2 kcal/min nutrient infusion, in healthy (open bar, $n = 12$) and critically ill (closed bar, $n = 13$) subjects. Data are mean \pm SE. $^aP < 0.05$ vs healthy subjects.

by analysis of the proximal gastric volume during the 2 hour period following the infusion. In healthy subjects, the proximal gastric volume had returned to baseline level within 30 min after cessation of the nutrient infusion (median = 18 min; IQR: 0-24 min). In patients, the time required for the proximal stomach to return to baseline was significantly longer than in healthy subjects (median = 106 min; IQR: 47-120 min; $P < 0.001$). In only 2 of the 13 patients, the volume had returned to baseline within 30 min of cessation of the infusion. In 6 patients, the proximal gastric volume had not returned to baseline level at 2 h after the nutrient infusion was ceased (Figure 3).

Fundic volume waves during fasting and in response to small intestinal nutrients (Figure 4)

The frequency of fundic volume waves was less in critically ill patients during both fasting and nutrient infusion, compared to healthy subjects ($P < 0.05$) (Figure 4). In addition, the volume amplitude of fundic waves was smaller in patients than in healthy subjects (44 ± 3 mL vs

87 ± 8 mL; $P < 0.001$).

Blood glucose concentration

Blood glucose concentrations were higher in critically ill patients at baseline (7.0 ± 0.3 mmol/L vs 5.2 ± 0.2 mmol/L; $P < 0.001$) and during nutrient infusion (8.3 ± 0.2 mmol/L vs 7.2 ± 0.2 mmol/L; $P < 0.01$), compared to healthy subjects. However, the magnitude of increase in blood glucose concentration during the infusion did not differ between the 2 groups.

DISCUSSION

This is the first study to evaluate the motor responses of the proximal stomach to small intestinal nutrient infusion in critically ill patients. Our data demonstrate that in these patients, (1) proximal gastric relaxation is delayed with no change in the magnitude of the response, (2) fundic wave activity is reduced, and (3) the recovery of proximal gastric volumes to pre-stimulation levels is delayed.

Although delayed gastric emptying is a major clinical problem in critically ill patients, only distal gastric motor activity has been previously examined^[2,11]. However, abnormal proximal gastric motility has been demonstrated in non-critically ill patients with gastroparesis, such as those with diabetes mellitus^[14,20,21], and may play an important role in slowing gastric emptying^[7,8]. Our findings provide a possible mechanism for the delay in liquid gastric emptying frequently found in critical illness. Failure of the relaxed proximal stomach to return to baseline volume after nutrient stimulation in these patients provides a reservoir for retention of gastric residue in the fundus. Such a prolonged pooling of gastric content is likely to contribute to both delayed gastric emptying and gastro-oesophageal reflux^[5,7,8,22]. Fundic volume waves are thought to be involved in the redistribution of proximal gastric content distally for emptying and high fundic wave activity is associated with accelerated gastric emptying of liquids^[23]. It would seem likely that reduced fundic wave activity may contribute to the slowing of gastric emptying.

The mechanisms underlying the changes in proximal gastric motility in critical illness are unknown. The initial delay in proximal gastric relaxation could relate to physical restriction from a combination of positive mechanical ventilation and high intra-abdominal pressure (reflected by a higher MDP) present in critical illness^[24]. However the eventual relaxation to normal values suggests that this is unlikely to be the cause. Impaired gastric accommodation has been described in diabetes mellitus with autonomic neuropathy^[25-27]. Autonomic dysfunction has also been reported in critically ill patients^[28] and could cause both a delay in gastric relaxation and potentially a prolonged recovery in gastric volume via impairment of different components of the autonomic nervous system. In light of recent reports of interactions between inflammatory mediators, neurotransmitters and intrinsic neural pathways^[26,29], it is also possible that increased cytokine production in critical illness may play a role. Sedative drugs have been reported to alter gastric emptying and proximal gastric motility^[30,31]. While propofol inhibits gastric emptying in animals^[30], its effects in humans are

less clear^[31,32]. A small study in humans showed that a combination of propofol and morphine could result in a smaller proximal gastric volume compared to morphine alone, but gastric emptying is similar between the two groups^[31]. The mechanisms underlying the prolonged recovery of the proximal stomach to baseline volume are also unknown. Although hyperglycemia increases proximal gastric relaxation in both healthy and diabetic subjects^[16,17], the elevation of blood glucose levels in our patients was minimal and in the 'physiological hyperglycemia' range, which seems unlikely to significantly contribute to the prolonged relaxation. Similarly, gastric relaxation due to opiate drugs such as morphine^[32] is unlikely to explain our findings, as they were withheld for 24 h prior to the study. The neurotransmitter nitric oxide is important in mediating proximal gastric relaxation^[33]. Nitric oxide synthesis is increased in critically ill patients^[34,35] and could contribute to prolonged proximal gastric relaxation. The discordant findings of impaired relaxation followed by failure to regain normal tone suggest the involvement of multiple mechanisms. Further studies are required to determine the involvement and interaction of potential mechanisms.

The bimodal pattern of proximal gastric relaxation in our healthy subjects in response to small intestinal nutrients is intriguing. This was a consistent observation in all the 12 healthy subjects. Physiologically, it is possible that the proximal gastric volume reduction in the middle of the infusion represents proximal gastric contractions to redistribute feed to the distal stomach. This pattern of proximal gastric response, however, has not previously been reported in barostat studies during intra-gastric^[22,23] or intra-duodenal^[36] nutrient delivery. In the Barbara *et al*^[36] study, intra-gastric volume recording was only performed for 30 min during duodenal nutrient infusion, which may have been too short to detect the second peak. Although the reasons for differences in the proximal gastric response reported to date remain unclear, they may relate to the site of nutrient administration and duration of infusion.

There were a number of issues that should be acknowledged in the current study. Intra-gastric delivery of nutrient was avoided for several reasons. Firstly, the frequently observed slow gastric emptying in this group of patients^[6] may lead to an unreliable assessment of the feed-back response, as a constant delivery of 2-3 kcal/min of nutrient to the small intestine is required^[9,10]. Secondly, gastric motility and emptying of a liquid meal can be altered by the presence of a barostat balloon, which redistributes the meal to the distal stomach, increases intra-gastric pressure and accelerates gastric emptying, with 50% of the liquid meal emptying in the first 10 min^[22]. Thereafter, the rate of emptying is dependent on the phasic-tonic contraction of the proximal stomach. In addition, although the effects of performing endoscopy on gastric motility are unknown, they are unlikely to be important in the context of nasogastric tube intubation. The procedure was performed using a skinny endoscope with minimal air inflation and all gastric contents were aspirated from the stomach immediately prior to the study. Barostat studies are best performed in the sitting, upright position^[19], but it is impossible to study critically ill patients in this posture. The current study was thus performed

in a 30 degree recumbent position in both patients and healthy subjects, to minimize the effects of posture on bag volume. Hebbard *et al*^[37] recommended that if upright posture is not possible, then the same posture should be controlled between the study groups. In addition, proximal gastric compliance was not assessed. Although this would be of major interest, it was not performed because of concern that positive intra-bag pressures would potentially interfere with patient ventilation, due to splinting of the diaphragm. Finally, although our patients were significantly older, we do not believe this would substantially affect the study results, as healthy aging does not affect proximal gastric motor responses to a meal^[38].

In conclusion, the proximal gastric response to small intestinal nutrients is abnormal in critical illness, characterised by a prolonged relaxation after nutrient stimulation and a reduction in fundic wave activity. The potential contribution of these proximal gastric motor abnormalities to delayed gastric emptying in critically ill patients requires further study.

Abstract

AIM: To investigate the effect of shenfu injection on gastrointestinal microcirculation after myocardial ischemic-reperfusion (IR) injury in rabbits and probe into the mechanism.

METHODS: Forty healthy flap-eared white rabbits were randomly divided into 4 groups: IR injury control group (group I), shenfu injection 5 mL/kg per h group (group II), shenfu injection 10 mL/kg per h group (group III) and shenfu injection 20 mL/kg per h group (group IV). The four groups were treated with Lactated Ringer's solution, shenfu injection 5, 10, and 20 mL/kg per h were infused intravenously 30 min before experiment respectively. The values of hemodynamics [mean arterial pressure (MAP), heart rate (HR), gastric intramucosal partial pressure of carbon dioxide (PCO₂), blood gas analysis and pH] were measured and compared with those before myocardial ischemia, 60 min after myocardial ischemia and 60, 90, and 180 min after reperfusion.

RESULTS: The MAP, HR and gastric intramucosal pH were (70.50 ± 4.50) kPa, (165 ± 14) beats per min, 7.032 ± 0.024 in group I 60 min after myocardial ischemia, which were significantly decreased compared with those before myocardial ischemia (88.50 ± 9.75 kPa, 217 ± 18 beats per min, 7.112 ± 0.035, *P* < 0.05). The MAP, HR and gastric intramucosal pH were significantly decreased in group I 60, 90, and 180 min after reperfusion (61.50 ± 5.25 kPa, 133 ± 31 beats per min, 6.997 ± 0.025) compared with those before reperfusion respectively (*P* < 0.05), whereas the values were insignificantly different in groups II, III or IV after reperfusion, compared with those before reperfusion, and there were no significant differences between groups II, III, and IV after reperfusion.

CONCLUSION: Pre-infusion of shenfu injection has a

protective effect on gastrointestinal microcirculation after myocardial IR injury in rabbits, in a dose independent manner.

INTRODUCTION

Ischemia-reperfusion injury is a significant etiological factor of organ dysfunction, and it is important to investigate protective measures for anti-ischemia reperfusion injury. Myocardial ischemia reperfusion injury can induce myocardial metabolic disturbance, organ and functional damage, hemodynamic change, cardiac output decrease, reduction of gastrointestinal tract blood flow and oxygen dysmetabolism^[1]. The gastrointestinal mucosa has rich blood supply, being fairly sensitive to ischemia and oxygen deficiency, and is usually involved first after hypoxia. It is one of internal organs that have decrease of blood flow early and obviously but recover lastly. In this study, we investigated the effect of shenfu injection on gastrointestinal microcirculation after myocardial ischemic-reperfusion injury and probed into the mechanism of protective effect of shenfu injection through animal experiments in rabbits. Shenfu injection is a traditional Chinese medicine. The main pharmaceutical compounds are shenfu and fuzi.

MATERIALS AND METHODS

Materials

This was a random controlled animal experimental study carried out in the Institute of Cardiology and Anesthesiology of Qingdao Medical University. Forty healthy flap-eared white rabbits were provided by Animal Centre of Affiliated Hospital of Qingdao Medical University [certificate number: FYXK (LU20030035)], including males and females, weighing 2.3-3.1 kg, with a

mean 2.46 ± 0.29 kg. They were fed with entire nutrition forage. Every rabbit ate about 150 g of foodstuffs, twice a day with free access to water. Rabbits were housed in an airy, quiet and light room with room temperature at 20°C - 22°C , one in each cage. Forty rabbits were randomly divided into 4 groups with 10 rabbits in a group, including ischemia-reperfusion control group (group I); shenfu injection 5 mL/kg per h group (group II); shenfu injection 10 mL/kg per h group (group III); shenfu injection 20 mL/kg per h group (group IV). Rabbits were fasted for 12 h before experiment. There was no significant difference in weight between four groups.

Methods

After being anaesthetized by an intravenous injection of thiopental sodium (20 g/L) with a dosage of 25 mg/kg, rabbits were incised at trachea, and an endotracheal catheter was inserted and connected to an animal breathing apparatus with 100% inhaling oxygen, 10-13 mL/kg tidal volume, 20-30 breath frequency per min and 1.2 inspiration/expiration ratio. Pressure of carbon dioxide at the end of expiration was kept at 4.7-5.3 kPa. A tube was inserted into right internal carotid vein for infusion of fluid and shenfu injection; an arterial puncture needle was inserted into the femoral artery and connected to a pressure-energy transducer to monitor blood pressure, heart rate and sample blood while mean artery pressure was kept between 69.75-90.00 kPa. Meanwhile, a 14F TRIP Tonometry catheter was inserted into stomach. During the experiment fentanyl (25 $\mu\text{g/kg}$) and vecuronium bromide (0.1 mg/kg) were administrated to maintain anaesthesia. We did not record baseline values until blood pressure, heart rate and breath were stable for 10 min while calculating pH according to Henderson-Hasselbalch formula^[2]. Groups I, II, III, and IV were infused with natrium lacticum Ringer's solution 8 mL/kg per h, shenfu injection 5 mL/kg per h, shenfu injection 10 mL/kg per h and shenfu injection 20 mL/kg per h through the vein respectively 30 min before the model of myocardial ischemia reperfusion was established. The pericardium was unfolded after chest was opened and the heart was exposed thoroughly. The left coronary artery anterior descending branch (LAD) was identified and main branch ligated at mid or upper 1/3 with double clinch. The ligature was unclamped for reperfusion after ischemia for 60 min.

Main observation index

Baseline levels of mean artery pressure, heart rate and pH value, at myocardial ischemia for 60 min and after reperfusion for 60, 90, and 180 min were recorded respectively.

Statistical analysis

All data were analyzed with SPSS 10.0 statistical package. Data were expressed as mean \pm SD, analyzed with Student's *t*-test between intra-group and with ANOVA between groups. A value of $P < 0.05$ was considered to have statistical significance.

Table 1 Physiologic indexes after myocardial ischemia-reperfusion injury (mean \pm SD, $n = 10$)

Group	Mean artery pressure (kPa)	Heart rate (beats/min)	pH value
Baseline level			
Group I	95.25 \pm 6.00	206 \pm 13	7.129 \pm 0.038
Group II	88.50 \pm 9.75	217 \pm 18	7.112 \pm 0.035
Group III	86.25 \pm 8.25	198 \pm 15	7.131 \pm 0.045
Group IV	90.75 \pm 6.75	221 \pm 22	7.122 \pm 0.037
Ischemia 60 min			
Group I	70.50 \pm 4.50 ^a	165 \pm 14 ^a	7.032 \pm 0.024 ^a
Group II	87.00 \pm 10.50	201 \pm 17	7.108 \pm 0.023
Group III	84.75 \pm 4.50	195 \pm 20	7.125 \pm 0.031
Group IV	87.75 \pm 5.25	213 \pm 16	7.119 \pm 0.026
Reperfusion 60 min			
Group I	61.50 \pm 5.25 ^{a,c}	133 \pm 31 ^{a,c}	6.997 \pm 0.025 ^{a,c}
Group II	85.50 \pm 9.00	197 \pm 12	7.121 \pm 0.022
Group III	96.75 \pm 6.00	199 \pm 16	7.114 \pm 0.032
Group IV	94.50 \pm 12.00	208 \pm 13	7.126 \pm 0.019
Reperfusion 90 min			
Group I	57.75 \pm 6.00 ^{a,c}	119 \pm 25 ^{a,c}	6.953 \pm 0.019 ^{a,c}
Group II	81.75 \pm 10.50	210 \pm 22	7.118 \pm 0.033
Group III	84.00 \pm 6.75	205 \pm 17	7.128 \pm 0.027
Group IV	81.00 \pm 11.25	214 \pm 21	7.125 \pm 0.026
Reperfusion 180 min			
Group I	48.75 \pm 3.00 ^{a,c}	94 \pm 16 ^{a,c}	6.911 \pm 0.017 ^{a,c}
Group II	86.25 \pm 5.25	204 \pm 25	7.127 \pm 0.024
Group III	90.75 \pm 9.00	216 \pm 21	7.132 \pm 0.034
Group IV	85.50 \pm 4.50	200 \pm 18	7.120 \pm 0.029

Group I: Ischemia-reperfusion control group; group II: Shenfu injection 5 mL/kg per h; group III: Shenfu injection 10 mL/kg per h; group IV: Shenfu injection 20 mL/kg per h. ^a $P < 0.05$ vs baseline level; ^c $P < 0.05$ vs ischemia 60 min.

RESULTS

None of the 40 rabbits died during experiment. Hemodynamics index and pH value changes of stomach mucosa are shown in Table 1.

DISCUSSION

Studies show^[3] that myocardial IR injury often induces gastric intramucosal ischemia and oxygen deficiency. The gastrointestinal microcirculation is very sensitive to ischemia and oxygen deficiency and the gastrointestinal mucous membrane is a perfect region for supervision, while the pH value of gastric intramucosa (Phi) has become a regional index for tissue perfusion. In recent years, the pH value of gastric intramucosa has been a sensitive index to reflect gastric intramucosal ischemia and oxygen deficiency^[4]. The main effective ingredients of shenfu injection are panaxoside and myoctionine^[5]. According to the literature, panaxoside not only has an important role in antistress, antioxygenation and myocardial ischemia, but also has definite protective and therapeutic activity against myocardial ischemia injury, renal ischemia reperfusion injury, and spinal cord ischemia injury^[6,7]. However, reports about its effect on gastrointestinal micro-circulation are rare. The current study showed that the mean arterial blood pressure and heart rate in group I decreased progressively, both

were lower than that in baseline condition ($P < 0.05$) in myocardial reperfusion model when myocardial ischemia lasted for 60 min, or after reperfusion for 60, 90, 180 min. However, those indexes of three shenfu groups were not significantly changed ($P > 0.05$) when myocardial ischemia lasted for 60 min, or after reperfusion for 60, 90, 180 min, and there were no significant differences between three shenfu groups. Therefore we suppose that hemodynamics were unstable after myocardial ischemia reperfusion, which induced the decrease of blood pressure and heart rate. On the other hand, shenfu injection could improve the hemodynamics during myocardial ischemia reperfusion, and the protective effect was not significantly dose dependent. Moreover, pH value of group I decreased significantly compared with that of baseline level ($P < 0.05$). The pH value of shenfu injection therapeutic groups II, III, IV did not change ($P > 0.05$), which proved that shenfu injection could improve and prevent the hypoperfusion and disturbance of oxygenation in gastrointestinal microcirculation after myocardial ischemia and reperfusion, and has an important protective role in gastrointestinal microcirculation. We designed 3 dose groups: 5, 10, and 20 mL/kg per h and discovered that the pH value in different groups was not changed significantly ($P > 0.05$). This showed that pre-infusion of shenfu injection had an effective protective function on gastrointestinal microcirculation after myocardial IR injury in rabbits, in a dose independent manner. After myocardial ischemia reperfusion, because of hemodynamic instability, gastrointestinal tract hypoperfusion, oxygenation disorder, generation of free radicals and the role of cytokines, activation and releasing of mediators of inflammation, gastrointestinal microcirculation was disturbed^[8,9], leading to gastric intramucosal ischemia, hypoxia, and pH decrease. The protection of shenfu injection on gastrointestinal microcirculation is associated with many factors^[10,11], such as myocardial preservation, stabilization of hemodynamics, antioxygenation, reduced production of free radicals, degradation of cytokines and inhibition of the activation and release of mediators of inflammation.

In summary, myocardial ischemia reperfusion injury can induce gastrointestinal microcirculation dysfunction.

Shenfu injection has protective effect on gastrointestinal microcirculation after myocardial IR injury in rabbits, with no obvious dose-effect relationship. Shenfu injection may improve gastrointestinal microcirculation mainly through myocardial preservation, and stabilization of hemodynamics. Our study provides strong evidence for the protective effect of shenfu injection against IR injury.

Abstract

AIM: To evaluate the relationship between leptin and systemic inflammation in acute pancreatitis.

METHODS: Consecutive patients with acute pancreatitis were included. Body mass index and serum samples were obtained at admission. Leptin, TNF- α , IL-6, -8 and -10 levels were determined by ELISA. Severity was defined according to Atlanta criteria.

RESULTS: Fifty-two (29 females) patients were studied. Overall body mass index was similar between mild and severe cases, although women with severe pancreatitis had lower body mass index ($P = 0.04$) and men showed higher body mass index ($P = 0.05$). No difference was found in leptin levels regarding the severity of pancreatitis, but higher levels tended to appear in male patients with increased body mass index and severe pancreatitis ($P = 0.1$). A multivariate analysis showed no association between leptin levels and severity. The strongest cytokine associated with severity was IL-6. Correlations of leptin with another cytokines only showed a trend for IL-8 ($P = 0.058$).

CONCLUSION: High body mass index was associated with severity only in males, which may be related to android fat distribution. Serum leptin seems not to play

a role on the systemic inflammatory response in acute pancreatitis and its association with severe outcome in males might represent a marker of increased adiposity.

INTRODUCTION

Obesity is a risk factor for severe acute pancreatitis (AP) and for the development of both local and systemic complications^[1]. A chronic, low grade, pro-inflammatory state has been described in human obesity, including increased plasma levels of IL-6, TNF- α , C-reactive protein and endothelial adhesion molecules^[2]. This may be due to the cytokine-synthesizing capabilities of adipose tissue driven by yet unknown signals, giving rise to insulin resistance and the metabolic syndrome^[3]. Actually, one third of the circulating IL-6 originates from adipose tissue, especially from the visceral depot^[4]. On the other side, the inflammatory cascade evoked by AP has a pivotal role in determining severity of the disease, and many cytokines and other acute reactants are well-established prognostic markers (i.e. IL-6, -8, -10, C reactive protein)^[5]. Coincidence of both a chronic and acute inflammatory scenarios (obesity and AP, respectively) with similar cytokine patterns may offer an explanation for the association between severe AP and obesity. Therefore, obese individuals may be prone to develop a more intense inflammatory reaction in response to AP that would lead to a dismal prognosis.

Leptin, the protein derived from the *Ob* gene, is an adipocyte-derived signal^[6], and its circulating concentrations are highly correlated with body fat mass^[7,8]. It has also been implied as a modulator of immunity with pro-inflammatory properties^[8,9], and it is highly correlated to C-reactive protein, independently of obesity^[10].

Research about leptin in AP is scarce. Two experimental

studies in animal models have suggested a protective role for leptin on AP by suppression of the pro-inflammatory response, reduction of leukocyte infiltration on pancreatic tissue and increased pancreatic repair^[11,12]. These results contrast with those found when studying non-pancreatic conditions, suggesting a tissue-specific protective role for leptin. Also, elevated plasma levels of leptin were found in patients with AP when compared to healthy controls with similar body mass index^[11]. However, distinction between severe and mild cases was not established.

Whether circulating leptin would have a pro- or anti-inflammatory role in AP, its serum concentrations should correlate with severity in AP, as has been reported for IL-6 and IL-10, respectively. It should also correlate with other cytokines previously found to be increased in severe AP (i.e. TNF- α , IL-6, -8, -10). The purpose of the present work was to measure serum concentrations of leptin and other cytokines in patients with severe and mild AP to identify a possible role of the former in the systemic inflammatory response, and in the prognosis assessment of AP.

MATERIALS AND METHODS

All patients with AP diagnosis admitted between March 2002 and August 2004 to a tertiary medical center were included in the study. Diagnosis of AP was based on typical clinical manifestations with at least a 3-fold increase of serum amylase and/or lipase. Whenever uncertainty about diagnosis existed, CT-scan was performed to confirm/rule out AP. Patients were excluded if they had received IV therapy before admission. HIV/AIDS patients were also excluded because of the confounding lipodystrophy and altered leptin levels described in these patients^[13].

The etiology of AP was classified as biliary, alcoholic, idiopathic or other. Weight and height from all patients were measured during the first 48 h from admission for body mass index (BMI) calculation. Prognostic severity by modified Ranson's criteria was recorded for each patient^[14].

Severe AP was considered when patients developed one or more local (i.e. necrosis, infected necrosis, abscess, pseudocyst) or systemic (i.e. renal or respiratory failure, cardiovascular collapse, coagulopathy, gastrointestinal bleeding, sepsis or multiple organ failure) complications according to the Atlanta classification of AP^[15]. Patients were managed by the medical house staff who were blinded as to the aims and methodology of this study.

During the first 24 h from admission, aliquots of a serum sample obtained from all patients were stored at -70°C , until laboratory determinations were performed. Serum leptin levels were measured in duplicate in the same run using a commercial ELISA kit for human leptin (Linco Research, MO, USA), with a sensitivity of 0.5 ng/mL. According to protocol insert, mean serum leptin levels from normal individuals (BMI: 18-25 kg/m²) are 3.8 ± 1.8 ng/mL for men, and 7.4 ± 3.7 ng/mL for women. TNF- α , IL-6, -8 and -10 concentrations were quantified using commercially available ELISA kits (Beckton Dickinson, NL, USA), according to the manufacturer's instructions.

BMI was expressed as mean \pm SD, while serum de-

^a*P* = 0.008, ^b*P* = 0.04, ^c*P* = 0.05, ^d*P* = 0.1 (Mann-Whitney U-test).

terminations were expressed as medians and ranges. Comparisons were carried out by means of the *t* test and Mann-Whitney U-test, as appropriate. A multivariate analysis was constructed to test the independent association of circulating leptin and severity, adjusted for potential confounders (gender and BMI). Correlations among cytokines and any other non-parametric variable were done using the Spearman rank-order test. All statistical analysis was performed using SPSS statistical software (Chicago, Illinois, USA). *P* < 0.05 was considered statistically significant.

Informed consent was obtained from all patients. This study was approved by the local Institutional Board for Human Research and designed according to international guidelines.

RESULTS

A total of 58 patients with AP were studied. Six patients were excluded from the analysis, four of them because of HIV/AIDS and two because of unavailability of serum for complete leptin and/or cytokines determinations (2 patients had severe AP, 33%).

There were 29 women (56%) and mean age of all patients was 42 ± 16 years. The most frequent AP etiology was biliary (*n* = 19), followed by hypertriglyceridemia (*n* = 7), alcoholic (*n* = 6) and post-ERCP (*n* = 4). Other causes included: acute episodes of chronic pancreatitis (*n* = 4), pancreas divisum (*n* = 2), drug-induced (*n* = 2) and hypercalcemia (*n* = 1); while 7 cases were considered idiopathic. First time AP was present in 31 patients (60%). Severity was identified in 14 cases (27%). Local complications occurred in 8 (15%) patients, whereas systemic complications developed in 11 (21%); presence of both complications was noted only in 5 cases. Six patients (12%) were admitted to the ICU and 4 had lethal AP (8%).

BMI according to severity status and gender is shown in Table 1. Although there was no difference between severe and mild cases in all patients, females with severe AP had significantly lower BMI when compared to mild

Table 4 Leptin correlation with other cytokines according to gender

		TNF- α <i>r</i> (<i>P</i>)	IL-6 <i>r</i> (<i>P</i>)	IL-8 <i>r</i> (<i>P</i>)	IL-10 <i>r</i> (<i>P</i>)
Leptin	All patients	NS	NS	0.265 (0.058)	NS
	Females	NS	NS	0.488 (0.007)	NS
	Males	0.487 (0.019)	0.397 (0.061)	NS	NS

cases; while an opposite association was observed in male patients. There was a positive correlation of BMI and leptin ($r = 0.476$, $P < 0.001$) in the whole group. Leptin levels were significantly higher in women when compared with men and a tendency for higher leptin levels was demonstrated in severe male cases. After multivariate analysis, there was no significant independent association between leptin serum levels and severity of AP, neither in the overall sample, nor after adjusting by gender and BMI (Table 2). There was no difference in leptin measurements between patients admitted or not to the ICU, or between a fatal outcome or not ($P = 0.41$ and $P = 0.34$, respectively). Time of evolution from onset of pain (1.7 ± 2 d) did not alter leptin values significantly (data not shown).

Predicted severity by modified Ranson's criteria correlated with Atlanta criteria ($r = 0.414$, $P = 0.002$), was significantly associated with increased levels of TNF- α ($P = 0.018$) and IL-8 ($P = 0.021$), and showed a tendency for increased IL-6 ($P = 0.096$); however, it did not correlate with leptin levels.

Levels of cytokines measured according to severity status (Atlanta criteria) and gender are shown in Table 3. TNF- α , IL-6 and IL-10 were higher in the group with severe AP. In the sub-analysis by gender, IL-6 was the only marker to remain higher in severe cases. Local complications were associated with higher median [range] levels of IL-6 [250 (9.5-590) *vs* 47 (0.7-537), $P = 0.004$], while systemic had increased levels of IL-6 [202 (62-590)

vs 40 (0.7-537), $P < 0.001$] and IL-10 [7.2 (0-54) *vs* 2.7 (0-560), $P = 0.025$]. Admission to the ICU was associated with elevated IL-6 [235 (62-590) *vs* 47 (0.7-537), $P = 0.006$] and IL-8 [258 (3.5-4596) *vs* 3.5 (0-1322), $P = 0.036$], and mortality was related with higher levels of TNF- α [75 (1.6-385) *vs* 0 (0-579), $P = 0.015$] and IL-8 [538 (269-4596) *vs* 3.5 (0-1322), $P = 0.005$].

In the whole group, leptin did not correlate significantly with any other cytokine, although a tendency was noted with IL-8 (Table 4). When only females were taken into account the latter resulted significant, whereas if only males were analyzed, leptin correlated significantly with TNF- α and tended to correlate with IL-6. However, TNF- α was significantly correlated with IL-8 ($r = 0.379$, $P = 0.006$) and IL-10 ($r = 0.317$, $P = 0.023$), IL-6 with IL-10 ($r = 0.412$, $P = 0.002$), and IL-8 with IL-10 ($r = 0.275$, $P = 0.048$). There was also a tendency for TNF- α with IL-6 ($r = 0.231$, $P = 0.1$).

DISCUSSION

Severe AP has a mortality around 24%-50%^[5,16]. Therefore, major efforts have focused on the discovery of prognostic markers for an early identification of severe cases, to anticipate a more aggressive diagnostic and therapeutic approach. The recognition of obesity as a risk factor for severe AP^[1] lead to the identification of other markers of obesity, such as android fat distribution and higher waist circumference, as more strongly associated with severity^[17]. These findings provided a possible link between AP and the so-called metabolic syndrome, which among certain criteria is characterized by a chronic pro-inflammatory condition^[3].

Particularly since the identification of human leptin in 1994, adipose tissue has been increasingly recognized as an endocrine organ capable of coordinating a variety of biological processes including not only energy metabolism, but neuroendocrine and immune functions^[4]. IL-6, TNF- α and leptin are among the principal immune-related

signals produced by adipose tissue^[3,4]. *In vitro* and *in vivo* experimental studies have shown that leptin is capable of promoting neutrophils activation and chemotaxis, inducing TNF- α and IL-6 from monocytes, promoting monocytes/macrophages activation and phagocytosis, enhancing lymphocytes proliferation and favouring a Th1 cytokine response^[8,18]. Also, it has been demonstrated that leptin can restore immune function under critical conditions such as starvation and it has been linked to autoimmunity^[8,9]. Consequently, adipose tissue and leptin seem to play a major role on immunological status, being the latter a pro-inflammatory signal.

On the pancreatic view, TNF- α , IL-1, -8, -10, and especially IL-6, have a major role on the pathophysiology of AP, as part of the inflammatory network evoked systemically^[5]. Experimental studies of AP in rats have shown that leptin levels increase after cerulein-induced pancreatitis, presumably from pancreatic origin (increase in leptin mRNA from the pancreas), and that exogenous administration is associated with diminished histological manifestations of pancreatitis and reduced plasma TNF- α ^[11]. Similarly, administration of leptin reduced the severity of ischemia/reperfusion-induced pancreatitis by diminishing morphological features of pancreatic damage and serum IL-1 β levels, while accelerated pancreatic repair by increasing pancreatic blood flow and DNA synthesis^[12]. These results are contrary to what would be expected according to other experimental studies evaluating the effect of leptin in non-pancreatic tissues^[8,9,18], and point-out a possible tissue-specific anti-inflammatory role in AP.

The absence of relationship between BMI and severity in the present study may be related to our reduced sample size, or to the predominance of female patients. Most reports on obesity as a prognostic marker of AP (including one meta-analysis) have not addressed whether this association may be modified by gender. However, two previous studies by our group have found that the association between obesity and severity is mostly seen in male patients^[17,19]. A clear explanation for this dichotomy on the risk of obesity on AP is unavailable yet, although it may be related to the higher waist to hip ratio or waist circumference (android fat distribution) found in males^[17].

Our results on the positive correlation of leptin with BMI, as well as the higher levels in females are in agreement with what has been previously described^[6]. Leptin levels did not differ between severe and mild cases, although male patients with severe AP had higher leptin levels in association with increased BMI, which may only represent a marker of increased adiposity^[6]. Moreover, these results were supported by the lack of association between leptin levels and severity in a multivariate analysis adjusted for gender and BMI. Similar findings occurred in patients with inflammatory bowel disease in whom leptin differences were entirely explained by variations in BMI, rather than disease activity^[20]. Furthermore, leptin did not correlate with any other cytokine in the whole group, while in the correlation by gender, leptin was neither correlated with the cytokines increased in severe cases (TNF- α and IL-6 for females, IL-6 and IL-8 for males, IL-10 for both). Although there was a positive association between TNF- α and leptin levels for males, all the evidences above make

it difficult to think that leptin plays a major role in the inflammatory response of AP; whether as a pro- or anti-inflammatory cytokine.

TNF- α , IL-6 and IL-10 were increased in the whole group of patients with severe AP, although IL-6 was the only cytokine that remained significantly higher in women and men with severe episodes, either in presence of local or systemic complications, or when admitted to the ICU. However, mortality was associated with elevation in serum levels of TNF- α and IL-8. Both cytokines, TNF- α and IL-8, were associated with Ranson's prognostic scale for mortality. Many studies have consolidated IL-6 as the cytokine with the most important prognostic utility for severity within the initial 24 h, although it seems not to be useful for prediction of death^[5,21-23]. This cytokine has also demonstrated use for identification of infected necrosis^[24]. Similarly, IL-8, TNF- α and IL-10 have early prognostic utility in AP: all of them are increased early in severe cases^[22,25] and IL-8 has been previously found increased in fatal AP^[26].

Konturek *et al.*, found that leptin levels were increased in patients with AP when compared to BMI- and age-matched controls, however this study did not distinguish mild from severe cases^[11]. It is well known that acute inflammatory conditions (i.e. AP) are associated with hyperglycemia, insulin resistance and increased levels of leptin, IL-6 and TNF- α ^[3]; and it is also recognized that insulin resistance leads to leptin resistance and further elevation of leptin concentrations^[27]. Therefore, this could be the explanation for previously reported increased leptin levels in AP that would result in even further increased levels if superimposed on a chronic inflammatory condition (i.e. obesity), as was observed in male patients with AP and higher BMI. Since our findings do not support leptin as being associated with a more severe inflammatory response and worse prognosis (i.e. severity, mortality or admission to ICU), it could represent just a bystander of the inflammatory reaction in AP; and unlike IL-6, IL-10 and TNF- α , not play a role on its pathophysiology.

The role of leptin as an anti-inflammatory and protective signal as was demonstrated by some experimental models in rats^[11,12], should have lead to significantly increased or decreased levels in severe cases, which was not demonstrated in our results; therefore, not ascertaining leptin as a protective signal in AP. This difference could only represent species differences in the actions for leptin, as has been shown with respect to leptin effects on glucocorticoids (these are decreased by leptin in mice, while not affected in humans)^[8].

In summary, our results do not support human leptin as a major pro-inflammatory signal involved in AP, nor as a protective and anti-inflammatory mediator. It seems neither to be the link between obesity and a higher rate of complications in AP; nor a prognostic marker.

Abstract

AIM: To address the role of *CD209* in celiac disease (CD) patients. Non-human leukocyte antigen (HLA) genetic factors in CD predisposition are poorly understood, and environmental factors like infectious pathogens may play a role. CD209 is a dendritic and macrophage surface molecule involved in pathogen recognition and immune activation. Recently, a functional variant in the promoter of the *CD209* gene (-336A/G) has been shown to affect the transcriptional *CD209* activity *in vitro* and it has been associated with a higher susceptibility to/or severity of infection.

METHODS: The study population was composed of two case-control cohorts of 103 and 386 CD patients and 312 y 419 healthy controls as well as a panel of 257 celiac families. Genotyping for the -336A/G *CD209* promoter polymorphism was performed using a TaqMan 5' allelic discrimination assay. HLA-DQ was determined by hybridization with allele specific probes.

RESULTS: Initially, the case-control and familial studies did not find any association of the -336 A/G *CD209* genetic variant with CD susceptibility. However, the stratification by HLA-DQ2 did reveal a significant association of CD209 promoter polymorphism in the

INTRODUCTION

Celiac disease (CD) is a chronic inflammatory disease with a multi-factorial origin. Genetically susceptible individuals show a pathological inflammatory response after exposure to gluten, a protein present in wheat, barley, rye and oats^[1]. Genetic studies in CD have revealed a strong influence of human leukocyte antigen (HLA) class II genes, specifically the alleles DQA1*0501 and DQB1*02 (HLA-DQ2) and to a lesser extent DQA1*0301 and DQB1*0302 (HLA-DQ8). However, other genes outside the HLA region must be also involved in CD susceptibility since the genetic susceptibility to CD indicated by the λ s (sibling risk/population frequency) is around 30%-60%, but no more than 40% to that sibling familial risk has been attributed to HLA^[2,3].

CD can be considered a model of autoimmune diseases, being for the moment the only one in which the environmental factor that triggers the inflammatory response (gluten) has been clearly identified^[4]. Nevertheless, it is suggested that other environmental factors may affect the disease onset. It has been speculated that certain viruses or pathogens may somehow alter the tolerance in the intestinal mucosa, or induce an inflammatory state in the intestinal mucosa, prone to react against gluten-derived

peptides^[5]. This additional environmental input might be of higher importance in those patients with low genetic susceptibility (e.g., patients without HLA-DQ2). The interaction between the pathogen and gut immune cells might be an essential mechanism in this pathway. In this regard, an important mediator of pathogen recognition by dendritic cells is CD209 or DC-SIGN (dendritic cell specific intercellular adhesion molecule 3 grabbing non-integrin), encoded by the *CD209* gene. CD209 is a type II transmembrane protein present in dendritic cells and macrophages and a member of the C-type lectin receptor family. Natural ligands of CD209 include self-molecules, ICAM-2 and ICAM-3, but it also binds to pathogens and pathogen-derived molecules. This interaction may be used by some pathogens as an immunoinvasive strategy through binding and internalization, although always as one among other alternative ways^[6]. Furthermore, the *CD209* gene is located within the 19p13.1 chromosomal region, showing a strong linkage with CD susceptibility in a genome-wide study^[7].

In the *CD209* promoter region, a putative functional variant (-336A/G; rs4804803) affecting a Sp1-like binding site has been described^[8]. This single nucleotide polymorphism (SNP) can affect the transcriptional *CD209* activity *in vitro* and is associated with a higher susceptibility to HIV-1 infection and a higher dengue fever severity.

On this basis, we aimed to investigate the possible involvement of *CD209* -336 genetic variant in CD susceptibility.

MATERIALS AND METHODS

Subjects

A total of 103 celiac disease patients and 312 ethnically matched healthy controls recruited from the Hospital Virgen de las Nieves (Granada, Spain) were initially studied to assess the influence of the -336A/G *CD209* polymorphism in celiac disease. Subsequently, a second larger cohort recruited from the Hospital Clínico San Carlos and Hospital La Paz (Madrid, Spain) and consisting of 386 celiac patients and 419 healthy controls was analyzed to obtain more conclusive results. The age at study of all patients was 7.1 ± 3.9 years, and the mean age for diagnosis was 2.7 ± 2.72 years. A total of 60% were women. We extended our study to a panel of 257 pairs of progenitors of the CD patients studied, specifically 103 families from Granada and 154 from Madrid were obtained, all of them composed of an affected child and their parents.

The participants from both the familial and case-control analyses were of Spanish white origin. All the samples were collected after informed consent was obtained. Celiac disease patients were diagnosed following the European Society for Paediatric Gastroenterology and Nutrition (ESPGAN) criteria^[9]. This study was approved by the ethics committee of the respective hospitals.

Genotyping

Taqman 5' allelic discrimination assay was performed to genotype the *CD209* -336 genetic variant. Primers

Table 1 Genotypic and allelic *CD209* frequencies in celiac patients ($n = 103$) and controls ($n = 312$) from the Granada area

Genotype	Celiac patients n (%)	Controls n (%)	P
AA	61 (59)	191 (61)	0.7
AG	36 (35)	109 (35)	
GG	6 (6)	12 (4)	
Allele			0.6
A	158 (77)	491 (78)	
G	48 (23)	133 (21)	

and probes were provided by Custom-Taqman-SNP-Genotyping-Assay Service (Applied Biosystems, Foster City, CA, USA). The primer sequences are 5' - GGACAGTGCCTTCCAGGAAGT -3' (sense) and 5' - TGTGTTACACCCCCTCCACTAG -3' (antisense). The sequences of Taqman MGB probes are 5'-TACCTGCCTACCCTTG-3' and 5'-CTGCCACCCCTTG-3'. The probes were labeled with the fluorescent dyes VIC and FAM, respectively. Polymerase chain reaction (PCR) was carried out in a total volume of 12.5 l using the following amplification protocol: denaturation at 95°C for 10 min, followed by 40 cycles of denaturation at 92°C for 15 s, and annealing and extension at 60°C for 1 min. Then genotype of each sample was attributed by measuring the allele-specific fluorescence in the ABI Prism 7000 or 7900 Sequence Detection System, using SDS 1.1 software for allele discrimination (Applied Biosystems).

HLA-DQ typing was performed in the respective laboratories as previously described^[10,11].

Statistical analysis

Allelic and genotypic frequencies were compared by means of χ^2 tests or Fisher's exact test when necessary (expected values below 5). Statistical analyses were performed with the statistical package EpiInfo v5.00 (CDC, Atlanta, USA). Transmission disequilibrium test (TDT), which assesses the preferential transmission of one allele over the other from heterozygous parents to affected sibs, was used to analyze the familial data.

RESULTS

Allelic and genotypic frequencies for *CD209* in celiac disease patients and controls are shown in Table 1 for the first cohort studied (Hospital Virgen de las Nieves, Granada). No significant differences were observed in any case. A similar result was obtained when family data were analyzed (27 G alleles transmitted *vs* 33 not transmitted, $P = 0.26$). However, due to the overwhelming and potentially masking influence of HLA-DQ2 (DQA1*0501 and DQB1*02) on celiac disease, we divided the patients into two groups according to the presence (+) or absence (-) of those alleles. No allele of *CD209* was significantly increased in any group of patients ($P = 0.11$) (Table 2). However, the different genotype distribution was significant in both groups of patients. The small sample

Table 2 Genotypic frequencies in HLA-DQ2 (+) and HLA-DQ2 (-) patients from the Granada area

Genotype	DQ2 (-) patients (n = 7)	DQ2 (+) patients (n = 96)
AA	2	59
AG	5	31
GG	0	6

Table 3 Genotypic CD209 frequencies in DQ2 (-) (n = 29) and DQ2 (+) (n = 357) celiac patients and controls (n = 419) from the Madrid area

Genotype	DQ2 (-) patients n (%)	DQ2 (+) patients n (%)	Controls n (%)
AA	18 (62)	207 (58)	255 (61)
AG	6 (21)	131 (37)	142 (34)
GG	5 (17)	19 (5)	22 (5)

3*2 contingency table DQ2- vs DQ2+: $P = 0.017$; 3*2 contingency table DQ2- vs controls: $P = 0.019$; carriers A vs GG DQ2 (-) vs DQ2 (+): $P = 0.026$ OR = 3.71 (1.10-11.78); carriers A vs GG DQ2 (-) vs controls: $P = 0.023$ OR = 3.76 (1.14-11.73).

size of the DQ2 (-) group ($n = 7$) could be responsible for the lack of statistical significance, therefore we decided to repeat the study using a higher number of patients.

A second cohort was then studied (Madrid) (Table 3) and we did obtain significant results. Genotypic frequencies were significantly different when DQ2 (+) celiac disease patients were compared with DQ2 (-) patients ($P = 0.017$) or with controls ($P = 0.019$) and an even higher significance was observed when DQ2 (+) celiac disease patients and controls (grouped because there are no significant differences between them) were considered together ($P = 0.013$). The differences seemed to be mostly due to the increased susceptibility to celiac disease occurrence in DQ2 (-) individuals carrying two copies of the allele *CD209* -336G (AA + AG individuals vs GG individuals, $P = 0.021$, OR = 3.73 (1.18-11.03), DQ2 (-) vs DQ2 (+) individuals and controls considered together). A family study with samples from Madrid was also performed to determine the influence of *CD209* on celiac disease after DQ2 stratification. However, the scarce number of families with DQ2 (-) children did not allow us to obtain any conclusion (there were only 4 families and one of the parents was heterozygous for the studied polymorphism and the allele A was transmitted just in one case).

DISCUSSION

The contribution of HLA class II genes to CD susceptibility is for the moment in the most reproducible and well established fact regarding CD genetics^[12]. Thus, 92%-93% of celiac disease patients carry DQA1*0501-DQB1*02 (DQ2), in sharp contrast with only 28% of the Spanish healthy controls. However, less is known regarding

the genetic factors contributing to CD predisposition in patients lacking the DQ2 allele. In this study we analyzed for the first time the contribution of -336 A/G *CD209* genetic variant to CD susceptibility, investigating the contribution of this polymorphism in both DQ2+ and DQ2- CD patients. Interestingly, we have shown that the *CD209*-336 polymorphism seems to be a genetic risk factor for CD in DQ2- patients in our population. We observed that in DQ2- patients the *CD209*-336 GG genotype was significantly overrepresented, suggesting that additional predisposition factors are more relevant in patients lacking the major susceptibility determinant, namely the antigen presenting HLA class II molecule DQA1*0501-DQB1*02. According to the results obtained in this study, *CD209*, more precisely, the promoter allele-336G, is one of those additional secondary genetic factors.

The *CD209* -336G allele is also associated with increased predisposition to parenteral HIV infection^[13]. The G allele favors the binding to the ubiquitous transcription factor Sp1, but paradoxically the transcription rate from the G allele seems to be lower than that from the A allele^[8]. Perhaps the lower amount of DC-SIGN protein on the cell surface might reduce the surveillance activity of sentinel cells, and therefore may promote the persistence of pathogens in the gut. The continued presence of pathogens may underlie in turn the inflammatory down-regulation in celiac disease patients. In fact, it has been suggested that some bacterial infections might play a relevant role in CD development^[1,5] and the hypothesis proposed could support the maintenance or facilitation of bacterial infection in CD onset.

In summary, the *CD209*-336 polymorphism for CD susceptibility exists in DQ2- patients in our population. It is necessary to analyze the possible contribution of other C-type lectin receptors (mannose receptor, endo-180, SIGNR1, dectin-1, dectin-2) that are able to bind to exogenous ligands as interesting candidate genes in CD predisposition, especially in DQ2 negative patients.

Abstract

AIM: To construct the expression vectors for prokaryotic and eukaryotic human augmentor of liver regeneration (hALR) and to study their biological activity.

METHODS: hALRcDNA clone was obtained from plasmid pGEM-T-hALR, and cDNA was subcloned into the prokaryotic expression vector pGEX-4T-2. The recombinant vector and pGEX-4T-2hALR were identified by enzyme digestion and DNA sequencing and transformed into *E. coli* JM109. The positively selected clone was induced by the expression of GST-hALR fusion protein with IPTG, then the fusion protein was purified by glutathione S-transferase (GST) sepharose 4B affinity chromatography, cleaved by thrombin and the hALR monomer was obtained and detected by measuring H thymidine incorporation.

RESULTS: The product of PCR from plasmid pGEM-T-hALR was examined by 1.5% sepharose electrophoresis. The specific strap was coincident with the theoretical one. The sequence was accurate and pGEX-4T-hALP digested by enzymes was coincident with the theoretical one. The sequence was accurate and the fragment was inserted in the positive direction. The recombinant vector was transformed into *E. coli* JM109. SDS-PAGE proved that the induced expressive fusion protein showed a single band with a molecular weight of 41 kDa. The product was purified and cleaved. The molecular weights of GST and hALR were 26 kDa, 15 kDa respectively. The recombinant fusion protein accounted for 31% of the total soluble protein of bacterial lysate. hALR added to the culture medium of adult rat hepatocytes in primary culture and HepG2 cell line could significantly enhance the rate of DNA synthesis compared to the relevant

control groups ($P < 0.01$).

CONCLUSION: Purified hALR has the ability to stimulate DNA synthesis of adult rat hepatocytes in primary culture and HepG2 cells *in vitro*, and can provide evidence for its clinical application.

INTRODUCTION

Transplantation of hepatocytes can be used to treat acute and chronic hepatic failure, and related hepatic diseases^[1,2]. Due to the difficulty to get satisfactory proliferation of transplanted cells, the hepatic function and superseding effect of the damaged hepatic parenchyma are not good^[3,4]. A large number of living hepatocytes are needed in the substituting period for metabolic disorder^[5]. But the source of donor hepatocytes is limited. All of above-mentioned factors influence hepatic transplantation.

Human augmentor of liver regeneration (hALR) is a stimulator of hepatic proliferation found in recent years. Compared to other growth factors, it can be used to restrain the growth of some tumor cells^[6,7]. Meanwhile, it can resist hepatic damage and reverse hepatic fibrosis^[8,9]. Application of this factor will improve the proliferating ability of culture *in vitro* and hepatocyte transplantation *in vivo*^[10].

MATERIALS AND METHODS

Materials

Plasmid pGEX-7-hALR containing 380 bp human regeneration promoter cDNA, prokaryote expression vector pGEX-4T-2 and host bacteria JM109 were conserved in our laboratory. Ligase T4 DNA, restrictive endonucleases *Bam*H1 and *Eco*R1, calf intestinal alkaline

phosphatase (CIP) and thrombin were obtained from American MBI Company. TaqDNA polymerase dNTP was purchased from Promega Company. Standard proteins with a low molecular weight and calibration kit for SDS electrophoresis were purchased from Pharmacia Company. MBI QIA-GEN gel callback sample box and emitting isotope H-TDR were bought from Shanghai Shenggong. Wistar male rats were provided by the Animal Center of our school.

Methods

In this research, recombinant hALRcDNA was cloned into plasmid pGEX-4T-2 with genes of fusion protein, and then recombinant vector was transformed into *E. coli* JM109. After digestion and sequencing, fusion protein expression was detected by SDS-PAGE electrophoresis. Affinity chromatography was used to purify GST-hALR after digestion by thrombin. After hALR was cloned into an expression plasmid of eukaryon with expressive green fluorescence protein (EGFP) as reporter gene, LO₂ hepatocytes were transfected by liposome transfection method. Transfection efficiency and instantaneous expression were observed after recombination. The biological activity of hALR was studied by detecting DNA synthetic rate as previously described^[11].

Oligonucleotide primer: According to the sequence of ALR, the specific primer of hALRcDNA was designed and the sequence identified by enzymes *Bam*HI and *Eco*RI was used to observe and reverse the primer. The upper primer p1 was 5'-CGGGATATGGGGACGCAGCAGAAGAAGCGGGAC-3', the lower primer p2 was 5'-GCCAATTCCTAGTCACAGGAGCCGACCTTCC-3'. After 35 cycles of amplification at 95°C for 1 min, at 64°C for 1 min, at 72°C for 1 min, 1.5% agarose gel electrophoresis was used to identify the purified genes.

DNA recombination and identification: Gene expression sequence of hALRcDNA was cloned into pGEX-4T-2 vector, and identified with enzymes *Bam*HI and *Eco*RI. The results were proved by Shanghai Physiologic Center.

Expression and purification of recombinant gene induced by eukaryon: Recombinant positive clone containing pGEX-4T-2-hALR was put into LB culture medium at 37°C, and IPTG (final concentration was 1 mmol/L) was added to induce expression for 4 h, then the bacilli were collected and broken by ultrasound pulverizer (4°C, 12 000 r/min, 20 min). The supernatant was collected and put into 2 × loading buffer. The expression of recombinant fusion protein was identified by SDS-PAGE electrophoresis.

Recombinant plasmid transfection of LO₂ hepatocytes: LO₂ hepatocytes were transferred into a cell culture flask in DMEM containing penicillin 100 U/mm, streptomycin 100 U/mm, 10% calf serum, tri-distilled water and incubated in 5% CO₂ at 37°C.

One day before liposome transfection, LO₂ hepatocytes 4×10^4 were loaded onto coverslips, put into 6-well plates and cultured with 1.5 mL DMEM containing 10% calf serum 5% CO₂ at 37°C until cells grew to 80% coverage. The cells were washed 2 times with normal saline. DNA-liposome complex was put into two six-well plates, 0.5 mL

of DMEM-SF without antibiotics was added into each well and the plates were slightly shaken to make the DNA-liposome mixture flow evenly over the cell surface. Cells were cultured in 5% CO₂ at 37°C for 5 h without change of supernatant, 0.5 mL of 30% of calf serum was added into DMEM and cultured for 24 h, then the medium was washed two times with normal saline, 1.5 mL of 10% of serum was added into DMEM.

Instantaneous expression of recombinant plasmid in LO₂ hepatocytes: LO₂ hepatocytes were cultured in different groups. The first group was vaccinated on coverslips after digestion by pancreatin, put into six-well plates and incubated. The cells were observed under fluorescent microscope after 12, 24, 48 h of transfection. The second group of hepatocytes was transfected with LO₂ hepatocytes of recombinant plasmid in DMEM-SE medium. The third group was transfected with blank material into blank plasmid, the upper clear liquid was drawn after one week of culture, then 30% of volume was added into routinely cultured HepG₂ cancerous cell medium and vaccinated into 12-well plates 5×10^5 /mL, the HepG₂ cells were incubated in routine culture medium in control group. Luciferase was added into each well after cultured for 24 h. The cells were collected, washed repeatedly with PBS, the infiltrative membrane was dried by airing, and put into a scintillation bottle with scintillation liquid. DNA synthesis rate (CPM value) was detected by a scintillometer. The third group was cultured routinely for 72 h, G418 200 µg/mL of calf serum was added to screen cells. The liquid was changed every 3 d.

Detection of biological activity of expression hALR: The primary hepatocytes were isolated by hepatic perfusion. In brief, 2.5 mL of mixed hepatocyte suspension and 15 mL of Percoll were centrifuged at 88 r/min, for 13 min, then the cells were collected and counted using a optical microscope. The separated hepatocytes and HepG₂ tumor cells were incubated respectively in cell culture plates, and then the supernatant was discarded. The third trial group was established by adding DMEM liquid separately containing hALR 5 ng/mL, 10 ng/mL, and 20 ng/mL.

Statistical Analysis: The data were dealt with by double factor variance analysis with SPSS 10.0 software package.

RESULTS

Construction and identification of pGEX-4T-2hALR: The reaction result of PCR augmentation of hALRcDNA (Figure 1) was coincident with hALRcDNA. There were the endonuclease sites of *Bam*HI, *Eco*RI on 5' - 3' ends.

Construction of pGEX-4T-2hALR after hALRcDNA acquired by PCR augmentation was performed using restriction endonucleases *Bam*HI and *Eco*RI. Gene segment was recycled by 1.5% sepharose electrophoresis. pGEX-4T-2 was cleaved by *Bam*HI and *Eco*RI, then the gene segment was recycled. Transformed susceptible bacteria JM109 were screened using ampicillin to yield 12 monoclonal colonies. The recycled vector segment was not recombined and cultured directly in the contrast LB culture medium after phosphorylation, but no clone appeared. Five monoclonal colonies were selected

randomly. The plasmid was digested by *Bam*HI and *Eco*RI to yield a band 5.3 kb (Figure 2). This indicated exogenous DNA was inserted. After digestion by *Bam*HI and *Eco*RI and recombinant plasmid, two bands of 4.9 kb and 380 bp were produced. In contrast to non-vector double cutting enzyme, 380 bp external DNA was inserted in pGEX-4T-2 between the cutting site of *Bam*HI and *Eco*RI. The recombinant plasmid-inserted 380 bp hALR was acquired. The structure of plasmid was completely satisfactory. Five positive clones were acquired. Therefore, a complete hRcDNA segment was inserted into pGEX-4T-2 plasmid between *Bam*HI and *Eco*RI.

Expression of hALR in *E. coli*: Expression of fusion protein GST-hALR was induced after the bacteria containing recombinant expression plasmid pGEX-4T-2hALR were induced by IPTG. The split product was detected by SDS-PAGE electrophoresis (Figure 3), a new band of 41 kDa was found in the recombinant bacteria, while the nonfusion protein GST band expressed by pGEX-4T-2hALR nonvector transformed bacteria was 26 kDa, indicating that molecular weight of the fusion protein was 41 kDa, the part of GST was 26 kDa, and the molecular weight of hALR was 15 kDa.

After the recombinant bacteria were split by ultrasound, its inclusion body and supernatant were detected by SDS-PAGE electrophoresis (Figure 4). The significant band of fusion protein (GST-hALR) was seen at the site of protein 41 kDa in upper clean liquid, but the weak band was seen at the same site in inclusion body, indicating that the fusion protein was expressed mainly in the soluble form in the upper liquid.

To identify the best expression condition, the expression period was analyzed. The result showed that the expression product of fusion protein in the LB liquid culture medium was ascended in 0-8 h after the

Figure 4 Comparison of inclusion body and supernatant. Lane1: marker; Lane2: inclusion body; Lane3: supernatant.

Figure 5 Digestion pEGFP-C1 and hALR. Lane1: 100 bp Ladder Marker; Lane2: pEGFP-c1 E/B; Lane3: pEGFP-c1; Lane4: hALR E/B.

transformed bacteria were induced with IPTG under 30°C. By the gel scanning system, the expression amount of GST-hALR at 8 h covered 31% soluble protein of bacteria.

Fusion protein in the supernatant was analyzed by SDS-PAGE, then deoxidized glutathione S-transferase (GST) was used to purify GST-hALR. The vector of pGEX-4T-2 had the cutting site of the thrombin between GST and multicloning, the function of thrombin could separate GST and hALR in the fusion protein. After fusion protein was split by thrombin, split GST and undigested fusion protein were filtered by glutathione sepharose 4B affinity chromatography. The purified hALR was acquired, and there were also single clean strips in the map of SDS-PAGE. Molecular weight was about 15 kDa. The concentration of the purified hALR was about 90.5% and the hALR protein concentration was about 0.87 mg/mL.

Construction and identification of recombinant plasmid pEGFP-C1-hALR: In the map of pEGFP-C1 multiple clones, *Eco*RI and *Bam*I II were in the region of MCS. *Eco*RI was in the front, *Bam*I II was in the rear, indicating that hALR could be inserted positively. pEGFP-C1 plasmid and ALRcDNA segment were cut respectively by *Eco*RI and *Bam*I II. The site of cut hALR PCR segment was at 400 bp, two light bands were seen in the uncut pEGFP-C1 plasmid due to the difficult spatial conformation of cycled plasmid. pEGFP-C1 was cut to linear molecule by enzymes, a light band was seen by electrophoresis, the velocity rate was slightly faster than that of uncut pEGFP-C1 plasmid by enzymes (Figure 5).

When the kanamycin plate was incubated overnight at 37°C, 15 clones sprouted which were cultured overnight with kanamycin LB culture medium at 37°C.

The site of PCR augmentation band of recombinant plasmid was similar to that of PCR augmentation band of bank DNA. There were two characteristic bands after recombinant plasmid was cut by enzymes. One band was at 400 bp, the other band was at 4.7 kb, suggesting that hALRcDNA was cloned into pEGFP-C1. Recombinant plasmid pEGFP-C1-hALR was constructed successfully.

The result of PCR was coincident with the theoretical one, the sequence of recombinant plasmid pEGFP-C1-hALR was right.

OD value of pEGFP-C1-hALR detected by ultraviolet spectrophotometer is shown in Table 1.

pEGFP-C1-hALR and its sequence might be used to transfect cells and to observe the expression condition of

Figure 6 Expression of green fluorescence protein of recombinant pEGFP- c1-ALR in LO₂ hepatocyte.

green fluorescence protein.

Expression of recombinant plasmid pEGFP-C1-hALR in LO₂ hepatocytes: LO₂ hepatocytes with recombinant plasmid pEGFP-C1-hALR for 12 h. One coverslip was taken from the 6-well plates transfected and observed under microscope. Cells were attached to the wall, cleavage phase of some cells were seen. The medium was washed 2 times with normal saline, digested by pancreatin. The cells were counted. Another coverslip was taken from the plates to observe the expression of green fluorescence under fluorescence microscope (Figure 6).

The green fluorescence was expressed in some cells after transfection of liposome for 12 h. Most of the expression was weak.

Detection of biological activity of hALR: The hepatocytes were separated by hepatic perfusion with IV collagenase. After separation and purification, the number of cells was about 2×10^8 /mL, the survival rate of cells was about 94%. CPM value detected by ³H-thymidine incorporation method was used to observe the influence of DNA synthesis rate of hALR on primary cultures of hepatocytes and HepG₂ cells cultured *in vitro* (Tables 2 and 3).

Seen from the above table, recombinant hALR might stimulate DNA synthesis of primary hepatocytes and HepG₂ cells compared to control group. There was a significantly statistical difference ($P < 0.01$). The different dose of hALR had different effects on primary hepatocytes and HepG₂ cells. Comparison of mean value between each group, there was a significant statistical difference ($P < 0.01$), indicating that DNA synthesis rate increased gradually with increasing dose of hALR.

DISCUSSION

Due to limited donor source and complication of the operation itself, liver transplantation *in situ* in treatment of terminal end hepatic disease has been widely used. The technique of hepatocyte transplantation developed at the end of the 1970's has gained more and more attention because one donor can provide hepatocytes for several recipients and the transplant technique is very simple^[8,12].

We studied the biological activity of the expression product by constructing expression vector of pronuclei and eukaryons of human augmenter of liver regeneration in order to provide experimental evidence for the study of hepatocellular source of hALR hepatocyte transplantation modified by gene and the clinical application of hALR. But there are three major problems in the transplantation of hepatocytes, namely the transplanting location, immune reaction, and proliferation of hepatocytes^[8]. When trans-planted in the parenchyma of spleen or in the abdo-minal cavity, hepatocyte transplantation always has better effects^[13]. When biological materials such as biological compatibility membrane are used, hollow fibers may form a barrier for the transplanted hepatocytes, which has solved the problem of host immune repulsive action, and increased interest in xenogenic hepatocyte transplantation^[11,14]. Transplanted hepatocytes perform the temporary maintenance of hepatic function and the temporary substitution for the damaged hepatocytes by proliferation *in vivo*. Since the desired results of culture *in vitro* and proliferation *in vivo* are difficult to get, the final result is not so good^[3,4]. Furthermore, to treat congenial metabolic defects with hepatocyte transplantation, a large quantity of hepatocytes that can express exogenic genes are needed^[15]. The traditional methods to improve the transforming rate such as 70% resection of liver, damaging the liver with CCL₄, can bring damage to the liver of the recipient. Therefore how to acquire a stronger

proliferation ability, how to culture plenty of cells *in vitro*, while ensure their biological activity and long lifespan are crucial problems.

With the advance in modern gene engineering techniques, especially combination of gene engineering techniques with modern surgical transplantation technique, a new curative technique is produced, namely genetically-modified cell transplantation, proliferation of the transplanted hepatocytes is possible to be solved through the modification of hepatocytes. HALR is a stimulator of hepatocyte proliferation that can bear temperature, with specificity for liver but without species specificity. HALR can accelerate synthesis of DNA of primary generative hepatocytes cultured *in vitro* and hepatogenous hepatic tumor cells and the proliferation of the cells, while it has no influence on the nonhepatic cells, showing that it has a specific role in accelerating proliferation of the hepatocytes. HALR is an important regeneration-regulating factor because it can accelerate the hepatocyte proliferation. HALR may accelerate proliferation of hepatic cells in 1/3 of models with partial resection of liver, indicating it is an important regeneration-regulating factor^[11,16-18]. In addition, it can protect the liver against damage, reverse hepatic fibrosis^[19,20] and take part in cell immune action. All these suggest that proliferation of the transplanted hepatocytes can be suppressed by the use of enhanced and modified regenerative cells. Regeneration-enhanced factor as a kind of special stimulating factor of growth of hepatic cells, has gained more and more attention of domestic and foreign scholars. It has a prospect to be used as an effective medicine to treat severe hepatic diseases.

Abstract

AIM: To evaluate the prevalence of isolated anti-HBc in patients with chronic hepatitis C virus (HCV) infection, and its relation to disease severity.

METHODS: We screened all patients with chronic HCV infection referred to King Faisal Specialist Hospital and Research Center for hepatitis B surface antigen (HBsAg), antibody to hepatitis B surface antigen (anti-HBs), and anti-HBc. One hundred and sixty nine patients who tested negative for both HBsAg and anti-HBs were included in this study.

RESULTS: Pathologically, 59 had biopsy-proven cirrhosis and 110 had chronic active hepatitis (CAH). Of these 169 patients, 85 (50.3%) tested positive for anti-HBc. Patients with CAH had significantly higher prevalence of isolated anti-HBc than patients with cirrhosis, 71 (64.5%) and 14 (23.7%) respectively ($P < 0.001$). Twenty-five patients were tested for HBV DNA by qualitative PCR. The test was positive in 3 of them (12%; occult HBV infection).

CONCLUSION: Isolated anti-HBc alone is common in Saudi patients with chronic HCV infection, and is significantly more common in those with CAH than those with cirrhosis. Therefore, a screening strategy that only tests for HBsAg and anti-HBs in these patients will miss a large number of individuals with isolated anti-HBc, who may be potentially infectious.

Helmy A, Al-Sebayel MI. Isolated antibody to hepatitis B core antigen in patients with chronic hepatitis C virus infection. *World J Gastroenterol* 2006; 12(27): 4406-4410

<http://www.wjgnet.com/1007-9327/12/4406.asp>

INTRODUCTION

Hepatitis B virus (HBV) and hepatitis C virus (HCV) infections account for a substantial proportion of acute and chronic liver diseases world-wide^[1-4], including Saudi Arabia^[5-7]. Both viruses share similar risk factors and modes of transmission and as a consequence, combined HBV and HCV infection is frequent especially in areas endemic for HBV, and among people at high risk of parenteral infection^[1-5]. Indeed, patients with HCV-related chronic liver disease (CLD) frequently show markers of previous HBV infection. Moreover, they may carry occult HBV infection. These features might influence clinical and biochemical features as well as stage of disease.

Screening patients with chronic HCV for the coexistence of HBV infection is usually based on serum testing for the presence hepatitis B surface antigen (HBsAg). This screening is critical, because HBV infection needs treatment if present, can be prevented by vaccination if absent, and may adversely affect liver pathology and the response to therapy.

Isolated hepatitis B core antibody (anti-HBc) represents either resolved HBV infection with loss of hepatitis B surface antibody (anti-HBs); occult chronic HBV infection with levels of the HBsAg below the limits of detection; or a false-positive test result. Many western publications have reported that 2%-5% of healthy blood donors have isolated anti-HBc^[8-10]. Similarly, isolated anti-HBc was reported in 125 (2%) of 6035 consecutive Saudi blood donors^[11]. In addition, we have previously shown that the prevalence of isolated anti-HBc in HBsAg negative potential liver donors is 32%, and is significantly higher in non-Saudi nationals (41.3%) compared with Saudi citizens (16.7%)^[12]. However, the prevalence of isolated anti-HBc in patients with chronic HCV infection has not been studied. Therefore, the aims of the present study were to

evaluate the prevalence of “isolated anti-HBc” in patients with chronic HCV infection, and to assess its relation to disease severity.

MATERIALS AND METHODS

The subjects included in this study are referrals to King Faisal Specialist Hospital and Research Center (KFSH&RC), Riyadh, Saudi Arabia, between January and December 2004.

Subjects included in this study ($n = 169$) are patients with confirmed chronic HCV infection genotype 4, and negative HBsAg and anti-HBs. HCV antibody testing was performed with an enzyme immunoassay (Abbott HCV EIA 2.0; Abbott Laboratories) and positive polymerase chain reaction (PCR) for HCV RNA for more than 6 mo. Routine liver function tests and diagnostic liver biopsy were done to all patients. Histological diagnosis was evaluated, using the modified Knodell's histological activity index,^[13] by a pathologist who was unaware of the patient's serological data.

Tests for HBsAg, anti-HBs, and anti-HBc were done using (Auszyme; Abbott Laboratories), (Ausab EIA; Abbott Laboratories) and (Hepatitis B Virus Core Antigen Corzyme; Abbott Laboratories) respectively. In addition, sera from a subgroup of patients ($n = 25$) who tested positive ($n = 19$) and negative ($n = 6$) for anti-HBc only were further tested for the presence of HBV DNA using nested-PCR with primers deduced from the core region. In the cases tested positive ($n = 3$), viral load was performed using HBV-Amplicor Monitor (Roche Molecular System). The lower limit of detection for this assay is 2000 copies/mL. As this study concentrates on isolated anti-HBc in patients with chronic HCV infection, subjects with overt HBV infection alone or in combination with HCV were excluded.

This study was approved by the Institutional Research Committee and the Review Board of the KFSH&RC.

Statistical analysis

Results were collected in a Microsoft *Excel* spread sheet, and expressed as mean \pm SD unless otherwise stated. Data were examined by the Pearson's correlation coefficient and two-tailed paired, un-paired Student's *t*-tests, Chi-Square, as appropriate Using SPSS Statistical Package version 10 (SPSS Chicago, IL, USA). Statistical significance was taken at the 5% level.

RESULTS

A summary of the demographic patient characteristics is shown in Table 1. A total of 169 patients with chronic HCV infection were included. Based on liver function testing, positive serum anti-HCV, positive HCV RNA, and liver histopathology, 59 patients had biopsy-proven cirrhosis and 110 had CAH. Of these 169 patients, 85 (50.3%) tested positive for anti-HBc. The potential mode of transmission was identified in 123 patients (72.8%), and includes blood transfusion, surgical and dental interventions before the availability of HCV testing. The remaining cases may fall under intra-familial spread. We

did not test the partners for HCV or HBV infection in this study. Therefore, the sexual transmission can not be excluded.

Comparison between patients with positive anti-HBc and negative anti-HBc

Compared with patients with negative anti-HBc, patients with chronic HCV infection and positive isolated anti-HBc antibody had significantly higher mean age, and significantly lower mean ALT levels ($P < 0.001$ and $P < 0.5$ respectively; Table 2). The mean AST levels were also less in patients with negative HBc antibody, though it did not reach statistical significance. In addition, and despite their higher mean age, patients with isolated anti-HBc antibody pathologically showed a significantly less cirrhotic and significantly more chronic hepatitis picture ($P < 0.001$, Table 2).

HBV DNA Polymerase Chain Reaction

Qualitative PCR testing for HBV DNA was performed in 25 cases (14.8%); 6 were negative for anti-HBc, and 19 were positive for isolated anti-HBc antibody. Positive serum HBV DNA was detected in 3 patients, all had positive isolated anti-HBc (15.8% of the 19 cases with positive anti-HBc, and 12% of the 25 cases tested by PCR), two were cirrhotic and the third was in the chronic inflammatory stage. The viral load in these 3 patients was 4820, 3800, and 4300 copies/mL respectively. Therefore, they represent an “occult HBV Infection”, and are potentially infectious.

Normalization Ratio, bilirubin, albumin, +ve anti-HBc) revealed the presence of raised INR ($P = 0.002$), increased ALP ($P = 0.006$), and -ve serum anti-HBc antibody ($P = 0.0001$) to independently predict liver cirrhosis in the studied cohort (Table 3).

DISCUSSION

The findings of this study suggest that > 50% of patients with chronic HCV infection for whom there is no serological evidence for HBV, when screened with HBsAg and anti-HBs, will be positive for anti-HBc antibody especially those in the chronic inflammatory stage of the disease.

HCV-infected patients should be tested for HBV markers to determine those who should receive HBV vaccination and those who need anti-HBV treatment. For patients with chronic HCV infection, prevention of HBV infection is critical, because this viral infection can be particularly severe and may adversely affect disease outcome.

Isolated Anti-HBc was previously reported to exist in 2% of 6035 Saudi blood donors^[11]. A figure that is similar to what has been reported elsewhere^[8-10]. The high prevalence of isolated anti-HBc antibody in patients with chronic HCV infection detected in this study (50.3%) has previously been reported in a similar study in patients with HCV with or without HIV-1 coinfection^[14]. This reflects the similar mode of transmission, high endemicity of both infections. Indeed, the detection of HBV DNA by PCR in these patients rules out the possibility of false positive results and confirms the diagnosis of occult coinfection.

Occult HBV infection may be manifested by having negative test results for HBsAg, but positive results for

HBV DNA. The frequency of occult HBV infection in patients with anti-HBc is controversial. In one study, occult HBV infection was reported in 33% of subjects with chronic liver disease due to HCV infection and was more frequent in subjects with isolated anti-HBc^[15]. Diagnosing occult HBV infection requires sensitive HBV-DNA PCR assay. The postulated mechanisms underlying occult HBV infection include mutations of HBV-DNA sequence, formation of immune complexes-containing HBV, an integration of HBV-DNA into host's chromosomes, HBV infection of leucocytes, altered host immune responses, and interference by other viruses. The clinical implications of occult HBV infection involve different clinical aspects including first; harboring potential risk of HBV transmission through blood transfusion, hemodialysis, and organ transplantation; second, causing cryptogenic liver disease; third, contributing to the development of acute exacerbation or even hepatocellular carcinoma; and fourth, affecting disease progression and response to treatment of patients with chronic HCV infection^[16].

The precise prevalence of occult HBV infection is variable. In the present study, we found occult HBV infection in 15.8% in patients with chronic HCV infection with positive anti-HBc antibody. Higher figures were detected in other studies. For example, using PCR with primer pairs from three different regions of the HBV genome, Jilg *et al* demonstrated that 32.9% of patients with anti-HBc alone are positive for HBV DNA, the majority of them showing very low HBV concentrations^[17]. Also, Feraro *et al* 2003 found occult HBV infection in 7 out of 22 patients with HCV. However, this was unrelated to anti-HBc status^[18]. Similarly, occult HBV infection was detected in 42% of HIV-infected patients, and was significantly common in subjects with concomitant HCV infection (80%) than those with HIV-1 infection alone^[14]. This supports the suggested policy of donor exclusion based on the anti-HBc and anti-HBs serology as a means to eliminate low grade carriers of HBV in endemic areas without jeopardizing the blood supply. This variation in the prevalence of occult HBV may be related to differences in prevalence of each viral infection in

different communities, differences in the PCR technique, or population selection bias. Highly sensitive, quantitative, and functional molecular analyses of HBV, combined with a well-designed prospective clinical assessment will provide the best approach for the future study of occult HBV infection.

The higher prevalence of anti-HBc antibody in patients with chronic HCV hepatitis than in patients with cirrhosis observed in this study may be explained by a possible inhibitory effect exerted by HBV on HCV replication^[19]. In agreement with this, a study by Kao *et al* showed that occult HBV infection does not have clinical significance in patients with chronic hepatitis C residing in areas where HBV infection is endemic^[15]. Furthermore, occult HBV infection had no effect on early response to PEG-INF alpha^[20]. Further follow up into the maintenance and post-treatment phases will clarify if and when occult HBV affects the sustained viral response. However, Giannini *et al* have reported a different observation^[21]. In their study, the positivity for markers of HBV infection was more frequent in the cirrhotic group as compared to patients with CAH. They also reported higher histological grading and scoring in patients with CAH with anti-HBc^[21]. Reasons of this disagreement are not clear, but a difference in the HCV genotype and duration of infection may be implicated, as most of our patients are genotype 4, while those included in Giannini study were Genotype 1b^[21]. Other factors that may aggravate the histological scoring and grading in the study of Giannini *et al* such as alcohol intake, may have contributed to this difference.

Finally, subjects with isolated anti-HBc who test negative for HBV DNA may have cleared HBV infection and lost undetectable anti-HBs or have a false-positive test result for anti-HBc due to cross-reacting antibodies present in individuals with HCV infection. For patients with isolated anti-HBc who have cleared HBV infection and have undetectable levels of anti-HBs, immunization with HBV vaccine may result in an anamnestic response, which is the presence of detectable anti-HBs within a few weeks after the first vaccination^[22,23].

The possible limitations of the present study include; First, KFSH&RC is a tertiary center, which raises a question regarding the generalizability of the findings. However, studies conducted in Europe show similar results^[10,24,25], which suggest that our conclusions are not specific to a particular geographic region. Second, we tested subjects for total anti-HBc level, rather than IgG and IgM isotypes. Therefore, acute HBV infection, in which only IgM antibody is present, can not be differentiated from the chronic one. Finally, not all subjects who tested negative for HBsAg and anti-HBs and positive anti-HBc underwent testing for HBV DNA. However, the subgroup tested for HBV DNA revealed positive cases (3 in 19, 15.8%), confirming the conclusions of this study. Missing isolated anti-HBc positivity, which represents occult HBV infection in > 10% of cases may have serious implication if these cases were used in organ donation, blood transfusion. They may also be misdiagnosed as cryptogenic liver disease, in patients who test negative for anti-HBsAg and HCV antibody.

In conclusion, isolated anti-HBV sero-pattern is a

common finding in patients with chronic HCV infection, and may represent an occult infection in a smaller percent. A screening strategy that tests only for HBsAg and anti-HBs in HCV-infected patients will miss a large number of individuals with isolated anti-HBc, and a smaller number of patients with occult HBV infection. Addition of anti-HBc antibody screening is recommended, to avoid the adverse implications of missed HBV occult co-infection

Abstract

AIM: To evaluate late effects of chemoradiation on gastrointestinal mucosa with an endoscopic scoring system and compare it to a clinical scoring system.

METHODS: Twenty-four patients going to receive chemoradiation after gastric surgery underwent endoscopy four wk after surgery and one year after the chemoradiation finished. Upper gastrointestinal findings were recorded according to a system proposed by World Organisation for Digestive Endoscopy (OMED) and clinical scoring was done with RTOG-EORTC radiation morbidity scoring systems.

RESULTS: There was no significant endoscopic difference in gastric and intestinal mucosa after chemoradiation ($P > 0.05$) and there was no association between endoscopic scores and clinical scores. Endoscopic changes were minimal.

CONCLUSION: Late effects after chemoradiation in operated patients with gastric cancers can be evaluated with an endoscopic scoring system objectively and this system is superior to clinical scoring systems.

INTRODUCTION

Irradiation of the gastric region has become popular in the setting of adjuvant treatment of resected high risk gastric cancer patients in recent years. It has been shown that adjuvant radiochemotherapy leads to a survival advantage in operated patients with gastric cancers^[1]. Gastrointestinal mucositis after radiation has been well studied especially in the oral cavity and oesophagus but chemotherapy induced gastrointestinal mucositis has been focused mainly on the small intestine^[2].

There is a lack of data about the mucositis of the stomach in the literature. Sartori *et al*^[3] reported gastric erosions after different chemotherapeutics but there is no study evaluating the effects of irradiation and chemotherapy on gastric and small intestinal mucosa and there is no standardised endoscopic scoring system to evaluate these effects. Ideally a mucositis scoring system should be objective, validated and reproducible across all clinical situations and applications. Because of the need of such a measurement instrument a number of different clinical scoring systems have been developed, most of them measuring oral mucositis (NCI-CTC, WHO, RTOG)^[4-6].

Endoscopy is considered to give the best estimation of gastrointestinal mucosal damage and is used extensively in the follow-up of operated gastrointestinal cancer patients. But there is no endoscopic evaluation or scoring system for chemoradiation induced gastrointestinal mucosal damage. Wachter *et al*^[7] proposed a scoring system for radiation induced proctitis based on the endoscopic terminology of the World Organisation for Digestive Endoscopy (OMED)^[8] and found it highly useful to show mucosal damage especially in asymptomatic patients (Table 1). Based on the study by Wachter *et al* we conducted the current research to evaluate the late effects of chemoradiation on gastrointestinal mucosa by using the terminology proposed by OMED.

MATERIALS AND METHODS

Patients

Between Jan 2001 and Jan 2005, a total of 102 patients received adjuvant chemoradiation for locally advanced

gastric adenocarcinoma (T3, T4 or nodal involvement) after operation at the Department of Radiation Oncology at Kartal State Hospital, Istanbul, Turkey. All these patients were invited to take part in the present study. Thirty-four of them accepted and gave informed consent.

Endoscopy was performed by the same experienced endoscopist at the Department of Gastroenterology in the presence of a resident who collected the data. It was done under standard conditions with a videogastroscope (Pentax 2980 type) 4 wk after the operation. Ten of 34 patients had total gastrectomy and esophagoenterostomy and were therefore excluded from the study. The remaining 24 comprised the study group and had a control endoscopy 1 year after the last day of radiation treatment.

In order to make a systematic description in patients who had a subtotal gastrectomy and any type of gastroenterostomy, the remaining stomach, stoma and 10-12 cm of intestine were examined endoscopically. The remaining stomach and the stoma was defined arbitrarily as part I representing the gastric mucosa and the intestinal tissue distal to the stoma as part II representing the intestinal mucosa.

Endoscopic findings were evaluated based on the terminology of OMED in both arbitrarily defined parts of examination separately.

Terminology of OMED as following:

-Telangiectasia:

- Grade 0: none
- Grade 1: single telangiectasia
- Grade 2: multiple non-confluent telangiectasia
- Grade 3: multiple confluent telangiectasia

-Congested mucosa:

- Grade 0: none
- Grade 1: focal reddening of the mucosa combined with an edematous mucosa
- Grade 2: diffuse not confluent reddening of the mucosa combined with an edematous mucosa
- Grade 3: diffuse confluent reddening of the mucosa combined with an edematous mucosa.

-Ulceration:

- Grade 0: none
- Grade 1: microulceration –superficial, < 1 cm²
- Grade 2: superficial > 1 cm²
- Grade 3: deep ulceration
- Grade 4: fistula, perforation

-Stricture:

- Grade 0: none
- Grade 1: > 2/3 of regular diameter
- Grade 2: 1/3 –2/3 of regular diameter
- Grade 3: < 1/3 regular diameter
- Grade 4: complete obstruction

-Necrosis:

- Grade 0: none
- Grade 1: necrosis

The highest grade of any one parameter qualified for the attribution to one of the given score levels regardless of the grade achieved in any other parameter. Pre and post treatment scores of the gastric and intestinal mucosa were compared.

Adjuvant treatment plan was similar to the intergroup study (INT- 0116) by MacDonald *et al*^[1]. Chemotherapy

Table 1 Endoscopy score system based on the system proposed by Wachter *et al*^[7]

	Congested mucosa	Telangiectasia	Ulceration	Stricture	Necrosis
Score 0	Grade 1	None	None	None	None
Score 1	Grade 2	Grade 1	None	None	None
Score 2	Grade 3	Grade 2	None	None	None
Score 3	Any	Grade 3	Grade 1	None	None
Score 4	Any	Any	Grade 2	Grade 1	None
Score 5	Any	Any	Grade > 3	Grade > 2	Any

Table 2 RTOG-EORTC late radiation morbidity scoring system (part for small/large intestine)

	Grade 0	Grade 1	Grade 2	Grade 3	Grade 4
Small/large intestine	None	Mild diarrhea, mild ramping, bowel movement 5 times daily, slight rectal discharge or bleeding	Moderate diarrhea and colic, bowel movement > 5 times daily, excessive rectal mucus or intermittent bleeding	Obstruction or bleeding requiring surgery	Necrosis, perforation, fistula

(CT) either with bolus fluorouracil and leucovorin or with infusional fluorouracil was administered before, together and after radiation. CT (bolus fluorouracil 425 mg/m² and leucovorin 20 mg/m² for 5 d or infusional fluorouracil 1 g/m² for 5 d) was initiated on day 1 and followed by radiochemotherapy (RT) beginning 28 days after the start of the initial cycle of CT. Radiochemotherapy consisted of 46 Gy at 2 Gy per d, 5 d per wk, for five wk either with bolus fluorouracil (400 mg/m²) and leucovorin (20 mg /m³) or infusional fluorouracil (1 g/m³) on the first 4 d and last 3 d of radiation. The radiation field included the tumor bed, and regional lymphatics with the technic described by Smalley *et al*. Tumor bed was defined by preoperative computed tomography or barium roentgenography. Perigastric, celiac, hepatoduodenal or hepatic portal and pancreaticoduodenal lymph nodes were included in the radiation field. Treatment was delivered either with 6 or with 15 MV photons by anterior and posterior parallel opposed fields. Kidneys were spared with personalised blocks. The equivalent of at least two thirds of one kidney was spared from the radiation field. One month after the completion of radiotherapy, two cycles of CT either with bolus fluorouracil (425 mg/m²) and leucovorin (20 mg/m²) or infusional fluorouracil (1 gr/m³) for five days were given one month apart.

For each patient side effects of radiation were documented by use of EORTC/RTOG score at the end of one year and endoscopic findings were compared with small/large intestine items of the morbidity scale (Table 2).

Statistical analysis

Statistical analysis was performed with Pearson Chi-square test. *P* < 0.05 was considered significant.

Table 3 Posttreatment endoscopic scores for gastric mucosa and their correlation with RTOG-EORTC scores

Post treatment endoscopic scoring for gastric mucosa	RTOG-EORTC late radiation morbidity scoring (small/large intestine)				
	0	1	2	3	4
0 (n = 13)	5	3	5	0	0
1 (n = 9)	5	0	4	0	0
2 (n = 0)	0	0	0	0	0
3 (n = 0)	0	0	0	0	0
4 (n = 2)	0	1	1	0	0
5 (n = 0)	0	0	0	0	0

Table 4 Posttreatment endoscopic scores for intestinal mucosa and their correlation with RTOG-EORTC scores

Post treatment endoscopic scoring for intestinal mucosa	RTOG-EORTC late radiation morbidity scoring (small/large intestine)				
	0	1	2	3	4
0 (n = 19)	9	3	7	0	0
1 (n = 4)	1	1	2	0	0
2 (n = 0)	0	0	0	0	0
3 (n = 0)	0	0	0	0	0
4 (n = 1)	0	0	1	0	0
5 (n = 0)	0	0	0	0	0

RESULTS

All of 24 patients (7 females and 17 males) completed the study and there were no dropouts due to deaths, or interruption of CT or RT. Mean age of the patients was 50.79 ± 11.36 years (range 34-73 years).

There was no significant difference in total scores between pre and post treatment endoscopic findings in gastric and intestinal mucosa ($P > 0.05$). In a subgroup analysis there was only in congestion group a significant difference between pre and post treatment endoscopic findings for gastric mucosa ($P = 0.006$) and intestinal mucosa ($P = 0.02$) but not for other subgroups.

Post treatment endoscopic scores for gastric mucosa and their correlation with RTOG-EORTC scores are shown in Table 3. Overall 13 patients (54.2%) had no endoscopic finding at all but 3 (23 %) of them were scored as RTOG-EORTC grade 1 and 5 (38.5%) as grade 2. In addition, 9 patients had an endoscopy score of 1, but 5 were scored as RTOG-EORTC grade 0 and 4 as grade 2. Even in patients with an endoscopy score of 4 the RTOG-EORTC score was 1 or 2. These results showed that there was no correlation between endoscopic and clinical scorings for gastric mucosa.

Post treatment endoscopic scores for intestinal mucosa and their correlation with RTOG-EORTC scores are shown in Table 4. Overall 3 patients (15.8%) with an endoscopic score of 0 were scored as RTOG-EORTC grade 1 and 7 (36.8%) as grade 2 but 9 (47.4%) as 0. One of 4 patients with endoscopic score 1 had a clinical score of 0, another one had a score of 1 and 2 had a score of 2. There was no correlation between endoscopic scoring and RTOG-EORTC scores for intestinal mucosa.

DISCUSSION

The role of adjuvant treatment has been controversial until now in resected gastric cancers^[9-11]. Most of the adjuvant treatments consisted of chemotherapy with a number of phase III trials and three meta-analyses on this subject^[12,13]. Survival advantage with adjuvant chemotherapy is very minor according to these meta-analyses. A randomised trial from the British Stomach Cancer Group^[14] concerning adjuvant radiation alone failed to demonstrate a survival benefit although locoregional failures were decreased from 27% to 10.6%. The recent MacDonald^[1] trial combining adjuvant chemotherapy with radiation showed a major

survival advantage in comparison to only chemotherapy or radiation. In a recent trial by Ajani *et al*^[15] preoperative chemoradiotherapy increased curative resection rate, overall survival duration and disease-free survival duration. After these publications many centers accepted this chemoradiation treatment protocol as their standard therapy after surgical resection of gastric cancer. But the long-term side effects of these therapies on gastrointestinal mucosa have not been well studied. If we take the 5-year survival rate of 36% and the 3-year survival rate of 50% into consideration^[1], the early detection of side effects becomes even more important.

Gastrointestinal mucositis representing the injury to the gastrointestinal tract is becoming recognised increasingly as a toxicity with many chemotherapy regimens and radiation^[2]. It can be identified all over the alimentary tract. But there is little data in the literature concerning gastrointestinal mucositis especially gastric and intestinal mucositis^[16], whereas esophageal mucositis is the best studied one^[17-19]. There is one study by Sartori *et al*^[3] describing gastric erosions after chemotherapy with cyclophosphamide, methotrexate and 5-fluorouracil.

In order to assess gastrointestinal mucositis a scoring system is needed which should be objective, validated and reproducible across all clinical conditions. Because of these a number of different clinical scoring systems have been developed, the majority of them measuring oral mucositis like NCI-CTC, WHO, RTOG^[20]. There is no clinical scoring system specially designed for gastric or intestinal damage. The RTOG-EORTC scale measures the late radiation morbidity^[20]. Most of the clinical systems measure acute toxicity and not the permanent damage to the gastrointestinal mucosa. But Yeoh *et al* have shown that permanent damage occurs in 70%-90% of patients undergoing radiotherapy and because the patients treated for gastric or pelvic cancer constitute the majority of long-term cancer survivors the prevalence of chronic toxicity becomes more important^[21,22]. Moreover some patients may be asymptomatic but still have GI mucositis^[23,24].

Endoscopy is the gold standard of evaluating the gastrointestinal mucosa. Endoscopic scoring systems are very rare in the literature regarding the chemotherapy or radiotherapy induced injury to the alimentary tract. Sartori *et al*^[3] have conducted a randomized and placebo controlled study evaluating the misoprostol and omeprazole in the prevention of chemotherapy-induced acute gastroduodenal mucosal injury and used an arbitrary endoscopic

score system comprising erosions or ulcers in gastric or duodenal mucosa. They repeated the same study design later with omeprazole and ranitidine and found the score system a useful tool for the detection of gastroduodenal injury after CT^[25]. But both of these studies measured only acute effects (namely 7 d) of CT and did not measure the effects of radiation^[3,25].

Wachter *et al*^[7] conducted a study on late rectal mucosal damage after conformal radiotherapy for prostatic carcinoma and used a six-scaled rectoscopy score for the evaluation of radiation induced proctitis. They concluded that for a valid and reliable correlation and comparison of radiation side effects an accurate objective tool like rectoscopy should be used. Chi *et al*^[26] have developed an endoscopic classification system of chronic radiation induced -proctopathy based on telangiectasia density and vascular coalescence. They found a good reproducibility rate among experienced endoscopists as well as gastroenterology fellows.

Based on these existing endoscopic scoring systems we planned to evaluate the late effects of chemoradiation on gastric and intestinal mucosa. Our study was unique because it evaluated the long-term (1 year) effects of both chemotherapy and radiation and it was not done on intact mucosa as the previous studies but after radical surgery.

The endoscopic score systems proposed by Sartori^[3] was not used because there were no items like stricture or necrosis representing long-term effects in their system. The system proposed by Wachter^[7] took all these parameters into consideration and was based on a terminology prepared by the OMED (World Gastroenterology Association). These terminologies are developed as the Minimal Standard Terminology for data processing in gastrointestinal endoscopy and used widely all over the world by gastroenterologists. Therefore we chose the system of Wachter which is proposed for radiation proctitis and evaluated this endoscopic scoring system on gastric and duodenal mucosa after chemoradiation for locally advanced gastric carcinomas with a resection before. The system was easy to use during routine endoscopy and easy for objective documentation. We could not find any significant difference in total scores between pre and post treatment endoscopic findings in gastric and intestinal mucosa. In a subgroup analysis there was only in congestion group a significant difference between pre and post treatment endoscopic findings for gastric and intestinal mucosa but not for other subgroups. Congestion is the first step in the mucosal damage and is mostly reversible. Therefore we can say that there was no significant chronic mucosal damage after chemoradiation and our endoscopic scoring system is a useful objective method to measure chronic damage. Our study also demonstrated that clinical scoring systems like RTOG-EORTC were not suitable to show gastrointestinal mucositis and there was no correlation between endoscopic and clinical scorings for gastric mucosa because the symptoms used in RTOG-EORTC might be caused by other physiological and individual factors. This observation was confirmed also by Wachter and Koc^[7,19]. Based on this disconnection between clinical and objective endoscopic scoring systems we propose to evaluate the chronic toxicity of chemoradiation with endoscopy and to decide discontinuation of therapy only after objective findings.

Endoscopic scoring systems are reliable and reproducible tools for the evaluation of gastric and duodenal mucosa after chemoradiation and might be of benefit because they show the gastrointestinal injury much more before it becomes clinically evident and give the best estimation of gastroduodenal mucositis in comparison to widely used clinical scoring systems where symptoms seem to be exaggerated due to multiple confounding variables.

In conclusion, there is no late gastroduodenal damage due to adjuvant chemoradiation in locally advanced gastric adenocarcinomas after operation.

Abstract

AIM: Celiac disease is characterized by life-long gluten intolerance. Clinical features of patients with celiac disease are variable. Studies about the prevalence of celiac disease in our country are scarce and there is no study on the prevalence of celiac disease in southern Iran. In the current study, clinical, laboratory and histological features of 52 patients with celiac disease were evaluated.

METHODS: In a cross sectional study we retrospectively studied the characteristics of 52 celiac patients at Ahwaz JundiShapour University Hospitals (AJSUH) from November 1, 1999 to 1st Sep 2004. Intestinal biopsy and serum antigliadin and anti-endomysium antibodies were used for the diagnosis of patients. Mucosal lesions were classified according to the criteria of Marsh. Antigliadin antibodies were measured with a commercial enzyme-linked immunosorbent assay. Anti-endomysium antibodies were analyzed by indirect immunofluorescence with the use of a section of monkey esophagus. Routine hematological and biochemical analyses and measurement of immunoglobulin levels were undertaken.

RESULTS: Male: female ratio was 1.08. The mean \pm SD patient age was 21 ± 4.5 years (range 10-70 years) and the most common symptoms were diarrhea and weight loss (78.8%) followed by fatigue (73.1%), pallor (65.4%), anorexia (40.4%), abdominal distention (32.7%), and failure to thrive (23.1%). Diarrhea and weight loss and fatigue were the most common findings. Iron deficiency anemia was found in 63.2% of patients and this became normal after adoption of a gluten-free diet in all patients. Immunoglobulin A, IgG antigliadin antibodies and IgA anti-endomysium antibodies were found in 33 and 48 cases, 78.8% and 85.4% of patients, respectively. Biopsy

of the small intestine revealed that 90.4% of patients had typical lesions according to the Marsh classification.

CONCLUSION: Although classical presentation was seen in most of the patients, atypical clinical manifestations of celiac disease should be kept in mind. In particular, patients with uncommon findings, such as short stature, and iron-deficiency anemia, should be screened for celiac disease. Further epidemiological studies in our area in the general population and in high risk groups seem to be indicated.

INTRODUCTION

Celiac disease (CD) is an autoimmune enteropathy characterized by chronic inflammation of the small intestinal mucosa and the presence of typical auto antibodies. In epidemiological studies the prevalence has been found extremely variable^[1]. The diagnosis can sometimes be difficult due to the wide spectrum of signs and symptoms. Environmental and genetic factors contribute to the clinical presentation of the disease^[2,3]. Prevalence rates of 1:120 to 1:300 have been reported in Western Europe^[4,5]. The clinical picture of the disease includes milder forms and older age at diagnosis^[6]. Screening programs within populations indicate that the disease is underdiagnosed^[7]. Adult celiac patients tend to remain asymptomatic or oligosymptomatic. However, the increased risk of autoimmune diseases and intestinal lymphoma or carcinoma in individuals with CD calls for screening on the slightest suspicion and the disease needs to be treated even when there are no symptoms^[8]. A previous report from Iran indicates an estimated prevalence of up to 1/166 for celiac disease^[9]. To the best of our knowledge few data have been available about the epidemiological features of adult CD in west southern of Iran (Khouzestan).

The aim of this study was to investigate prospectively the clinical picture of diagnosed adult CD in this area.

MATERIALS AND METHODS

Study group

All newly diagnosed cases of CD were registered prospectively from November 1, 1999 to 1st Sep 2004 at Ahwaz JundiShapour University Hospitals (AJSUH). A celiac disease-specific questionnaire was used for data collection and asked for name, birth date and present height and weight, and sought information on intermittent abdominal pain, constipation, diarrhea, known chronic diseases and, associated disorders and family history of celiac disease. Physical examination, blood chemistry, urinalysis, and examination of stool for occult blood, ova and parasites were performed for all patients. If clinically indicated, other para clinical workups such as thyroid function tests, colonoscopy, small bowel study and abdominal ultrasonography were requested. Prior to the diagnostic procedures, informed consent was obtained from all the patients in the study.

CD serology

Total serum IgA level was measured in all subjects to identify IgA deficient cases. IgA antibody titres against gliadin were measured using a commercial enzyme-linked immunosorbent assay (Biosystem, Madrid, Spain). An IgA antibody against gliadin greater than 20 AU/mL was considered positive. Serum IgA antibodies against endomysium were also measured by immunofluorescence (Biosystem).

Diagnostic criteria

Patients who tested positive for IgA antibodies against gliadin or IgA antibodies against endomysium and cases with IgA deficiency underwent upper endoscopy (with Pentax EG2930K endoscopic equipment after an overnight fasting), and six biopsies were taken from the second portion of the duodenum. The biopsy samples were incubated in neutral buffered formalin and processed according to standard procedures. All biopsy specimens were reviewed by two pathologists experienced in celiac disease pathology and graded according to the modified Marsh criteria (10:11).

Patients identified as having CD in biopsy specimens were started on a gluten-free diet. The patients were re-evaluated regularly by repeated IgA antibodies against endomysium serology and repeated upper endoscopy after 6 months. An excellent response was defined as complete elimination of all symptoms. Partial elimination or improvement of some symptoms was considered a good response.

Our study protocol was approved by the ethics committee of the *Ahwaz Jundishapur University of Medical Sciences*.

Statistical analysis

Collected data were coded, analysed and computed, using the Statistical Package for Social Sciences (SPSS) version 10 (SPSS Inc., Chicago, IL, USA). Simple statistics such as frequency, and standard deviation were used. Chi-square and Student's *t*-tests were used for comparison.

Figure 1 Presenting clinical picture of cases with celiac disease in our study.

RESULTS

A total of 52 patients were identified over the period of our study. Males numbered 27 and females 25 giving a male to female ratio of 1.08. The mean \pm SD patient age was 21 ± 4.5 years (range 10-70 years). Twenty-two of these 52 were adults whereas the remainder were children (< 15 years). Short stature and refractory anemia were the mode of presentation in 12 (54%) and 5 (22.7%) children respectively. The most common symptoms were diarrhea and weight loss (78.8%) followed by fatigue (73.1%), pallor (65.4%), anorexia (40.4%), abdominal distention (32.7%), and failure to thrive (23.1%). Diarrhea and weight loss and fatigue were the most common findings. Anemia was found in 63.2% of patients and this became normal after adoption of a gluten-free diet in all patients (Figure 1).

Anemia was suggestive of iron deficiency in all cases with low serum iron levels and elevated total iron binding capacity. Immunoglobulin A, IgG antigliadin antibodies and IgA anti-endomysium antibodies were found in 33 and 48 cases, 78.8 and 85.4% of patients, respectively. Biopsy of the small intestine revealed that 90.4% of patients had typical lesions according to the Marsh classification. Skeletal radiographs were normal in all patients. Bone mineral densitometry showed osteoporosis in each of the 7 adult patients in which this test was performed (defined as Z score less than -2.0). Follow up data was available in 46 cases. The mean follow up period was 38 mo. During the follow up period there was a significant gain in weight and improvement in symptoms and hemoglobin levels in all the cases. Only 10% (5 cases) had their first-degree relatives screened for the disease and all of them were negative.

DISCUSSION

We performed a prospective study on the newly diagnosed cases of CD in the south-West of Iran 1999-2004. There is a little clinical data available about celiac disease in this area where the disease is considered rare. This is due to lack of a registry system of celiac patients and awareness

of this disease and a delay in physicians reaching the diagnosis of celiac disease. The primary aim of this study was to describe the clinical features at presentation in a group of Iranian patients diagnosed with celiac disease in Khuzestan in west southern of Iran.

The demographic characteristics of adult celiac patients in our area were similar to the clinical features described from populations in New Zealand^[12], South Yorkshire^[13] and Sweden^[14] with a peak in diagnosis in the second decade of life^[15]. Our study shows a female to male ratio of 1.08 a female predominance in keeping with published studies^[11-15]. Twenty-two (42%) of biopsy-proven patients in our study had been diagnosed in childhood (< 15 years). More than 78.8% of patients in this survey presented with diarrhea. This frequency was higher than series of patients from Europe^[16] or Canada^[17]. Diarrhea with or without malabsorption syndrome is regarded as the classical presentation of celiac disease^[18]. In countries where the disease is considered to be common, the percent of patients presenting with diarrhea has been declining. In a study from Edinburgh only 50% presented with diarrhea^[19]. Other presentations have been termed atypical, silent, or sub clinical^[18] and include anemia, bone disease vague GI symptoms, or hypertransaminasemia of unknown origin. The higher rate of patients with the typical or classical presentation in our study suggests decreased awareness of celiac disease and its various atypical presentations among physicians in the south-West of Iran. Many of celiac patients in our study have had a previous diagnosis of irritable bowel syndrome. It is not usual practice to screen these patients for celiac disease. However, this diagnostic group represents a large percentage of patients seen in a gastroenterology practice^[20] and may in fact harbor a large number of undiagnosed celiac patients in our country. In a recent study by Shabazkhani *et al* one hundred and five cases of irritable bowel syndrome patients referred to a university clinic in Tehran, were tested for celiac disease. They found 12 (11.4%) cases with celiac specific antibodies (serum IgA antibodies against gliadin, IgG antibodies against gliadin and antibodies against endomysium), of which 11 (10%) proved to have celiac disease confirmed by duodenal biopsy. The authors suggested that all patients suffering from irritable bowel syndrome should be screened for celiac disease in Iran^[21]. We have noted a long duration of symptoms before diagnosis (mean of 3.5 year in our study) this was mostly due to a delay in reaching the diagnosis of CD and a previous diagnosis of irritable bowel syndrome in our cases.

A plausible explanation would be that physicians regard adult celiac disease as rare and fail to consider it in clinical situations other than the classical chronic diarrhea and malabsorption.

A repeated duodenal biopsy to demonstrate improvement of villous atrophy on gluten free diet is advisable for confirmation of diagnosis in CD^[22]. All the cases with CD in our study had a good response to GFD, thus obviating the need for a repeat biopsy to demonstrate improvement of duodenal villous atrophy. An association between celiac disease and autoimmune disorders, such as type I diabetes, autoimmune thyroid disease, and Sjögren's syndrome, has been well documented in the literature^[23].

Table 1 Frequency (%) of associated disorders in study group

Disorders	(n = 52)	%
Inflammatory bowel disease	8	15.3
Thyroid disease	6	11.6
Diabetes mellitus type 1	4	7.7
Collagen vascular disease	3	5.7
Total	21	40.3

We found a higher frequency of associated diseases (40.3%) than in most other studies (10%-15%)^[23], that could be due to the increasing age at diagnosis (Table 1). In our study, the percentage of celiac patients who had a diagnosis of inflammatory bowel disease and thyroid disease were 15.3% and 11.6%, respectively, compared to estimates of 3%-5% and 3% reported in the literature^[24]. Dermatitis herpetiformis and IgA deficiency are relatively common extraintestinal manifestations of celiac disease, but no patients were noted to have such extraintestinal manifestations in our cases. Our survey confirms the increased incidence of small bowel malignancies, adenocarcinoma, and EATCL, in celiac disease^[25]. The malignancies of two cases (male) were lymphoma and occurred in the jejunum. The patients presented with bowel obstruction, and anemia. These two cases had a long history of symptoms of celiac since childhood. Adherence to a gluten-free diet reduces the risk of developing malignancies^[26]. Therefore, earlier diagnosis may have prevented the development of malignancy. We don't know how well the patients with lymphoma had adhered to the diet from the time of celiac diagnosis to the time of lymphoma diagnosis. About 8% of patients in our study were diagnosed with celiac disease at age 40. Men were more prominent in this group. These patients also had a long duration of symptoms. There was a trend toward more hip fractures in patients diagnosed at age 40 compared to those diagnosed at age < 40. Earlier diagnosis may prevent the development of osteoporosis and subsequent fractures^[27]. There was a high frequency of metabolic bone disease and secondary hyperparathyroidism (up to 50%) in a cohort that was reported in untreated celiac disease cases from Turkey^[28]. Prevalence of metabolic bone disease in Iranian patients with CD is not known. Bone mineral densitometry showed osteoporosis in each of the 7 adult patients in which this test was performed (defined as Z score less than -2.0). These data underscore the need for adding calcium and vitamin D supplementation to gluten free diet even though they may be asymptomatic or show no biochemical or radiological evidence of bone disease. In summary, our study provides data about the clinical features of celiac disease in our area in south-West of Iran. The majority of patients who presented with diarrhea had a long duration of symptoms before diagnosis and we considered the diagnosis delayed. Celiac disease may not always present with classical clinical features so the possibility of this disease should be kept in mind. Celiac disease may results in a markedly increased risk for the development of small bowel malignancies and earlier diagnosis is very important. With the widespread

availability of screening tests for celiac disease, identifying cases in at risk groups by screening should also be considered.

Abstract

AIM: To retrospectively evaluate the vaccination-induced anti-HBs seroconversion rates in treatment-naïve and treatment-experienced chronic hepatitis C (CHC) patients. Also to prospectively evaluate the seroconversion rates in CHC patients during pegylated interferon (PEG) plus ribavirin (RIB) treatment.

METHODS: Seventy treatment-naïve CHC patients (group A), 22 sustained virological responders-SVR following interferon (IFN) plus RIB treatment CHC patients (group B) and 121 healthy subjects (group C) had been participated in the same HBV vaccination schedule (20 µg, 0-1-6 mo). Seroconversion was considered if anti-HBs levels were above 10 mIU/mL within 3 mo following the third dose of the vaccine. Moreover, we prospectively selected 30 non-cirrhotic CHC patients and evaluated them for the efficacy of the same vaccine schedule randomizing them in two groups: Group-1, 15 CHC patients received the first dose of the vaccine in parallel with the initiation of PEG plus RIB treatment and Group-2, 15 patients received the same vaccination schedule without concomitant treatment. Determination of anti-HBs was performed at mo 1, 2, and 7. Statistical analysis of data was based on ANOVA student's *t*-test and chi-square analysis ($P < 0.05$).

RESULTS: Fifty-eight of 70 group A patients (82.85%), 20/22 group B (90.9%) and 112/121 healthy subjects (92.56%) had been seroconverted. The seroconversion rates were significantly higher in the control group than in treatment-naïve CHC patients ($P = 0.04$). The

corresponding rates were comparable between group A and group B CHC patients ($P = 0.38$). The vast majority of non-responders (10/14, 71.43%) had been infected by genotype-1 of HCV. The seroconversion rates were comparable between group 1 and 2 CHC patients at mo 1 (20% versus 26.7%, $P = 0.67$), mo 2 (46.7% vs 60%, $P = 0.46$) and mo 7 (86.7% versus 93.3%, $P = 0.54$) of follow-up.

CONCLUSION: The immunogenicity of HBV vaccine seems to be lower in CHC patients compared to healthy subjects. SVR following IFN plus RIB treatment does not affect the antibody response to HBV vaccine. Infection by genotype-1 seems to negatively influence the seroconversion rates. Vaccination against HBV during PEG plus RIB combination treatment is not beneficial in terms of anti-HBs seroconversion rates.

INTRODUCTION

Hepatitis B virus (HBV) and hepatitis C virus (HCV) are two of the most common causes of chronic liver disease and hepatocellular carcinoma in the world. Both viral infections share many of the same routes of transmission, including parenteral exposure, promiscuous sex and vertical transmission^[1,2,3]. HBV infection can be prevented by the administration of a safe and immunogenic vaccine^[4,5,6] whereas no vaccine exists until now for HCV infection due to the high variability of the virus and its subsequent ability to escape immune surveillance.

Dual infection by HBV and HCV is clearly associated with more severe liver disease than infection by a single virus, whereas acute HBV infection in patients with chronic HCV-related liver disease is associated with a severe and often fulminant course of the disease^[7,8,9]. Hepatitis B vaccination is recommended for patients with chronic HCV infection without immunity to HBV^[10] in a cost-effectiveness approach^[11]. Several studies suggest that the immunogenicity of recombinant hepatitis B vaccine is decreased in patients with chronic hepatitis C, compared to healthy controls^[12,13], especially in those with advanced liver disease^[14]. In only one study from Taiwan, was the antibody response to hepatitis B surface antigen (anti-HBs) similar in chronic hepatitis C patients and healthy subjects, who were both susceptible to HBV infection, after the first, second and third dose of the vaccine^[15]. HCV viral load does not seem to correlate with the vaccination-induced anti-HBs response in chronic HCV infected patients vaccinated against HBV^[12,13] whereas the main predictive factors for non-response to HBV vaccine seem to be age (> 50 years), body weight (> 75 kg) and the presence of cirrhosis^[12,14]. The ideal time for HBV vaccination and the optimum HBV vaccination schedule (dose/interval) of chronic HCV infected patients have not been defined yet.

To our knowledge data about the impact of antiviral-immunomodulatory treatment against HCV infection on the safety and efficacy of the recombinant HBV vaccine are limited^[16]. Moreover, there are no data about the impact of pegylated-interferon alpha (PEG-IFN α) plus ribavirin (RIB) treatment in the vaccination-induced anti-HBs response rates in chronic HCV infected patients. In our study we retrospectively evaluated the vaccination-induced anti-HBs response rates in treatment-naïve chronic HCV infected patients and in chronic HCV infected patients who exhibit sustained virological response after interferon-alpha plus ribavirin treatment, in comparison with healthy-HBV susceptible subjects vaccinated against hepatitis B with available data. The second aim of the study was to prospectively evaluate the vaccination-induced anti-HBs response rates in a group of chronic hepatitis C patients during PEG-IFN α plus RIB treatment in order to gain information about the optimum period of HBV vaccination.

MATERIALS AND METHODS

The study was performed at the Hepatology Unit of Hippokration Hospital of Athens, Greece. In this study we retrospectively analyzed 92 patients with serologically, virologically and histologically confirmed chronic hepatitis C (CHC) and 121 healthy subjects, with available data from medical records between October 2000 and October 2004, for the immunogenicity of recombinant hepatitis B vaccine, at a regular dose (20 μ g) and classical vaccination schedule (0, 1, 6 mo). Seventy CHC patients had never experienced treatment for hepatitis C before (group A) and 22 CHC patients of the study population had been treated with interferon-alpha plus ribavirin and they had been characterized as sustained virological responders (group B), according to virological data. Sustained virological

response (SVR) was confirmed by undetectable serum HCV-RNA at the end of treatment and again six months after completion of treatment, as well as just before the beginning of the vaccination schedule. Healthy subjects with available data who had participated in the vaccination schedule were characterized as control group (group C).

All participants of the study population had their height and weight recorded at the beginning of the study and their body mass index (BMI) was calculated by dividing patient's weight (kg) by the squared height (m^2). Patients had also been queried about their drinking behavior, so an individual who had been drinking at least 30 gm of alcohol per day for at least 5 years was considered as an alcoholic and was excluded from the study. Patients excluded from our study were also those with histologically confirmed or clinically decompensated liver cirrhosis, transplanted HCV infected patients or those on waiting list for liver transplantation, patients with chronic renal failure, HIV-positive patients, patients with solid tumors or hematological malignancies, immunosuppressed patients in general or those who had ever received immunosuppressive treatment. Pregnant women and patients under 18 or over 70 years of age, as well as people, who had already been exposed to hepatitis B virus as confirmed by their serological status, were also excluded.

Routine biochemical and hematological tests were performed using automated techniques. Hepatitis B surface antigen (HBsAg), antibody to hepatitis B surface antigen (anti-HBs), and total antibody to hepatitis B core antigen (anti-HBc) as well as antibody to human immunodeficiency virus (anti-HIV) and antibody to hepatitis C virus (anti-HCV) were detected using routine commercially available enzyme immunoassays (Abbott Laboratories, Abbott Park, Illinois, USA). Serum HCV-RNA levels were measured in anti-HCV positive patients by a commercially-available quantitative polymerase chain reaction (PCR) assay (Cobas Amplicor HCV test, version 2, Roche Diagnostics, Branchburg, New Jersey, USA) and HCV genotype was defined in HCV-RNA positive patients using INNOLIPA HCV assay (Innogenetics, Belgium).

Liver biopsy was performed in CHC patients according to Menghini technique. Eligible anti-HCV positive/HCV-RNA positive patients had at least two available biochemical determinations of serum alanine transaminase (ALT) levels being above 60 IU/L (> 1.5 times the upper limit of normal) and had no contraindication to liver biopsy. Patients were excluded from liver biopsy if they had a serious medical condition (heart failure, renal failure, uncontrolled hypertension or diabetes mellitus *etc*), or elevated bleeding risk (platelets < 100 000/ mm^3 , prothrombin time \geq 16 s, treatment with heparin or coumadin, aspirin or non-steroidal anti-inflammatory drugs in the past 8 d). Liver tissue was fixed in 10% formalin and paraffin-embedded sections were stained with hematoxylin-eosin and trichrome stains. A single experienced hepatopathologist, who was blinded to clinical markers other than HCV-antibody status, evaluated all biopsy specimens that were scored according to Ishak scoring system (grade = 0-18, stage = 0-6)^[17]. As previously mentioned, CHC patients with histologically confirmed

cirrhosis were excluded from the study.

All patients and healthy subjects (controls) received 20 µg of recombinant DNA vaccine for hepatitis B (Engerix-B, GSK) intramuscularly (deltoid region) at three different time intervals (0, 1, 6 mo). Determination of anti-HBs antibodies was performed in all individuals of the study population within 3 mo following the third dose of the vaccine. Seroconversion was considered if anti-HBs levels were above 10 mIU/mL and non-reagent response if anti-HBs levels were below 10 mIU/mL.

Moreover, we prospectively selected 30 non-cirrhotic CHC patients and evaluated them for the efficacy of the same vaccine, using the same dose (20 µg) and treatment schedule (0, 1, 6 mo) randomized them (1/1 randomization) in two groups. In group-1, 15 patients received the first dose of the vaccine in parallel with the initiation of pegylated interferon-α2a plus ribavirin treatment, whereas in group-2, 15 patients received the same vaccination schedule without concomitant treatment for chronic hepatitis C. All group-1 patients were treated with fixed dose of pegylated interferon-α2a (180 µg/wk) and genotype-related ribavirin dose (800 mg/d for genotype 2/3 and 1000-1200 mg/d for genotype 1/4-infected patients, depending on baseline body weight < or ≥ 85 kg, respectively). The duration of treatment was genotype-based (24 wk for genotype 2/3 infected patients and 48 wk for genotype 1/4-infected ones). Determination of anti-HBs antibodies was performed in all CHC patients from both groups at baseline as well as one month following every dose of the vaccine (at mo 1, 2, and 7) and seroconversion was also considered if anti-HBs levels were above 10 mIU/mL.

The study conformed to the ethical guidelines of the 1975 Declaration of Helsinki. Written informed consent forms were obtained from the participants in the prospective schedule of the study before the liver biopsy procedure.

Statistical analysis of data was based on ANOVA student's *t*-test and chi-square analysis (χ^2). The results are presented as mean ± SD. A probability value of less than 5% ($P < 0.05$) was considered significant.

RESULTS

Group A, group B and group C participants of the study population were age, sex and BMI matched [age: 27.1 ± 4.0 versus 27.8 ± 4.4 versus 26.7 ± 4.5, respectively, $P = 0.63$, sex (male/female): 44/26 versus 14/8 versus 63/58, respectively, $P = 0.52$, BMI: 22.46 ± 1.6 versus 22.05 ± 0.8 versus 23.01 ± 1.4, respectively, $P = 0.43$]. Twenty seven of the 70 chronic HCV-infected patients from group A (38.57%) and 10 of 22 from group B (45.45%) were prior injecting drug users (IDU) whereas 13 patients from group A (18.57%) and 4 from group B (18.18%) had post-transfusion hepatitis (PTH) C. The rest of chronic hepatitis C patients from both groups had the cryptogenic form of transmission of HCV infection. Twenty five of 70 group-A patients (35.71%) and 9 of 22 group B ones (40.9%) had been infected by genotype-1 of HCV. The remaining 58 chronic HCV-infected patients of the study population had been infected by genotype-3 (50/58,

Table 1 Epidemiological, virological and histological baseline data of group-1 and group-2 CHC patients of the study population

	Group 1 (<i>n</i> = 15)	Group 2 (<i>n</i> = 15)	<i>P</i> -value
Age (yr)	26.9 ± 3.8	27.3 ± 4.1	0.510
Sex (male/female)	8/7	9/6	0.713
BMI (kg/m ²)	22.45 ± 1.8	22.12 ± 0.9	0.390
HCV-RNA (-log10 IU/mL)	5.32 ± 0.67	5.24 ± 0.52	0.765
Grade (0-18)	5.6 ± 2.3	4.2 ± 1.5	0.089
Stage (0-6)	1.3 ± 0.5	1.5 ± 0.7	0.276
Genotype (1/non-1)	3/12	2/13	0.624

86.2%) or 2 (8/58, 13.8%) of HCV.

Fifty-eight of the 70 group A patients (82.85%), 20 of the 22 group B ones (90.9%) and 112 of 121 healthy subjects (92.56%) had been seroconverted (anti-HBs ≥ 10 mIU/mL) within three months following the third dose of the vaccine. The vaccination-induced seroconversion rates were significantly higher in the control group than in treatment-naïve CHC patients ($P = 0.04$) whereas the corresponding rates were comparable between group A and group B CHC patients ($P = 0.38$). Overall, among the 92 CHC patients who had been evaluated, 78 (84.78%) had been seroconverted to anti-HBs, a percentage significantly lower than the corresponding one from the control group ($P < 0.05$). The finding that among the 14 non-responders to vaccination schedule chronic HCV-infected patients from both groups (12 treatment-naïve and 2 SVR's), the vast majority (10/14, 71.43%) had been infected by genotype-1 of HCV seems very important and needs further investigation.

Table 1 shows the epidemiological, virological and histological baseline data of group-1 and group-2 CHC patients of the study population. The two groups were comparable for all baseline parameters (age, sex, BMI, viral load, HCV-genotype, grade and stage of liver disease) before the initiation of the vaccination schedule, with (group-1) or without (group-2) concomitant antiviral-immunomodulatory treatment. The anti-HBs antibody response rates were comparable between these two groups of CHC patients at mo 1 (20% *vs* 26.7%, $P = 0.67$), mo 2 (46.7% *vs* 60%, $P = 0.46$) and mo 7 (86.7% *vs* 93.3%, $P = 0.54$) of follow-up, as shown in Figure 1.

DISCUSSION

The main findings of our study were that chronic HCV infected patients exhibit a lower response to recombinant HBV vaccine compared to healthy subjects, using the recommended dose (20 µg) and the typical vaccination schedule (0, 1, 6 mo), irrespective of the virological response to prior interferon-alpha plus ribavirin treatment. Moreover, we found that concomitant pegylated interferon-alpha plus ribavirin treatment does not influence the antibody response to HBV vaccine in chronic HCV infected treated patients.

Factors known to affect HBV vaccine immunogenicity include age, sex, BMI and smoking^[18]. In our study all

Figure 1 Anti-HBs antibody response rates between group-1 and group-2 CHC patients at one month following every dose of the vaccine (mo 1, 2, and 7).

these parameters except for the smoking behavior, which had not been taken under consideration, were comparable between the patients and the control group of the study population. Occult HBV infection (confirmed as serum HBV-DNA positivity by a sensitive PCR assay in the absence of serological markers of HBV infection) is considered to be associated with the absence of response to recombinant HBV vaccine^[19]. Cacciola *et al* reported that chronic HCV infected patients exhibit a particularly high incidence of occult HBV infection^[20], which means that the absence of serum HBV-DNA testing in our study population possibly represents a limitation of our study. On the other hand, the results of our study reflect the expected immunogenicity of HBV vaccine in chronic HCV-infected patients in the current clinical practice where HBV seronegative, chronic HCV-infected patients, are not routinely tested for serum HBV-DNA.

Hyporesponsiveness to HBV vaccine in chronic HCV infected patients had been previously demonstrated by other studies, especially in cirrhotic patients^[12,13,14]. Several factors can explain the reduced cellular and humoral arms of immune response in these patients, including the lymphocytopenia and the altered composition of the T-lymphocyte subpopulation in the peripheral blood, the inappropriate interaction between antigens, T-cells and T-cell receptor/major histocompatibility complex molecule, and the impaired proliferative response to T-cell activation by various mitogens^[14]. Liver cirrhosis, confirmed either by liver biopsy or signs of decompensation (jaundice, ascites, variceal bleeding, *etc*) was one of the exclusion criteria of our study population, suggesting that chronic HCV infected patients exhibit a lower response to HBV vaccine even in the absence of severe liver disease. A possible impairment in both humoral and cellular-mediated immune responses in non-cirrhotic chronic HCV-infected patients has been suggested to explain this low response to HBV vaccination in such individuals^[13,21].

HCV viral load does not seem to correlate with the vaccination-induced anti-HBs response in chronic HCV infected patients vaccinated against HBV^[13], a finding that was also observed in our study. Sustained virological response following interferon-alpha plus ribavirin combination treatment was not related to statistically

significant increase in anti-HBs seroconversion rates compared to untreated chronic HCV-infected patients in our study. On the other hand, there are some studies that suggest a negative correlation between viral load of HCV and antibody response to HBV vaccination^[12], considering that detection of leukocytes, monocytes/macrophages and B-lymphocytes HCV genomic sequences in chronic HCV-infected patients^[22] could possibly influence the immune response to HBV vaccine. The results of our study suggest that the sustained absence of viremia following interferon plus ribavirin combination treatment is possibly not enough to positively influence the impaired immune response of chronic HCV-infected patients. In concern to HCV genotype, there is only one study that showed a worse response to HBV vaccine in patients who had been infected by genotype-1 of HCV as compared to those infected by genotype 2 or 3^[23], suggesting that in genotype-1 infected patients a different HBV vaccination schedule with possibly higher doses and shorter intervals between the vaccine doses should be used in order to obtain a better response. As previously noted the majority of non-responders to vaccine of the chronic HCV-infected patients of our study population (71.43%) had been infected by genotype-1 of HCV, a finding that needs further investigation.

There is currently no consensus on the optimal HBV vaccination schedule for chronic HCV-infected patients, especially in those who need antiviral-immunomodulatory treatment. Nowadays pegylated interferon-alpha plus ribavirin represent the initial treatment of chronic hepatitis C patients. Interferon-alpha has been previously used as a co-stimulant in non-responders to primary HBV vaccination schedules^[24]. Chlabicz *et al* published a study that did not demonstrate any beneficial or detrimental effect of interferon-alpha on HBV vaccine immunogenicity^[16]. Moreover, this study suggests that vaccination against HBV during treatment with interferon-alpha is safe and well tolerated. It should be noted however that, in this study, the interferon-treated group was small and the patients had received varying numbers of interferon doses as well as different interferon types ($\alpha 2a$, $\alpha 2b$). In our study we evaluate the HBV vaccination induced anti-HBs seroconversion rates in chronic HCV-infected patients during fixed dose pegylated interferon-alpha plus ribavirin combination treatment. We found no differences in the anti-HBs seroconversion rates between the treatment-naïve and the treatment-experienced group of chronic HCV-infected patients; this finding needs further confirmation in prospectively scheduled large-scale controlled studies.

In conclusion, the immunogenicity of the recombinant HBV vaccine seems to be lower in chronic HCV-infected patients as compared to healthy subjects. Sustained virological response following interferon plus ribavirin combination treatment does not affect the antibody response to HBV vaccine in chronic HCV-infected patients, whereas infection by genotype-1 of HCV seems to negatively influence the anti-HBs seroconversion rates. Vaccination against HBV during pegylated interferon-alpha plus ribavirin combination treatment is not beneficial in terms of anti-HBs seroconversion rates, as compared

to treatment-naïve HBV-vaccinated chronic HCV-infected patients.

Abstract

Melanoma accounts for 1-3 per cent of all malignant tumors. Except cutaneous, other less common melanomas include, among others, those in the GI tract. However, their primary or secondary nature is often difficult to establish. Referring to the stomach, scattered cases of primary melanomas have been reported in the literature.

We report a case of a man with an ulcerated submucosal mass at the antrum of the stomach, manifested with dull upper abdominal pain, nausea, vomiting, fatigue and anemia. This lesion was histologically proved to be melanoma. A detailed clinical and laboratory investigation revealed no primary site elsewhere.

To our knowledge, very few cases of primary gastric melanoma have been reported. Our case is the fourth ever published and the first located at the antrum of the stomach. The debate upon the primitive nature of such lesions still persists. Thus, specific diagnostic criteria have been proposed.

INTRODUCTION

Primary gastrointestinal malignant melanoma is a very

rare entity. In contrast, metastatic melanoma to the gastrointestinal tract is found during diagnostic workup in 1%-4% of patients with a cutaneous primary and up to 60% of melanoma patients in autopsy^[1-4]. Several reports have addressed the debate on whether primary gastrointestinal melanoma actually exists by proposing certain diagnostic criteria^[5,6].

Primary melanomas located in the stomach are extremely rare. Although the cell of origin has not been identified since normal stomach epithelium lacks melanocytes, possible etiologies for the occurrence of primary melanoma have been described. Ectopic migration of melanocyte precursors or differentiation of the APUD cells to melanocytes has been advocated as possible mechanism for the development of malignant melanoma^[7,8]. Furthermore, benign melanosis of the stomach has been reported in association with melanoma of the esophagus documenting the presence of melanocytes in the stomach, rarely.

We report on a case of an ulcerated submucosal mass at the antrum of the stomach, which was histologically proved to be a melanoma. A detailed clinical and laboratory investigation revealed no primary site elsewhere.

CASE REPORT

A 58-year old male was referred to our clinic with a short history of nonspecific symptoms, including nausea, vomiting, dull upper abdominal pain and fatigue, aggravating in intensity over the last 24 h. He had a weight loss of 8 kg over the preceding 3 mo. Clinical examination was unremarkable and laboratory examination showed anemia (Ht: 28%). A fecal occult blood test was positive. Colonoscopy was negative. Endoscopic examination of the upper GI tract revealed a submucosal mass with ulceration at the antrum, 3 cm × 5 cm in size. Biopsy, conducted during endoscopy, revealed a malignant melanotic lesion. Gastric mucosa proved to be infiltrated, by numerous pleomorphic tumor cells with melanin deposits (Figure 1).

At exploratory laparotomy a melanotic lesion was found at the antrum with numerous melanotic lesions identified at the greater omentum (Figure 2). Subsequently, a subtotal gastrectomy with splenectomy was carried out.

Pathological report on the surgical specimen proved the melanotic nature of the tumor. The gastric malignant melanoma was extending through the muscularis propria without invading the serosa. The excised lymph nodes were examined and found negative for metastases and complete excision of the ulcerated lesion was reported. Deposits of

Figure 1 Primary malignant melanoma of the stomach. Gastric mucosa also viewed (HE, $\times 40$).

Figure 3 Primary gastric melanoma stained with Masson-Fontana. Plenty of granules of melanin are viewed ($\times 100$).

Figure 2 Surgical specimen of a subtotal gastrectomy and splenectomy for a primary melanoma located at the antrum of the stomach. Certain deposits of malignant melanocytes are viewed in the co-excised greater omentum.

Figure 4 Primary gastric melanoma stained with HMB-45 ($\times 100$).

malignant melanocytes, accumulated after migrating from the antrum to the greater omentum through the extensive vascular and lymphatic vessels, were ascertained in the co-excised omentum. Microscopic evaluation showed nests and sheets of epithelioid cells stained positive with Fontana-Masson (Figure 3). Immunohistochemical examination revealed a positive reaction with S-100 protein and HMB-45 antibodies (Figure 4).

The postoperative clinical investigation, as well as the follow-up did not reveal any other primary site. Ophthalmologic and dermatologic examinations were negative. In addition, anoscopy, chest CT and small-bowel barium contrast radiography were also negative for a primary site of melanoma.

The patient denied any further adjuvant therapy. Sixteen months after the operation he is disease-free, as follow-up endoscopic examination of the upper GI tract and abdominal CT revealed no signs of recurrence.

DISCUSSION

Non-cutaneous melanoma represents a rare form of melanoma. In a review of 84 836 cases of melanoma between 1985 and 1994, 91.2% were cutaneous, 5.2% ocular, 1.3% mucosal and 2.2% of unknown primary^[9]. Referring to GI mucosal sites, melanoma has been reported to arise in esophagus, anorectum and small intestine^[10-12]. Moreover, scattered cases of primary melanoma arising in the stomach have also been reported^[5,6,13].

The proposed primary sources, from which GI

melanomas are derived, are melanoblastic cells of the neural crest, which migrate to the ileum through the omphalomesenteric canal or APUD cells, which undergo neoplastic transformation^[14]. Although, there have been no reports on benign melanocytes in normal gastric epithelium, melanosis of the gastric mucosa in association with esophageal and anal malignant melanoma has been reported^[15]. Furthermore, the rare presence of melanosis of the esophageal mucosa is accounted for the occurrence of primary esophageal melanoma^[16]. Thus, it seems reasonable that primary gastric melanoma should be considered possible.

In order to avoid running the risk of misinterpretation of a metastasis to the gastric wall to primary lesion, several reports have issued criteria for the diagnosis of primary melanoma. Suggestive criteria of the primary nature of gastric melanoma include lack of concurrent or previous removal of a melanoma or atypical melanotic lesion from the skin, lack of other organ involvement and in-situ change in the overlying or adjacent GI epithelium. The latter, recognized histologically by the presence of atypical melanotic cells in the basal layer of the epithelium and extending in a "pagetoid" fashion into the more superficial epithelium, may be reported in 40%-100% of primary GI melanomas^[14,17]. Additionally, disease free survival of at least 12 mo after curative surgical excision of the involved organ has been proposed as a criterion for the distinction of a primary lesion from metastatic since 50% of patients

with stage IV melanoma or visceral disease from unknown primary will have died at 12 mo from diagnosis^[9,10].

Etiology of primary GI melanomas remains undefined. No predisposing factor has ever been proposed. In contrast, the rarity of these lesions is easily justified by the paucity of melanocytes in the gastrointestinal tract and the inherent protection from etiologic factors such as ultraviolet radiation^[10].

Manifestations of primary gastric melanoma include anemia and weight loss. Barium contrast radiography and endoscopy have some role in the initial diagnostic procedure. CT scan of the abdomen may reveal a gastric mass with or without evidence of lymph node metastases. Preoperative diagnosis is seldom made because of the non-specificity of the symptoms, including nausea, vomiting, abdominal pain, weight loss and anemia^[18]. Tissue sampling during endoscopy may provide the definitive diagnosis. The presence of pigmentation of an ulcer is the most common endoscopic finding. Immunohistochemical staining with HMB-45 and S-100 will confirm the presence of malignant melanocytes in the mucosa^[19].

Melanomas that arise on mucosal surfaces appear to be more aggressive and are associated with worse prognosis than cutaneous melanomas. The poorer prognosis may be related to delay in diagnosis, an inherently more aggressive behavior of mucosal melanomas or earlier dissemination because of the rich lymphatic and vascular supply of the GI tract mucosa^[10]. However, early detection of primary gastrointestinal melanomas and treatment with curative surgical excision can provide long-term disease free interval^[13].

Received: 2006-03-07 Accepted: 2006-03-27

or magnetic resonance imaging show an invasive tumor around the bile duct, the tumor should be diagnosed as malignant. The correct diagnosis is difficult when there is a discrepancy between the imaging and cytologic diagnosis. The sensitivity of bile cytology to detect malignancy is too low to make a conclusive diagnosis. We present a case of bile duct stricture due to xanthogranulomatous cholangitis where a cytological diagnosis of class V adenocarcinoma was made preoperatively. Microscopically, the bile duct was surrounded and narrowed by a xanthogranulomatous lesion, but no xanthogranulomatous cholecystitis (XGC) was seen.

Abstract

This article reports the case of a 34-year-old woman with xanthogranulomatous cholangitis who developed obstructive jaundice. Microscopically, the bile duct was surrounded and narrowed by a xanthogranulomatous lesion, but no xanthogranulomatous cholecystitis was seen. Although percutaneous cholangiograms done via the transhepatic biliary drainage showed smooth narrowing of the upper to middle bile duct, the cytology of bile was diagnosed as class V adenocarcinoma. Therefore, right extended hepatectomy and extrahepatic bile duct resection were performed. The differentiation of benign and malignant strictures at the hepatic hilum is often difficult. Xanthogranulomatous cholangitis is one possible diagnosis of a bile duct stricture. Precise review of all the preoperative information is required to make a correct diagnosis.

CASE REPORT

A 34-year-old woman visited a neighborhood doctor because of jaundice in January 2003. The serum total bilirubin concentration was 7.5 mg/dL. The serum alkaline phosphatase and γ -glutamyltranspeptidase concentrations were 1588 IU/L and 286 IU/L, respectively. There was no leukocytosis. The serum carcinoembryonic antigen, carbohydrate antigen 19-9, and α -fetoprotein levels were within normal limits. Percutaneous transhepatic cholangiodrainage (PTCD) was performed. The cholangiogram showed smooth stenosis of the common bile duct and both hepatic ducts (Figure 1). Bile cytology specimens from the PTCD revealed some cohesive groups of columnar cells with partial papillary growth (Figure 2A). The nucleocytoplasmic ratio was increased and variously sized round nuclei with granular chromatin and prominent nucleoli were observed (Figure 2B). The cytology of the bile was diagnosed as class V adenocarcinoma. She was transferred to our hospital for surgical treatment in February 2003. Computed tomograms of the abdomen demonstrated ascites, but no tumor mass was detected around the bile duct. A diagnostic laparoscopic examination revealed no peritoneal deposits. After percutaneous transhepatic embolization of the right portal vein, extended right hepatectomy and extrahepatic bile duct resection were performed. On inspection, the resected specimen showed wall thickening of the biliary tree from the hepatic duct to the common bile duct. However, the surface mucosa of the extrahepatic bile duct and gallbladder was smooth with no evident neoplastic change. Neither gallstones nor biliary sludge were seen. The cut surface of the bile duct showed a yellowish xanthomatous lesion expanding from the lamina propria toward the serosa (Figure 3). Microscopically, there was fibrous thickening and marked infiltration of foamy

INTRODUCTION

The differential diagnosis of bile duct strictures at the hepatic hilum is often difficult. When computed tomograms

Figure 1 Percutaneous transhepatic cholangiograms showing a stricture of the common bile duct and bilateral hepatic ducts, although the bile duct wall was smooth.

Figure 2 Microscopic cytology showing atypical columnar cells with various-sized round nuclei with granular chromatin and prominent nucleoli. A: Papanicolaou stain, $\times 200$; B: Papanicolaou stain, $\times 400$.

macrophages, lymphocytes, plasma cells, and eosinophils in the lamina propria of the bile duct mucosa (Figure 4). These fibrotic, inflammatory, and xanthogranulomatous changes were localized to the extrahepatic bile duct sparing the gallbladder, and resulted in luminal narrowing of the bile duct. The gallbladder showed mild infiltration of lymphocytes and plasma cells, thickening of the smooth muscle layer, and edema of the subserosa. Although the surface epithelia of the bile duct showed some hyperplastic

Figure 3 Gross features of the resected specimen showing the absence of a neoplastic lesion, with smooth mucosa in the right hepatic lobe and extrahepatic bile duct.

Figure 4 Microscopic view showing marked infiltration of foamy macrophages, lymphocytes, plasma cells, and eosinophils in the lamina propria of the bile duct mucosa. A: HE $\times 200$; B: HE $\times 400$.

features, namely increased luminal folds, no significant structural or cellular atypia were noted. A diagnosis of xanthogranulomatous cholangitis without cholecystitis was made.

DISCUSSION

XGC is a relatively rare inflammatory disease of the gallbladder. Xanthogranulomatous cholangitis is rare, though there are some reports of bile duct stenosis due to extension of XGC^[1,2]. The pathogenesis of XGC remains elusive; cystic duct obstruction with gallstones and bile stasis are thought to be important etiologic factors^[3,4]. In our case, there was no stone in the gallbladder or the bile duct, and XGC was never seen microscopically, although mild inflammation was seen in the gallbladder. Therefore, the cause of the xanthogranulomatous cholangitis in this case remains unclear.

The manifestations of this case were similar to those of other causes of bile duct stricture, and must be distinguished from gallstone disease, bile duct carcinoma, and primary sclerosing cholangitis (PSC). It is not known whether XGC and gallbladder carcinoma are associated; some authors have indicated an association, and it can be difficult to differentiate XGC from gallbladder carcinoma^[5,6]. We initially suspected that the bile stricture was PSC or a submucosal lesion like a MALToma, based on the smooth stricture of the bile duct seen in the

cholangiograms. However, we diagnosed the bile duct stricture as malignant adenocarcinoma because repeated bile duct cytology was class V adenocarcinoma. Two prospective studies of the bile cytology of biliary strictures have shown that the accuracy of brush cytology for cholangiocarcinoma is approximately 60%^[7,8]. In addition, Gerhards *et al* reported a false-positive diagnosis of malignancy resulted in a 15% resection rate for benign hilar strictures. They concluded that resection of a benign lesion mimicking a malignant stricture at the proximal bile duct could not be avoided^[9].

Xanthogranulomatous cholangitis is included in the differential diagnosis of benign and malignant strictures at the hepatic hilum. Precise reviews of all available findings are required to make the correct diagnosis. Finally, the surgeons must know that the bile cytologic diagnosis is sometimes falsely positive for malignancy.

Abstract

To report an extended multivisceral transplantation (MVTx) including right kidney and ascending colon in a patient with complicated Crohn's disease (CD). A 36-year old female suffering from short bowel syndrome and frozen abdomen due to fistulizing CD after multiple abdominal operations underwent MVTx of eight organs including stomach, pancreatoduodenal complex, liver, intestine, ascending colon, right kidney, right adrenal gland, and greater omentum in November 2003. Immunosuppression consisted of alemtuzumab, tacrolimus and steroids. The patient was off parenteral nutrition by postoperative wk 3. She experienced one episode of pneumonia. The patient recovered completely and discharged 2.5 mo and was doing well 30 mo after MVTx. This is one of the very rare cases in which a complete multivisceral graft of eight abdominal organs was transplanted orthotopically.

INTRODUCTION

Multivisceral transplantation (MVTx) has been attempted

since the idea of small bowel transplantation became a clinical reality. Starzl and Kraupp performed the first experimental MVTx in 1960^[1]. Starzl was also the first to perform a MVTx clinically in 1983 and 1986^[2]. Williams contributed another two MVTx patients whom he reported on in 1989^[3]. However, success rates were disappointing with two patients dying early after surgery due to uncontrollable bleeding and the other two due to lymphoma 3 and 6 mo after transplantation. Margreiter *et al*^[4] performed the first MVTx in an adult patient who left hospital free of total parenteral nutrition (TPN). Along with the slow but steady development of intestinal transplantation (ITx) since the late 1980s, the number of MVTx increased as well. Ninety-six MVTx had been reported to the Intestinal Transplant Registry before September 2001, accounting for approximately 13.6% of all intestinal transplants^[5]. Because the term MVTx is defined as transplantation of three or more visceral organs en-bloc, there is a considerable variation in number and combination of organs grafted. Additionally, different transplant techniques have been described reflecting the necessity for a tailor-made approach for each patient. Simultaneous MVTx and kidney transplantation (Ktx) have been reported episodically^[6-8], however none of them was performed in combination with parts of the colon.

In the following we report a MVTx including stomach, pancreatoduodenal complex, liver, intestine, ascending colon, right kidney, right adrenal gland, and greater omentum for a patient suffering from short bowel syndrome and frozen abdomen due to fistulizing Crohn's disease (CD) after multiple abdominal operations. The course was complicated due to secondary end-stage liver disease, decompensated renal insufficiency and sclerosing pancreatitis. This is one of the rare cases in which a complete cluster of eight abdominal organs was transplanted orthotopically. Special focus was put on the technical approach incorporating the right kidney including the right adrenal gland in a straight-forward fashion en-bloc into the multivisceral graft.

CASE REPORT

A 36-year old female patient was referred to our centre in June 2003 after continuous hospital stay over more than 1.5 years to undergo combined liver and intestinal transplantation because of very short bowel syndrome (15 cm residual jejunum) and total parenteral nutrition (TPN)-associated liver cirrhosis. Fistulizing CD was diagnosed in 1988. In November 2001 subtotal colectomy

was performed which was followed by postoperative ileus, recurrent intestinal leakages, recurrent anastomotic leakages with abdominal sepsis and multiple abdominal reoperations resulting in sequential subtotal small bowel resection. TPN was instituted in April 2002 rapidly leading to cholestatic liver disease. TPN-associated progressive liver cirrhosis with severe portal hypertension was diagnosed in autumn 2002. After a total of over 20 operations, the patient suffered from dehiscence of the abdominal wall until April 2004, when she was referred to our institution. Persistent intra-abdominal and transrectal bleeding due to intra-abdominal abscesses and portal hypertension required 8-10 units of packed red blood cells (RBC) per week. Urgent reoperation revealed extensive intra-abdominal scarring in terms of a frozen abdomen with complete obstruction of the abdominal cavity by the residual mesentery, extensive scarring of the retroperitoneum and an approximately 10 cm dehiscence of the abdominal wall. Hematomas and abscesses were drained, the bleeding situation could be stabilized and a closure of the abdominal wall was performed. However, since a surgical separation, also of the upper abdominal organs, was not possible due to extensive scarring, the indication for en-bloc MVTx was confirmed. In the following months, the patient suffered from recurrent decompensations of liver and kidney function.

After 5 mo, a blood group and body-weight matched, 13-year old donor was available, who died of brain death four days after a car accident. During donor procedure, preparation was limited to the resection of colon transversum, while the omentum was preserved at the greater curvature of stomach. Later on it was harvested en bloc together with the other grafts. Organs were perfused en bloc with 5 liters UW solution through the aorta, while small bowel perfusion was reduced after 1000 mL by occlusion of the superior mesenteric artery to avoid intestinal edema. The abdominal graft was harvested en bloc, including whole abdominal aorta and caval vein (CV) and all abdominal organs (Figure 1). In the back-table procedure the spleen was dissected and the left kidney was preserved for a different recipient. The aorta was sutured below the origin of the right renal artery in order to build a new celiac trunk as an offspring where all visceral arteries origin.

The recipient operation was started with a meticulous surgical dissection and exenteration of the abdominal cavity (Figure 2). The whole abdominal cavity and retroperitoneum were filled with massive collaterals because of severe portal hypertension which also explained the daily parastomal bleeding episodes prior to MVTx. Although a veno-venous bypass was used between left femoral vein and left axillar vein to reduce the venous blood flow in the abdomen, a total of 71 packed RBCs, 69 units of FFPs, and 5 units of platelet concentrates were transfused during the 11 h operation.

MVTx included stomach, pancreatoduodenal complex, small bowel, ascending colon, liver, right kidney, the adjacent right adrenal gland, and the greater omentum. Following vascular anastomoses were performed: Venous reconstruction was accomplished by inserting the retrohepatic caval vein including the right renal vein

Figure 1 Graft after perfusion and removal including liver stomach, duodenal-pancreatic complex, small intestine, ascending colon and right kidney (K). The greater omentum (O) was preserved to protect the bowels in case of abdominal dehiscence. The spleen was removed at the back-table. The aorta (Ao) was sutured below the offspring of the right renal artery and used as a neo-colic trunk.

Figure 2 Recipient operation with a meticulous surgical dissection and exenteration of the abdominal cavity. **A:** Recipient's steatotic liver and reminiscence of mesenterium and duodenal-pancreatic complex; **B:** During exenteration caval vein (CV) was resected and prepared for the orthotopic placement of the multivisceral graft. The aorta (Ao) was preserved in full length and both kidneys (K) of the recipient were left in place.

Figure 3 Venous and arterial reconstruction. **A:** Schematic demonstration of the multivisceral transplant. Venous reconstruction was accomplished by inserting the retrohepatic caval vein including the right renal vein (RV) into the recipient (CV) using standard end-to-end anastomosis of the suprahepatic inferior CV and of the infrahepatic CV between the insertion of the right donor RV and recipient RV. **B:** Arterial reconstruction was performed using the donor abdominal aorta with the natural offsprings of the celiac trunk (CT), superior mesenteric artery (SMA), and right renal artery (RA) and inserting it as aneo-celiac trunk at the site of the original recipient celiac trunk.

(RV) into the recipient (CV) using standard end-to-end anastomosis of the suprahepatic inferior CV and the infrahepatic CV between the insertion of the right donor RV and recipient RV. Arterial reconstruction was performed as previously described^[4,7,8] using the donor abdominal aorta with the natural offsprings of the celiac trunk (CT), superior mesenteric artery (SMA), and right renal artery (RA) and inserting it as neo-celiac trunk at the site of the original recipient celiac trunk (Figures 3A and 3B). After a cold ischemia time of 436 min and warm ischemia time of 31 min, reperfusion of the grafts was performed without any complications. Initial function of the organs was excellent including urine production of the transplanted kidney. Reestablishment of intestinal continuity was accomplished by end-to-side gastrostomy of the recipient cardia and donor fundus (Figure 3A), and terminal colostomy of the ascending colon in the lower right quadrant. The right donor ureter was inserted into the right recipient ureter in a side-to-end fashion. The described procedure enabled us to place the transplanted kidney and adrenal gland in almost-orthotopic position just ventrally to the remnant right recipient kidney. Because of the concomitant transplantation of the greater omentum, direct contact of the mesh with the transplanted intestine was avoided (Figure 4). The abdomen could be closed temporarily by an alloplastic mesh and approximated completely within 7 d after transplantation.

Immunosuppression consisted of alemtuzumab (Campath 1H), tacrolimus and steroids. Early enteral immunonutrition was commenced on postoperative d 1. The patient was off TPN by postoperative wk 3. She experienced one episode of pneumonia caused by citrobacter and enterococcus species which was successfully treated. The patient was discharged 2.5 mo after MVTx, with excellent graft function of all transplanted organs. During follow-up she experienced aspergillosis in the left sphenoidal sinus which was treated by drainage and antifungal therapy. There were no further complications and no rejection episodes. Tacrolimus

Figure 4 Situs after reperfusion. The right kidney (KTx) including the adrenal gland was grafted orthotopically. The greater omentum was used to cover the small bowel and the ascending colon (Co) to protect it against direct contact with the alloplastic mesh.

trough levels were adjusted to approximately 7-8 ng/mL 2 mo after MVTx was accompanied by administration of 5 mg prednisolone daily. She was doing well and recovered completely 30 mo after transplantation.

DISCUSSION

MVTx with varying combinations of visceral organs has been performed increasingly along with the improvements achieved in intestinal transplantation. Combined MVTx and KTx has been mentioned before^[9], but only documented in two patients, of them one underwent MVTx without the liver^[6,7]. Because recipients of MVTx normally have an extensive history of abdominal surgeries, abdominal exenteration and the transplant procedure itself are technically demanded. Secondary problems such as injury to adrenal glands with the potential effect of adrenal gland insufficiency may arise. We have described here a patient with previous extensive abdominal surgeries after fistulizing CD, subtotal colectomy, recurrent anastomotic leakages and prolonged intra-abdominal sepsis. Since extensive intra-abdominal and retroperitoneal scarring in terms of a frozen abdomen and retroperitoneal sclerosis were present and documented at an earlier point of time before transplantation during a massive intra-abdominal bleeding episode which required emergency surgery, the adrenal gland adjacent to the right kidney was included into the graft. This cautionary measure was proved to be important because neither of the adrenal glands was identifiable due to extensive scarring in the retroperitoneal suprarenal regions and intraoperative bleeding.

Regarding the vascular reanastomosis, two modifications of the originally described^[10] and frequently modified procedure for MVTx^[11] were used, representing the most appropriate and elegant solution for this patient. The donor abdominal aorta including CT, SMA and right RA was inserted into the recipient aorta as a neo-celiac trunk. Venous reconstruction was conducted in a way that allowed placing the right kidney and adrenal gland in almost orthotopic position with the end-to-end anastomosis between infrahepatic caval veins of the donor and recipient being located just between the right donor and recipient RAs. The piggy back procedure was not used as we were worried about potential venous congestion of the grafted organs when draining into the infrahepatic CV of the donor.

Being aware of recent reports about abdominal wall

transplantation for patients with dehiscence abdominal wall after repeat surgery^[12], we considered this option in the described patient, too. However, we decided to keep the greater omentum with the graft, thus preserving its natural role in protecting the bowels. Additionally, it induced rapid formation of granulation tissue covering the alloplastic mesh rapidly and leading to rapid reepithelialization of the abdominal wound.

In conclusion, orthotopic MVTx including the right kidney and adrenal gland is technically feasible using end-to-end cavocaval anastomoses. Transplantation of the greater omentum may obviate the need of composite grafts for reconstruction of the abdominal wall in some cases and simultaneous transplantation of the adrenal gland is effective in avoiding adrenal insufficiency due to repeat and extensive surgeries.

Abstract

Liver biopsy is generally considered a safe and highly useful procedure. It is frequently performed in an outpatient setting for diagnosis and follow-up in numerous liver disorders. Since its introduction at the end of the 19th century, broad experience, new imaging techniques and special needles have significantly reduced the rate of complications associated with liver biopsy. Known complications of percutaneous biopsy of the liver include hemoperitoneum, subcapsular hematoma, hypotension, pneumothorax and sepsis. Other intra-abdominal complications are less common. Hemobilia due to arterio-biliary duct fistula has been described, which has only rarely been clinically expressed as cholecystitis or pancreatitis. We report a case of a fifteen year-old boy who developed severe acute cholecystitis twelve days after a percutaneous liver biopsy performed in an outpatient setting. The etiology was clearly demonstrated to be hemobilia-associated, and the clinical course required the performance of a laparoscopic cholecystectomy. The post operative course was uneventful and the patient was discharged home. Percutaneous liver biopsy is a safe and commonly performed procedure. However, severe complications can occasionally occur. Both medical and surgical options should be evaluated while dealing with these rare incidents.

INTRODUCTION

The increasing clinical need for liver biopsies as well as the availability of imaging assistance have changed the nature of this procedure. A previously hazardous intervention requiring hospitalization has changed to a common, easy and safe one.

However, complications of percutaneous biopsy of the liver do occur. Hemoperitoneum, pneumothorax, sub-capsular hematoma, hypotension and sepsis have been previously documented. Hemobilia due to arterio-biliary duct fistula has been reported as well. Rarely, clinical manifestations such as cholecystitis or pancreatitis subsequently evolve.

CASE REPORT

An asymptomatic 15-year old boy presented with persistently elevated liver enzymes initially discovered on routine blood chemistries. History and physical examination revealed an athletic, healthy-appearing young man. He underwent percutaneous liver biopsy to evaluate the possible diagnosis of cryptogenic cirrhosis. The procedure was uneventful and he was discharged on the same day. The biopsy was non-diagnostic.

Twelve days later he presented to the emergency department (ED) complaining of nausea, vomiting and abdominal pain focusing in the right upper quadrant. No fever was noted and he did not appear to be jaundiced. His abdomen was soft, with mild right upper quadrant abdominal tenderness. Blood analysis showed: WBC $14.5 \times 10^3/\mu\text{L}$, total bilirubin 1.8 mg/dL, ALT/AST 54/26 U/L, amylase 60 U/L. An ultrasound (US) was performed showing a large blood clot in the gall bladder. There was no thickening of the gall bladder wall and no pericholecystic fluid evident on the US examination.

He was discharged home but returned to the ED two days later with similar complaints and physical findings. The US was repeated and the same finding was evident (Figure 1). At this time his white blood cell count was $19.5 \times 10^3/\mu\text{L}$, total bilirubin 2.6 mg/dL, ALT/AST 238/74 U/L.

Intravenous antibiotics were started, and the following day laparoscopy was performed, revealing a severely acutely inflamed gall bladder and gross evidence of macro- and micro-nodular cirrhosis. Intraoperative cholangiography (IOC) revealed a normal extrahepatic duct system and mildly dilated intrahepatic ducts (Figure 2). Laparoscopic cholecystectomy and liver biopsy were performed. The gall bladder specimen revealed severe wall-thickening,

Figure 1 Ultra-sonography of the abdomen showing distended gall bladder containing large blood clot.

Figure 3 The opened specimen revealing a blood clot.

Figure 2 Intra-operative cholangiogram with normal appearing anatomy.

and a thrombus cast of the gall bladder was found within (Figure 3). Liver biopsy revealed end stage liver disease characterized by cirrhosis and marked expansion of portal ducts (Figure 4). The patient recovered uneventfully and was discharged home on postoperative day two.

DISCUSSION

Since liver biopsy was introduced at the end of the 19th century^[1], broad experience has been gained in performing this essential procedure. Complications of percutaneous liver biopsy are fortunately uncommon, and have been well described. Ninety- six percent of such complications appear in the first 24 h^[2]. The remaining 4% usually have their clinical expression within 10 d. The incidence of complications is known to be higher in patients with either cirrhosis or neoplasm^[3]. The delay of twelve days before clinical manifestation of such a significant complication, as occurred in our patient who was ultimately found to have cirrhosis, is quite unusual.

The presence of blood in the biliary tree, hemobilia, was first described in 1948^[4]. It was first reported as a complication of liver biopsy in 1967^[5]. The incidence of hemobilia attributed to liver biopsy is less than 1%. In the largest reported series of complications induced by liver biopsies, hemobilia was noted in 4 of 68 276 patients (0.006%)^[2].

Figure 4 Hematoxylin & eosin stain of the liver sampled from the case.

The clinical manifestations of hemobilia vary and may be subtle. When blood flows in the extra-hepatic biliary system, symptoms which are similar to those caused by gall stones might be induced. Blood clots in the gall bladder itself can mimic biliary colic or induce cholecystitis. We found only five previous cases of this in the world's literature. Clots in the common bile duct can also cause obstructive jaundice and pancreatitis similar to that caused by choledocholithiasis. In this case hemobilia caused by percutaneous liver biopsy led to the formation of a large blood clot in the gall bladder. The clinical signs of biliary colic (and subsequently acute cholecystitis) led to further evaluation and ultimately to a laparoscopic cholecystectomy.

TO THE EDITOR

Sir, I read with great interest the recently published article in the *World Journal of Gastroenterology* by Jin and co-workers^[1] on the cloning and characterization of porcine aquaporin 1 water channel from the pig liver and studies on its expression in the porcine gastrointestinal system. The authors should be congratulated for making this important and valuable contribution to the field of aquaporin biology and porcine gastrointestinal physiology. However, there are a number of unresolved issues and controversies concerning the expression of aquaporins (especially aquaporin 1) in the gastrointestinal system that are worthy of additional comment and discussion by Jin and co-workers.

It is now well established that aquaporin (AQP) water channels are a family of membrane proteins that facilitate water movement across cell membranes in plants and animals. Thus far, at least 13 human aquaporins (AQP0-AQP12) have been identified^[2]. These proteins are selectively permeated by water (aquaporins)^[3] or water plus glycerol (aquaglyceroporins)^[4]. Aquaporins are strategically located at membrane sites in a variety of epithelial cells, most of which have well-defined transport functions; some are involved in fluid absorption, others in fluid secretion^[5]. Aquaporin 1 (AQP1) was the first member of the AQP family to be identified, initially

as a molecular component of the Colton blood group antigens in erythrocytes and subsequently cloned from kidney complementary DNA libraries and shown to possess water transporting activity^[6,7]. Although AQP1 has been found to be important in osmotic water movement across cell membranes of many epithelial and endothelial barriers, its expression in the gastrointestinal system is exclusively limited to microvascular endothelia (Figure 1) and other aquaporin isoforms are known to be expressed in the epithelial cell lining. These aquaporins include AQP3^[8-10], AQP4^[11-13], AQP5^[14,15], AQP8^[16,17], AQP9^[18] and AQP10^[19-22]. It is therefore clearly established that multiple aquaporin isoforms are present along the gastrointestinal system; some of these are classical aquaporins (i.e., AQP1, AQP4, AQP5, AQP8) and are probably mainly involved in water homeostasis^[23], whereas others are aquaglyceroporins (i.e., AQP3, AQP7, AQP9, AQP10) and are potentially involved in the facilitated movement of small uncharged organic molecules, such as glycerol^[4] as well as water. In the fluid-transporting epithelia of the kidney nephron, AQP1 is permeated by water, driven by osmotic gradients and AQP1 is abundant in the apical and basolateral membranes of renal proximal tubules and descending thin limbs and plays a key role in setting up and maintaining the counter-current multiplication system^[23,24]. Although AQP1 is known to be present in a number of extrarenal tissues, such as the ciliary body of the eye and the choroid plexus in the brain^[6,23,25], it has not been reported in normal epithelial cells lining the gastrointestinal system^[23]. The presence of AQP1 in gastrointestinal epithelial cells has only been reported in tumors of the colon, where it has been reported to contribute to tumor angiogenesis and the formation of high interstitial fluid pressures and high vascular permeability of tumor microvessels^[26].

Jin *et al*^[1] conclude that porcine AQP1 (pAQP1) is the first porcine aquaporin to be identified by means of molecular biology techniques. This is a valid and correct statement. However, the functional data they provide is from transfected CHO cells and red blood cells. The functional data presented by Jin *et al*^[1] may not be used to support the statement that pAQP1 plays a key role in fluid transport in epithelial and endothelial structures of the pig gut. Furthermore, the immunohistochemical and Northern blot data presented by the authors do not prove that the observed differences in pAQP1 mRNA and protein abundance in porcine liver, small intestine, colon and salivary glands are due to differential and

Figure 1 AQP1 expression in human and equine small intestine and kidney. In the small intestine of both species, AQP1 is present exclusively in microvessel endothelia and in erythrocytes (panels A and C). AQP1 is not expressed in epithelial cells or any other structures in the small intestine (panels A and C). In the kidney of both species specific AQP1 expression is abundant in the renal cortex, specifically in the apical (brush border) and basolateral membranes of proximal tubules and in microvessel endothelia (panels B and D). Some AQP1 expression is also seen within the glomerulus in podocytes (panels B and D).

functional expression; the differential expression observed is more likely to be the consequence of the dissimilar vascularization of these tissues which will indisputably affect the abundance of AQP1-positive endothelial cells.

Based on the evidence from studies by other investigators, it is probably premature to suggest that AQP1 is involved in fluid secretion, fluid absorption, digestive function and pathophysiology of the porcine gastrointestinal system^[1]. Multiple aquaporins are likely to be involved in the processes of fluid secretion and absorption in the digestive system. Aquaporins 3, 4, 8, 9 and 10 are also known to be expressed in strategic points along the gastrointestinal system^[13]. The presence of several different AQP isoforms along the gastrointestinal tract is likely to be related to the specific water-transporting functions of each of its segments. For example, salivary glands synthesize salivary amylase and mucus which are secreted along with electrolytes and water. The exocrine pancreas synthesizes proteases, lipases and amylases which are secreted with HCO_3^- and water. The liver and gallbladder are involved in bile salt synthesis, its secretion, storage and concentration, respectively. Gastric parietal cells secrete HCl into the lumen of the stomach and hence require AQP water channels for their secretory function. Finally, the small and large intestines absorb up to 8.5 L and 0.4 L of water every day (Figure 2).

Studies on AQP-knockout mice have shown that some of the observed phenotypes are quite mild, especially in the gastrointestinal system which is not surprising given that water transport across the digestive epithelial barriers seems to occur not only via aquaporin water channels but also via other transporters, co-transporters or channel systems. The mild phenotypes of AQP-knockout mice also suggest that other aquaporins participate in compensatory mechanisms resulting from the selective disruption of a particular AQP gene.

Figure 2 Summary of the gastrointestinal system's daily fluid balance (A) and the secretions of salivary glands, exocrine pancreas and liver (B).

The anatomical localization and molecular identity of AQPs in the gastrointestinal tract is not particularly well studied compared to other organs, such as the kidney. There are very few published models of water and small solute transport across the epithelium of the gut. Accordingly, the focus of future studies should be identification and subcellular localization of AQP proteins in the mammalian (human) gut. We have recently proposed a model (Figure 3) of water and small solute transport across the epithelium of the human gut which incorporates the functional contribution of AQP1, AQP3, AQP8 and AQP10^[21]. The data presented by Jin *et al*^[1] also confirm our findings^[23] and the findings of several other studies with regard to the distribution of the AQP1 protein in microvessel endothelia and bile ducts. However, further studies are still required to determine the expression of the recently identified members of the AQP family in the gastrointestinal system of humans in health and in diseases brought about by opportunistic bacteria (i.e., diarrhoea, colic and endotoxemia), immune disorders of the gut, such as Crohn's disease and cancers of gastrointestinal organs. From a biological viewpoint, it would be of interest to perform comparative studies of AQP expression and function in gut tissues derived from mammals, amphibians, reptiles and fish. Also, determining the expression of AQP proteins in guts of omnivores, herbivores and carnivores will help us gain a more complete understanding of the functions of these proteins in the mammalian gastrointestinal system.

Figure 3 Model of water and small solute transport across the absorptive epithelium of the human small intestine^[21]. The potential routes for water entry into the enterocyte from the luminal (apical) side are AQP10 and the sodium/glucose co-transporter SGLT1. SGLT1 is a secondary active transporter driven by the function of basolateral Na,K-ATPase which co-transport Na⁺ and glucose along with water into enterocytes. AQP8 (shown in parentheses) has been shown to be located in the sub-apical cytoplasm of absorptive epithelial cells. The basolateral water exit pathway is most likely to be the AQP3 protein^[10,28]. Although the location of the AQP7 protein has not yet been precisely determined, it may be involved in glycerol transport in the intestinal lacteal system.

ACKNOWLEDGMENTS

Acknowledgments to Reviewers of *World Journal of Gastroenterology*

Many reviewers have contributed their expertise and time to the peer review, a critical process to ensure the quality of *World Journal of Gastroenterology*. The editors and authors of the articles submitted to the journal are grateful to the following reviewers for evaluating the articles (including those were published and those were rejected in this issue) during the last editing period of time.

Daniel C Baumgart, MD, PhD, FEBG

Instructions to authors

GENERAL INFORMATION

World Journal of Gastroenterology (WJG, *World J Gastroenterol* ISSN 1007-9327 CN 14-1219/R) is a weekly journal of more than 48 000 circulation, published on the 7th, 14th, 21st and 28th of every month.

Original Research, Clinical Trials, Reviews, Comments, and Case Reports in esophageal cancer, gastric cancer, colon cancer, liver cancer, viral liver diseases, etc., from all over the world are welcome on the condition that they have not been published previously and have not been submitted simultaneously elsewhere.

Indexed and abstracted in

Current Contents/Clinical Medicine and Science Citation Index-Expanded, *Index Medicus*, MEDLINE and PubMed, Chemical Abstracts, EMBASE/Excerpta Medica, Abstracts Journals, Nature Clinical Practice Gastroenterology and Hepatology, CAB Abstracts and Global Health.ISI JCR 2003-2000 IF: 3.318, 2.532, 1.445 and 0.993.

Published by

The WJG Press

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed double-spaced on A4 (297 mm × 210 mm) white paper with outer margins of 2.5 cm. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, acknowledgements, References, Tables, Figures and Figure Legends. Neither the editors nor the Publisher is responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press, and may not be reproduced by any means, in whole or in part without the written permission of both the authors and the Publisher. We reserve the right to put onto our website and copy-edit accepted manuscripts. Authors should also follow the guidelines for the care and use of laboratory animals of their institution or national animal welfare committee.

Authors should retain one copy of the text, tables, photographs and illustrations, as rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for the loss or damage to photographs and illustrations in mailing process.

Online submission

Online submission is strongly advised. Manuscripts should be submitted through the Online Submission System at: <http://www.wjgnet.com/index.jsp>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (<http://www.wjgnet.com/wjg/help/instructions.jsp>) before attempting to submit online. Authors encountering problems with the Online Submission System may send an email you describing the problem to wjg@wjgnet.com for assistance. If you submit your manuscript online, do not make a postal contribution. A repeated online submission for the same manuscript is strictly prohibited.

Postal submission

Send 3 duplicate hard copies of the full-text manuscript typed double-spaced on A4 (297 mm × 210 mm) white paper together with any original photographs or illustrations and a 3.5 inch computer diskette or CD-ROM containing an electronic copy of the manuscript including all the figures, graphs and tables in native Microsoft Word format or *.rtf format to:

Editorial Office

World Journal of Gastroenterology

Editorial Department: Apartment 1066, Yishou Garden,
58 North Langxinzhuang Road,
PO Box 2345, Beijing 100023, China
E-mail: wjg@wjgnet.com
<http://www.wjgnet.com>
Telephone: +86-10-85381901
Fax: +86-10-85381893

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using a word-processing software. All submissions must be typed in 1.5 line spacing and in word size 12 with ample margins. The letter font is

Tahoma. For authors from China, one copy of the Chinese translation of the manuscript is also required (excluding references). Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Full manuscript title, running title, all author(s) name(s), affiliations, institution(s) and/or department(s) where the work was accomplished, disclosure of any financial support for the research, and the name, full address, telephone and fax numbers and email address of the corresponding author should be included. Titles should be concise and informative (removing all unnecessary words), emphasize what is new, and avoid abbreviations. A short running title of less than 40 letters should be provided. List the author(s)' name(s) as follows: initial and/or first name, middle name or initial(s) and full family name.

Abstract

An informative, structured abstract of no more than 250 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections: AIM: Only the purpose should be included. METHODS: The materials, techniques, instruments and equipments, and the experimental procedures should be included. RESULTS: The observatory and experimental results, including data, effects, outcome, etc. should be included. Authors should present *P* value where necessary, and the significant data should accompany. CONCLUSION: Accurate view and the value of the results should be included.

The format of structured abstracts is at: <http://www.wjgnet.com/wjg/help/11.doc>

Key words

Please list 6-10 key words that could reflect content of the study mainly from *Index Medicus*.

Text

For most article types, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include in appropriate Figures and Tables. Data should be presented in the body text or in Figures and Tables, but not in both.

Illustrations

Figures should be numbered as 1, 2, 3 and so on, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. No detailed legend should be involved under the figures. This part should be added into the text where the figures are applicable. Digital images: black and white photographs should be scanned and saved in TIFF format at a resolution of 300 dpi; color images should be saved as CMYK (print files) but not as RGB (screen-viewing files). Place each photograph in a separate file. Print images: supply images of size no smaller than 126 mm × 76 mm printed on smooth surface paper; label the image by writing the Figure number and orientation using an arrow. Photomicrographs: indicate the original magnification and stain in the legend. Digital Drawings: supply files in EPS if created by freehand and illustrator, or TIFF from photoshops. EPS files must be accompanied by a version in native file format for editing purposes. Existing line drawings should be scanned at a resolution of 1200 dpi and as close as possible to the size where they will appear when printed. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes of atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ...

Tables

Three-line tables should be numbered as 1, 2, 3 and so on, and mentioned clearly in the main text. Provide a brief title for each table. No detailed legend should be included under the tables. This part should be added into the text where the tables are applicable. The information should complement but not duplicate that contained in the text. Use one horizontal line under the title, a second under the column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. ^a*P*<0.05, ^b*P*<0.01 should be noted (*P*>0.05 should not be noted). If there are other series of *P* values, ^c*P*<0.05 and ^d*P*<0.01 are used. Third series of *P* values can be expressed as ^e*P*<0.05 and ^f*P*<0.01. Other notes in tables or under illustrations should be expressed as ¹*F*, ²*F*, ³*F*; or some other symbols with

a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, etc. in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscripts and who endorse the data and conclusions are included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should code the references according the citation order in text in Arabic numerals, put references codes in square brackets, superscript it at the end of citation content or the author name of the citation. For those citation content as the narrate part, the coding number and square brackets should be typeset normally. For example, Crohn's disease (CD) is associated with increased intestinal permeability^[1,2]. If references are directly cited in the text, they would be put together with the text, for example, from references [19,22-24], we know that...

When the authors code the references, please ensure that the order in text is the same as in reference part and also insure the spelling accuracy of the first author's name. Do not code the same citation twice.

PMID requirement

PMID roots in the abstract serial number indexed by PubMed (<http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=PubMed>). The author should supply the PMID for journal citation. For those references that have not been indexed by PubMed, a printed copy of the first page of the full reference should be submitted.

The accuracy of the information of the journal citations is very important. Through reference testing system (<http://www.aushome.cn/cgi-bin/index.pl>), the authors and editor could check the authors name, title, journal title, publication date, volume number, start page, and end page. We will interlink all references with PubMed in ASP file so that the readers can read the abstract of the citations online immediately.

Style for journal references

Authors: the first author should be typed in bold-faced letter. The surname of all authors should be typed with the initial letter capitalized and followed by their name in abbreviation (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). Title of the cited article and italicized journal title (Journal title should be in its abbreviation form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634]

Note: The author should test the references through reference testing system (<http://www.aushome.cn/cgi-bin/index.pl>)

Style for book references

Authors: the first author should be typed in bold-faced letter. The surname of all authors should be typed with the initial letter capitalized and followed by their name in abbreviation (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Patent (list all authors)

- 16 **Pagedas AC**, inventor; Ancel Surgical R&D Inc., assignee. Flexible endoscopic grasping and cutting device and positioning tool assembly. United States patent US 20020103498. 2002 Aug 1

Inappropriate references

Authors should always cite references that are relevant to their article, and avoid any inappropriate references. Inappropriate references include those that are linked with a hyphen and the difference between the two numbers at two sides of the hyphen is more than 5. For example, [1-6], [2-14] and [1, 3, 4-10, 22] are all considered as inappropriate references. Authors should not cite their own unrelated published articles.

Statistical data

Present as mean \pm SD or mean \pm SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as γ (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p*(B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose) 6.4 \pm 2.1 mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6 24.5 μ g/L; CO₂ volume fraction, 50 mL/L CO₂ not 5% CO₂; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format about how to accurately write common units and quantum is at: <http://www.wjgnet.com/wjg/help/15.doc>

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further mention.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindI*, *BamHI*, *Kbo I*, *Kpn I*, etc.

Biology: *H pylori*, *E coli*, etc.

SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. Author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, the final check list for authors, and responses to reviewers by a courier (such as EMS) (submission of revised manuscript by e-mail or on the *WJG* Editorial Office Online System is NOT available at present).

Language evaluation

The language of a manuscript will be graded before sending for revision.

(1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing; (4) Grade D: rejected. The revised articles should be in grade B or grade A.

Copyright assignment form

Please download CAF from <http://www.wjgnet.com/wjg/help/9.doc>.

We certify that the material contained in this manuscript:

Ms:

Title:

is original, except when appropriately referenced to other sources, and that written permission has been granted by any existing copyright holders. We agree to transfer to *WJG* all rights of our manuscript, including: (1) all copyright ownership in all print and electronic formats; (2) the right to grant permission to republish or reprint the stated material in whole or in part, with or without a fee; (3) the right to print copies for free distribution or sale; (4) the right to republish the stated material in a collection of articles or in any other format. We also agree that our article be put on the Internet.

Criteria for authorship: The *WJG* requests and publishes information about contributions of each author named to the submitted study. Authorship credit should be based on (1) direct participation in the study, including substantial contributions to conception and design of study, or acquisition of data, or analysis and interpretation of data; (2) manuscript writing, including drafting the article, or revising it critically for important intellectual content; (3) supportive work, including statistical analysis of data, or acquisition of funding, or administration, technology and materials support, or supervision, or supportive contributions. Authors should meet at least one of the three conditions. The *WJG* does not publish co-first authors and co-corresponding authors.

We hereby assign copyright transfer to *WJG* if this paper is accepted.

Author Name in full (Full names should be provided, with first name first, followed by middle names and family name at the last, eg, Eamonn MM Quigley). Handwritten names are not accepted.

Author Name in abbreviation (Family name is put first in full, followed by middle names and first name in abbreviation with first letter in capital, eg, Quigley EMM). Handwritten names are not accepted.

Final check list for authors

The format is at: <http://www.wjgnet.com/wjg/help/13.doc>

Responses to reviewers

Please revise your article according to the comments/suggestions of reviewers. The format for responses to the reviewers' comments is at: <http://www.wjgnet.com/wjg/help/10.doc>

COPY EDITOR FOR THIS ISSUE: James David Luketich, MD

World Journal of Gastroenterology (*World J Gastroenterol*, *WJG*), a leading international journal in gastroenterology and hepatology, has an established reputation for publishing first class research on esophageal cancer, gastric cancer, liver cancer, viral hepatitis, colorectal cancer, and *H pylori* infection, providing a forum for both clinicians and scientists, and has been indexed and abstracted in Current Contents/Clinical Medicine and Science Citation Index-Expanded, *Index Medicus*, MEDLINE and PubMed, Chemical Abstracts, EMBASE/Excerpta Medica, Abstracts Journals, Nature Clinical Practice Gastroenterology and Hepatology, CAB Abstracts and Global Health. ISI JCR 2003-2000 IF: 3.318, 2.532, 1.445 and 0.993. *WJG* is a weekly journal published by The *WJG* Press. The publication date is on 7th, 14th, 21st, and 28th every month. The *WJG* is supported by The National Natural Science Foundation of China, No. 30224801 and No.30424812, which was founded with a name of *China National Journal of New Gastroenterology* on October 1, 1995, and renamed as *WJG* on January 25, 1998.

Abstract

Bile secretion is dependent on the coordinated functions of a number of hepatobiliary transport systems. Cholestasis may be caused by an impairment of bile secretion, an obstruction of bile flow or a combination of the two. The common consequence of all forms of cholestasis is retention of bile acids and other potentially toxic compounds in the hepatocytes leading to apoptosis or necrosis of hepatocytes and eventually to chronic cholestatic liver disease. In certain cholestatic disorders there is also leakage of bile acids into the peribiliary space causing portal inflammation and fibrosis. The following pharmacological targets for treatment of intrahepatic cholestasis can be identified: stimulation of orthograde biliary secretion and retrograde secretion of bile acids and other toxic cholephils into the systemic circulation for excretion *via* the kidneys to reduce their retention in the hepatocytes; stimulation of the metabolism of hydrophobic bile acids and other toxic compounds to more hydrophilic, less toxic metabolites; protection of injured cholangiocytes against toxic effects of bile; inhibition of apoptosis caused by elevated levels of cytotoxic bile acids; inhibition of fibrosis caused by leakage of bile acids into the peribiliary space. The clinical results of ursodeoxycholic acid therapy of primary biliary cirrhosis may be regarded as the first success of this strategy.

INTRODUCTION

Great progress has been made in the last decade in our understanding of the molecular basis of bile formation and the pathobiology of cholestasis^[1-3]. Targets for medical therapy of cholestasis have been identified which help to understand the established treatments and facilitate the development of new drugs for cholestatic liver disease. In this short review, present concepts of bile formation and cholestasis are briefly summarized and medical treatment of cholestatic liver diseases is illustrated using primary biliary cirrhosis (PBC), the model disease for chronic cholestatic liver disease, as an example.

MOLECULAR MECHANISMS OF BILE FORMATION

Hepatocellular bile is formed by active transport of solutes into the bile canaliculi. Thereby, a local osmotic gradient is established between canalicular bile and sinusoidal plasma. This causes a flow of water, electrolytes and small solutes into the bile canaliculi, mainly *via* a paracellular pathway through the tight junctions which exhibit perm selectivity, and are impermeable for large and negatively charged solutes^[4].

The most important driving force for hepatocellular bile formation is the secretion of bile acids from the sinusoidal blood into the bile^[3]. Conjugated bile acids, which represent the major fraction of bile acids in the blood, are transported across the basolateral membrane of hepatocytes together with sodium by the sodium-taurocholate cotransporter (NTCP, *SLC10A1*). Unconjugated bile acids and a large variety of other organic anions including bilirubin are taken up by the hepatocytes *via* the organic anion-transporting polypeptide 2 (OATP2, *SLC21A6*). The rate limiting step for bile formation is the active transport of bile acids and other solutes across the canalicular membrane of hepatocytes. This concentrative step is driven by a number of ATP-dependent export pumps (ATP-binding-cassette-transport proteins also known as ABC-transporters). Bile salts are transported by the bile salt export pump (BSEP, *ABCB11*), whereas bilirubin diglucuronide, glutathione, divalent bile acids conjugates and a large variety of other conjugated organic anions are transported by the multidrug resistance associated protein 2 (MRP2, *ABCC2*)^[2].

A special ABC-transporter, namely the multidrug resistance P-glycoprotein 3 (MDR3, *ABCB4*), flips

phospholipids from the inner to the outer leaflet of the canalicular membrane. This flippase provides phosphatidylcholine for bile which forms mixed micelles with bile acids and cholesterol^[2].

The formation and final composition of bile depends on additional transporters in the canalicular membrane of hepatocytes as well as transporters in cholangiocytes which add cholangiocellular bile to hepatocellular bile. Among those, the chloride-bicarbonate anion exchanger 2 (AE2, *SLC10A2*) is present in the apical membrane of both hepatocytes and bile duct epithelial cells, whereas the cystic fibrosis transmembrane conductance regulator (CFTR, *ABCC7*), a chloride channel, is located in the apical membrane of bile duct epithelial cells only^[2].

The basolateral membrane of hepatocytes possesses a number of transporters which are expressed during cholestasis and transport solutes in a retrograde fashion back into the blood (see below). These are MRP4 (*ABCC4*) which transports bile acids together with glutathione^[5], MRP3 (*ABCC3*) which transports conjugated bilirubin and other organic anions^[2,6] and OST α /OST β , a heteromeric organic solute transporter which transports bile acids^[7]. During cholestasis, MRP3^[8] and OST α /OST β are also upregulated in the basolateral membrane of cholangiocytes^[9].

MOLECULAR MECHANISMS OF CHOLESTASIS

Cholestasis can be defined as an impairment of bile flow. The consequences are retention of bile acids, bilirubin and other cholephils in the liver and blood and a deficiency of bile acids in the intestine. Various forms of cholestasis can be caused by an impairment of bile secretion, an obstruction of bile flow or a combination of the two (Figure 1).

Impairment of bile secretion can be inborn, for instance in different forms of progressive familial intrahepatic cholestasis (PFIC), benign recurrent intrahepatic cholestasis (BRIC), or cystic fibrosis, and it also can be acquired by inflammation, toxins, drugs or hormones^[8,10].

Inborn defects of bile secretion: If BSEP is defective because of a gene mutation, PFIC2 or BRIC2^[11] can occur. PFIC2 can be identified by immunostaining of BSEP in liver biopsies^[12].

Mutations of MRP2 cause the Dubin Johnson syndrome, which is not a complete cholestasis, but a more selective defect of biliary secretion of organic anions such as bilirubin glucuronide. Mutations of MDR3 cause PFIC3 and mutations of CFTR cause cystic fibrosis^[2,8].

Acquired impairment of bile secretion: In inflammatory disorders such as sepsis, bacterial infections, viral hepatitis as well as toxin or drug-induced hepatitis, inflammatory cytokines can impair bile secretion. Thus, TNF α and IL-1 β down regulate NTCP and BSEP which are responsible for bile acid transport, as well as OATP2 and MRP2 which are responsible for transport of bilirubin and a variety of other organic ions^[13,14].

Figure 1 Causes of cholestasis. PBC: Primary biliary cirrhosis; PFIC: Progressive familial intrahepatic cholestasis; PSC: Primary sclerosing cholangitis; VBDS: Vanishing bile duct syndrome. For details see text.

Drugs can cause cholestasis by inhibiting the function of hepatobiliary transport proteins. Some drugs are known to inhibit BSEP directly from the inside of hepatocytes, which is called cis-inhibition. Examples are cyclosporine A, glibenclamide, troglitazone and bosentan^[15,16]. Other drugs, such as estradiol 17 β -D-glucuronide, must first be transported into the canalicular lumen by MRP2 and then act on BSEP from the luminal side, which is called trans-inhibition^[17].

Obstruction of bile flow can also be caused by inborn disorders, e.g. in cystic fibrosis or in PFIC3, and it can be acquired for instance in PBC, primary sclerosing cholangitis (PSC) or the vanishing bile duct syndrome (VBDS). Much more often obstructive cholestasis is caused by stones or tumours.

In cholestatic disorders caused by an initial injury of cholangiocytes (e.g. an immunological injury in the case of PBC), hydrophobic bile acids in bile (in millimolar concentrations) may aggravate the bile duct lesion and contribute to the destruction and loss of bile ducts resulting in progressive obstructive cholestasis. This may be called extracellular bile acid cytotoxicity in contrast to intracellular bile acid toxicity when bile acids accumulate in hepatocytes (in micromolar concentrations). Extracellular bile acid toxicity also occurs towards normal biliary epithelium when phospholipids in bile are low, as in the inborn defect of PFIC3 or in other "low phospholipid syndromes", in low phospholipid gallstone disease^[18] or in bile acid phospholipid imbalance in bile after liver transplantation^[19].

ADAPTIVE RESPONSES TO CHOLESTASIS

In order to compensate for the loss of biliary excretory function in cholestasis and to limit hepatocellular accumulation of potentially toxic biliary constituents, adaptive responses to cholestasis occur in the liver^[6,8,14,20,21], the kidney^[20-23] and the intestine^[22,24]. In the following only the adaptive changes in the liver are discussed.

Down regulation of NTCP and OATP2 reduces the uptake of bile acids and other organic anions in cholestasis and thus protects the hepatocytes against an overload

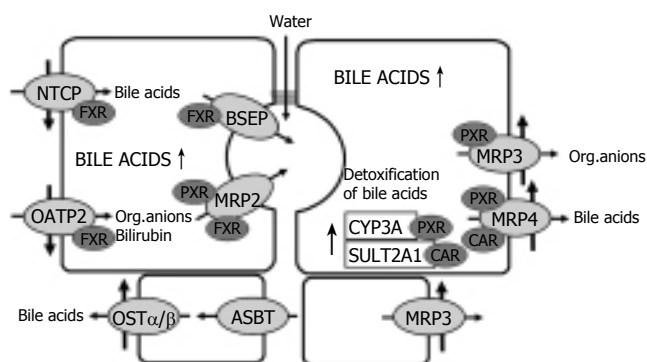

Figure 2 Adaptive responses to cholestasis. BSEP: Bile salt export pump; CAR: Constitutive androstane receptor; CYP3A: Cytochrome P450 enzyme 3A; FXR: Farnesoid X receptor; OATP: Organic anion transporting polypeptide; OST: Organic solute transporter; MRP: Multidrug resistance associated protein; NTCP: Sodium taurocholate co-transporting polypeptide; PXR: Pregnane X receptor; SULT2A1: Sulphotransferase 2A1. For details see text.

of bile acids and bilirubin^[3,25,26]. At the same time there is upregulation of MRP3 and MRP4 in the basolateral membrane^[14,22,27-29]. These transporters normally are expressed at a low level only. MRP4 pumps bile salts and bile salt conjugates together with glutathione from the cells into the blood and thus decreases bile acid retention in cholestatic hepatocytes. MRP3 mainly exports other organic anions. Prior to their extrusion from hepatocytes, hydrophobic bile acids and many xenobiotics are metabolized to more hydrophilic and less toxic compounds by cytochrome P-450 (CYP) 3A enzymes. A large fraction of bile acids is sulphated by the enzyme sulfotransferase 2A1 (Figure 2).

The major players in these adaptive regulations are the nuclear receptors FXR, PXR and CAR^[30]. The farnesoid X-receptor (FXR), a bile acid sensor, is mainly involved in the down regulation of NTCP, in the maintenance of BSEP function and in the up-regulation of MRP4 and MDR3. The pregnane X receptor (PXR), to which many xenobiotics bind, is mainly responsible for the up-regulation of MRP3 and various CYP enzymes, especially the family of CYP3A enzymes. There is evidence that more than one of these nuclear receptors can act on the same transporter. Recently, it has been demonstrated that the constitutive androstane receptor (CAR) up-regulates sulfotransferase 2A1 and MRP4 in a coordinated fashion facilitating the conjugation and export of hydrophobic bile acids^[31]. In addition to PXR, the peroxisome-proliferator-activated receptor α (PPAR α) up-regulates MDR3 (Figure 2).

It is of considerable interest that besides natural bile acids, bile acid derivatives such as ethyl-chenodeoxycholic acid are ligands for FXR^[32,33]. Ligands for PXR are many xenobiotics and drugs like rifampicin. Bilirubin and phenobarbital are ligands for CAR and fibrates as well as statins (e.g. pravastatin) bind to PPAR α .

These findings open an avenue for the development of drugs which bind to nuclear receptors which enhance normal compensatory mechanisms in cholestasis for the elimination of toxic compounds *via* alternative excretory routes.

Figure 3 Targets for medical treatment of intrahepatic cholestasis. BA: Bile acids. For details see text.

TARGETS FOR PHARMACOLOGICAL THERAPY

The common consequence of all forms of cholestasis is retention of bile acids in hepatocytes. Elevated levels of bile acids then can lead to apoptosis or necrosis of hepatocytes and eventually to chronic cholestatic liver disease^[34]. In certain cholestatic disorders there is also leakage of bile acids into the peribiliary space, causing portal inflammation and fibrosis *via* induction of chemokines and cytokines^[35]. Accordingly, the following pharmacological targets for treatment of intrahepatic cholestasis can be identified (Figure 3): stimulation of orthograde biliary secretion and retrograde secretion of bile acids and other toxic cholephils into the systemic circulation for excretion by the kidneys to reduce their retention in the hepatocytes; stimulation of the metabolism of hydrophobic bile acids and other toxic compounds to more hydrophilic but less toxic metabolites; protection of injured cholangiocytes against toxic effects of bile; inhibition of apoptosis caused by elevated levels of cytotoxic bile acids; inhibition of fibrosis caused by leakage of bile acids into the peribiliary space.

Stimulation of secretion

Secretion of bile acids and other potentially toxic compounds into the bile and blood may be stimulated by enhancing transporter expression and/or function at different levels, namely the levels of transcription, translation, targeting and protein activation.

In mice both cholic acid (CA) and UDCA stimulate the expression of Bsep and Mrp2 mRNA^[36]. One must, however, be aware that these findings may not hold true for men, because considerable species differences exist with regard to binding of bile acids to nuclear receptors and regulation of transporter expression by nuclear receptors. Rifampicin, a ligand of PXR, stimulates the expression of MRP2 at the transcriptional level in man^[37].

Ursodeoxycholic acid (UDCA) stimulates targeting of the transporters Bsep and Mrp2 to the canalicular membrane in the rat *via* at least two different signalling cascades^[38-40]. Immunoelectronmicroscopy with gold particles is employed to assess localization of Bsep in the canalicular membrane and in a subapical compartment of

rat liver. Bsep and Mrp2 in the canalicular membrane are markedly reduced when tauroolithocholic acid (TLCA) is administered in the perfused rat liver, but is maintained when tauroursodeoxycholic acid (TUDCA) is added^[38,40]. Enhanced expression of BSEP under UDCA treatment in men may contribute to a better elimination of bile acids from the blood. As shown by Poupon *et al*^[41], in collaboration with our group, UDCA decreases serum levels of the hydrophobic bile acid, chenodeoxycholic acid (CDCA) in PBC. As shown by Zollner *et al*^[41], expression of MRP2 mRNA and protein increases with the enrichment of UDCA in the liver during treatment of patients with PBC and UDCA. Accordingly, as shown by Poupon *et al*^[42], UDCA improves excretory function in PBC. Thus, in a randomised, placebo controlled study over two years, in patients with PBC, serum bilirubin was significantly lower in the UDCA group than in the placebo group.

Activation of transporters in the canalicular membrane by UDCA and phosphorylation may also occur^[43], which has not yet been sufficiently studied.

Stimulation of metabolism

Stimulation of the metabolism of hydrophobic bile acids produces more hydrophilic and less toxic compounds. Rifampicin, a drug used for the treatment of cholestatic pruritus, stimulates the expression of CYP3A4 mRNA in patients with gallstones. In line with this, Dilger *et al*^[44] showed that in patients with early stage PBC, rifampicin stimulates CYP3A metabolic activity as assessed by urinary 6 β -hydroxy cortisol, whereas UDCA has no effect.

Protection of cholangiocytes

Protection of cholangiocytes by making the bile more hydrophilic and less toxic appears to be an important therapeutic target. UDCA fulfils this requirement because it renders bile acid composition of bile more hydrophilic and increases biliary phospholipid secretion^[45].

Inhibition of apoptosis

Inhibition of apoptosis caused by elevated levels of hydrophobic bile acids^[46,47] may also be a therapeutic target in cholestasis. As shown by Rodrigues *et al*^[48,49], feeding of the hydrophobic bile acid deoxycholic acid (DCA) to rats increases hepatocyte apoptosis as assessed by the number of tunnel positive hepatocytes. Addition of UDCA inhibits this effect. Toxic bile acids such as CDCA can cause apoptosis of hepatocytes *via* the CD95 receptor with formation of a death inducing signalling complex (DISC) and activation of caspase 8. Caspase 8 then causes mitochondrial membrane permeability transition (MMPT) which leads to activation of effector caspases and apoptosis. In addition, UDCA stabilizes the mitochondrial membrane and inhibits MMPT and apoptosis^[48,49]. The antiapoptotic effect of UDCA has also been demonstrated in human hepatocytes^[50].

Inhibition of fibrosis

Inhibition of fibrosis may become an important

therapeutic target in the future. In the rat with common bile duct ligation, fibrosis can be inhibited by 6-ethyl CDCA (6-ECDCA). The antifibrotic effect of 6-ECDCA appears to be mediated *via* FXR and SHP^[51]. Recently, an antifibrotic effect of NOR-UDCA has been described in the Mdr2 knock-out mouse^[51]. It remains to be shown whether these findings are relevant to human cholestatic liver diseases, but they point towards a promising new way for the development of drugs to inhibit cholestatic fibrosis.

PHARMACOLOGICAL TREATMENT OF CHRONIC CHOLESTATIC LIVER DISEASES

In the following, primary biliary cirrhosis (PBC), the model disease for chronic cholestatic liver disease, is used as an example for the treatment of chronic cholestatic liver diseases by UDCA. PBC is characterized by an inflammatory lesion of interlobular bile ducts, which results in bile duct destruction and may progress to fibrosis and cirrhosis. Since the etiology of the disease is unknown, presently available therapies aim at inhibiting the underlying pathogenetic processes and delaying the progression of the disease.

The pathogenesis of this slowly progressive disease involves a still unknown immunologic injury of small interlobular bile ducts; aggravation of the bile duct lesion by cytotoxic bile acids; obstruction and loss of small bile ducts followed by cholestasis and retention of bile acids; hepatocyte injury, apoptosis, necrosis, fibrosis and eventually cirrhosis with liver failure.

UDCA, at present, is the only approved drug for PBC. It appears to exert its beneficial effects by rendering bile composition less toxic for the injured biliary epithelium, reducing the retention of bile acids in hepatocytes and inhibiting apoptosis^[10,34]. Immunosuppressive agents have met with limited success. They have been found useful in combination with UDCA in selected patients^[52,53].

In randomized, double-blind placebo-controlled trials UDCA at doses of 13-15 mg/kg body weight per day could improve serum liver tests including serum bilirubin and other serum markers of cholestasis^[42,54-56], the Mayo risk score^[56] and liver histology^[42,55]. As shown by Pares *et al*^[54] and Poupon *et al*^[57], UDCA inhibits histological progression in early stage PBC. As shown by Corpechot *et al*^[58], UDCA inhibits progression to severe liver fibrosis or cirrhosis in early stage PBC. In line with this is the observation that UDCA delays the onset of esophageal varices^[59]. A combined analysis of three of the largest trials showed that treatment with UDCA at doses of 13-15 mg/kg per day for up to 4 years can delay the time of liver transplantation or death^[60]. Within the first 2 years of treatment, however, a survival benefit was not seen. Doses lower than 10 mg/kg per day of UDCA are of little benefit in PBC^[61]. A meta-analysis of 8 randomized trials which showed no difference between UDCA and placebo in the effects on incidence of death, liver transplantation and death or liver transplantation^[62] has a number of shortcomings. In 6 of the 8 studies treatment was evaluated up to 24 mo only and the dose of UDCA was 10 mg/kg per

day or lower in two of the studies. Therefore, improvement of transplant free survival by UDCA as shown in the combined analysis of the three largest studies with doses of 13-15 mg/kg per day and a follow-up of 4 years may not have been detectable in this meta-analysis.

CONCLUSION

Better insight into the pathobiology of cholestasis has provided new concepts for pharmacological therapies of cholestatic liver diseases. Among those, therapy with UDCA has been studied most extensively. In PBC, the model disease for cholestatic liver diseases which has been highlighted in this review, the beneficial effects of UDCA have been documented by randomized controlled trials. Treatment with UDCA appears to be beneficial also in a number of other cholestatic disorders, such as primary sclerosing cholangitis (PSC)^[63-65], intrahepatic cholestasis of pregnancy^[66,67], liver disease in cystic fibrosis^[68-70], progressive familial intrahepatic cholestasis (PFIC)^[71] and some forms of drug-induced cholestasis^[10].

Abstract

Inflammatory bowel diseases, ulcerative colitis, and Crohn's disease, are chronic intestinal disorders of unknown etiology in which in genetically susceptible individuals, the mucosal immune system shows an aberrant response towards commensal bacteria. The gastrointestinal tract has developed ingenious mechanisms to coexist with its autologous microflora, but rapidly responds to invading pathogens and then returns to homeostasis with its commensal bacteria after the pathogenic infection is cleared. In case of disruption of this tightly-regulated homeostasis, chronic intestinal inflammation may be induced. Previous studies showed that some commensal bacteria are detrimental while others have either no influence or have a protective action. In addition, each host has a genetically determined response to detrimental and protective bacterial species. These suggest that therapeutic manipulation of imbalance of microflora can influence health and disease. This review focuses on new insights into the role of commensal bacteria in gut health and disease, and presents recent findings in innate and adaptive immune interactions. Therapeutic approaches to modulate balance of intestinal microflora and their potential mechanisms of action are also discussed.

INTRODUCTION

The continuous contact between commensal bacterial flora

and the single epithelial cell layer of the mucosal tissue is a characteristic feature of the gastrointestinal system. In particular, interaction between commensal bacteria and mucosal immune system plays an important role in keeping health and disease development. Inflammatory bowel diseases (IBD), ulcerative colitis (UC), and Crohn's disease (CD), are chronic intestinal disorders of unknown etiology in which in genetically susceptible individuals, the mucosal immune system shows an aberrant response towards luminal antigens such as dietary factors and/or commensal bacteria^[1]. The relation between a dysregulated bacterial ecosystem and mucosal inflammation in IBD has been demonstrated in a variety of clinical and basic literatures^[2-4]. For example, intestinal lesions of IBD predominate in the distal parts of the gastrointestinal tract where the commensal bacteria are most abundant. The presence of intestinal bacteria is essential for development of experimental colitis in several animal models, such as interleukin (IL)-10 gene knockout (KO) mice^[5], T cell receptor α -deficient mice^[6] and HLA-B27 transgenic rats^[7]. In CD, fecal stream diversion reduces gut inflammation and induces mucosal healing in the excluded intestinal segment, whereas infusion of intestinal contents rapidly induced flare-up of disease^[8].

The gastrointestinal tract has developed elaborate mechanisms to coexist with its autologous microflora, but rapidly respond to invading pathogens and then return to homeostasis with its commensal bacteria after the pathogenic infection is cleared. If these tightly regulated homeostatic mechanisms are disturbed, chronic intestinal inflammation may be induced^[9]. Previous studies demonstrated that some commensal bacteria are detrimental, and others have either no effect or have a protective action. In addition, each host has a genetically determined response to detrimental and protective bacterial species. Environmental and genetic factors modulate the relative balance of beneficial and detrimental bacterial species, suggesting that therapeutic manipulation of this balance can influence health and disease. This review focuses on new insights into the role of commensal bacteria in gut health and disease, and presents recent advances in therapeutic approaches to modulate imbalance of intestinal microflora in IBD patients.

THE INTESTINAL MICROFLORA IN HEALTH AND DISEASE

The gastrointestinal tract host a complex and dynamic microorganisms environment. Most members are from the

domain bacteria, but there are also representatives from archaea and eukarya, as well as virus^[10]. The intestinal habitat of an adult human individual contain more than 500 different species of bacteria, with 30-40 species comprising up to 99% of the total population^[10]. There is a progressive increase in the number of bacteria along the small bowel, from approximately 10^4 in the jejunum to 10^7 colony-forming units (CFU) per gram of luminal content at the ileal end, with predominance of gram-negative aerobes and some obligate anaerobes^[10]. Anaerobes are predominant in the colon, and bacterial counts reach around 10^{12} CFU per gram of luminal content. Bacteria contribute to 60% of the fecal mass. Individuals exhibit variation in the types and numbers of species within their microflora. Conventional culturing techniques could detect only ~30% of total bacteria in the gut^[11], but the use of molecular biologic techniques enhanced detection capability of numbers and diversity of microflora^[4,11].

Intestinal bacteria include native species that permanently colonize the tract and a variable set of microorganisms that transit temporarily through the gastrointestinal tract. Native bacteria are primarily acquired at birth and during the first year, but transient bacteria are being ingested continuously from the external environment. The fetal gut is sterile, and bacterial colonization, which is driven by contact between the infant and its environment, is influenced by the mode of delivery, hygiene levels and medications^[4]. At a few days after birth infant feces are rich in enterobacteria species, such as *E. coli* and *Bifidobacterium*, and these are soon influenced by feeding habits. Early colonization may also depend on genetic influences^[4]. The pattern appear to be determined in part by the host genotype, because similarity in fecal bacterial species is much higher within twins than in genetically unrelated couples who share environment and dietary habits^[10]. Intestinal microflora plays an essential role in the development of the gut immune system. Animals bred in a germ-free environment possess architectural abnormalities with crypt hyperplasia and lack of lymphoid follicle development. Immediately after exposure to microbes, the number of mucosal lymphocytes expands in the lamina propria and increases the number of IgA-secreting cells^[12,13].

Several studies using different methods have repeatedly demonstrated that the fecal microflora as well as metabolic activity differs between subjects with IBD and healthy controls^[14,15]. Recent molecular biology technique revealed that in CD patients the proportion of enterobacteria is increased^[16,17], and this finding is compatible with previous reports based in culture techniques^[14]. A large part of the dominant microflora (30%) was characterized in undefined phylogenetic groups, indicating a presence of major differences between CD and healthy individuals. Other studies confirmed that *Bacteroides vulgatus* was the only species shared by all CD patients in spite of unusual dominant species. From the results of analyses of mucosa-associated flora, Swidsinski *et al* found high concentrations of mucosal bacteria in patients with bowel inflammation, but not in controls^[18]. The concentrations of mucosal bacteria increased progressively with the severity of disease, both in inflamed and non-inflamed colon^[18]. They

log₁₀ numbers of organism/g tissue. Reproduction from reference 20.

hypothesize that the healthy mucosa is capable of holding back fecal bacteria and that this function is profoundly disturbed in patients with IBD. These observations are compatible with the report by Kleessen *et al*^[19]. They demonstrated that more bacteria were detected on the mucosal surface of IBD patients than on those of non-IBD controls^[19]. Bacterial invasion of the mucosa was evident in colonic specimens from the UC patients, in the ileal and the colonic specimens from the CD patients, but no bacteria were detected in the tissues of the controls. Colonic UC specimens were colonized by a variety of organisms, such as bacteria belonging to the gamma subdivision of *Proteobacteria*, the *Enterobacteriaceae*, the *Bacteroides/Prevotella* cluster, the *Clostridium histolyticum/Clostridium lituseburense* group, the *Clostridium coccoides/Eubacterium rectale* group, high G + C Gram-positive bacteria, or sulphate-reducing bacteria, while CD samples harbored mainly bacteria belonging to the former three groups. Previously, we also reported that the bacterial counts for both aerobes and anaerobes increased in UC patients^[20]. In particular, we detected the highest bacterial counts of *Bacteroides vulgatus* (Table 1). A high agglutination titer against *B. vulgatus*, *B. fragilis*, and *C. ramosum* was detected in most UC patients, and the percentage of positive immunoreactivity was much higher in UC patients than in healthy controls. The serum immunoreactivity (IgG) against 26-kDa protein derived from *B. vulgatus* outer-membrane was much higher in UC patients (53.8%) than in the control sera (9.1%) (Figure 1). These results suggest that *B. vulgatus* and a specific antibody response directed against it may play an important role in the pathogenesis of UC^[20].

MUCOSAL RESPONSE TO LUMINAL BACTERIA

General background

The search for specific pathogens that trigger intestinal inflammation failed to produce conclusive results^[21]. Instead, it has been found that reconstitution of germ-free mice with commensal bacteria can be enough to induce IBD in several gene-deficient as well as T cell

Figure 1 Western blot analysis of serum antibodies (IgG) against outer-membrane antigens of *Bacteroides vulgatus* isolated from an IBD patient. The arrow indicates specific band. Reproduced from reference 20 with permission.

transfer models of IBD in mice^[22-25]. Therefore, instead of a specific pathogen, a broad spectrum of bacteria may contribute to the induction of intestinal inflammation. Although metabolically active microbial cells and cell wall components, such as lipopolysaccharide (LPS) and peptidoglycan, present and contact to the host intestinal mucosa, pro-inflammatory responses are absent in the mucosa exposed to the resident luminal microflora. In contrast, the capability to respond to luminal pathogenic bacteria through recruitment of inflammatory cells from systemic circulation is remaining. The probable mechanisms underlying these responses are explained by the standpoints of innate and adaptive immune response^[26]. In the intestine, components of innate immunity are preexisting or rapidly activated, resulting in induction or regulation of the highly specific adaptive immune responses.

Recently, novel functions of mucosal dendritic cells (DC) have been reported. Dendritic cells are critical to innate and adaptive immunity as specialized antigen-presenting cells. Hendrik *et al* showed that lamina propria DCs form transepithelial dendrites which enable the cells to directly sample antigens, such as commensal bacterial components^[27]. It is likely that DCs take up directly intestinal antigens through transepithelial dendrites and activate an innate immune pathway that protects the mucosa from pathogenic bacteria.

Toll-like receptors and their signaling

Highly conserved structures of pathogenic and commensal bacteria, designated MAMPs (microbe-associated molecular patterns), are recognized by pattern-recognition receptors, such as TLR (Toll-like receptor)^[28-30]. TLRs comprise a family of pattern-recognition receptors that detect conserved molecular products of microorganisms, such as LPS and lipoteichoic acid (LTA), recognized by TLR4 and TLR2, respectively. TLRs are expressed both in epithelial cells and in phagocytic cells, thus functioning as sensors of microbial infection. They are critical to initiation of inflammatory and immune defense responses. The bacterial ligands recognized by TLRs are not unique

to pathogens, but are rather shared by entire classes of bacteria, and are produced by commensal bacteria as well. However, it remains unclear how the host distinguishes between pathogenic and commensal bacteria. Two major pathways are activated by TLRs^[28,30-32]. The first culminates in activating the transcription factor NF- κ B, which acts as a master switch for inflammation. It regulates the transcription of many genes that encode proteins involved in immunity and inflammation. The second leads to activation of MAP kinases p38 and Jun amino-terminal kinase (JNK), which also participate in increased transcription and regulate the stability of mRNAs that contain AU repeats. With the exception of TLR3, all TLRs activate NF- κ B and MAP kinases *via* a pathway that involves MyD88, IRAK (IL-1 receptor associated kinase)-4 and IRAK-1^[30]. There are specific differences in the ultimate gene expression profile that results from the activation of individual TLRs, although the precise mechanisms are unclear. A set of adaptor proteins that are differentially recruited to TLRs may be involved in the molecular basis of this specific gene induction^[33].

MyD88 is an adaptor protein for TLRs, and similar to TLRs, it has a Toll-IL-1 receptor (TIR) domain^[30-32,34]. Signaling may be initiated by recruitment of MyD88 to TLRs through TIR-TIR interactions. Interaction between MyD88 and TLRs leads to the recruitment of IRAK-4. IRAK-4 becomes activated and is phosphorylated to IRAK-1, resulting in activation of TRAF6^[34]. TRAF6 activation results in activation of NF- κ B and MAP kinases. Other proteins, such as Tollip, ECSIT, Pellinos, MEKK1 and MEKK3 have also been implicated in this pathway.

Recently, two different groups reported that MyD88-deficient mice reveal an increased susceptibility to dextran sodium sulfate (DSS) colitis^[35,36]. MyD88-deficient mice showed an increased mortality and morbidity, as well as aggravation of colitis, following DSS administration. In MyD88-deficient mice, mucosal proliferative zone was expanded and number of proliferating cells increased, indicating dysregulated proliferation and differentiation of intestinal epithelium. Interestingly, similar responses were also observed in TLR2- and TLR4-deficient mice. Increased susceptibility to intestinal injury in MyD88-deficient mice was accompanied with defective production of cytoprotective and reparative factors, such as IL-6, TNF, KC-1 and heat-shock proteins^[36]. These findings indicate that TLR signaling *via* the MyD88-dependent pathway conferred protection from the mortality, morbidity and colonic damage caused by the administration of the injurious agent DSS. Since DSS is capable to induce severe morbidity and mortality in wild mice where commensal microflora had been depleted by antibiotics, Authors have concluded that recognition of commensal microflora by TLRs is required for keeping intestinal homeostasis.

Several mechanisms have been proposed to explain how the epithelium discriminates pathogens from commensals in order to trigger TLR signaling. Although they express similar MAMP, pathogens differ from commensals mainly in their ability to colonize host mucosal surfaces and invade the host. Differences attributed to the differential expression of adhesion molecules. Recently-proposed speculation is that in the gut, the commensal-specific

TLR/MyD88 pathway permits the symbiotic relationship between the microflora and the host, while pathogen-specific virulence factors are required to trigger pro-inflammatory responses *via* the usage of additional TLR co-receptor and/or adaptor molecules for disease-causing organisms^[29,37].

NOD2/CARD15

The putative intracellular peptidoglycan receptor NOD2 (CARD15) is a member of the Apaf-1/CARD superfamily and is composed of an N-terminal caspase recruitment domain (CARD), a centrally located nucleotide-binding oligomerization domain (NOD) and 10C-terminal-located leucine-rich repeats (LRRs)^[38,39]. NOD2 was found to be expressed in antigen-presenting cells such as monocytes/macrophages, but more recent studies revealed abundant presence of NOD2 in epithelial Paneth cells of the small intestine as well as in other epithelial cells^[39,40]. NOD2 has been shown to recognize intracellular peptidoglycan fragments (e.g. muramyl dipeptide, MDP) through its LRR region leading to pro-inflammatory responses through activation of NF- κ B. NOD2 serves as an intracellular pattern recognition receptor to enhance host defense by inducing the production of antimicrobial peptides such as human beta-defensin-2^[39].

Several studies have shown that mutations in the LRR region of NOD2 are associated with susceptibility to Crohn's disease^[41]. The molecular mechanisms by which mutations in the NOD2 gene cause Crohn's disease are still emerging. However, it is supposed that decreased production of antimicrobial peptides, such as defensins, may promote bacterial-mediated inflammation in Crohn's disease^[39]. Recent study demonstrated that NOD2 mutation in CD potentiates NF- κ B activity and IL-1 β processing, suggesting initiation and/or promotion of mucosal inflammation^[42].

THERAPEUTIC STRATEGIES TARGETING MICROFLORA IN IBD

IBD continues to be an enigmatic disorder with obvious potential to improve therapeutic target and outcomes^[43]. Established therapies for IBD include the aminosalicylates, corticosteroids, and immunosuppressive drugs. An increasing number of novel and alternative therapeutic approaches are in progress^[43]. New biologic therapies include the targeting of proinflammatory cytokines, enhancement or infusion of anti-inflammatory cytokines, blocking intravascular adhesion molecules, and modifying T-cell functions. Recently, therapeutic approaches to modifying intestinal microflora have been attempted by using prebiotics and probiotics. In addition, antibiotic therapies continue to be used^[2,44-47].

Prebiotics

Prebiotics are nondigestible food constituents that benefit the host by selectively stimulating the growth or activity of one or a limited number of bacterial species already resident in the colon^[2]. Some examples of prebiotics are dietary fiber and some types of oligosaccharides. Intake of

prebiotics can significantly alter the colonic microflora by increasing the populations of certain bacteria and thereby quantitatively changing the composition of the microflora^[48,49]. These alterations may act beneficially, in part, by causing a luminal reduction of short-chain fatty acids (SCFAs), which are both important nutrients for the intestine and inducers of an acidic environment^[47,49-52]. Among the SCFAs, butyrate most effectively protects intestinal mucosa against injury and promotes mucosal healing^[49,53].

Lactosucrose: Lactosucrose, an indigestible oligosaccharide, is a water-soluble dietary fiber with the potency of modulating microflora. Ohkusa *et al* reported that a daily 6-gram intake of lactosucrose significantly increased the percentage of *Bifidobacterium* sp and the total number of bacteria in healthy subjects^[54,55]. The treatment also reduced fecal ammonia levels but had no effect on fecal SCFA, pH, and water content. It has been reported that an elemental diet or low-fat, low-residual diet decreases anaerobic bacteria and changes the composition of microflora in IBD patients. Teramoto *et al* showed that the continuous administration of lactosucrose for 2 wk led to an increase of *Bifidobacterium* and a decrease of *Bacteroidaceae* in patients with IBD^[55].

Oligofructose and inulin: Inulin and oligofructose are comparable to dietary fiber in that they are composed of multiple saccharide units, which are indigestible by the enzymes in mammalian small intestine. The saccharide chain in inulin is longer than in oligofructose. Inulin and oligofructose show similar physiological functions in the intestine. It is generally recognized that inulin stimulates the generation of butyrate and the growth of lactic acid bacteria (LAB) in the colons of healthy subjects^[50,56]. Videla *et al* examined the efficacy of inulin in a dextran sodium sulfate (DSS)-induced colitis model, demonstrating that it significantly attenuates inflammation as assessed by mucosal damage and both colonic eicosanoid and myeloperoxidase concentrations^[50]. The treatment also led to an increase of *Lactobacillus* and a decrease of luminal pH and fecal water content. To our knowledge, no clinical trials to confirm the benefit from either inulin or oligofructose have been performed.

Bran: The laxative effect of wheat bran has long been recognized. Although not potent, bran is used widely because of its harmlessness. A Swedish group examined the effect of wheat bran supplementation on the composition of fecal bile acid and microflora in juvenile patients with UC. Although the clinical activity was not described, wheat bran significantly decreased the number of *Bacteroides* and the concentration of total and unconjugated bile acid^[57,58].

Psyllium: Psyllium, also called Ispaghula husk or *Plantago ovata*, is a water-soluble dietary fiber. Buhman *et al* suggested that psyllium has a hypocholesterolemic effect, based on its hydrocolloid, a gel-forming potency^[59,60]. Feeding of psyllium significantly decreases the cholesterol content as well as the cholesterol 7- α hydroxylase activity in the rat liver. Hallert *et al* published the first report describing the clinical efficacy of psyllium in patients with UC^[61]. Psyllium significantly attenuates clinical symptoms compared with placebo treatment. After this first report was published, a large-scale clinical trial was organized in UC patients by Fernandez-Banares *et al*^[62]. In this trial, they

found no significant differences in the remission periods of patients given psyllium treatment and patients given sulfasalazine treatment, although there was an increase in fecal butyrate in the psyllium patients. The authors therefore concluded that psyllium may be as effective as sulfasalazine in maintaining remission in patients with CD.

Germinated barley foodstuff (GBF): GBF, which is derived from the aleuronic layer and scutellum fractions of germinated barley, consists mainly of dietary fiber and glutamine-rich protein^[47,48,51,52]. The fiber fraction of GBF consists mainly of low-lignified hemicellulose, which has a large water-holding capacity^[63]. GBF contains glutamine, which is another important nutrient for epithelial cells^[47,48,52,63]. In germination process, GBF obtains these two unique characteristics of being a glutamine-rich protein and having a conspicuous water holding capacity^[64]. In the intestinal lumen, the dietary fiber fraction of GBF is utilized efficiently by *Bifidobacterium* or *Lactobacillus* and converted to lactate and acetate. Coexistence of *Bifidobacterium* and *Eubacterium limosum* increases butyrate production from GBF^[65,66]. The endogenous bacterial butyrate produced from GBF is immediately absorbed by the intestinal epithelial cells and utilized by them as an efficient fuel. The water holding capacity of GBF is much higher than other representative water-insoluble dietary fibers, for example, wheat bran, cellulose powder, and sugar beet fiber.

Treatment of rat DSS colitis with GBF in a preventive mode led to a significant improvement of the clinical and pathological signs of colitis and a decrease in serum IL-8 and alpha 1-acid-glycoprotein^[64]. The improvements were associated with an induction of luminal butyrate and beneficial organisms, such as *Bifidobacterium* and *Eubacterium*. In a therapeutic mode, GBF was comparably effective against mucosal inflammation and more effective against diarrhea when compared with sulfasalazine^[64]. The anti-inflammatory action of GBF was markedly reduced by the concomitant administration of SCFA β -oxidation inhibitor (ibuprofen) and GBF, indicating a butyrate-dependent anti-inflammatory mechanism^[67]. In addition to its role as a preferential nutrient for colonocytes, the butyrate also acts as an anti-inflammatory agent by functionally inactivating nuclear factor- κ B^[68]. Of the GBF constituents, the fiber fraction, but not its protein fraction, drastically mitigated mucosal damage with an increase of luminal butyrate. GBF significantly increased the number of *Eubacterium* and *Bifidobacterium*, with a concomitant decrease in luminal pH. In the HLA-B27 transgenic rat, a representative model of spontaneous colitis, GBF improves the clinical and pathological signs of colitis with an increase in luminal butyrate levels^[69].

The first trial enrolled 10 patients with mild to moderately active UC who had been unresponsive to or intolerant of standard treatment^[70]. The patients consumed 30 g of GBF 3 times daily for 4 wk in a nonrandomized, open-label fashion. At 4 wk, treatment with GBF resulted in clinical and endoscopic improvement with an increase in fecal butyrate. Despite continued treatment with standard drugs, the patients had an exacerbation of the disease within 4 wk after discontinuing GBF treatment. A subsequent multicenter trial with 28 patients conducted in the same fashion showed a similar benefit from GBF. Eighteen pa-

tients with mild to moderately active UC were divided into two groups using a random allocation protocol. The control group ($n = 7$) were given a baseline anti-inflammatory therapy, and the GBF-treated group ($n = 11$) received 20 to 30 g of GBF daily together with the baseline treatment. After 4 wk of observation, the GBF group showed a significant decrease in clinical activity index scores compared with the control group. No side effects related to GBF were observed^[48]. GBF increased fecal concentrations of *Bifidobacterium* and *Eubacterium limosum*. Twenty-one patients with moderately active UC patients were treated with 20-30 g/d of GBF for 24 wk. GBF significantly reduced clinical activity as compared to the control group^[52]. Furthermore, GBF prolonged remission in UC patients^[51].

Probiotics

In the intestinal lumen of IBD patients, balance between commensal and detrimental bacteria has been broken down with secondary harm on immune system activities. However, the changes in microbiotic composition may be transient; and implantation of exogenous bacteria will have a limited applicability^[2,44,46]. Probiotics are live microorganisms administered to alter the intestinal microflora and confer a beneficial effect on health^[2]. Potential mechanisms of probiotic action include competitive interactions, production of antimicrobial metabolites, influences on the epithelium, and immune modulation^[2,44,46]. However, such changes may be transient, and therefore the implantation of exogenous bacteria has a limited usefulness at present. Restoring the microbial balance using probiotics may be the most physiologic and non-toxic way to prevent and treat IBD.

VSL#3: IL-10 knockout mice develop colitis when they are raised under conventional facilities but not under germ-free conditions. Prior treatment of IL-10 knockout mice with antibiotics prevented the subsequent onset of colitis, suggesting that the exposure to intestinal bacteria during the neonatal period influences later disease progression. The use of VSL#3, a probiotic preparation containing three strains of *Bifidobacterium*, four strains of *Lactobacilli*, and one strain of *Streptococcus salivarius* ssp. *thermophilus* completely normalized the physiological transport function and barrier integrity and also inhibited mucosal TNF α and IFN γ production^[71]. *In vitro* studies showed that epithelial barrier function and resistance to Salmonella invasion could be enhanced by exposure to a proteinaceous soluble factor secreted by the bacteria found in the VSL#3 compound^[72]. There are increasing number of reports describing anti-inflammatory effects of VSL#3^[46].

In a clinical trial, daily administration of VSL#3 prevented relapse of chronic pouchitis after induction of remission by antibiotics. Moreover, every patients relapsed within 3 mo of stopping VSL#3^[73]. These were replicated^[74,75], and prospective study was performed^[76]. In this study, 2 of 20 patients (2%) receiving VSL#3 for one year developed pouchitis versus 40% of placebo-treated patients. Uncontrolled pilot studies have indicated that VSL#3 maintained remission of UC in 75% of patients over 12 mo^[73,77]. The results showed that this probiotic preparation could colonize the intestine, and might be useful in maintaining remission in UC. As another study, 32

ambulatory patients with active UC received open label VSL#3, 3600 billion bacteria daily in two divided doses for 6 wk. Treatment of patients with mild to moderate UC, not responding to conventional therapy, with VSL#3 resulted in a combined induction of remission/response rate of 77% with no adverse events. At least some of the bacterial species incorporated in the probiotic product reached the target site in amounts that could be detected^[78].

Nissle1917: Previous trials have examined the efficacy of a non-pathogenic strain of *Escherichia coli* originally called Nissle1917. In the first pilot study, capsules containing this strain of *E coli* were compared with a placebo for the maintenance of prednisolone-induced remission of colonic CD^[79]. After 12 wk of treatment, there was no significant difference between the Nissle and control groups. Rembacken *et al* described a single-center trial in which 116 patients with UC were randomized to receive either mesalazine or this non-pathogenic *E coli* strain^[80]. Initial responses to treatment were similar, with remission being noted in 75% and 68% of those receiving mesalazine and *E coli*, respectively. Even more impressive were the maintenance benefits; respectively, 73% and 67% of patients remained in remission for 12 mo^[80].

***Clostridium butyricum*:** Araki *et al* reported that the anti-colitis effect of Japanese microbial preparation (MIYA-IRI-588) was examined in a dextran sulfate sodium (DSS)-induced rodent colitis model^[81]. This preparation itself did not display any therapeutic effect. Another probiotic mixture (*Lactobacillus*, *Clostridium butyricum* and *Streptococcus faecalis*; Biothree: Towa Kasei Co., Ltd, Tokyo, Japan) was also evaluated in a DSS colitis model, by Fukuda *et al*^[82]. Although the benefits on colon histology were not significant, diarrhea was significantly decreased by treatment in comparison to the control group^[66]. Further trials in patients with IBD would be desirable.

***Bifidobacterium*-fermented milk:** The preventive effect of lactic acid bacteria (LAB - *Bifidobacterium breve*, *Bifidobacterium bifidum* and *Lactobacillus acidophilus*)-fermented milk was determined in SAMP1/Yit mice^[83]. Administration of LAB-fermented milk to mice reduced histological injury scores, compared with those in saline-treated or unfermented milk-treated mice. Treatment with LAB-fermented milk also reduced ileal tissue weight and myeloperoxidase activity. Moreover, the tissue contents of immunoglobulin such as IgG1 and IgG2a were lower in the inflammatory regions in the LAB-fermented milk-treated group than in the control group. A decreased release of IFN- γ and TNF- α with an increase of IL-10 from mesenteric lymph node cells were observed in the LAB-fermented milk treated group.

***Lactococci*-secreting IL-10:** Steidler *et al* described the use of transgenic *Lactococcus lactis* capable of secreting bioactive IL-10 in both the DSS and IL-10 knockout models of colitis^[84,85]. The authors observed an inhibition of spontaneous colitis development in IL-10 knockout mice that was mediated by relatively low concentrations of the *Lactococcus*-borne cytokine. These experiments provide the basis for the use of genetically modified organisms designed for delivery of biologically relevant therapeutic molecules.

Synbiotics

A synbiotic is a combination of one or more probiotics and prebiotics^[86-88]. Prebiotics may enhance the survival of probiotic strains, as well as stimulating activity of the host's endogenous bacteria. Bengmark suggests that clinical effects vary from modest effects to significant effects as one goes from single-strain of probiotics < multistrain probiotics < or - < single-strain/single fiber synbiotics < multistrain/multifiber synbiotics^[87]. Kanamori *et al* reported that combination therapy with *Bifidobacterium breve*, *Lactobacillus casei*, and galactooligosaccharides dramatically improved the intestinal function in a girl with short bowel syndrome^[89]. Roller *et al* demonstrated that combination of oligofructose-enriched inulin combined with *Lactobacillus* and *Bifidobacterium* suppressed colon carcinogenesis by modulating functions of gut-associated lymphoid tissue^[90]. They also reported that same synbiotic formula stimulated secretion of secretory-IgA and IL-10 production in the cecum^[91]. A symbiotic preparation of *Bifidobacterium* combined with galacto-oligosaccharides protects against *Salmonella* infection in mice^[92]. Thus, synbiotics modulate mucosal immune responses and exert anti-inflammatory effects. We are not aware of any trial design to evaluate potential benefit of synbiotics in IBD patients.

Antibiotics

A few trials of antibacterial agents have been conducted in UC with controversial results. Oral vancomycin and intravenous metronidazole were not beneficial in active UC both as single or adjunctive given therapy^[93,94]. Tobramycin, a nonabsorbable, gram-negative specific antibiotic, induced a significant improvement in the short term compared to placebo in UC. However, the improvement was lost at long term follow-up. In addition, the association of tobramycin and metronidazole did not implement the outcome in patients with severe UC treated by conventional therapy (steroids)^[95]. In a double-blind placebo-controlled trial run on a small sample, the use of rifaximin (a nonabsorbable, wide-spectrum antibiotic) led to a significant improvement in both clinical and endoscopic activity^[96].

A more definite role for antibiotics in UC is in the treatment of pouchitis, where conditions are favourable to bacterial overgrowth^[2]. It has been suggested that anaerobes induce pouch inflammation, but some investigators have found a relative increase of aerobic bacteria in pouchitis. In pouchitis, *Bacteroides* species are present in low numbers, whereas *E coli* numbers are increased, but not correlated with the degree of inflammation. Luminal pH is increased, enhancing proteolytic enzyme activity and mucin degradation. Current data suggest that dysbiosis of luminal organisms contributes to pouch inflammation in a susceptible host. Treatment with metronidazole, ciprofloxacin and/or rifaximin leads to a significant decrease of the total number of the following anaerobes and aerobes in fecal samples: *Enterococci*, *Lactobacilli*, *Bifidobacteria*, and *Bacteroides*^[96].

Antibiotics are largely used in clinical practice for treating active CD and provide more satisfactory results. Controlled trials have supported this treatment^[97,98]. In a placebo-controlled trial, both low-dose (10 mg/kg per day)

and high-dose (20 mg/kg per day) metronidazole were more effective than a placebo in colonic CD. In a controlled trial to study the combination of metronidazole and ciprofloxacin versus methylprednisolone for active CD, after 12 wk there was no statistically significant difference in remission rates of the two groups. More recently, ciprofloxacin was shown to be effective as mesalazine in inducing remission in patients with active CD. Antibiotics do have a role in at least a subset of cases; but we must keep in mind that treatment with antibiotics may have some disadvantages, such as non-specific effect on the enteric flora, the possibility of inducing an antibiotic resistance, and the risk of *Clostridium difficile* superinfection.

In conclusion, the pathogenesis of IBD may be associated with imbalance in the intestinal microflora with a relative predominance of "aggressive" bacteria and paucity of "protective" organisms. Manipulation of the intestinal flora may represent a highly physiologic, nontoxic way to prevent and treat IBD. Although these strategies appear promising and may be actually useful in specific settings, more studies are needed to establish the relevance of these therapies.

Abstract

Living donor liver transplantation (LDLT) is an alternative therapeutic option for patients with end-stage hepatitis C virus (HCV) cirrhosis because of the cadaveric organ shortage. HCV infection is now a leading indication for LDLT among adults worldwide, and there is a worse prognosis with HCV recurrence. The antiviral strategy after transplantation, however, is currently under debate. Recent updates on the clinical and therapeutic aspects of living donor liver transplantation for HCV are discussed in the present review.

INTRODUCTION

The use of live donors for liver transplantation was initiated more than a decade ago as a solution to the cadaveric donor shortage for pediatric recipients^[1]. After the first successful case in an adult patient in 1994^[2], this procedure is now widely applied to adult recipients, especially in countries where the availability of brain-dead donors is severely restricted^[3] and also in the United States and European countries, due to a critical shortage

of cadaveric organs. Improved surgical techniques and the introduction of new immunosuppressive agents have enhanced the long-term results of living donor liver transplantation (LDLT), leading to an increased demand for liver transplantation that exceeds the number of potential donor organs. In initial experiences with adult LDLT in Japan, the most common indication was cholestatic liver disease, including primary biliary cirrhosis and primary sclerosing cholangitis in Japan. The number of LDLT patients indicated for hepatitis C virus (HCV) has recently increased rapidly.

A recent study^[4] of deceased donor liver transplantation (DDLT) reported that HCV infection was associated with a 23% increase in mortality and a 30% increase in the rate of graft failure. The poor results might be due to the recurrence of HCV disease in the graft^[5]. HCV-induced graft hepatitis and fibrosis/cirrhosis occur in 75% to 80% and 10 % to 30% of recipients, respectively, at 5 years^[6,7]. Once liver cirrhosis is established, the cumulative probability of developing clinical decompensation is close to 50% after 1 year and survival after decompensation is extremely short^[8]. Cholestatic hepatitis occurs in approximately 10% of patients infected with HCV and leads to accelerated graft failure and death^[9]. One of the hottest debates is the possibility of increased severity of recurrent HCV in LDLT patients. The benefit of LDLT might be offset if the outcome of LDLT for HCV patients is worse than that of DDLT. In this review, we describe current trends and controversies in LDLT for patients with HCV. Our results for LDLT and HCV are also reported.

CURRENT STATUS OF LDLT

According to the Japan Liver Transplantation Society^[10], the number of adult patients (≥ 18 years old) is increasing annually, and has reached 300 in 2003. The most common indication for adults has been hepatocellular carcinoma ($n = 311$), followed by primary biliary cirrhosis ($n = 255$), and HCV-related cirrhosis without carcinoma ($n = 113$). The 1, 3, and 5 year survival rates of all the adult patients were 76%, 72%, and 69%, respectively. Those of HCV-positive patients were 76%, 73%, and 65%, respectively.

In the United States in 2000, there was a high level of enthusiasm for adult LDLT, with 49 centers performing at least one LDLT. Overall, in experienced centers, about a third of adults on the waiting list had a potential living donor and half of them had undergone LDLT; thus, LDLT might be applicable for up to 15% of individuals on the list^[11]. The enthusiasm was, however, quickly tempered

Table 1 Comparison between LDLT and DDLT for hepatitis C virus cirrhosis

Study	Author	Year	Institution	N		Dif ¹	Protocol biopsy	Findings
				LDLT	DDLT			
Gaglio ^[23]		2003	Colombia U.	23	45	Yes	No	Cholestatic hepatitis in 17% of LDLT and 0% of DDLT ($P = 0.001$). No significant difference in incidence of Rec.
Shiffman ^[28]		2003	Virginia Commonwealth U.	22	53	No	Yes	79% patient survival in LDLT and 91% in DDLT during 3 year (NS). No significant difference in inflammation score in liver specimen after 3 years
Russo ^[29]		2004	UNOS data	279	3955	No	No	87% 1-year patient survival in both.
Thuluvath ^[30]		2004	UNOS data	207	408	No	No	No significant difference in patient survival ($P = 0.6$).
Van Vlierberghe ^[32]		2004	Ghent U.	17	26	No	No	Rec in 35% of LDLT and 38% of DDLT during 1 year ($P = 0.1$)
Bozorgzadeh ^[34]		2004	Rochester U.	35	65	No	No	Rec in 77% of LDLT and 72% of DDLT during 1 year (NS), 89% patient survival in LDLT and 75% in DDLT during 39 mo (NS)

¹ Difference in short-term outcomes or severity of virus recurrence between living and deceased donor liver transplantation. Abbreviations: Rec, Virus recurrence; U, University; NS, not significant; UNOS, United Network for Organ Sharing.

by the death of a donor in 2002 in the United States^[12]. Since 2001, the number of patients who have undergone LDLT has declined^[13]. Currently less than 5% of all adult liver recipients use living donors. By July 2005, 2734 LDLT cases had been performed. There were 1761 adult patients and HCV was the most common indication. HCV is the most common indication for LDLT^[14] and the number of HCV-positive patients is stable, approximately 100 per year between 2000 and 2002.

By the end of 2003, 1743 LDLT cases were recorded in the European Liver Transplantation Registry^[15]. According to the Transplant Procurement Management^[16], the number of LDLT peaked in 2003 and has gradually decreased over recent years. LDLT accounts for approximately 5% of the total liver transplants performed in Europe. Among the 806 LDLT cases from October 1991 to December 2001^[17], the overall 5-year graft survival rate was 75%, better for children than for adults (80% *vs* 66% at 3 years). Cirrhosis secondary to HCV infection is a leading indication for LDLT among adults in Europe^[18]. The number of LDLT patients is shown in the Table 1.

INDICATIONS

In areas with low deceased donor organ availability, the indications for LDLT are similar to those for DDLT. In contrast, in Western countries, LDLT is conducted in an attempt to alleviate the shortage of donor organs and to decrease the mortality among the patients awaiting transplants. That is, a balance needs to be achieved between the candidate's liver disease severity and the adequacy of a partial graft for transplantation. The candidate's liver disease should be advanced to the extent that transplantation is justified, but the liver disease cannot be so advanced that a partial graft will not provide adequate hepatic mass.

According to Russo's report^[19] a substantial proportion of patients were United Network for Organ Sharing (UNOS) status 3 at the time of LDLT (43%). The policy at their centers prior to the implementation of a model for end stage liver disease (MELD)-based allocation was not to proceed with LDLT in patients meeting UNOS status 2A criteria. Their patient survival rate was 57% with an average stay of 23 d in the intensive care unit. In

comparison, 1-year patient survival was 82% in DDLT recipients who were UNOS status 2A at the time of transplant^[20].

The waiting list mortality increases in patients with advanced liver disease and patients with a MELD score of 25 have a 20% 3-mo mortality^[21]. In general, it is uncommon to proceed with LDLT in patients with MELD scores above 25. Thus, depending on the region of the country and the average MELD score at the time of the transplant within the area served by the organ procurement organization, LDLT might offer patients transplantation before they die waiting for a deceased donor liver. The lower MELD score limit with LDLT is more controversial and varies from center to center. Russo^[19] commented that they do not proceed with LDLT in candidates with MELD scores under 11.

LDLT AS A RISK FACTOR FOR RECURRENCE OF HCV

One study from Barcelona^[22] reported that LDLT patients ($n = 22$) had younger donors, less graft steatosis, more frequent biliary complications, and earlier and more severe acute hepatitis compared with DDLT ($n = 95$) patients. A report from Colombia University^[23] indicates that cholestatic hepatitis or severe HCV recurrence occurs more frequently in LDLT. These reports indicate that more intensive antiviral therapy might be necessary for recipients of living donor grafts.

The possible causes of HCV recurrence include HLA matching between donor and recipient. Because cellular immune reactions restricted by both HLA class I and II antigens are involved in the recognition of HCV peptides^[24], HLA matching between donor and recipient could potentially increase damage to the graft from recurrent viral infections by facilitating host recognition of viral antigens^[6]. Recently, a beneficial effect of a complete HLA-DQ mismatch was reported in 14 patients after transplantation for HCV cirrhosis^[25]. Another possible cause might be related to liver regeneration^[26], although recent data^[27] did not support this hypothesis. *In vitro*, HCV internal ribosome entry site activity and replication are higher in actively dividing cells, and it is possible that

viral translation is enhanced by factors that stimulate the regeneration of hepatocytes. Moreover, there are experimental data suggesting that liver regeneration induces low density lipoprotein receptor expression, which might facilitate HCV entrance into the hepatocytes.

In contrast, comparable data between LDLT and DDLT for HCV was recently reported^[28]. Russo and colleagues^[29] compared patient and graft survival in recipients transplanted for chronic HCV who received a living donor organ ($n = 279$) and deceased donor organ ($n = 3955$) using the UNOS liver transplant database. One-year patient survival was 87% in both groups and 2-year patient survival was 83% and 81% in the living donor group and deceased donor group ($P = 0.68$), respectively. Similar results (DDLT, $n = 480$ vs LDLT, $n = 207$) were obtained from another analysis using the UNOS data base^[30]. Analyses from the Mayo Clinic^[31] and Gent University^[32] also demonstrated no negative impacts of LDLT on the results of liver transplantation for HCV-related cirrhosis.

These data should be interpreted with caution, however, because of the important clinical distinction between LDLT and DDLT recipients. At the time of transplantation, the LDLT group recipients are far less sick than their DDLT group counterparts^[33]. The LDLT ($n = 35$) and DDLT ($n = 65$) data from a single institution, Rochester University, were examined^[34]. Patient survival, graft survival, rate of HCV recurrence, severity of HCV recurrence, graft loss from HCV, and interval for HCV recurrence in DDLT and LDLT were similar. It remains unclear, however, whether LDLT is truly disadvantageous compared to DDLT for HCV-positive patients because the number of cases or follow-up duration is not yet sufficient.

According to the data from Russo^[29], from 1999 to 2000, the 1-year patient survival in the LDLT group increased from 69% to 90% ($P = 0.04$), and 1-year graft survival increased from 63% to 79% ($P = 0.16$). In contrast, in the DDLT group, 1-year patient and graft survival did not substantially change from 1999 to 2000. As a result, 1-year survival rates became similar between the LDLT and DDLT groups in 2000. The results indicated an experience effect and learning curve on outcomes after LDLT for HCV. Therefore, the initial reports indicating poorer results of LDLT might be due to technical problems from a lack of experience. Recent data indicating similar results between LDLT and DDLT might be due to the increased experience with LDLT. The multicenter adult to adult LDLT cohort study (A2ALL) might soon provide some answers to the questions about recurrent HCV after LDLT and DDLT^[35].

MANAGEMENT OF HCV

Therapy for recurrence in DDLT

If HCV recurs earlier and more severely after LDLT, a specific strategy for preventing the detrimental effects of HCV on living donor grafts must be developed. One strategy might be aggressive treatment for HCV. Treatment of recurrent HCV disease with interferon and ribavirin after DDLT is used in some centers^[36-38]. One standard regimen includes interferon- α 2b ($3 \text{ MU} \times 3$

per week) and ribavirin (1000 mg/d) for 6 mo. In a recent trial, polyethylene glycol-conjugated interferon therapy was used^[35,38-43], with a sustained viral response rate ranging from 13% to 47%.

Preemptive therapy for HCV after DDLT

Preemptive therapy in the early post-transplantation period with interferon either alone or in combination with ribavirin has been attempted in DDLT, although its effectiveness is controversial. In one study, HCV-positive recipients were randomized within 2 wk of transplantation to receive either interferon alone ($3 \text{ MU} \times 3$ per wk, $n = 30$) or placebo ($n = 41$) for 1 year^[39]. Only 17 patients could complete 1 year of interferon therapy. Eight patients (27%) in the interferon group and 22 (54%) of the untreated patients had recurrent hepatitis ($P = 0.02$). Patient and graft survival at 2 years did not differ between the groups, however, and the rate of viral persistence was not affected by treatment.

In another controlled trial^[43], 24 recipients were randomized at 2 weeks post-transplantation to receive interferon ($3 \text{ MU} \times 3$ per wk) or placebo for 6 mo. There were no differences in graft or patient survival. There were no differences between groups in the incidence of histological recurrence or its severity differed between groups. Recurrent HCV was delayed 408 d in treated patients versus 193 d in the control cohort.

In a case series by Mazzaferro^[44], 36 recipients were treated with interferon- α 2b ($3 \text{ MU} \times 3$ per wk) and ribavirin (10 mg/kg per d). They started treatment at a median of 18 d after the operation and treatment continued for 11 mo. After a median follow-up of 52 mo, the 5-year patient survival was 88%. Serum HCV RNA clearance was obtained in 12 patients (33%). They did not require further antiviral treatment because of negative HCV RNA in serum and normal liver histology for a median of an additional 36 mo. The former two randomized trials on preemptive interferon monotherapy demonstrated minimal benefits of the drug. In contrast, Mazzaferro reported more encouraging results, although their protocol brings into question how long therapy is needed once embarking on a preemptive strategy.

Re-transplantation

The approach to retransplantation for recurrent HCV varies widely among the transplant centers of DDLT^[11]. The results after retransplantation for HCV (45% at 5 years) are poorer than that for other causes^[45] (56%, $P < 0.001$). The patients with recurrent HCV in the early timing and graft failure within the first year have poor outcomes after retransplantation. These individuals should be considered contraindicated for retransplantation. The experience of retransplantation for HCV in LDLT has not been well accumulated.

OUR EXPERIENCE

We performed preemptive therapy for LDLT patients with HCV infection^[38]. From 1996 to 2004, 67 patients underwent LDLT for HCV cirrhosis at the Tokyo University Hospital. The patients were 51 men and 16

women and their ages ranged from 23 to 63 years (median 55). The HCV genotype was 1b in 53 patients (79%). Forty-one patients (61%) had hepatocellular carcinoma. All the patients received the same immunosuppressive regimens with tacrolimus and methylprednisolone.

All the patients preemptively received antiviral therapy consisting of interferon α -2b and ribavirin, which was started approximately 1 mo after the operation. The therapy was continued for 12 mo after the first negative HCV RNA test. The standard regimen included interferon α -2b (3 MU \times 3 per wk) and ribavirin (800 mg/d) for 6 mo. The patients were then observed without the therapy for 6 mo. The therapy was continued for at least 12 mo even if the HCV RNA test remained positive.

Therapy was discontinued when there was significant leukopenia (< 1500 /mL), thrombocytopenia ($< 50\,000$ /mL) despite application of granulocyte colony stimulating factor (Gran[®], Sankyo, Co. Ltd., Tokyo, Japan), hemolytic anemia (hemoglobin < 8 g/L), renal dysfunction (serum creatinine > 20 mg/L), depressive psychological status, or general fatigue. The subjects were removed from the protocol if they did not continue the therapy for 12 mo due to adverse effects or could not start the therapy due to early death.

Blood counts and liver function tests were checked every 2 wk for the first month, and at 4 wk intervals thereafter. Serum samples were collected once a month for quantitative HCV RNA detection. Protocol liver biopsy was not performed. The log-rank test was used to compare the survival rate of the HCV-positive patients with the HCV-negative patients who underwent transplantation during the same period ($n = 168$).

A total of 28 patients were excluded from the analysis; 12 patients were removed from the protocol because of early death ($n = 9$) or because of drug cessation ($n = 3$). Another 16 patients are currently on the protocol and were therefore excluded from the analysis. Of the remaining 39 patients, 16 (16/39; 41%) obtained a sustained virologic response. The cumulative 5-year survival of the HCV-positive patients was 84%, comparable with that of patients negative for HCV ($n = 168$, 86%).

CONCLUSIONS

LDLT will remain an indispensable therapeutic tool for HCV related end stage liver disease and an alternative to DDLT. The association between LDLT and early HCV recurrence remains to be determined, although most of the recent papers suggest that live donor graft has no effect on short-term outcome or severity of virus recurrence. If living donor graft is associated with early HCV recurrence and consequently poorer graft survival, an aggressive antiviral protocol might improve the outcome of LDLT for HCV.

Abstract

Despite the development of more sophisticated diagnostic techniques, pancreatic carcinoma has not yet been detected in the early stage. Surgical resection provides the only chance for cure or long-term survival. The resection rate has increased due to recent advances in surgical techniques and the application of extensive surgery. However, the postoperative prognosis has been poor due to commonly occurring liver metastasis, local recurrence and peritoneal dissemination. Recent molecular-biological studies have clarified occult metastasis, micrometastasis and systemic disease in pancreatic cancer. Several oncological problems in pancreatic cancer surgery are discussed in the present review.

INTRODUCTION

Over the past 30 years, the number of deaths in Japan due to pancreatic carcinoma has steadily increased from 4400 to 19000^[1] (Figure 1). It is the fifth most common cause of death due to malignant neoplasms (Figure 1). Regional pancreatectomy for carcinoma of pancreatic head region, introduced by Fortner^[2] in 1973, has impressed many

Japanese pancreatic surgeons. Consequently, the resection rate has gradually improved, but the postoperative prognosis is still poor in spite of the development of diagnostic modalities such as CT-scan, EUS, MRI and PET. In 1980, the Japan Pancreas Society (JPS) published the first edition of its "General Rules for Surgical and Pathological Studies on Cancer of the Pancreas". The fifth edition was published in 2002. The second English edition was published in 2003^[3]. The JPS also started a registration system for pancreatic carcinoma in 1981. According to the data of JPS, the 5-year survival of invasive ductal carcinoma of the pancreas after pancreatectomy is only 13.4%^[4] (Figure 2). JPS and UICC stage of invasive cancer and survival after pancreatectomy are shown in Figure 3^[4]. Comparison of survival curves according to the stage reveals that stratification is much better in the JPS classification than in UICC classification.

In 1981, we developed an antithrombogenic bypass catheter for the portal vein to decompress portal congestion or prevent hepatic ischemia caused by simultaneous resection of portal vein and hepatic artery^[5]. Since then, we have been aggressively performing extensive surgical resections including portal vein resection by the non touch isolation technique^[7,8] using this bypass method. The resection rate has been elevated and operative mortality has remarkably decreased. However, the postoperative prognosis is still poor due to high recurrence rate. The problems of surgical therapy for pancreatic cancer are discussed in this review.

ONCOLOGICAL PROBLEMS

Intrapancreatic carcinoma development

The indications for total pancreatectomy or pancreatoduodenectomy in pancreatic head cancer are one of the key problems in pancreatic cancer surgery. It is very important to know how the carcinoma has developed from the pancreatic head to the body or tail. A high incidence of development or multicentricity of the carcinoma of the pancreatic head to the body or tail has been reported^[9,10]. However, recent histopathological and immunocytochemical analysis of total pancreatectomy specimens have clarified that carcinoma development from head to body or tail is continuous^[11-13]. Therefore, intraoperative quick histopathological diagnosis combined with immunohistochemical staining using frozen section can diagnose intrapancreatic carcinoma development more precisely^[14,15].

Table 1 Comparative studies of extended versus standard operation for pancreatic cancer

Author	Yr	Results
Ishikawa <i>et al</i> ^[24]	1988	Retrospective study [standard (n = 37): 9%, 5-Y-S extended (n = 22): 28%, 5-Y-S
Mukaiya <i>et al</i> ^[25]	1998	Retrospective study 77 institutions, 501 patients: NS

Pedrazzoli <i>et al</i> ^[27]	1998	RCT [standard (n = 40) extended (n = 41)] overall survival: NS survival of node positive patients: extended > standard
Yeo <i>et al</i> ^[28]	2002	RCT [standard (n = 146) extended (n = 148)] mortality: NS, morbidity: extended > standard, survival: NS

RCT: Randomized controlled test; NS: Not significant.

Lymph node metastasis

Lymph node dissection is one of the important components in pancreatic cancer surgery. The high incidence of 56%^[16], 70.5%^[17], 73%^[18], 76%^[19], 77%^[20], and 86.4%^[21] in resected specimen of pancreatic cancer is the reason for wide dissection of lymph nodes in pancreatic cancer surgery. There are few reports about precise para-aortic lymph node metastasis. The incidence of para-aortic lymph node metastasis for pancreatic head carcinoma is reported to be 16% (7/44)^[17] and 26% (23/90), respectively^[20]. The incidence of pancreatic body and tail carcinoma is 13% (4/30)^[22] and 17% (4/27)^[21], respectively. The lymphatic flow from the pancreatic head tumor to the para-aortic lymph node via the posterior surface of the pancreatic head and around the superior mesenteric artery has been suspected^[17,18,23].

The efficacy of extended lymph node dissection in pancreatic cancer surgery has been suggested in a retrospective study^[24]. However, the efficacy of extended lymph node dissection has not been clarified in retrospective studies^[25,26] or in recent prospective randomized controlled tests for pancreatic cancer surgery (Table 1)^[27,28].

The incidence of perigastric lymph node metastasis in pancreatic cancer is relatively low^[20]. Therefore, pylorus preserving pancreatoduodenectomy (PPPD) is indicated for pancreatic head carcinoma, although its advantage over the classic Whipple operation has not been clarified^[29,30].

Vascular invasion

Portal vein resection is another problem in pancreatic cancer surgery. To prevent portal congestion in portal vein resection and hepatic ischemia in simultaneous resection of portal vein and hepatic artery, we developed a catheter-bypass procedure^[5,6] in our department in 1981 using antithrombogenic catheter, and isolated pancreatectomy combined with portal vein resection has thus been established^[8]. During the past 30 years, the operative mortality rate of pancreatoduodenectomy combined with portal vein resection has decreased, and portal vein resection in pancreatic cancer surgery has become a safe operative procedure. The reported mortality rate is 7.4% (2/27)^[31], 10% (6/63)^[32], 5% (3/58)^[33], 0% (0/31)^[34], 0/14^[35], 0/34^[36], 0/24^[37], and 3.2% (1/31)^[38]. From 1981 to 2003, 250 of 391 (63.9%) patients with pancreatic carcinoma underwent tumor resection in our

Figure 1 Trends in death due to malignant neoplasms in Japan.

department. Portal vein resection was performed in 171 of these 250 (68.4%) resected cases, and the mortality rate was 4.4% (11/250)^[39]. The indication and contraindication for portal vein resection have not yet been clarified in pancreatic cancer surgery. There are many reports about the benefit^[33,34,40] or no benefit^[41] of portal vein resection for curative resection or survival. The most important indication for portal vein resection in pancreatic cancer is the ability to obtain cancer-free surgical margins^[39].

In severe portal invasion cases, it is difficult to obtain cancer-free surgical margins, so the prognosis is poor^[39,42-44]. A recent diagnostic modality using intraportal endovascular ultrasonography provides precise information about the relationship between the pancreatic cancer and the portal vein wall, and planning of the operative procedure^[45-47].

Extrapancreatic nerve plexus invasion

Pancreatic carcinoma often invades the extrapancreatic nerve plexus^[48-51]. There is continuity of the intrapancreatic neural invasion into the extrapancreatic nerve plexus^[48]. The grade of intrapancreatic neural invasion correlates with the extrapancreatic nerve plexus invasion^[50,51] and the manner of neural invasion has no relationship with the behavior of lymph node metastasis^[50].

In pancreatic head carcinoma, complete dissection of extrapancreatic nerve plexus, especially the second portion of pancreatic head nerve plexus and nerve plexus around the superior mesenteric artery, is sometimes necessary to obtain a carcinoma-free surgical margin. However, complete resection of the nerve plexus around

Figure 2 Histology and survival after pancreatectomy. Survival of patients who underwent pancreatectomy is shown. NS, not significant.

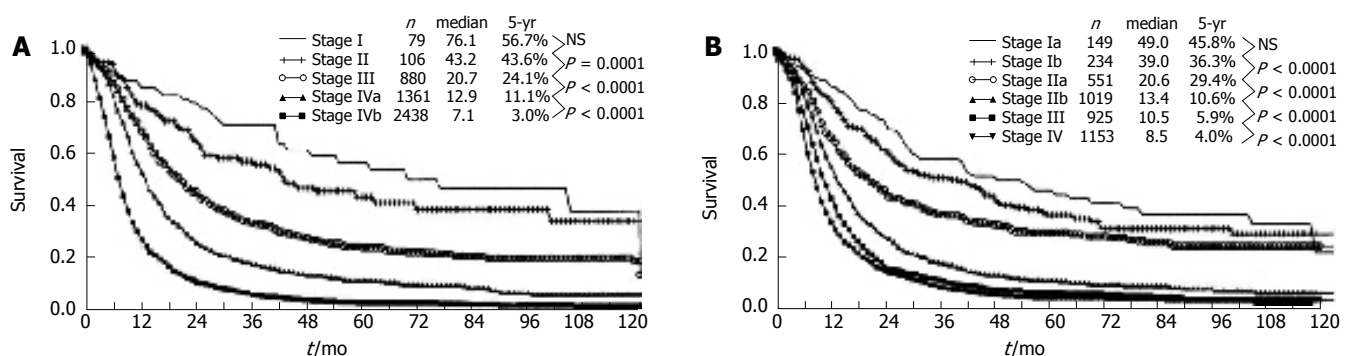

Figure 3 Survival after pancreatectomy according to JPS stage (A) and UICC stage (B). NS, not significant.

the superior mesenteric artery causes severe diarrhea after surgery, and the prognosis of positive carcinoma invasion to the extrapancreatic nerve plexus cases is very poor^[39,50,51]. The greatest cause of carcinoma-positive surgical margin is extrapancreatic nerve plexus carcinoma invasion^[39,48,50]. Recently, carcinoma invasion to the second portion of the pancreatic head nerve plexus can be diagnosed using intraportal endovascular ultrasonography^[45-47,52]. In our department, if patients have no carcinoma invasion to the second portion of the pancreatic head nerve plexus, the left semi-circular nerve plexus around the superior mesenteric artery is preserved to prevent postoperative diarrhea.

Postoperative recurrence

Even in extended surgery, a high incidence of postoperative liver metastasis, local recurrence, and peritoneal metastasis has been observed with a poor postoperative prognosis (Table 2)^[53-57]. The precise diagnosis of recurrence type is difficult even if modern diagnostic modalities are used. However, the local recurrence was 100% and the liver metastasis was 80% in 25 autopsy cases^[55]. The first cause of poor postoperative prognosis in pancreatic cancer is liver metastasis. Although occult liver metastasis may be suspected on the basis of extensive clinical data, no criteria have been definitely determined. Surgical therapy combined with effective adjuvant therapy is necessary in view of these types of recurrence.

Adjuvant therapy

Surgical therapy currently offers the only potential cure for pancreatic cancer. However the recurrence rate is very high and the long-term survival is poor.

The potential benefit of adjuvant therapy after resection of pancreatic cancer was first recognized by the randomized trial conducted by the Gastrointestinal Tumor Study Group (GITSG) using chemoradiotherapy almost 20 years ago^[58,59]. Since then, few randomized trials have shown a benefit of adjuvant treatment (Table 3)^[60-65]. The study of the European Study Group for Pancreatic Cancer (ESPAC-1) concluded that postoperative chemotherapy with fluorouracil plus leucovorin confers a benefit in terms of survival, whereas postoperative chemoradiotherapy has a deleterious effect on survival^[64]. The current study by Neuhaus *et al*^[65] indicates that the treatment with gemcitabine in patients with resected pancreatic cancer can result in improved disease-free survival as compared to observation.

A new and more effective adjuvant therapy must be established by prospective randomized trials using newly developed drugs^[66,67] or therapeutic modalities^[68]. Nevertheless, the individualized adjuvant therapy is very important in pancreatic cancer treatment^[69,70].

Occult metastasis and micrometastasis

Recent progress in immunohistochemistry and molecular biological studies has made it possible to clarify the occult metastasis and micrometastasis in pancreatic cancer. The

Trial	Comparison	Adjuvant treatment	Number of patients	Conclusions
GIITSG, 1985 ^[58] , 1987 ^[59]	CRT <i>vs</i> OBS	2 × (20 Gy in 10 fractions + 500 mgm ⁻² 5FU d 1-3) + weekly 5FU to recurrence	49 pancreatic patients randomised	Significant increase in median survival (20 <i>vs</i> 11 mo, <i>P</i> = 0.035) in 43 eligible patients
Norway, 1993 ^[60]	CT <i>vs</i> OBS	AMF (40 mgm ⁻² doxorubicin, 6 mgm ⁻² mytomycin C, 500 mgm ⁻² 5FU) once every 3 wk for six courses	61 patients (47 pancreatic, 14 ampullary) randomised 46 additional nonrandomised patients	Significant increase in median survival (23 <i>vs</i> 11 mo, <i>P</i> = 0.02) in 60 pancreatic and ampullary patients combined
EORTC, 1999 ^[61]	CRT <i>vs</i> OBS	2 × (20 Gy in 10 fractions + 25 mgkg ⁻¹ 5FU/FA d 1-5)	218 patients (120 pancreatic, 93 ampullary) randomised	NS increase in median survival (25 <i>vs</i> 19 mo, <i>P</i> = 0.21) in 207 eligible patients NS increase in median survival in 114 eligible pancreatic patients (17 <i>vs</i> 13 mo, <i>P</i> = 0.099)
Japan, 2002 ^[62]	CT <i>vs</i> OBS	6 mgm ⁻² mytomycin C d 1 + 310 mgm ⁻² 5FU d 1-5 and d 15-20 followed by 100 mgm ⁻² oral 5FU daily until recurrence	508 patients (173 pancreatic, 335 bile duct/gallbladder/ampullary) randomised	Significant survival benefit in gallbladder No difference in 158 eligible pancreatic patients No difference in 48 eligible ampullary patients
ESPAC1, 2001 ^[63] , 2004 ^[64]	CRT <i>vs</i> no CRT CT <i>vs</i> no CT	2 × (20 Gy in 10 fractions + 500 mgm ⁻² 5FU/FA d 1-3) (20 mgm ⁻² FA + 425 mgm ⁻² 5FU d 1-5) × six cycles	289 pancreatic patients randomised	NS decrease in survival for CRT (<i>P</i> = 0.05) in 289 patients Significant increase in survival for CT (<i>P</i> = 0.009) in 289 eligible patients
CONKO-001, 2005 ^[65]	CT <i>vs</i> OBS	1 gm ⁻² GEM, d 1, 8, 15, every 4 wk for 6 mo	368 pancreatic patients randomised	Significant increase in median DFS (14.2 <i>vs</i> 7.5 mo, <i>P</i> < 0.05) in 356 eligible patients

CRT: Chemoradiotherapy; CT: Chemotherapy; OBS: Observation; NS: Not significant; DFS: Disease-free survival.

Table 4 Incidence of pancreatic cancer cells in peripheral blood, bone marrow, and liver tissue

Author	Yr	Incidence
Tada <i>et al</i> ^[71]	1993	Peripheral blood, K- <i>ras</i> 2/6 (33%)
Juhl <i>et al</i> ^[72]	1994	Bone marrow, immunostaining: 15/26 (58%)
Inoue <i>et al</i> ^[73]	1995	Liver tissue, K- <i>ras</i> : 13/17 (76%)
Nomoto <i>et al</i> ^[74]	1996	Peripheral blood, K- <i>ras</i> : postoperative period 10/10 (100%)
Funaki <i>et al</i> ^[75]	1996	Peripheral blood, CEA mRNA: 3/9 (33%)
Aihara <i>et al</i> ^[76]	1997	Peripheral blood, Keratin 19m RNA: 2/38 (5%)
Miyazono <i>et al</i> ^[77]	1999	Peripheral blood, CEA mRNA: 13-21 (61.9%)
Uemura <i>et al</i> ^[78]	2004	Peripheral blood, K- <i>ras</i> : 9/26 (35%)

high incidence of K-*ras* point mutation of codon 12 in pancreatic cancer has been observed. Occult pancreatic cancer cells have been detected in peripheral blood, bone marrow and liver by studies of K-*ras*, CEA mRNA, keratin 19 mRNA, along with immunocytochemical staining (Table 4)^[71-78].

Occult lymph node metastasis in pancreatic cancer has been also detected by the studies of K-*ras* and immunostaining of cytokeratin or Ber-EP4 (Table 5)^[79-83].

The incidence of cancer cells from abdominal washing cytology is shown in Table 6^[84-89]. The incidence using conventional staining is 0%-17% (Table 6)^[84,86-89]. However

Vogel <i>et al</i> ^[85]	1999	Peritoneal washings 39%, bone marrow 38%, one of them positive: died within 19 mo, both negative: 5 y.s. 30% (<i>P</i> < 0.0001)
Castillo <i>et al</i> ^[86]	1995	Laparoscopy 16/94 (17%)
Leach <i>et al</i> ^[87]	1996	4/60 (7%)
Nomoto <i>et al</i> ^[88]	1997	Conventional: 0/18 (0%), immunostaining (CEA, CA19-9): 2/18 (11%)
Nakao <i>et al</i> ^[89]	1999	Conventional: 5/66 (8%), immunostaining 14/66 (22%) prognosis between cytology positive and negative: NS

a high incidence of 58%^[72], 39%^[85], and 22%^[89] by immunocytochemical staining using monoclonal antibodies against tumor-associated antigens and cytokeratins has been reported. The difference in prognosis between positive and negative occult metastases remains controversial.

CONCLUSION

Surgical techniques for pancreatic cancer have been developed, and the resection rate has increased in Japan over the past 30 years. However, the prognosis of stage IV patients with pancreatic cancer is still poor even after aggressive surgery because of its high recurrence rate. Occult metastasis and micrometastasis have been more precisely diagnosed by immunocytochemical and molecular biological studies. On the basis of such data, adjuvant multimodal therapies targeting occult metastasis and micrometastasis with radical surgery are recommended. The effectiveness of these adjuvant multimodal therapies must be clarified and more effective adjuvant therapies must be developed.

Abstract

AIM: To determine the current status in various aspects of gastric cancer patients and to find out the clinical correlation with prognostic role of serum interleukins in Thai patients.

METHODS: Sixty-eight patients were enrolled in this study at King Chulalongkorn Memorial Hospital during April 2003 to May 2005. Gastric cancer was histologically proven in 51 patients and gastric ulcer in 17 patients. Serum IL-6, IL-10, IL-12, and IL-18 levels were measured by enzyme-linked immunosorbent assay (ELISA).

RESULTS: There were 26 males (55.32%) and 21 females (44.68%) with their age ranging from 33 to 85 years (mean age 64.49 ± 13.83 years). The common presentations were weight loss (41.2%), dyspepsia (39.2%), and upper gastrointestinal bleeding (15.7%). A total of 35.3% gastric cancer patients and 6.3% of gastric ulcer patients were smokers ($P = 0.029$). Moreover, 32.4% of gastric cancer patients and 6.3% of gastric ulcer patients were alcoholic drinkers ($P = 0.044$). Lesion location was pyloric-antrum in 39.4%, gastric body in 39.4%, upper stomach in 12.2% and entire stomach in 6.1% of the patients. *H. pylori* infection was detected in 44.4%. The poorly-differentiated adenocarcinoma was the most common pathologic finding (60.7%). Surgical treatment was performed in 44.1% patients (total gastrectomy in 5.9%, subtotal gastrectomy in 32.4% and palliative bypass surgery in 5.9%). Systemic chemotherapy was given as an adjuvant therapy in 8.8% patients. Carcinomatosis peritonei were found in 18.8%

patients. The mean survival time was 13.03 ± 9.75 mo. The IL-18 level in gastric cancer patient group (58.54 ± 43.96 pg/mL) was significantly higher than that in gastric ulcer patient group (30.84 ± 11.18 pg/mL) ($P = 0.0001$) (95% CI was 42.20, 13.19). The cut point of IL-18 for diagnosis of gastric cancer was 40 pg/mL, the positive predictive value was 92.31%. The IL-6 level in gastric cancer patients with distant metastasis (20.21 ± 9.37 pg/mL) was significantly higher than that in those with no metastasis (10.13 ± 7.83 pg/mL) ($P = 0.037$) (95% CI was 19.51, 0.65). The role of IL-10 and IL-12 levels in gastric cancer patients was to provide data with no significant difference.

CONCLUSION: These findings demonstrate that serum IL-6 and IL-18, but not IL-10 and IL-12 levels may be the useful biological markers of clinical correlation and prognostic factor in patients with gastric cancer. Moreover, IL-18 could serve as a diagnostic marker for gastric cancer with a high positive predictive value.

INTRODUCTION

The most recent estimates of the world-wide incidence of cancer indicate that gastric cancer is the second most frequent cancer in the world after lung cancer, with over 900 000 new cases diagnosed every year^[1].

For the risk factors, many gastric ulcer patient studies conducted all over the world have shown that the elevated risk is associated with consumption of canned fruit, pickled and smoked foods^[2,3]. Many studies have found a positive association between tobacco use and relative risk among heavy drinkers as compared to non-drinkers and gastric carcinoma^[4,5]. *H. pylori*, a Gram-negative spiral-shaped bacterium, has been established as a major etiologic

agent of chronic gastritis and peptic ulcer diseases including duodenal ulcer (DU) and gastric ulcer (GU). The role of *H. pylori* infection in gastric adenocarcinoma and MALT is also increasingly recognized^[6,7].

The metastatic process of gastric cancer consists of tumor cell detachment, local invasion, motility, angiogenesis, vessel invasion, survival in the circulation, adhesion to endothelial cells, extravasation, and regrowth in different organs. In each step, causative molecules have been identified including cell-adhesion molecules, various growth factors, matrix degradation enzymes, and motility factors. Most of these molecules can be regarded as prognostic factors^[8].

Human IL-6 consists of 212 amino acids, including a hydrophobic signal sequence of 28 amino acids. Many different types of lymphoid and non-lymphoid cells produce IL-6, which is involved in the following multiple biological activities. IL-6 has a strong activity in stimulating the growth of human gastric cancer cell lines. These findings suggest that IL-6 may play a potential role in the pathogenesis of gastric cancer^[9].

IL-10 is an 18 Ku peptide and comprises 178 amino acids. This cytokine was first identified as an anti-inflammatory cytokine. The function of IL-10 is to act on the macrophages, inhibiting synthesis and suppressing gene of other cytokines^[10].

IL-12 was originally identified as a natural killer (NK) cell stimulatory factor, a disulfide-linked heterodimeric cytokine composed of 35 and 40 Ku subunits. IL-12, secreted principally by antigen presenting cells (APC), such as macrophages, B cells, and dendritic cells, activates NK cells and T cells to produce interferon- γ (IFN- γ), and augments their cytotoxic activity and proliferation. IL-12 has been recently found to induce anti-tumor effects against a variety of tumors *in vivo*^[11].

IL-18, formerly called interferon- γ -inducing factor, is a recently discovered cytokine that plays an important role in the TH1 response. IL-18 is produced by Kupffer cells, activated macrophages, keratinocytes, intestinal epithelial cells, and osteoblasts. Numerous investigations have noted the importance of IL-18 as a TH1 cytokine, especially in cooperation with IL-12, in anti-tumor immunity^[12,13].

Therefore, the purpose of this study was to investigate the possible involvement of serum IL-6, IL-10, IL-12, and IL-18 levels in determining clinicopathologic features and diagnostic yield as well as in predicting the spread of tumors, and most notably including the outcome measured as survival duration for patients with gastric carcinoma.

MATERIALS AND METHODS

Patients and blood samples

There were 68 patients enrolled in this study at King Chulalongkorn Memorial Hospital (Bangkok, Thailand) during April 2003 to May 2005. Gastric cancer was histologically proven in 51 patients and 17 gastric ulcer patients served as control. The Ethical Committee of the Faculty of Medicine, Chulalongkorn University, approved the study. Written informed consent was obtained from all patients. Immediately after blood sampling, serum was

Figure 1 Symptoms of gastric cancer patients.

obtained by centrifugation at 2000 r/min for 15 min at 4°C and stored at 80°C until later analysis. Serum IL-6, IL-10, IL-12 and IL-18 levels were determined using ELISA kits (Quantikine R&D Systems, Inc., Minneapolis, MN) according to the manufacturer's instructions. Briefly, serum samples were reacted with a monoclonal antibody that recognized an epitope of rat interleukins. After 2 h incubation and washing, streptavidin peroxidase-conjugated monoclonal antibody directed to a second epitope was added. This antibody bound to the interleukins captured by the first monoclonal antibody. The color reaction was terminated by a stop solution containing sulfuric acid, and absorbance was measured at 450 nm. Results were calculated from a standard curve generated by a four-parameter logistic curve-fit and expressed in pg/mL.

The clinical data collected included age, sex, symptoms, presentation, history of cigarette smoking and alcohol drinking, lesion site, histological type, metastasis, treatment, *H. pylori* status, blood chemistry, result of treatment, and survival time. The histological diagnosis was based on the morphological examination by hematoxylin and eosin-staining.

Statistical analysis

Data were expressed as mean \pm SD. Comparisons between groups were analyzed by the chi-square test for categorical variables and Student's *t* test with 95% confidence interval when appropriate for quantitative variables. Survival curves were constructed using the Kaplan-Meier method. The Pearson correlations were used. *P* values below 0.05 for a two-tailed test were considered statistically significant. All statistical analyses were performed using the SPSS software for Windows, version 11.5.

RESULTS

Of the 51 patients with gastric cancer, 26 were males (55.32%) and 21 were females (44.68%) with their age ranging from 33 to 85 years (mean age 64.49 ± 13.83 years). The common presentations included weight loss (41.2%), dyspepsia (39.2%), and upper gastrointestinal bleeding (15.7%) (Figure 1).

A total of 35.3% of gastric cancer patients and 6.3% of controls were smokers (*P* = 0.029). Moreover, 32.4% of gastric cancer patients and 6.3% of controls were alcoholic drinkers (*P* = 0.044).

Figure 2 Mean survival time of gastric cancer patients.

Figure 3 IL-18 levels in gastric cancer patients compared with gastric ulcer patients.

Lesion location was found in pyloric-antrum of 39.4% patients, gastric body of 39.4% patients, upper stomach of 12.2% patients and entire stomach of 6.1% patients. *H. pylori* infection was detected in 44.4% patients. The poorly differentiated adenocarcinoma was the most common pathologic finding (60.7%). Surgical treatment was performed in 44.1% patients (total gastrectomy in 5.9%, subtotal gastrectomy in 32.4% and palliative bypass surgery in 5.9%). Systemic chemotherapy was given as an adjuvant therapy in 8.8% patients. Carcinomatosis peritonei were found in 18.8% patients. The mean survival time was 13.03 ± 9.75 mo (Figure 2).

The IL-18 level in gastric cancer patient group (58.54 ± 43.96 pg/mL) was significantly higher than that in control group (30.84 ± 11.18 pg/mL) ($P = 0.0001$) (95% CI was 42.20, 13.19) (Figure 3). From the ROC curve, the cut point of IL-18 for diagnosis of gastric cancer was 40 pg/mL. The sensitivity was 52.17%, the specificity was 83.33%, and the positive predictive value was 92.31%.

The IL-6 level in gastric cancer patients with distant metastasis (20.21 ± 9.37 pg/mL) was significantly higher than that in those with no metastasis (10.13 ± 7.83 pg/mL) ($P = 0.037$) (95% CI was 19.51, 0.65) (Figure 4).

A significant clinical correlation was found between hematocrit level, serum albumin, survival time, and serum IL-6, IL-10 and IL-18 levels in gastric cancer patients (Table

Figure 4 IL-6 levels in gastric cancer with distant metastasis compared to those with no metastasis.

^{1,2} Pearson correlation are both significant at 0.01 level (2-tailed).

1). There was no significant correlation between *H. pylori* status and interleukin levels.

DISCUSSION

Gastric carcinoma is one of the most common malignant diseases worldwide. Although its incidence has declined dramatically in the United States of America and Western Europe over the past 60 years, the incidence still remains very high in developing countries^[14]. The factors leading to this variability among countries are still not clear. Some correlation exists between the occurrence of gastric carcinoma and the prevalence of *H. pylori* infection in different geographical areas^[15]. Current knowledge of the detailed mechanisms underlying the interplay between biological modulators and lesions induced by *H. pylori* is still incomplete. It is believed that chronic infection with *H. pylori* leads to alterations of the cell cycle, including increased epithelial cell replication, increased rate of cell death (apoptosis) and production of oxidants^[16,17]. In this study, the prevalence of *H. pylori* was 44.4%. There was no significant correlation between *H. pylori* status and interleukin levels.

In agreement with other studies, our study examined the effect of cigarette smoking and alcohol drinking as a risk factor for gastric cancer. From the mechanism viewpoint, the direct carcinogenic effect of cigarette smoking may derive from precursor gastric lesions. Indirect effects of inhaled cigarette smoking may involve

the nitrosamines in stomach. Alcohol could act as a contributory factor by causing chronic irritation of the gastric mucosa^[4,5].

Weight loss and dyspepsia were the most frequent initial symptoms in our patients, being consistent with those in Western studies^[18,19]. The current data indicate that the proportion of early, curable gastric cancer is small among Thai patients. Most of the cases in our study were in advanced stage (stages III and IV) with a very poor 5-year survival.

IL-18 is synthesized as an inactive precursor (pro-IL-18, 24 Ku), which is cleaved by IL-1 β -converting enzyme (ICE or caspase-1) into an active 18 kDa mature form^[20,21]. IL-18 has multiple biological activities *via* its capacity of stimulating innate immunity and both Th1 and Th2-mediated responses. It also exerts anti-tumor effects that are mediated by enhancement of NK cell activity, reduction of tumorigenesis, induction of apoptosis and inhibition of angiogenesis in tumor cells^[22,23]. In addition, recent data suggest that an inappropriate production of IL-18 contributes to the pathogenesis of cancers and may influence the clinical outcome of patients^[24]. This is the first study demonstrating that the levels of serum IL-18 are significantly elevated in gastric cancer patients compared with gastric ulcer patients. Although a high serum IL-18 level was not used as a significant prognostic factor in terms of overall survival, it was used as a diagnostic factor. The cut point of IL-18 for diagnosis of gastric cancer was 40 pg/mL. The sensitivity was 52.17%, the specificity was 83.33%, the positive predictive value was 92.31%. The pathways for IL-18 production and its mechanisms of action in patients with gastric cancer remain to be determined.

IL-6 is involved in many biological activities, including T-cell and B-cell growth and differentiation, IL-2 production and IL-2 receptor expression, hematopoietic stem cell growth, megakaryocyte maturation, acute phase protein synthesis, macrophage differentiation, mesangial cell, keratinocyte, and osteoclast cell growth, hybridoma, plasmacytoma, and myeloma growth, and stimulation of cancer-cell growth^[25]. Our data show that the IL-6 level in gastric cancer patients with distant metastasis is significantly higher than that in those with no metastasis. As a proof of the mechanism of IL-6 action, Tamm *et al*^[26] showed that IL-6 makes cancer cells increase their motogenic activity by autocrine pathway. IL-6 secreted from the cancer cells combines with IL-6, which is expressed on the surface of cancer cells, IL-6 and IL-6r act on the cancer cells directly. IL-6 may act through HGF on cancer cells by promoting and accelerating invasion as well as lymph node and/or hepatic metastasis^[27].

IL-12 is an immunoregulatory cytokine that triggers the development of a specific T cell-mediated immune response. IL-12 enhances the proliferation, cytokine production, and cytotoxic activity of T lymphocytes and NK cells, with consequent anti-tumor activity^[11]. Lissoni *et al*^[28] reported that serum IL-12 level is significantly higher in patients with metastatic renal cell carcinoma and breast cancer than in those with local solid neoplasms. Uno *et al*^[29] reported that phytohemagglutinin-induced production of IL-12 is lower in patients with gastric cancer

than in healthy controls, by examining peripheral blood mononuclear cells *in vitro*. In this study, we could not demonstrate any significant uses of IL-12 in gastric cancer patients as compared with gastric ulcer patients. Shibata *et al*^[30] reported that the production of IL-12 decreases significantly with advancing stages, and is the lowest in patients with distant metastases and cachexia.

For IL-10 level, the data indicate that intracellular IL-10 status on monocytes in patients with advanced gastric cancer is significantly increased compared with those with early disease or healthy individuals^[31]. In this study, we also found a correlation between IL-6, IL-10, and IL-18 levels and serum albumin. In our previous report, serum albumin level is another prognostic factor in gastric cancer at initial diagnosis, and the median survival time is reduced with a decrease in serum albumin level^[32].

In conclusion, our data demonstrate that serum IL-6 and IL-18, but not IL-10 and IL-12 levels, may be the useful biological markers for clinical correlation and prognostic factor in patients with gastric cancer. Moreover, IL-18 could serve as a diagnostic marker for gastric cancer with a high positive predictive value. Thus, the detailed mechanisms of IL-6 and IL-18 involving tumor progression should be further investigated.

Abstract

AIM: To investigate the effect of hot water-extracted *Lycium barbarum* (LBE) and *Rehmannia glutinosa* (RGE) on cell proliferation and apoptosis in rat and/or human hepatocellular carcinoma (HCC) cells.

METHODS: Rat (H-4-II-E) and human HCC (HA22T/VGH) cell lines were incubated with various concentrations (0-10 g/L) of hot water-extracted LBE and RGE. After 6-24 h incubation, cell proliferation ($n = 6$) was measured by a colorimetric method. The apoptotic cells ($n = 6$) were detected by flow cytometry. The expression of p53 protein ($n = 3$) was determined by SDS-PAGE and Western blotting.

RESULTS: Crude LBE (2-5 g/L) and RGE (2-10 g/L) dose-dependently inhibited proliferation of H-4-II-E cells by 11% ($P < 0.05$) to 85% ($P < 0.01$) after 6-24 h treatment. Crude LBE at a dose of 5 g/L suppressed cell proliferation of H-4-II-E cells more effectively than crude RGE after 6-24 h incubation ($P < 0.01$). Crude LBE (2-10 g/L) and RGE (2-5 g/L) also dose-dependently inhibited proliferation of HA22T/VGH cells by 14%-43% ($P < 0.01$) after 24 h. Crude LBE at a dose of 10 g/L inhibited the proliferation of HA22T/VGH cells more effectively than crude RGE ($56.8\% \pm 1.6\%$ vs $70.3\% \pm 3.1\%$ of control, $P = 0.0003 < 0.01$). The apoptotic cells significantly increased in H-4-II-E cells after 24 h treatment with higher doses of crude LBE (2-5 g/L) and RGE (5-10 g/L) ($P < 0.01$). The expression of p53 protein in H-4-II-E cells was 119% and 143% of the control group compared with the

INTRODUCTION

According to the official report by the Department of Health, Taiwan, malignant tumor is the first leading cause of death in 2004. Among cancers, hepatocellular carcinoma (HCC) is the second leading cause of death. The mortality rate for HCC is 31.17 per 100 000, accounting for 17.9% of cancer deaths in 2004. The rising incidence of HCC in at-high-risk patients with chronic hepatitis B or C is an important issue in Taiwan. Although early diagnosis and treatment improve survival, HCC is rarely cured and recurs frequently after regional therapy or transplantation^[1]. Recently, preventing HCC formation and HCC therapy are major research focuses.

Both *Lycium barbarum* (LBE) and *Rehmannia glutinosa* (RGE) have been commonly used as traditional Chinese medicine and herbal foods for health promotion in China. The active components of the fruit of LBE and the dried root of RGE primarily contain water-soluble polysaccharides. LBE and RGE can be extracted with hot water followed by precipitation with ethanol to obtain high quantity of polysaccharides^[2-4]. Polysaccharide-containing active components purified from these herbs have been recently studied for their physiological and pharmaceutical activities. LBE polysaccharides as glycopeptides isolated

from the fruit of LBE^[5,6] are water soluble and potent in immunomodulation, anti-lipid peroxidation^[6-9], and antitumor^[3]. RGE polysaccharides isolated from the dried root of RGE have also shown the properties of immunomodulation^[10-14] and antitumor^[15]. To few studies have investigated the effect of LBE and RGE extracts on HCC. The purpose of this study was to investigate the effect of crude hot water-extracted LBE and RGE on cell proliferation and apoptosis in HCC cells.

MATERIALS AND METHODS

Preparation of crude herbal extracts

LBE *L Radix* RGE (processed and dried RGE) were purchased from Chien Yuan Hang (Taipei, Taiwan). To maintain the quality and consistency of the ingredients, the crude extracts were prepared in a single batch with adequate quantity for this study. Dried LBE *L Radix* RGE (100 g) were incubated with 900 mL deionized water at 100°C for 2 h. The herbal juice was then centrifuged at 9000 r/min for 20 min to remove the precipitate. The remaining herbal juice was filtered with gauze. The filtered supernatant containing polysaccharides was precipitated with three volumes of 950 mL/L ethanol, concentrated (rotavapor R200 with glass assembly V; BÜCHI Labortechnik AG, Flawil, Switzerland) and lyophilized (freeze dry system Lyph-Lock 6; Labconco Corp., Kansas City, MO, USA)^[16].

Composition analysis of herbal extracts

The total carbohydrate content in hot water-extracted LBE and RGE was determined by phenol-sulfuric acid assay using glucose as a standard^[17]. The contents of crude protein, crude fat, moisture, and ash were measured using the Association of Official Analytical Chemists (AOAC) methods (981.10, 991.36, 925.10, 923.03)^[18].

Cell cultures and treatments

Rat (H-4-II-E, BCRC no. 60209) and human HCC (HA22T/VGH, BCRC no. 60168) cell lines were purchased from the Bioresources Collection and Research Center (BCRC) of the Food Industry Research and Development Institute (Hsinchu, Taiwan). Rat and human HCC cells (1×10^5 cells/mL) were grown in 850 mL/L minimum essential medium (MEM; GIBCO™, Invitrogen Corp., Carlsbad, CA, USA) with 150 mL/L fetal bovine serum (FBS; GIBCO™) or 900 mL/L Dulbecco's modified Eagle's medium (DMEM; GIBCO™) with 100 mL/L FBS, respectively, at 37°C in a humidified atmosphere of 950 mL/L air and 50 mL/L CO₂. Prior to addition of the treatment, the cells were grown to 80%-90% confluency and synchronized by incubating in serum-free basal medium (MEM or DMEM) for 24 h. The cells were then treated with various concentrations of crude LBE (0-5 g/L) or RGE (0-10 g/L) in the absence of serum for 0-24 h. The cells and medium were collected. Protein contents in the cells and medium were determined by the modified method of Lowry *et al.*^[19] using a Bio-Rad DC protein kit (Bio-Rad Laboratories, Hercules, CA, USA).

Cell proliferation assay

Cell proliferation was colorimetrically measured at 490 nm using a commercial proliferation assay kit (CellTiter 96® AQueous; Promega Corp., Madison, WI, USA). After treatment with various concentrations of crude LBE (0-5 g/L) or RGE (0-10 g/L) for 0-24 h, rat and human HCC cells ($n = 6$) in the 96-well plate were incubated with 20 µL MTS (3-(4, 5-dimethylthiazol-2-yl)-5-(3-carboxymethoxyphenyl)-2-(4-sulfophenyl)-2H-tetrazolium) solution containing 1.90 g/L MTS and 300 µmol/L phenazine methosulfate in Dulbecco's PBS (pH 6.0) for 2 h at 37°C in a humidified 50 mL/L CO₂ atmosphere^[20]. The absorbance of soluble formazan produced by cellular reduction of MTS was determined at 490 nm using an ELISA reader (Multiskan RC; Labsystems, Helsinki, Finland).

Flow cytometric analysis of cellular DNA content

The percentage of cells undergoing apoptosis and distributing in different phases of cell cycle were determined by propidium iodide (PI)-staining method using flow cytometry. After treatment for 24 h, the conditioned medium of rat H-4-II-E cells ($n = 6$) was centrifuged at 800 r/min for 5 min at 4°C to remove the supernatant. The trypsinized cells and cell pellet of the conditioned medium were washed with PBS, fixed in 2 mL of 700 mL/L cold ethanol, and stored at 4°C overnight. After washed twice with PBS, the ethanol-fixed cells were incubated with 3 µL RNase (10 g/L) at 37°C for 30 min, and stained with 1 mL PI (40 mg/L) in the dark. The cell suspension was then filtered through a 35 µm mesh, and analyzed by a flow cytometer (FACSCalibur; Becton Dickinson Biosciences, San Jose, CA, USA) within 2 h. Cellular DNA content was calculated using CellQuest software (Becton Dickinson Biosciences).

Analysis of p53 protein

After incubation with various concentrations of LBE (0-5 g/L) or RGE (0-10 g/L) for 24 h, the conditioned medium of rat H-4-II-E cells was centrifuged at 800 r/min for 5 min at 4°C to remove the supernatant. Rat H-4-II-E cells and cell pellet in the conditioned medium were re-suspended in lysis buffer (2 mol/L Tris, 5 mol/L NaCl, 50 g/L NP-40, 100 g/L sodium dodecylsulfate (SDS), and 5 g/L phenylmethylsulfonyl fluoride), centrifuged at 300 r/min for 5 min at 4°C. The supernatant (40 µg total protein) pooled from 3 independent experiments ($n = 3$) was mixed with 4 × sample buffer (0.25 mol/L Tris-HCl, pH 6.8, 80 g/L SDS, 200 mL/L glycerol, 100 g/L β-mercaptoethanol, and 1 g bromophenol blue)^[21] denatured at 100°C for 3 min, and applied to SDS-polyacrylamide gel electrophoresis (SDS-PAGE) (Bio-Rad Mini-PROTEAN 3 Cell; Bio-Rad Laboratories). Proteins were separated by 125 mL/L resolving gel (acrylamide: bisacrylamide = 37.5:1) with 40 mL/L stacking gel in the running buffer (25 mmol/L Tris, pH 8.3, 192 mmol/L glycine, and 1 g/L SDS) at 3 EV/cm per hour. Then the proteins were transferred onto nitrocellulose membrane (0.45 µm) using a semi-dry transfer unit (Hoefer Semiphor

Table 1 Composition of hot water-extracted *Lycium barbarum* and *Rehmannia glutinosa*¹

Ingredient (mg/g)	<i>Lycium barbarum</i> extract	<i>Rehmannia glutinosa</i> extract
Carbohydrate	762.8	700.4

TE 70, Amersham Biosciences Corp., San Francisco, CA, USA) in Towbin buffer (25 mmol/L Tris, 192 mmol/L glycine, 1 g/L SDS, and 100 mL/L methanol) at 6 mA/cm per hour^[22]. The membrane was washed with PBS, and incubated with a blocking buffer (50 g/L skim milk and 2 mL/L Tween-20 in PBS) for 2 h. Then the membrane was incubated with an anti-mouse monoclonal antibody (Santa Cruz Biotechnology, Inc., Santa Cruz, CA, USA) against p53 (Pab-246; 2 mg/L) or α -tubulin (TU-02; 1 mg/L) at room temperature for 2 h. Alpha-tubulin was used as an internal control. The membrane was washed three times with the wash buffer (2 mL/L Tween-20 in PBS), and incubated with 4 mg/L goat anti-mouse IgG-horseradish peroxidase conjugate (Santa Cruz Biotechnology, Inc.) for 2 h. The blot was washed three times again with the wash buffer, incubated with luminol reagent (PerkinElmer Life and Analytical Sciences, Inc., Boston, MA, USA) for 2 min, and exposed to an X-ray film (Eastman Kodak Co., Rochester, NY, USA) for 3-5 min. The bands were quantitated by an image analysis system (0.2-megapixel charge-coupled device camera, gel analysis system; EverGene Biotechnology, Taipei, Taiwan) and Phoretix 1D Lite software (version 4.0; Phoretix International Ltd., Newcastle upon Tyne, UK).

Statistical analysis

Data are expressed as mean \pm SD. Data were analyzed by one- and two-way analysis of variance (ANOVA) to determine the treatment effect using the Statistical Analysis System (SAS version 8.2; SAS Institute Inc., Cary, NC, USA). Fisher's least significant difference test was used to make *post hoc* comparisons if the treatment effect was demonstrated. $P < 0.05$ was considered statistically significant.

RESULTS

Composition analysis of herbal extracts

The extraction rate for crude LBE and RGE was 704 mg/g and 724 mg/g, respectively. Carbohydrate content, the major component, was 762.8 mg/g and 700.4 mg/g in crude LBE and RGE, respectively (Table 1). Moisture and protein contents in crude LBE and RGE were 221.6 mg/g and 134.7 mg/g as well as 92.4 mg/g and 47.2 mg/g, respectively. Fat and ash contents in these crude extracts were less than 5 mg/g.

Cell proliferation assay

Crude LBE and RGE at a dose of 1 g/L did not inhibit

cell proliferation up to 24 h incubation in rat H-4-II-E cells (Table 2). However, crude RGE at a dose of 1 g/L slightly increased cell proliferation of H-4-II-E cells at 18 h incubation compared with the control group (111.4% \pm 11.7% vs 100.0% \pm 5.9% of control, $P = 0.03 < 0.05$). Crude LBE (2-5 g/L) and RGE (2-10 g/L) dose-dependently inhibited cell proliferation by 11% ($P < 0.05$) to 85% ($P < 0.01$) compared with the control group after 6-24 h incubation. The inhibitory effect of crude LBE and RGE at lower doses (1-2 g/L) on cell proliferation was not significantly different. A higher dose (5 g/L) of crude LBE suppressed cell proliferation more efficiently ($P < 0.01$) than that of crude RGE. From the curves of four time points, the mean values of IC50 for crude LBE and RGE were 3.8 g/L and 6.9 g/L, respectively. Similar results in human HA22T/VGH cells, crude LBE (2-10 g/L) and RGE (2-5 g/L) dose-dependently inhibited cell proliferation by 14%-43% ($P < 0.01$) compared with the control group after 24 h incubation (Table 3). Cell proliferation was inhibited equivalently by crude LBE and RGE at lower doses (2-5 g/L). However, crude LBE at a higher dose (10 g/L) showed better suppression (56.8% \pm 1.6% vs 70.3% \pm 3.1% of control, $P = 0.0003 < 0.01$) on cell proliferation compared with the same dosage of crude RGE. The IC50 value for both crude LBE and RGE was above 10 g/L.

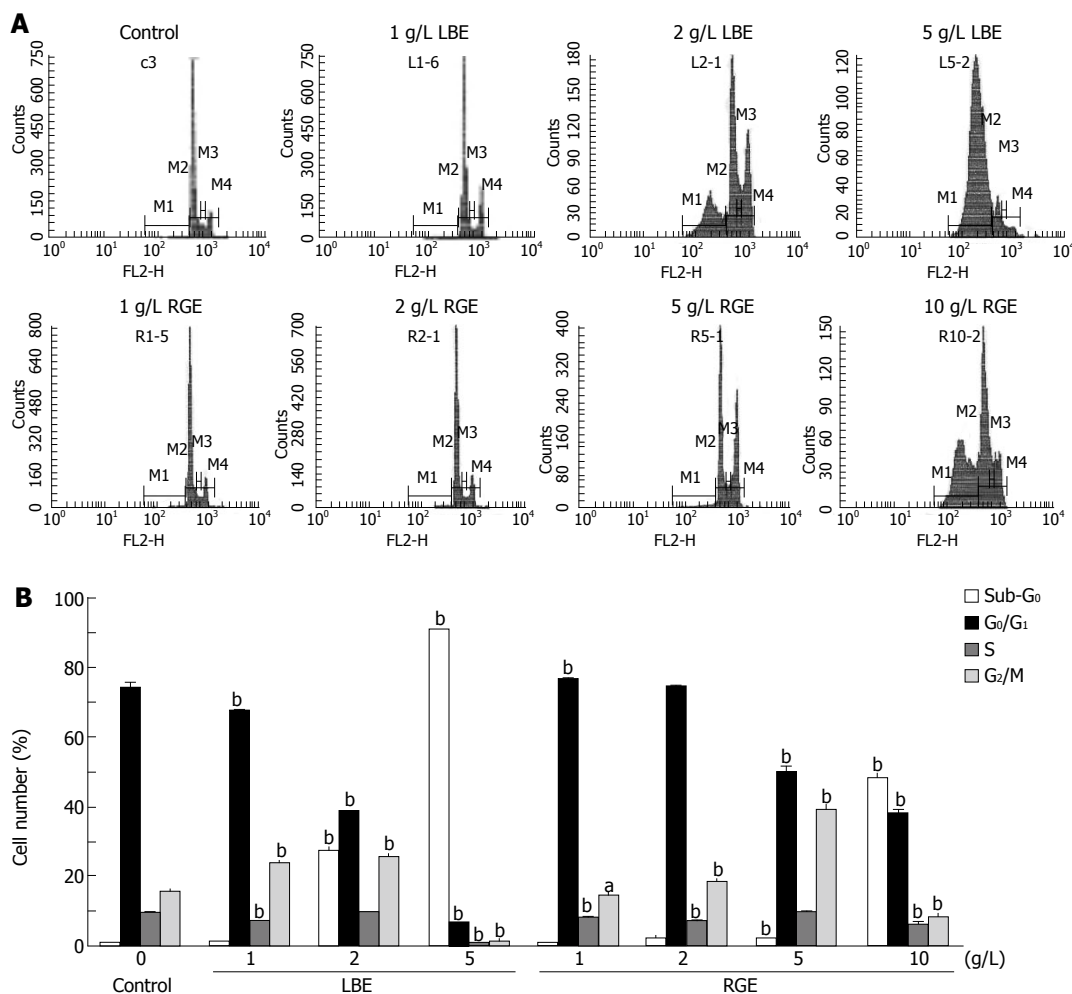

Figure 1 Representative DNA histograms (A) and percentage of cells in different cell cycle phases (B) after incubated with various concentrations of hot water-extracted LBE and RGE for 24 h in rat H-4-II-E cells determined by flow cytometry. Values are mean \pm SD ($n = 6$). Flow cytometric analysis of cellular DNA content

Cellular DNA content in cell cycle distribution was determined, and apoptosis was quantitated by the percentage of cells with sub-G₀ DNA content by flow cytometry (Figure 1A). Crude LBE and RGE at the doses above 2 g/L and 5 g/L, respectively, significantly increased the percentage of cells in sub-G₀ phase ($27.5\% \pm 0.5\%$ and $91.2\% \pm 0.3\%$ for 2 g/L and 5 g/L LBE, and $2.4\% \pm 0.2\%$ and $48.1\% \pm 2.0\%$ for 5 g/L and 10 g/L RGE, $P < 0.01$) compared with the control group ($1.0\% \pm 0.2\%$) (Figure 1B). The percentage of cells in G₀/G₁ phase was dose-dependently decreased by crude LBE and RGE. Crude LBE at lower doses (1-2 g/L) significantly increased the percentage of cells in G₂/M phase ($24.1\% \pm 0.4\%$ and $25.8\% \pm 0.3\%$, $P < 0.01$) compared with the control group ($15.8\% \pm 0.4\%$), but decreased the percentage of cells to $1.5\% \pm 0.1\%$ ($P < 0.01$) at a higher dose (5 g/L). Likewise, crude RGE at lower doses (2 g/L and 5 g/L) significantly increased the percentage of cells in G₂/M phase ($18.3\% \pm 0.4\%$ and $39.3\% \pm 2.1\%$, $P < 0.01$), but decreased the percentage of cells to $8.3\% \pm 0.7\%$ ($P < 0.01$) at a higher dose (10 g/L).

Analysis of p53 protein

After 24 h incubation with crude LBE and RGE, the expression of p53 protein in rat H-4-II-E cells was analyzed by SDS-PAGE and Western blotting (Figure 2A). After calibrated by an internal control (α -tubulin), the expression of p53 protein increased with the dosage of crude

Figure 2 Expression of p53 protein with the molecular weight of 53 ku visualized by Western blotting (A) and quantitated by an image analysis system (B) after incubation of rat H-4-II-E cells with various concentrations of hot water-extracted LBE and RGE for 24 h. Samples were pooled from 3 independent experiments ($n = 3$). Alpha-tubulin (55 ku) was used as an internal control.

LBE and RGE (Figure 2B). Crude LBE at higher doses (2-5 g/L) increased p53 expression to 119% and 143% of the

control group, respectively. Similarly, crude RGE at higher doses (5-10 g/L) increased p53 expression to 110% and 136% of the control group, respectively. However, lower doses of crude LBE (1 g/L) and RGE (1-2 g/L) suppressed p53 expression to 63%-70% of the control group.

DISCUSSION

Polysaccharides, a water-soluble bioactive component from LBE *L. Radix* RGE, showed antitumorigenic activity^[3,15]. The methods for the isolation of polysaccharides from these herbs are various in different studies. Different extraction methods and fractions could affect not only the ingredients but also the physiological activity of the extract. Our crude herbal extracts were prepared by hot water (100°C) extraction followed by ethanol (950 mL/L) precipitation. Gan *et al*^[3] extracted LBE with distilled water at 80°C after removal of pigment by acetone/petroleum (1:1) and oligosaccharides by 800 mL/L ethanol. The crude polysaccharide-protein complex was precipitated by ethanol, and the acidic fraction was further purified by diethylaminoethyl-cellulose anion exchange and Sephadex G200 column chromatography. Finally, a purified fraction (LBP_{3p}) contains 63.6% neutral sugars, 24.8% acidic sugars, and 7.6% proteins. The purified fraction showed antiproliferating and immunomodulating activity in S180-bearing mice. Compared with the purified LBP_{3p} fraction, our crude LBE contains lower sugars (88.4% *vs* 76.3%) and higher proteins (7.6% *vs* 13.5%). Zhang *et al*^[4] prepared purified fraction of RGE oligosaccharides by extraction with hot water and isolation with cation/anion exchange and charcoal column chromatography. The eluted fraction containing monosaccharides, disaccharides, trisaccharides, and other oligosaccharides but not polysaccharides exert a significant hypoglycemic effect in normal and alloxan-induced diabetic rats. Our crude extract did not contain certain water-insoluble active components in LBE and RGE. Scopoletin (7-hydroxy-6-methoxycoumarin), slightly soluble in water, could be excluded as extracted by hot water, and has been reported as an active component of the fruit of LBE for inhibiting cell proliferation of human prostate cancer PC3 cells^[23]. Furan derivatives, isolated from chloroform extract of the dried roots of RGE, have the immunomodulating and anti-coagulating activity^[24].

Our study found that both crude LBE and RGE suppressed cell proliferation in rat and human HCC cells in a dose-dependent manner. Consistent with our findings, Zhang *et al*^[25] showed that polysaccharide containing LBE extract inhibits cell proliferation of human hepatoma QGY7703 cells. Additionally, LBE polysaccharides (20-1000 mg/L) dose-dependently suppress cell growth of human leukemia HL-60 cells^[26]. The previous *in vivo* studies also showed that LBE exhibits the antitumorigenic activity in tumor-bearing mice^[3,27]. A polysaccharide-protein complex from LBE (LBP_{3p}) at 10 µg/g significantly reduces tumor weight and enhances immune functions in S180-bearing mice^[3]. RGE polysaccharide b with an average molecular weight of 160 ku has antitumorigenic and immunomodulating activity in S180-bearing mice^[13]. A clinical trial found 40.9% response rate in the advanced cancer patients

with lymphokine-activated killer (LAK) cells and interleukin-2 (IL-2) treatment combined with LBE polysaccharides compared with 16.1% response rate ($P < 0.05$) in those treated with LAK/IL-2 alone. These data indicate that LBE polysaccharides can be used as an adjuvant for the treatment of cancer^[28]. Chinese medicinal herbs containing RGE have been demonstrated to alleviate the adverse effects of high-dose methotrexate plus vincristine in post-operative osteogenic sarcoma patients with chemotherapy, suggesting that Chinese medicinal herbs containing RGE are less toxic compared with a traditional chemotherapy^[29]. The extract of LBE at the dose of 25 g/L and 5 g/L inhibited cell proliferation by 14% and 85%, and stimulated p53 protein expression by 19% and 43% in rat H-4-II-E cells after 24 h incubation. The extract of RGE at the dose of 5 g/L and 10 g/L inhibited cell proliferation by 23% and 76%, and stimulated p53 protein expression by only 10% and 36% in rat H-4-II-E cells after 24 h incubation. The inhibition of cell proliferation by LBE at the dose of 2 g/L was almost parallel to the stimulation of p53. However, the relationship between cell proliferation inhibition and p53 expression was not obvious in rat H-4-II-E cells treated with higher doses of LBE and RGE.

The percentage of cells in sub-G₀ phase significantly increased in H-4-II-E cells after 24 h treatment with higher doses of crude LBE (2-5 g/L) and RGE (5-10 g/L). A dramatic increased cell percentage in sub-G₀ phase by crude LBE and RGE at higher doses was probably due to late apoptotic/necrotic cells in sub-G₀ phase if undergoing autolysis, which could overestimate the apoptotic cells. The proliferation-inhibiting and apoptosis-inducing activity of crude LBE at higher doses (≥ 5 g/L) in HCC cells was more effective than that of crude RGE according to the mean values of IC₅₀ and the proportion of apoptotic cells. As initiating a significant increase in the percentage of cells in sub-G₀ phase by crude LBE (2 g/L) and RGE (5 g/L), the percentage of cells in G₂/M phase significantly increased. Additionally, the expression of p53 protein was correspondently stimulated as well after 24 h incubation with 2 g/L crude LBE and 5 g/L crude RGE. However, lower doses of crude LBE and RGE decreased the expression of p53 protein compared with the control group, which could be due to the overexposure to α -tubulin. The expression of p53 protein tended to be dose-dependently increased by crude LBE and RGE. The results suggest that higher doses of crude LBE and RGE arrest cells in G₂/M phase and p53 may be involved in mediating apoptosis. The mechanism of promoting G₂/M arrest by LBE and RGE has not been understood. It is proposed that LBE and RGE may inhibit nuclear factor- κ B to alter the expression of regulatory cell cycle proteins such as cyclin B and/or p21WAF1/Cip1. A previous study reported that LBE polysaccharides arrest cells in S phase and induce apoptosis with increased intracellular calcium in human hepatoma QGY7703 cells^[25]. Additionally, LBE (20-1000 mg/L) results in DNA fragmentation and positive TUNEL (terminal deoxynucleotidyl transferase-mediated dUTP nick end labeling) signals in human leukemia HL-60 cells, indicating that LBE induces apoptosis^[26]. Although the effect of LBE and RGE on apoptosis in normal hepatocytes has not been studied yet, the previous studies^[30,31] found

that LBE protects normal cells from apoptosis rather than stimulating apoptosis in tumor cells. LBE dose-dependently inhibits apoptosis induced by hydrocortisone in rat spleen *in vitro*^[30]. LBE extract shows cytoprotective effect against β -amyloid peptide-induced apoptosis in primary rat cortical neurons and dithiothreitol-induced caspase-3 activation in normal neural endoplasmic reticulum^[31]. The effect of LBE on apoptosis could be various due to different extraction methods, extraction fractions, dosages, tissues, and cell types (normal *vs* malignant). The low-molecular-weight RGE polysaccharides at the doses of 20 μ g/g and 40 μ g/g markedly increase the level of p53 mRNA to 3.3- and 3.2-fold, respectively, in Lewis lung cancer tissue of C57BL/6 mice^[15]. Activation of p53 tumor suppressor protein can lead to cell cycle arrest and apoptosis in response to DNA damage^[32]. Cell death induced through p53-mediating pathway is subsequently initiated by the activation of caspases followed by the characteristic apoptotic phenotype.

The mechanisms underlying regulation of apoptosis by LBE and RGE have not been clearly understood. Besides the induction of p53-mediated apoptosis, immunomodulation may contribute to antitumorigenesis. A polysaccharide-protein complex from LBE (LBP_{3p}) dose-dependently increases the expression of IL-2 and tumor necrosis factor (TNF)- α at the levels of mRNA and protein in human peripheral blood mononuclear cells^[33]. An *in vivo* study showed that LBP_{3p} administered orally at 10 μ g/g for 10 d inhibits cell growth of transplantable sarcoma S180 cells as well as increases macrophage phagocytosis, cell proliferation of spleen lymphocytes, the activity of cytotoxic T lymphocytes (CTL), and the expression of IL-2 mRNA in S180-bearing mice^[3]. RGE polysaccharide b at the intraperitoneal injection dose of 10 μ g/g or 20 μ g/g attenuates the decrease in CTL activity caused by excessive tumor growth through increasing the production of CD8⁺ (Lyt-2⁺) CTL and lowering the ratio of CD4⁺ to CD8⁺ (L3T4⁺) T lymphocyte subset in S180-bearing mice^[13]. An aqueous extract of RGE-steamed root dose-dependently suppresses the secretion of TNF- α by mouse astrocytes stimulated with substance P and lipopolysaccharide through the inhibition of IL-1 secretion, suggesting that RGE has the anti-inflammatory activity^[14]. Although crude LBE and RGE show antitumorigenic activity *in vitro*, it still remains to determine the antitumorigenic components of crude LBE and RGE, and molecular mechanisms for regulating the proliferation of HCC cells.

In conclusion, hot water-extracted LBE (2-5 g/L) and RGE (5-10 g/L) inhibit proliferation and stimulate apoptosis probably involved in p53 mediation in HCC cells. It is not known that whether hot water-extracted LBE and RGE have antiproliferative and apoptosis-stimulating effects on HCC *in vivo* and further studies are still required to verify their *in vivo* effects on both normal and malignant hepatocytes.

ACKNOWLEDGMENTS

The authors gratefully thank Dr. Ting-Jang Lu in the Institute of Food Science and Technology, National Taiwan University for providing suggestions in the preparation of crude polysaccharide extracts.

Abstract

AIM: To investigate whether a fuzzy logic model could predict colorectal cancer (CRC) risk engendered by smoking in hereditary non-polyposis colorectal cancer (HNPCC) patients.

METHODS: Three hundred and forty HNPCC mismatch repair (MMR) mutation carriers from the Creighton University Hereditary Cancer Institute Registry were selected for modeling. Age-dependent curves were generated to elucidate the joint effects between gene mutation (hMLH1 or hMSH2), gender, and smoking status on the probability of developing CRC.

RESULTS: Smoking significantly increased CRC risk in male hMSH2 mutation carriers ($P < 0.05$). hMLH1 mutations augmented CRC risk relative to hMSH2 mutation carriers for males ($P < 0.05$). Males had a significantly higher risk of CRC than females for hMLH1 non smokers ($P < 0.05$), hMLH1 smokers ($P < 0.1$) and hMSH2 smokers ($P < 0.1$). Smoking promoted CRC in a dose-dependent manner in hMSH2 in males ($P < 0.05$). Females with hMSH2 mutations and both sexes with the hMLH1 groups only demonstrated a smoking effect after an extensive smoking history ($P < 0.05$).

CONCLUSION: CRC promotion by smoking in HNPCC patients is dependent on gene mutation, gender and age. These data demonstrate that fuzzy modeling

INTRODUCTION

Accurate risk-stratification is essential for combating the 50000 yearly deaths from colorectal cancer (CRC) in the United States^[1]. The best-established risk factor is a familial predisposition to CRC, which is implicated in one-quarter of all CRC cases^[2]. While determining a family history can be readily accomplished, risk quantification which is critical for tailoring screening strategies, remains remarkably imprecise. For instance, even in documented carriers of CRC predisposing genes, clinical expression can be quite varied due to modulation by numerous confounding endogenous and exogenous variables^[3,4].

Hereditary non-polyposis colorectal cancer (HNPCC) represents a case in point. This autosomal dominant condition is the most common cancer predisposing syndrome engendering a $> 70\%$ lifetime risk of developing CRC^[5]. Furthermore, we have recently demonstrated that cigarette smoking of a male carrying hMLH1 mutations (versus hMSH2) increases the hazard of CRC by 1.4-, 1.6- and 2.0-fold respectively^[6]. However, optimal management strategies (colonoscopic surveillance versus prophylactic colectomy) are unclear secondary to characteristic phenotypic heterogeneity, i.e. marked variations in age of onset of cancers^[7]. Thus, HNPCC represents an excellent paradigm to study the gene-environment joint effect hypothesis.

Incorporating these important findings into clinical

practice is hindered by the inability to accurately quantitate the risk modulation engendered by the joint effects of genetics and environmental factors. Moreover, the inadequacy of conventional statistical approaches to model the complex nature of many of the CRC risk factors further limits application of these data to patient management. While landmark studies have explored the age of CRC diagnosis in HNPCC^[8], these estimates along with others in the literature have not yet factored in the genetic/environmental influences that determine the phenotypic heterogeneity. The focus of our study was on this phenotypic heterogeneity which is of major importance to clinicians who care for these challenging patients. We believe that by knowing the genetic and environmental risk factors, we can individualize more accurately the risk analysis, which, to our knowledge, has not been previously reported.

One approach from the engineering literature that has recently received attention for cancer risk assessment is fuzzy logic. This powerful modeling technique has been successfully used for pattern recognition and image processing and its unique ability to transcend the typical black or white approaches in standard modeling and to capture the “shades of gray” has great promise for clinical medicine^[9]. While typical statistical approaches function well when the data are normally distributed and values are near the mean, this approach is often inadequate at the threshold. For instance, a very high prostate specific antigen (PSA) has excellent predictive ability for prostate cancer, but the optimal clinical management of a patient with a mildly elevated value is unclear. Fuzzy logic overcomes these limitations of conventional statistics by allowing partial membership function. In our PSA example, instead of categorizing values as either normal or abnormal, a fuzzy approach would allow one to place a value as one quarter in the normal group and three-quarters in the abnormal group. Thus, through the creation of fuzzy sets, elements can have degrees of membership on a continuum (e.g. a value can be “normal, slightly elevated, moderately elevated or highly elevated”).

Another unique attribute of fuzzy modeling is that, unlike traditional models, it does not require prior knowledge of the system being modeled. It is a “model-free” form in which natural rules are developed from the data rather than imposing rules on the modeling system. The result of this “model-free” system is still a conversion from inputs to outputs, similar to traditional algorithms^[10]. Another strength of fuzzy modeling lies in its ability to model data points that may be outside of traditional inclusion boundaries and thus allowing accurate modeling with less data.

Past reports have demonstrated that fuzzy modeling can improve performance characteristics of tumor markers over conventional applications^[11-13]. Our previous work with conventional statistical approaches (COX proportional hazard modeling) indicated that tobacco use, gender and mutated gene play an important role in phenotypic presentation of CRC progression in HNPCC patients as a group, but lack the ability to predict an individual risk of CRC (e.g. not sensitive to dose effects or interactions of factors). We, therefore, explored the

Figure 1 Overview of fuzzy methodology.

ability of fuzzy modeling to predict CRC risk in germline mutation carriers in these individual HNPCC patients by factoring the gene type, gender and tobacco use status in the present study.

MATERIALS AND METHODS

Database

The Hereditary Cancer Center at Creighton University is one of the oldest and largest registries for diverse hereditary cancer syndrome, containing information on over 200 000 individuals of whom approximately 600 are verified MMR mutation carriers (Lynch Database). The database contains patient and family information, surveillance and treatment information as well as gene mutations and lifestyle data. The inclusion criteria were HNPCC as documented by either a MMR germline mutation positivity or clinical HNPCC from a patient who had a family member with a documented MMR mutation. For example, if the patient has HNPCC and his mother has a documented hMSH2 mutation, we would consider the patient to have an hMSH2 mutation. Tobacco data were obtained by self-report and family report or by abstraction from medical records. A patient was classified as a tobacco user if he/she reported ever regularly using (or was reported to have ever regularly used) cigarettes, cigars, a pipe, tobacco chew, or snuff. Five hundred and ninety-six mutation carriers were identified from 62 HNPCC families. For this analysis we only focused on cigarette smokers. Of these, 340 (60.4%) had information on tobacco use and were included in our study (158 nonsmokers and 182 smokers). In a further analysis, 271 patients (113 of 182 smokers and 158 nonsmokers) with a more detailed smoking history including calculated pack-years were selected.

Modeling

The entire modeling procedure was performed using the MatLab Fuzzy Toolbox (Matlab, Version 6.1-Release 13, Natick, MA). Figure 1 provides an overview of the basic fuzzy modeling algorithm. The data (either categorical or continuous) were inputted into the program and a clustering algorithm led to the development of membership functions. The fuzzy clustering method used produces descriptions of each of the input vectors as belonging to one (or more) fuzzy sets with a specific membership in each of the sets. The inclusion of a continuous variable (pack-years and age) produces non-categorical (aka, fuzzy) memberships. Rules are then developed from these membership functions which successfully produce a mapping from the input space to the output space as previously described^[10]. Furthermore,

Figure 2 Scattergram demonstrating the probability of developing CRC (cumulative lifetime risk) for each subject based on smoking status, \blacktriangle = Smokers, \square = Non-Smokers. Data are divided by gene mutation and sex with (A) hMLH1: Female, (B) hMLH1: Male, (C) hMSH2: Female and (D) hMSH2: Male ($P < 0.05$).

these rules represent fuzzy relationships between the variables, even if the variables themselves are categorical. The refinement of these rules is accomplished using the Adaptive Neural Fuzzy Inference System (ANFIS; 16) which acts as a feedback loop to further refine the rules until they are optimized to give the best fit to the data. Overfitting of the model to the data is not exclusively addressed. However, the clustering methods (subtractive clustering) employed in the modeling scheme tend to partition the data space in such a manner as to maximize the cluster density while simultaneously maximizing the separation of the clusters which would limit overfitting.

This modeling technique was applied to the patients selected from the Lynch database with gene mutation, sex, smoking status and age as the input and risk of developing colorectal cancer as the output. In a second study, the effect of pack years was added as an additional input. In this case, dividing a group of smokers with a given mutation, sex and age further by smoke years made the numbers in each group quite small. We therefore used the data as the training set and a theoretical set of conditions as the input to generate the model output. The models produced a cumulative risk of CRC that ranged between 0 and 1. Age and pack years were fuzzified in the program.

Statistical analysis

Results are presented either as a scattergram of the actual model output for each patient in the database (Figures 2-4) or as an output of the model given a set of theoretical conditions (Figure 5). The statistical procedures used followed the methods described by Steel and Torrie^[14]. The data for each cohort were paired and compared using a Kolmagrov-Smirnov (KS) 2-sample test. The KS test was considered to be conservative and useful when hypothesis about discrete distributions was tested. The test is motivated by the need to compare 2 independent samples and the null hypothesis is that each sample originates from

identical distributions (i.e., the data are from the same population). Critical values for the KS test are inversely proportional to the square root of the total number of observations. The nature of our data dictated that the critical values were computed using unequal populations ($n_1 \neq n_2$). Furthermore, the nature of the data and results only required a comparison of this type. Other analyses, such as a test of trend or analysis of variance, were not deemed beneficial.

RESULTS

Smoking status

The influence of genetic mutation combined with sex, smoking status and age is demonstrated in Figure 2. There was a clear impact of cigarette smoking on the age-adjusted risk of developing CRC for all conditions tested (gene mutated and gender).

When a male patient with the hMSH2 gene mutation carrier smokes, he markedly increased his risk of developing CRC by up to 2.4-fold at the age of 78 (Figure 2D, $P < 0.05$). In the case of a mutation in the hMLH1 gene, smoking increased the risk of CRC at the maximal age tested by approximately 1.3-fold for males when compared to non-smokers (Figure 2B). Females with the hMLH1 mutation showed a 1.3-fold increased risk of developing CRC and female smokers with the hMSH2 mutation had a 1.4-fold greater risk of developing CRC when compared to their non-smoking age-matched controls (Figures 2A and 2C).

Gene

The model output was then reexamined as a function of the genetic mutation (Figure 3). For males, patients with a hMLH1 mutation had either a 2.5- or a 1.3-fold greater risk of developing CRC than those with a hMSH2 for non-smokers and smokers respectively (Figures 3B and 3D, $P <$

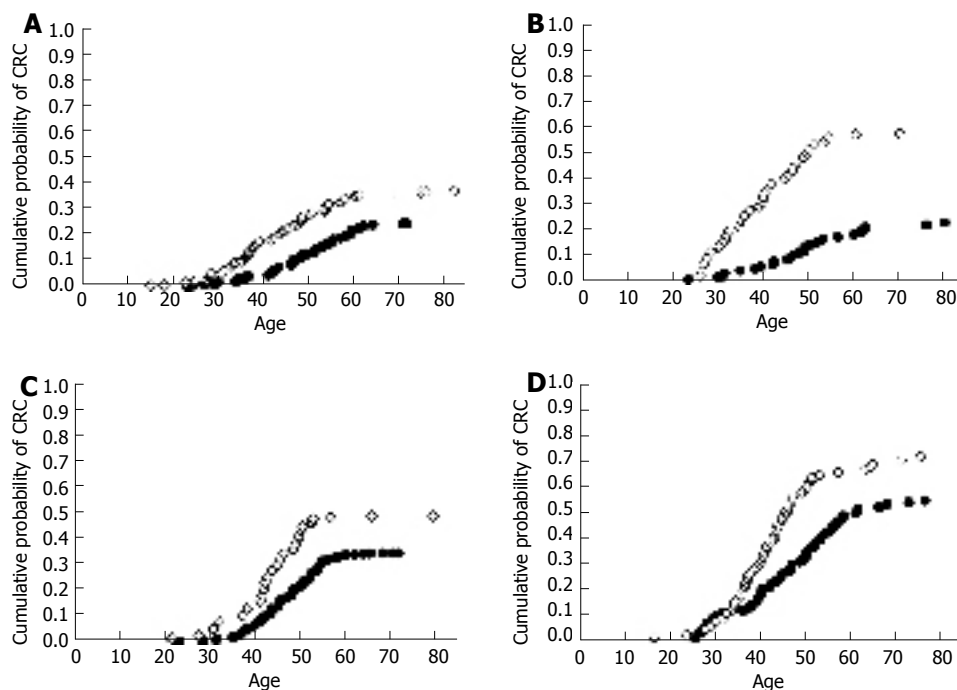

Figure 3 Scattergram demonstrating the probability of developing CRC (cumulative lifetime risk) for each subject based on genetic mutation, \diamond = hMLH1, \bullet = hMSH2. Data are divided by sex and smoking status with (A) Female: non-smokers ($P < 0.001$), (B) Female: smokers ($P < 0.001$), (C) Male: non-smokers ($P < 0.001$) and (D) Male: smokers ($P < 0.05$). The P values show the probability failing to reject the null hypothesis that the data originate from identical populations, indicating that the curves are different.

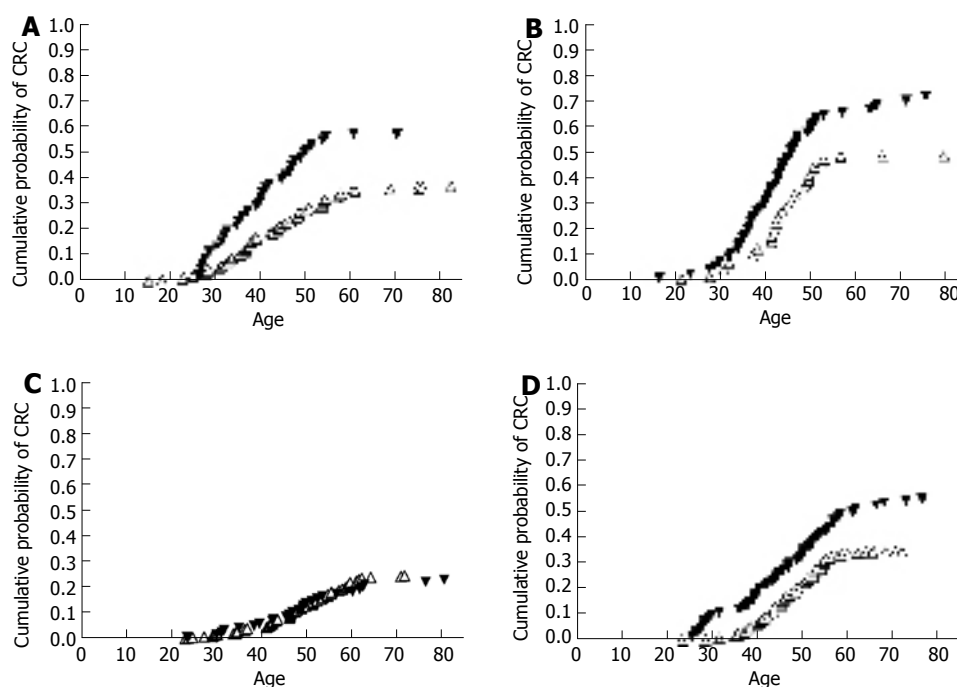

Figure 4 Scattergram demonstrating the probability of developing CRC (cumulative lifetime risk) for each subject based on gender, \triangle = female, \blacktriangledown = male. Data are divided by gene mutation and smoking status with (A) hMLH1: non-smokers, (B) hMLH1: smokers ($P < 0.1$), (C) hMSH2: non-smokers ($P > 0.05$) and (D) hMSH2: smokers ($P < 0.1$). The P values show the probability of failing to reject the null hypothesis that the data originate from identical populations, indicating that the curves are different.

0.05). The difference was greater for the non-smokers than the smokers because subjects with hMSH2 who smoke increased their rate of CRC greater than the non-smokers. Female non-smokers with the hMLH1 mutation showed a 1.5-fold increase in CRC risk as compared to the hMSH2 subjects, whereas it was 1.4-fold higher for smokers.

Gender

Figure 4 demonstrates that males had a greater risk of developing CRC than females when compared to an equivalent age, gene mutation and smoking status. Males had a significantly higher risk of CRC than females (1.5-fold) for non-smoking subjects with the hMLH1

mutations (Figure 4A, $P < 0.05$) and smokers (1.6-fold) (Figure 4B, $P < 0.1$). Smoking males with the hMSH2 mutation also had a greater risk of CRC than hMSH2 mutation harboring females by 1.6-fold (Figure 4D, $P < 0.01$), but the gender effect dissipated in nonsmokers (Figure 4C, $P > 0.05$).

Smoking dose response

A subset of the data which had an estimate of pack years was then modeled to determine if there was an association between lifetime quantities of cigarettes smoked and risk of CRC. The mean consumption was 24-pack years for patients who smoked cigarettes. Figure 5 demonstrates the

Figure 5 Probability of developing CRC (cumulative lifetime risk) based on a model containing pack years for (A) females with hMLH1 mutation ($P < 0.01$), (B) males with hMLH1 mutation ($P < 0.05$), (C) females with hMLH1 mutation ($P < 0.01$), and (D) males with hMSH2 mutation ($P < 0.01$). The P values show the probability of failing to reject the null hypothesis that the data originate from identical populations. The number of pack years is as follows: - = 0, -x = 10, --- = 20, -·- = 30 and -+ = 40.

risk of developing CRC as a function of pack years. For female smokers with a hMLH1 mutation (Figure 5A), the CRC risk was only increased after 30-pack years ($P < 0.01$), whereas for males (Figure 5B) the risk did not significantly increase until 40-pack years ($P < 0.05$). Similarly, females with a hMSH2 (Figure 5C) only demonstrated a smoking effect at 40-pack years ($P < 0.01$). Conversely, males with a hMSH2 mutation (Figure 5D) had an increased risk of developing CRC in a dose-dependent fashion in response to the number of cigarettes smoked over their lifetime ($P < 0.01$).

DISCUSSION

We have demonstrated herein that by using a fuzzy modeling approach, we could quantitatively predict the effect of environmental factors on risk of developing CRC in subjects who harbor a germline mutation for HNPCC. Importantly, we could calculate estimates for the impact of modifiable risk factors (i.e. smoking) on the occurrence of CRC in these high-risk patients and individualize the risk estimates by accounting for other major factors on the phenotypic variability in HNPCC patients: the mutated gene (hMLH1 versus hMSH2) and gender. Thus, we believe that these results may be a useful tool in patient counseling by providing concrete estimates of the impact of risk factor modification.

Our observations regarding the gene-environmental joint effects were made possible by the remarkable resource represented by the Creighton Hereditary Cancer Center Registry. Although it is one of the oldest and largest HNPCC registries in the world, a conventional statistical approach to this dataset is not powerful enough to detect the gene-environment joint effect and the dose-response of smoking and CRC^[15], because the relatively small subgroup size markedly reduces statistical power in conventional (e.g. Cox proportional hazard modeling) statistical approaches. One approach to mitigate these

concerns is to increase the size of groups (e.g. to evaluate effect of age by increasing 40-59, 60-79, *etc.*). However, such large groups have clear disadvantages. For instance, a 41-year old individual and a 58-year old individual may be quite biologically/ clinically different and yet are in the same stratum. Fuzzy modeling enables partial membership functions. For instance, a 43-year old individual may be considered to be 80% in the 40-50 group and 20% belonging to the 30-39 category, whereas a 59-year old individual may be 65% in the 50-59 group and 35% within the 60-70 group. Thus, fuzzy modeling allows us to account for the heterogeneity, i.e., “shades of gray” that is a hallmark of clinical medicine.

There are several lines of evidence that support the biological validity of our findings with fuzzy modeling. Cigarette use is an important risk factor for CRC, and 12% of all CRC deaths are attributed to smoking^[16]. Many studies indicate that cigarette smoking can increase the incidence of colon cancers by approximately two fold, however there are numerous contradictory reports^[17-19]. These discordant data have been clarified by the demonstration that cigarette smoking may selectively increase the risk for DNA mismatch repair^[20]. This may be related to the observation that smoking preferentially promotes microsatellite unstable (MSI-high) tumors. The molecular pathway is also seen in Lynch syndrome tumors^[19]. For instance, Yang *et al.*^[21] have recently reported that cigarette smoking increases the risk of developing MMR-deficient tumors by 3.1-fold. Additionally, Slattery *et al.*^[22] demonstrated that smoking 20 cigarettes per day increases the risk of MMR-deficient tumors by 1.6-fold in men (95% CI = 1.0-2.5) and 2.2-fold in women (95% CI = 1.4-3.5). Furthermore, they have documented a dose-dependent relationship between smoking and colorectal cancer^[22]. This dose-dependence underscores the plausibility of the cigarette-induced CRC risk. While we were able to discern an effect of smoking in our previous

study in HNPCC- cigarette smoking data set with Cox proportional hazard modeling, the lack of dose response raises concerns about the validity of the findings^[15]. Using fuzzy modeling we demonstrated a much clearer relationship. For instance, our dose response model predicts that female smokers with a hMLH1 mutation who have at least 30-pack years of smoking will have an increase in the lifetime risk of CRC by 2.2- fold. A 3.3-fold increase is seen for females with an hMSH2 mutation after 40 pack years. Males with a hMSH2 mutation have a more linear increase in their lifetime risk of developing CRC as a function of pack years.

This ability to quantitate an individual's risk is of paramount clinical importance due to the variability in CRC presentation that is characteristic of HNPCC. For instance, some members of a kindred may develop CRC at age 25 and 65 while other members may never develop it. Given this heterogeneity, "one size fits all" approach to management (the current state of the art) is clearly inadequate. Indeed, previous attempts to determine the optimal cancer prevention strategy (prophylactic colectomy versus colonoscopic surveillance) have failed to conclusively demonstrate the superiority of any single approach^[7]. Even determining the best colonoscopic intervals is unclear. While our group recommends annual colonoscopy starting at age 25^[23], a large number of negative examinations are expensive and have potential complications and may lead to patient complacency. Increasing surveillance intervals is fraught with danger given both the rapid adenoma to carcinoma transition and also the flat nature of the lesions, leading to a higher possibility of lesions being missed on colonoscopy^[23]. The consequences of inadequate screening are underscored by the report of Jarvinen and colleagues^[24], who noted that over a 15-year observation period, 8.4% of HNPCC patients who did not undergo screening would die of CRC whereas none of those who were in a screening program can succumb to this malignancy. Indeed, in mutation positive subjects, development of CRC occur in 42% of the non-screened but only 18% in patients receiving screening ($P < 0.02$)^[24]. Thus, implementation and adherence of a screening regimen are critical in protecting these high-risk patients against CRC.

It needs to be emphasized that the ability of fuzzy modeling to quantitate risk may be of considerable importance in counseling patients. For instance, being able to tell patients that their risk of CRC more than doubles with smoking may be more tangible than stating that smoking is detrimental to ones health, thereby providing a greater impetus for behavior modification. By accurately delineating risk, patients will be able to concretely identify modifiable risk factors and ascertain the impact of their lifestyle changes, thus providing positive reinforcement. In this regard, Halpert and colleagues^[25] noted that genetic testing of HNPCC patients may have a profound effect upon motivation for cancer prevention strategies such as colonoscopy. Improved adherence with CRC screening regimens from genetic testing and counseling is also documented by Hadley and associates^[26]. The malleability of CRC prevention behaviors in HNPCC patients is further highlighted by Adams and colleagues^[27] who

documented the effect of socio-economic considerations on age of resection of CRC in HNPCC patients. Thus, we believe that added information obtained by fuzzy modeling may have a dramatic effect on patient behavior and thus outcomes. There are previous demonstrations of the efficacy of fuzzy logic to cancer risk stratification. Fuzzy logic has been used with impressive success to improve the sensitivity of tumor markers in diagnosing cancer^[11-13].

There are several limitations of this report that need to be acknowledged. As any modeling, the accuracy of the results is dependent on quality of the data inputted. Many of our patients did not have data to quantitate pack-years. Bias in the database due to patient/family report is possible (e.g. having cancer may influence recollection of tobacco use history). Since tobacco use is not a "standard" risk-factor for CRC, we do not think this will impact the results. With smoking, there is always concern about confounding from "competing causes of mortality"^[28]. However we have recently shown that this effect is negligible for the smoking-CRC effect^[29]. Finally, while our modeling accurately reflects our database, the algorithms need to be validated in other databases.

In conclusion, a fuzzy modeling approach represents a promising means of predicting the phenotypic heterogeneity in colorectal cancer presentation in HNPCC mutation carriers. The methodology may be an important tool in unraveling the gene-environment joint effects in hereditary cancer syndromes. Furthermore, this may serve as the basis for future paradigms that determine individualized cancer prevention strategies in subjects harboring an inherited risk.

the levels of intracellular core-associated HBV DNA and extracellular production of HBsAg and HBeAg. The levels of intracellular core-associated viral RNA also decreased, but the expression of HBcAg in transfected cells showed almost no change. Consistent with *in vitro* results, levels of HBsAg in the sera of mice were dramatically decreased. More than 1.5 log₁₀ decrease in levels of serum HBV DNA and liver HBV RNA were observed in the APOBEC3G-treated groups compared with the control groups.

CONCLUSION: These findings indicate that APOBEC3G could suppress HBV replication and antigen expression both *in vivo* and *in vitro*, promising an advance in treatment of HBV infection.

Abstract

AIM: To investigate the effect of APOBEC3G mediated antiviral activity against hepatitis B virus (HBV) in cell cultures and replication competent HBV vector-based mouse model.

METHODS: The mammalian hepatoma cells Huh7 and HepG2 were cotransfected with various amounts of CMV-driven expression vector encoding APOBEC3G and replication competent 1.3 fold over-length HBV. Levels of HBsAg and HBeAg in the media of the transfected cells were determined by ELISA. The expression of HBcAg in transfected cells was detected by western blot. HBV DNA and RNA from intracellular core particles were examined by Northern and Southern blot analyses. To assess activity of the APOBEC3G *in vivo*, an HBV vector-based model was used in which APOBEC3G and the HBV vector were co-delivered *via* high-volume tail vein injection. Levels of HBsAg and HBV DNA in the sera of mice as well as HBV core-associated RNA in the liver of mice were determined by ELISA and quantitative PCR analysis respectively.

RESULTS: There was a dose dependent decrease in

INTRODUCTION

Hepatitis B virus (HBV) infection is a major cause of liver disease worldwide, ranging from acute and chronic hepatitis to cirrhosis and hepatocellular carcinoma^[1]. HBV replication involves reverse-transcription of a pregenomic RNA (pgRNA) intermediate inside nucleocapsids, which are formed by 180 or 240 core protein subunits. Inside the capsid, the viral polymerase converts pgRNA into minus-strand DNA, which in turn is completed to a double-stranded, relaxed circular DNA molecule^[2,3]. This life cycle places HBV into the large family of retroelements, which all require reverse-transcription of an RNA intermediate.

Recently, a cellular defense mechanism targeting a wide range of retroviruses was identified. It was shown that the propagation of HIV-1 strains lacking the accessory protein Vif is suppressed in nonpermissive cells due to expression of the cytidine deaminase APOBEC3G^[4,5]. Further studies revealed that A3G induces massive C→U deamination of single stranded retroviral DNA, resulting

in DNA degradation or lethal G→A hypermutation^[6-8]. In addition, APOBEC3F (another cytidine deaminase of APOBEC family) is also a potent retroviral restrictor, but its activity, unlike that of APOBEC3G, is partially resistant to HIV-1 Vif and results in retroviral hypermutation. Moreover, APOBEC3F and APOBEC3G appear to be coordinately expressed in a wide range of human tissues and are independently able to inhibit retroviral infection. Thus, APOBEC3F and APOBEC3G are likely to function alongside one another in the provision of an innate immune defense, with APOBEC3F functioning as the major contributor to HIV-1 hypermutation *in vivo*^[9]. Interestingly, APOBEC3G can also interfere with the HBV life cycle in cotransfected cells^[10,11]. Surprisingly, however, reduced levels of encapsidated viral pgRNA rather than extensive editing were found to be the major contributing factor^[10]. APOBEC3G-mediated editing did occur but was only detected in a minority of clones produced in transfected HepG2 hepatoma cells^[11].

In the present study, we performed a detailed analysis of the inhibition effect of APOBEC3G on hepatitis B virus replication in cell culture and in an HBV vector-based mouse model.

MATERIALS AND METHODS

Plasmid constructs

To construct expression vectors coding for human APOBEC3G (pXFA3G), total RNAs were extracted from peripheral blood mononuclear cells (PBMCs). RT-PCR amplification of human APOBEC3G sequence used forward primer 5'-CGGAATTCAAGCCTCACTT CAGAAACAC-3' and reverse primer 5'-CGAAGCTT TCTGCCTTCCTTAGAGACT G-3'. The PCR product was cloned into EcoRI/HindIII restriction sites of the CMV-driven expression vector fused with a hemagglutinin fusion epitope tag at its carboxy terminal end (pXF3H). Replication competent wild-type HBV 1.3 fold over-length plasmid (subtype, ayw) has been constructed previously in our laboratory.

Cell culture, transfection and harvesting

HuH-7 cells were grown at 37°C with 50 mL/L CO₂ in Dulbecco's modified Eagle medium, supplemented with 10% fetal calf serum (Invitrogen, CA, USA). The cells were plated at a density of 4.5×10^5 cells per well in 6-well plates 18 h prior to transfection. Transfection of cells was performed with lipofectamine 2000 (Invitrogen, CA, USA) following the user guidelines. On d 3 after transfection, the cells were removed from the culture dish by treatment with trypsin-EDTA, resuspended in culture medium, washed with phosphate-buffered saline, pelleted, and resuspended in 1 mL chilled lysis buffer (140 mmol/L NaCl, 1.5 mmol/L MgCl₂, 50 mmol/L Tris-HCl [pH 8.0]) containing 0.5% Nonidet P-40. Nuclei were removed *via* centrifugation for 5 min at 2000 r/min in an Eppendorf centrifuge, and the supernatant was cleared of cell debris by centrifugation for another 5 min at 14000 r/min.

HBV vector-based mouse model

For the *in vivo* experiments, 6 to 8 wk-old female BALB/c

mice were used. A total of 18 mice were randomly divided into 3 groups (6 mice in each). Replication competent pHBV1.3 (10 µg) and APOBEC3G expression vectors pXFA3G (10 µg) or pXF3H (10 µg) control plasmid DNA were co-injected into the tail vein of mice in a volume of Ringer's injection equivalent to 9% of the mouse body weight^[12,13]; the total volume was delivered within 5 s. The mouse sera were collected at indicated time after hydrodynamic injection, and secreted HBsAg levels and HBV DNA content were measured. All mouse experiments were carried out according to the guidelines established by the Institutional Animal Care and Use Committee at the Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China.

HBsAg and HBeAg assays and western blot analysis

Levels of HBsAg and HBeAg in the media of the transfected cells, and in the sera (1:100 diluted) of the treated mice were determined using ELISA (Shanghai Shiyeh Kehua Company, China). For western blot analysis, cytoplasmic lysates were incubated with 1 volume 2 × loading buffer containing 10% beta-mercaptoethanol for 10 min at 95°C before loading onto a 12.5% SDS-PAGE. Proteins were transferred onto nitrocellulose membrane *via* electroblotting. The membranes were incubated with HBV core specific rabbit antiserum (Santa Cruz, USA) or with anti-hemagglutinin fusion epitope monoclonal antibody (Santa Cruz, USA) followed by horseradish peroxidase-conjugated mouse anti-rabbit antibody. Proteins were visualized *via* enhanced chemiluminescence (Roche, Germany).

HBV DNA purification and analysis

The method for purification of cytoplasmic core-associated HBV DNA was adapted from Pugh *et al.*^[14]. Briefly, Huh7 cells were disrupted in lysis buffer (100 mmol/L Tris-HCl pH 8.0, 0.2% NP-40). The cell lysate was clarified by centrifugation at 13000 r/min for 1 min to pellet nuclei and insoluble material. The supernatant was adjusted to 6 mmol/L MgOAc₂ and incubated for 2 h at 37°C with 200 µg/mL of DNase I and 100 µg/mL of RNase A. Following digestion, the lysate was centrifuged for 1 min at 13000 r/min. The supernatant was incubated for 1 h at 55°C after addition of 10 mmol/L EDTA, 1% SDS, 100 mmol/L NaCl and 200 µg/mL of proteinase K. Finally, the sample was extracted with phenol: chloroform. The DNA was ethanol precipitated, resuspended in TE pH 8 (10 mmol/L Tris-HCl pH 7.5, 1 mmol/L EDTA) and digested with 100 ng/µL of RNase A for 30 min at 37°C. Purified DNA was subjected to Southern blot analysis. DNA samples were loaded onto 1.3% agarose gels, blotted onto nylon membranes, and probed with a Dig-labeled full-length HBV genome in EasyHyb hybridization solution (Roche, Germany).

For quantitative PCR, 100 µL mouse serum was adjusted to 6 mmol/L MgOAc₂ and incubated for 2 h at 37°C with 200 µg/mL of DNase I and 100 µg/mL of RNase A. Following proteinase K digestion, the sample was extracted with phenol: chloroform. HBV DNA levels were analyzed with the Light Cycle real-time PCR system (Roche, Germany), and primer sequences as follows: 5'-TCACAATACCGCAGAGTC-3' (nt231-248, forward), 5'

- AGCAACAGGAGGGATACA-3' (nt569-552, reverse). The pHBV1.0 vector containing the full-length HBV genome was used as a standard curve to calculate HBV copies per milliliter of serum.

RNA isolation and analysis

For Northern blot analysis, total RNA was extracted from transfected cells with TRIzol reagent (Invitrogen, USA) according to the manufacturer's instructions. Twenty microgram RNA was separated by electrophoresis on a 1% agarose gel and transferred onto nylon membrane, hybridized with a DIG-labeled DNA fragment covering the full-length HBV sequence. The probe was generated with a PCR DIG probe synthesis kit (Roche, Germany). For Northern blot analysis, RNA samples were resolved on MOPS-buffered 1.2% agarose gels containing 1.8% formaldehyde followed by capillary transfer onto nylon membranes and hybridization with a ³²P-labeled full-length HBV probe.

For quantitative RT-PCR, approximately 20 mg of liver tissue was obtained from mice for total RNA extraction with RNeasy total RNA kit (QIAGEN, Germany), according to the manufacturer's protocol. cDNA was synthesized from 2 µg of total RNA with oligo(dT)₁₅ primer in a total volume of 20 µL. Quantitative RT-PCR was performed with the Light Cycle real-time PCR system (Roche, Germany). The PCR primers are as follows, GAPDH: 5'-GTTGTCTCCTGCGACTTCA-3' (forward), 5'-GGTGGTCCAGGGTTTCTTA-3' (reverse); HBV: 5'-TCACAATACCGCAGAGTC-3' (nt231-248, forward), 5'-AGCAACAGGAGGGATACA-3' (nt569-552, reverse). A standard curve was constructed by the simultaneous amplification of serial dilutions of the expression plasmid encoding HBV used as templates. Target cDNAs were normalized to the endogenous RNA levels of the GAPDH. Quantitative amplification was carried out using the SYBR Green kit (Invitrogen, USA). Gene expression was determined using the relative quantification: $\Delta\Delta C_T = (C_{T\text{Target}} - C_{T\text{GAPDH}})_{\text{Test}} - (C_{T\text{Target}} - C_{T\text{GAPDH}})_{\text{Control}}$. C_T is the fractional cycle number that reaches a fixed threshold, C_{Test} is the test of HBV, and C_{Control} is the reference control (RNA from control group). ΔC_T is the difference between gene expression in treated cells and reference control cells. The fold increase was calculated using $2^{-\Delta\Delta C_T}$ [14].

RESULTS

Inhibitory effect of APOBEC3G on HBV DNA replication in cell culture

The mammalian hepatoma cells HuH-7 and HepG2 were co-transfected with replication-competent over-length 1.3 fold HBV and various amounts of a CMV-driven expression vector encoding APOBEC3G. In order to determine the efficiency of transfection, Western blot with polyclonal anti-HA and anti-HBV core antibody was used to analyze the expression of APOBEC3G and HBV core protein in co-transfected Huh7 cells. Three days after transfection, core-associated viral DNA was prepared from nuclease-treated cytoplasmic lysates and analyzed with Southern blotting. As shown in Figures 1 and 2, APOBEC3G and HBV core protein were expressed

Figure 1 Effect of APOBEC3G on HBV replication in cotransfected hepatoma cells. Cells were treated with lipofectamine 2000 reagents, and viral replicative DNA intermediates were analyzed with southern blotting 3 d after transfection. Numbers at the end of the lines indicate the amount of transfected plasmid DNA in micrograms. HBV, hepatitis B virus; RC, relaxed circular DNA; SS, single-stranded DNA.

Figure 2 Western blot analysis of cytoplasmic extracts from Huh7 cells cotransfected with indicated plasmids.

in co-transfected Huh7 cells. However, APOBEC3G reduced the level of replicative HBV intermediates in a dose-dependent manner. This inhibitory effect was also observed in HepG2 cell lines.

Inhibition of HBV gene expression by APOBEC3G in cell culture

To evaluate the effects of APOBEC3G on HBV gene expression, Huh7 cells were co-transfected with replication competent over-length HBV(pHBV1.3) and various amounts of CMV-driven expression vector encoding APOBEC3G 3 d after transfection. HBsAg and HBeAg levels were determined by ELISA. As shown in Figure 3, there was also a dose dependent decrease in the levels of extracellular production of HBsAg and HBeAg. However, western blot with polyclonal anti-HBV core antibody indicates that the levels of core protein were unaffected by APOBEC3G (Figure 2). In order to examine the effect of APOBEC3G on HBV RNA levels in co-transfected Huh7 cells, total cellular RNA derived from co-transfected Huh7 cells was hybridized with Dig-labeled probe. Northern blot indicated that the RNA levels of 3.5 kb, 2.4/2.1 kb in co-transfected Huh7 cells were significantly suppressed by APOBEC3G (Figure 4).

Figure 3 Effect of APOBEC3G on HBsAg and HBeAg secretion in the media of cotransfected Huh7 cells 3 d after transfection. HBsAg and HBeAg levels (S/N) were significantly reduced (error bar indicate standard error). Numbers at the end of the lines indicate the amount of transfected plasmid DNA in micrograms.

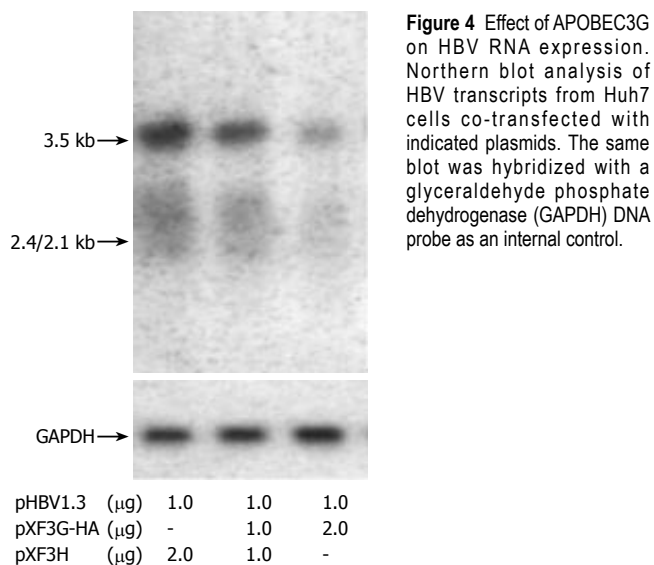

Figure 4 Effect of APOBEC3G on HBV RNA expression. Northern blot analysis of HBV transcripts from Huh7 cells co-transfected with indicated plasmids. The same blot was hybridized with a glyceraldehyde phosphate dehydrogenase (GAPDH) DNA probe as an internal control.

Inhibition of HBV replication and gene expression by APOBEC3G in mice

To examine whether APOBEC3G could also display HBV inhibition *in vivo*, replication-competent HBV plasmid (pHBV1.3) was co-transfected with pXFA3G or pXF3H (control plasmid) to mouse liver by hydrodynamic injection. As shown previously, hydrodynamic injection of pHBV1.3 into mouse resulted in HBV replication in the liver and secretion of viral antigens to the serum. Consistent with *in vitro* experiments, serum HBsAg and viral DNA in mice which received pHBV1.3 was suppressed dramatically at different time points by APOBEC3G compared with mice without APOBEC3G treatment (Figures 5 and 6). Real time RT-PCR quantification of core-associated HBV RNA in the liver of mice 3 d after injection with APOBEC3G expression plasmid was decreased about 50 times than that of control group (Figure 7).

Figure 5 Serum HBsAg levels in APOBEC3G treated mice. HBsAg levels (S/N) in the sera of BALB/c mice were significantly reduced after treatment with the APOBEC3G expression plasmids (error bar indicate standard error) in the indicated time points, $n = 6$ per treatment group.

Figure 6 Real time PCR quantification of HBV DNA in the sera of mice treated with APOBEC3G expression plasmid. BALB/c mice were coinjected with pHBV1.3 vector (10 μg) and APOBEC3G expression plasmid (10 μg) 3 d after injection. HBV DNA levels (mean ± SD) of sera were determined by quantitative PCR, $n = 6$ per treatment group.

Figure 7 Real time PCR quantification of core-associated HBV RNA in the liver of mice treated with indicated plasmids. BALB/c mice were coinjected with pHBV1.3 vector (10 μg) and APOBEC3G expression plasmid (10 μg) 3 d after injection. The levels of liver HBV RNA were determined by quantitative RT-PCR, normalized to GAPDH mRNA and are reported as a ratio of HBV mRNA/GAPDH mRNA (mean ± SD). $n = 6$ per treatment group.

DISCUSSION

This study explored the effects of human APOBEC3G suppressing HBV DNA production in mammalian hepatoma cells as well as in HBV vector-based mouse model. Our data confirm and extend recent results by

Turelli *et al*^[10] who reported A3G-mediated inhibition of HBV DNA production in human HuH-7 hepatoma cells. Previous studies suggested that G-to-A hypermutation can influence HBV pathogenesis. Specific G-to-A changes yield HBeAg-negative HBV variants, often isolated from patients with acute fulminant hepatitis, as well as HBV vaccine escape mutants^[17,18]. However, there is no evidence so far that APOBEC-induced lethal hypermutation represents an important innate defense mechanism down regulating hepadnavirus production. APOBEC3G-mediated editing did occur but was only detected in a minority of clones produced in transfected HepG2 hepatoma cells^[10]. Recently, Rosler *et al*^[19] demonstrated that APOBEC3G rendered HBV core protein associated full-length pregenomic RNA nuclease-sensitive. APOBEC3G-mediated editing of nucleic acids does not seem to represent an effective innate defense mechanism for hepadnaviruses.

During the course of an acute infection, HBV DNA clearance apparently occurs through noncytopathic mechanisms in which IFN- γ and TNF- α play an important role^[20,21]. APOBEC3G might participate in this type of antiviral response. Although APOBEC3G is not normally expressed in the liver^[10,22], recent study shows that APOBEC3G is induced by interferon- α stimulation in human hepatocytes and human primary monocyte-derived macrophages^[16,23]. It is possibly induced by interferon in the course of HBV infection. Several studies have shown that IFNs inhibit HBV replication *in vitro* in human hepatoma cells and HBV transgenic mice *in vivo*^[24-26]. Currently, IFN- α is approved for treatments of chronic hepatitis B. We speculate that APOBEC3G might be responsible for the anti-HBV action of IFNs in hepatic inflammation. Further analyses will be necessary to determine whether APOBEC3G play roles in the host innate defense against hepatitis viruses *in vivo*.

The hydrodynamic delivery of nucleic acids in the mouse was described by Liu *et al*^[11], who showed that the vast majority of the injected nucleic acid was delivered to the liver by this technique. Yang *et al*^[27] first demonstrated that hydrodynamic injection of a replication-competent HBV vector resulted in high levels of HBV replication in the livers of injected mice. In the vector-based model, HBV replicates in the liver of immunocompetent mice for 7 to 10 d, resulting in detectable levels of HBV RNA and antigens in the liver and HBV DNA and antigens in the serum. Several reports have documented the use of HBV vector model to examine the *in vivo* activity of co-HDI administered HBV-targeted unmodified siRNAs^[28,29] or vector-expressed short hairpin RNAs in silencing HBV gene expression^[30]. Most notably, we have demonstrated *in vivo* activity of APOBEC3G expression vector *via* standard intravenous administration. This is the first demonstration of APOBEC3G *in vivo* activity in a hepatitis animal model with a clinically viable route of administration. Although we have seen a more than 1.5log10 reduction of serum HBV levels with APOBEC3G in an HBV mouse model, however, the potential contribution of toxicity from the APOBEC3G has not been ruled out and needs to be investigated further.

Our work demonstrates APOBEC3G effectively inhibits HBV replication in culture cells and mammalian liver, suggesting that such an approach could be useful in the treatment of HBV infection. However, whether suppression of viral replication by APOBEC3G plays a role during natural HBV infection seems speculative at present, because expression of APOBEC3G in human liver tissue has not yet been shown. Nevertheless, a better understanding of the mechanisms of APOBEC3G action may help identify new therapeutic strategies against chronic hepatitis B.

Abstract

AIM: To investigate *in vivo*, whether CCK2 receptors (CCK2R) regulate proteins known to play a crucial role in cell proliferation and cancer development and analyse *in vitro* the molecular mechanisms that lead to Src activation; in particular, to identify the domains within the CCK2R sequence that are implicated in this activation.

METHODS: The expression and activation of Src and ERK were studied *in vivo* using immunofluorescence and western-blot techniques. We used pancreatic tissues derived from wild type or Elas-CCK2 mice that expressed the CCK2R in pancreatic acini, displayed an increased pancreatic growth and developed preneoplastic lesions. The pancreatic tumor cell line AR4-2J expressing the endogenous CCK2R or COS-7 cells transiently transfected with wild type or mutant CCK2R were used as *in vitro* models to study the mechanism of Src activation. Src activation was measured by *in vitro* kinase assays, ERK activation by western blot using anti-phospho-ERK antibodies and the involvement of Src in gastrin-induced cell proliferation by MTT test.

RESULTS: We showed *in vivo* that the targeted CCK2R expression in the pancreas of Elas-CCK2 mice, led to the activation of Src and the ERK pathway. Src was activated upstream of the ERK pathway by the CCK2R in pancreatic tumoral cells and contributed to the proliferative effects mediated by this receptor. *In vitro* results demonstrated

that activation of the Src/ERK pathway by the CCK2R required the NPXXY motif, located within the CCK2R sequence at the end of the 7th transmembrane domain, and suggested the putative role of Gq in this mechanism.

CONCLUSION: Deregulation of the Src/ERK pathway by the CCK2R might represent an early step that contributes to cell proliferation, formation of preneoplastic lesions and pancreatic tumor development.

INTRODUCTION

The CCK2 receptor (CCK2R or CCKBR) is a G protein-coupled receptor, mainly coupled to Gq proteins^[1]. Initially implicated in gastrin-mediated acid secretion CCK2R is now recognized to mediate mitogenic and anti-apoptotic effects on gastrointestinal and pancreatic cells^[2]. In the transgenic mice, Elas-CCK2, CCK2R expression has been targeted in pancreatic acinar cells using transcriptional elements of the elastase-1 promoter^[3]. Using this model, we have recently reported an increase in pancreatic growth as well as an acinar to ductal transdifferentiation, postulated to be a preneoplastic step in pancreatic carcinogenesis that precedes the development of tumours^[3]. Similar observations have been reported in two other transgenic models overexpressing TGF- α or a Kras mutant in exocrine pancreas^[4,5].

Src family kinases are non receptor protein tyrosine kinases that mediate a wide variety of biological effects including cell survival, adhesion and proliferation. They are activated by many growth factor receptors. In addition, p60-Src is well established as an oncogene, and overexpression of Src tyrosine kinase has been described in human pancreatic adenocarcinomas^[6]. Recently, Src inhibition by

AZM475271 demonstrated significant antitumorigenic and anti-metastatic activity in an orthotopic nude mouse model for human pancreatic cancer^[7]. However to our knowledge, there is currently little or no information regarding the deregulation of Src kinases in early stages of pancreatic carcinogenesis.

It is well established that numerous G protein-coupled receptors activate Src family kinases. However, very few publications have described the molecular mechanisms involved in Src activation by this receptor family. Molecular mechanisms of Src activation by CCK2R as well as the role of this kinase and related signalling pathways in the pathophysiological functions of CCK2R *in vivo* remain largely unknown. This study had two main aims: First, to investigate *in vivo*, using the Elas-CCK2 mouse model, whether CCK2R is involved in the regulation of proteins known to play a crucial role in cell proliferation and cancer development; Second, to analyse *in vitro* the molecular mechanisms that lead to Src activation and in particular, to identify the domains within the CCK2R sequence implicated in this activation.

MATERIALS AND METHODS

Animals

Homozygous Elas-CCK2 mice used in this study have been previously described^[3]. At least 3 homozygous Elas-CCK2 mice in a B6SJLF1 background and 3 corresponding control littermate mice were used (six months old). Mice were reared in routine animal facility of the IFR31 and maintained on a 12:12 h light-dark cycle. All the experiments were performed during the daytime. All procedures were approved by the IFR31 animal facility care committee.

Antibodies and materials

GAPDH was provided by Chemicon; phospho-tyr418-Src (IF and WB) by Biosource; ERK, Src (IF and WB) by Santa Cruz Biotechnology; phospho-ERK (IF and WB) by Cell Signaling; SRC (IP) by Oncogene Research Product; PP2, GP2A by Calbiochem.

Immunofluorescence staining

Mice were killed by decapitation and the pancreas was excised, fixed in Bouin's solution and embedded in paraffin using standard techniques. Immunofluorescence staining was performed as previously described^[8]. The detection was done using secondary antibodies coupled to Alexa Fluor 488. Slides were analyzed on a Nikon E400 microscope with a Sony DXC 950 camera and Visiolab 2000 software. For semi-quantitative comparisons, identical volumes of antibody were used for all samples and identical exposure times taken.

Western-blot analysis

Western-blot analyses were performed on dispersed acini from mouse pancreas prepared as previously described^[9], and on cell lysates or immunoprecipitates from AR4-2J or COS7 cells stimulated or not with gastrin. Fractions, containing identical levels of proteins, were separated

by SDS-PAGE and analyzed by western-blot with the indicated antibodies as described previously^[9].

Cell culture and proliferation assay

AR4-2J cells and COS-7 cells were grown in DMEM supplemented with 10% and 5% fetal calf serum (FCS), respectively, at 37°C in a 95% air, 5 mL/L CO₂ atmosphere. For proliferation assays, an optimal number of AR4-2J cells (4×10^4 cells) were plated in 35-mm dishes, serum-starved for 24 h, then treated for 48 h with gastrin (10 nmol/L). When indicated, cells were incubated with PP2 (10 μ mol/L). Cells were counted by using a Coulter electronic counter.

Src kinase assay

After gastrin stimulation, cells were lysed and Src immunoprecipitated with specific antibodies. Kinase assays were performed and analyzed as previously described^[10]. Proteins were separated by SDS-PAGE and the gel autoradiographed.

Construction of mutant receptor cDNAs and transient transfection

Mutant CCK2R, N386A-CCK2R was previously described^[9]. Plasmids coding for wild type or mutant CCK2R (6 μ g) were transiently transfected into COS-7 cells using the DEAE/dextran method as described previously^[1].

Statistical analysis

Data were expressed as mean \pm SE and Student's *t* test was performed using "GraphPad Prism". *P* < 0.05 was taken as significant.

RESULTS

Src status in Elas-CCK2 mice

Src activation was analyzed by immunohistochemical methods on pancreatic sections from control and Elas-CCK2 mice of 6 month old using antibodies specific for total Src or detecting the activated form of the protein phosphorylated on tyrosine 418 (P-Src). Acinar tissues derived from Elas-CCK2 mice demonstrated higher levels of Src activation as compared to control mice (Figure 1A, upper panels). In contrast, total Src protein expression was unchanged in the two mouse models (Figure 1A, lower panels).

To confirm and quantify Src activation, western-blot analyses were performed on lysates of acinar cells isolated from pancreas of control and Elas-CCK2 mice. Src activation in Elas-CCK2 mice was significantly elevated compared to controls (Figure 1B). Thus, the expression of the CCK2R in mouse pancreatic acini induced Src activation.

The ERK pathways in Elas-CCK2 mice

Activation of the ERK pathways by gastrin has previously been described *in vitro*^[10,11]. However, there is currently no *in vivo* information about the status of the ERK pathways in gastrin signaling. Immunofluorescence analysis was per-

Figure 1 CCK2R expression in acini of Elas-CCK2 mice induced the activation of Src. Immunohistochemistry analysis on paraffin-embedded pancreatic tissues or western-blots on lysates from isolated acinar cells were performed using antibodies specific for total Src (SRC) or detecting the activated form of the protein, PY418-Src (P-Src) as indicated. Representative data from 3 experiments (3 different animals in each group) are shown. **A:** Original magnification: 40 X; **B:** Blots were also probed with an antibody against GAPDH to ensure equal loading of proteins. Results of western-blots quantification are presented as mean \pm SE. ^b $P < 0.01$ vs control.

formed using antibodies specific for dually phosphorylated active ERK (P-ERK). Results demonstrated an increased immunoreactivity in acinar tissue of transgenic mice as compared to control mice (Figures 2A, upper panel). In addition, pancreatic acinar tissues of Elas-CCK2 mice also showed a higher level of total ERK expression as compared to control mice (Figure 2A, lower panel). These results were confirmed by western-blots performed on lysates of acinar cells isolated from pancreas of control and Elas-CCK2 mice (Figure 2B). Overall, these results were consistent with an upregulation of the ERK pathway in the pancreas of mice expressing the CCK2R.

Src activation by CCK2R in tumour pancreatic acinar cells

The pancreatic tumour cell line AR4-2J, that exhibits an acinar phenotype, was previously shown to express endogenous CCK2R^[12]. We used this model to analyse the role of Src in the pathophysiological functions of the CCK2R and the molecular mechanisms potentially involved in Src activation by this G protein-coupled

Figure 2 CCK2R expression in acini of Elas-CCK2 mice induces the activation of the ERK pathway. Immunohistochemistry analysis on paraffin-embedded pancreatic tissues or western-blots on lysates from isolated acinar cells were performed using antibodies specific for total ERK (ERK) or detecting the activated form of the protein, Phospho-ERK (P-ERK) as indicated. Representative data from 3 experiments (3 different animals in each group) are shown. **A:** Original magnification: 40 X; **B:** Blots were also probed with an antibody against GAPDH to ensure equal loading of proteins. Results of western-blots quantification are presented as mean \pm SE. ^a $P < 0.05$ vs control.

receptor.

We first confirmed that the CCK2R was able to induce Src activation. *In vitro* tyrosine-kinase assays were performed in anti-Src immunoprecipitates from cell lysates containing equal amounts of protein. We detected a rapid and significant increase in Src activation 15 s after stimulation of the CCK2R by gastrin (Figure 3A).

In order to address the role of Src family kinases in proliferation of tumour acinar cells induced by CCK2R, we measured AR4-2J proliferation in the presence or absence of the Src specific inhibitor, PP2, 48 h after gastrin stimulation. CCK2R activation by gastrin induced a significant increase of cell proliferation. Treatment of cells with PP2 totally inhibited CCK2R-induced AR4-2J proliferation (Figure 3B).

We previously reported that CCK2R associates with the α q subunit of heterotrimeric G-proteins^[1]. We therefore

Figure 3 Role of Src in proliferation of tumour pancreatic acinar cells induced by the CCK2R. AR4-2J cells were stimulated with Gastrin (10 nmol/L) for the times indicated (A) or 15 s (B). A: Src activity was determined as described in Methods. Immunoprecipitated proteins were also analysed by western-blot using anti-Src antibodies. Results of autoradiography quantification are presented as mean \pm SE. $^aP < 0.05$ vs control. B: Serum-starved AR4-2J cells were treated with Gastrin for 48 h in the presence or absence of PP2 (10 μ mol/L), and the proliferation determined as described in Methods. Data are presented as mean \pm SE. $^cP < 0.001$ vs control.

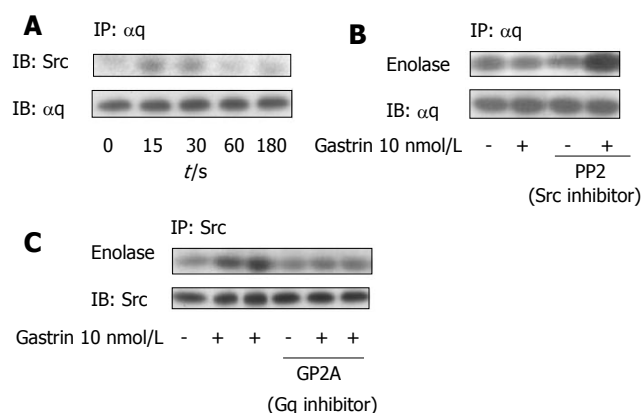

Figure 4 Src activation by the CCK2R in tumour pancreatic acinar cells (A-C). AR4-2J cells were stimulated with Gastrin (10 nmol/L) for the times indicated (A) or for 15 s (B, C). When indicated, cells were pretreated with 10 μ mol/L of PP2 or GP2A for 30 min. A: Cell lysates were immunoprecipitated (IP) with an anti- α q antibody and immunoblotted (IB) with the anti-Src antibody. The blots were also probed with the antibody used for immunoprecipitation to ensure equal loading of proteins; B, C: following immunoprecipitation with an anti- α q or an anti-Src antibody, Src activity was determined as described in Methods. Immunoprecipitated proteins were also analyzed by western blot using the anti- α q or anti-Src antibodies as indicated.

tested the hypothesis that G α q might be involved in gastrin-induced Src activation.

Src proteins were immunoprecipitated with specific antibodies and their association with G α q was analyzed by western blot with an anti- α q antibody. An increase in the amount of Src proteins coprecipitated with G α q was detected in response to gastrin (Figure 4A). This effect was time-dependent and the kinetic correlated with that of Src activation in this cellular model. We then

Figure 5 Involvement of the NPXXY motif in Src activation by the CCK2R. A: COS-7 cells transfected with the human CCK2R were stimulated with Gastrin (10 nmol/L) for the time indicated. Src kinase activity was determined as described in Methods. Immunoprecipitated proteins were also analyzed by western-blot using anti-Src antibodies. Results of autoradiography quantification are presented as mean \pm SE. $^aP < 0.05$ vs control, $^bP < 0.01$ vs control, $^cP < 0.001$ vs control; B: COS-7 cells transfected with the WT or N386A mutant CCK2R were stimulated or not with Gastrin (10 nmol/L) for 30 s and Src kinase activity determined as described in Methods. Immunoprecipitated proteins were also analysed by western-blot using anti-Src antibodies. Results of autoradiography quantification are presented as mean \pm SE. $^cP < 0.001$ vs control.

examined whether Src-like tyrosine kinase activity was in association with G α q following gastrin stimulation. An increase in tyrosine kinase activity was detected in anti-G α q immunoprecipitates after gastrin stimulation which was abolished when samples were treated with the specific Src inhibitor, PP2 (Figure 4B). In addition, pretreatment of the AR42J cells with a specific G α q inhibitor, GP2A, completely blocked the activation of Src by gastrin (Figure 4C).

Mechanism of CCK2R-induced Src activation in COS-7 cells

To further investigate the molecular mechanisms involved in Src activation by the CCK2R we used COS-7 cells transiently transfected with cDNAs coding for the human wild type CCK2R (WT-CCK2R) or mutant CCK2R. We first validated this model for CCK2R-induced Src activation. Lysates from cells stimulated or not with gastrin were immunoprecipitated with anti-Src antibodies and kinase assays performed as described in methods. A rapid activation of Src (15 s), still detectable at 1 and 5 min, was found in response to Gastrin (Figure 5A). Western-blot analysis for Src protein expression revealed an equal amount of the protein in transfected cells.

Recently, we reported that the NPXXY motif (X represents any amino acid), located at the end of the 7th transmembrane domain of the CCK2R, was involved in Gq-dependent signaling pathways induced by the CCK2R^[1,9]. In particular, mutation of the asparagine (N) into alanine (A) inhibits Gq-dependent pathways such as inositol triphosphate (IP3) production. We therefore tested the in-

Figure 6 Involvement of the NPXXY motif in ERK activation by the CCK2R. COS-7 cells transfected with the WT or N386A mutant CCK2R were stimulated or not with Gastrin (10 nmol/L) for 5 min (A) or the time indicated (B). When indicated, cells were pretreated with the Src inhibitor PP2 (10 μ mol/L). Equal amounts of protein were analyzed by western-blot using anti-phospho-ERK antibodies. Blots were also reprobated with antibodies directed against total ERK proteins. Results of autoradiography quantification are presented as mean \pm SE. ^b $P < 0.01$ vs control.

involvement of the NPXXY motif in Src activation by the CCK2R.

cDNAs coding for the WT receptor or the N386A mutant were transfected in COS-7 cells and Src activation was studied in response to Gastrin. Figure 5B clearly demonstrates that the CCK2R mutant cannot induce Src activation in response to Gastrin in contrast to the WT receptor.

In addition, we demonstrated that ERK activation following gastrin stimulation was completely blocked by the Src inhibitor PP2, indicating that CCK2R-induced ERK activation was totally Src-dependent in this cellular model (Figure 6A). As expected, activation of the ERK pathway was also blocked when the CCK2R was mutated on the NPXXY motif (Figure 6B). Thus, our results demonstrated the involvement of the conserved NPXXY motif within the receptor sequence in the activation of the Src/ERK pathway by the CCK2R, and suggested putative role of Gq in this mechanism.

DISCUSSION

It is well demonstrated that numerous G protein-coupled

receptors activate Src family kinases. However, very few publications have described the molecular mechanisms involved in Src activation by this receptor family. In the present study our results demonstrate that CCK2R-induced Src activation requires the NPXXY motif, and suggest a putative role of Gq in this mechanism. Indeed, this motif was previously described in Gq-dependent signalling pathways^[1,9]. In addition, we showed that Src and G α q are within one protein complex and we observed a Src-like tyrosine activity associated with Gq. However, despite the appearance of Src and G α q in the same immunocomplex, we cannot exclude the possibility that Src activation by G α q requires other protein. Our study also reveals that downstream of Src, activation of the ERK pathway by the CCK2R also requires the NPXXY motif.

The direct interaction of the Src SH3 domain with proline-rich motifs has been reported for the β 3 adrenergic and the purinergic P2Y2 receptors^[13,14]. Src family kinases also possess an SH2 domain that could directly bind to tyrosine-phosphorylated β 2 adrenergic receptor^[15]. We tested these two hypotheses in Src activation by the CCK2R. Indeed, the CCK2R has two proline-rich sequences which might interact with SH3 domains. In addition, it also has an ITIM-like motif within the C-terminus tail (LSYTTI) that is potentially phosphorylated on tyrosine residues, in turn leading to the recruitment of PLC γ through its SH2 domain^[16]. Mutation of the prolines into serines, as well as the replacement of the tyrosine 438 of the ITIM-like motif by a phenylalanine did not affect the activation of Src by the CCK2R in COS-7 cells (data not shown).

Transactivation of receptor tyrosine kinases is another mechanism by which G protein-coupled receptors activate Src family kinases. Recently, the CCK2R has been shown to transactivate the EGF receptor^[17-19]. However, this mechanism seems to be dependent on the cellular model. In the present study, we have observed that inhibition of the EGF receptor by AG1487 did not abolish CCK2R-mediated Src activation in AR42J and COS7 cells (data not shown).

Our study also shows that Src is activated upstream of the ERK pathway by the CCK2R in pancreatic tumor cells and contributes to the proliferative effects mediated by this receptor.

The development of cancer is thought to be dependent on the deregulation of normal signaling pathways involved in cell proliferation, thus conferring a growth advantage to cells. The role of Src and the ERK pathway in the regulation of cell growth is well documented. These signalling molecules have been implicated in the proliferative effects induced by tyrosine kinase receptors, cytokine receptors and G protein-coupled receptors. Activation of Src and ERK proteins has been observed in several human cancers and may contribute to the neoplastic phenotype. However, there is currently very little information regarding the role of the SRC/ERK pathway in the early stages of pancreatic carcinogenesis.

Here we report that the expression of the CCK2R in mouse pancreatic acinar tissue leads to strong activation of the Src tyrosine kinase and the ERK pathway. These transgenic mice display an increased growth of the pancreas

and preneoplastic lesions. They also develop pancreatic tumors with a ductal phenotype similar to what is observed in human pancreatic cancers. Deregulation of the Src/ERK pathway by the CCK2R in these transgenic mice might represent an early step that contributes to cell proliferation, formation of preneoplastic lesions and pancreatic tumor development. In addition, while several studies have reported the *in vitro* activation of Src and ERKs by gastrin^[10,11,20], this study is the first to demonstrate *in vivo* the up-regulation of the Src/ERK pathway by CCK2R.

In summary, our study describes the mechanism by which the CCK2R, a GPCR mainly coupled to Gq, activates Src. Our results show the involvement of the NPXXY motif within the receptor sequence in this activation, and suggest the putative role of Gq in this mechanism. Moreover, in pancreatic tumoral models we demonstrate *in vitro* and *in vivo* that the CCK2R activates the Src/ERK signaling pathway, a transduction cascade upregulated during tumorigenesis in human.

were measured. In addition, the roles of IGF-1 and hypogonadism were investigated.

RESULTS: Portasystemic shunting caused low turnover osteoporosis that was RANKL independent. Bone resorbing cytokine levels, including IL-1, IL-6 and TNF α , were not increased in serum and TNF α and RANKL expression were not upregulated in PBMC. Portasystemic shunting increased the circulating CD8+ T-cell population. Rapamycin decreased the circulating CD8+ T-cell population, increased CD8+ CD25+ T-regulatory cell population and improved all parameters of bone turnover.

CONCLUSION: Osteoporosis caused by portasystemic shunting may be partially ameliorated by rapamycin in the rat model of hepatic osteodystrophy.

Abstract

AIM: To study if T-cell activation related to portasystemic shunting causes osteoclast-mediated bone loss through RANKL-dependent pathways. We also investigated if T-cell inhibition using rapamycin would protect against bone loss in rats.

METHODS: Portasystemic shunting was performed in male Sprague-Dawley rats and rapamycin 0.1 mg/kg was administered for 15 wk by gavage. Rats received powdered chow and supplemental feeds to prevent the effects of malnutrition on bone composition. Weight gain and growth was restored after surgery in shunted animals. At termination, biochemical parameters of bone turnover and quantitative bone histology were assessed. Markers of T-cell activation, inflammatory cytokine production, and RANKL-dependent pathways

INTRODUCTION

Metabolic bone disease is a common complication of longstanding liver disease^[1,2]. Mechanisms underlying bone loss remain poorly understood and may involve imbalances in bone turnover and mineralization defects. We have shown that portasystemic shunting, a complication of advanced chronic liver disease, is a major pathogenic factor causing bone loss in rats^[3].

Excessive osteoclast activity, resulting in localized or generalized bone loss, occurs in various conditions associated with immune activation^[4,5]. Activated T-cells express receptor activator of nuclear factor- κ B ligand (RANKL) that bind to RANKL receptor on osteoclasts

activating osteoclastogenesis and bone loss^[4]. This pathway produces TNF α , IL-1, IL-6, IL-7, and M-CSF all of which have been implicated in bone loss^[6-10]. Blockage of RANKL by osteoprotegerin protects against bone loss^[4].

The profound impact of activated T-cells on bone has been established. Osteopenia develops in *ctla 4*^{-/-} mice where T-cells are spontaneously activated, whereas bone loss fails to occur in T-cell deficient nude mice even following ovariectomy^[11]. Further, RANKL expressing T-lymphocytes obtained from diseased rheumatoid arthritis joints transform healthy monocytes into osteoclast-like cells^[12]. We hypothesized that endotoxin-mediated T-cell activation related to portasystemic shunting may result in osteoclast-mediated bone loss through RANKL dependent pathways.

Employing biochemical parameters of bone turnover and quantitative bone histology, this study aimed to characterize the nature of the bone disease resulting from portasystemic shunting in rats. The role of T-cell activation and inflammatory cytokine production on RANKL-dependent pathways were specifically addressed.

MATERIALS AND METHODS

Animal Experimental design

Ten-week-old male Sprague-Dawley rats weighing 200-300 g were used in all experiments. The rats were housed individually in polypropylene cages at constant room temperature (22°C \pm 2°C), humidity (55%) and 12 h light-darkness cycles. Rats were fed powdered chow (Epol, Johannesburg, South Africa) and water was given *ad libitum*. Rats received a daily 50 mL supplement (Energy 44.52 kJ, protein 0.373 g, carbohydrates 1.456 g, fat 0.373 g). Food intake was measured daily in metabolic cages during four time periods: wk 3, 9, 12 and 15. Ethics committee approval was obtained and animals were treated according to ethical guidelines of the University of Pretoria.

Group I: *n* = 12 PSS. Laparotomy was performed, portal vein was ligated, transected and the distal limb anastomosed end-to-side to the IVC as previously described^[3,13].

Group II: *n* = 12 PSS + rapamycin. Portasystemic shunt was performed and rapamycin 0.1 mg/kg administered daily orally by gavage for 15 wk starting 1 wk after surgery. Two rats died during the study period.

Group III: *n* = 12 Sham control. Laparotomy was performed and the portal vein was clamped for 8 min.

Group IV: *n* = 12 Sham control + rapamycin. Following laparotomy controls received rapamycin 0.1 mg/kg, orally by gavage starting 1 wk following surgery and continued for 15 wk.

Analytical methods in sera and urine

Blood and urine samples were obtained at baseline and termination and frozen at -70°C. Urine was collected from rats individually housed in metabolic cages. Routine liver tests and testosterone were performed using a Beckman CX-9 and Access auto-analyzers respectively. 25-OH Vit D was determined using scintillation counting detection^[14]. Osteocalcin was measured using ELISA kit (Osteometer

BioTech, Herlev, Denmark). Cytokine levels were analyzed using an ELISA kit (Biotrac, Amersham, Buckinghamshire, United Kingdom). IGF-1 was measured using an ELISA kit (DRG Inc, Mountainside, USA). Urinary deoxypyridinoline was assessed using an enzyme-labeled immunoassay (Immunolite Pyrilinks-D, Los Angeles, USA).

Liver histology

Rat liver specimens were fixed in 40 g/L buffered formaldehyde and sectioned coronally in 3 μ m sections for immunoperoxidase staining utilizing antibodies to ED-1 (1:50 dilution; Serotec, Oxford, UK). Kupffer cells were counted by an experienced histopathologist in ten high power fields (Olympus BX 40, plan 40 x objective) demonstrating the most Kupffer cells. An average per high power field was then calculated.

Bone densitometry

Rats were anaesthetized and bone densitometry was performed using DEXA (DEXA QDR 4500TM, Hologic INC, Waltham, USA). Measurement stability was controlled daily by scanning a phantom. Whole-body and high-resolution scans of the right femur were performed at baseline and 16 wk using software for small animals (Hologic, INC, Waltham, USA).

Histomorphometry

Rats received intramuscular injections of 25 mg/kg tetracycline 13 and 3 d prior to termination. At termination the left tibia was removed, stored in 70% ethanol at 4°C, fixed in modified Millonig solution for 24 h, embedded in methyl methacrylate, sectioned at 5 μ m and stained by modified Masson technique. Histomorphometric analyses were performed manually using a Merz-Schenk integrating eyepiece. Trabecular bone was analyzed excluding sections within two fields at \times 250 magnification from either the growth plate or the cortices. At least 120 fields per animal were counted. Double tetracycline-labeling was assessed on 10 μ m thick unstained sections cut from the proximal tibia by fluorescent microscopy using a Merz-Schenk eyepiece. Variables and units used are approved by the American Society for Bone and Mineral Research^[15].

Flow cytometry

Peripheral blood obtained at termination were incubated with the following combinations of monoclonal antibodies: fluorescein isothiocyanate/phycoerythrin labeled CD4+/CD25+; CD8+/CD25+ (Immunotech, Beckman Coulter, Inc. Fullerton, USA). Analysis was performed on a Coulter Epics flow cytometer. Lymphocytes were gated on forward and side scatter. The percentage of CD3+ T-cells in the gate was deduced from the percentages for CD4+ and CD8+ T-cells.

Quantitative RT-PCR

Total RNA was extracted from PBMC using the Qiagen RNeasy kit. Aliquots of 8.5 μ L were used in a RT-PCR reaction in a total volume of 20 μ L (Roche, First strand cDNA synthesis kit, Mannheim, Germany).

Complementary DNA PCR primers were designed from sequences from Genbank or TIGR (Inqaba Biotech, Pretoria, South Africa). *tnf α* (Sense: 5'-atggccagaccctcac-3', Antisense: 5'-agcatagacggggcag-3'); *rankl* (Sense: 5'-tgga ggattttcaagctccgg-3'; Antisense: 5'-gccccaaagtacgtcgca-3') and *Gapdh* (Sense: 5'-ggccctcttggaagct-3'; Antisense 5'-aggtggaggaatgggagt-3'). The reaction mixture consisted of cDNA (1 μ L), 10 pmol of each primer, 1 μ L LightCycler FastStart DNA Master SYBR Green 1 Mix (Roche, Mannheim, Germany), 500 ng BSA (Gibco, BRL, Gaithersburg, MD) and 3 mol/L MgCl₂ in a total volume of 10 μ L. FastStart polymerase was activated and cDNA denatured by a pre-incubation of 10 min at 95°C. The template was amplified for 40 cycles of denaturation at 95°C for 0 s, annealing at 60°C for 8 s and extension at 72°C for 12 s. Standard curves were generated from series diluted cDNAs and analyzed using the Light Cycler quantification software.

Analytical methods of bone calcium content

Right femurs were dried for 6 h at 60°C, then ashed for 8 h in a muffle furnace at 600°C. Bones were weighed, and the length and mid-shaft thickness measured. The femurs were dissolved in 3 mL of 6mol/L HCl and diluted 3000x with demineralized/de-ionized water. Calcium content was determined against a 4 point standard curve ($r^2 = 0.9999$), using a Perkin-Elmer 3030 atomic absorption spectrophotometer as previously described by our group^[3].

Determination of 4-hydroxyproline in left femurs

Dried femurs were dissolved in 10 mL 6 mol/L HCl, at 100°C for 24 h and centrifuged for 5 min at 4000 r/min at 4°C. n-Tetracosane (C₂₄H₅₀) in chloroform was added to the eluates as internal standard. The eluates were dried in nitrogen, the amino acids derivatized with N-methyl-N (*t*-butyldimethylsilyl) trifluoroacetamide and analyzed using gas chromatography as previously reported by our group^[16].

Statistical analysis

Data were analyzed using SigmaStat and SigmaPlot for Windows version 4.0. Data were checked for normality and equal variance; if passed, ANOVA was performed and where failed, analysis of variance on ranks (Kruskal-Wallis) was conducted. Results are presented as means \pm standard deviation. Analysis of covariance was performed to compare groups with respect to change in BMD from wk 1 to 16. Pair-wise comparisons were performed using Fisher's LSD and for between group comparison Wilcoxon rank sum test was performed. Results were considered significant at $P < 0.05$.

RESULTS

Body mass and food intake

Body mass decreased after surgery in the portosystemic shunted animals despite feeding with powderized and supplemental feeds. Weight gain was restored by wk 3 in the shunted animals and remained parallel to the control groups throughout the study (Figure 1), confirming growth in shunted animals. The rate of weight gain from

Figure 1 Body mass change per week. r = Pearson correlation coefficient.

Figure 2 Food intake and body weight in PSS, PSS + rapamycin and SC + Rapamycin.

wk 2 as reflected in the Pearson correlation coefficient did not differ between the shunted and control animals (Figure 1). Powderized food intake remained lower in shunted animals during the first 12 wk of the study ($P < 0.01$). The supplemental feed was consumed by all animals daily. Food intake, corrected for body mass, showed no differences between the groups with total food intake (powderized + supplemental) being higher than the recommended intake for adult laboratory rats (15 g/d). Calcium and Vit D was further supplemented in the powderized chow. By wk 15 no difference in food consumption (powderized feed) was seen (Figure 2). Body mass was still significantly lower in shunted animals at termination (Figure 1).

Serum and urine biochemistries

No differences were seen at baseline. Transaminase levels were elevated in shunted groups and the control group receiving rapamycin. Serum total ALP was elevated in both shunted groups and confirmed to be of hepatic origin by electrophoresis. Serum albumin, testosterone and IGF-1 levels were significantly lower in both shunted groups. 25-OH vit D levels were not different between the groups at 16 wk (Table 1). Serum osteocalcin was significantly lower in the PSS group but not different in the PSS group receiving rapamycin compared to controls (Table 1). A trend towards higher u-DPD levels was observed in

shunted animals compared to control animals. Significantly higher u-DPD levels were seen in control animals receiving rapamycin.

DEXA, bone mass and composition

Mean whole body and femoral BMD were comparable at baseline. At 16 wk whole body and high resolution femoral BMD were significantly lower in portasystemic animals compared to controls (Table 2). BMD in PSS receiving rapamycin did not differ from controls. The change in BMD from baseline to wk 16 using pair-wise comparisons showed that the increase in BMD in the shunted group (group I) was significantly lower compared to the control group (*P* = 0.006). The increase in BMD in the PSS receiving rapamycin was comparable to controls (*P* = 0.07). Shunted animals had lower body mass, femoral length and thickness (Table 2). Femur mass, expressed as a function of body mass, was increased in PSS. Femoral calcium content, expressed as a function of femoral mass (mg Ca²⁺/mg femur), was not decreased in shunted animals, excluding significant osteomalacia. Femoral hydroxyproline levels tended to be lower in the PSS group compared with controls (Table 2). Unexpectedly, shunted and control rats receiving rapamycin had significantly higher femoral

reflected in the mineralization lag time, was significantly delayed in PSS rats, accounting for the accumulation of osteoid in these animals (Table 3). Bone resorption over 16 wk, as reflected in the total eroded surfaces, was significantly decreased in PSS animals, although active osteoclastic resorption at the time of sacrifice was comparable among groups (Table 3). Bone turnover in shunted animals was increased by rapamycin as evidenced by increase bone formation and resorption. Osteoid accumulation and the mineralization defect induced by shunting were largely normalized by rapamycin (Table 3).

T-cells, cytokine levels and *tnf α* and *rankl* expression

PSS increased the percentage of circulating CD3+ lymphocytes by 1.3 fold (*P* < 0.001) above that for control rats (Table 4). Rapamycin treatment of PSS rats returned the CD3+ T-cell population to that of control rats with an altered ratio of CD4+ to CD8+ T-cells of 3:1. No alteration occurred in either the size of the CD3+ population or the normal ratio of CD4+ to CD8+ T-cells in rapamycin treated control rats (Table 4). PSS did not affect the normal CD4+ or CD8+ T-cells fractions expressing CD25. There was a significant increase (*P* < 0.001) in the percentage of CD4+ and CD8+ T-cells expressing CD25 with rapamycin treatment in both PSS and control rats (Table 4). Serum levels of IL-1, IL-6 and TNF α were similar in all groups (Table 4). RT-PCR showed that TNF α gene expression in shunted and control animals was comparable. RANKL-expression was significantly lower in PSS animals.

DISCUSSION

We previously investigated the contribution of parenchymal inflammation, portal hypertension and portasystemic shunting to the development of metabolic bone disease using rat models. Only portasystemic shunting caused significant bone loss^[3]. The present study aimed to delineate the immune responses associated with portasystemic shunting and how this may influence bone loss in the rat. Further, the profound effect of activated T-cells on bone turnover has been well established^[11,12]. We set out to study the effect of T-cell inhibition using rapamycin, not shown to have adverse effects on bone composition (in contrast to cyclosporin and tacrolimus), on biochemical and histological bone parameters in rats

following portasystemic shunting.

The present study confirmed the adverse effect of portasystemic shunting on skeletal integrity as evident by a significant decrease in whole-body and femoral BMD. Quantitative bone histology documented hyperostoidosis and an increased mineralization lag time in shunted animals, suggesting a degree of impaired mineralization. Histological evidence of frank osteomalacia was absent. Serum 25-OH vitamin D levels and femoral calcium content were comparable between shunted and control animals, and ALP iso-enzymes in shunted animals originated from liver not bone, supporting the histological evidence that the low BMD observed in shunted animals was mainly the result of osteoporosis.

Femur mass per 100 g body mass was higher in shunted rats compared to controls. Trabecular bone loss is known to occur earlier and more extensive compared to cortical bone loss due to the large surface area available for resorption. The apparent discrepancy between the rise in femur mass per 100 g of body mass in portasystemic shunted animals may be explained by lean body mass being lost earlier and more rapidly than cortical bone mass so that a lag in cortical bone loss gives rise to an apparent increase in bone mass relative to body mass. Low-turnover osteoporosis may occur due to protein-energy malnutrition^[17]. IGF-1 and testosterone levels were decreased in the shunted rats. Malnutrition^[18] and liver disease^[19] have been associated with decreased circulating levels of IGF-1. Low testosterone levels have been previously documented in portasystemic shunted rats^[20] with osteoporosis^[3]. IGF-1 has previously been implicated in bone loss in chronic liver disease^[21,22].

It is not possible to exclude that malnutrition contributed to bone loss in shunted rats. Malnutrition is associated with advanced liver disease although muscle wasting independent of malnutrition may be a feature of liver cirrhosis^[23]. Reduced spontaneous locomotor activity due to altered histaminergic neurotransmission can reduce food intake in shunted rats^[24]. We could, however, document that food intake in the shunted animals met the nutritional requirements calculated for their body weights during four time periods. However, despite restoring growth and weight gain (Figure 1), osteoporosis still developed in the portasystemic shunted rats. This improved feeding protocol may explain the differences observed in the present study compared to

our previous study^[3] In our previous study weight loss was observed throughout the study period and TNF α levels were increased and vitamin D levels decreased in shunted animals. In the current study TNF α and vitamin D levels did not differ from the control animals suggesting a stable model due to improved feeding.

An important observation in the study was that portasystemic shunted animals receiving rapamycin had increased bone formation, whole body and high resolution BMD, as well as increased osteocalcin levels in serum and hydroxyproline content in femurs, compared to shunted animals not receiving rapamycin. These positive changes on bone turnover variables occurred despite lower body mass, IGF-1 and testosterone levels compared to controls. This finding further suggests that malnutrition and decreased IGF-1 and low testosterone levels can only partially explain osteoporosis observed in shunting.

Pro-inflammatory cytokines like IL-1, IL-6, TNF α and RANKL are known to activate osteoclastogenesis and cause high-turnover osteoporosis^[9-11,25]. Serum levels of IL-1, IL-6 and TNF α , and *tnf- α* and *rankl* gene expression in PBMC, were not increased in shunted rats. Instead, osteocalcin, a marker of bone formation, was significantly decreased and quantitative histomorphometry showed impaired bone formation, suggesting low-turnover bone disease in shunted rats. Collectively, these observations suggest that the pro-inflammatory cytokines studied, are not responsible for bone loss in portasystemic shunting.

Rapamycin decreased the circulating CD8+ T-cell population in PSS rats. Lymphocyte proliferation inhibition by rapamycin is known to be dependent on the activation pathway of the proliferative signal with CD8+ T-cell proliferation being more affected than CD4+ T-cell proliferation^[26-28]. The effect of rapamycin on the CD8+ T-cell population in PSS rats indicate that these cells are more activated than CD4+ T-cells.

Expression of the CD25 marker in this study does not appear to reflect cellular activation. There was no difference between the control group and PSS group with respect to fraction of CD4+ or CD8+ T-cells expressing the CD25 marker, suggesting that the cells expressing CD25 belong to a population of regulatory T-cells (Treg cells). Treg cells in mice and humans are associated with a restriction of most immune responses^[29]. No documentation of such cell populations in rats has been made. Rapamycin increased the percentage of CD4+ and CD8+ T-cells expressing CD25 for both normal and shunted rats. This has been proposed to be a component of the immunosuppressive properties of rapamycin^[30]. Although not much is known of the function of the CD8+CD25+ T-cell population in rodents, this population in humans has similar immunoregulatory characteristics to the CD4+CD25+ T-cell population^[31,32]. Murine studies indicate an inability of CD8+CD25+ T-cells to induce osteoclast differentiation^[33]. In shunted rats where the fraction of these cells was increased by rapamycin, increased bone formation was observed. An increase in this population of CD8+ T-cells by rapamycin in normal rats also increased hydroxyproline levels in femurs.

The overall changes in the lymphocyte population seen with rapamycin treatment of shunted rats are associated

with an increase in bone formation, whole body and high resolution BMD as well as higher circulating levels of osteocalcin and femoral hydroxyproline content. Although IL-1, IL-6, TNF α and RANKL do not appear to be involved in portasystemic shunting associated osteopenia, other cytokines that are modulated by rapamycin may be implicated. IFN γ suppresses osteoclast activity while macrophage production of IL-12, a major stimulator of lymphocyte IFN γ production is upregulated by rapamycin. T-cell production of IFN γ via an IL-12 mechanism may be important in the bone protection observed in rapamycin treated animals^[34,35]. An alternative explanation whereby rapamycin may increase bone formation is through mTOR a member of the phosphoinositide 3-kinase related kinase (PIKK) family, which plays a critical role in transducing proliferative signals mediated through the PI3K/Akt signalling pathway^[36]. The mTOR gene is expressed in osteoblasts^[37,38] and rapamycin has been shown to up-regulate growth factors like BMP-4 and latent TGF- β binding protein in certain cancer cell lines^[39]. This may present an additional pathway by which bone formation is stimulated by rapamycin.

In conclusion, we hypothesized that portasystemic shunting would result in T-cell activation, cytokine mediated osteoclastogenesis and high-turnover osteoporosis. Instead, we documented low-turnover osteoporosis, which was partially ameliorated by rapamycin. A better understanding of the direct mechanisms of rapamycin on bone is required.

significant increase in reg I receptor mRNA expression with pancreatitis. Immunohistochemistry localized this increase to the ductal cells, islets, and acinar cells.

CONCLUSION: Acute pancreatitis results in increased tissue reg I protein levels localized to the acinar and ductal cells, and a parallel threefold induction of reg I receptor in the ductal cells, islets, and acinar cells. These changes suggest that induction of reg I and its receptor may be important for recovery from acute pancreatitis.

Abstract

AIM: Pancreatic regenerating protein (reg I) stimulates pancreatic regeneration after pancreatectomy and is mitogenic to ductal and β -cells. This suggests that reg I and its receptor may play a role in recovery after pancreatic injury. We hypothesized that reg I and its receptor are induced in acute pancreatitis.

METHODS: Acute pancreatitis was induced in male Wistar rats by retrograde injection of 3% sodium taurocholate into the pancreatic duct. Pancreata and serum were collected 12, 24, and 36 hours after injection and from normal controls (4 rats/group). Reg I receptor mRNA, serum reg I protein, and tissue reg I protein levels were determined by Northern analysis, enzyme-linked immunosorbent assay (ELISA), and Western analysis, respectively. Immunohistochemistry was used to localize changes in reg I and its receptor.

RESULTS: Serum amylase levels and histology confirmed necrotizing pancreatitis in taurocholate treated rats. There was no statistically significant change in serum reg I concentrations from controls. However, Western blot demonstrated increased tissue levels of reg I at 24 and 36 h. This increase was localized primarily to the acinar cells and the ductal cells by immunohistochemistry. Northern blot demonstrated a

INTRODUCTION

Since its isolation in 1988 by Terazono *et al*^[1], much work has been done to elucidate the function of the regeneration protein, reg I. Reg I protein appears to function as a growth factor in the pancreas, as evidenced by its structural similarity to calcium-dependant lectins^[2], as well as its mitogenic effect on beta and ductal pancreatic cell lines^[3] and its ability to reverse surgically induced diabetes^[4,5]. Reg I gene expression has also been found in other tissues including gastric cells^[6], and rats with water immersion stress induced gastric lesions demonstrate an increase in reg I expression in gastric enterochromaffin-like cells during healing^[7]. Reg I is therefore involved in the regeneration and growth of gastrointestinal tissue. Furthermore, acute pancreatitis induces reg I gene expression and protein production in the pancreas^[8,9]. Recently, Kobayashi *et al* isolated the gene for reg I receptor^[10], which is part of the exostosins family of genes. Transfection of the gene into the pancreatic β -cell line RINm5F cells resulted in increased mitogenesis after exposure to reg I protein.

Since reg I and its receptor are linked to cellular

mitogenesis and may affect repair of damaged pancreas, we examined the role of their expression in acute pancreatitis.

MATERIALS AND METHODS

Induction of acute necrotizing pancreatitis

Acute necrotizing pancreatitis was induced in male Wistar rats using a 30 g/L sodium taurocholate solution according to a protocol described by Aho *et al* with slight modification^[11]. The animals (4 rats/group) were anesthetized with a 1:1 mixture of ketamine (100 mg/mL) and xylazine (20 g/L) dosed at 0.1 mL per 100 g of body mass injected subcutaneously. The abdominal cavity was then entered through a midline incision. The duodenum and pancreas were identified, the common biliopancreatic duct ligated at the hilum of the liver, and a duodenostomy made approximately 1 cm distal to the opening of the biliopancreatic duct into the duodenum. A polyethylene catheter with an inner diameter of 0.58 mm and an outer diameter of 0.965 mm was used to cannulate the pancreatic duct through the duodenostomy. A 30 g/L sodium taurocholate solution was slowly injected at a dose of 1 mL/kg at a constant infusion rate of 0.5 mL/min. The catheter was left in place for 30 min and then removed. The midline incision was then closed in a single layer closure. Control animals consisted of sham operated rats (open laparotomy with immediate closure) and healthy rats.

Harvesting of pancreas and serum

A total of 12 rats were operated on for induction of pancreatitis. Four rats were sacrificed at each time point (12, 24, and 36 h). Four rats per group (unoperated and sham operated) were used for controls. The pancreas was harvested and blood collected by cardiac puncture from each rat. A small portion of the head of the pancreas was fixed in formalin and sent for staining with hematoxylin and eosin (HE) and immunohistochemical staining with reg I mAb^[12]. The remaining pancreas was divided in half. One portion was immediately snap-frozen in liquid nitrogen and used for RNA isolation (below), and the other for protein isolation. This was performed by homogenization in buffer containing 125 mmol/L mannitol, 40 mmol/L sucrose, 5 mmol/L ethylenediamine tetraacetic acid (EDTA), and 5 mmol/L piperazine ethane sulfuric acid-Tris (PIPES-Tris) (pH 6.7). The homogenate was centrifuged at 4100 g for 30 min and the supernatant collected and frozen at -20°C. The concentration of total protein in the pancreas homogenates was quantified using the BioRad Protein Assay solution according to the manufacturer's protocol. The blood was centrifuged at 1800 g for 15 min. The supernatant (serum) was collected and stored at -20°C.

Serum amylase activity was determined by enzymatic reaction. Formaldehyde-fixed pancreatic specimens from each rat were stained with HE.

Preparation of reg I cDNA probe

Reg I cDNA probe was prepared by PCR using a plasmid with a reg I insert as a template^[3]. The sequences of the

oligonucleotide primers are 5'ACGCGTCGACTCATGACTCGCAACAAATATTTTC3' and 5'GGCACTGCAGTCAGGCTTTGAACTTGCAGAC3'. The PCR was carried out using digoxigenin-labeled uridine triphosphate (DIG-labeled UTP) (Roche Diagnostics, Mannheim, Germany) under the following conditions: denaturing at 94°C for 30 s, annealing at 57°C for 30 s, and elongation at 72°C for 1 min; 30 cycles were used.

Preparation of Reg I receptor cDNA probe

A Reg I receptor cDNA was prepared using double digestion of pCIneo-Reg I receptor cDNA plasmid^[10] with *Hind*III and *Not*I. Electrophoresis of the digestion complex was performed on 8 g/L agarose gel, the receptor band cut from the gel, and the cDNA extracted from the gel using the QIAEX II agarose gel extraction protocol (Qiagen, Valencia, CA). The reg I receptor cDNA fragment was labeled with digoxigenin (DIG) using the DIG High Prime DNA Labeling and Detection Starter Kit II (Boehringer Mannheim, Germany) as per manufacturers' protocol.

Northern blot

RNA was extracted from rat pancreatic and intestinal tissue using Trizol reagent (Gibco, Life Technologies, Rockville, MD). RNA extraction was performed with 1-bromo-3-chloropropane. RNA concentrations were determined by absorbance measurements at 260 nm, and the integrity confirmed by polyacrylamide gel electrophoresis. Equal amounts (20 µg) of total RNA were then used for all Northern blots. The membrane was equilibrated in 10 × saline-sodium citrate (SSC) buffer for 5 min. The RNA samples were prepared as follows: 50 µL TE buffer (TE: 10 mmol/L Tris, 0.1 mmol/L EDTA, pH 8.0), 20 µL of 37 g/L formaldehyde, 30 µL of 20 × SSC, and 20 µg RNA. The samples were heated at 60°C for 15 min and immediately chilled on ice for 3 min. Two hundred microliters of 10 × SSC were then added to each tube. The samples were applied to the nylon membrane using a Northern slot blot apparatus. Each well was washed with 500 µL SSC. The membrane with RNA was UV cross-linked and placed in 50 mL of DIG pre-hybridization solution at 48°C for 6 h. Hybridization with the DIG-labeled reg I receptor cDNA probe was carried out at 58°C for 12 h. After washing and blocking, the membrane was incubated in a 1:10 000 dilution of anti-DIG-alkaline phosphatase conjugate antibody solution at room temperature for 30 min. CSPD solution (Boehringer Mannheim) was used for detection. Gels were photographed using Polaroid 667 film and digitized using an Epson 636 scanner. Band density analysis was performed using the public domain NIH Image program (available at <http://rsb.info.nih.gov/nihi-image/>) to determine the quantity of nucleic acid product. To account for differences in the amounts of starting RNA between samples, the density of each reg band was normalized to that of the β-actin band for the same sample. Samples were run in duplicate and data are expressed as mean optical densitometric (OD) measurements ± SE.

Western blot on tissue homogenate to determine reg I levels

The tissue was homogenized in buffer containing 125

mmol/L mannitol, 40 mmol/L sucrose, 5 mmol/L EDTA, 5 mmol/L PIPES-Tris (pH 6.7), and 1 tablet of protease inhibitor cocktail per 50 mL of buffer. Total protein concentrations were determined using Bio-Rad protein assay. Electrophoresis was performed using equal amounts of total protein (10 µg/well) in a 100 g/L sodium dodecyl sulphate polyacrylamide gel (SDS-PAGE). The electrophoresis was carried out at 80 V for the first 15 min and then at 130 V for 45 min in SDS electrophoresis buffer. The protein was transferred to nitrocellulose membrane (Micron Separations, Inc., Westborough, MA) at 100 V for 1 h. The membrane was blocked overnight in 50 mL/L milk. A dilution of 1:5000 was used for the mouse anti-reg I mAb and incubated for 1 h with the membrane. After washing with T-TBS, the membrane was incubated for 45 min with a 1:2000 dilution of horse radish peroxidase-linked anti-mouse IgG. Detection was done using the ECL Western Blotting Detection System (Amersham Pharmacia, Piscataway, NJ). Human Reg 1 (hReg1) (10 µg) was used as a positive antibody control.

ELISA on serum samples to determine reg I concentration

Each well of the microtiter plate was coated with a mixture of 50 µL serum and 50 µL of coating buffer (20 mmol/L Na₂CO₃ and 35 mmol/L NaHCO₃). Serial dilutions of human reg I were used as standards. The wells were coated overnight, followed by blocking with a 3% BSA solution for 4 h. The mouse reg I mAb was diluted 1:1000 and incubated for 1 h^[12,13]. A dilution of 1:1000 was used for the secondary antibody and incubated for 45 min. Detection was performed by adding 100 µL of detection buffer (4.84 mL of 0.05 citric acid, 5.14 mL of 0.1 Na₂HPO₄, 30 µL of 300 mL/L peroxide, and 1 tablet of o-phenylenediamine) and measuring absorbance at 450 nm.

Development of anti-receptor antibodies

Two non-overlapping peptide sequences were identified that were contained in the extracellular domain of the Reg I receptor^[10] with predicted antigenicity and directly flanking specific amino acids thought to directly bind to Reg I (phage display experiment, unpublished data). PAELEKQLYSLPHWRTDC and RLLPEKDDA-GLPPPKATRGC were synthesized by solid phase synthesis (Biomolecules Midwest Inc., St. Louis, MO), purified by reverse phase high performance liquid chromatography (HPLC), and characterized by Mass Spectrometry. Peptides were coupled to KLH and used for immunization of rabbits. Rabbits were boosted at monthly intervals and bled 10–14 d after each boost. Antibody titer was determined in a microtiter plate ELISA using the conjugated peptide as the immobilized antigen. The immunoglobulin fraction was isolated using ImmunoPure (A/G) IgG purification system (Pierce, Rockford, IL) and the final antibody concentration was determined with the BCA Assay (Pierce).

Reg I receptor immunohistochemistry

Paraffin embedded sections were treated with Ficin (1:100 dilution, Sigma, St. Louis, MO) for 30 min at room temperature, washed, and were then treated with Avidin/Biotin blocking reagent (Vector Labs, Burlingame, CA) for

Figure 1 Serum amylase activity in pancreatitis rats (12, 24, 36 h) vs sham operated and normal controls. ^a $P < 0.05$.

Figure 2 HE stain of normal rat pancreas (A) and after taurocholate injection at 12, 24, and 36 h (B, C, and D). Induction of pancreatitis resulted in hemorrhage (thin arrows), infiltration of neutrophils ("n"), and necrosis (thick arrows).

20 min. Slides were subsequently treated with a Protein Block Reagent (Dako, Carpinteria, CA) and incubated with primary antibodies overnight at 4°C. Goat anti-rabbit biotinylated IgG secondary antibody was applied for 1 h at room temperature (1:1500, NEN Life Science, Boston, MA). Endogenous peroxidase activity was quenched by treatment with 10 mL/L hydrogen peroxide/PBS and sections were then incubated with streptavidin-horseradish peroxidase (SA-HRP) (1:1000 dilution, Dako) for 30 min. For receptor experiments, tyramide amplification was applied for 3 min (NEN Life Science, Boston, MA). Slides were extensively rinsed and again incubated with SA-HRP (Dako, 1:1000) for 30 min at room temperature. Slides were developed in DAB (Sigma, St. Louis, MO) and counterstained with hematoxylin (Richard Allan, Kalamazoo, MI).

Statistical analysis

Data were expressed as means \pm SE. Student's *t* test was used for analysis. $P < 0.05$ was taken as significant.

RESULTS

The presence of acute necrotizing pancreatitis in taurocholate-treated rats was confirmed by serum amylase activity and histology (Figures 1 and 2). As demonstrated in Figure 1 serum amylase levels at 12, 24, and 36 h were elevated ($P < 0.05$) when compared to both sham operated and normal control rats. Figure 1 demonstrates a rapid increase

Figure 3 Slot blot analysis with anti-reg I antibody of total protein (10 μ g/well) from normal rat pancreas and rat pancreas after induction of acute pancreatitis. Reg I protein levels in tissue increased after 24 h of pancreatitis. Human Reg I (hRegI) is shown as a loading control as described in MATERIALS AND METHODS.

Figure 4 Immunohistochemical staining of normal rat pancreas with anti-reg antibody (A) and of rat pancreas after 24 and 36 h of pancreatitis (B, C). There is a marked increase in reg I levels in acinar cells of the pancreas after pancreatitis. Stained acinar cells are marked with thin arrows, compared with lack of staining in Islet cells (thick arrow).

in amylase levels at 12 h with a gradual decline towards normal levels at 24 and 36 h. Figure 2 demonstrates histopathological worsening of pancreatitis in the pancreatic parenchyma after sodium taurocholate treatment as evidenced by hemorrhage (Figures 2 B, C) and necrosis (Figure 2D) when compared with control groups (Figure 2A).

Western blot analysis of pancreatic tissue showed a single band at 15-17 ku using a monoclonal antibody and demonstrated an increase in reg I protein in the 24 and 36 h pancreatitis groups compared to controls, although at 12 h, there was an initial decrease in reg I protein (Figure 3). Histologic examination showed that this appeared localized in the pancreatic acinar cells (Figure 4). Serum reg I protein levels were not significantly different in pancreatitis (0.43 ± 0.13 mg/L) when compared with sham-operated and normal controls (0.38 ± 0.15 mg/L) (data not shown).

Northern/slot blot analysis demonstrated a single band corresponding to the Reg I receptor mRNA and showed an increase in reg I receptor RNA expression in pancreatic tissue from the experimental pancreatitis groups compared to controls (Figure 5). Mean absorbance (A) \pm SE of reg I receptor signals on Northern/slot blot for control, 12, 24, and 36 h of pancreatitis were 24 ± 6 , 71 ± 15 , 66 ± 26 , and 75 ± 20 (all were significantly increased compared

Figure 5 Slot blot of reg I receptor during pancreatitis showed an increase in reg I receptor mRNA expression after induction of pancreatitis. The density of each reg band was normalized to that of β -actin band for the same sample as described in MATERIALS AND METHODS.

Figure 6 Immunohistochemical staining of pancreata from normal (A) and experimental pancreatitis (B-D) rats. There is an induction of reg I receptor expression in the acinar cells (a) and islets (i), and maintenance of reg I receptor expression in ductal cells (d) with pancreatitis.

to control, $P < 0.05$). Immunohistochemical staining with anti-reg I receptor antibody showed that although staining persisted in the ductal population, there was significant induction of receptor protein in both the islets and acinar cells (Figure 6).

DISCUSSION

Reg I is mitogenic to ductal and β -cells likely through the induction of the MAP kinase p38 pathway^[14]. This has been shown to be true in both cell culture and animal models of pancreatectomized rats. The data presented support the hypothesis that reg I is involved in regeneration after injury to the pancreas in the form of a sodium taurocholate-induced acute necrotizing pancreatitis. The pancreatic rats demonstrated an increase in reg I protein levels in pancreatic tissue after 24 h of pancreatitis. In the acutely inflamed pancreas it appeared that reg I protein was overproduced in the acinar cell population. This is consistent with the findings of others in both acute and chronic forms of pancreatitis^[15]. Although many genes are

differentially regulated in inflammatory states, microarray data by us and others have demonstrated increased Reg expression in experimental pancreatitis^[16,17]. Interestingly, serum reg I protein levels did not increase in parallel with acinar reg I RNA expression levels^[13]. This may be due to differences in cellular RNA turnover prior to stabilization of protein levels in serum, possibly through unidentified reg I binding proteins. Similar discord between protein and gene expression has been found in other systems^[18].

Baseline expression of reg I receptor is present in pancreatic ductal and beta cell lines, but not in acinar cell lines^[10,19]. These cells respond to reg I protein by proliferating, as measured by thymidine incorporation. Cells transfected with the receptor respond to reg I in a similar fashion^[10]. Acinar cells, which typically do not grow in response to reg I, do not express the receptor. It is therefore likely that the expression of the receptor is linked to the activity of cellular mitogenesis, and may be important in the proliferative response of pancreatic regeneration.

We found that pancreatitis significantly induced the expression of reg I receptor RNA in pancreatic tissue compared with baseline level. Immunohistochemical analysis with a polyclonal antibody to the reg I receptor localized the induced protein to the acinar cells and islets, and was only mildly present in ductal cells. This pattern of induction was in sharp contrast to the increase in reg I which was initially induced primarily in the acinar cells. While ductal cells typically proliferate after pancreatitis^[20], the additional induction of the protein in islets and acinar cells likely means that they are becoming responsive to the reg I protein which is being produced and secreted by the acinar cells.

Our present data suggest that increased reg I protein and receptor are important in the response of the pancreas to injury. Specifically, reg I may exert its mitogenic effect on all the cell populations after injury. It likely works in a paracrine fashion, since it is produced and secreted from acinar cells. The induction of the receptor after injury in the acinar cells and islets and its maintenance of expression in the ductal cells may allow the protein to enhance its regenerative effect.

Another new protein induced in pancreatitis is reg III, or pancreatitis associated protein (PAP). Seventy percent homologous to reg I, the pancreatic RNA and protein levels are increased even more dramatically in pancreatitis, and PAP protein is also increased in serum^[21,22]. We showed that the bovine form of reg III is mitogenic to pancreatic β - and ductal cells as well^[3]. It is possible that reg III protein interacts with the reg I receptor which may provide an important pathway for regeneration after injury.

Future experiments need to determine whether blocking the receptor will block the regenerative effect of reg I, and whether other members of the reg family, in particular reg III, can stimulate the receptor as well.

Abstract

AIM: To study the esophageal geometry and mechanosensation using endoscopic ultrasonography during volume-controlled ramp distensions in the distal esophagus.

METHODS: Twelve healthy volunteers underwent distension of a bag. During distension up to moderate pain the sensory intensity was assessed on a visual analogue scale (VAS). The esophageal deformation in terms of multidimensional stretch ratios and strains was calculated at different volumes and VAS levels. Distensions were done before and during administration of the anticholinergic drug butylscopolamine.

RESULTS: The stimulus-response (volume-VAS) curve did not differ without or with the administration of butylscopolamine. Analysis of stretch ratios demonstrated tensile stretch in circumferential direction, compression in radial direction and a small tensile stretch in longitudinal direction. A strain gradient existed throughout the esophageal wall with the largest circumferential deformation at the mucosal surface. The sensation intensity increased exponentially as function of the strains.

CONCLUSION: The method provides information of esophageal deformation gradients that correlate to the sensation intensity. Hence, it can be used to study mechanosensation in the human esophagus. Further studies are needed to determine the exact deformation stimulus for the esophageal mechanoreceptors.

INTRODUCTION

Acute and chronic pain in the upper gastrointestinal tract is a severe and frequent health care problem in terms of human suffering and enormous economic implications for the health care system^[1]. Thorough understandings of visceral pain mechanisms are necessary for developing diagnostic tools and optimal treatments. However, pain and related symptoms are difficult to study due to the heterogeneity of patients and confounders related to clinical pain^[2].

Human experimental pain models can be used as tools for better characterization and understanding of pain mechanisms. In recent years studies have been focused on mechanical distension^[3-5]. However, many experimental pain studies of hollow visceral organs have reached erroneous conclusions since the pressure, volume and wall tension are proxies of the deformation in the vicinity of mechanoreceptors and therefore only show indirect degree of association with the evoked responses. It has been demonstrated in several parts of the digestive tract including the esophagus that deformation (circumferential strain) is more closely associated with the distension-induced sensory responses than the distension pressure, volume or wall tension^[6-8]. Calculation of the strain, however, demands advanced methods. Recently, endoscopic ultrasonography has been used to obtain information about the geometry of the esophagus including wall and layer thicknesses for the purpose of computing wall tension, stress and strain during swallowing^[9-12]. However, none of these studies has carefully evaluated the sensory properties during esophageal distension.

In the present study, endoscopic ultrasonography was combined with controlled esophageal distension and sensory assessment to obtain information about the mecha-

nosensation. Since deformation is considered the most important parameter for mechanosensation^[6-8], we measured the needed geometric variables and computed multidimensional stretch ratios and strains in order to obtain new information about the relationship between stretch and evoked pain.

MATERIALS AND METHODS

Subjects

Twelve healthy subjects, 6 males and 6 females, median age 38 years (range 22-67 years) recruited from the hospital and university staff, volunteered to participate in the study. They did not suffer from previous or current gastrointestinal disease and had no gastrointestinal complaints. The volunteers did not take any drugs and abuse alcohol. The regional ethics committee approved the study protocol and the experiments were conducted in accordance with the revised Declaration of Helsinki. All volunteers were asked to give a written informed consent to participate in the experiment.

Probe design

The probe was constructed from a thin flexible tube and equipped at the end with a highly compliant latex balloon. The tube was connected to an infusion pump (Type 111, Ole Dich Instrument makers, Hvidovre, Denmark). Saline heated to body temperature was infused into the balloon at the rate of 25 mL per min. The 6-cm long balloon was made of natural rubber with a thickness of 0.2 mm. In the deflated state the largest transversal diameter of the balloon was 10 mm. The shape of the balloon became almost spherical when inflated. An ultrasonographic miniprobe was advanced through the probe lumen and the transducer was placed inside the balloon. The ultrasound system used a rotating 20-MHz transducer (model UM-3R; Olympus, Japan). The ultrasound transducer produced a real time 360-degree cross-sectional image of the esophagus.

Protocol

The subjects were fasted at least for 6 h. Studies were performed with the subjects in half supine position. The probe was lubricated and inserted through the nostrils. The tip of the probe was first advanced into the stomach. The lower esophageal sphincter (LES) was identified by pull-through manometry as a zone of resting pressure that decreases with swallowing. The balloon was placed 8 cm proximal to LES and the probe was fixed to the nose to prevent migration of the assembly during the study.

Distensions were done to precondition the tissue and served as learning sessions to facilitate the sensory rating. Since preconditioning is necessary to obtain reproducible results^[4], three distensions using a constant infusion rate of 25 mL/min were done until the pain threshold was reached (5 on the visual analogue scale (VAS). After the preconditioning distensions, two more distensions to 7 on the VAS (moderate pain level) were done. Then a bolus of 20 mg butylscopolamine was given intravenously to decrease distension-induced secondary smooth muscle contractions. The balloon was again inflated twice using

Figure 1 Transversal ultrasonographic image of the non-distended esophagus. The stippled lines indicate manual tracings of the mucosal inner surface (A) and the inner (B) and outer (C) lining of the combined muscle layers.

an infusion rate of 25 mL/min until 7 on the VAS was reached. The balloon was emptied for 2 min between the distensions. None of the volunteers experienced significant side effects due to the anti-cholinergic action of the drug. The total investigation time never exceeded 1.5 h.

Sensory assessment

The sensory intensity was assessed continuously during the mechanical distension by using an electronic VAS-meter (GMC-Medical, Hornslet, Denmark). The VAS data were amplified and analog-to-digital converted at a sampling rate of 10 Hz using the Openlab data acquisition system (GMC-Medical, Hornslet, Denmark). The digitized data were stored on a PC for later analysis.

Before commencement of the visceral mechanical stimulation, the subjects were trained in using the VAS. The sensations were produced by applying deep pressure in muscles of the right forearm. The intensity of non-painful stimuli was scored up to 5 on the VAS. Key anchor words to describe the sensations were: 1 = vague perception of mild sensation; 2 = definite perception of mild sensation; 3 = vague perception of moderate sensation; 4 = definite perception of moderate sensation; 5 = pain threshold. For the painful sensations the patients used the scale from 5-7 anchored at 6 = slight pain and 7 = moderate pain^[2].

Data analysis

Ultrasonographic images of the esophagus were recorded in real time during the studies using a super-VHS videotape recorder. The videotape recordings were captured in video streaming 120 + MB/s at a frame rate of 25 s⁻¹ and a resolution 756 × 576 by a high performance video grabber (I-Color, Image House A/S Copenhagen DK). All image measurements and calculations were performed off-line using an image analysis software package (Scion Image Beta 4.02 Win, Maryland). We selected one reference image at each pain intensity level from the distensions after preconditioning the tissue. The images were selected at points where contractions were not present. The mucosa and muscle layers were outlined manually (Figure 1). Once outlined, the software program automatically calculated the circumference and the area of the layers. The layer

thickness was computed from the circumferential length and area.

The steady state pressure, diameters, CSA and wall thickness values at each volume distension step were used for the computation of stretch ratios and strains.

The circumferential Cauchy strain ϵ was computed as the fractional change in circumference^[3].

$$e = \frac{C - C_0}{C_0} \quad (1)$$

where C is the circumference obtained at the serosal or mucosal surfaces or between layers at various degrees of distension, C_0 is the reference circumference obtained at unloaded conditions immediately prior to a distension. The strain in radial direction could be computed from the measured wall thickness h as

$$e = \frac{h - h_0}{h_0} \quad (2)$$

where h_0 is the reference thickness obtained at unloaded conditions immediately prior to a distension. In a similar way the strain could be computed for the individual wall layers.

In a mechanical analysis it may also be convenient to use the stretch ratio as a measure of deformation. The stretch ratio λ was determined for both the circumferential (θ), radial (r) and longitudinal (z) direction. The stretch ratio is defined as the length at loaded conditions (L) divided by a reference length at unloaded conditions (L_0).

$$\lambda = \frac{L}{L_0} \quad (3)$$

Thus the stretch ratio $\lambda = \epsilon + 1$. For circumferential and radial direction the stretch ratios could be determined from the experiments using the same principle as for the strain calculation. The stretch ratio in longitudinal direction λ_z was determined from the two other stretch ratios by using the law of mass conservation. Hence, $\lambda_z = 1/\lambda_\theta \lambda_r$ ^[3,4,13].

Statistical analysis

The results were expressed as mean \pm SE. At various volumes and VAS levels 1-7, the corresponding stretch ratios before and during administration of butylscopolamine were determined. Two-way-ANOVA was used for statistics. $P < 0.05$ was considered statistically significant.

RESULTS

Ultrasonographic and VAS data were obtained in all subjects. The distensions were done until moderate pain (VAS = 7) was experienced except in one subject in whom the distension was done only until the pain threshold (VAS = 5) was reached. Three subjects repeatedly got involuntary long lasting contractions in the esophagus after the pain threshold was reached. Butylscopolamine greatly reduced these contractions. One subject reported autonomic side-effects during the distensions manifested as tachycardia, nausea and sweating.

Figure 2 Transversal ultrasonographic images of the esophagus at different sensory perception levels. The esophagus is fairly circular at 3 on the visual analogue scale. The numbers refer to the sensory intensity at a visual analog scale with 5 as the pain threshold.

The preconditioning stimuli resulted in reproducible mechanical distensions and sensory-motor responses. Figure 2 shows the representative ultrasound images obtained at different VAS levels. The mean thickness of the mucosa and muscle layer in the resting state was 1.4 ± 0.02 mm and 2.4 ± 0.03 mm respectively. The esophageal folds almost disappeared at VAS level of 3 or higher where the geometry could be approximated as circular. The interface between the inner circular and outer longitudinal muscular layer could be visualized as a thin echogenic layer only at low volumes in the balloon. This layer was not consistently visible in the subjects at VAS levels of 2 or higher (Figure 2) and therefore could not be used in the strain analysis.

We found no difference in the volume-VAS data before and during butylscopolamine infusion (Figure 3-top, $F = 2.50$, $P = 0.12$). Consequently we used the data obtained during butylscopolamine infusion for the further analysis since contractions to some degree would bias the readings. Thus, the increased VAS primarily would be due to stretch of the wall rather than the active stress generated by the muscle tissue. Figure 3 also shows the circumferential, radial and longitudinal stretch ratios as function of volume and sensory intensity on the VAS for the mucosa and main muscle layers. In both layers, the circumferential deformation was tensile, whereas the radial deformation was compressive due to the decrease in layer thickness during the distensions. The computed longitudinal stretch ratio was tensile but less than the circumferential stretch ratio. Furthermore, the longitudinal stretch ratio did not increase further after 1 was reported on the VAS or a volume of 10 mL was reached. At the pain threshold (VAS 5) the mean circumferential, radial and longitudinal stretch ratios in the muscle layer were 1.7 ± 0.1 , 0.5 ± 0.04 and 1.2 ± 0.07 , respectively.

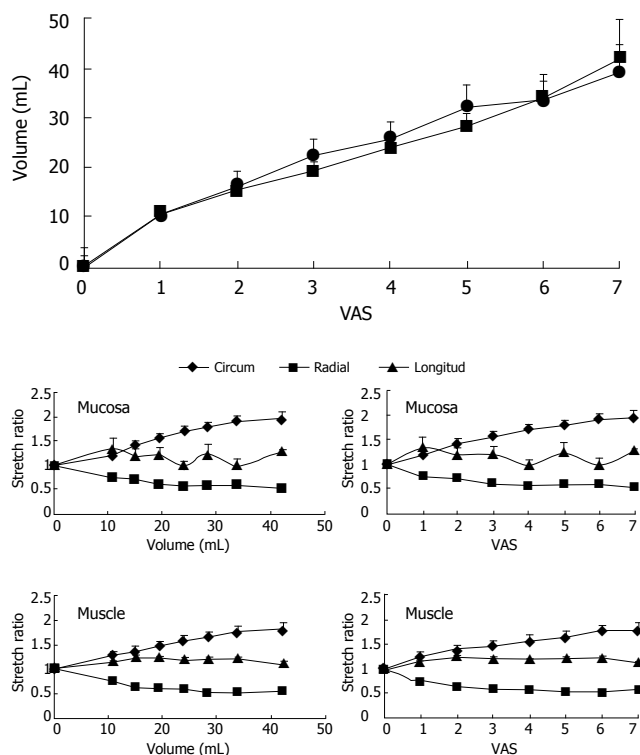

Figure 3 Illustration of the relation between volume and sensory intensity on the visual analogue scale (VAS) with 5 as the pain threshold (top graph). Since there was no difference in the curves obtained (triangles) before and during (squares) infusion of butylscopolamine, data obtained during butylscopolamine are given in this paper. The four figures show the circumferential, radial and longitudinal stretch ratios as function of volume and VAS in the mucosa and muscle layers (the circumferential data are from the mucosal surface and the outer muscle surface).

Figure 4 Sensory intensity on the visual analogue scale (VAS) with 5 as the pain threshold as function of the luminal cross-sectional area (CSA). A large variation was found in volunteers, which speaks in favor of using non-dimensional measures as the stretch ratio.

The sensory response showed a large variation between the volunteers. Figure 4 shows the sensation as function of luminal cross-sectional area (CSA). The rather large inter-individual variation speaks in favor of using non-dimensional measures such as stretch ratios rather than the volume or CSA. Figure 5 shows the circumferential stretch level at the mucosa and the inner and outer muscle layers. The circumferential deformation at the mucosal surface was larger than that at the outer muscle layer at high sensory levels. However, at low VAS levels the mucosal deformation was small, which was due to unfolding rather than stretch of the mucosa initially during the distensions. A strain gradient existed through the esophageal wall with

Figure 5 The top graph shows the circumferential stretch ratio at the mucosal surface (left), the interface between the submucosa and circumferential muscle layer (middle) and the serosal surface (right). The middle graph shows the same data in terms of the circumferential strain and sensory intensity on the visual analogue scale (VAS). There was a strain gradient throughout the esophageal wall with the largest deformation in the mucosa. The bottom graph shows the longitudinal strain as function of the sensory level. No increase in strain was seen during sensory intensity was increased. For convenience the data from all VAS are not shown.

the largest deformation in the mucosa and the sensation increased exponentially as function of the strain in both the mucosa and muscle layers (Figure 5). Longitudinal strain during distension seemed not to cause the sensation as the longitudinal strain did not increase further after VAS 1 (Figure 5 bottom). To evaluate further whether radial or circumferential strains were most important, we plotted the dispersion (SE/mean) of the radial and circumferential stretch ratio data from Figure 3. The circumferential stretch ratios in the muscle and mucosa layers showed the smallest dispersion (Figure 6).

DISCUSSION

The function of the esophagus is mechanical to a large extent. Swallowed contents are propelled through the esoph-

Figure 6 Dispersion (SE/mean) of the circumferential and radial strains in the mucosa and muscle. The dispersion was the lowest in circumferential direction.

agus into the stomach where the digestion starts. Methods traditionally used for clinical or basic investigations of the esophagus are endoscopy, manometry, pH-metry and radiographic examinations. Although these methods provide important data on esophageal motor function, little attention has been paid to the biomechanical and mechanosensory properties of the wall and determination of the wall deformation. During recent years ultrasonography has gained interest in studying gastrointestinal (GI) physiology and in clinical evaluation of the esophagus. In the current study, the stretch was tensile in circumferential direction, compressive in radial direction and tensile to a small degree in the longitudinal direction. A strain gradient existed throughout the esophageal wall with the largest circumferential deformation at the mucosal surface. The sensation intensity increased exponentially as function of the strains and the esophageal deformation gradients correlated to the sensation intensity.

Endoscopic ultrasonography is a non-invasive and safe method applicable in study of the esophagus. Two-dimensional B-mode ultrasonography has been utilized to assess the correlation between ultrasonographic images and histology^[13] and to determine biomechanical properties of the esophagus *in vitro*^[14]. Furthermore, Nicosia *et al*^[10] have used endoscopic ultrasonography in humans to study esophageal longitudinal muscle shortening and Miller *et al*^[11] have studied the correlation between wall changes and manometry during esophageal motility. Moreover, Pehlivanov *et al*^[9] showed that muscle geometry is changed during contractions in volunteers and patients with esophageal spasms. None of these studies has paid attention to the sensation provoked by balloon distension. Thus, despite these developments and the fact that the mechanical wall properties are important for normal function of the esophagus, the mechanosensory properties of the esophagus *in vivo* are still largely unknown. In this study we therefore intended to gain a better understanding of esophageal deformation and mechanosensory function.

Methodological aspects

In distensible biological tubes, the circumferential wall strain is of interest because the tensile stress is the largest in that direction during distension^[3,4,15]. The reasons for studying the stresses and strains in intact hollow organs are as follows: wall stress and strain data give valuable infor-

mation on the elastic properties^[4], mechanoreceptors do not respond directly to changes in pressure or volume but rather to changes in strain^[2], it is important to differentiate active properties such as phasic contractions and smooth muscle tone from passive tissue properties in pharmacological and biomechanical studies^[2,16,17], and intact organs maintain normal geometry in contrast to the tissue strips often used for length-tension measurements in physiological and pharmacological studies^[15,18].

In this study, we aimed to develop a new method for investigation of the mechanosensory properties in the esophagus, mainly in the state where contractions did not confound the analysis. The method is based on distension of a bag placed in the lumen with concomitant measurement of the distension pressure and the antral geometry in a selected cross-sectional plane by endoscopic real-time B-mode ultrasound. The ramp protocol ensured that we studied the elastic properties rather than viscoelastic properties^[4,15]. This ease the interpretation of the data since time-dependent confounders are significantly eliminated^[4]. The administration of the antimuscarinic drug butylscopolamine allowed us to investigate the active and passive tissue behavior. Since the volume-VAS curve did not differ between the distensions before and during butylscopolamine administration, we only analyzed the distensions after administration of butylscopolamine. This gives data that are easier to interpret as there is no significant influence of esophageal contractions. Butylscopolamine may not abolish all contractions. Therefore we analyzed the data between contractions if they were present. Since stretch as well as contractions may elicit pain, we primarily looked into the stretch-dependent pain mechanisms in this study. It has been found in other tissues as in the cardiovascular system that the baroreceptors depend on strains in the vicinity of the receptors^[15]. We have previously shown that strain is the most important biomechanical parameter for sensory responses in the gastrointestinal tract including the esophagus^[6-8]. Thus, in this study we were only concerned with the deformation as a stimulus for the mechanoreceptors.

The ultrasonographic technique makes the derivation of strains in multidimensional directions possible from the geometric data or due to use of the mass conservation principle. The strain calculations are based on direct measurements rather than on geometric assumptions such as a circular cross-section and the thickness of the layers measured in our study, which are consistent with the data presented by others^[10]. The fact that the lumen is not circular at low volumes makes it difficult to compute tension and stress based on Laplace's law^[3,4,15], but the strain analysis does not depend on the geometry as long as the surfaces and interfaces between layers can be clearly defined. In most cases we did not have any problems in identifying the tissue layers. Thus the error due to these measurements is considered small. However, the ultrasound images only show the primary convolution (folds) but not secondary and tertiary convolutions of the mucosa. If higher-order convolutions were present, this could result in a minor underestimation of the calculated stretch in the mucosa and a larger inter-individual variation. Unfortunately, we could

not clearly outline the interface between the two muscle layers at VAS levels above 3. Hence, we omitted presenting data on this interface.

Biomechanical and mechanosensory aspects

In the present study, the deformation was the largest in the circumferential direction, despite the presence of mucosal folds the circumferential deformation decreased through the wall with the largest values at the mucosal surface, and the sensation increased exponentially as function of the circumferential strain.

Gastrointestinal symptoms are often associated with disturbances in motility and sensory function. Several studies have attempted to investigate these properties by means of balloon distension^[19-21]. Unfortunately, the primary mechanism for symptoms elicited by GI distension remains unclear. It is well known that distension of the gastrointestinal tract elicits reflex-mediated inhibition and stimulation of motility via intrinsic or extrinsic neural circuits and induces visceral perceptions such as pain^[21]. Previous studies demonstrated that mechanoreceptors located in the intestinal wall play an important role in the stimulus-response function^[22-26]. It is, however, a common mistake to believe that mechanoreceptors are sensitive to variation in pressure, volume or tension. A large variation in the perception has been found in various studies and species^[27-29], suggesting that pressure is not the direct stimulus. The dogma that the mechanoreceptors are tension-sensitive receptors lying in-series or in-parallel with the muscle cells has also been prevalent for many years^[30]. This concept is borrowed from striated muscle physiologists and should yet be regarded as a working hypothesis, since no clear evidence supports it in GI studies. It is basically a uniaxial model that does not account for more complex biomechanical properties such as distribution of the deformation field and that different receptor populations may exist. There seems to be no evidence that the receptor is dependent of tension rather than strain. Instead, the receptors are stimulated by deformations acting on the intestinal wall due to changes in the transmural pressure^[31]. Thus, the mechanical distension stimulus and the biomechanical tissue properties must be taken into account in studies of the sensory-motor function in the esophagus.

It is well known that the passive elastic behavior of biological tissues is exponential^[3,4,15]. This mechanical feature protects the tissue against over-distension and damage at high luminal pressure loads while distending easily and facilitating flow in the physiological pressure range. In arteries, it has been demonstrated that collagen bears circumferential loads at high stress levels^[32,33]. As gastrointestinal tissue is rich in collagen^[34], it is likely that collagen is a major determinant of the passive mechanical properties. Though we did not evaluate the elastic properties in terms of stress-strain relations, the fact that the strain-VAS curve is exponential indicates that the exponential properties play a role in protecting tissue against high stress.

Our results may shed some light on the discussion regarding the visceral sensation receptors in human beings. The data suggest that at low loads the deformation occurs mainly in the muscle layer, whereas at higher loads,

the largest deformation occurs at the mucosal surface. Furthermore, the lowest dispersion has been found for the circumferential stretch ratio in the muscle layer. Though this analysis may be biased by measurement of errors for the two directions, the analysis may reveal that the most important mechanoreceptors are located in the muscle layer where they sense circumferential deformation. This view is also supported by other data showing that the circumferential deformation in the mucosa is much smaller than in the muscle layer at low loads, where the mucosa merely unfolds rather than stretches. However, the differences are small because the deformations in various directions depend on each other (due to the mass conservation principle) and require further analysis.

Conclusions and future clinical applications

We have developed a new method to study the strain-dependency of esophageal mechanoreceptors. The data point in the direction of a strain receptor sensitive to circumferential deformation in the muscle layer. The new test can be used to test drugs on esophageal mechanosensory function, and improve our understanding of the pathophysiology underlying the symptom induction in patients with pain and other symptoms relating to the esophagus.

Abstract

AIM: To evaluate the usefulness of various computed tomography (CT) findings including distribution of infiltration or fluid collection in differentiating the major etiologies of acute pancreatitis.

METHODS: We reviewed 75 relatively severe cases of acute pancreatitis of alcoholic ($n = 43$) or biliary stone ($n = 32$) etiology having infiltration or fluid collection on CT. We compared the pancreatic size, CT grading, presence or absence of biliary calculi, and dilatation of pancreatic or bile duct. We also evaluated degree and the distribution of infiltration and fluid collection in each group.

RESULTS: The sizes of pancreas were not different between alcohol group and stone group. Alcohol group showed higher CT grading than stone group ($P < 0.05$). Presence of biliary stone and duct dilatation was statistically significant in differentiating etiology ($P < 0.05$). Alcohol group showed significantly prominent peripancreatic pathology than stone group only in left peritoneal compartment ($P = 0.020$).

CONCLUSION: Alcoholic pancreatitis tends to form more prominent peripancreatic changes than gallstone pancreatitis in relatively severe cases. This is evident on the anterior aspect of left abdomen. Although clinical history and some CT findings usually are a major determinant of the etiology, this pattern of peripancreatic pathology may have an ancillary role in determining the etiologies of acute pancreatitis in the equivocal cases.

INTRODUCTION

Biliary stones and alcohol account for 70%-80% of all acute pancreatitis etiologies^[1]. Differentiation between etiologies is of great importance because it can affect the further diagnostic and therapeutic strategies. Diagnosis and treatment of gallstone pancreatitis require an endoscopic retrograde cholangiopancreatography (ERCP) with sphincterotomy, but it is not warranted in alcohol-induced pancreatitis^[2]. The risks associated with ERCP outweigh any benefit unless the causative biliary stone is present.

Computed tomography (CT) findings associated with gallstone pancreatitis such as presence of stone in the biliary system have been well defined. Clinical information about biliary colic or alcohol abuse is also very useful in diagnosis. Causes of acute pancreatitis are often easily determined. However, some cases lacking medical background or the localization of stones or sludge make cause determination difficult. Although CT findings cannot be a sole determinant of therapy in individual cases, it can play a complementary role especially in indeterminate cases.

The purpose of this study was to evaluate the usefulness of CT findings associated with acute pancreatitis and to differentiate between the two major causes of acute pancreatitis. Special focus was given to the degree and distribution of peripancreatic infiltrations and fluid collection.

MATERIALS AND METHODS

Patients

Abdominal CT scans of 86 patients who had CT diagnosis of acute pancreatitis and were evaluated to have an infiltration or fluid collection in the abdominal cavity were studied retrospectively. All of them could be graded as C, D,

Figure 1 Peripancreatic infiltration scores (1-3). **A:** Score 1 (Irregular peripancreatic infiltration without fluid collection). CT showing irregular strands of peripancreatic fat infiltrations in the compartment of RP (arrow), LP (open arrows), and LSR (arrowhead); **B:** Score 2 (Peripancreatic fluid collection with no or equivocal degree of mass effect). CT showing multiple fluid collections without mass effect in the compartment of RSR (arrows) and LSR (open arrows). Score 1 infiltrations in the compartment of RP and LP (arrowheads) are also seen; **C:** Score 3 (Peripancreatic fluid collection with definite mass effect to adjacent organs). CT showing score 3 fluid collection in the LP and LSR compartments (arrows) displacing or compressing adjacent bowels.

and E by the system suggested by Balthazar *et al.*^[3]. Grade C was defined as pancreatitis with peripancreatic infiltration only. Grades D and E were defined as the disease with single and multiple peripancreatic fluid collections, respectively. Data were not consecutive but extracted randomly from our radiology department CT database. The population was composed of 53 male patients and 33 female patients with a mean age of 56.5 (range, 20-85) years. Patients were divided into an alcohol group and a stone group based upon their clinical diagnosis made by taking into account all possible factors including past medical history such as alcohol abuse or biliary colic, results of radiological studies (ultrasonography, CT, and ERCP), and laboratory data.

Of the 86 patients, eleven were excluded from the study because of unknown causes ($n = 6$), causes other than alcohol abuse or biliary stone ($n = 3$), traumatic pancreatitis ($n = 1$), L-asparaginase-induced pancreatitis ($n = 1$), pancreatitis due to pancreatic divisum ($n = 1$), and cases that were indeterminable between alcoholic and stone pancreatitis ($n = 2$) clinically. The remaining 75 patients were composed of 49 male patients and 26 female patients, with a mean age of 51.3 (range, 27-85) years. Forty-three out of 75 patients (57.3%) were classified as alcohol group, while 32 out of 75 (42.7%) were classified as stone group.

The Institutional Review Board of our hospital did not require approval for retrospective clinical study.

CT protocol

Abdomen CT scans were performed with one of the two helical scanners (Somatom Plus or Somatom Plus 4; Siemens, Erlangen, Germany). Helical CT images of pre-contrast and contrast-enhanced scans were acquired using an 8-mm collimation and 10-mm/s speed (Table 1). Images were reconstructed at an 8-mm interval. A voltage of 120 kVp and amperage of 210 mAs were used. One hundred mL of non-ionic contrast material (Iopromide, Ultravist-300; Schering AG, Berlingen, Germany) was administered intravenously via the antecubital vein at a rate of 3 mL/s with a power injector (OP 100; Medrad, Pittsburgh, PA). Dual-phase contrast-enhancement scan technique was adopted with a delay time of 60-70 s and 200-220 s, respectively, in the majority of cases. Pancreatic

phase scan with a delay time of 30-40 s was available only in a small portion of the patients ($n = 13$) because of lacking of the clinical diagnosis of acute pancreatitis before CT examination. At least one of the two or three phases covered an entire abdominal cavity from diaphragmatic dome to symphysis pubis.

Image analysis

Two abdominal radiologists analyzed the CT findings in consensus. In patients undergoing multiple follow-up CT scans, only the initial study was selected for imaging analysis. The antero-posterior and transverse diameters of pancreatic head, as well as the thickest dimension of body or tail of pancreas were measured. We evaluated the severity of disease at the initial abdominal CT using the CT grading system introduced by Balthazar *et al.*^[3]. We classified them into a three-point-scale, and converted C, D, and E to 1, 2, and 3. We investigated the presence or absence of calculus. Calculus was thought to be present when we saw high attenuation in the biliary tree including gallbladder on pre-contrast scan without measurement of Hounsfield unit. We also examined whether the pancreatic or bile duct was dilated or not. The criteria for abnormal duct dilatation were over 8 mm in diameter for common bile duct and 3 mm in diameter for pancreatic duct.

To assess the distribution of peripancreatic infiltration or fluid collection, the abdominal cavity was divided into 6 compartments, namely right peritoneal (RP) compartment, right superior retroperitoneal (RSR) compartment, right inferior retroperitoneal (RIR) compartment, left peritoneal (LP) compartment, left superior retroperitoneal (LSR) compartment, and left inferior retroperitoneal (LIR) compartment. 'Right' and 'left' compartments were divided by median line of the body traversing the umbilicus and the spinous process of vertebra. 'Peritoneal' and 'retroperitoneal' compartments were divided by already-established anatomical interface between peritoneum and retroperitoneum. Finally, 'superior' and 'inferior' compartments were compartmentalized by the level of lower pole of the left kidney. Degrees of infiltration or fluid collection in each compartment were evaluated with a four-point scale from 0 to 3 (0: no infiltration, 1: irregular infiltrative attenuation without fluid collection, 2: fluid collection with no or equivocal degree of mass effect on

Table 1 CT differentiation of the cause of acute pancreatitis between alcohol and stone group (mean \pm SD)

Findings	Alcohol group (<i>n</i> = 43)	Stone group (<i>n</i> = 32)	<i>P</i>
Size of pancreas			
Anteroposterior diameter, Head	36.2 \pm 6.7 mm	37.3 \pm 6.6 mm	0.485
Transverse diameter, Head	30.7 \pm 5.6 mm	31.7 \pm 5.4 mm	0.434
Thickness, Body and Tail	22.3 \pm 5.2 mm	23.3 \pm 5.3 mm	0.406
CT grading score	2.3 \pm 0.8	1.9 \pm 1.0	0.047 ¹
Calculi in the biliary system	3/43 (7.0%)	22/32 (68.8%)	0.000 ¹
Duct dilatation			
Pancreatic duct	4/43 (9.0%)	10/32 (31.3%)	0.033 ¹

¹Data of statistical significance.

adjacent organ, 3: fluid collection with a definite mass effect on adjacent organ) (Figure 1). If major infiltration or fluid collection of one compartment slightly extended to another compartment, the minor lesion was disregarded. Pancreatic necrosis or pseudocyst was regarded and analyzed as a fluid collection. Infiltration scores of each abdominal compartment in one group were compared with those of the corresponding compartment of the other group. Student *t*-test (pancreatic size), likelihood ratio test (CT grading of acute pancreatitis, grading of infiltration and fluid collection), and Fisher's exact test (calculi and duct dilatation) with 95% confidence interval were used for the evaluation of statistical significance (SPSS for Windows 11.0, Chicago, IL).

RESULTS

The antero-posterior and transverse diameters of pancreatic head for the alcohol and stone group measured 36.2 \pm 6.7 mm \times 30.7 \pm 5.6 mm and 37.3 \pm 6.6 mm \times 31.7 \pm 5.4 mm, respectively. The thickness of pancreatic body or tail in great dimension was 22.3 \pm 5.2 mm and 23.3 \pm 5.3 mm, respectively. Differences in pancreas dimension between the alcohol and stone groups were not significant (*P* > 0.05, Student-*t* test).

Scores of alcohol and stone groups resulting from CT grading (converted from C, D, E to 1, 2, 3), were 2.33 \pm 0.81, and 1.94 \pm 0.95, respectively. Alcohol group showed more aggressive CT findings than stone group (*P* = 0.047, likelihood ratio test).

The alcohol group showed calculi in the biliary tree in 3 of 43 cases (7.0%), while 22 of 32 cases (68.8%) were calculus-positive in the stone group (*P* = 0.000, Fisher's exact test). However, only 5 of 22 stone-positive cases showed calculi in the distal common bile duct. Only 5 of 32 cases (15.6%) in stone group showed distal common bile duct calculi on CT scans. In the remaining cases of stone group, biliary calculi were located in the gallbladder (*n* = 11), intrahepatic duct (*n* = 1), common duct other than distal portion (*n* = 3), and simultaneously in the gallbladder and the common duct other than distal portion (*n* = 2).

Abnormal pancreatic duct dilatation was noted in 4 of 43 cases (9.3%) of alcohol group and in 10 of 32 cases (31.3%) stone group (*P* = 0.033, Fisher's exact test). Bile

Table 2 Comparison of infiltration scores of each abdominal compartment between alcohol group and stone group (mean \pm SD)

Compartment	Alcohol group (<i>n</i> = 43)	Stone group (<i>n</i> = 32)	<i>P</i>
RP	1.00 \pm 0.82	0.91 \pm 0.69	0.568
RSR	0.84 \pm 0.87	0.94 \pm 0.95	0.416
RIR	0.56 \pm 0.85	0.56 \pm 0.84	0.905
Total (right)	2.40 \pm 2.16	2.41 \pm 2.12	0.798
LP	1.67 \pm 0.97	1.00 \pm 0.92	0.020 ¹
LSR	1.49 \pm 0.88	1.13 \pm 0.83	0.119
LIR	0.51 \pm 0.28	0.83 \pm 0.52	0.240
Total (left)	3.67 \pm 2.20	2.41 \pm 1.79	0.153

Abbreviations indicating compartments defined in the text.

¹Data of statistical significance.

duct dilatation was positive in 2 of 43 cases in 19 of 32 cases (59.4%) alcohol group, 59.4% (19/32) of stone group (*P* = 0.000, Fisher's exact test). Abnormal dilatation of either the pancreatic or bile duct had a statistical significance in differentiating between the two groups.

Infiltration scores of each abdominal compartment are summarized in Table 2. The overall degree of peripancreatic infiltration of right abdomen (sum of scores of RP + RSR + RIR) was almost same each other (2.40 \pm 2.16) as in stone group (2.41 \pm 2.12) (*P* = 0.798, likelihood ratio test). However, in the left abdominal compartments (LP + LSR + LIR), stone group (2.41 \pm 1.79) showed a tendency of less peripancreatic infiltration than alcohol group, but not significant (3.67 \pm 2.20) (*P* = 0.153). Among the six abdominal compartments, only the peritoneal aspect of left abdomen (or LP compartment) showed a significant difference in peripancreatic change between the two groups (1.67 \pm 0.97 in alcohol group, 1.00 \pm 0.92 in stone group, *P* = 0.020, likelihood ratio test).

The representative cases of acute pancreatitis caused by biliary stone and alcohol are presented in Figures 2 and 3, respectively.

DISCUSSION

Acute pancreatitis has numerous causes and an obscure pathogenesis. The exact pathogenetic mechanism of acute pancreatitis has not been completely established especially in the field of alcohol-induced pancreatic injury. The basic pathogenesis of acute pancreatitis is pancreatic autodigestion. Premature activation of zymogens within acinar cells, escape of activated enzymes from acinar cells and pancreatic ducts start the autodigestive process. It has not been established how alcohol abuse induces premature zymogen activation and release. However, the mechanism of gallstone pancreatitis is known via animal models. A stone impacted in the ampulla of Vater raises intraductal pressure. Increased pressure makes the pancreatic duct epithelium permeable to molecules of up to 25 000 Da. Acute pancreatitis occurs when the pancreatic duct is perfused with active pancreatic enzymes, particularly when microvascular permeability is increased by the actions of histamine or prostaglandins. Thus, pancreatic zymogen activation and increased pancreatic duct permeability may

Figure 2 A 61-year old man with a clinical diagnosis of gallstone pancreatitis due to distal common bile duct stone. **A and B:** CT scans showing the peripancreatic infiltration or fluid collection predominantly in the right abdomen: score 1 infiltration in RP compartment (arrows), score 2 fluid collection in RSR compartment (open arrows). Distal common bile duct stone with bile duct dilatation also can be seen (arrowheads).

act sequentially initiating acute pancreatitis^[1,4].

Despite this background knowledge of the pathogenesis of acute pancreatitis, we cannot readily explain why alcohol-induced pancreatitis forms more peripancreatic infiltration or fluid collection than gallstone pancreatitis, especially on the anterior aspect of the left-sided abdomen. As a candidate of the possible explanation for this phenomenon, we assume that the state of intoxication as well as the pain-killing effect of alcohol may play a role in masking acute symptoms of pancreatitis and make patients delay to be hospitalized. On the contrary, biliary stone itself often causes severe pain even before the initiation of acute pancreatitis. However, we cannot explain more prominent involvement of the anterior aspect of the left-sided abdomen by alcohol-induced pancreatitis. This tendency of a more aggressive form of pancreatitis by alcohol-induced disease than stone-associated disease is supported by some previous studies^[5,6].

Most previous efforts to differentiate alcoholic and non-alcoholic pancreatitis have been based on laboratory data or clinical manifestations^[7-10], while there are few studies using imaging modality. The authors of these studies have tried at best, to visualize a stone or bile sludge in the biliary system^[11].

There was a prominent discrepancy between the rate of visible common bile duct stone on pre-contrast CT scan (15.6%) and the rate of common bile duct dilatation (59.4%) in our study. We think that this discrepancy is due to (1) a passed stone with post-inflammatory swelling of ampulla of Vater, (2) a muddy stone in the common bile duct that could not be differentiated from bile on CT scan without measurement of Hounsfield unit, or (3) pancreatic swelling because of acute pancreatitis itself.

Only 15.6% of patients with gallstone pancreatitis showed calculi impacted in the ampulla of Vater although 68.8% were positive for gallstone pancreatitis if the entire biliary tree was included. In other words, 31.2% of gall stone pancreatitis patients did not show any calculi in the biliary system on abdominal CT scans. In most of these cases, diagnosis of gallstone pancreatitis was achieved through other imaging modalities such as ultrasonography or ERCP. Still in a small number of cases, serum bilirubin tests and/or patient history were needed for their clinical diagnosis. Similar situations are not uncommon in daily practice making ancillary CT findings meaningful in the clinical determination of acute pancreatitis etiology.

Based on our analysis, we assumed that the extent

Figure 3 A 57-year old woman with score 1 infiltration in the RP and LP compartments (arrows) and score 2 fluid collections in the LP and LSR compartments (open arrows) is turned out to have a clinical diagnosis of alcoholic pancreatitis.

of the infiltration or fluid collections formed by acute pancreatitis could reflect the severity of the disease, as described by Balthazar *et al.*^[5]. Generally, infiltrations or fluid collections of acute pancreatitis tend to involve retroperitoneum rather than peritoneum because the pancreas is located in the retroperitoneal space^[12]. On this point of view, we divided the retroperitoneum into superior and inferior compartments, and we also assumed that, initially, infiltrations might extend to retroperitoneum around pancreas (or superior compartment of retroperitoneum), then simultaneously further inferiorly along the retroperitoneal space and anteriorly to peritoneal space. Therefore, it is necessary to compartmentalize retroperitoneum into superior and inferior and score each compartment independently to weight on the significance of retroperitoneal space as an initially-preferred pathway of disease spread.

Population of our study was confined to the patients who had peripancreatic pathologic findings at initial abdominal CT. Therefore, results from our study cannot be applied to all patients with acute pancreatitis, but should be restricted to the moderate or severe cases in which CT shows peripancreatic pathology. However, we have met relatively severe forms of acute pancreatitis much more frequently in daily CT practice, and these are the real cases needing differentiation of their etiologies. So, we think the results from our study could be helpful.

Pancreatic necrosis is undoubtedly a very important factor for poor prognosis of acute pancreatitis. It has

been proven that patients with necrotizing pancreatitis have much a higher mortality and complication rate than patients with simple pancreatitis^[13]. We regard a pancreatic necrosis as a mere fluid collection because we just want to know the meaning of the extent and distribution of fluid collection in differentiating major etiologies of acute pancreatitis. Whether the fluid is a necrotic pancreatic parenchyma or just a fluid remains unclear. However, we cannot agree that it is a potential limitation of our study.

Other limitations of our study are as follows, (1) Selection of patients was randomized but it was retrospective and not consecutive, possibly introducing potential selection bias; (2) The gold standard grouping of alcoholic and gallstone pancreatitis was the clinical diagnosis using medical records. Improper clinical history taking might play a role in incorrect determination of etiology of acute pancreatitis.

In conclusion, alcoholic pancreatitis tends to form more peripancreatic infiltrations or fluid collections than gallstone pancreatitis. This tendency is more prominent on the anterior (peritoneal) aspect of the left abdomen. Although clinical histories such as biliary colic or alcohol abuse and some CT findings favoring a gallstone pancreatitis usually are a major determinant of the etiology of acute pancreatitis, the degree and distribution of peripancreatic infiltration or fluid collection may have an ancillary role in differentiating the two major etiologies of acute pancreatitis especially in the case of insufficient clinical history or passed-out stone.

Abstract

AIM: To isolate putative pancreatic stem cells (PSCs) from human adult tissues of pancreas duct using serum-free, conditioned medium. The characterization of surface phenotype of these PSCs was analyzed by flow cytometry. The potential for pancreatic lineage and the capability of β -cell differentiation in these PSCs were evaluated as well.

METHODS: By using serum-free medium supplemented with essential growth factors, we attempted to isolate the putative PSCs which has been reported to express *nestin* and *pdx-1*. The Matrigel™ was employed to evaluate the differential capacity of isolated cells. Dithizone staining, insulin content/secretion measurement, and immunohistochemistry staining were used to monitor the differentiation. Fluorescence activated cell sorting (FACS) was used to detect the phenotypic markers of putative PSCs.

RESULTS: A monolayer of spindle-like cells was culti-

vated. The putative PSCs expressed *pdx-1* and *nestin*. They were also able to differentiate into insulin-, glucagon-, and somatostatin-positive cells. The spectrum of phenotypic markers in PSCs was investigated; a similarity was revealed when using human bone marrow-derived stem cells as the comparative experiment, such as CD29, CD44, CD49, CD50, CD51, CD62E, PDGFR- α , CD73 (SH2), CD81, CD105(SH3).

CONCLUSION: In this study, we successfully isolated PSCs from adult human pancreatic duct by using serum-free medium. These PSCs not only expressed *nestin* and *pdx-1* but also exhibited markers attributable to mesenchymal stem cells. Although work is needed to elucidate the role of these cells, the application of these PSCs might be therapeutic strategies for diabetes mellitus.

INTRODUCTION

Diabetes mellitus (DM)^[1], one of the global diseases, is the basis for insulin deficiency either due to the inability of insulin secreting β -cells (type I) or insulin resistance (type II) in somatic cells. In the case of type I DM treatment, islets of Langerhan transplantation has been demonstrated to restore normoglycemia^[2]. Nevertheless, prevalent application is still limited by the shortage of donor pancreas, emphasizing the importance of producing β -cells *in vitro* before their transplantation into patients. The putative pancreatic stem cells (PSCs) have been reported in endocrine, acinar, and duct cells of human^[3-5] and mouse studies^[6-8], and the capacity to differentiate pancreatic lineage cells has been demonstrated *in vitro*. However, the existence and the biological role of putative PSCs in β -cell neo-regeneration is still doubtful^[9].

Although the existence of PSCs has been reported in mice and humans, the methodological characterization of these PSCs is still ambiguous. The identification of PSC-specific biomarkers is required not only to define the PSCs operationally, but also to provide an efficient access for further purification. *Nestin*, an intermediate filament first identified in neuroepithelial stem cells, has been maintained as a marker of multi-lineage progenitor cells^[10]. In regeneration studies of pancreas, some *nestin* positive cells have been observed^[5]; *nestin* positive cells isolated from islets^[11,12], mesenchymal cells^[13], pancreatic ducts^[14] and vascular endothelial cells^[15] have been reported. In murine embryonic stem cell (mESC) studies, *nestin* positive cells could be selected and enriched by conventional medium cultivation for further neurogenesis^[16], the application in pancreas was worth contemplating^[17]. Pancreas duodenum homeobox-1 (*pdx-1*) is also essential for pancreatic development, insulin production, and glucose homeostasis. In animal models of partial pancreatectomy^[18], diabetic models of streptozotocin (STZ) treatment in mice^[19], injury and embryology studies^[20,21], the expression of *pdx-1* was detected. For the biological role of the interaction with multiple transcription factors and co-regulators, it was thought as a direct indicator of cells with pancreatic differentiation potentials^[22].

In the present study, we attempted to isolate putative PSCs from adult human pancreatic duct tissue rather than as in previous studies which used the animal model^[13] or the human fetus^[5]. Furthermore, to seek the potential biomarkers on these PSCs, the spectrum of phenotypic markers of human BMSCs was utilized and analyzed. These efforts attempt to investigate the properties of putative PSCs and demonstrate that β -cells could be induced by autogenous pancreatic tissue and possibly apply to diabetes therapy.

MATERIALS AND METHODS

Putative pancreatic stem cells (PSC) isolation

This research follows the tenets and regulations of the Declaration of Helsinki and has been reviewed by the Institutional Review Committee at Taipei Veterans General Hospital. Human pancreatic duct tissues at close proximity to the duct, originating from 4 identical donors, were dissected and digested by collagenase P (Roche Molecular Biochemicals, Mannheim, Germany) with HEPES-buffered saline for 7 h at 37°C. The digested tissue was washed two times with a HBS solution, pipetted up and down several times using a 10 mL syringe with a 22G needle, and placed into 10 cm Petri dishes with 10 mL of CMRL 1066 (5.6 mmol/L glucose, Gibco™, USA) media plus 10 mL/L Fetal bovine serum (FBS, Biological Industries, Israel). After two days incubation a sphere-like floating structure was observed. This suspended cell mass was collected by centrifugation, re-suspended using new serum-free ITSFn medium (composed: 1:1 of DMEM/F12, 0.6 g/L glucose, 25 µg/mL insulin, 100 µg/mL transferrin, 20 nmol/L progesterone, 60 µmol/L putrescine, 30 nmol/L selenium chloride, 2 mmol/L glutamine, 3 mmol/L sodium bicarbonate, 5 mmol/L HEPES buffer, 2 µg/mL heparin, 20

ng/mL human epidermal growth factor (EGF), 20 ng/mL human basic fibroblastic growth factor (b-FGF) and 20 ng/mL human hepatocyte growth factors, all growth factors were purchased from PerproTech, Israel) and placed into a new dish. The procedure was repeated twice to get rid of non-spherical masses and suspended cells, then the suspended cell mass was transferred to a 6 cm Falcon non-treated cultivation dish for plating, and cultivated using 10mL modified serum-free ITSFn medium. The medium was changed twice and sub-cultured once at a ratio of 1:5 in a week. The proliferation ability of putative PSC cells in passage 5, 10, 15, 20, 25 was examined by doubling time calculation.

Human bone marrow mesenchymal stem cell (BMMSC) isolation

Bone marrow aspirates were taken from the posterior iliac crest of normal adult donors (5 mL each; $n = 4$) and the isolation procedure followed our previous protocol^[23]. Briefly, the bone marrow was washed twice with equal volume of PBS and centrifuged at 300 g for 10 min at room temperature. All washed cells were re-suspended in PBS to 10 mL and nucleated cells were isolated with a Percoll density gradient (diluted with equal volume of 1.073 g/mL Percoll solution, then centrifuged at 900 g for 30 min). The mononuclear cells (MNCs) were then suspended in plates. Expansion medium consisted of Dulbecco's modified Eagle's medium with 1 g/L glucose (DMEM-LG, Gibco) and 10% fetal bovine serum (FBS; Gibco) supplemented with 10 ng/mL bFGF, 10 ng/mL EGF, 10 ng/mL PDGF-BB (R&D), 100 Units/mL penicillin, and 100 µg/mL streptomycin, and 2 mmol/L L-glutamine (Gibco). All of the nucleated cells were plated in 20 mL medium in a 75 cm² culture dish and incubated at 37°C with 5 mL/L CO₂. After 24-48 h, non-adherent cells were discarded, and adherent cells were thoroughly washed twice with phosphate-buffered saline (PBS). These adherent cells were then cultured through 5 passages and used in flow cytometry studies.

RT-PCR detects the expression of *nestin* and *pdx-1* in putative PSC

Trizol™ (Invitrogen, USA) reagent and GeneStrips™ (RNAure, USA) kits were employed for mRNA purification from putative PSC (passage 5). The Advantage RT-for-PCR Kit (Clontech; BD Biosciences, San Jose, CA) was used to synthesize the first strand of cDNA and 12 µL of extracted mRNA solution was utilized as the template. The experimental procedure followed the manufacturer's instructions. The sequence of primers used to detect human *nestin*, *pdx-1*, *insulin*, *glucagon* and *somatostatin* expression were as followed: *nestin*, forward: 5'-AGAGGGGAATTCCTG-GAG-3', reverse: 5'-CTGAGGACCAGGACTCTCTA-3'; *pdx-1* forward: 5'-CCTTTCCCATGGATGAAGTC-3', reverse: 5'-TGTCCTCCTCCTTTTCCAC-3'; *insulin* forward: 5'-CACACCTGGTGGAAGCTCTCT-3', reverse: 5'-GTAGAGGGAGCAGATGCTGGTA-3'; *glucagon* forward: 5'-ATCTGGACTCCAGGCGTGCC-3', reverse: 5'-AGCAATGAATTCCTTGGCAG-3'; *somatostatin* forward: 5'-TTCATCATCTACACGGC-3', reverse: 5'-GAGAG-

TAGAAGCAACCTACC-3'. Amplification was carried out with the program of 94°C for 30 s to denature, 55°C for 30 s for primer annealing and 72°C for 30 s to elongate the PCR product for 30 cycles. The reaction was done on a total volume of 25 μ L containing 0.5 μ mol/L of each primer, 200 μ mol/L dNTP, 2 units of Taq enzyme, and 5 μ L of synthesized cDNA in reaction buffer (500 mmol/L KCl, 100 mmol/L Tris-HCl, pH 8.4, 1.5 mmol/L MgCl₂ and 100 μ g/mL bovine serum albumin).

Pancreatic differentiation by basement-membrane-rich gel (Matrigel™)

The Matrigel™, a commercial preparation of murine basement membrane (BD biosciences, USA), was employed to induce pancreatic differentiation. Briefly, 1×10^4 cells of passage 10 and 20 were suspended with 1 mL medium and were placed on the top of the 6 cm plate coated with Matrigel™ (50 μ L per cm²) and were allowed to gel overnight before additional medium was added. Cell samples were taken for the following Dithizone and immunohistochemistry staining at different time points per week until the end of experimentation (4 wk).

Dithizone staining

Dithizone (DTZ, also named Diphenylthiocarbozone, Sigma, USA), which stains insulin-containing cells bright red, was used to quickly assess the presence of insulin-producing cells. The staining protocol followed was from the study by Shiroy, *et al* 2002^[24].

Immunofluorescent staining

The sphere aggregated by PSC differentiated in Matrigel™ was dug and embedded by O.C.T. (Sakura Finetechnical Co., USA) for frozen section. Sections were fixed by ice-cold acetone (50 mL/L) for 2 min at 4°C, and blocked with 5 g/L skim milk at room temperature for 2 h. The sections were then incubated in rabbit anti-glucagon (1: 500, Abcam, ab11195), rabbit anti-glucagon (1:500, Abcam, ab 930), and mouse anti-insulin (1:100, BioGenex, MU029-UC) antibodies in 5 g/L skim milk at 37°C for 2 h, washed twice by PBS, then followed with secondary antibody incubation (goat anti-mouse IgG with FITC conjugated for insulin detection, Jackson115-095-075, 1:500; goat anti-rabbit IgG with FITC conjugated for glucagon detection, Chemicon AP132F, 1:500; and goat anti-rabbit IgG- TRITC, Chemicon AP132R, 1:500). Specimens were washed in PBS three times after incubating with the secondary antibody and coverslips were applied using Fluoromount-G. The slide plating with HepG2 cells (ATCC) was used as a negative control (data not shown).

Measurement of insulin content/secretion

The differentiated cells from Matrigel™ were washed three times with PBS, and placed in 12-well dishes (Falcon, USA) with RPMI culture medium supplemented with 10 mL/L FBS and adjusted the glucose concentration up to 16 mmol/L (the RPMI contained 5 mmol/L glucose origin) then cultivated 48 h. The supernatant was collected and centrifuged to examine the insulin secretion, and kept at -80°C before use. The attached cells were treated with cold

Figure 1 Putative PSC isolated from adult pancreas. **A:** Morphology of cultivated putative PSCs; **B:** Cells aggregate when saturated. bar = 100 μ m.

acid-ethanol (0.1 N hydrochloric acid in absolute ethanol) and kept at 4°C overnight to examine insulin content by ELISA (Mercodia, Sweden). The clear supernatants were used to investigate the intracellular insulin content and the values obtained were normalized relative to the total protein content (protein assay reagent, Bio-Rad, USA). The RIN-m5F insulinoma cell line (CRL-11605, ATCC) and undifferentiated PSCs were used as controls.

Identification of cell phenotypic markers by FACS

Putative PSC of passage 10 and 20 was used for phenotypic marker identification by FACS. 1×10^5 cells were resuspended in 100 μ L PBS and incubated with primary antibodies at 4°C for 1 h with 1:100 dilutions. After washing twice with PBS, labeled cells were resuspended in 100 μ L PBS with 1 μ L goat anti-mouse IgG conjugated with FITC (Chemicon, AP124F) at 4°C for 1 h, then examined by flow cytometry (BD, USA). The information of antibodies used in investigation was listed in Table 1.

RESULTS

Putative stem cells with nestin expression isolated from adult human pancreas

Putative PSCs with the property of sphere-like cell mass formation were cultivated by a series protocol of isolation and the divergent adhesion to bacteria Petri dishes. Cells with spindle-like shape were observed after plating and served with DMEM/F12 ITSFn serum free medium. The morphological homogeneity of putative PSC was demonstrated (Figure 1A). While the density of culture cells increased, the sphere-like cell aggregation was shown (Figure 1B). The expression of *nestin* and *pdx-1* were detected by RT-PCR, with sustained expression of both genes detected through 20 passages completing this study (RT-PCR examined, Figure 2). The protein level of nestin and *pdx-1* was also examined by immunofluorescent staining (IF) revealing low protein intensity (data not shown). The experimental consistency was illustrated in the repeated examination of tissues from four individual donors.

The pancreatic differentiation potential of putative PSC

The differential competence of putative PSC was inspected by the growth in Matrigel™. The aggregation ability of the isolated PSCs (passage 10) was observed at d 3 after cell seeding (Figure 3A). Color formation was shown when stained with Dithizone at 4-wk after cell seeding, suggest-

Figure 2 Nestin and pdx-1 expressed in putative PSCs after 5 passages of cultivation. cDNA oriented from 4 individual donors (lane No. 1 to 4), 100 bp marker (M) and the plasmid cloned human nestin and pdx-1 gene with positive control (C) were shown.

ing that cells went through β -cell differentiation in MatrigelTM (Figure 3B).

The expression of *insulin*, *glucagon* and *somatostatin* via RNA level was detectable in the putative PSCs (passage 10) growth in MatrigelTM, comparatively; expression was barely illustrated in the group of cells without MatrigelTM (data not shown). Furthermore, the spheroid body of aggregated PSCs showed positive immune reactivity in IF staining (Figures 3 C-E). A similar result was observed in the examination of PSCs after 20 passages, suggesting the differentiation capacity of cells of pancreatic lineage could be preserved.

Measurement of insulin content in differentiated cells

The intracellular insulin content in the differentiating puta-

tive PSCs (the samples collected from individual donors were pooled together for measurement) were measured at

Figure 4 Measurement of Insulin content and secretion in differentiated putative PSCs.

Figure 5 Cell doubling time of putative PSC.

4-wk after cell seeding on Matrigel™ (Figure 4). Compared to the undifferentiated putative PSCs, differentiated PSCs collected at passage 10 and 20 demonstrated the obvious increase in intracellular insulin content/secretion when normalized to the total protein content ($P > 0.01$).

Comparative phenotypic markers spectrum between putative PSC and BMMSC was detected by flow cytometry

To further investigate the potential phenotypic markers in PSCs, the biomarkers that are commonly examined in bone marrow-derived cells were used as the candidates for selection, and the human BMSC was employed as a comparative study (Table 1). The similar patterns of CD29, CD44, CD51, CD81, SH2 and SH3 were illustrated from both cells. Comparatively, differential intensity was demonstrated on the markers CD38, CD49b, Cd49d, CD50, CD58, CD62E and CDGFR-alpha; the stronger intensity was shown in putative PSCs. The markers of CD62P were revealed only in some PSC but not in BMMSC. No significant difference was shown between the putative PSC batches collected from 4 individual donors,

moreover, the consistency was demonstrated in the studies of putative PSCs of passages 10 and 20.

Cell viability was monitored in long-period cultivation

A simplified cell proliferation method was used to monitor cell viability. The doubling time of 5, 10, 15, 20, 25 passages was illustrated in Figure 5. The cells proliferated rapidly at the beginning (32 h, approximately), however, a remarkable decrease was observed after 20 passages, and failure to proliferate occurred at approximately 30 passages.

DISCUSSION

The existence of putative PSC in pancreatic duct tissue of adult humans was illustrated in the present study. By using serum free medium with essential growth factors, cells with sphere-like mass aggregation were isolated. The putative PSC expressed both *nestin* and *pdx-1*, and these cells were able to differentiate into pancreatic lineage cells that express *insulin*, *glucagon* and *somatostatin* by Matrigel™. The potential biomarkers were evaluated by FACS, and the antibodies that identify common biomarkers of human bone marrow were used. As a comparative study of human BMSCs, the biomarkers of CD29, CD44, CD51, CD81, SH2 and SH3 (mesenchymal stem cell markers) were all detected on the surface of both cells and higher intensity in PSCs was illustrated in the markers of CD38, CD49b, Cd49d, CD50, CD58, CD62E and CDGFR-alpha. We also found that the expression of CD34, AC 133 (hematopoietic stem cell markers) and CD45 (endothelial marker) were not detected in either PSCs or BMSCs. The consistency of phenotypic patterns was demonstrated between individual (original cells from 4 identical donors) and the passages (to 20 passages).

Bone marrow (BM)-derived stem cells can be aspirated directly from donors. They can be cultured for *ex vivo* expansion. Previous studies demonstrated the pluripotency of these stem cells. They were able to differentiate into ectodermal^[25,26], endodermal^[26,27], mesodermal^[27], hepatic^[28], cardiac muscle^[29] and skeletal muscle^[30] progenitor cells. By using negative selection, a cell subpopulation isolated from bone marrow, muscle and brain cells have been shown to be able to differentiate into all three germ layers^[31]. This type of mesenchymal stem cells, termed multipotent adult progenitor cells (MAPCs), have the remarkable potential to differentiate not only into mesenchymal cells, but also into cells with visceral mesoderm, neuroectoderm, and endodermal features at the single cell level. Recently, Zhang, *et al.*^[32] demonstrated that the *nestin*-positive progenitor cells isolated from human fetal pancreas, and these cells also have the phenotype markers identical to mesenchymal stem cells (MSCs). In agreement with these results, our results supported these findings and further isolation of *nestin*- and *pdx-1*-positive adult human pancreatic stem cells, which co-expressed the identical MSC markers. These interesting findings also provide evidence to support the interpretation of the study by Ianus *et al.*^[33], that bone marrow derived cells have the capacity to be competently pancreatic islet beta cells. Moreover, the differential capacities and properties of MSCs from different organs are

worth additional attention and may be investigated in a subsequent study.

Nestin is a well-discussed marker of the pancreatic stem cells in embryology, *in vitro* cultivation and pancreatotomy-regeneration in animal models^[1,11,15,32]. However, a contradictory study provided evidence that *nestin*-lineage cells contribute to the microvasculature of pancreas but not endocrine cells of the islet^[1]. The elegant experiment performed by Suzuki *et al*^[3], had clearly demonstrated that the *nestin*-positive cells were isolated from the aggregated insulin-producing precursor and endothelium cells of pancreas by FACS assay^[3]. This result provided a reasonable explanation that the *nestin* antigen is expressed in a much broader precursor population of pancreas, including differentiated cells. The *pdx-1*, compared to the *nestin*, is more specific for pancreatic differentiation^[18-20]. In the present study, the strategy that both the *nestin*- and *pdx-1*- positive cells enriched by serum-free medium was employed followed the previous study of neuronal lineage stem cells isolated from murine embryonic stem cells^[9,16]. Our data supported the claim that the *nestin*- and *pdx-1* expressed stem cells can be isolated from adult pancreatic ducts and possess the differentiation potential of the pancreatic lineage. Moreover, we found that the sustained expression of *nestin* and *pdx-1* in PSCs further exhibited and correlated to the stem cell characteristics of the insulin-producing ability, stable passage and long-term maintenance *in vitro*. Thus, *nestin* and *pdx-1* could not only be the markers of pancreatic stem cells but also play an important role in the self-renewal of beta progenitor cells.

In summary, we use the serum-free method and successfully isolate pancreatic stem cells from adult human pancreatic duct. These PSCs not only expressed the *nestin* and *pdx-1* but also exhibited the markers of mesenchymal stem cells. PSCs and the usage of serum free medium may avoid the potential immune problem of xenogenic protein contamination. Furthermore, this approach should overcome the ethical and immunologic concerns associated with the use of fetal tissues and embryonic stem cells. Although more work is needed to elucidate the role of these PSCs, the application of these PSCs can further be extended and used as an alternative source for therapeutic strategies of diabetes mellitus.

no GSD at the first screening, 10 had developed GSD by 2002. The incidence was 3.56% per year (95% CI: 1.78% per year-6.24% per year). Using a Cox regression model, age (RR = 1.07, 95% CI: 1.00-1.14), waist circumference (RR = 1.12, 95% CI: 1.01-1.29), and ALT (RR = 1.13, 95%CI: 1.01-1.26) appeared to be significantly correlated with development of GSD.

CONCLUSION: Older age is a known risk factor for the development of GSD. Our study shows that greater waist circumference and elevated ALT levels are also associated with the development of GSD among type 2 diabetics in Kinmen.

Abstract

AIM: To assess the incidence of and risk factors for gallstone disease (GSD) among type 2 diabetics in Kinmen, Taiwan.

METHODS: A screening program for GSD was performed by two specialists who employed real-time abdominal ultrasound to examine the abdominal region after patients had fasted for at least eight hours. Screening, which was conducted in 2001, involved 848 patients diagnosed with type 2 diabetes. After exclusion of 63 subjects with prevalent GSD, 377 participants without GSD were invited in 2002 for a second round of screening. A total of 281 (74.5%) subjects were re-examined.

RESULTS: Among the 281 type 2 diabetics who had

INTRODUCTION

Gallstone disease (GSD), a digestive disorder with multifactorial origins, is very common worldwide. Within the past few years ultrasonographic studies have provided estimates of GSD prevalence and of predisposing factors in various populations^[1-5]. Although some controversy exists regarding the association between diabetes and GSD, population-based epidemiologic studies have demonstrated that diabetic subjects have an increased morbidity of GSD^[6-8]. Moreover, our previous report showed that the prevalence of overall GSD among type 2 diabetics is higher than in other general Chinese populations when using the same methods for GSD assessment^[5].

Previous study had explored the prevalence of GSD and associated factor among type 2 diabetics^[5], and cross-sectional studies provided useful information of disease prevalence, however, they did not present the incidence or new cases in the study population. One must re-examine the population after a period of time in order to determine incidence and causal relationships between risk factors and

disease. From a preventive medicine viewpoint, primary prevention of GSD should focus on risk factors responsible for the occurrence of GSD. To explore the incidence of and risk factors for GSD is essential to prevent its development and the cholecystectomy caused by this complication, which is often insidious in nature. Therefore, it is necessary to conduct a population-based study which estimates GSD incidence. This is in part due to the fact that more than half of subjects with GSD are unaware of their condition and diagnosed cases seem to represent a selected group based on clinical studies^[8]. Recently, however, a few population-based prospective studies have described the incidence and temporal relationship between the development of GSD and various risk factors among type 2 diabetics in Taiwan. The present study was conducted to explore the incidence and risk factors of GSD among type 2 diabetics in Kinmen, Taiwan based on a one-year follow-up period using real time abdominal ultrasound.

MATERIALS AND METHODS

Organization of gallstone disease screening for type 2 diabetics

Figure 1 shows the procedures for GSD screening between 2001 and 2002. Data used in this study were derived from a population-based screening for type 2 diabetes targeted to subjects aged 30 years or more in Kinmen, Taiwan, between January 1991 and December 1993. The details of the study design and execution have been described in full elsewhere^[9]. The identification of type 2 diabetes was based on the WHO definition in 1985^[10], namely, subjects with a fasting plasma glucose (FPG) ≥ 140 mg/dL or a 2 h postload glucose ≥ 200 mg/dL. Subjects with a history of type 2 diabetes and who had received medication were defined as known cases. However, in the GSD screening done in 2001, even patients who fulfilled the criteria of the revised WHO 1999 were enrolled. That is, additional patients with FPG ≥ 126 mg/dL and <140 mg/dL in 1991 to 1993 were also recruited^[11]. A total of 1123 type 2 diabetics aged 30 and over were identified based on face-to-face interviews carried out by the Yang-Ming Crusade, a volunteer organization of well-trained medical students of National Yang-Ming University. After exclusion of those who migrated or died, the remaining 858 type 2 diabetics formed a cohort to receive first round abdominal ultrasound in 2001. A total of 440 (51.3%) subjects were examined in first screening for GSD. Sixty-three out of 440 type 2 diabetics were diagnosed with GSD. The overall prevalence of GSD was 14.4%, including single stone 8.0% ($n = 35$), multiple stones 3.2% ($n = 14$), and cholecystectomy 3.2% ($n = 14$)^[5]. The 377 diabetics without GSD screened in 2001 were then invited by telephone calls or invitation letters in 2002 to receive a second round of abdominal examinations. Informed consent was obtained from all participants before the GSD screening^[5].

Data collection and diagnosis of gallstone disease

In the present study, fasting blood samples were drawn by public health nurses. Overnight fasting serum and plasma samples (preserved with EDTA and NaF) were collected and kept frozen (-20°C) until analysis for measurements

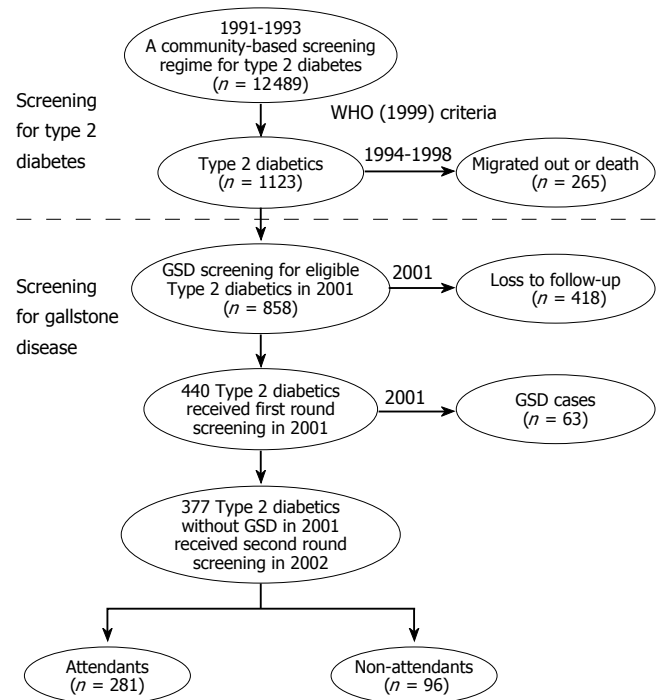

Figure 1 The procedure of screening for gallstone disease among type 2 diabetics during 2001-2002 in Kinmen.

of biochemistry markers. FPG concentrations were determined using the hexokinase-glucose-6-phosphate dehydrogenase method with a glucose (HK) reagent ldt (Gillford, Cberlin, OH). The BMI, waist circumference, uric acid, and HbA_{1c} data were also collected during the GSD screening in 2001. The duration of type 2 diabetes in patients who were previously diagnosed with the disease was confirmed by the questionnaire. In addition, the screening protocol for GSD was performed in 2001 and 2002. GSD was diagnosed by two specialists using real-time abdominal ultrasound to examine the abdominal region after participants had fasted for at least 8 h. GSD was identified based on the presence of “movable hyperechoic material with acoustic shadow. Cases of GSD were classified as follows: single gallbladder stone, multiple gallbladder stones, and cholecystectomy, excluding gallbladder polyps. Cases were identified as any type of GSD among type 2 diabetics.

Inter-observer reliability in ultrasound sonography

In order to set up a consistent diagnosis of GSD among two specialists, the Kappa statistic was used to assess inter-observer reliability among study specialists. A pilot study was performed with a randomly selected cohort ($n = 50$) of type 2 diabetics other than the study subjects. Our pilot study on inter-observer reliability showed a Kappa value for diagnosis of GSD of 0.77 (95%CI: 0.50-0.96).

Statistical analysis

Statistical analysis was performed using SAS software. The incidence of GSD was determined per year based on the ratio of the observed number of cases to the total number of patient-years at risk. Ninety-five percent confidence intervals (95% CI) for incidence were calculated using the Poisson distribution. In the univariate analysis, a *t*-test was

Table 1 Attendance rate of gallstone disease screening among type 2 diabetics in Kinmen

Variable	Eligible population	Screened population	Attendance rate
	<i>n</i>	<i>n</i>	(%)
Sex			
Male	167	121	72.5
Female	210	160	76.2
Age (yr)			
40-49	43	33	76.7
50-59	87	56	64.4
60-69	134	111	82.8
70+	113	81	71.7
Total	377	281	74.5

Table 2 Sex- and age-specific incidence of gallstone disease among type 2 diabetics in Kinmen

Variable	Incidence of any gallstone disease		
	No. of no GSD at first screening	New cases	Incidence density (% per year) (95%CI)
Sex			
Male	121	2	1.65 (0.03-5.10)
Female	160	8	5 (2.29-9.31)
<i>P</i> -value			0.12
Age (yr)			
40-49	33	0	0 (-)
50-59	56	2	3.57 (0.06-11.03)
60-69	111	4	3.6 (1.12-8.37)
70+	81	4	4.94 (1.53-11.47)
<i>P</i> -value			0.04
Total	281	10	3.56 (1.78-6.24)

applied for continuous variables. Multiple Cox regression was used to investigate the independence of factors associated with development of GSD. $P < 0.05$ was considered statistically significant. The results are presented as mean \pm SD.

RESULTS

Of 377 type 2 diabetics without GSD in 2001, 281 subjects attended the second round of abdominal ultrasound examinations in 2002. The overall attendance rate was thus about 74.5%. Subjects were considered as censored cases if the outcomes were not available. Table 1 shows that females had higher attendance rates than males (76.2% versus 72.5%), and old people (50-59 and over 70 year of age) had a slightly lower attendance rate than other age groups.

Table 2 presents gender-specific and age-specific one-year incidences of GSD. Overall incidence of GSD was 3.56% per year (95%CI: 1.78% per year-6.24% per year).

Table 3 Univariate analysis of risk factors for the development of gallstone disease among type 2 diabetics in Kinmen

Variables	Development of gallstone disease			Definitions of disease condition
	Yes	No	<i>P</i> value	
	Mean \pm SD	Mean \pm SD	for <i>t</i> test	
Age (yr)	69.90 \pm 8.79	63.11 \pm 10.72	0.04	-
Duration of diabetes (yr)	9.60 \pm 0.84	9.44 \pm 1.59	0.59	-
Fasting plasma glucose (mg/dL)	148.50 \pm 18.45	144.94 \pm 39.35	0.58	≥ 126 mg/dL
HbA1c (%)	8.19 \pm 0.93	8.33 \pm 2.05	0.69	$\geq 7\%$
Systolic blood pressure (mmHg)	152.49 \pm 13.91	145.08 \pm 16.35	0.16	≥ 140 mmHg
Diastolic blood pressure (mmHg)	89.55 \pm 9.40	86.74 \pm 9.52	0.36	≥ 90 mmHg
Body mass index (Kg/m ²)	26.57 \pm 1.07	25.36 \pm 2.87	0.01	≥ 27 kg/m ²
Waist circumference (cm)	89.74 \pm 7.95	85.23 \pm 7.52	0.000	≥ 90 cm for males or ≥ 80 cm for females
Total cholesterol (mg/dL)	220.09 \pm 20.57	210.99 \pm 26.82	0.000	≥ 200 mg/dL
Triglyceride (mg/dL)	178.50 \pm 38.95	144.28 \pm 66.72	0.11	≥ 200 mg/dL
AST (U/L)	25.40 \pm 6.95	22.40 \pm 8.15	0.01	≥ 40 U/L
ALT (U/L)	31.36 \pm 9.34	22.39 \pm 10.28	0.01	≥ 40 U/L
Uric acid (mg/dL)	6.07 \pm 1.20	5.94 \pm 1.29	0.76	≥ 7 mg/dL for males or ≥ 6 mg/dL for females

This incidence shows a clear trend with age ($P = 0.04$) with values increasing monotonically: from 0% per year at age 40-49 years to 3.57% per year at age 50-59 years, 3.60% per year at age 60-69 years to 4.94% per year at older ages. There was no consistent pattern by age group. Females had a slightly higher incidence (5.00% per year versus 1.65% per year, $P = 0.12$) than males, although the gender difference was not statistically significant.

Table 3 shows the risk factors for the development of GSD in type 2 diabetics by univariate analysis. The risk factors that were significantly related to the development of GSD included age (t , $T = 1.98$, $P = 0.04$), BMI ($T = 3.18$, $P = 0.01$), waist circumference ($T = 8.16$, $P = 0.0001$), total cholesterol ($T = 4.94$, $P = 0.0001$), AST ($T = 2.83$, $P = 0.01$), and ALT ($T = 2.69$, $P = 0.01$).

To assess the independence of the contributions of these factors to the development of GSD, the significant variables from univariate analysis for GSD were further examined using a Cox regression model including age, BMI, waist circumference, total cholesterol, AST, and ALT. As Table 4 shows, age (RR = 1.07, 95%CI: 1.00-1.14), waist circumference (RR = 1.12, 95%CI: 1.01-1.29), and ALT (RR = 1.13, 95%CI: 1.01-1.26) appeared to be independently correlated with development of GSD.

DISCUSSION

Incidence and risk factors for the development of gallstone disease

Abdominal ultrasound for GSD screening is viewed as a robust method. Previous clinical studies have shown reliable positive (0.99-1.00) and negative (0.90-0.96) predictive

Table 4 Cox regression model of risk factors associated with the development of gallstone disease among type 2 diabetics in Kinmen

Variables	Development of gallstone disease (yes vs no)	
	Relative risk	(95% CI)
Sex (female vs male)	2.60	0.52-13.11
Age (yr)	1.07	1.00-1.14
Body mass index (Kg/m ²)	1.03	0.57-1.34
Waist circumference (cm)	1.12	1.01-1.29
Total cholesterol (mg/dL)	1.01	0.98-1.03
AST (U/L)	0.91	0.77-1.07
ALT (U/L)	1.13	1.01-1.26

values of ultrasonographic diagnosis^[12]. In the present study, the annual incidence of overall GSD was higher than that in other general population-based studies^[12-15], implying that type 2 diabetes might be a positive risk factor for GSD development. Possible pathogenic reasons are that type 2 diabetes combined with GSD might induce acute cholecystitis more often and have a higher probability of progression to septicemia than does gallbladder dysfunction in non-diabetic patients^[16], and late-onset diabetic patients have a higher lithogenic bile index than non-diabetics after adjustment for sex and age^[17]. In addition, hyperglycemia in diabetic subjects might exert effects on gallbladder motility^[18].

An association between GSD and use of exogenous estrogens was confirmed^[19]. The lithogenic effects of estrogen are mediated in part by an increase in bile cholesterol saturation^[19]. However, previous studies showed that cholesterol GSD is common in Western populations whereas pigment GSD is major components in Taiwan^[1]. Unlike result for cholesterol GSD, our results did not show a causal relationship between female sex and development of pigment GSD. The different findings for Orientals from those shown for Occidentals suggest that cholesterol GSD has not yet become a major GSD component in Taiwanese diabetic populations.

Using both univariate analysis and a multiple Cox regression model, our study also demonstrated that age is a significant risk factor for the development of GSD. This result is not concordant with results from other studies that had longer screening intervals^[8,13,15]. Larger amounts of cholesterol secreted by the liver and decreases in the catabolism of cholesterol to bile acid were observed in the elderly^[20]. Although the long-term exposure to many other risk factors in the elderly might account for their increased chance of developing GSD^[5], age still remained a major factor leading to GSD development, irrespective of locality, standard of living, or after adjustment for other demographic and clinical characteristics in the multivariate analysis.

Several population-based studies demonstrated that liver cirrhosis represents a strong risk factor for GSD^[21,22]. The annual incidence of GSD in patients with cirrhosis appears to be about eight times higher than in the general

population^[21]. Alanine aminotransferase (ALT) has, for some time, been viewed as a sensitive indicator of liver-cell injury^[23]. Currently, the determination of serum ALT levels constitutes the most-frequently applied test for the identification of patients suffering from liver disease. This parameter also acts as a surrogate marker for disease severity and/or as an index of hepatic activity^[24]. Our results showing that elevated ALT levels constitute higher risk of GSD development suggest that appropriate integrated diagnosis and therapy in the early stage of liver dysfunction might eventually enable us to prevent incident GSD. Instead of being a sign of more serious liver disease like liver cirrhosis, further studies should be conducted to explore the possibility of whether elevated ALT levels is an indicator for GSD because it indicates a fatty liver (and thus a high BMI), and early stage of chronic liver disease.

Obesity could raise the saturation of bile by increasing biliary secretion of cholesterol, the latter probably depending on a higher synthesis of cholesterol in obese subjects^[25]. Being overweight at baseline was strongly associated with the incidence of GSD which was also suggested in epidemiologic studies^[13]. In this follow-up study, we found that a higher waist circumference rather than a higher BMI was significantly and positively associated with GSD development. Thus abdominal obesity might be more important than BMI for identifying diabetics at high risk of GSD. One possible reason is that due to a high correlation between BMI and waist circumference ($r = 0.64$), waist circumference might explain the effect of BMI on GSD development in type 2 diabetic subjects. Another possible reason is that a large waist circumference might be an unambiguous indicator of excess body fat, except in the presence of abdominal tumors or ascites, and might be a better estimate of overall body fat than is BMI. In addition, from the biological perspective, BMI becomes primarily a surrogate of lean body mass when BMI and height-adjusted waist circumference are included in the same model, because the variation in BMI attributable to adiposity is essentially controlled by the height-adjusted waist circumference variable^[14]. Nevertheless, further epidemiological and etiologic investigations are needed to explore the pathophysiological mechanism underlying gender-related differences in waist circumference and GSD among diabetics.

Methodological considerations

Although using a follow-up study design can clarify the temporal relationship of potential risk factors and the development of GSD, there are some limitations in the present study. First, the characteristics pertinent to the risk of type 2 diabetes for study subjects were not significantly different from non-respondents (except for age), indicating that subjects who did not return for follow-up might have more severe GSD. Also, we assumed that all the new GSD cases occurred in 2002. Since additional GSD cases could occur in subsequent years, the incidence of GSD may be underestimated. Second, all the patients had diabetes in the study population, therefore, an evaluation of the extent of GSD incidence in subjects without diabetes was difficult. Third, we did not attempt to estimate the incidence

of gallstone formation but rather the incidence of newly screened GSD. Our analysis only focused on clinically relevant GSD. Fourth, due to a shorter follow-up period, we did not have a large enough sample size to estimate the “true” effects between potential risk factors and the incidence of GSD. Further long-term studies should be conducted to explore the morbidity of GSD and plausible biological mechanisms underlying its development.

In conclusion, our reports show that the incidence of GSD is 3.56% per year. Significant risk factors for the development of GSD include not only older age, but also, higher waist circumference and elevated ALT levels among type 2 diabetics.

Abstract

AIM: To evaluate the levels of serum carnitine in patients with cancer in digestive organs and to compare them with other cancers in order to provide new insights into the mechanisms of cachexia.

METHODS: Fifty-five cachectic patients with or without gastrointestinal cancer were enrolled in the present study. They underwent routine laboratory investigations, including examination of the levels of various forms of carnitine present in serum (i.e., long-chain acylcarnitine, short-chain acylcarnitine, free carnitine, and total carnitine). These values were compared with those found in 60 cancer patients in good nutritional status as well as with those of 30 healthy control subjects.

RESULTS: When the cachectic patients with gastrointestinal cancer were compared with the cachectic patients without gastrointestinal cancer, the difference was $-6.8 \mu\text{mol/L}$ in free carnitine ($P < 0.005$), $0.04 \mu\text{mol/L}$ in long chain acylcarnitine ($P < 0.05$), $8.7 \mu\text{mol/L}$ in total carnitine ($P < 0.001$). In the cachectic patients with or without gastrointestinal cancer, the difference was $12.2 \mu\text{mol/L}$ in free carnitine ($P < 0.001$), $4.60 \mu\text{mol/L}$ in short chain acylcarnitine ($P < 0.001$), and $0.60 \mu\text{mol/L}$ in long-chain acylcarnitine ($P < 0.005$) and $17.4 \mu\text{mol/L}$ in total carnitine ($P < 0.001$). In the cachectic patients with gastrointestinal cancer and the healthy control subjects, the difference was $15.5 \mu\text{mol/L}$ in free carnitine ($P < 0.001$), $5.2 \mu\text{mol/L}$ in short-chain acylcarnitine ($P < 0.001$), $1.0 \mu\text{mol/L}$ in long chain acylcarnitine ($P < 0.001$), and $21.8 \mu\text{mol/L}$ in total carnitine ($P < 0.001$).

CONCLUSION: Low serum levels of carnitine in terminal neoplastic patients are decreased greatly due to the decreased dietary intake and impaired endogenous

synthesis of this substance. These low serum carnitine levels also contribute to the progression of cachexia in cancer patients.

INTRODUCTION

Cancer cachexia is a condition characterized by anorexia, chronic nausea, early satiety, muscle wasting, involuntary weight loss, lipolysis, weakness, fatigue, impaired mental and physical performance, decreased capacity of wound healing, impaired immunological function, and compromised quality of life. Cancer cachexia is associated with poor survival and decreased tolerance to both radiotherapy and chemotherapy^[1].

The prevalence of cachexia is about 60% in terminal cancer patients^[2]. Anorexia and nausea exacerbate the detrimental effects of tumor-related changes in protein metabolism on nutritional status, leading to increased morbidity and mortality^[3].

The mechanisms responsible for cachexia in cancer patients are poorly understood. One of the factors contributing to weight loss is the reduced food intake, which may be caused by a decrease in appetite or a tumor treatment^[4], mechanical obstruction of the gastrointestinal (GI) tract or intestinal malabsorption.

A decrease in food intake, combined with a decrease in physical exercise, leads to a decline in muscle mass and power.

Several studies have suggested that metabolic control of food intake also exists, in which the biochemical partitioning between fatty acid oxidation and synthesis is a vital signal indicating catabolic or anabolic energy status^[5]. Changes in energy metabolism influence energy intake via energy signals.

Energy signals are independent from body mass, but they inform the brain on the metabolic switch occurring subcellularly between fatty acid oxidation and synthesis^[6]. The combination of reduced energy intake and increased energy expenditure in cancer patients results in substantial weight loss. It has been shown that weight loss in cancer patients comprises both muscle mass and fat mass.

When there is a cancer, several metabolic changes are present in the whole body. It could be possible that one of these factors is represented by a decrease of endogenous synthesis of carnitine or by a reduction of exogenous assumption of carnitine.

Carnitine is a naturally occurring substance required for energy metabolism. In omnivores approximately 75% of carnitine sources come from diet and 25% from endogenous synthesis^[7]. Under normal conditions, omnivores absorb about 70%-80% of dietary carnitine^[8].

Human skeletal muscle, heart, liver, kidney and brain are capable of biosynthesizing carnitine from motioning and lysine to its immediate precursor gamma butyrobetaine^[9].

Carnitine is essential for the transport of long chain fatty acids across the mitochondrial membrane for fatty degradation and energy production and has the ability to shuttle short chain fatty acids from inside the mitochondria to the cytosol.

In a previous study^[10], we observed low serum levels of carnitine in patients with tumoral cachexia, which may be due to a decreased availability of carnitine in the diet or to the altered endogenous biosynthesis.

The aim of the present study was to evaluate the levels of serum carnitine in patients with cancer in digestive organs and to compare them with other cancers in order to provide new insights into the mechanisms of cachexia.

MATERIALS AND METHODS

Fifty-five patients eligible for this study had advanced malignancies localized in various parts of the body. The patients were in the terminal phase of their disease and only palliation was requested. All of them showed a weight loss above 5% in the 6 mo prior to enrollment in the study. Thirty cachectic patients with gastrointestinal cancer (16 males and 14 females, mean age 47.4 ± 7.6 years) had the following diagnoses: cancer of the stomach in 6, cancer of the small bowel in 6, cancer of the colon in 10, cancer of the rectum in 8. Twenty cachectic patients without gastrointestinal cancer (13 males and 12 females, mean age 49.1 ± 6.4 years) had the following diagnoses: lung cancer in 5, renal cell carcinoma in 5, malignant melanoma in 5, bladder cancer in 5, prostate cancer in 2, and breast cancer in 3. Forty of them underwent surgical intervention, while 31 received one or more chemotherapeutic treatments and 6 received radiotherapy. We also enrolled two groups of control subjects.

Sixty cancer patients were in good nutritional status (25 males and 35 females, mean age 48.6 ± 8.4 years). Their diagnoses were as follows: colorectal carcinoma in 10, lung cancer in 15, breast cancer in 10, gastric cancer in 3, bladder cancer in 7, renal cell carcinoma in 4, prostate cancer in 10, and testicular cancer in 1.

Table 1 Characteristics of the study population (mean \pm SD)

Parameter	Cachectic patients with gastrointestinal cancer (30)	Cachectic patients without gastrointestinal cancer (25)	Non cachectic patients with cancer (60)	Healthy subjects (30)
Sex M/F	16/14	13/12	25/35	15/15
Mean age (yr)	47.4 ± 7.6	49.1 ± 6.4	48.6 ± 8.4	51.3 ± 5.2
Height (cm)	158.9 ± 6.8	160.6 ± 7.1	159.4 ± 7.8	160.2 ± 6.4
Weight (kg)	46.8 ± 7.6	51.4 ± 6.9	60.2 ± 7.4	63.8 ± 11.3
SAP (mmHg)	151.8 ± 12.4	156 ± 13.2	152.4 ± 14.7	150.3 ± 16.8
DAP (mmHg)	84.2 ± 8.7	86.4 ± 7.1	80.1 ± 9.7	80.2 ± 10.6
Heart Rate bpm	94.2 ± 9.8	86.2 ± 11.1	84.2 ± 7.1	81.2 ± 10.2

A second control group consisted of 30 healthy individuals aged 51.3 ± 5.2 years. The patient group ($n = 4$) was examined in the morning between 8:00 a.m. and 10:00 a.m. after an overnight fast. Then, venous blood samples were taken and stored in tubes containing ethylenediamine tetra acetic acid (EDTA) or heparin (Table 1).

Serum or plasma was obtained by centrifugation. Serum was analyzed immediately, while plasma and urine were stored at -20°C before analysis. Serum carnitine levels were determined using the Cederblad and Lindstedt method modified by Brass and Hoppel^[7]. Plasma was treated with perchloric acid (final concentration 3% vol: vol) and centrifuged for 2 min at 10 000 r/min. Long-chain acylcarnitine was extracted from the pellet after alkaline hydrolysis, while free and short-chain acylcarnitines were extracted from the supernatant. The sum of short-chain acylcarnitine, free carnitine, and long-chain acylcarnitine was considered the serum of total carnitine level.

Creatinine concentrations were determined using a kinetic colorimetric reaction in the same samples used to measure the carnitine concentrations. All laboratory tests were performed using standard laboratory procedures.

All subjects followed a daily diet consisting of 1800 kcal/d with a content of total cholesterol < 300 mg/d, 50% carbohydrates, 20% proteins, and 30% fats (of which 10% were saturated fatty acids, 10% unsaturated fatty acids, and 10% polyunsaturated fatty acids).

Statistical analysis

The results are presented as mean \pm SD. The following two-tailed tests at $P < 0.05$ were used in the study: the Mann-Whitney U-test in the case of two independent samples and the Spearman's rank correlation coefficient test for univariate relationships between variables. In order to evaluate the independent effects of covariates on carnitine concentration, a stepwise multiple linear regression analysis was performed.

Data were analyzed using the statistical package SPSS for Windows 7.5 (SPSS Inc., Chicago, IL, USA).

RESULTS

Comparison of baseline characteristics

The four groups of subjects were comparable in age, height, systolic and diastolic pressure. The difference in weight was 4.50 kg ($P < 0.05$) between cachectic

patients with gastrointestinal cancer and cachectic patients without gastrointestinal cancer, 13.40 kg ($P < 0.001$) between cachectic patients with gastrointestinal cancer and neoplastic non-cachectic patients, and 17.0 kg between cachectic patients with gastrointestinal cancer and healthy subjects ($P < 0.001$). The difference in weight was 8.80 kg ($P < 0.001$) between cachectic patients without gastrointestinal cancer and non-cachectic patients, and 12.40 kg ($P < 0.001$) between cachectic patients without gastrointestinal cancer and healthy subjects.

Comparison of laboratory parameters

When the cachectic patients with gastro-intestinal cancer were compared to the cachectic patients without gastrointestinal cancer, the difference was 12.5 mg/dL in triglycerides ($P < 0.001$), 26.7 IU/L in ALP ($P < 0.001$) and 802.6 ng/mL in CEA ($P < 0.001$).

The difference was 6.8 $\mu\text{mol/L}$ in free carnitine ($P < 0.005$), 0.04 $\mu\text{mol/L}$ in long chain acylcarnitine ($P < 0.05$), 8.7 $\mu\text{mol/L}$ in total carnitine ($P < 0.001$).

When the cachectic patients with gastrointestinal cancer were compared to non cachectic patients with cancer, the difference was 5.8 mg/dL in bun ($P < 0.001$), 7.00 mg/dL in glucose ($P < 0.001$), 34.1 mg/dL in total cholesterol ($P < 0.001$), 31.3 mg/dL in triglycerides ($P < 0.001$), 8.60 IU/L in AST ($P < 0.001$), 45.8 IU/L in ALP ($P < 0.001$) and 815.6 ng/mL in CEA ($P < 0.001$). The difference was 12.2 $\mu\text{mol/L}$ in free carnitine ($P < 0.001$), 4.60 $\mu\text{mol/L}$ in short-chain acylcarnitine ($P < 0.001$), and 0.60 $\mu\text{mol/L}$ in long-chain acylcarnitine ($P < 0.005$) and 17.4 $\mu\text{mol/L}$ in total carnitine ($P < 0.001$).

When the cachectic patients with gastrointestinal cancer were compared to the healthy control subjects, the difference was 27.60 mg/dL in total cholesterol ($P < 0.001$), 25.8 mg/dL in triglycerides ($P < 0.001$), 13.0 IU/L in ALT ($P < 0.001$), 15.60 IU/L in AST ($P < 0.001$), and 76.8 IU/L in ALP ($P < 0.001$) and 845.1 ng/mL in CEA ($P < 0.001$). The difference was 15.5 $\mu\text{mol/L}$ in free carnitine ($P < 0.001$), 5.2 $\mu\text{mol/L}$ in short-chain acylcarnitine ($P < 0.001$), 1.0 $\mu\text{mol/L}$ in long-chain acylcarnitine ($P < 0.001$), and 21.8 $\mu\text{mol/L}$ in total carnitine ($P < 0.001$).

When the cachectic patients without gastrointestinal cancer were compared to the non cachectic patients with cancer, the difference was 3.2 mg/dL in bun ($P < 0.01$), 7.5 mg/dL in glucose ($P < 0.001$), 27.3 mg/dL in total cholesterol ($P < 0.001$), 18.8 mg in triglycerides ($P < 0.001$), 5.9 IU/L in AST ($P < 0.01$), 19.10 in ALP ($P < 0.001$), 5.40 $\mu\text{mol/L}$ in free carnitine ($P < 0.01$), 3.10 $\mu\text{mol/L}$ in short-chain acylcarnitine ($P < 0.005$), 8.7 $\mu\text{mol/L}$ in total carnitine ($P < 0.001$).

When the cachectic patients without gastrointestinal cancer were compared to the healthy controls, the difference was 5.40 mg/dL in Bun ($P < 0.005$), 20.8 mg/dL in total cholesterol ($P < 0.001$), 13.3 mg/dL in triglycerides ($P < 0.001$), 8.7 IU/L in ALT ($P < 0.001$), 12.9 IU/L in AST ($P < 0.001$), 50.1 IU/L in ALP ($P < 0.001$), 8.7 $\mu\text{mol/L}$ in free carnitine ($P < 0.001$), 3.7 $\mu\text{mol/L}$ in short-chain acylcarnitine ($P < 0.01$), 0.6 $\mu\text{mol/L}$ in long-chain acylcarnitine L ($P < 0.005$), 13.1 $\mu\text{mol/L}$ in total carnitine ($P < 0.001$).

Table 2 Laboratory parameters of subjects included in our study (mean \pm SD)

Parameter	Group 1 (30 pts)	Group 2 (25 pts)	Group 3 (60 pts)	Group 4 (30 pts)
Bun (mg/dL)	35.6 \pm 5.4	38.2 \pm 5.1	41.4 \pm 4.7	32.8 \pm 7.9
Glucose (mg/dL)	68.4 \pm 9.1	67.9 \pm 8.7	75.4 \pm 9.1	71.2 \pm 9.4
Creatinine (mg/dL)	0.87 \pm 0.37	0.91 \pm 0.25	1.06 \pm 0.20	0.97 \pm 0.21
Total Cholesterol (mg/dL)	160.1 \pm 13.9	166.9 \pm 14.2	194.2 \pm 8.7	187.7 \pm 10.8
Triglycerides (mg/dL)	144.3 \pm 13.2	156.8 \pm 10.9	175.6 \pm 9.6	170.1 \pm 9.8
ALT (IU/L)	49.7 \pm 9.8	45.4 \pm 7.9	46.1 \pm 7.8	36.7 \pm 4.4
AST (IU/L)	51.4 \pm 8.9	48.7 \pm 7.4	42.8 \pm 9.6	35.8 \pm 6.7
ALP (IU/L)	241.8 \pm 22.6	215.1 \pm 20.7	196 \pm 16.4	165 \pm 18.2
CEA (ng/mL)	847.2 \pm 196.4	44.6 \pm 13.1	31.6 \pm 15.8	2.1 \pm 1.4

Figure 1 Comparison of carnitine serum levels in four subject groups.

When non-cachectic cancer patients were compared to the healthy controls, the difference was 8.6 mg/dL in BUN ($P < 0.001$), 4.2 mg/dL in glucose ($P < 0.05$), 6.5 mg/dL in total cholesterol ($P < 0.005$), 5.5 mg in triglycerides ($P < 0.01$), 9.4 IU/L in ALT ($P < 0.001$), 7.00 IU/L in AST ($P < 0.001$), and 31.01 IU/L in ALP ($P < 0.001$).

In comparison of serum plasma carnitine in controls and neoplastic patients, there were no significant differences (Table 2).

The correlation studies in patients with gastrointestinal cancer showed a strong correlation between the following parameters: total carnitine ($r = 0.75$), short-chain acylcarnitine ($r = 0.70$), long-chain acylcarnitine ($r = 0.78$), free carnitine ($R = 0.70$), weight loss and total carnitine ($R = 0.81$), short chain acylcarnitine ($r = 0.78$), long chain acylcarnitine ($r = 0.71$), free carnitine ($r = 0.74$) and CEA.

The correlation studies in patients also showed a correlation between total carnitine ($r = 0.61$), short chain acylcarnitine ($r = 0.65$), and long chain acylcarnitine ($r = 0.64$) in free carnitine ($r = 0.61$) and weight loss.

No correlation was found between total carnitine or the fractions of carnitine and other biohumoral and demographic characteristics (Figure 1).

DISCUSSION

The current study demonstrated that patients with gastrointestinal cancer cachexia showed a significant decrease in fractions and total carnitine serum levels in

comparison with controls.

Malignant lesions are generally associated with weight loss, due to delay in the establishment of a diagnosis. Gastrointestinal cancer is characterized by malabsorption with excess fecal loss of ions and water, in addition to nutrient. Cachexia is associated with inflammatory or neoplastic condition that evokes an acute-phase response with an increase of cytokine production (such tumor necrosis factor, interleukin 1, 6 and interferon), and feeding does not reverse the macronutrient changes.

Patients with gastrointestinal cancer may also experience anorexia secondary to food aversion.

Gastrointestinal cancer presents with symptoms and signs such as loss of appetite, abdominal discomfort, decreased gastrointestinal transit with obstructive symptoms, weight loss, weakness, nausea and vomiting.

Diversion to food can be attributed to the location of the tumor, its rate of growth and size^[11].

Patients with growing tumors and poor intake due to bowel obstruction or severe dysphagia present with progressive nutritional deprivation as the main mechanism of cachexia.

The low plasma carnitine concentration in these patients is probably a consequence of decreased intake of carnitine and the carnitine precursors L-lysine and L-methionine.

Carnitine is critical for normal skeletal and heart muscle bioenergetics.

The decrease of carnitine and its derivatives in patients with cachexia can explain the sarcopenia.

In fact, skeletal muscle is the main reservoir in the body and possesses a carnitine concentration at least 50 to 200 times higher than in blood, where the average concentration is about 50 $\mu\text{mol/L}$ ^[12].

Administration of exogenous L- carnitine might improve the nutritional status in patients without gastrointestinal cancer and enhance muscle mass exerting a favorable effect on chronic fatigue syndrome in cancer patients.

The values of serum carnitine determination are questionable in respect to consequences and interpretation. This is due to the fact that serum carnitine represents approximately 3% of total body carnitine.

Rates of changes beyond the limits of 2%-3% in 1 mo can be considered abnormal. However, rates of changes within these limits may also be abnormal if divergent changes are seen in different body compartments (for example, depletion of skeletal muscle plus fluid overload caused by cardiac, hepatic, or renal disease; hypoalbuminemia or intravenous hydration)^[13,14].

Carnitine is required for long-chain fatty acid oxidation and assists in removing accumulated acyl groups from the mitochondria and plays an important role in detoxification^[15]. The reduced levels of carnitine seem to be related with both malabsorption and impaired carnitine production. A decrease in serum carnitine explains not only the sarcopenia but also indicates a bioenergetic deficit with the physical and mental fatigue detectable in patients^[16].

An increase in resting energy expenditure may contribute to weight loss in cancer patients. L-carnitine

has been shown to have physiologic effects on metabolism in cachexia models, presumably because of its ability to increase fatty oxidation^[17].

The decrease in total serum carnitine is associated with a decrease in acylcarnitine, a fundamental substance in brain metabolism. Deficiency in acyl carnitine can induce behavioral and cognitive changes (anxiety, depression and malignancy or treatment-related anorexia)^[18,19].

The direct relationship between total serum carnitine and short-chain and long-chain acylcarnitine levels in patients with gastrointestinal cancer cachexia and CEA suggests that the observed decrease in serum carnitine levels is directly influenced by the activity of gastrointestinal cancer.

In fact, malnutrition triggers a vicious circle in which neoplastic patients produce additional amounts of cytokines. The decrease in total and fractions of carnitine in patients without gastrointestinal cancer cachexia in comparison with cancer patients in good nutritional status and healthy control subjects suggests the alteration of endogenous biosynthesis of carnitine due to elevated cytokine production associated with cachexia. In fact, cachexia has a multifactorial pathogenesis and involves several neuronal systems that modulate production and transport of cell energy, such as hormones, neuropeptides, cytokines and neurotransmitters (serotonin and dopamine)^[20].

Since therapeutic options currently available for the treatment of these patients are not successful,

administration of carnitine may allow us to correct the unregulated immune response and improve the total energy expenditure^[21]. The total energy expenditure involves in fact resting energy expenditure (approximately 70%), voluntary energy expenditure (25%), and energy expenditure in digestion (5%).

Therefore, there is no evidence that supports the use of nutritional or pharmacological intervention to improve the likelihood of either survival or improved anti-neoplastic interventions^[22,23]. L-carnitine and L-acetylcarnitine may be effective at limiting the demands placed on cachectic patients by acute stresses, such as sudden increases in physical activity, immunological challenge or acute and chronic malnutrition.

Abstract

AIM: To analyze the percentages of hepatocytes with increased nuclear DNA content, i.e., tetraploid (4n) and octoploid (8n) nuclei, and then compared mononuclear and binuclear hepatocyte populations.

METHODS: The percentages of mononuclear diploid (2n), 4n, and 8n hepatocytes and those of binuclear $2 \times 2n$, $2 \times 4n$, and $2 \times 8n$ hepatocytes were determined with a method that can simultaneously measure hepatocyte nuclear DNA content and binuclearity in 62 patients with chronic hepatitis B or C. The percentage of 4n and 8n hepatocytes in the mononuclear hepatocyte population was compared with the percentage of $2 \times 4n$ and $2 \times 8n$ hepatocytes in the binuclear hepatocyte population.

RESULTS: The percentages of 4n and 8n hepatocytes in mononuclear hepatocytes and $2 \times 4n$ and $2 \times 8n$ hepatocytes in binuclear hepatocytes were similar, regardless of the activity or fibrosis grade of chronic hepatitis and regardless of the infecting virus.

CONCLUSION: The distribution of nuclear DNA content within mononuclear and binuclear hepatocyte populations was conserved during the course of chronic viral hepatitis.

INTRODUCTION

Hepatocyte polyploidization and binucleation are two important features of liver growth and physiology. In adult humans, the number of polyploid liver cells is reportedly 20%-45%^[1,2]. The importance of controlling hepatocyte polyploidization in both normal and pathological liver conditions has been reported. During postnatal growth, the liver parenchyma undergoes dramatic changes characterized by gradual polyploidization^[3]. In adults, hepatocyte polyploidization is differentially regulated upon loss of liver mass and liver damage. Partial hepatectomy induces marked cell proliferation followed by an increase in hepatocyte ploidy^[4]. In contrast, in different liver pathologies, such as hepatocellular carcinoma, growth shifts to a non-polyploidizing pattern and expansion of the diploid hepatocyte population is observed^[5].

We previously studied changes in hepatocyte ploidy and binuclearity profiles in patients with chronic viral hepatitis and found that the percentage of diploid hepatocytes was significantly reduced in patients with high hepatitis activity and marked fibrosis and that the polyploid hepatocyte fraction was increased in these patients^[6]. Thus, during chronic hepatitis, the changes in ploidization is similar to that observed after partial hepatectomy in adults. In this previous study, we validated a technique that allows simultaneous measurement of hepatocyte nuclear DNA content and hepatocyte binuclearity in the same liver sections. This is a technique that makes it possible to evaluate the DNA content of a binuclear hepatocyte.

In the present study, we used the same technique to analyze the nuclear DNA contents of mononuclear and binuclear hepatocytes, to compare the changes in the distribution of hepatocytes with different nuclear DNA content between mononuclear and binuclear hepatocyte populations during the course of human chronic hepatitis.

MATERIALS AND METHODS

Subjects

A total of 62 patients with chronic viral hepatitis (44 men

and 18 women, mean age 39.6 ± 5.7 years) were studied. An ultrasonography-guided needle liver biopsy had been performed on all patients between March 1996 and March 2001. Twenty-seven patients were chronically infected with hepatitis B virus (HBV), whereas the other 35 patients were infected with hepatitis C virus (HCV). On the basis of histological findings, hepatitis activity as determined with the METAVIR scoring system^[7] was A0 in 15 patients, A1 in 13 patients, A2 in 13 patients, and A3 in 21 patients, and the degree of fibrosis was F0 in 7 patients, F1 in 21 patients, F2 in 11 patients, and F3 in 23 patients.

Methods

Analyses of hepatocyte nuclear DNA content and hepatocyte binuclearity were performed as described previously^[6,8,9]. Three-micrometer-thick, paraffin-embedded liver tissue sections were incubated for 1 h with anti-cytokeratin antibody (1:50, KL1, Immunotech, S.A., Marseille, France) as the primary antibody for immunostaining of hepatocyte membrane, followed by a 30-min incubation with biotinylated swine anti-goat, mouse, rabbit immunoglobulin solution (1:200, Dako) and a 30-min incubation with FITC-conjugated streptavidin (1:200, Dako). Sections were then stained for 20 min with Hoechst 33342 (1 mg/L) to stain DNA. Tissue sections were then examined under a Zeiss inverted microscope (Axiovert 35, Carl Zeiss, Gottingen, Germany) equipped for epi-illumination. Images were captured with a cooled, charged coupled device (CCD) camera (KAF 1400-G2, class 2, Photometrics, Tucson, AZ) on 4056 grey levels. Automatic quantitative image analysis was performed in 12 bits with the IPLab Spectrum version 3.1 software. Hepatocytes were classified as mono- or binuclear hepatocytes on the basis of comparisons of fluorescent and membrane labelling images. Other liver cell types, which were defined by morphologic characteristics, were eliminated. Integrated fluorescence intensity was stored in computer files for analysis. A histogram of the fluorescence intensity per section was drawn, and the distribution of each hepatocyte population (2n [diploid] DNA content as the first peak on the histogram, 4n [tetraploid] DNA content as the second peak on the histogram, and 8n [octoploid] DNA content as the third peak on the histogram) was calculated. To develop a histogram of the fluorescence intensity of binuclear hepatocytes, we used the fluorescence intensity of the nucleus with the clearest edge when only one of the two nuclei of a binuclear hepatocyte had a clear edge on the image analyzed. When two nuclei had clear edges, we calculated the average of fluorescence intensity of the two nuclei and used this value as fluorescence intensity of the hepatocyte. A minimum of 300 hepatocytes on eight to 12 separate fields was studied. To ensure that the same cells were not counted twice, slides were read by two observers in a systematic manner of moving from right to left along the slide and then along successive descending lines. All analyses were performed blind to any sample-specific data.

Correlations between values were analyzed by Spearman test, and a $P < 0.05$ was accepted as statistically significant. The study was approved by the Institutional Review Board of Hopital Necker-Enfants Malades (Paris, France) and was carried out in accordance with the Helsinki declaration.

Figure 1 Correlation between percentage of hepatocytes with 4n or 8n nuclei in mononuclear hepatocyte population and percentage of hepatocytes with 2 x 4n or 2 x 8n nuclei in binuclear hepatocyte population. [$P < 0.0001$; correlation coefficient, 0.826 (0.726-0.892)].

RESULTS

We analyzed the percentages of binuclear hepatocytes with diploid (2n) nuclei and those with tetraploid (4n) or octoploid (8n) nuclei (namely binuclear $2 \times 2n$ and $2 \times 4n + 2 \times 8n$) and compared them with the percentages of mononuclear hepatocyte with 2n nucleus and those with 4n or 8n nucleus (namely mononuclear 2n and $4n + 8n$) in samples from patients with chronic viral hepatitis. We found a significant correlation between the percentages of mononuclear 4n and 8n hepatocytes and binuclear $2 \times 4n$ and $2 \times 8n$ hepatocytes ($P < 0.0001$; correlation coefficient, 0.826 [0.726-0.892]); the percentages of nuclei of 4n or 8n DNA content was maintained in the mononuclear hepatocyte population and in the binuclear hepatocyte population (Figure 1). This correlation was maintained when we focused specifically on patients with HBV or HCV. The correlation was also maintained regardless of activity of hepatitis, grade of liver fibrosis, age, or sex (data not shown). In contrast, there was no correlation between the percentage of binuclear $2 \times 4n$ and $2 \times 8n$ hepatocytes and the percentage of binuclear hepatocytes in the total hepatocyte population ($P = 0.1276$; correlation coefficient, 0.196 [-0.057-0.425]; Figure 2). The percentage of binuclear hepatocytes with increased nuclear DNA content ($2 \times 4n$ and $2 \times 8n$ hepatocytes), therefore, was not associated with the percentage of binuclear hepatocytes in the total hepatocyte population.

DISCUSSION

Flow cytometry can measure nuclear DNA content but cannot distinguish between nuclei of mononuclear hepatocytes and those of binuclear hepatocytes. In addition, morphologic observation of hematoxylin and eosin-stained sections can distinguish mononuclear and binuclear hepatocytes but cannot quantify nuclear DNA content. To our knowledge, the present study is the first to compare the distributions of nuclear DNA content between mononuclear and binuclear hepatocyte populations with a novel method that allowed evaluation of the distribution of nuclear DNA content ($2 \times$

Figure 2 Correlation between percentage of hepatocytes with $2 \times 4n$ or $2 \times 8n$ nuclei in binuclear hepatocyte population and that of binuclear hepatocytes as a portion of total hepatocytes. [$P = 0.1276$; correlation coefficient, $0.196 (-0.057-0.425)$].

$2n$, $2 \times 4n$, and $2 \times 8n$) exclusively in binuclear hepatocytes.

With respect to the hypothesis that mononuclear hepatocytes are stimulated to form binuclear hepatocytes, our findings suggest that both diploid and polyploid mononuclear hepatocytes are similarly stimulated to form binuclear hepatocytes, suggesting the possibility that the formation of binuclear hepatocytes is regulated by a single factor for both diploid and polyploid hepatocytes. Alternatively, it is possible that both diploid and polyploid hepatocytes are sensitive to a single stimulus for binuclear hepatocyte formation. This appears to be independent of viral infection and is maintained throughout the course of chronic hepatitis.

In a previous report^[6], we showed that the decrease in the percentage of diploid hepatocytes was correlated with the progression of chronic hepatitis. In addition, we showed there was a higher percentage of binuclear hepatocytes in patients with HBV infection than those with HCV infection. Our present results indicate that the percentage of diploid hepatocytes decreases in both mononuclear hepatocyte and binuclear hepatocyte populations, in a similar way according to the progression of chronic hepatitis. Also, the present data indicate that binuclear hepatocytes increase in patients infected with HBV, conserving the distribution of different nuclear DNA content ($2 \times 2n$, $2 \times 4n$, and $2 \times 8n$ hepatocytes).

The mechanisms that underlie hepatocyte polyploidiza-

tion are still largely unknown. The importance of binuclear hepatocyte formation as a step towards hepatocyte polyploidization has been reported. We previously provided direct evidence for the pivotal role of binuclear hepatocytes in the formation of $4n$ mononuclear hepatocytes, indicating a close association between binuclear hepatocyte formation and polyploid mononuclear hepatocyte formation *in vitro*^[9]. Our present study indicated that formation of polyploid mononuclear hepatocytes is associated with formation of polyploid binuclear hepatocyte in human chronic viral hepatitis. Further studies are needed to clarify the mechanisms that control hepatocyte polyploidization and binucleation during human chronic viral hepatitis. In addition, the influence of steatosis, which is often observed in case of chronic hepatitis C and can reduce replication in hepatocytes, on hepatocyte polyploidization and binucleation should be elucidated in the future.

Abstract

AIM: To investigate whether the degree of rectal distension could define the rectum functions as a conduit or reservoir.

METHODS: Response of the rectal and anal pressure to 2 types of rectal balloon distension, rapid voluminous and slow gradual distention, was recorded in 21 healthy volunteers (12 men, 9 women, age 41.7 ± 10.6 years). The test was repeated with sphincteric squeeze on urgent sensation.

RESULTS: Rapid voluminous rectal distension resulted in a significant rectal pressure increase ($P < 0.001$), an anal pressure decline ($P < 0.05$) and balloon expulsion. The subjects felt urgent sensation but did not feel the 1st rectal sensation. On urgent sensation, anal squeeze caused a significant rectal pressure decrease ($P < 0.001$) and urgency disappearance. Slow incremental rectal filling drew a rectometrogram with a "tone" limb representing a gradual rectal pressure increase during rectal filling, and an "evacuation limb" representing a sharp pressure increase during balloon expulsion. The curve recorded both the 1st rectal sensation and the urgent sensation.

CONCLUSION: The rectum has apparently two functions: transportation (conduit) and storage, both depending on the degree of rectal filling. If the fecal material received by the rectum is small, it is stored in the rectum until a big volume is reached that can affect a degree of rectal distension sufficient to initiate the defecation reflex. Large volume rectal distension evokes directly the rectoanal inhibitory reflex with a resulting defecation.

INTRODUCTION

The rectum, a continuation of the colon, acts to propel the stools to the exterior and is thus considered as a conduit^[1-3]. However, its function as a conduit for stools is controversial^[4-6]. Stools are palpable on digital rectal examination (DRE) in many healthy volunteers who do not feel the desire to defecate^[4-6]. Neil and Rampton^[5] reported that stools are present in the rectum in 31% of normal subjects. Stools are also palpated by DRE in the lower rectum of healthy subjects and appear in the radiograms. Our studies have shown that the rectum stores the stools if the quantity is small, while functions as a conduit if the stools received from the sigmoid colon are voluminous. A small stool volume reaching the rectum from the sigmoid colon probably does not affect rectal distension or evoke the rectoanal inhibitory reflex (RAIR). In such case the stools accumulate in the rectum until they reach a big distending volume that initiates the RAIR. On the other hand, big distending volumes of the stools propelled from the sigmoid colon appear to be able to initiate the RAIR and expel the stools without storage in the rectum. Accordingly, the rectal function as a storage organ or a conduit appears to depend on the volume of fecal matter passing from the sigmoid colon to the rectum and consequently on the degree of rectal distension the volume creates.

We thus hypothesized that rectal function as a conduit or reservoir would depend on the degree of rectal distension. This hypothesis was investigated in the current study.

MATERIALS AND METHODS

Subjects

Twenty-one healthy volunteers (12 men, 9 women, mean

age 41.7 ± 10.6 years, range 29-56 years) participated in the study. They were fully informed about the nature of the study, the tests to be done, and their role in the study. They had no anorectal complaint either in the past or at the time of enrolment. The mean stool frequency was 8.6 ± 1.2 times per week (range 8-11), being in accord with that of normal volunteers in our laboratory. Physical examination, including neurological assessment, was normal. Laboratory work was unremarkable. Sigmoidoscopy assured that the rectum was normal in all the subjects. The subjects gave an informed consent, and the study was approved by the Review Board and Ethics Committee of the Cairo University Faculty of Medicine.

Methods

The subject was instructed to fast for 12 h before the test, and the bowel was evacuated by saline enema. The rectum was distended by a thin polyethylene infinitely compliant balloon, 3 cm in diameter, which was attached to the end of a 10 F tube (London Rubber Industries Ltd, London, UK). The pressure measured within the balloon was considered to be representative of the rectal pressure. With the subject lying in the left lateral position and under no medication, the collapsed balloon was introduced into the rectum through the anus. The tube was connected to a strain gauge pressure transducer (Statham 23 bb, Oxnard, CA).

The anal and rectal pressures were separately measured with a saline-perfused tube. The 10 F tube with multiple side ports at its distal closed end was introduced through the anus for 2-3 cm to lie in the rectal neck (anal canal). Another tube was introduced for 8-10 cm to lie in the rectum. The tube was connected to a pneumohydraulic capillary infusion system (Arndorfer Medical Specialities, Greendale, WI), supplied with a pump that delivers saline solution continually via the capillary tube at a rate of 0.6 mL/min. The transducer outputs were registered on a rectilinear recorder (RS-3400, Gould Inc, Cleveland, OH). Occlusion of the recording orifice produced a pressure elevation of greater than 250 cm H₂O/s.

Prior to anal and rectal pressure recording, the gut was allowed a 20-min period to adapt to the rectal balloon and the manometric tubes in the anal canal and rectum. We recorded the response of the rectal and anal pressures to 2 types of rectal balloon distension: rapid voluminous distension and slow gradual distension. The rectal balloon was filled with 200 mL of normal saline in 10 s for rapid filling, and with increments of 20 mL in 10 s for slow filling. The test was performed at rest and while the anal sphincters were squeezed. The subjects were asked to report the onset of awareness of "something" in the rectum (the first rectal sensation) and the urgent sensation to defecate.

To ensure reproducibility of the results, the tests were repeated at least twice in the individual subjects and the mean value was calculated. The results were analyzed statistically by the Student's *t* test and the values were given as mean \pm SD.

RESULTS

The study was completed in all the subjects with no

Figure 1 Pressure tracing showing the rectal (A) and anal (B) pressure response to rapid balloon rectal distension with 200 mL of normal saline in 10 seconds. \uparrow = rectal balloon distension.

adverse side effects. The mean resting rectal pressure was 8.7 ± 0.9 cm H₂O (range 8-10) and the mean anal pressure was 73.6 ± 4.6 cm H₂O (range 65-79).

Rectal and anal pressure response to rapid voluminous rectal distension

Rectal balloon distension with 200 mL of normal saline in 10 s resulted in a significant increase of the rectal pressure and a decrease of the anal pressure (Figure 1). The balloon was expelled to the exterior. The mean rectal pressure was 63.4 ± 8.2 cm H₂O (range 56-82 cm H₂O, $P < 0.001$) and the mean anal pressure was 22.4 ± 2.6 cm H₂O (range 18-26 cm H₂O, $P < 0.01$). The subjects felt the urgent sensation followed by balloon expulsion, but did not feel the first rectal sensation. When the subject upon feeling the urgent sensation, was asked to squeeze the anal sphincters for seconds, the mean anal pressure rose to 146.8 ± 16.2 cm H₂O (range 128-166 cm H₂O), resulting in disappearance of the urgent sensation and a significant decrease in the rectal pressure to 10.8 ± 1.1 cm H₂O (range 8-12 cm H₂O, $P < 0.001$). The balloon was not expelled but stored in the rectum. After a few seconds however, if the patient was asked not to squeeze the sphincters, the urgent sensation recurred and the balloon was expelled.

The test was reproducible with no significant difference ($P < 0.05$) in the recorded pressure values. There was also no significant difference between men and women.

Rectal and anal pressure response to slow incremental rectal filling

During rectal filling with a small volume (20 mL in 10 s), rectometrograms were produced (Figure 2). The curve showed a "tone limb" representing the rectal pressure as it increased during rectal filling, and an "evacuation limb" representing the rectal pressure during the process of balloon expulsion. The tone limb carried the points of incidence of the first rectal and urgent sensations while displaying a gradual incline until expulsion started.

The evacuation limb described a "curve" which was continuous with the tone limb. It was manifested at a variable distance after the urgent sensation and depended on the subject's desire to evacuate. The evacuation curve had an ascending limb rising slowly as a continuation of the tone limb, and a vertical descending limb (Figure 2).

The mean rectal balloon distending volume was 78.3 ± 16.6 mL (range 53-108 mL) at the first sensation and 152.6 ± 18.9 mL (range 106-182 mL) at the urgent sensation. The mean rectal pressure was 51.7 ± 9.8 cm H₂O at the 1st rectal sensation and 62.9 ± 14.2 cm H₂O at the urgent

Figure 2 Pressure tracing (rectometrogram) showing the rectal (A) and anal (B) pressure response to balloon rectal distension in increments of 20 mL in 10 seconds.

sensation, while the mean anal pressure was 70.6 ± 5.2 cm H₂O and 18.7 ± 2.3 cm H₂O, respectively (Table 1).

The aforementioned results were reproducible with no significant difference when the test was repeated in the individual subjects.

DISCUSSION

The rectum presumably receives stools from the sigmoid colon, either in a big volume affecting rapid voluminous distension of the rectum, or in small masses affecting gradual rectal distension. The current study could shed some light on the rectal function during the rapid voluminous distension and the slow gradual rectal distension.

Rectum as a conduit

Rapid voluminous rectal distension seems to evoke the recto-anal inhibitory reflex as is evident from the increased rectal and decreased anal pressures as well as from balloon expulsion. The subjects feel the urgent sensation but not the first rectal sensation which is normally felt in the gradual rectal distension. In such conditions, the rectum is considered as a conduit, conducting the stools directly from the colon to the exterior. It is likely that the big voluminous rectal distension induces stimulation of the rectal mechanoreceptors with a resulting initiation of the defecation reflex. In this case the rectum evacuates the received stools and remains empty, provided the circumstances are opportune for defecation.

Squeeze of the anal sphincters could abort the urgent sensation and affect waning of the desire to defecate. The mechanism needs to be further discussed. If circumstances are inopportune for defecation, sphincteric squeeze causes rectal relaxation mediated by the voluntary anorectal inhibition reflex^[7]. However, after some time, the loaded rectum re-contracts probably due to re-stimulation of the rectal mechanoreceptors. If the desire to defecate is still opposed, the external sphincter contracts again. This process is repeated till either defecation is acceded to, or a prolonged contraction of the un-striped rectal detrusor tires out the striped short-contracting external anal sphincter which involuntarily relaxes leading to internal anal sphincter relaxation and opening of the rectal neck.

Rectum as a reservoir

Slow incremental rectal filling does not affect rectal

Table 1 Anal and rectal pressures at the 1st rectal sensation and urgent sensation on slow gradual rectal filling (mean \pm SD)

Pressure (cm H ₂ O)	Rectal		Anal	
	Mean	Range	Mean	Range
Basal	8.7 ± 0.9	8-10	73.6 ± 4.6	65-79
1 st rectal sensation	51.4 ± 9.8^d	32-68	70.6 ± 5.2	61-78
Urge	62.9 ± 14.2^d	45-86	18.7 ± 2.3^b	16-24

^b $P < 0.01$ vs the basal values; ^d $P < 0.001$ vs the basal values.

contraction until rectal filling reaches a large enough volume to stimulate the rectal mechanoreceptors and evoke the defecation reflex. During the period of slow gradual filling, the rectum presumably contains stools which are commonly palpated in some subjects during DRE. We postulate that in such cases the amount of stools received from the sigmoid colon is too small to stimulate the rectal mechanoreceptors or evoke the defecation reflex. In such conditions, the stools may remain accumulated in the rectum for an extended period during which the rectum acts as a “storage” organ. We speculate that stool storage in the rectum may affect its consistency and act as a contributing factor in the genesis of constipation. The storage function of the rectum is apparently due to the adaptability of its smooth muscle to small volume rectal distension. This mechanism of “receptive relaxation” is similar to that occurring in the stomach.

In conclusion, the rectum has apparently 2 functions: transportation (conduit) and storage, both depending on the degree of rectal distension. If the fecal material received by the rectum is small, it is stored in the rectum until a big volume accumulated affects rectal distension sufficient to initiate the defecation reflex. However, stool storage in the rectum may be a contributing factor in the genesis of constipation. Large volume rectal distension evokes directly the recto-anal inhibitory reflex with a resulting defecation.

Abstract

AIM: To investigate eradication rates, patient compliance and tolerability of a 1-wk Azithromycin-based quadruple therapy versus the 2-wk conventional therapy.

METHODS: A total of 129 *H pylori*-positive patients were randomized to either omeprazole 20 mg, bismuth subcitrate 240 mg, azithromycin 250 mg, and metronidazole 500 mg, all twice daily for 1-wk (B-OAzM) or omeprazole 20 mg, bismuth subcitrate 240 mg, amoxicillin 1g, and metronidazole 500 mg all twice daily for 2-wk (B-OAM). *H pylori* infection was defined at entry by histology and rapid urease test and cure of infection was determined by negative urea breath test.

RESULTS: *H pylori* eradication rates produced by B-OAzM and B-OAM were 74.1% and 70.4% respectively based on an intention to treat analysis, and 78.1% versus 75.7% respectively based on a per-protocol analysis. The incidence of poor compliance was lower, although not significantly so, in patients randomized to B-OAzM than for B-OAM (3.5% versus 4.3%) but intolerability was similar in the two groups (35% versus 33.3%).

CONCLUSION: 1-wk azithromycin based quadruple regimen achieves an *H pylori* eradication rate comparable to that of standard 2-wk quadruple therapy, and is associated with comparable patient compliance and complications.

Mousavi S, Toussy J, Yaghmaie S, Zahmatkesh M. Azithromycin in one week quadruple therapy for *H pylori* eradica-

INTRODUCTION

H pylori is a common human pathogen that has been shown to be a major factor in peptic ulcer disease. It has also been linked to gastric adenocarcinoma and gastric lymphoma^[1].

A number of antimicrobial agents have been used in various regimens to eradicate *H pylori*. Clinical trials are regularly undertaken to search for simpler but equally effective regimens^[2-4]. Azithromycin, a new generation macrolide, has some special attributes that suggest it would be a promising compound to be used in regimens for *H pylori* eradication. It is acid-stable, has a long half-life and achieves remarkably high concentration in the gastric tissue^[3,5]. There have been several clinical trials of azithromycin for the therapy of *H pylori* infection^[3,4,6,7]. As the pharmacological properties of azithromycin make it possible to use shorter courses, the problem has been to define an optimal dose and duration of azithromycin treatment in the course of therapy^[3,4]. On the other hand, in developed countries, regimens of one week's duration are recommended for *H pylori* eradication^[1,2] but in developing countries 1-wk regimens failed to eradicate the microbe. A minimum of 10 to 14 d of treatment were needed for eradication of the microbe, even in the presence of a favorable sensitivity profile^[8-10]. The aim of this study was to assess the efficacy of azithromycin in a 1-wk regimen compared with a conventional 2-wk regimen in Iran, so we compared two quadruple regimens; bismuth subcitrate, omeprazole, azithromycin, and metronidazole, for 1-wk (B-OAzM) and bismuth subcitrate, omeprazole, amoxicillin and metronidazole, for 2-wk (B-OAM) in *H pylori* eradication. The safety and tolerability of the two drugs combinations were also evaluated and compared.

MATERIALS AND METHODS

Patients considered for the study included individuals 18-80 years old with upper GI symptoms that were referred to our gastroenterology clinic for upper endoscopy. Patients with *H pylori* infection were included in the study. Other inclusion criteria included indication for treatment as per the National Institutes of Health (NIH)

Consensus Conference including: peptic ulcer disease, history of peptic ulcer, chronic gastritis, gastric mucosa associated lymphoid tissue, or intestinal metaplasia^[1,7]. Between October 2003 and October 2004, a total of 129 patients were enrolled in the study. All patients gave written informed consent before entering the study and the protocol was reviewed and approved by the Semnan Gastrointestinal and Liver diseases Research Center. The criteria for exclusion were: intake of proton pump inhibitors, antibiotic or bismuth salts within 4 wk prior to the study, stomach surgery, known hypersensitivity to one of the study medications, patients with liver cirrhosis, renal failure or other serious severe concomitant illness, pregnant women, and patients who had previously undergone eradication therapy. These criteria were ascertained by taking a complete history, physical examination, and appropriate hematological and biochemical tests. The demographic and endoscopic data of these patients are reported in Table 1.

On initial endoscopy, *H. pylori* infection was determined by rapid urease test and histological assessment. Rapid urease test was performed using two biopsy specimens; one from the antrum and the other from the corpus^[11]. Histological assessment of *H. pylori* status was performed using one further biopsy specimen from the antrum; within 3 cm of the pylorus (hematoxylin-eosin and Giemsa stains)^[12]. The patients were considered to be infected if both the urease test and histology were positive on initial testing. The patients that satisfied the inclusion criteria were randomly assigned to one of the following regimes; one group received a regimen of bismuth subcitrate 240 mg, omeprazole 20 mg, azithromycin (Azithromycin TC ®, Tehran shimi, Iran) 250 mg and metronidazole 500 mg, all bid, for 1-wk (B-OAzM) and the second group received a regimen of bismuth subcitrate 240 mg, omeprazole 20 mg, amoxicillin 1 g and metronidazole 500 mg, all bid, for 2-wk (B-OAM). Patients with duodenal or gastric ulcers continued on omeprazole (20 mg/d) for a total of 1 mo. Repeat examination was performed 1 wk and 4-8 wk after the cessation of therapy. Subjects recorded any side effects

and change in symptoms, and performed an exit interview and pill count to evaluate compliance and side effects. Hematological and biochemical analyses were performed at the last visit. *H. pylori* infection was determined by urea breath test (UBT) at the second examination. All patients were instructed to discontinue all proton pump inhibitors, H₂ blockers, and bismuth for at least 4 wk before UBT. Eradication was defined on the basis of a negative UBT (carbon 13-Isomax 2000 TM device); results under the 5 cut off were considered negative^[13].

Analysis of the two groups was conducted in the form of both per protocol (PP) and intention to treat (ITT). The ITT analysis for eradication was defined before the study to include all subjects who were randomized and received at least one dose of medication. The PP analysis for eradication included all subjects who took at least 80% of each study medication as prescribed.

The comparison of efficacy was evaluated using the χ^2 test. The analysis was performed using the SPSS 11.5 statistical package (SPSS, Chicago, IL).

RESULTS

The two groups were comparable in terms of common clinical variables that are summarized in Table 1. Three patients were lost to follow up (two from the B-OAM regimen and one subject from the B-OAzM regimen); also five patients discontinued the drugs because of severe side effects (three from the B-OAM regimen and two subject from the B-OAzM regimen). The remaining 121 patients completed the study as planned.

PP analysis: *H. pylori* infection was eradicated in 43 of 55 patients in the B-OAzM group (78.18%, CI0.95: 64.98%-88.18%) and in 50 of 66 patients in the B-OAM group (75.75%, CI0.95: 63.63%-85.46%); the difference was not statistically significant ($\chi^2 = 0.1$, $P = 0.75$).

In patients with peptic ulcer, *H. pylori* infection was eradicated in 19 of 25 patients in the B-OAzM group (76%, CI0.95: 54.87%-90.64%) and in 28 of 37 in the B-OAM group (75.67%, CI0.95: 58.8%-88.22%); the difference was not statistically significant ($\chi^2 < 0.001$, $P = 0.97$).

ITT analysis: *H. pylori* infection was eradicated in 74.13% (CI0.95: 60.95%-84.74%) in the B-OAzM group and 70.42% (CI0.95: 58.4%-80.67%) in the B-OAM group; the difference was not statistically significant ($\chi^2 = 0.3$, $P = 0.58$).

Complications: the overall results for side effects are summarized in Table 2. Complications were noted in 14 patients in the B-OAzM group (25.45%) and 17 patients in the B-OAM group (25.75%) with no statistically significant differences between the groups ($\chi^2 < 0.001$, $P = 0.96$). The symptoms were mild and did not necessitate any additional treatment except in the five patients that discontinued the drugs for severe complications.

DISCUSSION

Although various regimens have been recommended for *H. pylori* eradication, all of them include at least 2 antibiotics and one acid inhibitory drug^[1]. In western countries,

Table 2 Complications of drugs in *H pylori* treatment

Complication	B-OAM-2 wk regimen	B-OAZM-1 wk regimen	P value ²
<i>n</i>	69 ³	57 ³	
Diarrhea (%)	4 (5.7)	4 (7)

the most effective and usual regimens for preliminary treatment include; triple regimens for at least 1 wk, and use of clarithromycin as the antibiotic of choice against *H pylori*. Metronidazole, on the other hand, has largely been eliminated from first-line *H pylori* therapy because of its intolerability and high drug resistance^[14]. However, in developing countries, effective treatments for *H pylori* vary from those used in developed countries. For example in middle east countries it has been shown that one week regimens fail to eradicate the microbe and the course of treatment should be continued for at least 10-14 d to provide for eradication^[8-10]. Further, clarithromycin is not appropriate use because of its high price, drug resistance and unavailability^[15,16], and so metronidazole is a common and effective drug in *H pylori* treatment in this setting.

Although the prevalence of *H pylori* strains that are resistant to metronidazole varies from 46%-51% in Iran^[15-17], it has been shown that this drug in high doses (> 1 g) and in combination with other drugs remains effective against *H pylori*^[18-21]. Therefore, in Iran as also done in some Asian countries^[14,18] metronidazole is a very common drug used in *H pylori* eradication regimens^[22]. In Iran, the most common regimens for first-line treatment are 2-wk quadruple regimens that include; metronidazole, omeprazole, bismuth and tetracycline or amoxicillin^[22]. This conventional regimen introduced initially by Hosking, Deboer, Borody, and Laine as an effective regimen in *H pylori* treatment has confirmed efficiency of a 63%-93% eradication rate^[7,23-25]. On other hand, due to high rates of resistance to metronidazole, furazolidone was used instead of it, as first or particularly second line treatment^[26].

Although 2 wk regimens have been effective in *H pylori* eradication, some patients withdraw from their treatment because of the long duration and large number of tablets. Thus, in this study we showed that a quadruple regimen, where azithromycin replaced amoxicillin, the duration of the treatment can be decreased without any change in its effectiveness.

Azithromycin is a new macrolide related to clarithromycin with an effective role in *H pylori* eradication and it was reported that azithromycin has a synergic effect with esomeprazole, even in presence of drug resistance^[27]. In various studies the effectiveness of azithromycin has been evaluated in different doses from 500 mg to 3 g^[2,27-29], although in most studies this drug was used for 3 d (1.5 g

as in respiratory tract infection but at this dose it has less effect than clarithromycin^[3,5]. However, by increasing the total dose to 3 g, it has been shown that the effectiveness of azithromycin can be restored^[3,4,6,7].

This is the first study in which azithromycin was used at a prescribed amount of 3.5 g (250 mg bid for 7d) in the treatment of *H pylori* infection. Fortunately; the patients' tolerance was excellent. There were a few side effects based on biochemical tests, but most side effects were mild and disappeared with conservative therapy without the need to terminate the treatment.

Finally, in areas where clarithromycin cannot be used because of drug resistance or unavailability, azithromycin with a total dose of 3.5 g is an appropriate and safe drug for *H pylori* eradication regimen.

The effectiveness of furazolidone based *triple or quadruple regimens* has been evaluated in Iran^[15,22,25,26], but because of resistance to metronidazole, it seems possible that a combination of azithromycin and furazolidone instead of azithromycin and metronidazole will achieve more favorable eradication rates, although further evaluation is needed.

Abstract

AIM: To assess the efficacy and safety of *Saccharomyces boulardii* (*S. boulardii*) in acute watery diarrhoea and its role in reducing the frequency of episodes of diarrhoea in subsequent two months.

METHODS: Children from 2 mo to 12 years of age, with acute diarrhoea were selected according to inclusion criteria and randomised in *S. boulardii* group (treated with ORS, nutritional support and *S. boulardii*, 250 mg bid) and in control group (treated with ORS and nutritional support only). Active treatment phase was 5 d and each child was followed for two months afterwards. Frequency and consistency of stools as well as safety of drug was assessed on every visit. A comparison of two groups was done in terms of number of diarrhoeal episode in subsequent two months.

RESULTS: There were fifty patients in each group. Baseline characteristics such as mean age and the average frequency of stools were comparable in *S. boulardii* and control group at the time of inclusion in the trial. By d 3 it reduced to 2.7 and 4.2 stools per d respectively and by d 6 it reduced to 1.6 (*S. boulardii* Group) and 3.3 (control group). The duration of diarrhoea was 3.6 d in *S. boulardii* group whereas it was 4.8 d in control group ($P = 0.001$). In the following two months, *S. boulardii* group had a significantly lower frequency of 0.54 episodes as compared to 1.08 episodes in control group. The drug was well accepted and tolerated. There were no reports

INTRODUCTION

Acute infectious diarrhoeal disease is a worldwide problem with over two million deaths each year. Diarrhoeal diseases are a leading cause of childhood morbidity and mortality and over 200 000 children die every year (600 deaths per day) in Pakistan. Repeated episodes of diarrhoea lead to under-nutrition. In Pakistan, every child gets, on average, 5-6 episodes of diarrhoea per year.

Last couple of decades has seen greater understanding of pathogenesis and simple methods of management of diarrhoea. Various modalities of interventions have been used in different parts of the world to improve the diarrhoeal mortality and morbidity which include oral rehydration salt (ORS), cereal based ORS, antibiotics, anti-diarrhoeals, antispasmodics and anti-emetics. Some of these modalities later proved to have variable harmful effects. These harmful effects include worsening of diarrhoea, increased duration of diarrhoea, adverse effects on gut motility leading to paralytic ileus. In addition, there are other systemic untoward effects^[1,2].

Gastrointestinal disease is often a consequence of a myriad of factors, which disturb the bowel's complex ecosystem. The concept of modulating bacterial activities, directed towards improving gut microbial function, has a long history. The use of yoghurt (as probiotic) in the treatment of diarrhoea has been known for a long time. It is now recognised that the most frequently used method of influencing the gut flora composition is that of probiot-

ics. A probiotic is a living micro organism administered to promote the health of the host by treating or preventing infections owing to strains of pathogens^[3]. Bio-therapeutic agents are defined as probiotics registered as drugs.

The modern view of probiotic therapy derives from the concept of a well functioning gut barrier and a normal balanced microbiota.

Numerous probiotic agents have been studied for the management of diarrhoeal disease. In particular, the prevention and management of acute viral diarrhoea, the treatment of recurrent *Clostridium difficile* diarrhoea, as well as the control of antibiotic-associated diarrhoea seem to be areas of significant potential benefit. A few agents, including *Lactobacillus GG*, *Lactobacillus reuteri*, and *Saccharomyces boulardii* (*S. boulardii*), seem to be promising agents for the amelioration of the course of acute diarrhoea in children when used therapeutically^[4]. Amongst these, all are bacteria except *S. boulardii*, which is yeast.

S. boulardii is a non-pathogenic yeast first isolated from lychee fruits in Indonesia and used first in France to treat diarrhoea, in the beginning of the 1950s. A lyophilised form is in clinical use in Europe, Asia, Africa, and Central and South America.

Preclinical and experimental studies of *S. boulardii* have demonstrated an anti-inflammatory, antimicrobial, enzymatic, metabolic and antitoxinic activity. *S. boulardii* secretes a 54-KDa protease which has been shown to neutralize certain bacterial toxins; *S. boulardii* is also able to stimulate an immune response in the intestinal mucosa. It has a trophic effect by enhancing the metabolic function of the mucosa. *S. boulardii* releases polyamines, which are implicated in stimulating the enzymatic activity of the colonic mucosa^[3,5].

Based on our previous experience of use of *S. boulardii* in the treatment of diarrhoea, this study was undertaken to assess the efficacy of *S. boulardii* in the treatment of diarrhoea and reoccurrence of diarrhoea in subsequent two months.

MATERIALS AND METHODS

Patients

This randomised controlled clinical trial was carried out at Kharadar General Hospital, Karachi, catering to the needs of approximately one million population and situated in the middle and low-income community. An informed consent was obtained from parent/guardian of every child included in the trial. The children from 2 mo to 12 years of age presenting with acute watery diarrhoea of mild to moderate severity, fulfilling the inclusion criteria were included in this trial.

Children with severe inter-current illnesses, severe diarrhoea and dehydration requiring hospitalisation and intravenous therapy, presenting with temperature above 38.5°C, who were treated by any other anti-diarrhoeal/antibiotics in last 24 h as well as severely malnourished children were excluded from the trial. At inclusion, stool specimen was sent for bacterial culture and sensitivity as well as for Rota virus detection.

The study population of 100 children was randomised into two groups. In *S. boulardii* group, patients were

Table 1 Baseline characteristics

Positive	16%	20%	0.795
Negative	84%	80%	

managed by WHO-CDD protocol^[6] plus *S. boulardii* (250 mg bid) administered orally diluted in water or other semi-solid food. The product was manufactured by Hilton Pharma (Pvt) Ltd. under the license of Biocodex, France. In the control group patients were managed by WHO-CDD protocol only. The active treatment period was 5 d. Treatment of the subsequent episodes of diarrhoea was at the discretion of the treating physician.

All study participants were examined on d 0 (inclusion day), and followed up on d 3 and d 6 during active treatment phase and every month for two months thereafter for observation.

The first visit data collection included date of onset of diarrhoea, previous treatment (where applicable), weight of child, number and consistency of stools, vomiting, body temperature, sign of dehydration and any other data by clinical examination. The second visit information variables included date of stoppage of diarrhoea in case of inter-current recovery, weight of child, daily record of frequency and consistency of stools, tolerance and acceptability of treatment. Similarly on third visit, date of stoppage of diarrhoea in case of inter-current recovery, weight of child, daily record of frequency and consistency of stools, tolerance and acceptability of treatment were recorded in the study record forms.

A monthly observational follow-up data for two months included weight of child at monthly interval and any new episodes of diarrhoea in both the groups.

Statistical analysis

For statistical analysis, *t*-test was applied to measure the variation in means. *P* < 0.05 was taken as significant.

RESULTS

One hundred patients were analysed in the study, fifty patients in each group. Patient baseline characteristics in control and study groups were comparable (Table 1). Bacteria were isolated in 26% and 12% of the *S. boulardii* and control groups respectively while Rota virus detection

Table 2 Mean numbers of stools and duration of diarrhoea

	<i>S. boulardii</i>	Control	P value
Mean number of stools reported on d 0	9.5	8.8	0.37
Mean number of stools reported on d 3	2.8	4.4	0.01
Mean number of stools reported on d 6	1.6	3.3	0.001
Duration of diarrhoea (d)	3.6	4.8	0.001

Table 3 Number of episodes of diarrhoea

	<i>S. boulardii</i>	Control	P value
No. of episodes at 1 mo	0.2	0.64	0.001
No. of episodes at 2 mo	0.32	0.56	0.04

Table 4 Weight gain

	Group	% of mean weight gain	P value
% increase in wt. at 1 mo	<i>S. boulardii</i>	4.4	0.902
	Control	4.2	
% increase in wt. at 2 mo	<i>S. boulardii</i>	9.9	0.067
	Control	6.2	

revealed 16% and 20% positive for test and control group respectively.

On d 3 and d 6, there was a significant reduction in reported number of stools in *S. boulardii* group as compared to the control group. The mean duration of diarrhoea was 3.5 d in *S. boulardii* group and 4.8 d in the control group ($P = 0.001$) (Table 2).

Follow-up for the next two months also revealed interesting results. Mean numbers of episodes of diarrhoea by the end of two months, were 0.56 in control group as compared to 0.32 in *S. boulardii* group, which is almost half of that of control group (Table 3).

S. boulardii was well accepted and tolerated by the children and there were no reports of any side effects during the study period.

Table 4 also shows mean weight gain in both groups at mo 1 and 2. Although the difference of gain between the two groups has not reached statistical significance, the percentage of average increase in the experimental group was 9.9% as compared to 6.2% in the control group.

DISCUSSION

There are over 10^{9-12} bacteria per gram of faeces and about 400 different species, more than 10 times the human cells^[7]. The intestinal flora is intimately associated with the organ which contains it and with which it forms an ecosystem. Equilibrium within this ecosystem is essential to good health of the individual. It influences the structure, motility, physical and chemical conditions of intestinal tract, metabolic and enzyme activity of

mucosa and establishment and maturation of immune system. Finally and above all, the intestinal microbial flora forms a true resistance to colonisation of digestive tract by pathogenic microorganisms. Disruption of intestinal ecosystem occurs in many pathological situations such as infectious diarrhoea or diarrhoea and colitis linked to antibiotic treatment.

Despite awareness about preventive aspects of diarrhoea it remains one of the leading causes of morbidity and mortality in children, because of lack of clean water supply and sanitation.

Search for newer, less harmful agent is continued. Biological agents ("biotherapeutic agents" or "probiotics") have been used to treat a variety of infections, most notably infections of mucosal surfaces such as the gut and vagina. These biotherapeutic agents include certain bacteria and the yeast *S. boulardii*. Given orally, *S. boulardii* seem to be promising agents for the amelioration of the course of acute diarrhoea in children^[8].

The current study was based on our previous clinical observation, which revealed that children treated with *S. boulardii* had a decreased number of episodes of diarrhoea in following months.

This study verified our previous observation, as there was a 50% reduction in the number of episodes of diarrhoea in the treatment group as compared to control group (Table 2).

This study also showed a significant improvement in frequency and consistency of stool and reduction in duration of illness in patients who were given *S. boulardii* along with WHO-CDD protocol.

Several studies of *S. boulardii* have been done in children and adults in the treatment of acute diarrhoea^[9]. The results of our studies are consistent with some of these studies. However, the current study is the first one to observe the reduction in number of episodes of diarrhoea in the post-treatment follow-up period of two months. Stimulation of local immunity, as demonstrated by the increase of IgA, together with the enhancement of the trophic activity of the mucosa (through the release of polyamines) by *S. boulardii* may, at least in part, explain the long term effect of the yeast.

A meticulous follow-up of the patient resulted in very good compliance. No side effects were observed during the active treatment period with the use of *S. boulardii*. McFarland *et al* also highlight the safety profile in their review on *S. boulardii*^[10].

CONCLUSION

Based on our experience of this trial we conclude that *S. boulardii* is a useful and welcome addition to the treatment of acute diarrhoea in children. *S. boulardii* reduces the frequency of stool, and duration of illness. It also reduces the number of episodes of diarrhoea by 50% in the subsequent period of two months.

Though this is the first study of its kind in Pakistan, we are of the opinion that multicenter double blind placebo controlled trials need to be conducted to confirm our observations. Investigators have been using probiotics as

prophylaxis in childhood infection whereby it has been shown to reduce the rate of infection^[7,11].

ACKNOWLEDGMENTS

We would like to acknowledge with gratitude, support of Laboratoires Biocodex (France) and Hilton Pharma (Pvt.) Ltd. (Pakistan) for this study. Hilton Pharma also supplied *Saccharomyces boulardii* (Enflor) and logistic support for the follow up of patients during the course of the study.

Abstract

AIM: To demonstrate the necessity of intraoperative endoscopy in the diagnosis of secondary primary tumors of the upper digestive tract in patients with obstructive hypopharyngeal carcinoma.

METHODS: Thirty-one patients with hypopharyngeal squamous cell carcinoma had been operated, with radical intent, at our Institution in the period between 1978 and 2004. Due to obstructive tumor mass, in 7 (22.6%) patients, preoperative endoscopic evaluation of the esophagus and stomach could not be performed. In those patients, intraoperative endoscopy, made through an incision in the cervical esophagus, was standard diagnostic method for examination of the esophagus and stomach.

RESULTS: We found synchronous foregut carcinomas in 3 patients (9.7%). In two patients, synchronous carcinomas had been detected during preoperative endoscopic evaluation, and in one (with obstructive carcinoma) using intraoperative endoscopy. In this case, preoperative barium swallow and CT scan did not reveal the existence of second primary tumor within esophagus, despite the fact that small, but T2 carcinoma, was present.

CONCLUSION: It is reasonable to use intraoperative endoscopy as a selective screening test in patients with

obstructive hypopharyngeal carcinoma.

INTRODUCTION

The rate of synchronous primary cancers in the upper aerodigestive tract in the reported literature varies widely depending on the population surveyed and the thoroughness of the methods used to evaluate these patients^[1]. In 25 studies published over 25 years, the average rate of synchronous primary upper aerodigestive cancers was 4%, ranging from 1.5% to 18%^[2]. The relative risk of developing esophageal cancer in patients with head and neck cancer has been reported as being 3-20 times greater than that of control subjects from the general population^[3-5]. The phenomenon of neoplastic multicentricity could affect the therapeutic approach, and cause local treatment failure.

The aim of this study was to demonstrate the necessity of intraoperative endoscopy in the diagnosis of secondary primary tumors in upper digestive tract in the patients with obstructive carcinoma of the hypopharynx.

MATERIALS AND METHODS

In the period between January 1st, 1978 and January 1st, 2004, 31 patients with hypopharyngeal squamocellular carcinoma had been operated at the Department of Esophagogastric Surgery, First University Surgical Hospital, Clinical Center of Serbia. In most patients a complete preoperative work-up was performed. Tumor resectability was assessed by means of chest X-ray, barium swallow, esophagoscopy (flexible and rigid), tracheobronchoscopy, ENT evaluation, thoracic and neck CT scan and ultrasonography. In patients with obstructive

lesions, where preoperative esophagogastrosopic evaluation was not feasible, intraoperative endoscopy (with lugol staining method) through cervical esophagotomy was performed (Figure 1). Intraoperative endoscopy was performed in standard manner with diagnostic fiberoptic endoscope. Instrument was introduced in the esophagus through incision in the esophageal wall, made below lower border of the tumor. When tumor involved cervical esophagus and extended to the thoracic inlet, procedure was not feasible.

For the diagnosis of multiple separate (synchronous) primary carcinomas we followed standard criteria^[6]: (1) neoplasms must be clearly malignant as determined by histological evaluation; (2) each neoplasm must be geographically separate and distinct. The lesions should be separated by normal-appearing mucosa. If a second neoplasm is continuous to the initial primary tumor, or is separated by mucosa with intraepithelial neoplastic change, two lesions should be considered as confluent growth rather than multicentric carcinomas; (3) the possibility that the secondary neoplasm represents a metastasis should be excluded. The observation that the invasive carcinoma arises from an overlying epithelium, which demonstrates a transition from carcinoma *in situ* to invasive carcinoma is helpful, and when the separate foci have significant difference in histology, the diagnosis of separate primary cancer is appropriate.

RESULTS

Mean age of the patients in our study was 53.5 years (range 36-72 years). The male to female ratio was 1:2.1. The most common complaint was dysphagia (83.9%), indicating an advanced disease. We had no experience with stage I and II carcinoma. Stage III and IV accounted for 23 (74.2 %) and 8 (25.8%) respectively. Due to obstructive tumor mass, in 7 (22.6%) patients, preoperative contrast radiography was not conclusive, and preoperative endoscopic evaluation could not be performed. Obstructive tumors were predominantly localized in postcricoid region, and mostly infiltrating esophageal ostium. In those patients intraoperative endoscopy, made through incision on the cervical esophagus (below hypopharyngeal tumor), was standard diagnostic method for examination of the esophagus and stomach.

In our series, we found synchronous foregut carcinomas in 3 patients (9.7%), two of them with synchronous carcinoma of the thoracic esophagus, and one with stomach carcinoma. In two patients, synchronous carcinomas had been detected during preoperative endoscopic evaluation, and in one patient (with obstructive carcinoma) using intraoperative endoscopy. In this patient, preoperative barium swallow and CT scan did not detect existence of second primary tumor within esophagus despite the fact that small, but T2 carcinoma, was present.

DISCUSSION

With regards to risk factors for head and neck, or esophageal carcinomas, genetic factors and environmental factors, such as smoking and alcohol, have been reported

Figure 1 Intraoperative endoscopic evaluation through cervical esophagotomy, made just below the hypopharyngeal carcinoma.

to be important^[7,8]. These data suggest the concept of "field carcinogenesis"^[6]. According to Martins^[9] and Kumagai^[10] more than 70% of patients with synchronous hypopharyngeal carcinoma have second malignancy in the esophagus, but second gastric malignancy could not be detected. Kodama *et al*^[11] also reported high prevalence of synchronous carcinomas of the pharynx and esophagus. Gluckman *et al*^[12] recommended the use of panendoscopy in the evaluation of all head and neck cancers. Likewise, McGuirt^[13], Leipzig^[14], and Shapshay^[15] also recommended panendoscopy due to frequent association of head and neck, esophageal and lung carcinomas.

One of the most difficult problems we confront clinically, in the preoperative examination, is the subgroup of patients where esophageal and gastric fiberscopy (GIF) could not be performed due to obstructive hypopharyngeal mass. Without knowing the existence of multiple lesions, we cannot decide the proper therapeutic (surgical) plan. Martins *et al*^[9] reported that esophagoscopy and esophagography was attempted in 97% of patients in their series, but these examinations failed to evaluate the entire esophagus in 46% patients because of severe obstruction. In addition, very few patients (5 out of 36) underwent lugol staining during esophagoscopy. Although all patients were appropriately studied preoperatively, in only two cases multiple tumors were diagnosed before surgery. The remaining multiple synchronous carcinomas were obviously missed. Second primary tumor was, as a rule, located distal to the main obstructing carcinoma, preventing adequate total esophageal examination. Akiyama^[16] cited intraoperative esophagoscopy as an important step in such patients. However, this procedure is not possible when tumors widely infiltrate cervical esophagus. Intraoperative endoscopy made through incision below the tumor, could be performed in most patients with obstructive carcinoma of postcricoid region, even when tumors infiltrate the esophageal ostium.

To justify the selective use of intraoperative endoscopy as a diagnostic tool for patients with obstructive hypopharyngeal carcinoma, a number of issues need to be considered. The procedure should significantly improve the diagnosis of synchronous primary tumors when compared with non-invasive radiologic investigations, including barium swallow (BaSw) and chest computed tomography (CT) or magnetic resonance imaging (MRI). Symptom directed studies are not feasible because patients already have severe dysphagia due to obstructive proximal

Figure 2 Synchronous invasive carcinomas of the hypopharynx and thoracic esophagus.

carcinoma. In addition, second primary tumor could be of early stage and does not cause subjective symptoms even in absence of proximal obstruction. Kohmura *et al*^[6] support the view that in patients with obstructive hypopharyngeal carcinomas MRI should be performed. According to this data, esophageal mass lesions or hypertrophic mucosa detected by MRI require esophageal blunt dissection, due to possibility of multiple primary malignancies. In addition, Kohmura *et al*^[6] proposed that there is little chance of multiple malignancies in the esophagus if there are no abnormalities by MRI. They also pointed out that endoscopic evaluation is favorable whenever is feasible. However, many authors agree that the role of MRI in the examination of gastrointestinal tract, apart from the liver, is limited^[17,18]. CT has shown similar limitations in the diagnosis and staging of esophagogastric tumors with accuracy rate of only 60% or less^[19,20]. Many others^[21-23] agree that endoscopic ultrasonography (EUS) has clearly showed superior accuracy for T and N staging of esophageal and gastric carcinoma as compared with CT, but has the same limitations as endoscopic examination in the patients with obstructive tumors. Miniprobe sonography showed favourable results in the diagnosis and staging of esophageal tumors^[18], but unfortunately, in most institutions is not available in routine clinical practice.

The second issue to be addressed is whether the diagnosis of a second primary tumor would change the primary treatment approach for the individual patient. Panosetti *et al*^[24] in large series of patients, demonstrated that the discovery of a synchronous second primary tumor altered the treatment approach in 50% of patients. Many reports favour free jejunal interposition as a reconstructive method rather than gastric transposition^[25-27]. These approaches may leave behind a premalignant or malignant lesion in the esophagus. One of the strongest arguments for total pharyngolaryngoesophagectomy and gastric transposition is the presence, or possibility of synchronous or metachronous primary in the esophagus. But then, stomach should be completely evaluated by endoscopy and x-ray before surgery, due to possibility of presence of the malignant tumor within stomach. Since the stomach is commonly used for reconstruction of the digestive tract after esophagectomy, another substitute must be considered for patients with synchronous gastric cancer.

The third issue to consider is the prognosis of patients with synchronous primary tumors, and impact of detection

on overall survival. Advances in therapeutic methods have significantly improved local control rates. Still, many patients are developing distant metastases. Panosetti *et al*^[24] reviewed the impact of survival of patients with synchronous versus metachronous second primary tumors. In a large series, these authors demonstrated that patients who were initially seen with synchronous primary tumors had 5-year survival rates of 18% vs 55% for those with metachronous tumors. These suggest that the overall survival for patients with detectable synchronous primary is quite poor. Martins *et al*^[9] showed that more than 80% of second synchronous primaries were invasive carcinomas. In contrary, Kumagai^[10] and Kohmura^[6] found that most of the esophageal carcinomas accompanying advanced hypopharyngeal carcinomas were of early stage and that surgical excision could positively influence the prognosis. Thus, with the possibility of multiple intraesophageal cancer, endoscopic screening of the esophagus with lugol dye method in patients with head and neck cancer is necessary before treatment^[13,28,29]. In our series, single synchronous primary was relatively small, but invasive (pT2) tumor of the thoracic esophagus, was visible without lugol staining (Figure 2).

Considering low incidence of obstructive hypopharyngeal carcinomas and high sensitivity of intraoperative endoscopy in detection of second primary, there is no need to consider whether this diagnostic procedure is cost-effective or not. More important is that there are no complications related to the procedure. One of the things that might be of concern is potential contamination of the operating field during the procedure. In our experience there were no local infective complications associated with the procedure. Therefore, benefit of the procedure exceeds potential risk of local contamination.

In summary, it is reasonable to use intraoperative endoscopy as selective screening test in patients with obstructive hypopharyngeal carcinoma.

Abstract

AIM: To evaluate the prognostic value of some pathological variables in rectal cancer survival.

METHODS: 247 patients who underwent curative resection of rectal cancer were included in the study. The influence on survival of five pathological variables (histopathological tumor type, histopathological tumor grade differentiation, blood vessel invasion, perineural invasion and lymphatic invasion) was assessed using statistical analyses.

RESULTS: Overall 5-year survival was 71.2%. Univariate analysis of all tested variables showed an effect on survival but only the effect of lymphatic invasion was statistically significant. At stages three and four it had a negative effect on survival ($P = 0.0212$). Lymphatic invasion also significantly affected cancer related survival in multivariate analysis at stages three and four. At lower stages (stage 0, stage 1 and stage 2) multivariate analysis showed a negative effect of perineural invasion on cancer related survival.

CONCLUSION: Patients with lymphatic and perineural invasion have a higher risk for rectal cancer related death after curative resection. Examination of these variables should be an important step in detecting patients with a poorer prognosis.

INTRODUCTION

Rectal cancer is often a curable disease and survival is directly correlated with the stage of the tumor, assessed by indicating the depth of penetration of the tumor into the bowel wall (T stage), the extent of lymph node involvement (N stage), and the presence of distant metastases (M stage). Besides the degree of penetration and presence of nodal involvement or distant metastasis, many other clinical, histological and biomolecular variables have been evaluated in the prognosis of patients with rectal cancer, although most have not been prospectively validated^[1-3]. Among those, pathological factors are especially important as they may help to sub stratify tumors of same stage into different risk categories^[4].

In Slovenia as in most countries, patients with radically resected rectal cancer with negative lymph nodes do not receive adjuvant systemic therapy, since significant survival benefits have not yet been proven^[5]. One third of those patients, however, will develop local or distant metastases^[6]. Identifying such patients would be very important because they could benefit from adjuvant systemic treatment.

The aim of our study was to retrospectively examine five histopathological prognostic factors which are routinely assessed and which may help to identify patients who could be included in an adjuvant chemotherapy program.

Histopathological tumor type (H)

The majority of colorectal cancers are adenocarcinomas. Some subtypes, like mucinous carcinoma (defined in the recent TNM classification as tumors with mucinous areas comprising more than 50% of tumor), signet ring cell carcinoma, and undifferentiated carcinoma, have a worse prognosis than adenocarcinoma.

Degree of differentiation (G)

In some multivariate studies, the microscopic grade is predictive of survival; a higher grade is known to be associated with a significantly increased risk of an adverse outcome.

Blood vessel invasion (BVI)

Blood vessel (venous) invasion by tumor has been demonstrated to be a stage-independent adverse

prognostic factor by many analyses^[7-9]. However, some studies identifying venous invasion as an adverse factor on univariate analysis have failed to confirm its independent impact on prognosis in multivariate breakdowns^[12].

Lymphatic invasion (LI)

Similar disparate results have also been reported for lymphatic invasion^[10-11]. Therefore, data from existing studies are difficult to interpret. Nevertheless, the importance of venous and lymphatic invasion by the tumor is strongly suggested and largely confirmed by the literature^[4].

Perineural invasion (PNI)

PNI may influence prognosis after resection of rectal cancer. An abundant extramural autonomic nerve network is an anatomical feature of the rectum. The evidence for the importance of perineural invasion is weaker than for blood vessel or lymphatic invasion but it has been shown in some series to be a predictor of both local failure and worse survival^[13-15].

MATERIALS AND METHODS

Since 1998, data from all rectal cancer patients in our institution have been simultaneously registered in specially designed protocols, which contain preoperative, operative and postoperative parts and detailed pathological report.

The stage of the rectal cancer was defined according to the recent TNM classification^[16].

Blood vessel invasion was considered positive if the following criteria were fulfilled: tumor cells at endothelial surface, tumor cell thrombi inside the lumen of the vessel or destruction of the vascular wall by tumor. Lymphatic invasion was defined as positive when tumor cells were found within endothelium-lined space devoid of mural smooth muscle or elastic fibers. Perineural invasion was considered positive when tumor cells were detected along, or around, a nerve within the perineural space.

Data from all patients who were operated on between January 1998 and December 2003 were analyzed. Over this period 512 patients with rectal carcinoma underwent surgery, but only 247 patients were eligible for the study, which included patients with elective radical resection of a solitary rectal tumor who survived the first month after the operation.

All patients were followed up on regular basis: at 3 mo intervals during the first 2 years, at 6 mo intervals until 5th year and then yearly. Clinical examination, tumor markers (CEA and CA19-9) and ultrasound were performed at each appointment. Chest X-ray was performed every 6 mo during first 2 years and then yearly. Colonoscopy was performed yearly after the operation. Follow up was updated on March 1st 2005.

We analyzed the following pathological variables: Histopathological tumor type, tumor grade or differentiation (well, moderately well, poorly differentiated and undifferentiated), blood vessel invasion, lymphatic and perineural invasion (present or absent).

Mortality data was acquired from the Slovenian cancer

register and cause was verified for each deceased patient.

The research received approval from our ethics committee.

Survival was calculated using the Kaplan-Meier method and compared by log-rank test. Multivariate analysis was performed using Cox's regression model. All analyses were performed using statistical software SPSS for Windows 10.0.

RESULTS

The main operative procedures for rectal cancer in our institution are radical low anterior resection and abdominoperineal resection. Both procedures are executed according to principles of total mesorectal excision.

All patients were postoperatively managed by oncologists. The majority of patients with stage 3 and 4 disease received postoperative chemotherapy if there were no general contraindications.

The mean follow up time was 1055 days. The basic demographic analysis is shown in Table 1.

Most of the patients had stage 2 disease (47%), 29% had stage 3 and 22% stage 1. Only one percent of patients were at stage 0 and stage 4, as shown in Table 2.

5-year cancer related survival was calculated using Kaplan-Meier method and was 71.4% for all stages.

For stage 1, survival was 91%, for stage 2 74%, for stage 3 51% and for stage 4 33% (Figure 1).

For further analysis patients were divided into two groups according to stage. One group consisted of patients with stage zero, one and two tumors, and the second group consisted of patients with tumor stage three and four (Table 3).

The histopathological type of tumor and the degree of differentiation affected survival in lower and higher stages but this difference was not statistically significant.

Vascular and perineural invasion also showed no effect on 5-year survival in lower and higher stages.

Lymphatic invasion showed no effect on survival in lower stages but in higher stages, positive lymphatic invasion had a statistically significant negative effect on survival (log rank, $P = 0.0212$) (Figure 2).

Table 3 Univariate survival analysis of pathological variables according to stage

Variable	All Cases		LOWER STAGES (Stages 0, 1 and 2)		HIGHER STAGES (Stages 3 and 4)

Negative	188	86	76		68	

Figure 1 Cumulative 5-yr cancer related survival of all radically operated rectal cancer patients calculated with Kaplan-Meier method.

Figure 2 5-yr survival of radically operated rectal cancer (stage three and four) related to the presence or absence of lymphatic invasion. The difference is statistically significant ($P < 0.005$). Kaplan-Meier method.

Multivariate analysis

Using Cox regression model on all previous variables we obtained different results for the different stages. Examining patients with higher stages we again confirmed that lymphatic invasion is an important prognostic variable. In multivariate analysis, lymphatic invasion clearly emerged as a strong negative prognostic factor ($P = 0.022$).

On the other hand, when patients with lower stages were considered, another variable, perineural invasion, seemed to have the greatest effect on survival ($P = 0.036$).

DISCUSSION

Rectal cancer is one of the leading causes of cancer-related deaths in the developed world^[17].

Slovenia has one of the highest incidences of rectal cancer (men: 23.7 per 100 000, women 14.9 per 100 000). In 2001 there were 383 new cases of rectal cancer detected

and 128 cancer-related deaths^[18].

We know that more than two-thirds of patients with newly detected rectal cancer will undergo curative primary tumor resection and more than half will eventually die from the disease following surgery^[19]. Survival is clearly dependent on rectal cancer stage but there are many other variables that could help us in predicting outcome. During recent years there were many studies and methods which focused on identification of factors that could influence postoperative survival after curative rectal cancer resection. These include serial sectioning, immunohistochemistry, and polymerase chain reaction assays. Examining all regional lymph nodes with these methods would be preferred, but is expensive and time consuming and therefore not feasible in daily practice.

Sentinel node-mapping offers a potential solution. It has been introduced in colorectal cancer to improve staging by facilitating occult tumor cell assessment in lymph nodes

that are most likely to be tumor-positive^[20]. However, there is a large variation in identification rates and false-negative rates usually ascribed to the learning curve effect, differences in technique and tumor stage.

Compared to the methods described above, pathological variables, as assessed in this work, may have some advantages. They are not expensive and do not need any special resources.

In our study, lymphatic and perineural invasion were pathological variables that were significantly associated with poorer outcomes in high and low stage groups, respectively. The importance of lymphatic invasion was already recognized in the late 1980's. Minsky found that it was an independent prognostic factor by proportional hazard analysis^[21]. The importance of lymphatic invasion was confirmed in some later studies but also denied in others^[22]. In our work it had a clearly negative effect on survival in a univariate analysis. In a multivariate analysis, the negative effect was seen only in patients with node positive rectal cancer. We assume that positive lymph nodes facilitate lymphatic invasion that could precipitate further spreading of the disease.

According to available data, perineural invasion may influence the prognosis after resection of rectal cancer^[13]. In our work perineural invasion was associated with shorter survival in patients with lower stages of tumors. It is possible that the influence of positive perineural invasion in higher stages is masked by the importance of other parameters, and thus its role is clearly seen only in lower stages.

We must, however, mention some limitations of our study. First, although we report a 5-year overall survival, our median follow-up was 1055 d. However, we have used the Kaplan-Meier method to estimate 5-year survival. Second, we performed a retrospective study, and therefore our conclusions are limited by the bias inherent in an analysis of this nature.

In conclusion, additional pathological variables deserve more research to validate whether they will be helpful in predicting outcomes in rectal cancer patients. They are not expensive, are performed routinely and do not need any special resources. They could help with the identification of patients who would be predicted to have a poorer prognosis after curative resection of rectal cancer, who accordingly might benefit from adjuvant oncological treatment.

Abstract

AIM: To analyze the incidence of digestive system cancer in Changle of China over a 15-year period.

METHODS: The datasets were presented as time-series of China-standardized annual incidence during 1988-2002. Linear regression model was used to analyze the incidence of stomach, liver, esophagus and colorectal cancers.

RESULTS: Linear regression models for the time-series of stomach and esophagus cancer incidences for both men and women were statistically significant ($P < 0.05$); Regression models for liver cancer and for colorectal cancer were statistically significant for men ($P < 0.05$).

CONCLUSION: The incidence rates of stomach and esophagus cancers for both men and women had down tendencies. For men, liver cancer had a down trend of the incidence and colorectal cancer had an upward trend of the incidence rate.

INTRODUCTION

Cancer is the first cause of death in Fujian Province of

China, and the proportion of cancer-related deaths is the highest. The mortalities of malignant digestive system tumors in Changle during 1988-1991 were the highest in Fujian Province and the incidence (per 100 000 persons) of stomach, liver, esophagus and colorectal cancers in Changle is 104.3%, 37.3%, 25.6% and 7.4%, respectively^[1]. Since 1988, efforts have been made in prevention and treatment of tumors^[2]. However, the patterns and incidence of malignant digestive system tumors in Changle are not available. Monitoring and studying the incidence of malignant tumors can provide important information for prevention and control of tumors. Therefore, the aims of the present study were to examine the pattern and time trends of stomach, liver, esophagus and colorectal cancers from 1988-2002 in Changle.

MATERIALS AND METHODS

Cancer incidence data

Annual stomach, liver, esophagus and colorectal cancer cases were provided by the Tumor Registration Office of Changle. Data of the age- and sex-specific population in Changle were provided by the local police station. The incidence of these tumors was standardized with the age- and sex-specific population obtained from the National Population Overall Survey in 1983. The datasets were presented as time-series of China standardized annual incidence during 1988-2002.

Statistical analysis

Linear regression model was used to analyze the incidence of stomach, liver, esophagus and colorectal cancer. The SAS software package was used for all analyses^[3].

RESULTS

Standard incidence of digestive system cancer in men and women of Changle is shown in Table 1. The incidence of stomach, liver and esophagus cancer in men decreased with fluctuation while that of colorectal cancer increased slowly from 1988 to 2002 (Figures 1A and 1B). On average, the incidence of stomach, liver and esophagus cancer in males decreased 3.44%, 3.16% and 6.07%, respectively. The incidence of these tumors except for stomach cancer in females was not significantly different (Figure 1C). The incidence of stomach, liver and esophagus cancer in women decreased 2.21%, 1.20% and 2.50%, respectively. The incidence of colorectal cancer in men increased 5.51% from 1998 to 2002.

Table 1 Standard incidence of digestive system cancer per 100 000 persons in 1988-2002 in Changle (%)

Yr	Stomach cancer		liver cancer		Esophagus cancer		Colorectal cancer	
	Male	Female	Male	Female	Male	Female	Male	Female
1988	106.63	28.54	32.62	10.48	20.22	6.36	3.1	6.3
1989	114.41	36.55	35.09	9.87	24.96	8.18	4.96	4.69
1990	109.09	29.59	51.86	10.76	28.81	12.48	5.93	4.56
1991	103.21	34.52	38.62	12.78	30.76	9.95	4.89	1.18
1992	100.81	26.1	32.47	7.66	25.52	7.45	2.44	4.11

2001	74.28	27.71	33.12	5.17	11.15	4.29	9.12	5.38
2002	65.33	20.88	20.81	8.85	8.41	4.46	6.57	8.03

Table 2 Incidence of four tumors both in men and women in Changle from 1988 to 2002 (%)

Disease	Men			Women		
	Regression coefficient	R ²	P	Regression coefficient	R ²	P
Stomach cancer	3.16	0.851	< 0.001	0.72	0.415	0.009
Liver cancer	0.83	0.286	0.04	0.16	0.061	0.374
Esophagus cancer	1.33	0.736	< 0.001	0.48	0.567	0.001
Colorectal cancer	0.29	0.391	0.013	0.12	0.1	0.251

The incidence of digestive system tumors both in men and in women was analyzed by linear regression models (Table 2). The regression coefficients for both men and women, except for colorectal cancer, were negative. The incidence of stomach and esophagus cancer in both men and women decreased ($P < 0.05$). The incidence of liver cancer was decreased in men ($P < 0.05$) but not in women. The incidence of colorectal cancer increased in men ($P < 0.05$) but not in women.

DISCUSSION

This report presents the time-series analysis of standardized annual incidence of digestive system cancers in Changle City of China from 1988 to 2002. The incidence of stomach and esophagus cancers in men and women decreased 3.44% and 2.21%, respectively. The incidence of liver cancer decreased 3.16% in men but not in women. The incidence of colorectal cancer increased 5.51% in men but not in women.

The incidence of stomach and esophagus cancers in men and women decreased in Changle of China from 1988 to 2002, suggesting that the decreased incidence of these tumors is due to the development of economy and effect of tumor prevention in Changle. Epidemiological studies have shown that economic level and dietary habits are

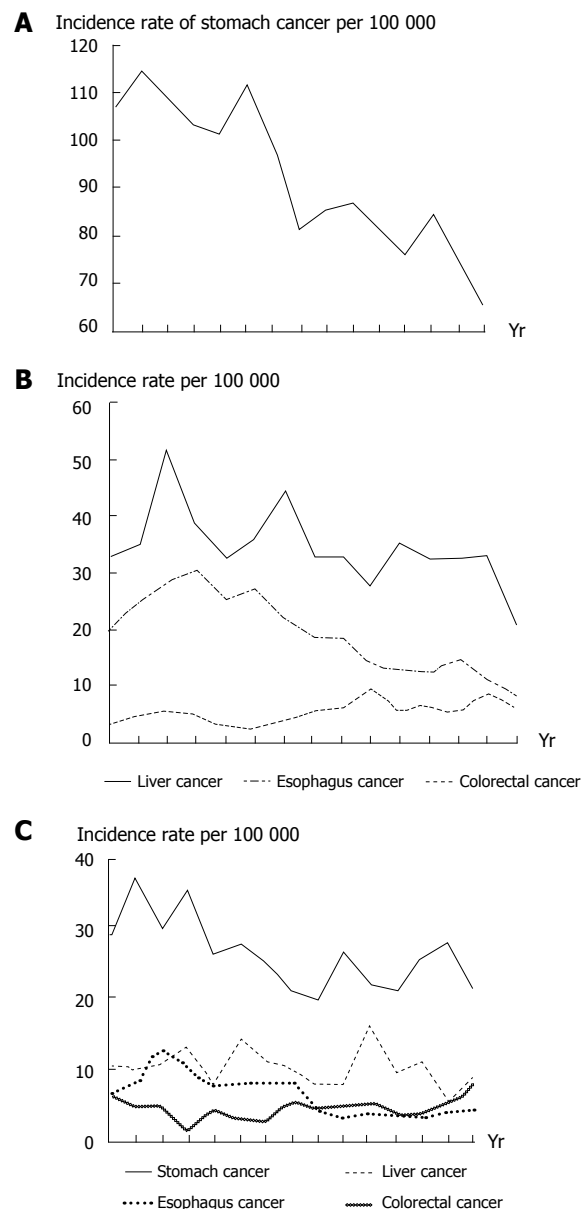

Figure 1 Incidence of stomach cancer (A) and liver, esophagus, colorectal cancer (B) in men, and four tumors (C) in women of Changle from 1988 to 2002.

associated with the incidence of stomach and esophagus cancer^[2,5-7]. Stomach cancer is the most common cancer in Japan and the Japanese have the highest mortality and incidence of stomach cancer in the world. The incidence and mortality of stomach cancer have declined in Japan^[4,8]. The incidence of stomach cancer in a region is related to both economic level and dietary habits. Before 1980s, people in Changle of China had a low living standard and were accustomed to eating salted food and low protein and vitamin C diet. As the economical level is raised and knowledge of tumor prevention is spread in Changle, the people have changed their dietary habits which plays an important role in decreasing the incidence of stomach and esophagus cancer. During 1988-2002, stomach cancer incidence decreased about 38.73% in males and 26.84% in females, and esophagus cancer incidence decreased about 58.41% in males and 29.87% in females in Changle of China. However, stomach cancer is still the most

common cancer in Changle and its incidence in males is still the highest in China although the disease incidence is declined. Therefore, research on preventive factors, such as eating habits, foods, additives, drug use, prevalence of *Helicobacter pylori* infection and environment pollution, is needed.

Our study showed that the digestive system cancer incidence was different in Changle. The incidence of stomach and esophagus cancer declined while colorectal cancer incidence increased in Changle, which is in accordance with the incidence in Japan^[11]. Colorectal cancer incidence tends to increase in males of Changle, and the incidence of the disease in males in 2002 was 2.12 times higher than that in 1988. Colorectal cancer is common in many developed countries^[12,13]. Countries where the people have a high fat intake also have high colorectal cancer incidence^[14]. High fat intake is a risk factor for colon polyp which may progress to colorectal cancer^[15], and 15%-25% of colorectal cancer cases may be attributable to high fat intake^[16]. Moreover, high vegetable and fruit consumption and less meat consumption are associated with a reduced incidence of colorectal cancer^[17-19]. Therefore, a variety of dietary interventions may have a positive impact on dietary behaviors associated with cancer risk^[20].

During 1988-2002, the incidence of liver cancer in males and females were 34.66% and 10.19% in Changle, respectively. It was reported that the incidence of liver cancer is decreased^[21] and liver cancer incidence is increased in China^[22,23].

The incidence of digestive system cancer is different in different areas of China. The reasons for the declined incidence remain unclear. Elimination of HBV-cofactors is likely to contribute to it. However, some risk factors for liver cancer, including smoking and alcohol consumption, are still highly prevalent in males in Changle of China. Therefore, our results might be affected by the lowest incidence in 2002. To confirm whether liver cancer incidence is decreased, further observations are required.

Abstract

AIM: To study the effects of chitosan gel and blending chiton/gelatin film on preventing peritoneal adhesion in rats.

METHODS: SD rats were randomly divided into 2 groups, group A treated with chitosan gel and group B with blending chiton/gelatin film. In group A, rats were randomly subdivided into 3 subgroups as groups A1, A2 and A3, and different methods were used to induce peritoneal adhesions at the dead end of vermiform process in each group as follows: Group A1 with trauma, A2 with talc powder and A3 with ligation of blood vessel. In each subgroup, rats were redivided into control group and experimental group whose treated vermiform processes were respectively coated with chitosan gel and normal saline immediately after the adhesion-induced treatments. In group B, all the rats received traumatic adhesion-induced treatments and then were randomly divided into 4 groups (groups B1, B2, B3, B4). Group B1 served as control group and were coated with normal saline in the vermiform processes immediately after the treatments, and groups B2, B3 and B4 with 100% chitosan film, chitosan film containing 10% gelatin and chiton film containing 50% gelatin, respectively. At 2 and 4 wk after the above treatments, half of the rats in each terminal group were belly opened, and the peritoneal adhesive situation was graded and histopathological changes were examined.

RESULTS: (1) In group A, regarding peritoneal adhesion situation: At both 2 and 4 wk after the treatments, for groups A1 and A3, the adhesive grades of experimental groups were significantly lower than those of the control group (2 wk: $H = 4.305$, $P < 0.05$ for A1, $H = 6.743$, $P < 0.01$ for A3; 4 wk: $H = 4.459$, $P < 0.05$ for A1, $H =$

4.493, $P < 0.05$ for A3). However, of group A2, there was no significant difference between the experimental and control groups (2 wk: $H = 0.147$, $P > 0.05$; 4 wk: $H = 1.240$, $P > 0.05$). Regarding pathological changes: In groups A1 and A3, the main pathological change was fibroplasia. In group A2, the main changes were massive foreign-body giant cell reaction and granuloma formation with fibroplasia of different degrees. (2) In group B, regarding degradation of film: With increase of the blended gelatin concentration, degrading speed of the film accelerated significantly. Regarding peritoneal adhesion situation: At both 2 and 4 wk after the treatments, the adhesive grades of B1 were the lowest among the four subgroups of B (2 wk: $H = 29.679$, $P < 0.05$; 4 wk: $H = 18.791$, $P < 0.05$). At 2 wk after the treatments, the grades of group B2 were significantly lower than that of groups B3 and B4 ($H = 4.025$, $P < 0.05$ for B2 vs B3; $H = 4.361$, $P < 0.05$ for B2 vs B4). At 4 wk, there were no significant differences of the grades between groups B2, B3 and B4. Regarding pathological changes: Inflammatory cell infiltration and fibroplastic proliferation were observed in the local treated serous membranes, which was the mildest in group B1. Slight foreign-body giant cell reactions were also found in groups B2, B3, and B4.

CONCLUSION: (1) Chitosan gel has preventive effect on traumatic or ischemic peritoneal adhesion, but no obvious effect on foreign body-induced peritoneal adhesion. (2) Chitosan film may exacerbate the peritoneal adhesion. Blending with gelatin to chitosan film can accelerate the degradation of the film, but can simultaneously facilitate the formation of peritoneal adhesion.

INTRODUCTION

Chitosan is the derivant of the chitin after deacetylation, and chitin is a main ingredient of the arthropod shells (such as shrimps, crabs and insects, etc), which is a kind of renewable natural resources and profuse in amount.

Since chitosan is innocuous, biodegradable and with ideal biocompatibility, it has been applied to develop biomaterials^[1,2]. In medical field, chitosan has antiseptic function and can facilitate the healing of wound. It has been widely studied on its potential use to be medical biomaterials. Because of its inhibitory effect on fibroblast growth and the function of mechanical isolation^[3], chitosan has been regarded highly in the prevention of peritoneal adhesion. To evaluate the effects of different types of chitosan on preventing traumatic peritoneal adhesion, a control study in rats was done in this paper.

MATERIALS AND METHODS

Experimental animals and grouping

Two hundred and forty SD rats, 120 females and 120 males, weighing 200-250 g, were provided by the Laboratory Animal Center of Zhejiang Province. They were randomly divided into group A (144 rats) and group B (96 rats). Group A was treated with chitosan gel and group B with blending chiton/gelatin film. In Group A, 144 rats were randomly divided into 3 subgroups (groups A1, A2, A3) with 48 rats in each. Different methods were used to induce peritoneal adhesion in the dead ends of the vermiform processes as follows: group A1 with trauma, group A2 with talc powder and group A3 with ligation of blood vessel. For each subgroup, 48 rats were randomly redivided into control group and experimental group with 24 rats in each. In group B, all the 96 rats received traumatic adhesion-induced treatments as group A1 and then were randomly divided into 4 groups (groups B1, B2, B3, B4) with 24 rats for each. Group B1 served as control group and groups B2, B3, and B4 served as experimental groups treated with 100% chitosan film, chitosan film containing 10% gelatin and chiton film containing 50% gelatin, respectively.

All the rats were fed under the same condition: 24°C -26°C of environmental temperature, about 40% of humidity, alternating 12 h light/dark cycle, free access to food and water.

Surgical methods: Under general anaesthesia with intraperitoneal injection of 3% amobarbital (60 mg/kg), the rats were immobilised in dorsal position, routinely degermed, abdominally incised through a median incision of 2-3 cm long, and the vermiform processes were searched and pulled out of the incision, then the terminal vermiform processes within a distance of 3 cm were treated as follows: In group A1, the anterior surface of serous membrane was scraped slightly with surgical blade till obvious congestion and small bleeding drops appeared. In group A2, talc powders were evenly smeared over the anterior surface of serous membrane. In group A3, the vermiform artery stem was ligated with No 0 surgical thread at the point of 3 cm from the dead end in the following way: loosely knotting the first loop, thrilling a thread with equivalent diameter to the vermiform artery stem through the first loop, tightening the first loop, knotting and tightening the second loop of the ligation knot, and pulling out the thrilled thread. The ligation resulted in a stricture of vermiform artery which induced ischemia of the distal vermiform tissue from the

ligation point. This method had been proved successful in inducing peritoneal adhesion in our former experiments. After the above treatments, for the experimental groups, the treated serous membranes within 3 cm distance from the dead ends were coated with chitosan gel in a dosage of 0.5 mL for each, and the vermiform processes were put back into the abdominal cavities, which were then closed. For the control groups, all the treatments were the same as those of the experimental groups except that the chitosan gel was replaced by normal saline. The duration from opening to closing the abdominal cavity was 5 min, so that the duration of exposure of intestines to air was the same for each rat. In group B, of all the rats, the anterior surfaces of vermiform processes were scraped slightly with surgical blade just as group A1, and the scraped surfaces of B2, B3, B4 were coated with films containing different percentages of gelatin at 0%, 10%, and 50% respectively. Group B1 was treated with normal saline as control. The duration from opening to closing the abdominal cavity was controlled just for 5 min.

At 2 and 4 wk after the surgery, 12 rats (6 females and 6 males) in each subgroup were randomly selected respectively for further study. The abdominal cavity was reopened under anaesthesia, and the grades of peritoneal adhesion were evaluated which existed between the treated vermiform processes and intestines, mesenteria and abdominal walls. After that, the vermiform processes with adhesions were resected, fixed with formalin and histopathologically examined.

Grading standard for the peritoneal adhesion

Referring to Phillips^[4] grading method of 5 levels and considering the characteristics of peritoneal adhesion in rats, we offered the following grading standard: Grade 0: no adhesions; Grade I: the ratio of adhesive area/the total treated area in the vermiform processes < 20%; Grade II: the ratio is about 40% Grade III: the ratio is about 60%; Grade IV: the ratio is $\geq 60\%$. Each rat was graded by three referees blindly and the average grade of the three was accepted as the adhesive grade of the rat.

Statistical analysis

The H-test of non-parametric statistics for ranked grouped data was used to analyze the differences of the peritoneal adhesive grades between the experimental and control groups. $P < 0.05$ was taken as significant.

RESULTS

Group A

Observation with naked eyes: The skin incisions of all rats healed in first grade. No obvious infection appeared in the abdominal cavity in all rats. In the experimental groups, no obvious residual of chitosan gel could be found at 2 wk after surgery.

Comparison of peritoneal adhesion level: As it shows in Table 1, in groups A1 (trauma-induced adhesion) and A3 (ischemia-induced adhesion), peritoneal adhesion grades of the experimental groups were significantly lower than those of the control groups ($P < 0.05$ or $P < 0.01$) both at 2 and 4 wk after the surgical treatments. While in

Table 1 Comparison of peritoneal adhesion between experimental and control groups in groups A1, A2, and A3

Group		Experimental group (total <i>n</i> = 12)					Control group (total <i>n</i> = 12)					<i>H</i>	<i>P</i>
		0	I	II	III	IV	0	I	II	III	IV		
A1	2 wk	1	7	4	0	0	5	6	1	0	0	4.305	< 0.05
	4 wk	2	7	3	0	0	6	6	0	0	0	4.459	< 0.05

A3	2 wk	0	5	5	2	0	2	8	2	0	0	6.743	< 0.01
	4 wk	2	5	4	1	0	6	5	1	0	0	4.493	< 0.05

Table 2 Comparison of peritoneal adhesion in group B rats

Group	<i>n</i>	2 wk (<i>n</i>)					4 wk (<i>n</i>)				
		0	I	II	III	IV	0	I	II	III	IV
B1	24	1	7	4	0	0	2	7	3	0	0
B2	24	1	3	3	4	1	0	3	3	5	1
B3	24	0	0	2	4	6	0	2	2	3	5
B4	24	0	0	0	2	10	0	2	1	5	4
<i>H</i>		29.679					18.791				
<i>P</i>		< 0.05					< 0.05				

group A2 (talc powder-induced adhesion), there was no significant difference in the peritoneal adhesion between the experimental and control groups ($P > 0.05$) both at 2 and 4 wk. The above results indicated that chitosan gel has perfect effect on preventing peritoneal adhesion induced by trauma and ischemia, but no obvious effect on adhesion induced by talc powder.

Comparison of pathological changes: In group A1, at 2 wk after the surgical treatments, there existed obvious fibroplasia and diffused lymphocytes infiltration in the treated serous membrane of the vermiform processes. While at 4 wk after the treatments, the main pathological change was fibroplasia. The above pathological changes in the experimental group were obviously milder than those in the control group. In group A2, at 2 wk, massive foreign-body giant cell reaction (FBGCR) and granuloma formation appeared in the treated vermiform processes with diffuse inflammatory cell infiltration. At 4 wk after the surgical treatment, foreign body granuloma and fibroplasia reaction aggravated with crystal appearing in the foreign-body giant cell. There was no significant difference in the adhesive severity between the experimental and the control groups. In group A3, 2 wk after the surgical treatments, full-thickness fibroplasias and lymphocyte infiltration appeared in the vermiform processes which was more severe in the serous layer. While at 4 wk after the treatment, the lymphocyte infiltration became lighter, but the fibroplasias aggravated obviously. The above pathological changes in the experimental group were obviously milder than that in the control group 2 wk after the treatment. However, at 4 wk, there was no significant difference between the experimental and control groups.

Group B

Observation with naked eyes: The skin incisions of all

rats healed in first grade. No obvious infection appeared in the abdominal cavities at 2 wk after the treatments in all rats. Chitosan film degradation: In group B2, no obvious changes occurred in the chitosan film at 2 wk, and even no obvious rupture could be found in the film at 4 wk after the surgical treatments. The films were only swollen and thinned at 4 wk. In group B3, the films with 10% gelatin were swollen at 2 wk, and degraded into fragments at 4 wk after the treatments. In group B4, the films with 50% gelatin were broken into pieces at 2 wk, and disappeared at 4 wk after the surgical treatments.

Comparison of peritoneal adhesion degree: As listed in Table 2, both at 2 wk and 4 wk after the surgical treatments, there existed significant differences among the four groups ($P < 0.05$) in the peritoneal adhesive degree. At 2 wk, all the differences were significant between every 2 groups ($P < 0.05$) except between groups B3 and B4. At 4 wk, there were significant differences between groups B1 and B2, B1 and B3, B1 and B4 ($P < 0.05$), but there was no significant difference between groups B2 and B3, B2 and B4, B3 and B4 ($P > 0.05$). All the above results indicated that both pure chitosan film and blending chiton/gelatin films could exacerbate peritoneal adhesion, as well as the blended gelatin.

Comparison of pathological changes: (1) At 2 wk after the surgical treatments, the adhesive vermiform processes of all rats were mainly with various degrees of edema, dilation and congestion of capillaries, infiltration of inflammatory cell and fibroplasias. The reaction became severer in the serous membrane than in other layers. The reactions in groups B2, B3, and B4 were more severe than those in group B1. There were slight foreign-body giant cell reaction in groups B2, B3 and B4 (Figure 1). (2) At 4 wk after the treatments, the acute inflammatory reaction decreased obviously in all groups except group B1. In all the other groups (B2, B3 and B4), the fibroplasia was aggravated obviously which caused formation of complete fibrous capsules around the implantation, with a thickest capsule wall in group B4 and a thinnest one in group B2. Furthermore, groups B2, B3, and B4 had obvious foreign-body giant cell reaction (Figure 2).

DISCUSSION

Peritoneal adhesion is an inevitable phenomenon of the natural repairing processes after peritoneal injury. In recent years, many researches have been done on the process and mechanism of peritoneal adhesion. To understand the

Figure 1 Histopathologic changes of the four B-groups at 2 wk after the surgical treatment.

Figure 2 Histopathologic changes of the four B-groups at 4 wk after the surgical treatment.

mechanism of peritoneal adhesion is very important for the prevention of its formation.

Animal studies indicated that the serous membrane injury caused by mechanical injury, ischemia of tissue, stimulation of foreign body and peritonitis was the main reason of peritoneal adhesion. However, whether it results in permanent fibrinous adhesions or not depends on the integrity of the fibrinolytic system^[5,6]. Generally speaking, the formation of peritoneal adhesion needs the following steps: step 1 is the formation of fibrinous gelatinous matrix. This happens within 3 h after the injury. The gelatinous matrix locates among the injured peritoneal membranes, which is the initiation of peritoneal adhesion. Step 2 occurs between 1-5 d after the injury. The fibrinous matrix is gradually replaced by the vascular granular tissues which contain fibroblasts, macrophagocytes and giant cells. Most of the fibrins disappear and are replaced by a large number of fibroblasts and collagen fibers, and then the fibrin network is formed. Step 3 takes place during 5-10 d after the injury. The fibroblasts acquire a regular alignment gradually and the collagen deposition is enriched. Step 4 is at 2 wk after the injury. The component cells, especially the fibroblasts, decrease obviously and are covered by mesothelial cells. Eventually, the fibrinous adhesions are formed. However, after peritoneal injury, the fibrin can be decomposed by fibrinolysin into fibrin degradation products (FDPs) in the course of fibrinous gelatinous matrix formation, which is unrelated with peritoneal adhesion. It generally occurs at 72-76 h after the injury. In brief, when peritoneal injury occurs, whether the wounds heal through adhesive fusion or through epithelization, mainly depends on the degree of local fibrinolysis and whether epislonal juxtaposition exists^[7].

Based on how and why the peritoneal adhesion happens, more than 10 preventive methods have been proposed. Among them, mechanical isolation seems to have the brightest prospect. At present, close attention has been paid to the following 4 materials which are used as mechanical isolation: EPTEE, oxidized regenerated cellulose (ORC), HA-CMC and chitosan^[8,9]. Chitosan is highly regarded as a biomaterial for prevention of peritoneal adhesion, because it has the functions of anti-infection, hemostasis, inhibiting growth of fibroblasts, mechanical isolation and moreover, it is biodegradable.

Chitosan is the derivant of deacetylated chitin. Chitin was discovered in 1811. Its molecular structure was determined by chemical method and X-ray diffraction in 1887. Chitin can be converted into chitosan after deacetylation. Chitosan is soluble, easily to be chemically modified because it contains many amid and hydroxyl. Meanwhile, this kind of natural polysaccharose is alkaline and has good biocompatibility and is biologically degradable. Its degradation products are acetylglucosamine and aminoglucose, which are atoxic for human bodies. The low molecular weight of chitosan and its oligosaccharide produced during degradation render it to have no immunogenicity and not to accumulate *in vivo*. The biological activity of chitosan mainly includes: (1) inhibiting the growth of bacteria and mold; (2) antineoplastic activity: It can selectively agglutinate the L1210 cells in leukemia and Ehrlich's cells in carcinomatous ascites, but does not affect the normal erythroid bone marrow cells; (3) immunological enhancement: It can efficaciously enhance the function of macrophages and the activity of hydrolase, stimulate the macrophage to produce lymphokine and initiate the immune response. But it cannot promote the production

of antibody; (4) anticoagulant activity: The chitosan after thioesterification has a similar chemical structure with heparin so that it has a good anticoagulant activity; (5) promoting tissue repair and hemostasis: Since the degrading product of chitosan is charged, it can induce platelet aggregation and activate the coagulation system. Chitosan can inhibit fibrous hyperplasia during wound healing and efficaciously enhance wound healing. Animal experiments in recent years have proven that chitosan gel has good effect in preventing peritoneal adhesion^[3,4].

All the 3 different animal models of peritoneal adhesion used in our study were monofactor-induced peritoneal adhesion, which made the study of effects of chitosan on preventing peritoneal adhesion due to different causes technologically possible. Observation at 2 and 4 wk after the surgical treatments in all the control groups showed that the incidence of peritoneal adhesion was 90.9% and 83.3% respectively, and most of the adhesions were graded as I and II. This proved that the animal model was reliable and stable.

In our study, different chitosan materials were used for the prevention of peritoneal adhesion, which turned out to have completely different results. Because the peritoneal adhesions in each group were caused by different methods, different preventing effect was observed. In group A (treated with chitosan gel), the chitosan gel film had satisfactory effects on the prevention of peritoneal adhesion due to injury or ischemia. At 2 wk after the treatments, the chitosan gel was completely biologically degraded. Moreover, the peritoneal adhesion level and pathological change in both groups A1 and A3 were milder than those in the control groups. This indicated that the chitosan gel had an evident preventing effect against peritoneal adhesion due to injury or ischemia. In group A2 (adhesions induced by talc powder), both histopathologic examination and adhesion grades indicated that the chitosan gel had no evident preventing effects on peritoneal adhesion induced by talc powder. The probable cause may be related with the pathological change in adhesions induced by talc powder, which mainly was foreign body granuloma reaction with massive fibroplasias. As long as the foreign body existed, the foreign body granuloma and fibroplasia reaction would remain persistent. Since the chitosan gel could be fastly degraded *in vivo* (within 2 wk after surgery), the acting time of the chitosan gel was too short to prevent against persistent foreign body granuloma reaction.

Chitosan gel is still imperfect because it is highly flowable. When chitosan gel is smeared at the surface of wounded peritoneum, it cannot come to a high concentration in the focus, resulting in weakened effect since its acting time is shortened. In order to improve the concentration of chitosan in the intraabdominal focus and make a more thoroughly mechanical isolation, some researchers used pure chitosan film instead to get a better effect on peritoneal adhesion prevention. However, our study indicated that such effort was disappointing.

In Group B2 (treated with pure chitosan film), at 4 wk after the treatments, the chitosan film was still undegraded. Such slow degrading speed was detrimental for an anti-peritoneal adhesion material because if the postsurgical

initial membranous adhesions cannot be degraded in time, it will form irreversible fibrinous adhesions, which cannot be inhibited by chitosan. On the contrary, the intraabdominal residual of undegraded chitosan film can evoke the foreign body reaction and result in fibrous capsule formation, which facilitates the formation of peritoneal adhesion. These were proved in our study: the adhesion grade in group B2 was higher than that in control group, and histopathologic examination indicated obvious foreign-body giant cell reaction at 2 and 4 wk after the surgical treatments.

Because the slow degradation of chitosan film weakened its anti-adhesive function, blending chiston/gelatin film was suggested to improve the *in vivo* degradation speed of chiston film. And experiments proved that the more gelatin added in the film, the more fastly the blending film *in vivo* degraded. However, there have been no experimental data about the effect of the blending chiston/gelatin film on the prevention of peritoneal adhesion.

Gelatin is a polypeptide mixture which is soluble in hot water. It is widely used in medical field as haemostat and dermagraft and dressing materials of wounds because it can be degraded quickly *in vivo*. In our study, the blending chiston/gelatin films with different concentration of gelatin were used in group B2 (10% gelatin) and B4 (50% gelatin), and the results indicated that the higher concentration of gelatin in the film, the more fastly it was degraded in the abdominal cavity of rats. However, our study indicated that the anti-peritoneal adhesion effect of the blending film was not ideal. The peritoneal adhesion grade was not only lower than that of the control group, but also lower than that of group B2 (with pure chiston film). The probable reasons are: although the blending chiston/gelatin film had a faster degradation speed, the film still could not be completely degraded even at 4 wk after the treatments in group B3 and at 2 wk in group B2. The residual blending film may cause foreign body reaction. In addition, gelatin is a polypeptide mixture which is probably antigenic and can cause immunological rejection. This in turn promotes and facilitates the formation of local peritoneal adhesions.

We conclude that: (1) Chitosan gel has perfect effect on preventing peritoneal adhesion due to injury or ischemia, but no evident effect on peritoneal adhesion induced by talc powder; (2) Pure chitosan film could not prevent peritoneal adhesion because of low *in vivo* degradation speed; (3) Chitosan film blended with gelatin could exacerbate peritoneal adhesion.

Abstract

AIM: To explore the anti-inflammatory mechanism of Diammonium Glycyrrhizinate in a rat model of ulcerative colitis induced by acetic acid.

METHODS: Sprague-Dawley female rats were divided into four groups: Diammonium Glycyrrhizinate group, dexamethasone group, acetic acid control and normal control group. Colonic inflammation was evaluated by disease activity index, gross morphologic damage, histological injury and colonic myeloperoxidase activity. Immunohistochemistry was used to detect the expression of NF- κ B, TNF- α and ICAM-1 in colonic mucosa.

RESULTS: Compared to the acetic acid control, both Diammonium Glycyrrhizinate and dexamethasone showed a significant anti-inflammatory effect ($P < 0.01$). The expression of NF- κ B, TNF- α and ICAM-1 in colonic mucosa was significantly lower in the Diammonium Glycyrrhizinate group and dexamethasone group than in the acetic acid group.

CONCLUSION: Diammonium Glycyrrhizinate could reduce inflammatory injury in a rat model of ulcerative colitis. This may occur via suppression of NF- κ B, TNF- α and ICAM-1 in colonic mucosa.

INTRODUCTION

Traditional drugs for ulcerative colitis, though quite effective, may exert severe side-effects. New therapeutic agents with less side-effects would be very useful. Diammonium Glycyrrhizinate (DG) is a substance that is extracted and purified from a traditional Chinese medicinal herb. The herb has been used traditionally for the treatment of hepatitis due to its anti-inflammatory effect, resistance to biologic oxidation, membranous protection and a weak steroidal action. However, it was not known whether DG might also be effective in other inflammatory conditions, such as ulcerative colitis. To explore a possible anti-inflammatory effect of DG in ulcerative colitis, the expression of NF- κ B, TNF- α and ICAM-1 in colonic mucosa was detected by immunohistochemistry in a rat model.

MATERIALS AND METHODS

Materials

Female SD rats were purchased from the Center of Experimental Animals in the 89th Hospital of PLA. NF- κ B, TNF- α and ICAM-1 antibodies and immunohistochemistry kits were purchased from Beijing Zhongshan Biotech Company. MPO kit was purchased from the Institute of Nanjing Jiancheng Biotechnology. DG was purchased from Jiangsu Chia Tai Tianqing Pharmaceutical Co., LTD (X20010756, DG0267).

Methods

Preparation of animal model: Forty SD rats were divided into four groups: DG group, dexamethasone group, acetic acid control and normal control group. All rats were fasted for twenty-four hour. Before the colonic infusion of acetic acid, 0.3 mL (30 mg/kg) Sodium pentobarbital was injected peritoneally. A polyethylene catheter was put into the colon extending a distance of eight centimeters beyond the anus. For DG, dexamethasone, and the acetic acid control groups, 1 mL of 10% (v/v) acetic acid was

Table 1 Morphologic injury scoring system

Morphologic injuries	Score
Local edema and congestion without ulcer	1
One ulcer without congestion or thick colonic wall	2
One ulcer with inflammation	3
Two ulcers, lesion diameter less than 1 cm	4
More than two ulcers with or without inflammation, lesion diameter 1-2 cm	5
Lesion diameter over 2 cm, one more score for one additional 1 cm increasing diameter	6-8

infused into the colon through this catheter^[1], held in place for 30 s, and then flushed with 5 mL normal saline. Only normal saline was infused into the colon in the normal control group. In the DG group, 40 mg/kg DG was injected intraabdominally every day for one week; in dexamethasone group, 0.2 mg/kg dexamethasone was injected intraabdominally cavity daily for one week; in the acetic acid control and normal control groups, equal volumes of normal saline were injected into the abdominal cavity daily for one week.

Preparation of colonic tissue samples: Seven days after acetic acid infusion, the body weight of each rat was measured and recorded. The distal colon was removed at the level of 8 cm from the anus. Samples were evaluated by morphological scores, and then cut into two parts-one for H&E staining and immunohistochemistry, the other for the detection of MPO activity.

Evaluation of colonic inflammation: Colonic inflammation was evaluated seven days after acetic acid infusion by disease activity index (DAI), morphologic injury, histological changes, and MPO activity. DAI was calculated as the sum of scores assigned as follows: percentage of body weight reduction (0: no change, 1: 1%-5%, 2: 6%-10%, 3: 11%-15%, 4: > 15%), Stool consistency (0: normal, 2: loose, 4: diarrhea) and the presence of fecal blood (0: normal, 2: positive occult blood test, 4: visible bleeding)^[2]. Morphologic injury was evaluated using the scoring system reported by Dieleman, with slight modifications^[3] (Table 1). Ten fields were selected randomly to estimate histological injury according to the scoring system listed in Table 2^[4]. A kit was used to detect MPO activity in the colonic mucosa.

Immunohistochemical detection of NF- κ B p65, TNF- α and ICAM-1: The expression of NF- κ B p65, TNF- α and ICAM-1 in colonic mucosa was detected by a SP immunohistochemistry kit. On each slide, five fields ($\times 400$) were selected randomly and the percentage of positive cells was counted among 1000 cells. The average of positive cells in five fields was the determined.

Statistical analysis

Data are presented as mean \pm SD, and statistical differences among groups were tested using the SPSS statistical software package. Based on the result of a test of homogeneity of variances, one-way ANOVA and SNK-q test were applied to test differences between different groups. A *P* value of 0.05 was set as the level of statistical significance.

Table 2 Histological scoring system

Histological changes	Score
Normal colonic mucosa	0
Cryptal defect less than 1/3	1
Cryptal defect 1/3-2/3	2
Slight inflammatory infiltration in proper lamina	3
Mucosal erosion or ulcer with significant inflammatory infiltration	4

Table 3 DAI, morphologic injury, histological changes, and MPO activity in rats assigned to the different treatment groups

Group	DAI	Morphologic injury	Histological changes	MPO activity (U/g tissue)
DG	3.10 \pm 0.54 ^{b,d,f}	2.80 \pm 0.76 ^{b,d,f}	3.22 \pm 0.88 ^{b,d,f}	0.67 \pm 0.06 ^{b,d,f}
Dexamethasone	1.90 \pm 0.43 ^{b,d}	1.70 \pm 0.54 ^{b,d}	1.76 \pm 0.59 ^{b,d}	0.38 \pm 0.05 ^{b,d}
Acetic acid control	6.70 \pm 0.84 ^b	6.30 \pm 0.95 ^b	5.96 \pm 0.97 ^b	1.32 \pm 0.09 ^b
Normal control	0.60 \pm 0.38	0.60 \pm 0.52	0.74 \pm 0.56	0.19 \pm 0.05

^b*P* < 0.01, vs Normal control group; ^d*P* < 0.01, vs Acetic acid control group; ^f*P* < 0.01, vs Dexamethasone group.

RESULTS

DAI, morphologic injury, histological changes, and MPO activity

1-2 d after colonic infusion of acetic acid, rats displayed diarrhea, pyemic stool, and reduced body weight. Morphologically, a dilated lumen, thickened wall, and brown or black color was observed continuously in the injured bowel. Edema, erosions, necrosis, superficial ulcerations, crypt abscesses, and inflammatory infiltration into the lamina propria were observed in the injured segment by light microscopy. In Table 3, according to DAI, scores of morphological and histological changes, and MPO activity, the colon showed significant pathogenic changes in the DG, dexamethasone, and acetic acid control groups compared to the normal control group that received saline alone (*P* < 0.01), which demonstrated that acetic acid infusion results in injuries that are comparable to those seen in humans with ulcerative colitis. These inflammatory indices were significantly improved by DG and dexamethasone (*P* < 0.01). The anti-inflammatory effect of DG was significantly lower than that of dexamethasone (*P* < 0.01).

Expression of NF- κ B p65, TNF- α and ICAM-1 in injured colon

In rats that received acetic acid, NF- κ B p65 was positive mainly in nuclei of most endothelial cells, epithelial cells and mononuclear cells, especially in the mucosa and submucosa. TNF- α and ICAM-1 were positive mainly in the cytoplasm, membrane and rarely in nuclei. ICAM-1 was positive in most endothelial cells and macrophages. TNF- α positive cells, including mononuclear cells, macrophages and neutrophils, were located densely in lamina propria and in proximity to the muscularis. The percentage of cells positive for these three molecules was significantly correlated.

Table 4 Expression of TNF- α , ICAM-1 and NF- κ B p65 in injured colon

Group	TNF- α		ICAM-1		NF- κ B p65	
	Percentage	Density	Percentage	Density	Percentage	Density
DG	32.2 \pm 8.2 ^{b,d,f}	37.3 \pm 7.0 ^{b,d,f}	34.3 \pm 8.2 ^{b,d,f}	36.1 \pm 6.1 ^{b,d,f}	23.3 \pm 5.2 ^{b,d,f}	31.2 \pm 7.8 ^{b,d,f}
Dexamethasone	17.9 \pm 5.6 ^{b,d}	19.0 \pm 5.2 ^{b,d}	18.7 \pm 5.7 ^{b,d}	18.5 \pm 5.2 ^{b,d}	15.5 \pm 4.3 ^{b,d}	17.6 \pm 4.9 ^{b,d}
Acetic acid control	52.5 \pm 9.1 ^b	74.1 \pm 9.5 ^b	60.2 \pm 8.3 ^b	70.7 \pm 9.7 ^b	44.5 \pm 8.9 ^b	51.5 \pm 9.8 ^b
Normal control	7.6 \pm 5.7	9.0 \pm 4.8	9.1 \pm 4.4	9.4 \pm 4.9	7.6 \pm 4.1	8.1 \pm 4.2

^b $P < 0.01$, vs Normal control group; ^d $P < 0.01$, vs Acetic acid control group; ^f $P < 0.01$, vs Dexamethasone group.

ted with the degree of inflammatory injury (Table 4), and these markers were rarely expressed in samples taken from the normal control group. The positive percentage and density of NF- κ B p65, TNF- α and ICAM-1 in injured colon was significantly higher than that in normal control. After DG or dexamethasone treatment, the positive percentage and density of these molecules were reduced significantly, which indicates that both DG and dexamethasone may inhibit the expression of these molecules. Also, the expression of these molecules was significantly lower in DG treated samples than in dexamethasone treated samples ($P < 0.01$).

DISCUSSION

DAI, morphologic injury and histological changes are usually applied to evaluate the severity of inflammatory injuries. MPO reflects the activity of neutrophils, which is also a good indicator of the acute inflammatory reaction^[5,6]. According to the indices mentioned above, a rat model of ulcerative colitis (acute phase) was induced by colonic infusion of acetic acid in these experiments. Compared with the acetic acid control group, these inflammatory indices were significantly improved by treatment with DG or dexamethasone.

To understand the molecular mechanism of the effect of DG in this experimental model, the expression of NF- κ B, ICAM-1 and TNF- α was detected by immunohistochemistry. All of these molecules are known to be upregulated in the acute inflammatory cascade, which plays an important role in the pathogenesis of ulcerative colitis^[7]. Activation of NF- κ B is key to the expression of many proinflammatory cytokines and adhesive molecules including ICAM-1 and TNF- α ^[8-11]. ICAM-1 induces the migration and infiltration of inflammatory cells into the lesion^[12,13], while TNF- α causes apoptosis of the colonic mucosa^[14,15]. Both ICAM-1 and TNF- α represent different key points in the progress of inflammatory injuries^[16,17]. TNF- α , ICAM-1 and NF- κ B were upregulated in the acetic acid control group, but reduced significantly after DG or dexamethasone treatment, which means that inhibition of these molecules was likely important for the protective effect of DG and dexamethasone.

As reported previously, NF- κ B is a key molecule in both the initiation and progression phase of the inflammatory reaction^[18,19]. Activated NF- κ B translocates into the nucleus and induces the expression of proinflammatory cytokines, adhesive molecules and chemokines. In this rat model, the expression of NF- κ B was inhibited by

both DG and dexamethasone, which means that the anti-inflammatory mechanism of DG may be similar to that of dexamethasone. Though the efficacy of DG was less than that of dexamethasone, its side-effects are expected to be less severe.

In summary, DG was efficacious in experimental ulcerative colitis induced in rats, and associated with insignificant side effects. This result suggests that DG may be a promising drug candidate for the treatment of ulcerative colitis.

Abstract

AIM: To investigate the expression of vascular endothelial growth factor-c (VEGF-C) mRNA and microvessel density (MVD) in human esophageal squamous cell carcinoma (ESCC) and its relationship with clinical significance.

METHODS: Specimens obtained from 43 patients undergoing surgical resection for ESCC were used in this study. The expression of VEGF-C mRNA was examined by *in situ* hybridization. Tumor MVD was determined immunohistochemically with anti-CD31 antibody and estimated by image analysis. Ten sections of adjacent normal mucosa were also examined.

RESULTS: VEGF-C mRNA expression was detected in cytoplasm of carcinoma cells. Of the 43 ESCC patients studied, 18 cases (41.9%) were positive for VEGF-C mRNA. No VEGF-C mRNA expression was observed in normal esophageal mucosa. VEGF-C mRNA expression correlated significantly with lymph node metastasis, TNM stage and depth of invasion ($P < 0.05$). Furthermore, histological grade (differentiation) tended to correlate with VEGF-C mRNA expression, but was not statistically significant ($P > 0.05$). In tumor lesions, the MVD was significantly greater than that in normal esophageal mucosa. MVD correlated significantly with lymph node metastasis, TNM stage and depth of invasion ($P < 0.05$), but not with histological grade (differentiation) ($P > 0.05$). Lesions with VEGF-C mRNA expression had a significantly higher MVD than that of those without VEGF-C mRNA expression ($P < 0.05$).

CONCLUSION: VEGF-C plays a role in lymphatic metastasis via lymphangiogenesis and angiogenesis in ESCC. VEGF-C is one of the important predictors of the biological behavior in ESCC.

INTRODUCTION

Lymph node metastasis is an important prognostic factor for human esophageal squamous cell carcinoma (ESCC)^[1]. Angiogenesis induced by a variety of growth factors such as vascular endothelial growth factor (VEGF), has been recently considered necessary for the growth, invasion and metastasis of solid tumors^[2]. Thus, measurement of vascular growth may be clinically important in esophageal cancer specimens. To assess angiogenesis, several markers of blood vessel endothelium have been developed for microscopic estimation of microvessel density (MVD) by immunohistochemistry, including CD31/PECAM-1, CD34, and factor VIII-related antigen (von Willebrand factor or vWF)^[3]. VEGF-C, a member of the VEGF family, stimulates the proliferation of both vascular and lymphatic endothelial cells via VEGF receptor (VEGFR)-2 and VEGFR-3 in many physiological and pathological processes^[2,4]. Previous reports have shown that VEGF-C expression in cancer tissues has a positive correlation with the risk of lymphatic metastasis in a variety of cancers^[5] including prostatic^[6], gastric^[7], oral^[8], lung^[9], colorectal^[10,11] and bladder carcinoma^[12]. A similar tendency has been reported for esophageal cancers, although a significant correlation between VEGF-C expression and the frequency of nodal metastasis is not always found^[13-15]. Hence, the precise role of VEGF-C in ESCC has not been clearly understood^[1]. Therefore, in the present study, VEGF-C mRNA expression in biopsy specimens of ESCC was examined by *in situ* hybridization (ISH) and the association between VEGF-C mRNA expression and clinicopathological factors, including the intratumoral microvessel density (MVD) as a measure of tumor angiogenesis in ESCC was investigated.

MATERIALS AND METHODS

Patients and tumor specimens

Tumor specimens from 43 ESCC patients (32 males and 11 females, mean age 62.5 years, range 47-76 years) undergoing surgical treatment in Jinhua People's Hospital from 1997 to 2002 were included in the study. Specimens were classified according to the TNM classification system by UICC and 10 normal esophageal tissues were collected as control. None of the patients received any radiotherapy or chemotherapy prior to the study. Histological grades, depth of invasion and lymph node metastasis are shown in Table 1.

Methods

In situ mRNA hybridization (ISH) analysis was performed as described previously with minor modifications^[16]. VEGF-C specific oligonucleotide probes were labeled with digoxin at the 5'-end and synthesized by Beijing Dingguo Co. Ltd (Dingguo, Beijing, China). The DNA oligonucleotide sequences used are 5'-TGTACAAGT GTCAGCTAAGG-3' and 5'-CCACATCTATACACAC CTCC-3'. Tissue sections (4 μ m-thick) were incubated with 50 mg/L proteinase K, and then hybridization was performed in a moist chamber for 16 h at 45°C, using a probe concentration of 100 ng/L. The sections were then incubated with a staining solution containing NBT/BCIP in a dark box for 1-2 h. Negative controls were performed in all cases by omitting the probes.

A mouse CD31 mAb (JC/70A, DAKO Corporation, Denmark) was used as a vascular endothelial marker^[3,17]. Immunohistochemical examination for CD31 was performed with EnVision kits to access MVD. In brief, after deparaffinization and rehydration, the sections were denatured for 3 min in a microwave oven in citrate buffer (0.01 mol/L, pH 6.0) for antigen retrieval. Endogenous peroxide activity was quenched with hydrogen peroxide, and the sections were incubated with goat serum for 20 min at room temperature to block nonspecific binding of anti-CD31 mAb (JC/70A, 1:50 dilution) and then for 16 h at 4°C at 1:50 dilution. Bound antibodies were detected by the EnVision system (DAKO Corporation, Denmark) and using 3, 3'-diaminobenzidine as the chromogen while nuclei were counterstained with hematoxylin. Negative controls were obtained by omission of the primary antibodies.

The results of ISH and MVD were examined by two of the authors with no prior knowledge of the identification of each section, using Leica Qwin image system (Leica Corporation, Germany). The expression of VEGF-C mRNA in the tissue was defined as positive if distinct staining was observed in at least 10% of tumor cells^[18]. For determination of MVD, the number of microvessels with positive reaction to JC/70A was counted in five randomly selected microcopy fields on the vascular areas within a section ($\times 200$, 0.7386 mm²/field) and the average was then calculated.

Statistical analysis

The data were evaluated by *t* test, Fisher's exact probability

Table 1 Correlation between VEGF-C mRNA expression in ESCC tissue and clinicopathological factors

Clinicopathological factors	<i>n</i>	VEGF-C mRNA <i>n</i> (%)	MVD/mm ² (mean \pm SD)

test or chi square test. *P* < 0.05 was considered statistically significant for all tests. All statistical analyses were performed using the SPSS 10.0 statistical package (SPSS, Inc, Chicago, IL).

RESULTS

Expression of VEGF-C mRNA in ESCC tissues

Of the 43 patients studied, 18 cases (41.9%) were positive for VEGF-C mRNA expression in cytoplasm. The specimens were divided into two categories by the staining pattern of VEGF-C mRNA, diffuse or focal staining of carcinoma cells (Figures 1A and 1B). In contrast, no VEGF-C mRNA in specimens of adjacent normal esophageal mucosa was stained.

CD 31 expression and MVD in ESCC tissues

Immunohistochemical expression of CD31 was detected in cytoplasm of vascular endothelial cells. Brown capillaries or small clusters standing out sharply from other tissues were found to be microvessels (Figures 2A and 2B). At the deepest invasive site of tumors, the MVD ranging 43-144/mm² (76.4 \pm 20.3/mm²) was significantly higher than that in normal esophageal mucosa (*P* < 0.01).

Correlation between VEGF-C mRNA expression and MVD and clinicopathological factors

VEGF-C mRNA expression in ESCC tissues was associated with the depth of tumor invasion, TNM stage and lymph node metastasis (*P* < 0.05), but not with histological grade (*P* > 0.05). Furthermore, MVD also correlated with TNM stage and lymph node metastasis in ESCC tissue (*P* < 0.05). No association was found between MVD and depth of tumor invasion and histological grade (*P* > 0.05). The patients were divided into VEGF-C mRNA positive and negative groups. The VEGF-C mRNA positive cases showed a higher MVD (79.5 \pm 30.9/mm²) than the VEGF-C mRNA negative cases (57.5 \pm 18.4/mm²) (*P* < 0.05) (Table 1).

Figure 1 Focal (A) and diffuse (B) expression of VEGF-C mRNA in ESCC tissue as blue granules in cytoplasm of tumor cells (*in situ* hybridization $\times 400$).

DISCUSSION

Recent studies have shown a significant relation between MVD, VEGF expression and prognosis in a variety of tumors including esophageal carcinoma^[19]. Among the VEGF family members, VEGF-C appears to affect the lymphatic system as a ligand for VEGFR-3, which is specifically expressed on lymphatic vessels, and VEGF-C is suspected to play an important role in lymphangiogenesis^[2,4,5]. But little is known about the mechanisms of lymphangiogenesis and lymphatic metastasis, while the effects of VEGF-C in ESCC remain controversial^[1]. In this study, we investigated the clinicopathological significance of VEGF-C mRNA expression in relation to the angiogenesis in ESCC. The results showed that 41.9% of patients with ESCC had expression of VEGF-C mRNA, which correlated significantly with lymph node metastasis, depth of tumor invasion and TNM stage, suggesting that VEGF-C plays a role in ESCC. It was reported that VEGF-C can be detected using immunohistochemical staining and RT-PCR, and VEGF-C expression in ESCC may play a key role in tumor progression and lymphatic metastasis^[13,14]. It was also reported that only histological grade, but not parameters involved in lymphatic spread, correlates with VEGF-C expression in ESCC^[15]. These contradictory findings can be explained by difference in analytic method. Even in immunohistochemical analysis, the result may differ depending on the selected site for assessment.

More interestingly, we found that VEGF-C mRNA expression was significantly correlated with MVD, indicating the grade of angiogenesis in ESCC. Tsurusaki *et al*^[6] and Akagi *et al*^[18] have failed to find any remarkable differences in blood vessel density between VEGF-C positive and negative prostatic and colorectal carcinoma specimens. Also, VEGF-C expression is not correlated with MVD in human gallbladder cancer^[20]. Whereas other studies reported that VEGF-C is associated with angiogenesis in breast cancer^[21], colorectal carcinoma^[22,23] and bladder transitional cell carcinoma^[12], and plays an important role in angiogenesis and lymphangiogenesis in lung cancer^[9] and malignant mesothelioma^[24]. It has been reported that VEGF-C can bind to both VEGFR-2 and VEGFR-3^[25]. The specificity of VEGF-C for its 2 receptor is known to be regulated by proteolytic processing.

Figure 2 Immunohistochemical staining of CD 31 in normal esophageal (A) and ESCC (B) tissue (EnVision $\times 400$).

Accordingly, only fully processed VEGF-C activates both VEGFR-2 and VEGFR-3, whereas the partially processed precursors act only through VEGFR-3^[26]. Activation of VEGFR-2 results in mitogenesis of vascular endothelial cells, whereas VEGFR-3 activation by VEGF-C is considered to induce proliferation of lymphatic endothelial cells. Furthermore, recent studies have revealed that VEGFR-3 is expressed in angiogenic blood vessels in certain pathological conditions. For example, VEGFR-3 expression can be detected in intratumor blood vessels of human breast cancer^[21], cutaneous melanoma^[27], head and neck squamous cell carcinoma^[28], gliomas as well as in vascular endothelial cells activated during formation of granulation tissue in skin^[29]. Thus, angiogenesis and lymphangiogenesis responses to VEGF-C have been found to depend on the expression of its receptors in blood and lymphatic endothelial cells of the target tissue.

In our present study, patients with VEGF-C mRNA expression had a significantly higher MVD than those without VEGF-C mRNA expression, suggesting that VEGF-C secreted from tumor cells may stimulate not only lymphangiogenesis but also angiogenesis, which are significantly correlated with lymph node metastasis in ESCC. As a rule, once cancer cells enter blood microvessels, they can reach regional lymph nodes through lymphatic vessels from blood vessels, via blood vessel-lymphatic vessel junctions. In fact, the lymphatic and vascular systems have numerous connections allowing disseminating tumor cells to pass rapidly from one system to the other. Furthermore, metastatic tumor cells expressing VEGF-C could grow in regional lymph nodes that they reached.

In conclusion, VEGF-C mRNA is expressed heterogeneously in tumor cells and plays an important role in angiogenesis and lymphangiogenesis, as well as growth and metastasis of ESCC. The combined examination of VEGF-C expression and MVD in biopsy specimens from ESCC patients can predict lymph node metastasis and select appropriate treatments.

Abstract

Endoscopic visualisation of gastric atrophy is usually not feasible with conventional endoscopy. Magnifying endoscopy is helpful to analyze the subepithelial microvascular architecture as well as the mucosal surface microstructure without tissue biopsy. Using this technique we were able to describe the normal gastric microvasculature pattern and we also identified characteristic patterns in two cases of autoimmune atrophic gastritis.

INTRODUCTION

Endoscopic visualisation of gastric atrophy is usually not feasible with conventional endoscopy. Except for the absence of rugae and visible vessels in the gastric corpus, macroscopic features, as observed during gastroscopy, are of very limited value in the evaluation of the presence of gastric atrophy^[1]. Although histology may be considered as a gold standard for detection of gastric atrophy, neither the original nor the revised version of the Sydney system reliably identifies more than half of the cases in patients

with confirmed atrophy^[2].

Magnifying endoscopy is a helpful procedure to analyze the subepithelial microvascular architecture as well as the mucosal surface microstructure without tissue biopsy^[3]. Using this technique we were able to observe the normal gastric microvasculature pattern and we also identified characteristic patterns in two cases of autoimmune atrophic gastritis.

CASE REPORT

Two male patients (aged 53 and 62 years), underwent upper gastrointestinal endoscopy due to anaemia and low serum B12 levels. Endoscopy was performed using the GIF-Q240Z (Olympus, Keymed, UK) high-resolution magnifying endoscope ($\times 115$ on a 20" screen, 7.9 μm resolution). Prior to endoscopy, a soft black hood was mounted on the tip of the scope, to enable the endoscopist to fix the focal distance at 2 mm between the tip of the scope and the gastric mucosa. Ordinary endoscopic findings were normal, however, magnified observation of the gastric mucosa showed normal gastric antral microvasculature (coil-shaped subepithelial capillary network (SECN) pattern) (Figure 1A), with disappearance of the normal honeycomb-like SECN and irregular collecting venules and areas of tubular structures in the gastric body mucosa (Figures 1B). Targeted biopsies from the gastric body showed glandular atrophy, intestinal metaplasia and inflammatory infiltrate in the gastric corpus, sparing the antrum, as in autoimmune gastritis (Figure 1C). On the other hand, the histological findings in the biopsied specimens from the antral mucosa showed no pathological changes. Histology showed no *Helicobacter pylori* micro-organisms. Serum anti-parietal cell antibodies were positive.

DISCUSSION

Autoimmune gastritis is characterized by autoimmune destruction of fundic and body glands. The marker for the most severe, end-stage form of diffuse corporal atrophic gastritis is pernicious anemia^[4]. However, no endoscopic findings specific for this entity have been reported.

The microvascular pattern of human gastric mucosa has recently been investigated^[5-7]. The normal gastric body and fundus mucosal microvessels show two major components: (1) subepithelial capillaries; and (2) collecting venules. Polygonal loops of subepithelial capillaries surround the neck of gastric pits. These loops form a honeycomb-like SECN and converge onto mucosal collecting

Figure 1 A: Magnified view of gastric antral mucosa in our patient. All parts of the antral mucosa demonstrated a coil-shaped subepithelial capillary network (SECN) in regular arrangement; B: Magnified endoscopic view of the gastric body mucosa in our patient. Loss of the normal SECN and collecting venules (arrows) in irregular shape and arrangement were evident. These findings are compatible with those of gastric atrophy; C: Histology reveals decreased density of glands, loss of specialised glands in the gastric body; D: Magnified view of normal gastric body mucosa in another healthy patient. Honeycomb-like SECN with collecting venules in regular arrangement can be seen clearly.

venules that drain down into the submucosa (Figure 1D). In the antral mucosa, the normal subepithelial capillaries form a coil-shaped network, while collecting venules are rarely seen.

Yao *et al* have demonstrated that the resolution of the GIF-Q240Z gastroscope is 7.9 μm . Since the minimal diameter of subepithelial capillaries in the gastric mucosa, as described in anatomic studies, is 8 μm , this endoscope is ideally suited to visualize microvessels and capillaries^[6].

Nakagawa *et al* have recently studied the usefulness of magnifying endoscopy for the diagnosis of *H. pylori*-induced histopathologic gastritis^[8]. The observed morphology of collecting venules was divided into the 3 patterns: (1) regular (R), which had the qualities of regularity in venules size, visible second or third order branches, and a uniform distance between venules; (2) irregular (I), which had the qualities of irregularity in size, inability to observe second or third order branches, and a lack of a uniform distance between the collecting venules, with venules sometimes fused to adjacent venules and sometimes lying horizontally; and (3) obscured (O), in which no collecting venules were visible. Observation of an R pattern indicates an absence of *H. pylori* infection and histopathologic gastritis. Observation of an O or I pattern indicates the presence of histopathologic gastritis from *H. pylori* infection, and an I pattern suggests the presence of gastric mucosal atrophy. We have also shown that in cases of gastric atrophy associated with *H. pylori* infection, the normal honeycomb-like subepithelial capillary network (SECN) in gastric body disappears and the collecting venules become irregular^[9].

The magnified endoscopic findings of diffuse atrophy in gastric body mucosa and normal antrum associated with autoimmune gastritis have not yet been described. In our cases, the magnified views in gastric antrum revealed a normal coil-shaped subepithelial capillary network. On the other hand, in gastric body mucosa we demonstrated loss of the normal honeycomb-like SECN pattern with irregular collecting venules, suggestive of corporal gastric atrophy, as well as areas with tubulovillous structures as seen in intestinal metaplasia. These magnified endoscopic findings were constantly detected in all parts of the gastric corpus that were examined. These patterns are suggested to be

characteristic of autoimmune gastritis and were confirmed by histology.

In summary, it seems that irregular collecting venules can be recognised both in autoimmune- and *H. pylori*-associated gastric atrophy. The dissemination of this finding can be used to help differentiate between these two types of gastritis. Gastric body predominant atrophy visualised by magnifying endoscopy, can be very useful in making a precise diagnosis of autoimmune gastritis.

Abstract

Leiomyomas are the most common benign tumors of the esophagus. They usually occur as a single lesion or as two or three nodules. Only two cases of esophageal multiple leiomyomas comprising more than 10 nodules have been reported previously. Moreover, there have been few reports of esophageal squamous cell carcinoma overlying submucosal tumors. We describe a 71-year-old man who was diagnosed as having a superficial esophageal cancer coexisting with two or three leiomyoma nodules. During surgery, 10 or more nodules that had not been evident preoperatively were palpable in the submucosal and muscular layers throughout the esophagus. As intramural metastasis of the esophageal cancer was suspected, we considered additional lymphadenectomy, but had to rule out this option because of the patient's severe anoxemia. Microscopic examination revealed that all the nodules were leiomyomas (20 lesions, up to 3 cm in diameter), and that invasion of the carcinoma cells was limited to the submucosal layer overlying a relatively large leiomyoma. This is the first report of superficial esophageal cancer coexisting with numerous solitary leiomyomas. Multiple minute leiomyomas are often misdiagnosed as intramural metastasis, and a leiomyoma at the base of a carcinoma lesion can also be misdiagnosed as tumor invasion. The present case shows that accurate diagnosis is required for the management of patients with coexisting superficial esophageal cancer and multiple leiomyomas.

INTRODUCTION

Leiomyomas are the most common benign tumors of the esophagus, accounting for roughly two-thirds of all benign tumors of this organ. Although its overall incidence reported in autopsy ranges from 0.005% to 5%,^[1,2] this may be an underestimation because many small lesions are missed at autopsy unless the esophagus is examined carefully. Studies involving detailed histological examinations have reported the frequency to be higher, at 7.9%^[3]. Since esophageal leiomyomas are generally slow-growing and the size of tumors may not change for many years, most affected patients are asymptomatic. Considering the risk of surgery and the patient's quality of life, non-surgical management is recommended.

Surgical resection of esophageal leiomyomas is warranted only when: (1) there is severe dysphagia due to giant or multiple lesions, (2) there is a possibility of symptomatic transformation, (3) there is a need to obtain a definitive histological diagnosis, (4) malignancy can only be ruled out by surgical removal, or (5) malignant epithelial tumors are also present.

Both giant and multiple lesions involving the entire esophagus can cause severe and debilitating dysphagia. The presence of a giant lesion itself is a risk factor for malignancy, and such lesions should be treated surgically even if they cause no symptoms. Otherwise, esophageal leiomyoma usually appears as a solitary tumor (97%). Occasionally (less than 2.4% of all cases), more than one esophageal leiomyoma; i.e., generally two or three, may occur in the same patient. Multiple leiomyomas of the esophagus are extremely rare, and only two such cases, involving more than 10 nodules, have been reported

previously^[4,5]. Diagnosis of medium-sized leiomyomas is generally easy using endoscopic ultrasonography (EUS) and computerized tomography (CT). However, this is difficult when multiple leiomyomas coexist with carcinoma lesions. In cases where carcinoma overlies a submucosal leiomyoma, there is a possibility of overestimating the extent of tumor invasion, and multiple minute leiomyomas are sometimes misdiagnosed as intramural metastasis.

Here, we describe a case of superficial esophageal squamous cell carcinoma (SCC) coexisting with multiple (more than 20) leiomyoma lesions, and we discuss the management of such patients and the histogenesis of carcinomas overlying esophageal submucosal tumors (SMT).

CASE REPORT

The patient is a 71-year-old man who presented with a cervical tumor in October 2000. He was diagnosed as having a malignant lymphoma of the thyroid and esophageal leiomyomas. The thyroid tumor disappeared completely after chemotherapy, and the patient maintained a status of complete remission. Barium swallow esophagograms showed two smoothly rounded defects. The larger tumor, 40 mm in diameter and exhibiting two or three bumps, was located in the middle third of the esophagus. The smaller one, 20 mm in diameter, was in the lower third of the esophagus (Figure 1A). Both tumors were covered by normal mucosa, and showed no signs of malignancy in CT and EUS examinations. Therefore, we diagnosed these SMTs as two (or possibly three) leiomyomas. One year later, in December 2001, no marked changes were evident in a barium swallow examination (Figure 1B). However, endoscopy revealed a superficial ulcerative tumor (24 mm in diameter) in the lower third of the esophagus, overlying the smaller SMT (Figure 2: Left). Chromoendoscopy with Lugol's iodine solution demonstrated that the polypoid lesion was located within the non-staining area and that part of the surface was covered by normal mucosa (Figure 2: Right). Multiple biopsies revealed that the ulcerative tumor was SCC. EUS demonstrated that the cancer overlaid one of the leiomyomas, originating in the muscular layer, suggesting that the cancer may have invaded only as far as the submucosal layer. In February 2002, the patient underwent esophagectomy with a gastric pull-up reconstruction and cervical anastomosis via abdominal, left cervical and right thoracotomy incisions at the Department of Surgery I, Iwate Medical University School of Medicine, Morioka, Japan. During the operation, 10 or more nodules that had not been evident preoperatively were palpable in the submucosal and muscular layers throughout the esophagus. Intramural metastasis of the esophageal cancer was therefore suspected, and additional lymphadenectomy was considered. However, this option was ruled out because of the patient's severe anoxemia.

The resected specimen showed a superficial ulcerative tumor and multiple SMTs of various sizes (Figure 3). Macroscopically, about 10 SMTs were evident throughout the esophagus. Each SMT appeared as a well demarcated round nodule, and none of the tumors

showed continuity with others, which is a characteristic feature of leiomyomatosis. Microscopically, more than 20 SMTs, measuring from 1 mm to 3 cm in diameter, were scattered throughout the esophagus (Figures 4 and 5: Arrows). All the SMTs showed low overall cellularity, and were composed of interlaced smooth-muscle cells with hypovascularity and no mitosis (Figure 5B). These findings are characteristic of leiomyoma. The ulcerative tumor overlaid one of the leiomyoma nodules in the lower third of the esophagus. The tumor was confirmed as SCC, and

Figure 4 Photomicrograph of cross-sections (squares) of the resected specimen. Leiomyoma tissue is located in all sections (arrows). **S-1**: CIS overlies the leiomyoma. The region of CIS extends to the oral side of the leiomyoma (bar). **S-2**: SCC invades the submucosal layer in a very narrow region. **S-3**: A section without abnormal macroscopic findings. Multiple small leiomyomas are observed only by microscopic examination.

extensive carcinoma in situ (CIS) was observed on the leiomyoma (Figures 4 S-1, 5A). On the oral side of the SMT, the cancer had invaded into the submucosal layer, without lymph node metastasis (Figures 4 S-2, 5C).

The patient was discharged one month after the operation. At the time of writing, three years later, no local recurrence or distant metastasis of the SCC or malignant lymphoma has been observed.

DISCUSSION

As a distinct entity, multiple leiomyoma of the esophagus involving solitary lesions needs to be clearly distinguished from diffuse leiomyomatosis. Multiple leiomyoma of the esophagus is extremely rare, and only two such cases, involving more than 10 lesions, have been reported previously^[4,5]. Bradford *et al* reported a patient with 14

Table 1 Cases of ESC located in the surface epithelium over benign tumors

	Authors	Age	Sex	Submucosal tumor (SMT)	Size of SMT (cm)	Depth of cancer invasion	Subviews and <Management>

13	Present case	73	Male	Leiomyoma	2.0 × 1.5	Submucosal layer	Multiple leiomyomas <Esophagectomy>

esophageal leiomyomas measuring 1 to 4 cm in diameter, and Seremetis *et al* reported another patient who had 15 such leiomyomas 0.4 to 6 cm in diameter. In our patient, more than 20 leiomyomas, measuring from 1 mm to 3 cm in diameter, were scattered throughout the esophagus.

There have been several reports of esophageal SCC coexisting with benign SMT^[6-14]. This presentation shows two types: one is the overlying type, where the carcinoma covers the benign SMT, and in the other type the two lesions are separate. Generally, most SMTs in the separate type are minute leiomyomas that are discovered only during postoperative examination of pathology specimens^[3]. This type of presentation is often encountered during esophagectomy for esophageal SCC. Otherwise, twelve cases of the overlying type have been reported previously^[6-14] and are summarized in Table 1. Although benign tumors of various sizes have been reported, all of them protruded into the esophageal lumen. Some investigators have speculated that the pathogenesis of the overlying type may involve chronic irritation of the esophageal mucosa, due to intraluminal protrusion of the SMT, leading to carcinoma development^[9-11]. This hypothesis has been suggested in reports of SCC coexisting with lipomas as well as leiomyomas^[15]. In the present patient, both overlying and separate types were observed. Although there were 20 leiomyomas scattered throughout the esophagus, the SCC overlaid a relatively large and protruding tumor. Thus, the size and location of SMTs might affect the degree to which the esophageal mucosa is exposed to chronic irritation.

Recently, curative endoscopic resection has been performed for patients with carcinomas overlying SMTs. However, such cases require accurate diagnosis of the depth of invasion using EUS^[7,8]. Mizobuchi *et al* reported a case in which an early esophageal SCC was overdiagnosed because the leiomyoma appeared to be a component of the carcinoma^[6]. In these reports, the authors emphasized that accurate diagnosis of the leiomyoma made it possible to avoid excessive surgery. Several diagnostic modalities, such as ballium swallow, endoscopy, CT and EUS, allow esophageal leiomyoma to be diagnosed effectively, and most of them have been

monitored^[16]. With these examinations, however, small leiomyomas are often difficult to diagnose. Indeed, as in the present case, a number of small SMTs may not be apparent preoperatively. During surgery, we were unable to completely rule out the possibility that some of the SMTs were intramural metastases of the ESC, as multiple leiomyoma of the esophagus is quite rare and intramural metastasis of esophageal superficial carcinoma is relatively common.

Since many coexisting carcinomas reported previously have been superficial, it has been speculated that the coexisting SMT may in fact inhibit the growth and invasion of the carcinoma^[10]. In the present case, the overlying SCC had invaded only as far as the mucosal layer, and submucosal invasion was limited to only a very narrow region where the SMT was absent. This case appears to support the speculation that SMT inhibits the growth of SCC. During the operation, lymphadenectomy was ruled out because of the patient's anoxemia. If conditions had been more favorable, the patient might have undergone more aggressive surgery. Therefore, in cases where a coexisting superficial carcinoma overlies a benign SMT, a more noninvasive therapeutic procedure (EMR, thoracoscopic approach, and omission of lymphadenectomy *etc.*) should be chosen.

Abstract

A 62-year-old man with progressive thickening of the gallbladder wall visited our outpatient clinic. The biliary amylase level in the common bile duct was 19900 IU/L and that of the gallbladder was 127000 IU/L, although endoscopic retrograde cholangiopancreatography revealed no pancreaticobiliary maljunction. Histology demonstrated a moderately differentiated adenocarcinoma of the gallbladder. Pancreatobiliary reflux and associated gallbladder carcinoma were confirmed in the present case, in the absence of a pancreaticobiliary maljunction. Earlier detection of the pancreatobiliary reflux and progressive thickening of the gallbladder wall might have led to an earlier resection of the gallbladder and improved this patient's poor prognosis.

INTRODUCTION

Regurgitation of pancreatic juice into the biliary tract (pancreatobiliary reflux) usually occurs in patients with pancreaticobiliary maljunction and is closely related to the occurrence of biliary malignancy^[1,2]. Bile mixed with pancreatic

juice is known to induce cellular proliferation and stimulate genetic alterations of the biliary tract epithelium, leading to hyperplasia, dysplasia and ultimately, carcinoma of the biliary tract mucosa^[3].

Here we describe a patient with pancreatobiliary reflux in the absence of pancreaticobiliary maljunction, who showed progressive thickening of the gallbladder wall, which developed into an advanced gallbladder carcinoma.

CASE REPORT

A 62-year-old man visited our outpatient clinic for further evaluation of diffuse thickening of the gallbladder wall, detected by ultrasonography, at an annual medical check-up. He had no symptoms, and the physical examination showed no abnormalities. Laboratory test results were within normal limits. The serum levels of carcinoembryonic antigen was 1.3 ng/mL and the carbohydrate antigen 19-9 level was 1.0 U/mL; that is, both were within normal limits. Computed tomography (CT) revealed diffuse thickening of the gallbladder wall and dilatation of the common bile duct to 12 mm (Figure 1A). The patient was followed, and CT was scheduled for 3 mo later. He returned 42 mo later with persistent right hypochondrialgia and slight tenderness in the right upper quadrant. Laboratory tests, including serum amylase and lipase, were within the normal range. The serum levels of carcinoembryonic antigen was up to 2.1 ng/mL and the carbohydrate antigen 19-9 level increased to 5.0 U/mL, but both were still within the normal limits. CT revealed progressive thickening of the gallbladder wall and carcinoma of the gallbladder was suspected (Figure 1B). Endoscopic retrograde cholangiopancreatography (ERCP) revealed no pancreaticobiliary maljunction, because the length of the common channel was 5 mm, sphincter of Oddi affected the pancreaticobiliary junction and a connection between two the ducts was not visible during the contraction phase of sphincter of Oddi (Figure 2A, B). The biliary amylase level in the common bile duct, sampled during ERCP, was 19900 IU/L. Extended cholecystectomy, bile duct resection, and lymph node dissection were performed. The amylase level in gallbladder bile, sampled during cholecystectomy, was 127000 IU/L. Amylase was measured by an enzymatic method using the substrate 3-ketobutyliden-β-2-chloro-4-nitrophenyl-maltopentaoside (Diacolor Neonate; Toyobo, Osaka, Japan), and the normal range of serum amylase at our institution was 130-400 IU/L. The histopathologic di-

Figure 1 A: CT reveals diffuse thickening of the gallbladder wall and dilatation of the common bile duct to 14 mm; B: After 42 mo, CT reveals progressive thickening of the gallbladder wall, suspicious for gallbladder carcinoma.

Figure 2 A ERCP shows no pancreaticobiliary maljunction, because sphincter of Oddi affected pancreaticobiliary junction and connection between pancreatic and biliary ducts was not visible during the contraction phase of sphincter of Oddi; B: ERCP in the relaxation phase of sphincter of Oddi shows the length of the common channel to be 5 mm long.

agnosis of the resected specimen was a moderately differentiated adenocarcinoma of the gallbladder's fundus with invasion of the serosa (Figure 3).

DISCUSSION

Pancreaticobiliary maljunction is defined as an abnormal union of the pancreatic and biliary ducts that is located outside the duodenal wall, where a sphincter system is not present^[1]. Thus, two ducts are always communicating, and pancreatic juice freely regurgitates into the biliary tract through this passage. Numerous clinical and experimental studies have supported a relationship between pancreaticobiliary reflux and biliary cancer in patients with pancreaticobiliary maljunction. Bile mixed with pancreatic juice is known to induce hyperplasia, metaplasia, and ultimately, carcinoma of the biliary tract mucosa in patients with pancreaticobiliary maljunction^[2,3]. In fact, biliary cancer is found in 15% to 67% of adult patients with pancreaticobiliary maljunction, and gallbladder carcinoma is found more often in patients with pancreaticobiliary maljunction without a congenital choledochal cyst^[4,5].

Pancreatobiliary reflux also occurred in our patient, in the absence of a pancreaticobiliary maljunction that was confirmed by elevated amylase levels in the bile sampled at

Figure 3 Histopathologic examination of the resected specimen demonstrates a moderately differentiated adenocarcinoma of the gallbladder (HE stain, × 40).

ERCP and cholecystectomy. It was suspected that the extremely high levels of pancreatic enzymes in the bile might have induced carcinoma of the gallbladder as seen in patients with pancreaticobiliary maljunction^[4,5]. It was speculated that pancreatic juice may regurgitate into the biliary system through a common terminal ampulla that is known to exist in 60%-90% of human subjects^[6]; as pressure generated in the pancreatic duct is usually greater than that observed in the biliary system, it allows for flow from the pancreas to the biliary system^[7,8]. The precise mechanism of the pancreatobiliary reflux without pancreaticobiliary maljunction, and especially its relation to the dysfunction of sphincter of Oddi, should be further clarified.

One of the imaging findings that suggest mucosal changes accompanied by pancreatobiliary reflux is diffuse thickening of the gallbladder wall that might reflect cellular proliferation of the gallbladder epithelium, in patients with pancreaticobiliary maljunction^[2]. In the present case, diffuse thickening of the gallbladder wall was confirmed on ultrasonography and CT, and its relation to pancreatobiliary reflux could be suggested.

In the present case, pancreatobiliary reflux and associated gallbladder carcinoma were confirmed, in the absence of pancreaticobiliary maljunction. Earlier detection of the pancreatobiliary reflux and progressive thickening of the gallbladder wall might have led to earlier resection of the gallbladder and improved this patient's poor prognosis.

Abstract

A rare case of peribiliary cysts accompanying bile duct carcinoma is presented. A 54-year-old man was diagnosed as having lower bile duct carcinoma and peribiliary cysts by diagnostic imaging. He underwent pylorus preserving pancreatoduodenectomy. As for the peribiliary cysts, a course of observation was taken. Over surgery due to misdiagnosis of patients with biliary malignancy accompanied by peribiliary cysts should be avoided.

INTRODUCTION

Hepatic peribiliary cysts are a poorly recognized liver disease characterized by multiple tiny cysts along the portal radicle. This type of lesion is derived from the cystic dilatation of intrahepatic extramural peribiliary glands around the intrahepatic large bile ducts^[1]. Although peribiliary cysts sometimes cause stricture of the intrahepatic bile duct and mimics intrahepatic cholangiocarcinoma^[2], to our knowledge there are no reports of this condition accompanying bile duct carcinoma. We report a rare case of peribiliary cysts accompanying bile duct carcinoma.

CASE REPORT

A 54-year-old Japanese man was admitted to a local hospital for complaints of jaundice. He was diagnosed with lower bile duct carcinoma and referred to our hospital after placement of endoscopic naso-biliary drainage. He had a history of heavy alcohol use and had been hospitalized for one year with alcoholism ten years previously. Physical examination results were generally unremarkable. The liver was palpable two fingerbreadths below the right costal margin. No ascites or edema was present. Laboratory examination revealed a normal complete blood count and normal coagulation. Liver function test results at admission to our hospital were as follows: aspartate aminotransferase (AST), 75 U/I; alanine aminotransferase (ALT), 133 U/I; alkaline phosphatase (ALP), 467 U; γ -glutamyl transpeptidase (GTP), 196 U/I; total bilirubin, 1.1 mg/mL; indocyanine green test (at 15 min), 6.2%. Hepatitis virus screening was negative and no tumor markers were elevated. Abdominal ultrasonography revealed multiple small cystic lesions and tubular anechoic areas along the umbilical portion of the portal vein that were difficult to differentiate with dilatation of the intrahepatic bile ducts. CT revealed a tumor in the lower bile duct and multiple small cystic lesions along the umbilical portion of the portal vein (Figure 1). Cholangiography *via* an endoscopic naso-biliary drainage tube revealed complete obstruction of the lower bile duct, smooth stenosis of the left hepatic duct, and a slight dilatation of the intrahepatic bile duct in the left lobe (Figure 2). Magnetic resonance cholangiopancreatography (MRCP) showed bead-like cystic lesions along the biliary tree in the left lobe of the liver (Figure 3). The left hepatic duct stenosis appeared to be caused by extramural compression by these cysts. Portal phase superior mesenteric arteriography and hepatic arteriography demonstrated no particular abnormalities. Based on these imaging studies, he was diagnosed as having lower bile duct carcinoma and peribiliary cysts. He underwent pylorus preserving pancreatoduodenectomy. As for the peribiliary cysts, a course of observation was decided upon. The carcinoma was a nodal infiltrating-type tumor sized 12 mm \times 8 mm existing in the lower bile duct.

The tumor was histopathologically diagnosed as a moderately differentiated tubular adenocarcinoma, pT3, pN0, pM0 and stage IIA^[3]. After the operation, minor leakage of the pancreatojejunostomy developed and was successfully treated by conservative therapy. He is alive without recurrence and symptoms 10 mo after surgery at this writing.

Figure 1 CT revealing multiple small cystic lesions along the umbilical portion of the portal vein (arrows).

Figure 2 Cholangiogram via endoscopic naso-biliary drainage tube revealing complete obstruction in the lower bile duct (black arrow) and smooth stenosis of the left hepatic duct (white arrows) and a slight dilatation of the intrahepatic bile duct in the left lobe.

DISCUSSION

Peribiliary cysts were first reported by Nakanuma *et al* in 1984^[4]. They speculated that the peribiliary cysts arose from cystic dilatation of the intrahepatic extramural peribiliary glands in the periductal connective tissue^[4]. A systematic study of autopsied livers disclosed that the disease is not uncommon; cystic changes of the peribiliary glands were found in 202 livers (20.2%) among 1000 consecutive autopsy livers^[1]. However, since the degree of cystic dilatation is quite variable, and the majority are recognizable microscopically, this disease is still poorly recognized in clinical practice^[5]. The precise mechanism for cystic dilatations of intrahepatic peribiliary glands is unclear. Peribiliary cysts are usually detectable in pre-existing hepatobiliary diseases such as liver cirrhosis, idiopathic portal hypertension, portal vein thrombosis, alcoholic liver disease, and adult-type polycystic kidney disease^[4,6,7]. Therefore, it has been speculated that circulation failure caused by the interference of blood flow through the portal vein causes morphological changes of extramural glands around the bile duct. Nakanuma presumed that, in cases of adult-type polycystic kidney disease, gene expression in the intrahepatic peribiliary glands related to this disease may lead to the formation of peribiliary cysts^[5]. In the case reported here, alcoholic liver injury did not develop into liver cirrhosis, and there were no findings of portal hypertension. Peribiliary cysts are also known to develop in patients with cystic dilatation of the intrahepatic biliary system after hepatic portoenterostomy^[8]. We speculate that in the case reported here, cholestasia due to lower bile duct cancer, in addition to alcoholic liver disease, might be related to the development of peribiliary cysts. However, whether peribiliary cysts existed before the development of bile duct cancer is uncertain, since he had not undergone diagnostic imaging before the onset of obstructive jaundice.

On diagnostic imaging, peribiliary cysts are characterized as clusters of relatively small multiple cystic lesions developing around the hepatic hilum and large branches of the portal vein, but not in liver parenchyma^[9]. Recently, MRCP has been reported to be useful in the diagnosis of peribiliary cysts. MRCP clearly depicts

Figure 3 Magnetic resonance cholangiopancreatogram showing bead-like cystic lesions (arrows) along the biliary tree in the left lobe of the liver.

multiple cysts as a string of bead-like structures or a foamy fringe along the hepatic hilum or larger bile ducts. Drip infusion cholangiographic (DIC) CT is also useful for diagnosing peribiliary cysts. On DIC-CT, peribiliary cysts are not filled with contrast material since these cysts do not communicate with the lumen of the biliary tree.

Peribiliary cysts have usually been considered to be clinically harmless. There are two reports describing obstructive jaundice secondary to the obstruction of bile ducts by peribiliary cysts^[2,10]. It is thought that surgery is not indicated for asymptomatic peribiliary cysts but they should be followed up^[9,11]. Misdiagnosis of peribiliary cysts as intrahepatic cholangiocarcinoma is a possibility^[2,12,13], and there are two reports concerning such patients undergoing hepatectomy on suspicion of intrahepatic cholangiocarcinoma^[12,13]. Precise diagnosis can be obtained easily by characteristic findings with diagnostic imaging if the attending clinician is knowledgeable about peribiliary cysts. Needless to say, unnecessary operations for patients with peribiliary cysts should be avoided.

There have been no reports of peribiliary cysts accompanying bile duct carcinoma. If knowledge of the clinical entity of peribiliary cysts becomes widespread, the number of patients with peribiliary cysts accompanying biliary malignancy is sure to increase. When peribiliary

cysts and biliary malignancy exist simultaneously, the operative procedure should be chosen according to the staging and extension of the malignancy as well as the positional relationship between the two lesions based on proper diagnosis. We chose not to select surgical therapy for the peribiliary cysts, on the basis that we diagnosed the stricture of the left hepatic duct as compression by peribiliary cysts, and hepatopancreatoduodenectomy, an indispensable procedure for resecting both the lower bile duct cancer and stricture of left hepatic duct, by itself is associated with high rates of postoperative complications and operative mortality^[14]. Over-surgery due to misdiagnosis for patients with biliary malignancy accompanied by peribiliary cysts should be avoided. However, peribiliary cysts have been reported to become gradually enlarged and increased in number in some cases^[15,16]. Long-term follow-up is obviously called for.

Abstract

A 54-year-old woman was admitted to our hospital with the complaint of right upper quadrant pain. Upon physical examination the vital signs of the patient were within normal ranges. Ultrasonography and computed tomography (CT) examination of the abdomen was obtained, which demonstrated a large dilated cystic structure, measuring approximately 68.6 mm × 48.6 mm, with marked distension and inflammation. Additionally, the enhanced CT was characterized by the non-enhanced wall of the gallbladder. As the third examination in this study, magnetic resonance imaging (MRI), namely coronal MRI and magnetic resonance cholangio-pancreatography (MRCP), were performed. The MRCP demonstrated a dilatation of the gallbladder but detected no neck of the gallbladder. Simple cholecystectomy was performed. Macroscopic findings included a distended and gangrenous gallbladder, and closer examination revealed a counterclockwise torsion of 360 degrees on the gallbladder mesentery. Coronal MRI and MRCP showing characteristic radiography may be useful in making a definitive diagnosis.

INTRODUCTION

Gallbladder volvulus is a relatively rare disease and well recognized in the elderly people. It has been reported in only about 300 cases in the literature ranging in age from 2 to 100 years old. Preoperative diagnosis of gallbladder volvulus has always been considered difficult. Although recent advances in radiographic finding have helped in the diagnosis of many diseases, abdominal computed tomography (CT) and Ultrasonography (US) remain nonspecific in diagnosing volvulus of the gallbladder. However, we could make definitive radiographic imaging by coronal magnetic resonance imaging (MRI) and magnetic resonance cholangio-pancreatography (MRCP).

CASE REPORT

A 54-year-old woman was admitted to our hospital with the complaint of right upper quadrant pain of approximately 5 hours in duration. Pain was accompanied by anorexia and nausea without vomiting and was not preceded by jaundice. She had no relevant past history. Upon physical examination the vital signs of the patient were within normal ranges. Right upper quadrant tenderness and Murphy's sign were detected in the abdominal examination. Laboratory data showed a leukocyte count of 11 800/mm³ and C-reactive protein (CRP) of 2.57 mg/dL. Initial treatment consisted of administering intravenous fluids and broad-spectrum antibiotics. Abdominal ultrasound US demonstrated a distended, fluid-filled neck of abnormal swelling, a normal-walled gallbladder with surrounding ascites and edema (Figure 1), but no stones. Secondary

Figure 1 Abdominal ultrasonography revealed an abnormally large floating gallbladder without gallstones, and a thickened gallbladder wall.

Figure 2 Abdominal enhanced computed tomography revealed a dilated gallbladder, but a non-enhanced gallbladder wall.

computed tomography (CT) examination of the abdomen was obtained. CT demonstrated a large dilated cystic structure, measuring approximately 68.6 mm × 48.6 mm, with marked distension and inflammation. Additionally, the enhanced CT was characterized by the non-enhanced wall of the gallbladder (Figure 2). As the third examination in this study, magnetic resonance imaging (MRI), namely coronal MRI and magnetic resonance cholangiopancreatography (MRCP), were performed. The MRCP demonstrated a dilatation of the gallbladder but detected no neck of the gallbladder (Figure 3). The coronal MRI revealed a dilated gallbladder, and additionally an invagination that identified the neck of the gallbladder (Figure 4). She was diagnosed with acute cholecystitis and volvulus of the gallbladder according to the findings of US, CT, MRI and MRCP and underwent percutaneous transhepatic gallbladder aspiration (PTGBA) for one day. Following the treatment, a hemobilia discharge from the PTGBA was noted, and she was diagnosed with necrotic gallbladder. Her pain was slightly improved, but she still had tenderness and high fever. She underwent open laparotomy, and simple cholecystectomy was performed. Macroscopic findings included a distended and gangrenous gallbladder, and closer examination revealed a counterclockwise torsion of 360 degrees on the gallbladder mesentery. De-torsion and cholecystectomy were easily performed (Figure 5). The histopathology report showed

Figure 3 MRCP demonstrated dilatation of the gallbladder, but its image identified no gallbladder neck.

Figure 4 Coronal MRI revealed a dilated gallbladder, and its invagination-like image identified the neck of the gallbladder.

Figure 5 At laparotomy, macroscopic findings showed a distended and gangrenous gallbladder along with a counterclockwise torsion of 360 degrees of the gallbladder mesentery.

necrosis and hemorrhage of the gallbladder without evidence of lithiasis. Nine days after the operation she was discharged with no complications.

DISCUSSION

First reported by Wendel in 1898^[1], volvulus of the gallbladder is a relatively uncommon phenomenon, with no more than 300 cases reported in the literature. It occurs in all age groups, with the highest incidence in elderly women, and a female-to-male ratio of 3:1. Perhaps the incidence would increase with a longer life expectancy rate^[2,3]. Gallstones are unlikely to be the cause of gallbladder torsion, as gallstones are not uniformly present in all patients reported with torsion. One study of

245 patients found stones in only 24.4%; 51% developed a clockwise torsion rotation^[4]. Although supportive evidence is lacking, inferences have been made in the literature linking gastric peristalsis to clockwise gallbladder torsion and colonic peristalsis to counterclockwise torsion^[5]. Because volvulus of the gallbladder is a relatively uncommon phenomenon, preoperative diagnosis of gallbladder torsion remains difficult. Therefore, most cases are diagnosed intraoperatively at present. Also, laboratory evaluations are often nonspecific. For example, white blood cell count (WBC), CRP and creatine phosphokinase (CPK) are frequently elevated, while liver function tests are commonly normal. In our case, WBC, CRP and CPK were elevated. Although recent advances in radiographic studies have helped in the diagnosis of many diseases, radiographic studies remain nonspecific in diagnosing volvulus of the gallbladder. Fewer than a dozen cases have been reported in the literature where a preoperative diagnosis was made. Ultrasound studies often reveal a large floating gallbladder without gallstones, and a thickened gallbladder wall. Specific ultrasound signs seen with gallbladder torsion include the presence of the gallbladder outside its normal anatomic fossa, inferior to the liver or in a transverse orientation with an echogenic conical structure^[6]. Additionally, CT findings are also nonspecific. A few cases of CT diagnosis of gallbladder torsion commented on radiographic findings of marked enlargement of the gallbladder with an unusual shape and configuration^[7,8]. MRI has been used to establish a diagnosis preoperatively. MRI findings include high signal intensity within the gallbladder wall on T1 weighted images, suggesting necrosis and hemorrhage consistent with gallbladder torsion. In the present case, MRCP revealed anatomic details of the neck of the gallbladder and cystic duct.

We consider the characteristics of these radiography images to be useful for differential diagnosis of torsion of the gallbladder from gallbladder stone and gallbladder cancer. Usui *et al* have reported that only MRCP made it possible to determine the relationships between the distorted bile ducts, the interrupted cystic duct, and the enlarged gallbladder, and it was a relatively non-invasive procedure^[9]. In addition, Shaikh *et al* have reported that the presence of a redundant mesentry was a prerequisite

for torsion^[10]. Although torsion of the gallbladder is a rare occurrence, the diagnosis should be considered in all patients presenting with right upper quadrant pain. If diagnosed early and treated, it remains a benign condition; however, a delay in diagnosis and management may lead to sequelae associated with gallbladder rupture and biliary peritonitis. US, CT, and magnetic resonance techniques, especially coronal MRI and MRCP, are useful in diagnosing volvulus of the gallbladder. About 300 cases have been described in the literature so far, but only a minor portion (putatively less than 50 cases) have preoperative imaging studies such as CT and MRI. Ours is the first case in the medical literature in English to report on volvulus of the gallbladder diagnosed by coronal MRI and MRCP showing characteristic radiography.

Abstract

Ophthalmological complications with interferon therapy are usually mild and reversible, not requiring the withdrawal of the treatment. We report a case of a patient who had visual loss probably associated with interferon therapy. Chronic hepatitis C virus infection (genotype 1a) was diagnosed in a 33-year old asymptomatic man. His past medical history was unremarkable and previous routine ophthalmologic check-up was normal. Pegylated interferon alpha and ribavirin were started. Three weeks later he reported painless reduction of vision. Ophthalmologic examination showed extensive intraretinal hemorrhages and cotton-wool spots, associated with inferior branch retinal vein thrombosis. Antiviral therapy was immediately discontinued, but one year later he persists with severely decreased visual acuity. This case illustrates the possibility of unpredictable and severe complications during pegylated interferon therapy.

<http://www.wjgnet.com/1007-9327/12/4602.asp>

INTRODUCTION

Pegylated interferon has been shown to be associated with high rates of sustained virological responses and has become the standard therapy of chronic hepatitis C. However, interferon therapy may be associated with severe adverse effects. We report the case of a patient who developed retinal vein thrombosis and visual loss probably related to the antiviral therapy.

CASE REPORT

A 33-year old asymptomatic Caucasian man was referred for investigation of abnormal liver enzymes. Chronic hepatitis C virus infection, genotype 1a, with viral load 220 400 IU/mL, was diagnosed, and a liver biopsy showed chronic hepatitis, with inflammatory activity A2 and fibrosis F2 according to the METAVIR system. Past medical history was unremarkable and negative for diabetes mellitus, arterial hypertension, dislipidemia, obesity, regular use of medications, smoking and illicit drug or alcohol abuse. Previous routine ophthalmologic check-up was normal, with a visual acuity 20/20. Pegylated interferon α 2b was started at the dose of 1.5 μ g/kg once weekly in combination with ribavirin 1000 mg/d. Three weeks later he reported painless blurring of vision. The ophthalmologic examination confirmed the reduction of the visual acuity and showed extensive intraretinal hemorrhages and cotton-wool spots, associated with inferior branch retinal vein thrombosis. Fluorescein angiography confirmed the venous occlusion (Figure 1). The antiviral therapy was immediately discontinued. Hematocrit, platelet count, glucose, prothrombin activity, creatinine, cholesterol and triglycerides levels were normal. Activated protein C resistance phenotype was normal. The levels of protein S, antithrombin III, homocysteine and fibrinogen were within the normal ranges. Plasma protein C was 50% (normal 58%-125%), compatible with heterozygous state. Cryoglobulins and antiphospholipids antibodies were negative. Factor V Q 506 and prothrombin gene 3'-UTR G20210A mutant alleles were absent. Doppler ultrasound of the heart and carotid arteries was normal. The patient developed macular edema which required panretinal photocoagulation. One year later, he persists with severely decreased visual acuity.

Figure 1 **A:** Fundus photograph of the right eye with extensive intraretinal hemorrhages and cotton-wool spots in the inferonasal and inferotemporal regions; **B:** Fluorescein angiography with segmental hypoperfusion, dilation and tortuosity of the retinal veins (arrow), compatible with inferior branch retinal vein thrombosis.

DISCUSSION

Ophthalmologic complications with interferon alpha therapy, such as retinopathy with cotton-wool spots, hemorrhages and macular edema, optic neuropathy and thrombotic microangiopathy, occur in less than 1% of treated patients. Individuals with diabetes, hypertension, dyslipidemia and hypercoagulable states are more prone to develop those changes. In most cases they are subclinical, mild and reversible, not requiring the withdrawal of the treatment.

The physiopathology of retinal vein thrombosis in patients with viral hepatitis is poorly understood, but may be related to both background predisposition and side effects of therapy. Protein C deficiency occurs in 1 of 250

controls and leads to impaired inhibition of clot formation, which is associated with an increased risk for venous thrombosis (relative risk, 7.3; annual incidence, 1%)^[1]. However, the frequency of venous thrombosis in protein C deficiency state is highly variable. Only a minority of affected individuals develop thrombosis, suggesting that the presence of another simultaneous risk factor is needed.

Both chronic hepatitis C and interferon therapy are associated with the formation of procoagulant antibodies, in particular antiphospholipids antibodies, which may predispose to thrombosis. In addition, interferon therapy induces the increase of plasma-activated complement C5a, a potent intravascular aggregator of granulocytes, favoring the development of microthrombi in small vessels^[2,3].

The patient developed a severe, early and sight losing complication of antiviral therapy. Most reported cases occurred in predisposed individuals 2 to 11 months after the beginning of standard alpha interferon therapy. However, one could speculate that interferon pegylation could modify both the pharmacokinetics of the drug and the timing of retinal vein thrombosis.

Since there are few reported cases of retinal vein thrombosis^[3-5], this case may represent a coincidence, not associated with interferon therapy. Nevertheless, it is noteworthy that the patient was asymptomatic and had a normal vision before antiviral therapy. Although current guidelines of therapy of chronic viral hepatitis do not support routine ophthalmologic screening and work-up for hypercoagulable states in all patients treated with interferon, this case illustrates the possibility of unpredictable and severe complications during pegylated interferon therapy.

Instructions to authors

GENERAL INFORMATION

World Journal of Gastroenterology (WJG, *World J Gastroenterol* ISSN 1007-9327 CN 14-1219/R) is a weekly journal of more than 48 000 circulation, published on the 7th, 14th, 21st and 28th of every month.

Original Research, Clinical Trials, Reviews, Comments, and Case Reports in esophageal cancer, gastric cancer, colon cancer, liver cancer, viral liver diseases, etc., from all over the world are welcome on the condition that they have not been published previously and have not been submitted simultaneously elsewhere.

Indexed and abstracted in

Current Contents/Clinical Medicine and Science Citation Index-Expanded, *Index Medicus*, MEDLINE and PubMed, Chemical Abstracts, EMBASE/Excerpta Medica, Abstracts Journals, Nature Clinical Practice Gastroenterology and Hepatology, CAB Abstracts and Global Health. ISI JCR 2003-2000 IF: 3.318, 2.532, 1.445 and 0.993.

Published by

The WJG Press

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed double-spaced on A4 (297 mm × 210 mm) white paper with outer margins of 2.5 cm. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, acknowledgements, References, Tables, Figures and Figure Legends. Neither the editors nor the Publisher is responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press, and may not be reproduced by any means, in whole or in part without the written permission of both the authors and the Publisher. We reserve the right to put onto our website and copy-edit accepted manuscripts. Authors should also follow the guidelines for the care and use of laboratory animals of their institution or national animal welfare committee.

Authors should retain one copy of the text, tables, photographs and illustrations, as rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for the loss or damage to photographs and illustrations in mailing process.

Online submission

Online submission is strongly advised. Manuscripts should be submitted through the Online Submission System at: <http://www.wjgnet.com/index.jsp>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (<http://www.wjgnet.com/wjg/help/instructions.jsp>) before attempting to submit online. Authors encountering problems with the Online Submission System may send an email you describing the problem to wjg@wjgnet.com for assistance. If you submit your manuscript online, do not make a postal contribution. A repeated online submission for the same manuscript is strictly prohibited.

Postal submission

Send 3 duplicate hard copies of the full-text manuscript typed double-spaced on A4 (297 mm × 210 mm) white paper together with any original photographs or illustrations and a 3.5 inch computer diskette or CD-ROM containing an electronic copy of the manuscript including all the figures, graphs and tables in native Microsoft Word format or *.rtf format to:

Editorial Office

World Journal of Gastroenterology

Editorial Department: Apartment 1066, Yishou Garden,
58 North Langxinzhuang Road,
PO Box 2345, Beijing 100023, China
E-mail: wjg@wjgnet.com
<http://www.wjgnet.com>
Telephone: +86-10-85381901
Fax: +86-10-85381893

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using a word-processing software. All submissions must be typed in 1.5 line spacing and in word size 12 with ample margins. The letter font is

Tahoma. For authors from China, one copy of the Chinese translation of the manuscript is also required (excluding references). Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Full manuscript title, running title, all author(s) name(s), affiliations, institution(s) and/or department(s) where the work was accomplished, disclosure of any financial support for the research, and the name, full address, telephone and fax numbers and email address of the corresponding author should be included. Titles should be concise and informative (removing all unnecessary words), emphasize what is new, and avoid abbreviations. A short running title of less than 40 letters should be provided. List the author(s)' name(s) as follows: initial and/or first name, middle name or initial(s) and full family name.

Abstract

An informative, structured abstract of no more than 250 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections: AIM: Only the purpose should be included. METHODS: The materials, techniques, instruments and equipments, and the experimental procedures should be included. RESULTS: The observatory and experimental results, including data, effects, outcome, etc. should be included. Authors should present *P* value where necessary, and the significant data should accompany. CONCLUSION: Accurate view and the value of the results should be included.

The format of structured abstracts is at: <http://www.wjgnet.com/wjg/help/11.doc>

Key words

Please list 6-10 key words that could reflect content of the study mainly from *Index Medicus*.

Text

For most article types, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include in appropriate Figures and Tables. Data should be presented in the body text or in Figures and Tables, but not in both.

Illustrations

Figures should be numbered as 1, 2, 3 and so on, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. No detailed legend should be involved under the figures. This part should be added into the text where the figures are applicable. Digital images: black and white photographs should be scanned and saved in TIFF format at a resolution of 300 dpi; color images should be saved as CMYK (print files) but not as RGB (screen-viewing files). Place each photograph in a separate file. Print images: supply images of size no smaller than 126 mm × 76 mm printed on smooth surface paper; label the image by writing the Figure number and orientation using an arrow. Photomicrographs: indicate the original magnification and stain in the legend. Digital Drawings: supply files in EPS if created by freehand and illustrator, or TIFF from photoshops. EPS files must be accompanied by a version in native file format for editing purposes. Existing line drawings should be scanned at a resolution of 1200 dpi and as close as possible to the size where they will appear when printed. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes of atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ...

Tables

Three-line tables should be numbered as 1, 2, 3 and so on, and mentioned clearly in the main text. Provide a brief title for each table. No detailed legend should be included under the tables. This part should be added into the text where the tables are applicable. The information should complement but not duplicate that contained in the text. Use one horizontal line under the title, a second under the column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. ^a*P*<0.05, ^b*P*<0.01 should be noted (*P*>0.05 should not be noted). If there are other series of *P* values, ^c*P*<0.05 and ^d*P*<0.01 are used. Third series of *P* values can be expressed as ^e*P*<0.05 and ^f*P*<0.01. Other notes in tables or under illustrations should be expressed as ¹*F*, ²*F*, ³*F*; or some other symbols with

a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, etc. in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscripts and who endorse the data and conclusions are included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should code the references according the citation order in text in Arabic numerals, put references codes in square brackets, superscript it at the end of citation content or the author name of the citation. For those citation content as the narrate part, the coding number and square brackets should be typeset normally. For example, Crohn's disease (CD) is associated with increased intestinal permeability^[1,2]. If references are directly cited in the text, they would be put together with the text, for example, from references [19,22-24], we know that...

When the authors code the references, please ensure that the order in text is the same as in reference part and also insure the spelling accuracy of the first author's name. Do not code the same citation twice.

PMID requirement

PMID roots in the abstract serial number indexed by PubMed (<http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=PubMed>). The author should supply the PMID for journal citation. For those references that have not been indexed by PubMed, a printed copy of the first page of the full reference should be submitted.

The accuracy of the information of the journal citations is very important. Through reference testing system (<http://www.aushome.cn/cgi-bin/index.pl>), the authors and editor could check the authors name, title, journal title, publication date, volume number, start page, and end page. We will interlink all references with PubMed in ASP file so that the readers can read the abstract of the citations online immediately.

Style for journal references

Authors: the first author should be typed in bold-faced letter. The surname of all authors should be typed with the initial letter capitalized and followed by their name in abbreviation (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). Title of the cited article and italicized journal title (Journal title should be in its abbreviation form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634]

Note: The author should test the references through reference testing system (<http://www.aushome.cn/cgi-bin/index.pl>)

Style for book references

Authors: the first author should be typed in bold-faced letter. The surname of all authors should be typed with the initial letter capitalized and followed by their name in abbreviation (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

- 16 **Pagedas AC**, inventor; Ancel Surgical R&D Inc., assignee. Flexible endoscopic grasping and cutting device and positioning tool assembly. United States patent US 20020103498. 2002 Aug 1

Inappropriate references

Authors should always cite references that are relevant to their article, and avoid any inappropriate references. Inappropriate references include those that are linked with a hyphen and the difference between the two numbers at two sides of the hyphen is more than 5. For example, [1-6], [2-14] and [1, 3, 4-10, 22] are all considered as inappropriate references. Authors should not cite their own unrelated published articles.

Statistical data

Present as mean \pm SD or mean \pm SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as γ (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p*(B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose) 6.4 \pm 2.1 mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6 24.5 μ g/L; CO₂ volume fraction, 50 mL/L CO₂ not 5% CO₂; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format about how to accurately write common units and quantum is at: <http://www.wjgnet.com/wjg/help/15.doc>

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further mention.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindI*, *BamHI*, *Kbo I*, *Kpn I*, etc.

Biology: *H pylori*, *E coli*, etc.

SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. Author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, the final check list for authors, and responses to reviewers by a courier (such as EMS) (submission of revised manuscript by e-mail or on the *WJG* Editorial Office Online System is NOT available at present).

Language evaluation

The language of a manuscript will be graded before sending for revision.

(1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing; (4) Grade D: rejected. The revised articles should be in grade B or grade A.

Copyright assignment form

Please download CAF from <http://www.wjgnet.com/wjg/help/9.doc>.

We certify that the material contained in this manuscript:

Ms:

Title:

is original, except when appropriately referenced to other sources, and that written permission has been granted by any existing copyright holders. We agree to transfer to *WJG* all rights of our manuscript, including: (1) all copyright ownership in all print and electronic formats; (2) the right to grant permission to republish or reprint the stated material in whole or in part, with or without a fee; (3) the right to print copies for free distribution or sale; (4) the right to republish the stated material in a collection of articles or in any other format. We also agree that our article be put on the Internet.

Criteria for authorship: The *WJG* requests and publishes information about contributions of each author named to the submitted study. Authorship credit should be based on (1) direct participation in the study, including substantial contributions to conception and design of study, or acquisition of data, or analysis and interpretation of data; (2) manuscript writing, including drafting the article, or revising it critically for important intellectual content; (3) supportive work, including statistical analysis of data, or acquisition of funding, or administration, technology and materials support, or supervision, or supportive contributions. Authors should meet at least one of the three conditions. The *WJG* does not publish co-first authors and co-corresponding authors.

We hereby assign copyright transfer to *WJG* if this paper is accepted.

Author Name in full (Full names should be provided, with first name first, followed by middle names and family name at the last, eg, Eamonn MM Quigley). Handwritten names are not accepted.

Author Name in abbreviation (Family name is put first in full, followed by middle names and first name in abbreviation with first letter in capital, eg, Quigley EMM). Handwritten names are not accepted.

Final check list for authors

The format is at: <http://www.wjgnet.com/wjg/help/13.doc>

Responses to reviewers

Please revise your article according to the comments/suggestions of reviewers. The format for responses to the reviewers' comments is at: <http://www.wjgnet.com/wjg/help/10.doc>

Abstract

Slow transit constipation has been traditionally considered and classified as a functional disorder. However, clinical and manometric evidence has been accumulating that suggests how most of the motility alterations in STC might be considered of neuropathic type. In addition, further investigations showed that subtle alterations of the enteric nervous system, not evident to conventional histological examination, may be present in these patients. In the present article we will discuss these evidences, and will try to put them in relation with the abnormal motor function of the large bowel documented in this pathological condition.

Bassotti G, Villanacci V. Slow transit constipation: A functional disorder becomes an enteric neuropathy. *World J Gastroenterol* 2006; 12(29): 4609-4613

<http://www.wjgnet.com/1007-9327/12/4609.asp>

INTRODUCTION

In gastroenterology practice, the most frequently encountered disorders are represented by those related to an abnormal function of the abdominal viscera, the so-called functional diseases^[1,2]. The term “functional” defines several variable combinations of chronic or recurrent gastrointestinal symptoms that do not have an identified underlying pathophysiology^[3], and that are often also labelled as “idiopathic”. Thus, the definition of functional relies on the exclusion of an organic disease, and it is

consequently thought to be related to abnormalities of its physiological properties or functions.

Among the so-called functional disorders, one of the most common is functional constipation, whose diagnostic criteria according to Rome II classification^[4] are reported in Table 1. Patients with functional constipation may be further classified in three subgroups: normal transit constipation, disorders of defecatory or rectal evacuation (outlet obstruction), and slow transit constipation (STC)^[5,6]. This latter condition affects mainly women, it is characterized by an often intractable constipation, a heavily delayed colonic transit up to true colonic inertia^[7,8], and it is usually attributed to disorders of colonic motor function^[9,10]. Indeed, several abnormal motor aspects have been described in STC, such as alterations of rectosigmoid contractile activity^[11], decreased colonic propulsive function^[12,13], abnormal response to food ingestion^[14,15], and overall reduced electrical or motor activity of the large bowel^[16,17]. It must also be taken into account that a further cause of delayed colonic transit may be due to the association with pelvic floor dyssynergia; this condition must be identified, since it is amenable of biofeedback treatment, which can normalize colonic transit^[18].

However, we still do not know how and why these abnormalities are present in STC patients. In recent years, clinical and manometric evidence has been accumulated that suggests how most of the motility alterations in STC might be considered as a neuropathic type. Moreover, other data showed that some subtle alterations of the enteric nervous system, not evident to conventional histological examination, may be present in these patients. In the present article we will discuss these evidences, and will try to put them in relation with the abnormal motor function of the large bowel documented in this pathological condition.

STC AS A NEUROPATHY: CLINICAL EVIDENCE

In several patients with STC subclinical features of autonomic neuropathy may be present^[19], and other studies described selective sensory and autonomic neuropathy in these subjects^[20], often with a positive family history, suggesting a genetic basis for this condition^[21]. Animal studies might help in elucidating these issues: for instance, transgenic mice with a targeted deletion of neurturin (a neurotrophin) display clinical and tissue phenotype similar to that found in STC, and display associated

Table 1 Rome II criteria for functional constipation (adapted from reference 4)

Two or more of the following for at least 12 wk (not necessarily consecutive) in the preceding 12 mo:

- Straining during > 25% of bowel movements;
 - Lumpy/hard stools for > 25% of bowel movements;
 - Sensation of incomplete evacuation for > 25% of bowel movements;
 - Sensation of anorectal blockage for > 25% of bowel movements;
 - Manual manoeuvres to facilitate > 25% of bowel movements (e.g., digital evacuation or support of the pelvic floor);
 - < 3 bowel movements per week
- Loose stools are not present, and there are insufficient criteria for irritable bowel syndrome

parasympathetic deficits^[22].

Moreover, since in a sizable proportion of STC patients the symptoms start after pelvic surgical procedures^[23-25] or following childbirth^[26] it has been hypothesized (although the anatomic proof has never been given) that pelvic nerve injury may occur following hysterectomy and childbirth, and that STC could be considered a disorder of pelvic autonomic nerves at least in a subgroup of patients^[27].

STC AS AN ENTERIC NEUROPATHY: INSTRUMENTAL EVIDENCE

Several manometric studies carried out in patients with STC have reported findings that suggest the presence of neuropathic-type abnormalities. Such abnormalities have been described in many instances with respect to the periodic motor activity of the rectosigmoid area (including the so-called rectal motor complex), that appears either decreased or disorganized^[28-30], the contractile colonic motor response following intravenous cholinergic stimulation, that in results impaired^[31], the early motor response following ingestion of a meal, reported as decreased or absent^[32], the overall daily colonic motility, usually decreased to a lesser or greater extent^[33,34], the daily organization of regular contractile colonic patterns, that is often impaired^[35], and the lack of propulsive response to intraluminal instillation of bisacodyl (a powerful stimulant of mass movements in healthy subjects)^[36].

It is worth noting that neuropathic-type abnormalities in patients with STC are not necessarily confined to the large bowel, but may be also documented in other viscera such as the esophagus^[37,38], the stomach^[39,40], the gallbladder^[41], and especially the small bowel^[42-45], suggesting the presence of a pan-enteric motor disorder in these patients, particularly in those with more severe symptoms.

STC AS AN ENTERIC NEUROPATHY: PATHOLOGICAL EVIDENCE

Most of the pathologic descriptions related to STC are pertinent to the large bowel, and only sporadic reports from other gastrointestinal viscera (terminal ileum) exist. Therefore, the discussion of pathological findings will

Figure 1 Interstitial cells of Cajal (arrows) at myenteric plexus level in a control subject (A) and in a patient with slow transit constipation (B). Note the considerable decrease of these cells in the patient (CD117, original magnification x 40). Panels C and D show the enteric glial cells (arrows) in the myenteric plexus of a control and of a patients with slow transit constipation, respectively. Note the important reduction of these cells in the patient, where only a few ones may be identified (S100, original magnification x 40).

focus on the colonic studies.

Conventional histology

Most studies employing routine light microscopy have failed to identify consistent abnormalities of the enteric nervous system (ENS) in patients with STC^[46-50], apart from the presence of melanosis coli. However, we have recently demonstrated that melanosis coli *per se* does not have any relationship with colonic ENS abnormalities (in particular with the loss of enteric neurons, as hypothesized in older studies only evaluating the submucosa) in these patients^[51].

Silver staining technique

Morphological abnormalities of colonic innervation have been described in STC patients using the silver staining technique introduced by Smith^[52]. These studies have generally reported a reduction in the total number of argyrophilic neurones and morphological neuronal and/or axonal abnormalities^[53,54]. However, the silver staining technique has been subsequently replaced by more modern and reliable immunohistochemical methods (see below).

Immunohistochemistry

Concerning the hypothesized imbalance of enteric neurotransmitters or the enzyme markers (mostly neuropeptides) in STC, the various studies (using immunostaining, immunoassays, or both methods) have frequently yielded inconsistent results. In fact, looking at the findings related to the most commonly investigated neuropeptides (VIP, substance P, neuropeptide Y and 5-HT), decreased, increased or unchanged levels or immunoreactivity has been described in these patients^[55-59]. Overall, on the basis of the above reports it might be stated that it is unlikely that alterations of the enteric neurotransmitters may play

a major role in the pathophysiology of STC. However, more recent observations suggest that an excessive production of nitric oxide in the colonic myenteric plexus of patients with STC could play a pathophysiological role, concurring in the persistent inhibition of contractions^[60,61].

More consistent results have been reported with respect to enteric neurons, interstitial cells of Cajal (ICC), and enteric glial cells (EGC). In fact, a decrease of enteric neural elements (neurons and/or neurofilaments) seems to be a constant feature in studies evaluating patients with STC severe enough to require surgery for symptoms' relief^[62-66], and these abnormalities are often associated with a reduced number of ICC^[67-71], although this latter finding is not constantly present^[72]. We have recently shown in a relatively large and homogeneous group of patients with severe and intractable STC, compared to age-matched controls, that the ICC are significantly decreased in patients (Figures 1 A and B), that the enteric neuronal loss may be partially due to apoptotic phenomena, and that these patients display a significantly decreased number of EGC with respect to controls (Figures 1 C and D), in both the submucosal and myenteric plexuses^[73].

STC AS AN ENTERIC NEUROPATHY: CLINICAL, INSTRUMENTAL, AND PATHOLOGICAL RELATIONSHIPS

On the basis of the above evidences, it seems now possible to track a link between the clinical picture, represented by severe constipation with heavily delayed colonic transit, often refractory to medical treatment, the instrumental manometric findings, that mostly show impaired motility and propulsive activity of the large bowel (sometimes with the participation of the upper gastrointestinal segments too), and the abnormalities of the colonic ENS.

The neuronal loss is likely to affect the motor activity of the large bowel, reducing the likelihood of enteric neurotransmission. This defect is then strengthened by the concomitant reduction of the number of ICC, a cell population of paramount importance for the correct homeostasis of gastrointestinal motility. In fact, the primary role of ICC as intestinal pacemakers has been established in experimental animal models, where it has been shown that a lack of ICC networks leads to the absence of slow waves and is accompanied by delayed or absent intestinal motility^[74,75]. A decreased ICC function might therefore impair the colonic electrical slow wave activity, thereby affecting the contractile response and causing delayed transit in STC patients. In addition, it has been recently demonstrated that in patients with STC the expression of c-kit mRNA and c-kit protein is significantly decreased compared to controls, suggesting that alterations in the c-kit signal pathway may play an important role in ICC reduction in such patients^[76].

An interesting findings, never described before, was the significant decrease of EGC in both the myenteric and submucous plexuses in STC patients compared to controls. This cell population originates from the neural crest and provides both mechanical and physiological support for neuronal elements^[77]. The chief known function of the

glia in the adult is the formation of myelin sheaths around axons, allowing the fast connections essential for the nervous system function. Moreover, EGC maintain the appropriate concentrations of ions and neurotransmitters in the neuronal environment and are essential regulators of the formation, maintenance and function of synapses, the key functional units of the nervous system^[78,79]. Since EGC are thought to act as intermediaries in enteric neurotransmission^[80], it is likely that their decrease could synergistically act in further weakening the already precarious neuroenteric balance due to the decrease of neuronal elements and ICC found in patients with STC.

STC AS AN ENTERIC NEUROPATHY: CONCLUSIONS

The case for reclassifying STC other than an "idiopathic" or "functional" disorder is built. In fact, as seen above, clinical, instrumental, and pathological evidences exist that all point toward to a (perhaps) more precise definition of this condition as a true enteric neuropathy. It is probably too early to target STC with a different label, but at least we are now aware of some basic pathophysiological mechanisms potentially responsible for the symptoms and the manometric abnormalities found in this condition. Moreover, apart from mere semantic considerations, the demonstration of such background abnormalities might reveal useful for more targeted therapeutic approaches. For instance, in a mouse model the blockage of Kit receptors caused transdifferentiation of intestinal ICC to a smooth muscle phenotype^[81]; if the same would occur in the human colon and if ICC do not die in STC but rather redifferentiate, it might be possible to create conditions that would shift the phenotype back toward ICC.

In conclusion, the advancement of our knowledge of the possible pathophysiological mechanisms of "functional" disorders is important for a more correct clinical and therapeutic approach. Further studies are obviously needed before we can drop the "idiopathic" label from these disorders.

Abstract

Intestinal failure is a condition characterized by malnutrition and/or dehydration as a result of the inadequate digestion and absorption of nutrients. The most common cause of intestinal failure is short bowel syndrome, which occurs when the functional gut mass is reduced below the level necessary for adequate nutrient and water absorption. This condition may be congenital, or may be acquired as a result of a massive resection of the small bowel. Following resection, the intestine is capable of adaptation in response to enteral nutrients as well as other trophic stimuli. Identifying factors that may enhance the process of intestinal adaptation is an exciting area of research with important potential clinical applications.

STRUCTURAL AND FUNCTIONAL ADAPTATION

The intestine has an inherent ability to adapt morphologically and functionally in response to internal and external environmental stimuli. In fact, intestinal adaptation may be considered as a paradigm of gene-environment interactions. The array of phenotypic adaptations includes the modification of brush border membrane (BBM) fluidity and permeability, as well as up- or down-regulation of carrier-mediated transport. In animal models, intestinal adaptation occurs following the loss of a major portion of the small intestine ("short

bowel syndrome", SBS), following chronic ingestion of ethanol, sublethal doses of abdominal irradiation, diabetes, aging, fasting and malnutrition^[1-5]. Following intestinal resection, morphological and functional changes occur depending upon the extent of the intestine removed, the site studied, and the lipid content of the diet^[6]. The increase in nutrient absorption compensates for the loss of absorptive surface area, and minimizes the malabsorption that could otherwise potentially occur. Therefore, intestinal adaptation has important implications in the survival potential and welfare of the host^[7]. However, in some cases such as diabetes, intestinal adaptation may have deleterious effects, with enhanced nutrient uptake exacerbating prevailing hyperglycemia, hyperlipidemia and obesity^[8].

The mechanisms of intestinal adaptation occur at a variety of levels: physiological, cellular and molecular. Signals of adaptation may relate to various hormone levels, transcription factors, ATP levels, or changes in the concentration of luminal solutes^[5]. The signals and mechanisms of the adaptive process may be different for the jejunum and ileum, as well as in the intestinal crypt and villous tip, explaining the site-specific alterations and differences between crypt and villous enterocytes^[3,4].

Rodents are commonly used in well-characterized models of assessing the process of intestinal adaptation^[9]. Following small bowel resection in the rat, the remnant intestinal mucosa undergoes compensatory alterations in an attempt to restore normal absorptive capacity^[10]. Morphologic and functional changes include increases in crypt depth and villous length, enterocyte proliferation, as well as increased electrolyte, glucose and amino acid uptake^[9,10].

The adaptive process has been defined in terms of transport kinetics. Changes usually occur in the value of the maximal transport rate (V_{max}) rather than in the Michaelis affinity (K_m) constant of specific nutrient transporters (sugars and amino acids)^[11,12]. Furthermore, there may be alterations in the passive permeability coefficients of nutrients transported passively such as short-, medium- and long chain fatty acids and cholesterol^[3,4,13]. The increased V_{max} results from either an up-regulation of the total number of transporters, an increased number of transporting mucosal cells, or an increase in the intrinsic activity of the transporter^[14,15]. Intestinal resection also selectively changes the passive permeability properties of the BBM, as demonstrated by the increased uptake of fatty acids following intestinal resection, an increase that was not due to the changes in the mucosal surface area or the effective resistance of

the intestinal unstirred water layer (UWL)^[16]. Indeed, this altered permeability is due to changes in the lipophilic properties of the BBM due to variations in the lipid content of the BBM^[17].

Intestinal adaptation in the rodent model of chronic diabetes involves changes at the transcriptional as well as the posttranscriptional level, leading to increased Na⁺-coupled sugar absorption^[18]. After inducing acute hyperglycemia in rats, there is rapid up-regulation of glucose transport across the basolateral membrane (BLM) of the enterocytes^[19]. In this model, both the vascular as well as luminal glucose infusion causes an increase in the glucose transport capacity across the BLM^[20]. However, no significant increase in BLM cytochalasin B binding or in GLUT2 protein abundance was observed, suggesting that there may be a post-translational event that increases the number of GLUT2 proteins available for transport, such as the movement of GLUT2 to the BLM from a preformed pool within the enterocyte. Alternatively, the “intrinsic activity” of the transporter may be altered in the absence of changes in the protein abundance. Changes in the intrinsic activity of glucose transporters have been observed with hyperglycemia^[21], diabetes^[22], low luminal glucose concentrations^[14] and following the activation of MAPK and PI3K^[15].

Following extensive intestinal resection, there is hyperplasia of the remaining bowel, which may be accompanied by the enhanced uptake of nutrients^[23]. The alterations in the cell kinetics that result in modification of the nutrition status may be specific or non-specific. *Non-specific mechanisms* involve alterations that result in changes in the intestinal mucosal mass and/or the villous surface area, leading to modifications in the uptake of all nutrients, including those that are absorbed passively^[24]. On the other hand, *specific mechanisms* involve up- or down-regulation of transporters responsible for the uptake of particular nutrients, such as sugars or amino acids^[3,4].

The observation that morphological modifications may accompany intestinal adaptation in the rodent small bowel resection model was first made by Dowling and Booth^[23]. The remaining intestine after resection is hyperplastic, with greater villous height and crypt depth, leading to enhance mucosal surface area. However, while enhanced nutrient absorption is observed, the morphological changes do not necessarily explain the alterations in nutrient uptake. For example, one week after an 80% small bowel resection, the remaining intestine increased its mass to 50%-70% of its pre-resection level, yet the uptake of glucose increased only to approximately 33% of the pre-resection level^[10]. Thus, enhanced nutrient absorption may not be solely explained by intestinal hyperplasia and/or hypertrophy.

It is clear that dynamic morphologic parameters of the intestine may also adapt. For instance, the crypt cell production rates or the enterocyte migration rates change in some situations of intestinal adaptation^[25]. It is important that morphological alterations are considered when estimating the kinetic parameters of absorption. Morphological modifications such as blunting of the mucosal growth or mucosal hyperplasia after intestinal resection are observed when Dexamethasone (Dex) is given subcutaneously^[26]. Both kinetics and dynamic

morphologic parameters are altered in the adaptive process, and the influence of resection on nutrient uptake is due in part to these kinetic alterations. This may be due to the altered cell kinetics changing the population of the enterocytes along the villus, thereby leading to variations in the number of cells with transporter, or the activity of the transporters^[27,28].

Many animal models of intestinal adaptation have been described: glucose uptake has been found to be increased during pregnancy^[24], lactation^[30], with the ingestion of a high carbohydrate diet^[31], hyperglycemia^[32], with diabetes^[33], high alcohol intake^[34] and after intestinal resection^[35]. On the other hand, glucose uptake is decreased with aging^[36], external abdominal radiation^[37] and with the use of total parenteral nutrition^[38]. Most transporters are up-regulated by the levels of dietary substrate levels, whereas toxic substances and essential amino acids have the opposite effect^[9,38-40]. These examples illustrate the diversity and variability of this intestinal adaptive process.

The adaptive response in humans is not well characterized. Increases in nutrient absorption have been documented^[41-43] in humans following resection. The role of morphological changes in this process, however, has not been conclusively demonstrated. Remnant small bowel lengthening and dilatation has been noted in patients with SBS, suggesting morphologic mechanisms in human intestinal adaptation^[44]. However, the mucosal adaptation typical in rodent models is not seen in the human adaptive response^[45,46]. Indeed, several studies have shown that no increases in villous height or crypt depth were detected among patients who underwent intestinal resection, as compared to healthy controls^[42,47].

With the existence of various relevant anatomical, physiological and biochemical differences between the human and rodent gastrointestinal tracts^[48], and a conspicuous lack of comparable human studies, the clinical adequacy of the rat as a model of intestinal adaptation remains to be determined. Although the morphological and functional changes that occur in the rodent following massive small bowel resection have been well characterized^[23,49], direct evidence for similar changes in humans is lacking. Accordingly, caution must be used when attempting to extrapolate findings from rodent studies to the human population. An alternative model, the neonatal piglet, has been used in short bowel studies^[50-52]. The neonatal pig has recently been used to determine the effects of IGF-1 and dietary manipulations in an intestinal resection model^[53,54]. The degree to which the results obtained using this model reflect human findings has yet to be determined, and the rodent remains a popular model for studies of intestinal adaptation.

DIETARY REGULATION

The topic of the dietary regulation of intestinal gene expression has been reviewed^[31,55]. Dietary constituents provide continual environmental signals that elicit the expression of a host of genes that influence intestinal adaptation^[56]. Every day, enterocytes are exposed to different nutrients that vary according to the nutrient intake of the host. For this reason, the intestine must be able to

adapt to variations in the dietary load and composition^[31,57]. The intestine, like many other biological and engineered systems, is quantitatively matched to prevailing peak loads with modest reserve capacities. Indeed, physiological capacities are optimal and most economical if they ascribe to the adage “enough, but not too much”^[57]. Therefore, intestinal enzymes and transporters are characterized by a “safety factor”, a parameter that represents the ratio of its capacity to the load placed on it^[58]. The maintenance of this reserve capacity is biosynthetically costly, but is necessary given the unpredictable nature of dietary contents.

Parenteral vs enteral nutrition

Small bowel atrophy is well characterized in rodent models using total parenteral nutrition^[59-61]. Not surprisingly, the presence of luminal nutrients also contributes greatly to the adaptive process. Intestinal adaptation following massive small bowel resection is limited, but not entirely abolished in the absence of luminal nutrition^[62]. The following sections detail the effects of the type and amount of various luminal nutrients on the adaptive process.

Lipids

Dietary fat content influences the uptake of hexoses and lipids into rabbit jejunum following ileal resection^[16]. More recently, using a rat model of SBS, Sukhotnik *et al* (2003) demonstrated that early feeding of a high fat diet increased lipid absorptive capacity of the intestinal remnant^[63]. The main mechanisms of this effect may be an acceleration of structural intestinal adaptation, resulting in an increased number of enterocytes. However, at the molecular and cellular level, a high fat diet decreased mucosal mRNA levels of the lipid binding protein FAT/CD36 and decreased oleic acid uptake by isolated enterocytes. This is in contrast to what is seen with the liver fatty acid binding protein (L-FABP), a cytosolic lipid binding protein. Mice that were chronically fed a diet enriched in sunflower oil had increased the liver fatty acid binding protein (L-FABP) mRNA levels in their small intestine^[64]. The effect was specific to this gene, as the intestinal fatty acid binding protein (I-FABP) was unaffected.

Not only the amount of fat, but also the type of dietary fat may influence intestinal function. Keelan *et al* (1996) tested the hypothesis that the intestinal morphology and uptake of nutrients after resection of the distal half of the small intestine in rats responds to alterations in the dietary content of saturated (SFA) and polyunsaturated (PUFA) fatty acids^[65]. Adult female Sprague-Dawley rats were subjected to a sham operation or to the surgical resection of the distal half of the small intestine. The animals were fed chow for 3 wk, then either chow or isocaloric semisynthetic SFA or PUFA diets for a further 2 wk. The *in vitro* jejunal uptake of glucose was twice as high in animals that had undergone resection and were fed SFA than in those fed PUFA. It was suggested that SFA was necessary in the diet to ensure that adequate adaptation takes place.

Thiesen and colleagues examined the effect of dietary lipids on lipid uptake in rats post-resection. Intestinal resection had no effect on the mRNA expression of early

response genes (ERGs), proglucagon, or the ileal lipid binding protein (ILBP), but was associated with reduced jejunal mRNA for ornithine decarboxylase (ODC) and for the liver fatty acid binding protein (L-FABP)^[66]. These resection-associated changes in gene expression were not linked with alterations in the intestinal uptake of long chain fatty acids or cholesterol. In animals undergoing intestinal resection and fed SFA or given control vehicle, there was a reduction in jejunal proglucagon mRNA expression as compared to those animals fed chow or PUFA. ODC mRNA expression in the jejunum of resected animals was reduced. Thus, dietary lipids modify the uptake of lipids in resected animals, and ODC and proglucagon may be involved in this adaptive response^[67].

The way by which dietary lipids alter gene expression and consequently change membrane composition and/or nutrient transport may be through the activation of peroxisome proliferator-activated receptors (PPAR), hepatic nuclear factor-4 (HNF-4), nuclear factor κ B (NF κ B), and sterol response element binding proteins 1c (SREBP1c)^[56]. By binding to these transcriptional factors, dietary lipids affect the rate of transcription and consequently the protein synthesis of nutrient transporters^[65,68]. It is also known that PPARs belong to the superfamily of receptors that include the glucocorticosteroid receptor (GR)^[69]. When the locally acting glucocorticosteroid (GC) budesonide was administered concomitantly with SFA diet, the jejunal uptake of glucose was increased but the ileal uptake of fructose was reduced^[70].

It has been suggested that dietary lipids participate in signal transduction involving the activation of second messengers, such as cAMP, Ca²⁺ and diacylglycerol, thereby changing the mRNA expression^[71]. Studies with glycosphingolipid have revealed the importance of these lipids and their metabolites in signaling pathways via the tyrosine kinase-linked receptors, a signal system mediated by protein kinase C (PKC), mitogen activated protein kinase (MAPK), other kinases, as well as mediated by the cytosolic Ca²⁺ concentration^[72]. More recently, additional new signals involved in the adaptive intestinal response 3 days after a 50% intestinal resection have been identified by cDNA microarray analysis, such as small proline-rich protein 2, involved in wound healing; glutathione reductase, a gene involved in intestinal apoptosis; NF-2 family members, also involved in apoptosis; etoposide-induced p53-mediated apoptosis; basic Kruppe-like factor, a transcription factor that activates the promoter for IGF-1; and prothymosin- α , involved in cell proliferation^[73,74]. These observations of altered expression of signals are useful to generate hypotheses that can be tested in future studies to establish whether these signals represent a primary or a secondary event.

The glycosphingolipid, phospholipid, cholesterol and fatty acid composition of plasma membranes may be modified in mammalian cells^[75]. For example, Keelan *et al*. (1990) demonstrated that alterations in dietary fatty acid saturation influence intestinal BBM phospholipid fatty acid composition in rats^[76]. The investigators proposed that the previously reported diet-associated changes in active and passive intestinal transport are due at least in part to these alterations in the fatty acid composition in BBM phospho-

lipids. A diet enriched with SFA is associated with increases in the saturation of BBM phospholipid fatty acids, while a diet enriched with PUFA is associated with an increase in the unsaturation of BBM phospholipid fatty acids^[3,4]. The degree of fatty acid unsaturation or saturation, as well as the cholesterol and ganglioside/glycosphingolipid content, are factors that influence the fluidity of the BBM^[77,78]. Changes in the fluidity of the BBM may alter the permeation of molecules and nutrients through this barrier, as well as the conformation of binding sites on transporter proteins such as SGLT1 and GLUT5^[79]. For example, alterations in BBM fluidity influence the passive uptake of lipids, as well as the carrier-mediated D-glucose uptake^[79,80]. While enhancement of fluidity increases the uptake of lipids, fluidization of BBM from enterocytes located on the villous tip decreases the uptake of D-glucose to levels seen in the BBM from enterocytes located on the crypts^[81]. The explanation for the effect of BBM fluidity on glucose uptake is unknown, but represents a potentially important post-translational process.

The lipid composition of cell membranes alters the passive permeability properties and transporter activity across the membrane^[75]. The altered membrane lipid composition may act in part by changing the viscosity or fluidity of the membrane, including the microenvironment surrounding the transporter. Meddings (1989) compared *in vivo* membrane lipid permeability within the same intestinal region, under conditions where membrane physical properties were radically altered by feeding rats an inhibitor of cholesterol synthesis^[82]. Marked reductions in membrane fluidity were observed due to the replacement of membrane cholesterol with its precursor 7-dehydrocholesterol. Associated with these alterations was a pronounced reduction in membrane lipid permeability. Therefore, BBM membrane lipid permeability, *in vivo*, appears to be correlated with the physical properties of the bilayer.

Recently, two types of specialized microdomains in the BBM have been identified: lipid rafts and caveolae. These regions are important in signal transduction as well as lipid and protein trafficking^[83-85]. They are enriched in saturated fatty acids, cholesterol and gangliosides^[84-86]. Feeding rats a diet enriched with gangliosides increases jejunal glucose uptake^[87]. Feeding a ganglioside-rich diet increases the ganglioside content and decreases the cholesterol content in the intestinal mucosa, plasma, retina and brain^[88]. Similar changes in the lipid composition of intestinal microdomains, or lipid rafts, occur following ganglioside feeding^[89]. Although SGLT1 has been localized to these microdomains in renal epithelial cells^[90], it is not known if sugar transporters reside in intestinal BBM microdomains. If this is the case, local changes in membrane fatty acids may affect the activity of transporter by altering the configuration of the protein, potentially exposing or masking the transporter binding sites and thereby modifying nutrient uptake. In addition, gangliosides may influence intestinal sugar transport *via* their effect on pro-inflammatory mediators, many of which are known to influence intestinal sugar transport^[91-93]. For example, in rats challenged with lipopolysaccharide, ganglioside feeding reduced the production of intestinal platelet activating factor, PGE2, LTB4, as well as reduced plasma levels of IL-1 β and TNF- α ^[94].

Carbohydrates

Dietary carbohydrate may induce the intestinal adaptive response by increasing the abundance of hexose transporters to facilitate a higher rate of sugar absorption^[11]. In a murine model, intestinal glucose uptake was directly correlated with the dietary carbohydrate load^[31,39,95]. The effect of dietary carbohydrate on nutrient transporter abundance has been reported in several animal models. For instance, the abundance of SGLT-1 in BBM and GLUT2 in the BLM were elevated in animals fed a high carbohydrate diet and associated with this enhanced level of protein was an increase in glucose absorption^[19,96,97]. As well, the GLUT5 transporter abundance was elevated with enhanced dietary fructose, leading to increased fructose uptake^[98].

The initiation of the dietary glucose-induced adaptive response occurs in the intestinal crypts, where the transport capacities of the nutrient transporters are programmed^[39,40,95,97]. In this mouse model, phlorizin binding was utilized as a means of measuring the glucose transporter site density. Changing the murine diet from a high to a low carbohydrate regimen reduced the amount of glucose transporter, as estimated from the density of phlorizin binding. The alteration in the density of phlorizin binding was first observed in the crypt cells, and over a three-day period was subsequently seen in the villous tip cells. This suggests that the crypt enterocytes respond to the high carbohydrate diet to increase their phloridzin binding; those cells then migrate up the villous over the next three days, contributing to the process of enhancing glucose uptake.

The enterocytes may adapt to the high carbohydrate diet by increasing the crypt cell turnover rate, enhancing the enterocyte migration rate, as well as by reprogramming the capability of nutrient transporters in the crypts to accommodate to the requirement for higher monosaccharide transporters^[97].

Animals fed a glucose-enriched diet have an increased glucose uptake, resulting from up-regulation of both BBM and BLM glucose transporters^[19,96,99]. The precocious introduction of dietary fructose causes enhanced expression of fructose transporters and fructose transport earlier during development, without changing glucose uptake^[97]. The substrates glucose and fructose are both specific in terms of up-regulation of their corresponding transporters, SGLT1 and GLUT5. Therefore, increasing the sugar composition of the diet results in increases in the transport of these nutrients. In contrast, increases in essential amino acids or other substances that are potentially toxic at high levels (such as iron, calcium or phosphorous) are associated with no change, or even reductions in transport^[38,100].

Furthermore, in many cases other nutrients may be equal or even more potent inducers of the transporter than its specific substrate. For example, young animals fed a diet enriched with polyunsaturated fatty acids (PUFA) have a decline in glucose uptake, as compared to animals fed a saturated fatty acid (SFA) enriched diet^[70,101,102]. Similarly, Vine *et al* (2002) studied the effect of various fatty acids on the passive and active transport properties of rat jejunum, and found that an SFA-enriched diet increased Na⁺-dependent glucose uptake when compared to a diet

enriched with n6 PUFA^[103]. In contrast, in aged rats, glucose uptake is increased by PUFA and not by SFA^[36].

Dietary fiber also modulates intestinal nutrient uptake. For example, a diet enriched with fermentable fiber increased glucose uptake and GLUT2 transporter abundance in dogs^[104]. *In vitro* studies, in which rat intestinal tissue was incubated with β -glucan isolated from barley or oats, show reductions in the uptake of stearic and linoleic acids (Drozdzowski *et al*, 2005, unpublished observations). Furthermore, many studies have investigated the effect of TPN supplemented with short chain fatty acids, the products of fiber fermentation. Increases in glucose uptake, GLUT2 mRNA and protein, and intestinal morphology were seen in normal rats as well as in rats following intestinal resection^[105-108].

Protein

Dietary protein also has an impact on the intestinal morphology and active amino acid transport^[40,109,110]. Both *in vitro*^[110] and *in vivo*^[109] rat experiments have shown that a high protein diet increases amino acid uptake in the jejunum. An alteration in the amount of dietary protein induces reversible adaptation of the non-essential amino acid transport rate^[111]. Feeding a high protein diet to mice induces a 77%-81% increment in the uptake of non-essential amino acids^[40], yet only a 32%-61% increase for essential amino acids. On the other hand, a protein-deficient regimen reduces uptake of non-essential amino acids, such as aspartate and proline, and maintains or increases uptake for essential amino acids and alanine. Thus, the nature of the adaptive response depends upon the type of amino acid and the needs of the animal.

Glutamine is a key metabolic fuel for enterocytes, mediating cellular nucleic acid synthesis and proliferation. Parenterally fed rats demonstrate decreased atrophy of the intestinal mucosa following glutamine supplementation^[112]. Glutamine administration also normalizes the reduced levels of intestinal adaptation in rats receiving total parenteral nutrition (TPN) following intestinal resection^[113]. It is noteworthy that some studies of oral glutamine supplementation in the rat have failed to document more than temporary mucosal proliferation^[114]. This indicates that mechanistic differences that are intrinsic to the method of glutamine administration may exist, and suggests that these may be significant in regulating the adaptive response.

Other amino acids may inhibit intestinal adaptation. Sukhotnik *et al* (2005) examined the effects of the parenteral administration of the nitric oxide precursor arginine to rats following 75% small bowel resection^[115]. Arginine supplementation was associated with lower cell proliferation indexes and greater enterocyte apoptosis. This observation led the investigators to conclude that arginine inhibits structural intestinal adaptation.

Polyamines

Polyamines are found in all eukaryotic cells^[116], and they play an important role in growth and differentiation^[117]. Polyamines are obtained either from the diet, or via synthesis from ornithine^[118]. Uda *et al* (2002) demonstrated that luminal perfusions of polyamines rapidly (in less

than 5 min) enhance intestinal glucose uptake in rats, and increase BBM SGLT1 protein^[119].

Polyamine synthesis or uptake may be an important event that initiates the adaptive hyperplasia seen in the intestinal remnant after partial small bowel resection. Enteral diets supplemented with ornithine alpha-ketoglutarate (OKG), a precursor for arginine, glutamine and polyamines, enhances intestinal adaptation in models of intestinal resection^[120,121]. Indeed, studies by both Tappenden *et al*^[122] and Thiesen *et al*^[66] suggest that ornithine decarboxylase (ODC), a key enzyme in polyamine synthesis, may mediate the adaptive process in rats that is stimulated by the administration of either glucocorticosteroids or short chain fatty acids to rats following intestinal resection.

The role of polyamines in the adaptation of the intestine during development has also been studied. Wild *et al* (2005, unpublished observations) showed that in postnatal rats, oral spermidine treatment resulted in the precocious expression of the intestinal sugar transporters (SGLT1, GLUT2 and GLUT5), as well as ODC. This led the investigators to conclude that oral polyamines induce precocious maturation of sugar transporters, which may be mediated by alterations in ODC gene expression.

HORMONAL REGULATION

Glucocorticosteroids

In a model of extensive intestinal resection (50% enterectomy), the proximal and distal intestinal remnants were adequate to assess the morphology and function at these sites^[11,112]. The glucocorticosteroid prednisone had no effect on the intestinal uptake of glucose or fructose in these resected animals^[70]. In contrast, the locally acting steroid budesonide increased by over 120% the value of the jejunal Vmax for the uptake of glucose, and increased by over 150% the ileal uptake of fructose. The protein abundance and mRNA expression of SGLT1, GLUT5, GLUT2 and Na⁺/K⁺ APTase α 1 and β 1 cannot explain the enhancing effect of budesonide on glucose and fructose uptake. Budesonide, prednisone and dexamethasone reduced the jejunal expression of the early response gene c-jun. In resected animals, the abundance of the mRNA of ODC in the jejunum was reduced, and glucocorticosteroids (GC) reduced the jejunal expression of the mRNA of proglucagon. These data suggest that the enhancing influence of GC on sugar uptake in resected animals may be achieved by post-translational processes involving signalling with c-jun, ODC and proglucagon, or other as yet unknown signals.

In contrast, the uptake of D-fructose by GLUT5 was similarly increased with budesonide and with prednisone. The increases in the uptake of fructose were not due to variations in the weight of the intestinal mucosa, food intake, or in GLUT5 protein or mRNA expression. There were no steroid-associated changes in mRNA expression of c-myc, c-jun, c-fos, of proglucagon, or of selected cytokines. However, the abundance of ileal ODC mRNA was increased with prednisone. Giving budesonide or prednisone to post-weaning rats for four weeks in doses equivalent to those used in clinical practice increases

fructose but not glucose uptake. This enhanced uptake of fructose was likely regulated by post-translational processes^[70].

Growth hormone

Growth hormone (GH) has been suggested as possessing pro-adaptive properties^[123]. In rats and piglets, GH administration results in an increase in small bowel length and function per unit length^[124]. Hypophysectomized rats undergo mucosal hypoplasia of the small bowel, as well as a reduced adaptive response following resection that is restored by GH^[125]. In contrast, transgenic mice expressing elevated levels of GH show hypertrophy of the small intestine^[124]. IGF-1 expression in the small bowel is regulated by GH and is believed to induce enterotrophic effects following resection^[113,126]. In a rat model of SBS, acute IGF-1 treatment of TPN fed rats produced sustained jejunal hyperplasia, and facilitated weaning from parenteral to enteral nutrition^[127]. GH administration to normal rats has been reported to have positive effects on mucosal growth and intestinal adaptation following massive resection^[128], although contradictory data exists^[129,130]. Human and rabbit studies have indicated that increased nutrient transport activity devoid of morphologic changes may be the method of GH-induced intestinal adaptation^[131].

GH administration has been shown to inhibit the liberation of glutamine from muscle during catabolic states in humans^[132], suggesting a possible role for combined GH and glutamine provision in adaptive bowel enhancement. Trials investigating any such synergism in the rat have yielded conflicting results. Some studies have failed to demonstrate an additive effect of GH and glutamine in the enhancement of post-resection intestinal adaptation^[133], while others have documented a positive synergistic effect^[134].

The mechanisms of action by which GH and/or glutamine may enhance the human adaptive process cannot be clearly surmised from the existing rodent data. Many studies have inherent deficits in terms of nutrient controls that could have contributed to the conflicting outcomes which have been described. The trophic effects of enteral nutrition on the adaptation process are well known^[3]. Studies evaluating the contribution of non-specific, nutrient-derived augmentation of the adaptation process, as well as the mechanisms of any such nutrient factor interactions, may be useful in defining more accurate and therapeutically applicable results.

Animal studies have confirmed the enhancing effect of GH on nutrient absorption^[123,124]. For example, GH has been shown to enhance the absorption of amino acids using *ex vivo* human BBM vesicles^[134]. An intestinal mucosal GH receptor has been described in rats and humans^[135], and GH promotes cell differentiation and clonal expansion of these differentiated cells^[136].

The use of growth hormone in human clinical studies has been investigated. It has been suggested that the efficacy of GH and/or glutamine therapy in the adaptive response of the small bowel may be based mainly upon the clinical status of the patient (for example, the

presence of a portion of the colon in continuity with the remaining resected small intestine)^[137]. Evaluation of the effect of such variables in the rat may facilitate further understanding of the pathology and physiology of the bowel adaptation process, as well as more clearly defining positive predictive indicators of the bowel's ability to be rehabilitated. Furthermore, existing human data has indicated that the administration of high concentrations of GH can actually increase patient morbidity and mortality^[138], demonstrating a primary need for equivalent clinical research in the testing of these factors.

In home parenteral nutrition (HPN)-dependent patients with SBS, the use of high dose recombinant human GH (0.4 mg/kg per day) in controlled^[138,139] and uncontrolled studies^[140] has led to variable results. These patients were given glutamine supplements by mouth or parenterally, and their diet was modified. In the randomized and placebo-controlled study of Scolapio *et al.*^[139], the subjects ingested a standardized 1500 kcal/d diet, which is clearly different from the hyperphagic diet consumed by many SBS patients^[140], and which may contribute to the physiological adaptation that occurs in the remaining intestine after extensive resection. It is unclear whether glutamine is beneficial for the adaptive response in humans, and in rat models of SBS, it is unclear whether glutamine supplementation is efficacious for the adaptive process^[2,141]. Furthermore, both a hyperphagic diet and the absence of malnutrition are needed for humans to achieve optimal intestinal adaptation^[44,142].

When HPN-dependent patients with SBS were provided a usual *ad libitum* hyperphagic diet, and given low doses of GH (0.05 mg/kg per day) for three weeks, there was significant improvement in the intestinal absorption of energy (15% \pm 5%), nitrogen (14% \pm 6%) and carbohydrate (10% \pm 4%)^[143]. The increased food absorption represented 37% \pm 16% of total parenteral energy delivery. Body weight, lean body mass, D-xylose absorption, insulin-like growth factor 1, and insulin-like growth factor binding protein 3 increased, whereas uptake of GH binding protein decreased. During treatment with GH, improvement in net intestinal absorption compared with placebo was 427 \pm 87 kcal/d, representing 19% \pm 8% of the total energy expenditure required to obtain energy balance equilibrium in patients with SBS^[140].

A review of the literature in this area by Matarese *et al.*^[144] noted that there were differences in gastrointestinal (GI) anatomy, dietary compliance, nutritional status, presence of mucosal disease, and diagnosis both within and between the studies. They concluded that “*administering recombinant human growth hormone alone or together with glutamine with or without a modified diet may be of benefit when the appropriate patients are selected for treatment*”.

Insulin-like growth factor 1

Insulin-like growth factor 1 (IGF-1) also proved to be efficient in increasing intestinal adaptation following resection in rats. IGF-1 treatment following 70% jejuno-ileal resection attenuated fat and amino acid malabsorption^[145] and increased total gut weight by up to 21%. The IGF-1 receptor was increased in the jejunum and

colon due to resection. Resection also increased circulating IGF-binding proteins (IGFBP). IGF-1 treatment had no effect on IGF-1 mRNA or IGF-1 receptor density, but increased IGFBP5 in the jejunum. This increase in IGFBP5 was correlated with jejunal growth after IGF-1 treatment^[146].

More recently, a study was conducted to determine the effect of IGF-1 on enterocyte kinetics following intestinal resection^[147]. IGF-I treatment in resected rats significantly increased jejunal mucosal mass by 20% and mucosal concentrations of protein and DNA by 36% and 33%, respectively, above the response to resection alone. These changes reflected an increase in enterocyte proliferation and an expansion of the proliferative compartment in the crypt. No further decrease in enterocyte apoptosis and increase in enterocyte migration were observed.

IGF-I treatment may also facilitate weaning from parenteral to enteral nutrition. After a 60% jejunoileal resection plus cecectomy, rats treated with recombinant human IGF-I (3 mg/kg body weight) or control vehicle were maintained exclusively with TPN for 4 d and were then transitioned to oral feeding. TPN and IGF-I were stopped 7 d after resection and rats were maintained with oral feeding for 10 more days. Acute IGF-I treatment induced sustained jejunal hyperplasia, as demonstrated from the presence of greater concentrations of both jejunal mucosal protein and DNA, and was associated with the maintenance of a greater body weight and serum IGF-I concentrations^[127].

A study was done using male transgenic mice with targeted smooth muscle IGF-1 overexpression^[148]. These animals and non-transgenic littermates underwent 50% proximal small bowel resection. The results showed that growth factor over-expression led to a unique mucosal response characterized by a persistent increase in remnant intestinal length and an increase in mucosal surface area. Therefore, IGF-1 signaling from within the muscle layer may be important in resection-induced intestinal adaptation.

Epidermal growth factor

Epidermal growth factor (EGF) up-regulates intestinal nutrient transport^[149]. This effect is mediated by PKC and PI3K^[150] and involves the redistribution of SGLT1 from microsomal pools to the BBM^[151]. After massive intestinal resection, endogenous EGF is increased in the saliva and is decreased in the urine^[152]. EGF stimulates intestinal adaptation after intestinal resection: the BBM surface area and the total absorptive area increased until d 10, and EGF treatment induced a further increase in BBM surface area^[153]. In a study by O'Brien and colleagues^[154], mice underwent a 50% small bowel resection or sham operation, and were then given orally an epidermal growth factor receptor (EGFR) inhibitor (ZD1839, 50 mg/kg per day) or control vehicle for 3 d. ZD1839 prevented EGFR activation, as well as the normal postresection increases in ileal wet weight, villus height, and crypt depth. Enterocyte proliferation was reduced two-fold in the resection group by ZD1839. These results more directly confirm the requirement of a functional EGFR as a mediator of the

postresection adaptation response. Interestingly, previous work has demonstrated that the EGFR is predominantly located on the BLM of enterocytes^[155], but after small bowel resection the EGFR shows redistribution from the BLM to the BBM, with no change in the total amount of EGFR^[156]. It is not known how this redistribution occurs. This is an important point, since modification of this process may represent a useful means to accelerate the intestinal adaptive process.

In a study by Knott *et al*^[157], laser capture microdissection (LCM) microscopy was used to elucidate the specific cellular compartment(s) responsible for postresection changes in EGFR expression. Mice underwent a 50% proximal resection or sham operation, and after three days frozen sections were taken from the remnant ileum. Individual cells from the villi, crypt, muscularis and mesenchymal compartments were isolated. EGFR mRNA expression for each cell compartment was quantified using real-time reverse transcription polymerase chain reaction (RT-PCR). EGFR expression was increased two-fold in the crypt after resection, directly correlating with the zone of cell proliferation. This supports the hypothesis that EGFR signaling is crucial for the mitogenic stimulus for adaptation. The additional finding of increased EGFR expression in the muscular compartment is novel, and may imply a role for EGFR in the muscular hyperplasia seen after massive small bowel resection. As noted previously, it is of interest that the muscle layer also appears to play a role in the adaptive response to IGF-1^[148].

The treatment of resected rats with EGF has been studied. In a study by Sham *et al*^[158], male juvenile rats underwent either transection or ileocecal resection leaving a 20-cm jejunal remnant. Resected animals were treated orally with placebo or recombinant human EGF. Resected EGF-treated animals lost significantly less weight than those in the transection group, absorbed significantly more 3-O-methylglucose, and had reduced intestinal permeability as determined by the lactulose/mannitol ratio. Work by Chung *et al*^[159] using rabbits showed that intestinal resection altered SGLT1 mRNA and protein expression along the crypt-villous axis, with expression being highest in the mid-villous region. Oral EGF normalized SGLT1 expression, resulting in a gradient of increasing expression from the base of the villus to the villous tip.

More recently, Nakai and colleagues^[160] investigated the role of EGF in stimulating intestinal adaptation following small bowel transplantation. Treatment of rats with EGF (intraperitoneally for three days) following intestinal transplantation resulted in increased glucose absorption, SGLT1 abundance and the villous height and crypt depth in the graft. This has not yet been studied in humans.

Keratinocyte growth factor

In a study by Yang *et al*^[161], adult C57BL/6J mice were randomized to a 55% mid-small bowel resection, resection with keratinocyte growth factor (KGF) administration (SBSKGF), or a sham-operated (control) group, and were killed at d 7. Ussing chamber studies showed that KGF increased the net transepithelial absorption of 3-O-methyl glucose as well as sodium-coupled alanine absorption, but

had no effect on epithelial permeability barrier function. Epithelial cells were separated along the crypt-villous axis with LCM, and epithelial KGF receptor (KGFR) mRNA abundance was studied using real time RT-PCR. KGF up-regulated KGFR mRNA abundance, predominately in the crypt and the lower portion of the villus.

Leptin

Leptin plays an important role in the regulation of body fat and satiety (reviewed in^[162]). Leptin reduces food intake^[163] and leptin-deficient mice develop obesity^[164]. Leptin may be a potential growth factor for the normal rat small intestine. The effect of 14 d of parenteral leptin administration (2 µg/kg per day) to rats following 80% small bowel resection was studied. Leptin was associated with a 44% increase in galactose absorption and a 14% increase in GLUT-5 abundance, but with no change in DNA content or in SGLT abundance. These findings suggest that leptin may potentially be clinically useful in patients with impaired intestinal function^[165].

Ghrelin

Ghrelin is a gastric hormone that is released in response to enteral nutrients. It has an opposite effect when compared to leptin, as it stimulates food intake^[166]. The role of ghrelin in intestinal adaptation is unknown.

Glucagon-like peptide 2

Animal studies have demonstrated a potential role for GLP-2 in the adaptive response following intestinal resection^[147]. Several investigators have demonstrated increases in plasma GLP-2 levels following intestinal resection in rats^[167-169]. In a study by Dahly *et al.*^[147], rats were subjected to 70% midjejunoileal resection or ileal transection, and were maintained with TPN or oral feeding. Resection-induced adaptive growth in TPN- and orally-fed rats was associated with a significant positive correlation between increases in plasma bioactive GLP-2 and proglucagon mRNA abundance in the colon of TPN-fed rats and in the ileum of orally fed rats. While these increases were transient in the TPN-fed group, luminal nutrients produced a sustained increase detected at 3 and 7 d post-resection. These data support a significant role for endogenous GLP-2 in the adaptive response to mid-small bowel resection in both TPN and orally fed rats^[147].

Recently, further correlations between post-resection GLP-2 levels, morphological indices, crypt cell proliferation rates and nutrient absorption have been made^[170]. In this study, an inverse correlation was found between post-prandial GLP-2 levels and fat or protein absorption as assessed by a 48 h balance study. These results, along with data obtained from studies showing that GLP-2 immunoneutralization inhibits post-resection adaptation^[171], further implicate GLP-2 as a post-resection mediator of adaptation.

GLP-2 administration in rats increases the adaptive response to massive intestinal resection^[172]. In this study, Sprague-Dawley rats were divided into two groups, with a 75% mid-jejunum-ileum resection and a sham operated groups. Animals were treated with 0.1 µg/g GLP-2 analog (protease resistant human GLP-2) or placebo given

subcutaneously twice daily for 21 d. The total weight of the rats and the mucosal mass per centimeter were compared between the groups. Administration of this peptide or its analogs was associated with an increase of the mucosal mass in the proximal jejunum and terminal ileum. The absorption and urinary excretion of oral D-xylose is proportional to intestinal mucosal surface area and transit time. While resection reduced D-xylose excretion and GLP-2 restored D-xylose excretion to levels above control values within 21 d of administration. This indicates that GLP-2 has a positive effect on intestinal morphology and absorptive function following resection.

More recently, Martin *et al.*^[173] investigated the effects of GLP-2 in a TPN-supported model of experimental short bowel syndrome. Juvenile Sprague-Dawley rats underwent a 90% small intestinal resection and were randomized to three groups: enteral diet and intravenous saline infusion, TPN only, and TPN plus 10 µg/kg per hour^{GLP-2}. TPN plus GLP-2 treatment resulted in increased bowel and body weight, villus height, intestinal mucosal surface area, and crypt cell proliferation. Intestinal permeability tests showed that GLP-2 reduced the lactulose-mannitol ratio indicating that GLP-2 lowered intestinal permeability when compared with the TPN alone. GLP-2 increased serum GLP-2 levels and intestinal SGLT-1 protein abundance compared with either TPN or enteral groups. This study demonstrates that GLP-2 is capable of stimulating intestinal adaptation in the absence of enteral feeding.

Because a number of hormones and growth factors have been shown to influence intestinal function, Washizawa *et al.*^[174] compared the effects of GLP-2, GH and KGF on markers of gut adaptation following massive small bowel resection (MSBR). KGF increased goblet cell numbers and TTF3, a cytoprotective trefoil peptide, in the small bowel and the colon. They also observed that while both GH and KGF increased colonic mucosal growth, GLP-2 exerted superior trophic effects on jejunal growth. GLP-2 also increased the glutathione/glutathione disulfide ratio, resulting in improved mucosal glutathione redox status throughout the bowel. Because of the differential effects of GLP-2, GH and KGF on gut adaptation following MSBR, the authors conclude that a combination of these agents may be most beneficial.

A pilot study to determine the efficacy of GLP-2 in patients with SBS has been completed. A non-placebo controlled study was conducted in 8 patients with SBS with an end-enterostomy type of anastomosis (6 had Crohn's disease and 4 were not receiving HPN)^[175]. Treatment with GLP-2 (400 µg subcutaneously twice a day for 35 d) increased intestinal absorption of energy, body weight, and lean body mass. Crypt depth and villous height were also increased in 5 and 6 patients, respectively.

A review by Jeppesen^[176] on the role of GLP-2 in the treatment of SBS concludes that "Currently, hormonal therapy in short-bowel patients should be considered experimental and it is only recommended in research studies. The optimal duration and concentration requirements for GLP-2 to induce beneficial effects on intestinal secretion, motility, morphology and most importantly absorption, are not known. Optimal dosage and administration of this new treatment to short-bowel patients may eventually result in long-term improvements in nutritional status and independence of

parenteral nutrition in a larger fraction of short-bowel patients".

SIGNALS OF INTESTINAL ADAPTATION

A number of studies have investigated the signals involved in intestinal adaptation using animal models of intestinal resection. Dodson *et al*^[177] identified three subsets of genes that were up-regulated by constructing a cDNA library from the remnant ileum of resected rats. This library was screened, and subtractive hybridization was used to identify genes that were induced following resection. These included genes involved with regulating the absorption and metabolism of nutrients. For example, L-FABP, apolipoprotein A-IV, cellular retinal binding protein II and ileal lipid binding protein were identified as genes that were induced following 70% intestinal resection in rats. Genes involved in cell cycle regulation were also identified. For example, phosphorylation and dephosphorylation are important regulators of the cell cycle, and PP1 δ , a subunit of a serine/threonine phosphatase was indeed up-regulated. Grp78, a member of the heat shock protein family was also increased. Grp78 resides in the ER and acts as a chaperone during protein assembly and transport. It may also have a protective role, and prevent apoptosis as a way of promoting the proliferative response following intestinal resection^[178,179].

Rubin *et al*^[180] further characterized the molecular and cellular mechanisms following 70% resection in rats. An immediate early gene, PC4/TIS7, was markedly increased soon after resection, with levels returning back to normal by one week post-resection. Although the function of this protein is unknown, it may be related to cytodifferentiation as it is expressed only in the villus and not in the crypts.

Erwin *et al*^[74] used cDNA microarrays to gain insight into the mechanism of intestinal adaptation. Mice underwent a 50% intestinal resection and three days afterwards RNA was extracted from the remnant ileum. Multiple genes were induced, and they divided these into four categories: (1) Apoptosis, DNA synthesis, repair and recombination (10 genes); (2) Oncogenes, tumor suppressors, cell cycle regulators (3 genes); (3) Stress response, ion channels and transport (4 genes); (4) Transcription factors and general DNA-binding proteins (1 gene). Many of the genes (ODC, c-neu, glucose-related protein, IGFBP-4) that were identified agreed with the results of other studies of intestinal resection. For example, ODC was increased in this study, and this agrees with previous findings that showed ODC to be involved in the adaptive process^[66,122,181]. Some new factors were also identified including glutathione reductase (involved in apoptosis), Basic Kruppel-like factor (transcriptional regulator that activates the IGF promoter), prothymosin- α (associated with increased cell proliferation), and eteptide induced p53 responsive mRNA (stress response protein involved in p53 mediated apoptosis).

Stern *et al*^[73] performed a similar analysis of gene expression following 50% intestinal resection in rats. The gene with the largest increase was identified as *spr2*, a novel gene unknown previously to be involved in intestinal adaptation. EGF administration post-resection further increased *spr2* expression and enhanced the

adaptive response. This protein plays a role in the terminal differentiation of stratified squamous epithelium. Its role in the intestinal epithelium is unclear and warrants further investigation.

Finally, a variety of other signals have been described as possibly playing a role in the process of intestinal adaptation. These include prostanoids^[182], uncoupling proteins^[183], peroxisome proliferation-activated receptor α (PPAR α)^[184], transforming growth factor- α ^[185], SPARC (secreted protein, acidic and rich in cysteine)^[186], Bcl-2^[187], endothelin-1^[188], erythropoietin^[189], the GATA family of zinc finger transcription factors^[190], hepatocyte growth factor^[191], the early response genes (ERG)^[192], PC4/TIS7^[180] and epimorphin^[193]. More recently, augmented Wnt signaling has been shown to enhance the adaptive response to massive small bowel resection^[194]. Several of these signals may be useful to modify in a clinical setting to enhance the intestinal adaptive response.

Microarray technology is a powerful tool that is constantly developing into a more sophisticated technique of identifying novel genes involved in physiological processes. Intestinal adaptation awaits further characterization by hypothesis-testing studies. From the information that is available at this time, it is clear that genes regulating the cell cycle, proliferation, differentiation and apoptosis are important components of the adaptive process.

CONCLUSION

The process of intestinal adaptation is complex and multifaceted. Although a number of trophic nutrients and non-nutritive factors have been identified in animal studies, successful and reproducible clinical trials are lacking. However, the functional adaptation of segmental bowel grafts has been studied. Benedetti *et al* (2001) reported a case study in which a segmental graft from a living donor demonstrated pregressive functional adaptation, as assessed by water and D-xylose absorption as well as fecal fat studies^[195]. Morphological adaptation has been documented in three patients following successful intestinal transplantation^[196]. In fact, more than 50% increases in villous height and absorptive surface area were seen at 6 mo, suggesting that functional changes in intestinal function are associated with morphological changes. Therefore, while human data is limited there is evidence indicating that the adaptive process occurs. Still, additional human studies are required before the clinical implications of the animal data can truly be established. Understanding the mechanisms underlying the adaptive process in humans may direct research toward strategies that maximize intestinal function and impart a true clinical benefit to patients with short bowel syndrome.

Abstract

The etiology of inflammatory bowel disease (IBD) has not yet been clarified and immunosuppressive agents which non-specifically reduce inflammation and immunity have been used in the conventional therapies for IBD. Evidence indicates that a dysregulation of mucosal immunity in the gut of IBD causes an overproduction of inflammatory cytokines and trafficking of effector leukocytes into the bowel, thus leading to an uncontrolled intestinal inflammation. Such recent advances in the understanding of the pathogenesis of IBD created a recent trend of novel biological therapies which specifically inhibit the molecules involved in the inflammatory cascade. Major targets for such treatment are inflammatory cytokines and their receptors, and adhesion molecules. A chimeric anti-TNF- α monoclonal antibody, infliximab, has become a standard therapy for CD and it is also likely to be beneficial for UC. Several anti-TNF reagents have been developed but most of them seem to not be as efficacious as infliximab. A humanized anti-TNF monoclonal antibody, adalimumab may be useful for the treatment of patients who lost responsiveness or developed intolerance to infliximab. Antibodies against IL-12 p40 and IL-6 receptor could be alternative new anti-cytokine therapies for IBD. Anti-interferon- γ and anti-CD25 therapies were developed, but the benefit of these agents has not yet been established. The selective blocking of migration of leukocytes into intestine seems to be a nice approach. Antibodies against $\alpha 4$ integrin and $\alpha 4\beta 7$ integrin showed benefit for IBD. Antisense oligonucleotide of intercellular adhesion molecule 1 (ICAM-1) may be efficacious for IBD. Clinical trials of such compounds have been either recently reported or are currently underway. In this article, we review the efficacy and safety of such novel biological therapies for IBD.

INTRODUCTION

Although the etiology of inflammatory bowel disease (IBD), such as, Crohn's disease (CD) and ulcerative colitis (UC), has not yet been fully addressed, there has been remarkable progress in the understanding of this field in the past decade. In normal bowels, the immune reaction is sophisticatedly regulated while keeping a balance between the effectors and the regulators, and as a result, the homeostasis of the gut is maintained. A lot of evidences indicate that mucosal immunity is dysregulated in the bowel of IBD^[1]. Two forms of IBD show distinct profiles of T cell mediated immunity. In the gut of CD, a strong Th1 reaction is induced, while the Th2 response is upregulated in the colon of UC^[2]. Particularly in CD, it is evident that Th1 dominant immunity plays an important role in the pathogenesis. In UC, although the relevance of elevated Th2 cytokines to the colonic inflammation has not yet been clarified, an increased proinflammatory cytokine production is also observed which seems to be related to the inflammation. For the development of intestinal inflammation, leukocyte trafficking to the gut is an important step^[3]. Adhesion molecules, such as integrins, mediate the selective binding between the leukocytes and the endothelial cells and thus the migration of leukocytes into the normal and inflamed intestine. The main classical medical treatments for IBD are steroids and immunosuppressive agents which non-specifically reduce immunity and inflammation. Recent advances in the understanding of the mechanism of bowel inflammation have led to a recent trend in the development of biological therapies which selectively inhibit the action of molecules essential to the inflammatory process. Major targets for such therapies are inflammatory cytokines and their receptors, and adhesion molecules. Re-

cently, numerous challenges have been performed to generate anti-cytokine and anti-integrin compounds to treat IBD. This article reviews the efficacy and safety of such novel biological therapies for IBD targeting cytokines, cytokine receptors and adhesion molecules.

INHIBITION OF TNF

TNF- α is a proinflammatory cytokine which is abundantly expressed in the gut of CD^[4-6]. In animal models of experimental colitis, treatment with anti-TNF- α antibody has been shown to be effective in the suppression of intestinal inflammation^[7,8]. As a result, this cytokine was considered to be an attractive target for the treatment of IBD and several anti-TNF reagents have thus been developed. These reagents include infliximab, CDP571, CDP870, etanercept, oncept and adalimumab. Infliximab is a chimeric IgG1 monoclonal antibody against TNF- α , which was created in late 1980s, and it has been demonstrated to be effective in reducing intestinal inflammation in CD as described below. Most of the other anti-TNF reagents are modified by a reduction of the mouse peptide sequence or are completely humanized in order to reduce the immunogenicity. Not all of the other anti-TNF reagents have been proven to be as effective in the treatment of CD as infliximab, and the efficacy of such reagents seems to be dependent, not only on the ability to neutralize soluble TNF- α , but also on the capacity to bind to the membrane-bound TNF- α on the cell surface, thereby mediating the apoptosis of the effector cells^[9].

Infliximab

Infliximab was demonstrated to be effective in both the induction and maintenance therapy for refractory luminal and fistulizing CD. In a randomized double-blind placebo-controlled trial, 108 patients with moderate-to-severe CD which is resistant to conventional therapy, were treated with the single intravenous infusion of either placebo or infliximab at a dose of 5 mg/kg, 10 mg/kg or 20 mg/kg. The rates of the clinical response at 4 wk were 81% for infliximab 5 mg/kg, 50% for infliximab 10 mg/kg and 64% for infliximab 20 mg/kg, all of which were significantly higher than that for the placebo-treated group. The clinical remission rate at 4 wk was also significantly higher in the infliximab-treated group than that in the placebo-treated group (33% *vs* 4%)^[10]. In a randomized, double-blind, placebo-controlled trial for the treatment of fistulizing disease, 94 CD patients with draining abdominal and perianal fistulas refractory to conventional therapy were treated with three intravenous infusions at wk 0, 2 and 6 of either a placebo or infliximab at a dose of 5 mg/kg or 10 mg/kg. The response rates were significantly greater in the infliximab 5 mg/kg group (68%) and in the infliximab 10 mg/kg group (56%) than that in the placebo-treated group (26%). The rates of a complete closure of the fistulas were also significantly higher in the infliximab 5 mg/kg group (55%) and in the infliximab 10 mg/kg group (38%) than in the placebo-treated group (13%)^[11]. The effectiveness of infliximab for the maintenance therapy for inflammatory CD was assessed in a large trial called ACCENT I. Three hundred and thirty-five responders to a single infusion of infliximab

were subsequently treated with 5 mg/kg infliximab at wk 2 and 6, followed by infusions of either 5 mg/kg or 10 mg/kg infliximab once every 8 wk until wk 54, or they were treated with placebo at wk 2 and 6, and subsequently every 8 wk. The rates of clinical response and remission at wk 30 and 54 was significantly greater in both groups receiving 5 mg/kg and 10 mg/kg infliximab every 8 wk than those in the placebo-treated group^[12]. In addition, an analysis comparing the scheduled and episodic treatment strategies of infliximab for CD was conducted based on the ACCENT I data. The efficacy of the scheduled therapy was better than episodic strategy in terms of CDAI score, clinical remission and response rates, improvement in IBDQ score, mucosal healing and CD-related hospitalization and surgery^[13]. For an evaluation of the infliximab maintenance therapy for fistulizing CD, ACCENT II trial was conducted. One hundred and ninety-six CD patients with draining perianal and enterocutaneous fistulas who responded to the induction therapy with three infusions of 5 mg/kg infliximab at wk 0, 2 and 6 received either a placebo or 5 mg/kg infliximab every 8 wk. The median time to the loss of response, response rate and complete fistula closure rate at wk 54 in the infliximab maintenance group were significantly greater than those in the placebo group^[14].

Regarding the safety of infliximab treatment, it is well tolerated in the majority of the patients. In randomized controlled clinical trials, the rates of adverse events occurring in infliximab-treated patients were comparable to those in placebo-treated patients^[10-12,14]. Serious side effects, however, have been reported and attention must be paid to the possible occurrence of serious infections and autoimmune disorders, as well as the theoretical threat of cancer and lymphoma. In an analysis of 500 infliximab-treated patients in Mayo Clinic, serious adverse events were observed in 8.6%, of which 6% was considered to possibly be related to infliximab^[15]. Such events included serious infections, severe infusion reactions, serum sickness-like reactions, drug-induced lupus, cancer, non-Hodgkin's lymphoma and demyelinating process. The infectious complications included fatal sepsis, pneumonia, viral gastroenteritis, abdominal abscesses requiring surgery and histoplasmosis. Five deaths (1%) were observed which were likely or possibly related to infliximab. The reactivation of latent tuberculosis has been reported elsewhere^[16], as a result, it is recommended that all patients be screened for latent tuberculosis before the initiation of this treatment regimen.

Infliximab is a mouse/human chimeric monoclonal antibody of which 25% is mouse peptide sequence. The murine component is ascribed to its immunogenicity, such as infusion-related reactions and serum sickness-like diseases. In such immunological reactions, the formation of antibodies against infliximab, called human anti-chimeric antibodies (HACA) is of particular concern as the presence of HACA is associated with an increased frequency of infusion reactions and the reduction in efficacy^[17]. Concomitant immunosuppressive therapy and premedication with 200 mg of hydrocortisone reduce the frequency of HACA formation^[17,18]. The scheduled infusions in the maintenance therapy have been shown to be associated

with the reduction of the rate of HACA formation^[13]. As a result, the regular infliximab-treatment every 8 wk is likely to be beneficial for CD patients, not only for the maintenance of the remission state but also for the avoidance of infusion reactions.

The efficacy of infliximab for the treatment of UC remains controversial as two randomized controlled trials for steroid-refractory UC resulted in opposite results. A study indicated the benefit of infliximab for UC since 50% (4 of 8 patients) of the infliximab-treated patients showed treatment success, while none of the 3 patients receiving a placebo showed response^[19]. However, this study was terminated prematurely because of a slow enrollment. Another study failed to show any benefit of infliximab over placebo as there was no significant difference between patients who received infliximab and placebo in the remission rates and an improvement in the activity scores^[20]. Recently, two large multicenter randomized trials, ACT1 and ACT2, have been performed. In both trials, 364 patients with active UC were randomized to receive placebo or infliximab in a dose of 5 mg/kg or 10 mg/kg at wk 0, 2, 6, 14 and 22 in ACT1, and at wk 0, 2 and 6 then every 8 wk through wk 46 in ACT2. In both trials, both 5 mg/kg and 10 mg/kg infliximab showed significantly greater percentages in both the induction and maintenance of clinical remission and response, and in mucosal healing than placebo at both wk 8 and 30^[21,22]. In addition, it was also recently demonstrated that infliximab is effective as a rescue therapy to avoid a colectomy or death in severe to moderately severe UC refractory to conventional therapies^[23]. As a result, infliximab thus appears to also be efficacious for the treatment of UC as well as for CD.

CDP571

CDP571 is a "humanized" IgG4 antibody against TNF- α , created by genetic engineering to replace the murine component other than the binding domain with parts of a human IgG4 molecule. The resulting molecule is a chimera of 95% human and 5% mouse residues. The first study of 31 patients with active CD demonstrated that CDP571 5 mg/kg resulted in a greater decrease in the mean CDAI score at wk 2 compared with placebo^[24]. After a promising pilot trial, CDP571 was tested in a placebo-controlled dose-finding trial^[25]. In this study, 169 patients were randomized to receive a single intravenous infusion of either CDP571 in a dose of 10 or 20 mg/kg, or placebo. At wk 2, the clinical response rate was significantly higher in the patients treated with CDP571 (45%) than in those received a placebo (27%). Re-treatment was performed either every 8 wk with a placebo or CDP571 10 mg/kg, or every 12 wk with a placebo or CDP571 10 mg/kg (4 groups). The clinical remission rates at wk 24 in CDP571-treated groups were not significantly different from those of the placebo-treated groups. In a subsequent, randomized, double-blind, placebo-controlled, multicenter study^[26], the efficacy and tolerability of CDP571 in 396 patients with active CD was evaluated. Among the patients treated with CDP571 10 mg/kg every 8 wk, the percentage of patients achieving a clinical response was significantly higher than in those receiving a placebo at wk 2 and 4. However, at wk 28

the difference was not statistically significant. As a result, CDP571 therapy showed a short term benefit in induction therapy, but it is not sufficient to maintain a long term effect. In a post-hoc exploratory analysis of a subgroup of patients with elevated baseline CRP levels, there was a significant difference in the number of patients showing a clinical response at wk 2 (CDP571, 49.5%; placebo, 15.5%), and at all time points from wk 12 to wk 28, thus leaving the possibility that CDP571 is more efficacious in a selected group of patients^[26]. CDP571 failed to show a steroid sparing effect in patients with steroid-dependent CD^[27]. CDP571 was well tolerated even in patients with CD who developed either infusion reactions or delayed-type hypersensitivity reactions to infliximab^[28]. From these results, CDP571 was considered to be safe but not as effective as infliximab for CD and further clinical development of this antibody for the treatment of CD has thus been discontinued.

CDP870

CDP870 is a pegylated Fab fragment of humanized anti-TNF monoclonal antibody. In a placebo-controlled dose-finding study^[29], 292 patients were randomized to receive a subcutaneous dose of CDP870 (100, 200, or 400 mg) or placebo at wk 0, 4, and 8. The group that received CDP870 400 mg showed greater clinical response rates than other groups at all time points. The clinical response rates of the CDP870 400 mg group were significantly higher than those of the placebo treated group at wk 2, 4, 8 and 10. The difference, however, did not reach statistical significance at wk 12. A greater dose separation was evident in the analysis of a patient subgroup with elevated CRP levels. In an exploratory analysis^[30] in 119 patients with increased CRP levels (≥ 10 mg/L), the differences in the clinical response between the 400 mg/dose (53.1%) and placebo (17.9%) were significant at 12 wk. These studies, therefore, indicated that CDP870 may be more effective in patients with elevated CRP levels. CDP870 seems to be safer and less immunogenic than infliximab. The efficacy, however, is likely to be lower than that of infliximab. The question arises whether physicians want to compromise on efficacy in the scope of better long-term safety. Further clinical trials are ongoing.

Etanercept

Etanercept is a genetically engineered fusion protein consisting of two recombinant human TNF p75 receptors linked to an Fc portion of human IgG1 fragment. The subcutaneous injection of etanercept at a dose of 25 mg twice weekly, which is an effective dose for rheumatoid arthritis, is a safe but ineffective dose for the treatment of patients with moderate to severe CD^[31].

Onercept

Onercept, a recombinant, fully human, soluble p55 TNF receptor has showed efficacy to CD in an open-label pilot study ($n = 12$)^[32]. A large, placebo-controlled, dose-finding study has been completed but the data have not yet been published. A press release by Serono (Geneve, Switzerland) revealed that the primary endpoint of this trial was not met.

Adalimumab

Adalimumab is a fully humanized anti-TNF monoclonal IgG1 antibody. This antibody is as efficacious as infliximab for the treatment of rheumatoid arthritis. *In vitro* studies revealed that this antibody is capable of inducing apoptosis in monocytes as infliximab^[33]. As adalimumab does not contain a mouse peptide sequence, it is expected to be less immunogenic and more tolerable than infliximab. Two uncontrolled pilot studies of adalimumab with CD patients who had lost responsiveness or developed intolerance to infliximab^[34,35] showed that subcutaneous adalimumab was well tolerated, thus suggesting a clinical benefit of adalimumab. In a phase 3, multicenter trial for active CD, clinical remission rates of patients who received adalimumab 160 mg at wk 0 and 80 mg at wk 2 was significantly higher than that of placebo at wk 4 (36% *vs* 12%)^[36]. From these results, adalimumab is likely to be efficacious for the treatment of CD and it could thus be an alternative therapy for the patients who either lost responsiveness or developed intolerance to infliximab.

INHIBITION OF OTHER INFLAMMATORY CYTOKINES

Anti-IL-12 p40 antibody

IL-12, a heterodimeric molecule composed of IL-12 p40 and IL-12 p35 subunits, plays a central role in Th1 development. IL-12 is abundantly produced in the gut of CD patients^[2]. In several animal models of Th1-mediated colitis, anti-IL-12 treatment effectively ameliorates intestinal inflammation^[37,38]. IL-12 p40 subunit is also a component of another Th1 cytokine, IL-23, in which p40 forms a heterodimer with p19 subunit. IL-12 p40 is, therefore, a potential target for the treatment of CD in which intestinal inflammation is Th1-mediated. A double-blind, placebo-controlled randomized study of a humanized IgG1 monoclonal antibody against IL-12 p40 (ABT-874) was performed in 79 patients with active CD^[39]. The patients were randomly assigned to receive seven weekly injections of 1 mg/kg anti-IL-12, 3 mg/kg anti-IL-12 or placebo subcutaneously either with or without 4 wk intervals between the first two injections. The patients who received 3 mg/kg anti-IL-12 for 7 wk showed a significantly greater clinical response rate than the patients treated with a placebo (75% *vs* 25%). The rates of remission were also higher in the 3 mg/kg anti-IL-12 group (38%) than in the placebo group (0%) but the difference did not reach statistical significance. The production of IL-12 and other Th1 and proinflammatory cytokines from patients' colonic lamina propria mononuclear cells dramatically decreased after the anti-IL-12 therapy. The most frequent adverse event was a local reaction at the injection site, which was observed with a greater rate in the anti-IL-12-treated group than in the placebo-treated group. Anti-drug antibody was formed in some patients who received anti-IL-12 antibody. No serious side effects requiring the discontinuation of the treatment, due to the anti-IL-12 therapy, were observed. Anti-IL-12 therapy is therefore considered to be a safe and effective treatment for active CD.

MRA (Anti-IL-6 receptor antibody)

IL-6 is one of the major inflammatory cytokines. IL-6 can transduce signals into cells without IL-6 receptor expression when IL-6 binds to soluble IL-6 receptor. The expression of IL-6 and soluble IL-6 receptor increases in patients with active CD^[40,41]. A pilot randomized double-blind placebo-controlled trial of a humanized anti-IL-6 receptor monoclonal antibody, MRA, with active CD was performed^[42]. Thirty-six patients were randomized biweekly to receive either a placebo, 8 mg/kg MRA or MRA/placebo alternately for 12 wk. The clinical remission rate with biweekly MRA was significantly higher than that with placebo (80% *vs* 31%). The acute phase responses such as ESR and CRP levels were rapidly suppressed 2 wk after the MRA injection. The incidence of adverse events was similar in all groups, and thus MRA treatment was generally well tolerated. It is, therefore, likely that anti-IL-6 receptor therapy is beneficial for active CD.

Fontolizumab (Anti-interferon- γ antibody)

Interferon- γ is a key cytokine that enhances the development of a Th1 immune response. Fontolizumab is a humanized monoclonal antibody directed against interferon- γ . A phase 2 study of fontolizumab at intravenous doses of 4 mg/kg or 10 mg/kg in 133 patients with moderate to severe active CD did not demonstrate efficacy at d 28. However, exploratory analyses based on 91 patients who received a second dose of fontolizumab at d 28 did demonstrate efficacy. This effect was most prominent in patients with elevated baseline concentrations of CRP^[43]. An additional phase 2 study of fontolizumab at lower subcutaneous doses of 1.0 mg/kg or 4.0 mg/kg in 196 patients with active CD did not demonstrate efficacy at d 28^[44]. These results indicate that a single dose may not be sufficient to achieve a significant improvement. Further clinical studies of fontolizumab for the induction and maintenance of remission in patients with CD are anticipated.

Anti-IL-2 receptor (CD25) antibodies

Daclizumab: IL-2 is a major T cell growth factor, which is secreted by activated T cells and acts via the high-affinity IL-2 receptor on T cells themselves to promote cell survival and proliferation. The IL-2 receptor α -chain (CD25) is a component of high-affinity IL-2 receptor and it is expressed on activated T cells. Daclizumab is a humanized monoclonal antibody to CD25, which blocks the binding of IL-2 to the IL-2 receptor. An open label pilot study of daclizumab suggested that it was beneficial for patients with active UC^[45]. However, a recent placebo-controlled phase 2 trial of daclizumab at intravenous doses of 1 mg/kg twice with a 4-wk interval or 2 mg/kg every 2 wk for a total of four doses in 159 patients with active UC failed to show any efficacy^[46].

Basiliximab: Basiliximab is a chimeric monoclonal antibody against CD25, which blocks the binding of IL-2 to the IL-2 receptor. Two uncontrolled pilot studies suggested that basiliximab in combination with steroids may be effective for steroid resistant UC^[47,48]. A large random-

ized controlled trial is required to confirm the therapeutic benefit of this compound.

INHIBITION OF ADHESION MOLECULES

Many adhesion molecules play an important role in trafficking leukocytes into the inflamed gut wall and they are up-regulated in both CD and UC^[49,50].

$\alpha 4$ -integrins, predominantly expressed on lymphocytes, usually exist in combination with a β subunit and interact with adhesion molecules expressed on endothelium. $\alpha 4\beta 1$ -integrin binds to vascular cellular adhesion molecule 1 (VCAM-1) and $\alpha 4\beta 7$ -integrin binds to mucosal addressing cell adhesion molecule 1 (MAdCAM-1). The interaction between $\alpha 4\beta 7$ -integrin and MAdCAM-1 is important in mediating lymphocytes homing to the gut mucosa^[51].

Leukocyte function-associated antigen 1 (LFA-1) expressed on leukocytes interacts with intercellular adhesion molecule 1 (ICAM-1), which is constitutively expressed at low levels on vascular endothelial cells and a subset of leukocytes, and they are up-regulated on many cell types in response to proinflammatory mediators^[52].

Natalizumab

Natalizumab, a humanized IgG4 anti- $\alpha 4$ -integrin monoclonal antibody, inhibits both $\alpha 4\beta 7$ -integrin/MAdCAM-1 interaction and $\alpha 4\beta 1$ /VCAM-1 binding.

In an initial small trial in 30 patients with active CD, a single 3 mg/kg intravenous infusion of natalizumab showed a short term effect in inducing remission at wk 2 and elevated circulating lymphocyte levels after the natalizumab infusion. Therefore, it is suggested that the natalizumab interrupted lymphocyte trafficking into the intestine^[53]. In a large placebo-controlled randomized trial including 248 patients with moderate to severe CD, patients were treated twice at 4 wk intervals with 3 or 6 mg/kg of natalizumab or placebo. A significantly higher number of patients achieved remission at wk 6 only in the 3 + 3 mg/kg natalizumab group compared with the two infusions of placebo group (44% *vs* 27%). The clinical response rates at wk 6 in all treatment groups were significantly higher than that in the placebo-treated group (3 mg/kg natalizumab + placebo: 59%, 3 + 3 mg/kg natalizumab: 71%, 6 + 6 mg/kg natalizumab: 57% and the two infusions of placebo group, 38%)^[54]. A larger phase 3 trial of ENACT-1 in 905 patients with moderate to severe CD failed to show a benefit for three intravenous infusions of 300 mg natalizumab every 4 wk. In a subgroup analysis, however, natalizumab-treated patients with concurrent immunosuppressive therapies, prior anti-TNF- α therapy or elevated CRP levels showed a significant response rate compared with placebo-treated patients^[55]. Three hundred and thirty-nine patients with CD who responded to natalizumab in ENACT-1 were re-randomized to maintenance therapy with natalizumab (300 mg) or a placebo for up to 12 additional monthly infusions. In this maintenance study (ENACT-2), natalizumab demonstrated a significant superiority over the placebo in its ability to sustain both the response and remission at all consecutive time points over a 6-mo period and enabled patients to be successfully withdrawn from

steroids^[56]. In an uncontrolled short term pilot study in 10 patients with active UC, a single 3 mg/kg intravenous infusion of natalizumab showed a short term benefit^[57].

Natalizumab is efficacious in multiple sclerosis (MS) as well^[58]. In MS, $\alpha 4\beta 1$ integrin/VCAM-1 binding appears to be a crucial step because anti- $\alpha 4\beta 1$ integrin antibody prevented the development of experimental autoimmune encephalomyelitis, a model of human MS^[59]. Against these effects of natalizumab in IBD and MS, 3 patients receiving repeated treatment with natalizumab developed JC virus related progressive multifocal leukoencephalopathy (PML)^[60-62]. PML, which almost invariably occurs in patients with AIDS or leukemia or in organ-transplant recipients, is a fatal opportunistic infection of the central nervous system caused by the reactivation of a clinically latent JC polyomavirus infection. Two patients with MS had been receiving the concomitant administration of interferon β -1a^[60,61] and 1 patient with CD had been treated with natalizumab monotherapy^[62]. These observations force us to reconsider both the efficacy and the potential risks associated with an inhibition of lymphocytes trafficking by anti- $\alpha 4$ integrin therapy.

MLN-02

MLN-02, a humanized anti- $\alpha 4\beta 7$ -integrin blocks specifically the $\alpha 4\beta 7$ -integrin/MAdCAM-1 interaction.

A randomized placebo-controlled trial in 185 patients with mild to moderately active CD treated with placebo, 0.5 mg/kg MLN-02 or 2.0 mg/kg MLN-02 intravenously on d 1 and 29 demonstrated that on d 57, 2.0 mg/kg MLN-02 showed significantly greater remission rates over the placebo (36.9% *vs* 20.7%). There was no significant difference between the actively treated and placebo-treated groups regarding the clinical response rates. No obvious differences in adverse events were noted among the three groups^[63].

A randomized placebo-controlled trial in 181 patients with moderately active UC treated with placebo, 0.5 mg/kg MLN-02, or 2.0 mg/kg MLN-02 intravenously on d 1 and 29 demonstrated that on d 43 the remission rates were significantly higher in the actively treated groups (0.5 mg/kg: 33%, 2.0 mg/kg: 34%) than in the placebo-treated group (15%). An infusion reaction occurred in one MLN-02-treated patient who developed mild angioedema^[64].

MLN-02 appears to be a generally well-tolerated and effective therapy especially for active UC, but further trials are necessary to confirm the efficacy of MLN-02 therapy for IBD.

Alicaforsen (ISIS 2302)

ISIS 2302 is a 20 base phosphorothioate oligodeoxynucleotide designed to specifically hybridize to the 3'-untranslated region of the human ICAM-1 mRNA. Treatment of ISIS 2302 *in vitro* resulted in a highly specific reduction in ICAM-1 mRNA and, consequently, a marked decrease in ICAM-1 protein expression^[65].

A pilot trial in patients with moderate CD (including 15 patients treated with 13 intravenous infusions of 0.5, 1.0 or 2.0 mg/kg ISIS 2302 *vs* 5 patients with placebo over 26 d) demonstrated a higher remission rate in ISIS 2302-treated group compared with the placebo-treated group on d 33

(47% *vs* 20%)^[66]. However, a placebo-controlled trial in 75 patients with steroid refractory CD failed to demonstrate efficacy as showed that the subcutaneous administration of ISIS 2302 induced only 3% of ISIS 2302-treated patients to clinical remission with complete steroid taper (0% in placebo-treated patients)^[67]. Another larger randomized placebo-controlled trial also failed to show any benefit of ISIS 2302 for active CD^[68]. Two hundred and ninety-nine patients with moderately active, steroid-dependent CD received placebo or ISIS 2302 (2 mg/kg intravenously three times a week) for 2 or 4 wk in mo 1 and 3. There were no differences in the steroid-free remission rates at wk 14 between the ISIS 2302-treated groups (2 wk: 20.2%, 4 wk: 21.2%) and the placebo-treated group (18.8%). However, a subgroup analysis using the area under the curve (AUC) of ISIS 2302 plasma concentration demonstrated an improvement of the clinical response for the highest AUC group (AUC > 65 $\mu\text{g} \times \text{h/mL}$). This suggested that ISIS 2302 may be effective when given in adequate doses. As a result, a dose ranging pilot trial of high dose ISIS 2302 in 22 patients with active CD was conducted. The patients, who were infused with high dose ISIS 2302 (250 mg to 350 mg) intravenously three times a week for 4 wk, showed a 41% remission rate. Five patients, however, withdrew due to infusion-related symptoms^[69].

A randomized placebo-controlled trial in 40 patients with mild to moderately active distal UC treated with 60 mL alicaforsen enema (0.1, 0.5, 2, or 4 mg/mL or placebo) once daily for 28 consecutive days showed a beneficial effect at the highest dose. Four mg/mL alicaforsen enema group showed a significant improvement in the disease activity index on d 29 and mo 3 in comparison to the placebo enema group^[70]. An open-label, uncontrolled study in 12 patients with chronic unremitting pouchitis treated with 240 mg alicaforsen enema nightly for 6 wk demonstrated a significant improvement in the pouchitis disease activity index and an endoscopic mucosal appearance at wk 6^[71].

The most consistently reported side effects of ISIS 2302 in all clinical trials were infusion reactions and a moderate increase in activated partial thromboplastin time.

CONCLUSION

Infliximab has changed the medical treatment of CD dramatically. This agent has been proven to be clearly effective for the induction and maintenance of remission for active CD meanwhile it is also generally well-tolerated. However, there are some patients who fail to respond to infliximab. In addition, some responders either lose responsiveness to infliximab during long-term therapy or develop intolerance to infliximab. The next issue will therefore be how to treat such patients who cannot be treated with infliximab. Adalimumab may be an alternative to infliximab. Anti-IL-12 and anti-IL-6 receptor therapies seem to be promising. The selective blocking of $\alpha 4$ integrin and $\alpha 4\beta 7$ integrin also demonstrated promising results, however, the side effects still need to be fully elucidated. We await the results of further clinical trials to include such novel compounds in the algorithm for the treatment of CD. Infliximab is likely to also be beneficial for UC. In addition, some other agents seem to be effective for the treatment of UC and

further clinical development is also underway. As a result, the management of UC may also dramatically improve in the near future owing to the use of such novel agents. The systematization of novel biological therapies for UC is therefore an issue that needs to be addressed in the future.

Abstract

With the many changes that have taken place in people's diet and lifestyle, colorectal cancer (CRC) has become a global concern. There were approximately 950 000 new cases diagnosed and 500 000 deaths recorded worldwide in 2000. It is the second most common type of cancer in the Western world, and it is the third most common type of digestive tumor in China. It is reported that the morbidity of CRC is 4.08/100 000 for men and 3.30/100 000 for women in China. Despite the rate of improvements in surgery, radiotherapy and chemotherapy, the overall five-year survival is around 50%. Therefore, novel treatment need to be developed in order to add to the therapeutic armamentarium. RNA interference (RNAi) is a sequence-specific post-transcriptional gene silencing mechanism, which is triggered by double-stranded RNA (dsRNA) and causes degradation of mRNA homologous in sequence to the dsRNA. This new approach has been successfully adopted to inhibit virus replication and tumorigenicity. Recent reports have described DNA vector-based strategies for delivery of small interfering RNA (siRNA) into mammalian cells, further expanding the utility of RNAi. With the development of the RNAi technology and deeper understanding of this field, a promising new modality of treatment appeared, which can be used in combination with the existing therapies. We reviewed the proceedings on the actualities and advancement of RNAi technology for colorectal cancer therapeutics.

INTRODUCTION

When viruses infect eukaryotic cells, or when transposons and transgenes are randomly integrated into host genomes, double-stranded RNA (dsRNA) is frequently produced from the foreign genes. Most eukaryotes, including humans, possess an innate cellular immune surveillance system that specifically responds to the presence of dsRNA and activates processes that act post-transcriptionally to silence the expression of the interloping genes^[1-4]. This mechanism is now commonly referred to as RNA interference or RNAi^[5]. During RNAi, long transcripts of dsRNA are rapidly processed into small interfering RNAs (siRNAs), which represent RNA duplexes of specific length and structure that finally guide sequence-specific degradation of mRNAs homologous in sequence to the siRNAs^[6,7]. siRNAs may be the best tools for target validation in biomedical research today and cancer therapeutics, because of their exquisite specificity, efficiency and endurance of gene-specific silencing. Some researches about RNAi technology for colorectal cancer has been reported in recent years. However, these new approaches face serious problems before they can offer a useful adjuvant role for the clinical trials for patients with colorectal cancer.

MECHANISM OF dsRNA INTERFERENCE

The key enzyme required for the processing of long dsRNAs to siRNA duplexes is the RNase III enzyme Dicer, which was characterized in extracts prepared from insect cells, *C. elegans* embryos, mouse cells and mast cells^[8-10]. Dicer contains an N-terminal RNA helicase domain, a Piwi, Argonaute, Zwiille/Pinhead (PAZ) domain^[11], two RNase III domains, and a C-terminal dsRNA-binding motif. The PAZ domain is also present in Argonaute proteins, whose genes represent a poorly characterized family present in dsRNA-responsive organisms. Argonaute1 (AGO1) and Argonaute2 (AGO2), two of the five Argonaute proteins of *D. melanogaster*, appear to be important for forming the mRNA-degrading sequence-specific endonuclease complex, also referred to as the RNA-induced silencing complex (RISC)^[12,13]. Dicer and AGO2 appear to interact in *D. melanogaster* Schneider 2 (S2) cells, probably through their PAZ domains; however, RISC and Dicer activity are separable, and RISC is unable to process dsRNA to siRNAs, suggesting that Dicer is not

a component of RISC. Possibly, the interaction between Dicer and AGO2 facilitates the incorporation of siRNA into RISC^[14]. The endonucleolytic subunit of RISC remains to be identified.

siRNA duplexes produced by the action of Dicer contain 5'-phosphates and free 3'-hydroxyl groups. The central base-paired region is flanked by two-to-three nucleotides of single-stranded 3'-overhangs. The 5' -phosphate termini of siRNAs is essential for guiding mRNA degradation^[15]. Nevertheless, for their application in gene targeting experiments, siRNAs may be used without 5'-phosphate termini because a kinase activity in the cell rapidly phosphorylates the 5' ends of synthetic siRNA duplexes. Under certain circumstances (e.g., injection experiments in *D. melanogaster*), 5'-phosphorylated siRNA duplexes may have slightly enhanced properties as compared with 5'-hydroxyl siRNAs^[16].

In *C. elegans*, introduction of approximately 300 bp dsRNA corresponding to a segment of the targeted gene may also give rise to the phenomenon of transitive RNAi^[17]. Transitive RNAi is characterized by the spread of silencing outside of the region targeted by the initiator dsRNA. Presumably, targeted mRNA serves as template for RNA-dependent RNA polymerase (RdRP) and forms new dsRNA that is processed by Dicer. Thus, secondary siRNAs are generated which may cleave the mRNA out of the region targeted by the ancestral dsRNA.

Until recently, the application of siRNAs in somatic cells was restricted to the delivery of chemically or enzymatically synthesized siRNAs^[18-20], but methods for intracellular expression of small RNA molecules have now been developed. Endogenous delivery is possible by inserting DNA templates for siRNAs into RNA polymerase III (pol III) transcription units, which are based on the sequences of the natural transcription units of the small nuclear RNA U6 or the human RNase P RNA H1. Two approaches are available for expressing siRNAs: (1) The sense and antisense strands constituting the siRNA duplex are transcribed from individual promoters^[20-22], or (2) siRNAs are expressed as fold-back stem-loop structures that give rise to siRNAs after intracellular processing by Dicer^[23,24]. The transfection of cells with plasmids that encode siRNAs, therefore, represents an alternative to direct siRNA transfection. The insertion of siRNA expression cassettes into (retro)viral vectors will also enable the targeting of primary cells refractory to transfection or electroporation of plasmid DNA.

siRNAs AS NOVEL THERAPEUTIC PLATFORM TECHNOLOGY

VEGF is one of the archetypal angiogenic growth factors and has received considerable attention. VEGF is a homodimeric 45 kDa glycoprotein, 5 different isoforms of which are reportedly expressed by endothelial cells. VEGF specifically acts on endothelial cells binding to a growing number of endothelial tyrosine kinase receptors including VEGFR-1 and VEGFR-2. Inhibition of VEGF activity or disabling the function of its receptors has been shown to inhibit both tumor growth and metastasis in a variety

of animal tumor models^[25,26]. Given the different isoforms and their various functions, the development of this RNAi technology and its ability to target specific VEGFs should facilitate both a greater understanding of this field and also the development of improved therapeutics.

Single base pair mutations that alter the function of tumor suppressor genes and oncogenes occur frequently during oncogenesis. The guardian of the genome, p53, is inactivated by point mutation in more than 45%-60% of human colorectal cancers. Synthetic small inhibiting RNAs (siRNAs) are highly sequence-specific reagents and discriminate between single mismatched target RNA sequences, and may represent a new avenue for gene therapy. Martinez LA^[27] demonstrated that a single base difference in siRNAs discriminates between mutant and WT p53 in cells expressing both forms, resulting in the restoration of WT protein function. Therefore, siRNAs may be used to suppress expression of point-mutated genes and provide the basis for selective and personalized antitumor therapy.

The products of bcl-2 genes are involved in the regulation of apoptosis and proliferation and are associated with prognosis in several malignancies, including colorectal adenocarcinoma. A statistically significant inverse association was found between Bcl-2 score and tumor recurrence. It is reported that some researchers use mRNA-cDNA interference for silencing bcl-2 expression in human LNCaP cells^[28]. These findings indicate that a novel gene silencing system may play a useful adjuvant role in the majority of patients with colorectal cancer.

One of the major limitations of current chemotherapy regimes is the bone marrow toxicity associated with these drugs. However, it is well recognized that subpopulations of tumor cells are resistant to particular chemotherapeutic agents and continue to grow in a selective manner in the presence of such drugs. These cells contain specific genes which render them resistant to particular compounds. One such gene is the multiple drug resistance (MDR1) gene which confers resistance to vinca alkaloids (vinblastine, vincristine), anthracyclins (adriamycin, daunorubicin), etoposide and paclitaxel. For reversal of MDR1 gene-dependent multidrug resistance (MDR), two small interfering RNA (siRNA) constructs were designed to inhibit MDR1 expression by RNA interference. Some data indicate that this approach may be applicable to cancer patients as a specific means to reverse tumors with a P-glycoprotein-dependent MDR phenotype back to a drug-sensitive one^[29].

Telomerase is an attractive molecular target toward which to direct cancer therapeutic agents because telomerase activity is present in most malignant cells but undetectable in most normal somatic cells. Kosciolk BA, *et al*^[30] evaluated the ability of siRNA to inhibit telomerase activity in human cancer cells. In their research, human cancer cell lines were transfected with 21 nt double-stranded RNA homologous to either the catalytic subunit of telomerase (human telomerase reverse transcriptase) or its template RNA [human telomerase RNA(hTR)]. Both types of agents reduced telomerase activity in a variety of human cancer cell lines representing both carcinomas and sarcomas. Inhibition was dose-dependent. Telomerase

inhibition by siRNA is notable because telomerase is regarded as restricted to the nucleus, whereas RNA interference is commonly regarded as restricted to the cytoplasm. Their results showed that telomerase activity in human cancer cells can be inhibited by short dsRNAs (siRNAs) targeting telomerase components. Inhibition was shown in a variety of carcinoma cell lines (HCT-15 colon carcinoma, HeLa cervical carcinoma, NCI H23 lung carcinoma, and A431 epidermoid carcinoma).

CRC typically develops over decades and involves multiple genetic events. This has led to the development of a multistep model of colorectal tumorigenesis. In order to identify genes that are important in the development of CRC, RNAi was used to disrupt expression of two of the genes identified by microarray analysis in a colon tumor cell line, HCT116. HCT116 cells were derived from a human colon carcinoma, and showed mutations in β -catenin and K-ras, but possessed wild-type p53^[31]. By examining the growth characteristics of these cells after RNAi both in vivo and in vitro, they hoped to identify targets critical for growth, apoptosis, and/or metastasis. It is clear from these results that siRNA directed against c-myc and survivin lowers the levels of these proteins without affecting the levels of a control protein, β -tubulin. Furthermore, transfection of siRNA oligonucleotides directed against both genes was as effective in reducing protein expression, as were experiments targeting each gene separately. In summary, they have demonstrated that the use of RNAi when coupled with microarray analysis provides an excellent system to define the role of specific genes that are dysregulated in cancer on both the *in vitro* and in vivo growth of the tumor^[32].

Somatic changes in CpG dinucleotide methylation occur quite commonly in human cancer cell DNA. Relative to DNA from normal human colonic cells, DNA from human colorectal cancer cells typically displays regional CpG dinucleotide hypermethylation amid global CpG dinucleotide hypomethylation. The role of the maintenance DNA methyltransferase (DNMT1) in the acquisition of such abnormal CpG dinucleotide methylation changes in colorectal cancer cells remains obvious. Some research indicated that human colorectal carcinogenesis is accompanied by a progressive dysregulation of DNMT1 expression and suggest that abnormalities in DNMT1 expression may contribute to the abnormal CpG dinucleotide methylation changes characteristic of human colorectal carcinoma cell DNA^[33]. Recently, there is a report that the controlled knockdown of DNA methyltransferase 1 (DNMT1) in human cancer resulted in growth arrest^[34]. Thus the method allows for a highly controlled approach to gene knockdown.

CONCLUSION

Since biotechnologists have adopted RNAi, it has already earned a place among the major technology platforms. Despite promising data, there are several challenges that need to be faced before RNAi can be used in patients. These include mode of delivery, the precise sequence of the siRNA or shRNA used, and cell type specificity. There are possible toxicities related to silencing of partially

homologous genes or induction of global gene suppression by activating the interferon response. Another potential problem is the inhibition of the function of endogenous miRNAs through competition for the RNAi machinery. Despite these hurdles, RNAi provides the opportunity to pursue an exciting new therapeutic approach to treat colorectal cancer^[35].

Abstract

AIM: It is known that thyroid hormones alter the bile acid metabolism in humans, however the effect on individual enzymes has been difficult to elucidate. This is mainly due to the lack of human liver cell lines producing bile acids. We used cultures of primary human hepatocytes to study the effects of triiodothyronine (T_3) on bile acid synthesis.

METHODS: Primary hepatocytes were isolated from liver tissue obtained from three different patients undergoing liver resection due to underlying malignancy. The hepatocytes were cultured under serum-free conditions and treated from d 1 to d 5 with culture containing 0.1 - 1000 nmol/L of T_3 . Bile acid formation and mRNA levels of key enzymes were analysed.

RESULTS: The lowest concentration of T_3 decreased cholic acid (CA) formation to 43%-53% of controls and chenodeoxycholic acid (CDCA) to 52%-75% of controls on d 5. The highest dose further decreased CA formation to 16%-48% of controls while CDCA formation remained at 50%-117% of controls. Expression of mRNA levels of cholesterol 7 α -hydroxylase (CYP7A1) and sterol 12 α -hydroxylase (CYP8B1) dose-dependently decreased. Sterol 27-hydroxylase (CYP27A1) levels also decreased, but not to the same extent.

CONCLUSION: T_3 dose-dependently decreased total bile acid formation in parallel with decreased expression of CYP7A1 and CYP8B1. CA formation is inhibited to a higher degree than CDCA, resulting in a marked decrease in the CA/CDCA ratio.

INTRODUCTION

The effect of thyroid hormone on human bile acid synthesis is still unclear. Several *in vivo* observations have suggested that thyroid hormone influences the bile acid synthesis^[1-3]. However, due to the lack of human *in vitro* tools such as cell lines synthesizing normal bile acids, investigators have not been able to study this at a cellular level. We have previously shown that primary human hepatocytes cultured under serum-free conditions in the presence of matrixgel (EHS) synthesize and conjugate normal bile acids^[4,5]. We also showed that under these conditions they synthesize bile acids with the same capacity and composition as under similar *in vivo* conditions.

In the conversion of cholesterol into bile acids two main pathways are recognized^[6-8]. The neutral pathway is initiated by the 7 α -hydroxylation of cholesterol, catalyzed by the microsomal rate-limiting enzyme cholesterol 7 α -hydroxylase (CYP7A1). The acidic pathway is initiated by the 27-hydroxylation of cholesterol, catalyzed by the mitochondrial enzyme sterol 27-hydroxylase (CYP27A1). In the acidic pathway the microsomal oxysterol 7 α -hydroxylase (CYP7B1) mediates the 7 α -hydroxylation. Humans synthesize two primary bile acids, cholic acid (CA) and chenodeoxycholic acid (CDCA). CA has a hydroxyl group at the 12th carbon distinguishing it from CDCA. The hydroxyl group is introduced by the microsomal enzyme sterol 12 α -hydroxylase (CYP8B1). Therefore, the total amount of intermediates (from either pathway) that undergoes 12 α -hydroxylation determines the ratio of CA to CDCA. Both pathways can synthesize CA and CDCA, however the acidic pathway is believed to produce mainly CDCA. The most important mechanism for regulation of bile acid synthesis is the portal flux of bile acids returning to the liver. The loss of bile acids in the intestine (5%-10%) is compensated by *de novo* synthesis.

In this study we examined the effect of different doses

of triiodothyronine (T₃) on bile acid formation and on mRNA levels of *CYP7A1*, *CYP8B1* and *CYP27A1* in cultures of primary human hepatocytes.

MATERIALS AND METHODS

Materials

RPA III™ kit and pTRI-cyclophilin-Human antisense control template were purchased from Ambion Inc.(Huntingdon, UK). ³⁵S-UTP was purchased from Hartmann Analytic GmbH(Braunschweig, Germany). William's medium E with glutamax, gentamycin, penicillin-streptomycin, Dulbecco's phosphate buffered saline, Trizol reagent and Superscript II RT were purchased from Invitrogen (Täby, Sweden). Actrapid (insulin) 100 IU/mL was from Novo Nordisk Pharma(Malmö, Sweden). Collagenase XI-S (Cat. No. C7557), methylthiazolyldiphenyl-tetrazolium bromide (Cat. No. M5655) and triiodothyronine (Cat. No. T6397) were purchased from Sigma-Aldrich (Sweden). Random hexamers (Cat. No. C1181), recombinant RNasin ribonuclease inhibitor (Cat. No. N2511) and RQ DNase I (Cat. No. M6101) were purchased from Promega (Southampton, UK). Taqman universal master mix (Cat. No. 4304437) and human cyclophilin pre-developed assay (now discontinued and replaced by Human PPIA endogenous control (Cat. No. 4310883E) were purchased from Applied Biosystems (Stockholm, Sweden). Dithiothreitol (Cat. No. 708984) was purchased from Roche(Bromma, Sweden).

Isolation of primary human hepatocytes

Human liver tissue was obtained from three different patients undergoing reduction hepatectomy for metastatic cancer to the liver where normal liver tissue was resected due to the localization of the tumor. Patient A was a 62 year old female, patient B a 47 year old male and patient C a 49 year old female.

Approval to use parts of resected human liver specimens for research was given by the ethics committee at Huddinge University Hospital and the patient's informed consent was obtained.

Hepatocytes were isolated by a two-step perfusion technique, utilizing EGTA and collagenase as described in detail by Li *et al*^[9]. In brief, liver tissue weighing between 20-150 g was cannulated in 1-2 vessels depending on the size and appearance. The tissue was then perfused with EGTA buffer for about 15 min at a flow rate of 20 mL/min, followed by perfusion with CO₂ (5%) buffered solution containing collagenase XI-S (200 mg /L) at 40°C for approximately 75 min.

Culture conditions

Hepatocytes (3.5 × 10⁶) were cultured under standard conditions in 60 mm culture dishes containing 200 µL EHS matrigel and 3 mL William's E medium with glutamax, supplemented with insulin (2 IU/L), penicillin G sodium (100 U/mL), streptomycin sulphate (100 µg/mL) and gentamycin (85 µg/mL). Cell culture media were collected and renewed everyday. Three 60 millimeter culture dishes each containing 3.5 × 10⁶ hepatocytes were used for each treat-

ment. The cells and media from three dishes were pooled when harvested. The cells were subjected to different concentrations of T₃ (0.1, 1, 10, 100 and 1000 nmol/L) during four days, from d 1 to d 5. On d 5 cell culture media were collected for bile acid analysis and the cells were harvested for RNA isolation and subsequent quantification of specific mRNAs.

Analysis of bile acids in cell culture media

Bile acids in cell culture media were analysed as previously described^[4]. Briefly, 2 mL of the harvested culture medium, together with deuterium labelled cholic acid (D₅) and chenodeoxycholic acid (D₄), was subjected to basic hydrolyzation to remove conjugates and the bile acids were extracted using acidic ether. Bile acids were analysed by gas chromatography-mass spectrometry, as described previously^[11,10].

Isolation of total RNA

Total RNAs were isolated using Trizol reagent as described by the manufacturer. RNA concentration was determined by spectrophotometry at 260 nm. The purity of the RNA was determined by spectrophotometry at 280 nm and the integrity checked by agarose gel electrophoresis stained with ethidium bromide.

Quantification of CYP7A1 by real time PCR

mRNA levels of CYP7A1 were determined using quantitative single-plex real time PCR. From each group, 40 µg of total RNA was incubated with 5 U of RQ DNase, 5 µL 10 × RQ buffer in a total volume of 50 µL at 37°C for 20 min, at 20°C for 15 min and finally at 70°C for 10 min. From this, 4 µg of DNase treated RNA was used for cDNA synthesis by mixing together with 2 µL random hexamer primers (100 ng/µL), 1 µL dNTP (10 mmol/L of each) in a total volume of 12 µL. After incubation at 65°C for 5 min, 25°C for 10 min and 42°C for 2 min, 2 µL of DTT (0.1 mol/L), 1 µL of RNasin (40 U/µL), 4 µL 5 × first strand buffer and 1 µL superscript II (200 U/µL) were added. The incubation was continued at 42°C for 50 min and at 70°C for 10 min. For real time PCR 3 µL undiluted cDNA/sample was used in triplicates.

Sequences for CYP7A1 primers and probe were kindly provided by Dr. Hermansson, AstraZeneca, Mölndal, Sweden. Reversed primer is: 5'AGA GCA CAG CCC AGG TAT G 3'; forward primer, 5' TGA TTT GGG GGA TTG CTA TA 3' (300 mmol/L); and probe 5' TGG TTC ACC CGT TTG CCT TCT CCT 3' (200 mmol/L). The taqman probe was labelled with FAM and TAMRA. The assays were performed according to ABI user bulletin #2 protocol in a total volume of 25 µL. VIC labelled human cyclophilin pre-developed taqman assay from Applied Biosystems was used for internal control. The assay was performed and analysed using ABI Prism 7700 sequence detector system.

Quantification of CYP8B1 and CYP27A1 by RNase protection assay

Abundance of specific mRNA was quantified using RPA III™. cRNA probes were synthesized using T3- or T7-polymerase and labelled with ³⁵S-UTP. Cyclophilin was

used as an internal standard and gave a protected fragment size of 103 bp.

The protected fragment size of the probe for CYP27A1 was 297 bp and for CYP8B1 442 bp. The assay was performed according to the manufacturer's protocol. In brief, 10-15 µg of total RNA was co-precipitated in 2.5 volumes of ethanol and 0.5 mol/L NH₄OAc with about 80 000 cpm of each probe at -20°C for 15 min. Following centrifugation at 15 000 rpm for 15 min the pellets were dissolved in 10 µL hybridisation buffer, heated to 95°C for 3 min and incubated at 46°C overnight. The hybridised RNA samples were then treated with RNase A and RNase A/T1 diluted 1:50 in RNase solution at 37°C and inactivated after 30 min by adding inactivation/precipitation solution. Following precipitation at -20°C for 15 min the samples were centrifuged at 15 000 r/min for 15 min and the pellets were air dried and dissolved in 10 µL of loading buffer.

The protected fragments were separated on a denaturing 5% polyacrylamide urea gel and detected and quantified using a Fuji BAS 1800 Phospho-imager.

Statistical analysis

The significance of differences between groups for the mRNA analysis was tested by a one-way ANOVA followed by a post-hoc test. To stabilize the variances, data were logarithmically transformed. Due to variances between patients, statistical analysis of the bile acid formation could not be performed.

RESULTS

Purity of hepatocyte preparations

We have analyzed the purity of the preparation of hepatocytes that we plated. Following the final low speed centrifugation step the cell pellet was resuspended in plating media and samples of the cell preparation were spotted onto microscopic glass slides, air dried and fixed in formalin. Preparations from 2 separate human cases were analyzed. Duplicate slides were exposed to antibodies for low molecular weight cytokeratins (AE1/AE3), albumin or hepatocyte specific antibody HEPR. The results showed that 93% of the cells in the preparation reacted with antibodies to cytokeratin, albumin and HEPR, indicating that 93% of the cells plated on culture dishes were epithelial (cytokeratin positive) and parenchymal hepatocytes (HEPR and albumin positive). Most of the remaining cells were small and appeared to be hematopoietic. Hematopoietic cells would not be expected to attach to culture dishes and would be removed by media changes.

Patient A

The cells were treated for 4 d (from d 1 to d 5) with different concentrations of T₃. The cell culture media were changed daily and collected on d 5 of culture after 24 h incubation. In control cells the total bile acid formation was 1515 ng/mL of culture media (920 ng CA and 595 ng CDCA per mL) and the CA/CDCA ratio 1.5. Treatment with 0.1 nmol/L of T₃ decreased total formation by

Table 1 Formation of CA and CDCA in primary human hepatocytes obtained from 3 patients

Patient	Addition of T ₃	CA	CDCA	Ratio
		ng/mL	Medium/24 h	CA/CDCA
A	Control	920	595	1.5
	0.1 nmol/L	400	310	1.3
	1 nmol/L	375	375	1.0
	10 nmol/L	340	390	0.9

	1 nmol/L	477	392	1.2
	10 nmol/L	395	425	0.9
	100 nmol/L	372	405	0.9
	1 µmol/L	382	420	0.9

The cells were cultured in a serum-free medium and treated with different concentrations of T₃ for 5 d. Bile acids were measured in the cell-free medium. CA: Cholic acid; CDCA: Chenodeoxycholic acid.

53% to 710 ng/mL and lowered the CA/CDCA ratio to 1.3 (Table 1). Higher doses of T₃ decreased bile acid formation even further in a dose dependent manner, down to 36% of control with a CA/CDCA ratio of 0.8 for the highest dose, 1000 nmol/L.

Expression of CYP7A1 mRNA levels was decreased by all doses of T₃ tested. Addition of 0.1 nmol/L of T₃ decreased CYP7A1 mRNA levels from 4.45 to 0.54 (arbitrary value) (12% of control), 10 nmol/L to 0.44 and 1000 nmol/L further down to 0.34 (8% of control). Two of the measure points were lost due to human error (Figure 1).

Similarly, expression of CYP8B1 mRNA decreased with T₃ treatment. Addition of 0.1 nmol/L of T₃ decreased CYP8B1 from 0.226 to 0.056 (arbitrary value) (12% of control), 10 nmol/L to 0.028 and 1000 nmol/L to 0.017 (8% of control) (Figure 1).

Also CYP27A1 mRNA levels decreased with T₃ treatment. Addition of 0.1 nmol/L lowered CYP27A1 levels from 1.050 to 0.408 (arbitrary value) (39% of control), 10 nmol/L to 0.373 and 1000 nmol/L to 0.334 (32% of control) (Figure 1).

Patient B

The bile acid formation in hepatocytes from patient B was much lower than in cells from patients A and C. In control cells the total bile acid formation was 340 ng/mL of culture media (280 ng CA and 60 ng CDCA per mL) and the CA/CDCA ratio was 4.7. Treatment with 0.1 nmol/L of T₃ decreased total formation by 47% to 180 ng/mL, and lowered CA/CDCA ratio to 3.0 (Table 1). Higher doses of T₃ decreased bile acid formation even further down to 34% of control and CA/CDCA ratio to 0.6 for

Figure 1 Patient A, effect of T₃ on CYP7A1, CYP8B1 and CYP27A1 mRNA levels normalized to cyclophilin and expressed as % of control.

Figure 2 Patient B, effect of T₃ on CYP7A1, CYP8B1 and CYP27A1 mRNA levels normalized to cyclophilin and expressed as % of control.

the highest dose, 1000 nmol/L.

Expression of CYP7A1 mRNA levels was decreased by all doses of T₃ tested but not to the same extent as in cells from patient A. Addition of 0.1 nmol/L of T₃ decreased CYP7A1 mRNA levels from 0.745 to 0.444 (arbitrary value) (60% of control), 1 nmol/L to 0.373, 10 nmol/L to 0.086, 100 nmol/L to 0.063 and 1000 nmol/L further down to 0.028 (4% of control) (Figure 2).

Similarly, expression of CYP8B1 decreased with T₃ treatment. Addition of 0.1 nmol/L of T₃ decreased CYP8B1 mRNA levels from 0.175 to 0.095 (arbitrary value) (54% of control), 1 nmol/L to 0.055, 10 nmol/L to 0.030, 100 nmol/L to 0.015 and 1000 nmol/L further down to 0.025 (14% of control) (Figure 2).

T₃ had a modest effect on the expression of CYP27A1 in patient B. Addition of 0.1 nmol/L of T₃ changed CYP27A1 mRNA levels from 0.420 to 0.480 (arbitrary value) (114% of control), 1 nmol/L to 0.370, 10 nmol/L to 0.445, 100 nmol/L to 0.365 and 1000 nmol/L down to 0.315 (75% of control) (Figure 2).

Patient C

In control cells total bile acid formation was 1308 ng/mL of culture media (805 ng CA and 502 ng CDCA per mL) and the CA/CDCA ratio was 1.6. Treatment with 0.1 nmol/L of T₃ decreased the total formation by 41% to 775 ng/mL and lowered the CA/CDCA ratio to 1.2 (Table 1). Higher doses of T₃ decreased bile acid formation to 61% of control and lowered the CA/CDCA further down to 0.9 for the highest dose, 1000 nmol/L.

Expression of CYP7A1 mRNA levels was decreased by all doses of T₃ tested, but not as strongly as in patients A and B. Addition of 0.1 nmol/L of T₃ decreased CYP7A1 mRNA levels from 3.15 to 1.64 (arbitrary value) (52% of control), 1 nmol/L to 2.06, 10 nmol/L to 1.06, 100 nmol/L to 0.81 and 1000 nmol/L further down to 0.65 (21% of control) (Figure 3).

Similarly, expression of CYP8B1 mRNA decreased with T₃ treatment. Addition of 0.1 nmol/L of T₃ decreased CYP8B1 mRNA levels from 0.093 to 0.070 (arbitrary value) (75% of control), 1 nmol/L to 0.040, 10 nmol/L to 0.050, 100 nmol/L and 1000 nmol/L both to

Figure 3 Patient C, effect of T₃ on CYP7A1, CYP8B1 and CYP27A1 mRNA levels normalized to cyclophilin and expressed as % of control.

0.033 (35% of control) (Figure 3).

Also CYP27A1 mRNA levels decreased with T₃ treatment. Addition of 0.1 nmol/L lowered CYP27A1 levels from 0.245 to 0.160 (arbitrary value) (65% of control), 1 nmol/L to 0.150, 10 nmol/L to 0.140, 100 nmol/L to 0.110 and 1000 nmol/L to 0.133 (54% of control) (Figure 3).

Following logarithmical transformation, statistical analysis of mRNA levels from all three patients showed that the highest dose (1000 nmol/L) of T₃ significantly decreased CYP7A1 mRNA levels ($P < 0.05$). CYP8B1 mRNA levels was significantly decreased by 10 and 100 nmol/L of T₃. Treatment with T₃ did not significantly decrease CYP27A1 mRNA levels.

DISCUSSION

In accordance with our previous studies^[4,5,11,12], CA and CDCA, constituted more than 95% of total sterols and the ratio between the two bile acids averaged 2.6.

T₃ dose-dependently decreased formation of bile acids to 44% of controls. The reduction of CA formation was greater than the decline in CDCA formation and

resulted in a marked decrease in the CA/CDCA ratio. These results are in reasonable agreement with previous *in vivo* studies. Angelin *et al*^[13] studied bile acid metabolism in hypothyroid patients before and during replacement therapy to euthyroid state and found that CDCA synthesis was stimulated by approximately 40%, whereas CA did not change with hormone treatment. However, the relative concentration of deoxycholic acid (DCA) in bile decreased from 30% to 19% and CDCA concomitantly increased with hormone therapy. This was confirmed by Kosuge *et al*^[2] who concluded that the characteristic effect of thyroid hormone on serum bile acid composition in man is the shift from the "family" of cholic to that of CDCA by showing that DCA is the most prominent bile acid in hypothyroid patients and that CDCA is the most prominent bile acid in hyperthyroid patients. Paulezki *et al*^[3] studied bile acid metabolism in hyperthyroid patients before and during treatment to euthyroid state and showed that thyroid hormone excess caused a 34% reduction in CA synthesis with no apparent change of CDCA synthesis and a 20% decrease in total bile acid synthesis. The authors suggested that thyroid hormone inhibited hepatic 12 α -hydroxylation.

In contrast to this, Sauter *et al* failed to show any effect of T₃ treatment on the serum levels of the bile acid intermediate 7 α -hydroxy-4-cholestene-3-one (C4) (believed to reflect CYP7A1 activity *in vivo*) in hypo- and hyperthyroidism before and after treatment to euthyroid state^[14]. A recent study by Galman *et al* showed that there are marked diurnal changes of C4 levels during the day^[15]. The authors could also see a weak but significant correlation of C4 with cholesterol and therefore corrected C4 levels for cholesterol. These findings make it difficult to evaluate the results of the C4 levels of the mentioned study. Also, the fact that C4 is the main substrate for CYP8B1 and that one study suggested that CYP8B1 might be inhibited by thyroid hormone needs to be considered.

The mRNA levels of the rate-limiting enzyme CYP7A1 in the neutral pathway were also dose-dependently decreased by T₃. Our data support the human promoter studies by Wang *et al* who found that thyroid hormone repressed CYP7A1 activity^[16]. Furthermore, Drover *et al* found a distinct thyroid hormone response element that mediates T₃ repression in the human CYP7A1 promoter^[17]. This is in contrast to the study in rats where Crestani *et al* failed to demonstrate an effect of thyroid hormone on the *Cyp7a1* promoter activity^[18]. However addition of 1 μ mol/L of T₄ to primary rat hepatocytes increased the transcriptional activity of *Cyp7a1* by 3.7 fold but did not alter steady state mRNA levels^[19].

In the present study we did not measure the enzyme activity of CYP7A1 because of lack of material, but since the effects on the mRNA levels were in agreement with the effects on the bile acid formation we believed that it would be unlikely that T₃ would have an opposite effect on the enzyme activity.

Similar to CYP7A1, the CYP8B1 mRNA levels were also dose-dependently decreased by T₃. Although previous *in vivo* data pointed towards an effect on CYP8B1, this is to our knowledge the first report of the effects of T₃ on human CYP8B1 mRNA levels. In rats however, T₃ has

been shown to suppress both Cyp8b1 activity and mRNA levels^[20].

Treatment with T₃ also decreased CYP27A1 levels, but to a much lower degree than CYP7A1 and CYP8B1. This finding is in line with the contention that CYP27A1 is regulated to a lower degree than CYP7A1 in humans, as has been shown in connection with bile acid mediated feedback regulation^[21]. According to a previous study by Stravitz *et al*^[22] *Cyp27a1* is not regulated by thyroid hormone at all in rat.

In a previous study^[4] we investigated the effect of the combination of T₃ and dexamethasone on bile acid synthesis in rat *vs* human hepatocytes. Since it was previously shown that T₃ and dexamethasone had a synergistic effect on *Cyp7a1* mRNA levels in primary rat hepatocytes^[19] and since neither T₃ nor dexamethasone alone had any effect in rat hepatocytes, we did not focus on the effect of T₃ or dexamethasone alone in primary human hepatocytes. However, we could see that T₃ and dexamethasone alone tended to decrease bile acid formation but had no consistent effect on CYP7A1 mRNA levels (data not shown). The results of the present study and the fact that combination of T₃ and dexamethasone did not change human bile acid formation or CYP7A1 mRNA levels in our prior study, suggest that dexamethasone might have an effect on human bile acid synthesis. This is very interesting and needs to be elucidated in future studies.

The concentrations of T₃ used in this study ranged from 0.1 nmol/L to 1000 nmol/L. The highest dose was included because this is a dose commonly used in combination with dexamethasone in cultures of primary rat hepatocytes. Reduction of methylthiazolyldiphenylterazolium bromide (MTT) showed no signs of cytotoxicity in the dose range used here (data not shown). It should be emphasized that the most dramatic effects were seen with the lowest T₃ concentration, supporting that the effects observed are physiological.

In conclusion, it has been shown that T₃ dose-dependently decreases bile acid formation and expression levels of CYP7A1 and CYP8B1 mRNAs in primary human hepatocytes. CYP27A1 is also decreased, but to a lower degree. CA formation is inhibited to a higher degree than CDCA formation, resulting in a marked decrease in the CA/CDCA ratio.

Abstract

AIM: To demonstrate the feasibility of using woodchuck samples on human microarrays, to provide insight into pathways involving positron emission tomography (PET) imaging tracers and to identify genes that could be potential molecular imaging targets for woodchuck hepatocellular carcinoma.

METHODS: Labeled cRNA from woodchuck tissue samples were hybridized to Affymetrix U133 plus 2.0 GeneChips®. Ten genes were selected for validation using quantitative RT-PCR and literature review was made.

RESULTS: Testis enhanced gene transcript (BAX Inhibitor 1), alpha-fetoprotein, isocitrate dehydrogenase 3 (NAD+) beta, acetyl-CoA synthetase 2, carnitine palmitoyltransferase 2, and N-myc2 were up-regulated and spermidine/spermine N1-acetyltransferase was down-regulated in the woodchuck HCC. We also found previously published results supporting 8 of the 10 most up-regulated genes and all 10 of the 10 most down-regulated genes.

CONCLUSION: Many of our microarray results were validated using RT-PCR or literature search. Hence, we believe that woodchuck HCC and non-cancerous liver samples can be used on human microarrays to yield meaningful results.

INTRODUCTION

Patients with chronic hepatitis originating from infection with hepatitis B virus (HBV) are among those with the highest risk for hepatocellular carcinoma (HCC). The role of HBV in hepatocarcinogenesis has been studied by many investigators, but still not entirely understood. The first case of hepatocellular adenomas in a woodchuck was reported by Fox in 1912^[1]. The model of hepatitis-induced HCC was later described by Summers in 1978^[2] and is now an accepted animal model for studying HBV-induced HCC^[3]. We have performed PET imaging with various positron-emitting radionuclide-labeled imaging tracers involved in the woodchuck hepatitis virus (WHV)-induced HCC animal model (details of the imaging study will be reported separately). Early studies in this project include investigating the genetic basis of pathways involving the tracers and looking for new genetic targets for molecular imaging.

In the past decade, microarray experiments have paved the way for thorough studies of gene expression. To date there has been no commercially available microarray to study gene expression in the woodchuck largely because the genome of this species has not been sequenced and it is not among the common animal models. Cross-species hybridization analysis is one of the methods to investigate genetic regulation of unusual species. Some authors have succeeded in using porcine samples on human Affymetrix GeneChips®^[4,5]. One group has demonstrated the feasibility of using normal woodchuck samples on commercially available human nylon membrane arrays that have since been discontinued^[6].

To the best of our knowledge, there have been no studies that used woodchuck samples on human

oligonucleotide arrays to explore differential gene expression in non-cancerous woodchuck liver versus HCC. In this study, we analyzed the woodchuck gene expression using human Affymetrix GeneChips[®] with validation of differential expression of selected genes with quantitative RT-PCR and literature search.

MATERIALS AND METHODS

RNA isolation

All animals received humane care and the study protocol complies with the institutional guidelines. Woodchucks were euthanized after PET imaging and the livers were immediately removed from the animal. A pathologist separated non-cancerous liver and HCC. Tissues were snap-frozen in liquid nitrogen and stored at -80°C. RNA was extracted with RNeasy Midi Kit from Qiagen (Valencia, CA) according to the recommended protocol. An RNA integrity number (RIN) was found using a Bioanalyzer 2100 from Agilent (Palo Alto, CA).

Preparation of cRNA and microarray hybridization

RNA analyses were performed in the Gene Expression Array Core Facility at Case Western Reserve University. cRNA was prepared and hybridized to Affymetrix Human U133 plus 2.0 GeneChips[®] (Santa Clara, CA) according to the manufacturer's instructions. Microarray results were delivered in the form of cab files.

Microarray data analysis

Two sample *t* tests of quality control data were performed using R 2.0.1 statistical software. Hybridization results were analyzed using GeneChip[®] Operating Software (GCOS) 1.2 from Affymetrix (Santa Clara, CA). All microarrays were scaled to the same average signal intensity so that they could be compared to one another. Microsoft Excel and Access (Redmond, WA) were used to screen the data for significant results. Significantly changed genes were found using a modified version of the criteria outlined

for a Comparison Analysis in the GeneChip[®] Expression Analysis: Data Analysis Fundamentals Manual from Affymetrix (Santa Clara, CA). The only criteria modified was to include signal fold changes for genes that were up-regulated by at least 1.5 or down-regulated by at least -1.5 in the HCC compared with the non-cancerous tissues.

RT-PCR

Available sequence information for woodchuck genes was found in the nucleotide database in the National Center for Biotechnology Information website (www.ncbi.nlm.nih.gov). These sequences were put into Applied Biosystems (Foster City, CA) for determination and production of optimal Custom Taqman[®] Gene Expression Assays. The Taqman[®] primer and probe sequences for our genes of interest are listed in Table 1. The Taqman[®] Assays and total RNA were given to the Gene Expression Array Core Facility. Assays were run in triplicate in a 15 µL reaction volume in a 384-well plate using a PRISM[®] 7900HT Sequence Detection System from Applied Biosystems (Foster City, CA). The RT-PCR assay consisted of a 2-minute incubation at 50°C, a 10-minute incubation at 95°C followed by 40 cycles of a 15-second incubation at 95°C, and then a 1-minute incubation at 60°C. Results were provided to us as values relative to a baseline sample. HCC was compared with the non-cancerous baseline sample from each animal, and > 2.5 or < 2.5 fold gene expression was considered up- or down-regulated, respectively.

RESULTS

Quality control

The first step in determining the usefulness of the results from a microarray study is to examine the quality control data. Table 2 shows some of RNA and microarray quality control data that we examined in this study. Two sample *t* tests were performed to see if there were differences between normal liver samples and HCC samples in any of the categories listed in Table 2. The "Percentage of

Table 2 Quality control data for cross-species hybridization

Samples	RNA integrity number (max = 10.0)	Average background	Noise	Percentage of genes called present	Scaling factor (scaled to 15)
W904Nb	7.5	33.750	1.00	9.0	2.959
W361N	7.8	34.170	0.97	9.5	2.970
W380N	9.7	32.089	0.93	9.9	2.955
W904T	9.8	36.880	1.07	10.3	2.206
W361T	9.2	35.720	1.05	10.5	2.355
W380T	9.9	31.610	0.94	10.8	2.463

Genes Called Present” and the “Scaling Factor” showed a statistically significant difference ($P < 0.05$) between the normal and the tumor samples. Housekeeping control and spiked control genes were qualitatively examined to have similar signal values and similar 3'-to-5' ratios across all of the samples.

Significantly changed genes

A number of the genes was found to be significantly changed in the HCC tissues compared with the normal portion of the liver from the same animal (Table 3). Sixty-six genes were found significantly changed in all three animals and 286 genes changed in 2 out of the 3 animals. Some genes with multiple probes on the microarray were also markedly changed. Of the 18 gene probes that were down-regulated in all 3 tumors, 5 presented metallothioneins, 3 for early growth response 1, and 2 for spermidine/spermine N1-acetyltransferase. Five genes were up-regulated in 2 probes in all 3 tumors: H2A histone family member Z, F-box protein 9, a disintegrin and metalloproteinase domain 10, butyrate-induced transcript 1, and ribophorin II.

We studied further into the 10 most up- and down-regulated genes that were common to all three HCC versus normal liver sample pairs (Table 4). Eight of the top 10 up-regulated genes found previously in literature are in agreement with our findings^[7-14]. We were unable to find any publication describing the up-regulation in any cancer for 2 of these genes, one of which was an open reading frame, but found published data supporting all of the 10 most down-regulated genes^[15-21].

One group used normal human and normal woodchuck liver samples on human nylon membrane arrays^[6]. To compare our results to theirs, we looked into 48 genes which were found to be commonly expressed in both normal human and normal woodchuck livers. We used 2 normal woodchuck liver samples from uninfected woodchucks on the Affymetrix human U133 plus 2.0 GeneChip[®] and found 21 of the 48 previously reported genes to be expressed. We were unable to find any probes on the GeneChip[®] for 3 of the 48 genes. We also explored the normal portion of the liver from 3 woodchucks with HCC and found 22 of the 48 genes were present in all 3 animals, 26 were present in 2 animals and 34 were present in at least 1 animal. Eighteen genes were present in both the normal liver from an uninfected woodchuck and the non-cancerous liver samples from all 3 woodchucks with HCC.

Table 3 Significantly changed genes

Sample pair (tumor vs normal)	Number of up-regulated genes ¹	Number of down-regulated genes ¹	Total number of changed genes
W904	596	205	801
W361	359	242	601
W380	215	81	296
W904, W361	142	47	189
W904, W380	66	3	69
W361, W380	19	9	28
W904, W361, W380	48	18	66

¹The data is presented as HCC vs normal portion of the liver sample where the normal sample is the baseline.

RT-PCR

Ten genes were selected for RT-PCR analysis. Two genes were selected to validate the microarray analysis because the microarray analyses demonstrated they were significantly changed (TEGT and SSAT). RT-PCR was also performed on other genes due to their role in metabolic pathways and hepatocellular carcinogenesis. The RT-PCR results along with the corresponding microarray results are shown in Table 5. It should be noted that the terms “no change” and “undetermined” are not the same. A sample with no change shows similar expression in the normal and tumor samples, whereas the undetermined means that expression could not be measured in either the normal or tumor sample using RT-PCR.

DISCUSSION

PET imaging allows clinicians to view *in vivo* distribution and uptake of a radiolabeled compound, or imaging tracer. It is a useful diagnostic tool when a tracer is used that is highly specific to its target. We investigated the performance of various tracers and their metabolism regulated at multiple levels in the woodchuck model of hepatitis virus-induced HCC. We conducted a microarray study to explore the transcriptional regulation of interesting genes.

There is a logical rationale to explain the disparity in quality control data between normal and tumor samples. In the normal tissue, there were fewer genes called “Present” and a larger scaling factor as shown in Table 2. More genes were up-regulated in the tumors than were down-regulated. Therefore, more genes were expressed in the tumors compared with the non-cancerous portion of the liver, hence the larger ‘Percentage of Genes Called Present’. The fact that fewer genes were called ‘Present’ in the non-cancerous samples is the likely reason for the lower overall average signal intensity, which would also mean that a larger scaling factor is needed to reach a target value compared with the tumor samples.

To determine if our microarray results were consistent with other studies, we compared our results using normal woodchuck liver samples from 2 uninfected animals on Affymetrix U133 plus 2.0 GeneChips[®] to the results of another group that used similar uninfected woodchuck

Table 4 Top 10 up- and down-regulated genes in common on all three tumor/normal sample pairs

¹This is the average fold change for all 3 HCC *vs* normal sample pairs.

Table 5 RT-PCR and microarray results

Gene	Process	W904		W361		W380	
		RT-PCR	Microarray	RT-PCR	Microarray	RT-PCR	Microarray
Testis enhanced gene transcript (BAX inhibitor 1) (TEGT)	Negative regulation of apoptosis	No change	Up	Up	Up	Up	Up
Spermidine/spermine N1-acetyltransferase (SSAT)	Polyamine metabolism	Down	Down	Down	Down	No change	Down
Acetyl-CoA synthetase 2 (thiokinase) (ACAS2) ¹	Metabolism, lipid biosynthesis	Up	Up	Up	Up	Up	No change
Alpha-fetoprotein (AFP)	Immune response, transport	Up	No change	Up	No change	Up	Up
Isocitrate dehydrogenase 3 (NAD+) beta (IDH3B)	Tricarboxylic acid cycle	Up	Up	Undetermined	No change	Up	Up
Carnitine palmitoyltransferase II (CPT2)	Lipid metabolism, fatty acid metabolism, transport	Up	No change	Up	No change	No change	No change
N-myc 2 (NMYC2)	Unknown	Undetermined	N/A	Up	N/A	Undetermined	N/A
C-myc (CMYC) ²	Regulation of transcription, DNA-dependent	Up	Up	Down	Up	No change	No change
Fatty-acid-Coenzyme A ligase, very long-chain 1 (FACVL1)	Lipid metabolism, fatty acid metabolism	Down	Down	Undetermined	Down	Up	No change
Hexokinase (GCKR) ³	Carbohydrate metabolism	Undetermined	No change	Undetermined	Up	Up	No change

¹RT-PCR results are for ACAS2, microarray results are for a hypothetical protein similar to ACAS2. ²RT-PCR results are for c-myc, microarray results are for a c-myc binding protein and a downstream target. ³RT-PCR results are for glucokinase regulatory protein, microarray results are for an EST similar to hexokinase domain containing 1.

liver samples on human nylon membrane arrays^[6]. Using the standard microarray protocol according to the manufacturer's instructions, we have demonstrated a large

overlap of results from the two studies as well as a high degree of similarity between the normal liver tissue from uninfected woodchucks and those of woodchucks with

HCC.

We found supporting data for 8 of the top 10 up-regulated genes and all 10 of the top 10 down-regulated genes (Table 4). The top two up-regulated genes (sterol-CoA desaturase and elongation of long chain fatty acids, family member 6) are involved in fatty acid biosynthesis, which suggests that fatty acid synthesis is up-regulated in HCC compared with the surrounding non-cancerous liver tissues in woodchucks.

Due to the limited number of woodchuck genes that have been sequenced (fewer than 600), we could not perform RT-PCR on all of the genes of interest, and in some cases the sequence was not available for the exact gene. *FACVL1*, *AFP*, *IDH3B*, *CPT2*, and *SSAT* had specific probes on the microarray; *ACAS2*, *CMYC*, *GCKR*, and *TEGT* were similar to what we had microarray probes for; and there was no probe on the microarray for *NMYC2*. The microarray results showed expression of a hypothetical protein similar to the 5' region of *ACAS2*, a c-myc binding protein, a c-myc downstream target, an EST similar to hexokinase domain containing 1, and an EST similar to *TEGT*. Of the 66 probes on the microarrays that significantly changed in all 3 pairs of samples, we validated 2 genes with available sequence information. *TEGT* was up-regulated and *SSAT* was down-regulated in the tumors as shown by both the microarray and RT-PCR analysis. *TEGT* is a negative regulator of apoptosis and has been shown to be up-regulated in cancer cells^[22] and *SSAT*, which is the rate limiting step in polyamine catabolism, has been shown to be induced at the transcriptional level to sensitize tumors for adjuvant treatment^[23].

We also investigated genes involved in carcinogenesis and various metabolic pathways. *IDH3B*, the rate-limiting enzyme in the tricarboxylic acid cycle, was up-regulated in 2 probes in the same 2 tumors and expression validated with RT-PCR. A hypothetical protein similar to *ACAS2*, which catalyzes the conversion of acetate to acetyl-CoA for use in many metabolic and biosynthetic pathways, was up-regulated in 2 tumors according to the microarray results and shown to be up-regulated in all 3 tumors with RT-PCR. *ACAS2* is of particular relevance because of the usage of the PET imaging tracer [¹¹C]-Acetate. Currently, it is not entirely known what pathways are responsible for the high uptake of acetate which can be seen in HCC compared with surrounding normal liver tissues in the PET images. We have demonstrated high up-regulation of the enzyme that catalyzes the formation of acetyl-CoA from acetate, so we hypothesize that this may be the first step involving [¹¹C]-Acetate.

An EST similar to hexokinase was up-regulated in 1 tumor according to the microarray results, and glucokinase regulatory protein (*GCKR*) was up-regulated in a different tumor based on RT-PCR. Sequence information for the woodchuck glucokinase gene was not available, so RT-PCR was performed on a *GCKR*, a negative regulator of glucokinase. Glucokinase is important for its role in PET imaging of [¹⁸F]-fluorodeoxyglucose (FDG). Glucokinase catalyzes the phosphorylation of FDG, thereby trapping it in the cell according to previous kinetic modeling data^[24]. Up-regulation of glucokinase or down-regulation of *GCKR* would be expected to result in higher uptake

of FDG in HCC compared with the non-cancerous liver tissues. However, our results were not conclusive and future work will require sequencing of the woodchuck hexokinase gene or examination of glucokinase regulation at the protein level.

CPT2, a protein that facilitates transport of long-chain fatty acids to the inner mitochondrial membrane for fatty acid metabolism, did not show any change according to the microarray results, but was found to be up-regulated in 2 of the 3 HCCs using RT-PCR. In the target sequence used to create the probes on the human microarray, there is a 436 residue overlap with 40.4% homology between the microarray *CPT2* target sequence and the woodchuck *CPT2* sequence used for RT-PCR. The lack of homology between the sequences might be the reason for not obtaining significant microarray results.

AFP, a serum marker for HCC in humans^[25], was up-regulated in one tumor and showed no change in the other two on the microarrays, while it was up-regulated in all three tumors as measured by using RT-PCR. *NMYC2*, which was found highly expressed in 60% of woodchuck HCCs^[26], was up-regulated in one tumor by using RT-PCR.

These results from using human Affymetrix GeneChips[®] provide a part of the foundation for our imaging work to explore the woodchuck model of virus-induced HCC. Future work will include more investigations of the regulation of pathways involving PET imaging tracers using enzyme assays and immunohistochemistry. Additional efforts will be focused on developing new radiolabeled antibodies and/or ligands for potential imaging targets found to be up-regulated in woodchuck HCC compared with surrounding non-neoplastic woodchuck hepatic tissues.

ACKNOWLEDGMENTS

The authors would thank Dr. Koc for use of his laboratory equipment, Dr. Patrick Leahy for many of his insightful conversations, Steve Schomisch for his assistance in maintaining the woodchucks, and Dr. MacLennan and Dr. Mehta for the pathological studies.

Abstract

AIM: To clarify the safety and feasibility of hepatectomy for huge hepatocellular carcinoma (HCC).

METHODS: A total of 4765 patients with HCC operated at Tongji Hospital were retrospectively studied, of them, 780 patients had huge HCC (10 cm or more in diameter). Hepatectomy was carried out on 634 patients (81.2%). The majority of the liver resection were major resections, and combined resection of the adjacent organs or structures was common (17.2%). The liver resection was combined with portal vein thrombectomy in 139 patients (21.9%).

RESULTS: Postoperative complications were common (26.8%) and required another laparotomy to prevent the complications in 5 patients (0.8%). The 30-d mortality was 2.2%. The main causes of postoperative deaths were liver failure ($n = 9$), postoperative bleeding ($n = 4$) and septic complication ($n = 1$). The 3-, 5- and 10-year survival rates after liver resection were 35.1%, 18.2% and 3.5%, respectively.

CONCLUSION: Hepatectomy for huge HCC is safe and effective. It should be used to treat patients with low surgical risks and resectable tumours.

INTRODUCTION

Hepatocellular carcinoma (HCC) is one of the most common malignancies worldwide, with an annual occurrence of at least one million new cases^[1-3].

Hepatic resection is the mainstay of treatment for resectable tumours because of the proven impact of adequate tumor removal on prognosis. Recent improvements in perioperative management have made partial hepatectomy safe.

Growing indications are related to the resection extent and the approach of surgery in patients with HCC, and the maximum prognosis benefit can be combined with optimal safety. Therefore, surgeons should balance the benefits of oncological clearance against the risks of inadequate parenchymal preservation after liver resection.

A non-cirrhotic liver can tolerate up to 80% liver resection. The regenerative capacity of the liver enables a functional compensation within a few weeks and regeneration to roughly 75% of the preoperative liver volume within 1 year. Such a favourable outcome, however, cannot be extrapolated to cirrhotic liver resection which is commonly carried out for HCC.

Hepatectomy for huge HCC is associated with a higher operative morbidity and mortality because of the extent of liver resection, and a histological margin of over 1 cm is usually recommended to cut down on intrahepatic tumor recurrence^[4-6]. Of the many prognostic factors associated with long-term survival, the size of tumor has a positive association after 'curative' resection for HCC^[6-10]. The aim of this retrospective study was to find out whether liver resection for huge HCC (tumor bigger than 10 cm in diameter) is efficacious and safe.

MATERIALS AND METHODS

A retrospective study was done on 4765 patients with HCC who were treated surgically at the Tongji Hospital, Wuhan, China from January 1972 to December 2002, and 780 (16.8%) patients had huge HCC over 10 cm in diameter. Liver resection was carried out on 634 patients (81.2%).

The criteria for liver resection for huge HCC with curative intention were good general condition of the patient, good cardiopulmonary and renal functions, Pugh-Child's A and B, normal indocyanine green test, tumor confined to one lobe of the liver, and no extrahepatic spread of disease with the exception of local invasion to

Table 1 Demographic data of 634 patients with huge hepatocellular carcinoma who underwent liver resection

Sex (male:female)	563:71
Age (yr) ¹	39 ± 9.5
Total bilirubin (μmol/L) ¹	12.5 ± 2.8
Alanine aminotransferase (U/L)	36 ± 8.5
Albumin (mmol/L) ¹	3.8 ± 0.15
Prothrombin times (seconds prolonged) ¹	1.48 ± 0.8
Maximum size of tumor (cm) ¹	14.1 ± 2.6

¹ mean ± SD. ² number of patient studied = 498.

adjacent organs.

Liver resection for huge liver tumours was performed as previously described^[11,12]. In brief, we routinely used the Pringle's manoeuvre to occlude the hepatic inflow. We divided the porta hepatis pedicle supplying the side of the liver to be resected as described by Launois^[13]. We then transected the liver parenchyma using finger-fracture technique with a haemostat along the plane of transection. The hepatic vein draining the part of the liver to be resected was ligated and divided intrahepatically. Then the portion of the liver to be resected by division of the ligaments was mobilized. This method of liver resection prevented laceration of the major vessels during mobilization of the liver, avoided rupturing of the huge tumor due to excessive traction, and excessive bleeding from the venous collaterals due to cirrhosis and portal hypertension by leaving mobilization of the liver near the end of liver resection. Oncological principles of ligating the vessels prior to manipulation of tumor were followed to diminish shedding of tumor cells into the blood stream.

RESULTS

Of the 780 patients with huge HCC of over 10 cm in diameter treated surgically, 634 (81.2%) underwent liver resection. The remaining 146 patients had unresectable tumors at laparotomy. The reasons for unresectability were: tumours too extensively involving the liver (*n* = 27), multiple secondary tumors (*n* = 56), severe liver cirrhosis (*n* = 44), and tumor infiltration into major vascular structures including the main portal vein, common hepatic artery or the hepatic veins (*n* = 19). These patients with unresectable HCC were treated with intraoperative transhepatic or transportal vein chemotherapy, or with chemotherapy *via* a totally implantable drug infusion system (*n* = 57), intraoperative microwave coagulation (*n* = 36), intraoperative cryotherapy (*n* = 45), or a biopsy of the liver tumor (*n* = 8).

The demographic data of the 634 patients who underwent liver resection are shown in Table 1. Majority of the patients underwent major liver resection. The terminology

Table 2 Type of operation (*n* = 634)

Type of liver resection	<i>n</i>	%
Resection of right three lobes	30	4.8
Resection of right half	44	6.9
Resection of left three lobes	39	6.2
Resection of left half	63	9.9
Segmentectomy 4, 5, 6	33	5.2
Segmentectomy 4, 5, 8	27	4.2
Segmentectomy 5, 6, 7	87	13.7
Segmentectomy 2, 3	128	20.2
Non-anatomical resections	183	28.9
Total	634	100
Combined organ resection		
Partial diaphragamectomy	12	1.9
Right adrenal gland resection	9	1.4
Distal gastrectomy	5	0.8
Transverse colectomy	11	1.7
Splenectomy	31	4.9
Splenectomy + devascularization	41	6.5
Portal vein thrombectomy	139	21.9
Total	248	39.1

of the liver resection used was included according to the recommendation by the International Hepato-Pancreato-Biliary Association. Combined resection of adjacent organs involving the tumor was common. A significant proportion of patient had tumor thrombi in the portal vein (Table 2).

The operative time was 98 ± 41 min, inflow occlusion time was 10.5 ± 2.7 min. Blood loss was 440 ± 250 mL and transfusion requirement was 480 ± 350 mL. Postoperative complications were common, such as reactive right pleural effusion (*n* = 135, 21.4%), significant ascites (*n* = 30, 4.7%), bleeding from stress ulceration (*n* = 11, 1.7%), postoperative hemorrhage on the surface of liver (*n* = 7, 1.3%), infected wound (*n* = 10, 1.6%), bile leakage (*n* = 7, 1.1%) and intraabdominal abscess (*n* = 6, 0.9%). Re-laparotomy to deal with the complications was required in 5 patients (0.8%). The 30-d mortality rate was 2.2%, 9 of 14 patients died of liver failure, 4 of 14 died of postoperative bleeding, and 1 died of septic complication. The 3-, 5- and 10-year survival rates were 35.1%, 18.2% and 3.5%, respectively (Figure 1).

Univariate analysis showed the following prognostic factors associated with significant improvement in survival: female sex, low serum alpha fetoprotein of less than 400 ng/mL, presence of tumor capsule, absence of extensive capsular infiltration by tumor, absence of tumor thrombus in main portal vein and satellite nodules (Table 3). On multivariate analysis, the significant prognostic factors for long-term survival were extensive capsular infiltration, tumor thrombus in portal vein, satellite nodules and intraoperative blood loss (Table 4).

DISCUSSION

HCC usually presents at a very late stage in its natural history because of the lack of symptoms in the early stage. The large size and the position of the liver behind the costal cartilages preclude the tumor from being readily palpable during early stage. Furthermore, the large functional reserve of the liver delays clinical presentation

with functional disturbances of the liver. Some patients present with large tumors in the liver in their first visits.

The tumor size is a significant risk factor for intrahepatic and extrahepatic spread^[14-16]. Whether the tumor's greatest diameter impacts on the disease-free interval and the overall survival remains unclear. Even when small HCCs are examined as a specific group, a better survival can still be observed with decreasing size of the tumor after resection^[7,9]. The frequency of intrahepatic metastasis increases by almost a third between HCC smaller and larger than 5 cm and the rate of portal vein tumor thrombosis is almost doubled^[15,16]. There is little information showing that patients with huge HCC over 10 cm in diameter without any extrahepatic metastases have long-term results after liver resection. Our study on 634 patients showed a 5-year survival of 18.2%. It is low when compared with reported series of patients with HCC unselected for the tumor size, the overall 5-year survival of these series ranges from 11% to 76% with a median around 30%, which might be due to the more advanced stage of cancer at the time of surgery.

One of the major concerns in operating on huge HCC is the operative mortality because of the extent of the liver resection, which is commonly involved in these huge tumors. The 30-d mortality of our patients was 2.2% which is low compared with that reported in the medical literature on HCC ranging from 0.5% to 21.5%, with a median of around 5% to 10%. Our low operative mortality

is probably related to the surgeons' experience and careful case selection.

Intraoperative blood loss can adversely affect the perioperative mortality of patients undergoing liver resection^[18-20]. There is evidence that blood transfusion may be associated with an increased risk of recurrence in patients operated for a hepato-biliary malignancy, due to impairment of the patient's immune response^[21]. Our method of liver resection^[11,12] can offer much to patients with huge HCC. As discussed previously, our technique not only cuts down the intraoperative bleeding, but also follows oncological principles. The other factor related to our good results is careful selection of patients. In cirrhotic liver resection, the onset of postoperative liver failure and mortality is related to the degree of preoperative liver failure^[22] and the extent of non-tumor liver parenchyma removed^[23]. An ideal candidate for liver resection in a patient with huge HCC is a patient with good liver function without ascites (Pugh-Child A).

Using univariate and multivariate analyses, we identified several prognostic factors, associated with a better long-term survival for patients with huge HCC after live resection. However, all these factors reflect the biologic

behavior of the tumor, and cannot be used to exclude patients from liver resection with an intention for a cure. They can be used as a guide to make decisions in balancing the risks of the operation against the potential benefits in a patient who has increased risks of mortality because of his general condition or borderline liver functions. In cirrhotic liver resection, resecting too generous a margin can result in a higher chance of postoperative liver failure. However, a negative histological margin is the only factor that the surgeon can control the long-term survival results. Therefore the tumor should be resected aiming at a 1cm gross margin although our study showed resection margin of above or below 1 cm had no impact on long-term survival provided that the histological margin was clear.

In conclusion, in carefully selected patients, liver resection in patients with HCC of 10 cm or more in diameter is safe.

Abstract

AIM: To evaluate the effectiveness of ultrasonographic screening for early detection of hepatocellular carcinoma (HCC).

METHODS: The data of 14 968 patients who had ultrasonography (US) for chronic liver diseases were collected into a database program from June 1995 to June 2005. The risk factors for HCC were also studied. A total of 6089 patients who had repeated US were enrolled, 264 patients were diagnosed with HCC during follow-up (mean, 39 mo).

RESULTS: The detection rate of small HCC (≤ 3 cm in diameter) was 67.7%. The tumor size detected by screening at the intervals of 6 mo was significantly smaller than that at longer intervals. Only 29.3% of HCC patients had an elevated serum alpha fetoprotein (AFP) level above 400 ng/mL. The risk of HCC development during follow-up was higher in patients with liver cirrhosis (10.9%) and hepatitis C (9.0%) than in patients with chronic hepatitis (4.2%), hepatitis B (4.9%) and non-B, non-C hepatitis (NBNC, 3.9%).

CONCLUSION: US screening at a interval of 6 mo is beneficial to high-risk patients over 40 years old and the early detection of HCC prolongs survival.

INTRODUCTION

Hepatocellular carcinoma (HCC) ranks fifth in frequency of cancers worldwide^[1-3]. As the prognosis of HCC is extremely poor and effective treatment for patients with advanced HCC has not yet been established, the early detection of HCC is important for its effective treatment. Chronic hepatitis B and C as well as cirrhosis, irrespective of their etiology, are recognized as the major factors increasing the risk of HCC^[4-7]. Thus, HCC screening has been extended to include patients with chronic hepatitis B or C as those with cirrhosis^[8,9]. The most important tumor marker for HCC is alpha-fetoprotein (AFP). The common method for screening high risk patients using AFP marker can detect more early tumors and prolong the survival of patients^[10]. Although HCC screening test has become an accepted procedure among high risk populations, there are still some arguments about its effectiveness because there is no randomized controlled study showing a decrease in disease mortality^[11,12]. In addition, the usefulness, frequency and cost-effectiveness of HCC screening may differ in different areas, which may reveal a different prevalence of hepatitis B or C. The aim of this study was to evaluate the usefulness of a screening system in early diagnosis of HCC and to assess the risk factors for HCC development in patients with chronic liver diseases.

MATERIALS AND METHODS

Patients

From June 1995 to June 2005, all data of patients undergone US for HCC or chronic liver diseases in our hospital were collected into a special database program. A total of 14 968 patients had 29 926 examinations during a period of 10 years. We excluded patients with a history of liver cancer or other diseases that might affect survival. In addition, patients with focal hepatic lesion detected at admission or within 3 mo after enrollment were also excluded. All patients were periodically followed up for occurrence of any liver disease. A total of 6089 patients enrolled in this study had US periodically for at least 1 year more.

To assess the risk factors for HCC development, the clinical parameters were collected from 1982 patients. We entered all detailed data into the database program. The age distribution was mostly between the fifth and seventh decades (data not shown). Seventy-seven percent of subjects were positive for hepatitis B surface antigen (HBsAg), 15.5% were positive for anti-hepatitis C virus

Table 1 Comparison of liver status at initial screening and detection of HCC

Liver status	Patients, <i>n</i> (%)	
	At initial screening	At detection of HCC
CH	63 (23.9)	9 (3.4)
LC	201 (76.1)	255 (96.6)
Child A	85 (42.2)	122 (47.8)
Child B	38 (19.0)	58 (22.7)
Child C	78 (14.9)	75 (26.1)

Table 2 Underlying liver diseases at initial US of patients with HCC, *n* (%)

Liver status	HBV (+)	HCV (+)	BC	NBNC	Total
CH	45 (17.3)	13 (4.9)	3 (1.1)	3 (0.6)	42 (23.5)
LC	145 (54.8)	37 (14.0)	2 (0.9)	17 (6.4)	201 (76.1)
Total	190 (72.1)	50 (18.9)	5 (2.0)	19 (7.0)	264 (100.0)

Table 3 Tumor size at diagnosis

Diameter (cm)	Patients, <i>n</i> (%)
≤ 2	106 (40.8)
> 2-3	70 (26.9)
> 3-5	57 (21.9)
> 5	27 (10.4)
Total	260 (100.0)

(anti-HCV), 0.5% were positive for both and 8.4% were negative for both.

All patients were prospectively monitored by measurement of serum AFP and US at the intervals of 3 mo or 12 mo according to the status of underlying liver disease. The mean follow-up time was 39 ± 28 mo. The duration of HCC development was calculated by the time interval between the date of initial US and diagnosis of HCC. When US showed a new focal lesion or the serum AFP was increased, additional investigations were performed, such as a repeated AFP test, contrast computed tomography, or magnetic resonance imaging. HCC was diagnosed by histology or typical imaging features and elevated serum AFP level (≥ 400 ng/mL).

Serum AFP level was measured by a commercial enzyme-linked immunosorbent assay kit (Abbott, North Chicago IL, USA). US was performed by internal physicians.

Statistical analysis

The data were analyzed using the chi square test, logistic regression, or Kaplan-Meier method. All statistical analyses were done with SAS program and SPSS for windows (7.5.1) (Kaplan-Meier method and Cox regression hazard model).

RESULTS

HCC was found in 264 patients by screening during follow-up, and the annual detection rate was 2.1%. At

Table 4 Tumor size according to US interval

US interval (mo)	Patients, <i>n</i> (%)	Tumor size (cm)
≤ 6	124 (47.2)	2.7 ± 1.3^a
≤ 3	26 (10.0)	3.4 ± 1.8
4-6	98 (37.2)	2.5 ± 1.1
> 6	140 (52.8)	3.4 ± 2.0
7-12	90 (34.0)	3.0 ± 2.1
> 12	50 (18.8)	4.4 ± 1.7
Total	264 (100.0)	3.1 ± 1.7

^a $P < 0.01$ vs > 6-mo group.

Table 5 Median survival according to tumor size

Diameter	Patients, <i>n</i> (%)	Median survival (mo)
≤ 2	106 (40.8)	42
> 2-3	70 (26.9)	35
> 3-5	57 (21.9)	20
> 5	26 (10.4)	10
Total	260 (100.0)	31

Table 6 Serum AFP level at detection of HCC

AFP level (ng/mL)	Patients, <i>n</i> (%)
≤ 20	107 (41.1)
≥ 1-400	86 (29.6)
> 400	70 (29.3)

enrollment, cirrhosis was found in 201 patients (76.1%), chronic hepatitis was diagnosed in 63 patients (23.9%). However, most patients (96.6%) progressed to liver cirrhosis when HCC was detected (Table 1). Of the 264 HCC patients, 190 (72.1%) were associated with hepatitis B, 50 (18.9%) with hepatitis C, and 19 (7.0%) not associated hepatitis B or C (Table 2).

The mean diameter of tumor at diagnosis was 3.1 ± 1.7 cm, and the detection rate of small HCC (≤ 3 cm) was 67.7%. Of the 260 patients, 27 (10.4%) had a tumor larger than 5 cm in diameter (Table 3). The mean diameter of the detected tumors at the intervals of 6 mo was significantly smaller than that at longer intervals (2.7 cm vs 3.4 cm, $P < 0.01$). However, there was no difference in tumor size at different time intervals (Table 4). The median survival time was 31 mo (Table 5) and the smaller the tumor size the longer the survival time. Of the 263 HCC patients, 70 (29.3%) had an elevated serum AFP level above 400 ng/mL (Table 6). However, the serum AFP levels were below 20 ng/mL in 107 patients (41.1%).

The incidence of HCC was higher in patients with liver cirrhosis (10.9%) than in those with chronic hepatitis (4.2%) and HBsAg carriers (1.5%). No patient with fatty liver developed HCC. The incidence of HCC was higher in hepatitis C-related group (9.0%) than in hepatitis B- (4.9%) and NBNC-related group (3.9%). However, there was no significant difference between hepatitis C and B patients older than 40 years.

DISCUSSION

The prognosis of HCC is poor especially in Africa and China^[13]. By contrast, the disease runs a more benign course in patients in low risk regions, although they have a mean survival time of only about 6 mo^[14]. The role of chronic infection with HBV and HCV in the etiology of liver cancer is well established^[15]. Some 360 million people are chronically infected and at risk of death due to cirrhosis and HCC. Five hundred thousand to 700 000 people die of HBV-related liver diseases each year^[16]. More than 170 million people worldwide are chronically infected with HCV, which is responsible for more than 100 000 cases of liver cancer per year^[17].

The usefulness, frequency, and cost-effectiveness of HCC screening may differ in different geographic areas or in different underlying liver disease populations because there may be differences in the incidence and growth characteristics^[9,11]. Although US screening for HCC is still controversial, it is a generally accepted strategy in East Asian countries. As patients with chronic hepatitis or cirrhosis may develop HCC, emphasis has been placed on the early detection of HCC when it is small, asymptomatic and potentially curable, by screening patients at high risk^[18]. Several trials in areas of high and low HCC incidence have demonstrated that screening can detect patients at early stage of the disease, increase the resection rate and prolong survival time. Randomized prospective studies in China on high risk patients showed that the survival rate of patients after HCC resection is 52.7% after three years^[19,20].

Cirrhosis is recognized as the major risk factor for HCC, and the annual risk of developing HCC is between 1% and 6%^[21-25]. In our study, the annual risk of HCC development in cirrhosis patients was 3.5%. Reported screening studies showed that 20%-56% of HCC patients have undiagnosed cirrhosis^[26,27]. Screening has been extended to include patients with chronic viral hepatitis as well as those with cirrhosis. The overall annual detection rate of HCC in surveillance studies including chronic hepatitis varies from 0.8% to 4.1%^[11,28-31]. In our study, the annual detection rate of chronic hepatitis was 1.19%.

If the sample size of the target population or the number of HCC cases is not large enough, it is difficult to evaluate the effectiveness of screening in a high-risk population with different status and etiology of liver diseases. Therefore, a large target population and a sufficient number of HCC cases can avoid sampling bias. In our study, the study subjects were enrolled from 29 926 patients who had US for HCC screening or for various chronic liver diseases. We enrolled 6089 patients who had US periodically for a period of at least 1 year by using a database program. Our study included a variety of liver diseases such as hepatitis B or C, fatty liver and liver cirrhosis-related hepatitis B and C, or non-B and C. Two hundred and sixty-four patients were found to have HCC during a mean 39-mo follow-up, and the annual detection rate was 2.0%.

As the sample size was large enough to allow estimation, we tried to evaluate the efficacy of HCC screening. Because our study was a clinic-based screening,

the incidence of HCC was higher than that of Sherman *et al*^[9]. In our study, 76.9% of patients with HCC had liver cirrhosis and 23.1% had chronic hepatitis. Furthermore, most of these cases progressed to liver cirrhosis before development of HCC. Although the incidence of HCC was higher in liver cirrhosis patients (10.7%) than in chronic hepatitis patients (4.0%), chronic hepatitis B or C might progress to cirrhosis and HCC, suggesting that surveillance is needed to include patients with chronic viral hepatitis over the age of 40 years in China.

Reported screening intervals vary from 3 to 12 mo. A 6-mo interval is generally accepted as a rational choice. However, some others prefer shorter intervals in high-risk patients^[32,33]. In our study, the mean diameter of tumor size at diagnosis was 3.1 ± 1.7 cm and the detection rate of small HCC (< 3 cm) was 67.7%. However, there was no difference in tumor size between different time intervals (Table 4). Although a shorter screening interval can detect earlier HCC, it decreases cost-effectiveness.

Whether early detection of tumors can prolong survival time remains unclear^[11]. In our study, the overall median survival of the screened group was 31 mo, suggesting that survival time correlates well with tumor size. Furthermore, survival time was remarkably improved when the detected tumor size was equal or smaller than 2 cm (Table 5). Although the resection rate was relatively low in our study, most tumors, especially those less than 3 cm in diameter, were amenable to non-surgical curative or effective therapy.

Only 70 of the 264 HCC patients (29.3%) had an elevated serum AFP level above 400 ng/mL. In addition, the serum AFP level was below 20 ng/mL in 41.1% of patients. Trials in China have shown that combination of US and AFP can achieve better results in screening HBsAg positive subjects^[21,34].

The incidence of HCC was higher in liver cirrhosis patients (10.9%) than in chronic hepatitis patients (4.2%). None of the patients with fatty liver developed HCC. The incidence of HCC was higher in hepatitis C-related group (9.0%) than in hepatitis B- (4.9%) and NBNC-related groups (3.9%). However, the incidence was not significantly different between hepatitis C and B in the group over 40 years of age. As the risk of HCC is negligible in hepatitis B patients under the age of 30 years and in hepatitis C patients under the age of 40 years, the screening would be better restricted to patients over the age of 40 years.

In conclusion, US screening at the intervals of 6 mo is beneficial to high-risk patients over the age of 40 years and prolongs survival. According to risk factors, the necessity for a screening test and a proper interval should be reconsidered.

Abstract

AIM: To study CD34, CD105, inducible nitric oxide synthase (iNOS), endogenous nitric oxide synthase (eNOS), and hypoxia-inducible factor 1 (HIF-1) α expression in human colorectal carcinomas.

METHODS: The tissue microarrays (TMAs) were made up of 80 cases of colorectal carcinoma and 80 cases of non-neoplasm colorectal mucosa. The expression of CD34, CD105, NOS and HIF-1 α was detected by immunohistochemistry (S-P).

RESULTS: iNOS and HIF-1 α expression in colorectal carcinoma was significantly higher than in non-neoplasm colorectal mucosa ($\chi^2 = 43.166$, $P < 0.01$; $\chi^2 = 10.4278$, $P < 0.01$); eNOS expression in colorectal carcinoma was significantly lower than in non-neoplasm colorectal mucosa ($\chi^2 = 11.354$, $P < 0.01$). The expression of iNOS correlated with differentiation ($\chi^2 = 18.141$, $P < 0.01$), invasive depth ($\chi^2 = 4.748$, $P < 0.01$), and Micro vessel density (MVD) ($t = 2.327$, $P < 0.05$). The expression of HIF-1 α was correlated with infiltrating depth ($\chi^2 = 4.397$, $P < 0.05$), Duke's staging ($\chi^2 = 4.255$, $P < 0.05$), and MVD ($t = 2.272$, $P < 0.05$). No correlation was found in eNOS expression.

CONCLUSION: Over-expression of iNOS and HIF-1 α in colorectal carcinoma is correlated with the biological character MVD.

Key words: Nitric oxide synthase; HIF-1 α ; Colorectal carcinoma; Angiogenesis

INTRODUCTION

Angiogenesis is an important step in the growth and metastasis of solid malignant tumors. To adapt to hypoxia, angiogenesis is essential for tumor growth. Tumor must over-express genes that encode angiogenic factors to induce new blood vessels^[1]. A number of angiogenic factors have been found, and there is interrelation among them, which has been widely researched. Nitric oxide synthase (NOS) and hypoxia-inducible factor 1 (HIF-1) α are two of these factors which may be correlated with angiogenesis. To screen out angiogenic factors is time-consuming and expensive. Tissue microarray (TMA) brings to pathologists a completely new method to solve this problem. TMA has many excellent features such as small volume, high information content, and assembling differently according to different needs. A number of results can be obtained through one experiment^[2], which reduces research time and improves efficiency greatly. Moreover, the most important advantage is a decrease of experimental error, because TMA can make all samples under the same experimental condition. To study NOS and HIF-1 α as angiogenic factors, we used immunohistochemistry to detect the expression of CD34 and CD105 and the expression of inducible NOS (iNOS), endogenous NOS (eNOS), and HIF-1 α in human colorectal carcinomas. TMAs consisting of 80 colorectal carcinoma and 80 non-neoplasm colorectal mucosa were employed to accomplish these studies.

MATERIALS AND METHODS

Patients

Eighty specimens were collected from 80 patients with colorectal carcinoma (median age 62.2 ± 5.9 years, range 29-88 years) who were operated in Qingdao Municipal Hospital (Shandong, China) from Oct 2003 to Mar 2004. Carcinoma and non-neoplasm colorectal mucosa (located at least 8 cm away from the margins of cancers) were taken from each sample. There were 6 cases of well-differ-

Figure 1 Tissue microarray. A: Block; B: Section (HE).

entiated adenocarcinoma, 59 cases of moderately differentiated adenocarcinoma and 15 cases of poorly differentiated adenocarcinoma. Among them, 30 cases had regional lymph node metastasis and 12 cases had distant metastasis. None of the patients received any chemotherapy or radiation therapy before surgical operation. The pathological diagnosis was made on the basis of the size, infiltrating depth, histological grade of the carcinoma, and lymph node and distant metastasis. The grading standard was in accordance with that established in the book *Practical and Surgical Pathology*^[3].

Tissue microarray

HE staining sections of all samples were observed firstly, and typical lesion positions were marked. Then the corresponding positions to these lesions were marked on paraffin wax. The empty TMA paraffin wax (45 mm \times 28 mm \times 7 mm) was holed through Tissue Arrayer (each diameter was 2 mm), and the tissues taken from marked positions were put in these holes tidily (each diameter was also 2 mm). The process was repeated for many times and the TMA paraffin wax was ready (Figure 1A). A different kind of tissue was put in it as a marker, which was kidney tissue in this experiment. Each TMA paraffin wax was sliced into 4 μ m thick sections.

Immunohistochemistry

The expression of CD34, CD105, NOS and HIF-1 α was stained by immunohistochemistry (S-P). The reagent kits were purchased from Fuzhou Maxim Co. Micro vessel density (MVD) was counted with different vessel markers CD34 and CD105 respectively. CD34 and CD105 antibodies were supplied from Neomarker Company, and working consistence was 0.2 mg/L, and 0.4 mg/L. iNOS and eNOS multi-clonal antibody was purchased from Neomarker Company; working consistence was 20 mg/L, and 20 mg/L, respectively; multi-clonal HIF-1 α antibody was from Santa Cruz Company; working consistence was 0.8 mg/L. Homogenous animal IgG that contained the same protein quantity was used instead of first antibody in negative control.

NOS and HIF-1 α staining was classified into two groups. Positive group includes: +++, most carcinoma cells were stained with a very strong intensity, and distributed in clusters; ++, a large number of carcinoma cells were stained with a moderate intensity, and distributed in

clusters occasionally; +, a few carcinoma cells were stained with a slight intensity. Negative group is defined as: -, no staining of carcinoma cells.

Counting of MVD in carcinoma tissues was in accordance with Weidner's standards with a minor modification. The sections were searched for the hot spots rich in vessels, which were located in or near the area of tumor tissues under a low power microscope (100 \times). MVD was counted under a high power (400 \times) microscope according to the standards that any stained endothelial cell or cells were identified as an independent vessel. These vessels must be clearly separated from each other. However, apparent vasa or vasa with red blood cells could be regarded as vessels. Three different HP vision fields were chosen on each of the sections. Stained vessels were counted by two pathologists under multi-ocular microscope simultaneously. The results were averaged as the relative value of the amount of vessels per unit area.

Statistical analysis

The difference of MVD between CD105 and CD34 staining was analyzed with paired sample *t*-test. The relation between MVD and expression of NOS and HIF-1 α was analyzed with *t*-test. Pearson-chi-square test was used for statistical analysis of the relation between clinical-pathological parameters and expression of NOS and HIF-1 α .

RESULTS

Tissue microarray evaluation

Every TMA section consisted of 36-46 samples, which were arrayed orderly. The shape of these samples was rounded or elliptoid, and a few samples were crimped or lost (Figure 1B). After TMA wax was sliced consecutively, one section was picked out for HE staining to make sure that the tissue still kept its histological feature. In fact, almost all samples could keep their histological feature in TMA wax which total depth was about 3 mm. Adjacent sections that contained all samples were selected. After antigen retrieval and IHC staining, 1-2 samples fell off from the sections. Therefore, the number of available samples was 78, and the availability was 97.5%.

Expression of CD34/CD105 and MVD

CD105 was mainly expressed in cytoplasm and plasmalemma of newborn endothelial cells. These positive cells were

Figure 2 CD105, CD34, iNOS, eNOS and HIF-1 α expressions in colorectal carcinoma (SP \times 400). **A:** CD105 in vessels; **B:** CD105 not in vessels; **C:** CD34; **D:** iNOS; **E:** eNOS; **F:** HIF-1 α .

shown as one cell or a group of cells, and most of them ranged in a line or an irregular goblet while a few of them formed lumen. CD105 was weakly expressed or absent in native blood vessels with thick walls or large lumina (Figure 2A). The vessels with positive CD34 staining formed lines or had obvious lumina. Endothelial cells of many large vessels with thick walls and smooth muscles showed positive staining, which was distinct from the sections of CD105 staining (Figure 2B and C). *t*-test showed that MVD by CD34 staining was significantly different from that by CD105 staining (27.5 ± 10.3 vs 14.0 ± 5.8 , $t = 4.782$, $P < 0.01$).

Expression of iNOS and eNOS

The positive rate of iNOS was 78.2% (61/78) in colorectal carcinoma, and 25.6% (20/78) in non-neoplasm mucosa of colorectal tissue. The difference between them was significant ($\chi^2 = 43.166$, $P < 0.01$). The positive granules of iNOS were mainly located in cytoplasm diffusely (Figure 2D). The positive rate of iNOS decreased with the descending of differentiation grade. Most ring carcinoma showed negative expression. The expression of eNOS showed positive or weak positive in non-neoplasm mucosa of colorectal tissue. The positive rate was 60.3% (47/78). The positive granules also located diffusely in cytoplasm, and some expressed in cell nucleus (Figure 2E). The expression of eNOS in colorectal carcinoma was 33.3% (26/78), which was statistically different from that in non-neoplasm mucosa of colorectal tissue ($\chi^2 = 11.354$, $P < 0.01$). The positive rate of eNOS also decreased with the descending of differentiation grade. (Table 1)

Expression of HIF-1 α

The positive rate of HIF-1 α was 69.2% (54/78) in colorectal carcinoma, and 43.6% (34/78) in non-neoplasm mucosa

Table 1 Relation between expression of iNOS, eNOS, HIF-1 α and clinical pathology, *n* (%)

Pathology	<i>n</i>	iNOS	eNOS	HIF-1 α
Histological grade				
Well differentiation	6	5 (83.3) ^b	3 (50)	2 (33.3)
Moderate differentiation	58	51 (87.9)	21 (36.2)	43 (74.1)

(-)	66	50 (75.8)	21 (31.8)	43 (65.2)
Duke's stage				
A, B	45	35 (77.8)	18 (40.0)	27 (60) ^c
C, D	33	26 (78.8)	8 (24.2)	27 (81.8)

^a: $P < 0.05$ between serous membrane positive group and negative group;

^c: $P < 0.05$ between Duke's stage A&B group and C&D group;

^b: $P < 0.01$ between different histological grade groups;

^d: $P < 0.01$ between serous membrane positive group and negative group.

of colorectal tissue ($\chi^2 = 10.4278$, $P < 0.01$). The positive granules mainly located in cell nucleus and cytoplasm (Figure 2F). A small number of HIF-1 α granules were expressed in inflammatory cells in the stroma of tumor.

Relation between NOS/HIF-1 α and MVD

Pearson-Chi-square test showed that the expression of iNOS was correlated with differentiation ($\chi^2 = 18.141$, $P < 0.01$), and infiltrating depth ($\chi^2 = 4.748$, $P < 0.01$). The

expression of eNOS had no significant difference in different groups. However, the expression of HIF-1 α was correlated with infiltrating depth ($\chi^2 = 4.397$, $P < 0.05$), and Duke's staging ($\chi^2 = 4.255$, $P < 0.05$). MVD of iNOS positive group was significantly higher than that of the negative group (14.3 ± 6.1 vs 10.6 ± 4.0 , $t = 2.327$, $P < 0.05$); HIF-1 α staining showed the same result (15.2 ± 5.4 vs 11.5 ± 4.3 , $t = 2.272$, $P < 0.05$), while the MVD between the two groups of eNOS staining had no significant difference (13.8 ± 5.4 vs 11.9 ± 4.7 , $t = 1.523$, $P > 0.05$).

DISCUSSION

Angiogenesis refers to the formation of new blood vessels from native blood vessels, which is very important to the growth and invasion of malignant solid tumors^[4]. In 1971, Folkman firstly put forward the viewpoint that the growth of tumor depends on angiogenesis^[5]. In tumor microenvironment angiogenesis needs many steps, which is a continuous process. The characteristics of micro vessels in tumors are different from that developed under normal physiological conditions. In fact, MVD has been extensively investigated and was found to be a useful prognostic marker in many types of cancers^[6].

At present, most researchers use immunohistochemistry (IHC) to study new blood vessel in tumors. Therefore it is necessary to select an appropriate marker of endothelial cells^[7]. Previous reports have demonstrated that MVD-CD34 is a better prognostic marker than MVD assessed by many other endothelial markers, such as von Willebrand factor (vWF), CD31. However, CD34 is a pan-endothelial cell marker, thus it is difficult to distinct newborn vessels from native vessels, and it may not be able to reflect the exact angiogenesis activity in a tumor. According to some previous reports, CD105 is an endothelial marker that appears to react only with the endothelial cells in the newly formed vessels, and in particular, the immature tumor blood vessels^[8]. Based on our study, we suggest that CD105 has a higher rate of positivity and stronger reactivity on the endothelial cells of new blood vessels^[9]. Therefore CD105 is a better marker for the endothelial cells of new blood vessels. In addition, CD105 monoclonal antibody in the experiment was suitable for paraffin sections. It overcame the limit that usual antibody is only used in frozen sections. Because frozen sections were more difficult to observe than paraffin sections, it led to the inconvenience for MVD counting under microscope. Using this antibody, we saved time and materials, and obtained better staining effect. Moreover, the result of the experiment was more reliable and accurate.

NOS includes eNOS and iNOS, which have different functions. eNOS is involved in many physiological functions of neural system, such as regulating the angioectasis and smooth muscle hyperplasia. iNOS expression in human diseases has long been investigated. NO production by iNOS in tumor infiltrating macrophages may be part of their anti-tumoral cytotoxic potential^[10]. On the other hand, the expression of iNOS in endothelial cells of tumor vessels and in cancer cells itself supports the assumption that the cancer uses this form to regulate the tumor vascularisation and blood flow.

eNOS exists in normal condition and only produce a slight number of NO, while iNOS is induced by activated cells to produce more NO which can promote the construction of tumor vessels. NO has been found to be a mediator of angiogenesis and blood flow^[11,12].

Hypoxia-inducible factor 1 (HIF-1) is a heterodimeric transcriptional factor composed of two basic-helix-loop-helix (bHLH)-PAS α and β subunits. HIF-1 α is the unique, O₂-regulated subunit that determines HIF-1 activity^[13]. A series of genes and proteins that may increase the survival of tumor cells under hypoxia conditions, including vascular endothelial growth factor (VEGF), insulin-like growth factor (IGF), iNOS, platelet-derived endothelial growth factor (PDEGF), glucose transporter 1, lactate dehydrogenase, erythropoietin and nitric oxide synthase gene, are regulated by HIF-1 α . Thus, HIF-1 α may play important roles in tumor progression. Furthermore, HIF-1 α is a critical factor of transcription in the pathway of vascular growth signals. It can activate many genes of angiogenic factors, which can lead to angiogenesis. Most studies about the effects of HIF-1 α on the neovascularization in malignancies have been done *in vitro* or in animal models. It has been confirmed that in many cancer cell lines, hypoxia can induce the expression of some proangiogenic factors, including VEGF, IGF, and PDEGF, through HIF-1 α -dependent manner. It has also been proven through the method of gene knockout that the loss of HIF-1 α may significantly suppress the growth of tumors including glioblastoma and malignant teratoma and most importantly, it may decrease the neovascularization of those malignancies. This provides a new approach for the treatment of tumor^[14].

Tissue chip is also called tissue microarray, which is a special biological chip invented by Kononen in 1998^[15]. Its principle is to remove hundreds of minute tissues from different primary blocks and place them into one arrayed block with high density. Tissue microarray is suitable for all analyses *in situ* such as antibody staining, immunohistochemistry, fluorescence *in situ* hybridization, Western blot. Thus we can investigate the different expression of tissues either at DNA and RNA level or protein level. Tissue microarray is characterized with small bulk and high-throughput, which can produce many results through one experiment^[2,16]. It can decrease experiment errors, greatly improve the efficiency of histopathological study, save experimental materials and reagents, and at the same time make the results more reliable and comparable^[17-19]. Bubendorf *et al.*^[20] made a large amount of tissue microarrays of tumor, in which ten blocks had 4788 samples from 130 kinds of tumor. These microarrays can be used to analyse the difference of newly found genes between normal tissues and tumor, from which we can acquire reliable results. By using the same method, Fernebro *et al.*^[21] also found that Ki67 positive cell index of rectal carcinoma was 0.5-1.0 (average 0.85) by the method of microarray, being not significantly different from that of routine examination method (0.54-1.0, average 0.81); moreover, both methods had the same result on p53 (average 75%). These indicate that we could get reliable and appropriate results with tissue microarray for IHC staining. We have made tissue microarrays consisting of 80 cases of colorectal carcinoma, each of which has 40-50

samples, arranging orderly. Its shape is round or oval, with few crimples and it does not fall off easily. By using tissue microarrays, it is feasible to examine clinical tissue samples on large-scale and with high efficiency, which is rapid, convenient, economical and precise.

by others (19%). Nearly one fifth of the patients did not share information about their disease with others to avoid being stigmatized. Lower levels of social support were significantly associated with living alone, being unemployed, being excluded from antiviral therapy, having psychiatric comorbidities, contracting HCV through intravenous drug use, having high levels of anxiety and depression as measured by the HAD and negative mood state as measured by the SIP. Patients reporting lower levels of social support also noted more physical symptoms as measured by the SIP.

CONCLUSION: Patients with hepatitis C often face significant social problems, ranging from social isolation to familial stress. The most common concerns reflect a limited insight of patients and their relatives and friends about the disease, the risk factors for its spread, and about potential consequences. Our data suggest that educational interventions targeting support persons and the stressors identified in our findings may lessen or alleviate the social strains patients with hepatitis C experience.

Abstract

AIM: To systematically examine the impact of the hepatitis C virus (HCV) diagnosis on patients' level of social support in a large-scale study.

METHODS: Patients evaluated and treated for HCV in a tertiary referral center were enrolled in a cross-sectional study. Demographic data, functional and emotional status as measured by the Hospital Anxiety and Depression Scale (HAD) and the Sickness Impact Profile (SIP), severity of liver disease, mode of acquisition, and physical and psychiatric comorbidities were collected from patients or abstracted from the medical record. All participants completed a semi-structured interview, addressing questions of social support.

RESULTS: A total of 342 patients (mean age 45.2 years; 37% women) were enrolled. Ninety-two (27%) patients described lower levels of support by family and friends. Nearly half of the participants (45%) noted the loss of at least one relationship due to the disease. Fears related to transmitting the disease (25%) were common and often associated with ignorance or even discrimination

INTRODUCTION

Hepatitis C virus (HCV) infection, a common and slowly progressing liver disease, negatively affects quality of life. Most studies addressing the important impact of HCV focus on patients undergoing antiviral therapy^[1-6]. However, even HCV-infected individuals outside of treatment have lower quality of life scores compared to uninfected controls^[7-9]. Negative social interactions may play a unique role as a determinant of quality of life in patients with HCV, as they often face stigmatization in their professional and private environment^[10-12]. Patients living with AIDS and stigmatizing diseases such as tuberculosis and leprosy

experience a deterioration or even complete collapse of their social support network^[13-15]. Despite recent evidence of negative stereotyping in patients with HCV, few studies have focused on the effect of the disease on the patients' interactions with family, friends or other important groups^[16]. Relatively little is known about possible correlations between social support and demographic and psychosocial or physical characteristics, or of the specific difficulties that patients experience in their lives^[17]. In this analysis we hypothesize that poor social support is associated with emotional and physical difficulties in patients with HCV both in and outside of treatment. Using mixed quantitative and qualitative methods, we propose to characterize the nature and the causes of social problems as an important first step in alerting healthcare providers of the major stressors these patients face.

MATERIALS AND METHODS

Patients

The schedules of all hepatologists practicing at a large Midwestern teaching hospital were reviewed daily between October 1998 and May 2003 for patients meeting the study inclusion criteria. Patients younger than 18 years of age, prisoners, those unable to communicate verbally, or provide informed consent were excluded from the study. No exclusions for concurrent liver disease (hepatitis A or B) or HIV status were made. Patients with a confirmed diagnosis of HCV were invited to participate on the day of their clinic visit.

Data collection

Once informed consent was obtained, participants were asked to provide demographic information, to undergo an extensive interview addressing psychosocial and health-orientated questions (see Appendix), and to complete health status and psychosocial survey measures. The interview was designed to range in length from 30 min to two hours. Each interview was recorded with a hand-held tape recorder and transcribed verbatim. After the interview, patients provided demographic information (age, gender, race, marital status, education, population of home town), and completed the Hospital Anxiety and Depression Scale (HAD), a self-assessment scale for mood disturbances in a non-psychiatric patient population^[18], and the Sickness Impact Profile (SIP), a behaviorally based health status measure including sub-scales for physical symptoms (Body Care and Movement, Ambulation, Mobility), psychosocial difficulties (Emotional Balance, Social Interaction, Alertness Behavior, physical ability to Communicate), as well as physical and psychosocial summary scores^[19].

A physician abstracted from the electronic medical record patients' psychiatric diagnoses, Charlson Comorbidity Index^[20], Child-Pugh score, dates of treatment for HCV infection (before, during, after interview), substance abuse, mode of transmission (drug use, blood transfusion/needle stick, tattoo/other/unknown), and response to treatment (durable responder, nonresponder/disease recurrence, naïve). Patients who were naïve either self-excluded from treatment or were

excluded based on physical comorbidities, psychiatric disease, or substance use. Based on clinical records from the attending hepatologist, no patient was determined to remain naïve based on a lack of social support.

Coding

For the construction of our codebook^[10,21] we used the quasi-statistical method as outlined by Miller and Crabtree^[22]. We also employed the qualitative computer software program Atlas.ti (version 4.2, Berlin, Germany) to aid in the management and analysis of data. Twenty trained interviewers, each with over one year of experience in interviewing, read 50 out of 150 randomly selected interviews and ranked the top ten themes in terms of overall frequency and importance. The primary investigator and two trained coders then synthesized this list to create the master codebook which included the central themes related to social support, stigmatization, and quality of life. Using this codebook, each transcript was then coded by two independent coders, one who had undergone a minimum of three weeks formal training and a master coder with at least one-year experience. The initial coding sheets of each coder were converted into a spreadsheet to determine a final kappa score that assessed the agreement between the evaluators. The coders then met and processed the codes for each case until 100% agreement was achieved between them. From this a master code databank was developed which was then used for the statistical calculations.

For this analysis, the chief code was for social support, noting where patients described a dominantly negative environment (coded as 'unsupportive') versus all others (coded as 'supportive'). We defined social support as involving sexual partners, family members, and friends. An 'unsupportive' social environment was defined as dominantly negative (e.g., 'They have basically excluded me; so I'm all alone now,' 'Relations with my husband are just not good any more.') Conversely, a 'supportive' social environment was defined as either positive or mixed (e.g., 'They are always there for me,' 'My in-laws won't have me in the house, but my wife and kids are okay with it.') When the interview was too conflicted or when too few details were provided, the code of 'cannot judge social situation' was used. These interviews were then excluded from the final analysis. The ordinal code of social support had an inter-coder reliability kappa score of 0.72, or what Landis and Kock label as a 'substantial' agreement between coders^[23].

Two coders then conducted a close textual analysis of each discussion of social support present in the interviews. For the purpose of this analysis we concentrated on two main domains: (1) the negative impact of HCV on social support, and (2) the reasons for this negative impact.

Statistical analysis

All analyses were performed using SPSS version 12.0 (SPSS, Inc. Chicago, Illinois, USA). We first summarized the demographics and clinical characteristics of the patient sample, excluding anyone with missing data on social support. We then examined demographic, psychosocial,

and clinical characteristics of the patient sample, both overall and by level of social support, treating the level of social support as binary ('supportive' versus 'unsupportive'). We tested for differences between groups using ANOVA for the means of continuous variables (age, Child-Pugh score, HAD, SIP) and Chi-Square and Fisher's Exact for categorical variables, where appropriate. We then examined factors associated with social support. $P < 0.05$ was considered statistically significant.

RESULTS

Patient characteristics

A total of 499 patients were approached, with 96 declining to participate, largely due to time constraints. Of the 403 patients successfully entered into the study, 61 were excluded due to either a technological failure in recording the interview ($n = 12$) or an inability to judge the social support code ($n = 49$). This left 342 patients in the total sample with a code for social support. This sample was (Table 1) predominantly male, white, and had acquired the disease mostly through intravenous drug use. Two hundred and fifty patients (73%) were categorized as having a 'supportive' and 92 (27%) as having an 'unsupportive' environment. Of all the patients in the study only 4 (3 with hepatitis B and 1 with HIV) had another chronic, sexually transmittable disease.

Bivariate analysis

Considering the cross-sectional design, participants were interviewed at different points during the evaluation of and/or treatment for HCV (pretreatment, treatment, post-treatment, naïve). Naïve patients (typically excluded from treatment due to psychiatric illness or substance use) reported more negative social experiences compared to patients in the pretreatment, treatment, and post-treatment groups (Table 2). Marital status (living without partner) and employment status (unemployed) were significantly associated with level of social support, while all other demographic and disease-related variables did not correlate. Psychiatric comorbidity and prior substance abuse as the mode of acquisition for HCV were associated with lower levels of support. The category of unsupportive social support also correlated with greater physical symptoms as measured by the physical summary scores of the SIP and all physical sub-scales (Body Care and Movement, Mobility, Ambulation). Similarly, lower support was associated with the psychosocial summary scores and all psychosocial sub-scales of the SIP (Emotional Balance, Social Interaction, Alertness, Communication), as well as higher scores for the depression and anxiety scales of the HAD (Table 2).

Thematic analysis

Two domains emerged as patients discussed their problems. First, they described the negative impact of the infection on their social support; second, they gave potential reasons for negative changes.

Negative impact of HCV on social support

five patients (45% of the total sample) noted that having HCV had resulted in the breakdown or loss of at least one relationship. The deterioration of their social network affected sexual relationships (59 patients, 17% of the total sample) and interactions with family members (56 participants, 16% of the total sample): "I am estranged from my family. My wife and I divorced a year and a half ago. I didn't understand what was going on with me. One element of this disease is depression and an inability to think coherently sometimes. Being irrational, it's hard on relationships." Forty individuals (12% of the total sample) noted that they had experienced the loss of at least one friend.

Twenty-nine patients (8% of the total sample) mentioned multiple sources of loss: "Basically I do not have any good relationships with anyone." For these patients, the HCV diagnosis led to what they described

as widespread social isolation. This feeling negatively impacted nearly all aspects of their social lives: "Well, it has affected my family, like even my parents and stuff. My mother's afraid to kiss me; she thinks it's like AIDS, you know. It caused a divorce." In 25 additional cases (7% of the total sample), it was the patients themselves who chose to withdraw from families or friends: "When I first found out that I had something wrong with my liver I was very upset and didn't want anyone around me and tried to keep people from me...Right at the moment I have spent a lot of time away from my family. I'm not really wanting to go around them until I find out for sure what's going on."

Underlying reasons for a loss of social support: Three dominant themes emerged when patients explained why their social support had been lessened because of their HCV infection. (1) Transmission of the virus: First, concerns about possible transmission of the virus were described as a major stressor by 84 patients (25% of the total sample). Most of these concerns, voiced by 69 patients (20% of the total sample), focused on sexual partners and family members: "I live with a woman who's deathly afraid of contracting HCV from me, so there's friction there." A smaller number of patients (n = 36; 11% of the total sample) were afraid that they might infect friends. Because of fears related to maternal-fetal transmission, 2% of the total sample mentioned concerns about having children, which included the decision to forgo having a family: "(I feel) like I am cootied- like I have cooties. I feel like even if I wanted to have children, I couldn't." However, these often excessive concerns also led to some appropriate precautions. Forty participants (12% of the total sample) stated that they had started using various precautions, including barrier methods for contraception as well as keeping all wounds bandaged, utensils clean, and/or warning others of potential infection risks. (2) Ignorance surrounding the disease: Ignorance, sometimes leading to frank discrimination, was described by 66 participants (19% of the total sample) as directly disrupting relations with family and/or friends. One young man stated: "I lost probably half my friends as they don't know what the disease is. They just automatically put up a front. I just don't see them anymore-fear of what may happen. So ignorance is how I like to put it." In

conjunction with these feelings, 61 patients (18% of the total sample) had decided that they would not tell others of their disease to decrease the chance of experiencing a negative reaction: "I don't tell anybody 'cause...people are stupid about this disease. Just like they're stupid about AIDS." A small group of patients ($n = 11$; 3% of the total sample) did not experience discrimination, but rather sensed that those around them simply did not understand that HCV was a serious disease that could affect physical and emotional functioning: "Family members still don't understand because you don't look sick, so therefore, you should still be able to do everything." (3) Stress caused by the disease: Eighty-three participants (24% of the total sample) experienced problems in their social environment, which they attributed to disease related stress. Such HCV related stress took several forms. One was the unpredictability of the infection's outcome, which left family members and/or friends worrying about the patient: "It's sort of depressing for my family members, because they're all really concerned. I've got daughters and they're worried that I'm going to die." For some patients, a major stressor of living with HCV was their own personal concerns for family and/or friends: "I've got to make sure that my family is provided for, 'cause I don't know if I'm going to croak here anytime."

Another frequently mentioned problem with detrimental effects on relationships was fatigue ($n = 49$, 14% of the total sample). Treatment or disease related fatigue limited the patient's ability to spend time with others: "Basically I am just non-functioning; cannot maintain relationship with my wife; I cannot work. I have two little boys I am not able to spend quality time with. I can spend time with them, but...I don't have the energy to go out and play baseball with them or any of that stuff."

A final source of stress, especially for families, was the financial burden that came either through a loss of work and/or through the cost of the antiviral medication ($n = 16$, 5% of the total sample). One patient explained the reaction of her husband to the treatment of her disease: "Not good, it's a lot of strain on him and stress and he's emotionally upset because of everything. And he's had to hold the whole road as far as work and we're in debt \$40 000. You know, that's the big one, the debt and money 'cause we don't have insurance. How are we ever going to pay for it?"

DISCUSSION

This is the first analysis to display the frequency and to characterize the nature of the relationship challenges that patients with HCV experience. About one third of this large group of HCV infected patients described a negative impact of their disease on personal relationships. The most devastating consequences were with breakups or major stressors on sexual relations as experienced by about 17% of the participants, and the loss of relationships with family members in an additional 16% of cases. Our results are consistent with prior studies focusing on patients with HIV/AIDS or tuberculosis, who also felt rejected by relatives and friends^[24,25]. While all chronic diseases can

potentially tax a social support network, a diagnosis with HCV appeared to carry with it unique challenges. Patients feared interactions with others, especially sexual partners, because of the perceived risk that they might infect them. Patients also complained that those close to them lacked information about HCV, that they harbored prejudices or simply did not consider the disease to be "real" and, therefore, serious. As a result, 7% of HCV positive patients in our study personally chose to withdraw from social contact with others.

A similar breakdown occurred outside of the home, with participants reporting that friends had shied away from them. As reported in prior studies, a substantial number of patients experienced frank stigmatization^[26-29]. Changes in employment, sometimes attributed to perceived stigmatization^[10], sometimes fatigue, created additional strains, as patients were facing financial problems exacerbated by the significant costs of the antiviral treatment.

Concerns about quality of life emerged with patients' estrangement from family and friends. Relationship deterioration can constitute an important stressor, which can limit a patient's ability to cope with a disease^[30-32]. Several studies have previously found that a lack of social support and personal coping resources can affect mood and trigger depression^[33-36].

Our bivariate analysis is consistent with the above mentioned theoretical considerations. Similar to prior reports, we noted an association between emotional problems, including depression, as measured by the HAD, and lower levels of social support^[37-39]. A lower level of support was also associated with higher scores for anxiety, as measured by the HAD, more psychiatric diagnoses as listed in the medical chart, and lower psychological well-being as measured by sub-scales and summary scores of the SIP. While studies have consistently found antiviral therapy to be associated with higher levels of depression^[40-45], our cross-sectional data did not show differences in the level of social support of those currently on therapy, as compared to those who were pre or post treatment. This may be surprising at first glance because of the known effects of antiviral therapy on mood. Yet our thematic analysis pointed to specific challenges-transmission risks, unpredictable outcomes, feelings of isolation and the perceived need to withdraw from others-that are not unique to patients undergoing treatment.

Interestingly, patients with lower levels of social support were also more likely to report more severe physical symptoms, as shown in higher SIP scores on Body Care and Movement, Mobility, and Ambulation. While we did not notice a relationship with the presence of cirrhosis or the Child Pugh score, a prognostic indicator for advanced liver disease, most of the patients did not have cirrhosis or had well compensated disease, thus, limiting the discriminating value of these variables. The underlying mechanisms for the relationship between poor social support and physical functioning are unclear^[46-49]. One explanation, as noted by patients in our study, was that worse physical functioning limited their ability to meet expectations of family and/or friends.

This study was shaped by the belief that patients' accounts accurately reflected their lived experience of having HCV. As such, the narrative findings were limited to patient recall. However, we maintain that an open account by patients is the best way to understand the breadth and depth of the problems affecting their social support. In addition, we interviewed a very large group of patients with HCV, enabling us to see which themes appeared most dominant, thereby decreasing the anecdotal nature of most qualitative findings.

The study was also cross-sectional in nature, thereby limiting causal evidence of whether social support difficulties actually resulted in worse mental and physical health. Future studies should assess patient's social support level prior to HCV testing in order to determine whether the knowledge of having the disease results in negative interpersonal consequences or whether patients with risk factors for HCV are instead prone to having social difficulties. Finally, the study population was representative of the non-urban Midwest of America. Our age and sex distribution are similar to those reported in many of the prominent studies on HCV^[50-53]. Also, our results found no significant association between social support and rural/urban living or ethnicity. However, as the majority of our participants were Caucasians, the study is not an ideal vehicle for examining the role of race or ethnicity in social support.

In conclusion, as far as we are aware, our results are the first to characterize in a large patient sample the negative consequences of carrying a diagnosis of HCV on patients' social support. Providers and case managers need to be aware of the themes expressed in this analysis, as fears of contamination, feelings of isolation or withdrawal from others may reduce the emotional willingness of patients to initiate and remain on antiviral therapy. Structured educational sessions for both the patient and their partners and families could help reduce the misunderstandings expressed here, such as the ignorance of the disease or the view that the disease is somehow not "real," which can further burden the resilience of patients with HCV to cope with their disease.

APPENDIX

- 1 Can you tell me what your condition is exactly? What physical limitations do you have and when were you initially diagnosed?
- 2 Could you tell us a little bit about yourself: the things you've done, your roles in life, who you are? What in your life are you most proud of?
- 3 Can you share with us anything specific that might have caused or helped cause your illness?
- 4 Have any of your family members had similar health problems? Does this family history worry you?
- 5 What impact has your physical condition had on the quality of your life? Would you say that your quality of life as compared with 1 year ago is better, about the same, or worse?
- 6 As you go through this experience, have you begun to think about yourself differently?
- 7 What has been the hardest thing for you to cope with related to this experience? How do you go about coping with your condition?
- 8 How does this illness make you feel emotionally? If there was one emotion that you would use to express how you feel, what would that be?
- 9 Since you were diagnosed, what would you say has been your biggest regret? Would you say you feel emotionally worse since you were diagnosed, about the same as before, or emotionally better off than before?
- 10 Can you share what health related worries you have? Do you worry more about your health than you do other aspects of your life? Did you share these worries with your doctor or nurse?
- 11 How would you describe your outlook or thoughts as you look to the future?
- 12 What are the various things that make your life meaningful for you? What do you turn to when you are in need of strength?

- 13 **We are interested in the impact this illness has had on your relationships:**
(1) **If you were in a crisis, who would you turn to?**
(2) **Do you have a spouse or significant other?**
How has that person reacted to your situation of being ill? When you think about when you were healthy, would you describe the two of you as closer, somehow further apart, or just as close as you always were? (3) **Can you describe the level of support you can find in your family? Can you explain why are you able or not able to rely on your family to help you through difficult times?** (4) **Would you say that you are close to others outside of your family? Why would you say that? What about co-workers, are they understanding and supportive?**
- 14 **Have you encountered any negative judgments from others because of your disease? If yes, can you say who has made you feel this way and under what circumstances?**
- 15 How has your disease affected your sense of control in your life? What are the situations where you feel you're not in control?
- 16 What has been your experience with your doctors here or elsewhere? Would you describe it as positive or negative and what has made it positive or negative? What in your eyes makes a good doctor?
- 17 Do you feel that you can ask your doctor or nurse any question? Do you worry that you may be taking their time with your concerns?
- 18 Where do you get most of your medical information? Is there a source you tend to rely or believe in the most? In general, are there other things about your health condition that you would like to learn from your doctor?
- 19 What is the most difficult part of following the treatment the doctor recommended for you? Can you describe situations where you are unable to follow the doctor's treatment, such as taking your medicines, watching your diet, or exercising?
- 20 Did you feel comfortable with your treatment decisions? Do you feel you had choices in your treatment and that they were respected? Who did you discuss your treatment decisions with; what really helped you to make up your mind?
- 21 Do you use other or supplemental, herbal, or alternative medicines, and if yes, what are those?
- 22 If you were to describe yourself as something- it can be anything in this world--an object, an animal, anything-- before when you were healthy and now, what two things would you choose?
- 23 Is there anything else that you would like to add that would help us to understand your experience?
- 24 Finally, is there anything you would like us to share with a social worker, a pastor, or your health care team about the way you are feeling?
- Interviewing Question Guideline (Bold indicates primary questions used in this analysis)

or after induction of endogenous p53 by UV irradiation. Repression by endogenous p53 was partially reversible by stably expressed HBx in both cell lines.

CONCLUSION: Stable expression of HBx leads to deregulation of apoptosis induced by UV irradiation depending on the cell line used. In an immortalized hepatocyte line HBx acted anti-apoptotic whereas expression in a carcinoma derived hepatocyte line HBx enhanced apoptosis.

Abstract

AIM: Hepatitis B virus protein X (HBx) has been shown to be weakly oncogenic *in vitro*. The transforming activities of HBx have been linked with the inhibition of several functions of the tumor suppressor p53. We have studied whether HBx may have different effects on p53 depending on the cell type.

METHODS: We used the human hepatoma cell line HepG2 and the immortalized murine hepatocyte line AML12 and analyzed stably transfected clones which expressed physiological amounts of HBx. P53 was induced by UV irradiation.

RESULTS: The p53 induction by UV irradiation was unaffected by stable expression of HBx. However, the expression of the cyclin kinase inhibitor p21^{waf/cip/sdi} which gets activated by p53 was affected in the HBx transformed cell line AML12-HBx9, but not in HepG2. In AML-HBx9 cells, p21^{waf/cip/sdi}-protein expression and p21^{waf/cip/sdi} transcription were deregulated. Furthermore, the process of apoptosis was affected in opposite ways in the two cell lines investigated. While stable expression of HBx enhanced apoptosis induced by UV irradiation in HepG2-cells, apoptosis was decreased in HBx transformed AML12-HBx9. P53 repressed transcription from the HBV enhancer I, when expressed from expression vectors

INTRODUCTION

The epidemiological association between chronic HBV infection and the development of hepatocellular carcinoma is well established^[1]. However, the molecular mechanism of transformation by HBV is unsolved. Among many potential factors, a viral regulatory protein named Hepatitis B virus protein X (HBx) is believed to contribute to oncogenesis in conjunction with other mechanisms. Stable expression of HBx showed a weak transforming effect in cell lines of liver origin^[2-5], in murine fibroblasts^[6,7] and in rat fibroblasts^[8-12]. Neither the molecular actions set in motion by HBx during the process of transformation, nor the role of HBx for HBV replication are well understood. HBx is dispensable for replication *in vitro*^[13], but under certain conditions HBx can enhance replication *in vitro*^[14-16]. In the woodchuck, a related virus of the same family of viruses, the hepadnaviridae^[17], the analog of HBx is essential for the establishment of infection^[18,19]. A plethora of *in vitro* activities and interactions with cellular partners by HBx have been reported^[22,23].

In the development of cancer, the delicate balance between cell proliferation and programmed cell death is often disturbed^[24]. Several functions of HBx are linked to transformation: HBx transactivates the transcription of cellular proto-oncogenes^[25-27], and is able to override cell

cycle check points^[28,29]. As the oncoproteins of many tumor viruses influence the course of apoptosis in order to transform their target cells^[30-32], several reports described the influence of stable and transient transfection of HBV products on apoptosis. Transfection of replication competent constructs of HBV^[33] and the closely related hepadnavirus woodchuck hepatitis virus^[34] enhanced apoptosis induction. This pro-apoptotic activity of hepadnavirus genomes was dependent on the integrity of the HBx-ORF^[33,34]. Several groups described a pro-apoptotic activity of HBx after transient and stable transfection^[33,34-48] whereas other groups described anti-apoptotic effects of HBx^[49-59].

The cellular tumor suppressor protein p53 is one of the key players in the induction of apoptosis after genotoxic events^[60,61]. Thus, besides influencing programmed cell death the transforming proteins of DNA tumor viruses target and inactivate p53 in quite diverse and elaborate ways^[31,32]. Several lines of evidence connect HBx with a disturbance of p53 functions. HBx binds to p53 *in vitro*^[62,63], the intracellular distribution of p53 appears to be affected by HBx^[4,64,65], p53-dependent and independent DNA repair functions are affected by HBx^[66-70]. Furthermore, HBx relieves the repression of transcription by the tumor suppressor p53 in transient reporter gene assays^[71-73], and influences the expression of the p53 induced cyclin kinase inhibitor p21^{waf/cip/sdi}^[74].

However, most of the experiments in these reports were done in transient transfection or even cell free *in vitro* systems. Because the number of HBx molecules in naturally infected cells is assumed to be low^[75-77] and transient transfections of HBx expression constructs yield very high amounts of HBx protein, we established cell lines stably expressing low amounts of HBx. Next, we studied the effect of HBx expression on several functions of p53 induced by stimuli that were designed to yield physiological p53 amounts in our cell lines. Using these *bona fide* natural conditions we were able to find that even low levels of HBx altered or even antagonized p53 functions.

MATERIALS AND METHODS

Cell lines

AML12: The highly differentiated murine hepatocyte line AML12^[78] derived from mice transgenic for TGF α can be transformed by HBx^[3]. AML12 clones stably transfected with and transformed by HBx and the control cell lines stably transfected with pSV2neo were obtained from N. Fausto. AML12 clones were cultured in Dulbecco's MEM/Nutrient Mix F12 supplemented with 10% FCS, 0.1 μ M Dexamethason, and ITS (Insulin, Transferrin, and Selene, 5 μ g/mL each).

HepG2: The differentiated but already transformed human hepatoblastoma line HepG2^[79] was cultivated in Mixed Medium/10% FCS.

CAT assay

For CAT assays, the cells per well were transfected with Lipofectamine (Life Technologies, Karlsruhe). Detection of CAT protein was done with the CAT-ELISA Kit

(Roche, Mannheim) according to the instructions of the manufacturer.

UV irradiation

All cell lines were plated out one day before irradiation. Directly before irradiation, the medium was removed and the cultures were washed with PBS. UV irradiation was done in the UV-Stratalinker (Stratagene, Leimen, Germany) at 254 nm. The cells were exposed to UV after removing the cover of the dishes.

For induction of apoptosis, 1000 cells were plated in triplicates on culture dishes with a diameter of 95 mm. After irradiation with the indicated energy in the stratalinker, the cell cultures were grown for 5-15 d, until colonies visible by eye were detected. After washing with PBS, the colonies were stained and fixed with 1% crystal violet in 20% methanol for 5 min. After washing with H₂O, the surviving colonies were counted. Each experiment was done in triplicate and repeated at least thrice.

Western blot

For the lysis of cells, 450 μ L of ice cold lysis buffer were added to each well of a six-well plate for 30 min on ice. The lysis was based on RIPA-buffer (0.01 mol/L Tris-HCl, pH 7.4; 0.15 mol/L NaCl; 1% (w/v) sodium desoxycholate; 0.1% (w/v) SDS; 1% Triton X-100) supplemented with Leupeptin and Aprotinin. To digest disturbing chromosomal DNA 250 U/mL Benzonase (Novagen, Merck, Darmstadt) was added to the lysis buffer. After the incubation period, the lysate was cleared by centrifugation at 20 000 g for 5 min. The protein content of the lysates was determined using the BCA assay and equal amounts of protein (20-50 μ g) were separated on an SDS gel. After blotting and incubation with the appropriate primary and secondary antibodies, the membranes were developed using Chemiluminescence Blotting Substrate from Boehringer Mannheim, Germany according to the manufacturer's instructions.

Antibodies

The following antibodies were used for the detection of the indicated proteins: murine p53: AB7 (biotinylated polyclonal sheep antibodies from Oncogene Science, via Dianova, Hamburg, Germany); human p53: mAb PAb1801 (PharMingen, Hamburg, Germany); murine p21: mAb AB4 (OP76 Oncogene, via Dianova, Hamburg, Germany); human p21: p21 (187) (sc-817), St Cruz Biotechnology.

As secondary antibody, we used POD-labeled anti-murine IgG from donkey (Jackson ImmunoResearch, via Dianova, Hamburg, Germany) or POD-streptavidin (Calbiochem, Bad Soden, Germany) for murine p53.

Northern blot

For Northern blot, total cellular RNA was extracted from the cells using TRIzol (Gibco). Twenty micrograms of DNase I digested RNA was separated on a glyoxal agarose gel (1% in 10 mmol/L Na₂HPO₄) and blotted onto positively charged nylon membrane. The blot was hybridized with a ³²P labeled p21-specific probe derived from pCMVp21 (murine).

Figure 1 RT-PCR for the detection of HBx-RNA in HepG2 cells stably transfected HBx-expression constructs. Total cellular RNA from clones obtained after stable transfection with expression vector pRCCMVX for wt-HBx (X1, X2, X3, X8, X10, and X18) or for inactive HBx (pRCCMVXM, XM1, XM2, XM6, XM12, XM14, and XM20) was amplified by RT-PCR with primers used for cloning the complete HBx-ORF.

Ribonucleotide protection assay (RPA)

For RPA, an RNA probe complementary to human p21 was transcribed with Maxiscript, Ambion from the construct pCMVsd^[80] according to the instructions of the manufacturer. As an internal control, we used actin transcribed from pTRI- β -Actin (Ambion, Austin, TX, USA).

The RNA probe was purified by electrophoresis in 5% acrylamide/8 mol/L urea gel. The probe (0.5–2 μ g) was labeled with biotin using the BrightStarTM Psoralen-Biotin kit (Ambion, Austin, TX, USA).

The RPA was performed with the HybSpeedTM RPA kit from (Ambion, Austin, TX, USA). After digestion of the samples as described in the manual of the kit, the samples were run on 5% PAGE/8 mol/L urea in TBE and blotted onto a positively charged nylon membrane (Amersham, Braunschweig). Signal detection was performed with streptavidin labeled with alkaline phosphatase using the BrightStarTM BioDetectTM kit from Ambion, Austin, TX, USA.

RT-PCR

For RT-PCR, 2 μ g of total cellular RNA extracted with Qiagen RNeasy was digested with DNase I for 45 min. One microgram of DNase I digested RNA was reverse transcribed with superscript (Gibco). One quarter of the reverse transcribed RNA was amplified with Taq polymerase (1' 94°C, 1' 54°C, 1' 72°C: \times 35 cycles) using HBx-specific primers, which had been used for cloning the complete HBx ORF into pRcCMV.

Constructs

pRcCMVX: The complete HBx ORF of an HBV genotype A genome (serotype adw2; isolate 991; EMBL accession no.: X51970) was cloned with the help of PCR into the *Eco*RI and *Xba*I-site of pCDNA3, Invitrogen, and controlled by sequencing.

pRcCMVXM: Identical to pRcCMVX except for two stop codons introduced by a G to A exchange of nt 1443 (GAA \rightarrow TAA)^[2] and a C to A exchange of nt 1684 (TCA \rightarrow TAA). Thus, translation of full-length HBx is stopped by exchange of nt 1443 after 23 aa and expression of presumed small HBx proteins is made impossible by exchange of nt 1684, which introduces a stop directly after the third start codon in frame in the HBx-ORF.

PS9: HBV enhancer I (nt 1040–1374 from EMBL accession no.: X51970) was cloned into pBLCAT3^[81].

pC53SN3: Expression vector for wt-p53^[82]. P53 is

expressed from the CMV enhancer in the vector pCMV.

pcDNA3p21 (murine): Murine p21 was cloned by RT-PCR with primers waf-AS and waf-S^[33] from total cellular RNA derived from AML12 cells. After *Eco*RI digestion, the amplicon was cloned into pCDNA3. Sequencing gave complete identity with murine p21 from GenBank.

RESULTS

Establishing HBx-expressing HepG2-cell lines

HepG2 cells—a completely transformed hepatoma cell line—were stably transfected with the HBx-expression construct pRcCMVX. As a negative control, HepG2 cells were transfected with the isogenic HBx protein expression-negative construct pRcCMVXM. Clones obtained after G418 treatment were analyzed for the expression of HBx-RNA expression by RT-PCR (Figure 1). 11/13 wt-HBx transfected and 11/11 HBxM transfected clones expressed HBx RNA detectable by RT-PCR. While all HBxM transfected clones expressed similar amounts of HBx RNA as judged by RT-PCR, it appeared as if HBx RNA expression in wt-HBx transfected clones varied significantly (Figure 1). This reminds of the findings in stably HBx transfected clones of rat fibroblast origin, where HBx expression was downregulated in most clones^[33].

Clone HepG2X8 expressing wt-HBx and control clone HepG2 XM2 transfected with the HBx-expression minus construct pRcCMVXM expressed similar amounts of HBx-RNA and were chosen to be studied in detail.

In comparison, we analyzed the immortalized murine hepatocyte line AML12^[78] and the AML12-clone HBx9 transformed by HBx^[3].

Analysis of HBx functions in HBx-expressing AML12 and HepG2 clones

One well-characterized function of HBx is its potential to transactivate virtually any promoter or enhancer. We were unable to detect HBx protein in stably transfected AML12 and HepG2 clones (data not shown and Ref. [3])—a problem encountered by many other groups. In order to show the presence of active HBx, we analyzed whether transcriptional activation by HBx could be detected in cell lines stably expressing HBx RNA. Indeed, the expression from HBV enhancer I was approximately sevenfold stronger in the HBx expressing cell line HepG2-X8 than in the control cell line HepG2-XM2 (Figure 2B). In AML12 cell transactivation by HBx was lower (Figure 2A).

Figure 2 HBx activates the HBV-Enhancer I *in vivo* and can partially counteract a repression by p53 induced by UV irradiation. CAT expression driven by Enhancer I of HBV is indicated as bars. AML12 (A) or HepG2 (B) derived cell lines expressing HBx (HepG2-X8 or AML12-HBx9) are indicated in black and the controls which did not express functional HBx (AML12 or HepG2-XM2) are shown in white bars. The cell lines were transfected with a CAT-expression vector driven by enhancer I of HBV in triplicate. Four hours after transfection, the cultures were irradiated with the indicated dose of UV. The lysis of the cells was done 18 h post irradiation.

Figure 3 Induction of p53- and p21^{wat/cip/sdi}-protein expression in HepG2-derived cell lines after irradiation with UV by immune blot. The dose of UV used for irradiation is indicated. The cells were lysed 18 h after irradiation with UV.

Table 1 Survival of HepG2- and AML12-derived HBx-expressing and control cell lines after irradiation with UV

	0 J/m ²	20 J/m ²	50 J/m ²
HepG2-XM2	100 ± 1.4	17.7 ± 8.0	1.0 ± 0.9
HepG2-X8	100 ± 20.9	1.1 ± 0.6	0.2 ± 0.1
HepG2-XM2	100 ± 11.8	15.8 ± 7.1	1.38 ± 1.5
HepG2-X8	100 ± 20.3	2.7 ± 1.5	0.0
HepG2-XM2	100 ± 15.6	13.5 ± 6.9	3.7 ± 0.8
HepG2-X8	100 ± 7.4	6.8 ± 0.5	1.7 ± 1.2
AML12	100 ± 5.1	4.3 ± 0.6	1.1 ± 1.0
AML12-HBx9	100 ± 14.2	13.5 ± 8.9	6.0 ± 2.2
AML12	100 ± 27.2	17.0 ± 6.3	0.6 ± 0.04
AML12-HBx9	100 ± 3.8	28.0 ± 7.0	6.8 ± 2.4
AML12	100 ± 4.4	11.0 ± 4.1	0.4 ± 0.5
AML12-HBx9	100 ± 4.6	17 ± 5.1	3.4 ± 1.8

The percentage of cells surviving UV-treatment of three independent experiments. For higher reproducibility the HBx-expressing and the control cell lines were irradiated in one batch.

HBx acts pro-apoptotic in HepG2- and anti-apoptotic in AML12-cell lines

To analyze the extent of apoptosis quantitatively, we investigated the survival of the cell lines under investigation after UV irradiation. Five hundred cells in triplicate were plated and irradiated with the dose indicated. Surviving colonies were counted after about 14 d. Table 1 shows that stable expression of HBx acts pro-apoptotic in HepG2-derived and anti-apoptotic in AML12-derived cell lines. The pro-apoptotic effect of HBx in HepG2-X8 was most obvious in cell lines irradiated with 20 J/m².

For example in one experiment 17.7% ± 8.0 cells of the control cell line HepG2-XM2 survived irradiation with 20 J/m², whereas only 1.1% ± 0.6 of identically treated HBx expressing HepG2-X8 cells were able to grow out to visible colonies. AML12 cells were more sensitive against UV irradiation. Expression of HBx acted anti-apoptotic in the HBx expressing AML12 cell line and enhanced the survival rates to similar levels as in HepG2XM control cells.

No influence of HBx on induction of p53 in HepG2- and in AML12-cell lines

p53 is a central protein in the induction of apoptosis^[83]. After many sublethal stimuli, a complex set of events takes place that results in an increased expression of p53 in the nucleus. Thus, we analyzed by immune blots of whole cell extracts whether HBx was able to modulate expression of p53 after UV irradiation of the cell lines. Irradiation with increasing doses (0-50 J/m²) of UV led to enhanced expression of p53 in control and HBx expressing cell lines (Figures 3 and 4). HBx had no effect on the induction of p53 in cell lines of AML12 and HepG2 origin. p53 expression was easily detectable after irradiation with 20 J/m² and maximal expression was reached after irradiation with 40-50 J/m² in the HepG2 and AML12 cell lines investigated (Figures 3 and 4). These data are in accordance with reports on p53 expression in HepG2-cells^[84], human^[85], and murine^[85,86] fibroblasts and primary rat keratinocytes^[87].

We also analyzed the kinetics of p53 induction after UV irradiation with 40 J/m². p53 levels increased after 1 h to reach a maximum 18 h after irradiation. Thereafter,

Figure 4 Induction of p53- and p21^{waf/cip/sdi}-protein expression in AML12-derived cell lines after irradiation with UV by immune blot. The dose of UV used for irradiation is indicated. The cells were lysed 18 h after irradiation with UV.

Figure 5 Kinetics of induced p53- and p21^{waf/cip/sdi}-protein expression after irradiation with UV by immune blot in AML12 cell lines. The time in hours after irradiation with 40 J/m² UV is indicated.

p53 expression decreased (Figure 5). Again, HBx had no influence on the kinetics of p53 induction after UV irradiation.

HBx counteracts a repression by UV irradiation *in vivo*

We next asked whether HBx may influence functions of p53. One extensively investigated activity of p53 is the ability to repress the transcription of many genes^[88]. Thus, we analyzed whether expression of the reporter gene CAT from HBV enhancer I is repressed by p53 - or other factors activated after induction of programmed cell death - *in vivo*. Irradiation of HepG2 and AML12-cell lines with increasing doses of UV caused indeed a strong repression of expression from HBV enhancer I (Figures 2A and B). The repression was highest at 40 J/m² (Figures 2A and B), the UV dose leading to maximum expression of p53 (Figures 2 and 3). However, a strong reduction of CAT-repression could already be observed at the lowest UV dose of 10 J/m² administered. Interestingly, in the tumor cell line HepG2 (Figure 2B), UV irradiation caused a much stronger repression of expression from enhancer I than in AML12 cells (Figure 2A).

In HBx expressing cell lines, the UV-induced repression was partially counteracted. This anti-repressive activity of HBx was strongest in AML12-HBx9 and still significant in HepG2 cells (Figures 2A and B). In the AML-cell line HBx9 irradiated with 40 J/m² the CAT-expression was 4.9-fold higher than in the parental cell line AML12 without HBx. Thus, HBx seems to be able to alleviate transcriptional repression by p53.

Induction of p53 and p21^{waf/cip/sdi} by UV irradiation

Because we observed that HBx influenced the extent of transcriptional repression by p53 we also wanted to analyze if HBx had any influence on transcriptional activation by p53. After UV irradiation, p53 is stabilized^[89] and acts as a

transcription factor by binding to the promoter of certain target genes leading to enhanced transcription from these promoters, for example of the cyclin kinase inhibitor p21^{waf/cip/sdi}^[90]. Thus, after UV irradiation, the expression of p21^{waf/cip/sdi} is enhanced^[86,91]. We therefore analyzed if stable expression of HBx influenced p53's transcriptional activation of the endogenous p21^{waf/cip/sdi}-promoter. UV irradiation of the cell lines with increasing doses of UV led to an increase of p21^{waf/cip/sdi} protein expression (Figures 3 and 4). As reported by other groups, irradiation with high doses of 40-50 J/m² UV again caused a decline of the induced p21^{waf/cip/sdi} protein expression^[86,91]. An analysis of the temporal regulation of p21^{waf/cip/sdi} protein expression (Figure 5) after UV irradiation in AML12 cells showed an undulation of p21^{waf/cip/sdi} protein expression in the parental cell line and the HBx transformed clone 9. A similar phenomenon was described in the mouse liver after 70% partial hepatectomy^[92]. However, these authors analyzed RNA expression and different time points. Interestingly, stable expression of HBx in HepG2 led to a lower expression of p21^{waf/cip/sdi}-protein. However, in the HBx transformed cell line AML12-HBx9, the level of p21^{waf/cip/sdi}-protein expression after UV irradiation changed from experiment to experiment and no reproducible data for p21 could be obtained, although p53-expression from identical blots (upper lane) gave reproducible results (Figures 4 and 5). It appeared as if the expression of p21^{waf/cip/sdi}-protein was deregulated in a seemingly random way by HBx because p21^{waf/cip/sdi}-protein expression was reproducible in the parental cell line (Figures 4 and 5).

Butz *et al* had described an uncoupling of the regularly inducible p21^{waf/cip/sdi}-RNA expression from the deregulated p21^{waf/cip/sdi}-protein expression upon genotoxic stress in some cell lines^[109]. Thus, we analyzed the induction of p21^{waf/cip/sdi}-RNA in the HBx transfected cell lines. Indeed, analysis of p21^{waf/cip/sdi}-RNA expression in the hepatocyte

Figure 6 Detection of p21^{waf/cip/sdi}-RNA by ribonuclease protection assay in the cell line HepG2-XM2 (A) and -HBx8 (B). Total cellular RNA was isolated from cell cultures irradiated with the indicated dose of UV 18 h after irradiation. As internal control actin was detected by RPA.

lines under investigation gave reproducible results. Irradiation with UV increased the expression of p21^{waf/cip/sdi}-RNA in the HBx-expressing cell lines HepG2-X8 and the control cell lines HepG2-XM2 and AML12 to reach a peak at 20-30 J/m² to decrease thereafter (Figures 6 and 7). Analysis of p21^{waf/cip/sdi}-RNA expression in the HBx expressing clone AML12-HBx9 - in contrast to analysis of p21^{waf/cip/sdi}-protein expression - gave reproducible results. However, no decline of p21^{waf/cip/sdi}-RNA expression was observed at higher doses of UV irradiation as with the other three cell lines under investigation (Figure 7). Quite in contrast, in the HBx-expressing clone AML12-HBx9 the amount of p21^{waf/cip/sdi}-RNA increased continuously even at the highest dose of UV irradiation of 50 J/m². Thus, HBx strongly influenced the regulation of p21^{waf/cip/sdi} expression in the HBx-transformed cell line AML12-HBx9.

CONCLUSION

One of the most important functions of p53 is the induction of programmed cell death in order to maintain the integrity of the genome by inhibiting the survival of cells with damaged DNA^[93]. To analyze the integrity of p53 function in cell lines stably expressing HBx RNA, we investigated several p53 activities during induction of apoptosis by UV. Irradiation with 20 J/m² quite uniformly induced massive cell death in all cell lines analyzed. The cell death was due to apoptosis because we observed nucleosomal DNA fragmentation in all cell lines under investigation (data not shown).

However, we observed that induction of apoptosis was enhanced in HBx expressing cell lines of HepG2-origin and reduced in HBx expressing cell lines of AML12-origin. These opposing effects of HBx are in agreement with the

Figure 7 Detection of p21^{waf/cip/sdi}-RNA by northern blot in the cell line AML12 (A) and the HBx-transformed clone AML12-HBx9 (B). Total cellular RNA was isolated from cell cultures irradiated with the indicated dose of UV 18 h after irradiation.

published results on the influence of HBx on programmed cell death. Several groups described a pro-apoptotic activity of HBx after transient and stable transfection^[33,34-48] whereas other groups described anti-apoptotic effects of HBx^[49-59].

We thus set out to study key events in the induction of apoptosis after UV irradiation. We investigated whether HBx had an effect on the induction of p53 in our cell lines. No evidence was found that HBx influenced the induction of p53 by UV. Neither p53's expression by stabilization of p53 as reported for adenovirus E1A or the large T-Antigen of SV40^[94] was increased, nor was p53's expression decreased in the presence of HBx as described for E6 of the papilloma viruses^[95]. Our results agree with reports from Refs. [85] and [97] who also did not find altered p53 induction or expression in HBV expressing HepG2 cells.

A widely accepted hypothesis assumes that a higher expression of the cyclin kinase inhibitor p21^{waf/cip/sdi} after DNA damage gives an advantage for survival because cells arrest in G₁ and gain time to repair DNA damage instead of succumbing to apoptosis^[88]. DNA damage induced in cell lines with a targeted deletion of the p21^{waf/cip/sdi}-gene led to programmed cell death, whereas the wt-cell line survived in cell cycle arrest^[97]. After induction, p53 binds as a transcription factor to the promoter of p21^{waf/cip/sdi} and increases its transcription^[90]. Our results on induction of p21^{waf/cip/sdi}-protein and RNA by UV irradiation in the control cell lines (AML12 and HepG2-XM2) are in accordance with data from literature^[86,87,91]. Interestingly, the HBx-expressing clone HepG2-clone X8 expressed less p21^{waf/cip/sdi} than the control. A decrease as well as an increase of p21^{waf/cip/sdi} expression in response to HBV infection has been described in literature. In microarrays, an enhanced expression of p21^{waf/cip/sdi} was seen in Hep3B and HepG2 lines stably expressing HBx^[96,98] and in the HBV expressing cell line HepG2.2.15^[99], decreased expression of p21^{waf/cip/sdi} was seen in HBV associated HCC^[100], in transiently transfected primary human hepatocytes^[101] and in two liver samples from patients with chronic HBV infection^[101].

The reason for the differential effect of HBx on the expression of p21^{waf/cip/sdi} in AML12 and HepG2 cell lines is unknown. However, transduction of HBx into primary human hepatocytes and stably transformed hepatocyte lines had reciprocal effects on the expression of several target genes^[101]. It appears possible that stable expression of HBx in the immortalized AML12 cell line mimics the situation found in acutely infected liver

with deregulated and in some circumstances enhanced p21^{waf/cip/sdi} expression^[100], whereas stable expression of HBx in hepatoma cell line HepG2 with slightly decreased expression of p21^{waf/cip/sdi} mirrors the situation found in HBV associated HCC^[100], i.e. in the endpoint of hepatocarcinogenesis.

It appears possible that HBx transactivates the enhancer of p21^{waf/cip/sdi} in AML12 cells directly, as has been reported for other cell lines^[74,96]. In addition, HBx may enhance the physiological activation of p21^{waf/cip/sdi} by p53. Haviv *et al.*^[102] have shown that HBx can drastically enhance p53 mediated transcriptional activation. In consequence, HBx expressing AML12 clones would express more p21^{waf/cip/sdi} than controls. Furthermore, HBx may have a stronger effect on the activation of the transcription factor *ets* in AML12 cells than in HepG2 cells, as *ets* has been suggested to play a crucial role in the transactivation of the p21^{waf/cip/sdi} enhancer by HBx^[96]. These assumptions would be in agreement with the higher and deregulated expression of p21^{waf/cip/sdi}-RNA in the HBx expressing AML12 cell line. An enhanced expression of p21^{waf/cip/sdi} in the HBx transformed cell line AML12-HBx9 reminds of findings in HTLV-1 transformed cell lines^[103,104]. Tax, the transforming protein of HTLV-1 virus^[105] has many functional similarities with HBx^[106]. The oncoprotein E7 of the papilloma viruses also enhances the expression of p21^{waf/cip/sdi}^[107,108]. As described for otherwise unrelated cell lines^[109], we also observed that the expression of p21^{waf/cip/sdi}-protein was deregulated and did not seem to correlate with p21^{waf/cip/sdi}-RNA-expression in HBx-expressing cell line AML12-HBx9 (Figures 4, 5 and 7).

Our results indicate that HBx is able to partially relieve repression of expression from the HBV enhancer I by physiological amounts of p53 as observed after induction by UV irradiation (Figure 2). Other groups reported complete relief of transcriptional repression by p53 after transient transfection of HBx^[71] or HBV-dimers^[72] or in *in vitro* transcription assays using *in vitro* translated p53 and HBx proteins^[73]. However, transient transfection of HBx expression constructs leads to high expression of HBx, whereas stable expression of HBx as in our experiments only leads to low level expression of HBx that may be more comparable to the natural situation in tissue of chronically infected individuals where detection of HBx is rather difficult because of its low level of expression^[75-77]. Moreover, in transient assays using expression vectors for p53 and HBx, a complete relief of transcriptional repression by p53 was only seen when 100-fold more HBx expression vector than p53 was used^[71]. When equal amounts of expression constructs were used, HBx was not able to relieve transcriptional repression by p53^[71,110]. Our results indicate that stable expression of HBx in hepatocyte lines antagonizes functions of physiological doses of p53 induced by UV and confirm the results of transient transfections^[71,72].

In summary, we found several p53 linked activities that were altered in cell lines stably expressing HBx. By use of conditions which closely match the natural situation, we were able to show that HBx is able to alleviate some of the p53 induced effects taking place after the induction of apoptosis by UV irradiation. The differences we observe

between the HBx expressing immortalized hepatocyte line AML12 and the hepatoma cell line HepG2 are due to a differential activation of intracellular signal transduction pathways - as found in inducible HBx expressing AML12-clones^[5,111] - and will be the subject of further investigations.

ACKNOWLEDGMENTS

This work was performed in partial fulfillment of the requirements for the Ph.D. thesis of N.F. and for the MD. thesis of E.Q.

We thank Dr. N. Fausto for the AML12 and AML12-HB9 cell line. We thank Dr. J. R. Smith, Baylor College of Medicine for the gift of the construct pCMVsdI and Dr. B. Vogelstein for pC53SN3.

Abstract

AIM: To undertake analysis of hepatitis A viral load, alanine aminotransferase (ALT), and viral genotypes with duration of viremia, and to correlate these parameters with CD4⁺/CD8⁺ lymphocyte populations that control cell-mediated immunity.

METHODS: Cell counts were carried out using fresh whole blood collected in EDTA vials using a fluorescence activated cell sorter. Hepatitis A virus (HAV) RNA was extracted from blood serum, reverse transcribed into cDNA and quantified by Real-Time polymerase chain reaction and was genotyped.

RESULTS: Among 11 patients, 10 could be analyzed completely. Of these, 3 had severe acute hepatitis (s-AH) and the remainder had a self-limited acute hepatitis A (AHA), with one patient with fulminant disease (encephalopathy Grade IV) dying on the 4th d. The ALT level was significantly higher both in AHA (1070.9 ± 894.3 ; $P = 0.0014$) and s-AH (1713.9 ± 886.3 ; $P = 0.001$) compared to normal controls (23.6 ± 7.2). The prothrombin time in s-AH patients (21.0 ± 2.0 ; $P = 0.02$) was significantly higher than in AHA (14.3 ± 1.1 ;

$P = 0.44$). The CD4⁺/CD8⁺ ratio in AHA patients (1.17 ± 0.11 ; $P = 0.22$) and s-AH (0.83 ± 0.12 ; $P = 0.0002$) were lower than seen in normal healthy controls (1.52). Self-limited cases had peak viral load at the beginning of analysis while in s-AH patients this occurred at the 15th or 30th d. In acute and severe groups, one patient each belonged to genotype IA, with the remaining 8 cases belonging to genotype IIIA. The only fulminant hepatic failure case belonged to genotype IA. HAV viral load and ALT values collected during the entire course of the self-limited infection were directly correlated but this was not the case for s-AH patients.

CONCLUSION: Based on a small-scale study, the persistently higher viral load of s-AH might be due to diminished cellular immunity and hemolysis. The duration of viremia was dependent on the host, as the viral genotype had no apparent role in clinical outcome of AVH and s-AH cases.

INTRODUCTION

Hepatitis A virus (HAV) is a common cause of acute viral infections in humans^[1]. It is a ubiquitous virus readily transmitted by the feco-oral route^[2-5]. Nucleotide sequence analysis of HAV has classified the virus in seven different genotypes, which include human (I, II, III, and VII) and simian (IV, V, and VI) genotypes^[6]. HAV infection follows a benign course; it is often asymptomatic in younger children, but can develop into a fatal fulminant form or severe acute hepatitis in older persons^[7-9].

To date, however, there is limited knowledge of viral load, or the length of viral persistence both in the blood circulation and in fecal excretion. It has been reported that a relapse may occur 30-90 d after the initial onset of the disease^[10-12] and virus has been detected in the stool of patients^[13]. Recently, outbreaks of HAV have occurred among hemophiliacs receiving organic solvent and detergent-treated factor VIII, a fact that stresses the potential usefulness of a reliable and widely applicable technique for quantifying viral load in blood samples^[14-18]. The level and the length of HAV viremia involve the additional risk of the carrier becoming an infectious source of hepatitis A^[19].

We undertook further examination of hepatitis A viremia during the course of infection to understand whether viral load was correlated with cell-mediated immunity. The pathogenetic mechanisms underlying hepatocellular injury in acute hepatitis are poorly understood^[20]. There is general agreement that HAV infection does not evolve to chronic hepatitis in man^[21], and immune mechanisms have been suspected of playing a major role in eliminating virus-infected liver cells^[22-24]. The aim of this study was to undertake analysis of HAV viral load, alanine aminotransferase, and viral genotypes with the duration of viremia, and to correlate these parameters with populations of CD4⁺/CD8⁺ lymphocytes that controls cell-mediated immunity.

MATERIALS AND METHODS

Patients and blood samples

Patients attending the Medical Out Patient Department of Lok Nayak Hospital, New Delhi, with the characteristic symptoms of acute viral hepatitis such as jaundice, fever, general malaise, fatigue, nausea, vomiting, anorexia and right upper quadrant discomfort, were screened for the study. Ten mL of blood were collected by venipuncture from those patients, who gave consent for five different visits. The study was approved by the ethical committee of Maulana Azad Medical College, as per the Declaration of Helsinki (1995). Consecutive blood samples were collected from 10 acute hepatitis A patients on the 0th, 7th, 15th, 30th and 45th d between July 2004 and June 2005. No sample was collected before the onset of symptoms. The '0th' d was defined as the first day when the patient presented after the onset of jaundice. Ten healthy subjects who had no evidence of liver disease or dysfunction were taken as control.

Serological tests

Laboratory examination of alanine aminotransferase (ALT), aspartate aminotransferase (AST), prothrombin time (PT), and total bilirubin levels were carried out by standard methods. IgM anti-HAV were detected by ELISA (HAVAB-MEIA); Abbott Laboratories, North Chicago, IL), IgM anti-HEV (Qiagen, Hilden, Germany), HBsAg (Qiagen, Hilden, Germany) and anti-HCV (Bio-Rad, San Francisco, CA, USA) were measured according to the manufacturer's protocol.

FACS analysis of T-lymphocyte profile

One milliliter whole blood was collected into a vial

containing EDTA and was employed for CD4⁺ (T helper) and CD8⁺ (T suppressor) cell counts within 24 h of collection, using a Fluorescence Activated Cell Sorter (FACS) (Becton Dickinson Electronics Laboratory, Mountain View, California). This system quantifies CD4⁺, CD8⁺ and CD3⁺ T lymphocytes as absolute numbers of lymphocytes per μL (mm^3) of blood, and the CD4⁺/CD8⁺ T lymphocyte ratio. Samples from healthy controls and patients were also run for cell counts using the manufacturer's protocol and reagents.

Primers, probe and standard for real-time amplification

HAV RNA was extracted using the QIAampTM viral RNA extraction kit (Qiagen, Germany). Viral RNA was amplified using primers derived from the most constant region, the 5' non-coding region (5' NCR)^[25,26]. The primers used were, forward primer HAV1 (22: 5'-TTT CCG GAG CCC CTC TTG-3'), as wild type (M14707) reverse primers HAV2 (85: 5'-AAA GGG AAA TTT AGC CTA TAG CC-3') and HAV3 (85: 5'-AAA GGG AAA ATT TAG CCT ATA GCC-3'), and HAV-probe (58: 5'-FAM-ACT TGA TAC CTC ACC GCC GTT TGC CT-TAMRA-3') and RNA standard representing the 5'NCR region was constructed according to Costa-Mattioli *et al*^[27].

Fluorogenic quantitative Real-Time PCR and direct sequencing

RT-PCR was carried out with a HAV quantification kit (Roche Diagnostics GmbH, Germany) according to the manufacturer's instructions. The total volume of the reaction mixture was 25 μL (15 μL of mastermix with 10 μL of the RNA template) in 0.2 mL tubes. The capillaries were sealed, centrifuged, and transferred to the Rotor Gene 3000 real-time PCR machine (Corbett Research, Sydney, Australia). Reverse-transcription was done for 15 min at 50°C followed by 5 min denaturation at 95°C. The corresponding cDNA's were amplified by PCR (20 s at 95°C, 30 s at 50°C acquiring FAM, and 20 s at 72°C) over 45 cycles, and an 87 bp fragment was obtained. The CT values from the clinical samples were plotted on the standard curve, and the number of copies was calculated automatically.

PCR amplification from part of the VP1/2A region of HAV genome was directly sequenced for genotyping^[28-30]. Sequencing was done with an ABI Prism 310 Genetic Analyzer (ABI, Foster City, CA). Sequencing analysis was performed using ClustalW and the phylogenetic inference by version 1.81 of the PHYLIP software package (Professor J. Felsenstein, Department of Genetics, University of Washington, Washington, DC).

Statistical analysis

All data were analyzed by two tailed tests, and a *P* value less than 0.05 was considered significant. We used chi-square test and student's t-test as appropriate.

RESULTS

Comparison of clinical features between AVH and s-AH groups

The average age of all patients was 20.8 ± 15.5 years

Table 1 Clinical, biochemical and immunological characterization of different groups (AVH, s-AH, and normal control)

Characteristic	AVH ¹	s-AH ²	Normal Control ³
No. of cases	07	03	10
Sex (M/F)	3/4	3/0	7/3
Age (mean \pm SD)	0.4 \pm 17.9	27.7 \pm 2.08	26.2 \pm 3.6
ALT (mean \pm SD; IU/L)	1070.9 \pm 894.3	1713.9 \pm 886.3	23.6 \pm 7.2
AST (mean \pm SD; IU/L)	621.3 \pm 242.8	1614 \pm 234.7	23.8 \pm 5.8
T. Bilirubin (mean \pm SD; mg/dL)	9.8 \pm 3.8	24.5 \pm 3.0	0.74 \pm 0.43
Prothrombin Time (Seconds)	14.3 \pm 1.1	21.0 \pm 2.0	12.5 \pm 0.5
Mean CD4 ⁺ /CD8 ⁺	1.17 \pm 0.11	0.83 \pm 0.12	1.52 \pm 0.11

ALT: AVH *vs* s-AH $P = 0.29$ (not significant); AVH *vs* NC $P = 0.0014$ (highly significant); **s-AH *vs* NC** $P = 0.001$ (highly significant); **AST:** AVH *vs* s-AH $P = 0.0034$ (highly significant); AVH *vs* NC $P = 0.00014$ (highly significant); s-AH *vs* NC $P = 0.00044$ (highly significant); **T. Bil:** AVH *vs* s-AH $P = 0.076$ (significant); AVH *vs* NC $P = 0.00017$ (highly significant); s-AH *vs* NC $P = 0.0023$ (highly significant); **PT:** AVH *vs* s-AH $P = 0.11$ (not significant); AVH *vs* NC $P = 0.44$ (not significant); s-AH *vs* NC $P = 0.02$ (significant); **Mean CD4⁺/CD8⁺:** AVH *vs* s-AH $P = 0.46$ (not significant); AVH *vs* NC $P = 0.22$ (not significant); s-AH *vs* NC $P = 0.0002$ (highly significant). **Note:** AVH¹ (Acute viral hepatitis); s-AH² (Severe acute hepatitis); NC³ (Normal Control).

and ranged from 3 to 59 years. The average age and sex ratio of two groups of patients is shown in Table 1. 10 of 11 patients could be followed completely, of which 3 progressed to severe acute hepatitis (s-AH), which is defined on the basis of a prothrombin time (PT) $< 40\%$ of normal range. The remainder of patients had self-limited acute hepatitis A (AHA) and one died of fulminant hepatic failure (Grade IV encephalopathy) at the 4th d of follow up. There was no difference between the groups with respect to clinical symptoms, such as flu-like prodromes (including arthralgia, or headache), fever, nausea, vomiting, abdominal pain, pruritus, and diarrhea.

Comparison of biochemical features between AVH and s-AH groups

In Figure 1, the time course of viral load and serum transaminase ALT levels is presented for all patients. ALT values for both groups followed a decreasing trend towards normal from the initial to final day of follow up. The mean liver function profile of s-AH patients was higher compared to the AVH cases as shown in Table 1. The mean prothrombin time (PT) of s-AH patients was (21.0 ± 2.0 ; $P = 0.02$) significantly higher than that of acute cases (14.3 ± 1.1 ; $P = 0.44$).

Comparison of immunological profiles between AVH and s-AH groups

The mean immunological (CD4⁺/CD8⁺) ratio in patients with acute viral hepatitis A was (1.17 ± 0.1) higher than that in the severe acute cases (0.83 ± 0.12). As shown in Table 1, the CD4⁺/CD8⁺ ratio in normal controls (NC) (1.52 ± 0.11) ratio was almost twice as high as in s-AH ($P = 0.0002$). There was no significant decrease in the immunological ratio of AVH cases compared to normal controls.

Comparison of viral load between AVH and s-AH groups

In the acute case, Ind-301, the viral load on the initial day was 4.5×10^5 , and decreased further to $> 10^3$ copies/mL. As shown in Figure 1, Ind-303 and Ind-306 followed almost similar trends with viral loads of 2.6×10^5 and 1.2×10^5 respectively at 0th d while $< 10^2$ copies/mL still persisted at the end of follow up. The viral load of Ind-304 was 1.0×10^5 at start and complete elimination of the virus with zero copies/mL was seen at the end of follow up, as shown in Figure 1. Patients Ind-308 and Ind-310 displayed a peak viral load at 0th d like the cases described above, while Ind-309 peaked on the 15th d, but values then decreased to less than 100 copies/mL in all three. In the severe cases Ind-302 and Ind-305, the viral load on the initial day of follow up was 1.2×10^5 and 1.1×10^5 respectively, and reached a peak on the 30th d, quite different from the acute case shown in Figure 1. At the end of follow up, the viral load was significantly higher ($> 1.0 \times 10^5$) as compared to AVH. In-patient Ind-307, viral load reached the peak (4.6×10^5) at 15th d and decreased subsequently to 4.3×10^4 copies/mL at the end of the follow up.

Comparison of genotype (s) between AVH and s-AH groups

In Table 2, the maximal viral load was compared with genotyping and geographical distribution. As shown in phylogenetic tree (Figure 2), the patients Ind-301 (DQ179131) and Ind-302 (DQ179132) were categorized as genotype IA, while the remainder Ind-303 (DQ179133), Ind-304 (DQ179134), Ind-305 (DQ179135), Ind-306 (DQ179136), Ind-307 (DQ179134), Ind-308 (DQ182495), Ind-309 (DQ182496), and Ind-310 (DQ182497) were classified as the IIIA genotype. The only fulminant hepatic failure case, Ind-274 (DQ182500), belonged to genotype I A.

DISCUSSION

Hepatitis A remains the most frequent form of viral hepatitis observed in a large number of countries^[31,32]. Recent publications have demonstrated that the duration of the viremic phase is much longer than assumed^[10,27]. A serum HAV viral load assay could therefore be helpful in the management of severe hepatitis A. Real-Time reverse transcription (Rotor Gene 3000, Corbett Research, Sydney, Australia), was used for the quantitative detection of the HAV genome in human sera in individuals who displayed varying disease courses^[27,33,34]. The fluorescence signal due to the cleavage of the fluorogenic probe is generated only if the target sequence for the probe is amplified by the PCR. Therefore, no signals are generated by non-specific amplification.

The alanine aminotransferase level of AVH cases on the initial day was significantly higher ($\geq 10^3$) and the decreased upon subsequent follow up, which corresponds to earlier findings that demonstrate a direct correlation of viral load with serum ALT^[27,35]. In our study, the mean prothrombin time in AVH was not higher while severe cases showed significant elevations compared to normal controls. This could be due to anemia (hemolysis) as this

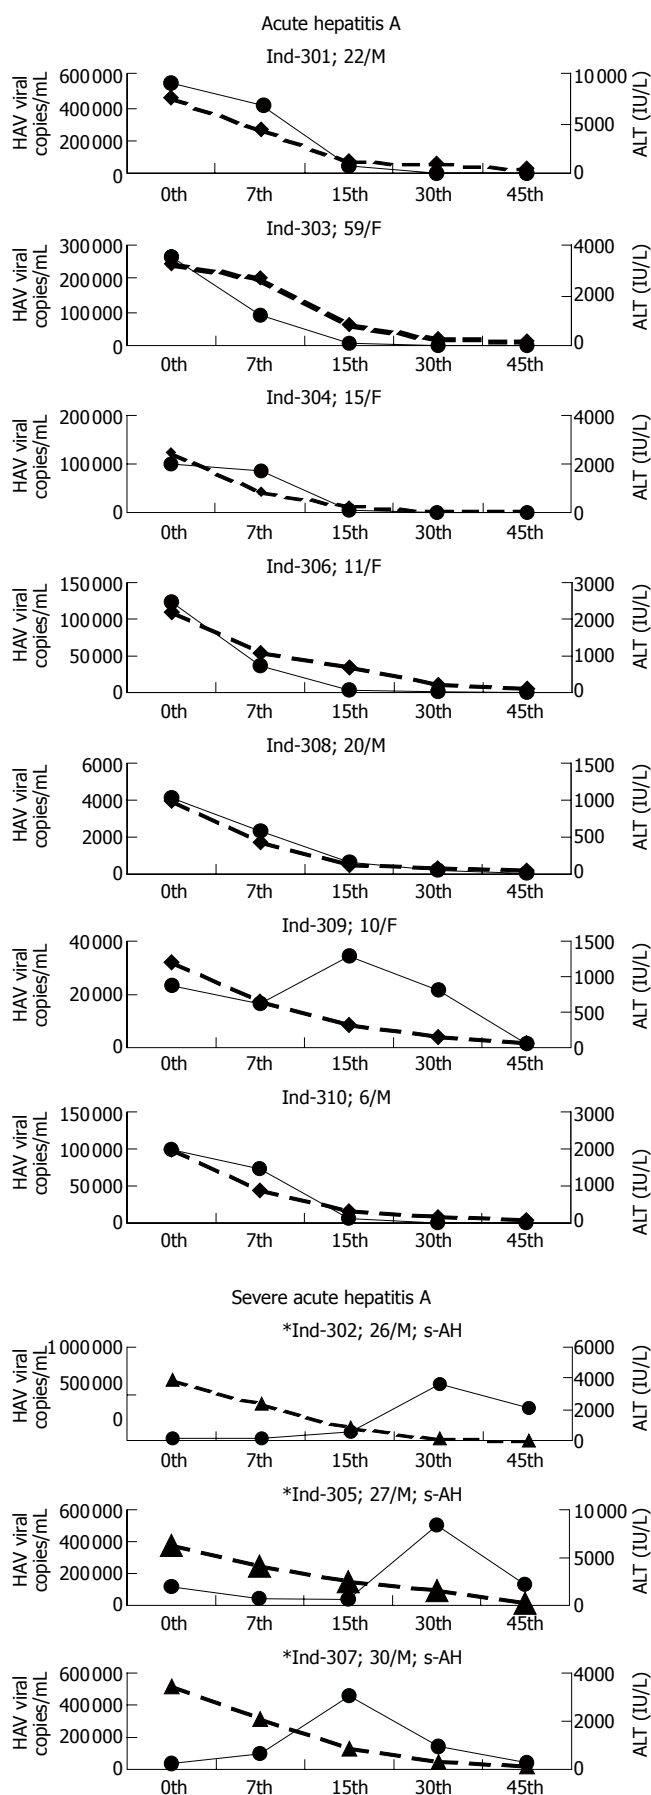

Figure 1 Relationship of hepatitis A virus (HAV) viral load (●) to levels of alanine aminotransferase (ALT) (▲) in serum at different day of follow up.

Table 2 Comparison of patient's genotypes to viral load and geographical distribution

Patients	Genotype	Maximal viral load Copies/mL	Geographical distribution
Ind-301	I A	4.5×10^5	New Delhi
¹ Ind-302	I A	6.0×10^5	New Delhi

Ind-310	III A	9.8×10^4	New Delhi

¹Represents severe acute hepatitis.

is not uncommon during viral hepatitis^[36]. We excluded glucose-6 phosphate dehydrogenase (G6PD) deficiency as a cause of hemolysis and anemia in our cases^[36,37].

The immunological changes in acute cases was not significantly different from those in severe hepatitis A. The lymphocyte ratio (mean $CD4^+/CD8^+$) of the severe patients was, however, significantly lower, which could be due to diminished cellular immunity as compared to the normal controls. Previous studies have also shown that generation of $CD4^+$ T cells in the thymus is severely impeded as either a direct or indirect consequence of active viral replication^[35,38]. We speculate that severe HAV infection may be triggered by diminished cellular immunity in susceptible patients, which may have increased the liver damage due to hepatitis A.

On the basis of our results, genome quantities measured on the first (0th) d of clinical diagnosis in HAV infected humans reached peaked copies/mL in acute viral hepatitis and attained normality towards the end of follow up. The kinetics of peak viral load attainment in s-AH was quite different from that in the acute self-limited cases since at the end of follow up high copies/mL still persisted, as shown in Figure 1. The acute results confirm the levels recently estimated by Chudy *et al*^[15]. The progression of severity due to diminished cellular immunity and hemolysis might be directly linked to high viral persistence throughout the follow up.

Most of the patients examined during acute self-limited illness belonged to genotype IIIA, other than Ind-301 who belonged to IA^[6]. Among the severe cases, Ind-302 belonged to IA while other two belonged to IIIA, which means genotypic variations likely do not play a crucial role in determination of the viral load as described earlier by Normann^[35]. The only FHF case, who died at the 4th d of follow up, belonged to genotype IA. The question arises whether the duration of viremia is dependent on the genotype, or the immunological and/or biochemical profile. Our results showed that the duration of the viremia was dependent on the host, as the viral genotype had no role in acute self-limited illness and severe acute hepatitis A cases. This differs considerably from earlier

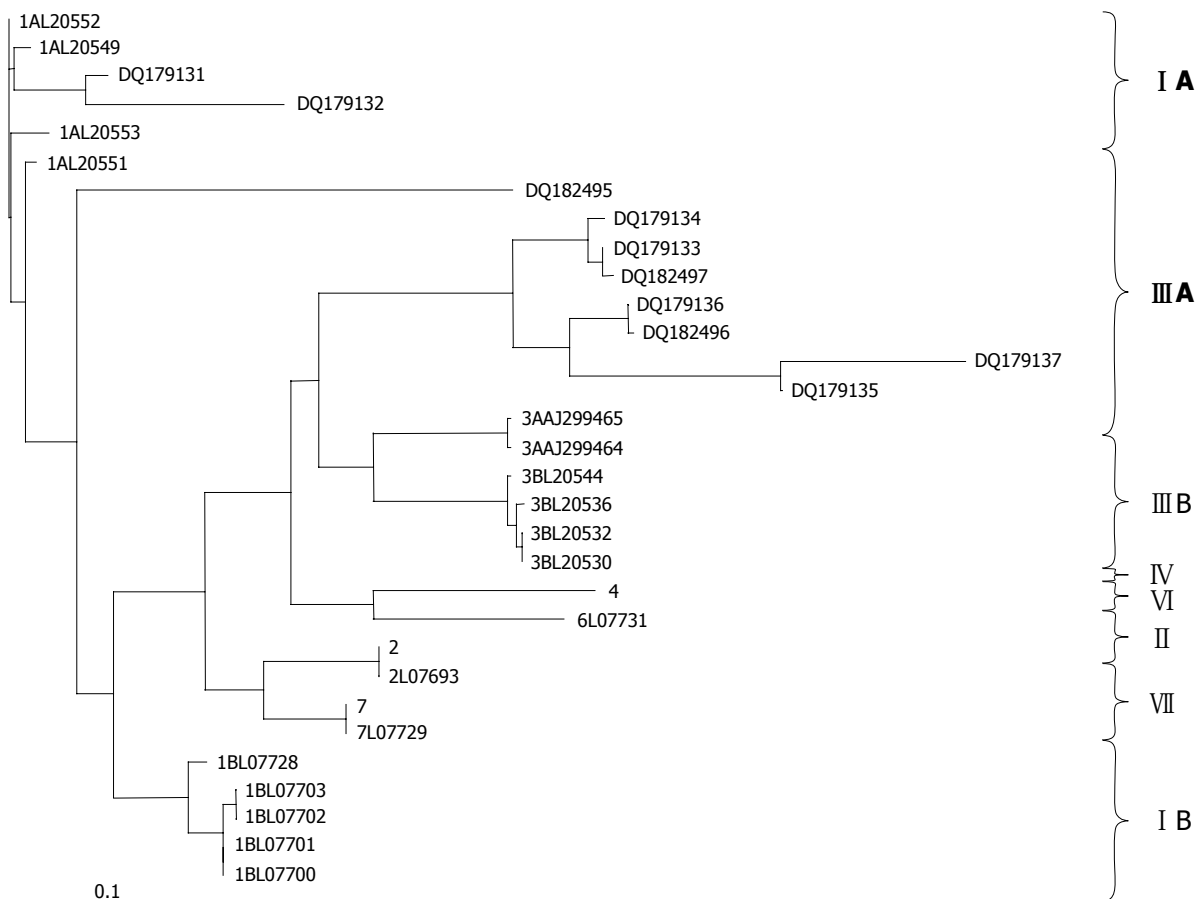

Figure 2 A neighbor-joining phylogenetic tree for isolates of hepatitis A virus based on the sequencing of the VP1-P2A region. Isolates DQ179131 (Ind-301), DQ179132 (Ind-302), DQ179133 (Ind-303), DQ179134 (Ind-304), DQ179135 (Ind-305), DQ179136 (Ind-306), DQ179137 (Ind-307), DQ182495 (Ind-308), DQ182496 (Ind-309), DQ182497 (Ind-310) were collected during the present study, in PCR Hepatitis Laboratory, MAM College and associated LNJ Hospital, New Delhi, India.

findings which showed that a long duration of viremia was found in patients infected with HAV genotype IA^[35].

In conclusion, HAV viral load and alanine aminotransferase (ALT) values collected during the entire course of a self-limited acute infection were directly correlated, but this was not found in s-AH cases. The duration of viremia was dependent on the host (biochemical and immunological profiles), as the viral genotype had no role in the various groups studied. The mean prothrombin time in severe acute hepatitis was higher than seen in acute self-limited illness. The immunological (CD4⁺/CD8⁺) ratio of s-AH was quite low compared to the acute self-limited illness, and s-AH patients showed diminished cellular immunity and complications. There was no difference in the final clinical outcome and recovery of liver function was seen in all patients. The limitation of the study is that the number of patients examined was relatively small. Therefore, there is a need for further research on the duration and magnitude of HAV viremia in a large cohort of human patients to properly document complications and management.

Abstract

AIM: To investigate the role of MHC class II in the modulation of gastric epithelial cell apoptosis induced by *H pylori* infection.

METHODS: After stimulating a human gastric epithelial cell line with bacteria or agonist antibodies specific for MHC class II and CD95, the quantitation of apoptotic and anti-apoptotic events, including caspase activation, BCL-2 activation, and FADD recruitment, was performed with a fluorometric assay, a cytometric bead array, and confocal microscopy, respectively.

RESULTS: Pretreatment of N87 cells with the anti-MHC class II IgM antibody RFD1 resulted in a reduction in global caspase activation at 24 h of *H pylori* infection. When caspase 3 activation was specifically measured, crosslinking of MHC class II resulted in markedly reduced caspase activation, while simple ligation of MHC class II did not. Crosslinking of MHC class II also resulted in an increased activation of the anti-apoptosis molecule BCL-2 compared to simple ligation. Confocal microscope analysis demonstrated that the pretreatment of gastric epithelial cells with a crosslinking anti-MHC class II IgM blocked the recruitment of FADD to the cell surface.

CONCLUSION: The ability of MHC class II to modulate gastric epithelial apoptosis is at least partially dependent on its crosslinking. The crosslinking of this molecule has anti-apoptotic effects during the earlier time points of *H pylori* infection. This effect is possibly mediated by the ability of MHC class II to modulate the activation of the pro-apoptotic receptor Fas by blocking the recruitment of

INTRODUCTION

H pylori infects over half of the people in the world. Seropositivity may reach 80%-100% in underdeveloped nations. This gram negative bacterium is a major contributor to chronic gastritis and peptic ulcer formation, and is strongly associated with gastric carcinoma and lymphoma^[1,2]. Gastric carcinoma remains the second most deadly form of cancer^[3]. While much is known about the clinical manifestations of *H pylori* infection, how this pathogen manipulates gastric epithelial cells in the host to its advantage are unknown. Previous reports by our group have demonstrated that MHC class II expressed on the surface of gastric epithelial cells serve as a receptor for *H pylori*^[4,5]. A potential consequence of bacterial interaction with MHC class II proteins is the subsequent crosslinking of these molecules. This may impact cellular responses key to the initiation and propagation of *H pylori* pathogenesis that results in tissue damage of the gastro-duodenal mucosa.

One such clinically significant cellular response to *H pylori* infection is apoptosis. The induction of apoptosis in MHC class II⁺ host cells able to direct the immune response would represent a mechanism by which the bacteria could impair local antigen presentation to T cells. Furthermore, induction of apoptosis would cause "leakiness" of the epithelium, leading to inflammation that could upregulate the expression of *H pylori* receptors on surrounding cells. For example, IFN γ , an inflammatory cytokine produced by CD4⁺ T cells within the infected gastric mucosa, upregulates class II MHC expression in gastric epithelial cells. However, uncontrolled epithelial apoptosis would

quickly lead to the destruction of *H pylori*'s niche within the gastric mucosa. Thus, mechanisms by which these bacteria could moderate the host apoptotic response must also be considered.

Previous reports show that CD95 (Fas) plays an important role in *H pylori*-mediated apoptosis of the gastric epithelium^[6,7]. Once Fas is activated on the cell surface, the FADD (Fas associated death domain) protein is recruited to the cytoplasmic domains of the trimerized Fas on the plasma membrane. FADD is then responsible for the activation of caspase 8. However, the interaction between *H pylori* receptors and pro-apoptotic death receptors such as Fas has not been well investigated. Combined with our previous data demonstrating the role of MHC class II in *H pylori* binding to gastric epithelial cells (GEC), it might be suggested that the complex dynamics regulating apoptosis during infection might be due to either complementary or antagonistic interactions between multiple signaling receptors on the cell surface. Furthermore, the possibility that MHC class II crosslinking modulates pro-death accessory molecules within the cytoplasm must also be investigated.

MATERIALS AND METHODS

Cell and Bacterial Culture

The human gastric epithelial cell line N87 was obtained from ATCC and cultured in RPMI containing 100 mL/L fetal calf serum and supplemented with glutamine. *H pylori* cag+ clinical isolate LC-11^[8] was grown on blood agar base (Becton Dickinson) at 37°C under microaerobic conditions and harvested into Brucella broth containing 100 mL/L fetal bovine serum. Bacteria in broth were rocked gently overnight at 37°C under microaerobic conditions prior to centrifugation. *H pylori* was resuspended in PBS and concentration was determined by absorbance at 530 nm using a spectrophotometer ($1 \text{ A} = 2 \times 10^8 \text{ cfu/mL}$) (DU-65 Becton Dickinson Instruments, Fullerton, CA).

Antibodies

Monoclonal anti-human MHC class II IgM (clone RFD1) was obtained from Serotec, Raleigh, NC. Monoclonal IgM antibody against CD-95 (clone IPO-4) used to induce apoptosis was obtained from Kamiya Biomedical Co., Seattle, WA. The hybridomas secreting anti-human MHC class II IVA-12 and L243 (mIgG) were obtained from ATCC and were used to produce ascites fluid in mice and the antibodies were purified with a protein G column. Anti-human CD95-PE was obtained from Becton Dickinson/Pharmingen, San Jose, CA. Alexa-conjugated secondary antibodies were obtained from Molecular Probes Inc., Eugene, OR.

Global Caspase Activation Assay

The global (non-specific) activation of caspases in our cell line was quantified using the Homogeneous Caspase Activation kit from Roche Applied Science, Indianapolis, IN. Cells were grown in serum containing media in 96-well plates at a seeding density of 10^4 cells/well for 18 h prior to treatment. After treatment, the media was aspirated and

a substrate-containing lysis solution was applied to the cells. After a 2 h incubation at 37°C, the cleaved substrate product resulting from the action of activated caspases was quantitated using a fluorometer ($\lambda = 521 \text{ nm}$).

Caspase 3 and BCL-2 activation

Caspase 3 activation and BCL-2 expression were quantitated using the Human Apoptosis Cytometric Bead Array kit from Becton Dickinson, Franklin Lakes, NJ. The experiments were conducted according to the kit instructions. Briefly, bead populations with distinct fluorescent intensities were coated with antibodies specific for activated caspase 3 and BCL-2. The capture beads, sample lysates, and PE-conjugated detection reagent were incubated together to form sandwich complexes. After washing, the beads were run through a flow cytometer to generate MFI data, which was then analyzed with Becton Dickinson CBA Analysis Software. Sample data was normalized with specific protein standards to provide quantification of the proteins of interest.

Confocal microscopy

Cells were grown on Collagen I-coated tissue culture inserts (BD Biosciences) to 50%-75% confluency. After cell permeabilization and intracellular staining, the inserts were mounted on glass slides with coverslips. Images were obtained on a Zeiss LSM510 META advanced laser scanning confocal microscope (LSCM). Approximately 50 separate images were obtained at 0.5-0.6 micron increments for X-Z axis reconstruction.

Statistical analysis

Data is presented as the mean \pm SE and analyzed using Student's *t* test. Significance is defined as $P < 0.05$.

RESULTS

Global Caspase Activation Assay

To determine the effect of MHC class II crosslinking at the cell surface on the activation of caspases, we cultured the gastric epithelial cell line N87 in the presence of 100 kU/L IFN γ for 48 h to induce the upregulation of surface MHC class II. Cells were then rested in serum containing medium alone for 2 d prior to bacterial and antibody treatment. Cells pretreated with antibody were exposed to RFD1 (10 mg/L) for 30 min prior to the addition of *H pylori*. Camptothecin (10 μM /L) was used as a positive control for caspase activation and an isotype antibody, which had no effect on the cells, was another control. After 24 h of infection, crosslinking MHC class II prior to the addition of *H pylori* significantly ($P < 0.05$) reduced global caspase activation compared to *H pylori* infected samples with no pretreatment (Figure 1).

Apoptosis Cytometric Bead Array

Caspase 3 is an effector caspase whose activation is central in the apoptosis pathway triggered by Fas trimerization. To specifically examine the activation of caspase 3 as a result of MHC class II ligation versus crosslinking, we used a cytometric bead array that incorporates antibodies

Figure 1 Total caspase activation detected using a colorimetric assay. (means of the treatments / control (untreated) samples).

Figure 3 The effects of ligating vs crosslinking N87 cell surface MHC class II molecules on BCL-2 expression. Using the apoptosis cytometric bead array kit, beads exposed to the samples were run through a flow cytometer to obtain MFI data. These results were normalized to BCL-2 standards to give values expressed as ng/L of BCL-2.

to the activated form of caspase 3. At 4 and 8 h treatment of IFN γ -treated N87 cells, crosslinking MHC class II with biotinylated anti-MHC class II IgG antibodies L243 and IVA12 resulted in a reduced activation of caspase 3 activation compared to ligating MHC class II with unbiotinylated cocktail. After 4 h of treatment, ligation of MHC class II resulted in a 103% increase in caspase 3 activation compared to a 33% increase after crosslinking. At 8 h of treatment, crosslinking MHC class II resulted in a negligible increase in caspase 3 activation compared with control, while ligation with the antibody cocktail increased caspase 3 activation by 33% over control (untreated) samples (Figure 2).

The expression of the anti-apoptotic BCL-2 molecule was measured simultaneously with caspase 3 activation. As crosslinking of MHC class II resulted in reduced activation of the pro-apoptotic caspase 3 compared to MHC class II ligation, MHC class II crosslinking but not ligation produced an increase in the expression of BCL-2. MHC class II crosslinked samples showed a 169% increase over control in BCL-2 expression at 4 h treatment. After 8 h treatment, the MHC class II crosslinked samples contained over 30 ng/L of BCL-2 while the untreated and MHC class II ligated samples had no detectable BCL-2 (Figure 3).

Figure 2 The effects of ligating vs crosslinking N87 cell surface MHC class II molecules on caspase 3 activation. Using the apoptosis cytometric bead array kit, beads exposed to the samples were run through a flow cytometer to obtain MFI data. These results were normalized to activated caspase 3 standards to give values expressed as pg/mL of activated caspase 3.

Confocal microscopy analysis of FADD recruitment

Fas aggregation induces the recruitment of the adapter protein Fas-associated death domain (FADD) to the cytoplasmic tail of Fas. To determine whether MHC class II crosslinking affects FADD recruitment, we did confocal microscopy in gastric epithelial cells treated with anti-Fas with and without pretreatment with anti-MHC class II. N87 cells were treated with 100 kU/L IFN γ for 48 h to increase the surface expression of MHC class II and Fas. Cells were then seeded onto filter inserts with media alone for 24 h before treatment. Prior to permeabilization, fixation, and staining, samples were A: left untreated (control), B: treated for 1 h with the anti-Fas IgM clone IPO-4 or C: pretreated with the anti-MHC class II IgM clone RFD1 for 30 min prior to adding IPO-4. After washing, the cells were then permeabilized and fixed to allow staining of intracellular FADD. The filter inserts were then mounted onto slides and immediately visualized with a confocal microscope. The large square panel represents an X-Y axis “top-down” perspective on the adherent N87 cells. The top and side rectangular panels in each figure represent X-Z axis reconstructions, which provide an elevation view of the apical and basolateral sides of the cell section (Figure 4).

DISCUSSION

Apoptosis accounts for most of the cell loss in the gastrointestinal tract^[9]. Because cellular turnover rate in the gut epithelium is so high, disturbances in the homeostasis of cell proliferation and cell death can potentially lead to disease states. If apoptosis were induced at a higher rate than new cell generation, tissue atrophy and ulceration might occur. Conversely, downregulation or blocking of apoptotic pathways might result in neoplasia. Furthermore, it is possible that hyperplasia is a response to pro-apoptotic stimuli or that increased apoptosis results from an induced hyperproliferative stimulus^[10]. These potential scenarios, and the molecular dynamics responsible

Figure 4 A: Viewing the X-Z panels, the FADD (stained red, with higher densities staining yellow) in untreated (control) cells distributed equally throughout the cytoplasm. "L" represents the apical (luminal) surface and "BL" represents the basolateral surface of the N87 monolayer; B: Labeled FADD in cells treated with the Fas trimerizing antibody is recruited to the apical surface, leaving much of the cytoplasm with reduced FADD staining; C: When the anti-MHC class II IgM RFD1 is applied to the cell monolayer 30 min prior to treatment with the Fas agonist IPO4 IgM, the recruitment of FADD to the cell surface is markedly reduced.

for them, become particularly important when considering the divergent clinical manifestations of *H. pylori* infection. Two clinical observations support the concept of mutually exclusive disease states resulting from a disturbance in the delicate balance between apoptosis and proliferation of the mucosal epithelium. The first stems from multiple studies that demonstrated patients exhibiting duodenal ulcers have a lower risk of developing gastric cancer^[11,12]. The second suggests an inverse association between *H. pylori* infection and esophageal adenocarcinoma^[13,14]. Although these correlations continue to be scrutinized, clearly, any factor affecting the apoptotic levels within or causing the formation of ulcerative or neoplastic epithelial tissue is critical in influencing the ultimate disease state. Therefore, the divergent and somewhat mutually exclusive nature of *H. pylori* disease pathology provides a strong incentive to elucidate the epithelial receptors for *H. pylori* during infection, and to investigate results of receptor ligation and crosslinking on host cell apoptosis.

The apoptosis-inducing effect of *H. pylori* on gastric epithelial cells has been thoroughly demonstrated^[4-7,10,15-18]. Furthermore, our group's findings demonstrated that MHC class II not only binds *H. pylori*, but also can initiate signals affecting apoptotic pathways. It suggests an important role for this molecule in influencing *H. pylori* pathogenesis. The literature offers conflicting reports on the apoptotic *vs* anti-apoptotic effects of MHC class II binding. More specifically, there are opposing reports on the effect of MHC class II ligation on the Fas death pathway in mouse and human B cells^[19,20]. Previous studies from our group have revealed that signals induced by the long term (72 h) crosslinking of MHC class II are pro-apoptotic^[4,5]. However, the results we have reported here indicate that crosslinking of MHC class II can induce anti-apoptotic effects at time points less than 24 h. Furthermore, we have demonstrated the ability of MHC class II crosslinking to inhibit a key component of the Fas death pathway. Our findings that MHC class II crosslinking inhibits *H. pylori*-induced caspase activation, that ligation *vs* crosslinking of MHC class II has differential effects on apoptotic-associated molecules, and that MHC class II crosslinking

inhibits FADD recruitment are intriguing because of their potential role in the divergent pathophysiologic host response to this human pathogen. By acting as a bacterial receptor, as well as modulating the important apoptotic processes during infection, MHC class II becomes a critically important molecule in the context of *H. pylori* pathogenesis. Nonetheless, it is important to continue to study all GEC surface molecules that have the potential to influence the signal events initiated by *H. pylori* binding. There is significant evidence that other surface molecules in addition to MHC class II are capable of binding *H. pylori*; there have been numerous studies demonstrating the role of Lewis b (Le^b) blood group antigen in *H. pylori* adherence to the epithelium^[22,23]. More recently, it has been suggested that the dimeric form of the trefoil protein TFF1 avidly binds *H. pylori*^[24]. The implications of each of these findings in the physical interaction between bacterium and host is important because of the need to understand the molecules responsible for bacterial adhesion. They are also important because of the possibility that a particular bacterial receptor influences the downstream signal transduction events initiated when *H. pylori* binds to a secondary receptor, or activates a death receptor.

Deciphering the complexity of *H. pylori* pathogenesis in order to reduce its contribution to human gastric disease will require continued investigation into the interactions between bacterial receptors and their effects on the host epithelial cell homeostasis.

Abstract

AIM: To study the effects of hepatic ischemia/reperfusion (I/R) injury on store-operated calcium channel (SOC) currents (I_{soc}) in freshly isolated rat Kupffer cells, and the effects of Ca^{2+} channel blockers, 2-aminoethoxydiphenyl borate (2-APB), SK&F96365, econazole and miconazole, on I_{soc} in isolated rat Kupffer cells after hepatic I/R injury.

METHODS: The model of rat hepatic I/R injury was established. Whole-cell patch-clamp techniques were performed to investigate the effects of 2-APB, SK&F96365, econazole and miconazole on I_{soc} in isolated rat Kupffer cells after hepatic I/R injury.

RESULTS: I/R injury significantly increased I_{soc} from $-80.4 \pm 25.2 \text{ pA}$ to $-159.5 \pm 34.5 \text{ pA}$ ($^bP < 0.01$, $n = 30$). 2-APB (20, 40, 60, 80, 100 $\mu\text{mol/L}$), SK&F96365 (5, 10, 20, 40, 50 $\mu\text{mol/L}$), econazole (0.1, 0.3, 1, 3, 10 $\mu\text{mol/L}$) and miconazole (0.1, 0.3, 1, 3, 10 $\mu\text{mol/L}$) inhibited I_{soc} in a concentration-dependent manner with IC_{50} of 37.41 $\mu\text{mol/L}$ ($n = 8$), 5.89 $\mu\text{mol/L}$ ($n = 11$), 0.21 $\mu\text{mol/L}$ ($n = 13$), and 0.28 $\mu\text{mol/L}$ ($n = 10$). The peak value of I_{soc} in the I-V relationship was decreased by the blockers in different concentrations, but the reverse potential of I_{soc} was not transformed.

CONCLUSION: SOC is the main channel for the influx of Ca^{2+} during hepatic I/R injuries. Calcium channel blockers, 2-APB, SK&F96365, econazole and miconazole,

INTRODUCTION

In clinical practice of hepatobiliary surgery, various factors, such as shock, inflammation, hepatic trauma, operation of liver and biliary tract (in case of necessities of interrupting hepatic portal vein), liver transplantation, are mutually related to common pathophysiological procedures, named hepatic ischemia/reperfusion (I/R) injury. Kupffer cells play an important role in hepatic I/R injury, hepatic I/R injury can be relieved when Kupffer cells are inactivated, and store-operated Ca^{2+} channels (SOC) are present both in almost all non-excitabile cells and in some excitabile cells^[1-4], but there is no report about SOC in Kupffer cells. 2-APB, SK&F96365, econazole and miconazole have been used as the blockers of SOC in many cells. In the present study, we investigated the effects of hepatic I/R injury on store-operated calcium channel currents (I_{soc}) in freshly isolated rat Kupffer cells, and the effects of calcium channel blockers, 2-APB, SK&F96365, econazole and miconazole on I_{soc} in isolated rat Kupffer cells after hepatic I/R injury.

MATERIALS AND METHODS

Materials

Male Sprague Dawley rats (Shanghai Institutes for Biological Sciences, Chinese Academy of Sciences), weighing 200-300 g, were used in all experiments.

Thapsigargin was obtained from Alexis Company. 2-aminoethoxydiphenyl borate (2-APB), SK&F96365 were obtained from Merck KcaA (Darmstadt, Germany). Collagenase IV, HEPES, EGTA, trypan blue, econazole, miconazole, CsCl, CsOH and the other chemicals were from Sigma (USA). The pipette solution contained 120.0 mmol/L CsCl, 1.0 mmol/L MgCl₂, 10.0 mmol/L EGTA, 10.0 mmol/L HEPES, 2 μmol/L thapsigargin, pH 7.3 (adjusted with CsOH). The bath solution contained 145 mmol/L NaCl, 2.8 mmol/L KCl, 10.0 mmol/L CaCl₂, 1.0 mmol/L CsCl, 2.0 mmol/L MgCl₂, 10.0 mmol/L glucose, 10.0 mmol/L HEPES, pH 7.3 (adjusted with NaOH). Ca²⁺-Mg²⁺-free Krebs-ringer-HEPES buffer solution contained 5 mmol/L KCl, 1 mmol/L KH₂PO₄, 115 mmol/L NaCl, 25 mmol/L HEPES, 0.5 mmol/L EGTA, pH 7.3 (adjusted with NaOH).

Hepatic I/R injury model

The model of rat partial hepatic I/R injury was established according to the procedures reported by Colletti *et al.*^[5] with minor modifications. Briefly, adult animals were anesthetized with pentobarbital sodium (50 mg/kg) and heparinized (1 U/g) via an intraperitoneal injection. A midline laparotomy was performed, then an atraumatic clip was used to interrupt the arterial and portal venous blood supply to the cephalad three lobes of liver. After 20 min for hepatic ischemia, the clip was removed followed by 40 min for hepatic reperfusion. Sham-operated control animals were treated in an identical fashion with the omission of vascular occlusion.

Cell preparation

Rat kupffer cells were enzymatically isolated from SD rats. Briefly, after the model was achieved, the portal vein and inferior vena cava were cannulated. The liver was initially perfused at a flow rate of 20-30 mL/min with a constant-flow system with modified oxygenated Ca²⁺-Mg²⁺-free Krebs-ringer-HEPES buffer solution (37°C) for about 5 min, followed by Krebs-ringer-HEPES buffer solution (37°C) containing collagenase IV for 10 min. After the perfusions, cephalad three lobes of the liver were excised and minced in Ca²⁺-Mg²⁺-free Krebs-ringer-HEPES solution (37°C) for 20 min. The cells were filtered through a 200 μm nylon mesh, and washed by centrifugation at 700 g for 7 min. Then we reserved sediment and poured about 20-30 mL PBS into the sediment, washed it by centrifugation at 50 g for 4 min, reserved supernatant and washed it by centrifugation at 700 g for 5 min, plated the sediment on glass cover-slips and incubated it at 37°C in DMEM for 1-2 h. Then the cells were washed 3-5 times with the bath solution. The cells attached to the bottom of glass cover-slips were kupffer cells. The spherical, smooth cells were used for the whole-cell patch-clamp studies. All experiments were performed at room temperature (20-24°C).

Electrophysiological recordings

An automatic micropipette puller (Model P-97, Sutter Instruments, Novato, CA) was used to pull the electrodes. The resistance of the capillary glass electrodes (GG217,

Figure 1 Whole-cell currents measured at the test potential from -120 mV to +80 mV in sham-operated control (A) and in rats with ischemia/reperfusion injuries (B).

World Precision, USA) used was 4-8 MΩ when filled with internal solution. An Axopatch 200B amplifier (Axon Instruments, USA) was used to record whole-cell currents with the filter set at 3 kHz, digitized at 5 kHz. The protocol of a series of depolarizing pulses from a holding potential of 0 mV to different membrane potentials (-120 mV to +80 mV) with a 20 mV increment was used for voltage clamp. Data analysis was performed using software (pCLAMP9.0, Axon Instruments, USA). The data were stored in computer for subsequent analysis. The blockers were added to the place around the cells with a rapid solution changer to investigate their effects on Isoc.

Statistical analysis

All values were expressed as mean ± SD. Appropriate *t*-test was used for the statistical analysis. ^a*P* < 0.05 and ^b*P* < 0.01 were considered statistically significant and apparently significant respectively.

RESULTS

Viability of isolated rat Kupffer cells

The isolated Kupffer cells showed polymorphism with typical polygon-like and star-like shapes. The purity and adhesion rate were 85% and 39.4%, respectively. The viability was over 80%. The isolated rat Kupffer cells were suitable for whole-cell patch clamp technique.

Isoc in isolated rat Kupffer cells

After the whole-cell configuration was established, cell membrane potential was clamped at 0 mV, and different test potentials from -120 to +80 mV with a 20 mV increment at a frequency of 0.2 Hz were applied. Following break-in, the currents in ischemia/reperfusion group (-159.5 ± 34.5 pA, *n* = 30) were greater than those in sham-operated control group (-80.4 ± 25.2 pA, *n* = 30) at the test potential of -100 mV (^b*P* < 0.01, Figure 1).

But the I-V curve relation and reversal potential were not transformed (Figure 2).

Effects of 2-APB on Isoc

In order to observe the effects of 2-APB on Isoc, 2-APB with different concentrations (20, 40, 60, 80, 100 $\mu\text{mol/L}$) was respectively added to periphery of Kupffer cells after the whole cell configuration was established. According to the whole-cell currents at the test potential of -100mV (Table 1), Isoc was blocked by 2-APB in a concentration-dependent fashion with the IC₅₀ of 37.41 $\mu\text{mol/L}$. But the I-V curve relation and reversal potential were not transformed (Figure 3A).

Effects of SK&F96365 on Isoc

In order to observe the effects of SK&F96365 on Isoc, SK&F96365 with different concentrations (5, 10, 20, 40, 50 $\mu\text{mol/L}$) was respectively added to periphery of Kupffer cells after the whole-cell configuration was established. According to the whole-cell currents at the test potential of -100mV (Table 2), Isoc was blocked by SK&F96365 in a concentration-dependent fashion with the IC₅₀ of 5.89 $\mu\text{mol/L}$. But the I-V curve relation and reversal potential were not transformed (Figure 3B).

Effects of econazole on Isoc

In order to observe the effects of econazole on Isoc, econazole with different concentrations (0.1, 0.3, 1, 3, 10 $\mu\text{mol/L}$) was respectively added to periphery of Kupffer cells after the whole-cell configuration was established. According to the whole-cell currents at the test potential of -100 mV (Table 3), Isoc was blocked by econazole in a concentration-dependent fashion with the IC₅₀ of 0.21 $\mu\text{mol/L}$. But the I-V curve relation and reversal potential were not transformed (Figure 3C).

Table 3 Effects of econazole on Isoc at the test potential of -100 mV (mean \pm SD, $n = 13$)

Group ($\mu\text{mol/L}$)	Peak current (pA)	t	Inhibitive rate (%)
Control	-147.2 \pm 35.7

^b $P < 0.01$ vs control.**Figure 2** I-V curve of whole-cell currents measured at -100 mV test potential. ^b $P < 0.01$ vs sham-operated control (●) (▲/I/R).

Effects of miconazole on Isoc

In order to observe the effects of miconazole on Isoc, miconazole with different concentrations (0.1, 0.3, 1, 3, 10 $\mu\text{mol/L}$) was respectively added to periphery of Kupffer cells after the whole-cell configuration was established. According to the whole-cell currents at the test potential of -100 mV (Table 4), Isoc was blocked by miconazole in a concentration-dependent fashion with the IC₅₀ of 0.28 $\mu\text{mol/L}$. But the I-V curve relation and reversal potential were not transformed (Figure 3D).

DISCUSSION

In this study, a rat hepatic I/R injury model was established. Kupffer cells were isolated and Isoc in Kupffer cells were detected.

Isoc can be activated by two ways, one is active way

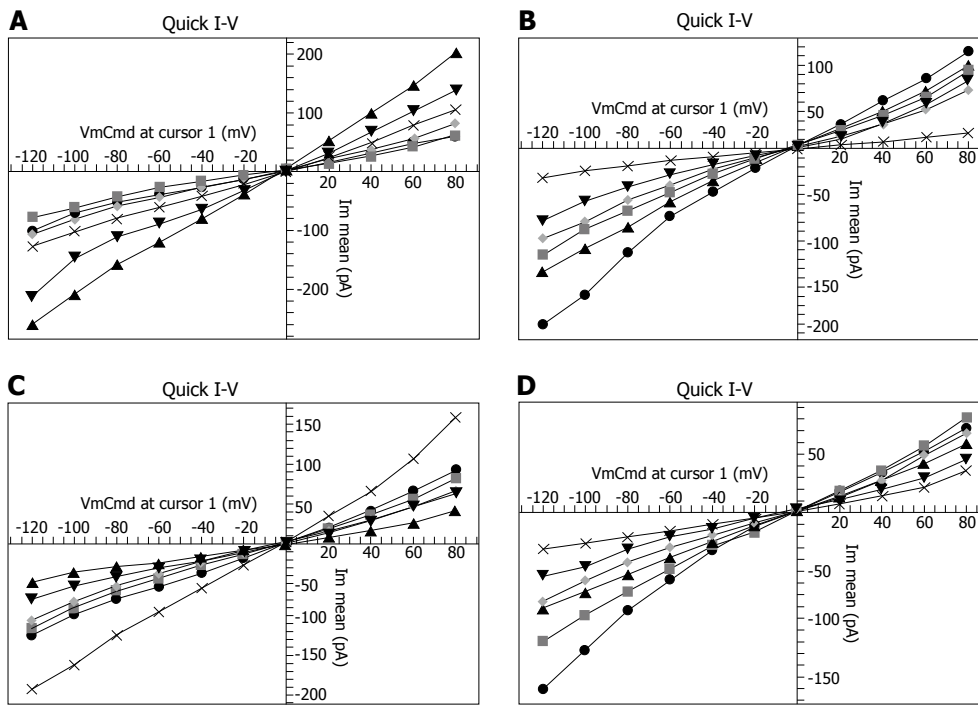

Figure 3 I-V curve of whole-cell currents at -100 mV test potential affected by 2-APB (A) (\blacktriangle /I/R, ∇ 20 $\mu\text{mol/L}$, \times 40 $\mu\text{mol/L}$, \bullet 60 $\mu\text{mol/L}$, \circ 80 $\mu\text{mol/L}$, \blacksquare 100 $\mu\text{mol/L}$), SK&F96365 (B) (\bullet /I/R, \blacktriangle 5 $\mu\text{mol/L}$, \times 10 $\mu\text{mol/L}$, ∇ 20 $\mu\text{mol/L}$, \blacktriangledown 40 $\mu\text{mol/L}$, \times 50 $\mu\text{mol/L}$), econazole (C) and (\times I/R, \bullet 0.1 $\mu\text{mol/L}$, \blacksquare 0.3 $\mu\text{mol/L}$, \blacklozenge 1 $\mu\text{mol/L}$, \blacktriangledown 3 $\mu\text{mol/L}$, \blacktriangle 10 $\mu\text{mol/L}$), miconazole (D) in a concentration-dependent inhibiting fashion (\bullet /I/R, \blacksquare 0.1 $\mu\text{mol/L}$, \blacktriangle 0.3 $\mu\text{mol/L}$, \blacklozenge 1 $\mu\text{mol/L}$, \blacktriangledown 3 $\mu\text{mol/L}$, \times 10 $\mu\text{mol/L}$).

induced by IP_3 ^[6-8], and the other way is EGTA induced by thapsigargin^[9]. The latter was chosen in our study.

Hepatic I/R injury can cause calcium overload in liver cells^[10-12]. Kupffer cells are considered to play a major role in hepatic I/R injury. The hepatic partial I/R process leads to activation of kupffer cells in ischemic and nonischemic areas of the liver, superoxide generation and proinflammatory cytokine production in Kupffer cells^[13]. An excess of reactive oxygen species (ROS) is generated by Kupffer cells activated during hepatic I/R injuries. All these events cause pathophysiological changes initiating a cascade of hepatocellular injury, necrosis, apoptosis, and subsequent inflammation^[14-16]. Inhibiting activation of Kupffer cells can relieve hepatic I/R injuries. Calcium overload is one of the important reasons for activation of Kupffer cells. In our study, I/R injuries could significantly increase Isoc of the Kupffer cells, suggesting that SOC has a close relation with hepatic I/R injuries and is the main channel for the influx of Ca^{2+} during calcium overload. Broad *et al.*^[17] showed that phospholipase C and polyphosphoinositides can activate capacitative calcium entry (CCE). Recent findings indicate that receptor-mediated activation of phospholipase C in intact cells activates TRPC3 diacylglycerol production, independently of G proteins, protein kinase C, or inositol 1, 4, 5-trisphosphate^[18]. The last source of ion channel is the transient receptor potential (TPR) channel family, which forms non-selective cations^[19] all these indicate that hepatic I/R injuries activate phospholipase C which induces activation of store-operated calcium channels or TRPC3 channels, finally leading to calcium overload of Kupffer cells which could exacerbate hepatic I/R injuries.

Sequentially, Isoc of Kupffer cells after hepatic I/R injuries could be blocked by 2-APB, SK&F96365, econazole and miconazole in a concentration-dependent fashion.

2-APB has the restraint effect on Isoc in many kinds of cells^[20,21] and is a blocker of SOC and TRP channels^[22-24]. Our data have shown that Isoc of Kupffer cells after hepatic I/R injuries is blocked by 2-APB in a concentration-dependent fashion from 20 $\mu\text{mol/L}$ to 100 $\mu\text{mol/L}$. 2-APB inhibits SOC by IP_3 way^[25,26]. Recent studies indicate that 2-APB may act as a direct blocker rather than as an IP_3 receptor antagonist while Icrac activity is rapidly blocked by extracellular 2-APB, but not by intracellular 2-APB^[27-30]. Furthermore, Broad *et al.*^[17] showed 2-APB abolishes CCE induced by thapsigargin even in DT40 cells deficient for all isoforms of IP_3 receptor, consistent with a direct action of 2-APB on the SOC themselves. Our data also suggest that 2-APB may act as a direct blocker for SOC. Therefore, 2-APB protects Kupffer cells against being activated after hepatic I/R injuries by blocking Isoc.

SK&F96365 could block Isoc in many cells such as HL-60 cells, thyroid gland FRTL-5 cells, thrombocytes as well as voltage-dependent Ca^{2+} channels (VDCCs) in GH3 pituitary cells and smooth muscle cells^[31], suggesting that SK&F96365 can be used as a blocker of SOC in non-excited cells without VDCCs. VDCCs have been proved to be Kupffer cells, but Ca^{2+} current induced by EGTA and thapsigargin could not be blocked by verapamil (a kind of blocker of VDCCs). In our study, Isoc of Kupffer cells after hepatic I/R injuries was blocked by SK&F96365 in a concentration-dependent fashion. The mechanism is not completely clear. Since SK&F96365 could block two different channels, SOC and VDCCs, it may act on the SOC directly.

Econazole and miconazole decrease intracellular calcium levels after activation of SOC channels^[32] and block Isoc in Jurkat T-cells, HL-60 leukocytes, HEL cells, *etc.* Our data demonstrate that Isoc of Kupffer cells after hepatic I/R injuries is blocked by econazole and miconazole in a

concentration-dependent fashion.

In conclusion, hepatic I/R injuries can activate Kupffer cells, probably by increasing Isoc in Kupffer cells and activated Kupffer cells exacerbate hepatic I/R injuries. 2-APB, SK&F96365, econazole and miconazole can inhibit Isoc of Kupffer cells after hepatic I/R injuries in a concentration-dependent fashion. They have obvious protective effects on I/R injury, probably by inhibiting Isoc of Kupffer cells and preventing activation of Kupffer cells.

Abstract

AIM: This study evaluated colorectal mucosal histamine release in response to blinded food challenge-positive and -negative food antigens as a new diagnostic procedure.

METHODS: 19 patients suffering from gastrointestinally mediated allergy confirmed by blinded oral provocation were investigated on grounds of their case history, skin prick tests, serum IgE detection and colorectal mucosal histamine release by *ex vivo* mucosa oxygenation. Intact tissue particles were incubated/stimulated in an oxygenated culture with different food antigens for 30 min. Specimens challenged with anti-human immunoglobulin E and without any stimulus served as positive and negative controls, respectively. Mucosal histamine release (% of total biopsy histamine content) was considered successful (positive), when the rate of histamine release from biopsies in response to antigens reached more than twice that of the spontaneous release. Histamine measurement was performed by radioimmunoassay.

RESULTS: The median (range) of spontaneous histamine release from colorectal mucosa was found to be 3.2 (0.1%-25.8%) of the total biopsy histamine content. Food antigens tolerated by oral provocation did not elicit mast cell degranulation 3.4 (0.4%-20.7%, $P = 0.4$), while anti-IgE and causative food allergens induced a significant histamine release of 5.4 (1.1%-25.6%, $P = 0.04$) and 8.1 (1.5%-57.9%, $P = 0.008$), respectively. 12 of 19 patients (63.1%) showed positive colorectal mucosal histamine release in accordance with the blinded oral challenge responding to the same antigen (s),

while the specificity of the functional histamine release to accurately recognise tolerated foodstuffs was found to be 78.6%. In comparison with the outcome of blinded food challenge tests, sensitivity and specificity of history (30.8% and 57.1%), skin tests (47.4% and 78.6%) or antigen-specific serum IgE determinations (57.9% and 50%) were found to be of lower diagnostic accuracy in gastrointestinally mediated allergy.

CONCLUSION: Functional testing of the reactivity of colorectal mucosa upon antigenic stimulation in patients with gastrointestinally mediated allergy is of higher diagnostic efficacy.

INTRODUCTION

Gastrointestinal complaints after the ingestion of certain foodstuffs often pose diagnostic problems in various clinical situations such as food hypersensitivity, enzyme deficiencies, irritable bowel syndrome, inflammatory bowel disease, dyspepsia, eosinophilic gastroenteritis and several others. However, identification of immunologically mediated food hypersensitivity at the gastrointestinal level remains problematic, since skin tests and allergen specific serum IgE detection (e.g. RAST) may fail to show clear signs of food-specific sensitisation^[1-5] and do not necessarily indicate symptomatic food allergy. This is also valid for functional tests using blood cells (basophil histamine, or leucotriene release), lymphocyte transformation tests or measurement of mediators in blood or serum^[6-8]. Oral provocation, referred to as the 'gold standard' for food allergy diagnosis, is both time consuming and cost intensive, may put the patient at a

more or less severe risk, allows only one food to be tested per day, is often difficult to evaluate and is without doubt an unpopular and irritating procedure for the patient^[1,5,8].

Consequently, different methodical approaches have emerged for the improvement and acceleration of the cumbersome diagnostic way to identify patients with food allergy primarily involving the gastrointestinal tract. Already in 1942, 1984 and 1997, direct endoscopic observation has repeatedly been claimed to be of diagnostic value for recognition of food allergy when antigenic solutions were applied to the intestinal mucosa^[9-11]. However, direct endoscopic evaluation of allergen application and endoscopic or fluoroscopic balloon perfusion techniques harbour similar disadvantages to those experienced in oral provocation tests. All of these tests require special conditions with strict medical supervision because of the risk of allergic reactions *in vivo* during endoscopy or allergen perfusion^[10-12]. Only a few allergens can be tested during one examination and, in case of an endoscopic allergen injection, the endoscopic procedure is prolonged by at least 20 min, providing a higher risk of procedure-related complications, bacterial translocation and discomfort to the patient^[10-14]. Finally, the outcome of these endoscopic methods and the results obtained from double-blind, placebo-controlled food challenge procedures have never been directly compared on a scientific basis. Nevertheless, this is absolutely necessary for an appropriate evaluation in routine practice with respect to their diagnostic effectiveness^[1,5,8].

Another possibility to identify food allergy at the gastrointestinal tract was described in 1989. Baenkler *et al* used endoscopically taken samples from the duodenum to show antigen-induced histamine release *ex vivo*^[15,16]. Since many patients with suspected gastrointestinally mediated allergy (GMA) have to undergo endoscopic procedures for differential diagnostic reasons, this approach has the advantage that the principle demonstration of a food-induced mediator release can be performed outside of the patient, thus avoiding the risk of allergic reactions *in vivo*. In addition, several food antigens can be tested simultaneously without further burden to the patient^[15-17]. However, performance of functional histamine release experiments requires certain laboratory equipment and, initially, should be compared with the 'gold standard' for food allergy diagnostics before introducing this approach into clinical practice.

Similar to Baenkler's approach using duodenal mucosa, functional histamine release should also be expected from mucosa of other regions of the intestine^[15-17], provided that these tissue samples contain large enough numbers of (mucosal) mast cells. However, *ex vivo* histamine release from viable tissue samples of the lower gastrointestinal tract in response to nutritive antigens has not yet been studied together with the standardised *in vivo* oral challenge tests in order to provide a direct comparison of the two diagnostic methods. For this reason, this study investigated the rate of histamine release from colorectal mucosal samples in a group of patients with proven food allergy and compared the results of *ex vivo* mucosa oxygenation with the outcome of standardised blinded oral provocation tests.

MATERIALS AND METHODS

Patients

A total of 19 patients (7 male, 12 female; median age 38.0, range 19-51 years) were included in this study (Tables 1 and 2). All patients gave their informed consent and the study protocol was approved by the local ethics committee (No. 331). All patients (100%) reported abdominal symptoms, nausea, pain, vomiting and/or diarrhoea (98%) after certain meals, while postprandial extraintestinal signs of allergy such as skin reactions, asthma bronchiale and allergic rhinoconjunctivitis occurred only in a small percentage of patients (32%). Every patient was assessed on grounds of their history and detailed skin prick tests of environmental allergens (moulds, fibres, bacteria, pollen, dust) and food allergens (fish, fruit, vegetables, grains and different types of wholemeal, flour, bran, tea, coffee, eggs, milk, and cheese). Serum IgE detection of the putative allergens was performed according to the patients' history or skin tests (Tables 1 and 2). In the case of uncertainties about non-tolerated foods, tests were conducted for basic foodstuff. Case history, skin test reactions and RAST results were then compared with the outcome of oral

Table 2 Clinical symptoms induced by blinded, placebo-controlled food challenge, atopy status and predominant type of allergy according to Coombs and Gell

Pat. No.	Main symptoms	Atopy status	Type of allergy
1	Diarrhoea, flush, pruritus	-	Type I (systemic IgE)
2	Abdominal pain, loose stools, bloating	+	Type I (systemic IgE)
3	Vomiting, diarrhoea	+	Type I (systemic IgE)
4	Abdominal pain, urticaria	-	Type I (local IgE)
5	Diarrhoea, abdominal pain, dyspepsia, vomiting	+	Type I (systemic IgE)
6	Diarrhoea	-	Type I (systemic IgE)
7	Vomiting, loose stools, right lower quadrant pain	+	Type I (systemic IgE)
8	Profuse watery diarrhoea	-	Type I (systemic IgE)
9	Diarrhoea, bloating, tachycardia	+	Type III (immune complexes present) or IV (?)
10	Pruritus, Rhinitis, tachycardia, bloating, diarrhoea	-	Type I (systemic IgE)
11	Colitis, diarrhoea, arthragia, rhinitis	-	Type I (systemic IgE)
12	Bloody diarrhoea, hypotension, abdominal pain, bloating	-	Type I (local IgE) and /or type III (immune complexes present)
13	Fever, diarrhoea, hypotension	+	Type I (systemic IgE)
14	Diarrhoea, vomiting, abdominal pain	-	Type IV (cellular hypersensitivity ?)
15	Bloating, diarrhoea, eosinophilia	+	Type I (systemic IgE)
16	Atopic eczema, diarrhoea, colitis, abdominal pain	+	Type I (local IgE) and /or type IV (cellular hypersensitivity ?)
17	Rhinitis, vomiting, diarrhoea	+	Type I (local IgE)
18	Diarrhoea, bloating	+	Type I (local IgE)
19	Eosinophilia, bloating, diarrhoea	+	Type I (systemic IgE)

Atopy status was defined as positive, when history or clinical manifestation of the patient gave evidence for milk crust, atopic eczema, asthma bronchiale and/or allergic rhino-conjunctivitis. For definition of the allergy type, the most dominant immunological signs were chosen to classify the ongoing allergic mechanisms in this population of patients with manifest gastrointestinally mediated allergy. However, some patients displayed symptoms that suggested more than one definitive type of allergy (see for example patient No. 9, 12, 16): Type I allergy (systemic IgE) was recognised when positive skin or antigen specific IgE levels were present in serum, type I allergy (local IgE) was diagnosed when intestinal lavage fluid contained elevated levels of IgE^[20]. Type III allergy was found in patients no. 9 and 12 who showed formation of either IgA, IgM and/or IgE immune complexes during or after allergen application by blinded food challenge. Additionally, type IV allergy was suspected in patients with heightened serum TNF levels during food challenge, and additionally in patient no. 14 who had a positive antigen-specific lymphocyte proliferation test.

challenge tests.

Food allergy was confirmed in each patient by blinded, placebo-controlled food challenge tests (BPCFC) adding the putative allergen to a basic diet containing rice, potato, oligopeptides (Survimed OPD, Fresenius, Germany) and tea. For provocation of flours (wheat, rye, soya, barley), commercially available allergen solutions for skin tests were used (Maser, Bochum, Germany). These were applied orally, while all other allergens were freshly prepared and given to the patients via a nasogastric tube^[5,18].

BPCFC was performed in a standardised fashion, while patients were hospitalised. Food antigen was administered in three different doses. Initially, a 1/20 dilution of the native allergen solution was administered, followed by 1/10 of the dose 3 h later and finally, a dose of 5 mL of the full strength native allergen solution was

provided^[18,19]. One single food antigen was tested per day. Placebo consisted of an oligopeptide-diet (protein source: hydrolysed soybean, Survimed OPD, Germany), which was also used for base-line nutrition (minimum: 1800 kcal/d), in conjunction with a rice-potato diet in order to prevent a catabolic state^[18,19]. A single blind challenge was performed in 42% (patients unaware of provocation protocol), while a double-blind challenge was carried out in 58% (patients and physicians unaware of the provocation protocol)^[18,19]. Blinding of the food antigens was managed by nutritionists, who were responsible for the preparation and addition of the allergens to usually tolerated foodstuff or to the oligopeptide solution, respectively.

Physicians selected the type of food to be tested either on the basis of the patients' history, previous results of skin prick tests and RAST tests or from a list of basic foodstuff. During the provocation procedure, the patients were provided with a peripheral venous line, and all medical staff involved was trained for medical intervention in case of an anaphylactic reaction. For the definition of food allergic reactions, a modified scoring system for symptoms was applied^[18] and main symptoms of patients evoked by the food challenge are listed in Table 2.

Food hypersensitivity was diagnosed only when food-specific immune events were detected through positive skin tests (mean wheal diameter of 3mm or greater than negative control^[1,9,18,19]), serum RAST-IgE (\geq class II^[8,19]) or through proof of intestinal IgE by endoscopically guided segmental lavage^[18,19] in conjunction with a reproducible clinical adverse reaction to the food antigen(s) applied^[1,5,8,18,19]. During BPCFC, at least one reproduction of an allergen induced clinical reaction and one or two placebo challenges were included for every patient. Whenever possible, both antigens causing clinical symptoms as well as tolerated antigens were applied to the patient, or else investigated on grounds of case history, skin tests, RAST and mucosal histamine release. In this way, a provocation allergen and a control allergen (Table 1) was determined for most patients (14 of 19 patients 74%), which enabled the direct comparison of the mucosal histamine release results with those of the BPCFC.

Before the execution of food challenge tests, additional examinations including endoscopy and histology of the upper and lower gastrointestinal tract were conducted^[5,18-20]. Patients with macroscopic alterations of the mucosa or with histological signs of acute inflammation (Crohn's Disease, ulcerative colitis *etc*) were excluded from the study as well as those suffering from other digestive diseases (e.g. celiac disease, autoimmuneopathy, mastocytosis, eosinophilic gastroenteritis *etc*).

At least two weeks in advance of colonoscopy and BPCFC, any antiallergenic, immunosuppressive or steroid treatments had been discontinued for all patients. Patients were prepared for colonoscopy using a commercial polyethyleneglycol solution. To facilitate colonoscopy, benzodiazepins (midazolam, diazepam) and meperidine were used at a dose of 2.5-10 mg (midazolam, diazepam) and 25-150 mg (meperidine), respectively^[20,21].

Colorectal mucosal histamine release

For colorectal mucosal histamine release by mucosa

oxygenation, 138 samples from the left-sided colon were obtained from all 19 patients. In 14 of 19 patients (74%), 10-12 mucosal samples were taken during colonoscopic examination. Whenever possible, 8 biopsies (4 repeats) were used for mucosa oxygenation and 2-4 for histological examination. The biopsies were immediately placed into a portable mucosa oxygenator (Intestino-Diagnostics, Erlangen, Germany) containing tubes filled with 2000 μ L of oxygenated Hank's solution (pO₂ 85-95 mmHg, pH 7.0, 37°C)^[16,17,20]. Each incubation medium was bubbled with a steady flow of room air to ensure sufficient oxygen pressure inside the biopsy, to facilitate allergen distribution into the tissue or mediator release from the tissue and to avoid ischemic damage of the tissue^[16,17,20,21].

Histamine release into the culture medium was measured at 0, 7.5, 15, and 30 min by removal of 200 μ L of the supernatant at each sampling time^[17,20,21]. To obtain as accurate histamine measurements as possible, each 200 μ L sample was immediately denatured by heating to 95°C for 5 min in order to destroy all histamine metabolising enzymes that may have been contained within the drawn supernatant^[16,17,20,21].

Allergen induced histamine release was achieved by addition of 200 μ L Hank's solution containing 5 μ L of native allergen solution to the culture medium at the sampling time of 0 min, thus providing a final concentration of 0.01 μ g allergen/mL. The same procedure was applied for positive control using anti-human immunoglobulin E except that 20 μ L of pure anti-IgE solution (Behringwerke, Marburg, Germany) were used for dilution. The final concentration of anti-human-IgE was 0.01 μ g/mL, which has previously been found to be the optimal stimulation concentration^[16,17]. For negative control (spontaneous mucosal histamine release), only 200 μ L Hank's solution were added to the culture medium. The stimulation procedure of the 8 samples of each patient was arranged as follows: two samples were studied for spontaneous mucosal histamine release (negative control), two for anti-IgE induced histamine release (positive control), two for a BPCFC-positive allergen (provocation allergen) and two for provocation negative, i.e. tolerated antigens (control allergen).

After a stimulation period of 30 min, the rest of the volume of 1400 μ L containing the biopsy (1200 μ L Hank's + 200 μ L stimulus) was also heated to 95°C for five minutes in order to determine the remaining tissue histamine content and to denature tissue histamine catabolising enzymes^[17,20,21].

Histamine measurement

Histamine was measured using a sensitive and specific radioimmunoassay (Histamine RIA, Beckman-Coulter, Krefeld, Germany)^[17,21,22]. The actual rate of histamine release was expressed as the percentage of the total tissue histamine content of the biopsy. This was calculated from the discharged histamine into the supernatant and the remaining histamine content in the tissue at the sampling time of 30 min^[17,20-22]. Intra-assay and inter-assay coefficients of variation for the histamine radioimmunoassay ($n > 150$ samples) were 6.2% and 8.8% for supernatants, and 13.7% and 18.2% for detection of

Table 3 Results from colorectal mucosal histamine release (% of total tissue histamine content) following *ex vivo* mucosa oxygenation in patients with GMA

Significance levels: ^a $P = 0.008$ vs spontaneous histamine release; ^b $P = 0.04$ vs spontaneous histamine release. HR: histamine release (average value from two measurements); no.: number; pat.: patient; anti-IgE: anti-immunoglobulin E. Control and provocation allergen are allergens, which were either tolerated or induced clinical symptoms during blinded oral food challenge procedures. Rates of histamine release are expressed as percentage (%) of total tissue histamine content. Each release value represents the average value from two repeat experiments (two separate biopsies).

the remaining tissue histamine content, respectively. The individual rates of histamine release were found to vary by up to 24.0% within the same person.

Histamine content was also measured in native allergen solutions to exclude histamine contamination.

Statistical analysis

From each patient, two rates of histamine release were obtained for each of the parameters spontaneous histamine release, anti-IgE, provocation and control allergen. The average value for each pair of release data was calculated and used for final statistics as listed in Table 3.

For descriptive statistics of the whole group, the median and range were chosen. Statistical comparisons were made using the *U*-test (Wilcoxon, Mann & Whitney) and significance levels are given in brackets. For comparison of the clinical tests, *ex vivo* biopsy stimulation by mucosa oxygenation was considered successful (positive) when the antigen containing solution caused an increase of the histamine release up to more than twice that of the spontaneous release.

RESULTS

Histamine release from colorectal tissue

Spontaneous histamine release from viable colorectal mucosal fragments amounted to only 3.2% of the total tissue histamine content, indicating that mast cells are able

Table 4 Colorectal mucosal histamine release in comparison with the outcome of oral provocation tests in patients with GMA

Positive BPCFC	4	9	13
Negative BPCFC	3	4	7
Column sum	7	13	

H: patients' history, BPCFC: (double- or single) blinded, placebo-controlled oral food challenge. Note: Only 13 of 19 patients (68%) felt confident to answer questions concerning suspected provocation antigens, while the remaining were uncertain or had no experience of adverse reactions to the particular antigen. For evaluation of the specificity of patients' history, data from only 7 patients (37%) were available. Patients' history: Sensitivity 30.8%, specificity 57.1%.

to maintain their normal metabolism and their mediators within granules during mucosa oxygenation (Table 3). Application of anti-human-IgE induced a clearly enhanced rate of histamine release of 5.4% ($P = 0.04$) within 30 min, confirming the functional reactivity of mucosal immune effector-and intestinal mucosal mast cells towards IgE-receptor cross-linking^[15-17,21,23]. Four of 17 patients (23.5%) were found to be unresponsive to the anti-IgE concentrations used. Interestingly, these patients had the highest rates of spontaneous histamine release, possibly indicating that mast cells had already been degranulated or that a high rate of spontaneous histamine secretion may exert some negative feed-back mechanisms on mast cell triggering by anti-IgE (Table 3).

Incubation of intact colorectal tissue with BPCFC-negative food antigens did not induce a significant increase in histamine release (median increase 1.2 fold; range 0.6-4.4 fold of spontaneous mediator release) in patients with GMA. Histamine release with control antigens amounted to 3.4% and was not statistically different from spontaneous histamine release (Table 3).

In contrast, provocation allergens that evoked clinically significant reactions in allergic individuals (BPCFC-positive food antigens) already induced a 2.6 fold increased rate of histamine release compared to the spontaneous release (range 0.9-24 fold) during 30 min of mucosa oxygenation. The percentage of histamine release in response to provocation allergens was 8.1% and significantly different from spontaneous histamine release ($P = 0.008$).

Colorectal mucosal histamine release in comparison with established clinical tests

Colorectal mucosal histamine release was positive in 12 of

19 patients (sensitivity 63.1%, Table 4), who experienced a reproducible clinical reaction in response to the same provocation antigen. In contrast, 3 of 14 patients (21.4% false positive) discharged significant histamine amounts although oral provocation was negative. Control antigens, tolerated by the patient during BPCFC, were also found to be negative with regard to histamine release in 11 of 14 patients (specificity 78.6%).

When comparing established clinical parameters for food allergy diagnostics with the outcome from blinded provocation tests (gold standard), a lower diagnostic accuracy was obtained through reference to patients' history (Table 5), skin test results (Table 6) and allergen-specific IgE detection in serum (Table 7) than with histamine release experiments.

The comparison between patients' history and BPCFC (Table 5) was somewhat impeded, since only 13 of 19 patients (68.4%) knew their allergen inducing clinical symptoms, 7 of 14 patients (50%) with recurrent gastrointestinal complaints tried to give exact answers on questions about their well tolerated foods, while all other individuals had significant uncertainties about adverse reactions to or tolerance of the food antigens tested.

DISCUSSION

Diagnosis and existence of gastrointestinal food allergy are still a matter of debate^[1,4,5,18]. To date, no exact diagnostic and practical relevant means are readily available for the gastroenterologist or endoscopist to examine the gastrointestinal mucosa for signs of food hypersensitivity, when patients with recurrent episodes of variable gastrointestinal complaints are referred for further diagnostics^[5,8,10]. One innovative approach for the diagnosis of food hypersensitivity by endoscopy may be the use of a mucosa oxygenation system, which allows culturing of small viable endoscopic samples outside of

the patient for immunological release experiments^[15-17,20,23]. Since histamine is one important and very early secreted mediator of different types of IgE and non-IgE mediated allergic reactions^[1,3,17,24], this study was designed to evaluate colorectal mucosal histamine release from patients with gastrointestinal food hypersensitivity. In contrast to allergic individuals with typical extraintestinal signs of type I food hypersensitivity, diagnostic problems have been repeatedly reported in this patient population primarily involving the gastrointestinal tract with symptoms of allergic diarrhoea, vomiting, nausea, *etc.* In addition, the frequency of local gastrointestinal allergy in several important clinical conditions is also still unclear^[1,4,5,8-11,25-27].

This study demonstrates that a significant histamine release can be induced from colorectal mucosa upon IgE receptor cross-linking or antigenic stimulation *ex vivo* by mucosa oxygenation using endoscopically taken samples^[15-17,23]. This confirms that functional antigen-specific tests using histamine as the primary test parameter are equally feasible with mucosa from the lower gastrointestinal tract as from the upper gastrointestinal tract (duodenum^[15]) or more long-lived mediators like mast cell tryptase or eosinophilic cationic protein^[20,23]. However, in contrast to previously published work featuring tryptase or eosinophilic cationic protein, histamine release tests using bioptic tissue bear the distinct practical advantage that they can be performed within a short period of time of only 30 min, providing the appropriate technique to rapidly destroy all histamine catabolising enzymes in the drawn culture supernatants is applied^[16,17,20,21]. The quick performance of mucosa oxygenation using histamine as a diagnostic parameter may qualify this test for its use in clinical practice, possibly as a refinement or complement of existing endoscopic-diagnostic procedures when patients with suspected gastrointestinal food allergy are being referred for diagnostic work-up.

Compared to other human tissues or isolated mast cells, histamine release from colorectal mucosa was found to be of a smaller magnitude than expected. This could be a result of the short cultivation period and of the fact that colorectal tissue harbours large quantities of histamine metabolising enzymes, which are still active within the viable cultured tissue at a physiological rate during mucosa oxygenation^[6,11,17,20,21,28]. However, compared with the spontaneous rate of histamine release, functional mast cell stimulation by anti-IgE or BPCFC-positive antigens achieved a significantly higher rate of histamine release, while control antigens showed a similar degree of histamine release as the spontaneous secretion. This study proved unambiguously the reactivity of histologically normal gut mucosa in allergic patients upon specific challenge. In view of that, gastroenterologists will find a valuable addition to their diagnostic methods through the establishment of a functional test using biopsies of the involved and reacting allergic shock organ^[15,21,23]. Depending on the number of biopsies taken during endoscopy, this functional test allows the simultaneous examination of different food antigens during mucosa oxygenation^[15-17,21]. In this way, any contact between the antigen and the patient's immune system is avoided and the patient is not put at risk of any allergic symptoms or

reactions.

Although only a small group of patients was investigated in this study, colorectal mucosal histamine release was found to yield a diagnostic sensitivity and specificity of 63.1% and 78.6%, while skin tests and serum IgE detection reached only a sensitivity and specificity of 47.3% and 78.6% or 57.5% and 50%, respectively. Similar low rates of diagnostic accuracy of the skin prick tests and RAST tests have also been reported by other investigators in GMA^[1,2,4,5,12,25-27]. This may be explained by the fact that sensitisation in the cutaneous and serological compartment may not always accurately reflect the immunological response of the mucosal microenvironment at the large surface area of the gastrointestinal tract^[1,18,25,27]. The presence of different (immunological) compartments with separate mechanisms for local IgE production in food hypersensitivity may also account for the known multitude of allergic manifestations in food allergy^[1,8,29]. This is illustrated by the fact that several individuals in this study experienced significant clinical symptoms during BPCFC despite negative skin or serum IgE tests, confirming the need for further diagnostic means directly targeting the involved shock organ^[1,5,25-27,29].

Mucosa oxygenation with histamine or more long-lived mediators bears the potential to predict the outcome of double-blind, placebo-controlled food challenges^[17,21,23]. Hence, a future cost-effective approach of the gastroenterologist to diagnose gastrointestinal food allergy could possibly be based on the additional use of gut mucosal histamine release (Table 4) to avoid time-consuming, cost-intensive and sometimes risky challenge procedures. However, the real value of such a diagnostic procedure has yet to be established within greater patient populations^[21,23]. The rationale of this proposal for future diagnostics is given by the fact that gut mucosal histamine release was proven to be of superior diagnostic value compared to that of the commonly used allergological means such as case history, skin prick tests or RAST tests, as these are not always concise or do not directly examine the involved organ in patients with GMA, respectively^[1,2,25,27]. The data presented here suggest that patients with a food antigen-induced mucosal histamine release exceeding more than twice the amount of the spontaneous one be could directly subjected to a specific elimination diet.

As part of appropriately provided health care, prospective long-term analysis of the clinical course of these patients is always necessary. Diminishing financial resources, however, dictate the need for more economical investigations, which may be sufficed by mucosa oxygenation. Although this approach is more invasive than blinded food challenges, it needs only one endoscopic examination with testing of several antigens, while DBPCFC needs at least one (in-patient) test day for each individual allergen application. The data presented here suggest that mucosa oxygenation could perhaps eliminate the need to perform DBPCFC in a significant number of patients suspected of having GMA^[16,17,21].

However, the fact that colorectal mucosal histamine release by mucosa oxygenation did not identify all BPCFC-positive allergens is more likely to be related to the

complex pathophysiology and compartmentalisation of gastrointestinal food allergy rather than to inadequately applied methods. Patients with positive provocation but negative colorectal histamine release, which was the case for 7 of 19 patients (36.8%), may develop their allergic reactions in more proximal parts of the gastrointestinal tract (e.g. stomach, duodenum). Or else, these patients may react only in blood or at extraintestinal sites, respond to the tested antigen mainly with other mediators rather than with histamine (e.g. arachidonic acid products, eosinophilic proteins *etc*) or may have produced the antigenic epitope after passage through the liver^[1,5,8,25,29]. Conversely, control allergens, which elicited a significant histamine release in 3 of 14 patients (21.4%), may fail to provoke a clinically significant reaction unless histamine catabolism is sufficiently active^[1,28]. In addition, the demonstration of food-specific histamine release from colorectal mucosa may also explain why some patients experience postprandial extraintestinal symptoms (urticaria, hypotension, asthma bronchiale *etc*) despite negative skin tests. In such cases, intestinally produced and released histamine may reach peripheral extraintestinal organs and activate their histamine receptors inducing classical extraintestinal allergic symptoms without the presence of food-specific IgE in the periphery. These different pathophysiological parameters in combination with several yet unknown or ill-defined factors (e.g. neurovegetative impulses, gut flora *etc*) contribute to or induce the great variability of clinical manifestations in GMA^[1,3-5,10,18,23,29].

Abstract

AIM: To characterize the tumor suppressor gene *p53* mutations and study the correlation of *p53* gene mutation and the expression of P53 protein in cholangiocarcinoma.

METHODS: A total of 36 unselected, frozen samples of cholangiocarcinoma were collected. *p53* gene status(exon 5-8) and P53 protein were examined by automated sequencing and immunohistochemical staining, combined with the clinical parameters of patients.

RESULTS: *p53* gene mutations were found in 22 of 36 (61.1%) patients. Nineteen of 36 (52.8%) patients were positive for P53 protein expression. There were significant differences in extent of differentiation and invasion between the positive and negative expression of P53 protein. However, there were no significant differences in pathologic parameters between the mutations and non-mutations.

CONCLUSION: The alterations of the *p53* gene evaluated by DNA sequence analysis is relatively accurate. Expression of P53 protein could not act as an independent index to estimate the prognosis of cholangiocarcinoma.

INTRODUCTION

Tumor suppressor gene, besides oncogene, is involved in the development of cancer, which inhibits cell proliferation and formation of tumor. Normally tumor suppressor gene counteracts with oncogene to protect an organism against cancer. The *p53* tumor suppressor gene is the most common mutated gene in human cancer^[1-9], occurring in approximately 50% cancers^[10-12]. Cholangiocarcinoma is among the most common malignant tumors. Mutation of *p53* is one of the most frequently encountered genetic alterations in cholangiocarcinoma. *p53* mutations play a central role in carcinogenesis of cholangiocarcinoma.

Alterations of the *p53* gene can be evaluated by DNA sequencing analysis and immunohistochemistry(IHC). P53 protein overexpression is considered a poor prognosis of cholangiocarcinoma^[13-17]. But IHC has shown controversial results over that of DNA sequencing analysis. We examined mutation status of *p53* gene by automated sequencing and IHC in 36 cases of cholangiocarcinoma and studied the correlation of *p53* gene mutation with clinical parameters and its clinical significance.

MATERIALS AND METHODS

Patients

A total of 36 unselected, frozen samples were obtained from patients with cholangiocarcinoma who had been treated by surgical resection from April 2000 to May 2005 in the Department of General Surgery of the First Affiliated Hospital of China Medical University and Hepatobiliary Surgery of the Affiliated Yantai Yuhuangding Hospital of Qingdao University Medical College. The types of cholangiocarcinoma included 18 cases of tubular adenocarcinomas, 9 cases of papillary adenocarcinomas, 4 cases of mucoid carcinomas and 5 cases of undifferentiated carcinoma. Among them, well-moderately differentiated was 25 and poorly differentiated was 11 cases respectively. There were 16 cases of T1 stage, 10 cases of T2 stage and 10 cases of T3 stage by the UICC standard. Lymph node metastasis was seen in 33 cases. Non- lymph node metastasis was seen in 3 cases. The patients contained 23 males

and 13 females, with age ranging from 36 to 71 (median, 61.2) years. All of the samples were frozen at -80°C until DNA extraction and subjected to histological diagnosis by a pathologist.

DNA extraction

DNA was extracted from tissues using a QIAamp DNA Micro kit: QIA (Germany). Tissue samples weighing less than 10 mg were placed into a 1.5 mL microcentrifuge tube. Immediately 180 μL buffer ATL and 20 μL proteinase K were added and mixed by pulse-vortexing for 15 s. Then they were incubated at 56°C overnight. Two hundred microliter buffer AL and 200 μL ethanol (100%) were added and incubated for 5 min at room temperature. After that, all of the lysates were applied onto the QIAamp MinElute column. Five hundred microliter buffer AW1 and buffer AW2 were added. After centrifugation, 100 μL buffer AE was applied to get DNA. DNA quantity was determined by the ratio of A260/280.

Primer sequences and PCR amplification

Table 1 shows primer sequences used for *p53* exons 5-8, which was synthesized by Hokkaido Bioscience Co. (Japan). PCR used a 20 μL reaction volume containing 1 unit of Hot start EXTaq DNA polymerase (Takara, Biochemical, Japan), 2 μL of $10 \times$ EXTaq buffer, 2 μL of dNTP mixture and each primer (8 pmol each for reaction) and 1 μL of DNA template. The condition of the first PCR is as follows: 96°C for 3 min for denaturation, 40 cycles of 96°C for 30 s, 60°C for 30 s, 72°C for 30 s with a final elongation step of 4 min at 72°C . Water was used as a negative control. Five microliters of PCR product were analyzed on 1% TBE gel electrophoresis. Each sample was repeated three times.

DNA sequencing

All of the PCR products were purified using Auto seq TMG-50 (Amersham Biochemical Company, USA). Big-Dye Terminator Cycle sequencing Ready Reaction (Perkin Elmer, USA) was used. The primers of sequencing were

the same as PCR primers. But its concentration was one tenth of PCR primers. The condition is as follows: 95°C for 4 min, 95°C for 30 s, 55°C for 30 s, 72°C for 30 s for 40 cycles with a final step of 4 min at 72°C . Both sense and antisense chains were analyzed on an ABI prism 310 Genetic Analyzer (Perkin Elmer). Each sample was repeated three times.

Immunohistochemistry

Five-micron sections were dewaxed in xylene and rehydrated. Endogenous peroxidase was destroyed by a 15-min treatment in 30 mL/L hydrogen peroxide (H_2O_2) in phosphate-buffered saline (PBS) at room temperature. The sections were blocked with a combination of normal mouse serum and then incubated with anti-*p53* protein (dilution 1:50, mouse anti-*p53* protein by Boster Co.), followed by biotinylated-conjugated sheep anti-mouse IgG (Boster Co.). The complex was visualized by diaminobenzidine (Boster Co.). The specificity of the reaction was confirmed by use of negative control, blank control and substitution control, in which PBS substituted the secondary antibody biotinylated-conjugated sheep anti-mouse IgG.

Statistical analysis

The results were analyzed with χ^2 test. $P < 0.05$ was taken as significant.

RESULTS

p53 gene mutations and expression of P53 protein in cholangiocarcinoma tissues

Positive band of exons 5-8 was found in all samples after PCR amplification (Figures 1 A-D). *p53* gene mutations were detected in 22 of 36 patients (61.1%) by DNA sequencing. Among them, there were 7 cases of exon 5 mutations, which were located on 161, 175 and 196 codons. All were transition (G:C/A:T). Six cases of exon 6 mutations were located on 209, 213 and 215 codons, of which 4 cases were of transition (G:C/A:T) and 2 cases

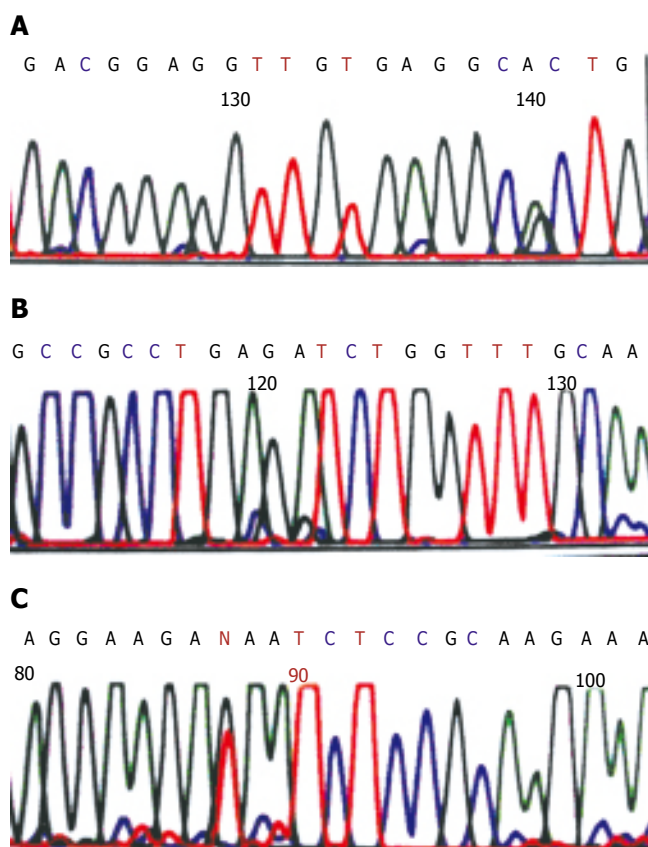

Figure 2 Tranversion of *p53* exons 5, 6, 8 in cholangiocarcinoma. **A:** Exons 5 (G: C/A: T); **B:** Exons 6 (G: C/A: T); **C:** Exons 8 (G→T).

Figure 3 P53 protein was positive in cholangiocarcinoma (SABC × 400).

of tranversion (G→T). Three cases of exon 7 mutations were located on 248, 252 codons. Six cases of exon 8 mutations were located on 282, 287, 289, 306 codons, of which 4 cases were of transition (G:C/A:T) and 2 cases of tranversion (G→T) (Figures 2 A-C).

Nineteen cases (52.8%) were positive for P53 protein. P53 protein localized in the nuclei of cholangic epithelial cells. Moreover, it was crisp and finely granular (Figure 3).

Correlation of *p53* gene mutation and clinical parameters

There were significant differences in degree of differentiation and invasion between the positive and negative samples of P53 protein expression ($P < 0.05$, P

Table 2 Correlation of mutation status of *p53* gene and P53 protein expression with pathologic parameters in cholangiocarcinoma

Pathologic character	<i>n</i>	<i>p53</i> gene mutation		P53 protein expression	
		Positive (<i>n</i> , %)	<i>P</i> value	Positive (<i>n</i> , %)	<i>P</i> value
Pathologic type					
Tubular carcinoma	18	11 (61.1)		10 (55.6)	
Papillary carcinoma	9	6 (66.7)		5 (55.6)	
Mucoid carcinoma	4	2 (50.0)		2 (50.0)	
Non-differentiated carcinoma	5	3 (60.0)	> 0.05	2 (40.0)	> 0.05
Differentiation					
Well-Moderate	25	13 (52.0)		9 (36.0)	
Poor	11	9 (81.8)	> 0.05	10 (90.9)	< 0.05 ^a
Invasion					
T1	16	7 (43.8)		2 (12.5)	
T2	10	8 (80.0)		8 (80.0)	
T3	10	7 (70.0)	> 0.05	9 (90.0)	< 0.05 ^c
Lymph node metastasis

N1	33	20 (60.6)	> 0.05	19 (57.5)	> 0.05

< 0.05). However, there were no significant differences in age, gender, degree of differentiation and invasion, lymph node metastasis, stage between the mutations and non-mutations ($P > 0.05$) (Table 2).

DISCUSSION

Cholangiocarcinoma is the second most common cancer of the hepatobiliary system. In recent years, the incidence and mortality of cholangiocarcinoma have been increasing in China^[18,19]. In most patients, the disease is only diagnosed at a late stage. Patients with obstructive jaundice are frequently at the advanced stage of the disease, which is contraindicated for operation^[20-26]. The development of molecular biology, the identification of molecular factors involved in cholangiocarcinoma carcinogenesis, and the elucidation of the mechanisms will significantly impact prevention, diagnosis, treatment and prognosis. *p53* gene is located on the short arm of chromosome 17, which consists of 11 exons. There are four mutation hot-spots(132-143, 174-179, 236-248, 272-281) within the core domain (exon 5-8), which are the key sites of biological activity of P53 protein^[27,28]. *p53* gene is an important regulator factor of cell proliferation. It is related to cell cycles, DNA repair, cell differentiation and apoptosis. In the presence of DNA damage the expression of *p53* is enhanced and induces G1 cell cycle arrest until DNA is repaired. If repair is insufficient, *p53* gene promotes apoptotic cell death. However, *p53* gene mutation cannot block cell proliferation. Through cooperation with inactivation of tumor suppressor genes and activation of oncogenes, cells transform into malignant ones and become a tumor. *p53* tumor suppressor gene is the most common mutated gene in human cancer and is frequently seen in cholangiocarcinoma. Recent studies have found that positive expression of P53 protein is related to invasion and lymph node metastasis in cholangiocarcinoma^[15,16].

p53 gene mutation could act as an index to estimate the prognosis of cholangiocarcinoma.

We examined mutation status of *p53* gene exons 5-8 by automated sequencing in 36 cases of cholangiocarcinoma. We found *p53* gene mutations in 22 of 36 (61.1 %) patients. Nineteen of 36 (52.8%) patients were positive for P53 protein expression. There were significant differences in extent of differentiation and invasion between positive and negative expression of P53 protein. However, there were no significant differences in age, gender, extent of differentiation, invasion, lymph node metastasis, and stage between the mutations and non-mutations.

Wild-type *p53* (non-mutated) has a short half-life of about 20 min. Mutant P53 protein has a greater stability with half-life prolonged up to 1.4-7 h. It can be detected by IHC method. But the use of different P53 antibodies and methods can result in a marked difference in the degree of overexpression, and varying levels of overexpression may also be noted in the same tumor specimen. IHC has been shown to have discordancy rates of 30%-35% compared with DNA sequencing. Thus, the determination of *p53* overexpression is not an accurate measure of *p53* function. Although DNA sequence analysis is a cumbersome, time-consuming and difficult method on archived material, it could provide a more accurate means of detecting *p53* mutations. Thus, we think *p53* gene mutation could not act as an independent index to estimate the prognosis of cholangiocarcinoma.

Abstract

AIM: Growth hormone (GH) directly interacts with the enterocyte stimulating ion absorption and reducing ion secretion induced by agonists of cAMP. Since nitric oxide (NO) is involved in the regulation of transepithelial ion transport and acts as a second messenger for GH hemodynamic effects, we tested the hypothesis that NO may be involved in the resulting effects of GH on intestinal ion transport.

METHODS: Electrical parameters reflecting trans-epithelial ion transport were measured in Caco-2 cell monolayers mounted in Ussing chambers and exposed to GH and cholera toxin (CT) alone or in combination, in the presence or absence of the NO synthase (NOS) inhibitor, N ω -nitro-L-arginine methyl ester (L-NAME). Similar experiments were conducted to determine cAMP and nitrite/nitrate concentrations. NOS expression was assayed by Western blot analysis.

RESULTS: L-NAME causes total abrogation of absorptive and anti-secretory effects by GH on intestinal ion transport. In addition, L-NAME was able to inhibit the GH-effects on intracellular cAMP concentration under basal conditions and in response to CT. GH induced a Ca²⁺-dependent increase of nitrites/nitrates production, indicating the involvement of the constitutive rather than the inducible NOS isoform, which was directly confirmed by Western blot analysis.

CONCLUSION: These results suggest that the GH effects on intestinal ion transport, either under basal conditions or in the presence of cAMP-stimulated ion

INTRODUCTION

Intestinal ion fluxes are regulated by several agents including neurotransmitters, hormones, or paracrine agents^[1]. We obtained evidence that growth hormone (GH) and nitric oxide (NO) act as modulators in this network^[2-5]. GH increases basal intestinal water and ion absorption in *in vivo* and *in vitro* animal models and is also capable of substantially reducing ion secretion induced by agonists of cAMP, cGMP, or intracellular Ca²⁺, the second messengers of ion secretion^[4,5]. Using the human intestinal cell line Caco-2, we showed that the GH effects on ion transport result from direct interaction with the enterocyte^[2]. Free radical NO acts as a second messenger of several GH effects on human metabolism^[6]. NO production is decreased in patients with untreated GH deficiency, while treatment with recombinant human growth hormone (rhGH) increases NO formation^[7]. In the past decade NO has emerged as a signalling molecule mediating a broad spectrum of intestinal processes, such as gastrointestinal motility, inflammatory changes, malignancy, mucosal blood flow and transepithelial ion transport^[8,9]. NO is a gas with a half life of less than 5 s generated through a series of regulated electron transfer steps by a family of P450-like enzymes, termed nitric oxide synthases (NOS)^[10,11]. Two NOS are continuously present and are termed constitutive nitric oxide synthase (cNOS). These two isoforms are Ca²⁺/calmodulin-dependent, produce small amounts of NO in

short bursts and are involved in homeostatic processes. A third isoform, which is Ca^{2+} /calmodulin-independent, is induced by intestinal injury and inflammation. This latter isoform, termed inducible nitric oxide synthase (iNOS), requires a lag period of at least 2–3 h and, once expressed, produces large amounts of NO for longer time^[13,12]. NO can be directly produced by enterocytes through both the constitutive and the inducible NOS isoforms^[3,13,14]. An important feature of the NO effect is its concentration-dependence. Leading to the concept that NO often acts as a double-edged sword mediator with beneficial as well as detrimental effects. While at lower concentrations it maintains a basal ion intestinal pro-absorptive tone, it increases in several pathologic states such as inflammatory bowel diseases, toxic megacolon, and infectious gastroenteritis, contributing to ion secretion^[8,12,15]. Recently, we showed that under basal conditions the intracellular cAMP concentration ([cAMP]i) is downregulated in the enterocyte by a cNOS-dependent NO production. Furthermore, in the presence of a cAMP-dependent stimulated secretion, cNOS is activated functioning as a breaking force of ion secretion^[3]. This raised the hypothesis that the enterocyte is capable of self-regulating its own ion transport process through the activation of the cNOS-NO pathway which is able to modulate the [cAMP]i level^[3]. The aim of this study was to determine whether NO is also involved in mediating the ion absorptive effects triggered by an extracellular stimulus. Specifically, we tested the hypothesis that the cNOS-NO-cAMP pathway is implicated in the pro-absorptive and in the anti-secretory effect induced by GH at the intestinal level. We used the Caco-2 in vitro cell model, previously validated for investigating the GH and the NO intestinal effects^[2].

MATERIALS AND METHODS

Cell culture

Caco-2 cells were obtained from the American Type Culture Collection (Rockville, MD). Cells were grown in Dulbecco's Modified Eagle's Medium (DMEM) with high glucose concentration (4.5 g/L) supplemented with 10% FCS, 1% nonessential amino acids, penicillin (50 mU/mL), streptomycin (50 mg/mL) and were incubated in 50 mL/L CO_2 -950 mL/L air. Medium was changed daily.

Ion transport studies

Cells were grown on uncoated polycarbonate transwell filters as previously described and used for intestinal transport studies at 15 d post-confluence^[3]. The filter area was 4.9 cm². Each filter was mounted in an Ussing chamber (World Precision Instrument, Sarasota, FL) as a flat sheet between the mucosal and the serosal compartment. Each compartment contained 10 mL of Ringer's solution with the following composition (in mmol/L): NaCl (114), KCl (10), Na_2HPO_4 (1.65), NaH_2PO_4 (0.3), CaCl_2 (1.25), MgCl_2 (1.1), NaHCO_3 (15), glucose (19). In experiments performed to investigate the role of Cl^- in the electrical response, SO_4^{2-} substituted Cl^- at an equimolar concentration. The incubation fluid was circulated by a thermostat-regulated circulating pump and continuously gassed with

95% O_2 -5% CO_2 . Transepithelial potential difference (PD), short-circuit current (Isc) and tissue ionic conductance (G) were monitored by an automatic voltage-clamp device (DVC 1000, World Precision Instrument, Sarasota, FL) as described elsewhere^[16], before and after mucosal or serosal addition of GH, cholera toxin (CT), and the specific NOS inhibitor N ω -nitro-L-arginine methyl ester (L-NAME). Isc is expressed as microamperes per square centimeter ($\mu\text{A}/\text{cm}^2$), G as millisiemens per square centimeter (mS/cm^2), and PD as millivolts (mV). Caco-2 cell monolayers, pre-incubated for 20 min with GH (4×10^{-9} mol/L) on the serosal side, were exposed to CT (6×10^{-8} mol/L) on the mucosal side, in the presence or the absence of L-NAME (2×10^{-4} mol/L) added to both sides. The maximal effective concentrations of GH, CT and L-NAME were determined by dose-response experiments (data not shown). Cell viability was evaluated at the end of each experiment by measuring the electrical response to the serosal addition of theophylline (5×10^{-3} mol/L).

Intracellular cAMP concentration determination

To test the hypothesis that GH specifically counteracts the CT-induced cAMP increase, we determined the modifications in [cAMP]i after 1 h of incubation with GH and CT, alone or in combination, and in the presence or the absence of L-NAME. [cAMP]i in Caco-2 cells which was measured by using a commercial kit (Biotrak cyclic AMP assay system; Amersham International, Amersham, UK), as previously described^[17].

Western blot analysis

Caco-2 cells were stimulated with GH (4×10^{-9} mol/L) for 1, 6 or 24 h. Cells were then scraped into PBS buffer and lysed in a buffer containing 1% Tergitol (Nonidet P-40) with the following composition: KCl, 60 mmol/L; β -mercaptoethanol, 14 mmol/L; EDTA, 2 mmol/L; HEPES pH 7.9, 15 mmol/L; sucrose, 0.3 mol/L; aprotinin, 5 $\mu\text{g}/\text{mL}$; leupeptin, 10 $\mu\text{g}/\text{mL}$; pepstatin, 2 $\mu\text{g}/\text{mL}$; phenylmethylsulfonyl fluoride, 0.1 mmol/L. Whole cellular extracts were centrifuged at 1500 g for 20 min at 4°C. Protein content was determined by the Bradford method (Bio-Rad Laboratories, Munchen, Germany). The supernatant containing the solubilized proteins was then boiled for 5 min in Laemmli buffer (tris-HCl pH 6.8, 62.5 mmol/L; SDS 2%; glycerol 10%; 2-mercaptoethanol 5%; bromophenol blue 0.001%). Cell proteins (50 $\mu\text{g}/\text{lane}$) were added to an SDS-polyacrylamide gel electrophoresis (PAGE) and transferred onto a nitrocellulose membrane (BioBlot-NC-Costar, Corning Incorporated, Canada). Blots were blocked with T-TBS buffer (tris-HCl pH 8.8, 10 mmol/L; NaCl, 150 mmol/L; Tween 20, 0.05%) containing 3% albumin, and probed for 1 h with affinity purified anti-human NOS1 (1:2000) dilution ratio, NOS2 (1:200) or NOS3 (1:1000) rabbit polyclonal antibodies. Bound antibody was detected with anti-rabbit immunoglobulin horseradish peroxidase-linked whole antibody and developed by chemiluminescence reaction (Amersham Pharmacia Biotech, UK). Gamma-interferon (50000 U/mL) was used as a positive control in experiments performed using anti-iNOS antibodies.

Figure 1 A: Time course of the effect on short-circuit current (Isc) of GH (4×10^{-9} mol/L) and L-NAME (2×10^{-4} mol/L), alone or in combination, to Caco-2 cells mounted in Ussing chambers; B: Isc peak after L-NAME or GH addition, alone or in combination, to Caco-2 cells mounted in Ussing chambers. Data are mean \pm SD of 6 different observations. ^a $P < 0.05$ GH vs L-NAME + GH.

Figure 2 A: Time course of the GH (4×10^{-9} mol/L) effect on CT (6×10^{-8} mol/L)-induced short-circuit current (Isc) increase in the absence or in the presence of L-NAME (2×10^{-4} mol/L) in Caco-2 cells mounted in Ussing chambers. The arrows indicate the time of addition of each agent; B: Maximal Isc increase after CT addition, alone or in the presence of GH alone or in combination with L-NAME. A total abrogation of the antagonistic effect of GH on the CT-induced electrical response was observed in the presence of L-NAME. Data are mean \pm SD of 6 different observations. ^a $P < 0.05$ CT alone vs GH + CT; ^c $P < 0.05$ GH + CT vs L-NAME + GH + CT.

Nitrite/nitrate ($\text{NO}_2^-/\text{NO}_3^-$) production

The combined concentration of nitrite and nitrate, the degradation products of NO in the culture medium, was determined by the Griess reaction after nitrate reduction^[18]. Total nitrite/nitrate production was referred to NO production. Experiments were performed using normal or Ca^{2+} -free Ringer's solution to investigate the involvement of the cNOS isoform (the Ca^{2+} /calmodulin-dependent isoform or NOS1). The modified Ringer's solution had the following composition (mmol/L): NaH_2PO_4 , 1.65; NaH_2PO_4 , 0.3; NaHCO_3 , 15; NaCl , 53; KCl , 10; Na_2SO_4 , 30.5; MgCl_2 , 2.35; glucose, 19; EDTA, 0.5.

Chemicals

All chemicals were of reagent grade and were obtained from Sigma Chemicals Co. (St. Louis, MO, USA). Culture media were from Life Technologies GIBCO BRL (Mascia e Brunelli, Milan, Italy). Transwell filters and supports were from Costar (Costar Italia, Milan, Italy). rhGH was obtained from Serono (Industria Farmaceutica Serono, Rome, Italy). Anti-cNOS and anti-iNOS polyclonal antibodies were obtained from Santa Cruz Biotechnology (Santa Cruz, CA, USA). Anti-iNOS polyclonal antibodies were purchased from Transduction Laboratories (ABD Company, Lexington, KY, USA).

Statistical analysis

Each experiment was run in duplicate and repeated at least 3 times. Results are expressed as mean \pm SD. Repeated-measures ANOVA were applied using the Bonferroni test for multiple comparisons. The significance was set at 5%. The SPSS software package for Windows (release 11.0.1;

SPSS Inc., Chicago, IL, USA) was used for statistical analysis.

RESULTS

Intestinal transport studies

GH (4×10^{-9} mol/L) and L-NAME (2×10^{-4} mol/L) caused opposite effects on basal Isc. GH induced a decrease and L-NAME induced an increase in Isc. Both effects were totally related to PD modifications, as no significant variations of G were recorded. Pre-treatment with L-NAME (2×10^{-4} mol/L) for 5 min almost abolished the electrical response to GH (Figure 1). The addition of CT (6×10^{-8} mol/L) to Caco-2 cells induced an increase in Isc. Both the GH and CT effects were Cl^- -dependent as demonstrated in the experiment done in Cl^- free Ringer solution. Thus, in the absence of Cl^- the electrical effects were virtually abolished indicating that they were entirely due to transepithelial Cl^- transport modifications (data not shown). Pre-incubation with GH for 20 min substantially reduced the CT effect on Isc. However, pre-incubation with L-NAME resulted in total abrogation of the antagonistic effect of GH on the CT-induced electrical response (Figure 2).

Intracellular cAMP concentration determination

Incubation with GH (4×10^{-9} mol/L) resulted in significant reduction of basal $[\text{cAMP}]_i$. On the contrary, incubation with CT induced an increase in $[\text{cAMP}]_i$. The addition of L-NAME produced a significant increase in basal and in CT-stimulated $[\text{cAMP}]_i$. Pre-incubation with GH for 20 min resulted in a reduction of the CT-induced $[\text{cAMP}]_i$ increase. Finally, the addition of L-NAME resulted in total inhibition of the GH-induced decrease in basal $[\text{cAMP}]_i$ as

Figure 3 Modification of intracellular cAMP concentration in Caco-2 cells after incubation with GH, CT, alone or in combination, in the presence or in the absence of L-NAME. Data are mean \pm SD of 6 different observations. ^a $P < 0.05$ vs control; ^c $P < 0.05$ CT alone vs GH + CT; ^e $P < 0.05$ GH + CT vs L-NAME + GH + CT.

Figure 4 The upper side of the figure shows the cNOS protein expression in Caco-2 cells after 1 h of incubation with GH and CT alone or in combination, as compared to tubulin expression. The cNOS protein expression is revealed by the appearance of 160-kD band that corresponds to human NOS 1 (neuronal NOS). Shown is a representation of 3 separate experiments. In the lower side of the figure an optical densitometry analysis of the bands is also reported.

well as a total abrogation of the GH effect on CT-induced [cAMP]_i increase (Figure 3). These results point to a role of NO either under basal conditions or in response to external stimuli which drive ion fluxes toward an absorption pattern.

Western blot analysis

Caco-2 cells showed low but detectable basal cNOS protein expression (Figure 4). Western blot analysis performed after 1 h of incubation with GH revealed the amplification of a 160 kD band corresponding to human NOS 1. Simultaneous incubation of Caco-2 cells with either GH or CT resulted in further amplification of the NOS 1 band (Figure 4). On the contrary, NOS 2 and NOS 3 protein expressions were undetectable in unstimulated cells and in cells exposed to GH and CT alone or in combination for up to

Figure 5 Effects of increasing concentration of GH on NO production in Caco-2 cells. Increasing concentrations of GH were added to Caco-2 cell monolayers and NO production was determined after 1 h of incubation. Data are mean \pm SD of 6 different observations.

Figure 6 Total NO production in Caco-2 cells under basal conditions and after stimulation with GH and CT, alone or in combination, in standard or in Ca²⁺-free medium. Data are mean \pm SD of 6 different observations. ^a $P < 0.05$ vs control.

24 h of incubation (data not shown).

Nitrite/nitrate (NO₂⁻/NO₃⁻) production

NO production by Caco-2 cells was determined in culture medium after 1 h of incubation with increasing GH doses. As shown in Figure 5 a dose-dependent increase in NO production was detected in response to the hormone. GH doses higher than 4 × 10⁻⁹ mol/L did not induce further increase in NO production, indicating a saturation pattern of the effect. Caco-2 cell stimulation with simultaneous exposure to GH and CT resulted in a further increase in NO production compared to each individual substance. The effect was Ca²⁺-dependent, since in the absence of Ca²⁺, the NO increase in response to GH addition was abolished. This data suggests an involvement of the constitutive rather than the inducible NOS isoform in the GH effect (Figure 6).

DISCUSSION

We have previously shown that GH is able to increase intestinal fluid absorption under basal conditions and to inhibit ion secretion elicited by the 3 main intracellu-

lar second messengers of bacterial enterotoxins: cAMP, cGMP and Ca^{2+} [2,4]. The data from this study provides new evidence on the ability of GH to regulate water and ion transport and implicates cNOS-NO activity for this effect. A complete abrogation of GH effects on Isc was seen in the presence of the specific NOS inhibitor L-NAME. An increase of cNOS activity and a subsequent Ca^{2+} -dependent production of NO were observed in enterocytes treated with GH. These effects were associated with a Cl⁻-dependent decrease in Isc, consistent with an anion absorptive effect. We have recently demonstrated that the CT-enterocyte interaction results in an enhanced NO production. Such an effect may be interpreted as a homeostatic mechanism operated by the enterocyte and functioning as a breaking force to limit ion secretion^[3]. cNOS-NO system is activated by a yet unknown sensing mechanism and reacts to balance the stimulated secretion. The data in this work support and extend this hypothesis and suggest that the modulation of the cNOS-NO activity could also be dependent on extracellular stimuli control, namely on the GH signal transduction. In all instances, the target of cNOS-NO is cAMP. Our results are similar to those obtained using NO donors, which are able to inhibit forskolin-stimulated cAMP production by adenylyl cyclase (AC) isoforms AC5 and AC6, in both T84 epithelial cells and mucosal scrapings from mouse colon^[19-21], and are in agreement with those previously obtained in isolated cholangiocytes^[22].

It has been recently suggested that GH inhibitory effect on intestinal ion secretion is related to the transactivation of epidermal growth factor (EGF) receptor and the subsequent activation of extracellular signal-regulated kinase (ERK, also known as p 44/42 mitogen activated protein kinase or MAPK) activity^[23]. Interestingly, a NO stimulation through ERK-dependent upregulation of cNOS gene transcription has been recently demonstrated for proinsulin C-peptide in endothelial cells^[24], and similar effects have been shown with the endothelium-derived hyperpolarizing factor (EDHF)^[25]. Thus, it is possible to also hypothesize that the NO-mediated GH effects at the intestinal level could involve a MAPK activation. It also remains to be clarified whether GH effects are mediated by Ca^{2+} . Overall the cNOS-NO system could be viewed as a regulator of ion transport acting on the enterocyte via three distinct patterns: (1) to keep cAMP production at a low level under basal conditions, in order to maintain an intestinal ion pro-absorptive tone; (2) during stimulation of ion secretion, such as that triggered by CT, to reduce ion secretion; (3) in response to extracellular pro-absorptive stimuli, namely acting as second messenger of the GH-induced ion absorption. In all these 3 instances the target of cNOS-NO is cAMP, the effect is Ca^{2+} -dependent and involves Cl⁻ transcellular flux. Thus the cNOS-NO-cAMP pathway plays a key role on the enterocyte fluid absorptive/secretory processes.
